Breakthrough

There is no reference available for this family and all known samples have version 1.0.0.

Pdb-strings in the samples suggest that this is an "exclusive" loader, known as "breakthrough" (maybe), e.g. C:\Users\Exclusiv\Desktop\хп-пробив\Release\build.pdb

The communication url parameters are pretty unique in this combination: gate.php?hwid=<guid>&os=<OS>&build=1.0.0&cpu=8

<OS> is one of: Windows95 Windows98 WindowsMe Windows95family WindowsNT3 WindowsNT4 Windows2000 WindowsXP WindowsServer2003 WindowsNTfamily WindowsVista Windows7 Windows8 Windows10

The tag is: *misp-galaxy:malpedia="Breakthrough"*

Broomstick

Oyster is a backdoor malware written in C++, first appearing in July 2023. It allows for remote sessions, supporting tasks like file transfer and command-line processing. This malware has been used by numerous threat actors as a tool to support ransomware intrusions. The distribution of Oyster has most likely been spread through various methods, which is suggested by the build identifiers in examined samples. Additionally, Oyster is capable of collecting basic system data and communicates with a command-and-control server (C2). It can execute commands via cmd.exe and run additional files.

The tag is: *misp-galaxy:malpedia="Broomstick"*

Broomstick is also known as:

Brute Ratel C4

Brute Ratel C4 (BRC4) is a commercial framework for red-teaming and adversarial attack simulation, which made its first appearance in December 2020. It was specifically designed to evade detection by endpoint detection and response (EDR) and antivirus (AV) capabilities. BRC4 allows operators to deploy a backdoor agent known as Badger (aka BOLDBADGER) within a target environment. This agent enables arbitrary command execution, facilitating lateral movement, privilege escalation, and the establishment of additional persistence avenues. The Badger backdoor agent can communicate with a remote server via DNS over HTTPS, HTTP, HTTPS, SMB, and TCP, using custom encrypted channels. It supports a variety of backdoor commands including shell command execution, file transfers, file execution, and credential harvesting. Additionally, the Badger agent can perform tasks such as port scanning, screenshot capturing, and keystroke logging. Notably, in September 2022, a cracked version of Brute Ratel C4 was leaked in the cybercriminal underground, leading to its use by threat actors.

The tag is: *misp-galaxy:malpedia="Brute Ratel C4"*

Brute Ratel C4 is also known as:

- BOLDBADGER
- BruteRatel

BTCWare

According to PCRisk, BTCWare is an updated version of a ransomware-type virus called Crptxxx. This ransomware is distributed via a malicious application called "Rogers Hi-Speed Internet". Once infiltrated, BTCWare encrypts files and appends filenames with the ".btcware" extension. Newer variants of this ransomware append .shadow, .payday, .wyvern, .nuclear, .aleta, .gryphon, .nopasaran, .blocking, .xfile, .master, .onyon, .theva, .cryptobyte or .cryptowin extensions to encrypted files. BTCWare then creates an HTM file ("*HOW_TO_FIX*!.hta.htm"), placing it on the desktop. Other variants of this ransomware use !*RESTORE_FILES*#!.inf file to store their ransom demanding message.

BundleBot

Bundlebot is an info stealer that abuses the single-file dotnet bundle which operates as a self-contained executable that does not require any preinstalled dotnet runtime version. Bundlebot functionality targets a wide variety of data including the victim's system information, browser data, telegram data, discord token, Facebook account information, and screenshots.

CaddyWiper

CaddyWiper is another destructive malware believed to be deployed to target Ukraine.

CaddyWiper wipes all files under C:\Users and all also all files under available drives from D: to Z: by overwriting the data with NULL value. If the target file is greater than 0xA00000 bytes in size (10MB), it will only wipe the first 0xA00000 bytes.

It also wipes disk partitions from \\.\PHYSICALDRIVE9 to \\.\PHYSICALDRIVE0 by overwriting the first 0x780 bytes with NULL.

The tag is: *misp-galaxy:malpedia="CaddyWiper"*

CaddyWiper is also known as:

- KillDisk.NCX

Carbanak

MyCERT states that Carbanak is a remote backdoor designed for espionage, data exfiltration, and to remote control.

The attacker deploy malware via spear phishing email to lure the user to open and run the

malicious attachment that will infect the machine. The main objective of this campaign is primarily to remotely control the infected machine and gain control of the internal destinations of money processing services such as Automated Teller Machines(ATM) and financial accounts. The following information are the malware capabilities:

Cardinal RAT

Cardinal RAT is a remote access Trojan capable of stealing username and credentials, cleaning out cookies from browsers, keylogging and capturing screenshots on targeted systems. It is delivered via a downloader dubbed “Carp” which uses malicious macros in Microsoft Excel documents to compile embedded source code into an executable, which then deploys the Cardinal RAT malware family.

The tag is: *misp-galaxy:malpedia="Cardinal RAT"*

Cardinal RAT is also known as:

CargoBay

CargoBay is a newer malware family which was first observed in 2022 and is notable for being written in the Rust language. CargoBay is likely based on source code taken from 'Black Hat Rust' GitHub project (https://github.com/skerkour/black-hat-rust). CargoBay is usually distributed via phishing emails, and the malware binaries may be disguised as legitimate applications. Upon execution, the malware starts by performing environmental checks such as checking its execution path and the configured system language. If the tests pass, then the malware proceeds to gather basic system information and register with its C2 via HTTP from which it receives JSON-formatted jobs to carry out. CargoBay can execute commands via the command line and downloading additional malware binaries.

The tag is: *misp-galaxy:malpedia="CargoBay"*

Casper

ESET describes Casper as a well-developed reconnaissance tool, making extensive efforts to remain unseen on targeted machines. Of particular note are the specific strategies adopted against anti-malware software. Casper was used against Syrian targets in April 2014, which makes it the most recent malware from this group publicly known at this time.

Chaos (Windows)

In-development ransomware family which was released in June 2021 by an unknown threat actor. The builder initially claimed to be a "Ryuk .Net Ransomware Builder" even though it was completely unrelated to the Ryuk malware family. Presently it appears to contain trojan-like features, but lacks features commonly found in ransomware such as data exfiltration.

The tag is: *misp-galaxy:malpedia="Chaos (Windows)"*

Chaperone

According to Kaspersky GReAT and AMR, TajMahal is a previously unknown and technically sophisticated APT framework discovered by Kaspersky Lab in the autumn of 2018. This full-blown spying framework consists of two packages named Tokyo and Yokohama. It includes backdoors, loaders, orchestrators, C2 communicators, audio recorders, keyloggers, screen and webcam grabbers, documents and cryptography key stealers, and even its own file indexer for the victim's machine. We discovered up to 80 malicious modules stored in its encrypted Virtual File System, one of the highest numbers of plugins they have ever seen for an APT toolset.

CHEESETRAY

CHEESETRAY is a sophisticated proxy-aware backdoor that can operate in both active and passive mode depending on the passed command-line parameters. The backdoor is capable of enumerating files and processes, enumerating drivers, enumerating remote desktop sessions, uploading and downloading files, creating and terminating processes, deleting files, creating a reverse shell, acting as a proxy server, and hijacking processes among its other functionality. The backdoor communicates with its C&C server using a custom binary protocol over TCP with port specified as a command-line parameter.

Chisel (Windows)

Chisel is an open-source project by Jaime Pillora (jpillora) that allows tunneling TCP and UDP connections via HTTP. It is available across platforms and written in Go. While benign in itself, Chisel has been utilized by multiple threat actors. It was for example observed by SentinelOne during a PYSA ransomware campaign to achieve persistence and used as backdoor. Github: https://github.com/jpillora/chisel

Choziosi (Windows)

Choziosi is a browser hijacker for Chrome. It was first seen in January 2022. It commonly infects users via pirated media downloads like games, software, wallpapers or movies. The initial infectors are available for several platforms such as Mac and Windows.

Its main component is the Chrome browser extension written in JavaScript with the purpose of serving advertisments and hijacking search requests to Google, Yahoo and Bing.

The tag is: *misp-galaxy:malpedia="Choziosi (Windows)"*

ChrGetPdsi Stealer

ChrGetPdsi is a basic infostealer written in Golang which is designed to steal browser history and logins, and targets Chrome, Edge, and Firefox. The output is written to a text file named chrgetpdsi.txt. Based on the samples analysed, the malware does not appear to have networking capabilities, and therefore it is likely that it is intended to be used in a post-compromise situation where the attacker already has access to the target system and can retrieve the created output file via other means.ChrGetPdsi has been observed being deployed by the Broomstick malware.

ClipBanker

The ClipBanker Trojan is known as an information stealer and spy trojan, it aims to steal and record any type of sensitive information from the infected environment such as browser history, cookies, Outlook data, Skype, Telegram, or cryptocurrency wallet account addresses. The main goal of this threat is to steal confidential information. The ClipBanker uses PowerShell commands for executing malicious activities. The thing that made the ClipBanker unique is its ability to record various banking actions of the user and manipulate them for its own benefit. The distribution method of the ClipBanker is through phishing emails or through social media posts that lure users to download malicious content.

Clop (Windows)

Clop is a ransomware which uses the .clop extension after having encrypted the victim's files. Another unique characteristic belonging with Clop is in the string: "Dont Worry C|0P" included into the ransom notes. It is a variant of CryptoMix ransomware, but it additionally attempts to disable Windows Defender and to remove the Microsoft Security Essentials in order to avoid user space detection.

The tag is: *misp-galaxy:malpedia="Clop (Windows)"*

CLOUDBURST

CLOUDBURST aka NickelLoader is an HTTP(S) downloader.

It recognizes a set of four basic commands, all five letters long, like abcde, avdrq, gabnc and dcrqv (alternatively: eknag, eacec, hjmwk, wohnp). The most important functionality is to load a received buffer, either as a DLL via the MemoryModule implementation, or as a shellcode.

It uses AES for encryption and decryption of network traffic. It usually sends the following information back to its C&C server: computer name, product name and the list of running processes. Typically, it uses two hardcoded parameter names for its initial HTTP POST requests: gametype and type (alternatively: type and code).

The CLOUDBURST payload is disguised as mscoree.dll and is side-loaded via a legitimate Windows

binary PresentationHost.exe with the argument -embeddingObject. It comes either as a trojanized plugin project for Notepad++ (usually FingerText by erinata), or as a standalone DLL loaded by a dropper, which is a trojanized plugin project as well (usually NppyPlugin by Jari Pennanen).

The CLOUDBURST malware was used in Operation DreamJob attacks against an aerospace company and a network running Microsoft Intune software in Q2-Q3 2022.

CloudEyE

CloudEyE (initially named GuLoader) is a small VB5/6 downloader. It typically downloads RATs/Stealers, such as Agent Tesla, Arkei/Vidar, Formbook, Lokibot, Netwire and Remcos, often but not always from Google Drive. The downloaded payload is xored.

The tag is: *misp-galaxy:malpedia="CloudEyE"*

CloudEyE is also known as:

- GuLoader
- vbdropper

CloudDuke

F-Secure describes CloudDuke as a malware toolset known to consist of, at least, a downloader, a loader and two backdoor variants. The CloudDuke downloader will download and execute additional malware from a preconfigured location. Interestingly, that location may be either a web address or a Microsoft OneDrive account. Both CloudDuke backdoor variants support simple backdoor functionality, similar to SeaDuke. While one variant will use a preconfigured C&C server over HTTP or HTTPS, the other variant will use a Microsoft OneDrive account to exchange commands and stolen data with its operators.

The tag is: *misp-galaxy:malpedia="CloudDuke"*

CloudDuke is also known as:

Cobalt Strike

Cobalt Strike is a paid penetration testing product that allows an attacker to deploy an agent named 'Beacon' on the victim machine. Beacon includes a wealth of functionality to the attacker, including, but not limited to command execution, key logging, file transfer, SOCKS proxying, privilege escalation, mimikatz, port scanning and lateral movement. Beacon is in-memory/file-less, in that it consists of stageless or multi-stage shellcode that once loaded by exploiting a vulnerability or executing a shellcode loader, will reflectively load itself into the memory of a process without touching the disk. It supports C2 and staging over HTTP, HTTPS, DNS, SMB named pipes as well as forward and reverse TCP; Beacons can be daisy-chained. Cobalt Strike comes with a toolkit for developing shellcode loaders, called Artifact Kit.

The Beacon implant has become popular amongst targeted attackers and criminal users as it is well written, stable, and highly customizable.

The tag is: *misp-galaxy:malpedia="Cobalt Strike"*

Cobalt Strike is also known as:

- Agentemis
- BEACON
- CobaltStrike
- cobeacon

CobInt

CobInt, is a self-developed backdoor of the Cobalt group. The modular tool has capabilities to collect initial intelligence information about the compromised machine and stream video from its desktop. If the operator decides that the system is of interest, the backdoor will download and launch CobaltStrike framework stager. It's CRM mailslot module was also observed being downloaded by ISFB.

Coinminer

Coinminer is an unwanted malicious software which uses the victim's computational power (CPU and RAM mostly) to mine for coins (for example Monero or Zcash). The malware achieves persistence by adding one of the opensource miners on startup without the victim's consensus. Most sophisticated coin miners use timer settings or cap the CPU usage in order to remain stealthy.

Cold$eal

Cold$eal is a packer for encrypting (sealing) malware. It contains some AV-evasion techniques as well as some sandbox-detection. It was developed by $@dok (aka Sadok aka Coldseal). It was available as a cryptor service under the url coldseal.us and was later sold as a toolkit consisting of the cryptor and a custom made cryptostub including a FuD garantee backed by free update to the cryptostub. The payload was encrypted using RC4 and added to the cryptostub as a resource. The encryption key itself was stored inside the resource as well. Upon start the cryptostub would extract the key, decrypt the payload and perform a selfinjection using the now decrypted payload. Note: The packed sample provided contains some harmless payload, while the unpacked sample is the bare cryptostub without a payload.

ColdStealer

ColdStealer is a relatively new malicious program that was discovered in 2022. Like many other stealers its main purpose is to steal credentials and information from web browsers, in addition to stealing cryptocurrency wallets, FTP credentials, various files and information about the system such as OS version, system language, processor type and clipboard data. When the infostealer collects information that will be stolen, it saves the information in the ZIP form instead of files in the memory. Doing so will allow the malware to bypass detection as there are no traces of files and execution. The only known method of delivering stolen information to cybercriminals is by sending a ZIP archive to the hardcoded command and control (C2) server.

Colibri Loader

According to cloudsek, Colibri Loader is a form of malware designed to facilitate the installation of additional malware types on an already compromised system. This loader employs various techniques to evade detection, such as excluding the Import Address Table (IAT) and utilizing encrypted strings to complicate analysis. Similar to other loader malware, Colibri can be utilized to deploy information-stealing malware, potentially leading to significant loss of sensitive data. As a result, users should exercise caution when encountering unfamiliar files on their systems.

ComeBacker

ComeBacker was found in a backdoored Visual Studio project that was used to target security researchers in Q4 2020 and early 2021.

It is an HTTP(S) downloader.

It uses the AES CBC cipher implemented through the OpenSSL's EVP interface for decryption of its configuration, and also for encryption and decryption of the client-server communication.

The parameter names in HTTP POST requests of the client are generated randomly. As the initial connection, the client exchanges the keys with the server via the Diffie–Hellman key agreement protocol for the elliptic curve secp521r1. The client generates a random 32-bytes long private key, and the server responds with its public key in a buffer starting with the wide character "0".

Next, the clients sends the current local time, and the server responds with a buffer containing multiple values separated with the pipe symbol. The typical values are the encrypted payload, the export to execute, and the MD5 hash of the decrypted DLL to verify the authenticity of the payload.

There are variants of ComeBacker without statically linked OpenSSL. In that case, the key exchange is omitted and AES CBC is replaced with HC-256.

ComLook

ComLook is a malicious plugin for the mail client "The Bat!", written in C++ and compiled with MSVC 10.0. It implements malicious commands like PutFile, GetFile, SetConfig, GetConfig, and Command. It contains hard-coded email addresses and other information, indicating a target in Azerbaijan. It was first uploaded to VirusTotal on January 12, 2022, and is associated with the APT group Turla. It appears to be a targeted deployment.

Conti (Windows)

Conti is an extremely damaging ransomware due to the speed with which it encrypts data and spreads to other systems. It was first observed in 2020 and it is thought to be led by a Russia-based

cybercrime group that goes under the Wizard Spider pseudonym. In early May 2022, the US government announced a reward of up to $10 million for information on the Conti ransomware gang.

Contopee

FireEye described this malware as a proxy-aware backdoor that communicates using a custom-encrypted binary protocol. It may use the registry to store optional configuration data. The backdoor has been observed to support 26 commands that include directory traversal, file system manipulation, data archival and transmission, and command execution.

CopperStealer

According to PCRIsk, CopperStealer, also known as Mingloa, is a malicious program designed to steal sensitive/personal information. It also has the capability to cause chain infections (i.e., download/install additional malware).

Significant activity of CopperStealer has been observed in Brazil, India, Indonesia, Pakistan, and the Philippines. At the time of research, this malware had been noted being spread via websites offering illegal activation tools ("cracks") for licensed software products.

https://www.fortinet.com/blog/threat-research/to-joke-or-not-to-joke-covid-22-brings-disaster-to-mbr

CoViper

PCRisk notes that CoViper is yet another Coronavirus/COVID-19-themed malware infection, most likely proliferated as a file related to the pandemic. It operates by rewriting the system Master Boot Record (MBR). It does not delete the original, but rather creates a backup and replaces it with a custom MBR.

Typically, malicious software that modifies MBRs do so to prevent the Operating System (OS) from being booted (i.e., started). It also displays a screen-encompassing message, often containing a ransom message - this disables user access to the device.

The tag is: *misp-galaxy:malpedia="CoViper"*

CoViper is also known as:

COZYDUKE

CozyDuke is not simply a malware toolset; rather, it is a modular malware platform formed around a core backdoor component. This component can be instructed by the C&C server to download and execute arbitrary modules, and it is these modules that provide CozyDuke with its vast array of functionality. Known CozyDuke modules include: • Command execution module for executing arbitrary Windows Command Prompt commands • Password stealer module • NT LAN Manager (NTLM) hash stealer module • System information gathering module • Screenshot module

The tag is: *misp-galaxy:malpedia="COZYDUKE"*

COZYDUKE is also known as:

- Cozer
- CozyBear
- CozyCar
- EuroAPT

CrackedCantil

According to ANY.RUN, this is a dropper for win.privateloader and its execution will lead to a cascade of downloads with a large variety of additional malware. The families include more loaders, information stealers, cryptominers, a proxy bot, and ultimately also ransomware. The execution order is orchestrated, e.g. as in data is stolen and exfiltrated before encryption. It is distributed through advertized cracked software, e.g. IDA Pro.

Crimson RAT

It was first discovered in 2017 and has since been used to attack organizations around the world. The malware is often distributed through phishing emails or by exploiting vulnerabilities in outdated security software. Once Crimson RAT is installed on a computer, it can be used to steal data, spy on users, and even take control of the infected computers.

Some of the features of Crimson RAT include:

Remote control of infected computers Data theft, such as passwords, files, and emails User spying Takeover of infected computers Locking of infected computers Extortion of payments

The tag is: *misp-galaxy:malpedia="Crimson RAT"*

Crimson RAT is also known as:

- SEEDOOR
- Scarimson

CrimsonIAS

According to ThreatConnect, CrimsonIAS is a Delphi-written backdoor dating back to at least 2017. It enables operators to run command line tools, exfiltrate files, and upload files to the infected machine. CrimsonIAS is notable as it listens for incoming connections only; making it different from typical Windows backdoors that beacons out.

The tag is: *misp-galaxy:malpedia="CrimsonIAS"*

CrimsonIAS is also known as:

CyberGate

According to Subex Secure, CyberGate is a Remote Access Trojan (RAT) that allows an attacker to gain unauthorized access to the victim's system. Attackers can remotely connect to the compromised system from anywhere around the world. The Malware author generally uses this program to steal private information like passwords, files, etc. It might also be used to install malicious software on the compromised systems.

The tag is: *misp-galaxy:malpedia="CyberGate"*

CyberGate is also known as:

- Rebhip

Dacls (Windows)

According to PCrisk, Dacls is the name of a remote access Trojan (RAT), a malicious program that allows cyber criminals to control infected computers remotely.

Research shows that this malware is tied to Lazarus Group (a group of cyber criminals) and targets Linux and the Windows Operating System. Typically, cyber criminals use RATs to steal sensitive, confidential information, infect systems with other malware, and so on. In any case, no RAT is harmless and should be uninstalled immediately.

The tag is: *misp-galaxy:malpedia="Dacls (Windows)"*

DADJOKE

DADJOKE was discovered as being distributed via email, targeting a South-East Asian Ministry of Defense. It is delivered as an embedded EXE file in a Word document using remote templates and a

unique macro using multiple GET requests. The payload is deployed using load-order hijacking with a benign Windows Defender executable. Stage 1 has only beacon+download functionality, made to look like a PNG file. Additional analysis by Kaspersky found 8 campaigns over 2019 and no activity prior to January 2019, DADJOKE is attributed with medium confidence to APT40.

DanaBot

Proofpoints describes DanaBot as the latest example of malware focused on persistence and stealing useful information that can later be monetized rather than demanding an immediate ransom from victims. The social engineering in the low-volume DanaBot campaigns we have observed so far has been well-crafted, again pointing to a renewed focus on “quality over quantity” in email-based threats. DanaBot’s modular nature enables it to download additional components, increasing the flexibility and robust stealing and remote monitoring capabilities of this banker.

danbot

Danbot is a backdoor malware that is originally written in C#. Recent versions of Danbot are written in C++. Danbot is capable of giving a remote attacker remote access features such as running a cmd command, upload and download files, move and copy files. The backdoor commands are transmitted by either using HTTP or DNS protocols. The commands are encapsulated in an XML file that gets stored in disk. Danbot's backdoor component picks up the XML file where it decodes and decrypts the commands.

DarkComet

DarkComet is one of the most famous RATs, developed by Jean-Pierre Lesueur in 2008. After being used in the Syrian civil war in 2011, Lesuer decided to stop developing the trojan. Indeed, DarkComet is able to enable control over a compromised system through use of a simple graphic user interface. Experts think that this user friendliness is the key of its mass success.

DarkGate

First documented in 2018, DarkGate is a commodity loader with features that include the ability to download and execute files to memory, a Hidden Virtual Network Computing (HVNC) module, keylogging, information-stealing capabilities, and privilege escalation. DarkGate makes use of legitimate AutoIt files and typically runs multiple AutoIt scripts. New versions of DarkGate have been advertised on a Russian language eCrime forum since May 2023.

The tag is: *misp-galaxy:malpedia="DarkGate"*

DarkGate is also known as:

- Meh
- MehCrypter

Darksky

DarkSky is a botnet that is capable of downloading malware, conducting a number of network and application-layer distributed denial-of-service (DDoS) attacks, and detecting and evading security controls, such as sandboxes and virtual machines. It is advertised for sale on the dark web for $20. Much of the malware that DarkSky has available to download onto targeted systems is associated with cryptocurrency-mining activity. The DDoS attacks that DarkSky can perform include DNS amplification attacks, TCP (SYN) flood, UDP flood, and HTTP flood. The botnet can also perform a check to determine whether or not the DDoS attack succeeded and turn infected systems into a SOCKS/HTTP proxy to route traffic to a remote server.

DarkTortilla

DarkTortilla is a complex and highly configurable .NET-based crypter that has possibly been active since at least August 2015. It typically delivers popular information stealers and remote access trojans (RATs) such as AgentTesla, AsyncRat, NanoCore, and RedLine. While it appears to primarily deliver commodity malware, Secureworks® Counter Threat Unit™ (CTU) researchers identified DarkTortilla samples delivering targeted payloads such as Cobalt Strike and Metasploit. It can also deliver "addon packages" such as additional malicious payloads, benign decoy documents, and executables. It features robust anti-analysis and anti-tamper controls that can make detection, analysis, and eradication challenging.

From January 2021 through May 2022, an average of 93 unique DarkTortilla samples per week were uploaded to the VirusTotal analysis service. Code similarities suggest possible links between DarkTortilla and other malware: a crypter operated by the RATs Crew threat group, which was active between 2008 and 2012, and the Gameloader malware that emerged in 2021.

Darktrack RAT

According to PCrisk, DarkTrack is a malicious program classified as a Remote Access Trojan (RAT). This type of malware enables remote access and control over an infected device. The level of control these programs have varies, however, some can allow user-level manipulation of the affected machine.

The functionalities of RATs likewise varies and so does the scope of potential misuse. DarkTrack has a broad range of functions/capabilities, which make this Trojan a highly-dangerous piece of software.

The tag is: *misp-galaxy:malpedia="Darktrack RAT"*

DarkVNC

According to Enigmasoft, DarkVNC malware is a hacking tool that is available for purchase online. it is can be used as a Virtual Network Computing service, which means that the attackers can get full access to the targeted system via this malware. However, unlike a genuine Virtual Network Computing utility, the DarkVNC threat operates in the background silently. Therefore, it is highly likely that the victims may not notice that their systems have been compromised.

Defray

Defray is ransomware that appeared in 2017, and is targeted ransomware, mainly on the healthcare vertical.

The distribution of Defray has several notable characteristics: According to Proofpoint: " Defray is currently being spread via Microsoft Word document attachments in email The campaigns are as small as several messages each The lures are custom crafted to appeal to the intended set of potential victims The recipients are individuals or distribution lists, e.g., group@ and websupport@ Geographic targeting is in the UK and US Vertical targeting varies by campaign and is narrow and selective "

DeimosC2

Trend Micro describes DeimosC2 as an open-source C&C framework that was released in June 2020. It is a fully-functional framework that allows for multiple attackers to access, create payloads for, and interact with victim computers. As a post-exploitation C&C framework, DeimosC2 will generate the payloads that need to be manually executed on computer servers that have been compromised through other means such as social engineering, exploitation, or brute-force attacks. Once it is deployed, the threat actors will gain the same access to the systems as the user account that the payload was executed as, either as an administrator or a regular user. Note that DeimosC2 does not perform active or privilege escalation of any kind.

The tag is: *misp-galaxy:malpedia="DeimosC2"*

DeliveryCheck

According to CERT-UA, this malware makes use of XSLT (Extensible Stylesheet Language Transformations) and COM-hijacking. Its specificity is the presence of a server part, which is usually installed on compromised MS Exchange servers in the form of a MOF (Managed Object Format) file using the Desired State Configuration (DCS) PowerShell tool), effectively turning a legitimate server into a malware control center.

The tag is: *misp-galaxy:malpedia="DeliveryCheck"*

DeliveryCheck is also known as:

- CAPIBAR
- GAMEDAY

Deprimon

According to ESET Research, DePriMon is a malicious downloader, with several stages and using many non-traditional techniques. To achieve persistence, the malware registers a new local port monitor – a trick falling under the “Port Monitors” technique in the MITRE ATT&CK knowledgebase. For that, the malware uses the “Windows Default Print Monitor” name; that’s why we have named it DePriMon. Due to its complexity and modular architecture, researcher believe it to be a framework.

DePriMon has been active since at least March 2017. DePriMon was detected in a private company, based in Central Europe, and at dozens of computers in the Middle East.

Dharma

According to MalwareBytes, the Dharma Ransomware family is installed manually by attackers hacking into computers over Remote Desktop Protocol Services (RDP). The attackers will scan the Internet for computers running RDP, usually on TCP port 3389, and then attempt to brute force the password for the computer.

Once they gain access to the computer they will install the ransomware and let it encrypt the computer. If the attackers are able to encrypt other computers on the network, they will attempt to do so as well.

The tag is: *misp-galaxy:malpedia="Dharma"*

Dharma is also known as:

- Arena
- Crysis
- Wadhrama
- ncov

DiamondFox

According to PCrisk, DiamondFox is highly modular malware offered as malware-as-a-service, and is for sale on various hacker forums. Therefore, cyber criminals who are willing to use DiamondFox do not necessarily require any technical knowledge to perform their attacks.

Once purchased, this malware can be used to log keystrokes, steal credentials (e.g., usernames, email addresses, passwords), hijack cryptocurrency wallets, perform distributed denial of service (DDoS) attacks, and to carry out other malicious tasks.

DiamondFox allows cyber criminals to choose which plug-ins to keep activated and see infection statistics in real-time.

DMSniff

DMSniff is a point-of-sale malware previously only privately sold. It has been used in breaches of small- and medium-sized businesses in the restaurant and entertainment industries. It uses a domain generation algorithm (DGA) to create lists of command-and-control domains on the fly.

The tag is: *misp-galaxy:malpedia="DMSniff"*

DMSniff is also known as:

Table 3534. Table References

https://www.flashpoint-intel.com/blog/dmsniff-pos-malware-actively-leveraged-target-medium-sized-businesses/

DneSpy

DneSpy collects information, takes screenshots, and downloads and executes the latest version of other malicious components in the infected system. The malware is designed to receive a “policy” file in JSON format with all the commands to execute. The policy file sent by the C&C server can be changed and updated over time, making dneSpy flexible and well-designed. The output of each executed command is zipped, encrypted, and exfiltrated to the C&C server. These characteristics make dneSpy a fully functional espionage backdoor.

Minodo

Since late February 2023, Minodo Backdoor campaigns have been employed to deliver either the Project Nemesis information stealer or more sophisticated backdoors like Cobalt Strike. This backdoor collects basic system information, which it then transmits to the C2 server. In return, it receives an AES-encrypted payload. Notably, the Minodo Backdoor is designed to contact a different C2 address for domain-joined systems. This suggests that more capable backdoors, such as Cobalt Strike, are downloaded on higher-value targets instead of Project Nemesis.

DOUBLEBACK

DOUBLEBACK is a newly discovered fileless malware deployed as part of an attack campaign that took place in December 2020. The threat actors responsible for the operations are tracked as UNC2529 by researchers. According to their findings, DOUBLEBACK is the final payload delivered onto the compromised systems. Its task is to establish and maintain a backdoor on the victim's machine.

DreamBot

2010 Gozi v2.0, Gozi ISFB, ISFB, Pandemyia(*) 2014 Dreambot (Gozi ISFB variant)

In 2014, a variant of Gozi ISFB was developed. Mainly, the dropper performs additional anti-vm checks (vmware, vbox, qemu), while the actual bot-dll remains unchanged in most parts. New

functionality, such as TOR support, was added though and often, the Fluxxy fast-flux network is used.

See win.gozi for additional historical information.

The tag is: *misp-galaxy:malpedia="DreamBot"*

Dridex

OxCERT blog describes Dridex as "an evasive, information-stealing malware variant; its goal is to acquire as many credentials as possible and return them via an encrypted tunnel to a Command-and-Control (C&C) server. These C&C servers are numerous and scattered all over the Internet, if the malware cannot reach one server it will try another. For this reason, network-based measures such as blocking the C&C IPs is effective only in the short-term." According to MalwareBytes, "Dridex uses an older tactic of infection by attaching a Word document that utilizes macros to install malware. However, once new versions of Microsoft Office came out and users generally updated, such a threat subsided because it was no longer simple to infect a user with this method." IBM X-Force discovered "a new version of the Dridex banking Trojan that takes advantage of a code injection technique called AtomBombing to infect systems. AtomBombing is a technique for injecting malicious code into the 'atom tables' that almost all versions of Windows uses to store certain application data. It is a variation of typical code injection attacks that take advantage of input validation errors to insert and to execute malicious code in a legitimate process or application. Dridex v4 is the first malware that uses the AtomBombing process to try and infect systems."

Drokbk

Drokbk stands out for its use of the GitHub platform as part of its C&C infrastructure. This makes it difficult to detect and remove, as GitHub is not traditionally associated with malicious activities.

Drokbk attacks have been linked to the Iranian APT group Nemesis Kitten. This group is believed to use Drokbk for cyberespionage and financial information theft activities.

DropBook

DropBook is a backdoor developed by the Molerats group and first appeared in late 2020. The

backdoor abuses Facebook and Dropbox platforms for C2 purposes, where fake Facebook accounts are used by the operators to control the backdoor by posting commands on the accounts.

Dtrack

Dtrack is a Remote Administration Tool (RAT) developed by the Lazarus group. Its core functionality includes operations to upload a file to the victim's computer, download a file from the victim's computer, dump disk volume data, persistence and more.

A variant of Dtrack was found on Kudankulam Nuclear Power Plant (KNPP) which was used for a targeted attack.

DUSTMAN

In 2019, multiple destructive attacks were observed targeting entities within the Middle East. The National Cyber Security Centre (NCSC), a part of the National Cybersecurity Authority (NCA), detected a new malware named "DUSTMAN" that was detonated on December 29, 2019. Based on analyzed evidence and artifacts found on machines in a victim's network that were not wiped by the malware. NCSC assess that the threat actor behind the attack had some kind of urgency on executing the files on the date of the attack due to multiple OPSEC failures observed on the infected network. NCSC is calling the malware used in this attack "DUSTMAN" after the filename and string embedded in the malware. "DUSTMAN" can be considered as a new variant of "ZeroCleare" malware, published in December 2019.

Dyre

The Dyre Banking Trojan, discovered in June 2014, targets online banking websites for credential theft and fraud. It uses a man-in-the-browser approach, encryption, and spam emails for distribution.

Dyre's architecture includes a dropper and main DLL module, with techniques for persistence and evasion. Its command and control infrastructure is hidden through proxies, and it can adapt using a domain generation algorithm and I2P integration. Researchers have linked Dyre to the Gozi and Neverquest families.

The tag is: *misp-galaxy:malpedia="Dyre"*

Easy Stealer

Easy Stealer is a new information stealer written in Golang that is under active development. Since July 2023, the information stealer has been sold on the underground market, advertising a variety of capabilities, such as the ability to target crypto wallets and passwords. Based on VirusTotal data, it appears that developer test samples were uploaded in June 2023. The panel for the stealer is installed on the buyer's own infrastructure, allowing for exclusive control. The stated pricing models are: $35 for 7 days, $115 for 30 days, and $250 for 90 days. Given its user-friendly panel design and the affordable price range, combined with similar capabilities to other information stealers, Easy Stealer is likely to see an increase in distribution among various cyber criminals as it continues through active development.

EDA2

EDA2 is a successor of HiddenTear. Just like HiddenTear it was developed as an open-source project by a security researcher and published on Github. It was meant as "educational ransomware" and purposefully had flaws in the encryption process that allow decryption of ransomed files.

This backfired, when threat actors began to modify HiddenTear and EDA2 source code. Some modifications introduced bugs where encrypted files were destroyed, others fixed the encryption flaws and made decryption without a key impossible.

The tag is: *misp-galaxy:malpedia="EDA2"*

Egregor

According to Heimdal, Egregor ransomware infection happens via a loader, then, in the victim's firewall, it enables the Remote Desktop Protocol. After this part, the malware is free to move inside the victim's network, identifying and disabling all the antivirus software it can find. The next step is the encryption of the data and the insertion of a ransom note named "RECOVER-FILES.txt" in all the compromised folders.

ELECTRICFISH

The application is a command-line utility and its primary purpose is to tunnel traffic between two IP addresses. The application accepts command-line arguments allowing it to be configured with a destination IP address and port, a source IP address and port, a proxy IP address and port, and a user name and password, which can be utilized to authenticate with a proxy server. It will attempt to establish TCP sessions with the source IP address and the destination IP address. If a connection is made to both the source and destination IPs, this malicious utility will implement a custom protocol, which will allow traffic to rapidly and efficiently be tunneled between two machines. If necessary, the malware can authenticate with a proxy to be able to reach the destination IP address. A configured proxy server is not required for this utility.

Elirks

Elirks is a basic backdoor Trojan, first discovered in 2010, that is primarily used to steal information from compromised systems. Mostly attacks using Elirks occurring in East Asia. One of the unique features of the malware is that it retrieves its C2 address by accessing a pre-determined microblog service or SNS. Attackers create accounts on those services and post encoded IP addresses or the domain names of real C2 servers in advance of distributing the backdoor. Multiple Elirks variants using Japanese blog services for the last couple of years.

ELMER

ELMER is a non-persistent proxy-aware HTTP backdoor written in Delphi, and is capable of performing file uploads and downloads, file execution, and process and directory listings. To retrieve commands, ELMER sends HTTP GET requests to a hard-coded CnC server, and parses the HTTP response packets received from the CnC server for an integer string corresponding to the command that needs to be executed.

Emotet

While Emotet historically was a banking malware organized in a botnet, nowadays Emotet is mostly seen as infrastructure as a service for content delivery. For example, since mid 2018 it is used by Trickbot for installs, which may also lead to ransomware attacks using Ryuk, a combination observed several times against high-profile targets. It is always stealing information from victims but what the criminal gang behind it did, was to open up another business channel by selling their infrastructure delivering additional malicious software. From malware analysts it has been classified into epochs depending on command and control, payloads, and delivery solutions which change over time. Emotet had been taken down by authorities in January 2021, though it appears to have sprung back to life in November 2021.

The tag is: *misp-galaxy:malpedia="Emotet"*

Emotet is also known as:

- Geodo
- Heodo

Epsilon Stealer

Epsilon Stealer is an information stealer sold as Malware as a Service by a new french actor called "Epsilon". This malware is distributed as a game, mainly on discord, but steals user credentials, crypto wallets, and stored cookies. It evades static detection by being packed with NSIS, which then launches a malicious Electron package.

The tag is: *misp-galaxy:malpedia="Epsilon Stealer"*

Exorcist

According to PCrisk, Exorcist is a ransomware-type malicious program. Systems infected with this malware experience data encryption and users receive ransom demands for decryption. During the encryption process, all compromised files are appended with an extension consisting of a ransom string of characters.

For example, a file originally named "1.jpg" could appear as something similar to "1.jpg.rnyZoV" following encryption. After this process is complete, Exorcist ransomware changes the desktop wallpaper and drops HTML applications - "[random-string]-decrypt.hta" (e.g. "rnyZoV-decrypt.hta") - into affected folders. These files contain identical ransom messages.

The tag is: *misp-galaxy:malpedia="Exorcist"*

Expiro

Expiro malware has been around for more than a decade, and the malware authors sill continue their work and update it with more features. Also the infection routine was changed in samples fround in 2017 (described by McAfee). Expiro "infiltrates" executables on 32- and 64bit Windows OS versions. It has capabilities to install browser extensions, change security behaviour/settings on the infected system, and steal information (e.g. account credentials). There is a newly described EPO file infector source code called m0yv in 2022, which is wrongly identified as expiro by some AVs.

The tag is: *misp-galaxy:malpedia="Expiro"*

Xtreme RAT

According to Trend MIcro, Extreme RAT (XTRAT, Xtreme Rat) is a Remote Access Trojan that can steal information. This RAT has been used in attacks targeting Israeli and Syrian governments last 2012.

This malware family of backdoors has the capability to receive commands such as File Management (Download, Upload, and Execute Files), Registry Management (Add, Delete, Query, and Modify Registry), Perform Shell Command, Computer Control (Shutdown, Log on/off), and Screen capture from a remote attacker. In addition, it can also log keystrokes of the infected systems.

The tag is: *misp-galaxy:malpedia="Xtreme RAT"*

Xtreme RAT is also known as:

FantomCrypt

According to PCrisk, Fantom is a ransomware-type virus that imitates the Windows update procedure while encrypting files. This is unusual, since most ransomware encrypts files stealthily without showing any activity. During encryption, Fantom appends the names of encrypted files with the ".locked4", ".fantom" or ".locked" extension.

FatalRat

According to PCrisk, FatalRAT is the name of a Remote Access Trojan (RAT). A RAT is a type of malware that allows the attacker to remotely control the infected computer and use it for various purposes.

Typically, RATs are used to access files and other data, watch computing activities on the screen and capture screenshots, steal sensitive information (e.g., login credentials, credit card details).

There are many legitimate remote administration/access tools on the Internet. It is common that cybercriminals use those tools with malicious intent too.

The tag is: *misp-galaxy:malpedia="FatalRat"*

FatalRat is also known as:

- Sainbox RAT

FatDuke

According to ESET Research, FatDuke is the current flagship backdoor of APT29 and is only deployed on the most interesting machines. It is generally dropped by the MiniDuke backdoor, but ESET also have seen the operators dropping FatDuke using lateral movement tools such as PsExec.The operators regularly repack this malware in order to evade detections. The most recent sample of FatDuke that ESET have seen was compiled on May 24, 2019. They have seen them trying to regain control of a machine multiple times in a few days, each time with a different sample.

Their packer, described in a later section, adds a lot of code, leading to large binaries. While the effective code should not be larger than 1MB, ESET have seen one sample weighing in at 13MB, hence our name for this backdoor component: FatDuke.

FDMTP

FDMTP is a newly discovered hacking tool developed in .NET, used by Earth Preta. It functions as a

simple malware downloader and is based on the TouchSocket framework over the Duplex Message Transport Protocol (DMTP). In one campaign, threat actors embedded FDMTP in the data section of a DLL. This allows it to be launched through DLL side-loading. The embedded network configurations are encoded and encrypted to enhance security and evade detection, utilizing Base64 and DES encryption methods. It has been observed to serve as a secondary control tool, often deployed by the PUBLOAD backdoor.

FFDroider

According to PCrisk, FFDroider is a malicious program classified as a stealer. It is designed to extract and exfiltrate sensitive data from infected devices. FFDroider targets popular social media and e-commerce platforms in particular.

The tag is: *misp-galaxy:malpedia="FFDroider"*

FFDroider is also known as:

Table 3675. Table References

Ficker Stealer

According to CyberArk, this malware is used to steal sensitive information, including login credentials, credit card information, cryptocurrency wallets and browser information from applications such as WinSCP, Discord, Google Chrome, Electrum, etc. It does all that by implementing a different approach than other stealers (we'll cover it later). Additionally, FickerStealer can function as a File Grabber and collect additional files from the compromised machine, and it can act as a Downloader to download and execute several second-stage malware.

The tag is: *misp-galaxy:malpedia="Ficker Stealer"*

Ficker Stealer is also known as:

FinFisher RAT

FinFisher is a commercial software used to steal information and spy on affected victims. It began with few functionalities which included password harvesting and information leakage, but now it is mostly known for its full Remote Access Trojan (RAT) capabilities. It is mostly known for being used in governmental targeted and lawful criminal investigations. It is well known for its anti-detection capabilities and use of VMProtect.

The tag is: *misp-galaxy:malpedia="FinFisher RAT"*

FinFisher RAT is also known as:

- FinSpy

FINTEAM

Recently, Check Point researchers spotted a targeted attack against officials within government finance authorities and representatives in several embassies in Europe. The attack, which starts with a malicious attachment disguised as a top secret US document, weaponizes TeamViewer, the popular remote access and desktop sharing software, to gain full control of the infected computer. This is achieved by sideloading another DLL among the legit TeamViewer.

The tag is: *misp-galaxy:malpedia="FINTEAM"*

FK_Undead

This malware family is mainly spread through various private server clients in bundles, and mainly tamper with user system network data packets through technical means such as TDI filtering, DNS hijacking, HTTP(s) injection, and HOSTS redirection, hijacking normal web page access to designated private server websites, and using security software cloud detection and killing data packet shielding, shutdown callback rewriting and other means to achieve counter-detection.

FudModule

FudModule is a user-mode DLL that gets the ability to read and write arbitrary kernel memory via the BYOVD technique. Its main goal is to turn off Windows system monitoring features, which is done by modifying kernel variables and removing kernel callbacks. Its actions may very likely affect various types of security products, e.g. EDRs, firewalls, antimalware and even digital forensics tools.

FuwuqiDrama

FuwuqiDrama is a server-side RAT. It manages client connections by utilizing I/O completion ports, which are usually used in high-performance server applications as an elegant solution to manage many clients at once.

It contains two distinguishing hardcoded lists.

First is a list of ~50 video files of South Korean TV series, having their titles translated to Mandarin Chinese, but encoded in the form of Pinyin romanization. That means the sounds are spelled in Latin alphabet without tone marks, for example meiyounihuobuxiaqu.avi represents Can't Live Without You (a K-drama from 2012) or wulalafufu.avi translates to Ohlala Couple (also from 2012).

Second is the list of the following corporations: NVIDIA, Amazon, Intel, Skype, 360Safe, Rising, Tencent, Mozilla, Adobe, Yahoo, Google. The same list is contained in some of the WannaCryptor samples.

FuwuqiDrama stores its configuration in the INI file data\package_con_x86.cat. It contains the port number and a bot identifier, all within a single section called Fuwuqi – the romanized Chinese

word for server.

GaboonGrabber

According to ANY.RUN, the GaboonGrabber is a malware developed in .NET that grabs its embedded resources to prepare multiple fileless stages. Additionally, it has the tendency to camouflage itself as a legitimate application, going so far as to mimic legitimate applications in its decompiled code. It also includes a steganographic image used to prepare further payloads.

GaboonGrabber's final stage can deploy various types of malware, including Snake Keylogger, AgentTesla, Redline, Lokibot, and more.

Gameover P2P

Gameover ZeuS is a peer-to-peer botnet based on components from the earlier ZeuS trojan. According to a report by Symantec, Gameover Zeus has largely been used for banking fraud and distribution of the CryptoLocker ransomware. In early June 2014, the U.S. Department of Justice announced that an international inter-agency collaboration named Operation Tovar had succeeded in temporarily cutting communication between Gameover ZeuS and its command and control servers.

Gandcrab

GandCrab was a Ransomware-as-a-Service (RaaS) emerged in January 28, 2018, managed by a criminal organization known to be confident and vocal, while running a rapidly evolving ransomware campaign. Through their aggressive, albeit unusual, marketing strategies and constant recruitment of affiliates, they were able to globally distribute a high volume of their malware.

In a surprising announcement on May 31, 2019, the GandCrab's operators posted on a dark web forum, announced the end of a little more than a year of ransomware operations, citing staggering profit figures. However, If there's one thing that sets these threat actors apart from other groups, it is that they are unpredictable; so there is always the possibility that they might re-surface in one form or another.

The tag is: *misp-galaxy:malpedia="Gandcrab"*

Gandcrab is also known as:

- GrandCrab

GhostSocks

GhostSocks, a Golang-based proxy malware, was first advertised as a Malware-as-a-Service (MaaS) on Russian-speaking underground forums in October 2023. It uses back-connect socket secure internet protocol (SOCKS5) connections and is available for rent for US $100 per month. In February 2024, the author of Lumma Stealer released an update introducing the integration of proxying capabilities. This feature, developed in partnership with GhostSocks, allows the use of infected hosts as SOCKS5 proxies and is available to all subscribers who purchase the "Professional" or higher tier plan. This integration allows Lumma Stealer users to establish a network of residential IP addresses for various purposes, including credential checking, spam distribution, or as general-purpose proxies.

Ghost RAT

According to Security Ninja, Gh0st RAT (Remote Access Terminal) is a trojan “Remote Access Tool” used on Windows platforms, and has been used to hack into some of the most sensitive computer networks on Earth.

Below is a list of Gh0st RAT capabilities. Take full control of the remote screen on the infected bot. Provide real time as well as offline keystroke logging. Provide live feed of webcam, microphone of infected host. Download remote binaries on the infected remote host. Take control of remote shutdown and reboot of host. Disable infected computer remote pointer and keyboard input. Enter into shell of remote infected host with full control. Provide a list of all the active processes. Clear all existing SSDT of all existing hooks.

GoldenSpy

According securityweek, GoldenSpy, the malware was observed as part of a campaign that supposedly started in April 2020, but some of the identified samples suggest the threat has been around since at least December 2016.

One of the compromised organizations, a global technology vendor that conducts government business in the US, Australia and UK, and which recently opened offices in China, became infected after installing “Intelligent Tax,” a piece of software from the Golden Tax Department of Aisino Corporation, which a local bank required for paying local taxes.

Although it worked as advertised, the software was found to install a hidden backdoor to provide remote operators with the possibility to execute Windows commands or upload and run files.

GoldDragon

GoldDragon was a second-stage backdoor which established a permanent presence on the victim's system once the first-stage, file-less, PowerShell-based attack leveraging steganography was executed. The initial attack was observed first in December 2017, when a Korean-language spear phishing campaing targeted organizations linked with Pyeongchang Winter Olympics 2018. GoldDragon was delivered once the attacker had gained an initial foothold in the targeted environment.

The malware was capable of a basic reconnaissance, data exfiltration and downloading of additional components from its C&C server.

The tag is: *misp-galaxy:malpedia="GoldDragon"*

GootKit

Gootkit is a banking trojan consisting of an x86 loader and a payload embedding nodejs as well as a set of js scripts. The loader downloads the payload, stores it in registry and injects it in a copy of the loader process. The loader also contains two encrypted DLLs intended to be injected into each browser process launched in order to place the payload in man in the browser and allow it to apply the webinjects received from the command and control server on HTTPx exchanges. This allows Gootkit to intercept HTTPx requests and responses, steal their content or modify it according to the webinjects.

Gozi

2000 Ursnif aka Snifula 2006 Gozi v1.0, Gozi CRM, CRM, Papras 2010 Gozi v2.0, Gozi ISFB, ISFB, Pandemyia(*) → 2010 Gozi Prinimalka → Vawtrak/Neverquest

In 2006, Gozi v1.0 ('Gozi CRM' aka 'CRM') aka Papras was first observed. It was offered as a CaaS, known as 76Service. This first version of Gozi was developed by Nikita Kurmin, and he borrowed code from Ursnif aka Snifula, a spyware developed by Alexey Ivanov around 2000, and some other kits. Gozi v1.0 thus had a formgrabber module and often is classified as Ursnif aka Snifula.

In September 2010, the source code of a particular Gozi CRM dll version was leaked, which led to Vawtrak/Neverquest (in combination with Pony) via Gozi Prinimalka (a slightly modified Gozi v1.0) and Gozi v2.0 (aka 'Gozi ISFB' aka 'ISFB' aka Pandemyia). This version came with a webinject module.

Grager

Grager is a backdoor deployed against three organizations in Taiwan, Hong Kong, and Vietnam in April 2024. Analysis of this backdoor revealed that it uses the Graph API to communicate with a command and control (C&C) server hosted on Microsoft OneDrive. The backdoor decrypts a client ID and refresh token for OneDrive from a blob contained within its file body. It supports the following commands:

- Retrieve machine information, including machine name, user, IP address, and machine architecture
- Download or upload a file
- Execute a file
- Gather file system information, including available drives, their sizes, and types of drives

Grateful POS

POS malware targets systems that run physical point-of-sale device and operates by inspecting the process memory for data that matches the structure of credit card data (Track1 and Track2 data), such as the account number, expiration date, and other information stored on a card's magnetic

stripe. After the cards are first scanned, the personal account number (PAN) and accompanying data sit in the point-of-sale system's memory unencrypted while the system determines where to send it for authorization. Masked as the LogMein software, the GratefulPOS malware appears to have emerged during the fall 2017 shopping season with low detection ratio according to some of the earliest detections displayed on VirusTotal. The first sample was upload in November 2017. Additionally, this malware appears to be related to the Framework POS malware, which was linked to some of the high-profile merchant breaches in the past.

GRIMAGENT

GRIMAGENT is a backdoor that can execute arbitrary commands, download files, create and delete scheduled tasks, and execute programs via scheduled tasks or via the ShellExecute API. The malware persists via a randomly named scheduled task and a registry Run key. The backdoor communicates to hard-coded C&C servers via HTTP requests with portions of its network communications encrypted using both asymmetric and symmetric cryptography. GRIMAGENT was used during some Ryuk Ransomware intrusions in 2020.

Hakbit

Hakbit ransomware is written in .NET. It uploads (some) files to be encrypted to a ftp-server. The ransom note is embedded - in earlier versions as plain string, then as base64 string. In some versions, these strings are slightly obfuscated.

Contact is via an email address hosted on protonmail. Hakbit (original) had hakbit@, more recent "KiraLock" has kiraransom@ (among others of course).

The tag is: *misp-galaxy:malpedia="Hakbit"*

Hakbit is also known as:

- Thanos Ransomware

Havex RAT

Havex is a remote access trojan (RAT) that was discovered in 2013 as part of a widespread

espionage campaign targeting industrial control systems (ICS) used across numerous industries and attributed to a hacking group referred to as "Dragonfly" and "Energetic Bear". Havex is estimated to have impacted thousands of infrastructure sites, a majority of which were located in Europe and the United States. Within the energy sector, Havex specifically targeted energy grid operators, major electricity generation firms, petroleum pipeline operators, and industrial equipment providers. Havex also impacted organizations in the aviation, defense, pharmaceutical, and petrochemical industries.

Once installed, Havex scanned the infected system to locate any Supervisory Control and Data Acquisition (SCADA) or ICS devices on the network and sent the data back to command and control servers. To do so, the malware leveraged the Open Platform Communications (OPC) standard, which is a universal communication protocol used by ICS components across many industries that facilitates open connectivity and vendor equipment interoperability. Havex used the Distributed Component Object Model (DCOM) to connect to OPC servers inside of an ICS network and collect information such as CLSID, server name, Program ID, OPC version, vendor information, running state, group count, and server bandwidth.

Havex was an intelligence-collection tool used for espionage and not for the disruption or destruction of industrial systems. However, the data collected by Havex would have aided efforts to design and develop attacks against specific targets or industries.

The tag is: *misp-galaxy:malpedia="Havex RAT"*

Havex RAT is also known as:

Havoc

First released in October 2022, the Havoc C2 Framework is a flexible post-exploitation framework written in Golang, C++, and Qt, with agents called 'Demons' written in C and ASM, created by @C5pider. Designed to support red team engagements and adversary emulation, it offers a robust set of capabilities tailored for offensive security operations. The framework, which is under active development, utilizes HTTP(s) and SMB as communication protocols for its implants. Havoc can generate implants, known as Demons, in several formats including EXE, DLL, and Shellcode. A notable feature of Havoc is its ability to bypass EDR by employing advanced evasion techniques such as sleep obfuscation, return address stack spoofing, and indirect syscalls. This capability

enhances its effectiveness in evading detection and circumventing security measures.

The tag is: *misp-galaxy:malpedia="Havoc"*

Havoc is also known as:

- Havokiz

HelloKitty (Windows)

Unit42 states that HelloKitty is a ransomware family that first surfaced at the end of 2020, primarily targeting Windows systems. The malware family got its name due to its use of a Mutex with the same name: HelloKittyMutex. The ransomware samples seem to evolve quickly and frequently, with different versions making use of the .crypted or .kitty file extensions for encrypted files. Some newer samples make use of a Golang packer that ensures the final ransomware code is only loaded in memory, most likely to evade detection by security solutions.

The tag is: *misp-galaxy:malpedia="HelloKitty (Windows)"*

HelloKitty (Windows) is also known as:

- KittyCrypt

HermeticWiper

According to SentinelLabs, HermeticWiper is a custom-written application with very few standard functions. It abuses a signed driver called "empntdrv.sys" which is associated with the legitimate Software "EaseUS Partition Master Software" to enumerate the MBR and all partitions of all Physical Drives connected to the victims Windows Device and overwrite the first 512 Bytes of every MBR and Partition it can find, rendering them useless. This malware is associated to the malware attacks against Ukraine during Russians Invasion in February 2022.

HiddenTear

HiddenTear is an open source ransomware developed by a Turkish programmer and later released as proof of concept on GitHub. The malware generates a local symmetric key in order to encrypt a configurable folder (/test was the default one) and it sends it to a centralized C&C server. Due to its small payload it was used as real attack vector over email phishing campaigns. Variants are still used in attacks.

The tag is: *misp-galaxy:malpedia="HiddenTear"*

Hive (Windows)

Hive is a strain of ransomware that was first discovered in June 2021. Hive was designed to be used by Ransomware-as-a-service providers, to enable novice cyber-criminals to launch ransomware attacks on healthcare providers, energy providers, charities, and retailers across the globe. In 2022 there was a switch from GoLang to Rust.

HyperBro

HyperBro is a RAT that has been observed to target primarily within the gambling industries, though it has been spotted in other places as well. The malware typically consists of 3 or more components: a) a genuine loader typically with a signed certification b) a malicious DLL loader loaded from the former component via DLL hijacking c) an encrypted and compressed blob that

decrypts to a PE-based payload which has its C2 information hardcoded within.

IcedID

According to Proofpoint, IcedID (aka BokBot) is a malware originally classified as a banking malware and was first observed in 2017. It also acts as a loader for other malware, including ransomware. The well-known IcedID version consists of an initial loader which contacts a Loader C2 server, downloads the standard DLL Loader, which then delivers the standard IcedID Bot. IcedID is developed and operated by the actor named LUNAR SPIDER.

As previously published, historically there has been just one version of IcedID that has remained constant since 2017. * In November 2022, Proofpoint researchers observed the first new variant of IcedID Proofpoint dubbed 'IcedID Lite' distributed as a follow-on payload in a TA542 Emotet campaign. It was dropped by the Emotet malware soon after the actor returned to the e-crime landscape after a nearly four-month break. * The IcedID Lite Loader observed in November 2022 contains a static URL to download a 'Bot Pack' file with a static name (botpack.dat) which results in the IcedID Lite DLL Loader, and then delivers the Forked version of IcedID Bot, leaving out the webinjects and backconnect functionality that would typically be used for banking fraud. * Starting in February 2023, Proofpoint observed the new Forked variant of IcedID. This variant was distributed by TA581 and one unattributed threat activity cluster which acted as initial access facilitators. The campaigns used a variety of email attachments such as Microsoft OneNote attachments and somewhat rare to see .URL attachments, which led to the Forked variant of IcedID.

win.icexloader

IceXLoader is a commercial malware used to download and deploy additional malware on infected machines. The latest version is written in Nim, a relatively new language utilized by threat actors the past two years, most notably by the NimzaLoader variant of BazarLoader used by the TrickBot group.

The v1 was written in AutoIT.

Ice IX

The ICE IX bot is a banking trojan derived of the Zeus botnet because it uses significant parts of Zeus's source code. ICE IX communicates using the HTTP protocol, so it can be considered to be a third-generation botnet. While it has been used for a variety of purposes, a primary threat of ICE IX comes from its manipulation of banking operations on compromised machines. As with any bot, execution of the bot results in establishing a master-slave relationship between the botmaster and the compromised computer.

ImprudentCook

ImprudentCook is an HTTP(S) downloader.

It was delivered in the Operation DreamJob type of activity targeting aerospace and defense companies in South Africa (in Q2 2022) and in Central Europe (in H1 2023), and against an unknown sector in South Korea back in Q2 2021.

It uses the AES cipher implemented through Windows Cryptographic Providers for decryption of its binary configuration, and also for encryption and decryption of the client-server communication.

It's hidden in an ADS stream (:dat or :zone) of its dropper, together with its configuration (:rsrc) and an AES-128 CBC key with an initialization vector for its decryption (:kgb or :data).

It contains two characteristic arrays of strings that represent cookie names for web services, including Bing, Daum and GitHub:

1. iKc;*uid;OAX;DMP_UID;PCID;_gid;_gat;csrftoken;NID;1P_JAR;JSESSIONID;WLS;SNID;* utma;BID;SRCHD;GsCK_AC;spintop;eader;XSRF-TOKEN;_gat_gtag_UA;webid_ enabled;EDGE_V;dtck_channel;dtmulti;UUID;XUID;ZIA;IUID;SSID;_gh_sess;_octo
2. channel;post_titles;xfw_exp;wiht_clkey;SGPCOUPLE;NRTK;fbp;uaid;SRCHUSR;GUC;HPVN;dtck_ blog;dtck_media;MUIDB;SRCHHPGUSR;SiteMain

It contains a string, "5.40" or "5.60", looking like version information.

InfinityLock

InfinityLock ransomware is a type of malicious software that encrypts a victim's files and demands a ransom payment in order to decrypt them. It is spread through phishing emails and malicious websites. Once a computer is infected with InfinityLock, it encrypts all important files, such as documents, photos, and videos. It then displays a message that demands the victim pay a ransom of $1,000 in Bitcoin in order to decrypt the files. If the victim does not pay the ransom, the files will be lost permanently.

InnaputRAT

InnaputRAT, a RAT capable of exfiltrating files from victim machines, was distributed by threat actors using phishing and Godzilla Loader. The RAT has evolved through multiple variants dating back to 2016. Recent campaigns distributing InnaputRAT beaconed to live C2 as of March 26, 2018.

win.innfirat

InnifiRAT is coded in .NET and targets personal data on infected devices, with it's top priority appearing to be bitcoin and litecoin wallet data.

InffiRAT also includes a backdoor which allows attackers to control the infected host remotely. Possibilities include loggin key stroke, taking pictures with webcam, accessing confidential information, formatting drives, and more.

It attempts to steal browser cookies to steal usernames and passwords and monitors the users activities with screenshot functionality.

Interception (Windows)

ESET noticed attacks against aerospace and military companies in Europe and the Middle East that took place between September and December 2019, which featured this family. They found a number of hints that points towards Lazarus as potential origin.

InvisiMole

InvisiMole had a modular architecture, starting with a wrapper DLL, and performing its activities using two other modules that were embedded in its resources, named RC2FM and RC2CL. They were feature-rich backdoors and turned the affected computer into a video camera, letting the attackers to spy the victim. The malicious actors behind this malware were active at least since 2013 in highly targeted campaigns with only a few dozen compromised computers in Ukraine and Russia. The wrapper DLL posed as a legitimate mpr.dll library and was placed in the same folder as explorer.exe, which made it being loaded during the Windows startup into the Windows Explorer process instead of the legitimate library. Malware came in both 32-bit and 64-bit versions, which made this persistence technique functional on both architectures.

The smaller of the modules, RC2FM, contained a backdoor with fifteen supported commands indexed by numbers. The commands could perform simple changes on the system and spying features like capturing sounds, taking screenshots or monitoring all fixed and removable drives.

The second module, RC2CL, offered features for collecting as much data about the infected computer as possible, rather than for making system changes. The module supported up to 84 commands such as file system operations, file execution, registry key manipulation, remote shell activation, wireless network scanning, listing of installed software etc. Though the backdoor was capable of interfering with the system (e.g. to log off a user, terminate a process or shut down the system), it mostly provided passive operations. Whenever possible, it tried to hide its activities by restoring the original file access time or safe-deleting its traces.

IRONHALO

```
IRONHALO is a downloader that uses the HTTP protocol to retrieve a Base64 encoded
payload from a hard-coded command-and-control (CnC) server and uniform resource
locator (URL) path.
The encoded payload is written to a temporary file, decoded and executed in a hidden
window. The encoded and decoded payloads are written to files named igfxHK[%rand%].dat
and igfxHK[%rand%].exe respectively, where [%rand%] is a 4-byte hexadecimal number
based on the current timestamp. It persists by copying itself to the current user□s
Startup folder.

ISFB

2006 Gozi v1.0, Gozi CRM, CRM, Papras 2010 Gozi v2.0, Gozi ISFB, ISFB, Pandemyia(*)

In September 2010, the source code of a particular Gozi CRM dll version was leaked. This led to two main branches: one became known as Gozi Prinimalka, which was merge with Pony and became Vawtrak/Neverquest.

The other branch became known as Gozi ISFB, or ISFB in short. Webinject functionality was added to this version.

There is one panel which often was used in combination with ISFB: IAP. The panel's login page comes with the title 'Login - IAP'. The body contains 'AUTHORIZATION', 'Name:', 'Password:' and a single button 'Sign in' in a minimal design. Often, the panel is directly accessible by entering the C2 IP address in a browser. But there are ISFB versions which are not directly using IAP. The bot accesses a gate, which is called the 'Dreambot' gate. See win.dreambot for further information.

ISFB often was protected by Rovnix. This led to a further complication in the naming scheme - many companies started to call ISFB Rovnix. Because the signatures started to look for Rovnix, other trojans protected by Rovnix (in particular ReactorBot and Rerdom) sometimes got wrongly labelled.

In April 2016 a combination of Gozi ISFB and Nymaim was detected. This breed became known as GozNym. The merge uses a shellcode-like version of Gozi ISFB, that needs Nymaim to run. The C2 communication is performed by Nymaim.

See win.gozi for additional historical information.

The tag is: *misp-galaxy:malpedia="ISFB"*

ISFB is also known as:

- Gozi ISFB
- IAP
- Pandemyia

JanelaRAT

According to Zscaler, JanelaRAT is a heavily modified variant of BX RAT. Its focus is set on harvesting LATAM financial data and its method of extracting window titles for transmission underscores its targeted and stealthy nature. With an adaptive approach utilizing dynamic socket configuration and exploiting DLL side-loading from trusted sources, JanelaRAT poses a significant threat.

jason

Jason is a graphic tool implemented to perform Microsoft exchange account brute-force in order to “harvest” the highest possible emails and accounts information. Distributed in a ZIP container the interface is quite intuitive: the Microsoft exchange address and its version shall be provided. Three brute-force methods could be selected: EWS (Exchange Web Service), OAB (Offline Address Book) or both (All). Username and password list can be selected and threads number should be provided in order to optimize the attack balance.

JessieConTea

JessieConTea is a remote access trojan that uses HTTP(S) for communication. It supports around 30 commands that include operations on the victim's filesystem, basic process management, file exfiltration (both plain and zipped), and the download and execution of additional tools from the attacker's arsenal. The commands are indexed by 32-bit integers, starting with the value 0x60D49D97.

The malware was delivered in-the-wild via trojanized applications like DeFi Wallet or Citrix Workspace.

JessieConTea generates POST parameters with a specific parameter name, jsessid, from which the initial part of its name is derived. Also, it contains a specific RTTI symbol ".?AVCHttpConn@@", which inspired the second part of the name. It uses RC4 for C&C traffic encryption.

Karius

According to checkpoint, Karius is a banking trojan in development, borrowing code from Ramnit, Vawtrack as well as Trickbot, currently implementing webinject attacks only.

It comes with an injector that loads an intermediate "proxy" component, which in turn loads the actual banker component.

Communication with the c2 are in json format and encrypted with RC4 with a hardcoded key.

In the initial version, observed in March 2018, the webinjects were hardcoded in the binary, while in subsequent versions, they were received by the c2.

KillDisk

KillDisk is a generic detection name used by ESET to refer to destructive malware with disk wiping capabilities, such as damaging boot sectors and overwriting then deleting (system) files, followed by a reboot to render the machine unusable. Although all KillDisk malware has similar functionality, as a generic detection, individual samples do not necessarily have strong code similarities or relationships. Such generic malware detections usually have many “sub-families”, distinguished by the detection suffix (e.g. KillDisk.NBO, KillDisk.NCV, and KillDisk.NCX). Sub-family variants that do have strong code similarities, are sometimes seen in separate cyberattacks and thus can help researchers make connections between them.

KleptoParasite Stealer

KleptoParasite Stealer is advertised on Hackforums as a noob-friendly stealer. It is modular and comes with a IP retriever module, a Outlook stealer (32bit/64bit) and a Chrome/Firefox stealer (32bit/64bit). Earlier versions come bundled (loader plus modules), newer versions come with a loader (167k) that grabs the modules.

PDB-strings suggest a relationship to JogLog v6 and v7.

Koadic

Koadic is an open-source post-exploitation framework for Windows, created by zerosum0x0 and available on GitHub. The framework is written in Python and can generate JScript and VBScript payloads which can be written to disk or mapped directly into memory. Its capabilities include remote desktop access, command execution, lateral movement via SMB, file transfer, credential theft using Mimikatz, port scanning, and system information collection. It can also collect specific system information and targeted files based on their name or extension.

Krachulka

According to ESET, this malware family is a banking trojan and was active in Brazil until the middle of 2019. Its most noticeable characteristic was its usage of well-known cryptographic methods to encrypt strings, as opposed to the majority of Latin American banking trojans that mainly use custom encryption schemes.

Kronos

Kronos malware is a sophisticated banking Trojan that first emerged in 2014. It is designed to target financial institutions and steal sensitive banking information. The malware is primarily spread through phishing campaigns and exploit kits. Once installed on a victim's computer, Kronos can capture login credentials, credit card details, and other personal information by keylogging and form grabbing techniques. It can also bypass security measures such as two-factor authentication. Kronos employs advanced evasion techniques to avoid detection by antivirus software and actively updates itself to evade security patches. It has been known to target a wide range of banking

systems and has affected numerous organizations worldwide. The malware continues to evolve, making it a significant threat to online banking security.

The tag is: *misp-galaxy:malpedia="Kronos"*

LambLoad

According to Microsoft, this is a downloader used in a supply chain attack involving a malicious variant of an application developed by CyberLink. It is centered around a legitimate CyberLink application installer that has been modified to include malicious code that downloads, decrypts, and loads a second-stage payload. The file, which was signed using a valid certificate issued to CyberLink Corp., is hosted on legitimate update infrastructure owned by CyberLink and includes checks to limit the time window for execution and evade detection by security products.

LatentBot

FireEye describes this malware as a highly obfuscated bot that has been in the wild since mid-2013. It has managed to leave hardly any traces on the Internet, is capable of watching its victims without ever being noticed, and can even corrupt a hard disk, thus making a PC useless.

Using Dynamic Threat Intelligence, they have observed multiple campaigns targeting multiple industries in the United States, United Kingdom, South Korea, Brazil, United Arab Emirates, Singapore, Canada, Peru and Poland – primarily in the financial services and insurance sectors. Although the infection strategy is not new, the final payload dropped – which they named LATENTBOT – caught attention since it implements several layers of obfuscation, a unique exfiltration mechanism, and has been very successful at infecting multiple organizations.

Latrodectus

First discovered in October 2023, BLACKWIDOW is a backdoor written in C that communicates over HTTP using RC4 encrypted requests. The malware has the capability to execute discovery commands, query information about the victim's machine, update itself, as well as download and execute an EXE, DLL, or shellcode. The malware is believed to have been developed by LUNAR SPIDER, the creators of IcedID (aka BokBot) Malware.

LightlessCan

LightlessCan is a complex HTTP(S) RAT, that is a successor of the Lazarus RAT named BlindingCan.

In Q2 2022 and Q1 2023, it was deployed in targeted attacks against an aerospace company in Spain and a technology company in India.

Besides the support for commands already present in BlindingCan, its most significant update is mimicked functionality of many native Windows commands: • ipconfig • net • netsh advfirewall firewall • netstat • reg • sc • ping (for both IPv4 and IPv6 protocols) • wmic process call create • nslookup • schstasks • systeminfo • arp

These native commands are often abused by the attackers after they have gotten a foothold in the target's system. Lightless is able to execute them discreetly within the RAT itself, rather than being executed visibly in the system console. This provides stealthiness, both in evading real-time monitoring solutions like EDRs, and postmortem digital forensic tools.

LightlessCan use RC6 for decryption of its configuration, and also for encryption and decryption of network traffic.

LimeRAT

```
## Description
Simple yet powerful RAT for Windows machines. This project is simple and easy to
understand, It should give you a general knowledge about dotNET malwares and how it
behaves.
```

Main Features

- **.NET**
- Coded in Visual Basic .NET, Client required framework 2.0 or 4.0 dependency, And server is 4.0
- **Connection**

- Using pastebin.com as ip:port , Instead of noip.com DNS. And Also using multi-ports
- **Plugin**
- Using plugin system to decrease stub’s size and lower the AV detection
- **Encryption**
- The communication between server & client is encrypted with AES
- **Spreading**
- Infecting all files and folders on USB drivers
- **Bypass**
- Low AV detection and undetected startup method
- **Lightweight**
- Payload size is about 25 KB
- **Anti Virtual Machines**
- Uninstall itself if the machine is virtual to avoid scanning or analyzing
- **Ransomware**
- Encrypting files on all HHD and USB with .Lime extension
- **XMR Miner**
- High performance Monero CPU miner with user idle\active optimizations
- **DDoS**
- Creating a powerful DDOS attack to make an online service unavailable
- **Crypto Stealer**
- Stealing Cryptocurrency sensitive data
- **Screen-Locker**
- Prevents user from accessing their Windows GUI
- **And more**
- On Connect Auto Task
- Force enable Windows RDP
- Persistence
- File manager
- Passowrds stealer
- Remote desktop
- Bitcoin grabber
- Downloader
- Keylogger

LiteDuke

According to CarbonBlack, LiteDuke is a third stage backdoor. It appears to use the same dropper as PolyglotDuke. Its payload makes use of an AES encrypted SQLite database to store its configuration. LiteDuke supports a large number of individual commands including host information retrieval, file upload and download, and the ability to execute other code. LiteDuke C2 servers appear to be compromised servers, and the malware communicates with them using normal HTTP requests. It attempts to use a realistic User-Agent string to blend in better with normal HTTP traffic. ESET have dubbed it LiteDuke because it uses SQLite to store information such as its configuration.

LiteHTTP

According to AlienVault, LiteHTTP bot is a new HTTP bot programmed in C#. The bot has the ability to collect system information, download and execute programs, and update and kill other bots present on the system.

LOBSHOT

According to PCrisk, LOBSHOT is a type of malware with a feature called hVNC (Hidden Virtual Network Computing) that allows attackers to access a victim's computer without being noticed. The hVNC component is effective in evading fraud detection systems. Also, LOBSHOT is being used to carry out financial crimes through the use of banking trojan and information-stealing

functionalities.

LockerGoga

According to Trend Micro, LockerGoga is a ransomware that has been used in multiple attacks, most notably against Altran Technologies and Norsk Hydro. It encrypts a range of documents and source code files but certain versions had little to no whitelist that would protect import system files such as the Windows Boot Manager.

Locky

Locky is a high profile ransomware family that first appeared in early 2016 and was observed being active until end of 2017. It encrypts files on the victim system and asks for ransom in order to have back original files. In its first version it added a .locky extension to the encrypted files, and in recent versions it added the .lukitus extension. The ransom amount is defined in BTC and depends on the actor.

Loda

Loda is a previously undocumented AutoIT malware with a variety of capabilities for spying on victims. Proofpoint first observed Loda in September of 2016 and it has since grown in popularity. The name Loda is derived from a directory to which the malware author chose to write keylogger logs. It should be noted that some antivirus products currently detect Loda as “Trojan.Nymeria”, although the connection is not well-documented.

The tag is: *misp-galaxy:malpedia="Loda"*

Loda is also known as:

- LodaRAT
- Nymeria

LokiLocker

LokiLocker is a .Net ransomware, which was seen first in August 2021. This malware is protected with NETGuard (modified ConfuserEX) using the additional KoiVM virtualization plugin. The victims were observed ti be scattered around the world, with main concentation in Estern Europe and Asia (BlackBerry).

The tag is: *misp-galaxy:malpedia="LokiLocker"*

LokiLocker is also known as:

Loki Password Stealer (PWS)

"Loki Bot is a commodity malware sold on underground sites which is designed to steal private data from infected machines, and then submit that info to a command and control host via HTTP POST.

This private data includes stored passwords, login credential information from Web browsers, and a variety of cryptocurrency wallets." - PhishMe

Loki-Bot employs function hashing to obfuscate the libraries utilized. While not all functions are hashed, a vast majority of them are.

Loki-Bot accepts a single argument/switch of '-u' that simply delays execution (sleeps) for 10 seconds. This is used when Loki-Bot is upgrading itself.

The Mutex generated is the result of MD5 hashing the Machine GUID and trimming to 24-characters. For example: "B7E1C2CC98066B250DDB2123".

Loki-Bot creates a hidden folder within the %APPDATA% directory whose name is supplied by the 8th thru 13th characters of the Mutex. For example: "%APPDATA%\ C98066\".

There can be four files within the hidden %APPDATA% directory at any given time: ".exe," ".lck," ".hdb" and ".kdb." They will be named after characters 13 thru 18 of the Mutex. For example: "6B250D." Below is the explanation of their purpose:

FILE EXTENSION FILE DESCRIPTION .exe A copy of the malware that will execute every time the user account is logged into .lck A lock file created when either decrypting Windows Credentials or Keylogging to prevent resource conflicts .hdb A database of hashes for data that has already been exfiltrated to the C2 server .kdb A database of keylogger data that has yet to be sent to the C2 server

If the user is privileged, Loki-Bot sets up persistence within the registry under HKEY_LOCAL_MACHINE. If not, it sets up persistence under HKEY_CURRENT_USER.

The first packet transmitted by Loki-Bot contains application data.

The second packet transmitted by Loki-Bot contains decrypted Windows credentials.

The third packet transmitted by Loki-Bot is the malware requesting C2 commands from the C2 server. By default, Loki-Bot will send this request out every 10 minutes after the initial packet it sent.

Communications to the C2 server from the compromised host contain information about the user and system including the username, hostname, domain, screen resolution, privilege level, system architecture, and Operating System.

The first WORD of the HTTP Payload represents the Loki-Bot version.

The second WORD of the HTTP Payload is the Payload Type. Below is the table of identified payload types:

BYTE PAYLOAD TYPE 0x26 Stolen Cryptocurrency Wallet 0x27 Stolen Application Data 0x28 Get C2 Commands from C2 Server 0x29 Stolen File 0x2A POS (Point of Sale?) 0x2B Keylogger Data 0x2C Screenshot

The 11th byte of the HTTP Payload begins the Binary ID. This might be useful in tracking campaigns or specific threat actors. This value value is typically "ckav.ru". If you come across a Binary ID that is different from this, take note!

Loki-Bot encrypts both the URL and the registry key used for persistence using Triple DES encryption.

The Content-Key HTTP Header value is the result of hashing the HTTP Header values that precede it. This is likely used as a protection against researchers who wish to poke and prod at Loki-Bot's C2 infrastructure.

Loki-Bot can accept the following instructions from the C2 Server:

BYTE INSTRUCTION DESCRIPTION 0x00 Download EXE & Execute 0x01 Download DLL & Load #1 0x02 Download DLL & Load #2 0x08 Delete HDB File 0x09 Start Keylogger 0x0A Mine & Steal Data 0x0E Exit Loki-Bot 0x0F Upgrade Loki-Bot 0x10 Change C2 Polling Frequency 0x11 Delete Executables & Exit

Suricata Signatures RULE SID RULE NAME 2024311 ET TROJAN Loki Bot Cryptocurrency Wallet Exfiltration Detected 2024312 ET TROJAN Loki Bot Application/Credential Data Exfiltration Detected M1 2024313 ET TROJAN Loki Bot Request for C2 Commands Detected M1 2024314 ET TROJAN Loki Bot File Exfiltration Detected 2024315 ET TROJAN Loki Bot Keylogger Data Exfiltration Detected M1 2024316 ET TROJAN Loki Bot Screenshot Exfiltration Detected 2024317 ET TROJAN Loki Bot Application/Credential Data Exfiltration Detected M2 2024318 ET TROJAN Loki Bot Request for C2 Commands Detected M2 2024319 ET TROJAN Loki Bot Keylogger Data Exfiltration Detected M2

looChiper

LooChiper is a Ransomware. It uses a nice but scary name: LooCipher. The name is at the same time an allusion to its capabilities (thank to the term “Cipher”) and to the popular mythological figure, Lucifer. Despite its evocative nickname, the functionalities of this malware are pretty straight forward, not very different from those belonging to many other ransomware families.

L0rdix

L0rdix is a multipurpose .NET remote access tool (RAT) first discovered being sold on underground forums in November 2018. Out of the box, L0rdix supports eight commands, although custom commands can be defined and added. These include:

Download and execute Update Open page (visible) Open page (invisible) Cmd Kill process Upload file HTTP Flood

L0rdix can extract credentials from common web browsers and steal data from crypto wallets and a target's clipboard. Optionally, L0rdix can deploy a cryptominer (XMRig) to its bots.

Lorenz

Tesorion describes Lorenz as a ransomware with design and implementation flaws, leading to impossible decryption with tools provided by the attackers. A free decryptor for 2021 versions was made available via the NoMoreRansom initiative. A new version of the malware was discovered in March 2022, for which again was provided a free decryptor, while the ransomware operators are not able to provide tools to decrypt affected files.

LPEClient

LPEClient is an HTTP(S) downloader that expects two command line parameters: an encrypted string containing two URLs (a primary and a secondary C&C server), and the path on the victim's file system to store the downloaded payload.

It sends detailed information about the victim's environment, like computer name, type and number of processors, computer manufacturer, product name, major and minor Windows versions, architecture, memory information, installed security software and the version of the ntoskrnl.exe from its version-information resource.

LPEClient uses specific 32-bit values to represent its execution state (0x59863F09 when connecting via the WinHTTP interface, 0xA9348B57 via WinINet), or the nature of HTTP requests to the C&C servers (0xF07D6B34 when sending system information, 0xEF8C0D51 when requesting a DLL

payload, 0xCB790A25 when reporting the successful loading of the DLL, 0xD7B20A96 when reporting the state of the the DLL execution). As the final step, malware looks for the export CloseEnv and executes it.

Luca Stealer

According to PCRisk, The Luca stealer can extract a variety of information from compromised machines. It targets data related to the following: operating system, device name, CPUs, desktop environment, network interface, user account name, preferred system language, running processes, etc.

This malicious program can steal information from over thirty Chromium-based browsers. From these applications, Luca can obtain Internet cookies, account log-in credentials (usernames/passwords), and credit card numbers. Additionally, the stealer can extract data from password manager and cryptowallet browser extensions compatible with over twenty browsers.

This malware also targets various messaging applications like Telegram, Discord, ICQ, Skype, Element, etc. It likewise aims to acquire information from gaming-related software such as Steam and Uplay (Ubisoft Connect). Furthermore, some versions of Luca can take screenshots and download the files stored on victims' devices.

Lumma Stealer

Lumma Stealer (aka LummaC2 Stealer) is an information stealer written in C language that has been available through a Malware-as-a-Service (MaaS) model on Russian-speaking forums since at least August 2022. It is believed to have been developed by the threat actor "Shamel", who goes by the alias "Lumma". Lumma Stealer primarily targets cryptocurrency wallets and two-factor authentication (2FA) browser extensions, before ultimately stealing sensitive information from the victim’s machine. Once the targeted data is obtained, it is exfiltrated to a C2 server via HTTP POST requests using the user agent "TeslaBrowser/5.5"." The stealer also features a non-resident loader that is capable of delivering additional payloads via EXE, DLL, and PowerShell.

The tag is: *misp-galaxy:malpedia="Lumma Stealer"*

Lumma Stealer is also known as:

- LummaC2 Stealer

Machete

According to ESET, Machete's dropper is a RAR SFX executable. Three py2exe components are dropped: GoogleCrash.exe, Chrome.exe and GoogleUpdate.exe. A single configuration file, jer.dll, is dropped, and it contains base64-encoded text that corresponds to AES-encrypted strings. GoogleCrash.exe is the main component of the malware. It schedules execution of the other two components and creates Windows Task Scheduler tasks to achieve persistence. Regarding the geolocation of victims, Chrome.exe collects data about nearby Wi-Fi networks and sends it to the Mozilla Location Service API. In short, this application provides geolocation coordinates when it's given other sources of data such as Bluetooth beacons, cell towers or Wi-Fi access points. Then the malware takes latitude and longitude coordinates to build a Google Maps URL. The GoogleUpdate.exe component is responsible for communicating with the remote C&C server. The configuration to set the connection is read from the jer.dll file: domain name, username and password. The principal means of communication for Machete is via FTP, although HTTP communication was implemented as a fallback in 2019.

MagicRAT

According to Talos, MagicRAT is programmed in C++ programming language and uses the Qt Framework by statically linking it to the RAT on 32- and 64-bit versions. The Qt Framework is a programming library for developing graphical user interfaces, of which this RAT has none. Talos thinks that the objective was to increase the complexity of the code, thus making human analysis harder. On the other hand, since there are very few examples (if any) of malware programmed with Qt Framework, this also makes machine learning and heuristic analysis detection less reliable. The RAT uses the Qt classes throughout its entire code. The configuration is dynamically stored in a QSettings class eventually being saved to disk, a typical functionality provided by that class.

MagicRAT provides the operator with a remote shell on the victim's system for arbitrary command execution, along with the ability to rename, move and delete files on the endpoint. The operator can determine the timing for the implant to sleep, change the C2 URLs and delete the implant from the infected system.

Magniber

According to TXOne, The Magniber ransomware was first identified in late 2017 when it was discovered using the Magnitude Exploit Kit to conduct malvertising attacks against users in South Korea. However, it has remained active since then, continually updating its tactics by employing

new obfuscation techniques and methods of evasion. In April 2022, Magniber gained notoriety for disguising itself as a Windows update file to lure victims into installing it. It then began spreading via JavaScript in September 2022.

Maktub

According to PCrisk, Maktub is ransomware distributed via zipped Word documents. Once the file is extracted and opened, Maktub infiltrates the system and encrypts files stored on the victim's computer. Maktub ransomware adds a .NORV, .gyul (or other random) extension to each file encrypted, thus, making it straightforward to determine which files are encrypted.

MASS Logger

MassLogger is a .NET credential stealer. It starts with a launcher that uses simple anti-debugging techniques which can be easily bypassed when identified. This first stage loader eventually XOR-decrypts the second stage assembly which then decrypts, loads and executes the final MassLogger payload.

The tag is: *misp-galaxy:malpedia="MASS Logger"*

Matanbuchus

According to PCrisk, Matanbuchus is a loader-type malicious program offered by its developers as Malware-as-a-Service (MaaS). This piece of software is designed to cause chain infections.

Since it is used as a MaaS, both the malware it infiltrates into systems, and the attack reasons can vary - depending on the cyber criminals operating it. Matanbuchus has been observed being used in attacks against US universities and high schools, as well as a Belgian high-tech organization.

Maze

Maze Ransomware encrypts files and makes them inaccessible while adding a custom extension containing part of the ID of the victim. The ransom note is placed inside a text file and an htm file. There are a few different extensions appended to files which are randomly generated.

Actors are known to exfiltrate the data from the network for further extortion. It spreads mainly using email spam and various exploit kits (Spelevo, Fallout).

The code of Maze ransomware is highly complicated and obfuscated, which helps to evade security solutions using signature-based detections.

The tag is: *misp-galaxy:malpedia="Maze"*

Maze is also known as:

- ChaCha

MedusaLocker

A Windows ransomware that will run certain tasks to prepare the target system for the encryption of files. MedusaLocker avoids executable files, probably to avoid rendering the targeted system unusable for paying the ransom. It uses a combination of AES and RSA-2048, and reportedly appends extensions such as .encrypted, .bomber, .boroff, .breakingbad, .locker16, .newlock, .nlocker, and .skynet.

The tag is: *misp-galaxy:malpedia="MedusaLocker"*

MedusaLocker is also known as:

- AKO Doxware
- AKO Ransomware
- MedusaReborn

Metamorfo

According to BitDefender, Metamorfo is a family of banker Trojans that has been active since mid-2018. It primarily targets Brazilians and is delivered mostly through Office files rigged with macros in spam attachments. Metamorfo is a potent piece of malware, whose primary capability is theft of banking information and other personal data from the user and exfiltration of it to the C2 server.

Midas

This malware written in C# is a variant of the Thanos ransomware family and emerged in October 2021 and is obfuscated using SmartAssembly. In 2022, ThreatLabz analysed a report of Midas ransomware was slowly deployed over a two month period (ZScaler). This ransomware features also its own data leak site as part of its double extortion strategy.

Mimic Ransomware

According to PCrisk, Mimic is a ransomware-type program. Malware within this classification is designed to encrypt data and demand ransoms for decryption. Evidence suggests that Mimic is based on the leaked CONTI ransomware builder. Mimic campaigns have been observed targeting English and Russian speaking users.

The tag is: *misp-galaxy:malpedia="Mimic Ransomware"*

Mimic Ransomware is also known as:

MimiKatz

Varonis summarizes Mimikatz as an open-source application that allows users to view and save authentication credentials like Kerberos tickets. Benjamin Delpy continues to lead Mimikatz developments, so the toolset works with the current release of Windows and includes the most up-to-date attacks.

Attackers commonly use Mimikatz to steal credentials and escalate privileges: in most cases, endpoint protection software and anti-virus systems will detect and delete it. Conversely, pentesters use Mimikatz to detect and exploit vulnerabilities in your networks so you can fix them.

The tag is: *misp-galaxy:malpedia="MimiKatz"*

miniBlindingCan

miniBlindingCan is an HTTP(S) orchestrator.

It is a variant of the BlindingCan RAT, having the same command parsing logic, but supporting only a small subset of commands available previously. The main operations are the update of the malware configuration, and the download and execution of additional payloads from the attackers' C&C.

The miniBlindingCan malware was used in Operation DreamJob attacks against aerospace and media companies in Q2-Q3 2022.

The tag is: *misp-galaxy:malpedia="miniBlindingCan"*

miniBlindingCan is also known as:

- AIRDRY.V2
- EventHorizon

MirrorBlast

According to Minerva Labs, MirrorBlast malware is a trojan that is known for attacking users' browsers. It usually pretends to be a legitimate browser add-on however it has now evolved additional capabilities, whereby other malwares are installed simultaneously. Recently, this trojan is thought to have tentative links to TA505 and PYSA groups.

The tag is: *misp-galaxy:malpedia="MirrorBlast"*

Mispadu

According to ESET Research, Mispadu is an ambitious Latin American banking trojan that utilizes McDonald's malvertising and extends its attack surface to web browsers. It is used to target the general public and its main goals are monetary and credential theft. In Brazil, ESET has seen it distributing a malicious Google Chrome extension that attempts to steal credit card data and online banking data, and that compromises the Boleto payment system.

The tag is: *misp-galaxy:malpedia="Mispadu"*

Mispadu is also known as:

- URSA

ModPipe

ModPipe is point-of-sale (POS) malware capable of accessing sensitive information stored in devices running ORACLE MICROS Restaurant Enterprise Series (RES) 3700 POS – a management software suite used by hundreds of thousands of bars, restaurants, hotels and other hospitality establishments worldwide. ModPipe uses modular architecture consisting of basic components and downloadable modules. One of them – named GetMicInfo – contains an algorithm designed to gather database passwords by decrypting them from Windows registry values. Exfiltrated credentials allow ModPipe's operators access to database contents, including various definitions and configuration, status tables and information about POS transactions.

MoleNet

MoleNet is a .NET downloader malware used by the Molerats group in targeted attacks in the Middle East. Before downloading additional payloads, it first collects information about the infected machine using WMI queries and sends the data to its operators. It was first discovered in 2020, however, Cybereason researchers showed that it has been in use since at least 2019, with infrastructure that operated since 2017.

Mount Locker

According to BlackBerry, MountLocker is a Ransomware-as-a-Service (RaaS), active since July 2020 The MountLocker ransomware was updated during early November 2020 to broaden the targeting of file types and evade security software. Victim's files are encrypted using ChaCha20, and file encryption keys are encrypted using RSA-2048. The ransomware appears to be somewhat secure; there are no trivial weaknesses allowing for easy key recovery and decryption of data. MountLocker does however use a cryptographically insecure method for key generation that may be prone to attack.

The tag is: *misp-galaxy:malpedia="Mount Locker"*

Mount Locker is also known as:

- DagonLocker
- MountLocker
- QuantumLocker

MyloBot

According to PCrisk, MyloBot is a high-risk trojan-type virus that allows cyber criminals to control the infected machine. MyloBot can be considered as a botnet, since all infected computers are connected to a single network. Depending on cyber criminals' goals, infected machines might be

misused or have additional infections applied.

The tag is: *misp-galaxy:malpedia="MyloBot"*

MyloBot is also known as:

- FakeDGA
- WillExec

Mystic Stealer

According to ZScaler, a new information stealer that was first advertised in April 2023, capable of stealing credentials from nearly 40 web browsers and more than 70 browser extensions, also targeting cryptocurrency wallets, Steam, and Telegram. The code is heavily obfuscated making use of polymorphic string obfuscation, hash-based import resolution, and runtime calculation of

constants. Mystic implements a custom binary protocol that is encrypted with RC4.

NedDnLoader

NedDnLoader is an HTTP(S) downloader that uses AES for C&C trafic encryption.

It sends detailed information about the victim's environment, like computer name, user name, type and free disk space of all drives, and a list of currently running processes. It uses three typical parameter names for HTTP POST requests: ned, gl, hl. The usual payload downloaded with NedDnLoader is Torisma.

The internal DLL name of NedDnLoader is usually Dn.dll, Dn64.dll or DnDll.dll. It is deployed either as a standalone payload or within a trojanized MFC application project. It contains specific RTTI symbols like ".?AVCWininet_Protocol@@" or ".?AVCMFC_DLLApp@@".

NESTEGG

NESTEGG is a memory-only backdoor that can proxy commands to other infected systems using a custom routing scheme. It accepts commands to upload and download files, list and delete files, list and terminate processes, and start processes. NESTEGG also creates Windows Firewall rules that allows the backdoor to bind to a specified port number to allow for inbound traffic.

NetfilterRootkit

NetfilterRootkit is a WFP application layer enforcement callout driver which is signed by Microsoft via the Windows Hardware Compatibility program. It was first discovered by Karsten Hahn. His team submitted the malware to Microsoft, which allowed Microsoft to start an investigation.

After Karsten Hahn published tweets and an article about the rootkit, Microsoft quickly responded with their own article. Their investigation revealed Chinese gamers as targets of the malware. The rootkit redirects traffic to the threat actor's IP. The threat actor can use the driver to spoof their geo-location to cheat, but it also allows account compromise of targeted players.

While this particular rootkit is not significant anymore, similar rootkits have been created since that are also signed by Microsoft via the Windows Hardware Compatibility program.

NetSupportManager RAT

Enigma Software notes that NetSupport Manager is a genuine application, which was first released

about twenty years ago. The purpose of the NetSupport Manager tool is to enable users to receive remote technical support or provide remote computer assistance. However, cyber crooks have hijacked this useful application and misappropriated it to use it in their harmful campaigns. The name of the modified version of the NetSupport Manager has been labeled the NetSupport Manager RAT.

NetWire RC

Netwire is a RAT, its functionality seems focused on password stealing and keylogging, but includes remote control capabilities as well.

Keylog files are stored on the infected machine in an obfuscated form. The algorithm is:

```
for i in range(0,num_read):
```

```
    buffer[i] = ((buffer[i]-0x24)^0x9D)&0xFF
```

The tag is: *misp-galaxy:malpedia="NetWire RC"*

NetWire RC is also known as:

- NetWeird
- NetWire
- Recam

NGLite

According to Unit42, NGLite is a backdoor Trojan that is only capable of running commands received through its C2 channel. While the capabilities are standard for a backdoor, NGLite uses a novel C2 channel that leverages a decentralized network based on the legitimate NKN to communicate between the backdoor and the actors.

NimBlackout

According to its author, NimBlackout is an adaptation of the @Blackout project originally developed in C++ by @ZeroMemoryEx, which consists of removing AV/EDRs using the gmer (BYOVD) driver. The main reason for this project was to understand how BYOVD attacks work, and then to provide a valid PoC developed in Nim.

The tag is: *misp-galaxy:malpedia="NimBlackout"*

NimBlackout is also known as:

Table 4384. Table References

NjRAT

RedPacket Security describes NJRat as "a remote access trojan (RAT) has capabilities to log keystrokes, access the victim’s camera, steal credentials stored in browsers, open a reverse shell, upload/download files, view the victim’s desktop, perform process, file, and registry manipulations, and capabilities to let the attacker update, uninstall, restart, close, disconnect the RAT and rename its campaign ID. Through the Command & Control (CnC) server software, the attacker has capabilities to create and configure the malware to spread through USB drives."

It is supposedly popular with actors in the Middle East. Similar to other RATs, many leaked builders may be backdoored.

The tag is: *misp-galaxy:malpedia="NjRAT"*

NjRAT is also known as:

- Bladabindi

- Lime-Worm

Nokki

Nokki is a RAT type malware which is believe to evolve from Konni RAT. This malware has been tied to attacks containing politically-motivated lures targeting Russian and Cambodian speaking individuals or organizations. Researchers discovered a tie to the threat actor group known as Reaper also known as APT37.

The tag is: *misp-galaxy:malpedia="Nokki"*

Ntospy

Ntospy is a credential stealer leveraging a well-established technique of abusing the Windows Network Provider interface, a method documented as early as 2004 and exemplified by tools like NPPSpy. Posing as a legitimate Network Provider DLL, Ntospy injects itself into the Windows authentication process, hijacking login attempts to harvest user credentials. It achieves this by registering a malicious Network Provider, typically named "credman," which intercepts authentication requests and redirects them to it malicious DLL.

Instead of immediately exfiltrating the stolen data, Ntospy employs a form of local storage, writing the captured credentials in cleartext to files disguised as harmless Microsoft Update packages using

the .msu file extension. These files are often planted in system directories with believable names like "c:/programdata/package cache/windows10.0-kb5009543-x64.msu," further masking their malicious purpose.

Adding to its stealth, Ntospy incorporates obfuscation techniques to evade detection. This includes using seemingly innocuous filenames for its DLL, often mimicking critical system files like "ntoskrnl.dll" to blend in. Some variants even go a step further by encrypting the credential storage file path within the DLL, requiring analysis and decryption to uncover its full functionality.

Ondritols

According to Symantec, this malware has been deployed against IT services companies in the U.S. and Europe. A multi-stage backdoor, the first stage is a downloader that authenticates to Microsoft Graph API and downloads the second stage payload from OneDrive and executes it. The main payload will download a publicly available file from GitHub. It will then create a folder in OneDrive named deviceId_n_<ip address> for each infected machine and upload a file to OneDrive to signal the attackers the status of a new infection.

OnionDuke

OnionDuke is a new sophisticated piece of malware distributed by threat actors through a malicious exit node on the Tor anonymity network appears to be related to the notorious MiniDuke, researchers at F-Secure discovered. According to experts, since at least February 2014, the threat actors have also distributed the threat through malicious versions of pirated software hosted on torrent websites.

Orcus RAT

Orcus has been advertised as a Remote Administration Tool (RAT) since early 2016. It has all the features that would be expected from a RAT and probably more. The long list of the commands is documented on their website. But what separates Orcus from the others is its capability to load custom plugins developed by users, as well as plugins that are readily available from the Orcus repository. In addition to that, users can also execute C# and VB.net code on the remote machine in real-time.

The tag is: *misp-galaxy:malpedia="Orcus RAT"*

Orcus RAT is also known as:

- Schnorchel

Ordinypt

This malware claims to be a ransomware, but it's actually a wiper. After execution, this malware terminates a number of processes such as database processes, likely to allow access to any files that these programs may have held open. Ordinypt will avoid wiping certain files and folders in order to prevent the infected machine from becoming unusable. Affected files are overwritten with null character and receive a random 5 character file extension. Finally, shadow copies are removed and Windows startup repair is disabled to complicate recovery of data from the affected system. The desktop background is changed and a ransom note is dropped for the victim. A C2 check-in occurs to keep track of the file extension used on that specific machine, as well as which BitCoin address was randomly provided for payment to the victim (drawn from a long list stored in the ransomware configuration).

PandaBanker

According to Arbor, Forcepoint and Proofpoint, Panda is a variant of the well-known Zeus banking trojan(*). Fox IT discovered it in February 2016.

This banking trojan uses the infamous ATS (Automatic Transfer System/Scripts) to automate online bank portal actions.

The baseconfig (c2, crypto material, botnet name, version) is embedded in the malware itself. It then obtains a dynamic config from the c2, with further information about how to grab the webinjects and additional modules, such as vnc, backsocks and grabber.

Panda does have some DGA implemented, but according to Arbor, a bug prevents it from using it.

The tag is: *misp-galaxy:malpedia="PandaBanker"*

PandaBanker is also known as:

- ZeusPanda

Panda Stealer

According to PCrisk, Panda is the name of a malicious program, which is classified as a stealer. It is a new variant of CollectorStealer.

The aim of this malware is to extract and exfiltrate sensitive and personal information from infected devices. Panda primarily targets data relating to cryptocurrency wallets.

This piece of malicious software has been observed being actively distributed via spam campaigns - large-scale operations during which thousands of scam emails are sent. The spam mail proliferating Panda stealer heavily targeted users from the United States, Germany, Japan, and Australia.

The deceptive email letters concerned business-related topics (e.g., fake product quote requests, etc.). Panda stealer is a dangerous program, and as such - its infections must be removed immediately upon detection.

Parallax RAT

Parallax is a Remote Access Trojan used by attackers to gain access to a victim’s machine. It was involved in one of the many infamous "coronamalware" campaigns. Basically, the attackers abused the COVID-19 pandemic news to lure victims into opening themed emails spreading parallax.

The tag is: *misp-galaxy:malpedia="Parallax RAT"*

Parallax RAT is also known as:

- ParallaxRAT

Peppy RAT

Peppy is a Python-based RAT with the majority of its appearances having similarities or definite overlap with MSIL/Crimson appearances. Peppy communicates to its C&C over HTTP and utilizes SQLite for much of its internal functionality and tracking of exfiltrated files. The primary purpose

of Peppy may be the automated exfiltration of potentially interesting files and keylogs. Once Peppy successfully communicates to its C&C, the keylogging and exfiltration of files using configurable search parameters begins. Files are exfiltrated using HTTP POST requests.

The tag is: *misp-galaxy:malpedia="Peppy RAT"*

PetrWrap

The PetrWrap Trojan is written in C and compiled in MS Visual Studio. It carries a sample of the Petya ransomware v3 inside its data section and uses Petya to infect the victim's machine. What's more, PetrWrap implements its own cryptographic routines and modifies the code of Petya in runtime to control its execution. This allows the criminals behind PetrWrap to hide the fact that they are using Petya during infection.

PHOTOFORK

PHOTOFORK is a downloader which is a modified version of GZIPLOADER. It was first detected in February 2023 and was distributed by TA581 along with an unattributed threat activity cluster that facilitated initial access. In this version, the configuration file is no longer encrypted using a simple XOR algorithm with a 64-byte key. Instead, it uses a custom algorithm previously used by the Standard core loader. This algorithm decrypts DLL strings that are needed to resolve handles to the necessary DLLs later on. The strings are decrypted using an algorithm that splits the data into DWORDs and XORs it against a random key. The main objective of PHOTOFORK remains the same as GZIPLOADER, i.e. to deliver an encrypted bot and core DLL loader (forked) that loads the Forked ICEDID bot into memory using a custom PE format.

The tag is: *misp-galaxy:malpedia="PHOTOFORK"*

PHOTOFORK is also known as:

Table 4500. Table References

Links
https://malpedia.caad.fkie.fraunhofer.de/details/win.photofork
https://www.proofpoint.com/us/blog/threat-insight/fork-ice-new-era-icedid

PHOTOLITE

PHOTOLITE is the lite version of the GZIPLOADER with limited capabilities i.e. for example it does not have any functionality to exfiltrate the host information. This new variant is observed as a follow-on payload in a TA542 Emotet campaign back in November'22. contains a static URL to download a "Bot Pack" file with a static name (botpack.dat) which results in the IcedID Lite DLL Loader, and then delivers the Forked version of IcedID Bot, leaving out the webinjects and backconnect functionality that would typically be used for banking fraud.

The tag is: *misp-galaxy:malpedia="PHOTOLITE"*

PHOTOLITE is also known as:

PIEHOP

According to Mandiant, PIEHOP is a disruption tool written in Python and packaged with PyInstaller version 2.1+ that has the capability to connect to a user supplied remote MSSQL server for uploading files and issuing remote commands to a RTU. PIEHOP expects its main function to be called via another Python file, supplying either the argument control=True or upload=True. At a minimum, it requires the following arguments: oik, user, and pwd, and if called with control=True, it must also be supplied with iec104.

Pikabot

Introducing Pikabot, an emerging malware family that comprises a downloader/installer, a loader, and a core backdoor component. Despite being in the early stages of development, it already demonstrates advanced techniques in evasion, injection, and anti-analysis. Notably, the loader component incorporates an array of sophisticated anti-debugging and anti-VM measures inspired by the open-source Al-Khaser project, while leveraging steganography to conceal its payload. Additionally, Pikabot utilizes a proprietary C2 framework and supports a diverse range of commands, encompassing host enumeration and advanced secondary payload injection options.

PLAY

According to PCrisk, PLAY is the name of a ransomware-type program. Malware categorized as such operates by encrypting data and demanding ransoms for the decryption.

After we executed a sample of this ransomware on our test machine, it encrypted files and appended their filenames with a ".PLAY" extension. For example, a file titled "1.jpg" appeared as "1.jpg.PLAY", "2.png" as "2.png.PLAY", etc. Once the encryption process was completed, PLAY created a text file named "ReadMe.txt" on the desktop.

The tag is: *misp-galaxy:malpedia="PLAY"*

PLAY is also known as:

- PlayCrypt

PlugX

RSA describes PlugX as a RAT (Remote Access Trojan) malware family that is around since 2008 and is used as a backdoor to control the victim's machine fully. Once the device is infected, an attacker can remotely execute several kinds of commands on the affected system.

Notable features of this malware family are the ability to execute commands on the affected machine to retrieve: machine information capture the screen send keyboard and mouse events keylogging reboot the system manage processes (create, kill and enumerate) manage services (create, start, stop, etc.); and manage Windows registry entries, open a shell, etc.

The malware also logs its events in a text log file.

The tag is: *misp-galaxy:malpedia="PlugX"*

PlugX is also known as:

- Destroy RAT
- Kaba
- Korplug
- RedDelta
- Sogu
- TIGERPLUG

PNGLoad

According to ESET Research, PNGLoad is a second-stage payload deployed by Worok on compromised systems and loaded either by CLRLoad or PowHeartBeat. PNGLoad has capabilities to download and execute additional payloads from a C&C server, which is likely how the attackers have deployed PNGLoad on systems compromised with PowHeartBeat. PNGLoad is a loader that uses bytes from PNG files to create a payload to execute. It is a 64-bit .NET executable - obfuscated with .NET Reactor - that masquerades as legitimate software.

The tag is: *misp-galaxy:malpedia="PNGLoad"*

poisonplug

According to FireEye, POISONPLUG is a highly obfuscated modular backdoor with plug-in capabilities. The malware is capable of registry or service persistence, self-removal, plug-in execution, and network connection forwarding. POISONPLUG has been observed using social platforms to host encoded C&C commands.

Pony

According to KnowBe4, Pony Stealer is a password stealer that can decrypt or unlock passwords for over 110 different applications including VPN, FTP, email, instant messaging, web browsers and much more. Pony Stealer is very dangerous and once it infects a PC it will turn the device into a botnet, allowing it to use the PCs it infects to infect other PCs.

PoshC2

PoshC2 is a proxy aware C2 framework used to aid penetration testers with red teaming, post-exploitation and lateral movement.

PoshC2 is primarily written in Python3 and follows a modular format to enable users to add their own modules and tools, allowing an extendible and flexible C2 framework. Out-of-the-box PoshC2 comes PowerShell/C# and Python3 implants with payloads written in PowerShell v2 and v4, C++ and C# source code, a variety of executables, DLLs and raw shellcode in addition to a Python3 payload. These enable C2 functionality on a wide range of devices and operating systems, including Windows, *nix and OSX.

The tag is: *misp-galaxy:malpedia="PoshC2"*

PostNapTea

PostNapTea aka SIGNBT is an HTTP(S) RAT that is written as a complex object-oriented project.

In 2022-2023, it was deployed against targets like a newspaper organization, agriculture-related entity or a software vendor. The initial access was usually achieved by exploiting vulnerabilities in widely-used software in South Korea.

It collects various information about the victim's computer, such as computer name, product name, OS details, system uptime, CPU information, system locale, time zone, network status, and malware configuration.

PostNapTea uses AES for encryption and decryption ot network traffic. There is a constant prefix SIGNBT occuring in its HTTP POST requests. The prefix is concatenated with 2 characters that identify the communication stage: • LG: logging into the C&C server • KE: acknowledging the succesful login to the C&C • FI: sending the status of a failed operation • SR: sending the status of a successful operation • GC: getting the next command

There are five classes that represent command groups: • CCButton: for file manipulation and screen capturing • CCBitmap: for network commands, implementing functionality of Windows commands often abused by attackers, like sc, reg, arp, net, ver, wmic, ping, whoami, netstat, tracert, lookup, ipconfig, systeminfo, and netsh advfirewall. • CCComboBox: for file system management • CCList: for process management • CCBrush: for control of the malware itself

It stores its configuration in JSON format. It resolves the Windows APIs it requires during runtime, via the Fowler–Noll–Vo (FNV) hash function.

Its internal name in the version-information resource is usually ppcsnap.dll or pconsnap.dll, which loosely inspired its code name.

Prestige

According to PCrisk, Prestige is ransomware - malware that prevents victims from accessing (opening) their files by encrypting them. Additionally, Prestige appends the ".enc" extension to filenames and drops the "README" file containing a ransom note. An example of how this ransomware modifies filenames: it renames "1.jpg" to "1.jpg.enc", "2.png" to "2.png.enc", and so forth.

pupy (Windows)

Pupy is an open-source, cross-platform RAT and post-exploitation framework mainly written in python. Pupy can be loaded from various loaders, including PE EXE, reflective DLL, Linux ELF, pure python, powershell and APK. Most of the loaders bundle an embedded python runtime, python library modules in source/compiled/native forms as well as a flexible configuration. They bootstrap a python runtime environment mostly in-memory for the later stages of pupy to run in. Pupy can communicate using various transports, migrate into processes, load remote python code, python packages and python C-extensions from memory.

The tag is: *misp-galaxy:malpedia="pupy (Windows)"*

PurpleFox

Purple Fox uses msi.dll function, 'MsiInstallProductA', to download and execute its payload. The payload is a .msi file that contains encrypted shellcode including 32-bit and 64-bit versions. once executed the system will be restarted and uses the 'PendingFileRenameOperations' registry to rename it’s components.

Upon restart the rootkit capability of Purple Fox is invoked. It creates a suspended svchost process and injects a DLL that will create a driver with the rootkit capability.

The latest version of Purple Fox abuses open-source code to enable it's rootkit components, which includes hiding and protecting its files and registry entries. It also abuses a file utility software to hide its DLL component, which deters reverse engineering.

PwndLocker

PwndLocker is a ransomware that was observed in late 2019 and is reported to have been used to target businesses and local governments/cities. According to one source, ransom amounts demanded as part of PwndLocker activity range from $175k USD to $650k USD depending on the size of the network. PwndLocker attempts to disable a variety of Windows services so that their data can be encrypted. Various processes will also be targeted, such as web browsers and software related to security, backups, and databases. Shadow copies are cleared by the ransomware, and encryption of files occurs once the system has been prepared in this way. Executable files and those that are likely to be important for the system to continue to function appear to be skipped by the ransomware, and a large number of folders mostly related to Microsoft Windows system files are also ignored. As of March 2020, encrypted files have been observed with the added extensions of .key and .pwnd. Ransom notes are dropped in folders where encrypted files are found and also on the user's desktop.

The tag is: *misp-galaxy:malpedia="PwndLocker"*

PwndLocker is also known as:

QakBot

QBot is a modular information stealer also known as Qakbot or Pinkslipbot. It has been active for years since 2007. It has historically been known as a banking Trojan, meaning that it steals financial data from infected systems, and a loader using C2 servers for payload targeting and download.

The tag is: *misp-galaxy:malpedia="QakBot"*

QakBot is also known as:

- Oakboat
- Pinkslipbot
- Qbot
- Quakbot

QUICKMUTE

QuickMute is a malware developed using the C/C++ programming language. Functionally provides download, RC4 decryption, and in-memory launch of the payload (waiting for a PE file with the export function "HttpsVictimMain"). To communicate with the management server, a number of protocols are provided, in particular: TCP, UDP, HTTP, HTTPS.

The tag is: *misp-galaxy:malpedia="QUICKMUTE"*

QUICKMUTE is also known as:

QuiteRAT

QuiteRAT is a simple remote access trojan written with the help of Qt libraries.

After sending preliminary system information to its C&C server, it expects a response containing either a supported command code or an actual Windows command (like systeminfo or ipconfig with parameters) to execute.

It was deployed in a campaign exploiting a ManageEngine ServiceDesk vulnerability (CVE-2022-47966).

The tag is: *misp-galaxy:malpedia="QuiteRAT"*

QuiteRAT is also known as:

- Acres

Racket Downloader

Racket Downloader is an HTTP(S) downloader.

It uses a custom substitution cipher for decryption of its character strings, and RC5 with a 256-bit key for encryption and decryption of network traffic.

It sends an HTTP POST request containing a particular value that inspired its name, like "?product_field=racket" or "prd_fld=racket".

Racket Downloader was deployed against South Korean targets running the Initech INISAFE CrossWeb EX software in Q2 2021 and Q1 2022.

Ragnarok

According to Bleeping Computer, the ransomware is used in targeted attacks against unpatched Citrix servers. It excludes Russian and Chinese targets using the system's Language ID for filtering. It also tries to disable Windows Defender and has a number of UNIX filepath references in its strings. Encryption method is AES using a dynamically generated key, then bundling this key up via RSA.

The tag is: *misp-galaxy:malpedia="Ragnarok"*

Ramnit

According to Check Point, Ramnit is primarily a banking trojan, meaning that its purpose is to steal login credentials for online banking, which cybercriminals can sell or use in future attacks. For this reason, Ramnit primarily targets individuals rather than focusing on particular industries.

Ramnit campaigns have been observed to target organizations in particular industries. For example, a 2019 campaign targeted financial organizations in the United Kingdom, Italy, and Canada.

The tag is: *misp-galaxy:malpedia="Ramnit"*

SNC

Ransomware SNC is a ransomware who encrypts files and asks for a variable amount of Bitcoin before releasing the decryption key to your files. The threat actor asks to be contacted for negotiating the right ransom fee.

The tag is: *misp-galaxy:malpedia="SNC"*

SNC is also known as:

Table 4641. Table References

Rapid Ransom

InfinityGroup notes that Rapid Ransomware, unlike regular Ransomware, stays active on the computer after initially encrypting the systems and also encrypts any new files that are created. It does this by creating auto-runs that are designed to launch the ransomware and display the ransom note every time the infected system is started.

The tag is: *misp-galaxy:malpedia="Rapid Ransom"*

Rapid Ransom is also known as:

Table 4642. Table References

Reaver

Reaver is a type of malware discovered by researchers at Palo Alto Networks in November 2017, but its activity dates back to at least late 2016. Researchers identified only ten unique samples of the malware, indicating limited use, and three different variants, noted as versions 1, 2, and 3. The malware is unique as its final payload masquerades as a control panel link (CPL) file. The intended targets of this activity are unknown as of this writing; however, it was used concurrently with the SunOrcal malware and the same C2 infrastructure used by threat actors who primarily target based on the "Five Poisons" - five perceived threats deemed dangerous to, and working against the interests of, the Chinese government.

RedCap

According to Trend Micro, this backdoor receives valid domain credentials as an argument and uses it to log on to the Exchange Server and use it for data exfiltration purposes. The main function of this stage is to take the stolen password from the argument and send it to the attackers as an attachment in an email. We also observed that the threat actors relay these emails via government Exchange Servers using vaild accounts with stolen passwords.

RedLine Stealer

RedLine Stealer is a malware available on underground forums for sale apparently as a standalone ($100/$150 depending on the version) or also on a subscription basis ($100/month). This malware harvests information from browsers such as saved credentials, autocomplete data, and credit card information. A system inventory is also taken when running on a target machine, to include details such as the username, location data, hardware configuration, and information regarding installed security software. More recent versions of RedLine added the ability to steal cryptocurrency. FTP and IM clients are also apparently targeted by this family, and this malware has the ability to upload and download files, execute commands, and periodically send back information about the infected computer.

The tag is: *misp-galaxy:malpedia="RedLine Stealer"*

RedLine Stealer is also known as:

- RECORDSTEALER

Regin

Regin is a sophisticated malware and hacking toolkit attributed to United States' National Security Agency (NSA) for government spying operations. It was first publicly revealed by Kaspersky Lab, Symantec, and The Intercept in November 2014. Regin malware targeted victims in a range of industries, telecom, government, and financial institutions. It was engineered to be modular and over time dozens of modules have been found and attributed to this family. Symantec observed around 100 infections in 10 different countries across a variety of organisations including private companies, government entities, and research institutes.

Remcos

Remcos (acronym of Remote Control & Surveillance Software) is a commercial Remote Access Tool to remotely control computers.

Remcos is advertised as legitimate software which can be used for surveillance and penetration testing purposes, but has been used in numerous hacking campaigns. Remcos, once installed, opens a backdoor on the computer, granting full access to the remote user. Remcos is developed by the cybersecurity company BreakingSecurity.

The tag is: *misp-galaxy:malpedia="Remcos"*

Remcos is also known as:

- RemcosRAT
- Remvio
- Socmer

Remexi

Remexi is a highly advanced and stealthy malware discovered in recent times. It employs sophisticated evasion techniques to infiltrate target systems and networks undetected. This malware utilizes various propagation vectors, including exploit kits, social engineering tactics, and compromised websites. Once inside a system, Remexi establishes persistence through rootkit capabilities and leverages coAmmand-and-control infrastructure to receive and execute malicious commands. It possesses keylogging and data exfiltration capabilities, enabling it to steal sensitive information such as login credentials and financial data. Additionally, Remexi can download and execute additional payloads, making it adaptable and capable of evolving its malicious activities over time.

Retefe (Windows)

Retefe is a Windows Banking Trojan that can also download and install additional malware onto the system using Windows PowerShell. It's primary functionality is to assist the attacker with stealing credentials for online banking websites. It is typically targeted against Swiss banks. The malware binary itself is primarily a dropper component for a Javascript file which builds a VBA file which in turn loads multiple tools onto the host including: 7zip and TOR. The VBA installs a new root certificate and then forwards all traffic via TOR to the attacker controlled host in order to effectively MITM TLS traffic.

REvil (Windows)

REvil Beta MD5: bed6fc04aeb785815744706239a1f243 SHA1: 3d0649b5f76dbbff9f86b926afbd18ae028946bf SHA256: 3641b09bf6eae22579d4fd5aae420476a134f5948966944189a70afd8032cb45 * Privilege escalation via CVE-2018-8453 (64-bit only) * Rerun with RunAs to elevate privileges * Implements a requirement that if "exp" is set, privilege escalation must be successful for full execution to occur * Implements target whitelisting using GetKetboardLayoutList * Contains debug console logging functionality * Defines the REvil registry root key as SOFTWARE\!test * Includes two variable placeholders in the ransom note: UID & KEY * Terminates processes specified in the "prc" configuration key prior to encryption * Deletes shadow copies and disables recovery * Wipes contents of folders specified in the "wfld" configuration key prior to encryption * Encrypts all non-whitelisted files on fixed drives * Encrypts all non-whitelisted files on network mapped drives if it is running with System-level privileges or can impersonate the security context of explorer.exe * Partially implements a background image setting to display a basic "Image text" message * Sends encrypted system data to a C2 domain via an HTTPS POST request (URI path building is not implemented.)

```
REvil 1.00
MD5: 65aa793c000762174b2f86077bdafaea
SHA1: 95a21e764ad0c98ea3d034d293aee5511e7c8457
SHA256: f0c60f62ef9ffc044d0b4aeb8cc26b971236f24a2611cb1be09ff4845c3841bc
* Adds 32-bit implementation of CVE-2018-8453 exploit
* Removes console debug logging
* Changes the REvil registry root key to SOFTWARE\recfg
* Removes the System/Impersonation success requirement for encrypting network mapped
drives
* Adds a "wipe" key to the configuration for optional folder wiping
* Fully implements the background image setting and leverages values defined in the
"img" configuration key
* Adds an EXT variable placeholder to the ransom note to support UID, KEY, and EXT
* Implements URI path building so encrypted system data is sent to a C2 pseudo-random
URL
* Fixes the function that returns the victim's username so the correct value is placed
in the stats JSON data
```

REvil 1.01 MD5: 2abff29b4d87f30f011874b6e98959e9 SHA1: 9d1b61b1cba411ee6d4664ba2561fa59cdb0732c SHA256: a88e2857a2f3922b44247316642f08ba8665185297e3cd958bbd22a83f380feb * Removes the exp/privilege escalation requirement for full execution and encrypts data regardless of privilege level * Makes encryption of network mapped drives optional by adding the "-nolan" argument

```
REvil 1.02
MD5: 4af953b20f3a1f165e7cf31d6156c035
SHA1: b859de5ffcb90e4ca8e304d81a4f81e8785bb299
SHA256: 89d80016ff4c6600e8dd8cfad1fa6912af4d21c5457b4e9866d1796939b48dc4
* Enhances whitelisting validation by adding inspection of GetUserDefaultUILanguage
and GetSystemDefaultUILanguage
* Partially implements "lock file" logic by generating a lock filename based on the
```

```
first four bytes of the Base64-decoded pk key, appending a .lock file extension, and
adding the filename to the list of whitelisted files in the REvil configuration (It
does not appear that this value is referenced after it is created and stored in
memory. There is no evidence that a lock file is dropped to disk.)
* Enhances folder whitelisting logic that take special considerations if the folder is
associated with "program files" directories
* Hard-codes whitelisting of all direct content within the Program Files or Program
Files x86 directories
* Hard-codes whitelisting of "sql" subfolders within program files
* Encrypts program files sub-folders that does not contain "sql" in the path
* Compares other folders to the list of whitelisted folders specified in the REvil
configuration to determine if they are whitelisted
* Encodes stored strings used for URI building within the binary and decodes them in
memory right before use
* Introduces a REvil registry root key "sub_key" registry value containing the
attacker's public key
```

REvil 1.03 MD5: 3cae02306a95564b1fff4ea45a7dfc00 SHA1: 0ce2cae5287a64138d273007b34933362901783d SHA256: 78fa32f179224c46ae81252c841e75ee4e80b57e6b026d0a05bb07d34ec37bbf * Removes lock file logic that was partially implemented in 1.02 * Leverages WMI to continuously monitor for and kill newly launched processes whose names are listed in the prc configuration key (Previous versions performed this action once.) * Encodes stored shellcode * Adds the -path argument: * Does not wipe folders (even if wipe == true) * Does not set desktop background * Does not contact the C2 server (even if net == true) * Encrypts files in the specified folder and drops the ransom note * Changes the REvil registry root key to SOFTWARE\QtProject\OrganizationDefaults * Changes registry key values from -→ to: * sub_key -→ pvg * pk_key -→ sxsP * sk_key -→ BDDC8 * 0_key -→ f7gVD7 * rnd_ext -→ Xu7Nnkd * stat -→ sMMnxpgk

```
REvil 1.04
MD5: 6e3efb83299d800edf1624ecbc0665e7
SHA1: 0bd22f204c5373f1a22d9a02c59f69f354a2cc0d
SHA256: 2ca64feaaf5ab6cf96677fbc2bc0e1995b3bc93472d7af884139aa757240e3f6
* Leverages PowerShell and WMI to delete shadow copies if the victim's operating
system is newer than Windows XP (For Windows XP or older, it uses the original command
that was executed in all previous REvil versions.)
* Removes the folder wipe capability
* Changes the REvil registry root key to SOFTWARE\GitForWindows
* Changes registry key values from --> to:
  * pvg --> QPM
  * sxsP --> cMtS
  * BDDC8 --> WGg7j
  * f7gVD7 --> zbhs8h
  * Xu7Nnkd --> H85TP10
  * sMMnxpgk --> GCZg2PXD
```

REvil v1.05 MD5: cfefcc2edc5c54c74b76e7d1d29e69b2 SHA1: 7423c57db390def08154b77e2b5e043d92d320c7 SHA256:

e430479d1ca03a1bc5414e28f6cdbb301939c4c95547492cdbe27b0a123344ea * Add new 'arn' configuration key that contains a boolean true/false value that controls whether or not to implement persistence. * Implements persistence functionality via registry Run key. Data for value is set to the full path and filename of the currently running executable. The executable is never moved into any 'working directory' such as %AppData% or %TEMP% as part of the persistence setup. The Reg Value used is the hardcoded value of 'lNOWZyAWVv' : * SOFTWARE\Microsoft\Windows\CurrentVersion\Run\lNOWZyAWVv * Before exiting, REvil sets up its malicious executable to be deleted upon reboot by issuing a call to MoveFileExW and setting the destination to NULL and the flags to 4 (MOVEFILE_DELAY_UNTIL_REBOOT). This breaks persistence however as the target executable specified in the Run key will no longer exist once this is done. * Changes registry key values from -→ to: * QPM -→ tgE * cMtS -→ 8K09 * WGg7j -→ xMtNc * zbhs8h -→ CTgE4a * H85TP10 -→ oE5bZg0 * GCZg2PXD -→ DC408Qp4

```
REvil v1.06
MD5: 65ff37973426c09b9ff95f354e62959e
SHA1: b53bc09cfbd292af7b3609734a99d101bd24d77e

* Updated string decoding function to break existing yara rules. Likely the result of
the blog posted by us.
* Modified handling of network file encryption. Now explicitly passes every possible
"Scope" constant to the WNetOpenEnum function when looking for files to encrypt. It
also changed the 'Resource Type" from RESOURCETYPE_DISK to RESOURCETYPE_ANY which will
now include things like mapped printers.
* Persistence registry value changed from 'lNOWZyAWVv' to 'sNpEShi30R'
* Changes registry key values from --> to:
  * tgE --> 73g
  * 8K09 --> vTGj
  * xMtNc --> Q7PZe
  * CTgE4a --> BuCrIp
  * oE5bZg0 --> lcZd7OY
  * DC408Qp4 --> sLF86MWC
```

REvil v1.07 MD5: ea4cae3d6d8150215a4d90593a4c30f2 SHA1: 8dcbcbefaedf5675b170af3fd44db93ad864894e SHA256: 6a2bd52a5d68a7250d1de481dcce91a32f54824c1c540f0a040d05f757220cd3 TBD

The tag is: *misp-galaxy:malpedia="REvil (Windows)"*

REvil (Windows) is also known as:

- Sodin
- Sodinokibi

Rhadamanthys

According to PCrisk, Rhadamanthys is a stealer-type malware, and as its name implies - it is designed to extract data from infected machines.

At the time of writing, this malware is spread through malicious websites mirroring those of genuine software such as AnyDesk, Zoom, Notepad++, and others. Rhadamanthys is downloaded alongside the real program, thus diminishing immediate user suspicion. These sites were promoted through Google ads, which superseded the legitimate search results on the Google search engine.

The tag is: *misp-galaxy:malpedia="Rhadamanthys"*

RMS

CyberInt states that Remote Manipulator System (RMS) is a legitimate tool developed by Russian organization TektonIT and has been observed in campaigns conducted by TA505 as well as numerous smaller campaigns likely attributable to other, disparate, threat actors. In addition to the availability of commercial licenses, the tool is free for non-commercial use and supports the remote administration of both Microsoft Windows and Android devices.

ROLLCOAST

ROLLCOAST is a ransomware program that encrypts files on logical drives attached to a system. ROLLCOAST is a Dynamic Linked Library (DLL) with no named exports. When observed by

Mandiant it uniquely had only one ordinal export 0x01. This suggested the sample was designed to avoid detection and be invoked within memory, possibly through BEACON provided to affiliates. Incident responders working on similar intrusions should capture memory for analysis.

The tag is: *misp-galaxy:malpedia="ROLLCOAST"*

ROLLCOAST is also known as:

- Arcane
- S4bb47h
- Sabbath

Rook

According to PCrisk, Rook is ransomware (an updated variant of Babuk) that prevents victims from accessing/opening files by encrypting them. It also modifies filenames and creates a text file/ransom note ("HowToRestoreYourFiles.txt"). Rook renames files by appending the ".Rook" extension. For example, it renames "1.jpg" to "1.jpg.Rook", "2.jpg" to "2.jpg.Rook".

Running RAT

NJCCIC characterizes RunningRAT as a remote access trojan (RAT) that operates using two DLL files. When the trojan is loaded onto a system, it executes the first DLL. This is used to disable anti-malware solutions, unpack and execute the main RAT DLL, and gain persistence. The trojan installs a Windows batch file dx.bat that attempts to kill the daumcleaner.exe task, a Korean security program. The file then attempts to remove itself. Once the second DLL is loaded into memory, the first DLL overwrites the IP address for the control server to change the address the trojan communicates with. The second DLL gathers information about the victim's system, including its operating system and driver and processor information. The RAT can log user keystrokes, copy the clipboard, delete files, compress files, clear event logs, shut down the machine, and more. The second DLL also uses several anti-bugging techniques.

RURansom

RURansom shows characteristics of typical ransomware, but despite its name, TrendMicro's assumptions after analysis showed that this malware is more a wiper than ransomware, because

the irreversible destruction of encrypted files.

Ryuk

Ryuk is a ransomware which encrypts its victim's files and asks for a ransom via bitcoin to release the original files. It is has been observed being used to attack companies or professional environments. Cybersecurity experts figured out that Ryuk and Hermes ransomware shares pieces of codes. Hermes is commodity ransomware that has been observed for sale on dark-net forums and used by multiple threat actors.

Sagerunex

According to Symantec, Sagerunex is a backdoor that is fairly resilient and implements multiple forms of communication with its command-and-control (C&C) server. Its logs are encrypted and the encryption algorithm used is AES256-CBC with 8192 rounds of SHA256 for key derivation based on a hardcoded key. It supports multiple modes methods for communicating via HTTP (proxy-aware).

Sality

F-Secure states that the Sality virus family has been circulating in the wild as early as 2003. Over the years, the malware has been developed and improved with the addition of new features, such as rootkit or backdoor functionality, and so on, keeping it an active and relevant threat despite the relative age of the malware.

Modern Sality variants also have the ability to communicate over a peer-to-peer (P2P) network, allowing an attacker to control a botnet of Sality-infected machines. The combined resources of the

Sality botnet may also be used by its controller(s) to perform other malicious actions, such as attacking routers.

Infection Sality viruses typically infect executable files on local, shared and removable drives. In earlier variants, the Sality virus simply added its own malicious code to the end of the infected (or host) file, a technique known as prepending. The viral code that Sality inserts is polymorphic, a form of complex code that is intended to make analysis more difficult.

Earlier Sality variants were regarded as technically sophisticated in that they use an Entry Point Obscuration (EPO) technique to hide their presence on the system. This technique means that the virus inserts a command somewhere in the middle of an infected file's code, so that when the system is reading the file to execute it and comes to the command, it forces the system to 'jump' to the malware's code and execute that instead. This technique was used to make discovery and disinfection of the malicious code harder.

Payload Once installed on the computer system, Sality viruses usually also execute a malicious payload. The specific actions performed depend on the specific variant in question, but generally Sality viruses will attempt to terminate processes, particularly those related to security programs. The virus may also attempt to open connections to remote sites, download and run additional malicious files, and steal data from the infected machine.

The tag is: *misp-galaxy:malpedia="Sality"*

SectopRAT

SectopRAT, aka ArechClient2, is a .NET RAT with numerous capabilities including multiple stealth functions. Arechclient2 can profile victim systems, steal information such as browser and crypto-wallet data, and launch a hidden secondary desktop to control browser sessions. Additionally, it has several anti-VM and anti-emulator capabilities.

ServHelper

ServHelper is written in Delphi and according to ProofPoint best classified as a backdoor.

ProofPoint noticed two distinct variant - "tunnel" and "downloader" (citation): "The 'tunnel' variant has more features and focuses on setting up reverse SSH tunnels to allow the threat actor to access the infected host via Remote Desktop Protocol (RDP). Once ServHelper establishes remote desktop access, the malware contains functionality for the threat actor to 'hijack' legitimate user accounts or their web browser profiles and use them as they see fit. The 'downloader' variant is stripped of the tunneling and hijacking functionality and is used as a basic downloader."

SharpStage

The SharpStage backdoor is a .NET malware with backdoor capabilities. Its name is a derivative of the main activity class called “Stage_One”. SharpStage can take screenshots, run arbitrary commands and downloads additional payloads. It exfiltrates data from the infected machine to a dropbox account by implementing a dropbox client in its code. SharpStage was seen used by the Molerats group in targeted attacks in the middle east.

The tag is: *misp-galaxy:malpedia="SharpStage"*

SharpStage is also known as:

- LastConn

ShellLocker

PCRIsk states that ShellLocker is a ransomware-type virus developed using .NET framework. It was first discovered by Jakub Kroustek and is virtually identical to another ransomware virus called Exotic.

Following infiltration, this virus encrypts stored data (video, audio, etc.) and renames encrypted files using the "[random_characters].L0cked" pattern (e.g., "sample.jpg" might be renamed to "gd&=AA0fgoi.L0cked"). Following successful encryption, ShellLocker opens a pop-up window containing ransom-demand message.

Silence

According to PCrisk, Truebot, also known as Silence.Downloader, is a malicious program that has botnet and loader/injector capabilities. This malware can add victims' devices to a botnet and cause chain system infections (i.e., download/install additional malicious programs/components).

There is significant variation in Truebot's infection chains and distribution. It is likely that the attackers using this malicious software will continue to make such changes.

The tag is: *misp-galaxy:malpedia="Silence"*

Silence is also known as:

- TrueBot

Sliver

According to VK9 Seecurity, Sliver is a Command and Control (C2) system made for penetration testers, red teams, and advanced persistent threats. It generates implants (slivers) that can run on virtually every architecture out there, and securely manage these connections through a central

server. Sliver supports multiple callback protocols including DNS, TCP, and HTTP(S) to make egress simple, even when those pesky blue teams block your domains. You can even have multiple operators (players) simultaneously commanding your sliver army.

SMAUG

According to PCrisk, Smaug ransomware is available for download on the dark web: it is for sale as Ransomware as a Service (RaaS). Therefore, cyber criminals who purchase it can perform ransomware attacks without having to develop malware of this type. Smaug is designed to encrypt files, rename them and create a ransom message.

The tag is: *misp-galaxy:malpedia="SMAUG"*

SMAUG is also known as:

Table 4871. Table References

SMOKEDHAM

According to Mandiant, SMOKEDHAM is dropped through a powershell script that contains the (C#) source code for this backdoor, which is stored in an encrypted variable. The dropper dynamically defines a cmdlet and .NET class for the backdoor, meaning the compiled code is only found in memory.

The tag is: *misp-galaxy:malpedia="SMOKEDHAM"*

https://www.mandiant.com/resources/burrowing-your-way-into-vpns

SmokeLoader

The SmokeLoader family is a generic backdoor with a range of capabilities which depend on the modules included in any given build of the malware. The malware is delivered in a variety of ways and is broadly associated with criminal activity. The malware frequently tries to hide its C2 activity by generating requests to legitimate sites such as microsoft.com, bing.com, adobe.com, and others. Typically the actual Download returns an HTTP 404 but still contains data in the Response Body.

The tag is: *misp-galaxy:malpedia="SmokeLoader"*

SmokeLoader is also known as:

- Dofoil
- Sharik
- Smoke
- Smoke Loader

Snake

Snake Ransomware is a Golang ransomware reportedly containing obfuscation not typically seen in Golang ransomware. This malware will remove shadow copies and kill processes related to SCADA/ICS devices, virtual machines, remote management tools, network management software, and others. After this, encryption of files on the device commences, while skipping Windows system folders and various system files. A random 5 character string is appended to encrypted files. According to Bleeping Computer, this ransomware takes an especially long time to encrypt files on a targeted machine. This ransomware is reported to target an entire network, rather than individual workstations.

Snatch

Snatch is a ransomware which infects victims by rebooting the PC into Safe Mode. Most of the existing security protections do not run in Safe Mode so that it the malware can act without expected countermeasures and it can encrypt as many files as it finds. It uses common packers such as UPX to hide its payload.

The tag is: *misp-galaxy:malpedia="Snatch"*

Snatch is also known as:

Socks5 Systemz

The Socks5 Systemz malware is a proxy botnet distributed via the PrivateLoader and Amadey loaders. Active since at least 2016, this botnet infects devices to use them as proxies for malicious activities, offering access for prices ranging from $1 to $140 per day in cryptocurrency. It employs a domain generation algorithm (DGA) to evade detection and enhance its resilience. Persistence is maintained through a Windows service named ContentDWSvc, with the malware injected into memory via a file called previewer.exe. To date, it has compromised approximately 10,000 devices globally, excluding Russia.

SodaMaster

This is a RAT that is usually loaded with one or more shellcode and/or reflective DLL injection techniques. The RAT uses RC4 or a hardcoded RSA key for traffic encryption/decryption. Its communication can either happen via a raw TCP socket or a HTTP POST request. Depending on the version, the RAT may remotely execute DLLs or shellcode.

solarmarker

Unit 42 notes that they identified a new version of SolarMarker, a malware family known for its infostealing and backdoor capabilities, mainly delivered through search engine optimization (SEO) manipulation to convince users to download malicious documents.

Some of SolarMarker's capabilities include the exfiltration of auto-fill data, saved passwords and saved credit card information from victims' web browsers. Besides capabilities typical for infostealers, SolarMarker has additional capabilities such as file transfer and execution of commands received from a C2 server.

The malware invests significant effort into defense evasion, which consists of techniques like

signed files, huge files, impersonation of legitimate software installations and obfuscated PowerShell scripts.

SPACESHIP

SPACESHIP searches for files with a specified set of file extensions and copies them to a removable drive. FireEye believes that SHIPSHAPE is used to copy SPACESHIP to a removable drive, which could be used to infect another victim computer, including an air-gapped computer. SPACESHIP is then used to steal documents from the air-gapped system, copying them to a removable drive inserted into the SPACESHIP-infected system

SPHijacker

According to Trend Micro, this is a tool designed to disable security products, adopting two approaches to achieve this purpose. One approach terminates the security product process by using a vulnerable driver, zamguard64.sys, published by Zemana (vulnerability designated as CVE-2018-5713). Meanwhile, another approach disables process launching by using a new technique that they named stack rumbling.

SpyEye

SpyEye is a malware targeting both Microsoft Windows browsers and Apple iOS Safari. Originated in Russia, it was available in dark forums for $500+ claiming to be the "The Next Zeus Malware". It performed many functionalities typical from bankers trojan such as keyloggers, auto-fill credit card modules, email backups, config files (encrypted), http access, Pop3 grabbers and FTP grabbers. SpyEye allowed hackers to steal money from online bank accounts and initiate transactions even while valid users are logged into their bank account.

Squirrelwaffle

According to Sophos, Squirrelwaffle is a malware loader that is distributed as a malicious Office document in spam campaigns. It provides attackers with an initial foothold in a victim's environment and a channel to deliver and infect systems with other malware. When a recipient opens a Squirrelwaffle-infected document and enables macros, a visual basic script typically downloads and executes malicious files and scripts, giving further control of the computer to an attacker. Squirrelwaffle operators also use DocuSign to try and trick the user into enabling macros in Office documents.

SquirtDanger

According to PaloAlto, SquirtDanger is a commodity botnet malware family that comes equipped with a number of characteristics and capabilities. The malware is written in C# (C Sharp) and has multiple layers of embedded code. Once run on the system, it will persist via a scheduled task that is set to run every minute. SquirtDanger uses raw TCP connections to a remote command and control (C2) server for network communications.

SSLoad

SSLoad is a Rust-based downloader that first emerged in January 2024 and is used to deliver secondary payloads. Early versions of the malware used a first-stage DLL that connected to a Telegram channel named 'SSLoad' to retrieve another URL. It then downloaded a compressed PE file using a hardcoded User-Agent (SSLoad/1.x) and Content-Type over HTTP. The downloaded file was then decompressed and executed directly in memory. The malware has since undergone several updates, including changes to the command-and-control (C2) communication and the supporting executables that load the malware. Recent versions of the malware bypass the first-stage DLL by loading SSLoad directly onto the victim's machine.

Stealc

Stealc is an information stealer advertised by its presumed developer Plymouth on Russian-speaking underground forums and sold as a Malware-as-a-Service since January 9, 2023. According to Plymouth's statement, stealc is a non-resident stealer with flexible data collection settings and its development is relied on other prominent stealers: Vidar, Raccoon, Mars and Redline.

Stealc is written in C and uses WinAPI functions. It mainly targets date from web browsers, extensions and Desktop application of cryptocurrency wallets, and from other applications (messengers, email clients, etc.). The malware downloads 7 legitimate third-party DLLs to collect sensitive data from web browsers, including sqlite3.dll, nss3.dll, vcruntime140.dll, mozglue.dll, freebl3.dll, softokn3.dll and msvcp140.dll. It then exfiltrates the collected information file by file to its C2 server using HTTP POST requests.

Stealerium

According to SecurityScorecard, Stealerium is an open-source stealer available on GitHub. The malware steals information from browsers, cryptocurrency wallets, and applications such as Discord, Pidgin, Outlook, Telegram, Skype, Element, Signal, Tox, Steam, Minecraft, and VPN clients. The binary also gathers data about the infected host, such as the running processes, Desktop and webcam screenshots, Wi-Fi networks, the Windows product key, and the public and private IP address. The stealer employs multiple anti-analysis techniques, such as detecting virtual machines, sandboxes, and malware analysis tools and checking if the process is being debugged. The malware also embedded a keylogger module and a clipper module that replaces cryptocurrency wallet addresses with the threat actor's addresses if the victim makes a transaction. The stolen information is sent to a Discord channel using a Discord Webhook.

StealthWorker Go

According to Fortinet, StealthWorker is a brute-force malware that has been linked to a compromised e-commerce website with an embedded skimmer that steals personal information and payment details. Before hackers can embed a skimmer, however, the first requirement is for

hackers to gain access to their target's backend. Hacker's commonly take advantage of vulnerabilities in the Content Management System (CMS) or its plugins to gain entry into the target's system. Another, simpler option is to use brute force attacks. Though quite slow, this method is still effective against administrators using weak or commonly used passwords.

STOP

STOP Djvu Ransomware it is a ransomware which encrypts user data through AES-256 and adds one of the dozen available extensions as marker to the encrypted file's name. It is not used to encrypt the entire file but only the first 5 MB. In its original version it was able to run offline and, in that case, it used a hard-coded key which could be extracted to decrypt files.

StrelaStealer

According to PCRisk, StrelaStealer seeks to extract email account log-in credentials. At the time of writing, this program targets Microsoft Outlook and Mozilla Thunderbird email clients.

Following successful infiltration, StrelaStealer searches for "logins.json" (account/password) and "key4.db" (password database) within the "%APPDATA%\Thunderbird\Profiles\" directory - by doing so, it can acquire the credentials for Thunderbird.

Alternatively, if Outlook credentials are targeted - StrelaStealer seeks out the Windows Registry from where it can retrieve the program's key and "IMAP User", "IMAP Server", as well as the "IMAP Password" values. Since the latter is kept in an encrypted form, the malicious program employs the Windows CryptUnprotectData feature to decrypt it prior to exfiltration.

SUNBURST

FireEye describes SUNBURST as a trojanized SolarWinds digitally-signed component of the Orion software framework that contains a backdoor that communicates via HTTP to third party servers. After an initial dormant period of up to two weeks, it uses a DGA to generate specific subdomains for a set C&C domain. The backdoor retrieves and executes commands, that include the ability to transfer files, execute files, profile the system, reboot the machine, and disable system services. The C2 traffic to the malicious domains is designed to mimic normal SolarWinds API communications: Orion Improvement Program (OIP) protocol. The backdoor uses multiple obfuscated blocklists to identify forensic and anti-virus tools running as processes, services, and drivers. Multiple trojanzied updates were digitally signed from March - May 2020 and posted to the SolarWinds updates website.

The tag is: *misp-galaxy:malpedia="SUNBURST"*

SUNBURST is also known as:

- Solorigate

SunCrypt

According to PCrisk, Suncrypt ransomware prevents victims from accessing files by encryption. It also renames all encrypted files and creates a ransom message. It renames encrypted files by appending a string of random characters as the new extension.

SVCReady

According to PCrisk, SVCReady collects information about the infected system such as username, computer name, time zone, computer manufacturer, BIOS, and firmware. Also, it gathers lists of running processes and installed software. SVCReady sends collected data to the C2 server. Additionally, SVCReady attempts to maintain its foothold on the system by creating a scheduled task.

SysJoker (Windows)

Sysjoker is a backdoor malware that was first discovered in December 2021 by Intezer. It is sophisticated and written from scratch in C++. Sysjoker is a cross-platform malware that has Linux, Windows, and macOS variants. Possible attack vectors for Sysjoker are email attachments, malicious advertisements, and trojanized software.

The tag is: *misp-galaxy:malpedia="SysJoker (Windows)"*

Sysraw Stealer

Sysraw stealer got its name because at some point, it was started as "ZSysRaw\sysraw.exe". PDB strings suggest the name "Clipsa" though. First stage connects to /WPCoreLog/, the second one to /WPSecurity/. Its behavior suggest that it is an info stealer. It creates a rather large amount of files in a subdirectory (e.g. data) named "1?[-+].dat" and POSTs them.

The tag is: *misp-galaxy:malpedia="Sysraw Stealer"*

Taurus Stealer

According to Zscaler, Taurus is a stealer that surfaced in June 2020. It is being developed by the author(s) that previously created Predator the Thief. The name overlaps partly with the StealerOne / Terra* family (also aliased Taurus Loader) but appears to be a completely disjunct project.

The tag is: *misp-galaxy:malpedia="Taurus Stealer"*

Taurus Stealer is also known as:

tDiscoverer

F-Secure described tDiscoverer (also known as HammerDuke) as interesting because it is written in .NET, and even more so because of its occasional use of Twitter as a C&C communication channel. Some HammerDuke variants only contain a hardcoded C&C server address from which they will retrieve commands, but other HammerDuke variants will first use a custom algorithm to generate a Twitter account name based on the current date. If the account exists, HammerDuke will then search for tweets from that account with links to image files that contain embedded commands for the toolset to execute.

TEARDROP

TEARDROP is a memory only dropper that runs as a service, spawns a thread and reads from the file “gracious_truth.jpg”, which likely has a fake JPG header. Next it checks that HKU\SOFTWARE\Microsoft\CTF exists, decodes an embedded payload using a custom rolling XOR algorithm and manually loads into memory an embedded payload using a custom PE-like file format. TEARDROP does not have code overlap with any previously seen malware. FireEye believe that this was used to execute a customized Cobalt Strike BEACON.

The tag is: *misp-galaxy:malpedia="TEARDROP"*

TEARDROP is also known as:

TellYouThePass

According to PCrisk, Tellyouthepass is one of many ransomware-type programs used to block access to files by encryption and keep them in this state unless a ransom is paid.

The program renames all encrypted files by adding the ".locked" extension and creates a ransom message in a text file called "README.html". For example, "1.jpg" is renamed by Tellyouthepass to "1.jpg.locked".

According to cyber criminals, this ransomware encrypts data using RSA-1024 and AES-256 cryptography algorithms.

TFlower

TFlower is a new ransomware targeting mostly corporate networks discovered in August, 2019. It is reportedly installed on networks by attackers after they gain access via RDP. TFlower displays a console showing activity being performed by the ransomware when it encrypts a machine, further indicating that this ransomware is triggered by the attacker post compromise, similar to Samsam/Samas in terms of TTP. Once encryption is started, the ransomware will conduct a status report to an apparently hard-coded C2. Shadow copies are deleted and the Windows 10 repair environment is disabled by this ransomware. This malware also will terminate any running Outlook.exe process so that the mail files can be encrypted. This ransomware does not add an extention to encrypted files, but prepends the marker "*tflower" and what may be the encrypted encryption key for the file to each affected file. Once encryption is completed, another status report is sent to the C2 server.

TigerLite

TigerLite is a TCP downloader.

It creates mutexes like "qtrgads32" or "Microsoft32".

It uses RC4 with the key "MicrosoftCorporationValidation@#$%^&*()!US" for decryption of its character strings, and a custom algorithm for encryption and decryption of network traffic.

It supports from 5 up to 8 commands with the following identifiers: 1111, 1234, 2099/3333, 4444, 8877, 8888, 9876, 9999. The commands mostly perform various types of execution - either of code received from the server, or native Windows commands, with their output collected and sent back to the server.

TigerLite is an intermediate step of a multi-stage attack, in which Tiger RAT is usually the next step. This malware was observed in attacks against South Korean entities in H1 2021.

The tag is: *misp-galaxy:malpedia="TigerLite"*

TigerLite is also known as:

Tiger RAT

This is third stage backdoor mentioned in the Kaspersky blog, "Andariel evolves to target South Korea with ransomware". The third stage payload was created via the second stage payload, is interactively executed in the operation and exists in both x64 and x86 versions. Most of them use Internet Explorer or Google Chrome icons and corresponding file names to disguise themselves as legitimate internet browsers. The malware decrypts the embedded payload at runtime. It uses an embedded 16-byte XOR key to decrypt the base64 encoded payload. The decrypted payload is another portable executable file that runs in memory. Before getting decrypted with a hardcoded XOR key, the backdoor also checks for sandbox environment. The backdoor has some code overlap with a know malware family PEBBLEDASH, attributed to Lazarus/LABYRINTH CHOLLIMA.

The tag is: *misp-galaxy:malpedia="Tiger RAT"*

Tinba

F-Secure notes that TinyBanker or short Tinba is usually distributed through malvertising (advertising content that leads the user to sites hosting malicious threats), exploit kits and spam email campaigns. According to news reports, Tinba has been found targeting bank customers in the United States and Europe.

If Tinba successfully infects a device, it can steal banking and personal information through webinjects. To do this, the malware monitors the user's browser activity and if specific banking portals are visited, Tinba injects code to present the victim with fake web forms designed to mimic the legitimate web site. The malware then tricks them into entering their personal information, log-in credentials, etc in the legitimate-looking page.

Tinba may also display socially-engineered messages to lure or pressure the user into entering their information on the fake page; for example, a message may be shown which attempts to convince the victim that funds were accidentally deposited to his account and must be refunded immediately.

The tag is: *misp-galaxy:malpedia="Tinba"*

Tinba is also known as:

- Illi
- TinyBanker
- Zusy

TinyNuke

TinyNuke (aka Nuclear Bot) is a fully-fledged banking trojan including HiddenDesktop/VNC server and a reverse socks4 server. It was for sale on underground marketplaces for $2500 in 2016. The program's author claimed the malware was written from scratch, but that it functioned similarly to the ZeuS banking trojan in that it could steal passwords and inject arbitrary content when victims visited banking Web sites. However, he then proceeded to destroy his own reputation on hacker forums by promoting his development too aggressively. As a displacement activity, he published his source code on Github. XBot is an off-spring of TinyNuke, but very similar to its ancestor.

The tag is: *misp-galaxy:malpedia="TinyNuke"*

TinyNuke is also known as:

- MicroBankingTrojan
- Nuclear Bot
- NukeBot
- Xbot

TinyTurlaNG

Cisco Talos states that TinyTurla-NG is a small “last chance” backdoor that is left behind to be used when all other unauthorized access/backdoor mechanisms have failed or been detected on the infected systems. TinyTurla-NG was seen as early as December 2023 targeting a Polish non-governmental organization (NGO) working on improving Polish democracy and supporting Ukraine during the Russian invasion.

The tag is: *misp-galaxy:malpedia="TinyTurlaNG"*

Torisma

Torisma is a complex HTTP(S) downloader, that can serve as an orchestrator handling the execution of additional payloads from the C&C server.

It uses VEST-32 for encryption and decryption of network traffic between the client and the server.

Typically, it uses these parameter names for its HTTP POST requests: ACTION, CODE, CACHE, REQUEST, RES. It sends the victim's MAC address in the initial request.

The response of the server informing the client about a successful authentication is "Your request has been accepted. ClientID: {f9102bc8a7d81ef01ba}". The client then requests additional data from the server, that decrypts to shellcode and its data parameters, and is executed. The client also creates a named pipe, \\.\pipe\fb4d1181bb09b484d058768598b, that allows inter-process communication with the executed shellcode.

Torisma was usually downloaded by NedDnLoader, and deployed in the Operation DreamJob campaigns starting around Q4 2019.

Trigona

According to PCrisk, Trigona is ransomware that encrypts files and appends the "._locked" extension to filenames. Also, it drops the "how_to_decrypt.hta" file that opens a ransom note. An example of how Trigona renames files: it renames "1.jpg" to "1.jpg._locked", "2.png" to "2.png._locked", and so forth.

It embeds the encrypted decryption key, the campaign ID, and the victim ID in the encrypted files.

The tag is: *misp-galaxy:malpedia="Trigona"*

Trigona is also known as:

Troldesh

According to Malwarebyte, Ransomware is a type of malware that prevents users from accessing their system or personal files and demands ransom payment in order to regain access. Ransom.Troldesh is spread by malspam, typically in the form of attached .zip files. This ransomware sometimes uses a CMS on a compromised site to host downloads.

Tuoni

According to its Github repo, Tuoni is a sophisticated, cross-platform red teaming framework designed to enhance cybersecurity education and training through large-scale cyber defense exercises. Developed using Java for robustness, Docker for versatility, and featuring an intuitive web browser interface, it supports and streamlines cyber exercises. With its modular, extendable plugin system, Tuoni offers Red Teamers the flexibility to tailor its capabilities for specific educational and exercise needs. Its user-friendly interface facilitates easy operation and efficient reporting, essential in training environments. Tuoni embodies a commitment to power, adaptability, and collaboration, aimed at empowering Red Teamers with a tool that meets the dynamic demands of modern cyber defense education.

TYPEFRAME

TYPEFRAME is a RAT.

It supports ~25 commands that include operations on the victim's filesystem, manipulation with its configuration, modification of the system's firewall, the download and execution of additional tools from the attacker's C&C and the uninstall via a self-delete batch. The commands are indexed by 16-bit integers, starting with the value 0x8000.

The RAT uses RC4 for decryption of its binary configuration. It has a statically linked OpenSSL 0.9.8k library used for SSL communication.

Typhon Stealer

According to PCrisk, Typhon is a stealer-type malware written in the C# programming language. Newer versions of this program are called Typhon Reborn (TyphonReborn). Malware within this classification is designed to extract data from infected systems. The older variants of Typhon have a broader range of functionalities, while Typhon Reborn versions are streamlined stealers.

The tag is: *misp-galaxy:malpedia="Typhon Stealer"*

Unidentified 080

This Trojan is a full-featured RAT capable of executing common tasks such as command execution and downloading/uploading files. This is implemented through a couple dozen C++ classes such as CMFile, CMFile, CMProcess, TFileDownload, TDrive, TProcessInfo, TSock, etc. The first stage custom installer utilizes the same classes. The Trojan uses HTTP Server API to filter HTTPS packets at port 443 and parse commands. It is also used by attackers to gather a target's data, make lateral movements and create SOCKS tunnels to their C2 using the Earthworm tunneler.Given that the Trojan is an HTTPS server itself, the SOCKS tunnel is used for targets without an external IP, so the C2 is able to send commands.

USBCulprit

According to Kaspersky, USBCulprit is a malware that is capable of scanning various paths in victim machines, collecting documents with particular extensions and passing them on to USB drives when they are connected to the system. It can also selectively copy itself to a removable drive in the

presence of a particular file, suggesting it can be spread laterally by having designated drives infected and the executable in them opened manually.

vanillarat

Description:

VanillaRat is an advanced remote administration tool coded in C#. VanillaRat uses the Telepathy TCP networking library, dnlib module reading and writing library, and Costura.Fody dll embedding library. Features:

```
Remote Desktop Viewer (With remote click)
File Browser (Including downloading, drag and drop uploading, and file opening)
Process Manager
Computer Information
Hardware Usage Information (CPU usage, disk usage, available ram)
Message Box Sender
Text To Speech
Screen Locker
Live Keylogger (Also shows current window)
Website Opener
Application Permission Raiser (Normal -> Admin)
Clipboard Text (Copied text)
Chat (Does not allow for client to close form)
Audio Recorder (Microphone)
Process Killer (Task manager, etc.)
Remote Shell
Startup
Security Blacklist (Drag client into list if you don't want connection. Press del. key
on client to remove from list)
```

VaporRage

According to Mandiant, VaporRage or BOOMMIC, is a shellcode downloader written in C that communicates over HTTPS. Shellcode Payloads are retrieved from a hardcoded C2 that uses an encoded host_id generated from the targets domain and account name. BOOMMIC XOR decodes the downloaded shellcode payload in memory and executes it.

The tag is: *misp-galaxy:malpedia="VaporRage"*

VaporRage is also known as:

Varenyky

In May 2019, ESET researchers observed a spike in ESET telemetry data regarding malware targeting France. After further investigations, they identified malware that distributes various types of spam. One of them is leading to a survey that redirects to a dodgy smartphone promotion while the other is a sextortion campaign. The spam targets the users of Orange S.A., a French ISP.

VictoryGate

VictoryGate was the name of a cryptomining botnet, which was disrupted by ESET researchers in April 2020. The used malware itself was also referred to as VictoryGate. It was spotted in May 2019

and targeted mainly Latin American users, specifically, Peru (Criptonizando states 90% of the botnet publication residing there). Both public and private sectors were targeted. This cryptojacking malware was specialized in Monero (XRM) cryptocurrency. VictoryGate shows very strong code overlap with win.orchard.

Vjw0rm

VJW0rm (aka Vengeance Justice Worm) is a publicly available, modular JavaScript RAT. Vjw0rm was first released in November 2016 by its primary author, v_B01 (aka Sliemerez), within the prominent DevPoint Arabic-language malware development community. VJW0rm appears to be the

JavaScript variant of a series of RATs with identical functionality released by the author throughout late 2016. Other variants include a Visual Basic Script (VBS) based worm titled vw0rm (Vengeance Worm), an AutoHotkey-based tool called vrw0rm (Vengeance Rise Worm), and a PowerShell-based variant called vdw0rm (Vengeance Depth Worm).

Vobfus

Malware of this family searches for computers on a network and creates copies of itself in folders with open access. For the program to be activated, the user must first run it on the computer. The code of this malware is written in the Visual Basic programming language and uses obfuscation, which is a distinguishing feature of this family. Code obfuscation complicates attempts by anti-virus software to analyze suspected malware.

Voldemort

Voldemort is a backdoor discovered by Proofpoint in August 2024. It is being distributed via phishing E-Mails and makes use of creative techniques such as using saved search files during the infection chain for obfuscation and Google Sheets for C2. While its broad targeting looks like it is related to ecrime, Proofpoint notes that the capabilities of the malware point towards espionage/APT activity.

Vyveva RAT

Vyveva is a remote access trojan that uses the Tor library for communication with C&C. Its use of fake TLS for camouflaging the network traffic is one of the typical Lazarus traits.

It uses a simple XOR for encryption of its configuration and network traffic.

It sends detailed information about the victim's environment, like computer name, user name, IP, code page, Windows version, architecture, and time zone.

It supports more than 20 commands that include operations on the victim's filesystem, basic process management, command line execution, file exfiltration, and the download and memory execution of an additional DLL from the C&C (by calling the expected export SamIPromote). As in many RATs from Lazarus arsenal, the commands are indexed by 32-bit integers. The lowest index is 0x3, followed by 0x10, which goes incrementally up to 0x26. Also, it can monitor newly connected drives and the number of logged-on users.

It has MPRD.dll as the internal DLL name, and a single export SamIInitialize.

Vyveva RAT was used in an attack against a freight logistics company in South Africa in June 2020.

The tag is: *misp-galaxy:malpedia="Vyveva RAT"*

Vyveva RAT is also known as:

wAgentTea

wAgentTea is an HTTP(S) downloader.

It was deployed mostly against South Korean targets like a pharmaceutical company (Q4 2020) or semiconductor industry (Q2 2023). In several cases, the initial access was obtained via exploitation of South Korean software like Initech's INISAFE CrossWeb EX or Dream Security's MagicLine4NX.

It uses AES-128 for encryption and decryption of its network traffic, and for decryption of its binary configuration.

There is a hard-coded list of parameter names used in its HTTP POST request: identy;tname;blogdata;content;thesis;method;bbs;level;maincode;tab;idx;tb;isbn;entry;doc; category;articles;portal

It contains a specific RTTI symbol ".?AVCHttp_socket@@".

https://killingthebear.jorgetesta.tech/actors/evil-corp

WastedLocker

WastedLocker is a ransomware detected to be in use since May 2020 by EvilCorp. The ransomware name is derived from the filename that it creates which includes an abbreviation of the victim's name and the string 'wasted'. WastedLocker is protected with a custom crypter, referred to as CryptOne by Fox-IT InTELL. On examination, this crypter turned out to be very basic and was used also by other malware families such as: Netwalker, Gozi ISFB v3, ZLoader and Smokeloader. The crypter mainly contains junk code to increase entropy of the sample and hide the actual code.

The tag is: *misp-galaxy:malpedia="WastedLocker"*

Waterbear

Waterbear, also known as DbgPrint in its earlier export function, has been active since 2009. The malware is presumably developed by the BlackTech APT group and adopts advanced anti-analysis and forward-thinking design. These designs include a sophisticated shellcode stager, the ability to load plugins on-the-fly, and overall evasiveness should the C2 server fail to respond with a valid session key.

The tag is: *misp-galaxy:malpedia="Waterbear"*

Waterbear is also known as:

- DbgPrint
- EYEWELL

Wave Stealer

Wave Stealer is an infostealer offered as Malware-as-a-Service by a French-speaking actor called "Wave". The threat actor has strong relationships with Nova Stealer's and Epsilon Stealer's groups. It's capabilities include passwords and crypto-wallet stealing, discord and telegram injection, and backup codes finder.

WebbyTea

WebbyTea is an HTTP(S) downloader that uses AES for C&C trafic encryption.

It sends detailed information about the victim’s environment, like proxy settings, system instalation date, Windows product name and version, manufacturer, product name, system boot time, time zone, computer name, user name, current time and a list of currently running processes. Data sent to the C&C server consists of the prefix "ci", a 16-characters long hexadecimal string representing the victim ID and an encrypted data about the victim’s system. After the payload is acquired from the server and successfully injected in a newly created explorer.exe process, the malware responds back with the same victim ID having the prefix changed to "cs".

The internal DLL name of the native WebbyTea is usually pe64.dll or webT64.dll (from which its name is derived).

The usual payload associated with WebbyTea is SnatchCrypto.

WebMonitor RAT

On its website, Webmonitor RAT is described as 'a very powerful, user-friendly, easy-to-setup and state-of-the-art monitoring tool. Webmonitor is a fully native RAT, meaning it will run on all Windows versions and languages starting from Windows XP and up, and perfectly compatible with all crypters and protectors.' Unit42 notes in their analysis that it is offered as C2-as-a-service and raises the controversial aspect that the builder allows to create client binaries that will not show any popup or dialogue during installation or while running on a target system.

WhiteBird

According to Dr.Web, WhiteBird is a backdoor written in C++ and designed to operate in both 32-bit and 64-bit Microsoft Windows operating systems. The configuration is encrypted with a single byte XOR key. An interesting feature is that the malware can be restricted to operate only within certain "working_hours" with a granularity of one minute.

The tag is: *misp-galaxy:malpedia="WhiteBird"*

WhiteBird is also known as:

WhiteSnake Stealer

WhiteSnake Stealer, discovered in February 2022, is a sophisticated .NET data-stealing malware that targets browsers, applications, and crypto wallets.

The builder can build payloads in different file formats such as EXE, SCR, COM, CMD, BAT, VBS, PIF, WSF, .hta, MSI, PY, DOC, DOCM, XLS, XLL, XLSM. Some of these (python, bash) allow the malware to run on Linux systems.

The stealer has two execution methods:

- Non-resident - the stealer auto-deletes itself after successful execution
- Resident - the stealer beacons out to the C2 (possibly in the TOR network)

WhiteSnake Stealer can gather system information, execute remote commands, spread through USB drives, and perform tasks like keylogging, file management, and webcam access.

The tag is: *misp-galaxy:malpedia="WhiteSnake Stealer"*

XDSpy

According to ESET Research, XDDown is a primary malware component and is strictly a downloader. It persists on the system using the traditional Run key. It downloads additional plugins from the hardcoded C&C server using the HTTP protocol. The HTTP replies contain PE binaries encrypted with a hardcoded two-byte XOR key. Plugins include a module for reconnaissance on the affected system, crawling drives, file exfiltration, SSID gathering, and grabbing saved passwords.

XehookStealer

Xehook is a .NET-based malware targeting Windows systems. It collects data from Chromium and Gecko browsers, supporting over 110 cryptocurrencies and 2FA extensions. CRIL found a potential link between Xehook Stealer, Agniane, and the Cinoshi project, suggesting a progression from a free MaaS model to the development of Xehook Stealer. SmokeLoader binaries were identified as a common vector for distributing Xehook Stealer. Xehook Stealer shares code overlaps with Agniane Stealer, indicating an evolutionary relationship.

xmrig

According to PCrisk, XMRIG is a completely legitimate open-source application that utilizes system CPUs to mine Monero cryptocurrency. Unfortunately, criminals generate revenue by infiltrating this app into systems without users' consent. This deceptive marketing method is called "bundling".

In most cases, "bundling" is used to infiltrate several potentially unwanted programs (PUAs) at once. So, there is a high probability that XMRIG Virus came with a number of adware-type applications that deliver intrusive ads and gather sensitive information.

The tag is: *misp-galaxy:malpedia="xmrig"*

Xorist

According to PCrisk, Xorist is a family of ransomware-type malware. After stealth system infiltration, ransomware from this family encrypts various files stored on the computer. After encrypting the files, this ransomware creates a 'How to Decrypt Files.txt text file on the victim's desktop. The file contains a message stating that the files can only be restored by paying a ransom.

Yanluowang

According to PCrisk, Yanluowang is ransomware that encrypts (and renames) files, ends all running processes, stops services, and creates the "README.txt" file containing a ransom note. It appends the ".yanluowang" extension to filenames. Cybercriminals behind Yanluowang are targeting enterprise entities and organizations in the financial sector.

Files encrypted by Yanluowang can be decrypted with this tool (it is possible to decrypt all files if the original file is larger than 3GB. If the original file is smaller than 3GB, then only smaller files can be decrypted).

The tag is: *misp-galaxy:malpedia="Yanluowang"*

Zacinlo

Bitdefender describes the primary features of the family as follows: Presence of a rootkit driver that protects itself as well as its other components, presence of man-in-the-browser capabilities that intercepts and decrypts SSL communications, and presence of an adware cleanup routine used to remove potential competition in the adware space. It also communicates with its C&C server, sending environment information such as installed AV and other applications. The malware also takes screenshots and does browser redirects, potentially manipulating the DOM tree. It also creates traffic in hidden windows, likely causing adfraud. The malware is generally very configurable and internally makes use of Lua scripts.

Zebrocy

According to brandefense, Zebrocy is malware that falls into the Trojan category, which the threat actor group APT28/Sofacy has used since 2015. Zebrocy malware consists of 3 main components; Backdoor, Downloader, and Dropper. The Downloader and Dropper take responsibility for discovery processes and downloading the main malware on the systems. At the same time, Backdoor undertakes the duties such as persistence in the system, espionage, and data extraction.

This malware, which is not considered new, has variants in many languages from the past to the present. These include programming languages such as Delphi, C#, Visual C++, VB.net, and Golang. Furthermore, we know advanced threat actors and groups revise their malicious software among their toolkits at certain time intervals using different languages and technologies.

The tag is: *misp-galaxy:malpedia="Zebrocy"*

Zeppelin

Zeppelin is a ransomware written in Delphi and sold a as-a-service. The Cylance research team notes that it is a clear evolution of the known VegaLocker, but they assessed it as a new family becaue of additionally developed modules that makes Zeppelin much more configurable than Vegalocker. There are executable variants of type DLL and EXE.

ZeroCleare

ZeroCleare is a destructive malware. It has been developed in order to wipe the master boot record section in order to damage a disk's partitioning. Attackers use the EldoS RawDisk driver to perform the malicious action, which is not a signed driver and would therefore not runnable by default. The attackers managed to install it by using a vulnerable version of VBoxDrv driver, which the DSE accepts and runs. Used to attack middle-east energy and industrial sectors.

ZeroEvil

ZeroEvil is a malware that seems to be distributed by an ARSguarded VBS loader.

It first connects to a gate.php (version=). Upon success, an embedded VBS gets started connecting to logs_gate.php (plugin=, report=). So far, only one embedded VBS was observed: it creates and starts a PowerShell script to retrieve all password from the Windows.Security.Credentials.PasswordVault. Apart from that, a screenshot is taken and a list of running processes generated.

The ZeroEvil executable contains multiple DLLs, sqlite3.dll, ze_core.DLL (Mutex) and ze_autorun.DLL (Run-Key).

Zeus OpenSSL

This family describes the Zeus-variant that includes a version of OpenSSL and usually is downloaded by Zloader.

In June 2016, the version 1.5.4.0 (PE timestamp: 2016.05.11) appeared, downloaded by Zloader

(known as DEloader at that time). OpenSSL 1.0.1p is statically linked to it, thus its size is roughly 1.2 MB. In subsequent months, that size increased up to 1.6 MB. In January 2017, with version 1.14.8.0, OpenSSL 1.0.2j was linked to it, increasing the size to 1.8 MB. Soon after also in January 2017, with version v1.15.0.0 the code was obfuscated, blowing up the size of the binary to 2.2 MB.

Please note that IBM X-Force decided to call win.zloader/win.zeus_openssl "Zeus Sphinx", after mentioning it as "a new version of Zeus Sphinx" in their initial post in August 2016. Malpedia thus lists the alias "Zeus XSphinx" for win.zeus_openssl - the X to refer to IBM X-Force.

Zeus Sphinx on the one hand has the following versioning ("slow increase") - 2015/09 v1.0.1.0 (Zeus Sphinx size: 1.5 MB) - 2016/02 v1.0.1.2 (Zeus Sphinx size: 1.5 MB) - 2016/04 v1.0.2.0 (Zeus Sphinx size: 1.5 MB)

Zeus OpenSSL on the other hand has the following versioning ("fast increase") - 2016/05 v1.5.4.0 (Zeus OpenSSL size: 1.2 MB) - 2017/01 v1.14.8.0 (Zeus OpenSSL size: 1.8 MB) - 2017/01 v1.15.0.0 (Zeus OpenSSL size: 2.2 MB)

The tag is: *misp-galaxy:malpedia="Zeus OpenSSL"*

Zeus OpenSSL is also known as:

- XSphinx

Zeus Sphinx

This family describes the vanilla Zeus-variant that includes TOR (and Polipo proxy). It has an almost 90% overlap with Zeus v2.0.8.9. Please note that IBM X-Force decided to call win.zloader/win.zeus_openssl "Zeus Sphinx", after mentioning it as "a new version of Zeus Sphinx" in their initial post in August 2016. Malpedia thus lists the alias "Zeus XSphinx" for win.zeus_openssl - the X to refer to IBM X-Force.

Zeus Sphinx on the one hand has the following versioning ("slow increase") - 2015/09 v1.0.1.0 (Zeus Sphinx size: 1.5 MB) - 2016/02 v1.0.1.2 (Zeus Sphinx size: 1.5 MB) - 2016/04 v1.0.2.0 (Zeus Sphinx size: 1.5 MB)

Zeus OpenSSL on the other hand has the following versioning ("fast increase") - 2016/05 v1.5.4.0 (Zeus OpenSSL size: 1.2 MB) - 2017/01 v1.14.8.0 (Zeus OpenSSL size: 1.8 MB) - 2017/01 v1.15.0.0 (Zeus OpenSSL size: 2.2 MB)

Zloader

This family describes the (initially small) loader, which downloads Zeus OpenSSL.

In June 2016, a new loader was dubbed DEloader by Fortinet. It has some functions borrowed from Zeus 2.0.8.9 (e.g. the versioning, nrv2b, binstorage-labels), but more importantly, it downloaded a Zeus-like banking trojan (→ Zeus OpenSSL). Furthermore, the loader shared its versioning with the Zeus OpenSSL it downloaded. The initial samples from May 2016 were small (17920 bytes). At some point, visualEncrypt/Decrypt was added, e.g. in v1.11.0.0 (September 2016) with size 27648 bytes. In January 2017 with v1.15.0.0, obfuscation was added, which blew the size up to roughly 80k, and the loader became known as Zloader aka Terdot. These changes may be related to the Moskalvzapoe Distribution Network, which started the distribution of it at the same time.

Please note that IBM X-Force decided to call win.zloader/win.zeus_openssl "Zeus Sphinx", after mentioning it as "a new version of Zeus Sphinx" in their initial post in August 2016. Malpedia thus lists the alias "Zeus XSphinx" for win.zeus_openssl - the X to refer to IBM X-Force.

The tag is: *misp-galaxy:malpedia="Zloader"*

Zloader is also known as:

- DELoader
- SILENTNIGHT
- Terdot

ZXShell

According to FireEye, ZXSHELL is a backdoor that can be downloaded from the internet, particularly Chinese hacker websites. The backdoor can launch port scans, run a keylogger, capture screenshots, set up an HTTP or SOCKS proxy, launch a reverse command shell, cause SYN floods, and transfer/delete/run files. The publicly available version of the tool provides a graphical user interface that malicious actors can use to interact with victim backdoors. Simplified Chinese is the language used for the bundled ZXSHELL documentation.

The tag is: *misp-galaxy:malpedia="ZXShell"*

ZXShell is also known as:

- Sensocode

Zyklon

According to FireEye, Zyklon or Zyklon HTTP is a publicly available, full-featured backdoor capable of keylogging, password harvesting, downloading and executing additional plugins, conducting distributed denial-of-service (DDoS) attacks, and self-updating and self-removal. The malware may communicate with its command and control (C2) server over The Onion Router (Tor) network if configured to do so. The malware can download several plugins, some of which include features such as cryptocurrency mining and password recovery, from browsers and email software. Zyklon also provides a very efficient mechanism to monitor the spread and impact.

The tag is: *misp-galaxy:malpedia="Zyklon"*

Microsoft Activity Group actor

Activity groups as described by Microsoft.

Microsoft Activity Group actor is a cluster galaxy available in JSON format at **this location** The JSON format can be freely reused in your application or automatically enabled in MISP.

authors

Various

PROMETHIUM

PROMETHIUM is an activity group that has been active as early as 2012. The group primarily uses Truvasys, a first-stage malware that has been in circulation for several years. Truvasys has been involved in several attack campaigns, where it has masqueraded as one of server common computer utilities, including WinUtils, TrueCrypt, WinRAR, or SanDisk. In each of the campaigns, Truvasys malware evolved with additional features—this shows a close relationship between the activity groups behind the campaigns and the developers of the malware.

https://blogs.technet.microsoft.com/mmpc/2016/12/14/twin-zero-day-attacks-promethium-and-neodymium-target-individuals-in-europe/

NEODYMIUM

NEODYMIUM is an activity group that is known to use a backdoor malware detected by Microsoft as Wingbird. This backdoor's characteristics closely match FinFisher, a government-grade commercial surveillance package. Data about Wingbird activity indicate that it is typically used to attack individual computers instead of networks.

The tag is: *misp-galaxy:microsoft-activity-group="NEODYMIUM"*

TERBIUM

Microsoft Threat Intelligence identified similarities between this recent attack and previous 2012 attacks against tens of thousands of computers belonging to organizations in the energy sector. Microsoft Threat Intelligence refers to the activity group behind these attacks as TERBIUM, following our internal practice of assigning rogue actors chemical element names.

The tag is: *misp-galaxy:microsoft-activity-group="TERBIUM"*

STRONTIUM

STRONTIUM has been active since at least 2007. Whereas most modern untargeted malware is

ultimately profit-oriented, STRONTIUM mainly seeks sensitive information. Its primary institutional targets have included government bodies, diplomatic institutions, and military forces and installations in NATO member states and certain Eastern European countries. Additional targets have included journalists, political advisors, and organizations associated with political activism in central Asia. STRONTIUM is an activity group that usually targets government agencies, diplomatic institutions, and military organizations, as well as affiliated private sector organizations such as defense contractors and public policy research institutes. Microsoft has attributed more 0-day exploits to STRONTIUM than any other tracked group in 2016. STRONTIUM frequently uses compromised e-mail accounts from one victim to send malicious e-mails to a second victim and will persistently pursue specific targets for months until they are successful in compromising the victims' computer.

The tag is: *misp-galaxy:microsoft-activity-group="STRONTIUM"*

STRONTIUM is also known as:

- APT 28
- APT28
- Pawn Storm
- Fancy Bear
- Sednit
- TsarTeam
- TG-4127
- Group-4127
- Sofacy
- Grey-Cloud

PLATINUM

PLATINUM has been targeting its victims since at least as early as 2009, and may have been active for several years prior. Its activities are distinctly different not only from those typically seen in untargeted attacks, but from many targeted attacks as well. A large share of targeted attacks can be characterized as opportunistic: the activity group changes its target profiles and attack geographies based on geopolitical seasons, and may attack institutions all over the world. Like many such groups, PLATINUM seeks to steal sensitive intellectual property related to government interests, but its range of preferred targets is consistently limited to specific governmental organizations, defense

institutes, intelligence agencies, diplomatic institutions, and telecommunication providers in South and Southeast Asia. The group's persistent use of spear phishing tactics (phishing attempts aimed at specific individuals) and access to previously undiscovered zero-day exploits have made it a highly resilient threat.

BARIUM

Microsoft Threat Intelligence associates Winnti with multiple activity groups—collections of malware, supporting infrastructure, online personas, victimology, and other attack artifacts that the Microsoft intelligent security graph uses to categorize and attribute threat activity. Microsoft labels activity groups using code names derived from elements in the periodic table. In the case of this malware, the activity groups strongly associated with Winnti are BARIUM and LEAD. But even though they share the use of Winnti, the BARIUM and LEAD activity groups are involved in very different intrusion scenarios. BARIUM begins its attacks by cultivating relationships with potential victims—particularly those working in Business Development or Human Resources—on various social media platforms. Once BARIUM has established rapport, they spear-phish the victim using a variety of unsophisticated malware installation vectors, including malicious shortcut (.lnk) files with hidden payloads, compiled HTML help (.chm) files, or Microsoft Office documents containing macros or exploits. Initial intrusion stages feature the Win32/Barlaiy implant—notable for its use of social network profiles, collaborative document editing sites, and blogs for C&C. Later stages of the intrusions rely upon Winnti for persistent access. The majority of victims recorded to date have been in electronic gaming, multimedia, and Internet content industries, although occasional intrusions against technology companies have occurred.

The tag is: *misp-galaxy:microsoft-activity-group="BARIUM"*

View relationships graph

BARIUM has relationships with:

- similar: misp-galaxy:threat-actor="APT41" with estimative-language:likelihood-probability="likely"

Table 5381. Table References

Links
https://blogs.technet.microsoft.com/mmpc/2017/01/25/detecting-threat-actors-in-recent-german-industrial-attacks-with-windows-defender-atp/

LEAD

In contrast, LEAD has established a far greater reputation for industrial espionage. In the past few years, LEAD's victims have included: Multinational, multi-industry companies involved in the manufacture of textiles, chemicals, and electronics Pharmaceutical companies A company in the chemical industry University faculty specializing in aeronautical engineering and research A company involved in the design and manufacture of motor vehicles A cybersecurity company focusing on protecting industrial control systems During these intrusions, LEAD's objective was to steal sensitive data, including research materials, process documents, and project plans. LEAD also steals code-signing certificates to sign its malware in subsequent attacks. In most cases, LEAD's attacks do not feature any advanced exploit techniques. The group also does not make special effort to cultivate victims prior to an attack. Instead, the group often simply emails a Winnti installer to potential victims, relying on basic social engineering tactics to convince recipients to run the attached malware. In some other cases, LEAD gains access to a target by brute-forcing remote access login credentials, performing SQL injection, or exploiting unpatched web servers, and then they copy the Winnti installer directly to compromised machines.

The tag is: *misp-galaxy:microsoft-activity-group="LEAD"*

GALLIUM

Microsoft Threat Intelligence Center (MSTIC) is raising awareness of the ongoing activity by a group we call GALLIUM, targeting telecommunication providers. When Microsoft customers have been targeted by this activity, we notified them directly with the relevant information they need to protect themselves. By sharing the detailed methodology and indicators related to GALLIUM activity, we're encouraging the security community to implement active defenses to secure the broader ecosystem from these attacks. To compromise targeted networks, GALLIUM target unpatched internet-facing services using publicly available exploits and have been known to target vulnerabilities in WildFly/JBoss. Once persistence is established in a network, GALLIUM uses common techniques and tools like Mimikatz to obtain credentials that allows for lateral movement across the target network. Within compromised networks, GALLIUM makes no attempt to obfuscate their intent and are known to use common versions of malware and publicly available toolkits with small modifications. The operators rely on low cost and easy to replace infrastructure that consists of dynamic-DNS domains and regularly reused hop points. This activity from GALLIUM has been identified predominantly through 2018 to mid-2019. GALLIUM is still active; however, activity levels have dropped when compared to what was previously observed.

The tag is: *misp-galaxy:microsoft-activity-group="GALLIUM"*

GALLIUM is also known as:

- Operation Soft Cell

View relationships graph

GALLIUM has relationships with:

- similar: misp-galaxy:threat-actor="Operation Soft Cell" with estimative-language:likelihood-probability="likely"
- similar: misp-galaxy:threat-actor="GALLIUM" with estimative-language:likelihood-probability="almost-certain"

PARINACOTA

One actor that has emerged in this trend of human-operated attacks is an active, highly adaptive group that frequently drops Wadhrama as payload. PARINACOTA impacts three to four organizations every week and appears quite resourceful: during the 18 months that we have been monitoring it, we have observed the group change tactics to match its needs and use compromised machines for various purposes, including cryptocurrency mining, sending spam emails, or proxying for other attacks. The group's goals and payloads have shifted over time, influenced by the type of compromised infrastructure, but in recent months, they have mostly deployed the Wadhrama ransomware. The group most often employs a smash-and-grab method, whereby they attempt to infiltrate a machine in a network and proceed with subsequent ransom in less than an hour. There are outlier campaigns in which they attempt reconnaissance and lateral movement, typically when they land on a machine and network that allows them to quickly and easily move throughout the environment. PARINACOTA's attacks typically brute forces their way into servers that have Remote Desktop Protocol (RDP) exposed to the internet, with the goal of moving laterally inside a network or performing further brute-force activities against targets outside the network. This allows the group to expand compromised infrastructure under their control. Frequently, the group targets built-in local administrator accounts or a list of common account names. In other instances, the group targets Active Directory (AD) accounts that they compromised or have prior knowledge of, such as service accounts of known vendors. The group adopted the RDP brute force technique that the older ransomware called Samas (also known as SamSam) infamously used. Other malware families like GandCrab, MegaCortext, LockerGoga, Hermes, and RobbinHood have also used this method in targeted ransomware attacks. PARINACOTA, however, has also been observed to adapt to any path of least resistance they can utilize. For instance, they sometimes discover unpatched systems and use disclosed vulnerabilities to gain initial access or elevate privileges.

The tag is: *misp-galaxy:microsoft-activity-group="PARINACOTA"*

View relationships graph

PARINACOTA has relationships with:

- uses: misp-galaxy:ransomware="Wadhrama" with estimative-language:likelihood-probability="likely"
- similar: misp-galaxy:threat-actor="PARINACOTA" with estimative-language:likelihood-probability="almost-certain"

GADOLINIUM

GADOLINIUM is a nation-state activity group that has been compromising targets for nearly a decade with a worldwide focus on the maritime and health industries. As with most threat groups, GADOLINIUM tracks the tools and techniques of security practitioners looking for new techniques they can use or modify to create new exploit methods. Historically, GADOLINIUM used custom-crafted malware families that analysts can identify and defend against. In response, over the last year GADOLINIUM has begun to modify portions of its toolchain to use open-source toolkits to obfuscate their activity and make it more difficult for analysts to track. Because cloud services frequently offer a free trial or one-time payment (PayGo) account offerings, malicious actors have found ways to take advantage of these legitimate business offerings. By establishing free or PayGo accounts, they can use cloud-based technology to create a malicious infrastructure that can be established quickly then taken down before detection or given up at little cost.

The tag is: *misp-galaxy:microsoft-activity-group="GADOLINIUM"*

View relationships graph

GADOLINIUM has relationships with:

- similar: misp-galaxy:threat-actor="APT40" with estimative-language:likelihood-probability="likely"

HAFNIUM

HAFNIUM primarily targets entities in the United States across a number of industry sectors, including infectious disease researchers, law firms, higher education institutions, defense contractors, policy think tanks, and NGOs. HAFNIUM has previously compromised victims by exploiting vulnerabilities in internet-facing servers, and has used legitimate open-source frameworks, like Covenant, for command and control. Once they’ve gained access to a victim network, HAFNIUM typically exfiltrates data to file sharing sites like MEGA. In campaigns unrelated to these vulnerabilities, Microsoft has observed HAFNIUM interacting with victim Office 365 tenants. While they are often unsuccessful in compromising customer accounts, this reconnaissance activity helps the adversary identify more details about their targets’ environments. HAFNIUM operates primarily from leased virtual private servers (VPS) in the United States.

Misinformation Pattern

AM!TT Technique.

Misinformation Pattern is a cluster galaxy available in JSON format at **this location** The JSON format can be freely reused in your application or automatically enabled in MISP.

authors

misinfosecproject

5Ds (dismiss, distort, distract, dismay, divide)

Nimmo's "4Ds of propaganda": dismiss, distort, distract, dismay (MisinfosecWG added divide in 2019). Misinformation promotes an agenda by advancing narratives supportive of that agenda. This is most effective when the advanced narrative pre-dates the revelation of the specific misinformation content. But this is often not possible.

The tag is: *misp-galaxy:amitt-misinformation-pattern="5Ds (dismiss, distort, distract, dismay, divide)"*

Facilitate State Propaganda

Organize citizens around pro-state messaging. Paid or volunteer groups coordinated to push state propaganda (examples include 2016 Diba Facebook Expedition, coordinated to overcome China's Great Firewall to flood the Facebook pages of Taiwanese politicians and news agencies with a pro-PRC message).

The tag is: *misp-galaxy:amitt-misinformation-pattern="Facilitate State Propaganda"*

Leverage Existing Narratives

Use or adapt existing narrative themes, where narratives are the baseline stories of a target

audience. Narratives form the bedrock of our worldviews. New information is understood through a process firmly grounded in this bedrock. If new information is not consitent with the prevailing narratives of an audience, it will be ignored. Effective campaigns will frame their misinformation in the context of these narratives. Highly effective campaigns will make extensive use of audience-appropriate archetypes and meta-narratives throughout their content creation and amplifiction practices. Examples include midwesterners are generous, Russia is under attack from outside.

The tag is: *misp-galaxy:amitt-misinformation-pattern="Leverage Existing Narratives"*

Table 5456. Table References

Competing Narratives

Advance competing narratives connected to same issue ie: on one hand deny incident while at same time expresses dismiss. MH17 (example) "Russian Foreign Ministry again claimed that “absolutely groundless accusations are put forward against the Russian side, which are aimed at discrediting Russia in the eyes of the international community" (deny); "The Dutch MH17 investigation is biased, anti-Russian and factually inaccurate" (dismiss).

Suppressing or discouraging narratives already spreading requires an alternative. The most simple set of narrative techniques in response would be the construction and promotion of contradictory alternatives centered on denial, deflection, dismissal, counter-charges, excessive standards of proof, bias in prohibition or enforcement, and so on.

These competing narratives allow loyalists cover, but are less compelling to opponents and fence-sitters than campaigns built around existing narratives or highly explanatory master narratives. Competing narratives, as such, are especially useful in the "firehose of misinformation" approach.

The tag is: *misp-galaxy:amitt-misinformation-pattern="Competing Narratives"*
