MedusaLocker

Observed as recently as May 2022, MedusaLocker actors predominantly rely on vulnerabilities in Remote Desktop Protocol (RDP) to access victims' networks. The MedusaLocker actors encrypt the victim's data and leave a ransom note with communication instructions in every folder containing an encrypted file. The note directs victims to provide ransomware payments to a specific Bitcoin wallet address. MedusaLocker appears to operate as a Ransomware-as-a-Service (RaaS) model based on the observed split of ransom payments. Typical RaaS models involve the ransomware developer and various affiliates that deploy the ransomware on victim systems. MedusaLocker ransomware payments appear to be consistently split between the affiliate, who receives 55 to 60 percent of the ransom; and the developer, who receives the remainder.

The tag is: *misp-galaxy:ransomware="MedusaLocker"*

Nefilim

According to Vitali Kremez and Michael Gillespie, this ransomware shares much code with Nemty 2.5. A difference is removal of the RaaS component, which was switched to email communications for payments. Uses AES-128, which is then protected RSA2048.

The tag is: *misp-galaxy:ransomware="Nefilim"*

View relationships graph

Nefilim has relationships with:

- related-to: misp-galaxy:ransomware="Nemty" with estimative-language:likelihood-probability="likely"

ProLock

PwndLocker is a ransomware that was observed in late 2019 and is reported to have been used to

target businesses and local governments/cities. According to one source, ransom amounts demanded as part of PwndLocker activity range from $175k USD to $650k USD depending on the size of the network. PwndLocker attempts to disable a variety of Windows services so that their data can be encrypted. Various processes will also be targeted, such as web browsers and software related to security, backups, and databases. Shadow copies are cleared by the ransomware, and encryption of files occurs once the system has been prepared in this way. Executable files and those that are likely to be important for the system to continue to function appear to be skipped by the ransomware, and a large number of folders mostly related to Microsoft Windows system files are also ignored. As of March 2020, encrypted files have been observed with the added extensions of .key and .pwnd. Ransom notes are dropped in folders where encrypted files are found and also on the user's desktop.

The tag is: *misp-galaxy:ransomware="ProLock"*

View relationships graph

ProLock has relationships with:

- dropped-by: misp-galaxy:botnet="Qbot" with estimative-language:likelihood-probability="likely"

Conti

Conti ransomware is a RaaS and has been observed encrypting networks since mid-2020. Conti was developed by the “TrickBot” group, an organized Russian cybercriminal operation. Their reputation has allowed the group to create a strong brand name, attracting many affiliates which has made Conti one of the most widespread ransomware strains in the world. One of the last known “Conti” attacks was against the government of Costa Rica in April 2022 causing the country to declare a state of emergency. Shortly after this final attack, the “Conti” brand disappeared. The group behind it likely switched to a different brand to avoid sanctions and start over with a new, clean

reputation.

The tag is: *misp-galaxy:ransomware="Conti"*

BlackCat

BlackCat (ALPHV) is ransomware written in Rust. The ransomware makes heavy use of plaintext JSON configuration files to specify the ransomware functionality. BlackCat has many advanced capabilities like escalating privileges and bypassing UAC make use of AES and ChaCha20 or Salsa encryption, may use the Restart Manager, can delete volume shadow copies, can enumerate disk volumes and network shares automatically, and may kill specific processes and services. The ransomware exists for both Windows, Linux, and ESXi systems. Multiple extortion techniques are used by the BlackCat gang, such as exfiltrating victim data before the ransomware deployment, threats to release data if the ransomw is not paid, and distributed denial-of-service (DDoS) attacks.

The tag is: *misp-galaxy:ransomware="BlackCat"*

BlackCat is also known as:

- ALPHV
- Noberus

HelloXD

HelloXD is a ransomware family performing double extortion attacks that surfaced in November 2021. During our research we observed multiple variants impacting Windows and Linux systems. Unlike other ransomware groups, this ransomware family doesn’t have an active leak site; instead it prefers to direct the impacted victim to negotiations through TOX chat and onion-based messenger instances.

Maui ransomware

Maui ransomware stand out because of a lack of several key features commonly seen with tooling from RaaS providers, such as an embedded ransom note to provide recovery instructions or

automated means of transmitting encryption keys to attackers. Instead, it is believed that Maui is manually operated, in which operators will specify which files to encrypt when executing it and then exfiltrate the resulting runtime artifacts. There are many aspects to Maui ransomware that are unknown, including usage context.

The tag is: *misp-galaxy:ransomware="Maui ransomware"*

Lorenz Ransomware

Lorenz is a ransomware group that has been active since at least February 2021 and like many ransomware groups, performs double-extortion by exfiltrating data before encrypting systems.

The tag is: *misp-galaxy:ransomware="Lorenz Ransomware"*

BlackBasta

Black Basta is a new ransomware strain discovered during April 2022 - looks in dev since at least early February 2022 - and due to their ability to quickly amass new victims and the style of their negotiations, this is likely not a new operation but rather a rebrand of a previous top-tier ransomware gang that brought along their affiliates.

The tag is: *misp-galaxy:ransomware="BlackBasta"*

View relationships graph

BlackBasta has relationships with:

BlackByte

BlackByte is recently discovered Ransomware with a .NET DLL core payload wrapped in JavaScript. It employs heavy obfuscation both in its JavaScript wrapper and .NET DLL core.

Once the JavaScript wrapper is executed, the malware will de-obfuscate the core payload and execute it in memory. The core .DLL is loaded and BlackByte will check the installed operating system language and terminate if an eastern European language is found.

It will proceed to check for the presence of several anti-virus and sandbox-related .DLLs, attempt to bypass AMSI, delete system shadow-copies in order to hinder system recovery, and modify several other system services (including Windows Firewall) in order to “prep” the system for encryption. Once the system is “ready” for encryption, it will download a symmetric key-file which will be used to encrypt files on the system. If this file is not found, the malware will terminate.

Unlike most Ransomware today, BlackByte uses a single symmetric encryption key, and does not generate a unique encryption key for each victim system, meaning the same key can be used to decrypt all files encrypted by the malware.

This makes for substantially easier key-management for the actors behind BlackByte at the cost of a weaker encryption scheme and easier victim system recovery (as there is only a single online point with a single key to maintain).

As with most Ransomware today, BlackByte has worming capabilities and can infect additional endpoints on the same network.

AvosLocker

In March 2022, the FBI and the U.S. Treasury Financial Crimes Enforcement Network released a joint advisory addressing AvosLocker and their activity targeting organizations across several critical infrastructure sectors. The RaaS gang deploys ransomware onto their victim's networks and systems, then threatens to leak their files on the dark web if they don't pay up. AvosLocker is both the name of the RaaS gang, as well as the name of the ransomware itself.

In May 2022, AvosLocker took responsibility for attacking and stealing data from the Texas-based healthcare organization, CHRISTUS Health. CHRISTUS Health runs hundreds of healthcare facilities across Mexico, the U.S., and South America. The group stole information from a cancer patient registry which included names, social security numbers, diagnoses, dates of birth, and other medical information. The nonprofit Catholic health system has more than 600 healthcare facilities in Texas, Louisiana, New Mexico, and Arkansas. There are also facilities in Columbia, Mexico, and

Chile.

Fortunately, the ransomware attack was quickly identified and was limited. While other healthcare organizations have not been as fortunate with ransomware attacks, the AvosLocker attack didn't impact CHRISTUS Health's patient care or clinical operations. CHRISTUS Health didn't reveal whether or not the security incident included ransomware, data exfiltration or extortion, but due to AvosLocker's reputation, it is more than likely that the incident included at least one of the three.

0Mega

0mega, a new ransomware operation, has been observed targeting organizations around the world. The ransomware operators are launching double-extortion attacks and demanding millions of dollars as ransom.

0mega ransomware operation launched in May and has already claimed multiple victims. 0mega maintains a dedicated data leak site that the attackers use to post stolen data if the demanded ransom is not paid. The leak site currently hosts 152 GB of data stolen from an electronics repair firm in an attack that happened in May. However, an additional victim has since been removed, implying that they might have paid the ransom to the 0mega group.

How does it work? Hackers add the .0mega extension to the encrypted file's names and create ransom notes (DECRYPT-FILES[.]txt). The ransom note has a link to a Tor payment negotiation site with a support chat to reach out to the ransomware group. To log in to this site, the victims are asked to upload their ransom notes with a unique Base64-encoded blob identity.

The tag is: *misp-galaxy:ransomware="0Mega"*

Atomsilo

AtomSilo is a new Ransomware recently seen in September 2021 during one of their attacks by exploiting a recently revealed vulnerability (CVE-2021-26084) in Atlassian's Confluence Collaboration Software for initial access. The Ransomware used the double extortion method which is gaining popularity among ransomware threat actors where they first, exfiltrate the confidential information and as a second step encrypt the system files.

Babuk-Locker

Babuk-Locker emerged in early 2021 as a Ransomware-as-a-Service (RaaS) gang targeting high-value “big game” enterprises across sectors like healthcare, telecommunications, finance, education, and government. It initially deployed crypto-ransomware—encrypting files using ChaCha8 encryption with keys secured via elliptic-curve Diffie-Hellman—and later added a double-extortion model involving data theft and leak site threats. Notable incidents include attacks on the Washington, D.C. Metropolitan Police Department and other organizations. In mid-2021, Babuk’s source code was leaked, prompting both a fragmentation of its core operations and emergence of variants like Babuk Tortilla and Babuk V2. Affiliates exploited vulnerabilities in ESXi hypervisors to deliver destructive variants, and law enforcement actions eventually disrupted key operators.

Bianlian

BianLian used subtle techniques to exploit, enumerate, and move laterally in victim networks to remain undetected and aggressively worked to counter Endpoint Detection & Response (EDR) protections during the encryption phase of their operations. The group has displayed signs of being new to the practical business aspects of ransomware and associated logistics. Generally they seemed to be experiencing the growing pains of a group of talented hackers new to this aspect of criminal extortion.

Infrastructure associated with the BianLian group first appeared online in December 2021 and their toolset appears to have been under active development since then. Finally, we have observed the BianLian threat actor tripling their known command and control (C2) infrastructure in the month of August, suggesting a possible increase in the actor's operational tempo.

Blackshadow

BlackShadow is a state-aligned cybercrime group reportedly linked to Iran's cyber operations, first identified in late 2020. Their operations blend data exfiltration with ransom threats, notably targeting Israeli organizations such as Cyberserve—a web hosting provider—and leaking data to inflict reputational damage. Victims included entities like Atraf (an LGBTQ dating app), tour booking services, and museums, reflecting political or ideological motivations over financial gain. Despite carrying out extortion, there is no evidence that BlackShadow employs typical encryption-based ransomware mechanics; instead, they leverage stolen data and the threat of public exposure.

Cheers

Cheers is a Linux-based ransomware variant observed starting in May 2022, engineered specifically to target VMware ESXi servers. The malware was developed from leaked Babuk ransomware source code and leverages the SOSEMANUK stream cipher combined with ECDH key exchange for encryption. It terminates all running virtual machines before renaming and encrypting log files and VM-related extensions—like .vmdk, .vmsn, and .vswp—appending a .Cheers extension. A ransom note titled "How To Restore Your Files.txt" is dropped per directory. The ransomware is attributed to the Chinese-affiliated group BRONZE STARLIGHT (also known as Emperor Dragonfly, DEV-0401), which has previously deployed other strains like Rook, NightSky, and Pandora. Cheers targets a range of industry sectors, with confirmed victims across healthcare, finance, logistics, and manufacturing.

Cuba

The Cuba Ransomware, also known as Colddraw Ransomware, was first identified in the threat landscape in 2019 and built a relatively small but selected list of victims. The group is also known as Fidel Ransomware, due to a characteristic marker placed at the beginning of all encrypted files. This file marker is used as an indicator for the ransomware and its decoder that the file has been encrypted. Despite its name and the Cuban nationalist style on its leak site, it is difficult to assert any connection or affiliation with the Republic of Cuba. The group has been linked to a Russian-language threat actor by Profero researchers due to some details of incorrect translation they discovered, as well as the discovery of a 404 page containing text in Russian on the threat actor's own leak site. According to BlackBerry, based on the analysis of the code strings used in the campaign analyzed in 2023, there were indications that the developer behind the Cuba ransomware speaks Russian. The ransomware operators use a double extortion approach, and following the USA, in August 2022, it was believed that the Cuba ransomware group had compromised 101 entities, demanding $145 million in ransom payments and receiving up to $60 million. The group used a similar set of TTPs, with only a slight change each year, as they generally consist of LOLBins (executables that are part of the operating system and can be exploited to support an attack), exploits, off-the-shelf and custom malware, as well as intrusion tools like Cobalt Strike and Metasploit. In 2022, the group allegedly developed a relationship with operators of the Industrial Spy market, using their platform as a means of data leakage.

Daixin

Daixin Team is a ransomware and data extortion group active since at least June 2022, known for targeting the healthcare sector, including hospitals, clinics, and related service providers. The group employs a double-extortion model—exfiltrating sensitive data before encrypting systems—and has leaked protected health information (PHI) to pressure victims. Intrusions often involve exploiting VPN vulnerabilities (notably in Fortinet FortiOS) and using compromised credentials for initial access. The ransomware uses AES for file encryption with RSA to protect the keys, and ransom notes direct victims to a Tor-based portal. The U.S. CISA, FBI, and HHS have issued joint advisories warning of the group's impact on healthcare delivery and patient safety

Dark Power

Dark Power is a ransomware group first observed in January 2023, known for targeting small to mid-sized organizations across education, healthcare, manufacturing, and information technology sectors. The group uses a double-extortion model, encrypting files and threatening to leak exfiltrated data via a Tor-based site if ransom demands are not met. Written in the Nim programming language, Dark Power ransomware appends the .dark_power extension to encrypted files and drops a ransom note named README.txt, giving victims 72 hours to contact them. The note typically demands payment in cryptocurrency and offers to negotiate. Victims have been observed in North America, Asia, and Europe, with attacks often involving exploitation of vulnerable public-facing systems or stolen credentials.

Darkangel

Dark Angels is a highly targeted ransomware and data-extortion group that emerged in spring 2022. Rather than using an affiliate-driven model, it orchestrates discreet, high-impact attacks on large organizations—often choosing one Fortune-level victim at a time. The group exfiltrates massive volumes of data (sometimes 10–100 TB), optionally deploys encryption on Windows or ESXi systems, and pressures victims via a Tor-hosted leak platform ("Dunghill Leak"). Their notable incidents include extorting a record $75 million from a Fortune 50 company in 2024 and demanding around $51 million from Johnson Controls. Dark Angels' operations emphasize stealth and precision over disruption, often avoiding high-profile media exposure and operating with low operational visibility.

Endurance

Endurance is a destructive ransomware variant first observed in 2023, developed and operated by the threat actor known as IntelBroker (also referred to as Butler Spider). Rather than encrypting files for decryption, it functions primarily as a data wiper, overwriting file contents, appending randomized filenames, and then deleting the files altogether. The source code for the malware was intentionally made public by the operator, indicating its use as both a tool and a statement. Endurance was used in high-profile breaches, including targeting government agencies, large enterprises, and telecommunications providers.

Entropy

Entropy is a ransomware first seen in 1st quarter of 2022, is being used in conjunction of Dridex infection. The ransomware uses a custom packer to pack itself which has been seen in some early dridex samples.

Groove

Groove was a short-lived ransomware group and cybercrime gang that emerged in August 2021 and became notable for its aggressive, publicity-driven tactics. Unlike traditional Ransomware-as-a-Service (RaaS) groups, Groove functioned more as a loose criminal collective, encouraging other threat actors to join forces in attacking U.S. entities, particularly in the government and financial sectors. The group ran a Tor-based leak site where it published stolen data, but its operators claimed to focus more on building an “underground alliance” than on ransomware deployment itself. Analysts noted overlaps between Groove and actors behind Babuk and BlackMatter, as well as forum personas known for data theft operations. By early 2022, Groove’s activity had largely ceased, with some experts suggesting the group was either a short-term recruitment campaign or a misinformation effort.

Hotarus

Hotarus is a ransomware and data extortion group first observed in March 2021, believed to be linked to threat actors of Latin American origin. The group has targeted entities in South America and the United States, including financial institutions, government agencies, and private companies. Hotarus is known for deploying both custom ransomware and publicly available tools, alongside stealing sensitive information for double-extortion purposes. The group has been observed exploiting vulnerable web services, using stolen credentials, and leveraging publicly available post-exploitation frameworks to gain persistence in victim networks. Encrypted files are

typically appended with extensions such as .hotarus or campaign-specific identifiers, and ransom notes direct victims to communicate via encrypted email services. Notably, in some campaigns, Hotarus deployed data leak threats without encrypting files, focusing solely on exposure as a pressure tactic.

Kelvin Security

Kelvin Security is a cybercrime group active since at least 2013, primarily known for hacktivism, data breaches, and website defacements rather than traditional ransomware operations. The group has claimed responsibility for intrusions targeting government agencies, educational institutions, and private companies across multiple regions, including Latin America, Europe, and the Middle East. While it has engaged in data theft and leak threats, there is no confirmed evidence that Kelvin Security operates a ransomware encryption component. Instead, their extortion model focuses on stealing sensitive data and threatening public disclosure, often publicizing breaches via social media and underground forums. The group's activities have been linked to politically motivated campaigns as well as financially motivated breaches. Victim selection appears opportunistic, exploiting vulnerabilities in web servers, poorly configured databases, and exposed credentials.

Lapsus$

Lapsus$ is a cyber extortion group first observed in late 2021, known for high-profile breaches and data theft campaigns against major global companies rather than traditional ransomware encryption. The group primarily focuses on data exfiltration and public leak threats without encrypting victim systems. Lapsus$ uses a combination of social engineering, SIM swapping, MFA fatigue attacks, and purchasing access from insiders or access brokers to infiltrate corporate networks. Their victim list includes Microsoft, Okta, NVIDIA, Samsung, Uber, and telecom operators, with operations targeting multiple regions worldwide. Once inside, Lapsus$ actors exfiltrate source code, proprietary data, and customer information, often leaking samples to pressure victims into negotiation. The group is known for a brash and public-facing style, communicating directly with followers on Telegram channels and occasionally mocking victims. Several members, including minors, have been arrested in the UK, but the group's activities have persisted in some form.

Midas

This malware written in C# is a variant of the Thanos ransomware family and emerged in October 2021 and is obfuscated using SmartAssembly. In 2022, ThreatLabz analysed a report of Midas ransomware was slowly deployed over a two month period (ZScaler). This ransomware features also its own data leak site as part of its double extortion strategy.

Eraleign

A new ransomware group is said to have emerged in mid-April 2024, under the name "APT73." It's worth noting that the group reportedly self-proclaimed as an APT, which stands for "Advanced Persistent Threat" in the cybersecurity field. According to research, much of the available information about the aforementioned group came from another ransomware group known as LockBit. This is evident as the group, on its Data Leak Site (DLS) website, added pages such as "Contact Us," "How to buy Bitcoin," "Web Security Bug Bounty," and "Mirrors." Another relevant fact is that this group is also known as Ransomware Eraleig. This is because the group allegedly used a domain in the past to disclose information about victims. There is no information available about any Tactics, Techniques, and Procedures associated with this ransomware group, nor about the latest artifacts used for encryption purposes.

darkrace

DarkRace is a moderately destructive ransomware strain observed since 2024. It encrypts files and appends a randomized extension (e.g., .1352FF327) that varies per victim. Implemented as a 32-bit Windows application, it disables antivirus defenses, deletes volume shadow copies, terminates processes, and drops ransom note files for payment negotiation. Technical weaknesses in its encryption have enabled developers to produce a universal decryptor that works against DarkRace and related variants.

dan0n

dAn0n is a data-extortion actor that first appeared in April 2024. Operating primarily in a leak-focused extortion model, they publish stolen data on a Tor-hosted site rather than encrypting files. Their victims include organizations across sectors like business services, technology, healthcare, transportation, and legal—all largely based in the United States, with a few in Ireland and South Korea. Activity surged in May 2024, landing them in the top 10 most active ransomware actors that month. Despite limited branding efforts, their smaller operational footprint has allowed for swift, targeted breaches that prioritize rapid data exposure over elaborate cryptographic tactics.

8base

8Base emerged in early 2022 and rapidly escalated its ransomware operations by mid-2023, positioning itself as a “simple pen tester” while executing a relentless double-extortion scheme: encrypting files using AES-256 CBC mode (appending the “.8base” extension) and threatening to leak stolen data via a Tor-accessible leak site. The group leverages initial access methods such as phishing and SmokeLoader, disables security mechanisms like Volume Shadow Copy and firewalls, and deploys persistence via registry and startup entries. Targeting primarily small and medium-sized organizations across sectors such as manufacturing, finance, IT, and healthcare in regions

including the U.S., Brazil, and Europe, 8Base has drawn comparisons to Phobos and RansomHouse for its tactics and ransom-note style. In early 2025, international law enforcement operations disrupted the group, resulting in the arrest of four key actors, seizure of servers, and warnings to hundreds of potential victims.

black suit

BlackSuit is a type of malicious software classified as ransomware. Its operation involves multifaceted extortion, encrypting and exfiltrating victim data, and hosting public data leak sites for victims who fail to meet its demands. BlackSuit's activities first began in early May 2023. Designed to prevent access to files by encrypting them, this ransomware appends the ".blacksuit" extension to the names of all affected files. Furthermore, it changes the desktop wallpaper and creates a ransom note file named "README.BlackSuit.txt." This threat actor targets large corporations, small and medium-sized enterprises (SMEs), with no apparent specific discrimination regarding industry or type of victim.

rhysida

Rhysida is a ransomware-as-a-service (RAAS) group that emerged in May 2023. The group utilizes a namesake ransomware through phishing attacks and Cobalt Strike to breach the targets' networks and deploy their payloads.

The group threatens to publicly distribute exfiltrated data if the ransom is not paid, and it’s worth mentioning that Rhysida is still in the early stages of development.

The ransomware leaves PDF notes in the affected folders, instructing victims to contact the group through its portal, and payment is made via Bitcoin.

After encryption, the ransomware appends the extension ".ryshida" to encrypted files.

For encryption purposes, Trend Micro published an analysis stating that the ransomware uses a 4096-bit RSA key and AES-CTR for encryption.

In addition to the encryption method, Trend Micro published an analysis of the Ryshida Ransomware attack chain.

Finally, the group has a website on the Tor network hosting the companies that have been breached.

medusa

The ransomware landscape remains active in 2024, with various ransomware groups attacking a wide range of organizations. In this context, Medusa Ransomware has emerged as a significant cyber threat, standing out for its data encryption and extortion operations.

Medusa Ransomware appeared in 2021, quickly becoming one of the most feared cyber threats. This malware encrypts critical files and demands ransoms in cryptocurrency, exploiting vulnerabilities in corporate and institutional systems. Known for its advanced phishing tactics, Medusa infiltrates networks with ease, causing significant damage.

Critical sectors such as healthcare and finance have been severely impacted, facing operational

disruptions and substantial financial losses. The ransomware continuously evolves, making it difficult for security experts to neutralize it. Medusa's rapid adaptation to new security defenses underscores the urgent need for more robust cybersecurity measures, emphasizing the importance of proactive cybersecurity.

The rise of Medusa Ransomware serves as a global warning about the dangers of sophisticated cyber threats and the need for ongoing preparedness.

lorenz

Tesorion describes Lorenz as a ransomware with design and implementation flaws, leading to impossible decryption with tools provided by the attackers. A free decryptor for 2021 versions was made available via the NoMoreRansom initiative. A new version of the malware was discovered in March 2022, for which again was provided a free decryptor, while the ransomware operators are not able to provide tools to decrypt affected files.

crosslock

CrossLock ransomware was first observed in April 2023, targeting an IT services firm in Brazil using a double-extortion approach—encrypting data and threatening to leak it publicly. Written in Go, it uses a hybrid encryption scheme combining ChaCha20 for file encryption with Curve25519 for key protection. Victims see their files renamed with the .crlk extension and ransom notes titled ---CrossLock_readme_To_Decrypt---.txt. The malware includes advanced techniques like Event Tracing for Windows (ETW) bypass and process mimicking (e.g., Cybereason processes) for stealth. It was publicly tracked until July 2023, after which activity (and its leak site) went offline.

cyclops

Cyclops ransomware was rebranded as Knight around mid-2023, emerging initially in early 2023. It operates as a Ransomware-as-a-Service (RaaS), targeting multiple platforms including Windows, macOS, Linux, and ESXi systems. Crafted in Go, it uses strong encryption algorithms like ChaCha20 and Curve25519. Knight includes both a full and "lite" encryptor, supports batch attacks, hosts a Tor leak site, and offers a web portal for affiliates—positioning itself as a scalable and partner-friendly ransomware operation. Affiliates can manage deployments, track payments, and negotiate with victims through a sophisticated RaaS platform.

dragonforce

Research on the operators of the DragonForce ransomware was conducted, and it was identified that the group emerged around mid-November 2023. They employ the same method as many other ransomware groups, using double extortion in their attacks, i.e., data encryption and extortion for the publication of the attacks.

Initially, according to research, it was identified that another hacktivist group, also named DragonForce and based in Malaysia, conducted several campaigns in 2021 and 2022 against various government organizations and agencies across the Middle East and Asia. Additionally, the hacktivist group announced in 2022 its intention to initiate ransomware attacks. However, due to the limitation and difficulty in obtaining substantial information, no direct link could be established.

The activities of the DragonForce ransomware group were identified in November 2023 through a clandestine forum, where they announced their victims via data leaks.

Some samples related to the DragonForce ransomware group were obtained, and it was concluded that the group uses a binary (ransomware) based on LockBit Black. In other words, this threat group took advantage of the previously leaked builder from another ransomware group, LockBit, and incorporated these samples into their attacks to encrypt data.

The company Cyble published an analysis indicating that the ransomware used by DragonForce has a 99% similarity to the LockBit Black ransomware, suggesting the use of the leaked builder.

It is worth noting that the ransomware performs the entire operational routine, terminating processes, encrypting specific files, and subsequently creating a ransom note for the victim.

ransomhub

A new ransomware group is said to have emerged in the cyber threat landscape. This time, it is a group known as RansomHub. The group emerged in mid-February 2024 and has already listed several organizations as alleged victims of their attacks, resulting from extortion through encryption and data leaks.

play

Initially observed in June 2022, the Play ransomware (a.k.a PlayCrypt) operates through double extortion, targeting numerous organizations in Latin America. Its Initial Access method is quite similar to other ransomwares, involving attacks such as Phishing, Exposed Services to the Internet, and Valid Account compromises.

On April 19, 2023, the security company Symantec published two new tools developed by the Play group. These tools allow the malicious actor to enumerate and exfiltrate data from the internal network. The post mentions the following: "Play threat actors use the .NET infostealer to enumerate software and services via WMI, WinRM, Remote Registry, and Remote Service. The malware checks for the existence of security and backup software, as well as remote administration tools and other programs, saving the information in .CSV files that are compressed into a .ZIP file for later manual exfiltration by threat actors." These tools make use of the following .NET frameworks (Costura, AlphaVSS).

cactus

The CACTUS ransomware is said to have emerged around March 2023. The group became known for exploiting vulnerabilities to gain initial access and maintain a presence within the organization's infrastructure. There is little known information about the ransomware group, except that it emerged on the mentioned date and, following encryption, a text file named 'cAcTuS.readme.txt' would be created. Additionally, encrypted files were altered to the '.cts1' extension, and data exfiltration and victim extortion were conducted through the use of the service known as Tox. As mentioned earlier, the ransomware especially exploits vulnerabilities in VPNs, also utilizing obfuscation techniques to conceal its activities, such as employing UPX and utilizing encryption algorithms like OpenSSL, AES OCB, ChaCha20_Poly1305, system reinitializations, and others.

dunghill

Dunghill Leak is the publicly branded data leak site (DLS) operated by the Dark Angels ransomware group, established circa January 2023. Rather than a standalone encryption threat, it serves as the disclosure and extortion platform where stolen victim data is published if ransom demands are ignored. Dark Angels is known for highly targeted “big game hunting” tactics, exfiltrating tens to hundreds of terabytes of corporate data, often without encrypting systems. Victims include major industry players—like Johnson Controls, Sabre, Sysco, and a Fortune 50 firm—which reportedly paid a record-breaking $75 million USD ransom. The leak site is complemented by a mirrored Telegram channel for distributing victim announcements and maintaining negotiation traffic.

insane ransomware

Insane is a relatively obscure ransomware family first reported in late 2021, with few confirmed incidents in public threat intelligence. It encrypts victim files using symmetric encryption (AES) combined with RSA for key protection and appends the .insane extension to affected files. The ransom note, typically named INSANE_README.txt, directs victims to contact the operators via email for decryption instructions. Based on limited reporting, Insane does not appear to operate as a Ransomware-as-a-Service (RaaS) platform; instead, it seems to be deployed by the core operators in targeted attacks. Initial access methods are not well-documented, but suspected vectors include phishing attachments and exploitation of exposed RDP services. The group's small footprint in open-source intelligence suggests limited distribution or use in highly selective campaigns.

risen

Risen, which is a fully optimized and high-speed program, is the result of our years of experience in the field of malware writing. Risen is written in C language and completely using winapi. We produced many products with different features and options, but we came to the conclusion that none of the options have the benefit and efficiency they should; So, instead of spending time on useless and inefficient options, we decided to spend all our time on the strength, speed and security of our cryptography, and that's how we created Risen. Software features in version 1:

 -Encryption security, utilizing Chacha20 and RSA 2048 algorithms.
 -High encryption speed and software optimization
 -compatible with all versions of Windows on any hardware without any issues.
 -Automatic option settings, its easy to using and default configuration set to the best mode.
 -Utilization of Threadpool method and queue creation for encryption.
 -A powerful file unlocker, unlock files without closing processes.
 -Safe deletion of backups, shadow copies, and all windows logs.
 -A blog, Leak website, and management panel on TOR for leaking data of non-paying companies.

brain cipher

In mid-June 2024, a new ransomware operation named Brain Cipher emerged, notably targeting Indonesia's National Data Center. This attack disrupted immigration operations at airports and various other government services. The payload employed by this group is based on the leaked LockBit 3.0 builder. Comparative analyses have confirmed significant similarities between Brain

Cipher and LockBit 3.0 samples. Notably, the attackers modified the ransomware to not only append a new extension to encrypted files but also to encrypt the filenames themselves. Additionally, it was identified that the group appears to be in its early stages, as evidenced by their use of the leaked LockBit 3.0 builder and their recent operations. After encrypting the data, the ransomware generates ransom notes named “added_extension.README.txt.” These notes contain a description of what occurred and a link to the attackers' website hosted on the Tor network.

good day

Good Day is a ransomware variant within the ARCrypter family, first observed in May 2023. It gained prominence due to its reticent financial extortion model and custom branding—victims are greeted with a “Good day” message upon landing on individualized Tor-based victim portals. The malware is typically delivered via phishing campaigns disguising payloads as legitimate Windows updates. It utilizes a robust encryption workflow, including deletion of volume shadow copies and process evasion mechanisms. Notably, Good Day has been linked to the Cloak ransomware group through shared data leak infrastructure and overlapping leak portal behaviors.

holyghost

HolyGhost is a ransomware group first publicly reported in July 2022, believed to be operated by a North Korean state-sponsored threat actor tracked as APT43 or Andariel, a subgroup of the Lazarus Group. The group has been active since at least June 2021, using a double-extortion model that combines encryption of victim files with threats to leak stolen data via a Tor site. Early HolyGhost variants (BTLC_C.exe) used a custom file extension .h0lyenc, while later builds added more robust encryption, obfuscation, and evasion capabilities. Targeted victims include small and medium-sized businesses in manufacturing, finance, education, and event planning, primarily in the United States, South Korea, Brazil, and India. Intrusion methods include exploitation of vulnerable public-facing applications, credential theft, and possibly the use of purchased access from other threat actors. Unlike purely criminal groups, HolyGhost is suspected of being leveraged for both revenue generation and strategic cyber operations in support of DPRK objectives.

chilelocker

ChileLocker first emerged in August 2022 and is considered part of the broader ARCrypter ransomware family. It employs a double-extortion model, encrypting Windows and Linux/VMware ESXi systems and threatening data leaks. ChileLocker uses the NTRU public key cryptosystem for encryption and typically appends the .crypt extension to affected files. Following encryption, it drops a ransom note—often named readme_for_unlock.txt—and directs victims to a password-protected Tor negotiation portal, with the password provided in the note. The group also disables recovery mechanisms by deleting shadow copies. Its initial access tactics include exploitation of misconfigured RDP access, phishing, malicious installers, botnets, fake updates, and malvertising. The ransomware has impacted victims across various regions, including Chile, Mexico, Canada, Spain, and others.

adminlocker

AdminLocker was first observed around December 2021 and appears to be a lone operator or small group, with no clear Ransomware-as-a-Service (RaaS) model reported. It uses single-extortion

tactics—encrypting files without publicly documented data exfiltration—primarily targeting enterprise and personal systems via methods such as malicious email attachments, cracked software installers, P2P downloads, and malvertising. The ransomware employs symmetric and asymmetric encryption (likely AES combined with RSA) to lock files, appending extensions such as .admin1, .admin2, .admin3, .1admin, .2admin, and .3admin; victims receive a “!!!Recovery File.txt” ransom note with instructions to pay via Tor and Bitcoin. Notable for its multiple simultaneous variants with varied extensions, it reportedly allows victims to decrypt up to five small files as “proof” before demanding ransom. No high-profile sector- or region-specific campaigns are publicly documented.

sarcoma

Sarcoma is a ransomware group that emerged in October 2024 and has been actively targeting various organizations. Sarcoma's attack methods include phishing campaigns, exploiting n-day vulnerabilities, and supply chain attacks. Once inside a network, they use RDP exploitation, lateral movement, and data exfiltration tactics. Sarcoma has claimed responsibility for attacks against Unimicron, a PCB manufacturer, Kelowna Springs Golf Club, Popular Life Insurance, CP Construplan, ADT Freight Services Australia, Micon National. These attacks have resulted in data exfiltration, with Sarcoma threatening to leak or having already leaked stolen data. Specifically, Sarcoma has exfiltrated 377 GB of SQL files and sensitive documents from Unimicron, 3.8 GB of data from Kelowna Springs, 36 GB of data from Popular Life Insurance, 2 GB of data from ADT Freight Services Australia, and 34 GB of data from Micon National. The group is known for its aggressive tactics against industrial organizations.

chort

Chort is a relatively new data-extortion ransomware group that surfaced in late 2024, with confirmed activity beginning in October–November 2024. It operates under a double-extortion model—exfiltrating sensitive data before encrypting systems—and organizes victims via a Tor-hosted data leak site (DLS). The group has targeted organizations in the U.S. education sector (including schools and nonprofits) and in Kuwait's agriculture sector, among others. Technical behaviors include execution via PowerShell and removal of shadow copies to disrupt recovery. The group's approach emphasizes public pressure through data exposure rather than technical innovation.

contfr

Launched around September 2024, ContFR is a French-speaking RaaS that uses a Tor-hosted platform to provide ransomware embedded in PDF files (targeting both Windows and macOS). The group offers a tiered subscription model—"TEST," "BASIC," and "ELITE"—allowing affiliates varying degrees of customization, offline capability, and support based on the package purchased. As of the

latest reporting, no victims are publicly listed, though data leak publications likely require a subscription to access. The operation suggests an organized, business-like structure, distinct from opportunistic one-off strains.

safepay

SafePay ransomware started in October 2024 as a new ransomware service, using some of the leaked LockBit source code. Soon after launching, the group made a big impact in the ransomware world, hacking at least 33 organizations by December 9.

The first version of SafePay was created by modifying the LockBit source code. It adds the ".safepay" extension to files that it encrypts and includes a ransom note called "readme_safepay.txt." This version uses a three-step XOR method with a random single-byte key, making it hard for security researchers to analyse.

The group’s technical infrastructure includes both a dark web blog and a presence on the TON network for victim communications. Their attack methodology follows a double extortion model,

combining traditional file encryption with data theft to maximise pressure on victims. SafePay operators typically move from initial access to ransomware deployment in under 24 hours, significantly faster than the industry average. . Among the Tactics, Techniques, and Procedures (TTPs) of the SafePay group, notable characteristics include the use of compromised VPN credentials as an initial access vector, extensive use of living-off-the-land binaries (LOLBins), and sophisticated privilege escalation techniques. The group frequently employs ShareFinder.ps1 for network reconnaissance and uses WinRAR for data archival before exfiltration. Post encryption, SafePay directs victims to their negotiation portal accessible through both Tor and TON networks.

The group has demonstrated sophisticated operational security measures, including a Cyrillic-language-based killswitch that prevents execution in eastern European countries.

gwisin

Gwisin is a targeted ransomware group first publicly reported in July 2022, believed to operate primarily within South Korea. The group's name means "ghost" in Korean, reflecting its stealthy approach. Gwisin has been observed conducting attacks on critical sectors, including healthcare, pharmaceutical, and manufacturing industries. It uses custom-built payloads tailored for each victim, capable of encrypting both Windows and Linux/VMware ESXi environments, and often executes attacks during national holidays to maximize operational disruption. Gwisin employs a double-extortion model—exfiltrating sensitive data before encryption—and communicates with victims in Korean-language ransom notes. Initial access vectors are not fully confirmed in open-source reporting, but suspected methods include exploiting vulnerable VPN appliances and leveraging stolen administrative credentials. The group is known for extensive pre-encryption

reconnaissance to identify high-value systems and backups.

ctblocker

aka Critroni
CTB-Locker emerged in mid-2014, introducing a new era of ransomware by leveraging elliptic curve cryptography (ECC), Tor-based C&C communication, and Bitcoin payments—earning its name from “Curve-Tor-Bitcoin Locker.” It was packaged and sold as a ransomware kit for approximately $1,500–$3,000, allowing affiliates to deploy customized campaigns. The malware encrypts user data (including network and removable drives), changes desktop wallpapers, and appends file extensions like .CTBL, .CTB2, or randomized strings. Victims receive instructions for payment, typically within a limited timeframe, or risk permanent data loss. In 2015–2017, law enforcement and cybersecurity firms (including McAfee and Kaspersky) disrupted the network, arrested operators, and facilitated decryption tools.

dataf locker

DataF Locker is a ransomware variant first observed in 2024, closely tied to the Babuk ransomware lineage. It operates under a double-extortion model, encrypting files by appending the .dataf extension and threatening to leak exfiltrated data if the ransom isn't paid. Victims receive a ransom note named How To Restore Your Files.txt, with satisfaction of specified recovery procedures. Observations suggest use of typical intrusion vectors such as phishing, exploit tools, or leaked credential abuse, although detailed delivery methods and leak infrastructure remain under-documented in high-tier intelligence reports.

br0k3r

Br0k3r is not a conventional ransomware gang, but rather an Iran-linked cyber espionage and access brokerage group leveraging its foothold within victim networks to facilitate ransomware operations. Active since around 2017, the group provides privileged domain access—often sold or shared directly—with known ransomware operators such as ALPHV/BlackCat, NoEscape, and RansomHouse, receiving a portion of each successful ransom payout. Victims have included U.S. schools, municipal governments, financial and healthcare organizations, as well as targets in Israel, Azerbaijan, and the UAE. Br0k3r's strategy merges espionage with criminal collaboration, allowing them to support both state-aligned intelligence objectives and financial incentives.

cs-137

Cs-137 is a newly observed ransomware strain that first appeared in January 2025. It employs the ChaCha20 cipher for encryption and appends obfuscated filenames with a random 10-character alphanumeric identifier while preserving the original file extension. In its current testing phase, it drops a ransom note with a randomized filename (e.g. ABCDEF-README.txt) and sets a randomly named image file as the desktop wallpaper. The note references a Tor-based extortion portal—though access is not yet active, indicating the operation's early development stage. The strategy suggests single-extortion behavior, focused on disrupting access rather than data theft or leak threats.

DORRA

A new ransomware variant has been identified, named DORRA. It is worth mentioning in advance that this variant is derived from the Makop ransomware family.

This variant encrypts data by adding the “.DORRA” extension to files, as well as a unique ID and the ransomware developer’s email address.

After encrypting the data, the payload creates a ransom note as a text file named “README-WANING.txt,” through which victims are instructed to contact the threat actor via the provided email to decrypt the data.

Interestingly, this variant uses a simple email address hosted on Microsoft’s Outlook service as the contact method.

The tag is: *misp-galaxy:ransomware="DORRA"*

View relationships graph

HSHARADA

The ransomware was identified in early April 2023 and is said to target English-speaking users and potentially other languages. The extension added to encrypted files is: ".m9SRob" (potentially random). The ransom note is named "m9SRob-README.txt". There are no further details about the mentioned group or potentially files. The fact is that it adds an ID for each victim.

The tag is: *misp-galaxy:ransomware="HSHARADA"*

Hunt

Hunt ransomware is a variant of the Dharma/CrySIS ransomware family. This variant creates a unique ID for each victim, appends the extension '.hunt' to encrypted files, and leaves a ransom note known as info-hunt.txt.

The Dharma/CrySIS ransomware family emerged around mid-2016 as a Ransomware-as-a-Service (RaaS) program, utilizing various initial intrusion methods such as phishing, disguising as legitimate software, and exploiting open RDP connections.

This variant uses AES-256 encryption (CBC mode) or DES+RSA and demands payment to recover files. Upon execution, the ransomware generates a 256-bit AES decryption key, which is then encrypted along with random bytes using the RSA-1024 algorithm and stored at the end of the encrypted file.

The ransomware is written in C/C++ and compiled using MS Visual Studio. Regarding geographic attribution, it has been identified in use by threat actors from Russia, Ukraine, India, and other countries.

a1project

The locker is written in C/C++/ASM.
It supports all systems starting from Windows 2003, has a separate binary for ESXi, and uses a unified encrypted file format across all systems.
WINDOWS:
 • Two encryption modes: patch-based and file header.
 • Extensive configuration settings: from ignoring specific paths/extensions to terminating services/processes, unlocking occupied files, working with network shares, and more.
 • Arguments available for shutting down Hyper-V virtual machines, deleting backups, network scanning with logged-in user tokens.
 • Each build includes an obfuscated PowerShell script.
 • Execution is password-protected.
 • The locker itself is shellcode for x86/x64; if you have custom execution methods, we can provide the shellcode.
ESXI:
 • Encrypts files in patches, with configurable path exclusions.
The default configuration is pre-set to avoid disrupting Windows/ESXi/Linux systems.

Our commission is 20% of payouts

babuk-bjorka

On January 26th, Babuk's dedicated leak site (DLS) was "relaunched". Bjorka (Telegram: @bjorkanesiaaaa) is the current administrator. Upon launch, the DLS was populated mainly by victims previously claimed by other groups such as RansomHub, Lockbit3, and Funksec. At this current time there is no apparent connection to the original Babuk operation besides reusing the Babuk site template and logos. The groups is also known as Babuk2 by other trackers.

It is important to note that the original Babuk DLS was hosted and available up until February 26th, 2024.

d0glun

D0glun is a crypto-ransomware strain first observed in January 2025, believed to be derived from Babuk via an intermediary variant known as Cheng Xilun. It uses AES-256 symmetric encryption and appends filenames with patterns such as .@D0glun@<original extension> or similar. The malware encrypts files rapidly, changes the desktop wallpaper, and drops ransom notes typically named @, Desktopcxl.txt, or help.exe. The campaign has shown signs of shared infrastructure and code reuse from Cheng Xilun, but there is no confirmed evidence of a large-scale or mature operation. Its activity so far suggests it is being tested or deployed by a small group or individual rather than a structured affiliate network.

Shinra

SHINRA ransomware is a variant of the Proton ransomware family, known for its malicious activities involving data encryption and demanding a ransom for data decryption.

After encrypting files, the ransomware renames them with a sequence of random characters and appends the ".SHINRA3" extension to the filenames.

It is worth noting that this ransomware uses AES and ECC encryption algorithms to lock files on the victim's computer. Following the encryption, it creates a ransom note named "SHINRA-Recovery.txt."

There are not many details about its operation or methods of infecting its victims, but after encryption, the victim needs to send an email regarding recovery to the addresses provided, including their ID as generated by the ransomware:

Qq.decrypt@gmail.com Qq.encrypt@gmail.com ethan@fastmsg.info

The ransomware also changes the victim's wallpaper, displaying the need to send the data and contact the threat actor.

Yashma

Cisco Talos has identified a new, previously unknown threat actor of Vietnamese origin conducting a ransomware operation that began at least on June 4, 2023.

The ongoing attack utilizes a variant of the Yashma Ransomware, likely targeting multiple geographical areas and mimicking the characteristics of WannaCry.

The threat actor uses an unusual technique to deliver the ransom note, as instead of embedding the ransom note strings in the binary, the actor downloads the ransom note from a GitHub repository controlled by ,the actor by executing an embedded batch file.

Talos stated that this threat actor targets victims in English-speaking countries, Bulgaria, China, and Vietnam, as the GitHub account of the actor "nguyenvientphat" contains ransomware notes written in the languages of these countries. The presence of the ransom note may indicate that the actor intends to expand its geographical area of operation.

The company also stated that the threat actor may have Vietnamese origin because the GitHub account name and email contact in the ransom notes fake the name of a legitimate organization. The ransom note also asks victims to contact between 19:00 and 23:00 UTC +07:00, coinciding with the Vietnam time zone.

A difference was also identified in the Vietnamese language ransom note, as it begins with "Sorry, your file is encrypted!" compared to the other notes that state "Oops, your files are encrypted!". By saying "sorry," the threat actor may intend to show greater sensitivity to victims in Vietnam, indicating that the attackers themselves are Vietnamese.

Talos further mentioned that the threat actor started the campaign around June 4, 2023, as they joined GitHub and created a public repository called "Ransomware." In the repository, the threat actor added text files of ransom notes in five languages: English, Bulgarian, Vietnamese, simplified Chinese, and traditional Chinese.

The note presents the email address "nguyenvietphat[.]n@gmail[.]com," for victims to contact them. At the time of analysis, no Bitcoin was observed in the wallet, and the ransom note did not specify an amount, indicating that the ransomware operation could still be in its early stages.

The threat actor deployed a variant of the Yashma ransomware, which they compiled on June 4, 2023. It is worth noting that Yashma is a 32-bit executable written in .NET and a renamed version of the Chaos Ransomware V5, which appeared in May 2022. In the variant, most of Yashma's features remained unchanged and were described by BlackBerry security researchers, with some notable modifications.

The ransomware stores the ransom note text as strings in the binary, but this Yashma variant executes an embedded batch file, which contains the commands to download the ransom note from the actor-controlled GitHub repository. This modification avoids endpoint detection solutions and antivirus software, which typically detect embedded ransom note strings in the binary.

Previous versions of Yashma established persistence on the victim's machine in the Run registry key and by dropping a Windows shortcut file pointing to the executable path of the ransomware in the startup folder. The identified variant also established persistence in the Run registry key. However, it was modified to create a ".url" favorites file in the startup folder pointing to the executable located in "%AppData%\Roaming\svchost.exe."

Additionally, the threat actor chose to maintain Yashma's anti-recovery capability in this variant. After encrypting a file, the ransomware wipes the content of the original unencrypted files, writes a single "?" character, and then deletes the file. This technique makes it more difficult for incident responders and forensic analysts to recover deleted files from the victim's hard drive.

ghost

aka Cring / Ghost (Cring)

Beginning early 2021, Ghost actors began attacking victims whose internet facing services ran outdated versions of software and firmware. This indiscriminate targeting of networks containing vulnerabilities has led to the compromise of organizations across more than 70 countries, including organizations in China. Ghost actors, located in China, conduct these widespread attacks for financial gain. Affected victims include critical infrastructure, schools and universities, healthcare, government networks, religious institutions, technology and manufacturing companies, and numerous small- and medium-sized businesses.

Ghost actors rotate their ransomware executable payloads, switch file extensions for encrypted files, modify ransom note text, and use numerous ransom email addresses, which has led to variable attribution of this group over time. Names associated with this group include Ghost, Cring, Crypt3r, Phantom, Strike, Hello, Wickrme, HsHarada, and Rapture. Samples of ransomware files Ghost used during attacks are: Cring.exe, Ghost.exe, ElysiumO.exe, and Locker.exe.

mimic-guram

Mimic v.10 Ransomware-as-a-Service (RaaS). The malware is designed to target various operating systems (Windows, ESXi, NAS, FreeBSD) and features network-wide deployment, file obfuscation, backup destruction, UAC bypass, and multithreaded encryption. The service offers additional tools like NTLM password decryption and call-based extortion. They prohibit attacks on CIS countries and require active participation, with decryption tools available for a fee currently 800USD.

blackberserk

Black Berserk is a relatively unsophisticated ransomware strain analyzed in late 2023. It operates under a single-extortion model—encrypting files and demanding payment, with no documented abilities or threats for data exfiltration or public leaks. In observed cases, the malware appends the .Black extension to encrypted files (e.g., 1.jpg.Black) and leaves a ransom note titled Black_Recover.txt, which urges victims to make contact to negotiate payment or test decryption with benign files. The infection method appears opportunistic, delivered via isolated incidents or broad malware distribution—not linked to targeted campaigns or infrastructure. There is no evidence of it functioning as a RaaS operation or targeting any specific victim profiles or sectors.

antibrok3rs

Antibrok3rs emerged as an access broker (not a ransomware operator itself) linked to the aftermath of the 2023 MOVEit supply-chain exploitation. From November 2024 through early 2025, this actor has posted stolen data from at least 15 energy-sector victims, including U.S. utilities such as CenterPoint Energy, Entergy, Nevada Energy, and Appalachian Power—data likely obtained via the MOVEit breach. While some analysts suspected ties to the Cl0P ransomware collective, Antibrok3rs publicly denied any such affiliation. The extortion model centers on data leakage without accompanying file encryption—a purely leak-based threat. No delivery, encryption, or ransom note behaviors have been observed, nor is there evidence of RaaS activity.

core

Core ransomware surfaced in early 2025 as a new variant within the broader Makop family. It employs a single-extortion model, focusing on encrypting files and demanding payment, without public data-leak threats. The malware appends the .core extension to encrypted files and is delivered via typical exploit vectors known to RaaS campaigns. Core does not showcase advanced double-extortion tactics seen in other modern strains, but it stands out for its familial lineage and continued evolution from Makop ancestors.

2023lock

2023Lock is a ransomware strain first observed in January 2024, believed to be an evolution of the Venus and Zeoticus families and a direct precursor to the later TrinityLock variant. It employs a hybrid encryption method combining XChaCha20 and curve25519xsalsa20poly1305, appending the “.2023lock” extension to encrypted files. Upon infection, it delivers ransom notes in HTML, TXT, and HTA formats containing decryption instructions. Unlike many modern ransomware groups, there is no evidence that 2023Lock engages in double extortion or data exfiltration, operating purely through file encryption to pressure victims into payment. Its codebase and operational patterns strongly align with TrinityLock, which emerged a few months later with more sophisticated extortion tactics.

arcrypter

ArcRypt (also known as ARCrypter or ChileLocker) was first identified in August 2022, originally targeting government entities in Latin America and subsequently expanding globally. The group employs a single-extortion model—there is no evidence of a data-leak threat or RaaS ecosystem. The malware encrypts files using extensions such as .crypt, .crYpt, and .crYptA3, and uniquely drops the ransom note before commencing encryption. It has variants for both Windows and Linux, including a Go-based Linux version. Communication with victims occurs via Tor-based portals, evolving over time from a single shared site to individualized mirror sites for each victim. In some cases, threat actors have instructed victims to contact them using Tox, creating a Tox profile for communication. Targets have included Chile's government infrastructure, Colombia's

Invima agency, and organizations in China and Canada.

axxes

Axxes ransomware emerged as a rebranded version of the previously known Midas ransomware group, with roots also tracing back through Haron and Avaddon lineage. It operates via a single-extortion model, encrypting files and appending the .axxes extension. Victims receive both an “RESTORE_FILES_INFO.hta” and a “.txt” ransom note. The ransomware performs extra actions like determining the device’s geolocation, modifying the Windows Firewall, changing file extensions, and terminating processes using taskkill.exe. Its known targets span the U.S., UAE, France, and China, including at least one high-profile victim—The H Dubai hotel. This group appears financially motivated, leveraging historical branding and code of earlier groups for its operations.

astralocker

AstraLocker first appeared in 2021, likely as a fork of Babuk ransomware using leaked source code. It follows a single-extortion, smash-and-grab approach: distributed directly via phishing Microsoft Word documents containing embedded OLE objects. Once executed, it kills security and backup processes, deletes shadow copies, and encrypts files using modified HC-128 and Curve25519 algorithms, appending extensions like .Astra or .babyk. A “smash-and-grab” style attack, it’s less methodical than more sophisticated campaigns—deploying ransomware immediately upon user action rather than conducting prolonged network reconnaissance. In mid-2022, the operator ceased ransomware operations, releasing decryptors and announcing a pivot to cryptojacking.

jsworm

JSWorm is a ransomware family that first appeared in May 2019 and is notable for undergoing multiple rebrands and evolutions, later appearing under names such as Nemty, Nefilim, Offwhite, Fusion, and Milihpen. Initially, it was distributed via malicious spam emails containing JavaScript files, hence the “JS” in its name. Later versions moved to targeted intrusions, leveraging compromised RDP services and vulnerable network appliances for initial access. JSWorm encrypts files using AES-256 encryption with RSA-2048 for key protection and appends campaign-specific extensions (e.g., .JSWORM, .Nemty, .Nephilim). The group adopted a double-extortion model in its later stages, stealing data before encryption and threatening to leak it via Tor-hosted sites. Its victimology spans various sectors worldwide, including manufacturing, energy, healthcare, and professional services. The continuous rebranding suggests an effort to evade detection, disrupt attribution, and maintain pressure on victims.

crynox

Crynox (sometimes referred to as “Crynox Ransomware”) appears to be a generic file-locker threat that appends .crynox to encrypted files and drops a ransom note (read_it.txt) instructing victims to contact crynoxWARE@proton.me. It seems to use RSA-4096 and AES for encryption and may change desktop wallpaper, but there’s no evidence of double-extortion or leak site operation. Distribution methods cited include phishing, pirated software, and malicious websites.

ailock

AiLock is a Ransomware-as-a-Service (RaaS) group first identified in March 2025. It employs a double-extortion approach—encrypting files and threatening to report breaches to regulators or share stolen data with competitors if the ransom isn't paid. Victims have just 72 hours to respond and up to five days to pay; failure to pay results in data leaks and destruction of recovery tools. The ransomware appends the extension .AiLock to encrypted files, changes file icons to a green padlock with the "AiLock" name, and replaces the desktop wallpaper with a distinctive robot-skull logo. It employs a hybrid encryption scheme, combining ChaCha20 for file encryption with NTRUEncrypt for securing metadata, and uses a multi-threaded design (path-traversal and encryption threads with IOCP) for efficiency. While active campaigns and leak sites are confirmed, specific sectors,

regions, and intrusion methods remain undisclosed in public sources.

cerbersyslock

CerBerSysLock first appeared in December 2017 as a cryptoransomware imposter, leveraging Cerber-style branding to deceive victims. It uses XOR-based encryption to lock files and appends extensions such as .CerBerSysLocked0009881. Victims receive a ransom note titled “HOW TO DECRYPT FILES.txt”, which falsely claims to be from the Cerber ransomware. The note includes an email contact—TerraBytefiles@scryptmail.com—and instructs victims to reference their ID (e.g., "CerBerSysLocked0009881") when communicating. The ransomware is technically linked to the Xorist family and is generally considered an opportunistic, low-profile scam rather than part of a broader Ransomware-as-a-Service (RaaS) operation.

blackbit

BlackBit ransomware was first observed in August 2022 and is a .NET-based strain that closely mimics the design and functionality of LockBit 3.0, indicating either a fork of LockBit's leaked builder or deliberate imitation. It uses a double-extortion model, encrypting victim files and threatening to leak stolen data via a Tor-based site. BlackBit employs AES symmetric encryption for file contents and RSA asymmetric encryption for key protection, appending the .BlackBit extension to affected files. The malware also includes features for terminating processes, deleting volume shadow copies, and disabling recovery mechanisms. Initial access vectors are not comprehensively documented but are consistent with phishing, exploitation of vulnerable public-facing services, and the use of compromised credentials. Victims have been identified across various sectors, including technology, manufacturing, and professional services, though its activity level has been far lower than LockBit's.

dharma

Dharma is a prolific ransomware family active since at least 2016, evolving from the earlier CrySiS ransomware. It operates under a Ransomware-as-a-Service (RaaS) model, allowing affiliates to deploy customized builds with their own contact emails and extensions. Dharma typically appends encrypted files with patterns like .id-[victimID].[email].dharma or other campaign-specific suffixes. Initial access is often gained through exposed Remote Desktop Protocol (RDP) services secured with weak or stolen credentials, sometimes combined with brute-force attacks. The malware encrypts files using AES with RSA to secure the keys and drops ransom notes in text files and pop-up windows. Numerous variants have emerged over time, each linked to different affiliates, making attribution difficult.

aptlock

Aptlock surfaced in early 2025 and is characterized by a single-extortion model combined with threats of data leakage. The ransomware encrypts files on Windows systems, appending the extension .aptlock, and then changes the victim's desktop wallpaper. Victims receive a ransom note named read_me_to_access.txt informing them that their critical company data has been exfiltrated and will be deleted or leaked if they don't act. They are given 72 hours to initiate contact via Tor-based chat access (using credentials provided in the note), with further warnings issued if no engagement occurs within 5 days. Specific details about intrusion vectors, encryption algorithms used, or known affiliate operators remain undisclosed in public threat intelligence. No reliable evidence links Aptlock to Ransomware-as-a-Service operations or lists any known affiliates.

elpaco

Elpaco is a variant of Mimic ransomware that emerged around August 2023. Designed with significant customization and stealth in mind, it targets Windows systems by abusing the Everything search utility to optimize file discovery and accelerate encryption. Operators exploit various initial access methods—most notably RDP brute-force and the Zerologon vulnerability (CVE-2020-1472)—to gain access, escalate privileges, and deliver the payload. The ransomware uses a 7z SFX dropper, deploys multi-threaded encryption, disables recovery options, and self-deletes after execution, leaving victims with encrypted files bearing Elpaco-specific extensions. It's recognized for its adaptability and advanced features compared to earlier Mimic variants.

fargo

Fargo is a ransomware variant that surfaced in 2022, primarily targeting Microsoft SQL Server (MSSQL) systems. Believed to be a variant of the TargetCompany ransomware family, Fargo uses brute-force or credential-stuffing attacks on exposed MSSQL instances to gain access, then executes payloads via SQL Server commands. Once deployed, it encrypts files using a combination of symmetric and asymmetric algorithms, appends the .Fargo3 (or similar) extension, and drops a ransom note directing victims to contact operators via email. It also attempts to delete system backups and shadow copies to prevent recovery. Fargo has been observed targeting organizations in multiple sectors, with a concentration of victims in South Korea and other parts of Asia.

freeworld

FreeWorld is a ransomware variant first observed in September 2023, and is believed to be derived from the Mimic ransomware family. It is deployed through coordinated campaigns dubbed DB#JAMMER, which exploit poorly secured Microsoft SQL (MSSQL) servers exposed to the internet. Attackers gain initial access via brute force, leverage the xp_cmdshell feature to execute shell commands, disable defenses, deploy remote access tools like Cobalt Strike and AnyDesk, and eventually deliver the FreeWorld payload. The ransomware encrypts files using hybrid encryption and appends the .FreeWorldEncryption extension. Victims receive a ransom note titled FreeWorld-Contact.txt, directing them on payment and data recovery steps.

The tag is: *misp-galaxy:ransomware="freeworld"*

colossus

Colossus ransomware was first observed in September 2021, when ZeroFox researchers uncovered the variant attacking a U.S.-based automotive group. It employs a double-extortion model, using Themida packing and sandbox evasion to disable defenses and deliver encrypted payloads. Victims are urged to visit a support site—hosted at a domain like colossus.support—to negotiate payment, or face large-scale data dumps and increasing ransom amounts tied to countdown timers. Operators demonstrated familiarity with RaaS playbooks, drawing architectural parallels to groups like EpsilonRed, BlackCocaine, and REvil/Sodinokibi.

globe

Globe is a ransomware family that first appeared in August 2016, notable for its highly customizable codebase that allows operators to configure ransom note text, encryption algorithms, and file extensions. Globe uses symmetric encryption (RC4 or AES) to lock files and typically appends custom extensions such as .GLOBE, .PURPLE, .HNY, or others set by the attacker. The malware is distributed through malicious spam emails with infected attachments, compromised websites, and exploit kits. Globe's flexibility made it attractive to low-skilled actors, resulting in many different variants in the wild. The family has primarily targeted small to medium-sized businesses and individual users across multiple regions, with no clear geographic focus.

backmydata

BackMyData is a variant of the Phobos ransomware family, first observed in early 2024. It follows a double-extortion model: encrypting files and threatening data exposure. The ransomware primarily targets organizations via weak or misconfigured RDP access (e.g., remote desktop services), though phishing and initial-stage payloads like SmokeLoader have also been noted. Technical behavior includes AES-256 file encryption, with keys secured via a public RSA-2048 key embedded in the binary. Post-infection actions involve disabling firewalls, deleting volume shadow copies, inhibiting recovery functionality, and establishing persistence through registry Run keys and startup folder entries. Encrypted files receive the extension .BACKMYDATA, and victims are left with ransom notes (info.txt, info.hta, or .backmydata) that instruct them to contact attackers via email or Session Messenger. A significant incident involved a coordinated attack on Romania's Hipocrate Information System (HIS), impacting 26 hospitals and causing widespread system outages across nearly 100 facilities, with ransom demands of approximately 3.5 BTC (~$175,000).

hermes

Hermes is a ransomware family first observed in the wild in February 2017, believed to have been developed by a group operating out of Asia. It originally appeared as a Ransomware-as-a-Service (RaaS) offering on underground forums but later saw deployment in targeted attacks. Hermes uses AES-256 encryption to lock victim files and appends a variety of extensions (including .hrm and campaign-specific variants). The ransom note, often named DECRYPT_INFORMATION.html or DECRYPT_INFORMATION.txt, provides payment instructions via email. The ransomware gained notoriety in 2018 when it was used as a destructive wiper in the Far Eastern International Bank (FEIB) heist in Taiwan, where attackers deployed Hermes to cover their tracks after a SWIFT fraud operation. Over time, Hermes code has been re-used and integrated into other ransomware families, including some Ryuk builds, suggesting code sharing or purchase from the original developer. Distribution vectors have included phishing campaigns, malicious attachments, and exploitation of RDP services.

babylockerkz

BabyLockerKZ is a variant of MedusaLocker ransomware, first observed in late 2023. It operates under a double-extortion model, combining file encryption with data exfiltration and extortion. Technically, it reuses MedusaLocker's AES + RSA-2048 hybrid encryption, appends the .hazard file extension to encrypted files, and includes a unique autorun registry key ("BabyLockerKZ") alongside dedicated public/private key data inserted into registry values. Initial access is achieved through opportunistic methods like RDP compromises, with lateral movement facilitated by compromised credentials and tools such as Mimikatz. The variant employs a custom toolkit codenamed paid_memes, which includes tools like "Checker" for scanning credentials, facilitating automation, and bridging toolsets for further exploitation. Starting late 2022, its operators have compromised over 100 organizations per month, initially targeting European victims before shifting toward Latin America in 2023.

arcane

Arcane first emerged in mid-2021 under the UNC2190 cluster and later rebranded as Sabbath,

continuing its operations against critical infrastructure like hospitals, schools, and educational entities. It follows a double-extortion model—encrypting data (using ROLLCOAST/Eruption malware) while also exfiltrating sensitive information and threatening to leak it. Victims have included institutions in the U.S. and Canada across sectors such as healthcare, education, and natural resources. Initial intrusion tactics involved deployment of Cobalt Strike with custom profiles, DLL-based in-memory execution, and signed TLS certificates, plus use of stealthy GET requests ending with “kitten.gif.” Specific encryption algorithms or file extensions have not been publicly confirmed. The group appears to operate in an affiliate-style model but remains under single management rather than a full RaaS platform.

kasseika

Kasseika is a ransomware variant first publicly reported in January 2024, identified as a new evolution of the BlackMatter/LockBit ransomware codebase. The malware appends the .kasseika extension to encrypted files and uses a double-extortion model, combining file encryption with threats to publish stolen data on a Tor-based leak site. Early analysis revealed that Kasseika shares several traits with LockBit 3.0, including encryption routines, obfuscation methods, and ransom note structure, but with modified branding and negotiation portals. Initial access vectors have not been widely confirmed, though patterns from related ransomware suggest the use of compromised credentials, RDP exploitation, and vulnerabilities in public-facing services. Victims have been observed in North America, Europe, and Asia, spanning industries like manufacturing, logistics, and professional services.

catb

CatB ransomware was first observed in late 2022, gaining attention for abusing DLL hijacking via the Microsoft Distributed Transaction Coordinator (MSDTC) service—loading a malicious payload through DLL sideloading methods. The malware arrives in a two-stage dropper: the first DLL unpacks and launches the main payload (commonly named oci.dll), which subsequently encrypts files using hybrid RSA/AES cryptography. Unlike conventional ransomware, CatB does not rename files or distribute typical ransom notes; instead, it prepends the ransom message directly to the start of each encrypted file, making detection more difficult. Victims are instructed to contact the attackers via email (e.g., catB9991@protonmail.com or fishA001@protonmail.com), with the ransom demand escalating daily. Initial analysis suggests CatB may be a rebrand or evolution of Pandora ransomware, sharing various code artifacts and operational behavior.

cerberimposter

Cerber Imposer is a post-2019 rebrand of the Cerber ransomware family, resurfacing in late 2021 with updated targeting of enterprise environments. Unlike its classic counterpart, Cerber Imposer utilizes the .locked file extension and includes a unique recovery note named *RECOVERY_README*.html. It does not reuse the original Cerber codebase; instead it borrows branding while operating under new cryptographic implementations and deployment tactics. Threat actors have leveraged known remote code execution vulnerabilities in Atlassian Confluence (CVE-2021-26084) and GitLab (CVE-2021-22205) to deliver this ransomware. The rebranded variant has compromised servers in the U.S., Germany, China, and Russia, indicating a broader scope of targeting than originally seen with early Cerber campaigns.

darkylock

Darky Lock is a commodity-style ransomware strain first identified in July 2022, derived from publicly available Babuk source code. Victim systems undergo file encryption with an added ".darky" extension, and a "Restore-My-Files.txt" ransom note is placed in all impacted locations. The malware attempts to disable backup mechanisms, including shadow copies and specific applications. Its distribution leverages phishing and trojanized installers, complemented by payloads dropped via frameworks like Empire, Metasploit, and Cobalt Strike.

bidon

BIDON is a variant of the Monti ransomware family, first observed around mid-2023. It employs a double-extortion strategy—encrypting victims' files and simultaneously threatening to leak stolen data if the ransom isn't paid. Notably, it appends the .PUUUK extension to encrypted files and drops a readme.txt ransom note outlining the extortion demands. The note offers a free decryption of two files as proof of capability and emphasizes that only authorized company personnel (e.g., top management) should engage. BIDON specifically targets corporate and enterprise organizations, not home users, and warns victims not to involve law enforcement or third-party recovery firms. It represents a shift toward more aggressive extortion tactics within the Monti lineage.

deathgrip

DeathGrip is a Ransomware-as-a-Service (RaaS) that emerged around June 2024, offering malware payloads built with leaked LockBit 3.0 and Yashma/Chaos builders. Designed to lower technical barriers, it enables even low-skilled operators to deploy highly capable ransomware attacks. DeathGrip campaigns typically employ AES-256 encryption, delete shadow copies and recovery

features, and modify system settings to hinder restoration. Earlier infections include low-tier ransom demands (e.g., around $100), reflecting entry-level targeting, though its flexible tooling allows a range of payload configurations.

blacksnake

BlackSnake is a Ransomware-as-a-Service (RaaS) operation that first appeared in August 2022, when its operators began recruiting affiliates on underground forums with an unusually low revenue share of 15%. It primarily targets home users rather than large enterprises and does not maintain a public leak site. Built on the Chaos ransomware code base, it features both file encryption and a cryptocurrency clipper module to steal funds from victims. The ransomware is developed in .NET and includes safeguards to avoid execution in Turkish or Azerbaijani environments, suggesting geographic targeting preferences. Infections result in encrypted files and ransom notes instructing victims to make contact via email for payment negotiations. The group's operational scale and visibility remain limited compared to major RaaS families.

bert

BERT ransomware (also tracked as Water Pombero) first emerged in April 2025, rapidly targeting both Windows and Linux systems across Asia, Europe, and the U.S., with confirmed victims in healthcare, technology, electronics, and event services sectors. Its Windows variant employs a PowerShell-based loader that escalates privileges, disables Defender, UAC, and the firewall, then downloads the ransomware payload. The Linux version aggressively encrypts with up to 50 concurrent threads, forcibly shuts down VMware ESXi VMs to prevent recovery, and appends extensions like .encryptedbybert or .encrypted_by_bert. BERT uses AES encryption, and later variants feature optimized multithreading via ConcurrentQueue and DiskWorker threads. Analysts note code similarities with REvil and Babuk ESXi lockers, potentially pointing to shared development lineage or code reuse.

black nevas

BlackNevas ransomware — also referred to as “Trial Recovery” — was first observed in November 2024. It is a direct derivative of the Trigona ransomware family and continues the lineage’s focus on extortion over public shaming. BlackNevas operators support a double-extortion model, encrypting files using AES-256 with RSA-4112-protected keys, and appending the .-encrypted or .ENCRYPTED file extension to affected files. Hybrid payloads are available for Windows, Linux, NAS, and VMware ESXi platforms.

While BlackNevas does not host its own data leak site, it reportedly collaborates with other ransomware groups for data publication — known partners include Kill Security, Hunters International, DragonForce, Blackout, Embargo Team, and Mad Liberator. The group has predominantly targeted large enterprises in sectors such as finance, telecommunications, manufacturing, healthcare, and legal. Initial access is commonly achieved via phishing or exploitation of vulnerabilities, with lateral movement facilitated through SMB enumeration and optional LAN-wide propagation.

leaknet

In the cyber-undergrounds, we're exploring shadowed corridors of the digital world in search of inside information. we're a digital watchdog operating at the intersection of cybersecurity, internet freedom, and investigative journalism. We delve into the hidden corners of the web, exposing truths and uncovering stories that are often buried by mainstream media or

distorted by corporate interests.

This project isn't just for tech experts or privacy advocates. It's for everyone who values transparency, freedom, and integrity in a connected world. Operating independently, we're free from corporate influence and political bias, enabling us to report with uncompromising honesty. Our work resonates with a diverse audience cybersecurity experts, digital rights activists, journalists, and anyone who values an internet free from control.

In a world where the lines between truth and agenda grow increasingly blurred, we're building something bold, the space where the truth of the internet can be uncovered, untamed and unfiltered. Our project is an independent voice for digital freedom, committed to shining a light on the internet's most vital and vulnerable spaces: cybersecurity, privacy, and the right to information without compromise.

In a landscape clouded by agendas and profit, we are here to do one thing: deliver the truth, boldly and beautifully. Join us as we push back against the systems that seek to compromise our digital freedoms and carve a path toward a more transparent, liberated internet.

RAT

remote administration tool or remote access tool (RAT), also called sometimes remote access trojan, is a piece of software or programming that allows a remote "operator" to control a system as if they have physical access to that system..

RAT is a cluster galaxy available in JSON format at **this location** The JSON format can be freely reused in your application or automatically enabled in MISP.

Back Orifice 2000

Back Orifice 2000 (often shortened to BO2k) is a computer program designed for remote system administration. It enables a user to control a computer running the Microsoft Windows operating system from a remote location. The name is a pun on Microsoft BackOffice Server software. Back Orifice 2000 is a new version of the famous Back Orifice backdoor trojan (hacker's remote access tool). It was created by the Cult of Dead Cow hackers group in July 1999. Originally the BO2K was released as a source code and utilities package on a CD-ROM. There are reports that some files on that CD-ROM were infected with CIH virus, so the people who got that CD might get infected and spread not only the compiled backdoor, but also the CIH virus.

The tag is: *misp-galaxy:rat="Back Orifice 2000"*

NJRat

NJRat is a remote access trojan (RAT), first spotted in June 2013 with samples dating back to November 2012. It was developed and is supported by Arabic speakers and mainly used by cybercrime groups against targets in the Middle East. In addition to targeting some governments in the region, the trojan is used to control botnets and conduct other typical cybercrime activity. It infects victims via phishing attacks and drive-by downloads and propagates through infected USB keys or networked drives. It can download and execute additional malware, execute shell commands, read and write registry keys, capture screenshots, log keystrokes, and spy on webcams.

The tag is: *misp-galaxy:rat="NJRat"*

NJRat is also known as:

- Njw0rm

Predator Pain

Unlike Zeus, Predator Pain and Limitless are relatively simple keyloggers. They indiscriminately steal web credentials and mail client credentials, as well as capturing keystrokes and screen captures. The output is human readable, which is good if you are managing a few infected machines only, but the design doesn't scale well when there are a lot of infected machines and logs involved.

The tag is: *misp-galaxy:rat="Predator Pain"*

Predator Pain is also known as:

- PredatorPain

Dendroid

Dendroid is malware that affects Android OS and targets the mobile platform. It was first discovered in early of 2014 by Symantec and appeared in the underground for sale for $300. Some things were noted in Dendroid, such as being able to hide from emulators at the time. When first discovered in 2014 it was one of the most sophisticated Android remote administration tools known at that time. It was one of the first Trojan applications to get past Google's Bouncer and caused researchers to warn about it being easier to create Android malware due to it. It also seems to have

follow in the footsteps of Zeus and SpyEye by having simple-to-use command and control panels. The code appeared to be leaked somewhere around 2014. It was noted that an apk binder was included in the leak, which provided a simple way to bind Dendroid to legitimate applications.

The tag is: *misp-galaxy:rat="Dendroid"*

Kiler RAT

This remote access trojan (RAT) has capabilities ranging from manipulating the registry to opening

a reverse shell. From stealing credentials stored in browsers to accessing the victims webcam. Through the Command & Control (CnC) server software, the attacker has capabilities to create and configure the malware to spread utilizing physic devices, such as USB drives, but also to use the victim as a pivot point to gain more access laterally throughout the network. This remote access trojan could be classified as a variant of the well known njrat, as they share many similar features such as their display style, several abilities and a general template for communication methods . However, where njrat left off KilerRat has taken over. KilerRat is a very feature rich RAT with an active development force that is rapidly gaining in popularity amongst the middle eastern community and the world.

Remote Utilities

Remote Utilities is a free remote access program with some really great features. It works by pairing two remote computers together with what they call an "Internet ID." You can control a total of 10 PCs with Remote Utilities.

The tag is: *misp-galaxy:rat="Remote Utilities"*

Table 10982. Table References

Links
https://www.remoteutilities.com/

Ammyy Admin

Ammyy Admin is a completely portable remote access program that’s extremely simple to setup. It

works by connecting one computer to another via an ID supplied by the program.

The tag is: *misp-galaxy:rat="Ammyy Admin"*

Ammyy Admin is also known as:

- Ammyy

Table 10983. Table References

Links
http://ammyy-admin.soft32.com/

Ultra VNC

UltraVNC works a bit like Remote Utilities, where a server and viewer is installed on two PCs, and the viewer is used to control the server.

The tag is: *misp-galaxy:rat="Ultra VNC"*

Table 10984. Table References

Links
http://www.uvnc.com/

AeroAdmin

AeroAdmin is probably the easiest program to use for free remote access. There are hardly any settings, and everything is quick and to the point, which is perfect for spontaneous support.

The tag is: *misp-galaxy:rat="AeroAdmin"*

Table 10985. Table References

Links
http://www.aeroadmin.com/en/

Windows Remote Desktop

Windows Remote Desktop is the remote access software built into the Windows operating system. No additional download is necessary to use the program.

The tag is: *misp-galaxy:rat="Windows Remote Desktop"*

RemotePC

RemotePC, for good or bad, is a more simple free remote desktop program. You’re only allowed one connection (unless you upgrade) but for many of you, that’ll be just fine.

The tag is: *misp-galaxy:rat="RemotePC"*

Table 10986. Table References

Links
https://www.remotepc.com/

Seecreen

Seecreen (previously called Firnass) is an extremely tiny (500 KB), yet powerful free remote access program that's absolutely perfect for on-demand, instant support.

The tag is: *misp-galaxy:rat="Seecreen"*

Seecreen is also known as:

- Firnass

Table 10987. Table References

NanoCore

In September of 2015, a DigiTrust client visited a web link that was providing an Adobe Flash Player update. The client, an international retail organization, attempted to download and run what appeared to be a regular update. The computer trying to download this update was a back office system that processed end of day credit card transactions. This system also had the capability of connecting to the corporate network which contained company sales reports. DigiTrust experts were alerted to something malicious and blocked the download. The investigation found that what appeared to be an Adobe Flash Player update, was a Remote Access Trojan called NanoCore. If installation had been successful, customer credit card data, personal information, and internal sales information could have been captured and monetized. During the analysis of NanoCore, our experts found that there was much more to this RAT than simply being another Remote Access Trojan.

The tag is: *misp-galaxy:rat="NanoCore"*

Xsser

Xsser mRAT is a piece of malware that targets iOS devices that have software limitations removed. The app is installed via a rogue repository on Cydia, the most popular third-party application store for jailbroken iPhones. Once the malicious bundle has been installed and executed, it gains persistence - preventing the user from deleting it. The mRAT then makes server-side checks and proceeds to steal data from the user's device and executes remote commands as directed by its command-and-control (C2) server.

The tag is: *misp-galaxy:rat="Xsser"*

Xsser is also known as:

- mRAT

Quaverse

Quaverse RAT or QRAT is a fairly new Remote Access Tool (RAT) introduced in May 2015. This RAT is marketed as an undetectable Java RAT. As you might expect from a RAT, the tool is capable of grabbing passwords, key logging and browsing files on the victim's computer. On a regular basis for the past several months, we have observed the inclusion of QRAT in a number of spam campaigns.

The tag is: *misp-galaxy:rat="Quaverse"*

Quaverse is also known as:

- QRAT

Cardinal

Cardinal is a remote access trojan (RAT) discovered by Palo Alto Networks in 2017 and has been active for over two years. It is delivered via a downloader, known as Carp, and uses malicious macros in Microsoft Excel documents to compile embedded C# programming language source code into an executable that runs and deploys the Cardinal RAT. The malicious Excel files use different tactics to get the victims to execute it.

Trochilus

Trochilus is a remote access trojan (RAT) first identified in October 2015 when attackers used it to infect visitors of a Myanmar website. It was then used in a 2016 cyber-espionage campaign, dubbed "the Seven Pointed Dagger," managed by another group, "Group 27," who also uses the PlugX trojan. Trochilus is primarily spread via emails with a malicious .RAR attachment containing the malware. The trojan's functionality includes a shellcode extension, remote uninstall, a file manager, and the ability to download and execute, upload and execute, and access the system information. Once present on a system, Trochilus can move laterally in the network for better access. This trojan operates in memory only and does not write to the disk, helping it evade detection.

Matryoshka

Their most commonly used initial attack vector is a simple, yet alarmingly effective, spearphishing attack, infecting unsuspecting victims via a malicious email attachment (usually an executable that has been disguised as something else). From there, Matryoshka runs second stage malware via a dropper and covertly installs a Remote Access Toolkit (RAT). This is done using a reflective loader technique that allows the malware to run in process memory, rather than being written to disk. This not only hides the install of the RAT but also ensures that the RAT will be 'reinstalled' after system restart.

Mangit

First discovered by Trend Micro in June, Mangit is a new malware family being marketed on both the Dark web and open internet. Users have the option to rent the trojan's infrastructure for about $600 per 10-day period or buy the source code for about $8,800. Mangit was allegedly developed by "Ric", a Brazilian hacker, who makes himself available via Skype to discuss rental agreements. Once the malware is rented or purchased, the user controls a portion of the Mangit botnet, the trojan, the dropper, an auto-update system, and the server infrastructure to run their attacks. Mangit contains support for nine Brazillian banks including Citibank, HSBC, and Santander. The malware can also be used to steal user PayPal credentials. Mangit has the capability to collect banking credentials, receive SMS texts when a victim is accessing their bank account, and take over victim's browsers. To circumvent two-factor authentication, attackers can use Mangit to lock victim's browsers and push pop-ups to the victim asking for the verification code they just received.

Revenge-RAT

Revenge v0.1 was a simple tool, according to a researcher known as Rui, who says the malware's author didn't bother obfuscating the RAT's source code. This raised a question mark with the researchers, who couldn't explain why VirusTotal scanners couldn't pick it up as a threat right away.Revenge, which was written in Visual Basic, also didn't feature too many working features, compared to similar RATs. Even Napolean admitted that his tool was still in the early development stages, a reason why he provided the RAT for free.

vjw0rm 0.1

"Vengeance Justice Worm" was first discovered in 2016 and is a highly multifunctional, modular, publicly available "commodity malware", i.e., it can be purchased by those interested through various cybercrime and hacking related forums and channels.

VJwOrm is a JavaScript-based malware and combines characteristics of Worm, Information Stealer, Remote-Access Trojan (RAT), Denial-of-Service (DOS) malware, and spam-bot.

VJw0rm is propagated primarily by malicious email attachments and by infecting removeable storage devices.

Once executed by the victim, the very heavily obfuscated VJw0rm will enumerate installed drives and, if a removeable drive is found, VJwOrm will infect it if configured to do so.

It will continue to gather victim information such as operating system details, user's details,

installed anti-virus product details, stored browser cookies, the presence of vbc.exe on the system (Microsoft's .NET Visual Basic Compiler, this indicates that .NET is installed on the system and can affect the actor's choice of additional malware delivery), and whether the system has been previously infected.

VJw0rm will then report this information back to its command-and-control server and await further commands, such as downloading and executing additional malware or employing any of its other numerous capabilities.

Finally, VJw0rm establishes persistency in the form of registry auto-runs, system startup folders, a scheduled-task, or any combination of these methods.

The tag is: *misp-galaxy:rat="vjw0rm 0.1"*

vjw0rm 0.1 is also known as:

- Vengeance Justice Worm
- VJw0rm
- VJwOrm

rokrat

ROKRAT is a remote access trojan (RAT) that leverages a malicious Hangual Word Processor (HWP) document sent in spearphishing emails to infect hosts. The HWP document contains an embedded Encapsulated PostScript (EPS) object. The object exploits an EPS buffer overflow vulnerability and downloads a binary disguised as a .JPG file. The file is then decoded and the ROKRAT executable is initiated. The trojan uses legitimate Twitter, Yandex, and Mediafire websites for its command and control communications and exfiltration platforms, making them difficult to block globally. Additionally, the platforms use HTTPS connections, making it more difficult to gather additional data on its activities. Cisco's Talos Group identified two email campaigns. In one, attackers send potential victims emails from an email server of a private university in Seoul, South Korea with a sender email address of "kgf2016@yonsei.ac.kr," the contact email for the Korea Global Forum, adding a sense of legitimacy to the email. It is likely that the email address was compromised and used by the attackers in this campaign. The second is less sophisticated and sends emails claiming to be from a free Korean mail service with a the subject line, "Request Help" and attached malicious HWP filename, "I'm a munchon person in Gangwon-do, North Korea." The ROKRAT developer uses several techniques to hinder analysis, including identifying tools usually used by malware analysts or within sandbox environments. Once it has infected a device, this trojan can execute commands, move a file, remove a file, kill a process, download and execute a file, upload documents, capture screenshots, and log keystrokes. Researchers believe the developer is a native Korean speaker and the campaign is currently targeting Korean-speakers.

RATAttack

RATAttack is a remote access trojan (RAT) that uses the Telegram protocol to support encrypted communication between the victim's machine and the attacker. The Telegram protocol also provides a simple method to communicate to the target, negating the need for port forwarding. Before using RATAttack, the attacker must create a Telegram bot and embed the bot's Telegram token into the trojan's configuration file. When a system is infected with RATAttack, it connects to the bot's Telegram channel. The attacker can then connect to the same channel and manage the RATAttack clients on the infected host machines. The trojan's code was available on GitHub then was taken down by the author on April 19, 2017.

DNSMessenger

Talos recently analyzed an interesting malware sample that made use of DNS TXT record queries and responses to create a bidirectional Command and Control (C2) channel. This allows the attacker to use DNS communications to submit new commands to be run on infected machines and return the results of the command execution to the attacker. This is an extremely uncommon and evasive way of administering a RAT. The use of multiple stages of Powershell with various stages being completely fileless indicates an attacker who has taken significant measures to avoid detection.

htpRAT

On November 8, 2016 a non-disclosed entity in Laos was spear-phished by a group closely related to known Chinese adversaries and most likely affiliated with the Chinese government. The attackers utilized a new kind of Remote Access Trojan (RAT) that has not been previously observed or reported. The new RAT extends the capabilities of traditional RATs by providing complete remote execution of custom commands and programming. htpRAT, uncovered by RiskIQ cyber investigators, is the newest weapon in the Chinese adversary's arsenal in a campaign against

Association of Southeast Asian Nations (ASEAN). Most RATs can log keystrokes, take screenshots, record audio and video from a webcam or microphone, install and uninstall programs and manage files. They support a fixed set of commands operators can execute using different command IDs —'file download' or 'file upload,' for example—and must be completely rebuilt to have different functionality. htpRAT, on the other hand, serves as a conduit for operators to do their job with greater precision and effect. On the Command and Control (C2) server side, threat actors can build new functionality in commands, which can be sent to the malware to execute. This capability makes htpRAT a small, agile, and incredibly dynamic piece of malware. Operators can change functionality, such as searching for a different file on the victim's network, simply by wrapping commands.

FALLCHILL

According to trusted third-party reporting, HIDDEN COBRA actors have likely been using FALLCHILL malware since 2016 to target the aerospace, telecommunications, and finance industries. The malware is a fully functional RAT with multiple commands that the actors can issue from a command and control (C2) server to a victim's system via dual proxies. FALLCHILL typically infects a system as a file dropped by other HIDDEN COBRA malware or as a file downloaded unknowingly by users when visiting sites compromised by HIDDEN COBRA actors. HIDDEN COBRA actors use an external tool or dropper to install the FALLCHILL malware-as-a-service to establish persistence. Because of this, additional HIDDEN COBRA malware may be present on systems compromised with FALLCHILL.

BONDUPDATER

BONDUPDATER is a PowerShell-based Trojan first discovered by FireEye in mid-November 2017, when OilRig targeted a different Middle Eastern governmental organization. The BONDUPDATER Trojan contains basic backdoor functionality, allowing threat actors to upload and download files, as well as the ability to execute commands. BONDUPDATER, like other OilRig tools, uses DNS tunneling to communicate with its C2 server. During the past month, Unit 42 observed several attacks against a Middle Eastern government leveraging an updated version of the BONDUPDATER malware, which now includes the ability to use TXT records within its DNS tunneling protocol for its C2 communications.

The tag is: *misp-galaxy:rat="BONDUPDATER"*

FlawedAmmy

During the month of October, Check Point researchers discovered a widespread malware campaign spreading a remote access trojan (dubbed “FlawedAmmy”) that allows attackers to take over victims’ computers and data. The campaign was the latest and most widespread delivering the ‘FlawedAmmyy’ RAT, following a number of campaigns that have spread this malware in recent months. The Trojan allows attackers to gain full access to the machine’s camera and microphone, collect screen grabs, steal credentials and sensitive files, and intrusively monitor the victims’ actions. As a result, FlawedAmmy is the first RAT to enter the Global Threat Index’s top 10 ranking.

The tag is: *misp-galaxy:rat="FlawedAmmy"*

Felipe

The Zscaler ThreatLabZ team came across a new strain of infostealer Trojan called Felipe, which silently installs itself onto a user’s system and connects to a command-and-control (C&C) server to send system information from the compromised system. This malware is compiled for both 32-bit and 64-bit Windows operating systems. Felipe basically steals the victim’s debit and credit card information and sends it, along with other personal information, to the remote C&C server. It also sets a date and time to perform other malicious activity upon successful infection of the victim machine.

The tag is: *misp-galaxy:rat="Felipe"*

Table 11095. Table References

SDBbot

SDBbot is a new remote access Trojan (RAT) written in C++ that has been delivered by the Get2 downloader in recent TA505 campaigns. Its name is derived from the debugging log file (sdb.log.txt) and DLL name (BotDLL[.]dll) used in the initial analyzed sample. It also makes use of application shimming [1] for persistence. SDBbot is composed of three pieces: an installer, a loader, and a RAT component.

The tag is: *misp-galaxy:rat="SDBbot"*

SDBbot is also known as:

- SDB bot

Table 11101. Table References

Links
https://www.proofpoint.com/us/threat-insight/post/ta505-distributes-new-sdbbot-remote-access-trojan-get2-downloader

Sepulcher

A China-based APT has been sending organizations spear-phishing emails that distribute a never-before-seen intelligence-collecting RAT dubbed Sepulcher.

Researchers discovered the new malware being distributed over the past six months through two separate campaigns. The first, in March, targeted European diplomatic and legislative bodies, non-profit policy research organizations and global organizations dealing with economic affairs. The second, in July, targeted Tibetan dissidents. They tied the campaigns to APT group TA413, which researchers say has been associated with Chinese state interests and is known for targeting the Tibetan community.

“Based on the use of publicly known sender addresses associated with Tibetan dissident targeting and the delivery of Sepulcher malware payloads, [we] have attributed both campaigns to the APT actor TA413,” said Proofpoint researchers in a Wednesday analysis. “The usage of publicly known

Tibetan-themed sender accounts to deliver Sepulcher malware demonstrates a short-term realignment of TA413's targets of interest."

The tag is: *misp-galaxy:rat="Sepulcher"*

https://cyware.com/news/chinese-apt-ta413-found-distributing-sepulcher-malware-176a0969

Guildma

The campaign spreads via phishing emails posing as invoices, tax reports, invitations and similar types of messages containing a ZIP archive attachment with a malicious LNK file. When a user opens the malicious LNK file, it abuses the Windows Management Instrumentation Command-line tool and silently downloads a malicious XSL file. The XSL file downloads all of Guildma's modules and executes a first stage loader, which loads the rest of the modules. The malware is then active and waits for commands from the C&C server and/or specific user interactions, such as opening a webpage of one of the targeted banks.

The tag is: *misp-galaxy:rat="Guildma"*

Guildma is also known as:

- Astaroth

DarkWatchman

In late November, Prevailion's Adversarial Counterintelligence Team (PACT) identified what appeared to be a malicious javascript-based Remote Access Trojan (RAT) that uses a robust Domain Generation Algorithm (DGA) to identify its Command and Control (C2) infrastructure and that utilizes novel methods for fileless persistence, on-system activity, and dynamic run-time capabilities like self-updating and recompilation. This RAT, which PACT refers to by its internal codename "DarkWatchman", has been observed being distributed by email and represents an evolution in fileless malware techniques, as it uses the registry for nearly all temporary and permanent storage and therefore never writes anything to disk, allowing it to operate beneath or around the detection threshold of most security tools. PACT has reverse engineered the DGA, dynamically analyzed the malware, investigated the Threat Actor's (TA) web-based infrastructure, and consolidated the results of our analysis into the following report.

The tag is: *misp-galaxy:rat="DarkWatchman"*

DarkWatchman is also known as:

Table 11105. Table References

STRRAT

STRRAT is a Java-based RAT with a JavaScript wrapper/dropper that was discovered in 2020. Its core payload (a .JAR file) is contained under several layers of obfuscation and encoding inside the JavaScript wrapper/dropper.

STRRAT is propagated by malicious email attachments. Its capabilities include standard RAT functionalities (remote access, remote command execution), browser and email-client credential harvesting, and a unique ransomware-like functionality – if instructed, it will add a “.crimson” extension to files on the device, rendering them inoperable (though they can be easily recovered because their content is not modified).

Unlike many Java-based malware, STRRAT does not require Java to be installed on the infected system in order to operate. When the JavaScript wrapper/dropper is executed, if a suitable Java runtime installation is not found, one will be downloaded and installed in order to assure the contained Java payload can execute.

The tag is: *misp-galaxy:rat="STRRAT"*

Table 11107. Table References

Links
https://www.deepinstinct.com/blog/understanding-the-windows-javascript-threat-landscape

COATHANGER

Chinese FortiGate RAT. The COATHANGER malware is a remote access trojan (RAT) designed specifically for Fortigate appliances. It is used as second-stage malware, and does not exploit a new vulnerability. Intelligence services MIVD & AIVD refer to the malware as COATHANGER based on a string present in the code./nThe COATHANGER malware is stealthy and persistent. It hides itself by hooking system calls that could reveal its presence. It survives reboots and firmware upgrades./nMIVD & AIVD assess with high confidence that the malicious activity was conducted by a state-sponsored actor from the People’s Republic of China. This is part of a wider trend of Chinese political espionage against the Netherlands and its allies./nMIVD & AIVD assess that use of COATHANGER may be relatively targeted. The Chinese threat actor(s) scan for vulnerable edge devices at scale and gain access opportunistically, and likely introduce COATHANGER as a communication channel for select victims.

The tag is: *misp-galaxy:rat="COATHANGER"*

Intrusion Attempts:Login attempts has relationships with:

- similar: misp-galaxy:mitre-attack-pattern="Brute Force - T1110" with estimative-language:likelihood-probability="likely"
- similar: misp-galaxy:mitre-attack-pattern="Password Guessing - T1110.001" with estimative-language:likelihood-probability="likely"
- similar: misp-galaxy:mitre-attack-pattern="Password Cracking - T1110.002" with estimative-language:likelihood-probability="likely"
- similar: misp-galaxy:mitre-attack-pattern="Password Spraying - T1110.003" with estimative-language:likelihood-probability="likely"
- similar: misp-galaxy:mitre-attack-pattern="Credential Stuffing - T1110.004" with estimative-language:likelihood-probability="likely"

Intrusion Attempts:New attack signature

An attack using an unknown exploit.

The tag is: *misp-galaxy:rsit="Intrusion Attempts:New attack signature"*

Intrusions:Privileged Account Compromise

Compromise of a system where the attacker gained administrative privileges.

The tag is: *misp-galaxy:rsit="Intrusions:Privileged Account Compromise"*

View relationships graph

Intrusions:Privileged Account Compromise has relationships with:

- similar: misp-galaxy:mitre-attack-pattern="Valid Accounts - T1078" with estimative-

language:likelihood-probability="likely"

Intrusions:Unprivileged Account Compromise

Compromise of a system using an unprivileged (user/service) account.

The tag is: *misp-galaxy:rsit="Intrusions:Unprivileged Account Compromise"*

View relationships graph

Intrusions:Unprivileged Account Compromise has relationships with:

- similar: misp-galaxy:mitre-attack-pattern="Valid Accounts - T1078" with estimative-language:likelihood-probability="likely"

Intrusions:Application Compromise

Compromise of an application by exploiting (un-)known software vulnerabilities, e.g. SQL injection.

The tag is: *misp-galaxy:rsit="Intrusions:Application Compromise"*

View relationships graph

Intrusions:Application Compromise has relationships with:

- similar: misp-galaxy:mitre-attack-pattern="Exploit Public-Facing Application - T1190" with estimative-language:likelihood-probability="likely"

Intrusions:System Compromise

Compromise of a system, e.g. unauthorised logins or commands. This includes compromising attempts on honeypot systems.

The tag is: *misp-galaxy:rsit="Intrusions:System Compromise"*

Intrusions:Burglary

Physical intrusion, e.g. into corporate building or data-centre.

The tag is: *misp-galaxy:rsit="Intrusions:Burglary"*

Availability:Denial of Service

Denial of Service attack, e.g. sending specially crafted requests to a web application which causes the application to crash or slow down.

The tag is: *misp-galaxy:rsit="Availability:Denial of Service"*

View relationships graph

Availability:Denial of Service has relationships with:

- similar: misp-galaxy:mitre-attack-pattern="Network Denial of Service - T1498" with estimative-language:likelihood-probability="likely"

Availability:Distributed Denial of Service

Distributed Denial of Service attack, e.g. SYN-Flood or UDP-based reflection/amplification attacks.

The tag is: *misp-galaxy:rsit="Availability:Distributed Denial of Service"*

View relationships graph

Availability:Distributed Denial of Service has relationships with:

- similar: misp-galaxy:mitre-attack-pattern="Network Denial of Service - T1498" with estimative-language:likelihood-probability="likely"

Availability:Misconfiguration

Software misconfiguration resulting in service availability issues, e.g. DNS server with outdated DNSSEC Root Zone KSK.

The tag is: *misp-galaxy:rsit="Availability:Misconfiguration"*

Availability:Sabotage

Physical sabotage, e.g cutting wires or malicious arson.

The tag is: *misp-galaxy:rsit="Availability:Sabotage"*

Availability:Outage

Outage caused e.g. by air condition failure or natural disaster.

The tag is: *misp-galaxy:rsit="Availability:Outage"*

Information Content Security:Unauthorised access to information

Unauthorised access to information, e.g. by abusing stolen login credentials for a system or application, intercepting traffic or gaining access to physical documents.

The tag is: *misp-galaxy:rsit="Information Content Security:Unauthorised access to information"*

Information Content Security:Unauthorised modification of information

Unauthorised modification of information, e.g. by an attacker abusing stolen login credentials for a system or application or a ransomware encrypting data. Also includes defacements.

The tag is: *misp-galaxy:rsit="Information Content Security:Unauthorised modification of information"*

View relationships graph

Information Content Security:Unauthorised modification of information has relationships with:

- similar: misp-galaxy:mitre-attack-pattern="Data Manipulation - T1565" with estimative-language:likelihood-probability="likely"

Information Content Security:Data Loss

Loss of data, e.g. caused by harddisk failure or physical theft.

The tag is: *misp-galaxy:rsit="Information Content Security:Data Loss"*

Information Content Security:Leak of confidential information

Leaked confidential information like credentials or personal data.

The tag is: *misp-galaxy:rsit="Information Content Security:Leak of confidential information"*

Fraud:Unauthorised use of resources

Using resources for unauthorised purposes including profit-making ventures, e.g. the use of e-mail to participate in illegal profit chain letters or pyramid schemes.

The tag is: *misp-galaxy:rsit="Fraud:Unauthorised use of resources"*

Fraud:Copyright

Offering or Installing copies of unlicensed commercial software or other copyright protected materials (Warez).

The tag is: *misp-galaxy:rsit="Fraud:Copyright"*

Fraud:Masquerade

Type of attack in which one entity illegitimately impersonates the identity of another in order to benefit from it.

The tag is: *misp-galaxy:rsit="Fraud:Masquerade"*

Fraud:Phishing

Masquerading as another entity in order to persuade the user to reveal private credentials. This IOC most often refers to a URL, which is used to phish user credentials.

The tag is: *misp-galaxy:rsit="Fraud:Phishing"*

View relationships graph

Fraud:Phishing has relationships with:

- similar: misp-galaxy:mitre-attack-pattern="Phishing - T1566" with estimative-language:likelihood-probability="likely"

Vulnerable:Weak crypto

Publicly accessible services offering weak crypto, e.g. web servers susceptible to POODLE/FREAK attacks.

The tag is: *misp-galaxy:rsit="Vulnerable:Weak crypto"*

Vulnerable:DDoS amplifier

Publicly accessible services that can be abused for conducting DDoS reflection/amplification attacks, e.g. DNS open-resolvers or NTP servers with monlist enabled.

The tag is: *misp-galaxy:rsit="Vulnerable:DDoS amplifier"*

View relationships graph

Vulnerable:DDoS amplifier has relationships with:

- similar: misp-galaxy:mitre-attack-pattern="Network Denial of Service - T1498" with estimative-language:likelihood-probability="likely"

Vulnerable:Potentially unwanted accessible services

Potentially unwanted publicly accessible services, e.g. Telnet, RDP or VNC.

The tag is: *misp-galaxy:rsit="Vulnerable:Potentially unwanted accessible services"*

Vulnerable:Information disclosure

Publicly accessible services potentially disclosing sensitive information, e.g. SNMP or Redis.

The tag is: *misp-galaxy:rsit="Vulnerable:Information disclosure"*

Vulnerable:Vulnerable system

A system which is vulnerable to certain attacks. Example: misconfigured client proxy settings (example: WPAD), outdated operating system version, XSS vulnerabilities, etc.

The tag is: *misp-galaxy:rsit="Vulnerable:Vulnerable system"*

Other:Uncategorised

All incidents which don't fit in one of the given categories should be put into this class or the incident is not categorised.

The tag is: *misp-galaxy:rsit="Other:Uncategorised"*

Other:Undetermined

The categorisation of the incident is unknown/undetermined.

The tag is: *misp-galaxy:rsit="Other:Undetermined"*

Test:Test

Meant for testing.

The tag is: *misp-galaxy:rsit="Test:Test"*

Sector

Activity sectors.

Windows Event Log Access Tampering Via Registry

Detects changes to the Windows EventLog channel permission values. It focuses on changes to the Security Descriptor Definition Language (SDDL) string, as modifications to these values can restrict access to specific users or groups, potentially aiding in defense evasion by controlling who can view or modify a event log channel. Upon execution, the user shouldn't be able to access the event log channel via the event viewer or via utilities such as "Get-EventLog" or "wevtutil".

The tag is: *misp-galaxy:sigma-rules="Windows Event Log Access Tampering Via Registry"*

View relationships graph

Windows Event Log Access Tampering Via Registry has relationships with:

Suspicious Path In Keyboard Layout IME File Registry Value

Detects usage of Windows Input Method Editor (IME) keyboard layout feature, which allows an attacker to load a DLL into the process after sending the WM_INPUTLANGCHANGEREQUEST message. Before doing this, the client needs to register the DLL in a special registry key that is assumed to implement this keyboard layout. This registry key should store a value named "Ime File" with a DLL path. IMEs are essential for languages that have more characters than can be represented on a standard keyboard, such as Chinese, Japanese, and Korean.

The tag is: *misp-galaxy:sigma-rules="Suspicious Path In Keyboard Layout IME File Registry Value"*

View relationships graph

Suspicious Path In Keyboard Layout IME File Registry Value has relationships with:

Persistence Via Disk Cleanup Handler - Autorun

Detects when an attacker modifies values of the Disk Cleanup Handler in the registry to achieve persistence via autorun. The disk cleanup manager is part of the operating system. It displays the dialog box [...] The user has the option of enabling or disabling individual handlers by selecting or clearing their check box in the disk cleanup manager's UI. Although Windows comes with a number of disk cleanup handlers, they aren't designed to handle files produced by other applications. Instead, the disk cleanup manager is designed to be flexible and extensible by enabling any developer to implement and register their own disk cleanup handler. Any developer can extend the available disk cleanup services by implementing and registering a disk cleanup handler.

The tag is: *misp-galaxy:sigma-rules="Persistence Via Disk Cleanup Handler - Autorun"*

Potential Registry Persistence Attempt Via Windows Telemetry

Detects potential persistence behavior using the windows telemetry registry key. Windows telemetry makes use of the binary CompatTelRunner.exe to run a variety of commands and perform the actual telemetry collections. This binary was created to be easily extensible, and to that end, it relies on the registry to instruct on which commands to run. The problem is, it will run any arbitrary command without restriction of location or type.

The tag is: *misp-galaxy:sigma-rules="Potential Registry Persistence Attempt Via Windows Telemetry"*

View relationships graph

Potential Registry Persistence Attempt Via Windows Telemetry has relationships with:

- related-to: misp-galaxy:mitre-attack-pattern="Scheduled Task - T1053.005" with estimative-language:likelihood-probability="almost-certain"

Uncommon Extension In Keyboard Layout IME File Registry Value

Detects usage of Windows Input Method Editor (IME) keyboard layout feature, which allows an attacker to load a DLL into the process after sending the WM_INPUTLANGCHANGEREQUEST message. Before doing this, the client needs to register the DLL in a special registry key that is assumed to implement this keyboard layout. This registry key should store a value named "Ime File" with a DLL path. IMEs are essential for languages that have more characters than can be represented on a standard keyboard, such as Chinese, Japanese, and Korean.

The tag is: *misp-galaxy:sigma-rules="Uncommon Extension In Keyboard Layout IME File Registry Value"*

UAC Notification Disabled

Detects when an attacker tries to disable User Account Control (UAC) notification by tampering with the "UACDisableNotify" value. UAC is a critical security feature in Windows that prevents unauthorized changes to the operating system. It prompts the user for permission or an administrator password before allowing actions that could affect the system's operation or change settings that affect other users. When "UACDisableNotify" is set to 1, UAC prompts are suppressed.

The tag is: *misp-galaxy:sigma-rules="UAC Notification Disabled"*

View relationships graph

UAC Notification Disabled has relationships with:

- related-to: misp-galaxy:mitre-attack-pattern="Bypass User Account Control - T1548.002" with estimative-language:likelihood-probability="almost-certain"

Potential ClickFix Execution Pattern - Registry

Detects potential ClickFix malware execution patterns by monitoring registry modifications in RunMRU keys containing HTTP/HTTPS links. ClickFix is known to be distributed through phishing campaigns and uses techniques like clipboard hijacking and fake CAPTCHA pages. Through the fakecaptcha pages, the adversary tricks users into opening the Run dialog box and pasting clipboard-hijacked content, such as one-liners that execute remotely hosted malicious files or scripts.

The tag is: *misp-galaxy:sigma-rules="Potential ClickFix Execution Pattern - Registry"*

View relationships graph

Potential ClickFix Execution Pattern - Registry has relationships with:

- related-to: misp-galaxy:mitre-attack-pattern="Malicious Link - T1204.001" with estimative-language:likelihood-probability="almost-certain"

https://github.com/SigmaHQ/sigma/tree/master/rules/windows/registry/registry_set/registry_set_asep_reg_keys_modification_wow6432node_currentversion.yml

UAC Secure Desktop Prompt Disabled

Detects when an attacker tries to change User Account Control (UAC) elevation request destination via the "PromptOnSecureDesktop" value. The "PromptOnSecureDesktop" setting specifically determines whether UAC prompts are displayed on the secure desktop. The secure desktop is a separate desktop environment that's isolated from other processes running on the system. It's designed to prevent malicious software from intercepting or tampering with UAC prompts. When "PromptOnSecureDesktop" is set to 0, UAC prompts are displayed on the user's current desktop instead of the secure desktop. This reduces the level of security because it potentially exposes the prompts to manipulation by malicious software.

The tag is: *misp-galaxy:sigma-rules="UAC Secure Desktop Prompt Disabled"*

View relationships graph

UAC Secure Desktop Prompt Disabled has relationships with:

- related-to: misp-galaxy:mitre-attack-pattern="Bypass User Account Control - T1548.002" with estimative-language:likelihood-probability="almost-certain"

https://github.com/SigmaHQ/sigma/tree/master/rules/windows/registry/registry_set/registry_set_hide_file.yml

Directory Service Restore Mode(DSRM) Registry Value Tampering

Detects changes to "DsrmAdminLogonBehavior" registry value. During a Domain Controller (DC) promotion, administrators create a Directory Services Restore Mode (DSRM) local administrator account with a password that rarely changes. The DSRM account is an “Administrator” account that logs in with the DSRM mode when the server is booting up to restore AD backups or recover the server from a failure. Attackers could abuse DSRM account to maintain their persistence and access to the organization’s Active Directory. If the "DsrmAdminLogonBehavior" value is set to "0", the administrator account can only be used if the DC starts in DSRM. If the "DsrmAdminLogonBehavior" value is set to "1", the administrator account can only be used if the local AD DS service is stopped. If the "DsrmAdminLogonBehavior" value is set to "2", the administrator account can always be used.

The tag is: *misp-galaxy:sigma-rules="Directory Service Restore Mode(DSRM) Registry Value Tampering"*

View relationships graph

Directory Service Restore Mode(DSRM) Registry Value Tampering has relationships with:

- related-to: misp-galaxy:mitre-attack-pattern="Modify Authentication Process - T1556" with estimative-language:likelihood-probability="almost-certain"

Potential Persistence Via Disk Cleanup Handler - Registry

Detects when an attacker modifies values of the Disk Cleanup Handler in the registry to achieve persistence. The disk cleanup manager is part of the operating system. It displays the dialog box [...] The user has the option of enabling or disabling individual handlers by selecting or clearing their check box in the disk cleanup manager’s UI. Although Windows comes with a number of disk

cleanup handlers, they aren't designed to handle files produced by other applications. Instead, the disk cleanup manager is designed to be flexible and extensible by enabling any developer to implement and register their own disk cleanup handler. Any developer can extend the available disk cleanup services by implementing and registering a disk cleanup handler.

The tag is: *misp-galaxy:sigma-rules="Potential Persistence Via Disk Cleanup Handler - Registry"*

Suspicious DNS Query Indicating Kerberos Coercion via DNS Object SPN Spoofing

Detects DNS queries containing patterns associated with Kerberos coercion attacks via DNS object spoofing. The pattern "1UWhRCAAAAA..BAAAA" is a base64-encoded signature that corresponds to

a marshaled CREDENTIAL_TARGET_INFORMATION structure. Attackers can use this technique to coerce authentication from victim systems to attacker-controlled hosts. It is one of the strong indicators of a Kerberos coercion attack, where adversaries manipulate DNS records to spoof Service Principal Names (SPNs) and redirect authentication requests like CVE-2025-33073.

The tag is: *misp-galaxy:sigma-rules="Suspicious DNS Query Indicating Kerberos Coercion via DNS Object SPN Spoofing"*

View relationships graph

Suspicious DNS Query Indicating Kerberos Coercion via DNS Object SPN Spoofing has relationships with:

- related-to: misp-galaxy:mitre-attack-pattern="LLMNR/NBT-NS Poisoning and SMB Relay - T1557.001" with estimative-language:likelihood-probability="almost-certain"
- related-to: misp-galaxy:mitre-attack-pattern="Forced Authentication - T1187" with estimative-language:likelihood-probability="almost-certain"

DNS Query To Remote Access Software Domain From Non-Browser App

An adversary may use legitimate desktop support and remote access software, such as Team Viewer, Go2Assist, LogMein, AmmyyAdmin, etc, to establish an interactive command and control

channel to target systems within networks. These services are commonly used as legitimate technical support software, and may be allowed by application control within a target environment. Remote access tools like VNC, Ammyy, and Teamviewer are used frequently when compared with other legitimate software commonly used by adversaries. (Citation: Symantec Living off the Land)

CobaltStrike Named Pipe Pattern Regex

Detects the creation of a named pipe matching a pattern used by CobaltStrike Malleable C2 profiles

The tag is: *misp-galaxy:sigma-rules="CobaltStrike Named Pipe Pattern Regex"*

View relationships graph

CobaltStrike Named Pipe Pattern Regex has relationships with:

- related-to: misp-galaxy:mitre-attack-pattern="Process Injection - T1055" with estimative-language:likelihood-probability="almost-certain"

Table 11386. Table References

Anydesk Temporary Artefact

An adversary may use legitimate desktop support and remote access software, such as Team Viewer, Go2Assist, LogMein, AmmyyAdmin, etc, to establish an interactive command and control channel to target systems within networks. These services are commonly used as legitimate technical support software, and may be allowed by application control within a target environment. Remote access tools like VNC, Ammyy, and Teamviewer are used frequently when compared with other legitimate software commonly used by adversaries. (Citation: Symantec

ScreenConnect Temporary Installation Artefact

An adversary may use legitimate desktop support and remote access software, such as Team Viewer, Go2Assist, LogMein, AmmyyAdmin, etc, to establish an interactive command and control channel to target systems within networks. These services are commonly used as legitimate technical support software, and may be allowed by application control within a target environment. Remote access tools like VNC, Ammyy, and Teamviewer are used frequently when compared with other legitimate software commonly used by adversaries. (Citation: Symantec Living off the Land)

Potential RipZip Attack on Startup Folder

Detects a phishing attack which expands a ZIP file containing a malicious shortcut. If the victim expands the ZIP file via the explorer process, then the explorer process expands the malicious ZIP file and drops a malicious shortcut redirected to a backdoor into the Startup folder. Additionally, the file name of the malicious shortcut in Startup folder contains {0AFACED1-E828-11D1-9187-B532F1E9575D} meaning the folder shortcut operation.

The tag is: *misp-galaxy:sigma-rules="Potential RipZip Attack on Startup Folder"*

View relationships graph

Potential RipZip Attack on Startup Folder has relationships with:

- related-to: misp-galaxy:mitre-attack-pattern="Boot or Logon Autostart Execution - T1547" with estimative-language:likelihood-probability="almost-certain"

Potential Startup Shortcut Persistence Via PowerShell.EXE

Detects PowerShell writing startup shortcuts. This procedure was highlighted in Red Canary Intel Insights Oct. 2021, "We frequently observe adversaries using PowerShell to write malicious .lnk files into the startup directory to establish persistence. Accordingly, this detection opportunity is likely to identify persistence mechanisms in multiple threats. In the context of Yellow Cockatoo, this persistence mechanism eventually launches the command-line script that leads to the installation of a malicious DLL"

The tag is: *misp-galaxy:sigma-rules="Potential Startup Shortcut Persistence Via PowerShell.EXE"*

View relationships graph

Potential Startup Shortcut Persistence Via PowerShell.EXE has relationships with:

GoToAssist Temporary Installation Artefact

An adversary may use legitimate desktop support and remote access software, such as Team Viewer, Go2Assist, LogMein, AmmyyAdmin, etc, to establish an interactive command and control channel to target systems within networks. These services are commonly used as legitimate technical support software, and may be allowed by application control within a target environment. Remote access tools like VNC, Ammyy, and Teamviewer are used frequently when compared with other legitimate software commonly used by adversaries. (Citation: Symantec Living off the Land)

Potential DLL Injection Via AccCheckConsole

Detects the execution "AccCheckConsole" a command-line tool for verifying the accessibility implementation of an application's UI. One of the tests that this checker can run are called "verification routine", which tests for things like Consistency, Navigation, etc. The tool allows a user to provide a DLL that can contain a custom "verification routine". An attacker can build such DLLs and pass it via the CLI, which would then be loaded in the context of the "AccCheckConsole" utility.

The tag is: *misp-galaxy:sigma-rules="Potential DLL Injection Via AccCheckConsole"*

Remote Access Tool - ScreenConnect Execution

An adversary may use legitimate desktop support and remote access software, such as Team Viewer, Go2Assist, LogMein, AmmyyAdmin, etc, to establish an interactive command and control

channel to target systems within networks. These services are commonly used as legitimate technical support software, and may be allowed by application control within a target environment. Remote access tools like VNC, Ammyy, and Teamviewer are used frequently when compared with other legitimate software commonly used by adversaries. (Citation: Symantec Living off the Land)

New Remote Desktop Connection Initiated Via Mstsc.EXE

Detects the usage of "mstsc.exe" with the "/v" flag to initiate a connection to a remote server. Adversaries may use valid accounts to log into a computer using the Remote Desktop Protocol (RDP). The adversary may then perform actions as the logged-on user.

The tag is: *misp-galaxy:sigma-rules="New Remote Desktop Connection Initiated Via Mstsc.EXE"*

View relationships graph

New Remote Desktop Connection Initiated Via Mstsc.EXE has relationships with:

- related-to: misp-galaxy:mitre-attack-pattern="Remote Desktop Protocol - T1021.001" with estimative-language:likelihood-probability="almost-certain"

Table 11661. Table References

Remote Access Tool - Anydesk Execution From Suspicious Folder

An adversary may use legitimate desktop support and remote access software, such as Team Viewer, Go2Assist, LogMein, AmmyyAdmin, etc, to establish an interactive command and control channel to target systems within networks. These services are commonly used as legitimate technical support software, and may be allowed by application control within a target environment. Remote access tools like VNC, Ammyy, and Teamviewer are used frequently when compared with other legitimate software commonly used by adversaries. (Citation: Symantec Living off the Land)

ManageEngine Endpoint Central Dctask64.EXE Potential Abuse

Detects the execution of "dctask64.exe", a signed binary by ZOHO Corporation part of ManageEngine Endpoint Central. This binary can be abused for DLL injection, arbitrary command and process execution.

The tag is: *misp-galaxy:sigma-rules="ManageEngine Endpoint Central Dctask64.EXE Potential Abuse"*

View relationships graph

ManageEngine Endpoint Central Dctask64.EXE Potential Abuse has relationships with:

- related-to: misp-galaxy:mitre-attack-pattern="Dynamic-link Library Injection - T1055.001" with estimative-language:likelihood-probability="almost-certain"

Change Default File Association Via Assoc

Detects file association changes using the builtin "assoc" command. When a file is opened, the default program used to open the file (also called the file association or handler) is checked. File association selections are stored in the Windows Registry and can be edited by users, administrators, or programs that have Registry access or by administrators using the built-in assoc utility. Applications can modify the file association for a given file extension to call an arbitrary program when a file with the given extension is opened.

The tag is: *misp-galaxy:sigma-rules="Change Default File Association Via Assoc"*

View relationships graph

Change Default File Association Via Assoc has relationships with:

- related-to: misp-galaxy:mitre-attack-pattern="Change Default File Association - T1546.001" with estimative-language:likelihood-probability="almost-certain"

PowerShell Download and Execution Cradles

Detects PowerShell download and execution cradles.

The tag is: *misp-galaxy:sigma-rules="PowerShell Download and Execution Cradles"*

View relationships graph

PowerShell Download and Execution Cradles has relationships with:

- related-to: misp-galaxy:mitre-attack-pattern="Command and Scripting Interpreter - T1059" with estimative-language:likelihood-probability="almost-certain"

Table 11752. Table References

PowerShell MSI Install via WindowsInstaller COM From Remote Location

Detects the execution of PowerShell commands that attempt to install MSI packages via the Windows Installer COM object (`WindowsInstaller.Installer`) hosted remotely. This could be indication of malicious software deployment or lateral movement attempts using Windows Installer functionality. And the usage of WindowsInstaller COM object rather than msiexec could be an attempt to bypass the detection.

The tag is: *misp-galaxy:sigma-rules="PowerShell MSI Install via WindowsInstaller COM From Remote Location"*

View relationships graph

PowerShell MSI Install via WindowsInstaller COM From Remote Location has relationships with:

- related-to: misp-galaxy:mitre-attack-pattern="PowerShell - T1059.001" with estimative-language:likelihood-probability="almost-certain"
- related-to: misp-galaxy:mitre-attack-pattern="System Binary Proxy Execution - T1218" with estimative-language:likelihood-probability="almost-certain"
- related-to: misp-galaxy:mitre-attack-pattern="Ingress Tool Transfer - T1105" with estimative-language:likelihood-probability="almost-certain"

Active Directory Database Snapshot Via ADExplorer

Detects the execution of Sysinternals ADExplorer with the "-snapshot" flag in order to save a local copy of the active directory database. This can be used by attackers to extract data for Bloodhound, usernames for password spraying or use the meta data for social engineering. The snapshot doesn't contain password hashes but there have been cases, where administrators put passwords in the comment field.

The tag is: *misp-galaxy:sigma-rules="Active Directory Database Snapshot Via ADExplorer"*

View relationships graph

Active Directory Database Snapshot Via ADExplorer has relationships with:

- related-to: misp-galaxy:mitre-attack-pattern="Domain Account - T1087.002" with estimative-language:likelihood-probability="almost-certain"
- related-to: misp-galaxy:mitre-attack-pattern="Domain Groups - T1069.002" with estimative-language:likelihood-probability="almost-certain"

Remote Access Tool - UltraViewer Execution

An adversary may use legitimate desktop support and remote access software, such as Team Viewer, Go2Assist, LogMein, AmmyyAdmin, etc, to establish an interactive command and control channel to target systems within networks. These services are commonly used as legitimate technical support software, and may be allowed by application control within a target environment. Remote access tools like VNC, Ammyy, and Teamviewer are used frequently when compared with other legitimate software commonly used by adversaries. (Citation: Symantec Living off the Land)

The tag is: *misp-galaxy:sigma-rules="Remote Access Tool - UltraViewer Execution"*

View relationships graph

Remote Access Tool - UltraViewer Execution has relationships with:

Remote Access Tool - AnyDesk Execution

An adversary may use legitimate desktop support and remote access software, such as Team Viewer, Go2Assist, LogMein, AmmyyAdmin, etc, to establish an interactive command and control channel to target systems within networks. These services are commonly used as legitimate technical support software, and may be allowed by application control within a target environment. Remote access tools like VNC, Ammyy, and Teamviewer are used frequently when compared with other legitimate software commonly used by adversaries. (Citation: Symantec Living off the Land)

Attempts of Kerberos Coercion Via DNS SPN Spoofing

Detects the presence of "UWhRC....AAYBAAAA" pattern in command line. The pattern "1UWhRCAAAAA..BAAAA" is a base64-encoded signature that corresponds to a marshaled CREDENTIAL_TARGET_INFORMATION structure. Attackers can use this technique to coerce authentication from victim systems to attacker-controlled hosts. It is one of the strong indicators of a Kerberos coercion attack, where adversaries manipulate DNS records to spoof Service Principal Names (SPNs) and redirect authentication requests like in CVE-2025-33073. If you see this pattern in the command line, it is likely an attempt to add spoofed Service Principal Names (SPNs) to DNS records, or checking for the presence of such records through the `nslookup` command.

The tag is: *misp-galaxy:sigma-rules="Attempts of Kerberos Coercion Via DNS SPN Spoofing"*

View relationships graph

Attempts of Kerberos Coercion Via DNS SPN Spoofing has relationships with:

- related-to: misp-galaxy:mitre-attack-pattern="LLMNR/NBT-NS Poisoning and SMB Relay - T1557.001" with estimative-language:likelihood-probability="almost-certain"
- related-to: misp-galaxy:mitre-attack-pattern="Forced Authentication - T1187" with estimative-language:likelihood-probability="almost-certain"

NodeJS Execution of JavaScript File

Detects execution of JavaScript or JSC files using NodeJs binary node.exe, that could be potentially suspicious. Node.js is a popular open-source JavaScript runtime that runs code outside browsers and is widely used for both frontend and backend development. Adversaries have been observed abusing Node.js to disguise malware as legitimate processes, evade security defenses, and maintain persistence within target systems. Because Node.js is commonly used, this rule may generate false positives in some environments. However, if such activity is unusual in your environment, it is highly suspicious and warrants immediate investigation.

The tag is: *misp-galaxy:sigma-rules="NodeJS Execution of JavaScript File"*

View relationships graph

NodeJS Execution of JavaScript File has relationships with:

- related-to: misp-galaxy:mitre-attack-pattern="JavaScript - T1059.007" with estimative-language:likelihood-probability="almost-certain"

Table 11907. Table References

FileFix - Suspicious Child Process from Browser File Upload Abuse

Detects potentially suspicious subprocesses such as LOLBINs spawned by web browsers. This activity could be associated with the "FileFix" social engineering technique, where users are tricked into launching the file explorer via a browser-based phishing page and pasting malicious commands into the address bar. The technique abuses clipboard manipulation and disguises command execution as benign file path access, resulting in covert execution of system utilities.

The tag is: *misp-galaxy:sigma-rules="FileFix - Suspicious Child Process from Browser File Upload Abuse"*

View relationships graph

FileFix - Suspicious Child Process from Browser File Upload Abuse has relationships with:

- related-to: misp-galaxy:mitre-attack-pattern="Malicious Copy and Paste - T1204.004" with estimative-language:likelihood-probability="almost-certain"

Remote Access Tool - LogMeIn Execution

An adversary may use legitimate desktop support and remote access software, such as Team Viewer, Go2Assist, LogMein, AmmyyAdmin, etc, to establish an interactive command and control channel to target systems within networks. These services are commonly used as legitimate technical support software, and may be allowed by application control within a target environment. Remote access tools like VNC, Ammyy, and Teamviewer are used frequently when compared with other legitimate software commonly used by adversaries. (Citation: Symantec Living off the Land)

The tag is: *misp-galaxy:sigma-rules="Remote Access Tool - LogMeIn Execution"*

View relationships graph

Remote Access Tool - LogMeIn Execution has relationships with:

Remote Access Tool - GoToAssist Execution

An adversary may use legitimate desktop support and remote access software, such as Team Viewer, Go2Assist, LogMein, AmmyyAdmin, etc, to establish an interactive command and control channel to target systems within networks. These services are commonly used as legitimate technical support software, and may be allowed by application control within a target environment. Remote access tools like VNC, Ammyy, and Teamviewer are used frequently when compared with other legitimate software commonly used by adversaries. (Citation: Symantec Living off the Land)

The tag is: *misp-galaxy:sigma-rules="Remote Access Tool - GoToAssist Execution"*

Change Default File Association To Executable Via Assoc

Detects when a program changes the default file association of any extension to an executable. When a file is opened, the default program used to open the file (also called the file association or handler) is checked. File association selections are stored in the Windows Registry and can be edited by users, administrators, or programs that have Registry access or by administrators using the built-in assoc utility. Applications can modify the file association for a given file extension to call an arbitrary program when a file with the given extension is opened.

PowerShell Defender Threat Severity Default Action Set to 'Allow' or 'NoAction'

Detects the use of PowerShell to execute the 'Set-MpPreference' cmdlet to configure Windows Defender's threat severity default action to 'Allow' (value '6') or 'NoAction' (value '9'). This is a highly suspicious configuration change that effectively disables Defender's ability to automatically mitigate threats of a certain severity level. An attacker might use this technique via the command line to bypass defenses before executing payloads.

The tag is: *misp-galaxy:sigma-rules="PowerShell Defender Threat Severity Default Action Set to 'Allow' or 'NoAction'"*

View relationships graph

PowerShell Defender Threat Severity Default Action Set to 'Allow' or 'NoAction' has relationships with:

- related-to: misp-galaxy:mitre-attack-pattern="Disable or Modify Tools - T1562.001" with estimative-language:likelihood-probability="almost-certain"

Suspicious Microsoft OneNote Child Process

Detects suspicious child processes of the Microsoft OneNote application. This may indicate an attempt to execute malicious embedded objects from a .one file.

The tag is: *misp-galaxy:sigma-rules="Suspicious Microsoft OneNote Child Process"*

View relationships graph

Suspicious Microsoft OneNote Child Process has relationships with:

- related-to: misp-galaxy:mitre-attack-pattern="Phishing - T1566" with estimative-language:likelihood-probability="almost-certain"
- related-to: misp-galaxy:mitre-attack-pattern="Spearphishing Attachment - T1566.001" with estimative-language:likelihood-probability="almost-certain"

Uncommon Link.EXE Parent Process

Detects an uncommon parent process of "LINK.EXE". Link.EXE in Microsoft incremental linker. Its a utility usually bundled with Visual Studio installation. Multiple utilities often found in the same folder (editbin.exe, dumpbin.exe, lib.exe, etc) have a hardcode call to the "LINK.EXE" binary without checking its validity. This would allow an attacker to sideload any binary with the name "link.exe" if one of the aforementioned tools get executed from a different location. By filtering the known locations of such utilities we can spot uncommon parent process of LINK.EXE that might be suspicious or malicious.

The tag is: *misp-galaxy:sigma-rules="Uncommon Link.EXE Parent Process"*

View relationships graph

Uncommon Link.EXE Parent Process has relationships with:

- related-to: misp-galaxy:mitre-attack-pattern="System Binary Proxy Execution - T1218" with

estimative-language:likelihood-probability="almost-certain"

Obfuscated PowerShell MSI Install via WindowsInstaller COM

Detects the execution of obfuscated PowerShell commands that attempt to install MSI packages via the Windows Installer COM object (`WindowsInstaller.Installer`). The technique involves manipulating strings to hide functionality, such as constructing class names using string insertion (e.g., 'indowsInstaller.Installer'.Insert(0,'W')) and correcting malformed URLs (e.g., converting 'https://' to 'https://') at runtime. This behavior is commonly associated with malware loaders or droppers that aim to bypass static detection by hiding intent in runtime-generated strings and using legitimate tools for code execution. The use of `InstallProduct` and COM object creation, particularly combined with hidden window execution and suppressed UI, indicates an attempt to install software (likely malicious) without user interaction.

The tag is: *misp-galaxy:sigma-rules="Obfuscated PowerShell MSI Install via WindowsInstaller COM"*

View relationships graph

Obfuscated PowerShell MSI Install via WindowsInstaller COM has relationships with:

- related-to: misp-galaxy:mitre-attack-pattern="Command Obfuscation - T1027.010" with estimative-language:likelihood-probability="almost-certain"

Enumeration for Credentials in Registry

Adversaries may search the Registry on compromised systems for insecurely stored credentials. The Windows Registry stores configuration information that can be used by the system or other

programs. Adversaries may query the Registry looking for credentials and passwords that have been stored for use by other programs or services

The tag is: *misp-galaxy:sigma-rules="Enumeration for Credentials in Registry"*

View relationships graph

Enumeration for Credentials in Registry has relationships with:

- related-to: misp-galaxy:mitre-attack-pattern="Credentials in Registry - T1552.002" with estimative-language:likelihood-probability="almost-certain"

Finger.EXE Execution

Detects execution of the "finger.exe" utility. Finger.EXE or "TCPIP Finger Command" is an old utility that is still present on modern Windows installation. It Displays information about users on a specified remote computer (typically a UNIX computer) that is running the finger service or daemon. Due to the old nature of this utility and the rareness of machines having the finger service. Any execution of "finger.exe" can be considered "suspicious" and worth investigating.

The tag is: *misp-galaxy:sigma-rules="Finger.EXE Execution"*

View relationships graph

Finger.EXE Execution has relationships with:

- related-to: misp-galaxy:mitre-attack-pattern="Ingress Tool Transfer - T1105" with estimative-language:likelihood-probability="almost-certain"

Potential Binary Proxy Execution Via Cdb.EXE

Detects usage of "cdb.exe" to launch arbitrary processes or commands from a debugger script file

The tag is: *misp-galaxy:sigma-rules="Potential Binary Proxy Execution Via Cdb.EXE"*

View relationships graph

Potential Binary Proxy Execution Via Cdb.EXE has relationships with:

- related-to: misp-galaxy:mitre-attack-pattern="Native API - T1106" with estimative-language:likelihood-probability="almost-certain"
- related-to: misp-galaxy:mitre-attack-pattern="System Binary Proxy Execution - T1218" with estimative-language:likelihood-probability="almost-certain"
- related-to: misp-galaxy:mitre-attack-pattern="Trusted Developer Utilities Proxy Execution - T1127" with estimative-language:likelihood-probability="almost-certain"

Potential Windows Defender AV Bypass Via Dump64.EXE Rename

Detects when a user is potentially trying to bypass the Windows Defender AV by renaming a tool to dump64.exe and placing it in the Visual Studio folder. Currently the rule is covering only usage of procdump but other utilities can be added in order to increase coverage.

The tag is: *misp-galaxy:sigma-rules="Potential Windows Defender AV Bypass Via Dump64.EXE Rename"*

View relationships graph

Potential Windows Defender AV Bypass Via Dump64.EXE Rename has relationships with:

- related-to: misp-galaxy:mitre-attack-pattern="LSASS Memory - T1003.001" with estimative-language:likelihood-probability="almost-certain"

Registry Export of Third-Party Credentials

Detects the use of reg.exe to export registry paths associated with third-party credentials. Credential stealers have been known to use this technique to extract sensitive information from the registry.

The tag is: *misp-galaxy:sigma-rules="Registry Export of Third-Party Credentials"*

View relationships graph

Registry Export of Third-Party Credentials has relationships with:

- related-to: misp-galaxy:mitre-attack-pattern="Credentials in Registry - T1552.002" with estimative-language:likelihood-probability="almost-certain"

Table 12221. Table References

Remote Access Tool - NetSupport Execution

An adversary may use legitimate desktop support and remote access software, such as Team Viewer, Go2Assist, LogMein, AmmyyAdmin, etc, to establish an interactive command and control channel to target systems within networks. These services are commonly used as legitimate technical support software, and may be allowed by application control within a target environment. Remote access tools like VNC, Ammyy, and Teamviewer are used frequently when compared with other legitimate software commonly used by adversaries. (Citation: Symantec Living off the Land)

Monitoring For Persistence Via BITS

BITS will allow you to schedule a command to execute after a successful download to notify you that the job is finished. When the job runs on the system the command specified in the BITS job will be executed. This can be abused by actors to create a backdoor within the system and for persistence. It will be chained in a BITS job to schedule the download of malware/additional binaries and execute the program after being downloaded.

The tag is: *misp-galaxy:sigma-rules="Monitoring For Persistence Via BITS"*

https://github.com/SigmaHQ/sigma/tree/master/rules/windows/process_creation/proc_creation_win_dirlister_execution.yml

Local Groups Reconnaissance Via Wmic.EXE

Detects the execution of "wmic" with the "group" flag. Adversaries may attempt to find local system groups and permission settings. The knowledge of local system permission groups can help adversaries determine which groups exist and which users belong to a particular group. Adversaries may use this information to determine which users have elevated permissions, such as the users found within the local administrators group.

The tag is: *misp-galaxy:sigma-rules="Local Groups Reconnaissance Via Wmic.EXE"*

View relationships graph

Local Groups Reconnaissance Via Wmic.EXE has relationships with:

- related-to: misp-galaxy:mitre-attack-pattern="Local Groups - T1069.001" with estimative-language:likelihood-probability="almost-certain"

Directory Removal Via Rmdir

Detects execution of the builtin "rmdir" command in order to delete directories. Adversaries may delete files left behind by the actions of their intrusion activity. Malware, tools, or other non-native files dropped or created on a system by an adversary may leave traces to indicate to what was done within a network and how. Removal of these files can occur during an intrusion, or as part of a post-intrusion process to minimize the adversary's footprint.

The tag is: *misp-galaxy:sigma-rules="Directory Removal Via Rmdir"*

View relationships graph

Directory Removal Via Rmdir has relationships with:

- related-to: misp-galaxy:mitre-attack-pattern="File Deletion - T1070.004" with estimative-language:likelihood-probability="almost-certain"

Disabling Windows Defender WMI Autologger Session via Reg.exe

Detects the use of reg.exe to disable the Event Tracing for Windows (ETW) Autologger session for Windows Defender API and Audit events. By setting the 'Start' value to '0' for the 'DefenderApiLogger' or 'DefenderAuditLogger' session, an attacker can prevent these critical security events from being logged, effectively blinding monitoring tools that rely on this data. This is a powerful defense evasion technique.

The tag is: *misp-galaxy:sigma-rules="Disabling Windows Defender WMI Autologger Session via Reg.exe"*

View relationships graph

Disabling Windows Defender WMI Autologger Session via Reg.exe has relationships with:

- related-to: misp-galaxy:mitre-attack-pattern="Disable or Modify Tools - T1562.001" with estimative-language:likelihood-probability="almost-certain"

Suspicious LNK Command-Line Padding with Whitespace Characters

Detects exploitation of LNK file command-line length discrepancy, where attackers hide malicious commands beyond the 260-character UI limit while the actual command-line argument field supports 4096 characters using whitespace padding (e.g., 0x20, 0x09-0x0D). Adversaries insert non-printable whitespace characters (e.g., Line Feed \x0A, Carriage Return \x0D) to pad the visible section of the LNK file, pushing malicious commands past the UI-visible boundary. The hidden payload, executed at runtime but invisible in Windows Explorer properties, enables stealthy execution and evasion—commonly used for social engineering attacks. This rule flags suspicious use of such padding observed in real-world attacks.

The tag is: *misp-galaxy:sigma-rules="Suspicious LNK Command-Line Padding with Whitespace Characters"*

View relationships graph

Suspicious LNK Command-Line Padding with Whitespace Characters has relationships with:

- related-to: misp-galaxy:mitre-attack-pattern="Malicious File - T1204.002" with estimative-language:likelihood-probability="almost-certain"

Visual Studio Code Tunnel Shell Execution

Detects the execution of a shell (powershell, bash, wsl...) via Visual Studio Code tunnel. Attackers can abuse this functionality to establish a C2 channel and execute arbitrary commands on the system.

The tag is: *misp-galaxy:sigma-rules="Visual Studio Code Tunnel Shell Execution"*

View relationships graph

Visual Studio Code Tunnel Shell Execution has relationships with:

- related-to: misp-galaxy:mitre-attack-pattern="Web Protocols - T1071.001" with estimative-language:likelihood-probability="almost-certain"

Table 12685. Table References

Schedule Task Creation From Env Variable Or Potentially Suspicious Path Via Schtasks.EXE

Detects Schtask creations that point to a suspicious folder or an environment variable often used by malware

The tag is: *misp-galaxy:sigma-rules="Schedule Task Creation From Env Variable Or Potentially Suspicious Path Via Schtasks.EXE"*

View relationships graph

Schedule Task Creation From Env Variable Or Potentially Suspicious Path Via Schtasks.EXE has relationships with:

- related-to: misp-galaxy:mitre-attack-pattern="Scheduled Task - T1053.005" with estimative-language:likelihood-probability="almost-certain"

Suspicious ScreenSave Change by Reg.exe

Adversaries may establish persistence by executing malicious content triggered by user inactivity. Screensavers are programs that execute after a configurable time of user inactivity and consist of Portable Executable (PE) files with a .scr file extension

The tag is: *misp-galaxy:sigma-rules="Suspicious ScreenSave Change by Reg.exe"*

View relationships graph

Suspicious ScreenSave Change by Reg.exe has relationships with:

- related-to: misp-galaxy:mitre-attack-pattern="Screensaver - T1546.002" with estimative-language:likelihood-probability="almost-certain"

Suspicious Group And Account Reconnaissance Activity Using Net.EXE

Detects suspicious reconnaissance command line activity on Windows systems using Net.EXE Check if the user that executed the commands is suspicious (e.g. service accounts, LOCAL_SYSTEM)

The tag is: *misp-galaxy:sigma-rules="Suspicious Group And Account Reconnaissance Activity Using Net.EXE"*

View relationships graph

Suspicious Group And Account Reconnaissance Activity Using Net.EXE has relationships with:

- related-to: misp-galaxy:mitre-attack-pattern="Local Account - T1087.001" with estimative-language:likelihood-probability="almost-certain"
- related-to: misp-galaxy:mitre-attack-pattern="Domain Account - T1087.002" with estimative-language:likelihood-probability="almost-certain"
