Timestomp - T1099

Adversaries may take actions to hide the deployment of new, or modification of existing files to obfuscate their activities. Timestomping is a technique that modifies the timestamps of a file (the modify, access, create, and change times), often to mimic files that are in the same folder. This is done, for example, on files that have been modified or created by the adversary so that they do not appear conspicuous to forensic investigators or file analysis tools. Timestomping may be used along with file name [Masquerading](https://attack.mitre.org/techniques/T1036) to hide malware and tools. (Citation: WindowsIR Anti-Forensic Techniques)

Regsvr32 - T1117

Regsvr32.exe is a command-line program used to register and unregister object linking and embedding controls, including dynamic link libraries (DLLs), on Windows systems. Regsvr32.exe can be used to execute arbitrary binaries. (Citation: Microsoft Regsvr32)

Adversaries may take advantage of this functionality to proxy execution of code to avoid triggering security tools that may not monitor execution of, and modules loaded by, the regsvr32.exe process because of whitelists or false positives from Windows using regsvr32.exe for normal operations. Regsvr32.exe is also a Microsoft signed binary.

Regsvr32.exe can also be used to specifically bypass process whitelisting using functionality to load COM scriptlets to execute DLLs under user permissions. Since regsvr32.exe is network and proxy aware, the scripts can be loaded by passing a uniform resource locator (URL) to file on an external Web server as an argument during invocation. This method makes no changes to the Registry as the COM object is not actually registered, only executed. (Citation: LOLBAS Regsvr32) This variation of the technique is often referred to as a "Squiblydoo" attack and has been used in campaigns targeting governments. (Citation: Carbon Black Squiblydoo Apr 2016) (Citation: FireEye Regsvr32 Targeting Mongolian Gov)

Regsvr32.exe can also be leveraged to register a COM Object used to establish Persistence via [Component Object Model Hijacking](https://attack.mitre.org/techniques/T1122). (Citation: Carbon Black Squiblydoo Apr 2016)

InstallUtil - T1118

InstallUtil is a command-line utility that allows for installation and uninstallation of resources by executing specific installer components specified in .NET binaries. (Citation: MSDN InstallUtil) InstallUtil is located in the .NET directories on a Windows system: <code>C:\Windows\Microsoft.NET\Framework\v<version>\InstallUtil.exe</code> and <code>C:\Windows\Microsoft.NET\Framework64\v<version>\InstallUtil.exe</code>. InstallUtil.exe is digitally signed by Microsoft.

Adversaries may use InstallUtil to proxy execution of code through a trusted Windows utility. InstallUtil may also be used to bypass process whitelisting through use of attributes within the binary that execute the class decorated with the attribute <code>[System.ComponentModel.RunInstaller(true)]</code>. (Citation: LOLBAS Installutil)

CMSTP - T1191

The Microsoft Connection Manager Profile Installer (CMSTP.exe) is a command-line program used to install Connection Manager service profiles. (Citation: Microsoft Connection Manager Oct 2009) CMSTP.exe accepts an installation information file (INF) as a parameter and installs a service profile leveraged for remote access connections.

Adversaries may supply CMSTP.exe with INF files infected with malicious commands. (Citation: Twitter CMSTP Usage Jan 2018) Similar to [Regsvr32](https://attack.mitre.org/techniques/T1117) / ”Squiblydoo”, CMSTP.exe may be abused to load and execute DLLs (Citation: MSitPros CMSTP Aug 2017) and/or COM scriptlets (SCT) from remote servers. (Citation: Twitter CMSTP Jan 2018) (Citation: GitHub Ultimate AppLocker Bypass List) (Citation: Endurant CMSTP July 2018) This execution may also bypass AppLocker and other whitelisting defenses since CMSTP.exe is a legitimate, signed Microsoft application.

CMSTP.exe can also be abused to [Bypass User Account Control](https://attack.mitre.org/techniques/T1088) and execute arbitrary commands from a malicious INF through an auto-elevated COM

interface. (Citation: MSitPros CMSTP Aug 2017) (Citation: GitHub Ultimate AppLocker Bypass List) (Citation: Endurant CMSTP July 2018)

Keychain - T1142

Keychains are the built-in way for macOS to keep track of users' passwords and credentials for many services and features such as WiFi passwords, websites, secure notes, certificates, and Kerberos. Keychain files are located in <code>~/Library/Keychains/</code>,<code>/Library/Keychains/</code>, and <code>/Network/Library/Keychains/</code>. (Citation: Wikipedia keychain) The <code>security</code> command-line utility, which is built into macOS by default, provides a useful way to manage these credentials.

To manage their credentials, users have to use additional credentials to access their keychain. If an adversary knows the credentials for the login keychain, then they can get access to all the other credentials stored in this vault. (Citation: External to DA, the OS X Way) By default, the passphrase for the keychain is the user’s logon credentials.

https://en.wikipedia.org/wiki/Keychain_(software)

Launchctl - T1152

Launchctl controls the macOS launchd process which handles things like launch agents and launch

daemons, but can execute other commands or programs itself. Launchctl supports taking subcommands on the command-line, interactively, or even redirected from standard input. By loading or reloading launch agents or launch daemons, adversaries can install persistence or execute changes they made (Citation: Sofacy Komplex Trojan). Running a command from launchctl is as simple as <code>launchctl submit -l <labelName> — /Path/to/thing/to/execute "arg" "arg" "arg"</code>. Loading, unloading, or reloading launch agents or launch daemons can require elevated privileges.

Adversaries can abuse this functionality to execute code or even bypass whitelisting if launchctl is an allowed process.

The tag is: *misp-galaxy:mitre-attack-pattern="Launchctl - T1152"*

Table 6801. Table References

Source - T1153

This technique has been deprecated and should no longer be used.

The <code>source</code> command loads functions into the current shell or executes files in the current context. This built-in command can be run in two different ways <code>source /path/to/filename [arguments]</code> or <code>.**This technique has been deprecated and should no longer be used.** /path/to/filename [arguments]</code>. Take note of the space after the ".". Without a space, a new shell is created that runs the program instead of running the program within the current context. This is often used to make certain features or functions available to a shell or to update a specific shell's environment.(Citation: Source Manual)

Adversaries can abuse this functionality to execute programs. The file executed with this technique does not need to be marked executable beforehand.

The tag is: *misp-galaxy:mitre-attack-pattern="Source - T1153"*

Table 6802. Table References

Links
https://attack.mitre.org/techniques/T1153
https://ss64.com/bash/source.html

Trap - T1154

The <code>trap</code> command allows programs and shells to specify commands that will be executed upon receiving interrupt signals. A common situation is a script allowing for graceful termination and handling of common keyboard interrupts like <code>ctrl+c</code> and <code>ctrl+d</code>. Adversaries can use this to register code to be executed when the shell

encounters specific interrupts either to gain execution or as a persistence mechanism. Trap commands are of the following format <code>trap 'command list' signals</code> where "command list" will be executed when "signals" are received.(Citation: Trap Manual)(Citation: Cyberciti Trap Statements)

The tag is: *misp-galaxy:mitre-attack-pattern="Trap - T1154"*

https://ss64.com/bash/trap.html

HISTCONTROL - T1148

The <code>HISTCONTROL</code> environment variable keeps track of what should be saved by the <code>history</code> command and eventually into the <code>~/.bash_history</code> file when a user logs out. This setting can be configured to ignore commands that start with a space by simply setting it to "ignorespace". <code>HISTCONTROL</code> can also be set to ignore duplicate commands by setting it to "ignoredups". In some Linux systems, this is set by default to "ignoreboth" which covers both of the previous examples. This means that “ ls” will not be saved, but “ls” would be saved by history. <code>HISTCONTROL</code> does not exist by default on macOS, but can be set by the user and will be respected. Adversaries can use this to operate without leaving traces by simply prepending a space to all of their terminal commands.

The tag is: *misp-galaxy:mitre-attack-pattern="HISTCONTROL - T1148"*

Table 6804. Table References

Defacement - T1491

Adversaries may modify visual content available internally or externally to an enterprise network, thus affecting the integrity of the original content. Reasons for [Defacement](https://attack.mitre.org/techniques/T1491) include delivering messaging, intimidation, or claiming (possibly false) credit for an intrusion. Disturbing or offensive images may be used as a part of [Defacement](https://attack.mitre.org/techniques/T1491) in order to cause user discomfort, or to pressure compliance with accompanying messages.

The tag is: *misp-galaxy:mitre-attack-pattern="Defacement - T1491"*

Table 6805. Table References

Links

https://attack.mitre.org/techniques/T1491

AppleScript - T1155

macOS and OS X applications send AppleEvent messages to each other for interprocess communications (IPC). These messages can be easily scripted with AppleScript for local or remote IPC. Osascript executes AppleScript and any other Open Scripting Architecture (OSA) language scripts. A list of OSA languages installed on a system can be found by using the <code>osalang</code> program. AppleEvent messages can be sent independently or as part of a script. These events can locate open windows, send keystrokes, and interact with almost any open application locally or remotely.

Adversaries can use this to interact with open SSH connection, move to remote machines, and even present users with fake dialog boxes. These events cannot start applications remotely (they can start them locally though), but can interact with applications if they're already running remotely. Since this is a scripting language, it can be used to launch more common techniques as well such as a reverse shell via python (Citation: Macro Malware Targets Macs). Scripts can be run from the command-line via <code>osascript /path/to/script</code> or <code>osascript -e "script here"</code>.

The tag is: *misp-galaxy:mitre-attack-pattern="AppleScript - T1155"*

Geofencing - T1581

Adversaries may use a device's geographical location to limit certain malicious behaviors. For example, malware operators may limit the distribution of a second stage payload to certain geographic regions.(Citation: Lookout eSurv)

[Geofencing](https://attack.mitre.org/techniques/T1581) is accomplished by persuading the user to grant the application permission to access location services. The application can then collect, process, and exfiltrate the device's location to perform location-based actions, such as ceasing malicious behavior or showing region-specific advertisements.

One method to accomplish [Geofencing](https://attack.mitre.org/techniques/T1581) on Android is to use the built-in Geofencing API to automatically trigger certain behaviors when the device enters or exits a specified radius around a geographical location. Similar to other [Geofencing](https://attack.mitre.org/techniques/T1581) methods, this requires that the user has granted the `ACCESS_FINE_LOCATION` and `ACCESS_BACKGROUND_LOCATION` permissions. The latter is only required if the application targets Android 10 (API level 29) or higher. However, Android 11 introduced additional permission controls that may restrict background location collection based on user permission choices at runtime. These additional controls include "Allow only while using the app", which will effectively prohibit background location collection.(Citation: Android

Geofencing API)

Similarly, on iOS, developers can use built-in APIs to setup and execute geofencing. Depending on the use case, the app will either need to call `requestWhenInUseAuthorization()` or `requestAlwaysAuthorization()`, depending on when access to the location services is required. Similar to Android, users also have the option to limit when the application can access the device's location, including one-time use and only when the application is running in the foreground.(Citation: Apple Location Services)

[Geofencing](https://attack.mitre.org/techniques/T1581) can be used to prevent exposure of capabilities in environments that are not intended to be compromised or operated within. For example, location data could be used to limit malware spread and/or capabilities, which could also potentially evade application analysis environments (ex: malware analysis outside of the target geographic area). Other malicious usages could include showing language-specific [Input Prompt](https://attack.mitre.org/techniques/T1411)s and/or advertisements.

The tag is: *misp-galaxy:mitre-attack-pattern="Geofencing - T1581"*

Emond - T1519

Adversaries may use Event Monitor Daemon (emond) to establish persistence by scheduling malicious commands to run on predictable event triggers. Emond is a [Launch Daemon](https://attack.mitre.org/techniques/T1160) that accepts events from various services, runs them through a simple rules engine, and takes action. The emond binary at <code>/sbin/emond</code> will load any rules from the <code>/etc/emond.d/rules/</code> directory and take action once an explicitly defined event takes place. The rule files are in the plist format and define the name, event type, and action to take. Some examples of event types include system startup and user authentication. Examples of actions are to run a system command or send an email. The emond service will not launch if there is no file present in the QueueDirectories path <code>/private/var/db/emondClients</code>, specified in the [Launch Daemon](https://attack.mitre.org/techniques/T1160) configuration file at<code>/System/Library/LaunchDaemons/com.apple.emond.plist</code>.(Citation: xorrior emond Jan 2018)(Citation: magnusviri emond Apr 2016)(Citation: sentinelone macos persist Jun 2019)

Adversaries may abuse this service by writing a rule to execute commands when a defined event occurs, such as system start up or user authentication.(Citation: xorrior emond Jan 2018)(Citation: magnusviri emond Apr 2016)(Citation: sentinelone macos persist Jun 2019) Adversaries may also be able to escalate privileges from administrator to root as the emond service is executed with root

privileges by the [Launch Daemon](https://attack.mitre.org/techniques/T1160) service.

The tag is: *misp-galaxy:mitre-attack-pattern="Emond - T1519"*

https://www.xorrior.com/emond-persistence/

Hooking - T1617

Adversaries may utilize hooking to hide the presence of artifacts associated with their behaviors to evade detection. Hooking can be used to modify return values or data structures of system APIs and function calls. This process typically involves using 3rd party root frameworks, such as Xposed or Magisk, with either a system exploit or pre-existing root access. By including custom modules for root frameworks, adversaries can hook system APIs and alter the return value and/or system data structures to alter functionality/visibility of various aspects of the system.

The tag is: *misp-galaxy:mitre-attack-pattern="Hooking - T1617"*

Table 6809. Table References

Links
https://attack.mitre.org/techniques/T1617

Sudo - T1169

The sudoers file, <code>/etc/sudoers</code>, describes which users can run which commands and from which terminals. This also describes which commands users can run as other users or groups. This provides the idea of least privilege such that users are running in their lowest possible permissions for most of the time and only elevate to other users or permissions as needed, typically by prompting for a password. However, the sudoers file can also specify when to not prompt users for passwords with a line like <code>user1 ALL=(ALL) NOPASSWD: ALL</code> (Citation: OSX.Dok Malware).

Adversaries can take advantage of these configurations to execute commands as other users or spawn processes with higher privileges. You must have elevated privileges to edit this file though.

The tag is: *misp-galaxy:mitre-attack-pattern="Sudo - T1169"*

Table 6810. Table References

Links
https://attack.mitre.org/techniques/T1169

Hooking - T1179

Windows processes often leverage application programming interface (API) functions to perform tasks that require reusable system resources. Windows API functions are typically stored in dynamic-link libraries (DLLs) as exported functions.

Hooking involves redirecting calls to these functions and can be implemented via:

- **Hooks procedures**, which intercept and execute designated code in response to events such as messages, keystrokes, and mouse inputs. (Citation: Microsoft Hook Overview) (Citation: Elastic Process Injection July 2017)
- **Import address table (IAT) hooking**, which use modifications to a process's IAT, where pointers to imported API functions are stored. (Citation: Elastic Process Injection July 2017) (Citation: Adlice Software IAT Hooks Oct 2014) (Citation: MWRInfoSecurity Dynamic Hooking 2015)
- **Inline hooking**, which overwrites the first bytes in an API function to redirect code flow. (Citation: Elastic Process Injection July 2017) (Citation: HighTech Bridge Inline Hooking Sept 2011) (Citation: MWRInfoSecurity Dynamic Hooking 2015)

Similar to [Process Injection](https://attack.mitre.org/techniques/T1055), adversaries may use hooking to load and execute malicious code within the context of another process, masking the execution while also allowing access to the process's memory and possibly elevated privileges. Installing hooking mechanisms may also provide Persistence via continuous invocation when the functions are called through normal use.

Malicious hooking mechanisms may also capture API calls that include parameters that reveal user authentication credentials for Credential Access. (Citation: Microsoft TrojanSpy:Win32/Ursnif.gen!I Sept 2017)

Hooking is commonly utilized by [Rootkit](https://attack.mitre.org/techniques/T1014)s to conceal files, processes, Registry keys, and other objects in order to hide malware and associated behaviors. (Citation: Symantec Windows Rootkits)

Masquerading - T1655

Adversaries may attempt to manipulate features of their artifacts to make them appear legitimate or benign to users and/or security tools. Masquerading occurs when the name, location, or appearance of an object, legitimate or malicious, is manipulated or abused for the sake of evading defenses and observation. This may include manipulating file metadata, tricking users into misidentifying the file type, and giving legitimate task or service names.

Renaming abusable system utilities to evade security monitoring is also a form of [Masquerading](https://attack.mitre.org/techniques/T1655)

The tag is: *misp-galaxy:mitre-attack-pattern="Masquerading - T1655"*

Impersonation - T1656

Adversaries may impersonate a trusted person or organization in order to persuade and trick a target into performing some action on their behalf. For example, adversaries may communicate with victims (via [Phishing for Information](https://attack.mitre.org/techniques/T1598), [Phishing](https://attack.mitre.org/techniques/T1566), or [Internal Spearphishing](https://attack.mitre.org/techniques/T1534)) while impersonating a known sender such as an executive, colleague, or third-party vendor. Established trust can then be leveraged to accomplish an adversary's ultimate goals, possibly against multiple victims.

In many cases of business email compromise or email fraud campaigns, adversaries use impersonation to defraud victims — deceiving them into sending money or divulging information that ultimately enables [Financial Theft](https://attack.mitre.org/techniques/T1657).

Adversaries will often also use social engineering techniques such as manipulative and persuasive language in email subject lines and body text such as `payment`, `request`, or `urgent` to push the victim to act quickly before malicious activity is detected. These campaigns are often specifically targeted against people who, due to job roles and/or accesses, can carry out the adversary's goal.

Impersonation is typically preceded by reconnaissance techniques such as [Gather Victim Identity Information](https://attack.mitre.org/techniques/T1589) and [Gather Victim Org Information](https://attack.mitre.org/techniques/T1591) as well as acquiring infrastructure such as email domains (i.e. [Domains](https://attack.mitre.org/techniques/T1583/001)) to substantiate their false identity.(Citation: CrowdStrike-BEC)

There is the potential for multiple victims in campaigns involving impersonation. For example, an adversary may [Compromise Accounts](https://attack.mitre.org/techniques/T1586) targeting one organization which can then be used to support impersonation against other entities.(Citation: VEC)

The tag is: *misp-galaxy:mitre-attack-pattern="Impersonation - T1656"*

https://www.crowdstrike.com/cybersecurity-101/business-email-compromise-bec/

Phishing - T1566

Adversaries may send phishing messages to gain access to victim systems. All forms of phishing are electronically delivered social engineering. Phishing can be targeted, known as spearphishing. In spearphishing, a specific individual, company, or industry will be targeted by the adversary. More generally, adversaries can conduct non-targeted phishing, such as in mass malware spam campaigns.

Adversaries may send victims emails containing malicious attachments or links, typically to execute malicious code on victim systems. Phishing may also be conducted via third-party services, like social media platforms. Phishing may also involve social engineering techniques, such as posing as a trusted source, as well as evasive techniques such as removing or manipulating emails or metadata/headers from compromised accounts being abused to send messages (e.g., [Email Hiding Rules](https://attack.mitre.org/techniques/T1564/008)).(Citation: Microsoft OAuth Spam 2022)(Citation: Palo Alto Unit 42 VBA Infostealer 2014) Another way to accomplish this is by [Email Spoofing](https://attack.mitre.org/techniques/T1672)(Citation: Proofpoint-spoof) the identity of the sender, which can be used to fool both the human recipient as well as automated security tools,(Citation: cyberproof-double-bounce) or by including the intended target as a party to an existing email thread that includes malicious files or links (i.e., "thread hijacking").(Citation: phishing-krebs)

Victims may also receive phishing messages that instruct them to call a phone number where they are directed to visit a malicious URL, download malware,(Citation: sygnia Luna Month)(Citation: CISA Remote Monitoring and Management Software) or install adversary-accessible remote management tools onto their computer (i.e., [User Execution](https://attack.mitre.org/techniques/T1204)).(Citation: Unit42 Luna Moth)

Keychain - T1579

Adversaries may collect the keychain storage data from an iOS device to acquire credentials. Keychains are the built-in way for iOS to keep track of users' passwords and credentials for many services and features such as Wi-Fi passwords, websites, secure notes, certificates, private keys, and VPN credentials.

On the device, the keychain database is stored outside of application sandboxes to prevent unauthorized access to the raw data. Standard iOS APIs allow applications access to their own keychain contained within the database. By utilizing a privilege escalation exploit or existing root access, an adversary can access the entire encrypted database.(Citation: Apple Keychain Services)(Citation: Elcomsoft Decrypt Keychain)

Exfiltration Over Command and Control Channel Mitigation - T1041

Mitigations for command and control apply. Network intrusion detection and prevention systems that use network signatures to identify traffic for specific adversary malware can be used to mitigate activity at the network level. Signatures are often for unique indicators within protocols and may be based on the specific obfuscation technique used by a particular adversary or tool, and will likely be different across various malware families and versions. Adversaries will likely change tool command and control signatures over time or construct protocols in such a way to avoid detection by common defensive tools. Disable or Remove Feature or Program - M1042

Disable or remove unnecessary and potentially vulnerable software, features, or services to reduce the attack surface and prevent abuse by adversaries. This involves identifying software or features that are no longer needed or that could be exploited and ensuring they are either removed or properly disabled. This mitigation can be implemented through the following measures:

Remove Legacy Software:

- Use Case: Disable or remove older versions of software that no longer receive updates or security patches (e.g., legacy Java, Adobe Flash).
- Implementation: A company removes Flash Player from all employee systems after it has reached its end-of-life date.

Disable Unused Features:

- Use Case: Turn off unnecessary operating system features like SMBv1, Telnet, or RDP if they are not required.
- Implementation: Disable SMBv1 in a Windows environment to mitigate vulnerabilities like EternalBlue.

Control Applications Installed by Users:

- Use Case: Prevent users from installing unauthorized software via group policies or other management tools.
- Implementation: Block user installations of unauthorized file-sharing applications (e.g., BitTorrent clients) in an enterprise environment.

Remove Unnecessary Services:

- Use Case: Identify and disable unnecessary default services running on endpoints, servers, or network devices.
- Implementation: Disable unused administrative shares (e.g., C$, ADMIN$) on workstations.

Restrict Add-ons and Plugins:

- Use Case: Remove or disable browser plugins and add-ons that are not needed for business purposes.
- Implementation: Disable Java and ActiveX plugins in web browsers to prevent drive-by attacks.

Limit Access to Resource Over Network - M1035

Restrict access to network resources, such as file shares, remote systems, and services, to only those users, accounts, or systems with a legitimate business requirement. This can include employing technologies like network concentrators, RDP gateways, and zero-trust network access (ZTNA) models, alongside hardening services and protocols. This mitigation can be implemented through the following measures:

Audit and Restrict Access:

- Regularly audit permissions for file shares, network services, and remote access tools.
- Remove unnecessary access and enforce least privilege principles for users and services.
- Use Active Directory and IAM tools to restrict access based on roles and attributes.

Deploy Secure Remote Access Solutions:

- Use RDP gateways, VPN concentrators, and ZTNA solutions to aggregate and secure remote access connections.
- Configure access controls to restrict connections based on time, device, and user identity.
- Enforce MFA for all remote access mechanisms.

Disable Unnecessary Services:

- Identify running services using tools like netstat (Windows/Linux) or Nmap.
- Disable unused services, such as Telnet, FTP, and legacy SMB, to reduce the attack surface.
- Use firewall rules to block traffic on unused ports and protocols.

Network Segmentation and Isolation:

- Use VLANs, firewalls, or micro-segmentation to isolate critical network resources from general

access.

- Restrict communication between subnets to prevent lateral movement.

Monitor and Log Access:

- Monitor access attempts to file shares, RDP, and remote network resources using SIEM tools.
- Enable auditing and logging for successful and failed attempts to access restricted resources.

Tools for Implementation

File Share Management:

- Microsoft Active Directory Group Policies
- Samba (Linux/Unix file share management)
- AccessEnum (Windows access auditing tool)

Secure Remote Access:

- Microsoft Remote Desktop Gateway
- Apache Guacamole (open-source RDP/VNC gateway)
- Zero Trust solutions: Tailscale, Cloudflare Zero Trust

Service and Protocol Hardening:

- Nmap or Nessus for network service discovery
- Windows Group Policy Editor for disabling SMBv1, Telnet, and legacy protocols
- iptables or firewalld (Linux) for blocking unnecessary traffic

Network Segmentation:

- pfSense for open-source network isolation

Image File Execution Options Injection Mitigation - T1183

This type of attack technique cannot be easily mitigated with preventive controls since it is based on the abuse of operating system design features. For example, mitigating all IFEO will likely have unintended side effects, such as preventing legitimate software (i.e., security products) from operating properly. (Citation: Microsoft IFEOorMalware July 2015) Efforts should be focused on preventing adversary tools from running earlier in the chain of activity and on identifying subsequent malicious behavior.

Identify and block potentially malicious software that may be executed through IFEO by using whitelisting (Citation: Beechey 2010) tools, like AppLocker, (Citation: Windows Commands JPCERT) (Citation: NSA MS AppLocker) that are capable of auditing and/or blocking unknown executables.

Table 6834. Table References

Links
https://attack.mitre.org/mitigations/T1070

Exploitation of Remote Services Mitigation - T1210

Segment networks and systems appropriately to reduce access to critical systems and services to controlled methods. Minimize available services to only those that are necessary. Regularly scan the internal network for available services to identify new and potentially vulnerable services. Minimize permissions and access for service accounts to limit impact of exploitation.

Update software regularly by employing patch management for internal enterprise endpoints and servers. Develop a robust cyber threat intelligence capability to determine what types and levels of threat may use software exploits and 0-days against a particular organization. Make it difficult for adversaries to advance their operation through exploitation of undiscovered or unpatched vulnerabilities by using sandboxing, if available. Other types of virtualization and application

microsegmentation may also mitigate the impact of some types of exploitation. The risks of additional exploits and weaknesses in implementation may still exist. (Citation: Ars Technica Pwn2Own 2017 VM Escape)

Security applications that look for behavior used during exploitation such as Windows Defender Exploit Guard (WDEG) and the Enhanced Mitigation Experience Toolkit (EMET) can be used to mitigate some exploitation behavior. (Citation: TechNet Moving Beyond EMET) Control flow integrity checking is another way to potentially identify and stop a software exploit from occurring. (Citation: Wikipedia Control Flow Integrity) Many of these protections depend on the architecture and target application binary for compatibility and may not work for all software or services targeted.

Restrict File and Directory Permissions - M1022

Restricting file and directory permissions involves setting access controls at the file system level to limit which users, groups, or processes can read, write, or execute files. By configuring permissions appropriately, organizations can reduce the attack surface for adversaries seeking to access sensitive data, plant malicious code, or tamper with system files.

Enforce Least Privilege Permissions:

- Remove unnecessary write permissions on sensitive files and directories.
- Use file ownership and groups to control access for specific roles.

Example (Windows): Right-click the shared folder → Properties → Security tab → Adjust permissions for NTFS ACLs.

Harden File Shares:

- Disable anonymous access to shared folders.
- Enforce NTFS permissions for shared folders on Windows.

Example: Set permissions to restrict write access to critical files, such as system executables (e.g., `/bin` or `/sbin` on Linux). Use tools like `chown` and `chmod` to assign file ownership and limit access.

On Linux, apply: `chmod 750 /etc/sensitive.conf chown root:admin /etc/sensitive.conf`

File Integrity Monitoring (FIM):

- Use tools like Tripwire, Wazuh, or OSSEC to monitor changes to critical file permissions.

Audit File System Access:

- Enable auditing to track permission changes or unauthorized access attempts.
- Use auditd (Linux) or Event Viewer (Windows) to log activities.

Restrict Startup Directories:

- Configure permissions to prevent unauthorized writes to directories like `C:\ProgramData\Microsoft\Windows\Start Menu`.

Example: Restrict write access to critical directories like `/etc/`, `/usr/local/`, and Windows directories such as `C:\Windows\System32`.

- On Windows, use icacls to modify permissions: `icacls "C:\Windows\System32" /inheritance:r /grant:r SYSTEM:(OI)(CI)F`
- On Linux, monitor permissions using tools like `lsattr` or `auditd`.

File System Permissions Weakness Mitigation - T1044

Use auditing tools capable of detecting file system permissions abuse opportunities on systems within an enterprise and correct them. Limit privileges of user accounts and groups so that only authorized administrators can interact with service changes and service binary target path locations. Toolkits like the PowerSploit framework contain PowerUp modules that can be used to explore systems for service file system permissions weaknesses. (Citation: Powersploit)

Identify and block potentially malicious software that may be executed through abuse of file, directory, and service permissions by using whitelisting (Citation: Beechey 2010) tools, like AppLocker, (Citation: Windows Commands JPCERT) (Citation: NSA MS AppLocker) that are capable of auditing and/or blocking unknown programs. Deny execution from user directories such as file download directories and temp directories where able. (Citation: Seclists Kanthak 7zip Installer)

Turn off UAC's privilege elevation for standard users <code>[HKEY_LOCAL_MACHINE\SOFTWARE\Microsoft\Windows\CurrentVersion\Policies\System]</code>to automatically deny elevation requests, add: <code>"ConsentPromptBehaviorUser"=dword:00000000</code> (Citation: Seclists Kanthak 7zip Installer). Consider enabling installer detection for all users by adding:

<code>"EnableInstallerDetection"=dword:00000001</code>. This will prompt for a password for installation and also log the attempt. To disable installer detection, instead add: <code>"EnableInstallerDetection"=dword:00000000</code>. This may prevent potential elevation of privileges through exploitation during the process of UAC detecting the installer, but will allow the installation process to continue without being logged.

Exploitation for Privilege Escalation Mitigation - T1068

Update software regularly by employing patch management for internal enterprise endpoints and servers. Develop a robust cyber threat intelligence capability to determine what types and levels of threat may use software exploits and 0-days against a particular organization. Make it difficult for adversaries to advance their operation through exploitation of undiscovered or unpatched vulnerabilities by using sandboxing, if available. Other types of virtualization and application microsegmentation may also mitigate the impact of some types of client-side exploitation. The risks of additional exploits and weaknesses in implementation may still exist. (Citation: Ars Technica Pwn2Own 2017 VM Escape)

Security applications that look for behavior used during exploitation such as Windows Defender Exploit Guard (WDEG) and the Enhanced Mitigation Experience Toolkit (EMET) can be used to mitigate some exploitation behavior. (Citation: TechNet Moving Beyond EMET) Control flow integrity checking is another way to potentially identify and stop a software exploit from occurring. (Citation: Wikipedia Control Flow Integrity) Many of these protections depend on the architecture and target application binary for compatibility and may not work for software components targeted for privilege escalation.

Extra Window Memory Injection Mitigation - T1181

This type of attack technique cannot be easily mitigated with preventive controls since it is based on the abuse of operating system design features. For example, mitigating specific API calls will likely have unintended side effects, such as preventing legitimate software (i.e., security products) from operating properly. Efforts should be focused on preventing adversary tools from running earlier in the chain of activity and on identifying subsequent malicious behavior.

Although EWM injection may be used to evade certain types of defenses, it is still good practice to identify potentially malicious software that may be used to perform adversarial actions and audit and/or block it by using whitelisting (Citation: Beechey 2010) tools, like AppLocker, (Citation: Windows Commands JPCERT) (Citation: NSA MS AppLocker) or Software Restriction Policies (Citation: Corio 2008) where appropriate. Network Denial of Service Mitigation - T1498

When flood volumes exceed the capacity of the network connection being targeted, it is typically necessary to intercept the incoming traffic upstream to filter out the attack traffic from the legitimate traffic. Such defenses can be provided by the hosting Internet Service Provider (ISP) or by a 3rd party such as a Content Delivery Network (CDN) or providers specializing in DoS mitigations.(Citation: CERT-EU DDoS March 2017)

Depending on flood volume, on-premises filtering may be possible by blocking source addresses sourcing the attack, blocking ports that are being targeted, or blocking protocols being used for transport.(Citation: CERT-EU DDoS March 2017)

As immediate response may require rapid engagement of 3rd parties, analyze the risk associated to

critical resources being affected by Network DoS attacks and create a disaster recovery plan/business continuity plan to respond to incidents.(Citation: CERT-EU DDoS March 2017)

Exploit Public-Facing Application Mitigation - T1190

Application isolation and least privilege help lesson the impact of an exploit. Application isolation will limit what other processes and system features the exploited target can access, and least privilege for service accounts will limit what permissions the exploited process gets on the rest of the system. Web Application Firewalls may be used to limit exposure of applications.

Segment externally facing servers and services from the rest of the network with a DMZ or on separate hosting infrastructure.

Use secure coding best practices when designing custom software that is meant for deployment to externally facing systems. Avoid issues documented by OWASP, CWE, and other software weakness identification efforts.

Regularly scan externally facing systems for vulnerabilities and establish procedures to rapidly patch systems when critical vulnerabilities are discovered through scanning and through public disclosure.

Behavior Prevention on Endpoint - M1040

Behavior Prevention on Endpoint refers to the use of technologies and strategies to detect and block potentially malicious activities by analyzing the behavior of processes, files, API calls, and other endpoint events. Rather than relying solely on known signatures, this approach leverages

heuristics, machine learning, and real-time monitoring to identify anomalous patterns indicative of an attack. This mitigation can be implemented through the following measures:

Suspicious Process Behavior:

- Implementation: Use Endpoint Detection and Response (EDR) tools to monitor and block processes exhibiting unusual behavior, such as privilege escalation attempts.
- Use Case: An attacker uses a known vulnerability to spawn a privileged process from a user-level application. The endpoint tool detects the abnormal parent-child process relationship and blocks the action.

Unauthorized File Access:

- Implementation: Leverage Data Loss Prevention (DLP) or endpoint tools to block processes attempting to access sensitive files without proper authorization.
- Use Case: A process tries to read or modify a sensitive file located in a restricted directory, such as /etc/shadow on Linux or the SAM registry hive on Windows. The endpoint tool identifies this anomalous behavior and prevents it.

Abnormal API Calls:

- Implementation: Implement runtime analysis tools to monitor API calls and block those associated with malicious activities.
- Use Case: A process dynamically injects itself into another process to hijack its execution. The endpoint detects the abnormal use of APIs like `OpenProcess` and `WriteProcessMemory` and terminates the offending process.

Exploit Prevention:

- Implementation: Use behavioral exploit prevention tools to detect and block exploits attempting to gain unauthorized access.
- Use Case: A buffer overflow exploit is launched against a vulnerable application. The endpoint detects the anomalous memory write operation and halts the process.

https://attack.mitre.org/mitigations/T1004

Compile After Delivery Mitigation - T1500

This type of technique cannot be easily mitigated with preventive controls or patched since it is based on the abuse of operating system design features. For example, blocking all file compilation may have unintended side effects, such as preventing legitimate OS frameworks and code development mechanisms from operating properly. Consider removing compilers if not needed, otherwise efforts should be focused on preventing adversary tools from running earlier in the chain of activity and on identifying subsequent malicious behavior.

Identify unnecessary system utilities or potentially malicious software that may be used to decrypt, deobfuscate, decode, and compile files or information, and audit and/or block them by using whitelisting (Citation: Beechey 2010) tools, like AppLocker, (Citation: Windows Commands JPCERT) (Citation: NSA MS AppLocker) or Software Restriction Policies (Citation: Corio 2008) where appropriate. Windows Remote Management Mitigation - T1028

Disable the WinRM service. If the service is necessary, lock down critical enclaves with separate WinRM infrastructure, accounts, and permissions. Follow WinRM best practices on configuration of authentication methods and use of host firewalls to restrict WinRM access to allow communication only to/from specific devices. (Citation: NSA Spotting)

Commonly Used Port Mitigation - T1043

Network intrusion detection and prevention systems that use network signatures to identify traffic for specific adversary malware can be used to mitigate activity at the network level. Signatures are often for unique indicators within protocols and may be based on the specific protocol used by a particular adversary or tool, and will likely be different across various malware families and versions. Adversaries will likely change tool C2 signatures over time or construct protocols in such a way as to avoid detection by common defensive tools. (Citation: University of Birmingham C2)

Application Isolation and Sandboxing - M1048

Application Isolation and Sandboxing refers to the technique of restricting the execution of code to a controlled and isolated environment (e.g., a virtual environment, container, or sandbox). This method prevents potentially malicious code from affecting the rest of the system or network by limiting access to sensitive resources and critical operations. The goal is to contain threats and minimize their impact. This mitigation can be implemented through the following measures:

Browser Sandboxing:

- Use Case: Implement browser sandboxing to isolate untrusted web content, preventing malicious web pages or scripts from accessing sensitive system files.
- Implementation: Use tools like Google Chrome's built-in sandbox or deploy solutions like Bromium to secure user web interactions.

Application Virtualization:

- Use Case: Deploy critical or high-risk applications in a virtualized environment to ensure any compromise does not affect the host system.
- Implementation: Use application virtualization platforms to run applications in isolated environments.

Email Attachment Sandboxing:

- Use Case: Route email attachments to a sandbox environment to detect and block malware before delivering emails to end-users.
- Implementation: Integrate security solutions with sandbox capabilities to analyze email attachments.

Endpoint Sandboxing:

- Use Case: Run all downloaded files and applications in a restricted environment to monitor their behavior for malicious activity.
- Implementation: Use endpoint protection tools for sandboxing at the endpoint level.

Table 6913. Table References

Links
https://attack.mitre.org/mitigations/T1133

Access Token Manipulation Mitigation - T1134

Access tokens are an integral part of the security system within Windows and cannot be turned off. However, an attacker must already have administrator level access on the local system to make full use of this technique; be sure to restrict users and accounts to the least privileges they require to do their job.

Any user can also spoof access tokens if they have legitimate credentials. Follow mitigation guidelines for preventing adversary use of [Valid Accounts](https://attack.mitre.org/techniques/T1078). Limit permissions so that users and user groups cannot create tokens. This setting should be defined for the local system account only. GPO: Computer Configuration > [Policies] > Windows Settings > Security Settings > Local Policies > User Rights Assignment: Create a token object. (Citation: Microsoft Create Token) Also define who can create a process level token to only the local and network service through GPO: Computer Configuration > [Policies] > Windows Settings > Security Settings > Local Policies > User Rights Assignment: Replace a process level token. (Citation: Microsoft Replace Process Token)

Also limit opportunities for adversaries to increase privileges by limiting Privilege Escalation opportunities.

The tag is: *misp-galaxy:mitre-course-of-action="Access Token Manipulation Mitigation - T1134"*

Spearphishing via Service Mitigation - T1194

Determine if certain social media sites, personal webmail services, or other service that can be used for spearphishing is necessary for business operations and consider blocking access if activity cannot be monitored well or if it poses a significant risk.

Because this technique involves use of legitimate services and user interaction on the endpoint, it's difficult to fully mitigate. However, there are potential mitigations. Users can be trained to identify social engineering techniques and spearphishing emails with malicious links. To prevent the downloads from executing, application whitelisting can be used. Anti-virus can also automatically quarantine suspicious files.

The tag is: *misp-galaxy:mitre-course-of-action="Spearphishing via Service Mitigation - T1194"*

Table 6919. Table References

Supply Chain Compromise Mitigation - T1195

Apply supply chain risk management (SCRM) practices and procedures (Citation: MITRE SE Guide 2014), such as supply chain analysis and appropriate risk management, throughout the life-cycle of a system.

Leverage established software development lifecycle (SDLC) practices (Citation: NIST Supply Chain 2012):

- Uniquely Identify Supply Chain Elements, Processes, and Actors
- Limit Access and Exposure within the Supply Chain
- Establish and Maintain the Provenance of Elements, Processes, Tools, and Data
- Share Information within Strict Limits
- Perform SCRM Awareness and Training
- Use Defensive Design for Systems, Elements, and Processes
- Perform Continuous Integrator Review
- Strengthen Delivery Mechanisms
- Assure Sustainment Activities and Processes
- Manage Disposal and Final Disposition Activities throughout the System or Element Life Cycle

A patch management process should be implemented to check unused dependencies, unmaintained and/or previously vulnerable dependencies, unnecessary features, components, files, and documentation. Continuous monitoring of vulnerability sources and the use of automatic and manual code review tools should also be implemented as well. (Citation: OWASP Top 10 2017)

Local Job Scheduling Mitigation - T1168

Limit privileges of user accounts and remediate Privilege Escalation vectors so only authorized users can create scheduled jobs. Identify and block unnecessary system utilities or potentially malicious software that may be used to schedule jobs using whitelisting tools.

The tag is: *misp-galaxy:mitre-course-of-action="Local Job Scheduling Mitigation - T1168"*

Table 6922. Table References

Links
https://attack.mitre.org/mitigations/T1168

Control Panel Items Mitigation - T1196

This type of attack technique cannot be easily mitigated with preventive controls since it is based on the abuse of operating system design features. For example, mitigating specific Windows API calls and/or execution of particular file extensions will likely have unintended side effects, such as preventing legitimate software (i.e., drivers and configuration tools) from operating properly. Efforts should be focused on preventing adversary tools from running earlier in the chain of activity and on identification of subsequent malicious behavior.

Restrict storage and execution of Control Panel items to protected directories, such as <code>C:\Windows</code>, rather than user directories.

Index known safe Control Panel items and block potentially malicious software using whitelisting (Citation: Beechey 2010) tools like AppLocker (Citation: Windows Commands JPCERT) (Citation: NSA MS AppLocker) that are capable of auditing and/or blocking unknown executable files.

Consider fully enabling User Account Control (UAC) to impede system-wide changes from illegitimate administrators. (Citation: Microsoft UAC)

Domain Generation Algorithms Mitigation - T1483

This technique may be difficult to mitigate since the domains can be registered just before they are used, and disposed shortly after. Malware researchers can reverse-engineer malware variants that use DGAs and determine future domains that the malware will attempt to contact, but this is a time and resource intensive effort.(Citation: Cybereason Dissecting DGAs)(Citation: Cisco Umbrella DGA Brute Force) Malware is also increasingly incorporating seed values that can be unique for each instance, which would then need to be determined to extract future generated domains. In some cases, the seed that a particular sample uses can be extracted from DNS traffic.(Citation: Akamai DGA Mitigation) Even so, there can be thousands of possible domains generated per day; this makes it impractical for defenders to preemptively register all possible C2 domains due to the cost. In some cases a local DNS sinkhole may be used to help prevent DGA-based command and control at a reduced cost.

Network intrusion detection and prevention systems that use network signatures to identify traffic for specific adversary malware can be used to mitigate activity at the network level. Signatures are often for unique indicators within protocols and may be based on the specific protocol used by a particular adversary or tool, and will likely be different across various malware families and versions. Adversaries will likely change tool C2 signatures over time or construct protocols in such a way as to avoid detection by common defensive tools. (Citation: University of Birmingham C2)

Out-of-Band Communications Channel - M1060

Establish secure out-of-band communication channels to ensure the continuity of critical communications during security incidents, data integrity attacks, or in-network communication failures. Out-of-band communication refers to using an alternative, separate communication path

that is not dependent on the potentially compromised primary network infrastructure. This method can include secure messaging apps, encrypted phone lines, satellite communications, or dedicated emergency communication systems. Leveraging these alternative channels reduces the risk of adversaries intercepting, disrupting, or tampering with sensitive communications and helps coordinate an effective incident response.(Citation: TrustedSec OOB Communications)(Citation: NIST Special Publication 800-53 Revision 5)

Restrict Web-Based Content - M1021

Restricting web-based content involves enforcing policies and technologies that limit access to potentially malicious websites, unsafe downloads, and unauthorized browser behaviors. This can include URL filtering, download restrictions, script blocking, and extension control to protect against exploitation, phishing, and malware delivery. This mitigation can be implemented through

the following measures:

Deploy Web Proxy Filtering:

- Use solutions to filter web traffic based on categories, reputation, and content types.
- Enforce policies that block unsafe websites or file types at the gateway level.

Enable DNS-Based Filtering:

- Implement tools to restrict access to domains associated with malware or phishing campaigns.
- Use public DNS filtering services to enhance protection.

Enforce Content Security Policies (CSP):

- Configure CSP headers on internal and external web applications to restrict script execution, iframe embedding, and cross-origin requests.

Control Browser Features:

- Disable unapproved browser features like automatic downloads, developer tools, or unsafe scripting.
- Enforce policies through tools like Group Policy Management to control browser settings.

Monitor and Alert on Web-Based Threats:

- Use SIEM tools to collect and analyze web proxy logs for signs of anomalous or malicious activity.
- Configure alerts for access attempts to blocked domains or repeated file download failures.

Third-party Software Mitigation - T1072

Evaluate the security of third-party software that could be used in the enterprise environment. Ensure that access to management systems for third-party systems is limited, monitored, and secure. Have a strict approval policy for use of third-party systems.

Grant access to Third-party systems only to a limited number of authorized administrators. Ensure proper system and access isolation for critical network systems through use of firewalls, account privilege separation, group policy, and multi-factor authentication. Verify that account credentials that may be used to access third-party systems are unique and not used throughout the enterprise network. Ensure that any accounts used by third-party providers to access these systems are traceable to the third-party and are not used throughout the network or used by other third-party providers in the same environment. Ensure third-party systems are regularly patched by users or the provider to prevent potential remote access through [Exploitation for Privilege Escalation](https://attack.mitre.org/techniques/T1068).

Ensure there are regular reviews of accounts provisioned to these systems to verify continued business need, and ensure there is governance to trace de-provisioning of access that is no longer required.

Where the third-party system is used for deployment services, ensure that it can be configured to deploy only signed binaries, then ensure that the trusted signing certificates are not co-located with the third-party system and are instead located on a system that cannot be accessed remotely or to which remote access is tightly controlled.

SID-History Injection Mitigation - T1178

Clean up SID-History attributes after legitimate account migration is complete.

Consider applying SID Filtering to interforest trusts, such as forest trusts and external trusts, to exclude SID-History from requests to access domain resources. SID Filtering ensures that any authentication requests over a trust only contain SIDs of security principals from the trusted domain (i.e. preventing the trusted domain from claiming a user has membership in groups outside of the domain).

SID Filtering of forest trusts is enabled by default, but may have been disabled in some cases to allow a child domain to transitively access forest trusts. SID Filtering of external trusts is automatically enabled on all created external trusts using Server 2003 or later domain controllers. (Citation: Microsoft Trust Considerations Nov 2014) (Citation: Microsoft SID Filtering Quarantining Jan 2009) However note that SID Filtering is not automatically applied to legacy trusts or may have been deliberately disabled to allow inter-domain access to resources.

SID Filtering can be applied by: (Citation: Microsoft Netdom Trust Sept 2012)

- Disabling SIDHistory on forest trusts using the netdom tool (<code>netdom trust <TrustingDomainName> /domain:<TrustedDomainName> /EnableSIDHistory:no</code> on the domain controller).
- Applying SID Filter Quarantining to external trusts using the netdom tool (<code>netdom trust <TrustingDomainName> /domain:<TrustedDomainName> /quarantine:yes</code> on the domain controller) Applying SID Filtering to domain trusts within a single forest is not recommended as it is an unsupported configuration and can cause breaking changes. (Citation: Microsoft Netdom Trust Sept 2012) (Citation: AdSecurity Kerberos GT Aug 2015) If a domain within a forest is untrustworthy then it should not be a member of the forest. In this situation it is necessary to first split the trusted and untrusted domains into separate forests where SID Filtering can be applied to an interforest trust.

https://attack.mitre.org/mitigations/T1188

Drive-by Compromise Mitigation - T1189

Drive-by compromise relies on there being a vulnerable piece of software on the client end systems. Use modern browsers with security features turned on. Ensure all browsers and plugins kept updated can help prevent the exploit phase of this technique.

For malicious code served up through ads, adblockers can help prevent that code from executing in the first place. Script blocking extensions can help prevent the execution of JavaScript that may commonly be used during the exploitation process.

Browser sandboxes can be used to mitigate some of the impact of exploitation, but sandbox escapes may still exist. (Citation: Windows Blogs Microsoft Edge Sandbox) (Citation: Ars Technica Pwn2Own 2017 VM Escape)

Other types of virtualization and application microsegmentation may also mitigate the impact of client-side exploitation. The risks of additional exploits and weaknesses in implementation may still exist. (Citation: Ars Technica Pwn2Own 2017 VM Escape)

Security applications that look for behavior used during exploitation such as Windows Defender Exploit Guard (WDEG) and the Enhanced Mitigation Experience Toolkit (EMET) can be used to mitigate some exploitation behavior. (Citation: TechNet Moving Beyond EMET) Control flow integrity checking is another way to potentially identify and stop a software exploit from occurring. (Citation: Wikipedia Control Flow Integrity) Many of these protections depend on the architecture and target application binary for compatibility.

Credential Dumping Mitigation - T1003

Windows

Monitor/harden access to LSASS and SAM table with tools that allow process whitelisting. Limit credential overlap across systems to prevent lateral movement opportunities using [Valid Accounts](https://attack.mitre.org/techniques/T1078) if passwords and hashes are obtained. Ensure that local administrator accounts have complex, unique passwords across all systems on the network. Do not put user or admin domain accounts in the local administrator groups across systems unless they are tightly controlled, as this is often equivalent to having a local administrator account with the same password on all systems. Follow best practices for design and administration of an enterprise network to limit privileged account use across administrative tiers. (Citation: Microsoft Securing Privileged Access)

On Windows 8.1 and Windows Server 2012 R2, enable Protected Process Light for LSA. (Citation: Microsoft LSA)

Identify and block potentially malicious software that may be used to dump credentials by using whitelisting (Citation: Beechey 2010) tools, like AppLocker, (Citation: Windows Commands JPCERT) (Citation: NSA MS AppLocker) or Software Restriction Policies (Citation: Corio 2008) where appropriate. (Citation: TechNet Applocker vs SRP)

With Windows 10, Microsoft implemented new protections called Credential Guard to protect the LSA secrets that can be used to obtain credentials through forms of credential dumping. It is not configured by default and has hardware and firmware system requirements. (Citation: TechNet Credential Guard) It also does not protect against all forms of credential dumping. (Citation: GitHub SHB Credential Guard)

Manage the access control list for “Replicating Directory Changes” and other permissions associated with domain controller replication. (Citation: AdSecurity DCSync Sept 2015) (Citation: Microsoft Replication ACL)

Consider disabling or restricting NTLM traffic. (Citation: Microsoft Disable NTLM Nov 2012)

Linux

Scraping the passwords from memory requires root privileges. Follow best practices in restricting access to escalated privileges to avoid hostile programs from accessing such sensitive regions of memory.

Encrypt Network Traffic - M1009

Application developers should encrypt all of their application network traffic using the Transport Layer Security (TLS) protocol to ensure protection of sensitive data and deter network-based attacks. If desired, application developers could perform message-based encryption of data before passing it for TLS encryption.

iOS's App Transport Security feature can be used to help ensure that all application network traffic is appropriately protected. Apple intends to mandate use of App Transport Security (Citation: TechCrunch-ATS) for all apps in the Apple App Store unless appropriate justification is given.

Android's Network Security Configuration feature similarly can be used by app developers to help ensure that all of their application network traffic is appropriately protected (Citation: Android-NetworkSecurityConfig).

Use of Virtual Private Network (VPN) tunnels, e.g. using the IPsec protocol, can help mitigate some types of network attacks as well.

The tag is: *misp-galaxy:mitre-course-of-action="Encrypt Network Traffic - M1009"*

Application Developer Guidance - M1013

Application Developer Guidance focuses on providing developers with the knowledge, tools, and best practices needed to write secure code, reduce vulnerabilities, and implement secure design principles. By integrating security throughout the software development lifecycle (SDLC), this mitigation aims to prevent the introduction of exploitable weaknesses in applications, systems, and APIs. This mitigation can be implemented through the following measures:

Preventing SQL Injection (Secure Coding Practice):

- Implementation: Train developers to use parameterized queries or prepared statements instead of directly embedding user input into SQL queries.
- Use Case: A web application accepts user input to search a database. By sanitizing and validating user inputs, developers can prevent attackers from injecting malicious SQL commands.

Cross-Site Scripting (XSS) Mitigation:

- Implementation: Require developers to implement output encoding for all user-generated content displayed on a web page.
- Use Case: An e-commerce site allows users to leave product reviews. Properly encoding and escaping user inputs prevents malicious scripts from being executed in other users' browsers.

Secure API Design:

- Implementation: Train developers to authenticate all API endpoints and avoid exposing sensitive information in API responses.
- Use Case: A mobile banking application uses APIs for account management. By enforcing token-based authentication for every API call, developers reduce the risk of unauthorized access.

Static Code Analysis in the Build Pipeline:

- Implementation: Incorporate tools into CI/CD pipelines to automatically scan for vulnerabilities during the build process.
- Use Case: A fintech company integrates static analysis tools to detect hardcoded credentials in their source code before deployment.

Threat Modeling in the Design Phase:

- Implementation: Use frameworks like STRIDE (Spoofing, Tampering, Repudiation, Information Disclosure, Denial of Service, Elevation of Privilege) to assess threats during application design.
- Use Case: Before launching a customer portal, a SaaS company identifies potential abuse cases, such as session hijacking, and designs mitigations like secure session management.

Tools for Implementation:

- Static Code Analysis Tools: Use tools that can scan for known vulnerabilities in source code.
- Dynamic Application Security Testing (DAST): Use tools like Burp Suite or OWASP ZAP to

simulate runtime attacks and identify vulnerabilities.

- Secure Frameworks: Recommend secure-by-default frameworks (e.g., Django for Python, Spring Security for Java) that enforce security best practices.

Encrypt Sensitive Information - M1041

Protect sensitive information at rest, in transit, and during processing by using strong encryption algorithms. Encryption ensures the confidentiality and integrity of data, preventing unauthorized access or tampering. This mitigation can be implemented through the following measures:

Encrypt Data at Rest:

- Use Case: Use full-disk encryption or file-level encryption to secure sensitive data stored on devices.
- Implementation: Implement BitLocker for Windows systems or FileVault for macOS devices to encrypt hard drives.

Encrypt Data in Transit:

- Use Case: Use secure communication protocols (e.g., TLS, HTTPS) to encrypt sensitive data as it travels over networks.
- Implementation: Enable HTTPS for all web applications and configure mail servers to enforce STARTTLS for email encryption.

Encrypt Backups:

- Use Case: Ensure that backup data is encrypted both during storage and transfer to prevent unauthorized access.
- Implementation: Encrypt cloud backups using AES-256 before uploading them to Amazon S3 or Google Cloud.

Encrypt Application Secrets:

- Use Case: Store sensitive credentials, API keys, and configuration files in encrypted vaults.
- Implementation: Use HashiCorp Vault or AWS Secrets Manager to manage and encrypt secrets.

Database Encryption:

- Use Case: Enable Transparent Data Encryption (TDE) or column-level encryption in database management systems.
- Implementation: Use MySQL's built-in encryption features to encrypt sensitive database fields such as social security numbers.

The tag is: *misp-galaxy:mitre-course-of-action="Encrypt Sensitive Information - M1041"*

Table 6959. Table References

Links
https://attack.mitre.org/mitigations/M1041

Active Directory Configuration - M1015

Implement robust Active Directory (AD) configurations using group policies to secure user accounts, control access, and minimize the attack surface. AD configurations enable centralized control over account settings, logon policies, and permissions, reducing the risk of unauthorized access and lateral movement within the network. This mitigation can be implemented through the following measures:

Account Configuration:

- Implementation: Use domain accounts instead of local accounts to leverage AD's centralized management, including group policies, auditing, and access control.
- Use Case: For IT staff managing shared resources, provision domain accounts that allow IT teams to log in centrally, reducing the risk of unmanaged, rogue local accounts on individual machines.

Interactive Logon Restrictions:

- Implementation: Configure group policies to restrict interactive logons (e.g., direct physical or RDP logons) for service accounts or privileged accounts that do not require such access.
- Use Case: Prevent service accounts, such as SQL Server accounts, from having interactive logon privileges. This reduces the risk of these accounts being leveraged for lateral movement if compromised.

Remote Desktop Settings:

- Implementation: Limit Remote Desktop Protocol (RDP) access to specific, authorized accounts. Use group policies to enforce this, allowing only necessary users to establish RDP sessions.
- Use Case: On sensitive servers (e.g., domain controllers or financial databases), restrict RDP access to administrative accounts only, while all other users are denied access.

Dedicated Administrative Accounts:

- Implementation: Create domain-wide administrative accounts that are restricted from interactive logons, designed solely for high-level tasks (e.g., software installation, patching).
- Use Case: Create separate administrative accounts for different purposes, such as one set of accounts for installations and another for managing repository access. This limits exposure and helps reduce attack vectors.

Authentication Silos:

- Implementation: Configure Authentication Silos in AD, using group policies to create access zones with restrictions based on membership, such as the Protected Users security group. This restricts access to critical accounts and minimizes exposure to potential threats.
- Use Case: Place high-risk or high-value accounts, such as executive or administrative accounts, in an Authentication Silo with extra controls, limiting their exposure to only necessary systems. This reduces the risk of credential misuse or abuse if these accounts are compromised.

Tools for Implementation:

- Active Directory Group Policies: Use Group Policy Management Console (GPMC) to configure, deploy, and enforce policies across AD environments.
- PowerShell: Automate account configuration, logon restrictions, and policy application using PowerShell scripts.
- AD Administrative Center: Manage Authentication Silos and configure high-level policies for critical user groups within AD.

The tag is: *misp-galaxy:mitre-course-of-action="Active Directory Configuration - M1015"*

User Account Management - M1018

User Account Management involves implementing and enforcing policies for the lifecycle of user accounts, including creation, modification, and deactivation. Proper account management reduces the attack surface by limiting unauthorized access, managing account privileges, and ensuring accounts are used according to organizational policies. This mitigation can be implemented through the following measures:

Enforcing the Principle of Least Privilege

- Implementation: Assign users only the minimum permissions required to perform their job functions. Regularly audit accounts to ensure no excess permissions are granted.
- Use Case: Reduces the risk of privilege escalation by ensuring accounts cannot perform unauthorized actions.

Implementing Strong Password Policies

- Implementation: Enforce password complexity requirements (e.g., length, character types). Require password expiration every 90 days and disallow password reuse.
- Use Case: Prevents adversaries from gaining unauthorized access through password guessing or brute force attacks.

Managing Dormant and Orphaned Accounts

- Implementation: Implement automated workflows to disable accounts after a set period of inactivity (e.g., 30 days). Remove orphaned accounts (e.g., accounts without an assigned owner) during regular account audits.
- Use Case: Eliminates dormant accounts that could be exploited by attackers.

Account Lockout Policies

- Implementation: Configure account lockout thresholds (e.g., lock accounts after five failed login attempts). Set lockout durations to a minimum of 15 minutes.
- Use Case: Mitigates automated attack techniques that rely on repeated login attempts.

Multi-Factor Authentication (MFA) for High-Risk Accounts

- Implementation: Require MFA for all administrative accounts and high-risk users. Use MFA mechanisms like hardware tokens, authenticator apps, or biometrics.
- Use Case: Prevents unauthorized access, even if credentials are stolen.

Restricting Interactive Logins

- Implementation: Restrict interactive logins for privileged accounts to specific secure systems or management consoles. Use group policies to enforce logon restrictions.

- Use Case: Protects sensitive accounts from misuse or exploitation.

Tools for Implementation

Built-in Tools:

- Microsoft Active Directory (AD): Centralized account management and RBAC enforcement.
- Group Policy Object (GPO): Enforce password policies, logon restrictions, and account lockout policies.

Identity and Access Management (IAM) Tools:

- Okta: Centralized user provisioning, MFA, and SSO integration.
- Microsoft Azure Active Directory: Provides advanced account lifecycle management, role-based access, and conditional access policies.

Privileged Account Management (PAM): - CyberArk, BeyondTrust, Thycotic: Manage and monitor privileged account usage, enforce session recording, and JIT access.

Threat Intelligence Program - M1019

A Threat Intelligence Program enables organizations to proactively identify, analyze, and act on cyber threats by leveraging internal and external data sources. The program supports decision-making processes, prioritizes defenses, and improves incident response by delivering actionable intelligence tailored to the organization's risk profile and operational environment. This mitigation can be implemented through the following measures:

Establish a Threat Intelligence Team:

- Form a dedicated team or assign responsibility to existing security personnel to collect, analyze, and act on threat intelligence.

Define Intelligence Requirements:

- Identify the organization's critical assets and focus intelligence gathering efforts on threats targeting these assets.

Leverage Internal and External Data Sources:

- Collect intelligence from internal sources such as logs, incidents, and alerts. Subscribe to external threat intelligence feeds, participate in ISACs, and monitor open-source intelligence (OSINT).

Implement Tools for Automation:

- Use threat intelligence platforms (TIPs) to automate the collection, enrichment, and dissemination of threat data.
- Integrate threat intelligence with SIEMs to correlate IOCs with internal events.

Analyze and Act on Intelligence:

- Use frameworks like MITRE ATT&CK to map intelligence to adversary TTPs.
- Prioritize defensive measures, such as patching vulnerabilities or deploying IOCs, based on analyzed threats.

Share and Collaborate:

- Share intelligence with industry peers through ISACs or threat-sharing platforms to enhance collective defense.

Evaluate and Update the Program:

- Regularly assess the effectiveness of the threat intelligence program.
- Update intelligence priorities and capabilities as new threats emerge.

Tools for Implementation

Threat Intelligence Platforms (TIPs):

- OpenCTI: An open-source platform for structuring and sharing threat intelligence.
- MISP: A threat intelligence sharing platform for sharing structured threat data.

Threat Intelligence Feeds:

- Open Threat Exchange (OTX): Provides free access to a large repository of threat intelligence.
- CIRCL OSINT Feed: A free source for IOCs and threat information.

Automation and Enrichment Tools:

- TheHive: An open-source incident response platform with threat intelligence integration.
- Yeti: A platform for managing and structuring knowledge about threats.

Analysis Frameworks:

- MITRE ATT&CK Navigator: A tool for mapping threat intelligence to adversary behaviors.
- Cuckoo Sandbox: Analyzes malware to extract behavioral indicators.

Community and Collaboration Tools:

- ISAC Memberships: Join industry-specific ISACs for intelligence sharing.
- Slack/Discord Channels: Participate in threat intelligence communities for real-time collaboration.

User Execution Mitigation - T1204

Use user training as a way to bring awareness to common phishing and spearphishing techniques and how to raise suspicion for potentially malicious events. Application whitelisting may be able to prevent the running of executables masquerading as other files.

If a link is being visited by a user, block unknown or unused files in transit by default that should not be downloaded or by policy from suspicious sites as a best practice to prevent some vectors, such as .scr, .exe, .lnk, .pif, .cpl, etc. Some download scanning devices can open and analyze compressed and encrypted formats, such as zip and RAR that may be used to conceal malicious files in [Obfuscated Files or Information](https://attack.mitre.org/techniques/T1027).

If a link is being visited by a user, network intrusion prevention systems and systems designed to scan and remove malicious downloads can be used to block activity. Solutions can be signature and behavior based, but adversaries may construct files in a way to avoid these systems.

The tag is: *misp-galaxy:mitre-course-of-action="User Execution Mitigation - T1204"*

Table 6974. Table References

https://attack.mitre.org/mitigations/T1204

Restrict Registry Permissions - M1024

Restricting registry permissions involves configuring access control settings for sensitive registry keys and hives to ensure that only authorized users or processes can make modifications. By limiting access, organizations can prevent unauthorized changes that adversaries might use for persistence, privilege escalation, or defense evasion. This mitigation can be implemented through the following measures:

Review and Adjust Permissions on Critical Keys

- Regularly review permissions on keys such as `Run`, `RunOnce`, and `Services` to ensure only authorized users have write access.
- Use tools like `icacls` or `PowerShell` to automate permission adjustments.

Enable Registry Auditing

- Enable auditing on sensitive keys to log access attempts.
- Use Event Viewer or SIEM solutions to analyze logs and detect suspicious activity.
- Example Audit Policy: `auditpol /set /subcategory:"Registry" /success:enable /failure:enable`

Protect Credential-Related Hives

- Limit access to hives like `SAM`,`SECURITY`, and `SYSTEM` to prevent credential dumping or other unauthorized access.
- Use LSA Protection to add an additional security layer for credential storage.

Restrict Registry Editor Usage

- Use Group Policy to restrict access to regedit.exe for non-administrative users.
- Block execution of registry editing tools on endpoints where they are unnecessary.

Deploy Baseline Configuration Tools

- Use tools like Microsoft Security Compliance Toolkit or CIS Benchmarks to apply and maintain secure registry configurations.

Tools for Implementation

Registry Permission Tools:

- Registry Editor (regedit): Built-in tool to manage registry permissions.
- PowerShell: Automate permissions and manage keys. `Set-ItemProperty -Path "HKLM:\Software\Microsoft\Windows\CurrentVersion\Run" -Name "KeyName" -Value "Value"`
- icacls: Command-line tool to modify ACLs.

Monitoring Tools:

- Sysmon: Monitor and log registry events.

- Event Viewer: View registry access logs.

Policy Management Tools:

- Group Policy Management Console (GPMC): Enforce registry permissions via GPOs.
- Microsoft Endpoint Manager: Deploy configuration baselines for registry permissions.

The tag is: *misp-galaxy:mitre-course-of-action="Restrict Registry Permissions - M1024"*

Table 6975. Table References

Links
https://attack.mitre.org/mitigations/M1024

User Account Control - M1052

User Account Control (UAC) is a security feature in Microsoft Windows that prevents unauthorized changes to the operating system. UAC prompts users to confirm or provide administrator credentials when an action requires elevated privileges. Proper configuration of UAC reduces the risk of privilege escalation attacks. This mitigation can be implemented through the following measures:

Enable UAC Globally:

- Ensure UAC is enabled through Group Policy by setting `User Account Control: Run all administrators in Admin Approval Mode` to `Enabled`.

Require Credential Prompt:

- Use Group Policy to configure UAC to prompt for administrative credentials instead of just confirmation (`User Account Control: Behavior of the elevation prompt`).

Restrict Built-in Administrator Account:

Set `Admin Approval Mode` for the built-in Administrator account to `Enabled` in Group Policy.

Secure the UAC Prompt:

- Configure UAC prompts to display on the secure desktop (`User Account Control: Switch to the secure desktop when prompting for elevation`).

Prevent UAC Bypass:

- Block untrusted applications from triggering UAC prompts by configuring `User Account Control: Only elevate executables that are signed and validated`.
- Use EDR tools to detect and block known UAC bypass techniques.

Monitor UAC-Related Events:

- Use Windows Event Viewer to monitor for event ID 4688 (process creation) and look for

suspicious processes attempting to invoke UAC elevation.

Tools for Implementation

Built-in Windows Tools:

- Group Policy Editor: Configure UAC settings centrally for enterprise environments.
- Registry Editor: Modify UAC-related settings directly, such as `EnableLUA` and `ConsentPromptBehaviorAdmin`.

Endpoint Security Solutions:

- Microsoft Defender for Endpoint: Detects and blocks UAC bypass techniques.
- Sysmon: Logs process creations and monitors UAC elevation attempts for suspicious activity.

Third-Party Security Tools:

- Process Monitor (Sysinternals): Tracks real-time processes interacting with UAC.
- EventSentry: Monitors Windows Event Logs for UAC-related alerts.

The tag is: *misp-galaxy:mitre-course-of-action="User Account Control - M1052"*

Privileged Process Integrity - M1025

Privileged Process Integrity focuses on defending highly privileged processes (e.g., system services, antivirus, or authentication processes) from tampering, injection, or compromise by adversaries. These processes often interact with critical components, making them prime targets for techniques like code injection, privilege escalation, and process manipulation. This mitigation can be implemented through the following measures:

Protected Process Mechanisms:

- Enable RunAsPPL on Windows systems to protect LSASS and other critical processes.
- Use registry modifications to enforce protected process settings: `HKEY_LOCAL_MACHINE\SYSTEM\CurrentControlSet\Control\Lsa\RunAsPPL`

Anti-Injection and Memory Protection:

- Enable Control Flow Guard (CFG), DEP, and ASLR to protect against process memory tampering.
- Deploy endpoint protection tools that actively block process injection attempts.

Code Signing Validation:

- Implement policies for Windows Defender Application Control (WDAC) or AppLocker to enforce

execution of signed binaries.

- Ensure critical processes are signed with valid certificates.

Access Controls:

- Use DACLs and MIC to limit which users and processes can interact with privileged processes.
- Disable unnecessary debugging capabilities for high-privileged processes.

Kernel-Level Protections:

- Ensure Kernel Patch Protection (PatchGuard) is enabled on Windows systems.
- Leverage SELinux or AppArmor on Linux to enforce kernel-level security policies.

Tools for Implementation

Protected Process Light (PPL):

- RunAsPPL (Windows)
- Windows Defender Credential Guard

Code Integrity and Signing:

- Windows Defender Application Control (WDAC)
- AppLocker
- SELinux/AppArmor (Linux)

Memory Protection:

- Control Flow Guard (CFG), Data Execution Prevention (DEP), ASLR

Process Isolation/Sandboxing:

- Firejail (Linux Sandbox)
- Windows Sandbox
- QEMU/KVM-based isolation

Kernel Protection:

- PatchGuard (Windows Kernel Patch Protection)
- SELinux (Mandatory Access Control for Linux)
- AppArmor

Privileged Account Management - M1026

Privileged Account Management focuses on implementing policies, controls, and tools to securely manage privileged accounts (e.g., SYSTEM, root, or administrative accounts). This includes restricting access, limiting the scope of permissions, monitoring privileged account usage, and ensuring accountability through logging and auditing.This mitigation can be implemented through the following measures:

Account Permissions and Roles:

- Implement RBAC and least privilege principles to allocate permissions securely.
- Use tools like Active Directory Group Policies to enforce access restrictions.

Credential Security:

- Deploy password vaulting tools like CyberArk, HashiCorp Vault, or KeePass for secure storage and rotation of credentials.
- Enforce password policies for complexity, uniqueness, and expiration using tools like Microsoft Group Policy Objects (GPO).

Multi-Factor Authentication (MFA):

- Enforce MFA for all privileged accounts using Duo Security, Okta, or Microsoft Azure AD MFA.

Privileged Access Management (PAM):

- Use PAM solutions like CyberArk, BeyondTrust, or Thycotic to manage, monitor, and audit privileged access.

Auditing and Monitoring:

- Integrate activity monitoring into your SIEM (e.g., Splunk or QRadar) to detect and alert on anomalous privileged account usage.

Just-In-Time Access:

- Deploy JIT solutions like Azure Privileged Identity Management (PIM) or configure ephemeral roles in AWS and GCP to grant time-limited elevated permissions.

Tools for Implementation

Privileged Access Management (PAM):

- CyberArk, BeyondTrust, Thycotic, HashiCorp Vault.

Credential Management:

- Microsoft LAPS (Local Admin Password Solution), Password Safe, HashiCorp Vault, KeePass.

Multi-Factor Authentication:

- Duo Security, Okta, Microsoft Azure MFA, Google Authenticator.

Linux Privilege Management:

- sudo configuration, SELinux, AppArmor.

Just-In-Time Access:

- Azure Privileged Identity Management (PIM), AWS IAM Roles with session constraints, GCP Identity-Aware Proxy.

Multiband Communication Mitigation - T1026

Network intrusion detection and prevention systems that use network signatures to identify traffic for specific adversary malware can be used to mitigate activity at the network level. Signatures are often for unique indicators within protocols and may be based on the specific protocol used by a particular adversary or tool, and will likely be different across various malware families and versions. Adversaries will likely change tool C2 signatures over time or construct protocols in such a way as to avoid detection by common defensive tools. (Citation: University of Birmingham C2)

https://attack.mitre.org/mitigations/T1206

Operating System Configuration - M1028

Operating System Configuration involves adjusting system settings and hardening the default configurations of an operating system (OS) to mitigate adversary exploitation and prevent abuse of system functionality. Proper OS configurations address security vulnerabilities, limit attack surfaces, and ensure robust defense against a wide range of techniques. This mitigation can be implemented through the following measures:

Disable Unused Features:

- Turn off SMBv1, LLMNR, and NetBIOS where not needed.
- Disable remote registry and unnecessary services.

Enforce OS-level Protections:

- Enable Data Execution Prevention (DEP), Address Space Layout Randomization (ASLR), and Control Flow Guard (CFG) on Windows.
- Use AppArmor or SELinux on Linux for mandatory access controls.

Secure Access Settings:

- Enable User Account Control (UAC) for Windows.
- Restrict root/sudo access on Linux/macOS and enforce strong permissions using sudoers files.

File System Hardening:

- Implement least-privilege access for critical files and system directories.
- Audit permissions regularly using tools like icacls (Windows) or getfacl/chmod (Linux/macOS).

Secure Remote Access:

- Restrict RDP, SSH, and VNC to authorized IPs using firewall rules.
- Enable NLA for RDP and enforce strong password/lockout policies.

Harden Boot Configurations:

- Enable Secure Boot and enforce UEFI/BIOS password protection.
- Use BitLocker or LUKS to encrypt boot drives.

Regular Audits:

- Periodically audit OS configurations using tools like CIS Benchmarks or SCAP tools.

Tools for Implementation

Windows:

- Microsoft Group Policy Objects (GPO): Centrally enforce OS security settings.
- Windows Defender Exploit Guard: Built-in OS protection against exploits.
- CIS-CAT Pro: Audit Windows security configurations based on CIS Benchmarks.

Linux/macOS:

- AppArmor/SELinux: Enforce mandatory access controls.
- Lynis: Perform comprehensive security audits.
- SCAP Security Guide: Automate configuration hardening using Security Content Automation Protocol.

Cross-Platform:

- Ansible or Chef/Puppet: Automate configuration hardening at scale.
- OpenSCAP: Perform compliance and configuration checks.

The tag is: *misp-galaxy:mitre-course-of-action="Operating System Configuration - M1028"*

Links
https://attack.mitre.org/mitigations/M1028

Remote Data Storage - M1029

Remote Data Storage focuses on moving critical data, such as security logs and sensitive files, to secure, off-host locations to minimize unauthorized access, tampering, or destruction by adversaries. By leveraging remote storage solutions, organizations enhance the protection of forensic evidence, sensitive information, and monitoring data. This mitigation can be implemented through the following measures:

Centralized Log Management:

- Configure endpoints to forward security logs to a centralized log collector or SIEM.
- Use tools like Splunk Graylog, or Security Onion to aggregate and store logs.
- Example command (Linux): `sudo auditd | tee /var/log/audit/audit.log | nc <remote-log-server> 514`

Remote File Storage Solutions:

- Utilize cloud storage solutions like AWS S3, Google Cloud Storage, or Azure Blob Storage for sensitive data.
- Ensure proper encryption at rest and access control policies (IAM roles, ACLs).

Intrusion Detection Log Forwarding:

- Forward logs from IDS/IPS systems (e.g., Zeek/Suricata) to a remote security information system.
- Example for Suricata log forwarding: `outputs:
- type: syslog protocol: tls address: <remote-syslog-server>`

Immutable Backup Configurations:

- Enable immutable storage settings for backups to prevent adversaries from modifying or deleting data.
- Example: AWS S3 Object Lock.

Data Encryption:

- Ensure encryption for sensitive data using AES-256 at rest and TLS 1.2+ for data in transit. Tools: OpenSSL, BitLocker, LUKS for Linux.

The tag is: *misp-galaxy:mitre-course-of-action="Remote Data Storage - M1029"*

Limit Software Installation - M1033

Prevent users or groups from installing unauthorized or unapproved software to reduce the risk of introducing malicious or vulnerable applications. This can be achieved through allowlists, software restriction policies, endpoint management tools, and least privilege access principles. This mitigation can be implemented through the following measures:

Application Whitelisting

- Implement Microsoft AppLocker or Windows Defender Application Control (WDAC) to create and enforce allowlists for approved software.
- Whitelist applications based on file hash, path, or digital signatures.

Restrict User Permissions

- Remove local administrator rights for all non-IT users.
- Use Role-Based Access Control (RBAC) to restrict installation permissions to privileged accounts only.

Software Restriction Policies (SRP)

- Use GPO to configure SRP to deny execution of binaries from directories such as `%AppData%`, `%Temp%`, and external drives.
- Restrict specific file types (`.exe`, `.bat`, `.msi`, `.js`, `.vbs`) to trusted directories only.

Endpoint Management Solutions

- Deploy tools like Microsoft Intune, SCCM, or Jamf for centralized software management.
- Maintain a list of approved software, versions, and updates across the enterprise.

Monitor Software Installation Events

- Enable logging of software installation events and monitor Windows Event ID 4688 and Event ID 11707 for software installs.
- Use SIEM or EDR tools to alert on attempts to install unapproved software.

Implement Software Inventory Management

- Use tools like OSQuery or Wazuh to scan for unauthorized software on endpoints and servers.
- Conduct regular audits to detect and remove unapproved software.

Tools for Implementation

Application Whitelisting:

- Microsoft AppLocker
- Windows Defender Application Control (WDAC)

Endpoint Management:

- Microsoft Intune
- SCCM (System Center Configuration Manager)
- Jamf Pro (macOS)
- Puppet or Ansible for automation

Software Restriction Policies:

- Group Policy Object (GPO)
- Microsoft Software Restriction Policies (SRP)

Monitoring and Logging:

- Splunk
- OSQuery
- Wazuh (open-source SIEM and XDR)
- EDRs

Inventory Management and Auditing:

- OSQuery
- Wazuh

https://attack.mitre.org/mitigations/M1033

Credential Access Protection - M1043

Credential Access Protection focuses on implementing measures to prevent adversaries from obtaining credentials, such as passwords, hashes, tokens, or keys, that could be used for unauthorized access. This involves restricting access to credential storage mechanisms, hardening configurations to block credential dumping methods, and using monitoring tools to detect suspicious credential-related activity. This mitigation can be implemented through the following measures:

Restrict Access to Credential Storage:

- Use Case: Prevent adversaries from accessing the SAM (Security Account Manager) database on Windows systems.
- Implementation: Enforce least privilege principles and restrict administrative access to credential stores such as `C:\Windows\System32\config\SAM`.

Use Credential Guard:

- Use Case: Isolate LSASS (Local Security Authority Subsystem Service) memory to prevent credential dumping.
- Implementation: Enable Windows Defender Credential Guard on enterprise endpoints to isolate secrets and protect them from unauthorized access.

Monitor for Credential Dumping Tools:

- Use Case: Detect and block known tools like Mimikatz or Windows Credential Editor.
- Implementation: Flag suspicious process behavior related to credential dumping.

Disable Cached Credentials:

- Use Case: Prevent adversaries from exploiting cached credentials on endpoints.
- Implementation: Configure group policy to reduce or eliminate the use of cached credentials (e.g., set Interactive logon: Number of previous logons to cache to 0).

Enable Secure Boot and Memory Protections:

- Use Case: Prevent memory-based attacks used to extract credentials.
- Implementation: Configure Secure Boot and enforce hardware-based security features like DEP (Data Execution Prevention) and ASLR (Address Space Layout Randomization).

The tag is: *misp-galaxy:mitre-course-of-action="Credential Access Protection - M1043"*

Table 6987. Table References

Links
https://attack.mitre.org/mitigations/M1043

Limit Hardware Installation - M1034

Prevent unauthorized users or groups from installing or using hardware, such as external drives, peripheral devices, or unapproved internal hardware components, by enforcing hardware usage policies and technical controls. This includes disabling USB ports, restricting driver installation, and implementing endpoint security tools to monitor and block unapproved devices. This mitigation can be implemented through the following measures:

Disable USB Ports and Hardware Installation Policies:

- Use Group Policy Objects (GPO) to disable USB mass storage devices:
- Navigate to Computer Configuration > Administrative Templates > System > Removable Storage Access.
- Deny write and read access to USB devices.
- Whitelist approved devices using unique serial numbers via Windows Device Installation Policies.

Deploy Endpoint Protection and Device Control Solutions:

- Use tools like Microsoft Defender for Endpoint, Symantec Endpoint Protection, or Tanium to monitor and block unauthorized hardware.
- Implement device control policies to allow specific hardware types (e.g., keyboards, mice) and block others.

Harden BIOS/UEFI and System Firmware:

- Set strong passwords for BIOS/UEFI access.
- Enable Secure Boot to prevent rogue hardware components from loading unauthorized firmware.

Restrict Peripheral Devices and Drivers:

- Use Windows Device Manager Policies to block installation of unapproved drivers.
- Monitor hardware installation attempts through endpoint monitoring tools.

Disable Bluetooth and Wireless Hardware:

- Use GPO or MDM tools to disable Bluetooth and Wi-Fi interfaces across systems.
- Restrict hardware pairing to approved devices only.

Logging and Monitoring:

- Enable logging for hardware installation events in Windows Event Logs (Event ID 20001 for

Device Setup Manager).

- Use SIEM solutions (e.g., Splunk, Elastic Stack) to detect unauthorized hardware installation activities.

Tools for Implementation

USB and Device Control:

- Microsoft Group Policy Objects (GPO)
- Microsoft Defender for Endpoint
- Symantec Endpoint Protection
- McAfee Device Control

Endpoint Monitoring:

- EDRs
- OSSEC (open-source host-based IDS)

Hardware Whitelisting:

- BitLocker for external drives (Windows)
- Windows Device Installation Policies
- Device Control

BIOS/UEFI Security:

- Secure Boot (Windows/Linux) Firmware management tools like Dell Command Update or HP Sure Start

The tag is: *misp-galaxy:mitre-course-of-action="Limit Hardware Installation - M1034"*

Table 6988. Table References

https://attack.mitre.org/mitigations/M1034

Path Interception Mitigation - T1034

Eliminate path interception weaknesses in program configuration files, scripts, the PATH environment variable, services, and in shortcuts by surrounding PATH variables with quotation marks when functions allow for them (Citation: Microsoft CreateProcess). Be aware of the search order Windows uses for executing or loading binaries and use fully qualified paths wherever appropriate (Citation: MSDN DLL Security). Clean up old Windows Registry keys when software is uninstalled to avoid keys with no associated legitimate binaries.

Periodically search for and correct or report path interception weaknesses on systems that may have been introduced using custom or available tools that report software using insecure path configurations (Citation: Kanthak Sentinel).

Require that all executables be placed in write-protected directories. Ensure that proper permissions and directory access control are set to deny users the ability to write files to the top-level directory <code>C:</code> and system directories, such as <code>C:\Windows\</code>, to reduce places where malicious files could be placed for execution.

Identify and block potentially malicious software that may be executed through the path interception by using whitelisting (Citation: Beechey 2010) tools, like AppLocker (Citation: Windows Commands JPCERT) (Citation: NSA MS AppLocker) or Software Restriction Policies, (Citation: Corio 2008) that are capable of auditing and/or blocking unknown executables.

The tag is: *misp-galaxy:mitre-course-of-action="Path Interception Mitigation - T1034"*

Scheduled Task Mitigation - T1053

Limit privileges of user accounts and remediate Privilege Escalation vectors so only authorized administrators can create scheduled tasks on remote systems. Toolkits like the PowerSploit framework contain PowerUp modules that can be used to explore systems for permission weaknesses in scheduled tasks that could be used to escalate privileges. (Citation: Powersploit)

Configure settings for scheduled tasks to force tasks to run under the context of the authenticated account instead of allowing them to run as SYSTEM. The associated Registry key is located at <code>HKLM\SYSTEM\CurrentControlSet\Control\Lsa\SubmitControl</code>. The setting can be configured through GPO: Computer Configuration > [Policies] > Windows Settings > Security Settings > Local Policies > Security Options: Domain Controller: Allow server operators to schedule tasks, set to disabled. (Citation: TechNet Server Operator Scheduled Task)

Configure the Increase Scheduling Priority option to only allow the Administrators group the rights to schedule a priority process. This can be can be configured through GPO: Computer Configuration > [Policies] > Windows Settings > Security Settings > Local Policies > User Rights Assignment: Increase scheduling priority. (Citation: TechNet Scheduling Priority)

Identify and block unnecessary system utilities or potentially malicious software that may be used to schedule tasks using whitelisting (Citation: Beechey 2010) tools, like AppLocker, (Citation: Windows Commands JPCERT) (Citation: NSA MS AppLocker) or Software Restriction Policies (Citation: Corio 2008) where appropriate. (Citation: TechNet Applocker vs SRP)

Account Use Policies - M1036

Account Use Policies help mitigate unauthorized access by configuring and enforcing rules that govern how and when accounts can be used. These policies include enforcing account lockout mechanisms, restricting login times, and setting inactivity timeouts. Proper configuration of these policies reduces the risk of brute-force attacks, credential theft, and unauthorized access by limiting the opportunities for malicious actors to exploit accounts. This mitigation can be implemented through the following measures:

Account Lockout Policies:

- Implementation: Configure account lockout settings so that after a defined number of failed login attempts (e.g., 3-5 attempts), the account is locked for a specific time period (e.g., 15 minutes) or requires an administrator to unlock it.
- Use Case: This prevents brute-force attacks by limiting how many incorrect password attempts can be made before the account is temporarily disabled, reducing the likelihood of an attacker successfully guessing a password.

Login Time Restrictions:

- Implementation: Set up login time policies to restrict when users or groups can log into systems. For example, only allowing login during standard business hours (e.g., 8 AM to 6 PM) for non-administrative accounts.
- Use Case: This prevents unauthorized access outside of approved working hours, where login attempts might be more suspicious or harder to monitor. For example, if an account that is only supposed to be active during the day logs in at 2 AM, it should raise an alert or be blocked.

Inactivity Timeout and Session Termination:

- Implementation: Enforce session timeouts after a period of inactivity (e.g., 10-15 minutes) and require users to re-authenticate if they wish to resume the session.
- Use Case: This policy prevents attackers from hijacking active sessions left unattended. For example, if an employee walks away from their computer without locking it, an attacker with physical access to the system would be unable to exploit the session.

Password Aging Policies:

- Implementation: Enforce password aging rules, requiring users to change their passwords after a defined period (e.g., 90 days) and ensure passwords are not reused by maintaining a password history.
- Use Case: This limits the risk of compromised passwords being used indefinitely. Regular password changes make it more difficult for attackers to reuse stolen credentials.

Account Expiration and Deactivation:

- Implementation: Configure user accounts, especially for temporary or contract workers, to automatically expire after a set date or event. Accounts that remain unused for a specific period should be deactivated automatically.
- Use Case: This prevents dormant accounts from becoming an attack vector. For example, an attacker can exploit unused accounts if they are not properly monitored or deactivated.

Tools for Implementation:

- Group Policy Objects (GPOs) in Windows: To enforce account lockout thresholds, login time restrictions, session timeouts, and password policies.
- Identity and Access Management (IAM) solutions: For centralized management of user accounts, session policies, and automated deactivation of accounts.
- Security Information and Event Management (SIEM) platforms: To monitor and alert on unusual login activity, such as failed logins or out-of-hours access attempts.
- Multi-Factor Authentication (MFA) Tools: To further enforce secure login attempts, preventing brute-force or credential stuffing attacks.

https://attack.mitre.org/mitigations/M1036

Filter Network Traffic - M1037

Employ network appliances and endpoint software to filter ingress, egress, and lateral network traffic. This includes protocol-based filtering, enforcing firewall rules, and blocking or restricting traffic based on predefined conditions to limit adversary movement and data exfiltration. This mitigation can be implemented through the following measures:

Ingress Traffic Filtering:

- Use Case: Configure network firewalls to allow traffic only from authorized IP addresses to public-facing servers.
- Implementation: Limit SSH (port 22) and RDP (port 3389) traffic to specific IP ranges.

Egress Traffic Filtering:

- Use Case: Use firewalls or endpoint security software to block unauthorized outbound traffic to prevent data exfiltration and command-and-control (C2) communications.
- Implementation: Block outbound traffic to known malicious IPs or regions where communication is unexpected.

Protocol-Based Filtering:

- Use Case: Restrict the use of specific protocols that are commonly abused by adversaries, such

as SMB, RPC, or Telnet, based on business needs.

- Implementation: Disable SMBv1 on endpoints to prevent exploits like EternalBlue.

Network Segmentation:

- Use Case: Create network segments for critical systems and restrict communication between segments unless explicitly authorized.
- Implementation: Implement VLANs to isolate IoT devices or guest networks from core business systems.

Application Layer Filtering:

- Use Case: Use proxy servers or Web Application Firewalls (WAFs) to inspect and block malicious HTTP/S traffic.
- Implementation: Configure a WAF to block SQL injection attempts or other web application exploitation techniques.

The tag is: *misp-galaxy:mitre-course-of-action="Filter Network Traffic - M1037"*

Table 6993. Table References

Links
https://attack.mitre.org/mitigations/M1037

Logon Scripts Mitigation - T1037

Restrict write access to logon scripts to specific administrators. Prevent access to administrator accounts by mitigating Credential Access techniques and limiting account access and permissions of [Valid Accounts](https://attack.mitre.org/techniques/T1078).

Identify and block potentially malicious software that may be executed through logon script modification by using whitelisting (Citation: Beechey 2010) tools like AppLocker (Citation: Windows Commands JPCERT) (Citation: NSA MS AppLocker) that are capable of auditing and/or blocking unknown programs.

The tag is: *misp-galaxy:mitre-course-of-action="Logon Scripts Mitigation - T1037"*

https://attack.mitre.org/mitigations/T1037

Environment Variable Permissions - M1039

Restrict the modification of environment variables to authorized users and processes by enforcing strict permissions and policies. This ensures the integrity of environment variables, preventing adversaries from abusing or altering them for malicious purposes. This mitigation can be implemented through the following measures:

Restrict Write Access:

- Use Case: Set file system-level permissions to restrict access to environment variable configuration files (e.g., `.bashrc`, `.bash_profile`, `.zshrc`, `systemd` service files).
- Implementation: Configure `/etc/environment` or `/etc/profile` on Linux systems to only allow root or administrators to modify the file.

Secure Access Controls:

- Use Case: Limit access to environment variable settings in application deployment tools or CI/CD pipelines to authorized personnel.
- Implementation: Use role-based access control (RBAC) in tools like Jenkins or GitLab to ensure only specific users can modify environment variables.

Restrict Process Scope:

- Use Case: Configure policies to ensure environment variables are only accessible to the processes they are explicitly intended for.
- Implementation: Use containerized environments like Docker to isolate environment variables to specific containers and ensure they are not inherited by other processes.

Audit Environment Variable Changes:

- Use Case: Enable logging for changes to critical environment variables.
- Implementation: Use `auditd` on Linux to monitor changes to files like `/etc/environment` or application-specific environment files.

The tag is: *misp-galaxy:mitre-course-of-action="Environment Variable Permissions - M1039"*

Table 6995. Table References

Links
https://attack.mitre.org/mitigations/M1039

Process Hollowing Mitigation - T1093

This type of attack technique cannot be easily mitigated with preventive controls since it is based on the abuse of operating system design features. For example, mitigating specific API calls will likely have unintended side effects, such as preventing legitimate software (i.e., security products) from operating properly. Efforts should be focused on preventing adversary tools from running earlier in the chain of activity and on identifying subsequent malicious behavior.

Although process hollowing may be used to evade certain types of defenses, it is still good practice to identify potentially malicious software that may be used to perform adversarial actions and audit and/or block it by using whitelisting (Citation: Beechey 2010) tools, like AppLocker, (Citation: Windows Commands JPCERT) (Citation: NSA MS AppLocker) or Software Restriction Policies (Citation: Corio 2008) where appropriate. (Citation: TechNet Applocker vs SRP)

The tag is: *misp-galaxy:mitre-course-of-action="Process Hollowing Mitigation - T1093"*

Restrict Library Loading - M1044

Restricting library loading involves implementing security controls to ensure that only trusted and verified libraries (DLLs, shared objects, etc.) are loaded into processes. Adversaries often abuse Dynamic-Link Library (DLL) Injection, DLL Search Order Hijacking, or LD_PRELOAD mechanisms to execute malicious code by forcing the operating system to load untrusted libraries. This mitigation can be implemented through the following measures:

Enforce Safe Library Loading Practices:

- Enable `SafeDLLSearchMode` on Windows.
- Restrict `LD_PRELOAD` and `LD_LIBRARY_PATH` usage on Linux systems.

Code Signing Enforcement:

- Require digital signatures for all libraries loaded into processes.
- Use tools like Signtool, and WDAC to enforce signed DLL execution.

Environment Hardening:

- Secure library paths and directories to prevent adversaries from placing rogue libraries.
- Monitor user-writable directories and system configurations for unauthorized changes.

Audit and Monitor Library Loading:

- Enable `Sysmon` on Windows to monitor for suspicious library loads.

- Use `auditd` on Linux to monitor shared library paths and configuration file changes.

Use Application Control Solutions:

- Implement AppLocker, WDAC, or SELinux to allow only trusted libraries.

Tools for Implementation

Windows-Specific Tools:

- AppLocker: Application whitelisting for DLLs.
- Windows Defender Application Control (WDAC): Restrict unauthorized library execution.
- Signtool: Verify and enforce code signing.
- Sysmon: Monitor DLL load events (Event ID 7).

Linux-Specific Tools:

- auditd: Monitor changes to library paths and critical files.
- SELinux/AppArmor: Define policies to restrict library loading.
- ldconfig and chattr: Secure LD configuration files and prevent unauthorized modifications.

Cross-Platform Solutions:

- Wazuh or OSSEC: File integrity monitoring for library changes.
- Tripwire: Detect and alert on unauthorized library modifications.

Data Staged Mitigation - T1074

Identify system utilities, remote access or third-party tools, users or potentially malicious software that may be used to store compressed or encrypted data in a publicly writeable directory, central location, or commonly used staging directories (e.g. recycle bin) that is indicative of non-standard behavior, and audit and/or block them by using file integrity monitoring tools where appropriate. Consider applying data size limits or blocking file writes of common compression and encryption utilities such as 7zip, RAR, ZIP, or zlib on frequently used staging directories or central locations and monitor attempted violations of those restrictions.

The tag is: *misp-galaxy:mitre-course-of-action="Data Staged Mitigation - T1074"*

Table 7000. Table References

Links

Do Not Mitigate - M1055

The Do Not Mitigate category highlights scenarios where attempting to mitigate a specific technique may inadvertently increase the organization's security risk or operational instability. This could happen due to the complexity of the system, the integration of critical processes, or the potential for introducing new vulnerabilities. Instead of direct mitigation, these situations may call for alternative strategies such as detection, monitoring, or response. The Do Not Mitigate category underscores the importance of assessing the trade-offs between mitigation efforts and overall system integrity. This mitigation can be implemented through the following measures:

Complex Systems Where Mitigation is Risky:

- Interpretation: In certain systems, direct mitigation could introduce new risks, especially if the system is highly interconnected or complex, such as in legacy industrial control systems (ICS). Patching or modifying these systems could result in unplanned downtime, disruptions, or even safety risks.
- Use Case: In a power grid control system, attempting to patch or disable certain services related to device communications might disrupt critical operations, leading to unintended service outages.

Risk of Reducing Security Coverage:

- Interpretation: In some cases, mitigating a technique might reduce the visibility or effectiveness of other security controls, limiting an organization's ability to detect broader attacks.
- Use Case: Disabling script execution on a web server to mitigate potential PowerShell-based attacks could interfere with legitimate administrative operations that rely on scripting, while attackers may still find alternate ways to execute code.

Introduction of New Vulnerabilities:

- Interpretation: In highly sensitive or tightly controlled environments, implementing certain mitigations might create vulnerabilities in other parts of the system. For instance, disabling default security mechanisms in an attempt to resolve compatibility issues may open the system to exploitation.
- Use Case: Disabling certificate validation to resolve internal communication issues in a secure environment could lead to man-in-the-middle attacks, creating a greater vulnerability than the original problem.

Negative Impact on Performance and Availability:

- Interpretation: Mitigations that involve removing or restricting system functionalities can have unintended consequences for system performance and availability. Some mitigations, while effective at blocking certain attacks, may introduce performance bottlenecks or compromise essential operations.
- Use Case: Implementing high levels of encryption to mitigate data theft might result in significant performance degradation in systems handling large volumes of real-time transactions.

The tag is: *misp-galaxy:mitre-course-of-action="Do Not Mitigate - M1055"*

Table 7002. Table References

Links
https://attack.mitre.org/mitigations/M1055

Data Loss Prevention - M1057

Data Loss Prevention (DLP) involves implementing strategies and technologies to identify, categorize, monitor, and control the movement of sensitive data within an organization. This includes protecting data formats indicative of Personally Identifiable Information (PII), intellectual property, or financial data from unauthorized access, transmission, or exfiltration. DLP solutions integrate with network, endpoint, and cloud platforms to enforce security policies and prevent accidental or malicious data leaks. (Citation: PurpleSec Data Loss Prevention) This mitigation can be implemented through the following measures:

Sensitive Data Categorization:

- Use Case: Identify and classify data based on sensitivity (e.g., PII, financial data, trade secrets).
- Implementation: Use DLP solutions to scan and tag files containing sensitive information using predefined patterns, such as Social Security Numbers or credit card details.

Exfiltration Restrictions:

- Use Case: Prevent unauthorized transmission of sensitive data.
- Implementation: Enforce policies to block unapproved email attachments, unauthorized USB usage, or unencrypted data uploads to cloud storage.

Data-in-Transit Monitoring:

- Use Case: Detect and prevent the transmission of sensitive data over unapproved channels.
- Implementation: Deploy network-based DLP tools to inspect outbound traffic for sensitive content (e.g., financial records or PII) and block unapproved transmissions.

Endpoint Data Protection:

- Use Case: Monitor and control sensitive data usage on endpoints.
- Implementation: Use endpoint-based DLP agents to block copy-paste actions of sensitive data and unauthorized printing or file sharing.

Cloud Data Security:

- Use Case: Protect data stored in cloud platforms.
- Implementation: Integrate DLP with cloud storage platforms like Google Drive, OneDrive, or AWS to monitor and restrict sensitive data sharing or downloads.

The tag is: *misp-galaxy:mitre-course-of-action="Data Loss Prevention - M1057"*

Valid Accounts Mitigation - T1078

Take measures to detect or prevent techniques such as [OS Credential Dumping](https://attack.mitre.org/techniques/T1003) or installation of keyloggers to acquire credentials through [Input Capture](https://attack.mitre.org/techniques/T1056). Limit credential overlap across systems to prevent access if account credentials are obtained. Ensure that local administrator accounts have complex, unique passwords across all systems on the network. Do not put user or admin domain accounts in the local administrator groups across systems unless they are tightly controlled and use of accounts is segmented, as this is often equivalent to having a local administrator account with the same password on all systems.

Follow best practices for design and administration of an enterprise network to limit privileged

account use across administrative tiers. (Citation: Microsoft Securing Privileged Access)

Audit domain and local accounts as well as their permission levels routinely to look for situations that could allow an adversary to gain wide access by obtaining credentials of a privileged account. (Citation: TechNet Credential Theft) (Citation: TechNet Least Privilege) These audits should also include if default accounts have been enabled, or if new local accounts are created that have not be authorized.

Applications and appliances that utilize default username and password should be changed immediately after the installation, and before deployment to a production environment. (Citation: US-CERT Alert TA13-175A Risks of Default Passwords on the Internet) When possible, applications that use SSH keys should be updated periodically and properly secured.

Multilayer Encryption Mitigation - T1079

Network intrusion detection and prevention systems that use network signatures to identify traffic for specific adversary malware can be used to mitigate activity at the network level. Use of encryption protocols may make typical network-based C2 detection more difficult due to a reduced ability to signature the traffic. Prior knowledge of adversary C2 infrastructure may be useful for domain and IP address blocking, but will likely not be an effective long-term solution because adversaries can change infrastructure often. (Citation: University of Birmingham C2)

Email Collection Mitigation - T1114

Use of encryption provides an added layer of security to sensitive information sent over email. Encryption using public key cryptography requires the adversary to obtain the private certificate along with an encryption key to decrypt messages.

Use of two-factor authentication for public-facing webmail servers is also a recommended best practice to minimize the usefulness of user names and passwords to adversaries.

Identify unnecessary system utilities or potentially malicious software that may be used to collect email data files or access the corporate email server, and audit and/or block them by using whitelisting (Citation: Beechey 2010) tools, like AppLocker, (Citation: Windows Commands JPCERT) (Citation: NSA MS AppLocker) or Software Restriction Policies (Citation: Corio 2008) where appropriate. https://technet.microsoft.com/en-us/library/cc733026.aspx

Automated Collection Mitigation - T1119

Encryption and off-system storage of sensitive information may be one way to mitigate collection of files, but may not stop an adversary from acquiring the information if an intrusion persists over a long period of time and the adversary is able to discover and access the data through other means. A keylogger installed on a system may be able to intercept passwords through [Input Capture](https://attack.mitre.org/techniques/T1056) and be used to decrypt protected documents that an adversary may have collected. Strong passwords should be used to prevent offline cracking of encrypted documents through [Brute Force](https://attack.mitre.org/techniques/T1110) techniques.

Identify unnecessary system utilities, third-party tools, or potentially malicious software that may be used to collect files and audit and/or block them by using whitelisting (Citation: Beechey 2010) tools, like AppLocker, (Citation: Windows Commands JPCERT) (Citation: NSA MS AppLocker) or Software Restriction Policies (Citation: Corio 2008) where appropriate. (Citation: TechNet Applocker vs SRP)

Data Encoding Mitigation - T1132

Network intrusion detection and prevention systems that use network signatures to identify traffic for specific adversary malware can be used to mitigate activity at the network level. Signatures are often for unique indicators within protocols and may be based on the specific obfuscation technique used by a particular adversary or tool, and will likely be different across various malware families and versions. Adversaries will likely change tool C2 signatures over time or construct protocols in such a way as to avoid detection by common defensive tools. (Citation: University of Birmingham C2)

Hidden Window Mitigation - T1143

Whitelist programs that are allowed to have this plist tag. All other programs should be considered suspicious.

The tag is: *misp-galaxy:mitre-course-of-action="Hidden Window Mitigation - T1143"*

Table 7026. Table References

Links
https://attack.mitre.org/mitigations/T1143

Create Account Mitigation - T1136

Use and enforce multifactor authentication. Follow guidelines to prevent or limit adversary access to [Valid Accounts](https://attack.mitre.org/techniques/T1078) that may be used to create privileged accounts within an environment.

Adversaries that create local accounts on systems may have limited access within a network if access levels are properly locked down. These accounts may only be needed for persistence on individual systems and their usefulness depends on the utility of the system they reside on.

Protect domain controllers by ensuring proper security configuration for critical servers. Configure access controls and firewalls to limit access to these systems. Do not allow domain administrator accounts to be used for day-to-day operations that may expose them to potential adversaries on unprivileged systems.

The tag is: *misp-galaxy:mitre-course-of-action="Create Account Mitigation - T1136"*

Table 7027. Table References

Links
https://attack.mitre.org/mitigations/T1136

Application Shimming Mitigation - T1138

There currently aren't a lot of ways to mitigate application shimming. Disabling the Shim Engine isn't recommended because Windows depends on shimming for interoperability and software may become unstable or not work. Microsoft released an optional patch update - KB3045645 - that will remove the "auto-elevate" flag within the sdbinst.exe. This will prevent use of application shimming to bypass UAC.

Changing UAC settings to "Always Notify" will give the user more visibility when UAC elevation is requested, however, this option will not be popular among users due to the constant UAC interruptions.

The tag is: *misp-galaxy:mitre-course-of-action="Application Shimming Mitigation - T1138"*

Table 7028. Table References

Links
https://attack.mitre.org/mitigations/T1138

Spearphishing Attachment Mitigation - T1193

Network intrusion prevention systems and systems designed to scan and remove malicious email attachments can be used to block activity. Solutions can be signature and behavior based, but adversaries may construct attachments in a way to avoid these systems.

Block unknown or unused attachments by default that should not be transmitted over email as a best practice to prevent some vectors, such as .scr, .exe, .pif, .cpl, etc. Some email scanning devices can open and analyze compressed and encrypted formats, such as zip and rar that may be used to conceal malicious attachments in [Obfuscated Files or Information](https://attack.mitre.org/techniques/T1027).

Because this technique involves user interaction on the endpoint, it's difficult to fully mitigate. However, there are potential mitigations. Users can be trained to identify social engineering techniques and spearphishing emails. To prevent the attachments from executing, application whitelisting can be used. Anti-virus can also automatically quarantine suspicious files.

The tag is: *misp-galaxy:mitre-course-of-action="Spearphishing Attachment Mitigation - T1193"*

Table 7029. Table References

Links
https://attack.mitre.org/mitigations/T1193

Bash History Mitigation - T1139

There are multiple methods of preventing a user's command history from being flushed to their .bash_history file, including use of the following commands: <code>set +o history</code> and <code>set -o history</code> to start logging again; <code>unset HISTFILE</code> being added to a user's .bash_rc file; and <code>ln -s /dev/null ~/.bash_history</code> to write commands to <code>/dev/null</code>instead.

The tag is: *misp-galaxy:mitre-course-of-action="Bash History Mitigation - T1139"*

Table 7030. Table References

Service Stop Mitigation - T1489

Ensure proper process, registry, and file permissions are in place to inhibit adversaries from disabling or interfering with critical services. Limit privileges of user accounts and groups so that only authorized administrators can interact with service changes and service configurations. Harden systems used to serve critical network, business, and communications functions. Operate intrusion detection, analysis, and response systems on a separate network from the production environment to lessen the chances that an adversary can see and interfere with critical response functions.

The tag is: *misp-galaxy:mitre-course-of-action="Service Stop Mitigation - T1489"*

Table 7048. Table References

Links
https://attack.mitre.org/mitigations/T1489

Multi-factor Authentication - M1032

Multi-Factor Authentication (MFA) enhances security by requiring users to provide at least two forms of verification to prove their identity before granting access. These factors typically include:

- **Something you know**: Passwords, PINs.
- **Something you have**: Physical tokens, smartphone authenticator apps.
- **Something you are**: Biometric data such as fingerprints, facial recognition, or retinal scans.

Implementing MFA across all critical systems and services ensures robust protection against account takeover and unauthorized access. This mitigation can be implemented through the following measures:

Identity and Access Management (IAM):

- Use IAM solutions like Azure Active Directory, Okta, or AWS IAM to enforce MFA policies for all user logins, especially for privileged roles.
- Enable conditional access policies to enforce MFA for risky sign-ins (e.g., unfamiliar devices, geolocations).

Authentication Tools and Methods:

- Use authenticator applications such as Google Authenticator, Microsoft Authenticator, or Authy for time-based one-time passwords (TOTP).
- Deploy hardware-based tokens like YubiKey, RSA SecurID, or smart cards for additional security.
- Enforce biometric authentication for compatible devices and applications.

Secure Legacy Systems:

- Integrate MFA solutions with older systems using third-party tools like Duo Security or Thales SafeNet.
- Enable RADIUS/NPS servers to facilitate MFA for VPNs, RDP, and other network logins.

Monitoring and Alerting:

- Use SIEM tools to monitor failed MFA attempts, login anomalies, or brute-force attempts against MFA systems.
- Implement alerts for suspicious MFA activities, such as repeated failed codes or new device registrations.

Training and Policy Enforcement:

- Educate employees on the importance of MFA and secure authenticator usage.
- Enforce policies that require MFA on all critical systems, especially for remote access, privileged accounts, and cloud applications.

SSL/TLS Inspection - M1020

SSL/TLS inspection involves decrypting encrypted network traffic to examine its content for signs of malicious activity. This capability is crucial for detecting threats that use encryption to evade detection, such as phishing, malware, or data exfiltration. After inspection, the traffic is re-encrypted and forwarded to its destination. This mitigation can be implemented through the following measures:

Deploy SSL/TLS Inspection Appliances:

- Implement SSL/TLS inspection solutions to decrypt and inspect encrypted traffic.
- Ensure appliances are placed at critical network choke points for maximum coverage.

Configure Decryption Policies:

- Define rules to decrypt traffic for specific applications, ports, or domains.
- Avoid decrypting sensitive or privacy-related traffic, such as financial or healthcare websites, to comply with regulations.

Integrate Threat Intelligence:

- Use threat intelligence feeds to correlate inspected traffic with known indicators of compromise (IOCs).

Integrate with Security Tools:

- Combine SSL/TLS inspection with SIEM and NDR tools to analyze decrypted traffic and generate alerts for suspicious activity.
- Example Tools: Splunk, Darktrace

Implement Certificate Management:

- Use trusted internal or third-party certificates for traffic re-encryption after inspection.
- Regularly update certificate authorities (CAs) to ensure secure re-encryption.

Monitor and Tune:

- Continuously monitor SSL/TLS inspection logs for anomalies and fine-tune policies to reduce false positives.

The tag is: *misp-galaxy:mitre-course-of-action="SSL/TLS Inspection - M1020"*

Lock Bootloader - M1003

On devices that provide the capability to unlock the bootloader (hence allowing any operating system code to be flashed onto the device), perform periodic checks to ensure that the bootloader is locked.

The tag is: *misp-galaxy:mitre-course-of-action="Lock Bootloader - M1003"*

Table 7054. Table References

Links
https://attack.mitre.org/mitigations/M1003

Network Segmentation - M1030

Network segmentation involves dividing a network into smaller, isolated segments to control and limit the flow of traffic between devices, systems, and applications. By segmenting networks, organizations can reduce the attack surface, restrict lateral movement by adversaries, and protect critical assets from compromise.

Effective network segmentation leverages a combination of physical boundaries, logical separation through VLANs, and access control policies enforced by network appliances like firewalls, routers, and cloud-based configurations. This mitigation can be implemented through the following measures:

Segment Critical Systems:

- Identify and group systems based on their function, sensitivity, and risk. Examples include payment systems, HR databases, production systems, and internet-facing servers.
- Use VLANs, firewalls, or routers to enforce logical separation.

Implement DMZ for Public-Facing Services:

- Host web servers, DNS servers, and email servers in a DMZ to limit their access to internal systems.
- Apply strict firewall rules to filter traffic between the DMZ and internal networks.

Use Cloud-Based Segmentation:

- In cloud environments, use VPCs, subnets, and security groups to isolate applications and enforce traffic rules.
- Apply AWS Transit Gateway or Azure VNet peering for controlled connectivity between cloud segments.

Apply Microsegmentation for Workloads:

- Use software-defined networking (SDN) tools to implement workload-level segmentation and prevent lateral movement.

Restrict Traffic with ACLs and Firewalls:

- Apply Access Control Lists (ACLs) to network devices to enforce "deny by default" policies.
- Use firewalls to restrict both north-south (external-internal) and east-west (internal-internal) traffic.

Monitor and Audit Segmented Networks:

- Regularly review firewall rules, ACLs, and segmentation policies.
- Monitor network flows for anomalies to ensure segmentation is effective.

Test Segmentation Effectiveness:

- Perform periodic penetration tests to verify that unauthorized access is blocked between network segments.

The tag is: *misp-galaxy:mitre-course-of-action="Network Segmentation - M1030"*

Table 7055. Table References

Links
https://attack.mitre.org/mitigations/M1030

Application Vetting - M1005

Enterprises can vet applications for exploitable vulnerabilities or unwanted (privacy-invasive or malicious) behaviors. Enterprises can inspect applications themselves or use a third-party service.

Enterprises may impose policies to only allow pre-approved applications to be installed on their devices or may impose policies to block use of specific applications known to have issues. In Bring Your Own Device (BYOD) environments, enterprises may only be able to impose these policies over an enterprise-managed portion of the device.

Application Vetting is not a complete mitigation. Techniques such as [Evade Analysis Environment](https://attack.mitre.org/techniques/T1523) exist that can enable adversaries to bypass vetting.

The tag is: *misp-galaxy:mitre-course-of-action="Application Vetting - M1005"*

Table 7056. Table References

Links
https://attack.mitre.org/mitigations/M1005

Exploit Protection - M1050

Deploy capabilities that detect, block, and mitigate conditions indicative of software exploits. These capabilities aim to prevent exploitation by addressing vulnerabilities, monitoring anomalous behaviors, and applying exploit-mitigation techniques to harden systems and software.

Operating System Exploit Protections:

- Use Case: Enable built-in exploit protection features provided by modern operating systems, such as Microsoft's Exploit Protection, which includes techniques like Data Execution Prevention (DEP), Address Space Layout Randomization (ASLR), and Control Flow Guard (CFG).
- Implementation: Enforce DEP for all programs and enable ASLR to randomize memory addresses used by system and application processes. Windows: Configure Exploit Protection through the Windows Security app or deploy settings via Group Policy. `ExploitProtectionExportSettings.exe -path "exploit_settings.xml"` Linux: Use Kernel-level hardening features like SELinux, AppArmor, or GRSEC to enforce memory protections and prevent exploits.

Third-Party Endpoint Security:

- Use Case: Use endpoint protection tools with built-in exploit protection, such as enhanced memory protection, behavior monitoring, and real-time exploit detection.
- Implementation: Deploy tools to detect and block exploitation attempts targeting unpatched software.

Virtual Patching: - Use Case: Use tools to implement virtual patches that mitigate vulnerabilities in applications or operating systems until official patches are applied. - Implementation: Use Intrusion Prevention System (IPS) to block exploitation attempts on known vulnerabilities in outdated applications.

Hardening Application Configurations:

- Use Case: Disable risky application features that can be exploited, such as macros in Microsoft Office or JScript in Internet Explorer.
- Implementation: Configure Microsoft Office Group Policies to disable execution of macros in downloaded files.

Update Software - M1051

Software updates ensure systems are protected against known vulnerabilities by applying patches and upgrades provided by vendors. Regular updates reduce the attack surface and prevent adversaries from exploiting known security gaps. This includes patching operating systems, applications, drivers, and firmware. This mitigation can be implemented through the following measures:

Regular Operating System Updates

- Implementation: Apply the latest Windows security updates monthly using WSUS (Windows Server Update Services) or a similar patch management solution. Configure systems to check for updates automatically and schedule reboots during maintenance windows.
- Use Case: Prevents exploitation of OS vulnerabilities such as privilege escalation or remote code execution.

Application Patching

- Implementation: Monitor Apache's update release notes for security patches addressing vulnerabilities. Schedule updates for off-peak hours to avoid downtime while maintaining security compliance.
- Use Case: Prevents exploitation of web application vulnerabilities, such as those leading to unauthorized access or data breaches.

Firmware Updates

- Implementation: Regularly check the vendor's website for firmware updates addressing vulnerabilities. Plan for update deployment during scheduled maintenance to minimize business disruption.
- Use Case: Protects against vulnerabilities that adversaries could exploit to gain access to network devices or inject malicious traffic.

Emergency Patch Deployment

- Implementation: Use the emergency patch deployment feature of the organization's patch management tool to apply updates to all affected Exchange servers within 24 hours.
- Use Case: Reduces the risk of exploitation by rapidly addressing critical vulnerabilities.

Centralized Patch Management

- Implementation: Implement a centralized patch management system, such as SCCM or ManageEngine, to automate and track patch deployment across all environments. Generate regular compliance reports to ensure all systems are updated.
- Use Case: Streamlines patching processes and ensures no critical systems are missed.

Tools for Implementation

Patch Management Tools:

- WSUS: Manage and deploy Microsoft updates across the organization.
- ManageEngine Patch Manager Plus: Automate patch deployment for OS and third-party apps.
- Ansible: Automate updates across multiple platforms, including Linux and Windows.

Vulnerability Scanning Tools:

- OpenVAS: Open-source vulnerability scanning to identify missing patches.

The tag is: *misp-galaxy:mitre-course-of-action="Update Software - M1051"*

Table 7062. Table References

Links
https://attack.mitre.org/mitigations/M1051

Vulnerability Scanning - M1016

Vulnerability scanning involves the automated or manual assessment of systems, applications, and networks to identify misconfigurations, unpatched software, or other security weaknesses. The process helps prioritize remediation efforts by classifying vulnerabilities based on risk and impact, reducing the likelihood of exploitation by adversaries. This mitigation can be implemented through the following measures:

Proactive Identification of Vulnerabilities

- Implementation: Use tools like Nessus or OpenVAS to scan endpoints, servers, and applications for missing patches and configuration issues. Schedule regular scans to ensure timely identification of vulnerabilities introduced by new deployments or updates.
- Use Case: A scan identifies unpatched software, such as outdated Apache servers, which could be exploited via CVE-XXXX-XXXX. The server is promptly patched, mitigating the risk.

Cloud Environment Scanning

- Implementation: Use cloud-specific vulnerability management tools like AWS Inspector, Azure Security Center, or GCP Security Command Center to identify issues like open S3 buckets or overly permissive IAM roles.
- Use Case: The scan detects a misconfigured S3 bucket with public read access, which is remediated to prevent potential data leakage.

Network Device Scanning

- Implementation: Use tools to scan network devices for vulnerabilities, such as weak SNMP strings or outdated firmware. Correlate scan results with vendor advisories to prioritize updates.
- Use Case: Scanning detects a router running outdated firmware vulnerable to CVE-XXXX-YYYY. The firmware is updated to a secure version.

Web Application Scanning

- Implementation: Use dynamic application security testing (DAST) tools such as OWASP ZAP or Burp Suite to scan for common vulnerabilities like SQL injection or cross-site scripting (XSS). Perform regular scans post-deployment to identify newly introduced vulnerabilities.
- Use Case: A scan identifies a cross-site scripting vulnerability in a form input field, which is promptly remediated by developers.

Prioritizing Vulnerabilities

- Implementation: Use vulnerability scoring frameworks like CVSS to assess severity. Integrate vulnerability scanning tools with ticketing systems to assign remediation tasks based on criticality.
- Use Case: A critical vulnerability with a CVSS score of 9.8 affecting remote access servers is prioritized and patched first.

Tools for Implementation

Open Source Tools:

- OpenVAS: Comprehensive network and system vulnerability scanning.
- OWASP ZAP: Dynamic scanning of web applications for vulnerabilities.
- Nmap with NSE Scripts: Network scanning with scripts to detect vulnerabilities.

User Training - M1017

User Training involves educating employees and contractors on recognizing, reporting, and preventing cyber threats that rely on human interaction, such as phishing, social engineering, and other manipulative techniques. Comprehensive training programs create a human firewall by empowering users to be an active component of the organization's cybersecurity defenses. This mitigation can be implemented through the following measures:

Create Comprehensive Training Programs:

- Design training modules tailored to the organization's risk profile, covering topics such as phishing, password management, and incident reporting.
- Provide role-specific training for high-risk employees, such as helpdesk staff or executives.

Use Simulated Exercises:

- Conduct phishing simulations to measure user susceptibility and provide targeted follow-up training.
- Run social engineering drills to evaluate employee responses and reinforce protocols.

Leverage Gamification and Engagement:

- Introduce interactive learning methods such as quizzes, gamified challenges, and rewards for successful detection and reporting of threats.

Incorporate Security Policies into Onboarding:

- Include cybersecurity training as part of the onboarding process for new employees.
- Provide easy-to-understand materials outlining acceptable use policies and reporting procedures.

Regular Refresher Courses:

- Update training materials to include emerging threats and techniques used by adversaries.
- Ensure all employees complete periodic refresher courses to stay informed.

Emphasize Real-World Scenarios:

- Use case studies of recent attacks to demonstrate the consequences of successful phishing or social engineering.
- Discuss how specific employee actions can prevent or mitigate such attacks.

The tag is: *misp-galaxy:mitre-course-of-action="User Training - M1017"*

Table 7068. Table References

Links
https://attack.mitre.org/mitigations/T1062

DCShadow Mitigation - T1207

This type of attack technique cannot be easily mitigated with preventive controls since it is based on the abuse of AD design features. For example, mitigating specific AD API calls will likely have unintended side effects, such as preventing DC replication from operating properly. Efforts should be focused on preventing adversary tools from running earlier in the chain of activity and on identification of subsequent malicious behavior.

The tag is: *misp-galaxy:mitre-course-of-action="DCShadow Mitigation - T1207"*

Table 7069. Table References

Links
https://attack.mitre.org/mitigations/T1207

Password Policies - M1027

Set and enforce secure password policies for accounts to reduce the likelihood of unauthorized access. Strong password policies include enforcing password complexity, requiring regular password changes, and preventing password reuse. This mitigation can be implemented through

the following measures:

Windows Systems:

- Use Group Policy Management Console (GPMC) to configure:
- Minimum password length (e.g., 12+ characters).
- Password complexity requirements.
- Password history (e.g., disallow last 24 passwords).
- Account lockout duration and thresholds.

Linux Systems:

- Configure Pluggable Authentication Modules (PAM):
- Use `pam_pwquality` to enforce complexity and length requirements.
- Implement `pam_tally2` or `pam_faillock` for account lockouts.
- Use `pwunconv` to disable password reuse.

Password Managers:

- Enforce usage of enterprise password managers (e.g., Bitwarden, 1Password, LastPass) to generate and store strong passwords.

Password Blacklisting:

- Use tools like Have I Been Pwned password checks or NIST-based blacklist solutions to prevent users from setting compromised passwords.

Regular Auditing:

- Periodically audit password policies and account configurations to ensure compliance using tools like LAPS (Local Admin Password Solution) and vulnerability scanners.

Tools for Implementation

Windows:

- Group Policy Management Console (GPMC): Enforce password policies.
- Microsoft Local Administrator Password Solution (LAPS): Enforce random, unique admin passwords.

Linux/macOS:

- PAM Modules (pam_pwquality, pam_tally2, pam_faillock): Enforce password rules.
- Lynis: Audit password policies and system configurations.

Cross-Platform:

- Password Managers (Bitwarden, 1Password, KeePass): Manage and enforce strong passwords.

- Have I Been Pwned API: Prevent the use of breached passwords.
- NIST SP 800-63B compliant tools: Enforce password guidelines and blacklisting.

Data Backup - M1053

Data Backup involves taking and securely storing backups of data from end-user systems and critical servers. It ensures that data remains available in the event of system compromise, ransomware attacks, or other disruptions. Backup processes should include hardening backup systems, implementing secure storage solutions, and keeping backups isolated from the corporate network to prevent compromise during active incidents. This mitigation can be implemented through the following measures:

Regular Backup Scheduling: - Use Case: Ensure timely and consistent backups of critical data. - Implementation: Schedule daily incremental backups and weekly full backups for all critical servers and systems.

Immutable Backups: - Use Case: Protect backups from modification or deletion, even by attackers. - Implementation: Use write-once-read-many (WORM) storage for backups, preventing ransomware from encrypting or deleting backup files.

Backup Encryption: - Use Case: Protect data integrity and confidentiality during transit and storage. - Implementation: Encrypt backups using strong encryption protocols (e.g., AES-256) before storing them in local, cloud, or remote locations.

Offsite Backup Storage: - Use Case: Ensure data availability during physical disasters or onsite breaches. - Implementation: Use cloud-based solutions like AWS S3, Azure Backup, or physical offsite storage to maintain a copy of critical data.

Backup Testing: - Use Case: Validate backup integrity and ensure recoverability. - Implementation: Regularly test data restoration processes to ensure that backups are not corrupted and can be recovered quickly.

Execution Prevention - M1038

Prevent the execution of unauthorized or malicious code on systems by implementing application

control, script blocking, and other execution prevention mechanisms. This ensures that only trusted and authorized code is executed, reducing the risk of malware and unauthorized actions. This mitigation can be implemented through the following measures:

Application Control:

- Use Case: Use tools like AppLocker or Windows Defender Application Control (WDAC) to create whitelists of authorized applications and block unauthorized ones. On Linux, use tools like SELinux or AppArmor to define mandatory access control policies for application execution.
- Implementation: Allow only digitally signed or pre-approved applications to execute on servers and endpoints. (e.g., `New-AppLockerPolicy -PolicyType Enforced -FilePath "C:\Policies\AppLocker.xml"`)

Script Blocking:

- Use Case: Use script control mechanisms to block unauthorized execution of scripts, such as PowerShell or JavaScript. Web Browsers: Use browser extensions or settings to block JavaScript execution from untrusted sources.
- Implementation: Configure PowerShell to enforce Constrained Language Mode for non-administrator users. (e.g., `Set-ExecutionPolicy AllSigned`)

Executable Blocking:

- Use Case: Prevent execution of binaries from suspicious locations, such as `%TEMP%` or `%APPDATA%` directories.
- Implementation: Block execution of `.exe`, `.bat`, or `.ps1` files from user-writable directories.

Dynamic Analysis Prevention: - Use Case: Use behavior-based execution prevention tools to identify and block malicious activity in real time. - Implemenation: Employ EDR solutions that analyze runtime behavior and block suspicious code execution.

The tag is: *misp-galaxy:mitre-course-of-action="Execution Prevention - M1038"*

Table 7074. Table References

Links
https://attack.mitre.org/mitigations/M1038

Software Configuration - M1054

Software configuration refers to making security-focused adjustments to the settings of applications, middleware, databases, or other software to mitigate potential threats. These changes help reduce the attack surface, enforce best practices, and protect sensitive data. This mitigation can be implemented through the following measures:

Conduct a Security Review of Application Settings:

- Review the software documentation to identify recommended security configurations.

- Compare default settings against organizational policies and compliance requirements.

Implement Access Controls and Permissions:

- Restrict access to sensitive features or data within the software.
- Enforce least privilege principles for all roles and accounts interacting with the software.

Enable Logging and Monitoring:

- Configure detailed logging for key application events such as authentication failures, configuration changes, or unusual activity.
- Integrate logs with a centralized monitoring solution, such as a SIEM.

Update and Patch Software Regularly:

- Ensure the software is kept up-to-date with the latest security patches to address known vulnerabilities.
- Use automated patch management tools to streamline the update process.

Disable Unnecessary Features or Services:

- Turn off unused functionality or components that could introduce vulnerabilities, such as debugging interfaces or deprecated APIs.

Test Configuration Changes:

- Perform configuration changes in a staging environment before applying them in production.
- Conduct regular audits to ensure that settings remain aligned with security policies.

Tools for Implementation

Configuration Management Tools:

- Ansible: Automates configuration changes across multiple applications and environments.
- Chef: Ensures consistent application settings through code-based configuration management.
- Puppet: Automates software configurations and audits changes for compliance.

Security Benchmarking Tools:

- CIS-CAT: Provides benchmarks and audits for secure software configurations.
- Aqua Security Trivy: Scans containerized applications for configuration issues.

Vulnerability Management Solutions:

- Nessus: Identifies misconfigurations and suggests corrective actions.

Logging and Monitoring Tools:

- Splunk: Aggregates and analyzes application logs to detect suspicious activity.

Code Signing - M1045

Code Signing is a security process that ensures the authenticity and integrity of software by digitally signing executables, scripts, and other code artifacts. It prevents untrusted or malicious code from executing by verifying the digital signatures against trusted sources. Code signing protects against tampering, impersonation, and distribution of unauthorized or malicious software, forming a critical defense against supply chain and software exploitation attacks. This mitigation can be implemented through the following measures:

Enforce Signed Code Execution:

- Implementation: Configure operating systems (e.g., Windows with AppLocker or Linux with Secure Boot) to allow only signed code to execute.
- Use Case: Prevent the execution of malicious PowerShell scripts by requiring all scripts to be signed with a trusted certificate.

Vendor-Signed Driver Enforcement:

- Implementation: Enable kernel-mode code signing to ensure that only drivers signed by trusted vendors can be loaded.
- Use Case: A malicious driver attempting to modify system memory fails to load because it lacks a valid signature.

Certificate Revocation Management:

- Implementation: Use Online Certificate Status Protocol (OCSP) or Certificate Revocation Lists (CRLs) to block certificates associated with compromised or deprecated code.
- Use Case: A compromised certificate used to sign a malicious update is revoked, preventing further execution of the software.

Third-Party Software Verification:

- Implementation: Require software from external vendors to be signed with valid certificates before deployment.
- Use Case: An organization only deploys signed and verified third-party software to prevent supply chain attacks.

Script Integrity in CI/CD Pipelines:

- Implementation: Integrate code signing into CI/CD pipelines to sign and verify code artifacts before production release.

- Use Case: A software company ensures that all production builds are signed, preventing tampered builds from reaching customers.

Key Components of Code Signing

- Digital Signature Verification: Verifies the authenticity of code by ensuring it was signed by a trusted entity.
- Certificate Management: Uses Public Key Infrastructure (PKI) to manage signing certificates and revocation lists.
- Enforced Policy for Unsigned Code: Prevents the execution of unsigned or untrusted binaries and scripts.
- Hash Integrity Check: Confirms that code has not been altered since signing by comparing cryptographic hashes.

https://attack.mitre.org/mitigations/M1045

Boot Integrity - M1046

Boot Integrity ensures that a system starts securely by verifying the integrity of its boot process, operating system, and associated components. This mitigation focuses on leveraging secure boot mechanisms, hardware-rooted trust, and runtime integrity checks to prevent tampering during the boot sequence. It is designed to thwart adversaries attempting to modify system firmware, bootloaders, or critical OS components. This mitigation can be implemented through the following measures:

Implementation of Secure Boot:

- Implementation: Enable UEFI Secure Boot on all systems and configure it to allow only signed bootloaders and operating systems.
- Use Case: An adversary attempts to replace the system's bootloader with a malicious version to gain persistence. Secure Boot prevents the untrusted bootloader from executing, halting the attack.

Utilization of TPMs:

- Implementation: Configure systems to use TPM-based attestation for boot integrity, ensuring that any modification to the firmware, bootloader, or OS is detected.
- Use Case: A compromised firmware component alters the boot sequence. The TPM detects the change and triggers an alert, allowing the organization to respond before further damage.

Enable Bootloader Passwords:

- Implementation: Protect BIOS/UEFI settings with a strong password and limit physical access to

devices.

- Use Case: An attacker with physical access attempts to disable Secure Boot or modify the boot sequence. The password prevents unauthorized changes.

Runtime Integrity Monitoring:

- Implementation: Deploy solutions to verify the integrity of critical files and processes after boot.
- Use Case: A malware infection modifies kernel modules post-boot. Runtime integrity monitoring detects the modification and prevents the malicious module from loading.

Sudo Mitigation - T1169

The sudoers file should be strictly edited such that passwords are always required and that users can't spawn risky processes as users with higher privilege. By requiring a password, even if an adversary can get terminal access, they must know the password to run anything in the sudoers file.

The tag is: *misp-galaxy:mitre-course-of-action="Sudo Mitigation - T1169"*

Table 7092. Table References

Links
https://attack.mitre.org/mitigations/T1169

Hooking Mitigation - T1179

This type of attack technique cannot be easily mitigated with preventive controls since it is based on the abuse of operating system design features. For example, mitigating all hooking will likely have unintended side effects, such as preventing legitimate software (i.e., security products) from operating properly. Efforts should be focused on preventing adversary tools from running earlier in the chain of activity and on identifying subsequent malicious behavior.

The tag is: *misp-galaxy:mitre-course-of-action="Hooking Mitigation - T1179"*

Table 7093. Table References

Links
https://attack.mitre.org/mitigations/T1179

Pre-compromise - M1056

Pre-compromise mitigations involve proactive measures and defenses implemented to prevent adversaries from successfully identifying and exploiting weaknesses during the Reconnaissance and Resource Development phases of an attack. These activities focus on reducing an organization's attack surface, identify adversarial preparation efforts, and increase the difficulty for attackers to conduct successful operations. This mitigation can be implemented through the following measures:

Limit Information Exposure:

- Regularly audit and sanitize publicly available data, including job posts, websites, and social media.
- Use tools like OSINT monitoring platforms (e.g., SpiderFoot, Recon-ng) to identify leaked information.

Protect Domain and DNS Infrastructure:

- Enable DNSSEC and use WHOIS privacy protection.

- Monitor for domain hijacking or lookalike domains using services like RiskIQ or DomainTools.

External Monitoring:

- Use tools like Shodan, Censys to monitor your external attack surface.
- Deploy external vulnerability scanners to proactively address weaknesses.

Threat Intelligence:

- Leverage platforms like MISP, Recorded Future, or Anomali to track adversarial infrastructure, tools, and activity.

Content and Email Protections:

- Use email security solutions like Proofpoint, Microsoft Defender for Office 365, or Mimecast.
- Enforce SPF/DKIM/DMARC policies to protect against email spoofing.

Training and Awareness:

- Educate employees on identifying phishing attempts, securing their social media, and avoiding information leaks.

The tag is: *misp-galaxy:mitre-course-of-action="Pre-compromise - M1056"*

Antivirus/Antimalware - M1049

Antivirus/Antimalware solutions utilize signatures, heuristics, and behavioral analysis to detect, block, and remediate malicious software, including viruses, trojans, ransomware, and spyware. These solutions continuously monitor endpoints and systems for known malicious patterns and suspicious behaviors that indicate compromise. Antivirus/Antimalware software should be deployed across all devices, with automated updates to ensure protection against the latest threats. This mitigation can be implemented through the following measures:

Signature-Based Detection:

- Implementation: Use predefined signatures to identify known malware based on unique patterns such as file hashes, byte sequences, or command-line arguments. This method is effective against known threats.
- Use Case: When malware like "Emotet" is detected, its signature (such as a specific file hash) matches a known database of malicious software, triggering an alert and allowing immediate quarantine of the infected file.

Heuristic-Based Detection:

- Implementation: Deploy heuristic algorithms that analyze behavior and characteristics of files

and processes to identify potential malware, even if it doesn't match a known signature.

- Use Case: If a program attempts to modify multiple critical system files or initiate suspicious network communications, heuristic analysis may flag it as potentially malicious, even if no specific malware signature is available.

Behavioral Detection (Behavior Prevention):

- Implementation: Use behavioral analysis to detect patterns of abnormal activities, such as unusual system calls, unauthorized file encryption, or attempts to escalate privileges.
- Use Case: Behavioral analysis can detect ransomware attacks early by identifying behavior like mass file encryption, even before a specific ransomware signature has been identified.

Real-Time Scanning:

- Implementation: Enable real-time scanning to automatically inspect files and network traffic for signs of malware as they are accessed, downloaded, or executed.
- Use Case: When a user downloads an email attachment, the antivirus solution scans the file in real-time, checking it against both signatures and heuristics to detect any malicious content before it can be opened.

Cloud-Assisted Threat Intelligence:

- Implementation: Use cloud-based threat intelligence to ensure the antivirus solution can access the latest malware definitions and real-time threat feeds from a global database of emerging threats.
- Use Case: Cloud-assisted antivirus solutions quickly identify newly discovered malware by cross-referencing against global threat databases, providing real-time protection against zero-day attacks.

Tools for Implementation:

- Endpoint Security Platforms: Use solutions such as EDR for comprehensive antivirus/antimalware protection across all systems.
- Centralized Management: Implement centralized antivirus management consoles that provide visibility into threat activity, enable policy enforcement, and automate updates.
- Behavioral Analysis Tools: Leverage solutions with advanced behavioral analysis capabilities to detect malicious activity patterns that don't rely on known signatures.

Audit - M1047

Auditing is the process of recording activity and systematically reviewing and analyzing the activity and system configurations. The primary purpose of auditing is to detect anomalies and identify potential threats or weaknesses in the environment. Proper auditing configurations can also help to meet compliance requirements. The process of auditing encompasses regular analysis of user behaviors and system logs in support of proactive security measures.

Auditing is applicable to all systems used within an organization, from the front door of a building to accessing a file on a fileserver. It is considered more critical for regulated industries such as, healthcare, finance and government where compliance requirements demand stringent tracking of user and system activates.This mitigation can be implemented through the following measures:

System Audit:

- Use Case: Regularly assess system configurations to ensure compliance with organizational security policies.
- Implementation: Use tools to scan for deviations from established benchmarks.

Permission Audits:

- Use Case: Review file and folder permissions to minimize the risk of unauthorized access or privilege escalation.
- Implementation: Run access reviews to identify users or groups with excessive permissions.

Software Audits:

- Use Case: Identify outdated, unsupported, or insecure software that could serve as an attack vector.
- Implementation: Use inventory and vulnerability scanning tools to detect outdated versions and recommend secure alternatives.

Configuration Audits:

- Use Case: Evaluate system and network configurations to ensure secure settings (e.g., disabled SMBv1, enabled MFA).
- Implementation: Implement automated configuration scanning tools like SCAP (Security Content Automation Protocol) to identify non-compliant systems.

Network Audits:

- Use Case: Examine network traffic, firewall rules, and endpoint communications to identify unauthorized or insecure connections.
- Implementation: Utilize tools such as Wireshark, or Zeek to monitor and log suspicious network behavior.

Encrypting a hard disk partition to prevent cleartext access to a file system.

The tag is: *misp-galaxy:mitre-d3fend="Disk Encryption"*

Table 7123. Table References

Links
https://d3fend.mitre.org/technique/d3f:DiskEncryption

Local File Permissions

Restricting access to a local file by configuring operating system functionality.

The tag is: *misp-galaxy:mitre-d3fend="Local File Permissions"*

Table 7124. Table References

Links
https://d3fend.mitre.org/technique/d3f:LocalFilePermissions

Network Node Inventory

Network node inventorying identifies and records all the network nodes (hosts, routers, switches, firewalls, etc.) in the organization's architecture.

The tag is: *misp-galaxy:mitre-d3fend="Network Node Inventory"*

Network Node Inventory is also known as:

- System Discovery
- System Inventorying

Table 7125. Table References

Links
https://d3fend.mitre.org/technique/d3f:NetworkNodeInventory

Credential Compromise Scope Analysis

Determining which credentials may have been compromised by analyzing the user logon history of a particular system.

The tag is: *misp-galaxy:mitre-d3fend="Credential Compromise Scope Analysis"*

Table 7126. Table References

Links

https://d3fend.mitre.org/technique/d3f:CredentialCompromiseScopeAnalysis

Indirect Branch Call Analysis

Analyzing vendor specific branch call recording in order to detect ROP style attacks.

The tag is: *misp-galaxy:mitre-d3fend="Indirect Branch Call Analysis"*

Table 7127. Table References

Links
https://d3fend.mitre.org/technique/d3f:IndirectBranchCallAnalysis

Software Inventory

Software inventorying identifies and records the software items in the organization's architecture.

The tag is: *misp-galaxy:mitre-d3fend="Software Inventory"*

Software Inventory is also known as:

- Software Discovery
- Software Inventorying

Table 7128. Table References

Links
https://d3fend.mitre.org/technique/d3f:SoftwareInventory

Process Termination

Terminating a running application process on a computer system.

The tag is: *misp-galaxy:mitre-d3fend="Process Termination"*

Table 7129. Table References

Links
https://d3fend.mitre.org/technique/d3f:ProcessTermination

Connection Attempt Analysis

Analyzing failed connections in a network to detect unauthorized activity.

The tag is: *misp-galaxy:mitre-d3fend="Connection Attempt Analysis"*

Connection Attempt Analysis is also known as:

- Network Scan Detection

Table 7130. Table References

Links
https://d3fend.mitre.org/technique/d3f:ConnectionAttemptAnalysis

Message Encryption

Encrypting a message body using a cryptographic key.

The tag is: *misp-galaxy:mitre-d3fend="Message Encryption"*

Table 7131. Table References

Links
https://d3fend.mitre.org/technique/d3f:MessageEncryption

Segment Address Offset Randomization

Randomizing the base (start) address of one or more segments of memory during the initialization of a process.

The tag is: *misp-galaxy:mitre-d3fend="Segment Address Offset Randomization"*

Segment Address Offset Randomization is also known as:

- ASLR
- Address Space Layout Randomization

Table 7132. Table References

Links
https://d3fend.mitre.org/technique/d3f:SegmentAddressOffsetRandomization

Restore Configuration

Restoring an software configuration.

The tag is: *misp-galaxy:mitre-d3fend="Restore Configuration"*

Table 7133. Table References

Links
https://d3fend.mitre.org/technique/d3f:RestoreConfiguration

Decoy Network Resource

Deploying a network resource for the purposes of deceiving an adversary.

The tag is: *misp-galaxy:mitre-d3fend="Decoy Network Resource"*

Table 7134. Table References

Links
https://d3fend.mitre.org/technique/d3f:DecoyNetworkResource

Software Update

Replacing old software on a computer system component.

The tag is: *misp-galaxy:mitre-d3fend="Software Update"*

Table 7135. Table References

Links
https://d3fend.mitre.org/technique/d3f:SoftwareUpdate

Decoy File

A file created for the purposes of deceiving an adversary.

The tag is: *misp-galaxy:mitre-d3fend="Decoy File"*

Table 7136. Table References

Links
https://d3fend.mitre.org/technique/d3f:DecoyFile

DNS Traffic Analysis

Analysis of domain name metadata, including name and DNS records, to determine whether the domain is likely to resolve to an undesirable host.

The tag is: *misp-galaxy:mitre-d3fend="DNS Traffic Analysis"*

DNS Traffic Analysis is also known as:

- Domain Name Analysis

Table 7137. Table References

Links
https://d3fend.mitre.org/technique/d3f:DNSTrafficAnalysis

Operational Dependency Mapping

Operational dependency mapping identifies and models the dependencies of the organization's activities on each other and on the organization's performers (people, systems, and services.) This may include modeling the higher- and lower-level activities of an organization forming a hierarchy, or layering, of the dependencies in an organization's activities.

The tag is: *misp-galaxy:mitre-d3fend="Operational Dependency Mapping"*

Table 7138. Table References

Links
https://d3fend.mitre.org/technique/d3f:OperationalDependencyMapping

Logical Link Mapping

Logical link mapping creates a model of existing or previous node-to-node connections using network-layer data or metadata.

The tag is: *misp-galaxy:mitre-d3fend="Logical Link Mapping"*

Table 7139. Table References

Links
https://d3fend.mitre.org/technique/d3f:LogicalLinkMapping

Web Session Activity Analysis

Monitoring changes in user web session behavior by comparing current web session activity to a baseline behavior profile or a catalog of predetermined malicious behavior.

The tag is: *misp-galaxy:mitre-d3fend="Web Session Activity Analysis"*

Table 7140. Table References

Links
https://d3fend.mitre.org/technique/d3f:WebSessionActivityAnalysis

Physical Link Mapping

Physical link mapping identifies and models the link connectivity of the network devices within a physical network.

The tag is: *misp-galaxy:mitre-d3fend="Physical Link Mapping"*

Physical Link Mapping is also known as:

- Layer 1 Mapping

Table 7141. Table References

Links
https://d3fend.mitre.org/technique/d3f:PhysicalLinkMapping

Authentication Event Thresholding

Collecting authentication events, creating a baseline user profile, and determining whether authentication events are consistent with the baseline profile.

The tag is: *misp-galaxy:mitre-d3fend="Authentication Event Thresholding"*

Table 7142. Table References

Links
https://d3fend.mitre.org/technique/d3f:AuthenticationEventThresholding

Operating System Monitoring

The operating system software, for D3FEND's purposes, includes the kernel and its process management functions, hardware drivers, initialization or boot logic. It also includes and other key system daemons and their configuration. The monitoring or analysis of these components for unauthorized activity constitute **Operating System Monitoring**.

The tag is: *misp-galaxy:mitre-d3fend="Operating System Monitoring"*

Table 7143. Table References

Links
https://d3fend.mitre.org/technique/d3f:OperatingSystemMonitoring

Forward Resolution Domain Denylisting

Blocking a lookup based on the query's domain name value.

The tag is: *misp-galaxy:mitre-d3fend="Forward Resolution Domain Denylisting"*

Forward Resolution Domain Denylisting is also known as:

- Forward Resolution Domain Blacklisting

Table 7144. Table References

Links
https://d3fend.mitre.org/technique/d3f:ForwardResolutionDomainDenylisting

Per Host Download-Upload Ratio Analysis

Detecting anomalies that indicate malicious activity by comparing the amount of data downloaded versus data uploaded by a host.

The tag is: *misp-galaxy:mitre-d3fend="Per Host Download-Upload Ratio Analysis"*

Table 7145. Table References

Links
https://d3fend.mitre.org/technique/d3f:PerHostDownload-UploadRatioAnalysis

IPC Traffic Analysis

Analyzing standard inter process communication (IPC) protocols to detect deviations from normal protocol activity.

The tag is: *misp-galaxy:mitre-d3fend="IPC Traffic Analysis"*

IPC Traffic Analysis is also known as:

- IPC Analysis

Table 7146. Table References

Links
https://d3fend.mitre.org/technique/d3f:IPCTrafficAnalysis

Application Configuration Hardening

Modifying an application's configuration to reduce its attack surface.

The tag is: *misp-galaxy:mitre-d3fend="Application Configuration Hardening"*

Table 7147. Table References

Links
https://d3fend.mitre.org/technique/d3f:ApplicationConfigurationHardening

Network Traffic Community Deviation

Establishing baseline communities of network hosts and identifying statistically divergent inter-community communication.

The tag is: *misp-galaxy:mitre-d3fend="Network Traffic Community Deviation"*

Table 7148. Table References

Links

https://d3fend.mitre.org/technique/d3f:NetworkTrafficCommunityDeviation

Inbound Session Volume Analysis

Analyzing inbound network session or connection attempt volume.

The tag is: *misp-galaxy:mitre-d3fend="Inbound Session Volume Analysis"*

Table 7149. Table References

Links
https://d3fend.mitre.org/technique/d3f:InboundSessionVolumeAnalysis

Kernel-based Process Isolation

Using kernel-level capabilities to isolate processes.

The tag is: *misp-galaxy:mitre-d3fend="Kernel-based Process Isolation"*

Table 7150. Table References

Links
https://d3fend.mitre.org/technique/d3f:Kernel-basedProcessIsolation

RPC Traffic Analysis

Monitoring the activity of remote procedure calls in communication traffic to establish standard protocol operations and potential attacker activities.

The tag is: *misp-galaxy:mitre-d3fend="RPC Traffic Analysis"*

RPC Traffic Analysis is also known as:

- RPC Protocol Analysis

Table 7151. Table References

Links
https://d3fend.mitre.org/technique/d3f:RPCTrafficAnalysis

Restore Database

Restoring the data in a database.

The tag is: *misp-galaxy:mitre-d3fend="Restore Database"*

Table 7152. Table References

Links

https://d3fend.mitre.org/technique/d3f:RestoreDatabase

Decoy Persona

Establishing a fake online identity to misdirect, deceive, and or interact with adversaries.

The tag is: *misp-galaxy:mitre-d3fend="Decoy Persona"*

Table 7153. Table References

Links
https://d3fend.mitre.org/technique/d3f:DecoyPersona

Stack Frame Canary Validation

Comparing a value stored in a stack frame with a known good value in order to prevent or detect a memory segment overwrite.

The tag is: *misp-galaxy:mitre-d3fend="Stack Frame Canary Validation"*

Table 7154. Table References

Links
https://d3fend.mitre.org/technique/d3f:StackFrameCanaryValidation

Hardware Component Inventory

Hardware component inventorying identifies and records the hardware items in the organization's architecture.

The tag is: *misp-galaxy:mitre-d3fend="Hardware Component Inventory"*

Hardware Component Inventory is also known as:

- Hardware Component Discovery
- Hardware Component Inventorying

Table 7155. Table References

Links
https://d3fend.mitre.org/technique/d3f:HardwareComponentInventory

Data Inventory

Data inventorying identifies and records the schemas, formats, volumes, and locations of data stored and used on the organization's architecture.

The tag is: *misp-galaxy:mitre-d3fend="Data Inventory"*

Data Inventory is also known as:

- Data Discovery
- Data Inventorying

Table 7156. Table References

Links
https://d3fend.mitre.org/technique/d3f:DataInventory

Script Execution Analysis

Analyzing the execution of a script to detect unauthorized user activity.

The tag is: *misp-galaxy:mitre-d3fend="Script Execution Analysis"*

Table 7157. Table References

Links
https://d3fend.mitre.org/technique/d3f:ScriptExecutionAnalysis

TPM Boot Integrity

Assuring the integrity of a platform by demonstrating that the boot process starts from a trusted combination of hardware and software and continues until the operating system has fully booted and applications are running. Sometimes called Static Root of Trust Measurement (STRM).

The tag is: *misp-galaxy:mitre-d3fend="TPM Boot Integrity"*

TPM Boot Integrity is also known as:

- STRM
- Static Root of Trust Measurement

Table 7158. Table References

Links
https://d3fend.mitre.org/technique/d3f:TPMBootIntegrity

Local Account Monitoring

Analyzing local user accounts to detect unauthorized activity.

The tag is: *misp-galaxy:mitre-d3fend="Local Account Monitoring"*

Table 7159. Table References

Links

https://d3fend.mitre.org/technique/d3f:LocalAccountMonitoring

IO Port Restriction

Limiting access to computer input/output (IO) ports to restrict unauthorized devices.

The tag is: *misp-galaxy:mitre-d3fend="IO Port Restriction"*

Table 7160. Table References

Links
https://d3fend.mitre.org/technique/d3f:IOPortRestriction

Email Removal

The email removal technique deletes email files from system storage.

The tag is: *misp-galaxy:mitre-d3fend="Email Removal"*

Email Removal is also known as:

- Email Deletion

Table 7161. Table References

Links
https://d3fend.mitre.org/technique/d3f:EmailRemoval

Dynamic Analysis

Executing or opening a file in a synthetic "sandbox" environment to determine if the file is a malicious program or if the file exploits another program such as a document reader.

The tag is: *misp-galaxy:mitre-d3fend="Dynamic Analysis"*

Dynamic Analysis is also known as:

- Malware Detonation
- Malware Sandbox

Table 7162. Table References

Links
https://d3fend.mitre.org/technique/d3f:DynamicAnalysis

Memory Boundary Tracking

Analyzing a call stack for return addresses which point to unexpected memory locations.

The tag is: *misp-galaxy:mitre-d3fend="Memory Boundary Tracking"*

Table 7163. Table References

Links
https://d3fend.mitre.org/technique/d3f:MemoryBoundaryTracking

Database Query String Analysis

Analyzing database queries to detect [SQL Injection](https://capec.mitre.org/data/definitions/66.html).

The tag is: *misp-galaxy:mitre-d3fend="Database Query String Analysis"*

Table 7164. Table References

Links
https://d3fend.mitre.org/technique/d3f:DatabaseQueryStringAnalysis

File Content Analysis

Employing a pattern matching algorithm to statically analyze the content of files.

The tag is: *misp-galaxy:mitre-d3fend="File Content Analysis"*

Table 7165. Table References

Links
https://d3fend.mitre.org/technique/d3f:FileContentAnalysis

Configuration Inventory

Configuration inventory identifies and records the configuration of software and hardware and their components throughout the organization.

The tag is: *misp-galaxy:mitre-d3fend="Configuration Inventory"*

Table 7166. Table References

Links
https://d3fend.mitre.org/technique/d3f:ConfigurationInventory

Endpoint Health Beacon

Monitoring the security status of an endpoint by sending periodic messages with health status, where absence of a response may indicate that the endpoint has been compromised.

The tag is: *misp-galaxy:mitre-d3fend="Endpoint Health Beacon"*

Endpoint Health Beacon is also known as:

- Endpoint Health Telemetry

Table 7167. Table References

Links
https://d3fend.mitre.org/technique/d3f:EndpointHealthBeacon

Sender Reputation Analysis

Ascertaining sender reputation based on information associated with a message (e.g. email/instant messaging).

The tag is: *misp-galaxy:mitre-d3fend="Sender Reputation Analysis"*

Table 7168. Table References

Links
https://d3fend.mitre.org/technique/d3f:SenderReputationAnalysis

Restore Network Access

Restoring a entity's access to a computer network.

The tag is: *misp-galaxy:mitre-d3fend="Restore Network Access"*

Table 7169. Table References

Links
https://d3fend.mitre.org/technique/d3f:RestoreNetworkAccess

Standalone Honeynet

An environment created for the purpose of attracting attackers and eliciting their behaviors that is not connected to any production enterprise systems.

The tag is: *misp-galaxy:mitre-d3fend="Standalone Honeynet"*

Table 7170. Table References

Links
https://d3fend.mitre.org/technique/d3f:StandaloneHoneynet

Hierarchical Domain Denylisting

Blocking the resolution of any subdomain of a specified domain name.

The tag is: *misp-galaxy:mitre-d3fend="Hierarchical Domain Denylisting"*

Hierarchical Domain Denylisting is also known as:

- Hierarchical Domain Blacklisting

Table 7171. Table References

Links
https://d3fend.mitre.org/technique/d3f:HierarchicalDomainDenylisting

Session Duration Analysis

Analyzing the duration of user sessions in order to detect unauthorized activity.

The tag is: *misp-galaxy:mitre-d3fend="Session Duration Analysis"*

Table 7172. Table References

Links
https://d3fend.mitre.org/technique/d3f:SessionDurationAnalysis

Scheduled Job Analysis

Analysis of source files, processes, destination files, or destination servers associated with a scheduled job to detect unauthorized use of job scheduling.

The tag is: *misp-galaxy:mitre-d3fend="Scheduled Job Analysis"*

Scheduled Job Analysis is also known as:

- Scheduled Job Execution

Table 7173. Table References

Links
https://d3fend.mitre.org/technique/d3f:ScheduledJobAnalysis

Operational Risk Assessment

Operational risk assessment identifies and models the vulnerabilities of, and risks to, an organization's activities individually and as a whole.

The tag is: *misp-galaxy:mitre-d3fend="Operational Risk Assessment"*

Operational Risk Assessment is also known as:

- Mission Risk Assessment

Table 7174. Table References

Links

https://d3fend.mitre.org/technique/d3f:OperationalRiskAssessment

Credential Rotation

Expiring an existing set of credentials and reissuing a new valid set

The tag is: *misp-galaxy:mitre-d3fend="Credential Rotation"*

Table 7175. Table References

Links
https://d3fend.mitre.org/technique/d3f:CredentialRotation

System File Analysis

Monitoring system files such as authentication databases, configuration files, system logs, and system executables for modification or tampering.

The tag is: *misp-galaxy:mitre-d3fend="System File Analysis"*

Table 7176. Table References

Links
https://d3fend.mitre.org/technique/d3f:SystemFileAnalysis

Authentication Cache Invalidation

Removing tokens or credentials from an authentication cache to prevent further user associated account accesses.

The tag is: *misp-galaxy:mitre-d3fend="Authentication Cache Invalidation"*

Table 7177. Table References

Links
https://d3fend.mitre.org/technique/d3f:AuthenticationCacheInvalidation

Client-server Payload Profiling

Comparing client-server request and response payloads to a baseline profile to identify outliers.

The tag is: *misp-galaxy:mitre-d3fend="Client-server Payload Profiling"*

Table 7178. Table References

Links
https://d3fend.mitre.org/technique/d3f:Client-serverPayloadProfiling

Byte Sequence Emulation

Analyzing sequences of bytes and determining if they likely represent malicious shellcode.

The tag is: *misp-galaxy:mitre-d3fend="Byte Sequence Emulation"*

Byte Sequence Emulation is also known as:

- Shellcode Transmission Detection

Table 7179. Table References

Links
https://d3fend.mitre.org/technique/d3f:ByteSequenceEmulation

Shadow Stack Comparisons

Comparing a call stack in system memory with a shadow call stack maintained by the processor to determine unauthorized shellcode activity.

The tag is: *misp-galaxy:mitre-d3fend="Shadow Stack Comparisons"*

Table 7180. Table References

Links
https://d3fend.mitre.org/technique/d3f:ShadowStackComparisons

Identifier Reputation Analysis

Analyzing the reputation of an identifier.

The tag is: *misp-galaxy:mitre-d3fend="Identifier Reputation Analysis"*

Table 7181. Table References

Links
https://d3fend.mitre.org/technique/d3f:IdentifierReputationAnalysis

Restore File

Restoring a file for an entity to access.

The tag is: *misp-galaxy:mitre-d3fend="Restore File"*

Table 7182. Table References

Links
https://d3fend.mitre.org/technique/d3f:RestoreFile

Organization Mapping

Organization mapping identifies and models the people, roles, and groups with an organization and the relations between them.

The tag is: *misp-galaxy:mitre-d3fend="Organization Mapping"*

Table 7183. Table References

Links
https://d3fend.mitre.org/technique/d3f:OrganizationMapping

Account Locking

The process of temporarily disabling user accounts on a system or domain.

The tag is: *misp-galaxy:mitre-d3fend="Account Locking"*

Table 7184. Table References

Links
https://d3fend.mitre.org/technique/d3f:AccountLocking

System Call Filtering

Configuring a kernel to use an allow or deny list to filter kernel api calls.

The tag is: *misp-galaxy:mitre-d3fend="System Call Filtering"*

Table 7185. Table References

Links
https://d3fend.mitre.org/technique/d3f:SystemCallFiltering

File Hashing

Employing file hash comparisons to detect known malware.

The tag is: *misp-galaxy:mitre-d3fend="File Hashing"*

Table 7186. Table References

Links
https://d3fend.mitre.org/technique/d3f:FileHashing

Sender MTA Reputation Analysis

Characterizing the reputation of mail transfer agents (MTA) to determine the security risk in emails.

The tag is: *misp-galaxy:mitre-d3fend="Sender MTA Reputation Analysis"*

Table 7187. Table References

Links
https://d3fend.mitre.org/technique/d3f:SenderMTAReputationAnalysis

Firmware Verification

Cryptographically verifying firmware integrity.

The tag is: *misp-galaxy:mitre-d3fend="Firmware Verification"*

Table 7188. Table References

Links
https://d3fend.mitre.org/technique/d3f:FirmwareVerification

Exception Handler Pointer Validation

Validates that a referenced exception handler pointer is a valid exception handler.

The tag is: *misp-galaxy:mitre-d3fend="Exception Handler Pointer Validation"*

Exception Handler Pointer Validation is also known as:

- Exception Handler Validation

Table 7189. Table References

Links
https://d3fend.mitre.org/technique/d3f:ExceptionHandlerPointerValidation

Remote Terminal Session Detection

Detection of an unauthorized remote live terminal console session by examining network traffic to a network host.

The tag is: *misp-galaxy:mitre-d3fend="Remote Terminal Session Detection"*

Table 7190. Table References

Links
https://d3fend.mitre.org/technique/d3f:RemoteTerminalSessionDetection

User Data Transfer Analysis

Analyzing the amount of data transferred by a user.

The tag is: *misp-galaxy:mitre-d3fend="User Data Transfer Analysis"*

Table 7191. Table References

Links
https://d3fend.mitre.org/technique/d3f:UserDataTransferAnalysis

Passive Certificate Analysis

Collecting host certificates from network traffic or other passive sources like a certificate transparency log and analyzing them for unauthorized activity.

The tag is: *misp-galaxy:mitre-d3fend="Passive Certificate Analysis"*

Table 7192. Table References

Links
https://d3fend.mitre.org/technique/d3f:PassiveCertificateAnalysis

Process Segment Execution Prevention

Preventing execution of any address in a memory region other than the code segment.

The tag is: *misp-galaxy:mitre-d3fend="Process Segment Execution Prevention"*

Process Segment Execution Prevention is also known as:

- Execute Disable
- No Execute

Table 7193. Table References

Links
https://d3fend.mitre.org/technique/d3f:ProcessSegmentExecutionPrevention

Credential Revoking

Deleting a set of credentials permanently to prevent them from being used to authenticate.

The tag is: *misp-galaxy:mitre-d3fend="Credential Revoking"*

Table 7194. Table References

Links
https://d3fend.mitre.org/technique/d3f:CredentialRevoking

Access Modeling

Access modeling identifies and records the access permissions granted to administrators, users, groups, and systems.

The tag is: *misp-galaxy:mitre-d3fend="Access Modeling"*

Table 7195. Table References

Links
https://d3fend.mitre.org/technique/d3f:AccessModeling

Driver Load Integrity Checking

Ensuring the integrity of drivers loaded during initialization of the operating system.

The tag is: *misp-galaxy:mitre-d3fend="Driver Load Integrity Checking"*

Table 7196. Table References

Links
https://d3fend.mitre.org/technique/d3f:DriverLoadIntegrityChecking

Domain Name Reputation Analysis

Analyzing the reputation of a domain name.

The tag is: *misp-galaxy:mitre-d3fend="Domain Name Reputation Analysis"*

Table 7197. Table References

Links
https://d3fend.mitre.org/technique/d3f:DomainNameReputationAnalysis

System Configuration Permissions

Restricting system configuration modifications to a specific user or group of users.

The tag is: *misp-galaxy:mitre-d3fend="System Configuration Permissions"*

Table 7198. Table References

Links
https://d3fend.mitre.org/technique/d3f:SystemConfigurationPermissions

File Integrity Monitoring

Detecting any suspicious changes to files in a computer system.

The tag is: *misp-galaxy:mitre-d3fend="File Integrity Monitoring"*

Table 7199. Table References

Links
https://d3fend.mitre.org/technique/d3f:FileIntegrityMonitoring

File Carving

Identifying and extracting files from network application protocols through the use of network stream reassembly software.

The tag is: *misp-galaxy:mitre-d3fend="File Carving"*

Table 7200. Table References

Links
https://d3fend.mitre.org/technique/d3f:FileCarving

Executable Denylisting

Blocking the execution of files on a host in accordance with defined application policy rules.

The tag is: *misp-galaxy:mitre-d3fend="Executable Denylisting"*

Executable Denylisting is also known as:

- Executable Blacklisting

Table 7201. Table References

Links
https://d3fend.mitre.org/technique/d3f:ExecutableDenylisting

Connected Honeynet

A decoy service, system, or environment, that is connected to the enterprise network, and simulates or emulates certain functionality to the network, without exposing full access to a production system.

The tag is: *misp-galaxy:mitre-d3fend="Connected Honeynet"*

Table 7202. Table References

Links
https://d3fend.mitre.org/technique/d3f:ConnectedHoneynet

User Account Permissions

Restricting a user account's access to resources.

The tag is: *misp-galaxy:mitre-d3fend="User Account Permissions"*

Table 7203. Table References

Links
https://d3fend.mitre.org/technique/d3f:UserAccountPermissions

Process Code Segment Verification

Comparing the "text" or "code" memory segments to a source of truth.

The tag is: *misp-galaxy:mitre-d3fend="Process Code Segment Verification"*

Table 7204. Table References

Links
https://d3fend.mitre.org/technique/d3f:ProcessCodeSegmentVerification

Certificate Pinning

Persisting either a server's X.509 certificate or their public key and comparing that to server's presented identity to allow for greater client confidence in the remote server's identity for SSL connections.

The tag is: *misp-galaxy:mitre-d3fend="Certificate Pinning"*

Table 7205. Table References

Links
https://d3fend.mitre.org/technique/d3f:CertificatePinning

DNS Allowlisting

Permitting only approved domains and their subdomains to be resolved.

The tag is: *misp-galaxy:mitre-d3fend="DNS Allowlisting"*

DNS Allowlisting is also known as:

- DNS Whitelisting

Table 7206. Table References

Links
https://d3fend.mitre.org/technique/d3f:DNSAllowlisting

Integrated Honeynet

The practice of setting decoys in a production environment to entice interaction from attackers.

The tag is: *misp-galaxy:mitre-d3fend="Integrated Honeynet"*

Table 7207. Table References

Links
https://d3fend.mitre.org/technique/d3f:IntegratedHoneynet

RF Shielding

Adding physical barriers to a platform to prevent undesired radio interference.

The tag is: *misp-galaxy:mitre-d3fend="RF Shielding"*

Table 7208. Table References

Links
https://d3fend.mitre.org/technique/d3f:RFShielding

System Call Analysis

Analyzing system calls to determine whether a process is exhibiting unauthorized behavior.

The tag is: *misp-galaxy:mitre-d3fend="System Call Analysis"*

Table 7209. Table References

Links
https://d3fend.mitre.org/technique/d3f:SystemCallAnalysis

Peripheral Firmware Verification

Cryptographically verifying peripheral firmware integrity.

The tag is: *misp-galaxy:mitre-d3fend="Peripheral Firmware Verification"*

Table 7210. Table References

Links
https://d3fend.mitre.org/technique/d3f:PeripheralFirmwareVerification

Network Traffic Policy Mapping

Network traffic policy mapping identifies and models the allowed pathways of data at the network, tranport, and/or application levels.

The tag is: *misp-galaxy:mitre-d3fend="Network Traffic Policy Mapping"*

Network Traffic Policy Mapping is also known as:

- DLP Policy Mapping
- Firewall Mapping
- IPS Policy Mapping
- Web Security Gateway Policy Mapping

Table 7211. Table References

Links

IP Reputation Analysis

Analyzing the reputation of an IP address.

The tag is: *misp-galaxy:mitre-d3fend="IP Reputation Analysis"*

Table 7212. Table References

Links
https://d3fend.mitre.org/technique/d3f:IPReputationAnalysis

Reverse Resolution Domain Denylisting

Blocking a reverse DNS lookup's answer's domain name value.

The tag is: *misp-galaxy:mitre-d3fend="Reverse Resolution Domain Denylisting"*

Reverse Resolution Domain Denylisting is also known as:

- Reverse Resolution Domain Blacklisting

Table 7213. Table References

Links
https://d3fend.mitre.org/technique/d3f:ReverseResolutionDomainDenylisting

Executable Allowlisting

Using a digital signature to authenticate a file before opening.

The tag is: *misp-galaxy:mitre-d3fend="Executable Allowlisting"*

Executable Allowlisting is also known as:

- File Signature Authentication

Table 7214. Table References

Links
https://d3fend.mitre.org/technique/d3f:ExecutableAllowlisting

Decoy User Credential

A Credential created for the purpose of deceiving an adversary.

The tag is: *misp-galaxy:mitre-d3fend="Decoy User Credential"*

Table 7215. Table References

Links
https://d3fend.mitre.org/technique/d3f:DecoyUserCredential

Active Physical Link Mapping

Active physical link mapping sends and receives network traffic as a means to map the physical layer.

The tag is: *misp-galaxy:mitre-d3fend="Active Physical Link Mapping"*

Active Physical Link Mapping is also known as:

- Active Physical Layer Mapping

Table 7216. Table References

Links
https://d3fend.mitre.org/technique/d3f:ActivePhysicalLinkMapping

System Daemon Monitoring

Tracking changes to the state or configuration of critical system level processes.

The tag is: *misp-galaxy:mitre-d3fend="System Daemon Monitoring"*

Table 7217. Table References

Links
https://d3fend.mitre.org/technique/d3f:SystemDaemonMonitoring

URL Analysis

Determining if a URL is benign or malicious by analyzing the URL or its components.

The tag is: *misp-galaxy:mitre-d3fend="URL Analysis"*

Table 7218. Table References

Links
https://d3fend.mitre.org/technique/d3f:URLAnalysis

Active Certificate Analysis

Actively collecting PKI certificates by connecting to the server and downloading its server certificates for analysis.

The tag is: *misp-galaxy:mitre-d3fend="Active Certificate Analysis"*

Table 7219. Table References

Links
https://d3fend.mitre.org/technique/d3f:ActiveCertificateAnalysis

User Session Init Config Analysis

Analyzing modifications to user session config files such as .bashrc or .bash_profile.

The tag is: *misp-galaxy:mitre-d3fend="User Session Init Config Analysis"*

User Session Init Config Analysis is also known as:

- User Startup Config Analysis

Table 7220. Table References

Links
https://d3fend.mitre.org/technique/d3f:UserSessionInitConfigAnalysis

Emulated File Analysis

Emulating instructions in a file looking for specific patterns.

The tag is: *misp-galaxy:mitre-d3fend="Emulated File Analysis"*

Table 7221. Table References

Links
https://d3fend.mitre.org/technique/d3f:EmulatedFileAnalysis

Homoglyph Detection

Comparing strings using a variety of techniques to determine if a deceptive or malicious string is being presented to a user.

The tag is: *misp-galaxy:mitre-d3fend="Homoglyph Detection"*

Table 7222. Table References

Links
https://d3fend.mitre.org/technique/d3f:HomoglyphDetection

Pointer Authentication

Comparing the cryptographic hash or derivative of a pointer's value to an expected value.

The tag is: *misp-galaxy:mitre-d3fend="Pointer Authentication"*

Table 7223. Table References

Links
https://d3fend.mitre.org/technique/d3f:PointerAuthentication

Bootloader Authentication

Cryptographically authenticating the bootloader software before system boot.

The tag is: *misp-galaxy:mitre-d3fend="Bootloader Authentication"*

Bootloader Authentication is also known as:

- Secure Boot

Table 7224. Table References

Links
https://d3fend.mitre.org/technique/d3f:BootloaderAuthentication

Restore Email

Restoring an email for an entity to access.

The tag is: *misp-galaxy:mitre-d3fend="Restore Email"*

Table 7225. Table References

Links
https://d3fend.mitre.org/technique/d3f:RestoreEmail

Broadcast Domain Isolation

Broadcast isolation restricts the number of computers a host can contact on their LAN.

The tag is: *misp-galaxy:mitre-d3fend="Broadcast Domain Isolation"*

Broadcast Domain Isolation is also known as:

- Network Segmentation

Table 7226. Table References

Links
https://d3fend.mitre.org/technique/d3f:BroadcastDomainIsolation

Credential Transmission Scoping

Limiting the transmission of a credential to a scoped set of relying parties.

The tag is: *misp-galaxy:mitre-d3fend="Credential Transmission Scoping"*

Credential Transmission Scoping is also known as:

- Phishing Resistant Authentication

Table 7227. Table References

Links
https://d3fend.mitre.org/technique/d3f:CredentialTransmissionScoping

Process Suspension

Suspending a running process on a computer system.

The tag is: *misp-galaxy:mitre-d3fend="Process Suspension"*

Table 7228. Table References

Links
https://d3fend.mitre.org/technique/d3f:ProcessSuspension

Domain Account Monitoring

Monitoring the existence of or changes to Domain User Accounts.

The tag is: *misp-galaxy:mitre-d3fend="Domain Account Monitoring"*

Table 7229. Table References

Links
https://d3fend.mitre.org/technique/d3f:DomainAccountMonitoring

URL Reputation Analysis

Analyzing the reputation of a URL.

The tag is: *misp-galaxy:mitre-d3fend="URL Reputation Analysis"*

Table 7230. Table References

Links
https://d3fend.mitre.org/technique/d3f:URLReputationAnalysis

Message Authentication

Authenticating the sender of a message and ensuring message integrity.

The tag is: *misp-galaxy:mitre-d3fend="Message Authentication"*

Table 7231. Table References

Links
https://d3fend.mitre.org/technique/d3f:MessageAuthentication

Transfer Agent Authentication

Validating that server components of a messaging infrastructure are authorized to send a particular message.

The tag is: *misp-galaxy:mitre-d3fend="Transfer Agent Authentication"*

Table 7232. Table References

Links
https://d3fend.mitre.org/technique/d3f:TransferAgentAuthentication

Network Traffic Filtering

Restricting network traffic originating from any location.

The tag is: *misp-galaxy:mitre-d3fend="Network Traffic Filtering"*

Table 7233. Table References

Links
https://d3fend.mitre.org/technique/d3f:NetworkTrafficFiltering

Biometric Authentication

Using biological measures in order to authenticate a user.

The tag is: *misp-galaxy:mitre-d3fend="Biometric Authentication"*

Table 7234. Table References

Links

https://d3fend.mitre.org/technique/d3f:BiometricAuthentication

File Hash Reputation Analysis

Analyzing the reputation of a file hash.

The tag is: *misp-galaxy:mitre-d3fend="File Hash Reputation Analysis"*

Table 7235. Table References

Links
https://d3fend.mitre.org/technique/d3f:FileHashReputationAnalysis

Protocol Metadata Anomaly Detection

Collecting network communication protocol metadata and identifying statistical outliers.

The tag is: *misp-galaxy:mitre-d3fend="Protocol Metadata Anomaly Detection"*

Table 7236. Table References

Links
https://d3fend.mitre.org/technique/d3f:ProtocolMetadataAnomalyDetection

Process Spawn Analysis

Analyzing spawn arguments or attributes of a process to detect processes that are unauthorized.

The tag is: *misp-galaxy:mitre-d3fend="Process Spawn Analysis"*

Table 7237. Table References

Links
https://d3fend.mitre.org/technique/d3f:ProcessSpawnAnalysis

Multi-factor Authentication

Requiring proof of two or more pieces of evidence in order to authenticate a user.

The tag is: *misp-galaxy:mitre-d3fend="Multi-factor Authentication"*

Table 7238. Table References

Links
https://d3fend.mitre.org/technique/d3f:Multi-factorAuthentication

Decoy Public Release

Issuing publicly released media to deceive adversaries.

The tag is: *misp-galaxy:mitre-d3fend="Decoy Public Release"*

Table 7239. Table References

Links
https://d3fend.mitre.org/technique/d3f:DecoyPublicRelease

Administrative Network Activity Analysis

Detection of unauthorized use of administrative network protocols by analyzing network activity against a baseline.

The tag is: *misp-galaxy:mitre-d3fend="Administrative Network Activity Analysis"*

Table 7240. Table References

Links
https://d3fend.mitre.org/technique/d3f:AdministrativeNetworkActivityAnalysis

Restore User Account Access

Restoring a user account's access to resources.

The tag is: *misp-galaxy:mitre-d3fend="Restore User Account Access"*

Table 7241. Table References

Links
https://d3fend.mitre.org/technique/d3f:RestoreUserAccountAccess

Reverse Resolution IP Denylisting

Blocking a reverse lookup based on the query's IP address value.

The tag is: *misp-galaxy:mitre-d3fend="Reverse Resolution IP Denylisting"*

Reverse Resolution IP Denylisting is also known as:

- Reverse Resolution IP Blacklisting

Table 7242. Table References

Links
https://d3fend.mitre.org/technique/d3f:ReverseResolutionIPDenylisting

Input Device Analysis

Operating system level mechanisms to prevent abusive input device exploitation.

The tag is: *misp-galaxy:mitre-d3fend="Input Device Analysis"*

Table 7243. Table References

Links
https://d3fend.mitre.org/technique/d3f:InputDeviceAnalysis

Reissue Credential

Issue a new credential to a user which supercedes their old credential.

The tag is: *misp-galaxy:mitre-d3fend="Reissue Credential"*

Table 7244. Table References

Links
https://d3fend.mitre.org/technique/d3f:ReissueCredential

Host Shutdown

Initiating a host's shutdown sequence to terminate all running processes.

The tag is: *misp-galaxy:mitre-d3fend="Host Shutdown"*

Table 7245. Table References

Links
https://d3fend.mitre.org/technique/d3f:HostShutdown

Data Exchange Mapping

Data exchange mapping identifies and models the organization's intended design for the flows of the data types, formats, and volumes between systems at the application layer.

The tag is: *misp-galaxy:mitre-d3fend="Data Exchange Mapping"*

Data Exchange Mapping is also known as:

- Data Flow Mapping
- Information Exchange Mapping

Table 7246. Table References

Links
https://d3fend.mitre.org/technique/d3f:DataExchangeMapping

Process Self-Modification Detection

Detects processes that modify, change, or replace their own code at runtime.

The tag is: *misp-galaxy:mitre-d3fend="Process Self-Modification Detection"*

Table 7247. Table References

Links
https://d3fend.mitre.org/technique/d3f:ProcessSelf-ModificationDetection

Passive Logical Link Mapping

Passive logical link mapping only listens to network traffic as a means to map the the whole data link layer, where the links represent logical data flows rather than physical connections.

The tag is: *misp-galaxy:mitre-d3fend="Passive Logical Link Mapping"*

Passive Logical Link Mapping is also known as:

- Passive Logical Layer Mapping

Table 7248. Table References

Links
https://d3fend.mitre.org/technique/d3f:PassiveLogicalLinkMapping

One-time Password

A one-time password is valid for only one user authentication.

The tag is: *misp-galaxy:mitre-d3fend="One-time Password"*

One-time Password is also known as:

- OTP

Table 7249. Table References

Links
https://d3fend.mitre.org/technique/d3f:One-timePassword

Service Binary Verification

Analyzing changes in service binary files by comparing to a source of truth.

The tag is: *misp-galaxy:mitre-d3fend="Service Binary Verification"*

Table 7250. Table References

Links
https://d3fend.mitre.org/technique/d3f:ServiceBinaryVerification

Dead Code Elimination

Removing unreachable or "dead code" from compiled source code.

The tag is: *misp-galaxy:mitre-d3fend="Dead Code Elimination"*

Table 7251. Table References

Links
https://d3fend.mitre.org/technique/d3f:DeadCodeElimination

Hardware-based Process Isolation

Preventing one process from writing to the memory space of another process through hardware based address manager implementations.

The tag is: *misp-galaxy:mitre-d3fend="Hardware-based Process Isolation"*

Hardware-based Process Isolation is also known as:

- Virtualization

Table 7252. Table References

Links
https://d3fend.mitre.org/technique/d3f:Hardware-basedProcessIsolation

Domain Trust Policy

Restricting inter-domain trust by modifying domain configuration.

The tag is: *misp-galaxy:mitre-d3fend="Domain Trust Policy"*

Table 7253. Table References

Links
https://d3fend.mitre.org/technique/d3f:DomainTrustPolicy

Forward Resolution IP Denylisting

Blocking a DNS lookup’s answer’s IP address value.

The tag is: *misp-galaxy:mitre-d3fend="Forward Resolution IP Denylisting"*

Forward Resolution IP Denylisting is also known as:

- Forward Resolution IP Blacklisting

Table 7254. Table References

Links
https://d3fend.mitre.org/technique/d3f:ForwardResolutionIPDenylisting

Container Image Analysis

Analyzing a Container Image with respect to a set of policies.

The tag is: *misp-galaxy:mitre-d3fend="Container Image Analysis"*

Container Image Analysis is also known as:

- Container Image Scanning

Table 7255. Table References

Links
https://d3fend.mitre.org/technique/d3f:ContainerImageAnalysis

Active Logical Link Mapping

Active logical link mapping sends and receives network traffic as a means to map the whole data link layer, where the links represent logical data flows rather than physical connection

The tag is: *misp-galaxy:mitre-d3fend="Active Logical Link Mapping"*

Table 7256. Table References

Links
https://d3fend.mitre.org/technique/d3f:ActiveLogicalLinkMapping

Mandatory Access Control

Controlling access to local computer system resources with kernel-level capabilities.

The tag is: *misp-galaxy:mitre-d3fend="Mandatory Access Control"*

Table 7257. Table References

Links
https://d3fend.mitre.org/technique/d3f:MandatoryAccessControl

System Firmware Verification

Cryptographically verifying installed system firmware integrity.

The tag is: *misp-galaxy:mitre-d3fend="System Firmware Verification"*

Table 7258. Table References

Links
https://d3fend.mitre.org/technique/d3f:SystemFirmwareVerification

File Creation Analysis

Analyzing the properties of file create system call invocations.

The tag is: *misp-galaxy:mitre-d3fend="File Creation Analysis"*

Table 7259. Table References

Links
https://d3fend.mitre.org/technique/d3f:FileCreationAnalysis

System Init Config Analysis

Analysis of any system process startup configuration.

The tag is: *misp-galaxy:mitre-d3fend="System Init Config Analysis"*

System Init Config Analysis is also known as:

- Autorun Analysis
- Startup Analysis

Table 7260. Table References

Links
https://d3fend.mitre.org/technique/d3f:SystemInitConfigAnalysis

Passive Physical Link Mapping

Passive physical link mapping only listens to network traffic as a means to map the physical layer.

The tag is: *misp-galaxy:mitre-d3fend="Passive Physical Link Mapping"*

Passive Physical Link Mapping is also known as:

- Passive Physical Layer Mapping

Table 7261. Table References

Links
https://d3fend.mitre.org/technique/d3f:PassivePhysicalLinkMapping

Process Lineage Analysis

Identification of suspicious processes executing on an end-point device by examining the ancestry and siblings of a process, and the associated metadata of each node on the tree, such as process execution, duration, and order relative to siblings and ancestors.

The tag is: *misp-galaxy:mitre-d3fend="Process Lineage Analysis"*

Process Lineage Analysis is also known as:

- Process Tree Analysis

Table 7262. Table References

Links
https://d3fend.mitre.org/technique/d3f:ProcessLineageAnalysis

Homoglyph Denylisting

Blocking DNS queries that are deceptively similar to legitimate domain names.

The tag is: *misp-galaxy:mitre-d3fend="Homoglyph Denylisting"*

Homoglyph Denylisting is also known as:

- Homoglyph Blacklisting

Table 7263. Table References

Links
https://d3fend.mitre.org/technique/d3f:HomoglyphDenylisting

File Content Rules

Employing a pattern matching rule language to analyze the content of files.

The tag is: *misp-galaxy:mitre-d3fend="File Content Rules"*

File Content Rules is also known as:

- File Content Signatures
- File Signatures

Table 7264. Table References

Links
https://d3fend.mitre.org/technique/d3f:FileContentRules

Inbound Traffic Filtering

Restricting network traffic originating from untrusted networks destined towards a private host or enclave.

The tag is: *misp-galaxy:mitre-d3fend="Inbound Traffic Filtering"*

Table 7265. Table References

Links
https://d3fend.mitre.org/technique/d3f:InboundTrafficFiltering

Outbound Traffic Filtering

Restricting network traffic originating from a private host or enclave destined towards untrusted networks.

The tag is: *misp-galaxy:mitre-d3fend="Outbound Traffic Filtering"*

Table 7266. Table References

Links
https://d3fend.mitre.org/technique/d3f:OutboundTrafficFiltering

Unlock Account

Restoring a user account's access to resources by unlocking a locked User Account.

The tag is: *misp-galaxy:mitre-d3fend="Unlock Account"*

Table 7267. Table References

Links
https://d3fend.mitre.org/technique/d3f:UnlockAccount

Host Reboot

Initiating a host's reboot sequence to terminate all running processes.

The tag is: *misp-galaxy:mitre-d3fend="Host Reboot"*

Table 7268. Table References

Links
https://d3fend.mitre.org/technique/d3f:HostReboot

Email Filtering

Filtering incoming email traffic based on specific criteria.

The tag is: *misp-galaxy:mitre-d3fend="Email Filtering"*

Table 7269. Table References

Links
https://d3fend.mitre.org/technique/d3f:EmailFiltering

mitre-data-component

Data components are parts of data sources. .

mitre-data-component is a cluster galaxy available in JSON format at **this location** The JSON format can be freely reused in your application or automatically enabled in MISP.

authors

MITRE

Active Directory Object Access

Object access refers to activities where AD objects (e.g., user accounts, groups, policies) are accessed or queried. Example: Windows Event ID 4661 logs object access attempts. Examples:

- Attribute Access: e.g., `userPassword`, `memberOf`, `securityDescriptor`.
- Group Enumeration: Enumerating critical group members (e.g., Domain Admins).
- User Attributes: Commonly accessed attributes like `samAccountName`, `lastLogonTimestamp`.
- Policy Access: Accessing GPOs to understand security settings.

Data Collection Measures:

- Audit Policies:
- Enable "Audit Directory Service Access" under Advanced Audit Policies (Success and Failure).
- Path: `Computer Configuration > Policies > Windows Settings > Security Settings > Advanced Audit Policy Configuration > Audit Policies > Object AccessEnable: Audit Directory Service Access` (Success and Failure).
- Captured Events: IDs 4661, 4662.
- Event Forwarding: Use WEF to centralize logs for SIEM analysis.
- SIEM Integration: Collect and parse logs (e.g., 4661, 4662) using tools like Splunk or Azure Sentinel.
- Log Filtering:

- Focus on sensitive objects/attributes like:
- `Domain Admins` group.
- `userPassword`, `ntSecurityDescriptor`.
- Enable EDR Monitoring:
- Detect processes accessing sensitive AD objects (e.g., samAccountName, securityDescriptor).
- Log all attempts to enumerate critical groups (e.g., "Domain Admins").

The tag is: *misp-galaxy:mitre-data-component="Active Directory Object Access"*

Table 7270. Table References

Links

Active Directory Object Creation

Creating new objects in AD, such as user accounts, groups, organizational units (OUs), or trust relationships. Logged as Event ID 5137. Examples:

- User Account Creation: New user account.
- Group Creation: New security/distribution group.
- OU Creation: New organizational unit.
- Service Account Creation: New service account for automation or malicious tasks.
- Trust Object Creation: Trust relationship with another domain.

Data Collection Measures:

- Audit Policy:
- Enable "Audit Directory Service Changes" (Success and Failure).
- Path: `Computer Configuration > Policies > Windows Settings > Security Settings > Advanced Audit Policy Configuration > Audit Policies > Directory Service Changes`.
- Key Event: Event ID 5137 (object creation).
- Log Forwarding: Use WEF to centralize logs for SIEM tools (e.g., Splunk).
- Enable EDR Monitoring:
- Track processes that create new accounts or modify AD objects.
- Correlate object creation with suspicious commands (e.g., net user /add).

The tag is: *misp-galaxy:mitre-data-component="Active Directory Object Creation"*

Table 7271. Table References

Links

Active Directory Credential Request

Requests for authentication credentials via Kerberos or other methods like NTLM and LDAP queries. Examples:

- Kerberos TGT and Service Tickets (Event IDs 4768, 4769)
- NTLM Authentication Events
- LDAP Bind Requests

Data Collection Measures:

- Security Event Logging:
- Enable “Audit Kerberos Authentication Service” or "`Audit Kerberos Service Ticket Operations`."
- Captured Events: IDs 4768, 4769, 4624.
- Windows Event Forwarding (WEF): Forward domain controller logs to SIEM.
- SIEM Integration: Use tools like Splunk or Azure Sentinel for log analysis.
- Kerberos Debug Logging:
- Registry Key: HKLM\SYSTEM\CurrentControlSet\Control\Lsa\Kerberos\Parameters.
- Set DWORD LogLevel to 1.
- Azure AD Logs: Monitor Sign-In Logs for authentication and policy issues.
- Enable EDR Monitoring:
- Use EDR to detect suspicious processes querying authentication mechanisms (e.g., lsass.exe memory access).

The tag is: *misp-galaxy:mitre-data-component="Active Directory Credential Request"*

Table 7272. Table References

Links

Active Directory Object Deletion

Object deletion in AD (e.g., user accounts, groups, OUs) is logged as Event ID 5141. Examples:

- User Account: Deleted user.
- Group: Deleted security/distribution group.
- Organizational Unit (OU): Loss of configurations or policies.
- Service Account: Disrupted operations or cover tracks.
- Trust Object: Removed domain trust, disrupting connectivity.

Data Collection Measures:

- Audit Policy:
- Enable "Audit Directory Service Changes" (Success and Failure).
- Path: `Computer Configuration > Policies > Windows Settings > Security Settings > Advanced Audit Policy Configuration > Audit Policies > Directory Service Changes`.
- Key Event: Event ID 5141.
- Log Forwarding: Use WEF to centralize logs for SIEM tools (e.g., Splunk).
- Enable EDR Monitoring:
- Detect processes or users that initiate unauthorized object deletions.
- Monitor tools and scripts that may delete key directory objects.

The tag is: *misp-galaxy:mitre-data-component="Active Directory Object Deletion"*

Table 7273. Table References

Links

Active Directory Object Modification

Changes to AD objects (e.g., users, groups, OUs) are logged as Event ID 5136 (Object Modification) or 5163 (Attribute Changes). Examples:

- User Account: Modifying attributes (e.g., group membership, enabling/disabling accounts).
- Group Membership: Adding/removing members.
- OU: Changing properties/permissions (e.g., delegation).
- Service Account: Modifying SPNs or other attributes.
- Object Attributes: Changes to passwords, logon hours, or control flags.

Data Collection Measures:

- Audit Policy:
- Enable "Audit Directory Service Changes" (Success and Failure).
- Path: `Computer Configuration > Policies > Windows Settings > Security Settings > Advanced Audit Policy Configuration > Audit Policies > Directory Service Changes`.
- Key Events: 5136 (modifications), 5163 (attribute changes).
- Log Forwarding:
- Use WEF to centralize logs for SIEM.
- Parse logs to extract: Object Name, Attribute Changed, Initiator Account Name.
- Enable EDR Monitoring:
- Detect changes to critical attributes (e.g., memberOf, logonHours).
- Track processes modifying directory service objects (e.g., Set-ADUser or dsmod).
- Enable EDR Monitoring:

- Detect changes to critical attributes (e.g., memberOf, logonHours).
- Track processes modifying directory service objects (e.g., Set-ADUser or dsmod).

The tag is: *misp-galaxy:mitre-data-component="Active Directory Object Modification"*

Table 7274. Table References

Links

Windows Registry Key Access

The action of opening a specific Windows Registry key, typically to read its associated value. This activity can be used for system configuration, application settings retrieval, and security policies.

Data Collection Measures:

- Windows Event Logs
- Event ID 4656 - Handle to an Object was Requested: Logs attempts to open registry keys.
- Event ID 4663 - An Object was Accessed: Captures read/write operations on registry keys.
- Event ID 4657 - Registry Value Modification: Useful for detecting changes to registry keys after being accessed.
- Sysmon
- Sysmon Event ID 13 - Registry Value Set: Captures modifications to existing registry keys.
- Endpoint Detection and Response (EDR) Solutions
- Provide telemetry on registry key access activities, especially when linked to suspicious processes.

The tag is: *misp-galaxy:mitre-data-component="Windows Registry Key Access"*

Table 7275. Table References

Links

Windows Registry Key Creation

Initial construction of a new registry key within the Windows operating system.

Data Collection Measures:

- Windows Event Logs
- Event ID 4656 - Registry Object Handle Requested: Tracks registry key access, including newly created keys.
- Event ID 4657 - Registry Value Modification: Detects modifications to an existing registry key after creation.
- Sysmon (System Monitor) for Windows

- Sysmon Event ID 12 - Registry Key Created: Logs when a new registry key is created.

The tag is: *misp-galaxy:mitre-data-component="Windows Registry Key Creation"*

Table 7276. Table References

Links

Windows Registry Key Deletion

The removal of a registry key within the Windows operating system.

Data Collection Measures:

- Windows Event Logs
- Event ID 4658 - Registry Key Handle Closed: Captures when a handle to a registry key is closed, which may indicate deletion.
- Event ID 4660 - Object Deleted: Logs when a registry key is deleted.
- Sysmon (System Monitor) for Windows
- Sysmon Event ID 12 - Registry Key Deleted: Logs when a registry key is removed.
- Sysmon Event ID 13 - Registry Value Deleted: Captures removal of specific registry values.
- Endpoint Detection and Response (EDR) Solutions
- Monitor registry deletions for suspicious behavior.

The tag is: *misp-galaxy:mitre-data-component="Windows Registry Key Deletion"*

Table 7277. Table References

Links

Windows Registry Key Modification

Changes made to an existing registry key or its values. These modifications can include altering permissions, modifying stored data, or updating configuration settings.

Data Collection Measures:

- Windows Event Logs
- Event ID 4657 - Registry Value Modified: Logs changes to registry values, including modifications to startup entries, security settings, or system configurations.
- Sysmon (System Monitor) for Windows
- Sysmon Event ID 13 - Registry Value Set: Captures changes to specific registry values.
- Sysmon Event ID 14 - Registry Key & Value Renamed: Logs renaming of registry keys, which may indicate evasion attempts.
- Endpoint Detection and Response (EDR) Solutions

- Monitor registry modifications for suspicious behavior.

The tag is: *misp-galaxy:mitre-data-component="Windows Registry Key Modification"*

Table 7278. Table References

Links

User Account Authentication

An attempt (successful and failed login attempts) by a user, service, or application to gain access to a network, system, or cloud-based resource. This typically involves credentials such as passwords, tokens, multi-factor authentication (MFA), or biometric validation.

Data Collection Measures:

- Host-Based Authentication Logs
- Windows Event Logs
- Event ID 4776 – NTLM authentication attempt.
- Event ID 4624 – Successful user logon.
- Event ID 4625 – Failed authentication attempt.
- Event ID 4648 – Explicit logon with alternate credentials.
- Linux/macOS Authentication Logs
- `/var/log/auth.log`, `/var/log/secure` – Logs SSH, sudo, and other authentication attempts.
- AuditD – Tracks authentication events via PAM modules.
- macOS Unified Logs – `/var/db/diagnostics` captures authentication failures.
- Cloud Authentication Logs
- Azure AD Logs
- Sign-in Logs – Tracks authentication attempts, MFA challenges, and conditional access failures.
- Audit Logs – Captures authentication-related configuration changes.
- Microsoft Graph API – Provides real-time sign-in analytics.
- Google Workspace & Office 365
- Google Admin Console – `User Login Report` tracks login attempts and failures.
- Office 365 Unified Audit Logs – Captures logins across Exchange, SharePoint, and Teams.
- AWS CloudTrail & IAM
- Tracks authentication via `AWS IAM AuthenticateUser` and `sts:GetSessionToken`.
- Logs failed authentications to AWS Management Console and API requests.
- Container Authentication Monitoring
- Kubernetes Authentication Logs
- kubectl audit logs – Captures authentication attempts for service accounts and admin users.

- Azure Kubernetes Service (AKS) and Google Kubernetes Engine (GKE) – Logs IAM authentication events.

Application Log Content

Application Log Content refers to logs generated by applications or services, providing a record of their activity. These logs may include metrics, errors, performance data, and operational alerts from web, mail, or other applications. These logs are vital for monitoring application behavior and detecting malicious activities or anomalies. Examples:

- Web Application Logs: These logs include information about requests, responses, errors, and security events (e.g., unauthorized access attempts).
- Email Application Logs: Logs contain metadata about emails sent, received, or blocked (e.g., sender/receiver addresses, message IDs).
- SaaS Application Logs: Activity logs include user logins, configuration changes, and access to sensitive resources.
- Cloud Application Logs: Logs detail control plane activities, including API calls, instance modifications, and network changes.
- System/Application Monitoring Logs: Logs provide insights into application performance, errors, and anomalies.

This data component can be collected through the following measures:

Configure Application Logging

- Enable logging within the application or service.
- Examples:
- Web Servers: Enable access and error logs in NGINX or Apache.
- Email Systems: Enable audit logging in Microsoft Exchange or Gmail.

Centralized Log Management

- Use log management solutions like Splunk, or a cloud-native logging solution.
- Configure the application to send logs to a centralized system for analysis.

Cloud-Specific Collection

- Use services like AWS CloudWatch, Azure Monitor, or Google Cloud Operations Suite for cloud-based applications.
- Ensure logging is enabled for all critical resources (e.g., API calls, IAM changes).

SIEM Integration

- Integrate application logs with a SIEM platform (e.g., Splunk, QRadar) for real-time correlation and analysis.
- Use parsers to standardize log formats and extract key fields like timestamps, user IDs, and error codes.

The tag is: *misp-galaxy:mitre-data-component="Application Log Content"*

Cloud Storage Access

Cloud storage access refers to the retrieval or interaction with data stored in cloud infrastructure. This data component includes activities such as reading, downloading, or accessing files and objects within cloud storage systems. Common examples include API calls like GetObject in AWS S3, which retrieves objects from cloud buckets. Examples:

- AWS S3 Access: An adversary uses the `GetObject` API to retrieve sensitive data from an AWS S3 bucket.
- Azure Blob Storage Access: A user accesses a blob in Azure Storage using `Get Blob` or `Get Blob Properties`.
- Google Cloud Storage Access: An adversary uses `storage.objects.get` to download objects from - OpenStack Swift Storage Access: A user retrieves an object from OpenStack Swift using the `GET` method.

This data component can be collected through the following measures:

Enable Logging for Cloud Storage Services

- AWS S3: Enable Server Access Logging to capture API calls like `GetObject` and store them in a designated S3 bucket.
- Azure Storage: Enable Azure Storage Logging to capture operations like `GetBlob` and log metadata.
- Google Cloud Storage: Enable Data Access audit logs for `storage.objects.get` API calls.
- OpenStack Swift: Configure middleware for object logging to capture GET requests.

Centralize and Aggregate Logs

- Use a centralized logging solution (e.g., Splunk, ELK, or a cloud-native SIEM) to ingest and analyze logs from different cloud providers.
- AWS Example: Use AWS CloudTrail to collect API activity logs and forward them to your SIEM.
- Azure Example: Use Azure Monitor and Log Analytics to analyze storage access logs.

Correlate with IAM Logs

- Combine storage access logs with IAM activity logs to correlate user actions with specific permissions and identities.

The tag is: *misp-galaxy:mitre-data-component="Cloud Storage Access"*

User Account Creation

The initial establishment of a new user, service, or machine account within an operating system, cloud environment, or identity management system.

Data Collection Measures:

- Host-Based Logging
- Windows Event Logs
- Event ID 4720 – A new user account was created.
- Event ID 4732/4735 – A user was added to a privileged group.
- Event ID 4798 – Enumeration of user accounts.
- Linux/macOS Authentication Logs
- `/var/log/auth.log`, `/var/log/secure` – Logs `useradd`, `adduser`, `passwd`, and `groupmod` activities.
- AuditD – Detects new account creation via PAM (`useradd`, `usermod`).
- OSQuery – The `users` table tracks newly created accounts.
- Cloud-Based Logging
- Azure AD Logs
- Azure AD Audit Logs – Tracks new user and service account creation.
- Azure Graph API – Provides logs on new account provisioning.
- AWS IAM & CloudTrail Logs
- CreateUser, CreateRole – Tracks new IAM user creation.
- AttachRolePolicy – Identifies privilege escalation via account creation.
- Google Workspace & Office 365 Logs
- Google Admin Console – Logs user creation in User Accounts API.
- Microsoft 365 Unified Audit Log – Tracks new account provisioning.
- Container & Network Account Creation Logs
- Kubernetes Account Creation Logs
- kubectl audit logs – Detects new service account provisioning.
- GKE/Azure AKS Logs – Track new container service accounts.

The tag is: *misp-galaxy:mitre-data-component="User Account Creation"*

Table 7282. Table References

User Account Deletion

The removal of a user, service, or machine account from an operating system, cloud identity management system, or directory service.

Data Collection Measures:

- Host-Based Logging
- Windows Event Logs
- Event ID 4726 – A user account was deleted.
- Event ID 4733/4735 – A user was removed from a privileged group.
- Event ID 1102 – Security log was cleared (potential cover-up).
- Linux/macOS Authentication Logs
- `/var/log/auth.log`, `/var/log/secure` – Logs `userdel`, `deluser`, `passwd -l`.
- AuditD – Tracks account deletions via PAM events (`userdel`).
- OSQuery – The `users` table can detect account removal.
- Cloud-Based Logging
- Azure AD Logs
- Azure AD Audit Logs – Tracks user and service account deletions.
- Azure Graph API – Monitors identity changes.
- AWS IAM & CloudTrail Logs
- `DeleteUser`, `DeleteRole` – Tracks IAM user deletion.
- DetachRolePolicy – Identifies privilege revocation before deletion.
- Google Workspace & Office 365 Logs
- Google Admin Console – Logs user removal activities.
- Microsoft 365 Unified Audit Log – Captures deleted accounts in Active Directory.
- Container & Network Account Deletion Logs
- Kubernetes Service Account Deletion
- kubectl audit logs – Detects when service accounts are removed from pods.
- GKE/Azure AKS Logs – Track containerized identity removals.

The tag is: *misp-galaxy:mitre-data-component="User Account Deletion"*

Table 7283. Table References

OS API Execution

Calls made by a process to operating system-provided Application Programming Interfaces (APIs). These calls are essential for interacting with system resources such as memory, files, and hardware, or for performing system-level tasks. Monitoring these calls can provide insight into a process's intent, especially if the process is malicious.

Data Collection Measures:

- Endpoint Detection and Response (EDR) Tools:
- Leverage tools to monitor API execution behaviors at the process level.
- Example: Sysmon Event ID 10 captures API call traces for process access and memory allocation.
- Process Monitor (ProcMon):
- Use ProcMon to collect detailed logs of process and API activity. ProcMon can provide granular details on API usage and identify malicious behavior during analysis.
- Windows Event Logs:
- Use Event IDs from Windows logs for specific API-related activities:
- Event ID 4688: A new process has been created (can indirectly infer API use).
- Event ID 4657: A registry value has been modified (to monitor registry-altering APIs).
- Dynamic Analysis Tools:
- Tools like Cuckoo Sandbox, Flare VM, or Hybrid Analysis monitor API execution during malware detonation.
- Host-Based Logs:
- On Linux/macOS systems, leverage audit frameworks (e.g., `auditd`, `strace`) to capture and analyze system call usage that APIs map to.
- Runtime Monitors:
- Runtime security tools like Falco can monitor system-level calls for API execution.
- Debugging and Tracing:
- Use debugging tools like gdb (Linux) or WinDbg (Windows) for deep tracing of API executions in real time.

The tag is: *misp-galaxy:mitre-data-component="OS API Execution"*

User Account Modification

Changes made to an existing user, service, or machine account, including alterations to attributes, permissions, roles, authentication methods, or group memberships.

Data Collection Measures:

- Host-Based Logging
- Windows Event Logs
- Event ID 4738 – A user account was changed.
- Event ID 4725 – A user account was disabled.
- Event ID 4724 – An attempt was made to reset an account's password.
- Event ID 4767 – A user account was unlocked.
- Linux/macOS Authentication Logs
- `/var/log/auth.log`, `/var/log/secure` – Tracks account modifications (`usermod`, `chage`, `passwd`).
- AuditD – Monitors account changes (`useradd`, `usermod`, `gpasswd`).
- OSQuery – Queries the `users` table for recent modifications.
- Cloud-Based Logging
- Azure AD Logs
- Azure AD Audit Logs – Tracks modifications to users and security groups.
- Azure Graph API – Captures changes to authentication policies and MFA settings.
- AWS IAM & CloudTrail Logs
- `ModifyUser`, `UpdateLoginProfile` – Captures changes to IAM user attributes.
- `AttachUserPolicy`, `AddUserToGroup` – Detects policy and group modifications.
- Google Workspace & Office 365 Logs
- Google Admin Console – Logs account changes, role modifications, and group membership updates.
- Microsoft 365 Unified Audit Log – Captures modifications to security settings and privileged account changes.
- Container & Network Account Modification Logs
- Kubernetes Service Account Changes
- kubectl audit logs – Detects service account modifications in Kubernetes clusters.
- GKE/Azure AKS Logs – Monitors role and permission changes.

The tag is: *misp-galaxy:mitre-data-component="User Account Modification"*

Table 7286. Table References

Network Share Access

Opening a network share, which makes the contents available to the requestor (ex: Windows EID 5140 or 5145)

Data Collection Measures:

- Windows:
- Event ID 5140 – Network Share Object Access Logs every access attempt to a network share.
- Event ID 5145 – Detailed Network Share Object Access Captures granular access control information, including the requesting user, source IP, and access permissions.
- Sysmon Event ID 3 – Network Connection Initiated Helps track SMB connections to suspicious or unauthorized network shares.
- Enable Audit Policy for Network Share Access: `auditpol /set /subcategory:"File Share" /success:enable /failure:enable`
- Enable PowerShell Logging to Detect Unauthorized SMB Access: `Set-ExecutionPolicy RemoteSigned`
- Restrict Network Share Access with Group Policy (GPO): `Computer Configuration → Windows Settings → Security Settings → Local Policies → User Rights Assignment` Set "Access this computer from the network" to restrict unauthorized accounts.
- Linux/macOS:
- AuditD (`open`, `read`, `write`, `connect` syscalls) Detects access to NFS, CIFS, and SMB network shares.
- Lsof (`lsof | grep nfs` or `lsof | grep smb`) Identifies active network share connections.
- Mount (`mount | grep nfs` or `mount | grep cifs`) Lists currently mounted network shares.
- Enable AuditD for SMB/NFS Access: `auditctl -a always,exit -F arch=b64 -S open -F path=/mnt/share -k network_share_access`
- Monitor Active Network Shares Using Netstat: `netstat -an | grep :445`
- Endpoint Detection & Response (EDR):
- Detects abnormal network share access behavior, such as unusual account usage, large file transfers, or encrypted file activity.

The tag is: *misp-galaxy:mitre-data-component="Network Share Access"*

Table 7287. Table References

Links

Network Connection Creation

The initial establishment of a network session, where a system or process initiates a connection to a local or remote endpoint. This typically involves capturing socket information (source/destination IP, ports, protocol) and tracking session metadata. Monitoring these events helps detect lateral movement, exfiltration, and command-and-control (C2) activities.

Data Collection Measures:

- Windows:
- Event ID 5156 – Filtering Platform Connection - Logs network connections permitted by Windows Filtering Platform (WFP).
- Sysmon Event ID 3 – Network Connection Initiated - Captures process, source/destination IP, ports, and parent process.
- Linux/macOS:
- Netfilter (iptables), nftables logs - Tracks incoming and outgoing network connections.
- AuditD (`connect` syscall) - Logs TCP, UDP, and ICMP connections.
- Zeek (`conn.log`) - Captures protocol, duration, and bytes transferred.
- Cloud & Network Infrastructure:
- AWS VPC Flow Logs / Azure NSG Flow Logs - Logs IP traffic at the network level in cloud environments.
- Zeek (conn.log) or Suricata (network events) - Captures packet metadata for detection and correlation.
- Endpoint Detection & Response (EDR):
- Detect anomalous network activity such as new C2 connections or data exfiltration attempts.

The tag is: *misp-galaxy:mitre-data-component="Network Connection Creation"*

Table 7288. Table References

Links

Cloud Storage Creation

Cloud Storage Creation refers to the initial creation of a new cloud storage resource, such as buckets, containers, or directories, within a cloud environment. This action is critical to track as it might indicate the legitimate provisioning of resources or unauthorized actions taken by adversaries to stage, store, or exfiltrate data. Examples:

- AWS S3 Bucket Creation: An AWS user creates a new S3 bucket using the `CreateBucket` API call.
- Azure Blob Storage Container Creation: A user creates a new container in Azure Blob Storage using the `Create Container` operation.
- Google Cloud Storage Bucket Creation: A Google Cloud user creates a new bucket using `storage.buckets.create`.

- OpenStack Swift Container Creation: A user creates a new container in OpenStack Swift using the `PUT` method.

This data component can be collected through the following measures:

Enable Logging for Cloud Storage Services

- AWS S3: Enable AWS CloudTrail to log CreateBucket API actions.
- Azure Blob Storage: Enable Azure Monitor and Diagnostic Logs for storage account activity. Use Azure Event Grid to capture Create Container operations.
- Google Cloud Storage: Enable Data Access logs in Cloud Audit Logs to monitor storage.buckets.create API calls.
- OpenStack Swift: Configure Swift logging to capture PUT requests to new containers.

Centralized Logging and Analysis

- Forward logs to centralized platforms like Splunk or cloud-native SIEM solutions for correlation and analysis.

The tag is: *misp-galaxy:mitre-data-component="Cloud Storage Creation"*

Cloud Service Disable

This data component refers to monitoring actions that deactivate or stop a cloud service in a cloud control plane. Examples include disabling essential logging services like AWS CloudTrail (`StopLogging` API call), Microsoft Azure Monitor Logs, or Google Cloud's Operations Suite (formerly Stackdriver). Disabling such services can hinder visibility into adversary activities within the cloud environment. Examples:

- AWS CloudTrail StopLogging: This action stops logging of API activity for a particular trail, effectively reducing the monitoring and visibility of AWS resources and activities.
- Microsoft Azure Monitor Logs: Disabling these logs hinders the organization's ability to detect anomalous activities and trace malicious actions.
- Google Cloud Logging: Disabling cloud logging removes visibility into resource activity,

preventing monitoring of service access or configuration changes.

- SaaS Applications: Stopping logging removes visibility into user activities, such as email access or file downloads, enabling undetected malicious behavior.

This data component can be collected through the following measures:

Enable and Monitor Cloud Service Logging

- Ensure logging is enabled for all cloud services, including administrative actions like StopLogging.
- Example: Use AWS Config to verify that CloudTrail is enabled and enforce logging as a compliance rule.

API Monitoring

- Use API monitoring tools to detect calls like StopLogging or equivalent service-stopping actions in other platforms.
- Example: Monitor AWS CloudWatch for specific API events such as StopLogging and flag unauthorized users.

SIEM Integration

- Collect logs and events from the cloud control plane into a centralized SIEM for real-time analysis and correlation.
- Example: Ingest AWS CloudTrail logs into Splunk or Azure Monitor logs into Sentinel.

Cloud Security Posture Management (CSPM) Tools

- Leverage CSPM tools like Prisma Cloud, Dome9, or AWS Security Hub to detect misconfigurations or suspicious activity, such as disabled logging.
- Example: Set alerts for changes to logging configurations in CSPM dashboards.

Configure Alerts in Cloud Platforms

- Create native alerts in cloud platforms to detect service stoppages.
- Example: Configure an AWS CloudWatch alarm to trigger when StopLogging is invoked.

The tag is: *misp-galaxy:mitre-data-component="Cloud Service Disable"*

Table 7291. Table References

Links

Cloud Storage Deletion

Cloud Storage Deletion refers to the removal or destruction of cloud storage infrastructure, such as buckets, containers, or directories, within a cloud environment. Monitoring this activity is critical to detecting potential unauthorized or malicious actions, such as data destruction by adversaries or accidental deletions that may lead to data loss. Examples:

- AWS S3 Bucket Deletion: An AWS user deletes an S3 bucket using the `DeleteBucket` API call.
- Azure Blob Storage Container Deletion: A user deletes a container in Azure Blob Storage using the `Delete Container` operation.
- Google Cloud Storage Bucket Deletion: A Google Cloud user deletes a bucket using the `storage.buckets.delete` API.
- OpenStack Swift Container Deletion: A user deletes a container in OpenStack Swift using the `DELETE` method.

This data component can be collected through the following measures:

Enable Logging for Cloud Storage Services

- AWS S3: Enable AWS CloudTrail to log DeleteBucket API actions.
- Azure Blob Storage: Enable Azure Monitor and Diagnostic Logs to capture Delete Container operations. Use Azure Event Grid to capture and trigger alerts for container deletion.
- Google Cloud Storage: Enable Data Access logs in Cloud Audit Logs to monitor storage.buckets.delete API calls.
- OpenStack Swift: Configure Swift logging to capture DELETE requests for containers.

Centralized Logging and Analysis

- Use platforms like Splunk or native SIEMs to forward and analyze logs for anomalies in cloud storage deletions.

The tag is: *misp-galaxy:mitre-data-component="Cloud Storage Deletion"*

Table 7292. Table References

Links

Cloud Storage Enumeration

Cloud Storage Enumeration involves retrieving a list of available cloud storage infrastructure, such as buckets, containers, or objects, within a cloud environment. This activity may be performed for legitimate administrative purposes or malicious reconnaissance by adversaries seeking to identify accessible storage resources.Examples:

- AWS S3 Bucket Enumeration: An AWS user lists all buckets using the `ListBuckets` API call.
- Azure Blob Storage Container Enumeration: A user retrieves a list of all containers within a storage account using the Azure Storage SDK or API.
- Google Cloud Storage Bucket Enumeration: A Google Cloud user lists all buckets within a project using the `storage.buckets.list` API.
- OpenStack Swift Container Enumeration: A user retrieves a list of containers in OpenStack Swift using the `GET` method on the storage endpoint.

This data component can be collected through the following measures:

Enable Logging for Cloud Storage Enumeration

- AWS S3: Enable AWS CloudTrail to capture ListBuckets and ListObjects API calls.
- Azure Blob Storage: Enable Azure Monitor and Diagnostic Logs to capture enumeration operations like List Containers. Use Azure Event Grid to trigger alerts for container enumeration.
- Google Cloud Storage: Enable Audit Logs in Google Cloud to track storage.buckets.list API activity.
- OpenStack Swift: Configure Swift logging to capture GET requests for container enumeration.

Centralized Log Aggregation

- Use platforms like Splunk or native SIEM solutions to collect and analyze enumeration logs.

The tag is: *misp-galaxy:mitre-data-component="Cloud Storage Enumeration"*

Table 7293. Table References

Links

Cloud Service Enumeration

Cloud service enumeration involves listing or querying available cloud services in a cloud control plane. This activity is often performed to identify resources such as virtual machines, storage buckets, compute clusters, or other services within a cloud environment. Examples include API calls like `AWS ECS ListServices`, `Azure ListAllResources`, or `Google Cloud ListInstances`. Examples:

AWS Cloud Service Enumeration: The adversary gathers details about existing ECS services to identify opportunities for privilege escalation or exfiltration. - Azure Resource Enumeration: The adversary collects information about virtual machines, resource groups, and other Azure assets for reconnaissance purposes. - Google Cloud Resource Enumeration: The attacker seeks to map the environment and find misconfigured or underutilized resources for exploitation. - Office 365 Service Enumeration: The attacker may look for data repositories or collaboration tools to exfiltrate sensitive information.

This data component can be collected through the following measures:

Enable Cloud Activity Logging

- Ensure cloud service logs are enabled for API calls and resource usage.
- Example: Enable AWS CloudTrail, Azure Monitor, or Google Cloud Logging to track resource queries.

Centralize Logs in a SIEM

- Aggregate logs from cloud control planes into a centralized SIEM (e.g., Splunk, Azure Sentinel).
- Example: Collect AWS CloudTrail logs and set up alerts for API calls related to service enumeration.

Use Native Cloud Security Tools

- Leverage cloud-native security solutions like AWS GuardDuty, Azure Defender, or Google Security Command Center.
- Example: Use GuardDuty to detect anomalous API activity, such as ListServices being executed by an unknown user.

Implement Network Flow Logging

- Monitor and analyze VPC flow logs to identify lateral movement or enumeration activity.
- Example: Inspect flow logs for unexpected traffic between compute instances and the cloud control plane.

API Access Monitoring

- Monitor API keys and tokens used for enumeration to identify misuse or compromise.
- Example: Use AWS Secrets Manager or Azure Key Vault to manage and rotate keys securely.

The tag is: *misp-galaxy:mitre-data-component="Cloud Service Enumeration"*

Table 7294. Table References

Links

Scheduled Job Creation

The establishment of a task or job that will execute at a predefined time or based on specific triggers.

*Data Collection Measures: *

- Windows Event Logs:
- Event ID 4698 (Scheduled Task Created) – Detects the creation of new scheduled tasks.
- Event ID 4702 (Scheduled Task Updated) – Identifies modifications to existing scheduled jobs.
- Event ID 106 (TaskScheduler Operational Log) – Provides details about scheduled task execution.
- Sysmon (Windows):
- Event ID 1 (Process Creation) – Detects the execution of suspicious tasks started by `schtasks.exe`, `at.exe`, or `taskeng.exe`.
- Linux/macOS Monitoring:
- AuditD: Monitor modifications to `/etc/cron*`, `/var/spool/cron/`, and `crontab` files.
- Syslog: Capture cron job execution logs from `/var/log/cron`.
- OSQuery: Query the `crontab` and `launchd` tables for scheduled job configurations.
- Endpoint Detection and Response (EDR) Tools:
- Track scheduled task creation and modification events.

- SIEM & XDR Detection Rules:
- Monitor for scheduled jobs created by unusual users.
- Detect tasks executing scripts from non-standard directories.

The tag is: *misp-galaxy:mitre-data-component="Scheduled Job Creation"*

Table 7295. Table References

Links

Logon Session Creation

The successful establishment of a new user session following a successful authentication attempt. This typically signifies that a user has provided valid credentials or authentication tokens, and the system has initiated a session associated with that user account. This data is crucial for tracking authentication events and identifying potential unauthorized access. Examples:

- Windows Systems
- Event ID: 4624
- Logon Type: 2 (Interactive) or 10 (Remote Interactive via RDP).
- Account Name: JohnDoe
- Source Network Address: 192.168.1.100
- Authentication Package: NTLM
- Linux Systems
- /var/log/utmp or /var/log/wtmp:
- Log format: login user [tty] from [source_ip]
- User: jane
- IP: 10.0.0.5
- Timestamp: 2024-12-28 08:30:00
- macOS Systems
- /var/log/asl.log or unified logging framework:
- Log: com.apple.securityd: Authentication succeeded for user 'admin'
- Cloud Environments
- Azure Sign-In Logs:
- Activity: Sign-in successful
- Client App: Browser
- Location: Unknown (Country: X)
- Google Workspace
- Activity: Login

- Event Type: successful_login
- Source IP: 203.0.113.55

This data component can be collected through the following measures:

- Windows Systems
- Event Logs: Monitor Security Event Logs using Event ID 4624 for successful logons.
- PowerShell Example: `Get-EventLog -LogName Security -InstanceId 4624`
- Linux Systems
- Log Files: Monitor `/var/log/utmp`, `/var/log/wtmp`, or `/var/log/auth.log` for logon events.
- Tools: Use `last` or `who` commands to parse login records.
- macOS Systems
- Log Sources: Monitor `/var/log/asl.log` or Apple Unified Logs using the `log show` command.
- Command Example: `log show --predicate 'eventMessage contains "Authentication succeeded"' --info`
- Cloud Environments
- Azure AD: Use Azure Monitor to analyze sign-in logs. Example CLI Query: `az monitor log-analytics query -w <workspace_id> --analytics-query "AzureActivity | where ActivityStatus == 'Success' and OperationName == 'Sign-in'"`
- Google Workspace: Enable and monitor Login Audit logs from the Admin Console.
- Office 365: Use Audit Log Search in Microsoft 365 Security & Compliance Center for login-related events.
- Network Logs
- Sources: Network authentication mechanisms (e.g., RADIUS or TACACS logs).
- Enable EDR Monitoring:
- EDR tools monitor logon session activity, including the creation of new sessions.
- Configure alerts for: Suspicious logon types (e.g., Logon Type 10 for RDP or Type 5 for Service). Logons from unusual locations, accounts, or devices.
- Leverage EDR telemetry for session attributes like source IP, session duration, and originating process.

The tag is: *misp-galaxy:mitre-data-component="Logon Session Creation"*

Table 7296. Table References

Cloud Storage Metadata

Cloud Storage Metadata provides contextual information about cloud storage infrastructure and its associated activity. This data may include attributes such as storage name, size, owner, permissions,

creation date, region, and activity metadata. It is essential for monitoring, auditing, and identifying anomalies in cloud storage environments. Examples:

- AWS S3 Bucket Metadata: Metadata about an S3 bucket includes the bucket name, region, creation date, owner, storage class, and permissions.
- Azure Blob Storage Metadata: Metadata for an Azure Blob container includes container name, access level (e.g., private or public), size, and tags.
- Google Cloud Storage Metadata: Metadata includes bucket name, storage class, location, labels, lifecycle policies, and versioning status.
- OpenStack Swift Metadata: Metadata for a Swift container includes name, access level, quota, and custom attributes.

This data component can be collected through the following measures:

Enable Logging for Metadata Collection

- AWS S3: Use AWS CloudTrail to log `GetBucketAcl`, `GetBucketPolicy`, and `HeadBucket` API calls.
- Azure Blob Storage: Use Azure Monitor to log container metadata retrieval and updates.
- Google Cloud Storage: Enable Google Cloud Audit Logs to capture `storage.buckets.get` and `storage.buckets.update`.
- OpenStack Swift: Enable logging of `HEAD` or `GET` requests to containers.

Centralized Log Aggregation

- Use a SIEM solution (e.g., Splunk) to aggregate and analyze metadata retrieval and modification logs.
- Correlate metadata access with user actions, IP addresses, and other contextual data.

API Polling

- Use cloud SDKs or APIs to periodically query metadata for analysis:
- AWS CLI Example: `aws s3api get-bucket-acl --bucket company-sensitive-data`
- Azure CLI Example: `az storage container show --name customer-records`
- Google Cloud CLI Example: `gcloud storage buckets describe user-uploads`

The tag is: *misp-galaxy:mitre-data-component="Cloud Storage Metadata"*

Table 7297. Table References

Links

Cloud Service Metadata

Cloud service metadata refers to the contextual and descriptive information about cloud services, including their name, type, purpose, configuration, and activity around them. This metadata is essential for understanding the roles and functions of cloud services, their operational status, and

their potential misuse. Examples:

- Azure Service Metadata: Metadata describing a resource in Azure, such as an Azure Storage Account or a Virtual Machine.
- AWS Cloud Service Metadata: Metadata for an AWS EC2 instance collected using the `DescribeInstances` API call.
- Google Cloud Service Metadata: Metadata for a Google Compute Engine instance collected using `gcloud compute instances describe`.
- Office 365 Metadata: Metadata about an Office 365 SharePoint site.

This data component can be collected through the following measures:

Enable Cloud Metadata APIs

- Leverage APIs provided by cloud providers to query metadata about services.
- AWS: Use AWS CLI or SDKs for `DescribeInstances`, `DescribeBuckets`, etc.
- Azure: Use `az resource list` or SDKs.
- Google Cloud: Use `gcloud compute instances describe` or related commands.
- Office 365: Use Microsoft Graph API.

Centralize Metadata in a Security Platform

- Aggregate metadata from multiple clouds into a SIEM or CSPM (Cloud Security Posture Management) tool.
- Example: Integrate AWS CloudTrail with Splunk or Azure Monitor with Sentinel.

Enable Continuous Monitoring

- Set up automated jobs or workflows to regularly query and update metadata.
- Example: Use AWS Config to track resource configurations and changes over time.

Configure Access and Logging

- Enable logging for API queries to ensure access and usage of metadata are monitored.
- Example: Use AWS CloudTrail to log API activity for metadata queries.

Use Cloud Security Tools

- Employ CSPM tools like Prisma Cloud, Wiz, or Dome9 to gather metadata and identify misconfigurations.
- Example: Prisma Cloud provides consolidated views of metadata for resources across AWS, Azure, and GCP.

The tag is: *misp-galaxy:mitre-data-component="Cloud Service Metadata"*

Table 7298. Table References

Links

Cloud Storage Modification

Cloud Storage Modification involves tracking changes made to cloud storage infrastructure, including updates to settings, permissions, or stored data. Examples include modifying object access control lists (ACLs), uploading new objects, or updating bucket policies. Examples:

AWS S3: An object is uploaded or its ACL is modified. - Azure Blob Storage: A blob's metadata or permissions are updated. - Google Cloud Storage: An object's lifecycle policy is updated, or a bucket policy is changed. - OpenStack Swift: Modifications to container settings or uploading of new objects.

This data component can be collected through the following measures:

Enable Logging

- AWS S3: Enable AWS CloudTrail to log API events like PutObject, PutObjectAcl, and PutBucketPolicy.
- Azure Blob Storage: Use Azure Monitor to log write and update operations.
- Google Cloud Storage: Enable Google Cloud Audit Logs to track storage.objects.update and storage.buckets.update.
- OpenStack Swift: Enable logging for PUT and POST requests to track object uploads and container metadata updates.

Use Cloud Monitoring Tools

- Integrate with tools like AWS Config, Azure Security Center, or Google Cloud Monitoring to detect configuration drift or unauthorized changes.

Centralized Log Aggregation

- Use a SIEM (e.g., Splunk) to aggregate logs across multiple cloud providers for unified monitoring and analysis.

Periodic API Queries

- AWS CLI Example: Query recent modifications to bucket policies: `aws s3api get-bucket-policy --bucket sensitive-data`
- Azure CLI Example: List changes to a blob container: `az storage blob show --container-name private-docs`
- Google Cloud CLI Example: Check metadata updates: `gcloud storage objects describe gs://user-uploads/document.txt`

The tag is: *misp-galaxy:mitre-data-component="Cloud Storage Modification"*

Table 7299. Table References

Cloud Service Modification

Cloud service modification refers to changes made to the configuration, settings, or data of a cloud service. These modifications can include administrative changes such as enabling or disabling features, altering permissions, or deleting critical components. Monitoring these changes is critical to detect potential misconfigurations or malicious activity. Examples:

- AWS Cloud Service Modifications: A user disables AWS CloudTrail logging (StopLogging) or deletes a CloudWatch configuration rule (DeleteConfigRule).
- Azure Cloud Service Modifications: Changes to Azure Role-Based Access Control (RBAC) roles, such as adding a new Contributor role to a sensitive resource.
- Google Cloud Service Modifications: Deletion of a Google Cloud Storage bucket or disabling a Google Cloud Function.
- Office 365 Cloud Service Modifications: Altering mailbox permissions or disabling auditing in Microsoft 365.

This data component can be collected through the following measures:

Enable Cloud Audit Logging

- AWS: Enable AWS CloudTrail for logging management events such as StopLogging or DeleteTrail.
- Azure: Use Azure Activity Logs to monitor resource changes and access actions.
- Google Cloud: Enable Google Cloud Audit Logs to track API calls, resource modifications, and policy changes.
- Office 365: Use Unified Audit Logs in Microsoft Purview to track administrative actions.

Centralize Log Storage

- Consolidate logs from all cloud providers into a SIEM or CSPM (Cloud Security Posture Management) tool.
- Example: Use Splunk or Elastic Stack to ingest and analyze logs from AWS, Azure, and Google Cloud.

Automate Alerts for Sensitive Changes

- Configure alerts for high-risk actions, such as disabling logging or modifying IAM roles.
- AWS Example: Use AWS Config rules to detect and notify changes to critical services.
- Azure Example: Set up Azure Monitor alerts for write actions on sensitive resources.

Enable Continuous Monitoring

- Use tools like AWS Security Hub, Azure Defender, or Google Chronicle to continuously monitor cloud service modifications for anomalies.

The tag is: *misp-galaxy:mitre-data-component="Cloud Service Modification"*

Table 7300. Table References

Links

Network Traffic Content

The full packet capture (PCAP) or session data that logs both protocol headers and payload content. This allows analysts to inspect command and control (C2) traffic, exfiltration, and other suspicious activity within network communications. Unlike metadata-based logs, full content analysis enables deeper protocol inspection, payload decoding, and forensic investigations.

Data Collection Measures:

- Network Packet Capture (Full Content Logging)
- Wireshark / tcpdump / tshark
- Full packet captures (PCAP files) for manual analysis or IDS correlation. `tcpdump -i eth0 -w capture.pcap`
- Zeek (formerly Bro)
- Extracts protocol headers and payload details into structured logs. `echo "redef Log::default_store = Log::ASCII;" > local.zeek | zeek -Cr capture.pcap local.zeek`
- Suricata / Snort (IDS/IPS with PCAP Logging)
- Deep packet inspection (DPI) with signature-based and behavioral analysis. `suricata -c /etc/suricata/suricata.yaml -i eth0 -l /var/log/suricata`
- Host-Based Collection
- Sysmon Event ID 22 – DNS Query Logging, Captures DNS requests made by processes, useful for detecting C2 domains.
- Sysmon Event ID 3 – Network Connection Initiated, Logs process-to-network connection relationships.
- AuditD (Linux) – syscall=connect, Monitors outbound network requests from processes. `auditctl -a always,exit -F arch=b64 -S connect -k network_activity`
- Cloud & SaaS Traffic Collection
- AWS VPC Flow Logs / Azure NSG Flow Logs / Google VPC Flow Logs, Captures metadata about inbound/outbound network traffic.
- Cloud IDS (AWS GuardDuty, Azure Sentinel, Google Chronicle), Detects malicious activity in cloud environments by analyzing network traffic patterns.

Firewall Rule Modification

The creation, deletion, or alteration of firewall rules to allow or block specific network traffic. Monitoring changes to these rules is critical for detecting misconfigurations, unauthorized access, or malicious attempts to bypass network protections. Examples:

- Rule Creation: Adding a new rule to allow inbound traffic on port 3389 (RDP).
- Rule Deletion: Deleting a rule that blocks inbound traffic from untrusted IP ranges.
- Rule Modification: Changing a rule to allow traffic from "any" source IP instead of a specific trusted range.
- Audit Log Metadata: Logs indicating "Firewall rule modified by admin@domain.com."
- Platform-Specific Scenarios
- Azure: Altering rules in an Azure Network Security Group (NSG).
- AWS: Modifying Security Group rules to allow traffic.
- Windows: Changes tracked in Security Event Logs (EID 4950 or 4951).

This data component can be collected through the following measures:

Cloud Control Plane

- Azure: Collect rule modification logs from Azure Firewall Activity Logs.
- Example Command: `az network firewall policy rule-collection-group rule-collection list --policy-name <policy-name>`
- AWS: Use CloudTrail to track `AuthorizeSecurityGroupIngress` or `RevokeSecurityGroupIngress` actions. Example: `aws ec2 describe-security-groups`
- Google Cloud: Use gcloud commands to extract firewall rules: `gcloud compute firewall-rules list --format=json`

Host-Based Firewalls

- Windows:
- Collect events from the Windows Security Event Log (EID 4950: A rule has been modified).
- Use PowerShell to track rule changes: `Get-NetFirewallRule -PolicyStore PersistentStore`

- Linux:
- Monitor iptables or nftables rule modifications: `iptables -L -v`
- Use auditd for real-time monitoring: `auditctl -w /etc/iptables.rules -p wa`
- macOS: Use pfctl to monitor rule changes: `sudo pfctl -sr`

SIEM Integration

- Collect logs from cloud platforms, host systems, and network appliances for centralized monitoring.

API Monitoring

- Monitor API calls for firewall rule modifications.

The tag is: *misp-galaxy:mitre-data-component="Firewall Rule Modification"*

Table 7303. Table References

Links

Network Traffic Flow

Summarized network packet data that captures session-level details such as source/destination IPs, ports, protocol types, timestamps, and data volume, without storing full packet payloads. This is commonly used for traffic analysis, anomaly detection, and network performance monitoring.

Data Collection Measures:

- Network Flow Logs (Metadata Collection)
- NetFlow
- Summarized metadata for network conversations (no packet payloads).
- sFlow (Sampled Flow Logging)
- Captures sampled packets from switches and routers.
- Used for real-time traffic monitoring and anomaly detection.
- Zeek (Bro) Flow Logs
- Zeek logs session-level details in logs like conn.log, http.log, dns.log, etc.
- Host-Based Collection
- Sysmon Event ID 3 – Network Connection Initiated
- Logs process-level network activity, useful for detecting malicious outbound connections.
- AuditD (Linux) – syscall=connect
- Monitors system calls for network connections. `auditctl -a always,exit -F arch=b64 -S connect -k network_activity`
- Cloud & SaaS Flow Monitoring

- AWS VPC Flow Logs
- Captures metadata for traffic between EC2 instances, security groups, and internet gateways.
- Azure NSG Flow Logs / Google VPC Flow Logs
- Logs ingress/egress traffic for cloud-based resources.

The tag is: *misp-galaxy:mitre-data-component="Network Traffic Flow"*

Table 7306. Table References

Links

Kernel Module Load

The process of loading a kernel module into the operating system kernel. Kernel modules are object files that extend the kernel's functionality, such as adding support for device drivers, new filesystems, or additional system calls. This action can be legitimate (e.g., loading a driver) or malicious (e.g., adding a rootkit).

Data Collection Measures:

- Linux:
- Auditd: Enable auditing of kernel module loading. Example rule: `-a always,exit -F arch=b64 -S init_module,delete_module`.
- Syslog: Monitor `/var/log/syslog` or `/var/log/messages` for entries related to kernel module loads.
- Systemd Journal: Use `journalctl` to query logs for module loading events: `journalctl -k | grep "Loading kernel module"`

- macOS:
- Unified Logs: Use the `log` command to query kernel module events: `log show --predicate 'eventMessage contains "kextload"' --info`
- Endpoint Security Framework (ESF): Monitor for `ES_EVENT_TYPE_AUTH_KEXTLOAD` (kernel extension loading events).
- Kernel-Specific Tools:
- Lsmod: Use `lsmod` to list loaded kernel modules in real-time.
- Kprobe/eBPF: Use extended Berkeley Packet Filter (eBPF) or Kernel Probes (kprobes) to monitor kernel events, including module loading. Example using eBPF tools like BCC: `sudo python /path/to/bcc/tools/kprobe -v do_init_module`
- Enable EDR Monitoring:
- Configure alerts for: Suspicious kernel module loads from non-standard paths (e.g., /tmp). Unexpected or unsigned kernel modules.
- Review detailed telemetry data provided by the EDR for insight into who initiated the module load, the file path, and whether the module was signed.

The tag is: *misp-galaxy:mitre-data-component="Kernel Module Load"*

Named Pipe Metadata

Contextual data about a named pipe on a system, including pipe name and creating process (ex: Sysmon EIDs 17-18)

Data Collection Measures:

- Windows:
- Sysmon Event ID 17: Logs the creation of a named pipe.
- Sysmon Event ID 18: Logs connection attempts to a named pipe.
- Windows Security Event ID 5145: Logs access attempts to named pipes via SMB shares.
- ETW (Event Tracing for Windows): Provides deep telemetry into named pipe interactions.

- Linux/macOS:
- AuditD (`mkfifo`, `open`, `read`, `write` syscalls): Tracks FIFO (named pipe) creation and usage.
- Lsof (`lsof -p <PID>` or `lsof | grep PIPE`): Lists active named pipes and associated processes.
- Strace (`strace -e open <process>`): Monitors named pipe interactions.
- Endpoint Detection & Response (EDR):
- Capture named pipe events as part of process tracking.
- Memory Forensics:
- Volatility Plugin (`pipescan`): Enumerates named pipes in system memory.
- Rekall Framework: Identifies active named pipes and associated processes.

Active DNS

"Domain Name: Active DNS" data component captures queried DNS registry data that highlights current domain-to-IP address resolutions. This data includes both direct queries to DNS servers and records that provide mappings between domain names and associated IP addresses. It serves as a critical resource for tracking active infrastructure and understanding the network footprint of an organization or adversary. Examples:

- DNS Query Example: `nslookup example.com`, `dig example.com A`
- PTR Record Example: `dig -x 192.168.1.1`

- Tracking Malicious Domains: DNS logs reveal repeated queries to suspicious domains like malicious-site.com. The IPs resolved by these domains may be indicators of compromise (IOCs).
- DNS Record Types
- A/AAAA Record: Maps domain names to IP addresses (IPv4/IPv6).
- CNAME Record: Canonical name records, often used for redirects.
- MX Record: Mail exchange records, used to route emails.
- TXT Record: Can include security information like SPF or DKIM policies.
- SOA Record: Start of authority record for domain management.
- NS Record: Lists authoritative name servers for the domain.

This data component can be collected through the following measures:

- System Utilities: Use built-in tools like `nslookup`, `dig`, or host on Linux, macOS, and Windows to perform active DNS queries.
- DNS Logging
- Windows DNS Server: Enable DNS Analytical Logging to capture DNS queries and responses.
- Bind DNS: Enable query logging in the named.conf file.
- Cloud Provider DNS Logging
- AWS Route 53: Enable query logging through CloudWatch or S3:
- Google Cloud DNS: Enable logging for Cloud DNS queries through Google Cloud Logging.
- Network Traffic Monitoring: Use tools like Wireshark or Zeek to analyze DNS queries within network traffic.
- Security Information and Event Management (SIEM) Integration: Aggregate DNS logs in a SIEM like Splunk to create alerts and monitor patterns.
- Public OSINT Tools: Use OSINT platforms like VirusTotal, or PassiveTotal to collect information on domains and their associated IP addresses.

The tag is: *misp-galaxy:mitre-data-component="Active DNS"*

Table 7312. Table References

Links

Drive Access

Refers to the act of accessing a data storage device, such as a hard drive, SSD, USB, or network-mounted drive. This data component logs the opening or mounting of drives, capturing activities such as reading, writing, or executing files within an assigned drive letter (e.g., `C:\`, `/mnt/drive`) or mount point. Examples:

- Removable Drive Insertion: A USB drive is inserted, assigned the letter `F:\`, and files are accessed.

- Network Drive Mounting: A network share `\\server\share` is mapped to the drive `Z:\`.
- External Hard Drive Access: An external drive is connected, mounted at `/mnt/backup`, and accessed for copying files.
- System Volume Access: The system volume `C:\` is accessed for modifications to critical files.
- Cloud-Synced Drives: Cloud storage drives like OneDrive or Google Drive are accessed via local mounts.

This data component can be collected through the following measures:

Windows Event Logs - Relevant Events: - Event ID 4663: Logs access to file or folder objects. - Event ID 4656: Tracks a handle to an object like a drive or file. - Configuration: - Enable auditing for "Object Access" in Local Security Policy. - Use Group Policy for broader deployment: `Computer Configuration > Windows Settings > Security Settings > Advanced Audit Policy Configuration > Object Access`

Linux System Logs

- Command-Line Monitoring: Use the `dmesg` or `journalctl` command to monitor drive mount/unmount events.
- Auditd Configuration: Add an audit rule for drive access: `auditctl -w /mnt/drive -p rwxa -k drive_access`
- Review logs via `/var/log/audit/audit.log`.

macOS System Logs

- Command-Line Monitoring: Use `diskutil list` or `fs_usage` to monitor drive access and mount points.
- Unified Logs: Query unified logs using log show for drive-related activities: `log show --info | grep "mount"`

Endpoint Detection and Response (EDR) Tools

- Use EDR solutions to monitor drive activities and collect detailed forensic data.

SIEM Tools

- Ingest logs from endpoints to detect drive access patterns. Configure rules to alert on unusual or unauthorized drive access.

The tag is: *misp-galaxy:mitre-data-component="Drive Access"*

Table 7313. Table References

Links

File Access

To events where a file is opened or accessed, making its contents available to the requester. This includes reading, executing, or interacting with files by authorized or unauthorized entities.

Examples include logging file access events (e.g., Windows Event ID 4663), monitoring file reads, and detecting unusual file access patterns. Examples:

- File Read Operations: A user opens a sensitive document (e.g., financial_report.xlsx) on a shared drive.
- File Execution: A script or executable file is accessed and executed (e.g., malware.exe is run from a temporary directory).
- Unauthorized File Access: An unauthorized user attempts to access a protected configuration file (e.g., `/etc/passwd` on Linux or `System32` files on Windows).
- File Access Patterns: Bulk access to multiple files in a short time (e.g., mass access to documents on a file server).
- File Access via Network: Files on a network share are accessed remotely (e.g., logs of SMB file access).

This data component can be collected through the following measures:

Windows

- Windows Event Logs: Event ID 4663: Captures file system auditing details, including who accessed the file, access type, and file name.
- Sysmon:
- Event ID 11: Logs file creation time changes.
- Event ID 1 (process creation): Can provide insight into files executed.
- PowerShell: Commands to monitor file access in real-time: `Get-WinEvent -FilterHashtable @{LogName='Security'; ID=4663}`

Linux

- Auditd: Monitor file access events using audit rules: `auditctl -w /path/to/file -p rwxa -k file_access`
- View logs: `ausearch -k file_access`
- Inotify: Use inotify to track file access on Linux: `inotifywait -m /path/to/watch -e access`

macOS

- Unified Logs: Monitor file access using the macOS Unified Logging System.
- FSEvents: File System Events can track file accesses: `fs_usage | grep open`

Network Devices

- SMB/CIFS Logs: Monitor file access over network shares using logs from SMB or CIFS protocol.
- NAS Logs: Collect logs from network-attached storage systems for file access events.

SIEM Integration

- Collect file access logs from all platforms (Windows, Linux, macOS) and centralize in a SIEM for

correlation and analysis.

The tag is: *misp-galaxy:mitre-data-component="File Access"*

Table 7314. Table References

Links

Process Access

Refers to an event where one process attempts to open another process, typically to inspect or manipulate its memory, access handles, or modify execution flow. Monitoring these access attempts can provide valuable insight into both benign and malicious behaviors, such as debugging, inter-process communication (IPC), or process injection.

Data Collection Measures:

- Endpoint Detection and Response (EDR) Tools:
- EDR solutions that provide telemetry on inter-process access and memory manipulation.
- Sysmon (Windows):
- Event ID 10: Captures process access attempts, including:
- Source process (initiator)
- Target process (victim)
- Access rights requested
- Process ID correlation
- Windows Event Logs:
- Event ID 4656 (Audit Handle to an Object): Logs access attempts to system objects.
- Event ID 4690 (Attempted Process Modification): Can help identify unauthorized process changes.
- Linux/macOS Monitoring:
- AuditD: Monitors process access through syscall tracing (e.g., `ptrace`, `open`, `read`, `write`).
- eBPF/XDP: Used for low-level monitoring of kernel process access.
- OSQuery: Query process access behavior via structured SQL-like logging.
- Procmon (Process Monitor) and Debugging Tools:
- Windows Procmon: Captures real-time process interactions.
- Linux strace / ptrace: Useful for tracking process behavior at the system call level.

The tag is: *misp-galaxy:mitre-data-component="Process Access"*

Table 7315. Table References

Links

Container Creation

"Container Creation" data component captures details about the initial construction of a container in a containerized environment. This includes events where a new container is instantiated, such as through Docker, Kubernetes, or other container orchestration platforms. Monitoring these events helps detect unauthorized or potentially malicious container creation. Examples:

- Docker Example: `docker create my-container`, `docker run --name=my-container nginx:latest`
- Kubernetes Example: `kubectl run my-pod --image=nginx`, `kubectl create deployment my-deployment --image=nginx`
- Cloud Container Services Example
- AWS ECS: Task or service creation (`RunTask` or `CreateService`).
- Azure Container Instances: Deployment of a container group.
- Google Kubernetes Engine (GKE): Creation of new pods via GCP APIs.

This data component can be collected through the following measures:

- Docker Audit Logging: Enable Docker daemon logging to capture `create` commands. Configure the Docker daemon to use a log driver such as `syslog` or `json-file`.
- Kubernetes Audit Logs: Enable Kubernetes API server audit logging:
- Cloud Provider Logs
- AWS CloudTrail: Enable logging for ECS `RunTask` or `CreateService` events.
- Azure Monitor: Enable activity logging for container group creation.
- GCP Cloud Logging: Monitor API calls such as `container.projects.zones.clusters.create`.
- SIEM Integration: Use a SIEM to collect logs from Docker, Kubernetes, or cloud platforms.

The tag is: *misp-galaxy:mitre-data-component="Container Creation"*

Table 7316. Table References

Links

Drive Creation

The activity of assigning a new drive letter or creating a mount point for a data storage device, such as a USB, network share, or external hard drive, enabling access to its content on a host system. Examples:

- USB Drive Insertion: A USB drive is plugged in and automatically assigned the letter `E:\` on a Windows machine.
- Network Drive Mapping: A network share `\\server\share` is mapped to the drive `Z:\`.
- Virtual Drive Creation: A virtual disk is mounted on `/mnt/virtualdrive` using an ISO image or a virtual hard disk (VHD).
- Cloud Storage Mounting: Google Drive is mounted as `G:\` on a Windows machine using a cloud

sync tool.

- External Storage Integration: An external HDD or SSD is connected and assigned `/mnt/external` on a Linux system.

This data component can be collected through the following measures:

Windows Event Logs

- Relevant Events:
- Event ID 98: Logs the creation of a volume (mount or new drive letter assignment).
- Event ID 1006: Logs removable storage device insertions.
- Configuration: Enable "Removable Storage Events" in the Group Policy settings: `Computer Configuration > Administrative Templates > System > Removable Storage Access`

Linux System Logs

- Command-Line Monitoring: Use `dmesg` or `journalctl` to monitor mount events.
- Auditd Configuration: Add audit rules to track mount points.
- Logs can be reviewed in /var/log/audit/audit.log.

macOS System Logs

- Unified Logs: Monitor system logs for mount activity:
- Command-Line Tools: Use `diskutil list` to verify newly created or mounted drives.

Endpoint Detection and Response (EDR) Tools

- EDR solutions can log removable drive usage and network-mounted drives. Configure EDR policies to alert on suspicious drive creation events.

SIEM Tools

- Centralize logs from multiple platforms into a SIEM (e.g., Splunk) to correlate and alert on suspicious drive creation activities.

The tag is: *misp-galaxy:mitre-data-component="Drive Creation"*

Table 7317. Table References

Links

Container Enumeration

"Container Enumeration" data component captures events and actions related to listing and identifying active or available containers within a containerized environment. This includes information about running, stopped, or configured containers, such as their names, IDs, statuses, or associated images. Monitoring this activity is crucial for detecting unauthorized discovery or reconnaissance efforts. Examples:

- Docker Example: `docker ps`, `docker ps -a`
- Kubernetes Example: `kubectl get pods`, `kubectl get deployments`
- Cloud Container Services Example
- AWS ECS: API Call: ListTasks or ListContainers
- Azure Kubernetes Service: API Call: List pod or container instances.
- Google Kubernetes Engine (GKE): API Call: Retrieve deployments and their associated containers.

This data component can be collected through the following measures:

- Docker Audit Logging: Enable Docker daemon logging to capture enumeration commands. Use tools like auditd to monitor terminal activity involving docker ps or similar commands.
- Kubernetes Audit Logs: Enable Kubernetes API server audit logging. Capture events where users query resources such as pods, deployments, or services.
- Cloud Provider Logs
- AWS CloudTrail: Enable logging for API calls like ListTasks or DescribeTasks.
- Azure Monitor: Enable activity logging to track container-related queries.
- GCP Cloud Logging: Track API events involving container enumerations or deployments.
- SIEM Integration: Collect logs from Docker, Kubernetes, and cloud services for centralized analysis.

The tag is: *misp-galaxy:mitre-data-component="Container Enumeration"*

Table 7318. Table References

Links

Command Execution

Command Execution involves monitoring and capturing the execution of textual commands (including shell commands, cmdlets, and scripts) within an operating system or application. These commands may include arguments or parameters and are typically executed through interpreters such as `cmd.exe`, `bash`, `zsh`, `PowerShell`, or programmatic execution. Examples:

- Windows Command Prompt
- dir – Lists directory contents.
- net user – Queries or manipulates user accounts.
- tasklist – Lists running processes.
- PowerShell
- Get-Process – Retrieves processes running on a system.
- Set-ExecutionPolicy – Changes PowerShell script execution policies.
- Invoke-WebRequest – Downloads remote resources.

- Linux Shell
- ls – Lists files in a directory.
- cat /etc/passwd – Reads the user accounts file.
- curl http://malicious-site.com – Retrieves content from a malicious URL.
- Container Environments
- docker exec – Executes a command inside a running container.
- kubectl exec – Runs commands in Kubernetes pods.
- macOS Terminal
- open – Opens files or URLs.
- dscl . -list /Users – Lists all users on the system.
- osascript -e – Executes AppleScript commands.

This data component can be collected through the following measures:

Enable Command Logging

- Windows:
- Enable PowerShell logging: `Set-ExecutionPolicy Bypass`, `Set-ItemProperty -Path "HKLM:\SOFTWARE\Policies\Microsoft\Windows\PowerShell\ScriptBlockLogging" -Name EnableScriptBlockLogging -Value 1`
- Enable Windows Event Logging:
- Event ID 4688: Tracks process creation, including command-line arguments.
- Event ID 4104: Logs PowerShell script block execution.
- Linux/macOS:
- Enable shell history logging in `.bashrc` or `.zshrc`: `export HISTTIMEFORMAT="%d/%m/%y %T "`, `export PROMPT_COMMAND='history -a; history -w'`
- Use audit frameworks (e.g., `auditd`) to log command executions. Example rule to log all `execve` syscalls: `-a always,exit -F arch=b64 -S execve -k cmd_exec`
- Containers:
- Use runtime-specific tools like Docker's --log-driver or Kubernetes Audit Logs to capture exec commands.

Integrate with Centralized Logging

- Collect logs using a SIEM (e.g., Splunk) or cloud-based log aggregation tools like AWS CloudWatch or Azure Monitor. Example Splunk Search for Windows Event 4688: `index=windows EventID=4688 CommandLine=*`

Use Endpoint Detection and Response (EDR) Tools

- Monitor command executions via EDR solutions

Deploy Sysmon for Advanced Logging (Windows)

- Use Sysmon's Event ID 1 to log process creation with command-line arguments

The tag is: *misp-galaxy:mitre-data-component="Command Execution"*

Table 7319. Table References

Links

File Creation

A new file is created on a system or network storage. This action often signifies an operation such as saving a document, writing data, or deploying a file. Logging these events helps identify legitimate or potentially malicious file creation activities. Examples include logging file creation events (e.g., Sysmon Event ID 11 or Linux auditd logs).

This data component can be collected through the following measures:

Windows

- Sysmon: Event ID 11: Logs file creation events, capturing details like the file path, hash, and creation time.
- Windows Event Log: Enable "Object Access" auditing in Group Policy to track file creation under Event ID 4663.
- PowerShell: Real-time monitoring of file creation:`Get-WinEvent -FilterHashtable @{LogName='Security'; ID=4663}`

Linux

- Auditd: Use audit rules to monitor file creation: `auditctl -w /path/to/directory -p w -k file_creation`
- View logs: `ausearch -k file_creation`
- Inotify: Monitor file creation with inotifywait: `inotifywait -m /path/to/watch -e create`

macOS

- Unified Logs: Use the macOS Unified Logging System to capture file creation events.
- FSEvents: Use File System Events to monitor file creation: `fs_usage | grep create`

Network Devices

- NAS Logs: Monitor file creation events on network-attached storage devices.
- SMB Logs: Collect logs of file creation activities over SMB/CIFS protocols.

SIEM Integration

- Forward logs from all platforms (Windows, Linux, macOS) to a SIEM for central analysis and alerting.

The tag is: *misp-galaxy:mitre-data-component="File Creation"*

Table 7320. Table References

Links

WMI Creation

Initial construction of a WMI object, such as a filter, consumer, subscription, binding, or providers.

Data Collection Measures:

- Windows Security Event Logs:
- Event ID 5861 (WMI Permanent Event Subscription)
- Event ID 5860 (WMI Event Filter Activity)
- Event ID 5857 (WMI Event Consumer Activity)
- Sysmon Logs:
- Sysmon Event ID 19 – WMI Event Filter Created
- Sysmon Event ID 20 – WMI Event Consumer Created
- Sysmon Event ID 21 – WMI Event Binding Created
- Endpoint Detection & Response (EDR)
- Detects WMI-based persistence techniques.

The tag is: *misp-galaxy:mitre-data-component="WMI Creation"*

Table 7321. Table References

Links

Instance Creation

The initial provisioning and construction of a virtual machine (VM) or compute instance within a cloud infrastructure environment. This activity involves defining and allocating resources such as CPU, memory, storage, and networking to spin up a new compute instance. Examples:

- AWS: creating an EC2 instance using RunInstances API calls.
- Azure, creating a VM through the Azure Resource Manager (ARM).
- GCP, an `instance.insert` action recorded.

Data Collection Measures:

- AWS CloudTrail: CloudTrail logs stored in S3 or accessible via CloudWatch.
- Azure Activity Logs: Accessible in Azure Monitor or exported to a storage account.
- GCP Audit Logs: Logs Explorer or BigQuery.

The tag is: *misp-galaxy:mitre-data-component="Instance Creation"*

Table 7322. Table References

Links

Image Creation

Initial construction of a virtual machine image within a cloud environment. Virtual machine images are templates containing an operating system and installed applications, which can be deployed to create new virtual machines. Monitoring the creation of these images is important because adversaries may create custom images to include malicious software or misconfigurations for later exploitation. Examples:

- Azure Compute Service Image Creation
- Example: Creating a virtual machine image in Azure using Azure CLI: `az image create --resource-group MyResourceGroup --name MyImage --source MyVM`
- AWS EC2 AMI (Amazon Machine Image) Creation
- Example: Creating an AMI from an EC2 instance: `aws ec2 create-image --instance-id i-1234567890abcdef0 --name "MyAMI" --description "An AMI for my app"`
- Google Cloud Compute Engine Image Creation
- Example: Creating a custom image using gcloud: `gcloud compute images create my-custom-image --source-disk my-disk --source-disk-zone us-central1-a`
- VMware vSphere
- Example: Exporting a VM to create an OVF (Open Virtualization Format) template: This could later be imported into other environments with potential tampering.

This data component can be collected through the following measures:

Enable Cloud Platform Logging

- Azure: Enable "Activity Logs" to capture image-related events such as PUT requests to `Microsoft.Compute/images`.
- AWS: Use AWS CloudTrail to monitor `CreateImage` API calls.
- Google Cloud: Enable "Cloud Audit Logs" to track custom image creation events under `compute.googleapis.com/images`.

API Monitoring

- Monitor API activity to track the creation of new images using:
- AWS SDK/CLI `CreateImage`.
- Azure REST API for image creation.
- Google Cloud Compute Engine APIs.

Cloud SIEM Integration

- Ingest cloud platform logs into a centralized SIEM for real-time monitoring and alerting.

Malware Content

Code, strings, signatures, and other identifying characteristics of a malicious payload stored within a malware repository. It includes both static (file-based) and dynamic (behavioral or execution-based) components that can be analyzed for threat intelligence, detection, and prevention purposes. Examples:

- Static Analysis:
- Executable Code: Analyze binary data to identify unique patterns, obfuscated code, or embedded resources.
- Strings Extraction: Use tools like strings or YARA rules to identify hardcoded URLs, IPs, filenames, or suspicious function calls.
- Signatures: Extract cryptographic hashes (MD5, SHA256) of files to track known malware variants or detect previously unseen samples.
- Dynamic Analysis:
- Behavioral Observations: Monitor execution traces to capture API calls, registry modifications, or network traffic patterns indicative of malicious behavior.
- Memory Analysis: Examine memory dumps to uncover injected code or runtime-decrypted payloads.

- Artifacts: Record file system changes, process creation events, and command-line arguments.
- Threat Intelligence Integration:
- Campaign Attribution: Associate observed code snippets or signatures with known APT campaigns or ransomware families.
- Indicator Sharing: Share identified Indicators of Compromise (IOCs) with threat intelligence platforms (e.g., MISP, OpenCTI).
- Examples of Malware Content:
- Embedded C2 domains (e.g., malicious-domain.com hardcoded in the payload).
- Fileless malware indicators, such as PowerShell scripts invoking Invoke-Mimikatz.
- Malware-specific signatures, such as unique PE header values for a particular strain.

Data Collection Measures:

- Collection from Public Malware Repositories:
- VirusTotal: Obtain samples for static analysis.
- Hybrid Analysis: Gather execution data from sandbox analysis.
- Any.Run: Access interactive malware execution traces.
- MalwareBazaar: Download malware samples for research and signature generation.
- Automate data extraction using repository APIs (e.g., VirusTotal API for hash lookups or sample retrieval).
- Internal Malware Labs:
- Sandbox Environments: Use dynamic malware analysis tools such as Cuckoo Sandbox or Joe Sandbox to execute and monitor malware in a controlled environment. Capture runtime behavior logs, memory dumps, and file system changes.
- Reverse Engineering: Disassemble binaries with tools like IDA Pro, Ghidra, or Radare2 to identify malicious functionality and extract code patterns.
- EDR/Endpoint Telemetry:
- Collect samples of malicious binaries or scripts from infected endpoints using tools like CrowdStrike, Carbon Black, or SentinelOne.
- Extract memory-resident payloads from live systems for analysis.
- Threat Intelligence Platforms:
- Gather contextual metadata for identified malware using tools like OpenCTI, Recorded Future, or ThreatConnect. Participate in intelligence-sharing groups such as ISACs (e.g., FS-ISAC, IT-ISAC).
- Custom Data Collection Pipelines: Use open-source tools like malwoverview or Maltrail to automate sample downloads, hash extraction, and IOC generation.

Process Creation

Refers to the event in which a new process (executable) is initialized by an operating system. This can involve parent-child process relationships, process arguments, and environmental variables. Monitoring process creation is crucial for detecting malicious behaviors, such as execution of unauthorized binaries, scripting abuse, or privilege escalation attempts.

Data Collection Measures:

- Endpoint Detection and Response (EDR) Tools:
- EDRs provide process telemetry, tracking execution flows and arguments.
- Windows Event Logs:
- Event ID 4688 (Audit Process Creation): Captures process creation with associated parent process.
- Sysmon (Windows):
- Event ID 1 (Process Creation): Provides detailed logging
- Linux/macOS Monitoring:
- AuditD (execve syscall): Logs process creation.
- eBPF/XDP: Used for low-level monitoring of system calls related to process execution.
- OSQuery: Allows SQL-like queries to track process events (process_events table).
- Apple Endpoint Security Framework (ESF): Monitors process creation on macOS.
- Network-Based Monitoring:

- Zeek (Bro) Logs: Captures network-based process execution related to remote shells.
- Syslog/OSSEC: Tracks execution of processes on distributed systems.
- Behavioral SIEM Rules:
- Monitor process creation for uncommon binaries in user directories.
- Detect processes with suspicious command-line arguments.

The tag is: *misp-galaxy:mitre-data-component="Process Creation"*

Table 7329. Table References

Pod Creation

The initial deployment or instantiation of a new pod in a containerized environment. This includes creating a pod manually, through orchestration tools (Kubernetes), or via Infrastructure-as-Code (IaC) configurations. A Pod is the smallest deployable unit in Kubernetes, typically containing one or more containers. Creation methods include: - Direct pod deployment (`kubectl run`, `kubectl apply`) - Automated deployment via CI/CD pipelines (e.g., ArgoCD, Jenkins, GitOps) - Infrastructure-as-Code (IaC) templates (e.g., Terraform, Helm Charts) - API-based deployments via Kubernetes control plane (create_pod API calls) - Pods can be ephemeral (short-lived) or persistent (part of a StatefulSet or Deployment).

Data Collection Measures:

- Kubernetes Audit Logs
- Captures all API requests, including pod `create` events.
- Kube-api server Logs
- Monitors API calls related to pod deployments and modifications. Related Events: `PodSandboxChanged`, `SyncLoop`, `Created pod`
- Container Runtime Logs
- Logs from CRI-O, containerd, or Docker capture pod creation events. Related Events: `container start`, `container create`
- Cloud Provider Logs
- GKE, EKS, AKS logs provide insights into Kubernetes API interactions.
- SIEM & Log Aggregation
- Integrates Kubernetes logs into SIEM solutions.
- EDR/XDR Solutions
- Monitors container-based activity for anomalous pod creations.

The tag is: *misp-galaxy:mitre-data-component="Pod Creation"*

Table 7330. Table References

Certificate Registration

Certificate Registration refers to the collection and analysis of information about digital certificates, including current, revoked, and expired certificates. Sources such as Certificate Transparency logs and other public resources provide visibility into certificates issued for specific domains or organizations. Monitoring certificate registrations can help identify potential misuse, such as unauthorized certificates or signs of adversary reconnaissance. Examples:

- Certificate Transparency Logs: These logs record the issuance of SSL/TLS certificates by trusted Certificate Authorities (CAs).
- Revoked Certificates: Information about certificates that have been invalidated before their expiration date.
- Expired Certificates: Reports of expired certificates for a domain, which may indicate lax security practices or opportunities for adversaries to exploit expired credentials.
- Domain Monitoring for Certificates: Maps SSL/TLS certificates to domains and subdomains, helping to identify any rogue certificates.
- Public Certificate Directories: Services providing APIs to query issued certificates for analysis.

This data component can be collected through the following measures:

Use Certificate Transparency Monitors

- Tools like crt.sh, CertStream, or APIs provided by certificate authorities (CAs) allow you to monitor issued certificates in real-time.
- Example: Use CertStream to stream certificate issuance logs and filter for domains of interest.

Analyze Certificate Revocation Sources

- Monitor CRLs or query OCSP responders to detect revoked certificates.
- Configure tools like OpenSSL or browsers to validate certificate revocation status automatically.

Leverage Public Scanning Tools

- Use tools such as SSL Labs, Censys, or Shodan to scan for certificate details related to your domain or network.

Automate Certificate Monitoring

- Set up automated scripts or services to parse Certificate Transparency logs for anomalies.
- Example: Automate searches on crt.sh to identify certificates issued for typo-squatted domains.

Integrate with Threat Intelligence

- Enrich certificate data with threat intelligence feeds to detect connections to known adversary-controlled infrastructure.

- Tools like VirusTotal can identify malicious certificates based on associated indicators.

The tag is: *misp-galaxy:mitre-data-component="Certificate Registration"*

Table 7331. Table References

Links

Response Content

Captured network traffic that provides details about responses received during an internet scan. This data includes both protocol header values (e.g., HTTP status codes, IP headers, or DNS response codes) and response body content (e.g., HTML, JSON, or raw data). Examples:

- HTTP Scan: A web server responds to a probe with an HTTP 200 status code and an HTML body indicating the default page is accessible.
- DNS Scan: A DNS server replies to a query with a resolved IP address for a domain, along with details like Time-To-Live (TTL) and authoritative information.
- TCP Banner Grab: A service listening on a port (e.g., SSH or FTP) responds with a banner containing service name, version, or other metadata.

Data Collection Measures:

- Network Traffic Monitoring:
- Deploy packet capture tools like Wireshark, tcpdump, or Suricata to log both headers and body content of response traffic.
- Use network appliances like firewalls, intrusion detection systems (IDS), or intrusion prevention systems (IPS) with logging enabled to capture scan responses.
- Cloud Logging Services:
- AWS VPC Flow Logs: Capture metadata about network flows, including source and destination, protocol, and response codes.
- GCP Packet Mirroring: Use mirrored packets to analyze responses.
- Azure NSG Flow Logs: Record network traffic flow information for analysis.
- Specific Tools:
- Zmap or Masscan: Can perform internet-wide scans and collect response content for analysis.
- Nmap: Use custom scripts to capture and log detailed response data during scans.

The tag is: *misp-galaxy:mitre-data-component="Response Content"*

Table 7332. Table References

Snapshot Creation

The process of taking a point-in-time copy of a cloud storage volume (files, settings, configurations, etc.), virtual machine (VM), or database that can be created and deployed in cloud environments.

Data Collection Measures:

- Cloud Platform Logs (IaaS)
- AWS CloudTrail Logs: Monitor API calls related to snapshot creation (`CreateSnapshot`).
- Azure Monitor Logs: Track snapshot creation (`Microsoft.Compute/snapshots/write`).
- Google Cloud Logging: Detect `compute.disks.createSnapshot`.

The tag is: *misp-galaxy:mitre-data-component="Snapshot Creation"*

Table 7333. Table References

Links

Container Start

"Container Start" data component captures events related to the activation or invocation of a container within a containerized environment. This includes starting a previously stopped container, restarting an existing container, or initializing a container for runtime. Monitoring these activities is critical for identifying unauthorized or unexpected container activations, which may indicate potential adversarial activity or misconfigurations. Examples:

- Docker Example: `docker start <container_name>`, `docker restart <container_name>`
- Kubernetes Example: Kubernetes automatically restarts containers as part of pod lifecycle management (e.g., due to health checks or configuration changes).
- Cloud-Native Example
- AWS ECS: API Call: StartTask to activate a stopped ECS task.
- Azure Container Instances: Command to restart a container group instance.
- GCP Kubernetes Engine: Automatic restarts as part of node or pod management.

This data component can be collected through the following measures:

- Docker Audit Logging: Enable Docker logging to capture start and restart events. Use tools like auditd to monitor terminal activity involving container lifecycle commands.
- Kubernetes Audit Logs: Enable Kubernetes API server audit logging.
- Cloud Provider Logs
- AWS CloudTrail: Capture StartTask or related API calls for ECS.
- Azure Monitor: Track activity in container groups that indicate start or restart events.
- GCP Cloud Logging: Record logs related to pod restarts or scaling events in Kubernetes Engine.
- SIEM Integration: Collect logs from Docker, Kubernetes, and cloud services to correlate

container start events.

The tag is: *misp-galaxy:mitre-data-component="Container Start"*

Table 7334. Table References

Links

Service Creation

The registration of a new service or daemon on an operating system.

Data Collection Measures:

- Windows Event Logs
- Event ID 4697 - Captures the creation of a new Windows service.
- Event ID 7045 - Captures services installed by administrators or adversaries.
- Event ID 7034 - Could indicate malicious service modification or exploitation.
- Sysmon Logs
- Sysmon Event ID 1 - Process Creation (captures service executables).
- Sysmon Event ID 4 - Service state changes (detects service installation).
- Sysmon Event ID 13 - Registry modifications (captures service persistence changes).
- PowerShell Logging
- Monitor `New-Service` and `Set-Service` PowerShell cmdlets in Event ID 4104 (Script Block Logging).
- Linux/macOS Collection Methods
- AuditD & Syslog Daemon Logs (`/var/log/syslog`, `/var/log/messages`, `/var/log/daemon.log`)
- AuditD Rules:
- `auditctl -w /etc/systemd/system -p wa -k service_creation`
- Detects changes to `systemd` service configurations.
- Systemd Journals (`journalctl -u <service_name>`)
- Captures newly created systemd services.
- LaunchDaemons & LaunchAgents (macOS)
- Monitor `/Library/LaunchDaemons/` and `/Library/LaunchAgents/` for new plist files.

The tag is: *misp-galaxy:mitre-data-component="Service Creation"*

Table 7335. Table References

Links

Volume Creation

The initial provisioning of block storage volumes in cloud or on-prem environments, typically used for data storage, backup, or workload scaling.

Data Collection Measures:

- Cloud-Based Logging & Monitoring
- AWS CloudTrail
- `CreateVolume` – Logs the creation of new Amazon Elastic Block Store (EBS) volumes.
- `RunInstances` – Can be correlated to detect automatic volume provisioning.
- Azure Monitor & Log Analytics
- `Microsoft.Compute/disks/write` – Captures creation of new managed/unmanaged disks.
- `Microsoft.Storage/storageAccounts/write` – Detects creation of new Azure Blob Storage volumes.
- Google Cloud Logging (GCP)
- `compute.disks.insert` – Tracks new persistent disk creation.
- `compute.instances.attachDisk` – Logs attachment of a volume to a running VM.
- OpenStack Logs
- `volume.create` – Captures new storage volume provisioning.
- `cinder.volume.create` – Logs OpenStack Cinder block storage creation.
- Host-Based & SIEM Detection
- Linux/macOS System Logs
- `/var/log/syslog` & `/var/log/messages` – Detects new mount points or attached storage.
- `dmesg | grep "new disk"` – Identifies kernel messages for volume attachment.
- AuditD: Tracks `mkfs` (filesystem creation) for new volume provisioning.
- Windows Event Logs
- Event ID 1006 (Storage Management Events) – Captures disk volume creation.
- Event ID 5145 (Object Access: File Share) – Detects access to newly created storage shares.

The tag is: *misp-galaxy:mitre-data-component="Volume Creation"*

Table 7336. Table References

Links

Firewall Disable

The deactivation, misconfiguration, or complete stoppage of firewall services, either on a host or in a cloud control plane. Such activity may involve turning off firewalls, modifying rules to disable protection, or deleting firewall-related configurations and activity logs. Examples:

- Disabling Host-Based Firewalls: Stopping the Windows Defender Firewall service or using `iptables -F` to flush all rules on a Linux system.
- Cloud Firewall Modification or Deactivation: Modifying or deleting security group rules in AWS or disabling a network firewall in Azure.
- Activity Log Deletion: Writing or deleting entries in Azure Firewall Activity Logs to hide unauthorized firewall changes.
- Temporary Disable for Malicious Operations: Temporarily disabling a firewall to allow malicious files or traffic, then re-enabling it to avoid detection.
- Using Command-Line Tools to Stop Firewalls: Running commands like `Set-NetFirewallProfile -Enabled False on Windows or systemctl stop ufw` on Linux.

This data component can be collected through the following measures:

Cloud Control Plane

- Azure Activity Logs:
- Enable logging of administrative actions, such as stopping or modifying Azure Firewall configurations.
- Use Azure Monitor to track specific firewall-related actions, including disabling or rule deletion.
- AWS CloudTrail Logs:
- Monitor `RevokeSecurityGroupIngress` or `RevokeSecurityGroupEgress` events to detect rule changes in AWS Security Groups.
- Google Cloud Platform Logs:
- Collect logs from the Firewall Rules resource in Google Cloud Operations Suite to detect rule deletions or modifications.

Host-Level Firewalls

- Windows Firewall Event Logs:
- Enable logging of firewall state changes:
- Security Event ID 2004: Firewall service stopped.
- Security Event ID 2005: Firewall service started.
- Use Sysmon for process creation events tied to firewall commands or scripts (Sysmon Event ID 1).
- Linux Firewall Logs: Use auditd to track commands like iptables, firewalld, or ufw: `auditctl -a always,exit -F arch=b64 -S execve -k firewall_disable`
- macOS Firewall: Monitor changes to the macOS Application Firewall using the log show command.

Network-Level Monitoring

- IDS/IPS Alerts: Deploy IDS/IPS systems to monitor abnormal traffic flows that could indicate firewall disablement.

- NetFlow Data: Analyze NetFlow or packet capture data for traffic patterns inconsistent with firewall enforcement.

SIEM and CSPM Tools

- SIEM Integration: Use tools like Splunk or QRadar to centralize and analyze firewall disablement events from both hosts and cloud platforms.
- Cloud Security Posture Management (CSPM): Use CSPM solutions to monitor misconfigurations and track deactivation of critical cloud services like firewalls.

The tag is: *misp-galaxy:mitre-data-component="Firewall Disable"*

Table 7337. Table References

Links

File Deletion

Refers to events where files are removed from a system or storage device. These events can indicate legitimate housekeeping activities or malicious actions such as attackers attempting to cover their tracks. Monitoring file deletions helps organizations identify unauthorized or suspicious activities.

This data component can be collected through the following measures:

Windows

- Sysmon: Event ID 23: Logs file deletion events, including details such as file paths and responsible processes.
- Windows Event Log: Enable "Object Access" auditing to monitor file deletions.
- PowerShell: `Get-WinEvent -FilterHashtable @{LogName='Security'; ID=4663} | Where-Object {$_.Message -like 'DELETE'}`

Linux

- Auditd: Use audit rules to capture file deletion events: `auditctl -a always,exit -F arch=b64 -S unlink -S rename -S rmdir -k file_deletion`
- Query logs: `ausearch -k file_deletion`
- Inotify: Use inotifywait to monitor file deletions: `inotifywait -m /path/to/watch -e delete`

macOS

- Endpoint Security Framework (ESF): Monitor events like ES_EVENT_TYPE_AUTH_UNLINK to capture file deletion activities.
- FSEvents: Track file deletion activities in real-time: `fs_usage | grep unlink`

SIEM Integration

- Forward file deletion logs to a SIEM for centralized monitoring and correlation with other events.

The tag is: *misp-galaxy:mitre-data-component="File Deletion"*

Table 7338. Table References

Links

Instance Deletion

Removal of a virtual machine (VM) or compute instance within a cloud infrastructure. This activity results in the termination and deletion of the allocated resources (e.g., CPU, memory, storage), making the instance unavailable for future use. Examples:

- AWS: instance deletion involves the `TerminateInstances` API call, which is recorded in CloudTrail logs.
- Azure: VM deletion can be monitored via Azure Activity Logs, showing the `Microsoft.Compute/virtualMachines/delete` operation.
- GCP: instance deletion is logged as an instance.delete operation within GCP Audit Logs.

*Data Collection Measures:

- AWS CloudTrail: CloudTrail logs stored in S3 or forwarded to CloudWatch.
- Azure Activity Logs: Accessible via Azure Monitor or exported to a storage account.
- GCP Audit Logs: Logs Explorer or BigQuery.

The tag is: *misp-galaxy:mitre-data-component="Instance Deletion"*

Table 7339. Table References

Links

Image Deletion

Removal of a virtual machine image in a cloud infrastructure (ex: Azure Compute Service Images DELETE) Examples:

- Azure Compute Service Image Deletion
- Example: Deleting a virtual machine image using Azure CLI: `az image delete --name MyImage --resource-group MyResourceGroup`
- AWS EC2 AMI (Amazon Machine Image) Deletion
- Example: Deregistering an AMI in AWS: `aws ec2 deregister-image --image-id ami-1234567890abcdef0`
- Google Cloud Compute Engine Image Deletion
- Example: Deleting a custom image in Google Cloud: `gcloud compute images delete my-custom-image`
- VMware vSphere

- Example: Deleting a VM image/template from a vSphere environment:

This data component can be collected through the following measures:

Enable Cloud Platform Logging

- Azure: Enable "Activity Logs" to capture DELETE requests to `Microsoft.Compute/images`.
- AWS: Use AWS CloudTrail to monitor `DeregisterImage` or `DeleteSnapshot` API calls.
- Google Cloud: Enable "Cloud Audit Logs" to track image deletion events under `compute.googleapis.com/images`.

API Monitoring

- Monitor API activity to track the deletion of images using:
- AWS SDK/CLI `DeregisterImage` or `DeleteSnapshot`.
- Azure REST API DELETE operations for images.
- Google Cloud Compute Engine APIs for image deletion.

Cloud SIEM Integration

- Ingest logs into a centralized SIEM platform for monitoring and alerting:

Event Correlation

- Correlate image deletion events with unusual account activity or concurrent unauthorized operations.

The tag is: *misp-galaxy:mitre-data-component="Image Deletion"*

Table 7340. Table References

Links

Driver Load

The process of attaching a driver, which is a software component that allows the operating system and applications to interact with hardware devices, to either user-mode or kernel-mode of a system. This can include benign actions (e.g., hardware drivers) or malicious behavior (e.g., rootkits or unsigned drivers). Examples:

- Legitimate Driver Loading: A new graphics driver from a vendor like NVIDIA or AMD is loaded into the system.
- Unsigned Driver Loading: A driver without a valid digital signature is loaded into the kernel.
- Rootkit Installation: A malicious rootkit driver is loaded to manipulate kernel-mode processes.
- Anti-Virus or EDR Driver Loading: An Endpoint Detection and Response (EDR) solution loads its driver to monitor system activities.
- Driver Misuse: A legitimate driver is loaded and exploited to execute malicious actions, such as

using vulnerable drivers for bypassing defenses (e.g., Bring Your Own Vulnerable Driver (BYOVD) attacks).

This data component can be collected through the following measures:

Windows

- Sysmon Logs:
- Event ID 6: Captures driver loading activity, including file path, hashes, and signature information.
- Configuration: Ensure Sysmon is configured with a ruleset that monitors driver loading events
- Windows Event Logs: Enable "Audit Kernel Object" to capture kernel-related driver loading events.

Linux

- Auditd: Configure audit rules to capture driver loading events: `auditctl -w /lib/modules/ -p rwxa -k driver_load`
- Kernel Logs (dmesg): Use dmesg to monitor driver-related activities: `dmesg | grep "module"`
- Syslog or journald: Review logs for module insertion or removal activities.

macOS

- Unified Logs: Use the macOS unified logging system to monitor kext (kernel extension) loads: `log show --predicate 'eventMessage contains "kext load"'`
- Endpoint Security Framework: Monitor driver loading via third-party security tools that leverage Apple's Endpoint Security Framework.

SIEM Tools

- Ingest driver load logs from Sysmon, Auditd, or macOS unified logs into a centralized SIEM (e.g., Splunk).
- Create rules to detect unsigned drivers, rootkit activity, or known vulnerable drivers.

EDR Solutions

- Use EDR tools to detect and alert on anomalous driver loading activity.

The tag is: *misp-galaxy:mitre-data-component="Driver Load"*

Table 7341. Table References

Links

Driver Metadata

to contextual data about a driver, including its attributes, functionality, and activity. This can involve details such as the driver's origin, integrity, cryptographic signature, issues reported during

its use, and runtime behavior. Examples include metadata captured during driver integrity checks, hash validation, or error reporting. Examples:

- Driver Signature Validation: A driver is validated to ensure it is signed by a trusted Certificate Authority (CA).
- Driver Hash Verification: The hash of a driver is compared to a known good hash stored in a database.
- Driver Compatibility Issues: A driver error is logged due to compatibility issues with a particular version of the operating system.
- Vulnerable Driver Identification: Metadata indicates the driver version is outdated or contains a known vulnerability.
- Monitoring Driver Integrity: Drivers are monitored for any unauthorized modifications to their binary or associated files.

This data component can be collected through the following measures:

Windows

- Windows Event Logs:
- Event ID 3000-3006: Logs metadata about driver signature validation.
- Event ID 2000-2011 (Windows Defender Application Control): Tracks driver integrity and policy enforcement.
- Sysmon Logs: Configure Sysmon to capture driver loading metadata (Event ID 6).
- Driver Verifier: Use Driver Verifier to collect diagnostic and performance data about drivers, including stability and compatibility metrics.
- PowerShell: Use commands to retrieve metadata about installed drivers: `Get-WindowsDriver -Online | Select-Object Driver, ProviderName, Version`

Linux

- Auditd: Configure audit rules to monitor driver interactions and collect metadata: `auditctl -w /lib/modules/ -p rwxa -k driver_metadata`
- dmesg: Use `dmesg` to extract kernel logs with driver metadata: `dmesg | grep "module"`
- lsmod and modinfo: Commands to list loaded modules and retrieve metadata about drivers: `lsmod` | `modinfo <module_name>`

macOS

- Unified Logs: Collect metadata from system logs about kernel extensions (kexts): `log show --predicate 'eventMessage contains "kext load"' --info`
- kextstat: Command to retrieve information about loaded kernel extensions: `kextstat`

SIEM Tools

- Ingest Driver Metadata: Collect driver metadata logs from Sysmon, Auditd, or macOS logs into

SIEMs like Splunk or Elastic.

Vulnerability Management Tools

- Use these tools to collect metadata about vulnerable drivers across enterprise systems.

The tag is: *misp-galaxy:mitre-data-component="Driver Metadata"*

Table 7342. Table References

Links

Drive Modification

The alteration of a drive letter, mount point, or other attributes of a data storage device, which could involve reassignment, renaming, permissions changes, or other modifications. Examples:

- Drive Letter Reassignment: A USB drive previously assigned `E:\` is reassigned to `D:\` on a Windows machine.
- Mount Point Change: On a Linux system, a mounted storage device at `/mnt/external` is moved to `/mnt/storage`.
- Drive Permission Changes: A shared drive's permissions are modified to allow write access for unauthorized users or processes.
- Renaming of a Drive: A network drive labeled "HR_Share" is renamed to "Shared_Resources."
- Modification of Cloud-Integrated Drives: A cloud storage mount such as Google Drive is modified to sync only specific folders.

This data component can be collected through the following measures:

Windows Event Logs

- Relevant Events:
- Event ID 98: Indicates changes to a volume (e.g., drive letter reassignment).
- Event ID 1006: Logs permission modifications or changes to removable storage.
- Configuration: Enable "Storage Operational Logs" in the Event Viewer: `Applications and Services Logs > Microsoft > Windows > Storage-Tiering > Operational`

Linux System Logs

- Auditd Configuration: Add audit rules to track changes to mounted drives: `auditctl -w /mnt/ -p w -k drive_modification`
- Command-Line Monitoring: Use `dmesg` or `journalctl` to observe drive modifications.

macOS System Logs

- Unified Logs: Collect mount or drive modification events: `log show --info | grep "Volume modified"`

- Command-Line Monitoring: Use `diskutil` to track changes:

Endpoint Detection and Response (EDR) Tools

- Configure policies in EDR solutions to monitor and log changes to drive configurations or attributes.

SIEM Tools

- Aggregate logs from multiple systems into a centralized platform like Splunk to correlate events and alert on suspicious drive modification activities.

The tag is: *misp-galaxy:mitre-data-component="Drive Modification"*

Table 7343. Table References

Passive DNS

"Domain Name: Passive DNS" captures logged historical and real-time domain name system (DNS) data. This includes records of domain-to-IP address resolutions over time, enabling analysts to track the evolution of domain infrastructure, uncover historical patterns of use, and detect malicious activities tied to domains and their associated IP addresses. Examples:

- Historical Resolutions
- Shared IP Usage
- Temporal Patterns
- Malicious Domain Clustering
- Historical Lookback

This data component can be collected through the following measures:

- Passive DNS Platforms: Use platforms that specialize in passive DNS collection and analysis:
- Tools: Farsight DNSDB, RiskIQ PassiveTotal, PassiveDNS.
- Threat Intelligence Feeds: Integrate passive DNS data from commercial or open-source threat intelligence providers.
- Custom DNS Collectors: Deploy custom tools to capture DNS traffic at the network level for analysis.
- Cloud DNS Services: Leverage cloud DNS services (e.g., AWS Route 53, Azure DNS) that maintain DNS query logs.

The tag is: *misp-galaxy:mitre-data-component="Passive DNS"*

Table 7344. Table References

Links

Domain Registration

"Domain Name: Domain Registration" data component captures information about the assignment, ownership, and metadata of domain names. This information is often sourced from registries like WHOIS and includes details such as registrant names, contact information, registration dates, expiration dates, and registrar details. This data is invaluable for tracking domain ownership, detecting malicious domain registrations, and identifying trends in adversary behavior. Examples:

- Registrant Information: WHOIS lookup of example.com
- Registration and Expiration Dates: A domain registered a week before being used in phishing attacks.
- Domain Status: Status codes like clientTransferProhibited or serverHold indicate domain restrictions or potential hijacking activity.
- Name Server Information: Name servers point to a public DNS provider often associated with malicious campaigns.
- Privacy Protection: A domain uses WHOIS privacy protection to hide registrant details.

This data component can be collected through the following measures:

- WHOIS Services: Use tools or services to perform WHOIS lookups:
- WHOIS APIs: Automate domain registration lookups with APIs:
- Registrar Platforms: Directly query domain registrars (e.g., GoDaddy, Namecheap) for detailed registration data.
- Threat Intelligence Platforms: Integrate domain registration data from services like Recorded Future, RiskIQ, or PassiveTotal for enriched analysis.

The tag is: *misp-galaxy:mitre-data-component="Domain Registration"*

Links

Snapshot Deletion

The removal of a point-in-time backup of a cloud storage volume, virtual machine (VM), or database.

Data Collection Measures:

- AWS CloudTrail
- Logs `DeleteSnapshot` API calls in EC2, RDS, and EBS services.
- Azure Monitor Logs
- Tracks snapshot deletions via `Microsoft.Compute/snapshots/delete` API calls.
- Google Cloud Logging
- Detects snapshot removal through `compute.disks.deleteSnapshot` events.

The tag is: *misp-galaxy:mitre-data-component="Snapshot Deletion"*

Table 7346. Table References

Links

Volume Deletion

The removal of a cloud-based or on-premise block storage volume. This action permanently deletes the allocated storage and may result in data loss if not backed up.

Data Collection Measures:

- Cloud Logging & APIs
- AWS CloudTrail Logs
- `eventName: DeleteVolume` (tracks volume deletions)
- Azure Monitor Logs
- `operationName: Microsoft.Compute/disks/delete`
- `status: Success | Failure` (flag unauthorized delete attempts)
- Google Cloud Audit Logs
- `protoPayload.methodName: "v1.compute.disks.delete"`
- `authenticationInfo.principalEmail` (identifies the user deleting the volume)
- System & Host-Based Logging
- Linux & macOS Logs:
- `/var/log/syslog` or `/var/log/messages` for volume detach/deletion actions
- Windows Event Logs:
- Event ID 98 (Storage Class Memory)
- Event ID 225 (Volume Removal Detected)
- Event ID 12 (Disk Removal Notification)

The tag is: *misp-galaxy:mitre-data-component="Volume Deletion"*

Firewall Enumeration

Querying and extracting a list of available firewalls or their associated configurations and rules. This activity can occur across host systems and cloud control planes, providing insight into the state and configuration of firewalls that protect the environment. Examples:

- Querying Host-Based Firewalls: Using Windows PowerShell commands like `Get-NetFirewallRule` or Linux commands such as `iptables -L` or `firewalld --list-all`.

- Cloud Firewall Rule Listing: Running commands like `az network firewall list` for Azure or `aws ec2 describe-security-groups` for AWS.
- Using Management APIs: Leveraging APIs like Google Cloud Firewall's `list` API method or AWS's DescribeSecurityGroups API. Identifying Misconfigurations: Extracting firewall rules to identify "allow all" policies or rules that lack logging.
- Enumerating with CLI Tools: Using CLI commands like `gcloud compute firewall-rules list` to extract firewall settings in Google Cloud.

This data component can be collected through the following measures:

Cloud Control Plane

- Azure Activity Logs:Collect logs from Azure Firewall to monitor rule listing commands. Enable logging for `az network firewall` commands.
- AWS CloudTrail: Monitor calls to `DescribeSecurityGroups` or `DescribeNetworkAcls` APIs. Google Cloud Operations Suite: Collect logs for `gcloud compute firewall-rules list` or API calls to `firewalls.list`.

Host-Based Firewalls

- Windows Event Logs: Use PowerShell transcription logs to capture commands like `Get-NetFirewallRule`.
- Linux Auditd: Track executions of commands like `iptables -L` or `ufw status` using auditd: `auditctl -a always,exit -F arch=b64 -S execve -k firewall_enum`
- macOS: Monitor logs for firewall-related queries via the Console app or log monitoring tools.

SIEM Integration

- Collect logs from endpoints and cloud platforms to centralize data and detect enumeration activity.

Endpoint Detection and Response (EDR)

- Use EDR tools to track enumeration commands or API calls performed on managed devices.

CSPM Tools

- Deploy Cloud Security Posture Management tools to monitor for unauthorized enumeration of firewall rules or configurations.

The tag is: *misp-galaxy:mitre-data-component="Firewall Enumeration"*

Table 7348. Table References

Links

Group Enumeration

Extracting group lists from identity systems identifies permissions, roles, or configurations.

Adversaries may exploit high-privilege groups or misconfigurations. Examples:

- AWS CLI: `aws iam list-groups`
- PowerShell: `Get-ADGroup -Filter *`
- (Saas) Google Workspace: Admin SDK Directory API
- Azure: `Get-AzureADGroup`
- Microsoft 365: Graph API `GET https://graph.microsoft.com/v1.0/groups`

Data Collection Measures:

- Cloud Logging: Enable AWS CloudTrail, Azure Activity Logs, and Google Workspace Admin Logs for group-related actions.
- Directory Monitoring: Track logs like AD Event ID 4662 (object operations).
- API Monitoring: Log API activity like AWS IAM queries.
- SaaS Monitoring: Use platform logs (e.g., Office 365 Unified Audit Logs).
- SIEM Integration: Centralize group query tracking.

The tag is: *misp-galaxy:mitre-data-component="Group Enumeration"*

Table 7349. Table References

Links

Instance Enumeration

The process of retrieving or querying a list of virtual machine instances or compute instances within a cloud infrastructure. This activity provides a view of all available or running instances, typically including their associated metadata such as instance ID, name, state, and configuration details. Examples:

- AWS: instance enumeration involves the `DescribeInstances` API call, which retrieves information about running or stopped EC2 instances.
- Azure: VM enumeration can be monitored via the `Microsoft.Compute/virtualMachines/read` operation.
- GCP: instance enumeration is logged as an `instance.list` operation within GCP Audit Logs.

Data Collection Measures:

- AWS CloudTrail: CloudTrail logs stored in S3 or forwarded to CloudWatch.
- Azure Activity Logs: Accessible via Azure Monitor or exported to a storage account.
- GCP Audit Logs: Logs Explorer or BigQuery.

The tag is: *misp-galaxy:mitre-data-component="Instance Enumeration"*

Table 7350. Table References

Links

Pod Enumeration

Extracting a list of running or existing pods within a containerized cluster environment. Pods are the smallest deployable units in a Kubernetes cluster and typically represent an application or workload. Enumeration of pods provides insight into the structure and state of applications running in the cluster, such as the names of pods, their namespaces, and their associated metadata.

Data Collection Measures:

- Kubernetes API Server Audit Logs:
- Enable Audit Logging in Kubernetes to capture API requests, such as GET `/api/v1/pods`.
- Container Runtime Logs:
- Collect runtime-level logs from tools like CRI-O, containerd, or Docker, which might show relevant API calls for pod enumeration.
- EDR and SIEM:
- Endpoint Detection and Response (EDR) tools, if configured with cluster-level visibility, can monitor user commands like `kubectl get pods`.
- SIEM platforms (e.g., Splunk) can ingest Kubernetes API logs to detect enumeration patterns.
- Host-Based Monitoring:
- Monitor processes and commands executed on nodes where `kubectl` is installed using tools like auditd, Sysmon for Linux, or kernel modules.

The tag is: *misp-galaxy:mitre-data-component="Pod Enumeration"*

Table 7351. Table References

Links

Snapshot Enumeration

The process of listing or retrieving metadata about existing snapshots in a cloud environment.

Data Collection Measures:

- AWS CloudTrail
- Logs API calls such as `DescribeSnapshots`, `ListSnapshots`, and `GetSnapshotAttributes`.
- Azure Monitor Logs
- Tracks snapshot enumeration via `Microsoft.Compute/snapshots/read`.
- Google Cloud Logging
- Detects snapshot listing through `compute.disks.listSnapshots`.

The tag is: *misp-galaxy:mitre-data-component="Snapshot Enumeration"*

Table 7352. Table References

Script Execution

The execution of a text file that contains code via the interpreter.

Data Collection Measures:

- Windows Event Logs:
- Event ID 4104 (PowerShell Script Block Logging) – Captures full command-line execution of PowerShell scripts.
- Event ID 4688 (Process Creation) – Detects script execution by tracking process launches (`powershell.exe`, `wscript.exe`, `cscript.exe`).
- Event ID 5861 (Script Execution) – Captures script execution via Windows Defender AMSI logging.
- Sysmon (Windows):
- Event ID 1 (Process Creation) – Monitors script execution initiated by scripting engines.
- Event ID 11 (File Creation) – Detects new script files written to disk before execution.
- Endpoint Detection and Response (EDR) Tools:
- Track script execution behavior, detect obfuscated commands, and prevent malicious scripts.
- PowerShell Logging:
- Enable Module Logging: Logs all loaded modules and cmdlets.
- Enable Script Block Logging: Captures complete PowerShell script execution history.
- SIEM Detection Rules:
- Detect script execution with obfuscated, encoded, or remote URLs.
- Alert on script executions using `-EncodedCommand` or `iex(iwr)`.

Firewall Metadata

Contextual information about firewalls, including their configurations, policies, status, and other details such as names and associated rules. This metadata provides valuable insights into the operational state and configurations of firewalls, both in cloud control planes and host systems. Examples:

- Firewall Name and Configuration: The name, type, and purpose of a firewall such as "Azure Firewall - Production Environment."
- Policy Details: Capturing firewall policy details, such as "Allow inbound TCP 443 to web servers."
- Firewall Status: Status indicators like "Active," "Disabled," or "Pending Updates."
- Audit Log Metadata: Log entries showing administrative changes, such as "Policy modified by admin@domain.com."
- Rules Associated with Firewalls: Rules specifying source/destination IP ranges, protocols, and ports.
- Tagging Information: Tags like "Environment: Production" or "Owner: NetworkOps."

This data component can be collected through the following measures:

Cloud Control Plane

- Azure: Use Azure Activity Logs and Network Watcher to collect metadata for Azure Firewall.
- Example: `az network firewall show --name <firewall-name>`
- AWS: Use AWS CloudTrail and describe commands: `aws ec2 describe-security-groups`
- Google Cloud: Use gcloud commands to extract metadata: `gcloud compute firewall-rules list --format=json`

Host-Based Firewalls

- Windows: Use PowerShell to gather metadata: `Get-NetFirewallRule -PolicyStore PersistentStore`
- Linux: Query iptables or nftables rulesets: `iptables -S`
- macOS: Use pfctl to extract metadata: `sudo pfctl -sr`

SIEM Integration

- Collect logs from cloud platforms, host systems, and network appliances.

API Monitoring

- Monitor API calls for metadata requests. Example (AWS): `Capture DescribeSecurityGroups or DescribeNetworkAcls` calls via CloudTrail.

Endpoint Detection and Response (EDR)

- Use EDR solutions to monitor firewall management tools for configuration changes or queries.

The tag is: *misp-galaxy:mitre-data-component="Firewall Metadata"*

Table 7355. Table References

Links

File Metadata

contextual information about a file, including attributes such as the file's name, size, type, content (e.g., signatures, headers, media), user/owner, permissions, timestamps, and other related properties. File metadata provides insights into a file's characteristics and can be used to detect malicious activity, unauthorized modifications, or other anomalies. Examples:

- File Ownership and Permissions: Checking the owner and permissions of a critical configuration file like /etc/passwd on Linux or C:\Windows\System32\config\SAM on Windows.
- Timestamps: Analyzing the creation, modification, and access timestamps of a file.
- File Content and Signatures: Extracting the headers of an executable file to verify its signature or detect packing/obfuscation.
- File Attributes: Analyzing attributes like hidden, system, or read-only flags in Windows.
- File Hashes: Generating MD5, SHA-1, or SHA-256 hashes of files to compare against threat intelligence feeds.
- File Location: Monitoring files located in unusual directories or paths, such as temporary or user folders.

This data component can be collected through the following measures:

Windows

- Sysinternals Tools: Use `AccessEnum` or `PSFile` to retrieve metadata about file access and permissions.
- Windows Event Logs: Enable object access auditing and monitor events like 4663 (Object Access) and 5140 (A network share object was accessed).
- PowerShell: Use Get-Item or Get-ChildItem cmdlets: `Get-ChildItem -Path "C:\Path\To\Directory" -Recurse | Select-Object Name, Length, LastWriteTime, Attributes`

Linux

- File System Commands: Use `ls -l` or stat to retrieve file metadata: `stat /path/to/file`
- Auditd: Configure audit rules to log metadata access: `auditctl -w /path/to/file -p wa -k file_metadata`
- Filesystem Integrity Tools: Tools like tripwire or AIDE (Advanced Intrusion Detection Environment) can monitor file metadata changes.

macOS

- FSEvents: Use FSEvents to track file metadata changes.

- Endpoint Security Framework (ESF): Capture metadata-related events via ESF APIs.
- Command-Line Tools: Use ls -l or xattr for file attributes: `ls -l@ /path/to/file`

SIEM Integration

- Forward file metadata logs from endpoint or network devices to a SIEM for centralized analysis.

The tag is: *misp-galaxy:mitre-data-component="File Metadata"*

Table 7356. Table References

Links

Firmware Modification

Changes made to firmware, which may include its settings, configurations, or underlying data. This can encompass alterations to the Master Boot Record (MBR), Volume Boot Record (VBR), or other firmware components critical to system boot and functionality. Such modifications are often indicators of adversary activity, including malware persistence and system compromise. Examples:

- Changes to Master Boot Record (MBR): Modifying the MBR to load malicious code during the boot process.
- Changes to Volume Boot Record (VBR): Altering the VBR to redirect boot processes to malicious locations.
- Firmware Configuration Changes: Modifying BIOS/UEFI settings such as disabling Secure Boot.
- Firmware Image Tampering: Updating firmware with a malicious or unauthorized image.
- Logs or Errors Indicating Firmware Changes: Logs showing unauthorized firmware updates or checksum mismatches.

This data component can be collected through the following measures:

- BIOS/UEFI Logs: Enable and monitor BIOS/UEFI logs to capture settings changes or firmware updates.
- Firmware Integrity Monitoring: Use tools or firmware security features to detect changes to firmware components.
- Endpoint Detection and Response (EDR) Solutions: Many EDR platforms can detect abnormal firmware activity, such as changes to MBR/VBR or unauthorized firmware updates.
- File System Monitoring: Monitor changes to MBR/VBR-related files using tools like Sysmon or auditd.
- Windows Example (Sysmon): Monitor Event ID 7 (Raw disk access).
- Linux Example (auditd): `auditctl -w /dev/sda -p wa -k firmware_modification`
- Network Traffic Analysis: Capture firmware updates downloaded over the network, particularly from untrusted sources. Use network monitoring tools like Zeek or Wireshark to analyze firmware-related traffic.
- Secure Boot Logs: Collect and analyze Secure Boot logs for signs of tampering or unauthorized

configurations. Example: Use PowerShell to retrieve Secure Boot settings on Windows: `Confirm-SecureBootUEFI`

- Vendor-Specific Firmware Tools: Many hardware vendors provide tools for firmware integrity checks.Examples:
- Intel Platform Firmware Resilience (PFR).
- Lenovo UEFI diagnostics.

The tag is: *misp-galaxy:mitre-data-component="Firmware Modification"*

Table 7357. Table References

Links

File Modification

Changes made to a file, including updates to its contents, metadata, access permissions, or attributes. These modifications may indicate legitimate activity (e.g., software updates) or unauthorized changes (e.g., tampering, ransomware, or adversarial modifications). Examples:

- Content Modifications: Changes to the content of a configuration file, such as modifying `/etc/ssh/sshd_config` on Linux or `C:\Windows\System32\drivers\etc\hosts` on Windows.
- Permission Changes: Altering file permissions to allow broader access, such as changing a file from `644` to `777` on Linux or modifying NTFS permissions on Windows.
- Attribute Modifications: Changing a file's attributes to hidden, read-only, or system on Windows.
- Timestamp Manipulation: Adjusting a file's creation or modification timestamp using tools like `touch` in Linux or timestomping tools on Windows.
- Software or System File Changes: Modifying system files such as `boot.ini`, kernel modules, or application binaries.

This data component can be collected through the following measures:

Windows

- Event Logs: Enable file system auditing to monitor file modifications using Security Event ID 4670 (File System Audit) or Sysmon Event ID 2 (File creation time changed).
- PowerShell: Use Get-ItemProperty or Get-Acl cmdlets to monitor file properties: `Get-Item -Path "C:\path\to\file" | Select-Object Name, Attributes, LastWriteTime`

Linux

- File System Monitoring: Use tools like auditd with rules to monitor file modifications: `auditctl -w /path/to/file -p wa -k file_modification`
- Inotify: Use inotifywait to watch for real-time changes to files or directories: `inotifywait -m /path/to/file`

macOS

- Endpoint Security Framework (ESF): Monitor file modification events using ESF APIs.
- Audit Framework: Configure audit rules to track file changes.
- Command-Line Tools: Use fs_usage to monitor file activities: `fs_usage -w /path/to/file`

SIEM Tools

- Collect logs from endpoint agents (e.g., Sysmon, Auditd) and file servers to centralize file modification event data.

The tag is: *misp-galaxy:mitre-data-component="File Modification"*

Table 7358. Table References

Links

Group Metadata

Group metadata includes attributes like name, permissions, purpose, and associated user accounts or roles, which adversaries may exploit for privilege escalation. Examples:

- Active Directory: `Get-ADGroup -Identity "Domain Admins" -Properties Members, Description`
- Azure AD: `Get-AzureADGroup -ObjectId <GroupId>`
- Google Workspace: <code>GET <a href="https://admin.googleapis.com/admin/directory/v1/groups/<groupKey&gt" class="bare">https://admin.googleapis.com/admin/directory/v1/groups/<groupKey&gt;</code>
- AWS IAM: `aws iam list-group-policies --group-name <group_name>`
- Office 365: <code>GET <a href="https://graph.microsoft.com/v1.0/groups/<id&gt" class="bare">https://graph.microsoft.com/v1.0/groups/<id&gt;</code>

Data Collection Measures:

- Cloud Logging:
- AWS CloudTrail for IAM group-related activities.
- Azure AD Sign-In/Audit logs for metadata changes.
- Google Admin Activity logs for API calls.
- Directory Logging: Log metadata access (e.g., Windows Event ID 4662).
- API Monitoring: Log API calls to modify group metadata (e.g., Microsoft Graph API).
- SIEM Integration: Centralize group metadata logs for analysis.

The tag is: *misp-galaxy:mitre-data-component="Group Metadata"*

Table 7359. Table References

Links

Group Modification

Changes made to a group, such as membership, name, or permissions (ex: Windows EID 4728 or 4732, AWS IAM UpdateGroup). Examples:

- Active Directory:
- Event ID 4728: Member added to a global group.
- Event ID 4732: Member added to a local group.
- Azure AD: `Set-AzureADGroup -ObjectId <GroupId> -DisplayName "New Name"`
- AWS IAM: `aws iam update-group --group-name <GroupName> --new-path "/admin/"`
- Google Workspace: Modify permissions via Admin SDK API: <code>PATCH <a href="https://admin.googleapis.com/admin/directory/v1/groups/<groupKey>" class="bare">https://admin.googleapis.com/admin/directory/v1/groups/<groupKey>;</code>
- Office 365: Modify groups via Graph API: <code>PATCH <a href="https://graph.microsoft.com/v1.0/groups/<groupId>" class="bare">https://graph.microsoft.com/v1.0/groups/<groupId>;</code>

Data Collection Measures:

- Directory Logging:
- Windows: Log EIDs 4728 (add), 4729 (remove).
- Azure AD: Enable "Audit logs."
- Google Workspace: Enable Admin Activity logs.
- Office 365: Use Unified Audit Logs.
- Cloud Monitoring:
- AWS: Log `UpdateGroup`, `AttachGroupPolicy`, `RemoveUserFromGroup`.
- Azure: Track modifications via Audit logs.
- API Monitoring: Log Google Admin SDK and Microsoft Graph API calls.
- SIEM Integration: Centralize and monitor group modification logs.

The tag is: *misp-galaxy:mitre-data-component="Group Modification"*

Host Status

Logging, messaging, and other artifacts that highlight the health and operational state of host-based

security sensors, such as Endpoint Detection and Response (EDR) agents, antivirus software, logging services, and system monitoring tools. Monitoring sensor health is essential for detecting misconfigurations, sensor failures, tampering, or deliberate security control evasion by adversaries.

Data Collection Measures:

- Windows Event Logs:
- Event ID 1074 (System Shutdown): Detects unexpected system reboots/shutdowns.
- Event ID 6006 (Event Log Stopped): Logs when Windows event logging is stopped.
- Event ID 16 (Sysmon): Detects configuration state changes that may indicate log tampering.
- Event ID 12 (Windows Defender Status Change) – Detects changes in Windows Defender state.
- Linux/macOS Monitoring:
- `/var/log/syslog`, `/var/log/auth.log`, `/var/log/kern.log`
- Journald (journalctl) for kernel and system alerts.
- Endpoint Detection and Response (EDR) Tools:
- Monitor agent health status, detect sensor tampering, and alert on missing telemetry.
- Mobile Threat Intelligence Logs:
- Samsung Knox, SafetyNet, iOS Secure Enclave provide sensor health status for mobile endpoints.

Image Metadata

contextual information associated with a virtual machine image, such as its name, resource group, status (active or inactive), type (custom or prebuilt), size, creation date, and permissions. This metadata is critical for understanding the state and configuration of virtual machine images in cloud environments. Examples:

- Azure Compute Service Image Metadata Example:
- Name: MyCustomImage

- Resource Group: MyResourceGroup
- State: Available
- Type: Managed Image
- AWS EC2 AMI Metadata Example:
- Image ID: ami-1234567890abcdef0
- Name: ProdImage
- State: Available
- Platform: Windows
- Google Cloud Compute Engine Image Metadata Example:
- Image Name: webserver-image
- Project: my-project-id
- Family: webserver
- Source Disk: my-disk-id
- VMware vSphere Template Metadata Example:
- Name: LinuxTemplate
- Disk Size: 40GB
- Network Adapter: VM Network

This data component can be collected through the following measures:

Cloud Platform-Specific Tools

- Azure:
- Use Azure CLI to query metadata: `az image show --name MyCustomImage --resource-group MyResourceGroup`
- AWS:
- Use AWS CLI to describe AMI metadata: `aws ec2 describe-images --image-ids ami-1234567890abcdef0`
- Google Cloud:
- Use Google Cloud SDK to retrieve image metadata: `gcloud compute images describe webserver-image`

APIs

- Azure: `GET /subscriptions/{subscriptionId}/resourceGroups/{resourceGroupName}/providers/Microsoft.Compute/images/{imageName}`
- AWS: `DescribeImages` API.
- Google Cloud: `GET https://compute.googleapis.com/compute/v1/projects/{project}/global/images/{image}`.

Cloud Management Portals

- View metadata directly from the cloud provider's management console or dashboard.

SIEM Integration

- Aggregate metadata into SIEM platforms for centralized monitoring:

The tag is: *misp-galaxy:mitre-data-component="Image Metadata"*

Table 7363. Table References

Links

Instance Modification

Changes made to a virtual machine (VM) or compute instance, including alterations to its configuration, metadata, attached policies, or operational state. Such modifications can include updating metadata, attaching or detaching resource policies, resizing instances, or modifying network configurations. Examples:

- AWS: instance modifications include API actions like `ModifyInstanceAttribute`, `ModifyInstanceMetadataOptions`, or `RebootInstances`.
- Azure: modifications can be tracked through operations like `Microsoft.Compute/virtualMachines/write`.
- GCP: instance modification events include operations like `instances.setMetadata`, `instances.addResourcePolicies`, or `instances.resize`.

Data Collection Measures:

- AWS CloudTrail: Log Location: Stored in S3 or forwarded to CloudWatch.
- Azure Activity Logs: Log Location: Accessible via Azure Monitor or exported to a storage account.
- GCP Audit Logs: Log Location: Logs Explorer or BigQuery.

Instance Start

The initiation or activation of a virtual machine instance within a cloud infrastructure. This action typically involves starting an existing instance that had been stopped or paused, allowing it to resume operation. Examples:

- Google Cloud Platform (GCP): Starting an instance through `instance.start` API activity.
- AWS: Logging of `StartInstances` in AWS CloudTrail for EC2 instances.
- Azure: `Microsoft.Compute/virtualMachines/start` entries indicate a VM instance being started.

Data Collection Measures:

- Google Cloud Platform: Enable GCP Audit Logs for Compute Engine.
- Log Event: Look for instance.start entries in Cloud Logging.
- Amazon Web Services (AWS): AWS CloudTrail.
- Log Event: Search for StartInstances events associated with EC2.
- Microsoft Azure: Azure Activity Logs.
- Log Event: Filter for Microsoft.Compute/virtualMachines/start operations.

The tag is: *misp-galaxy:mitre-data-component="Instance Start"*

Table 7366. Table References

Links

Instance Stop

The deactivation or shutdown of a virtual machine instance within a cloud infrastructure. This action typically involves stopping a running instance, which halts its operation and releases certain associated resources, such as CPU and memory. Examples:

- Google Cloud Platform (GCP): `instance.stop` events recorded in GCP Audit Logs indicate the deactivation of an instance.
- Amazon Web Services (AWS): `StopInstances` actions in AWS CloudTrail indicate EC2 instances being stopped.
- Microsoft Azure: `Microsoft.Compute/virtualMachines/deallocate` or `stop` events in Azure Activity Logs represent a virtual machine being stopped or deallocated.

The tag is: *misp-galaxy:mitre-data-component="Instance Stop"*

Table 7367. Table References

Links

Module Load

When a process or program dynamically attaches a shared library, module, or plugin into its memory space. This action is typically performed to extend the functionality of an application, access shared system resources, or interact with kernel-mode components.

Data Collection Measures:

- Event Logging (Windows):
- Sysmon Event ID 7: Logs when a DLL is loaded into a process.
- Windows Security Event ID 4688: Captures process creation events, often useful for correlating module loads.
- Windows Defender ATP: Can provide visibility into suspicious module loads.
- Event Logging (Linux/macOS):
- AuditD (`execve` and `open` syscalls): Captures when shared libraries (`.so` files) are loaded.
- Ltrace/Strace: Monitors process behavior, including library calls (`dlopen`, `execve`).
- MacOS Endpoint Security Framework (ESF): Monitors library loads (`ES_EVENT_TYPE_NOTIFY_DYLD_INSERT_LIBRARIES`).
- Endpoint Detection & Response (EDR):
- Provide real-time telemetry on module loads and process injections.
- Sysinternals Process Monitor (`procmon`): Captures loaded modules and their execution context.
- Memory Forensics:
- Volatility Framework (`malfind`, `ldrmodules`): Detects injected DLLs and anomalous module loads.
- Rekall Framework: Useful for kernel-mode module detection.
- SIEM and Log Analysis:
- Centralized log aggregation to correlate suspicious module loads across the environment.
- Detection rules using correlation searches and behavioral analytics.

Process Modification

Changes made to a running process, such as writing data into memory, modifying execution behavior, or injecting code into an existing process. Adversaries frequently modify processes to execute malicious payloads, evade detection, or gain escalated privileges.

Data Collection Measures:

- Endpoint Detection and Response (EDR) Tools:
- EDRs can monitor memory modifications and API-level calls.
- Sysmon (Windows):
- Event ID 8 (CreateRemoteThread) – Detects cross-process thread injection, commonly used in process hollowing.
- Event ID 10 (Process Access) – Detects access attempts to another process, often preceding injection attempts.
- Linux/macOS Monitoring:
- AuditD (ptrace, mmap, mprotect syscalls): Detects memory modifications and debugging attempts.
- eBPF/XDP: Monitors low-level system calls related to process modifications.
- OSQuery: The processes table can be queried for unusual modifications.
- Network-Based Monitoring:
- Zeek (Bro) Logs: Captures lateral movement attempts where adversaries remotely modify a

process.

- Syslog/OSSEC: Monitors logs for suspicious modifications.

The tag is: *misp-galaxy:mitre-data-component="Process Modification"*

Table 7372. Table References

Links

Pod Modification

Changes made to a pod's configuration or control data within a containerized cluster. This can include updating settings such as resource limits, environment variables, annotations, labels, or even the containers running within the pod. Pod modifications are often executed using commands like kubectl set, kubectl patch, or kubectl edit.

Data Collection Measures:

- Kubernetes API Server Audit Logs:
- Capture all API calls related to pod modification, such as PATCH, PUT, or UPDATE methods on v1/pods.
- Runtime Security Tools:
- Tools like Falco, Sysdig, and Kube-bench can monitor pod modifications at runtime and alert on policy violations.
- Container Orchestration Logs:
- Monitor events logged by Kubernetes itself (e.g., `kubectl logs -n kube-system kube-controller-manager`).
- SIEM and EDR Solutions:
- Use SIEM platforms (e.g., Splunk) to aggregate API server logs and detect patterns of unauthorized or suspicious pod modifications.
- Endpoint Detection and Response (EDR) tools configured with container visibility can monitor commands like `kubectl` set or `kubectl patch`.
- Host-Based Monitoring:
- Collect and analyze logs for processes executing `kubectl` commands or interacting with Kubernetes configuration files (e.g., `.kube/config`).

The tag is: *misp-galaxy:mitre-data-component="Pod Modification"*

Table 7373. Table References

Links

Response Metadata

Contextual information about an Internet-facing resource collected during a scan, including details

such as open ports, running services, protocols, and versions. This metadata is typically derived from interpreting scan results and helps build a profile of the targeted system. Examples:

- Port and Service Details:
- Open ports (e.g., 22, 80, 443).
- Identified services running on those ports (e.g., SSH, HTTP, HTTPS).
- Service Versions: Detected software version information (e.g., Apache 2.4.41, OpenSSH 8.2).
- Operating System Information: OS fingerprinting data (e.g., Linux Kernel 5.4.0).
- TLS/SSL Certificate Data: Information about the TLS/SSL certificate, such as the expiration date, issuer, and cipher suites.

Data Collection Measures:

- Scanning Tools:
- Nmap: Collects port, service, and version information using commands like nmap -sV <IP>.
- Masscan: High-speed scanning tool for discovering open ports and active services.
- Zmap: Focused on large-scale Internet scanning, collecting metadata about discovered services.
- Shodan API: Retrieves scan metadata for publicly exposed devices and services.
- Network Logs:
- Use logs from firewalls, intrusion detection systems (IDS), or intrusion prevention systems (IPS) to gather metadata from scan attempts. Example: Zeek or Suricata logs for incoming scan traffic.
- OSINT Platforms: Platforms like Censys, GreyNoise, or Shodan provide aggregated metadata about Internet-facing resources.
- Cloud Metadata Services: AWS Security Hub, Azure Monitor, or GCP Security Command Center can collect and centralize scan-related metadata for Internet-facing resources in cloud environments.

Social Media

Established, compromised, or otherwise acquired by adversaries to conduct reconnaissance, influence operations, social engineering, or other cyber threats.

Data Collection Measures:

- API Monitoring
- Social media APIs (e.g., Twitter API, Facebook Graph API) can extract behavioral patterns of accounts.
- Web Scraping
- Extracts public profile data, friend lists, or interactions to identify impersonation attempts.
- Threat Intelligence Feeds
- External feeds track malicious personas linked to disinformation campaigns or phishing.
- OSINT Tools
- Maltego, SpiderFoot, and OpenCTI can map social media persona relationships.
- Endpoint Detection
- EDR logs user behavior and alerts on suspicious social media interactions.
- SIEM Logging
- Detects access to known phishing pages or social media abuse via proxy logs.
- Dark Web Monitoring
- Identifies compromised social media credentials being sold.

The tag is: *misp-galaxy:mitre-data-component="Social Media"*

Links

Snapshot Modification

Changes made to a cloud snapshot's metadata, attributes, or control settings. These modifications may involve adjusting access permissions, changing retention policies, or altering encryption

settings.

Data Collection Measures:

- AWS CloudTrail
- Tracks API calls such as `ModifySnapshotAttribute`, `ResetSnapshotAttribute`, and `ModifySnapshotTier`.
- Azure Monitor Logs
- Logs changes via `Microsoft.Compute/snapshots/write`.
- Google Cloud Logging
- Captures modifications through `compute.snapshots.setIamPolicy` and `compute.snapshots.patch`.

The tag is: *misp-galaxy:mitre-data-component="Snapshot Modification"*

Links

Service Modification

Changes made to an existing service or daemon, such as modifying the service name, start type, execution parameters, or security configurations.

*Data Collection Measures: *

- Windows Event Logs
- Event ID 7040 - Detects modifications to the startup behavior of a service.
- Event ID 7045 - Can capture changes made to existing services.
- Event ID 7036 - Tracks when services start or stop, potentially indicating malicious tampering.
- Event ID 4697 - Can detect when an adversary reinstalls a service with different parameters.
- Sysmon Logs
- Sysmon Event ID 13 - Detects changes to service configurations in the Windows Registry (e.g., `HKLM\SYSTEM\CurrentControlSet\Services\`).
- Sysmon Event ID 1 - Can track execution of `sc.exe` or `PowerShell Set-Service`.
- PowerShell Logging
- Event ID 4104 (Script Block Logging) - Captures execution of commands like `Set-Service`, `New-Service`, or `sc config`.
- Command-Line Logging (Event ID 4688) - Tracks usage of service modification commands:
- `sc config <service_name> start= auto`
- `sc qc <service_name>`
- Linux/macOS Collection Methods
- Systemd Journals (`journalctl -u <service_name>`) Tracks modifications to systemd service

configurations.

- Daemon Logs (`/var/log/syslog`, `/var/log/messages`, `/var/log/daemon.log`) Captures changes to service state and execution parameters.
- AuditD Rules for Service Modification
- Monitor modifications to `/etc/systemd/system/` for new or altered service unit files: `auditctl -w /etc/systemd/system/ -p wa -k service_modification`
- Track execution of `systemctl` or `service` commands: `auditctl -a always,exit -F arch=b64 -S execve -F a0=systemctl -F key=service_mod`
- OSQuery for Linux/macOS Monitoring
- Query modified services using OSQuery's `processes` or `system_info` tables: `SELECT * FROM systemd_units WHERE state != 'running';`
- macOS Launch Daemon/Agent Modification
- Monitor for changes in:
- `/Library/LaunchDaemons/`
- `/Library/LaunchAgents/`
- Track modifications to `.plist` files indicating persistence attempts.

Process Termination

The exit or termination of a running process on a system. This can occur due to normal operations, user-initiated commands, or malicious actions such as process termination by malware to disable security controls.

Data Collection Measures:

- Endpoint Detection and Response (EDR) Tools:
- Monitor process termination events.
- Windows Event Logs:
- Event ID 4689 (Process Termination) – Captures when a process exits, including process ID and parent process.
- Event ID 7036 (Service Control Manager) – Monitors system service stops.
- Sysmon (Windows):
- Event ID 5 (Process Termination) – Detects when a process exits, including parent-child relationships.

- Linux/macOS Monitoring:
- AuditD (`execve`, `exit_group`, `kill` syscalls) – Captures process termination via command-line interactions.
- eBPF/XDP: Monitors low-level system calls related to process termination.
- OSQuery: The processes table can be queried for abnormal exits.

The tag is: *misp-galaxy:mitre-data-component="Process Termination"*

Conceal and reveal both facts and fictions to support a deception story

The tag is: *misp-galaxy:engage-framework="EAC0015 - Information Manipulation"*

EAC0016 - Network Manipulation

Make changes to network properties and functions to achieve a desired effect.

The tag is: *misp-galaxy:engage-framework="EAC0016 - Network Manipulation"*

EAC0017 - Hardware Manipulation

Alter the hardware configuration of a system to limit what an adversary can do with the device.

The tag is: *misp-galaxy:engage-framework="EAC0017 - Hardware Manipulation"*

EAC0018 - Security Controls

Alter security controls to make the system more or less vulnerable to attack.

The tag is: *misp-galaxy:engage-framework="EAC0018 - Security Controls"*

EAC0019 - Baseline

Identify key system elements to establish a baseline and be prepared to reset a system to that baseline when necessary.

The tag is: *misp-galaxy:engage-framework="EAC0019 - Baseline"*

EAC0020 - Isolation

Configure devices, systems, networks, etc. to contain activity and data, thus preventing the expansion of an engagement beyond desired limits.

The tag is: *misp-galaxy:engage-framework="EAC0020 - Isolation"*

EAC0021 - Attack Vector Migration

Move a malicious link, file, or device from its intended location to an engagement system or network for execution/use.

The tag is: *misp-galaxy:engage-framework="EAC0021 - Attack Vector Migration"*

EAC0022 - Artifact Diversity

Present the adversary with a variety of network and system artifacts.

The tag is: *misp-galaxy:engage-framework="EAC0022 - Artifact Diversity"*

EAC0023 - Introduced Vulnerabilities

Intentionally introduce vulnerabilities into the environment for the adversary to exploit.

The tag is: *misp-galaxy:engage-framework="EAC0023 - Introduced Vulnerabilities"*

SAC0001 - Operational Objective

Define the objective of the desired end-state of your adversary engagement operations.

The tag is: *misp-galaxy:engage-framework="SAC0001 - Operational Objective"*

SAC0002 - Persona Creation

Plan and create a fictitious human user through a combination of planted data and revealed behavior patterns.

The tag is: *misp-galaxy:engage-framework="SAC0002 - Persona Creation"*

SAC0003 - Storyboarding

Plan and create the deception story.

The tag is: *misp-galaxy:engage-framework="SAC0003 - Storyboarding"*

SAC0004 - Cyber Threat Intelligence

The process of analyzing actionable knowledge about adversaries and their malicious activities, enabling defenders and their organizations to reduce harm through better security decision-making

The tag is: *misp-galaxy:engage-framework="SAC0004 - Cyber Threat Intelligence"*

SAC0005 - Gating Criteria

Define the set of events that would lead to the unnegotiable pause or conclusion to the operation.

The tag is: *misp-galaxy:engage-framework="SAC0005 - Gating Criteria"*

SAC0006 - After-Action Review

Review of operational activities.

The tag is: *misp-galaxy:engage-framework="SAC0006 - After-Action Review"*

SAC0012 - Engagement Environment

Design the systems and network for the operation.

The tag is: *misp-galaxy:engage-framework="SAC0012 - Engagement Environment"*

SAC0009 - Threat Model

A risk assessment that models organizational strengths and weaknesses

The tag is: *misp-galaxy:engage-framework="SAC0009 - Threat Model"*

EAP0001 - Collect

Gather adversary tools, observe tactics, and collect other raw intelligence about the adversary's activity.

The tag is: *misp-galaxy:engage-framework="EAP0001 - Collect"*

EAP0002 - Detect

Establish or maintain awareness regarding adversary activity.

The tag is: *misp-galaxy:engage-framework="EAP0002 - Detect"*

EAP0003 - Prevent

Stop all or part of the adversary's ability to conduct their operation as intended.

The tag is: *misp-galaxy:engage-framework="EAP0003 - Prevent"*

EAP0004 - Direct

Encourage or discourage the adversary from conducting their operation as intended.

The tag is: *misp-galaxy:engage-framework="EAP0004 - Direct"*

EAP0005 - Disrupt

Impair an adversary's ability to conduct their operation as intended.

The tag is: *misp-galaxy:engage-framework="EAP0005 - Disrupt"*

EAP0006 - Reassure

Add authenticity to deceptive components to convince an adversary that an environment is real.

The tag is: *misp-galaxy:engage-framework="EAP0006 - Reassure"*

EAP0007 - Motivate

Encourage an adversary to conduct part or all of their mission.

The tag is: *misp-galaxy:engage-framework="EAP0007 - Motivate"*

SAP0001 - Plan

Identify and align an operation with a desired end-state.

The tag is: *misp-galaxy:engage-framework="SAP0001 - Plan"*

SAP0002 - Analyze

Retrospective review of information gained from an operation .

The tag is: *misp-galaxy:engage-framework="SAP0002 - Analyze"*

EGO0001 - Expose

Reveal the presence of ongoing adversary operations.

The tag is: *misp-galaxy:engage-framework="EGO0001 - Expose"*

EGO0002 - Affect

Negatively impact the adversaries operations.

The tag is: *misp-galaxy:engage-framework="EGO0002 - Affect"*

EGO0003 - Elicit

Learn about adversaries tactics, techniques, and procedures (TTPs).

The tag is: *misp-galaxy:engage-framework="EGO0003 - Elicit"*

SGO0001 - Prepare

Help the defender think about what they want to accomplish with operations.

The tag is: *misp-galaxy:engage-framework="SGO0001 - Prepare"*

SGO0002 - Understand

Make sure that the defender is capturing, utilizing, and refining knowledge learned to improve the defender's posture.

The tag is: *misp-galaxy:engage-framework="SGO0002 - Understand"*

EAV0001 - Vulnerability to Manipulated Artifacts

When adversaries interact with the environment or personas, they are vulnerable when they collect, observe, or manipulate system artifacts or information. Manipulated data may cause them to reveal behaviors, use additional or more advanced capabilities against the target, and/or impact their dwell time.

The tag is: *misp-galaxy:engage-framework="EAV0001 - Vulnerability to Manipulated Artifacts"*

EAV0002 - Vulnerability to Deception by Decoy Data

When adversaries interact with the environment or personas, they are vulnerable to collecting, or in some way interacting with, manipulated or decoy data. In those cases the data may increase their tolerance for imperfections in the environment and improve the overall believability of the ruse.

The tag is: *misp-galaxy:engage-framework="EAV0002 - Vulnerability to Deception by Decoy Data"*

EAV0003 - Exposure to Detection during Trust Exploitation

When adversaries exploit a trusted relationship, such as using an account to access or move in the environment, they are vulnerable to triggering tripwires or engaging in anomalous behavior.

The tag is: *misp-galaxy:engage-framework="EAV0003 - Exposure to Detection during Trust Exploitation"*

EAV0004 - Vulnerability to Uncontrolled Phishing Detonation

When adversaries use phishing emails to gain access to victim systems, they have no control over where a malicious attachment is detonated from, or where a link is clicked.

The tag is: *misp-galaxy:engage-framework="EAV0004 - Vulnerability to Uncontrolled Phishing Detonation"*

EAV0005 - Vulnerability to Malware Analysis Environment

When adversaries' malware is detonated, they may be encouraged to operate in an unintended environment.

The tag is: *misp-galaxy:engage-framework="EAV0005 - Vulnerability to Malware Analysis Environment"*

EAV0006 - Vulnerability to Manipulated Reconnaissance Data

When adversaries collect targeting information from open or closed data sources, they are vulnerable to being influenced by manipulated or misleading data.

The tag is: *misp-galaxy:engage-framework="EAV0006 - Vulnerability to Manipulated Reconnaissance Data"*

EAV0007 - Vulnerability to Adversary Plan Influence

When adversaries interact with engagement environments and personas, their future capability, targeting, and/or infrastructure requirements are vulnerable to influence.

The tag is: *misp-galaxy:engage-framework="EAV0007 - Vulnerability to Adversary Plan Influence"*

EAV0008 - Vulnerability to Engaging Decoy Victims

When adversaries maintain drive-by sites, they provide a pathway for beginning engagements and may be unable to differentiate real from deceptive victims.

The tag is: *misp-galaxy:engage-framework="EAV0008 - Vulnerability to Engaging Decoy Victims"*

EAV0009 - Exposure of Targeting Preferences

When adversaries maintain drive-by sites and collect information about potential victims, they may reveal information about their targeting preferences by selecting or rejecting an arbitrary victim.

The tag is: *misp-galaxy:engage-framework="EAV0009 - Exposure of Targeting Preferences"*

EAV0010 - Exposure to Anomaly Detection

When adversaries interact with network or system resources, they are vulnerable to triggering tripwires or engaging in easily detectable, anomalous behavior.

The tag is: *misp-galaxy:engage-framework="EAV0010 - Exposure to Anomaly Detection"*

EAV0011 - Exposure of Previous Collection Activities

When adversaries use previously stolen information to access or move laterally within an environment, they may reveal previous collection activities.

The tag is: *misp-galaxy:engage-framework="EAV0011 - Exposure of Previous Collection Activities"*

EAV0012 - Vulnerability to Uncontrolled Physical Media Usage

When adversaries use hardware peripherals, removable media, or connected transient cyber assets, they must rely on physical access or have limited control over when and where hardware additions are connected in the target network.

The tag is: *misp-galaxy:engage-framework="EAV0012 - Vulnerability to Uncontrolled Physical Media Usage"*

EAV0013 - Vulnerability to Resource Dependency

When adversaries rely on specific resources to be enabled, accessible, and/or vulnerable, they are vulnerable to their operations being disrupted if the resources are disabled, removed, or otherwise made invulnerable.

The tag is: *misp-galaxy:engage-framework="EAV0013 - Vulnerability to Resource Dependency"*

EAV0014 - Vulnerability to Uncontrolled Supply Chain Deployment

When adversaries manipulate supply chain mechanisms prior to receipt by a final consumer, they forfeit control over when and where the product is connected in the target network.

The tag is: *misp-galaxy:engage-framework="EAV0014 - Vulnerability to Uncontrolled Supply Chain Deployment"*

EAV0015 - Vulnerability to Poisoned Trusted Relationship

When adversaries exploit a trusted relationship, they are vulnerable to collecting and acting on manipulated data provided by the trusted party.

The tag is: *misp-galaxy:engage-framework="EAV0015 - Vulnerability to Poisoned Trusted Relationship"*

EAV0016 - Exposure to Monitoring when Abusing Features

When adversaries utilize or abuse system features, software, or other resources, they may be vulnerable to monitoring or Man-in-the-Middle manipulation.

The tag is: *misp-galaxy:engage-framework="EAV0016 - Exposure to Monitoring when Abusing Features"*

EAV0017 - Vulnerability to Capability Revelation on Honeypots

When adversaries discover enabled, accessible, or intentionally weakened/overly permissive resources in the environment (production or isolated), they are vulnerable to revealing additional or more advanced capabilities when exploiting or using said resource.

The tag is: *misp-galaxy:engage-framework="EAV0017 - Vulnerability to Capability Revelation on Honeypots"*

EAV0018 - Vulnerability to Counter-Social Engineering

When adversaries interact directly with victims, they are vulnerable to being socially engineered or otherwise manipulated by an aware user.

The tag is: *misp-galaxy:engage-framework="EAV0018 - Vulnerability to Counter-Social Engineering"*

EAV0019 - Exposure of Intent via Resource Interaction

When adversaries discover a diverse set of accessible resources and decoy artifacts on the target, they are vulnerable to revealing their targeting preferences and capabilities.

The tag is: *misp-galaxy:engage-framework="EAV0019 - Exposure of Intent via Resource Interaction"*

EAV0020 - Vulnerability to Network Traffic Manipulation

When adversaries move data across the network or interact with remote resources, they are vulnerable to network manipulations such as impacts to network availability, traffic filtering, degraded speeds, etc.

The tag is: *misp-galaxy:engage-framework="EAV0020 - Vulnerability to Network Traffic Manipulation"*

EAV0021 - Vulnerability to Exfiltration Interception (MitM)

When adversaries exfiltrate data, their data are vulnerable to observation or manipulation via Man-in-the-Middle activities.

The tag is: *misp-galaxy:engage-framework="EAV0021 - Vulnerability to Exfiltration Interception (MitM)"*

EAV0022 - Vulnerability to Resource Depletion on Honey-Credentials

When adversaries use brute-force techniques to access accounts or encrypted data, they are vulnerable to wasting resources if the artifact has no valid credentials or is locked in some other way.

The tag is: *misp-galaxy:engage-framework="EAV0022 - Vulnerability to Resource Depletion on Honey-Credentials"*

EAV0023 - Vulnerability to Signature-Based Detection

When adversaries use easily identifiable techniques, or generate signaturable patterns in data or traffic, they are vulnerable to detection of their activity.

The tag is: *misp-galaxy:engage-framework="EAV0023 - Vulnerability to Signature-Based Detection"*

EAV0024 - Vulnerability to Wasting Resources on Honey-Data

When adversaries discover inaccessible but perceived as interesting data or data streams, they are vulnerable to wasting resources or revealing additional capabilities in an effort to access the content.

The tag is: *misp-galaxy:engage-framework="EAV0024 - Vulnerability to Wasting Resources on Honey-Data"*

EAV0025 - Exposure of Targeting Preferences during Recon

When adversaries collect targeting information from open or closed data sources, they may reveal their targeting preferences.

The tag is: *misp-galaxy:engage-framework="EAV0025 - Exposure of Targeting Preferences during Recon"*

EAV0026 - Exposure of Capabilities via Drive-by Site

When adversaries maintain drive-by sites, they reveal information about their targeting capabilities.

The tag is: *misp-galaxy:engage-framework="EAV0026 - Exposure of Capabilities via Drive-by Site"*

EAV0027 - Vulnerability to Malware Dynamic Analysis

When adversaries' malware is detonated, they are vulnerable to dynamic analysis, which can reveal how the malware interacts with system resources.

The tag is: *misp-galaxy:engage-framework="EAV0027 - Vulnerability to Malware Dynamic Analysis"*

EAV0028 - Vulnerability to Presence Revelation via Beaconing Artifact

When adversaries collect manipulated artifacts, they are vulnerable to revealing their presence when using or moving the artifacts elsewhere in the engagement environment.

The tag is: *misp-galaxy:engage-framework="EAV0028 - Vulnerability to Presence Revelation via Beaconing Artifact"*

EAV0029 - Vulnerability to Wasting Resources on Large Data Exfil

When adversaries attempt to exfiltrate, manipulate, or move massive data objects, they are vulnerable to wasting resources to accomplish the task.

The tag is: *misp-galaxy:engage-framework="EAV0029 - Vulnerability to Wasting Resources on Large Data Exfil"*

EAV0030 - Vulnerability to Wasting Resources on Honey-Data

When adversaries discover inaccessible (but possibly valuable) data or data streams, they are vulnerable to wasting resources or revealing additional capabilities in an effort to access the content.

The tag is: *misp-galaxy:engage-framework="EAV0030 - Vulnerability to Wasting Resources on Honey-Data"*

EAV0031 - Vulnerability to Physical Observation

When adversaries gain physical access to a device or environment they are vulnerable to observation or other physical domain consequences.

The tag is: *misp-galaxy:engage-framework="EAV0031 - Vulnerability to Physical Observation"*

EAV0032 - Vulnerability to MitM on Physical Process Control

When adversaries attempt to remotely manipulate, damage or effect some change in the physical environment, they are vulnerable to Man-in-the-Middle manipulations.

The tag is: *misp-galaxy:engage-framework="EAV0032 - Vulnerability to MitM on Physical Process Control"*

Assets

A list of asset categories that are commonly found in industrial control systems..

authors

MITRE

Control Server

A device which acts as both a server and controller, that hosts the control software used in communicating with lower-level control devices in an ICS network (e.g. Remote Terminal Units (RTUs) and Programmable Logic Controllers (PLCs)).

The tag is: *misp-galaxy:mitre-ics-assets="Control Server"*

Table 7427. Table References

Links
https://nvlpubs.nist.gov/nistpubs/SpecialPublications/NIST.SP.800-82r2.pdf

Data Historian

A centralized database located on a computer installed in the control system DMZ supporting external corporate user data access for archival and analysis using statistical process control and other techniques.

The tag is: *misp-galaxy:mitre-ics-assets="Data Historian"*

Table 7428. Table References

Links

Engineering Workstation

The engineering workstation is usually a high-end very reliable computing platform designed for configuration, maintenance and diagnostics of the control system applications and other control system equipment. The system is usually made up of redundant hard disk drives, high speed network interface, reliable CPUs, performance graphics hardware, and applications that provide configuration and monitoring tools to perform control system application development, compilation and distribution of system modifications.

The tag is: *misp-galaxy:mitre-ics-assets="Engineering Workstation"*

Field Controller/RTU/PLC/IED

Controller terminology depends on the type of system they are associated with. They provide

typical processing capabilities. Controllers, sometimes referred to as Remote Terminal Units (RTU) and Programmable Logic Controllers (PLC), are computerized control units that are typically rack or panel mounted with modular processing and interface cards. The units are collocated with the process equipment and interface through input and output modules to the various sensors and controlled devices. Most utilize a programmable logic-based application that provides scanning and writing of data to and from the IO interface modules and communicates with the control system network via various communications methods, including serial and network communications

The tag is: *misp-galaxy:mitre-ics-assets="Field Controller/RTU/PLC/IED"*

Human-Machine Interface

In computer science and human-computer interaction, the Human-Machine Interface (HMI) refers to the graphical, textual and auditory information the program presents to the user (operator) using computer monitors and audio subsystems, and the control sequences (such as keystrokes with the computer keyboard, movements of the computer mouse, and selections with the touchscreen) the user employs to control the program. Currently the following types of HMI are the most common: Graphical user interfaces(GUI) accept input via devices such as computer keyboard and mouse and provide articulated graphical output on the computer monitor. Web-based user interfaces accept input and provide output by generating web pages which are transported via the network and viewed by the user using a web browser program. The operations user must be able to control the system and assess the state of the system. Each control system vendor provides a unique look-and-feel to their basic HMI applications. An older, not gender-neutral version of the term is man-machine interface (MMI). The system may expose several user interfaces to serve different kinds of users. User interface screens may be optimized to provide the appropriate information and control interface to operations users, engineering users and management users.

The tag is: *misp-galaxy:mitre-ics-assets="Human-Machine Interface"*

Input/Output Server

The Input/Output (I/O) server provides the interface between the control system LAN applications and the field equipment monitored and controlled by the control system applications. The I/O server, sometimes referred to as a Front-End Processor (FEP) or Data Acquisition Server (DAS),

converts the control system application data into packets that are transmitted over various types of communications media to the end device locations. The I/O server also converts data received from the various end devices over different communications mediums into data formatted to communicate with the control system networked applications.

The tag is: *misp-galaxy:mitre-ics-assets="Input/Output Server"*

Safety Instrumented System/Protection Relay

A safety instrumented system (SIS) takes automated action to keep a plant in a safe state, or to put it into a safe state, when abnormal conditions are present. The SIS may implement a single function or multiple functions to protect against various process hazards in your plant. The function of protective relaying is to cause the prompt removal from service of an element of a power system when it suffers a short circuit or when it starts to operate in any abnormal manner that might cause damage or otherwise interfere with the effective operation of the rest of the system.

The tag is: *misp-galaxy:mitre-ics-assets="Safety Instrumented System/Protection Relay"*

Groups

Groups are sets of related intrusion activity that are tracked by a common name in the security community. Groups are also sometimes referred to as campaigns or intrusion sets. Some groups have multiple names associated with the same set of activities due to various organizations tracking the same set of activities by different names. Groups are mapped to publicly reported technique use and referenced in the ATT&CK for ICS knowledge base. Groups are also mapped to reported software used during intrusions..

Groups is a cluster galaxy available in JSON format at **this location** The JSON format can be freely reused in your application or automatically enabled in MISP.

authors

MITRE

ALLANITE

ALLANITE is a suspected Russian cyber espionage group, that has primarily targeted the electric

utility sector within the United States and United Kingdom. The group's tactics and techniques are reportedly similar to Dragonfly / Dragonfly 2.0, although ALLANITE's technical capabilities have not exhibited disruptive or destructive abilities. It has been suggested that the group maintains a presence in ICS for the purpose of gaining understanding of processes and to maintain persistence.

The tag is: *misp-galaxy:mitre-ics-groups="ALLANITE"*

Dragonfly

Dragonfly is a cyber espionage group that has been active since at least 2011. They initially targeted defense and aviation companies but shifted to focus on the energy sector in early 2013. They have also targeted companies related to industrial control systems. A similar group emerged in 2015 and was identified by Symantec as Dragonfly 2.0. There is debate over the extent of the overlap between Dragonfly and Dragonfly 2.0, but there is sufficient evidence to lead to these being tracked as two separate groups.

The tag is: *misp-galaxy:mitre-ics-groups="Dragonfly"*

Dragonfly 2.0

Dragonfly 2.0 is a suspected Russian threat group which has been active since at least late 2015. Dragonfly 2.0's initial reported targets were a part of the energy sector, located within the United States, Switzerland, and Turkey. There is debate over the extent of overlap between Dragonfly 2.0 and Dragonfly, but there is sufficient evidence to lead to these being tracked as two separate groups.

The tag is: *misp-galaxy:mitre-ics-groups="Dragonfly 2.0"*

HEXANE

HEXANE is a threat group that has targeted ICS organization within the oil & gas, and telecommunications sectors. Many of the targeted organizations have been located in the Middle East including Kuwait. HEXANE's targeting of telecommunications has been speculated to be part of an effort to establish man-in-the-middle capabilities throughout the region. HEXANE's TTPs appear similar to APT33 and OilRig but due to differences in victims and tools it is tracked as a separate entity.

The tag is: *misp-galaxy:mitre-ics-groups="HEXANE"*

Lazarus group

Lazarus group is a suspected North Korean adversary group that has targeted networks associated with civilian electric energy in Europe, East Asia, and North America. Links have been established associating this group with the WannaCry ransomware from 2017.3 While WannaCry was not an ICS focused attack, Lazarus group is considered to be a threat to ICS. North Korean group definitions are known to have significant overlap, and the name Lazarus Group is known to encompass a broad range of activity. Some organizations use the name Lazarus Group to refer to any activity attributed to North Korea. Some organizations track North Korean clusters or groups such as Bluenoroff, APT37, and APT38 separately, while other organizations may track some activity associated with those group names by the name Lazarus Group.

The tag is: *misp-galaxy:mitre-ics-groups="Lazarus group"*

XENOTIME

XENOTIME is a threat group that has targeted and compromised industrial systems, specifically safety instrumented systems that are designed to provide safety and protective functions. Xenotime has previously targeted oil & gas, as well as electric sectors within the Middle east, Europe, and North America. Xenotime has also been reported to target ICS vendors, manufacturers, and organizations in the middle east. This group is one of the few with reported destructive capabilities.

The tag is: *misp-galaxy:mitre-ics-groups="XENOTIME"*

Levels

Based on the Purdue Model to aid ATT&CK for ICS users to understand which techniques are applicable to their environment..

Levels is a cluster galaxy available in JSON format at **this location** The JSON format can be freely reused in your application or automatically enabled in MISP.

authors

MITRE

Level 0

The I/O network level includes the actual physical processes and sensors and actuators that are directly connected to process equipment.

The tag is: *misp-galaxy:mitre-ics-levels="Level 0"*

Level 1

The control network level includes the functions involved in sensing and manipulating physical processes. Typical devices at this level are programmable logic controllers (PLCs), distributed control systems, safety instrumented systems and remote terminal units (RTUs).

The tag is: *misp-galaxy:mitre-ics-levels="Level 1"*

Level 2

The supervisory control LAN level includes the functions involved in monitoring and controlling physical processes and the general deployment of systems such as human-machine interfaces (HMIs), engineering workstations and historians.

The tag is: *misp-galaxy:mitre-ics-levels="Level 2"*

Software

Software is a generic term for custom or commercial code, operating system utilities, open-source software, or other tools used to conduct behavior modeled in ATT&CK for ICS..

Software is a cluster galaxy available in JSON format at **this location** The JSON format can be freely reused in your application or automatically enabled in MISP.

Backdoor.Oldrea, Havex

Backdoor.Oldrea is a Remote Access Trojan (RAT) that communicates with a Command and Control (C2) server. The C2 server can deploy payloads that provide additional functionality. One payload has been identified and analyzed that enumerates all connected network resources, such as computers or shared resources, and uses the classic DCOM-based (Distributed Component Object Model) version of the Open Platform Communications (OPC) standard to gather information about connected control system devices and resources within the network.

The tag is: *misp-galaxy:mitre-ics-software="Backdoor.Oldrea, Havex"*

https://www.hydro.com/en/media/on-the-agenda/cyber-attack/

NotPetya

NotPetya is malware that was first seen in a worldwide attack starting on June 27, 2017. The main purpose of the malware appeared to be to effectively destroy data and disk structures on compromised systems. Though NotPetya presents itself as a form of ransomware, it appears likely that the attackers never intended to make the encrypted data recoverable. As such, NotPetya may be more appropriately thought of as a form of wiper malware. NotPetya contains self-propagating ("wormable") features to spread itself across a computer network using the SMBv1 exploits EternalBlue and EternalRomance.

The tag is: *misp-galaxy:mitre-ics-software="NotPetya"*

Tactics

A list of all 11 tactics in ATT&CK for ICS.

Tactics is a cluster galaxy available in JSON format at **this location** The JSON format can be freely reused in your application or automatically enabled in MISP.

authors

MITRE

Collection

The adversary is trying to gather data of interest and domain knowledge on your ICS environment to inform their goal. Collection consists of techniques adversaries use to gather domain knowledge and obtain contextual feedback in an ICS environment. This tactic is often performed as part of Discovery, to compile data on control systems and targets of interest that may be used to follow through on the adversary’s objective. Examples of these techniques include observing operation states, capturing screenshots, identifying unique device roles, and gathering system and diagram schematics. Collection of this data can play a key role in planning, executing, and even revising an ICS-targeted attack. Methods of collection depend on the categories of data being targeted, which can include protocol specific, device specific, and process specific configurations and functionality. Information collected may pertain to a combination of system, supervisory, device, and network related data, which conceptually fall under high, medium, and low levels of plan operations. For example, information repositories on plant data at a high level or device specific programs at a low level. Sensitive floor plans, vendor device manuals, and other refs may also be at risk and exposed on the internet or otherwise publicly accessible.

The tag is: *misp-galaxy:mitre-ics-tactics="Collection"*

Table 7461. Table References

Links
https://www.blackhat.com/docs/asia-16/materials/asia-16-Spenneberg-PLC-Blaster-A-Worm-Living-Solely-In-The-PLC.pdf

http://www.research.lancs.ac.uk/portal/files/196578358/sample_sigconf.pdf
https://www.us-cert.gov/ncas/alerts/TA17-293A

Command and Control

The adversary is trying to communicate with and control compromised systems, controllers, and platforms with access to your ICS environment. Command and Control consists of techniques that adversaries use to communicate with and send commands to compromised systems, devices, controllers, and platforms with specialized applications used in ICS environments. Examples of these specialized communication devices include human machine interfaces (HMIs), data historians, SCADA servers, and engineering workstations (EWS). Adversaries often seek to use commonly available resources and mimic expected network traffic to avoid detection and suspicion. For instance, commonly used ports and protocols in ICS environments, and even expected IT resources, depending on the target network. Command and Control may be established to varying degrees of stealth, often depending on the victim's network structure and defenses.

The tag is: *misp-galaxy:mitre-ics-tactics="Command and Control"*

Table 7462. Table References

Links
https://attack.mitre.org/wiki/Technique/T1090

Discovery

The adversary is trying to figure out your ICS environment. Discovery consists of techniques that adversaries use to survey your ICS environment and gain knowledge about the internal network, control system devices, and how their processes interact. These techniques help adversaries observe the environment and determine next steps for target selection and Lateral Movement. They also allow adversaries to explore what they can control and gain insight on interactions between various control system processes. Discovery techniques are often an act of progression into the environment which enable the adversary to orient themselves before deciding how to act. Adversaries may use Discovery techniques that result in Collection, to help determine how available resources benefit their current objective. A combination of native device communications and functions, and custom tools are often used toward this post-compromise information-gathering objective.

The tag is: *misp-galaxy:mitre-ics-tactics="Discovery"*

Table 7463. Table References

Links
https://attack.mitre.org/wiki/Technique/T1049
https://attack.mitre.org/wiki/Technique/T1040
https://attack.mitre.org/wiki/Technique/T1018

Evasion

The adversary is trying to avoid being detected.Evasion consists of techniques that adversaries use to avoid detection by both human operators and technical defenses throughout their compromise. Techniques used for evasion include removal of indicators of compromise, spoofing communications and reporting, and exploiting software vulnerabilities. Adversaries may also leverage and abuse trusted devices and processes to hide their activity, possibly by masquerading as master devices or native software. Methods of defense and operator evasion for this purpose are often more passive in nature, as opposed to Inhibit Response Function techniques. They may also vary depending on whether the target of evasion is human or technological in nature, such as security controls. Techniques under other tactics are cross-listed to evasion when those techniques include the added benefit of subverting operators and defenses.

The tag is: *misp-galaxy:mitre-ics-tactics="Evasion"*

https://attack.mitre.org/wiki/Technique/T1014
http://ieeexplore.ieee.org/stamp/stamp.jsp?tp=&arnumber=6142258

Execution

The adversary is trying to run malicious code. Execution consists of techniques that result in adversary-controlled code running on a local or remote system, device, or other asset. This execution may also rely on unknowing end users or the manipulation of device operating modes to run. Adversaries may infect remote targets with programmed executables or malicious project files that operate according to specified behavior and may alter expected device behavior in subtle ways. Commands for execution may also be issued from command-line interfaces, APIs, GUIs, or other available interfaces. Techniques that run malicious code may also be paired with techniques from other tactics, particularly to aid network Discovery and Collection, impact operations, and inhibit response functions.

The tag is: *misp-galaxy:mitre-ics-tactics="Execution"*

Impact

The adversary is trying to manipulate, interrupt, or destroy your ICS systems, data, and their surrounding environment. Impact consists of techniques that adversaries use to disrupt, compromise, destroy, and manipulate the integrity and availability of control system operations, processes, devices, and data. These techniques encompass the influence and effects resulting from adversarial efforts to attack the ICS environment or that tangentially impact it. Impact techniques can result in more instantaneous disruption to control processes and the operator, or may result in more long term damage or loss to the ICS environment and related operations. The adversary may leverage Impair Process Control techniques, which often manifest in more self-revealing impacts on operations, or Inhibit Response Function techniques to hinder safeguards and alarms in order to follow through with and provide cover for Impact. In some scenarios, control system processes can appear to function as expected, but may have been altered to benefit the adversary's goal over the course of a longer duration. These techniques might be used by adversaries to follow through on their end goal or to provide cover for a confidentiality breach. Loss of Productivity and Revenue, Theft of Operational Information, and Damage to Property are meant to encompass some of the more granular goals of adversaries in targeted and untargeted attacks. These techniques in and of themselves are not necessarily detectable, but the associated adversary behavior can potentially be mitigated and/or detected.

The tag is: *misp-galaxy:mitre-ics-tactics="Impact"*

Impair Process Control

The adversary is trying to manipulate, disable, or damage physical control processes. Impair Process Control consists of techniques that adversaries use to disrupt control logic and cause determinantal effects to processes being controlled in the target environment. Targets of interest may include active procedures or parameters that manipulate the physical environment. These techniques can also include prevention or manipulation of reporting elements and control logic. If an adversary has modified process functionality, then they may also obfuscate the results, which are often self-revealing in their impact on the outcome of a product or the environment. The direct physical control these techniques exert may also threaten the safety of operators and downstream users, which can prompt response mechanisms. Adversaries may follow up with or use Inhibit Response Function techniques in tandem, to assist with the successful abuse of control processes to result in Impact.

Initial Access

The adversary is trying to get into your ICS environment. Initial Access consists of techniques that adversaries may use as entry vectors to gain an initial foothold within an ICS environment. These

techniques include compromising operational technology assets, IT resources in the OT network, and external remote services and websites. They may also target third party entities and users with privileged access. In particular, these initial access footholds may include devices and communication mechanisms with access to and privileges in both the IT and OT environments. IT resources in the OT environment are also potentially vulnerable to the same attacks as enterprise IT systems. Trusted third parties of concern may include vendors, maintenance personnel, engineers, external integrators, and other outside entities involved in expected ICS operations. Vendor maintained assets may include physical devices, software, and operational equipment. Initial access techniques may also leverage outside devices, such as radios, controllers, or removable media, to remotely interfere with and possibly infect OT operations.

The tag is: *misp-galaxy:mitre-ics-tactics="Initial Access"*

authors

MITRE

Activate Firmware Update Mode

Adversaries may activate firmware update mode on devices to prevent expected response functions from engaging in reaction to an emergency or process malfunction. For example, devices such as protection relays may have an operation mode designed for firmware installation. This mode may halt process monitoring and related functions to allow new firmware to be loaded. A device left in update mode may be placed in an inactive holding state if no firmware is provided to it. By entering and leaving a device in this mode, the adversary may deny its usual functionalities.

The tag is: *misp-galaxy:mitre-ics-techniques="Activate Firmware Update Mode"*

Alarm Suppression

Adversaries may target protection function alarms to prevent them from notifying operators of critical conditions. Alarm messages may be a part of an overall reporting system and of particular interest for adversaries. Disruption of the alarm system does not imply the disruption of the reporting system as a whole. In the Maroochy Attack, the adversary suppressed alarm reporting to the central computer. A Secura presentation on targeting OT notes a dual fold goal for adversaries attempting alarm suppression: prevent outgoing alarms from being raised and prevent incoming alarms from being responded to. The method of suppression may greatly depend on the type of alarm in question: An alarm raised by a protocol message. An alarm signaled with I/O. An alarm bit set in a flag and read In ICS environments, the adversary may have to suppress or contend with multiple alarms and/or alarm propagation to achieve a specific goal to evade detection or prevent intended responses from occurring.2 Methods of suppression may involve tampering or altering device displays and logs, modifying in memory code to fixed values, or even tampering with assembly level instruction code.

The tag is: *misp-galaxy:mitre-ics-techniques="Alarm Suppression"*

Automated Collection

Adversaries may automate collection of industrial environment information using tools or scripts. This automated collection may leverage native control protocols and tools available in the control systems environment. For example, the OPC protocol may be used to enumerate and gather information. Access to a system or interface with these native protocols may allow collection and enumeration of other attached, communicating servers and devices.

The tag is: *misp-galaxy:mitre-ics-techniques="Automated Collection"*

Block Command Message

Adversaries may block a command message from reaching its intended target to prevent command execution. In OT networks, command messages are sent to provide instructions to control system devices. A blocked command message can inhibit response functions from correcting a disruption or unsafe condition. In the 2015 attack on the Ukranian power grid, malicious firmware was used to render communication devices inoperable and effectively prevent them from receiving remote

command messages.

The tag is: *misp-galaxy:mitre-ics-techniques="Block Command Message"*

Block Reporting Message

Adversaries may block or prevent a reporting message from reaching its intended target. Reporting messages relay the status of control system devices, which can include event log data and I/O values of the associated device. By blocking these reporting messages, an adversary can potentially hide their actions from an operator. Blocking reporting messages in control systems that manage physical processes may contribute to system impact, causing inhibition of a response function. A control system may not be able to respond in a proper or timely manner to an event, such as a dangerous fault, if its corresponding reporting message is blocked. In the 2015 attack on the Ukranian power grid, malicious firmware was used to render communication devices inoperable and effectively block messages from being reported.

The tag is: *misp-galaxy:mitre-ics-techniques="Block Reporting Message"*

Block Serial COM

Adversaries may block access to serial COM to prevent instructions or configurations from reaching target devices. Serial Communication ports (COM) allow communication with control system devices. Devices can receive command and configuration messages over such serial COM. Devices also use serial COM to send command and reporting messages. Blocking device serial COM may also block command messages and block reporting messages. A serial to Ethernet converter is often connected to a serial COM to facilitate communication between serial and Ethernet devices. One approach to blocking a serial COM would be to create and hold open a TCP session with the Ethernet side of the converter. A serial to Ethernet converter may have a few ports open to facilitate multiple communications. For example, if there are three serial COM available — 1, 2 and 3 --, the converter might be listening on the corresponding ports 20001, 20002, and 20003. If a

TCP/IP connection is opened with one of these ports and held open, then the port will be unavailable for use by another party. One way the adversary could achieve this would be to initiate a TCP session with the serial to Ethernet converter at 10.0.0.1 via Telnet on serial port 1 with the following command: telnet 10.0.0.1 20001.

The tag is: *misp-galaxy:mitre-ics-techniques="Block Serial COM"*

Brute Force I/O

Adversaries may brute force I/O addresses on a device and attempt to exhaustively perform an action. By enumerating the full range of I/O addresses, an adversary may manipulate a process function without having to target specific I/O interfaces. More than one process function manipulation and enumeration pass may occur on the targeted I/O range in a brute force attempt.

The tag is: *misp-galaxy:mitre-ics-techniques="Brute Force I/O"*

Table 7476. Table References

https://www.welivesecurity.com/wp-content/uploads/2017/06/Win32_Industroyer.pdf

Change Program State

Adversaries may attempt to change the state of the current program on a control device. Program state changes may be used to allow for another program to take over control or be loaded onto the device.

The tag is: *misp-galaxy:mitre-ics-techniques="Change Program State"*

https://github.com/MDudek-ICS/TRISIS-TRITON-HATMAN/tree/master/decompiled_code/library

Command-Line Interface

Adversaries may utilize command-line interfaces (CLIs) to interact with systems and execute commands. CLIs provide a means of interacting with computer systems and are a common feature

across many types of platforms and devices within control systems environments. Adversaries may also use CLIs to install and run new software, including malicious tools that may be installed over the course of an operation. CLIs are typically accessed locally, but can also be exposed via services, such as SSH, Telnet, and RDP. Commands that are executed in the CLI execute with the current permissions level of the process running the terminal emulator, unless the command specifies a change in permissions context. Many controllers have CLI interfaces for management purposes.

The tag is: *misp-galaxy:mitre-ics-techniques="Command-Line Interface"*

Commonly Used Port

Adversaries may communicate over a commonly used port to bypass firewalls or network detection systems and to blend in with normal network activity, to avoid more detailed inspection. They may use the protocol associated with the port, or a completely different protocol. They may use commonly open ports, such as the examples as follows TCP:80 (HTTP), TCP:443 (HTTPS), TCP/UDP:53 (DNS), TCP:1024-4999 (OPC on XP/Win2k3), TCP:49152-65535 (OPC on Vista and later), TCP:23 (TELNET), UDP:161 (SNMP), TCP:502 (MODBUS), TCP:102 (S7comm/ISO-TSAP), TCP:20000 (DNP3), TCP:44818 (Ethernet/IP)

The tag is: *misp-galaxy:mitre-ics-techniques="Commonly Used Port"*

https://nvlpubs.nist.gov/nistpubs/SpecialPublications/NIST.SP.800-82r2.pdf

Connection Proxy

Adversaries may use a connection proxy to direct network traffic between systems or act as an intermediary for network communications. The definition of a proxy can also be expanded to encompass trust relationships between networks in peer-to-peer, mesh, or trusted connections between networks consisting of hosts or systems that regularly communicate with each other. The network may be within a single organization or across multiple organizations with trust relationships. Adversaries could use these types of relationships to manage command and control communications, to reduce the number of simultaneous outbound network connections, to provide resiliency in the face of connection loss, or to ride over existing trusted communications paths

between victims to avoid suspicion.

The tag is: *misp-galaxy:mitre-ics-techniques="Connection Proxy"*

Damage to Property

Adversaries may cause damage and destruction of property to infrastructure, equipment, and the surrounding environment when attacking control systems. This technique may result in device and operational equipment breakdown, or represent tangential damage from other techniques used in an attack. Depending on the severity of physical damage and disruption caused to control processes and systems, this technique may result in Loss of Safety. Operations that result in Loss of Control may also cause damage to property, which may be directly or indirectly motivated by an adversary seeking to cause impact in the form of Loss of Productivity and Revenue. The German Federal Office for Information Security (BSI) reported a targeted attack on a steel mill under an incidents affecting business section of its 2014 IT Security Report. These targeted attacks affected industrial operations and resulted in breakdowns of control system components and even entire installations. As a result of these breakdowns, massive impact and damage resulted from the uncontrolled shutdown of a blast furnace. In the Maroochy Attack, Vitek Boden gained remote computer access to the control system and altered data so that whatever function should have occurred at affected pumping stations did not occur or occurred in a different way. This ultimately led to 800,000 liters of raw sewage being spilled out into the community. The raw sewage affected local parks, rivers, and even a local hotel. This resulted in harm to marine life and produced a sickening stench from the community's now blackened rivers. A Polish student used a remote controller device to interface with the Lodz city tram system in Poland.345 Using this remote, the student was able to capture and replay legitimate tram signals. This resulted in damage to impacted trams, people, and the surrounding property. Reportedly, four trams were derailed and were forced to make emergency stops.4 Commands issued by the student may have also resulted in tram collisions, causing harm to those on board and the environment outside.

The tag is: *misp-galaxy:mitre-ics-techniques="Damage to Property"*

Data Destruction

Adversaries may perform data destruction over the course of an operation. The adversary may drop or create malware, tools, or other non-native files on a target system to accomplish this, potentially leaving behind traces of malicious activities. Such non-native files and other data may be removed over the course of an intrusion to maintain a small footprint or as a standard part of the post-intrusion cleanup process. Data destruction may also be used to render operator interfaces unable to respond and to disrupt response functions from occurring as expected. An adversary may also destroy data backups that are vital to recovery after an incident. Standard file deletion commands are available on most operating system and device interfaces to perform cleanup, but adversaries may use other tools as well. Two examples are Windows Sysinternals SDelete and Active@ Killdisk.

The tag is: *misp-galaxy:mitre-ics-techniques="Data Destruction"*

Data Historian Compromise

Adversaries may compromise and gain control of a data historian to gain a foothold into the control system environment. Access to a data historian may be used to learn stored database archival and analysis information on the control system. A dual-homed data historian may provide adversaries an interface from the IT environment to the OT environment. Dragos has released an updated

analysis on CrashOverride that outlines the attack from the ICS network breach to payload delivery and execution.1 The report summarized that CrashOverride represents a new application of malware, but relied on standard intrusion techniques. In particular, new artifacts include refs to a Microsoft Windows Server 2003 host, with a SQL Server. Within the ICS environment, such a database server can act as a data historian. Dragos noted a device with this role should be expected to have extensive connections within the ICS environment. Adversary activity leveraged database capabilities to perform reconnaissance, including directory queries and network connectivity checks.

The tag is: *misp-galaxy:mitre-ics-techniques="Data Historian Compromise"*

Table 7483. Table References

Links
https://dragos.com/wp-content/uploads/CRASHOVERRIDE2018.pdf

Data from Information Repositories

Adversaries may target and collect data from information repositories. This can include sensitive data such as specifications, schematics, or diagrams of control system layouts, devices, and processes. Examples of target information repositories include reference databases and local machines on the process environment.

The tag is: *misp-galaxy:mitre-ics-techniques="Data from Information Repositories"*

Default Credentials

Adversaries may leverage manufacturer or supplier set default credentials on control system devices. These default credentials may have administrative permissions and may be necessary for initial configuration of the device. It is general best practice to change the passwords for these accounts as soon as possible, but some manufacturers may have devices that have passwords or usernames that cannot be changed. Default credentials are normally documented in an instruction manual that is either packaged with the device, published online through official means, or published online through unofficial means. Adversaries may leverage default credentials that have not been properly modified or disabled.

The tag is: *misp-galaxy:mitre-ics-techniques="Default Credentials"*

Table 7485. Table References

Links

https://nvlpubs.nist.gov/nistpubs/SpecialPublications/NIST.SP.800-82r2.pdf

Denial of Control

Adversaries may cause a denial of control to temporarily prevent operators and engineers from interacting with process controls. An adversary may attempt to deny process control access to cause a temporary loss of communication with the control device or to prevent operator adjustment of process controls. An affected process may still be operating during the period of control loss, but not necessarily in a desired state. In the Maroochy attack, the adversary was able to temporarily shut an investigator out of the network preventing them from issuing any controls.

The tag is: *misp-galaxy:mitre-ics-techniques="Denial of Control"*

https://www.welivesecurity.com/wp-content/uploads/2017/06/Win32_Industroyer.pdf

Denial of Service

Adversaries may perform Denial-of-Service (DoS) attacks to disrupt expected device functionality. Examples of DoS attacks include overwhelming the target device with a high volume of requests in a short time period and sending the target device a request it does not know how to handle. Disrupting device state may temporarily render it unresponsive, possibly lasting until a reboot can occur. When placed in this state, devices may be unable to send and receive requests, and may not perform expected response functions in reaction to other events in the environment. Some ICS devices are particularly sensitive to DoS events, and may become unresponsive in reaction to even a simple ping sweep. Adversaries may also attempt to execute a Permanent Denial-of-Service (PDoS) against certain devices, such as in the case of the BrickerBot malware. Adversaries may exploit a software vulnerability to cause a denial of service by taking advantage of a programming error in a program, service, or within the operating system software or kernel itself to execute adversary-controlled code. Vulnerabilities may exist in software that can be used to cause a or denial of service condition. Adversaries may have prior knowledge about industrial protocols or control devices used in the environment through Control Device Identification. There are examples of adversaries remotely causing a Device Restart/Shutdown by exploiting a vulnerability that induces uncontrolled resource consumption. In the Maroochy attack, the adversary was able to shut an investigator out of the network.

The tag is: *misp-galaxy:mitre-ics-techniques="Denial of Service"*

Denial of View

Adversaries may cause a denial of view in attempt to disrupt and prevent operator oversight on the status of an ICS environment. This may manifest itself as a temporary communication failure between a device and its control source, where the interface recovers and becomes available once the interference ceases. An adversary may attempt to deny operator visibility by preventing them from receiving status and reporting messages. Denying this view may temporarily block and prevent operators from noticing a change in state or anomalous behavior. The environment's data and processes may still be operational, but functioning in an unintended or adversarial manner. In the Maroochy attack, the adversary was able to temporarily shut an investigator out of the network, preventing them from viewing the state of the system.

The tag is: *misp-galaxy:mitre-ics-techniques="Denial of View"*

Detect Operating Mode

Adversaries may gather information about the current operating state of a PLC. CPU operating modes are often controlled by a key switch on the PLC. Example states may be run, prog, stop, remote, and invalid. Knowledge of these states may be valuable to an adversary to determine if they are able to reprogram the PLC.

The tag is: *misp-galaxy:mitre-ics-techniques="Detect Operating Mode"*

Table 7489. Table References

Links
Triton contains a file named TS_cnames.py which contains default definitions for key state (TS_keystate). Key state is referenced in TsHi.py.[Triton contains a file named TS_cnames.py which contains default definitions for key state (TS_keystate). Key state is referenced in TsHi.py.]

Detect Program State

Adversaries may seek to gather information about the current state of a program on a PLC. State information reveals information about the program, including whether it's running, halted, stopped, or has generated an exception. This information may be leveraged as a verification of malicious program execution or to determine if a PLC is ready to download a new program.

The tag is: *misp-galaxy:mitre-ics-techniques="Detect Program State"*

Table 7490. Table References

Links
https://github.com/MDudek-ICS/TRISIS-TRITON-HATMAN/tree/master/decompiled_code/library

Device Restart/Shutdown

Adversaries may forcibly restart or shutdown a device in the ICS environment to disrupt and potentially cause adverse effects on the physical processes it helps to control. Methods of device restart and shutdown exist as built-in, standard functionalities. This can include interactive device web interfaces, CLIs, and network protocol commands, among others. Device restart or shutdown may also occur as a consequence of changing a device into an alternative mode of operation for testing or firmware loading. Unexpected restart or shutdown of control system devices may contribute to impact, by preventing expected response functions from activating and being received in critical states. This can also be a sign of malicious device modification, as many updates require a shutdown in order to take affect. For example, DNP3's function code 0x0D can reset and reconfigure DNP3 outstations by forcing them to perform a complete power cycle. In the 2015 attack on the Ukranian power grid, the adversaries gained access to the control networks of three different energy companies. The adversaries scheduled disconnects for the uniterruptable power supply (UPS) systems so that when power was disconnected from the substations, the devices would shut down and service could not be recovered.

The tag is: *misp-galaxy:mitre-ics-techniques="Device Restart/Shutdown"*

Drive-by Compromise

Adversaries may gain access to a system during a drive-by compromise, when a user visits a website as part of a regular browsing session.With this technique, the user's web browser is targeted and exploited simply by visiting the compromised website. The adversary may target a specific community, such as trusted third party suppliers or other industry specific groups, which often visit the target website. This kind of targeted attack relies on a common interest, and is known as a strategic web compromise or watering hole attack. The National Cyber Awareness System (NCAS) has issued a Technical Alert (TA) regarding Russian government cyber activity targeting critical infrastructure sectors. Analysis by DHS and FBI has noted two distinct categories of victims in the Dragonfly campaign on the Western energy sector: staging and intended targets. The adversary targeted the less secure networks of staging targets, including trusted third-party suppliers and related peripheral organizations. Initial access to the intended targets used watering hole attacks to target process control, ICS, and critical infrastructure related trade publications and informational websites.

The tag is: *misp-galaxy:mitre-ics-techniques="Drive-by Compromise"*

Engineering Workstation Compromise

Adversaries may compromise and gain control of an engineering workstation as an Initial Access technique into the control system environment. Access to an engineering workstation may occur as a result of remote access or by physical means, such as a person with privileged access or infection by removable media. A dual-homed engineering workstation may allow the adversary access into multiple networks. For example, unsegregated process control, safety system, or information system networks. An Engineering Workstation is designed as a reliable computing platform that configures, maintains, and diagnoses control system equipment and applications. Compromise of an engineering workstation may provide access to and control of other control system applications

and equipment. In the Maroochy attack, the adversary utilized a computer, possibly stolen, with proprietary engineering software to communicate with a wastewater system.

The tag is: *misp-galaxy:mitre-ics-techniques="Engineering Workstation Compromise"*

Execution through API

Adversaries may attempt to leverage Application Program Interfaces (APIs) used for communication between control software and the hardware. Specific functionality is often coded into APIs which can be called by software to engage specific functions on a device or other software, such as Change Program State of a program on a PLC.

The tag is: *misp-galaxy:mitre-ics-techniques="Execution through API"*

https://www.midnightbluelabs.com/blog/2018/1/16/analyzing-the-triton-industrial-malware

Exploit Public-Facing Application

Adversaries may attempt to exploit public-facing applications to leverage weaknesses on Internet-facing computer systems, programs, or assets in order to cause unintended or unexpected behavior. These public-facing applications may include user interfaces, software, data, or commands. In particular, a public-facing application in the IT environment may provide adversaries an interface into the OT environment. ICS-CERT analysis has identified the probable initial infection vector for systems running GE's Cimplicity HMI with a direct connection to the Internet.

The tag is: *misp-galaxy:mitre-ics-techniques="Exploit Public-Facing Application"*

Table 7495. Table References

Links
https://www.us-cert.gov/ics/alerts/ICS-ALERT-14-281-01B

Exploitation for Evasion

Adversaries may exploit a software vulnerability to take advantage of a programming error in a program, service, or within the operating system software or kernel itself to evade detection. Vulnerabilities may exist in software that can be used to disable or circumvent security features. Adversaries may have prior knowledge through Control Device Identification about security features implemented on control devices. These device security features will likely be targeted directly for exploitation. There are examples of firmware RAM/ROM consistency checks on control devices being targeted by adversaries to enable the installation of malicious System Firmware.

The tag is: *misp-galaxy:mitre-ics-techniques="Exploitation for Evasion"*

Exploitation of Remote Services

Adversaries may exploit a software vulnerability to take advantage of a programming error in a program, service, or within the operating system software or kernel itself to enable remote service abuse. A common goal for post-compromise exploitation of remote services is for lateral movement to enable access to a remote system. ICS asset owners and operators have been affected by ransomware (or disruptive malware masquerading as ransomware) migrating from enterprise IT to ICS environments: WannaCry, NotPetya, and BadRabbit. In each of these cases, self-propagating (“wormable”) malware initially infected IT networks, but through exploit (particularly the SMBv1-targeting MS17-010 vulnerability) spread to industrial networks, producing significant impacts.

The tag is: *misp-galaxy:mitre-ics-techniques="Exploitation of Remote Services"*

Table 7497. Table References

Links
https://attack.mitre.org/techniques/T1210/
https://dragos.com/blog/industry-news/implications-of-it-ransomware-for-ics-environments/

External Remote Services

Adversaries may leverage external remote services as a point of initial access into your network. These services allow users to connect to internal network resources from external locations. Examples are VPNs, Citrix, and other access mechanisms. Remote service gateways often manage connections and credential authentication for these services. External remote services allow administration of a control system from outside the system. Often, vendors and internal engineering groups have access to external remote services to control system networks via the corporate network. In some cases, this access is enabled directly from the internet. While remote access enables ease of maintenance when a control system is in a remote area, compromise of remote access solutions is a liability. The adversary may use these services to gain access to and execute attacks against a control system network. Access to valid accounts is often a requirement. As they look for an entry point into the control system network, adversaries may begin searching for existing point?to?point VPN implementations at trusted third party networks or through remote support employee connections where split tunneling is enabled. In the Maroochy Attack, the adversary was able to gain remote computer access to the system over radio. The 2015 attack on the Ukranian power grid showed the use of existing remote access tools within the environment to access the control system network. The adversary harvested worker credentials, some of them for VPNs the grid workers used to remotely log into the control system networks.3245 The VPNs into these networks appear to have lacked two?factor authentication.

The tag is: *misp-galaxy:mitre-ics-techniques="External Remote Services"*

Graphical User Interface

Adversaries may attempt to gain access to a machine via a Graphical User Interface (GUI) to enhance execution capabilities. Access to a GUI allows a user to interact with a computer in a more visual manner than a CLI. A GUI allows users to move a cursor and click on interface objects, with a mouse and keyboard as the main input devices, as opposed to just using the keyboard. If physical access is not an option, then access might be possible via protocols such as VNC on Linux-based and Unix-based operating systems, and RDP on Windows operating systems. An adversary can use this access to execute programs and applications on the target machine. In the 2015 attack on the Ukrainian power grid, the adversary utilized the GUI of HMIs in the SCADA environment to open

breakers.

The tag is: *misp-galaxy:mitre-ics-techniques="Graphical User Interface"*

http://technet.microsoft.com/en-us/magazine/2008.06.srp.aspx
https://technet.microsoft.com/en-us/library/ee791851.aspx

Hooking

Adversaries may hook into application programming interface (API) functions used by processes to redirect calls for persistent means. Windows processes often leverage these API functions to perform tasks that require reusable system resources. Windows API functions are typically stored in dynamic-link libraries (DLLs) as exported functions. One type of hooking seen in ICS involves redirecting calls to these functions via import address table (IAT) hooking. IAT hooking uses modifications to a process's IAT, where pointers to imported API functions are stored.

The tag is: *misp-galaxy:mitre-ics-techniques="Hooking"*

https://www.wired.com/images_blogs/threatlevel/2010/11/w32_stuxnet_dossier.pdf

I/O Module Discovery

Adversaries may use input/output (I/O) module discovery to gather key information about a control system device. An I/O module is a device that allows the control system device to either receive or send signals to other devices. These signals can be analog or digital, and may support a number of different protocols. Devices are often able to use attachable I/O modules to increase the number of inputs and outputs that it can utilize. An adversary with access to a device can use native device functions to enumerate I/O modules that are connected to the device. Information regarding the I/O modules can aid the adversary in understanding related control processes.

The tag is: *misp-galaxy:mitre-ics-techniques="I/O Module Discovery"*

Indicator Removal on Host

Adversaries may attempt to remove indicators of their presence on a system in an effort to cover their tracks. In cases where an adversary may feel detection is imminent, they may try to overwrite, delete, or cover up changes they have made to the device.

The tag is: *misp-galaxy:mitre-ics-techniques="Indicator Removal on Host"*

Table 7503. Table References

Internet Accessible Device

Adversaries may gain access into industrial environments directly through systems exposed to the internet for remote access rather than through External Remote Services. Minimal protections provided by these devices such as password authentication may be targeted and compromised. In the case of the Bowman dam incident, adversaries leveraged access to the dam control network through a cellular modem. Access to the device was protected by password authentication, although the application was vulnerable to brute forcing.

The tag is: *misp-galaxy:mitre-ics-techniques="Internet Accessible Device"*

https://www.us-cert.gov/ics/advisories/ICSA-11-094-02B

Location Identification

Adversaries may perform location identification using device data to inform operations and targeted impact for attacks. Location identification data can come in a number of forms, including geographic location, location relative to other control system devices, time zone, and current time. An adversary may use an embedded global positioning system (GPS) module in a device to figure out the physical coordinates of a device. NIST SP800-82 recommends that devices utilize GPS or another location determining mechanism to attach appropriate timestamps to log entries1. While this assists in logging and event tracking, an adversary could use the underlying positioning mechanism to determine the general location of a device. An adversary can also infer the physical location of serially connected devices by using serial connection enumeration. An adversary attempt to attack and cause Impact could potentially affect other control system devices in close proximity. Device local-time and time-zone settings can also provide adversaries a rough indicator of device location, when specific geographic identifiers cannot be determined from the system.

The tag is: *misp-galaxy:mitre-ics-techniques="Location Identification"*

https://www.hydro.com/en/media/on-the-agenda/cyber-attack/

Loss of Productivity and Revenue

Adversaries may cause loss of productivity and revenue through disruption and even damage to the availability and integrity of control system operations, devices, and related processes. This technique may manifest as a direct effect of an ICS-targeting attack or tangentially, due to an IT-targeting attack against non-segregated environments. In some cases, this may result from the postponement and disruption of ICS operations and production as part of a remediation effort. Operations may be brought to a halt and effectively stopped in an effort to contain and properly remove malware or due to the Loss of Safety.

The tag is: *misp-galaxy:mitre-ics-techniques="Loss of Productivity and Revenue"*

https://www.darkreading.com/attacks-breaches/how-a-manufacturing-firm-recovered-from-a-devastating-ransomware-attack/d/d-id/1334760

Loss of Safety

Adversaries may cause loss of safety whether on purpose or as a consequence of actions taken to accomplish an operation. The loss of safety can describe a physical impact and threat, or the potential for unsafe conditions and activity in terms of control systems environments, devices, or processes. For instance, an adversary may issue commands or influence and possibly inhibit safety mechanisms that allow the injury of and possible loss of life. This can also encompass scenarios resulting in the failure of a safety mechanism or control, that may lead to unsafe and dangerous execution and outcomes of physical processes and related systems. The German Federal Office for Information Security (BSI) reported a targeted attack on a steel mill in its 2014 IT Security Report. These targeted attacks affected industrial operations and resulted in breakdowns of control system components and even entire installations. As a result of these breakdowns, massive impact resulted in damage and unsafe conditions from the uncontrolled shutdown of a blast furnace. A Polish student used a remote controller device to interface with the Lodz city tram system in Poland.567 Using this remote, the student was able to capture and replay legitimate tram signals. As a consequence, four trams were derailed and twelve people injured due to resulting emergency stops. The track controlling commands issued may have also resulted in tram collisions, a further risk to those on board and nearby the areas of impact.

The tag is: *misp-galaxy:mitre-ics-techniques="Loss of Safety"*

Loss of View

Adversaries may cause a sustained or permanent loss of view where the ICS equipment will require local, hands-on operator intervention; for instance, a restart or manual operation. By causing a sustained reporting or visibility loss, the adversary can effectively hide the present state of operations. This loss of view can occur without affecting the physical processes themselves.

The tag is: *misp-galaxy:mitre-ics-techniques="Loss of View"*

Man in the Middle

Adversaries with privileged network access may seek to modify network traffic in real time using man-in-the-middle (MITM) attacks. This type of attack allows the adversary to intercept traffic to

and/or from a particular device on the network. If a MITM attack is established, then the adversary has the ability to block, log, modify, or inject traffic into the communication stream. There are several ways to accomplish this attack, but some of the most-common are Address Resolution Protocol (ARP) poisoning and the use of a proxy. A MITM attack may allow an adversary to perform the following attacks: Block Reporting Message, Modify Parameter, Unauthorized Command Message, Spoof Reporting Message

The tag is: *misp-galaxy:mitre-ics-techniques="Man in the Middle"*

Table 7511. Table References

Manipulate I/O Image

Adversaries may manipulate the I/O image of PLCs through various means to prevent them from functioning as expected. Methods of I/O image manipulation may include overriding the I/O table via direct memory manipulation or using the override function used for testing PLC programs. During the PLC scan cycle, the state of the actual physical inputs is copied to a portion of the PLC memory, commonly called the input image table. When the program is scanned, it examines the input image table to read the state of a physical input. When the logic determines the state of a physical output, it writes to a portion of the PLC memory commonly called the output image table. The output image may also be examined during the program scan. To update the physical outputs, the output image table contents are copied to the physical outputs after the program is scanned. One of the unique characteristics of PLCs is their ability to override the status of a physical discrete input or to override the logic driving a physical output coil and force the output to a desired status.

The tag is: *misp-galaxy:mitre-ics-techniques="Manipulate I/O Image"*

Table 7512. Table References

Manipulation of Control

Adversaries may manipulate physical process control within the industrial environment. Methods

of manipulating control can include changes to set point values, tags, or other parameters. Adversaries may manipulate control systems devices or possibly leverage their own, to communicate with and command physical control processes. The duration of manipulation may be temporary or longer sustained, depending on operator detection. Methods of Manipulation of Control include: Man-in-the-middle, Spoof command message, Changing setpoints

The tag is: *misp-galaxy:mitre-ics-techniques="Manipulation of Control"*

Table 7513. Table References

In addition, Stuxnet can apply inappropriate command sequences or parameters to cause damage to property.]

Masquerading

Adversaries may use masquerading to disguise a malicious application or executable as another file, to avoid operator and engineer suspicion. Possible disguises of these masquerading files can include commonly found programs, expected vendor executables and configuration files, and other commonplace application and naming conventions. By impersonating expected and vendor-relevant files and applications, operators and engineers may not notice the presence of the underlying malicious content and possibly end up running those masquerading as legitimate functions. Applications and other files commonly found on Windows systems or in engineering workstations have been impersonated before. This can be as simple as renaming a file to effectively disguise it in the ICS environment.

The tag is: *misp-galaxy:mitre-ics-techniques="Masquerading"*

Modify Alarm Settings

Adversaries may modify alarm settings to prevent alerts that may inform operators of their presence or to prevent responses to dangerous and unintended scenarios. Reporting messages are a standard part of data acquisition in control systems. Reporting messages are used as a way to transmit system state information and acknowledgements that specific actions have occurred. These messages provide vital information for the management of a physical process, and keep

operators, engineers, and administrators aware of the state of system devices and physical processes. If an adversary is able to change the reporting settings, certain events could be prevented from being reported. This type of modification can also prevent operators or devices from performing actions to keep the system in a safe state. If critical reporting messages cannot trigger these actions then a Impact could occur. In ICS environments, the adversary may have to use Alarm Suppression or contend with multiple alarms and/or alarm propagation to achieve a specific goal to evade detection or prevent intended responses from occurring. Methods of suppression often rely on modification of alarm settings, such as modifying in memory code to fixed values or tampering with assembly level instruction code. In the Maroochy Attack, the adversary disabled alarms at four pumping stations. This caused alarms to not be reported to the central computer.

Modify Control Logic

Adversaries may place malicious code in a system, which can cause the system to malfunction by modifying its control logic. Control system devices use programming languages (e.g. relay ladder logic) to control physical processes by affecting actuators, which cause machines to operate, based on environment sensor readings. These devices often include the ability to perform remote control logic updates. Program code is normally edited in a vendor-specific Integrated Development Environment (IDE) that relies on proprietary tools and features. These IDEs allow an engineer to perform host target development and may have the ability to run the code on the machine it is programmed for. The IDE will transmit the control logic to the testing device, and will perform the required device-specific functions to apply the changes and make them active. An adversary may attempt to use this host target IDE to modify device control logic. Even though proprietary tools are often used to edit and update control logic, the process can usually be reverse-engineered and reproduced with open-source tools. An adversary can de-calibrate a sensor by removing functions in control logic that account for sensor error. This can be used to change a control process without actually spoofing command messages to a controller or device. It is believed this process happened in the lesser known over-pressurizer attacks build into Stuxnet. Pressure sensors are not perfect at translating pressure into an analog output signal, but their errors can be corrected by calibration. The pressure controller can be told what the “real” pressure is for given analog signals and then automatically linearize the measurement to what would be the “real” pressure. If the linearization is overwritten by malicious code on the S7-417 controller, analog pressure readings will be “corrected” during the attack by the pressure controller, which then interprets all analog pressure readings as perfectly normal pressure no matter how high or low their analog values are. The pressure controller then acts accordingly by never opening the stage exhaust valves. In the meantime, actual pressure keeps rising. In the Maroochy Attack, Vitek Boden gained remote computer access to the control system and altered data so that whatever function should have

occurred at affected pumping stations did not occur or occurred in a different way. The software program installed in the laptop was one developed by Hunter Watertech for its use in changing configurations in the PDS computers. This ultimately led to 800,000 liters of raw sewage being spilled out into the community.

The tag is: *misp-galaxy:mitre-ics-techniques="Modify Control Logic"*

Modify Parameter

Adversaries may modify parameters used to instruct industrial control system devices. These devices operate via programs that dictate how and when to perform actions based on such parameters. Such parameters can determine the extent to which an action is performed and may specify additional options. For example, a program on a control system device dictating motor processes may take a parameter defining the total number of seconds to run that motor. An adversary can potentially modify these parameters to produce an outcome outside of what was intended by the operators. By modifying system and process critical parameters, the adversary may cause Impact to equipment and/or control processes. Modified parameters may be turned into dangerous, out-of-bounds, or unexpected values from typical operations. For example, specifying that a process run for more or less time than it should, or dictating an unusually high, low, or invalid value as a parameter. In the Maroochy Attack, Vitek Boden gained remote computer access to the control system and altered data so that whatever function should have occurred at affected pumping stations did not occur or occurred in a different way. The software program installed in the laptop was one developed by Hunter Watertech for its use in changing configurations in the PDS computers. This ultimately led to 800,000 liters of raw sewage being spilled out into the community.

Module Firmware

Adversaries may install malicious or vulnerable firmware onto modular hardware devices. Control system devices often contain modular hardware devices. These devices may have their own set of firmware that is separate from the firmware of the main control system equipment. This technique is similar to System Firmware, but is conducted on other system components that may not have the same capabilities or level of integrity checking. Although it results in a device re-image, malicious device firmware may provide persistent access to remaining devices. An easy point of access for an adversary is the Ethernet card, which may have its own CPU, RAM, and operating system. The adversary may attack and likely exploit the computer on an Ethernet card. Exploitation of the Ethernet card computer may enable the adversary to accomplish additional attacks, such as the following: Delayed Attack - The adversary may stage an attack in advance and choose when to launch it, such as at a particularly damaging time. Brick the Ethernet Card - Malicious firmware may be programmed to result in an Ethernet card failure, requiring a factory return. Random Attack or Failure - The adversary may load malicious firmware onto multiple field devices. Execution of an attack and the time it occurs is generated by a pseudo-random number generator. A Field Device Worm - The adversary may choose to identify all field devices of the same model, with the end goal of performing a device-wide compromise. Attack Other Cards on the Field Device - Although it is not the most important module in a field device, the Ethernet card is most accessible to the adversary and malware. Compromise of the Ethernet card may provide a more direct route to compromising other modules, such as the CPU module.

The tag is: *misp-galaxy:mitre-ics-techniques="Module Firmware"*

Monitor Process State

Adversaries may gather information about the physical process state. This information may be used to gain more information about the process itself or used as a trigger for malicious actions. The sources of process state information may vary such as, OPC tags, historian data, specific PLC block information, or network traffic.

The tag is: *misp-galaxy:mitre-ics-techniques="Monitor Process State"*

https://nvlpubs.nist.gov/nistpubs/SpecialPublications/NIST.SP.800-82r2.pdf

Network Connection Enumeration

Adversaries may perform network connection enumeration to discover information about device communication patterns. If an adversary can inspect the state of a network connection with tools, such as netstat, in conjunction with System Firmware, then they can determine the role of certain devices on the network. The adversary can also use Network Sniffing to watch network traffic for details about the source, destination, protocol, and content.

The tag is: *misp-galaxy:mitre-ics-techniques="Network Connection Enumeration"*

Table 7520. Table References

Network Service Scanning

Network Service Scanning is the process of discovering services on networked systems. This can be achieved through a technique called port scanning or probing. Port scanning interacts with the TCP/IP ports on a target system to determine whether ports are open, closed, or filtered by a firewall. This does not reveal the service that is running behind the port, but since many common services are run on specific port numbers, the type of service can be assumed. More in-depth testing includes interaction with the actual service to determine the service type and specific version. One of the most-popular tools to use for Network Service Scanning is Nmap. An adversary may attempt to gain information about a target device and its role on the network via Network Service Scanning techniques, such as port scanning. Network Service Scanning is useful for determining potential vulnerabilities in services on target devices. Network Service Scanning is closely tied to. Scanning ports can be noisy on a network. In some attacks, adversaries probe for specific ports using custom tools. This was specifically seen in the Triton and PLC-Blaster attacks.

The tag is: *misp-galaxy:mitre-ics-techniques="Network Service Scanning"*

Table 7521. Table References

Links
https://nvlpubs.nist.gov/nistpubs/SpecialPublications/NIST.SP.800-82r2.pdf

Network Sniffing

Network sniffing is the practice of using a network interface on a computer system to monitor or capture information1 regardless of whether it is the specified destination for the information. An adversary may attempt to sniff the traffic to gain information about the target. This information can vary in the level of importance. Relatively unimportant information is general communications to and from machines. Relatively important information would be login information. User credentials may be sent over an unencrypted protocol, such as Telnet, that can be captured and

obtained through network packet analysis. Network sniffing can be a way to discover information for Control Device Identification. In addition, ARP and Domain Name Service (DNS) poisoning can be used to capture credentials to websites, proxies, and internal systems by redirecting traffic to an adversary.

The tag is: *misp-galaxy:mitre-ics-techniques="Network Sniffing"*

Point & Tag Identification

Adversaries may collect point and tag values to gain a more comprehensive understanding of the process environment. Points may be values such as inputs, memory locations, outputs or other process specific variables.1 Tags are the identifiers given to points for operator convenience. Collecting such tags provides valuable context to environmental points and enables an adversary to map inputs, outputs, and other values to their control processes. Understanding the points being collected may inform an adversary on which processes and values to keep track of over the course of an operation.

The tag is: *misp-galaxy:mitre-ics-techniques="Point & Tag Identification"*

Program Download

Adversaries may perform a program download to load malicious or unintended program logic on a device as a method of persistence or to disrupt response functions or process control. Program download onto devices, such as PLCs, allows adversaries to implement custom logic. Malicious PLC programs may be used to disrupt physical processes or enable adversary persistence. The act of a program download will cause the PLC to enter a STOP operation state, which may prevent response functions from operating correctly.

The tag is: *misp-galaxy:mitre-ics-techniques="Program Download"*

Program Organization Units

Program Organizational Units (POUs) are block structures used within PLC programming to create programs and projects. POUs can be used to hold user programs written in IEC 61131-3 languages: Structured text, Instruction list, Function block, and Ladder logic. They can also provide additional functionality, such as establishing connections between the PLC and other devices using TCON. Stuxnet uses a simple code-prepending infection technique to infect Organization Blocks (OB). For example, the following sequence of actions is performed when OB1 is infected: Increase the size of the original block. Write malicious code to the beginning of the block. Insert the original OB1 code after the malicious code.

The tag is: *misp-galaxy:mitre-ics-techniques="Program Organization Units"*

Table 7525. Table References

Program Upload

Adversaries may attempt to upload a program from a PLC to gather information about an industrial process. Uploading a program may allow them to acquire and study the underlying logic. Methods of program upload include vendor software, which enables the user to upload and read a program running on a PLC. This software can be used to upload the target program to a workstation, jump box, or an interfacing device.

The tag is: *misp-galaxy:mitre-ics-techniques="Program Upload"*

Table 7526. Table References

Links
https://www.wired.com/images_blogs/threatlevel/2010/11/w32_stuxnet_dossier.pdf

Project File Infection

Adversaries may attempt to infect project files with malicious code. These project files may consist of objects, program organization units, variables such as tags, documentation, and other configurations needed for PLC programs to function. Using built in functions of the engineering software, adversaries may be able to download an infected program to a PLC in the operating environment enabling further execution and persistence techniques. Adversaries may export their own code into project files with conditions to execute at specific intervals.3 Malicious programs allow adversaries control of all aspects of the process enabled by the PLC. Once the project file is downloaded to a PLC the workstation device may be disconnected with the infected project file still executing.

The tag is: *misp-galaxy:mitre-ics-techniques="Project File Infection"*

Remote File Copy

Adversaries may copy files from one system to another to stage adversary tools or other files over the course of an operation. Copying of files may also be performed laterally between internal victim systems to support Lateral Movement with remote Execution using inherent file sharing protocols such as file sharing over SMB to connected network shares. In control systems environments, malware may use SMB and other file sharing protocols to move laterally through industrial networks.

The tag is: *misp-galaxy:mitre-ics-techniques="Remote File Copy"*

Remote System Discovery

Remote System Discovery is the process of identifying the presence of hosts on a network1, and details about them. This process is common to network administrators validating the presence of machines and services, as well as adversaries mapping out a network for future-attack targets. An adversary may attempt to gain information about the target network via network enumeration techniques such as port scanning. One of the most popular tools for enumeration is Nmap. Remote System Discovery allows adversaries to map out hosts on the network as well as the TCP/IP ports that are open, closed, or filtered. Remote System Discovery tools also aid in by attempting to connect to the service and determine its exact version. The adversary may use this information to pick an exploit for a particular version if a known vulnerability exists.

The tag is: *misp-galaxy:mitre-ics-techniques="Remote System Discovery"*

https://nvlpubs.nist.gov/nistpubs/SpecialPublications/NIST.SP.800-82r2.pdf

Replication Through Removable Media

Adversaries may move onto systems, such as those separated from the enterprise network, by copying malware to removable media which is inserted into the control systems environment. The adversary may rely on unknowing trusted third parties, such as suppliers or contractors with access privileges, to introduce the removable media. This technique enables initial access to target devices that never connect to untrusted networks, but are physically accessible. Operators of the German nuclear power plant, Gundremmingen, discovered malware on a facility computer not connected to the internet. The malware included Conficker and W32.Ramnit, which were also found on eighteen removable disk drives in the facility. The plant has since checked for infection and cleaned up more than 1,000 computers.9 An ESET researcher commented that internet

disconnection does not guarantee system safety from infection or payload execution.

Rogue Master Device

Adversaries may setup a rogue master to leverage control server functions to communicate with slave devices. A rogue master device can be used to send legitimate control messages to other control system devices, affecting processes in unintended ways. It may also be used to disrupt network communications by capturing and receiving the network traffic meant for the actual master device. Impersonating a master device may also allow an adversary to avoid detection. In the Maroochy Attack, Vitek Boden falsified network addresses in order to send false data and instructions to pumping stations.

https://technet.microsoft.com/en-us/library/ee791851.aspx

Role Identification

Adversaries may perform role identification of devices involved with physical processes of interest in a target control system. Control systems devices often work in concert to control a physical process. Each device can have one or more roles that it performs within that control process. By collecting this role-based data, an adversary can construct a more targeted attack. For example, a power generation plant may have unique devices such as one that monitors power output of a generator and another that controls the speed of a turbine. Examining devices roles allows the adversary to observe how the two devices work together to monitor and control a physical process. Understanding the role of a target device can inform the adversary's decision on what action to take, in order to cause Impact and influence or disrupt the integrity of operations. Furthermore, an adversary may be able to capture control system protocol traffic. By studying this traffic, the adversary may be able to determine which devices are outstations, and which are masters. Understanding of master devices and their role within control processes can enable the use of Rogue Master Device.

The tag is: *misp-galaxy:mitre-ics-techniques="Role Identification"*

Rootkit

Adversaries may deploy rootkits to hide the presence of programs, files, network connections, services, drivers, and other system components. Rootkits are programs that hide the existence of malware by intercepting and modifying operating-system API calls that supply system information. Rootkits or rootkit-enabling functionality may reside at the user or kernel level in the operating system, or lower. Firmware rootkits that affect the operating system yield nearly full control of the system. While firmware rootkits are normally developed for the main processing board, they can also be developed for I/O that can be attached to the asset. Compromise of this firmware allows the modification of all of the process variables and functions the module engages in. This may result in commands being disregarded and false information being fed to the main device. By tampering with device processes, an adversary may inhibit its expected response functions and possibly enable Impact.

The tag is: *misp-galaxy:mitre-ics-techniques="Rootkit"*

https://technet.microsoft.com/en-us/library/ee791851.aspx

Screen Capture

Adversaries may attempt to perform screen capture of devices in the control system environment. Screenshots may be taken of workstations, HMIs, or other devices that display environment-relevant process, device, reporting, alarm, or related data. These device displays may reveal information regarding the ICS process, layout, control, and related schematics. In particular, an HMI can provide a lot of important industrial process information. Analysis of screen captures may provide the adversary with an understanding of intended operations and interactions between critical devices.

https://www.symantec.com/security-center/writeup/2017-030708-4403-99

Scripting

Adversaries may use scripting languages to execute arbitrary code in the form of a pre-written script or in the form of user-supplied code to an interpreter. Scripting languages are programming languages that differ from compiled languages, in that scripting languages use an interpreter, instead of a compiler. These interpreters read and compile part of the source code just before it is executed, as opposed to compilers, which compile each and every line of code to an executable file. Scripting allows software developers to run their code on any system where the interpreter exists. This way, they can distribute one package, instead of precompiling executables for many different systems. Scripting languages, such as Python, have their interpreters shipped as a default with many Linux distributions. In addition to being a useful tool for developers and administrators, scripting language interpreters may be abused by the adversary to execute code in the target environment. Due to the nature of scripting languages, this allows for weaponized code to be deployed to a target easily, and leaves open the possibility of on-the-fly scripting to perform a task.

Serial Connection Enumeration

Adversaries may perform serial connection enumeration to gather situational awareness after gaining access to devices in the OT network. Control systems devices often communicate to each other via various types of serial communication mediums. These serial communications are used to

facilitate informational communication, as well as commands. Serial Connection Enumeration differs from I/O Module Discovery, as I/O modules are auxiliary systems to the main system, and devices that are connected via serial connection are normally discrete systems. While IT and OT networks may work in tandem, the exact structure of the OT network may not be discernible from the IT network alone. After gaining access to a device on the OT network, an adversary may be able to enumerate the serial connections. From this perspective, the adversary can see the specific physical devices to which the compromised device is connected to. This gives the adversary greater situational awareness and can influence the actions that the adversary can take in an attack.

The tag is: *misp-galaxy:mitre-ics-techniques="Serial Connection Enumeration"*

Service Stop

Adversaries may stop or disable services on a system to render those services unavailable to legitimate users. Stopping critical services can inhibit or stop response to an incident or aid in the adversary's overall objectives to cause damage to the environment. Services may not allow for modification of their data stores while running. Adversaries may stop services in order to conduct Data Destruction.

Spearphishing Attachment

Adversaries may use a spearphishing attachment, a variant of spearphishing, as a form of a social engineering attack against specific targets. Spearphishing attachments are different from other forms of spearphishing in that they employ malware attached to an email. All forms of spearphishing are electronically delivered and target a specific individual, company, or industry. In this scenario, adversaries attach a file to the spearphishing email and usually rely upon User Execution to gain execution and access.

The tag is: *misp-galaxy:mitre-ics-techniques="Spearphishing Attachment"*

Standard Application Layer Protocol

Adversaries may establish command and control capabilities over commonly used application layer protocols such as HTTP(S), OPC, RDP, telnet, DNP3, and modbus. These protocols may be used to disguise adversary actions as benign network traffic. Standard protocols may be seen on their associated port or in some cases over a non-standard port. Adversaries may use these protocols to reach out of the network for command and control, or in some cases to other infected devices within the network.

The tag is: *misp-galaxy:mitre-ics-techniques="Standard Application Layer Protocol"*

Supply Chain Compromise

Adversaries may perform supply chain compromise to gain control systems environment access by means of infected products, software, and workflows. Supply chain compromise is the manipulation of products, such as devices or software, or their delivery mechanisms before receipt by the end consumer. Adversary compromise of these products and mechanisms is done for the goal of data or system compromise, once infected products are introduced to the target environment. Supply chain compromise can occur at all stages of the supply chain, from manipulation of development tools and environments to manipulation of developed products and tools distribution mechanisms. This may involve the compromise and replacement of legitimate software and patches, such as on third party or vendor websites. Targeting of supply chain compromise can be done in attempts to infiltrate the environments of a specific audience. In control systems environments with assets in both the IT and OT networks, it is possible a supply chain compromise affecting the IT environment could enable further access to the OT environment. F-Secure Labs analyzed the approach the adversary used to compromise victim systems with Havex. The adversary planted trojanized software installers available on legitimate ICS/SCADA vendor websites. After being downloaded, this software infected the host computer with a Remote Access Trojan (RAT).

The tag is: *misp-galaxy:mitre-ics-techniques="Supply Chain Compromise"*

System Firmware

System firmware on modern assets is often designed with an update feature. Older device firmware may be factory installed and require special reprograming equipment. When available, the firmware update feature enables vendors to remotely patch bugs and perform upgrades. Device firmware updates are often delegated to the user and may be done using a software update package. It may also be possible to perform this task over the network. An adversary may exploit the firmware update feature on accessible devices to upload malicious or out-of-date firmware. Malicious modification of device firmware may provide an adversary with root access to a device, given firmware is one of the lowest programming abstraction layers. In the 2015 attack on the Ukranian power grid, the adversaries gained access to the control networks of three different energy companies. The adversaries developed malicious firmware for the serial-to-ethernet devices which rendered them inoperable and severed connections between the control center and the substation.

The tag is: *misp-galaxy:mitre-ics-techniques="System Firmware"*

https://nvlpubs.nist.gov/nistpubs/SpecialPublications/NIST.SP.800-82r2.pdf

Theft of Operational Information

Adversaries may steal operational information on a production environment as a direct mission outcome for personal gain or to inform future operations. This information may include design documents, schedules, rotational data, or similar artifacts that provide insight on operations. In the Bowman Dam incident, adversaries probed systems for operational data.

The tag is: *misp-galaxy:mitre-ics-techniques="Theft of Operational Information"*

Unauthorized Command Message

Adversaries may send unauthorized command messages to instruct control systems devices to perform actions outside their expected functionality for process control. Command messages are used in ICS networks to give direct instructions to control systems devices. If an adversary can send an unauthorized command message to a control system, then it can instruct the control systems device to perform an action outside the normal bounds of the device's actions. An adversary could potentially instruct a control systems device to perform an action that will cause an Impact. In the Maroochy Attack, the adversary used a dedicated analog two-way radio system to send false data and instructions to pumping stations and the central computer. In the 2015 attack on the Ukranian power grid, the adversaries gained access to the control networks of three different energy companies. The adversaries used valid credentials to seize control of operator workstations and access a distribution management system (DMS) client application via a VPN. The adversaries used these tools to issue unauthorized commands to breakers at substations which caused a loss of power to over 225,000 customers over various areas.

The tag is: *misp-galaxy:mitre-ics-techniques="Unauthorized Command Message"*

User Execution

Adversaries may rely on a targeted organizations' user interaction for the execution of malicious code. User interaction may consist of installing applications, opening email attachments, or granting higher permissions to documents. Adversaries may embed malicious code or visual basic code into files such as Microsoft Word and Excel documents or software installers. Execution of this code requires that the user enable scripting or write access within the document. Embedded code may not always be noticeable to the user especially in cases of trojanized software

The tag is: *misp-galaxy:mitre-ics-techniques="User Execution"*

https://www.youtube.com/watch?v=eywmb7UDODY&feature=youtu.be&t=939
https://securelist.com/bad-rabbit-ransomware/82851/

Utilize/Change Operating Mode

Adversaries may place controllers into an alternate mode of operation to enable configuration setting changes for evasive code execution or to inhibit device functionality. Programmable controllers typically have several modes of operation. These modes can be broken down into three main categories: program run, program edit, and program write. Each of these modes puts the device in a state in which certain functions are available. For instance, the program edit mode allows alterations to be made to the user program while the device is still online. By driving a device into an alternate mode of operation, an adversary has the ability to change configuration settings in such a way to cause a Impact to equipment and/or industrial process associated with the targeted device. An adversary may also use this alternate mode to execute arbitrary code which could be used to evade defenses.

The tag is: *misp-galaxy:mitre-ics-techniques="Utilize/Change Operating Mode"*

Valid Accounts

Adversaries may steal the credentials of a specific user or service account using credential access techniques. In some cases, default credentials for control system devices may be publicly available. Compromised credentials may be used to bypass access controls placed on various resources on hosts and within the network, and may even be used for persistent access to remote systems. Compromised and default credentials may also grant an adversary increased privilege to specific systems and devices or access to restricted areas of the network. Adversaries may choose not to use malware or tools, in conjunction with the legitimate access those credentials provide, to make it harder to detect their presence or to control devices and send legitimate commands in an unintended way. Adversaries may also create accounts, sometimes using predefined account names and passwords, to provide a means of backup access for persistence. The overlap of credentials and permissions across a network of systems is of concern because the adversary may be able to pivot across accounts and systems to reach a high level of access (i.e., domain or enterprise administrator) and possibly between the enterprise and operational technology environments. Adversaries may be able to leverage valid credentials from one system to gain access to another system. In the 2015 attack on the Ukranian power grid, the adversaries used valid credentials to interact directly with the client application of the distribution management system (DMS) server via a VPN and native remote access services to access employee workstations hosting HMI applications.2 The adversaries caused outages at three different energy companies, causing loss of power to over 225,000 customers over various areas.

The tag is: *misp-galaxy:mitre-ics-techniques="Valid Accounts"*

Wireless Compromise

Adversaries may perform wireless compromise as a method of gaining communications and unauthorized access to a wireless network. Access to a wireless network may be gained through the compromise of a wireless device.12 Adversaries may also utilize radios and other wireless communication devices on the same frequency as the wireless network. Wireless compromise can be done as an initial access vector from a remote distance. A joint case study on the Maroochy Shire Water Services event examined the attack from a cyber security perspective.3 The adversary disrupted Maroochy Shire's radio-controlled sewage system by driving around with stolen radio equipment and issuing commands with them. Boden used a two-way radio to communicate with and set the frequencies of Maroochy Shire's repeater stations. A Polish student used a modified TV remote controller to gain access to and control over the Lodz city tram system in Poland. The remote controller device allowed the student to interface with the tram's network to modify track settings and override operator control. The adversary may have accomplished this by aligning the controller to the frequency and amplitude of IR control protocol signals. The controller then enabled initial access to the network, allowing the capture and replay of tram signals

Stealth Falcon - G0038

[Stealth Falcon](https://attack.mitre.org/groups/G0038) is a threat group that has conducted targeted spyware attacks against Emirati journalists, activists, and dissidents since at least 2012. Circumstantial evidence suggests there could be a link between this group and the United Arab Emirates (UAE) government, but that has not been confirmed. (Citation: Citizen Lab Stealth Falcon

Gamaredon Group - G0047

[Gamaredon Group](https://attack.mitre.org/groups/G0047) is a suspected Russian cyber espionage threat group that has targeted military, NGO, judiciary, law enforcement, and non-profit organizations in Ukraine since at least 2013. The name [Gamaredon Group](https://attack.mitre.org/groups/G0047) comes from a misspelling of the word "Armageddon", which was detected in the adversary's early campaigns.(Citation: Palo Alto Gamaredon Feb 2017)(Citation: TrendMicro Gamaredon April 2020)(Citation: ESET Gamaredon June 2020)(Citation: Symantec Shuckworm January 2022)(Citation: Microsoft Actinium February 2022)

In November 2021, the Ukrainian government publicly attributed [Gamaredon Group](https://attack.mitre.org/groups/G0047) to Russia's Federal Security Service (FSB) Center 18.(Citation: Bleepingcomputer Gamardeon FSB November 2021)(Citation: Microsoft Actinium February 2022)

Charming Kitten - G0058

[Charming Kitten](https://attack.mitre.org/groups/G0058) is an Iranian cyber espionage group that has been active since approximately 2014. They appear to focus on targeting individuals of interest to Iran who work in academic research, human rights, and media, with most victims having been located in Iran, the US, Israel, and the UK. [[Charming Kitten](https://attack.mitre.org/groups/G0058) often tries to access private email and Facebook accounts, and sometimes establishes a foothold on victim computers as a secondary objective. The group's TTPs overlap extensively with another group, [Magic Hound](https://attack.mitre.org/groups/G0059), resulting in reporting that may not distinguish between the two groups' activities.(Citation: ClearSky Charming Kitten Dec 2017)

Volt Typhoon - G1017

[Volt Typhoon](https://attack.mitre.org/groups/G1017) is a People's Republic of China (PRC) state-sponsored actor that has been active since at least 2021 primarily targeting critical infrastructure organizations in the US and its territories including Guam. [Volt Typhoon](https://attack.mitre.org/groups/G1017)'s targeting and pattern of behavior have been assessed as pre-positioning to enable lateral movement to operational technology (OT) assets for potential destructive or disruptive attacks. [Volt Typhoon](https://attack.mitre.org/groups/G1017) has emphasized stealth in operations using web shells, living-off-the-land (LOTL) binaries, hands on keyboard activities, and stolen credentials.(Citation: CISA AA24-038A PRC Critical Infrastructure February 2024)(Citation: Microsoft Volt Typhoon May 2023)(Citation: Joint Cybersecurity Advisory Volt Typhoon June 2023)(Citation: Secureworks BRONZE SILHOUETTE May 2023)

Sharpshooter - G0104

Operation [Sharpshooter](https://attack.mitre.org/groups/G0104) is the name of a cyber espionage campaign discovered in October 2018 targeting nuclear, defense, energy, and financial companies. Though overlaps between this adversary and [Lazarus Group](https://attack.mitre.org/groups/G0032) have been noted, definitive links have not been established.(Citation: McAfee Sharpshooter December 2018)

APT34 - G0057

APT34 is an Iranian cyber espionage group that has been active since at least 2014. The group has targeted a variety of industries, including financial, government, energy, chemical, and telecommunications, and has largely focused its operations within the Middle East. FireEye assesses that the group works on behalf of the Iranian government based on infrastructure details that contain references to Iran, use of Iranian infrastructure, and targeting that aligns with nation-state interests. APT34 loosely aligns with public reporting related to OilRig, but may not wholly align due to companies tracking threat groups in different ways. (Citation: FireEye APT34 Dec 2017)

APT37 - G0067

[APT37](https://attack.mitre.org/groups/G0067) is a North Korean state-sponsored cyber espionage group that has been active since at least 2012. The group has targeted victims primarily in South Korea, but also in Japan, Vietnam, Russia, Nepal, China, India, Romania, Kuwait, and other parts of the Middle East. [APT37](https://attack.mitre.org/groups/G0067) has also been linked to the following campaigns between 2016-2018: Operation Daybreak, Operation Erebus, Golden Time, Evil New Year, Are you Happy?, FreeMilk, North Korean Human Rights, and Evil New Year 2018.(Citation: FireEye APT37 Feb 2018)(Citation: Securelist ScarCruft Jun 2016)(Citation: Talos Group123)

North Korean group definitions are known to have significant overlap, and some security researchers report all North Korean state-sponsored cyber activity under the name [Lazarus Group](https://attack.mitre.org/groups/G0032) instead of tracking clusters or subgroups.

FIN7 - G0046

[FIN7](https://attack.mitre.org/groups/G0046) is a financially-motivated threat group that has been active since 2013. [FIN7](https://attack.mitre.org/groups/G0046) has primarily targeted the retail, restaurant, hospitality, software, consulting, financial services, medical equipment, cloud services, media, food and beverage, transportation, and utilities industries in the U.S. A portion of [FIN7](https://attack.mitre.org/groups/G0046) was run out of a front company called Combi Security and often used point-of-sale malware for targeting efforts. Since 2020, [FIN7](https://attack.mitre.org/groups/G0046) shifted operations to a big game hunting (BGH) approach including use of [REvil](https://attack.mitre.org/software/S0496) ransomware and their own Ransomware as a Service (RaaS), Darkside. FIN7 may be linked to the [Carbanak](https://attack.mitre.org/groups/G0008) Group, but there appears to be several groups using [Carbanak](https://attack.mitre.org/software/S0030) malware and are therefore tracked separately.(Citation: FireEye FIN7 March 2017)(Citation: FireEye FIN7 April 2017)(Citation: FireEye CARBANAK June 2017)(Citation: FireEye FIN7 Aug 2018)(Citation: CrowdStrike Carbon Spider August 2021)(Citation: Mandiant FIN7 Apr 2022)

Kimsuky - G0094

[Kimsuky](https://attack.mitre.org/groups/G0094) is a North Korea-based cyber espionage group that has been active since at least 2012. The group initially focused on targeting South Korean government entities, think tanks, and individuals identified as experts in various fields, and expanded its operations to include the UN and the government, education, business services, and manufacturing sectors in the United States, Japan, Russia, and Europe. [Kimsuky](https://attack.mitre.org/groups/G0094) has focused its intelligence collection activities on foreign policy and national security issues related to the Korean peninsula, nuclear policy, and sanctions. [Kimsuky](https://attack.mitre.org/groups/G0094) operations have overlapped with those of other North Korean cyber espionage actors likely as a result of ad hoc collaborations or other limited resource sharing.(Citation: EST Kimsuky April 2019)(Citation: Cybereason Kimsuky November 2020)(Citation: Malwarebytes Kimsuky June 2021)(Citation: CISA AA20-301A Kimsuky)(Citation: Mandiant APT43 March 2024)(Citation: Proofpoint TA427 April 2024)

[Kimsuky](https://attack.mitre.org/groups/G0094) was assessed to be responsible for the 2014 Korea Hydro & Nuclear Power Co. compromise; other notable campaigns include Operation STOLEN PENCIL (2018), Operation Kabar Cobra (2019), and Operation Smoke Screen (2019).(Citation: Netscout Stolen Pencil Dec 2018)(Citation: EST Kimsuky SmokeScreen April 2019)(Citation: AhnLab Kimsuky Kabar Cobra Feb 2019)

North Korean group definitions are known to have significant overlap, and some security researchers report all North Korean state-sponsored cyber activity under the name [Lazarus Group](https://attack.mitre.org/groups/G0032) instead of tracking clusters or subgroups.

In 2023, [Kimsuky](https://attack.mitre.org/groups/G0094) has used commercial large language models to assist with vulnerability research, scripting, social engineering and reconnaissance.(Citation: MSFT-AI)

OilRig - G0049

[OilRig](https://attack.mitre.org/groups/G0049) is a suspected Iranian threat group that has targeted Middle Eastern and international victims since at least 2014. The group has targeted a variety of sectors, including financial, government, energy, chemical, and telecommunications. It appears the group carries out supply chain attacks, leveraging the trust relationship between organizations to attack their primary targets. The group works on behalf of the Iranian government based on infrastructure details that contain references to Iran, use of Iranian infrastructure, and targeting that aligns with nation-state interests.(Citation: FireEye APT34 Dec 2017)(Citation: Palo Alto OilRig April 2017)(Citation: ClearSky OilRig Jan 2017)(Citation: Palo Alto OilRig May 2016)(Citation: Palo Alto OilRig Oct 2016)(Citation: Unit42 OilRig Playbook 2023)(Citation: Unit 42 QUADAGENT July 2018)

Black Basta - S1070

[Black Basta](https://attack.mitre.org/software/S1070) is ransomware written in C++ that has been offered within the ransomware-as-a-service (RaaS) model since at least April 2022; there are variants that target Windows and VMWare ESXi servers. [Black Basta](https://attack.mitre.org/software/S1070) operations have included the double extortion technique where in addition to demanding ransom for decrypting the files of targeted organizations the cyber actors also threaten to post sensitive information to a leak site if the ransom is not paid. [Black Basta](https://attack.mitre.org/software/S1070) affiliates have targeted multiple high-value organizations, with the largest number of victims based in the U.S. Based on similarities in TTPs, leak sites, payment sites, and negotiation tactics, security researchers assess the [Black Basta](https://attack.mitre.org/software/S1070) RaaS operators could include current or former members of the [Conti](https://attack.mitre.org/software/S0575) group.(Citation: Palo Alto Networks Black Basta August 2022)(Citation: Deep Instinct Black Basta August 2022)(Citation: Minerva Labs Black Basta May 2022)(Citation: Avertium Black Basta June 2022)(Citation: NCC Group Black Basta June 2022)(Citation: Cyble Black Basta May 2022)

cd00r - S1204

[cd00r](https://attack.mitre.org/software/S1204) is an open-source backdoor for UNIX and UNIX-variant operating systems that was orginally released in 2000. [cd00r](https://attack.mitre.org/software/S1204) source code is primarily based on a packet-capturing program as it utilizes a sniffer to listen for specific sequences of network traffic or "secret knock" before executing the attacker's code.(Citation: Hartrell cd00r 2002)(Citation: Lumen J-Magic JAN 2025)

The tag is: *misp-galaxy:mitre-malware="cd00r - S1204"*

cd00r - S1204 is also known as:

COATHANGER - S1105

[COATHANGER](https://attack.mitre.org/software/S1105) is a remote access tool (RAT) targeting FortiGate networking appliances. First used in 2023 in targeted intrusions against military and government entities in the Netherlands along with other victims, [COATHANGER](https://attack.mitre.org/software/S1105) was disclosed in early 2024, with a high confidence assessment linking this malware to a state-sponsored entity in the People's Republic of China. [COATHANGER](https://attack.mitre.org/software/S1105) is delivered after gaining access to a FortiGate device, with in-the-wild observations linked to exploitation of CVE-2022-42475. The name [COATHANGER](https://attack.mitre.org/software/S1105) is based on a unique string in the malware used to encrypt configuration files on disk: <code>"She took his coat and hung it up"</code>.(Citation: NCSC-NL COATHANGER Feb 2024)

FjordPhantom - S1208

[FjordPhantom](https://attack.mitre.org/software/S1208) is a malicious Android application first discovered in September 2024 with targets in Southeast Asia, specifically Indonesia, Thailand, and Vietnam. [FjordPhantom](https://attack.mitre.org/software/S1208) was distributed through email and messaging applications. Once installed, the application launches a virtualization solution to steal important information, such as bank accounts, and to manipulate the user interface. The malicious activity from the virtualization solution runs alongside legitimate banking applications.(Citation: Promon FjordPhantom Oct2024)

NotPetya - S0368

[NotPetya](https://attack.mitre.org/software/S0368) is malware that was used by [Sandworm Team](https://attack.mitre.org/groups/G0034) in a worldwide attack starting on June 27, 2017. While [NotPetya](https://attack.mitre.org/software/S0368) appears as a form of ransomware, its main purpose was to destroy data and disk structures on compromised systems; the attackers never intended to make the encrypted data recoverable. As such, [NotPetya](https://attack.mitre.org/software/S0368) may be more appropriately thought of as a form of wiper malware. [NotPetya](https://attack.mitre.org/software/S0368) contains worm-like features to spread itself across a computer network using the SMBv1 exploits EternalBlue and EternalRomance.(Citation: Talos Nyetya June 2017)(Citation: US-CERT NotPetya 2017)(Citation: ESET Telebots June 2017)(Citation: US District Court Indictment GRU Unit 74455 October 2020)

Pikabot - S1145

[Pikabot](https://attack.mitre.org/software/S1145) is a backdoor used for initial access and follow-on tool deployment active since early 2023. [Pikabot](https://attack.mitre.org/software/S1145) is notable for extensive use of multiple encoding, encryption, and defense evasion mechanisms to evade defenses and avoid analysis. [Pikabot](https://attack.mitre.org/software/S1145) has some overlaps with [QakBot](https://attack.mitre.org/software/S0650), but insufficient evidence exists to definitively link these two malware families. [Pikabot](https://attack.mitre.org/software/S1145) is frequently used to deploy follow on tools such as [Cobalt Strike](https://attack.mitre.org/software/S0154) or ransomware variants.(Citation: Zscaler Pikabot 2023)(Citation: Elastic Pikabot 2024)(Citation: Logpoint Pikabot 2024)

LightSpy - S1185

First observed in 2018, LightSpy is a modular malware family that initially targeted iOS devices in Southern Asia before expanding to Android and macOS platforms. It consists of a downloader, a main executable that manages network communications, and functionality-specific modules, typically implemented as `.dylib` files (iOS, macOS) or `.apk` files (Android). LightSpy can collect VoIP call recordings, SMS messages, and credential stores, which are then exfiltrated to a command and control (C2) server.(Citation: MelikovBlackBerry LightSpy 2024)

Tor - S0183

[Tor](https://attack.mitre.org/software/S0183) is a software suite and network that provides increased anonymity on the Internet. It creates a multi-hop proxy network and utilizes multilayer encryption to protect both the message and routing information. [Tor](https://attack.mitre.org/software/S0183) utilizes "Onion Routing," in which messages are encrypted with multiple layers of encryption; at each step in the proxy network, the topmost layer is decrypted and the contents forwarded on to the next node until it reaches its destination. (Citation: Dingledine Tor The Second-

Generation Onion Router)

CrackMapExec - S0488

[CrackMapExec](https://attack.mitre.org/software/S0488), or CME, is a post-exploitation tool developed in Python and designed for penetration testing against networks. [CrackMapExec](https://attack.mitre.org/software/S0488) collects Active Directory information to conduct lateral movement through targeted networks.(Citation: CME Github September 2018)

NPPSPY - S1131

NPPSPY is an implementation of a theoretical mechanism first presented in 2004 for capturing credentials submitted to a Windows system via a rogue Network Provider API item. NPPSPY captures credentials following submission and writes them to a file on the victim system for follow-on exfiltration.(Citation: Huntress NPPSPY 2022)(Citation: Polak NPPSPY 2004)

NACE

version 2.1 - The Statistical Classification of Economic Activities in the European Community, commonly referred to as NACE (for the French term "nomenclature statistique des activités économiques dans la Communauté européenne"), is the industry standard classification system used in the European Union..

NACE is a cluster galaxy available in JSON format at **this location** The JSON format can be freely reused in your application or automatically enabled in MISP.
