# AN EXPLICIT HYBRID ESTIMATE FOR  $L(1/2 + it, \chi)$

GHAITH A. HIARY

ABSTRACT. An explicit hybrid estimate for  $L(1/2+it, \chi)$  is derived, where  $\chi$  is a Dirichlet character modulo  $q$ . The estimate applies when  $t$  is bounded away from zero, and is most effective when  $q$  is powerfull, yielding an explicit Weyl bound in this case. The estimate takes a particularly simple form if  $q$  is a sixth power. Several hybrid lemmas of van der Corput–Weyl type are presented.

### 1. INTRODUCTION

Let  $\chi$  be a Dirichlet character modulo q. Let  $L(1/2+it, \chi)$  be the corresponding Dirichlet L-function on the critical line. Let  $\tau(q)$  be the number of divisors of q. If  $|t| \geq 3$ , say, we define the analytic conductor of  $L(1/2 + it, \chi)$  to be  $\mathfrak{q} := q|t|$ .

We are interested in finding an explicit hybrid estimate for  $L(1/2+it, \chi)$  in terms of q and  $\tau(q)$ . Specifically, we would like to find constants c,  $\kappa_1$ ,  $\kappa_2$ ,  $\kappa_3$ , and  $t_0 \geq 3$ as small as possible, such that

<span id="page-0-2"></span>(1) 
$$
|L(1/2 + it, \chi)| \leq c \tau(q)^{\kappa_1} \mathfrak{q}^{\kappa_2} \log^{\kappa_3} \mathfrak{q}, \qquad (|t| \geq t_0).
$$

If  $|t| \leq t_0$ , then estimating  $L(1/2 + it, \chi)$  reduces, essentially, to bounding pure character sums. Barban, Linnik, and Tshudakov [\[1\]](#page-23-0) gave Big-O bounds for such sums, as well as some applications.

The convexity bound in our context is  $L(1/2+it, \chi) \ll \mathfrak{q}^{1/4}$ . This can be derived using the standard method of the approximate functional equation. Habsieger derived such an approximate equation in [\[4\]](#page-23-1). And we use this in §[7](#page-21-0) to prove that if  $\chi$  is a primitive character<sup>[1](#page-0-0)</sup> modulo  $q > 1$ , then we have the convexity bound

<span id="page-0-3"></span>(2) 
$$
|L(1/2 + it, \chi)| \le 124.46 \mathfrak{q}^{1/4}, \qquad (\mathfrak{q} \ge 10^9, |t| \ge \sqrt{q}).
$$

Previously, Rademacher [\[11\]](#page-23-2) derived the explicit bound

(3) 
$$
|L(\sigma+it,\chi)| \leq \left(\frac{q|1+\sigma+it|}{2\pi}\right)^{\frac{1+\eta-\sigma}{2}} \zeta(1+\eta),
$$

valid if  $0 < \eta \leq 1/2$ ,  $\sigma \leq 1 + \eta$ , and  $\chi \pmod{q}$  is primitive. This is nearly a convexity bound except for an additional  $\eta > 0$  in the exponent.

Using partial summation, we obtain an explicit bound applicable for any  $t$ . Specifically, if  $\chi$  is primitive modulo  $q > 1$ , then we obtain in §[7](#page-21-0) that

(4) 
$$
|L(1/2+it,\chi)| \leq 4q^{1/4}\sqrt{(|t|+1)\log q}.
$$

<span id="page-0-0"></span><sup>1</sup>We consider the principal character as neither primitive nor imprimitive.

The bound [\(4\)](#page-0-1) is weaker than the convexity bound in general, but it can be useful in the limited region where  $t$  is small.

Our main result is Theorem [1.2.](#page-1-0) This theorem supplies the first example of an explicit hybrid Weyl bound (i.e. with  $\kappa_2 = 1/6$  in [\(1\)](#page-0-2)) for an infinite set of Dirichlet L-functions; namely, the set of Dirichlet L-functions corresponding to powerfull moduli. Theorem [1.2](#page-1-0) takes a particularly simple form if q is a sixth power and  $\chi$ is primitive, yielding Corollary [1.1](#page-1-1) below.

<span id="page-1-1"></span>**Corollary 1.1.** Let  $\chi$  be a primitive Dirichlet character modulo q. If q is a sixth power, then

(5) 
$$
|L(1/2+it,\chi)| \leq 9.05\tau(q) \mathfrak{q}^{1/6} \log^{3/2} \mathfrak{q}, \qquad (|t| \geq 200).
$$

In the notation of [\(1\)](#page-0-2), Corollary [1.1](#page-1-1) asserts that if q is a sixth power and  $\chi$  is primitive, then the choice  $c = 9.05$ ,  $\kappa_1 = 1$ ,  $\kappa_2 = 1/6$ ,  $\kappa_3 = 3/2$ , and  $t_0 = 200$  is admissible. The constant  $\kappa_3 = 3/2$  arises from two sources: a dyadic division that contributes 1, and the Weyl differencing method (see [\[13,](#page-24-0) §5.4]) which contributes 1/2. The constant  $\kappa_1 = 1$  arises, in part, when counting the number of solutions to quadratic congruence equations in the Weyl differencing method. The  $\kappa_2 = 1/6$ arises from proving that, on average, square-root cancellation occurs in certain short segments of the dyadic pieces  $\sum_{V \leq n < 2V} \frac{\chi(n)}{n^{1/2+it}}$ . The constant  $c = 9.05$  is largely contributed by the part of the main sum over  $\mathfrak{q}^{1/3} \ll n \ll \mathfrak{q}^{2/3}$ . Last, the constant  $t_0 = 200$  is due to technical reasons, and can be lowered with some work.

We state the main theorem below. See §[2](#page-2-0) for the definitions of sqf $(q)$ , cbf $(q)$ , spf(q), B, B<sub>1</sub>, D, and  $\Lambda(D)$ . For now we remark that if  $\chi$  is primitive, then  $B = B_1 = 1$ . And if q is sixth power, then sqf(q) = cbf(q) = spf(q) = 1. The number  $\Lambda(D)$  is bounded by  $\tau(D)$ , and D is usually of size about  $q^{1/3}$ .

<span id="page-1-0"></span>**Theorem 1.2.** Let  $\chi$  be a Dirichlet character modulo q. If  $|t| \ge 200$ , then

(6) 
$$
|L(1/2 + it, \chi)| \leq \mathfrak{q}^{1/6} Z(\log \mathfrak{q}) + W(\log \mathfrak{q})
$$

where

$$
Z(X) := 6.6668\sqrt{\text{cbf}(q)} - 16.0834\,\text{spf}(q) + 15.6004\,\text{spf}(q)X
$$
  
+ 1.7364\sqrt{\Lambda(D)\,\text{cbf}(q)(65.5619 - 17.1704X - 2.4781X^2 + 0.6807X^3)}  
+ 1.7364\sqrt{\Lambda(D)\,\text{cbf}(q)B\tau(D/B)(-1732.5 - 817.82X + 71.68X^2 + 47.57X^3)},

 $W(X) := -101.152 - 195.696B_1 \,\text{sqf}(q) + 19.092X + 94.978B_1 \,\text{sqf}(q)X.$ 

For many applications, it suffices to focus on the case where  $\chi$  is primitive. For if not, then letting  $\chi_1 \pmod{q_1}$  be the primitive character inducing  $\chi$  and using the Euler product and analytic continuation of  $L(s, \chi)$ , we have

<span id="page-1-2"></span>(7) 
$$
|L(1/2+it,\chi)| \le |L(1/2+it,\chi_1)| \prod_{\substack{p|q \ p \nmid q_1}} (1+1/\sqrt{p}).
$$

Thus, we obtain an explicit bound on  $L(1/2+it, \chi)$  by bounding  $L(1/2+it, \chi_1)$  and using the inequality [\(7\)](#page-1-2). In our proof of Theorem [1.2,](#page-1-0) though, we bound general sums of the form  $(8)$ , and keep track of the dependence on B and  $B_1$ .

The main devices in our proofs are the hybrid van der Corput–Weyl Lemmas [4.1](#page-7-0) and [4.2.](#page-9-0) These lemmas provide explicit bounds for sums of the form

<span id="page-2-1"></span>(8) 
$$
\sum_{n=N+1}^{N+L} \chi(n) e^{2\pi i f(n)},
$$

where we take  $f(x) = -\frac{t}{2\pi} \log x$  in our application. A pleasant feature of the resulting bounds is that they naturally split into two main terms, one originating from  $\chi(n)$  and the other originating from  $n^{-iqt}$ . In particular, we can detect cancellation in the  $q$  and  $t$  aspects separately, then combine the savings routinely using the well-spacing Lemma [3.1.](#page-3-0)

<span id="page-2-2"></span>The starting point in our proof of Theorem [1.2](#page-1-0) is the Dirichlet series

(9) 
$$
L(1/2 + it, \chi) = \sum_{n=1}^{\infty} \frac{\chi(n)}{n^{1/2+it}},
$$

valid for  $\chi$  nonprincipal. (If  $\chi$  is principal, we use a bound for the Riemann zeta function.) We partition the sum in [\(9\)](#page-2-2) into four parts:  $1 \ll n \ll \frac{q^{1/3}}{q}$  which is bounded trivially,  $\mathfrak{q}^{1/3} \ll n \ll \mathfrak{q}^{2/3}$  for which Lemma [4.1](#page-7-0) is used,  $\mathfrak{q}^{2/3} \ll n \ll \mathfrak{q}$ for which Lemma [4.2](#page-9-0) is used, and the tail  $q \ll n$  which is bounded using the Pólya–Vinogradov inequality.

We remark that the restriction in Corollary [1.1](#page-1-1) that  $q$  is a sixth power may be relaxed to  $q$  is a cube provided that one starts with a main sum of length about  $\sqrt{\mathfrak{q}}$  (as in the approximate functional equation) instead of the main sum [\(9\)](#page-2-2). One then applies van der Corput lemmas analogous to those in [\[9\]](#page-23-3), but for the twisted sums [\(8\)](#page-2-1).

Interest in powerfull modulus L-functions has grown recently, both from theoret-ical and computational perspectives. Milićević [\[10\]](#page-23-4) has recently derived sub-Weyl bounds for pure character sums to prime-power modulus. And the author [\[7\]](#page-23-5) had derived an algorithm to compute hybrid sums to powerfull modulus in  $\mathfrak{q}^{1/3+o(1)}$ time. If q is smooth (but not necessarily powerfull) or prime, then one can obtain explicit hybrid subconvexity bounds by deriving an explicit version of Heath-Brown's q-analogue of the van der Corput method in [\[5\]](#page-23-6), and an explicit version of Heath-Brown's hybrid Burgess method in [\[6\]](#page-23-7).

### 2. NOTATION

,

<span id="page-2-0"></span>Let  $\chi$  be a Dirichlet character modulo q. We factorize the modulus

$$
(10) \t q := p_1^{a_1} \cdots p_\omega^{a_\omega}
$$

where the  $p_j$  are distinct primes and  $a_j \geq 1$ . For each prime power  $p^a$ , we define

(11) 
$$
C_1(p^a) := p^{\lceil a/2 \rceil}, \qquad D_1(p^a) := p^{a - \lceil a/2 \rceil},
$$

then extend the definitions multiplicatively; i.e.  $C_1(q) = C_1(p_1^{a_1}) \cdots C_1(p_\omega^{a_\omega})$ . In addition, we define

(12) 
$$
C(p^{a}) := p^{\lceil a/3 \rceil}, \qquad D(p^{a}) := \begin{cases} 1 & a = 1, \\ p^{a-2\lceil a/3 \rceil + 1} & p = 2 \text{ and } a > 1, \\ p^{a-2\lceil a/3 \rceil} & p \neq 2 \text{ and } a > 1, \end{cases}
$$

4 G.A. HIARY

then extend the definitions multiplicatively. Since the quantities  $C_1(q)$ ,  $D_1(q)$ ,  $C(q)$ , and  $D(q)$  will appear often, it is useful to introduce the short-hand notation  $C_1 := C_1(q), D_1 := D_1(q), C := C(q),$  and  $D := D(q)$ . For example,  $C_1D_1 = q$ .

Some additional arithmetic factors will appear in our estimates:  $(m, n) \geq 0$  is the greatest common divisor of m and n,  $\omega(m)$  is the number of distinct prime divisors of m, and  $\Lambda(m)$  is the number of solutions of the congruence  $x^2 \equiv 1 \pmod{m}$  with  $0 \leq x < m$ . Explicitly,

(13) 
$$
\Lambda(m) = \begin{cases} 2^{\omega(m)-1}, & m \equiv 2 \pmod{4}, \\ 2^{\omega(m)}, & m \not\equiv 2 \pmod{4} \text{ and } m \not\equiv 0 \pmod{8}, \\ 2^{\omega(m)+1}, & m \equiv 0 \pmod{8}. \end{cases}
$$

We define  $\Lambda := \Lambda(D)$ , and

(14) 
$$
\operatorname{sqf}(p^{a}) := p^{\lceil a/2 \rceil - a/2}, \qquad \operatorname{cbf}(p^{a}) := p^{\lceil a/3 \rceil - a/3},
$$

$$
\operatorname{spf}(p^{a}) := \frac{p^{\lceil a/2 \rceil - \lceil a/3 \rceil / 2 - a/6}}{\sqrt{D(p^{a})}},
$$

then extend the definitions multiplicatively. Note that  $\text{sqf}(q)$  is determined by the primes  $p_j|q$  such that  $a_j \not\equiv 0 \pmod{2}$  and  $cbf(q)$  by the primes  $p_j$  such that  $a_j \not\equiv 0$ (mod 3). If q is a square, then sqf(q) = 1. If q is a cube, then  $cbf(q) = 1$ . And if q is a sixth power, then  $\text{sqf}(q) = \text{cbf}(q) = 1$  and  $\text{spf}(q) \leq 1$ .

The numbers B and  $B_1$  that appear in Theorem [1.2](#page-1-0) are defined in Lemma [3.3.](#page-5-0)

In the remainder of the paper, we use the following notation:  $\exp(x) = e^x$  is the usual exponential function,  $[x]$  is the closest integer to x,  $||x||$  is the distance to the closest integer to x,  $\overline{\ell}$  (mod C) is the modular inverse of  $\ell$  (mod C) if it exists, and

(15) 
$$
\text{sgn}(x) = \begin{cases} 1, & x \ge 0, \\ 0, & x < 0. \end{cases}
$$

Acknowledgments. I thank Tim Trudgian for pointing out the reference [\[11\]](#page-23-2).

#### 3. Preliminary Lemmas

<span id="page-3-0"></span>**Lemma 3.1.** Let  $\{y_r : r = 0, 1, ...\}$  be a set of real numbers. Suppose that there is a number  $\delta > 0$  such that  $\min_{r \neq r'} |y_r - y_{r'}| \geq \delta$ . If  $P \geq 2$  and  $y \geq x$  then

<span id="page-3-1"></span>(16) 
$$
\sum_{y_r \in [x,y]} \min(P, \|y_r\|^{-1}) \le 2(y-x+1)(2P+\delta^{-1}\log(eP/2)).
$$

If  $P < 2$ , then replace the r.h.s. by  $2(y - x + 1)(P + \delta^{-1})$ .

*Proof.* We may assume that  $\delta \leq 1/2$ , otherwise the bounds follow on trivially estimating the number of points  $y_r$  in  $[x, y]$  by  $2(y - x) + 1$  and using the trivial bound  $\min(P, \|y_r\|^{-1}) \leq P$ .

For each integer  $k \in [x, y]$ , we consider the interval  $[k - 1/2, k + 1/2]$ . There are at most two points  $y_r$  in  $[k - \delta, k + \delta)$ , say  $y_k^+ \in [k, k + \delta)$  and  $y_k^- \in [k - \delta, k)$ . If no such points exist, then we insert one (or both) of them subject to the condition  $|y_k^+ - y_k^-| \ge \delta$ . To preserve the  $\delta$ -spacing condition, we slide the remaining points in  $(y_k^+, k+1/2]$  (resp.  $[k-1/2, y_k^-)$ ) to the right of  $y_k^+$  (resp. left of  $y_k^-$ ) in the obvious way. It is possible that a point falls off each edge, in which case we may

discard it. This is permissible since the overall procedure that we described can only increase the magnitude of the sum in [\(16\)](#page-3-1).

We have  $y_k^+ = k + \rho_k \delta$  for some  $\rho_k \in [0, 1)$ , and so  $y_k^- \leq k + (\rho_k - 1)\delta$ . Hence, using the inequality  $\min(P, \|y_r\|^{-1}) + \min(P, \|y_{r'}\|^{-1}) \le \min(2P, \|y_r\|^{-1} + \|y_{r'}\|^{-1}),$ and the formula  $||y_r|| = |y_r - k|$  if  $|y_r - k| \leq 1/2$ , we obtain

(17) 
$$
\sum_{|y_r-k|\leq \frac{1}{2}} \min(P, \|y_r\|^{-1}) \leq \sum_{0 \leq r \leq \frac{1}{2\delta}} \min\left(2P, \frac{1}{\delta(r+\rho_k)} + \frac{1}{\delta(r+1-\rho_k)}\right).
$$

We observe that

(18) 
$$
\frac{1}{\delta(r+\rho_k)} + \frac{1}{\delta(r+1-\rho_k)} = \frac{1}{\delta} \frac{2r+1}{r^2+r+\rho_k-\rho_k^2} \le \frac{2}{\delta r}.
$$

Combining this with the observation  $\frac{2}{r\delta} \geq 2P$  if  $r \leq \frac{1}{\delta P}$ , we conclude that

<span id="page-4-0"></span>(19) 
$$
\sum_{|y_r-k|\leq \frac{1}{2}} \min(P, \|y_r\|^{-1}) \leq 2P\lceil 1/\delta P \rceil + \sum_{\lceil 1/\delta P \rceil \leq r \leq 1/2\delta} \frac{2}{r\delta}.
$$

To bound the sum over  $r$ , we isolate the first term and estimate the remainder by an integral. If  $P \geq 2$  (so that the integral below makes sense), then this gives the bound

(20) 
$$
\sum_{\lceil 1/\delta P \rceil \le r \le 1/2\delta} \frac{2}{r\delta} \le 2P + 2\delta^{-1} \int_{1/\delta P}^{1/2\delta} \frac{1}{x} dx.
$$

The integral evaluates to  $log(P/2)$ . Therefore, the r.h.s. in [\(19\)](#page-4-0) is bounded by  $2\delta^{-1} + 2P + 2P + 2\delta^{-1} \log(P/2)$ . So the lemma follows if  $P \ge 2$  as the cardinality of  $\{k : x \le k \le y\}$  is  $\le y - x + 1$ . Finally, if  $P < 2$ , then the sum on the r.h.s. in (19) is empty, and so the bound is  $2\delta^{-1} + 2P$ . [\(19\)](#page-4-0) is empty, and so the bound is  $2\delta^{-1} + 2P$ .

<span id="page-4-1"></span>**Lemma 3.2.** Let f be an analytic function on a disk of radius  $\lambda(L-1)$  centered at  $N + 1$ , where  $\lambda > 1$  and  $1 \leq L \in \mathbb{Z}$ . If there is a number  $\eta$  and an integer  $J \geq 0$ such that  $\frac{|f^{(j)}(N+1)|}{j!} \lambda^{j} (L-1)^{j} \leq \frac{\eta}{\lambda^{j}}$  for  $j > J$ , then

(21) 
$$
\left| \sum_{n=N+1}^{N+L} \chi(n) e^{2\pi i f(n)} \right| \leq \nu_J(\lambda, \eta) \max_{0 \leq \Delta < L} \left| \sum_{n=N+1+\Delta}^{N+L} \chi(n) e^{2\pi i P_J(n-N-1)} \right|,
$$

where

(22) 
$$
P_J(x) := \sum_{j=0}^J \frac{f^{(j)}(N+1)x^j}{j!}, \quad \nu_J(\lambda, \eta) := \left(1 + \frac{\lambda^{-J}}{\lambda - 1}\right) \exp\left(\frac{2\pi\eta\lambda^{-J}}{\lambda - 1}\right).
$$

*Proof.* If  $L = 1$ , the lemma is trivial. So assume that  $L > 1$ . We apply the Taylor expansion to obtain

(23) 
$$
f(N+1+z) = P_J(z) + \sum_{j>J} \frac{f^{(j)}(N+1)}{j!} z^j, \qquad (|z| \le \lambda(L-1)).
$$

Using the Taylor expansion once more,

(24) 
$$
e^{2\pi i (f(N+1+z)-P_J(z))} =: \sum_{j=0}^{\infty} c_j(J,N)z^j, \qquad (|z| \le \lambda(L-1)).
$$

So if we define  $\nu_J^* := \sum_{j=0}^{\infty} |c_j(J,N)(L-1)^j|$ , then partial summation gives

(25) 
$$
\left| \sum_{n=N+1}^{N+L} \chi(n) e^{2\pi i f(n)} \right| \leq \nu_{J}^{*} \max_{0 \leq \Delta < L} \left| \sum_{n=N+1+\Delta}^{N+L} \chi(n) e^{2\pi i P_{J}(n-N-1)} \right|.
$$

To estimate the coefficients  $c_j(J, N)$ , we use the Cauchy theorem applied with a circle of radius  $\lambda(L-1)$  around the origin. In view of the growth condition on the derivatives of  $f$ , this yields

(26) 
$$
|c_j(J,N)| \leq \frac{1}{2\pi} \left| \oint \frac{e^{2\pi i (f(N+1+z) - P_J(z))}}{z^{j+1}} dz \right| \leq \frac{\exp\left(\frac{2\pi \eta \lambda^{-J}}{\lambda-1}\right)}{\lambda^j (L-1)^j}.
$$

Noting that  $c_i(J, N) = 0$  for  $1 \leq j \leq J$ , we therefore deduce that

(27) 
$$
\nu_J^* \le \exp\left(\frac{2\pi\eta\lambda^{-J}}{\lambda-1}\right) \left[1 + \sum_{j>J} \frac{(L-1)^j}{\lambda^j (L-1)^j}\right] = \nu_J(\lambda, \eta).
$$

<span id="page-5-0"></span>**Lemma 3.3.** There exists an integer  $\tilde{L}$  such that  $\chi(1 + C_1x) = e^{2\pi i \tilde{L}x/D_1}$  for all  $x \in \mathbb{Z}$ . If  $\chi$  is primitive, then  $B_1 := (\tilde{L}, D_1) = 1$ . Furthermore, there exist integers  $L_0$  and  $L$  such that  $\chi(1+Cx) = e^{4\pi i L_0 x/CD + 2\pi i L x^2/D}$  for all  $x \in \mathbb{Z}$ . If  $\chi$ is primitive, then L can be chosen so that  $B := (L, D) = 1$ .

*Proof.* We start with the decomposition  $\chi = \chi_1 \cdots \chi_{\omega}$ , where  $\chi_j$  is a Dirichlet character modulo  $p_j^{a_j}$ . By [\[8,](#page-23-8) Lemma 3.4], there exists an integer  $\tilde{L}_j$  such that

(28) 
$$
\chi_j(1 + C_1(p_j^{a_j})x) = e^{2\pi i \tilde{L}_j x/D_1(p_j^{a_j})}
$$

for all  $x \in \mathbb{Z}$ . Hence,

(29) 
$$
\chi(1+C_1x)=\chi_1(1+C_1x)\cdots\chi_\omega(1+C_1x)=e^{2\pi i\tilde{L}x/D_1},
$$

where, noting that  $C_1D_1 = q$ , we have

(30) 
$$
\tilde{L} = q \sum_{j=1}^{\omega} \tilde{L}_j / p_j^{a_j}
$$

Let  $B_1 = (\tilde{L}, D_1)$ . It is clear that  $\chi(1+qx/B_1) = 1$  for all x. So  $q/B_1$  is an induced modulus for  $\chi$ . In particular, if  $B > 1$  then  $\chi$  is imprimitive. This completes the proof of the first part of the lemma.

.

For the second part, we use [\[7,](#page-23-5) Lemma 4.2]. Consider first the case  $p_j^{a_j} \notin \{4, 8\}$ and  $a_j > 1$ . Then there are integers  $L_{0,j}$  and  $L_j$  such that

<span id="page-5-1"></span>(31) 
$$
\chi_j(1 + C(p_j^{a_j})x) = e^{\frac{4\pi i L_{0,j}x}{C(p_j^{a_j})D(p_j^{a_j})} + \frac{2\pi i L_jx^2}{D(p_j^{a_j})}}
$$

for all  $x \in \mathbb{Z}$ , and moreover we can take  $L_{0,j} = -L_j$ . If  $a_j = 1$ , then  $C(p_j^{a^j}) = p_j^{a_j}$ . So  $\chi_j(1+C(p_j^{a_j})x)=1$  and we can take  $L_{0,j}=L_j=0$ . If  $p_j^{a_j}=4$ , then either  $L_{0,j} = 0$  and  $\tilde{L}_j = 1$  or  $\chi$  is principal. If  $p_j^{a_j} = 8$ , then either  $L_{0,j} = L_j = 1$ , or  $L_{0,j} = 2$  and  $L_j = 0$  (an imprimitive character), or  $L_{0,j} = -1$  and  $L_j = 1$ , or  $\chi$  is principal. Put together, we have

(32) 
$$
\chi(1+Cx) = \chi_1(1+Cx)\cdots\chi_\omega(1+Cx) = e^{\frac{4\pi i L_0 x}{CD} + \frac{2\pi i L x^2}{D}}
$$

where

(33) 
$$
L_0 = C^2 D \sum_{j=1}^{\omega} \frac{L_{0,j}}{C(p_j^{a_j})^2 D(p_j^{a_j})}, \qquad L = C^2 D \sum_{j=1}^{\omega} \frac{L_j}{C(p_j^{a_j})^2 D(p_j^{a_j})}.
$$

It remains to prove that if  $\chi$  is primitive then  $B = 1$ . To this end, we note that  $\frac{Lq^2}{B^2C^2D}$  is an integer. So if we show that  $\frac{2L_0q}{BC^2D}$  is an integer too, then  $\chi(1+qx/B)$  = 1 for all  $x \in \mathbb{Z}$ . In particular, if  $B > 1$ , then  $q/B$  is a nontrivial induced modulus and  $\chi$  is imprimitive, which completes the proof of the second part of the lemma.

Now, to show that  $\frac{2L_0q}{BC^2D}$  is an integer, we first note that  $\frac{L_0q}{C^2}$  is always an integer. (Recall that  $L_0 = 0$  if  $a_j = 1$ .) Furthermore, if  $a_j = 1$  then  $(D, p_j) = 1$  and so  $(B, p<sub>j</sub>) = 1$ . In light of this, we may assume that  $a<sub>j</sub> > 1$  for all j.

We consider two possibilities. If  $p_j^{a_j} \notin \{4, 8\}$  for any j, then  $C^2D = q$  (if q is odd) or 2q (if q is even), and in any case  $L_{0,j} = -L_j$  for all j. The last fact implies in turn that  $L_0 = -L$ , hence  $B = (L_0, D)$ . In particular, B divides  $L_0$  and we conclude that  $\frac{2L_0q}{BC^2D} = \frac{L_0}{B}$  or  $\frac{2L_0}{B}$  and so is an integer in either case.

On the other hand, if  $p_j^{a_j} \in \{4, 8\}$  for some j, then  $C^2D = 2q$  and we appeal to the remark following [\(31\)](#page-5-1). Accordingly, if  $\chi$  is primitive and  $p_j^{a_j} \in \{4, 8\}$  then  $L_j = 1$  and so L must be odd. This shows that  $B = (L, D/2)$ . In addition, we have

(34) 
$$
L_0 = L - \begin{cases} \frac{C^2 (L_j - L_{0,j})}{4} \frac{D}{2} & p_1^{a_1} = 4, \\ \frac{C^2 (L_j - L_{0,j})}{8} \frac{D}{2} & p_1^{a_1} = 8. \end{cases}
$$

Therefore, given the possibilities for  $L_{0,j}$  and  $L_j$  stated after [\(31\)](#page-5-1), we see if  $\chi$  is primitive then  $L_0 \equiv L \pmod{D/2}$ , and so  $B = (L_0, D/2)$ . This shows that B is a divisor of  $L_0$ , hence  $\frac{2L_0q}{BC^2D} = \frac{L_0}{B}$  is an integer.

<span id="page-6-1"></span>**Lemma 3.4.** Let  $M, N \in \mathbb{Z}_{\geq 1}$ ,  $W_M(m) := 1 - m/M$ , and  $d_m(N) := (2m, N)$ . Then

<span id="page-6-0"></span>(35) 
$$
\sum_{m=1}^{M} W_M(m) \frac{d_m(N)}{m} \le \tau(N) \log M, \qquad \sum_{m=1}^{M} W_M(m) d_m(N) \le \tau(N) M.
$$

Proof. We prove the first bound, the second one being analogous. Let us write  $N = 2<sup>a</sup>N'$  with N' odd. We induct on a. If  $a = 0$ , then  $d_m(N) = (m, N)$  and the result follows because

(36)  

$$
\sum_{m=1}^{M} W_M(m) \frac{d_m(N)}{m} \le \sum_{\substack{r|N \ r \le 2M}} \sum_{\substack{1 \le m' \le M/r}} W_M(r m') \frac{1}{m'}
$$

$$
\le \tau(N) \sum_{\substack{1 \le m' \le M}} W_M(m') \frac{1}{m'}
$$

$$
\le \tau(N) \log M.
$$

If  $a = 1$ , then  $d_m(N) = 2d_m(N')$ . So using the previous calculation and observing that  $2\tau(N') = \tau(N)$  yields the desired bound.

Henceforth, we may assume that  $a \geq 2$ . We may further assume that  $M > 2$ , for if  $M = 1$  or 2 then the lemma is trivial.

Since N is even by hypothesis, then  $d_m(N) = 2(m, N/2)$ . Using this, and dividing the sum over  $m$  into even and odd terms, we obtain

<span id="page-7-1"></span>(37) 
$$
\sum_{m=1}^{M} W_M(m) \frac{d_m(N)}{m} = 2 \sum_{1 \le m' \le \lfloor M/2 \rfloor} W_M(2m') \frac{(2m', N/2)}{2m'} + 2 \sum_{0 \le m' \le \lfloor (M-1)/2 \rfloor} W_M(2m' + 1) \frac{(2m' + 1, N/2)}{2m' + 1}.
$$

We have  $W_M(2m') \leq W_{\lceil M/2 \rceil}(m')$  and, by definition,  $(2m', N/2) = d_{m'}(N/2)$ . It follows by induction that the first sum on the r.h.s. of [\(37\)](#page-7-1) is bounded by  $\tau(N/2) \log[M/2]$ . Furthermore, the second sum is clearly bounded by (38)

$$
\sum_{0 \le m' \le \lfloor (M-1)/2 \rfloor} W_M(2m'+1) \frac{(2m'+1, N')}{m'+1/2} \le 2(1-1/M) + \sum_{1 \le m \le M} W_M(m) \frac{d_m(N')}{m},
$$

which, by induction, is  $\leq 2(1-1/M) + \tau(N') \log M$ . Therefore, using the bound  $\log[M/2] \leq \log M + 1/M - \log 2$  and the formula  $\tau(N/2) + \tau(N') = \tau(N)$ , we arrive at

(39) 
$$
\sum_{m=1}^{M} W_M(m) \frac{d_m(N)}{m} \le \tau(N) \log M + (2 - 2/M + \tau(N/2)/M - \tau(N/2) \log 2).
$$

We conclude that the bound [\(35\)](#page-6-0) holds provided that  $\tau(N/2) \geq 4$ . This is always fulfilled if  $a \ge 2$  unless  $N = 4$  or 8. But the lemma follows in these cases also by direct calculation. direct calculation.

## 4. Hybrid van der Corput–Weyl lemmas

<span id="page-7-0"></span>**Lemma 4.1.** Suppose that f is a function satisfying the hypothesis of Lemma [3.2](#page-4-1) for some  $\lambda > 1$ ,  $\eta \geq 0$ , and with  $J = 1$ . If  $f(x)$  is real for real x, then

(40) 
$$
\left| \sum_{n=N+1}^{N+L} \chi(n) e^{2\pi i f(n)} \right| \leq \frac{2\nu_1(\lambda, \eta) C_1}{\pi} \left( \log \frac{D_1}{2B_1} + \frac{7}{4} + \frac{\pi}{2} \right) + \frac{\nu_1(\lambda, \eta) C_1}{\pi} \min \left( \frac{\pi B_1 L}{q}, ||q f'(N+1)/B_1||^{-1} \right).
$$

*Proof.* Applying Lemma [3.2](#page-4-1) with  $J = 1$  gives

<span id="page-7-2"></span>(41) 
$$
\left| \sum_{n=N+1}^{N+L} \chi(n) e^{2\pi i f(n)} \right| \leq \nu_1(\lambda, \eta) \max_{0 \leq \Delta < L} \left| \sum_{n=N+1+\Delta}^{N+L} \chi(n) e^{2\pi i P_1(n-N-1)} \right|,
$$

where  $P_1(x) = f(N+1) + f'(N+1)x$ . Let  $\Delta^*$  be where the maximum is achieved on the r.h.s. of [\(41\)](#page-7-2). Let  $N^* := N + \Delta^*$  and  $L^* = L - \Delta^*$ . So we have

<span id="page-7-3"></span>(42) 
$$
\left| \sum_{n=N+1}^{N+L} \chi(n) e^{2\pi i f(n)} \right| \leq \nu_1(\lambda, \eta) \left| \sum_{n=N^*+1}^{N^*+L^*} \chi(n) e^{2\pi i P_1(n-N-1)} \right|.
$$

We split the range of summation  $N^*+1 \leq n \leq N^*+L^*$  into arithmetic progressions along the residue classes  $\ell \pmod{C_1}$ . For each residue class  $0 \leq \ell \leq C_1$ , the terms in the progression  $n \equiv \ell \pmod{C_1}$  are indexed by the integers k that verify  $N^*+1 \leq \ell+C_1k \leq N^*+L^*$ . So we have  $\lceil (N^*+1-\ell)/C_1 \rceil \leq k \leq \lfloor (N^*+L^*-\ell)/C_1 \rfloor$ . Using the formula  $[x + \delta] - |x| = 1$ , valid for any x and  $\delta \in (0, 1)$ , we deduce that  $\lceil (N^*+1-\ell)/C_1 \rceil - \lfloor (N^*-\ell)/C_1 \rfloor = 1$ . Therefore, if we define  $H_\ell := \lceil (N^*-\ell)/C_1 \rceil$ , then each  $\ell$  determines an integer  $\Omega_{\ell} \leq [L^*/C_1]$  such that (we use the triangle inequality below)

$$
(43)\quad \left|\sum_{n=N^*+1}^{N^*+L^*}\chi(n)e^{2\pi i P_1(n-N-1)}\right| \leq \sum_{\ell=0}^{C_1-1}\left|\sum_{k=H_{\ell}+1}^{H_{\ell}+\Omega_{\ell}}\chi(\ell+C_1k)e^{2\pi i P_1(\ell+C_1k-N-1)}\right|.
$$

From Lemma [3.3,](#page-5-0) and the formula  $\chi(\ell+C_1k) = \chi(\ell)\chi(1+C_1\overline{\ell}k)$ , valid for  $(\ell, q) = 1$ , we deduce that there are integers  $\gamma_1$  and  $B_1$  such that  $(\gamma_1, D_1) = 1$ ,  $B_1|D_1$ , and

(44) 
$$
\chi(\ell + C_1 k) = \chi(\ell) e^{2\pi i B_1 \gamma_1 \bar{\ell} k / D_1}, \qquad (\ell, q) = 1.
$$

If  $(\ell, q) > 1$ , then  $\chi(\ell + C_1 k) = 0$ . Therefore,

<span id="page-8-0"></span>(45) 
$$
\left| \sum_{n=N^*+1}^{N^*+L^*} \chi(n) e^{2\pi i P_1(n-N-1)} \right| \leq \sum_{\substack{\ell=0 \\ (\ell,q)=1}}^{C_1-1} \left| \sum_{k=H_\ell+1}^{H_\ell+\Omega_\ell} e^{2\pi i (B_1 \gamma_1 \overline{\ell}/D_1 + C_1 f'(N+1))k} \right|.
$$

Let us define

(46) 
$$
z_f := \left[\frac{qf'(N+1)}{B_1}\right], \qquad \delta_f := \pm \left\|\frac{qf'(N+1)}{B_1}\right\|,
$$

where  $\delta_f$  is positive if  $z_f$  is obtained by rounding down, and negative if  $z_f$  is obtained by rounding up. In either case, since  $D_1C_1 = q$  by construction, we have  $C_1 f'(N+1) = (z_f + \delta_f) B_1/D_1$ . Therefore,

(47) 
$$
\left\| \frac{B_1 \gamma_1 \overline{\ell}}{D_1} + C_1 f'(N+1) \right\| = \left\| \frac{\gamma_1 \overline{\ell} + z_f + \delta_f}{D_1/B_1} \right\| =: U_{\gamma_1 \overline{\ell} + z_f + \delta_f}.
$$

In view of this, it follows by the Kusmin–Landau Lemma in [\[2,](#page-23-9) Lemma 2] that the inner sum in [\(45\)](#page-8-0) satisfies

(48) 
$$
\left| \sum_{k=H_{\ell}+1}^{H_{\ell}+\Omega_{\ell}} e^{2\pi i (B_1 \gamma_1 \overline{\ell}/D_1 + C_1 f'(N+1))k} \right| \leq \min \left( \Omega_{\ell}, \frac{1}{\pi} U_{\gamma_1 \overline{\ell} + z_f + \delta_f}^{-1} + 1 \right).
$$

Given this, we divide the sum over  $\ell$  in [\(45\)](#page-8-0) into segments of length  $D_1/B_1$ .

(49) 
$$
\left[\frac{uD_1}{B_1}, \frac{(u+1)D_1}{B_1}\right), \quad u \in \mathbb{Z}, \quad 0 \le u < \frac{B_1C_1}{D_1}.
$$

Over each segment, we can get an easy handle on  $U_{\gamma_1\bar{\ell}+z_f+\delta_f}$ . Indeed, as  $\ell$  runs over the reduced residue classes modulo q (hence reduced modulo  $D_1/B_1$ ) in a given segment,  $\gamma_1 \overline{\ell} + z_f$  runs over a subset of the residue classes modulo  $D_1/B_1$ , hitting each class at most once. Therefore, summing over the  $B_1C_1/D_1$  segments, and recalling that  $\Omega_{\ell} \leq [L/C_1]$  by construction, we obtain (50)

<span id="page-8-1"></span>
$$
\left|\sum_{n=N^*+1}^{N^*+L^*}\chi(n)e^{2\pi i P_1(n-N-1)}\right|\leq \frac{B_1C_1}{D_1}\sum_{\ell\,(\text{mod}\, D_1/B_1)}\min\left(\lceil L/C_1\rceil,\frac{1}{\pi}U_{\ell+\delta_f}^{-1}+1\right).
$$

We choose the residue class representatives mod  $D_1/B_1$  to be in  $[-D_1/2B_1, D_1/2B_1)$ if  $\delta_f \geq 0$ , and in  $(-D_1/2B_1, D_1/2B_1]$  if  $\delta_f < 0$ . In either case, let  $\ell$  denote the

representative of  $\ell$ . Since  $0 \leq |\delta_f| \leq 1/2$ , we deduce the formula

(51) 
$$
U_{\ell+\delta_f} = \begin{cases} \frac{|\tilde{\ell}| + \text{sgn}(\tilde{\ell})\delta_f}{D_1/B_1} & \tilde{\ell} \neq 0, \\ \frac{|\delta_f|}{D_1/B_1} & \tilde{\ell} = 0. \end{cases}
$$

Now, if  $\delta_f \geq 0$ , we isolate the terms corresponding to  $\tilde{\ell} = 0$  and  $\tilde{\ell} = -1$  (if they exist) on the r.h.s. of [\(50\)](#page-8-1). And if  $\delta_f < 0$ , we isolate the terms for  $\tilde{\ell} = 0$  and  $\tilde{\ell} = 1$ . Moreover, we use the lower bound  $U_{\pm 1+\delta_f} \geq B_1/2D_1$  to control the term  $\ell = \pm 1$ . Then we sum over the remaining  $\tilde{\ell}$ , pairing the terms for  $\tilde{\ell}$  and  $-\tilde{\ell} - 1$  if  $\delta_f \geq 0$ , and the terms for  $\tilde{\ell}$  + 1 and  $-\tilde{\ell}$  if  $\delta_f < 0$ . In summary, assuming that  $D_1/B_1 \geq 2$ (so there are at least two residue class modulo  $D_1/B_1$ ), we obtain

<span id="page-9-1"></span>
$$
\sum_{\ell \, (\text{mod } D_1/B_1)} \min\left( \lceil L/C_1 \rceil, \frac{1}{\pi} U_{\ell+\delta_f}^{-1} + 1 \right) \le \min\left( \lceil L/C_1 \rceil, \frac{1}{\pi} U_{\delta_f}^{-1} + 1 \right) + \left( \frac{2D_1}{\pi B_1} + 1 \right) + \left( \frac{D_1}{B_1} - 2 \right) + \frac{D_1}{\pi B_1} \sum_{1 \le \ell < \frac{D_1}{2B_1}} \left( \frac{1}{\ell + |\delta_f|} + \frac{1}{\ell + 1 - |\delta_f|} \right).
$$

The second sum over  $\ell$  on the r.h.s. of [\(52\)](#page-9-1) is bounded by

<span id="page-9-2"></span>(53) 
$$
\sum_{1 \leq \ell < \frac{D_1}{2B_1}} \frac{2\ell+1}{\ell^2+\ell+\lvert \delta_f \rvert - \delta_f^2} \leq \frac{3}{2} + \sum_{2 \leq \ell < \frac{D_1}{2B_1}} \frac{2}{\ell} \leq \frac{3}{2} + 2\log\left(\frac{D_1}{2B_1}\right).
$$

It is easy to check that the last two estimates still hold if  $D_1/B_1 = 1$ . Hence, substituting [\(53\)](#page-9-2) into [\(52\)](#page-9-1) we obtain, on noting that  $[L/C_1] \leq L/C_1 + 1$ ,

(54) 
$$
\sum_{\ell \, (\text{mod } D_1/B_1)} \min\left( \lceil L/C_1 \rceil, \frac{1}{\pi} U_{\ell+\delta_f}^{-1} + 1 \right) \le \min\left( \frac{L}{C_1}, \frac{1}{\pi} U_{\delta_f}^{-1} \right) + \frac{2D_1}{\pi B_1} \left( 1 + \frac{\pi}{2} + \frac{3}{4} \right) + \frac{2D_1}{\pi B_1} \log\left( \frac{D_1}{2B_1} \right).
$$

We multiply the last estimate by the outside factor  $B_1C_1/D_1$  in [\(50\)](#page-8-1). This gives

<span id="page-9-3"></span>(55) 
$$
\left| \sum_{n=N^*+1}^{N^*+L^*} \chi(n) e^{2\pi i P_1(n-N-1)} \right| \leq \frac{B_1 C_1}{D_1} \left( \min \left( \frac{L}{C_1}, \frac{1}{\pi} U_{\delta_f}^{-1} \right) + \frac{2C_1}{\pi} \left( \log \frac{D_1}{2B_1} + \frac{7}{4} + \frac{\pi}{2} \right) \right)
$$

Finally, we use the formula  $U_{\delta_f}^{-1} = ||q f'(N+1)/B_1||^{-1}D_1/B_1$ , and substitute [\(55\)](#page-9-3) back into [\(42\)](#page-7-3). After straightforward rearrangements, we obtain the lemma.  $\Box$ 

.

<span id="page-9-0"></span>**Lemma 4.2.** Suppose that f is a function satisfying the hypothesis of Lemma [3.2](#page-4-1) for some  $\lambda > 1$ ,  $\eta \geq 0$ , and with  $J = 2$ . Let  $d_m := (2m, D/B)$ . If  $f(x)$  is real for real x, then

<span id="page-10-5"></span>(56)  

$$
\left|\sum_{n=N+1}^{N+L} \chi(n)e^{2\pi i f(n)}\right|^2 \le \frac{4\nu_2(\lambda, \eta)^2 \Lambda CL}{\pi} \left(\log \frac{D}{2B} + \frac{7}{4} + \frac{3\pi}{2\Lambda}\right) + \frac{4\nu_2(\lambda, \eta)^2 \Lambda C^2}{\pi} \sum_{m=1}^{\lceil L/C \rceil} \left(1 - \frac{m}{\lceil L/C \rceil}\right) \times \min\left(\frac{\pi d_m BL}{CD}, \left\|\frac{mC^2 Df''(N+1)}{B d_m}\right\|^{-1}\right).
$$

*Proof.* We apply Lemma [3.2](#page-4-1) with  $J = 2$  to the sum. This yields (similarly to the beginning of the proof of Lemma [4.1\)](#page-7-0) that

<span id="page-10-0"></span>(57) 
$$
\left| \sum_{n=N+1}^{N+L} \chi(n) e^{2\pi i f(n)} \right| \leq \nu_2(\lambda, \eta) \left| \sum_{n=N^*+1}^{N^*+L^*} \chi(n) e^{2\pi i P_2(n-N-1)} \right|,
$$

where  $P_2(x) = f(N + 1) + f'(N + 1)x + f''(N + 1)x^2/2$  and  $[N^* + 1, N^* + L^*] \subset$  $[N+1, N+L]$ . We split the range of summation on the r.h.s. of [\(57\)](#page-10-0) into arithmetic progressions along the residue classes  $\ell$  modulo C. Letting  $K_{\ell} := \lfloor (N^* - \ell)/C \rfloor$ and  $\Delta_{\ell} := \lfloor (N^* + L^* - \ell)/C \rfloor - K_{\ell}$ , we have

<span id="page-10-2"></span>(58) 
$$
\sum_{n=N^*+1}^{N^*+L^*} \chi(n) e^{2\pi i P_2(n-N-1)} = \sum_{\ell=0}^{C-1} \sum_{k=K_{\ell}+1}^{K_{\ell}+\Delta_{\ell}} \chi(\ell+Ck) e^{2\pi i P_2(\ell+Ck-N-1)}.
$$

We make use of the following properties of  $\Delta_{\ell}$ . First, by construction, we have

<span id="page-10-3"></span>(59) 
$$
\sum_{\ell=0}^{C-1} \Delta_{\ell} = L^* \leq L.
$$

Second, using the periodicity of  $\Delta_{\ell}$  as a function of  $\ell \pmod{C}$ , and the change of variable  $r \equiv N^* - \ell \pmod{C}$ , we obtain

<span id="page-10-1"></span>(60) 
$$
\sum_{\ell=0}^{C-1} \sqrt{\Delta_{\ell}} = \sum_{r=0}^{C-1} \sqrt{\lfloor (L^*+r)/C \rfloor} \le \sum_{r=0}^{C-1} \sqrt{\lfloor (L+r)/C \rfloor}.
$$

Furthermore, supposing that  $L \equiv \ell_0 \pmod{C}$ , where  $0 \leq \ell_0 < C$ , we obtain on considering the summation ranges  $0 \le r \le C - \ell_0 - 1$  and  $C - \ell_0 \le r \le C - 1$  in [\(60\)](#page-10-1) separately that

(61) 
$$
\sum_{r=0}^{C-1} \sqrt{\lfloor (L+r)/C \rfloor} = (C - \ell_0) \sqrt{\frac{(L-\ell_0)}{C}} + \ell_0 \sqrt{\frac{(L-\ell_0)}{C}} + 1.
$$

If we view the r.h.s. above as a function of  $0 \leq \ell_0 < C$ , say  $p(\ell_0)$ , then its maximum is achieved when  $\ell_0 = 0$ . Thus,

(62) 
$$
\sum_{\ell=0}^{C-1} \sqrt{\Delta_{\ell}} \le p(0) = \sqrt{CL}.
$$

Also, we have the bound

<span id="page-10-4"></span>(63) 
$$
\sum_{\ell=0}^{C-1} \Delta_{\ell}^{2} \le \frac{L^{2}}{C} + (\tilde{\rho} - \tilde{\rho}^{2})C, \qquad \tilde{\rho} := \ell_{0}/C.
$$

We are now ready to return to  $(58)$ . Lemma [3.3](#page-5-0) asserts that there is a polynomial  $g_{\ell}(x)$  of degree 2 in x such that

(64) 
$$
\chi(\ell + Ck) = \chi(\ell)e^{2\pi i g_{\ell}(k)}, \qquad (\ell, q) = 1,
$$

where  $g_{\ell}(x) = \alpha_{\ell} x + B \gamma \bar{\ell}^2 x^2/D$ ,  $(\gamma, q) = 1$ , and  $B|D$ . Therefore, applying the Cauchy–Schwarz inequality to the r.h.s. in [\(58\)](#page-10-2), we obtain

<span id="page-11-1"></span>(65) 
$$
\left| \sum_{n=N^*+1}^{N^*+L^*} \chi(n) e^{2\pi i P_2(n-N-1)} \right|^2 \leq C \sum_{\substack{\ell=0 \\ (\ell,q)=1}}^{C-1} \left| \sum_{k=K_{\ell}+1}^{K_{\ell}+\Delta_{\ell}} e^{2\pi i Q_{\ell}(k)} \right|^2.
$$

where  $Q_{\ell}(x) := g_{\ell}(x) + P_2(\ell + Cx - N - 1)$ . We bound the inner sum using the van der Corput–Weyl Lemma in [\[2,](#page-23-9) Lemma 5]. In fact, we use the more precise form of the lemma at the bottom of page 1273. This form implies that if  $M$  is a positive integer then

<span id="page-11-0"></span>(66) 
$$
\Big|\sum_{k=K_{\ell}+1}^{K_{\ell}+\Delta_{\ell}} e^{2\pi i Q_{\ell}(k)}\Big|^2 \leq (\Delta_{\ell}+M)\Big(\frac{\Delta_{\ell}}{M}+\frac{2}{M}\sum_{m=1}^{M}\Big(1-\frac{m}{M}\Big)|S'_{m}(\ell)|\Big),
$$

where

(67) 
$$
S'_{m}(\ell) := \sum_{r=K_{\ell}+1}^{K_{\ell}+\Delta_{\ell}-m} e^{2\pi i (Q_{\ell}(r+m)-Q_{\ell}(r))}.
$$

Substituting [\(66\)](#page-11-0) into [\(65\)](#page-11-1), and using the properties [\(59\)](#page-10-3) and [\(63\)](#page-10-4), together with the upper bound  $\Delta_{\ell} \leq [L/C]$ , we obtain (68)

<span id="page-11-3"></span>
$$
\left| \sum_{n=N^*+1}^{N^*+L^*} \chi(n) e^{2\pi i P_2(n-N-1)} \right|^2 \leq CL + \frac{L^2 + \tilde{\rho}(1-\tilde{\rho})C^2}{M} + 2C \left( 1 + \frac{[L/C]}{M} \right) \sum_{m=1}^M \left( 1 - \frac{m}{M} \right) \sum_{\substack{\ell=0 \\ (\ell,q)=1}}^{C-1} |S'_m(\ell)|.
$$

Since  $Q_{\ell}(x)$  is a quadratic polynomial, we have the simpler expression

(69) 
$$
|S'_{m}(\ell)| = \left| \sum_{r=K_{\ell}+1}^{K_{\ell}+\Delta_{\ell}-m} e^{2\pi i (2mB\gamma \overline{\ell}^{2}/D+mC^{2}f''(N+1))r)} \right|
$$

We plan to bound  $S'_m(\ell)$  using the Kusmin–Landau Lemma in [\[2,](#page-23-9) Lemma 2]. With this in mind, recall the definition  $d_m = (2m, D/B)$ . Let

.

.

(70) 
$$
m' = \frac{2m}{d_m}, \qquad P_m := \frac{D}{B d_m}.
$$

 $Let<sup>2</sup>$  $Let<sup>2</sup>$  $Let<sup>2</sup>$ 

(71)  

$$
w_m := [P_m m C^2 f''(N+1)] = \left[ \frac{m' C^2 D f''(N+1)}{2B} \right],
$$

$$
\epsilon_m := ||P_m m C^2 f''(N+1)|| = \pm \left\| \frac{m' C^2 D f''(N+1)}{2B} \right\|
$$

<span id="page-11-2"></span><sup>&</sup>lt;sup>2</sup>If each prime factor of q occurs with multiplicity  $> 1$ , then  $C^2D = q$  if q is odd, and  $C^2D = 2q$ if  $q$  is even. So the expressions that follow can be simplified in this case.

Here,  $\epsilon_m$  is positive if  $w_m$  is obtained by rounding down, and negative if  $w_m$  is obtained by rounding up. Hence,

(72) 
$$
\left\| \frac{2m \overline{B} \gamma \overline{\ell}^2}{D} + m \overline{C}^2 f''(N+1) \right\| = \left\| \frac{m' \gamma \overline{\ell}^2 + w_m + \epsilon_m}{P_m} \right\|
$$

Letting  $U_{z,m} := \|z/P_m\|$ , the Kusmin–Landau Lemma furnishes the estimate

(73) 
$$
|S'_{m}(\ell)| \leq \min\left(\Delta_{\ell} - m, \frac{1}{\pi}U_{m'\gamma\overline{\ell}^2 + w_m + \epsilon_m, m}^{-1} + 1\right).
$$

Therefore, using the inequality  $\Delta_{\ell} \leq [L/C]$  yields

(74) 
$$
\mathcal{S}_{m} = \sum_{\substack{\ell=0 \ (\ell,q)=1}}^{C-1} |S'_{m}(\ell)| \leq \sum_{\substack{\ell=0 \ (\ell,q)=1}}^{C-1} \min \left( \left[ L/C \right] - m, \frac{1}{\pi} U^{-1}_{m' \gamma \overline{\ell}^{2} + w_{m} + \epsilon_{m}, m} + 1 \right).
$$

To get an explicit expression for  $U_{z,m}$ , we consider subsums of  $\mathcal{S}_m$  over the segments

(75) 
$$
[uP_m, (u+1)P_m), u \in \mathbb{Z}, 0 \le u < C/P_m.
$$

To this end, let

(76) 
$$
\Lambda_m := \# \{ 0 \le x < P_m : x^2 \equiv 1 \pmod{P_m} \}.
$$

As  $\ell$  runs over the reduced residue classes in each segment, then since  $(m'\gamma, P_m) = 1$ and  $\bar{\ell}$  is squared, if  $m'\gamma\bar{\ell}^2+w_m$  hits a residue class modulo  $P_m$ , it does so  $\Lambda_m$ times. Let  $\mathcal{R}_m$  denote the classes that are hit. We have that the cardinality of  $\mathcal{R}_m$  is  $\leq P_m/\Lambda_m$ . If  $\epsilon_m \geq 0$  we take  $\mathcal{R}_m \subset [-P_m/2, P_m/2]$  while if  $\epsilon_m < 0$  we take  $\mathcal{R}_m \subset (-P_m/2, P_m/2]$ . Furthermore, given  $m'\gamma \bar{\ell}^2 + w_m$ , let  $\tilde{\ell} \in \mathcal{R}_m$  denote the class representative that it hits. Then, summing over the  $C/P_m$  segments, we obtain

(77) 
$$
\mathcal{S}_m \leq \frac{C\Lambda_m}{P_m} \sum_{\tilde{\ell} \in \mathcal{R}_m} \min \left( \left[ L/C \right] - m, \frac{1}{\pi} U_{\tilde{\ell} + \epsilon_m, m}^{-1} + 1 \right),
$$

and we have the formula

(78) 
$$
U_{\tilde{\ell}+\epsilon_m,m} = \begin{cases} \frac{|\tilde{\ell}| + \text{sgn}(\tilde{\ell})\epsilon_m}{P_m} & \tilde{\ell} \neq 0, \\ \frac{|\epsilon_m|}{P_m} & \tilde{\ell} = 0. \end{cases}
$$

At worst, the classes that are hit concentrate in  $[-P_m/2\Lambda_m, P_m/2\Lambda_m]$ . If  $\epsilon_m \geq 0$ , we isolate the terms corresponding to  $\tilde{\ell} = 0$  and  $\tilde{\ell} = -1$  (if they exist), and pair the remaining terms for  $\tilde{\ell}$  and  $-\tilde{\ell}-1$ . While if  $\epsilon_m < 0$ , we isolate the terms for  $\ell = 0$ and  $\tilde{\ell} = 1$ , and pair the remaining terms for  $\tilde{\ell} + 1$  and  $-\tilde{\ell}$ . Since  $0 \leq |\epsilon_m| \leq 1/2$ and  $P_m/\Lambda_m \geq 1$ , this gives

(79) 
$$
\mathcal{S}_m \leq \frac{C\Lambda_m}{P_m} \min\left( \left[ L/C \right] - m, \frac{P_m}{\pi |\epsilon_m|} + 1 \right) + \frac{C\Lambda_m}{P_m} \left( \frac{2P_m}{\pi} + 1 \right) + \frac{C\Lambda_m}{P_m} \left( \frac{P_m}{\Lambda_m} - 1 \right) + \frac{C\Lambda_m}{\pi} \sum_{1 \leq \ell < \frac{P_m}{2\Lambda_m}} \left( \frac{1}{\ell + |\epsilon_m|} + \frac{1}{\ell + 1 - |\epsilon_m|} \right).
$$

.

Furthermore,

$$
(80) \qquad \sum_{1 \leq \ell < \frac{P_m}{2\Lambda_m}} \left( \frac{1}{\ell + |\epsilon_m|} + \frac{1}{\ell + 1 - |\epsilon_m|} \right) \leq \sum_{1 \leq \ell < \frac{P_m}{2\Lambda_m}} \frac{2\ell + 1}{\ell^2 + \ell} \leq \frac{3}{2} + 2\log\frac{P_m}{2\Lambda_m}
$$

Hence, using to the trivial inequalities  $\lceil L/C \rceil \, < L/C + 1$  and  $1 \, \leq \, \Lambda_m \, \leq \, P_m$ , together with the observation  $P_m|D$  so that  $\Lambda_m = \Lambda(P_m) \leq \Lambda(D) = \Lambda$ , we obtain

.

$$
(81) \quad \mathcal{S}_m \le \frac{C\Lambda_m}{P_m} \min\left(L/C - m, \frac{P_m}{\pi|\epsilon_m|}\right) + \frac{2C\Lambda}{\pi} + 2C + \frac{C\Lambda}{\pi} \left(\frac{3}{2} + 2\log\frac{D}{2B}\right).
$$

Now, we have  $\sum_{1 \le m \le M} (1 - m/M) = (M - 1)/2$ . So summing over m we obtain

<span id="page-13-0"></span>(82) 
$$
\sum_{m=1}^{M} \left(1 - \frac{m}{M}\right) S_m \leq C \sum_{m=1}^{M} \left(1 - \frac{m}{M}\right) \frac{\Lambda_m}{P_m} \min\left(L/C - m, \frac{P_m}{\pi |\epsilon_m|}\right) + C(M-1) + \frac{C\Lambda(M-1)}{\pi} \left(\frac{7}{4} + \log \frac{D}{2B}\right).
$$

In [\(82\)](#page-13-0), we choose  $M = [L/C]$ , so that  $M = L/C + 1 - \tilde{\rho}$ . Then we substitute the resulting expression into [\(68\)](#page-11-3), which gives

<span id="page-13-1"></span>(83)  
\n
$$
\left| \sum_{n=N^{*}+1}^{N^{*}+L^{*}} \chi(n) e^{2\pi i P_{2}(n-N-1)} \right|^{2} \leq CL + \frac{L^{2} + \tilde{\rho}(1-\tilde{\rho})C^{2}}{L/C + 1 - \tilde{\rho}} + 4C^{2} \sum_{m=1}^{\lceil L/C \rceil} \left( 1 - \frac{m}{\lceil L/C \rceil} \right) \frac{\Lambda_{m}}{P_{m}} \min \left( L/C - m, \frac{P_{m}}{\pi |\epsilon_{m}|} \right) + 4CL + \frac{4\Lambda CL}{\pi} \left( \frac{7}{4} + \log \frac{D}{2B} \right).
$$

At this point, we may assume that  $L \geq C$ , otherwise the lemma is trivial due to the first term in [\(56\)](#page-10-5). Given this assumption, it is easy to check that the second term in [\(83\)](#page-13-1), viewed as a function of  $\tilde{\rho}$ , has no critical points in the interval [0, 1), and so it is monotonic over that interval. Comparing the values at  $\tilde{\rho} = 0$  and  $\tilde{\rho} = 1$ , we deduce that the maximum is at  $\tilde{\rho} = 1$ . Using this in [\(83\)](#page-13-1), and substituting the result into  $(57)$  (after squaring both sides there) yields the lemma.

### 5. Proof of Theorem [1.2](#page-1-0)

If  $\chi = \chi_0$  is the principal character, then

(84) 
$$
L(s, \chi_0) = \zeta(s) \prod_{p|q} (1 - p^{-s}).
$$

Bounding the product above trivially, we obtain

(85) 
$$
|L(1/2+it,\chi_0)| \le |\zeta(1/2+it)| \prod_{p|q} (1+1/\sqrt{p}) \le |\zeta(1/2+it)| \tau(q).
$$

(Note that this is a large overestimate, but it is still fine since the difficult part of the proof is  $\chi \neq \chi_0$ .) Combining this with the bound for the Riemann zeta function in [\[9\]](#page-23-3), we arrive at

<span id="page-13-2"></span>(86) 
$$
|L(1/2+it,\chi_0)| \leq 0.63\tau(q) \mathfrak{q}^{1/6} \log \mathfrak{q}, \qquad (|t| \geq 3).
$$

So the theorem follows in this case. Henceforth, we assume that  $\chi$  is nonprincipal, and so  $q > 2$ .

Let  $\rho = 1.3$ , which is a parameter that will control the size of the segments in our dyadic subdivision. The starting point of the dyadic subdivision is

(87) 
$$
v_0 = \left[ \frac{C|t|^{1/3}}{(\rho - 1)^2} \right].
$$

We assume that  $|t| \ge t_0 \ge \rho^3/(\rho-1)^3$  where  $t_0 := 200$ . Since  $q > 2$  by assumption, then  $\mathfrak{q} \geq \mathfrak{q}_0 := 3t_0$ .

<span id="page-14-0"></span>From the Dirichlet series definition of  $L(s, \chi)$ , we have

(88) 
$$
|L(1/2 + it, \chi)| \le \left| \sum_{n=1}^{\infty} \frac{\chi(n)}{n^{1/2 + it}} \right|.
$$

We divide the summation range on the r.h.s. of [\(88\)](#page-14-0) into an initial sum followed by dyadic segments  $[\rho^{\ell}v_0, \rho^{\ell+1}v_0]$ . This gives

(89) 
$$
|L(1/2 + it, \chi)| \leq \left| \sum_{n=1}^{v_0 - 1} \frac{\chi(n)}{n^{1/2 + it}} \right| + \sum_{\ell=0}^{\infty} \left| \sum_{\rho \ell v_0 \leq n < \rho^{\ell+1} v_0} \frac{\chi(n)}{n^{1/2 + it}} \right|.
$$

The  $\ell$ -th dyadic segment is subdivided into blocks of length  $L_{\ell}$  where

(90) 
$$
L_{\ell} = \begin{cases} \left\lceil \frac{(\rho - 1)\rho^{\ell}v_{0}}{|t|^{1/3}} \right\rceil, & 0 \leq \ell < \ell_{0} := \frac{\log(CD|t|^{2/3}/v_{0})}{\log \rho} \\ \left\lceil \frac{(\rho - 1)\rho^{\ell}v_{0}}{|t|^{1/2}} \right\rceil, & \ell_{0} \leq \ell < \ell_{1} := \frac{\log(q|t|/5v_{0})}{\log \rho}, \\ \left\lceil \frac{(\rho - 1)\rho^{\ell}v_{0}}{|t|} \right\rceil, & \ell_{1} \leq \ell, \end{cases}
$$

plus a (possibly empty) boundary block. (Note that our assumption  $|t| \ge t_0$  and the fact  $CD \le q$  imply that  $\ell_0 < \ell_1$ .) So there are  $R_\ell = \lceil (\rho - 1) \rho^\ell v_0 / L_\ell \rceil$  blocks in the  $\ell$ -th segment. The r-th block in the  $\ell$ -th segment begins at

(91) 
$$
N_{r,\ell} + 1 = \lceil \rho^{\ell} v_0 \rceil + r L_{\ell}, \qquad (0 \leq r < R_{\ell}).
$$

We first bound the initial sum, then we bound the sum over each range of  $\ell$  separately.

5.1. Initial sum. The initial sum is bounded trivially using the triangle inequality, the fact  $|\chi(n)/n^{1/2+it}| \leq 1/\sqrt{n}$ , and on comparing with the integral  $\int_0^{v_0-1} \frac{1}{\sqrt{x}} dx$ . Recalling that  $C/q^{1/3} = \text{cbf}(q)$ , this gives

<span id="page-14-2"></span>(92) 
$$
\left|\sum_{n=1}^{v_0-1} \frac{\chi(n)}{n^{1/2+it}}\right| \le 2\sqrt{v_0-1} \le \mathfrak{v}_0\sqrt{\text{cbf}(q)}\mathfrak{q}^{1/6}, \qquad \mathfrak{v}_0 := \frac{2}{\rho-1}.
$$

5.2. **Sum over**  $0 \leq \ell < \ell_0$ . Using the Cauchy–Schwarz inequality we obtain

<span id="page-14-1"></span>
$$
(93) \qquad \left| \sum_{0 \leq \ell < \ell_0} \sum_{\rho^{\ell} v_0 \leq n < \rho^{\ell+1} v_0} \frac{\chi(n)}{n^{1/2+it}} \right|^2 \leq (\ell_0 + 1) \sum_{0 \leq \ell < \ell_0} \left| \sum_{\rho^{\ell} v_0 \leq n < \rho^{\ell+1} v_0} \frac{\chi(n)}{n^{1/2+it}} \right|^2
$$

We partition the  $\ell$ -th dyadic segment in [\(93\)](#page-14-1) into blocks of length  $L_{\ell}$ . Then we apply partial summation to each segment to remove the weighting factor  $1/\sqrt{n}$ .

Finally, we apply the Cauchy–Schwarz inequality to the sum of the blocks. This yields

<span id="page-15-0"></span>(94) 
$$
\left| \sum_{\rho^{\ell}v_0 \leq n < \rho^{\ell+1}v_0} \frac{\chi(n)}{n^{1/2+it}} \right|^2 \leq \frac{R_{\ell}}{\rho^{\ell}v_0} \sum_{r=0}^{R_{\ell}-1} \max_{0 \leq \Delta \leq L_{\ell}} \left| \sum_{n=N_{r,\ell}+1}^{N_{r,\ell}+\Delta} \frac{\chi(n)}{n^{it}} \right|^2.
$$

We estimate the inner sum in [\(94\)](#page-15-0) via Lemma [4.2.](#page-9-0) To this end, let

(95) 
$$
\lambda = \frac{1}{\sqrt{\rho - 1}}, \qquad f(x) = -\frac{t}{2\pi} \log x,
$$

and  $1 \leq L = \Delta \leq L_{\ell}$ . (Note that  $\lambda > 1$ , as required by the lemma.) We have

<span id="page-15-1"></span>(96) 
$$
\frac{\lambda(L_{\ell}-1)}{N_{r,\ell}+1} < \frac{1}{\lambda|t|^{1/3}} < 1.
$$

So  $f(N_{r,\ell} + 1 + z)$  is analytic on a disk of radius  $|z| \leq \lambda (L_{\ell} - 1)$ . Moreover, as a consequence of [\(96\)](#page-15-1),

(97) 
$$
\frac{|f^{(j)}(N_{r,\ell}+1)|}{j!}\lambda^{j}(L-1)^{j} = \frac{|t|\lambda^{j}(L-1)^{j}}{2\pi j(N_{r,\ell}+1)^{j}} \leq \frac{1}{2\pi j\lambda^{j}}, \qquad (j \geq 3).
$$

In particular, the required bound on  $|f^{(j)}(N_{r,\ell}+1)|/j!$  in Lemma [4.2](#page-9-0) holds with  $\eta = 1/6\pi$ . Therefore, letting  $\nu_2 = \nu_2(1/\sqrt{\rho-1}, 1/6\pi)$  and

(98) 
$$
y_{r,m,\ell} := \frac{mC^2 Df''(N_{\ell,r}+1)}{Bd_m} = \frac{m}{d_m} \frac{C^2 Dt}{2\pi B} \frac{1}{(N_{r,\ell}+1)^2},
$$

Lemma [4.2](#page-9-0) gives that the r.h.s. in [\(93\)](#page-14-1) is bounded by

<span id="page-15-4"></span>(99) 
$$
\frac{4\nu_2^2 \Lambda}{\pi} (\ell_0 + 1) \sum_{0 \le \ell < \ell_0} (*_\ell + *_\ell),
$$

where

(100) 
$$
*_\ell := \frac{CL_\ell R_\ell^2}{\rho^\ell v_0} \left( \log \frac{D}{2B} + \frac{7}{4} + \frac{3\pi}{2\Lambda} \right)
$$

$$
*_\ell := \frac{C^2 R_\ell}{\rho^\ell v_0} \sum_{m=1}^{[L_\ell/C]} W(m) \sum_{r=0}^{R_\ell - 1} \min \left( \frac{\pi d_m BL_\ell}{CD}, \frac{1}{\|y_{r,m,\ell}\|} \right)
$$

where for brevity we write

(101) 
$$
W(m) = 1 - \frac{m}{\lceil L_{\ell}/C \rceil}.
$$

We consider the term  $*_\ell$  first since it is easier to handle. Since  $(\rho-1)^2v_0/|t|^{1/3} \geq C$ , we obtain

,

.

.

<span id="page-15-2"></span>(102) 
$$
\frac{(\rho - 1)\rho^{\ell}v_0}{|t|^{1/3}} \le L_{\ell} \le \frac{(\rho - 1)\rho^{\ell+1}v_0}{|t|^{1/3}}
$$

And the upper bound in [\(102\)](#page-15-2) gives  $(\rho - 1)^2 v_0/L_{\ell} \ge 1$ . Hence,

<span id="page-15-3"></span>(103) 
$$
\frac{(\rho - 1)\rho^{\ell}v_0}{L_{\ell}} \le R_{\ell} \le \frac{(\rho - 1)\rho^{\ell+1}v_0}{L_{\ell}}
$$

As can be seen from [\(103\)](#page-15-3) and the definition of  $L_{\ell}$ , we have

<span id="page-15-5"></span>(104) 
$$
R_{\ell} \le \rho |t|^{1/3}, \qquad (0 \le \ell < \ell_0).
$$

Using this bound, the bound [\(103\)](#page-15-3), and the inequality  $\Lambda \geq 2$  (valid since  $q > 2$  by assumption), we arrive at

(105) 
$$
\sum_{0 \le \ell < \ell_0} *_\ell \le (\ell_0 + 1)\rho^2(\rho - 1)C|t|^{1/3}\left(\log\frac{D}{2} + \frac{7}{4} + \frac{3\pi}{4}\right).
$$

Furthermore, by our choice of  $v_0$ , we have

<span id="page-16-2"></span>(106) 
$$
\ell_0 + 1 \leq \frac{\log (\rho(\rho - 1)^2 D|t|^{1/3})}{\log \rho}.
$$

Therefore, using the inequality  $\log \frac{D|t|^{1/3}}{2} \leq \log q^{1/3}$ , the formula  $C/q^{1/3} = \text{cbf}(q)$ , and incorporating the additional factor  $\ell_0 + 1$  from [\(99\)](#page-15-4) into our estimate, gives

<span id="page-16-3"></span>(107) 
$$
(\ell_0+1)\sum_{0\leq \ell < \ell_0} *_\ell \leq \mathfrak{v}_1 \mathrm{cbf}(q) \mathfrak{q}^{1/3} Z_1(\log \mathfrak{q}), \qquad \mathfrak{v}_1 := \frac{\rho^2(\rho-1)}{27 \log^2 \rho},
$$

where

(108) 
$$
Z_1(X) := (X - \log t_0 + 21/4 + 9\pi/4) (X + 3\log(2\rho(\rho - 1)^2))^2.
$$

The term  $**_{\ell}$  in [\(99\)](#page-15-4) is more complicated to handle. First, we apply Lemma [3.1](#page-3-0) to estimate the sum over  $r$  there. To this end, note that

(109) 
$$
(N_{r+1,\ell}+1)^2 - (N_{r,\ell}+1)^2 \ge 2[\rho^{\ell}v_0]L_{\ell}, \qquad (0 \le r < R_{\ell}-1).
$$

Moreover, by construction,  $N_{R_{\ell}-1,\ell} + 1 \leq \lfloor \rho^{\ell+1} v_0 \rfloor$  and  $N_{0,\ell} + 1 \geq \lceil \rho^{\ell} v_0 \rceil$ . Hence,

<span id="page-16-0"></span>(110)  

$$
|y_{r+1,m,\ell} - y_{r,m,\ell}| \ge \frac{m}{d_m} \frac{C^2 D|t|}{2\pi B} \frac{2\lceil \rho^{\ell} v_0 \rceil L_{\ell}}{\lfloor \rho^{\ell+1} v_0 \rfloor^4}, \qquad (0 \le r < R_{\ell} - 1),
$$

$$
|y_{R_{\ell}-1,m,\ell} - y_{0,m,\ell}| \le \frac{m}{d_m} \frac{C^2 D|t|}{2\pi B} \frac{\rho^2 - 1}{\lfloor \rho^{\ell+1} v_0 \rfloor^2}.
$$

We apply Lemma [3.1](#page-3-0) to the sequence  $\{y_{r,m,\ell}\}_r$  with  $y = y_{R_{\ell-1},m,\ell}, x = y_{0,m,\ell}$ ,  $P = \pi d_m BL_{\ell}/CD$ , and (since  $y_{r,m,\ell}$  is monotonic in r) with  $\delta$  equal to the lower bound for  $|y_{r+1,m,\ell} - y_{r,m,\ell}|$  in [\(110\)](#page-16-0). Using these parameter choices, Lemma [3.1](#page-3-0) gives

$$
(111) \sum_{r=0}^{R_{\ell}-1} \min\left(\frac{\pi d_m BL_{\ell}}{CD}, \frac{1}{\|y_{r,m,\ell}\|}\right) \le 2(y-x+1)(2P+\delta^{-1}\log(e\max\{P,2\}/2)).
$$

Multiplying out the brackets, we obtain four terms:  $2(y-x)\delta^{-1}\log(e\max\{P,2\}/2)),$  $2\delta^{-1}\log(e\max\{P,2\}/2)), 4(y-x)P$ , and 4P. We estimate the sum of each term over  $m$  with the aid of the following inequalities, which are either straightforward to prove (left two inequalities) or are a consequence of Lemma [3.4.](#page-6-1)

<span id="page-16-1"></span>(112) 
$$
\sum_{m=1}^{\lceil L_{\ell}/C \rceil} W(m) \leq \frac{L_{\ell}}{2C}, \qquad \sum_{m=1}^{\lceil L_{\ell}/C \rceil} W(m) \frac{d_{m}}{m} \leq \tau(D/B) \log \lceil L_{\ell}/C \rceil, \sum_{m=1}^{\lceil L_{\ell}/C \rceil} W(m) m \leq \frac{L_{\ell}^{2}}{2C^{2}}, \qquad \sum_{m=1}^{\lceil L_{\ell}/C \rceil} W(m) d_{m} \leq \tau(D/B) \lceil L_{\ell}/C \rceil.
$$

Combining [\(102\)](#page-15-2), [\(104\)](#page-15-5), [\(110\)](#page-16-0), and [\(112\)](#page-16-1), together with the bound (here we use  $L_{\ell} \geq C$ 

(113) 
$$
\log\left(e\max\{P,2\}/2\right) \leq \log\left(\frac{e\pi L_{\ell}}{2C}\right),
$$

we routinely deduce the estimates

$$
\frac{C^{2}R_{\ell}}{\rho^{\ell}v_{0}} \sum_{m=1}^{[L_{\ell}/C]} W(m) \frac{(\rho^{2}-1)\lfloor \rho^{\ell+1}v_{0}\rfloor^{2}}{\lceil \rho^{\ell}v_{0}\rceil L_{\ell}} \log\left(\frac{e\pi L_{\ell}}{2C}\right) \leq \mathcal{B}_{1}(\ell)
$$
\n
$$
\frac{C^{2}R_{\ell}}{\rho^{\ell}v_{0}} \sum_{m=1}^{[L_{\ell}/C]} W(m) \frac{d_{m}}{m} \frac{2\pi B}{C^{2}D|t} \frac{\lfloor \rho^{\ell+1}v_{0}\rfloor^{4}}{\lceil \rho^{\ell}v_{0}\rceil L_{\ell}} \log\left(\frac{e\pi L_{\ell}}{2C}\right) \leq \mathcal{B}_{2}(\ell)
$$
\n(114)\n
$$
\frac{C^{2}R_{\ell}}{\rho^{\ell}v_{0}} \sum_{m=1}^{[L_{\ell}/C]} W(m) \frac{4\pi d_{m}BL_{\ell}}{CD} \frac{m}{d_{m}} \frac{C^{2}D|t|}{2\pi B} \frac{\rho^{2}-1}{\lceil \rho^{\ell+1}v_{0}\rceil^{2}} \leq \mathcal{B}_{3}(\ell)
$$
\n
$$
\frac{C^{2}R_{\ell}}{\rho^{\ell}v_{0}} \sum_{m=1}^{[L_{\ell}/C]} W(m) d_{m} \frac{4\pi BL_{\ell}}{CD} \leq \mathcal{B}_{4}(\ell),
$$

where

(115)  
\n
$$
\mathcal{B}_1(\ell) := \frac{\rho^3(\rho^2 - 1)}{2} C|t|^{1/3} \log\left(\frac{e\pi L_{\ell}}{2C}\right),
$$
\n
$$
\mathcal{B}_2(\ell) := \frac{2\pi\rho^5}{(\rho - 1)} \frac{\rho^{\ell} v_0}{D|t|^{1/3}} B\tau(D/B) \log\left(\frac{eL_{\ell}}{C}\right) \log\left(\frac{e\pi L_{\ell}}{2C}\right),
$$
\n
$$
\mathcal{B}_3(\ell) := \rho^3(\rho - 1)^3(\rho^2 - 1)C|t|^{1/3},
$$
\n
$$
\mathcal{B}_4(\ell) := 4\pi\rho^2(\rho - 1)^2 \frac{\rho^{\ell} v_0}{D|t|^{1/3}} B\tau(D/B).
$$

Incorporating the additional factor  $\ell_0+1$  from [\(93\)](#page-14-1) into our estimate, we therefore conclude that

<span id="page-17-0"></span>(116) 
$$
(\ell_0+1)\sum_{0\leq\ell<\ell_0}**_{\ell}\leq \sum_{j=1}^4(\ell_0+1)\sum_{0\leq\ell<\ell_0}\mathcal{B}_j(\ell).
$$

We estimate the sum over  $\ell$  in [\(116\)](#page-17-0) as a geometric progression. To this end, we use the bound on  $\ell_0$  in [\(106\)](#page-16-2), the bound

(117) 
$$
L_{\ell} \leq \rho(\rho - 1)CD|t|^{1/3}, \qquad (0 \leq \ell < \ell_0).
$$

which follows directly from the definitions of  $L_\ell$  and  $\ell_0,$  and consequently the bound

(118) 
$$
\log\left(\frac{e\pi L_{\ell}}{2C}\right) \le \log\left(\frac{e\pi\rho(\rho-1)D|t|^{1/3}}{2}\right), \qquad (0 \le \ell < \ell_0).
$$

After some rearrangements, this yields

(119)  
\n
$$
(\ell_0 + 1) \sum_{0 \le \ell < \ell_0} B_1(\ell) \le \mathfrak{v}_2 \operatorname{cbf}(q) \mathfrak{q}^{1/3} Z_2(\log \mathfrak{q}), \qquad \mathfrak{v}_2 := \frac{\rho^3(\rho^2 - 1)}{54 \log^2 \rho},
$$
\n
$$
(\ell_0 + 1) \sum_{0 \le \ell < \ell_0} B_2(\ell) \le \mathfrak{v}_3 \operatorname{cbf}(q) B_7(D/B) \mathfrak{q}^{1/3} Z_3(\log \mathfrak{q}), \qquad \mathfrak{v}_3 := \frac{2\pi \rho^6}{27(\rho - 1)^2 \log \rho},
$$
\n
$$
(\ell_0 + 1) \sum_{0 \le \ell < \ell_0} B_3(\ell) \le \mathfrak{v}_4 \operatorname{cbf}(q) \mathfrak{q}^{1/3} Z_4(\log \mathfrak{q}), \qquad \mathfrak{v}_4 := \frac{\rho^3(\rho - 1)^3(\rho^2 - 1)}{9 \log^2 \rho},
$$
\n
$$
(\ell_0 + 1) \sum_{0 \le \ell < \ell_0} B_4(\ell) \le \mathfrak{v}_5 \operatorname{cbf}(q) B_7(D/B) \mathfrak{q}^{1/3} Z_5(\log \mathfrak{q}), \qquad \mathfrak{v}_5 := \frac{4\pi \rho^3(\rho - 1)}{3 \log \rho}.
$$

where

$$
Z_2(X) := (X + 3\log(e\pi\rho(\rho - 1)) (X + 3\log(2\rho(\rho - 1)^2))^2
$$
  
\n
$$
Z_3(X) := (X + 3\log(2e\rho(\rho - 1)) (X + 3\log(e\pi\rho(\rho - 1))) \times (X + 3\log(2\rho(\rho - 1)^2))
$$
  
\n
$$
Z_4(X) := (X + 3\log(2\rho(\rho - 1)^2))^2
$$
  
\n
$$
Z_5(X) := X + 3\log(2\rho(\rho - 1)^2)
$$

Therefore,

<span id="page-18-0"></span>(121)  
\n
$$
(\ell_0 + 1) \sum_{0 \le \ell < \ell_0} **_{\ell} \le \mathfrak{v}_2 \operatorname{cbf}(q) \mathfrak{q}^{1/3} Z_2(\log \mathfrak{q}) + \mathfrak{v}_3 B \tau(D/B) \operatorname{cbf}(q) \mathfrak{q}^{1/3} Z_3(\log \mathfrak{q}) + \mathfrak{v}_4 \operatorname{cbf}(q) \mathfrak{q}^{1/3} Z_4(\log \mathfrak{q}) + \mathfrak{v}_5 B \tau(D/B) \operatorname{cbf}(q) \mathfrak{q}^{1/3} Z_5(\log \mathfrak{q}).
$$

We combine [\(121\)](#page-18-0) and [\(107\)](#page-16-3), and use the inequality  $\sqrt{x+y} \leq \sqrt{x} + \sqrt{y}$  with  $x, y \geq 0$ . This gives (122)

$$
\sqrt{\left(\ell_0+1\right)\sum_{0\leq\ell<\ell_0}(*_{\ell}+**_{\ell})}\leq\sqrt{\mathrm{cbf}(q)}\left(\sqrt{Z_6(\log\mathfrak{q})}+\sqrt{B\tau(D/B)Z_7(\log\mathfrak{q})}\right)\mathfrak{q}^{1/6}
$$

where

(123) 
$$
Z_6(X) := \mathfrak{v}_1 Z_1(X) + \mathfrak{v}_2 Z_2(X) + \mathfrak{v}_4 Z_4(X),
$$

$$
Z_7(X) := \mathfrak{v}_3 Z_3(X) + \mathfrak{v}_5 Z_5(X).
$$

Finally, we substitute this back into [\(93\)](#page-14-1) which yields

<span id="page-18-1"></span>(124) 
$$
\left| \sum_{0 \leq \ell < \ell_0} \sum_{\rho^{\ell} v_0 \leq n < \rho^{\ell+1} v_0} \frac{\chi(n)}{n^{1/2+it}} \right| \leq \frac{2\nu_2}{\sqrt{\pi}} \sqrt{\Lambda \cot(q) Z_6 (\log q)} \mathfrak{q}^{1/6} + \frac{2\nu_2}{\sqrt{\pi}} \sqrt{\Lambda \cot(q) B \tau(D/B) Z_7 (\log q)} \mathfrak{q}^{1/6}.
$$

5.3. Sum over  $\ell_0 \leq \ell \leq \ell_1$ . Applying the triangle inequality and partial summation gives

<span id="page-19-0"></span>
$$
(125) \sum_{\ell_0 \leq \ell < \ell_1} \left| \sum_{\rho \ell v_0 \leq n < \rho^{\ell+1} v_0} \frac{\chi(n)}{n^{1/2+it}} \right| \leq \sum_{\ell_0 \leq \ell < \ell_1} \frac{1}{(\rho^{\ell} v_0)^{1/2}} \sum_{r=0}^{R_{\ell}-1} \max_{0 \leq \Delta \leq L_{\ell}} \left| \sum_{n=N_{r,\ell}+1}^{N_{r,\ell}+\Delta} \frac{\chi(n)}{n^{it}} \right|.
$$

We bound the inner sum in [\(125\)](#page-19-0) via Lemma [4.1.](#page-7-0) Using a similar analysis as in the beginning of Section 5.2, one verifies that the required analyticity conditions on  $f(x) = -\frac{t}{2\pi} \log x$  in Lemma [4.1](#page-7-0) hold with  $J = 1$ ,  $\lambda = 1/\sqrt{\rho - 1}$ , and  $\eta = 1/4\pi$ . Therefore, if we let  $\nu_1 = \nu_1(1/\sqrt{\rho-1}, 1/4\pi)$  and

(126) 
$$
x_{r,\ell} := \frac{qf'(N_{\ell,r}+1)}{B_1} = -\frac{qt}{2\pi B_1} \frac{1}{N_{r,\ell}+1},
$$

then by Lemma [4.1](#page-7-0) the inner double sum in [\(125\)](#page-19-0) is bounded by

<span id="page-19-1"></span>(127) 
$$
\frac{2\nu_1}{\pi} \frac{C_1 R_\ell}{(\rho^\ell v_0)^{1/2}} \left( \log \frac{D_1}{2B_1} + \frac{7}{4} + \frac{\pi}{2} \right) + \frac{\nu_1}{\pi} \frac{C_1}{(\rho^\ell v_0)^{1/2}} \sum_{r=0}^{R_\ell - 1} \min \left( \frac{\pi B_1 L_\ell}{q}, \frac{1}{\|x_{r,\ell}\|} \right).
$$

We bound the sum over  $r$  in [\(127\)](#page-19-1) using Lemma [3.1.](#page-3-0) To this end, note that

<span id="page-19-2"></span>
$$
(128) \quad |x_{r+1,\ell} - x_{r,\ell}| \ge \frac{q|t|}{2\pi B_1} \frac{L_\ell}{\lfloor \rho^{\ell+1} v_0 \rfloor^2}, \qquad |x_{R_\ell - 1,\ell} - x_{0,\ell}| \le \frac{q|t|}{2\pi B_1} \frac{\rho - 1}{\lfloor \rho^{\ell+1} v_0 \rfloor}.
$$

Furthermore, since the sequence  $x_{r,\ell}$  is monotonic in r, we may set  $\delta$  in Lemma [3.1](#page-3-0) to be the lower bound for  $|x_{r+1,\ell} - x_{r,\ell}|$  in [\(128\)](#page-19-2), set  $y - x$  as the upper bound for  $|x_{R_{\ell}-1,\ell}-x_{0,\ell}|$  in [\(128\)](#page-19-2), and set  $P = \pi B_1 L_{\ell}/q$ . (Note that  $P \ge 2$ .) Therefore, applying the lemma, and multiplying out the bracket in the resulting bound  $2(y (x+1)(2P + \delta^{-1} \log(eP/2))$ , gives

(129)  
\n
$$
\sum_{r=0}^{R_{\ell}-1} \min\left(\frac{\pi B_1 L_{\ell}}{q}, \frac{1}{\|x_{r,\ell}\|}\right) \le \left(\frac{2(\rho-1)\lfloor \rho^{\ell+1} v_0 \rfloor}{L_{\ell}} + \frac{4\pi B_1}{q|t|} \frac{\lfloor \rho^{\ell+1} v_0 \rfloor^2}{L_{\ell}}\right) \log\left(\frac{e\pi B_1 L_{\ell}}{2q}\right) + \frac{2(\rho-1)|t|L_{\ell}}{\lfloor \rho^{\ell+1} v_0 \rfloor} + \frac{4\pi B_1 L_{\ell}}{q}.
$$

Using similar inequalities as in Section 5.2, we deduce that

$$
(130) \quad \frac{(\rho-1)\rho^{\ell}v_0}{|t|^{1/2}} \le L_{\ell} \le \frac{(\rho-1)\rho^{\ell+1}v_0}{|t|^{1/2}} \le \frac{1}{5}\rho(\rho-1)q|t|^{1/2}, \qquad (\ell_0 \le \ell < \ell_1).
$$

Consequently, since  $B_1 \leq D_1$ , we have

(131) 
$$
\log\left(\frac{e\pi B_1L_\ell}{2q}\right) \leq \log\left(\frac{e\pi\rho(\rho-1)D_1|t|^{1/2}}{10}\right), \qquad (\ell_0 \leq \ell < \ell_1).
$$

Using these inequalities, the formulas  $\sqrt{q}/D_1 = \text{sqf}(q)$ ,  $C_1/(\sqrt{CD}q^{1/6}) = \text{spf}(q)$ , and executing the geometric sum over  $\ell$ , we therefore conclude that (132)

<span id="page-20-1"></span>
$$
\sum_{\ell_0\leq \ell<\ell_1}\frac{C_1}{(\rho^\ell v_0)^{1/2}}\sum_{r=0}^{R_\ell-1}\min\left(\frac{\pi B_1L_\ell}{q},\frac{1}{\|x_{r,\ell}\|}\right)\leq\\ \mathfrak{v}_8\operatorname{spf}(q)\mathfrak{q}^{1/6}Z_8(\log \mathfrak{q})+\mathfrak{v}_9\operatorname{sqf}(q)B_1Z_8(\log \mathfrak{q})+\mathfrak{v}_{10}\operatorname{spf}(q)\mathfrak{q}^{1/6}+\mathfrak{v}_{11}\operatorname{sqf}(q)B_1,
$$

where

(133) 
$$
Z_8(X) := X + 2\log(e\pi\rho(\rho - 1)/10)
$$

and

(134) 
$$
\mathfrak{v}_8 := \frac{\rho^{3/2}}{\sqrt{\rho} - 1}, \qquad \mathfrak{v}_9 := \frac{2\pi \rho^{5/2}}{\sqrt{5}(\rho - 1)(\sqrt{\rho} - 1)}, \n\mathfrak{v}_{10} := \frac{2\rho^{3/2}(\rho - 1)^2}{\sqrt{\rho} - 1}, \qquad \mathfrak{v}_{11} := \frac{4\pi \rho^{3/2}(\rho - 1)}{\sqrt{5}(\sqrt{\rho} - 1)}.
$$

Furthermore, using the bound

(135) 
$$
R_{\ell} \le \rho |t|^{1/2}, \qquad (\ell_0 \le \ell < \ell_1).
$$

we obtain

<span id="page-20-0"></span>(136) 
$$
\sum_{\ell_0 \leq \ell < \ell_1} \frac{C_1 R_\ell}{(\rho^\ell v_0)^{1/2}} \left( \log \frac{D_1}{2B_1} + \frac{7}{4} + \frac{\pi}{2} \right) \leq \mathfrak{v}_{12} \operatorname{spf}(q) \mathfrak{q}^{1/6} Z_9(\log \mathfrak{q}),
$$

where

(137) 
$$
\mathfrak{v}_{12} := \frac{\rho^{3/2}}{2(\sqrt{\rho} - 1)}, \qquad Z_9(X) = X - 2\log(2\sqrt{t_0}) + \frac{7}{2} + \pi.
$$

We substitute [\(136\)](#page-20-0) and [\(132\)](#page-20-1) into [\(127\)](#page-19-1) and [\(125\)](#page-19-0), which gives (after some simplification)

$$
(138)
$$

<span id="page-20-3"></span>
$$
\sum_{\ell_0 \leq \ell < \ell_1} \left| \sum_{\rho \ell v_0 \leq n < \rho^{\ell+1} v_0} \frac{\chi(n)}{n^{1/2+it}} \right| \leq
$$
\n
$$
\frac{\nu_1}{\pi} \left( \mathfrak{v}_8 \operatorname{spf}(q) \mathfrak{q}^{1/6} Z_8(\log \mathfrak{q}) + \mathfrak{v}_9 \operatorname{sqf}(q) B_1 Z_8(\log \mathfrak{q}) + \mathfrak{v}_{10} \operatorname{spf}(q) \mathfrak{q}^{1/6} + \mathfrak{v}_{11} \operatorname{sqf}(q) B_1 \right) + \frac{2\nu_1}{\pi} \mathfrak{v}_{12} \operatorname{spf}(q) \mathfrak{q}^{1/6} Z_9(\log \mathfrak{q}).
$$

5.4. Sum over  $\ell_1 \leq \ell$ . Like before, we apply the triangle inequality, partial sum-mation, and Lemma [3.2](#page-4-1) with  $J = 0$ , to obtain

<span id="page-20-2"></span>
$$
(139) \sum_{\ell_1 \leq \ell} \left| \sum_{\rho^{\ell} v_0 \leq n < \rho^{\ell+1} v_0} \frac{\chi(n)}{n^{1/2+it}} \right| \leq \sum_{\ell_1 \leq \ell} \frac{\nu_0}{(\rho^{\ell} v_0)^{1/2}} \sum_{r=0}^{R_{\ell}-1} \max_{0 \leq \Delta \leq L_{\ell}} \left| \sum_{n=N_{r,\ell}+1}^{N_{r,\ell}+\Delta} \chi(n) \right|.
$$

Here,  $\nu_0 := \nu_0(1/\sqrt{\rho-1}, 1/2\pi)$ . We use the bound for non-principal characters at the bottom of page 139 of [\[7\]](#page-23-5). Specifically, if  $\chi \pmod{q}$  is non-principal, then  $|\sum_{n} \chi(n)| \leq 2\sqrt{q} \log q$ . Using this in [\(139\)](#page-20-2), we deduce that the r.h.s. is

<span id="page-21-1"></span>(140) 
$$
\leq 2\nu_0\sqrt{q}\log q \sum_{\ell_1\leq \ell} \frac{1}{(\rho^{\ell}v_0)^{1/2}} \leq \frac{2\sqrt{5}\nu_0\sqrt{\rho}}{\sqrt{\rho}-1} \frac{\log q}{\sqrt{|t|}} \leq \nu_0\mathfrak{v}_{13}Z_{10}(\log \mathfrak{q}),
$$

where

(141) 
$$
\mathfrak{v}_{13} := \frac{2\sqrt{5}\sqrt{\rho}}{(\sqrt{\rho}-1)\sqrt{t_0}}, \qquad Z_{10}(X) := X - \log t_0.
$$

5.5. **Summary.** We combine  $(92)$ ,  $(124)$ ,  $(138)$ , and  $(140)$ , then evaluate the resulting numerical constants with  $\rho = 1.3$ . This yields the theorem.

## 6. Proof of Corollary [1.1](#page-1-1)

We may assume that  $q > 1$ , otherwise the corollary follows from the bound [\(86\)](#page-13-2) for principal characters. By Lemma [3.3,](#page-5-0) if  $\chi$  is primitive, then  $B = B_1 = 1$ . Also, since q is a sixth power then  $\text{sqf}(q) = \text{cbf}(q) = 1$  and  $\text{spf}(q) \leq 1$ . Therefore, the functions  $Z(X)$  and  $W(X)$  in Theorem [1.2](#page-1-0) satisfy

$$
(142)
$$

$$
Z(X) \le -9.416 + 15.6004X + 1.4327\sqrt{\Lambda(D)}X^{3/2} + 12.1673\sqrt{\Lambda(D)\tau(D)}X^{3/2},
$$
  
 
$$
W(X) \le -296.84 + 114.07X,
$$

where we used that for  $X \geq \log(2t_0)$  we have

(143) 
$$
65.5619 - 17.1704X - 2.4781X^{2} + 0.6807X^{3} \le 0.6807X^{3},
$$

$$
-1732 - 817.82X + 71.68X^{2} + 47.57X^{3} \le 49.1X^{3}.
$$

These inequalities are verified using Mathematica.

It is easy to see that  $\Lambda(p^a) \leq \tau(p^a)$  which, by multiplicativity, implies that  $\sqrt{\Lambda(D)\tau(D)} \leq \tau(D)$ . Furthermore, since q is a sixth power and  $q > 1$ , then  $\tau(D) \leq 0.572\tau(q)$  (as can be seen by considering the case  $q = 2^{6a}$ ),  $\tau(q) \geq 7$ , and  $q \geq 2^6$ . Substituting these bounds into the expressions for  $Z(X)$  and  $W(X)$ , we verify via Mathematica that

(144) 
$$
Z(X) \le \tau(q)(-1.3451 + 2.2287X + 7.2695X^{3/2}) \le 7.95\tau(q)X^{3/2},
$$

$$
W(X) \le \tau(q)(-42.4056 + 16.2958X) \le 16.30\tau(q)X.
$$

holds for  $X \geq \log(2^6 t_0)$ . Therefore,

(145) 
$$
|L(1/2+it,\chi)| \leq 7.95\tau(q) \mathfrak{q}^{1/6} \log^{3/2} \mathfrak{q} + 16.30\tau(q) \log \mathfrak{q}.
$$

Finally, using the bound  $\mathfrak{q} \geq 2^6 t_0$ , we deduce that  $|L(1/2+it,\chi)| \leq 9.05\tau(q)\mathfrak{q}^{1/6} \log^{3/2} \mathfrak{q}$ , proving the corollary.

7. Proofs of bounds [\(4\)](#page-0-1) and [\(2\)](#page-0-3)

<span id="page-21-0"></span>*Proof of bound* [\(4\)](#page-0-1). Since  $\chi$  is nonprincipal, we have

(146) 
$$
L(1/2 + it, \chi) = \sum_{n \le M} \frac{\chi(n)}{n^{1/2+it}} + \mathcal{R}_M(t, \chi),
$$

where the remainder  $\mathcal{R}_M(t,\chi) := \sum_{n>M}^{\infty} \chi(n) n^{-1/2-it}$  is just the tail of the Dirichlet series. (We do not require that  $M > 0$  be an integer.) To estimate the tail, we use partial summation [\[12,](#page-24-1) formula (1)],

<span id="page-22-0"></span>(147) 
$$
\left| \sum_{M < n \le M_2} \frac{\chi(n)}{n^{1/2+it}} \right| \le \frac{1}{\sqrt{M_2}} \left| \sum_{n \le M_2} \chi(n) \right| + \frac{1}{\sqrt{M}} \left| \sum_{n \le M} \chi(n) \right| + (1/2 + |t|) \int_M^{M_2} \left| \sum_{1 \le n \le u} \chi(n) \right| u^{-3/2} du.
$$

We bound the character sums on the r.h.s. of  $(147)$  using the Pólya-Vinogradov inequality in [\[3,](#page-23-10) §23]. This asserts that if  $\chi$  is a primitive character modulo  $q > 1$ then  $|\sum_{N_1 \leq n \leq N_2} \chi(n)| \leq \sqrt{q} \log q$ . Substituting this in [\(147\)](#page-22-0), taking the limit  $M_2 \rightarrow \infty$ , and executing the integral gives

(148) 
$$
|L(1/2+it,\chi)| \leq 2\sqrt{M} + \frac{2\sqrt{q}\log q}{\sqrt{M}}(|t|+1).
$$

The claimed bound follows on choosing  $M = (|t| + 1)\sqrt{q} \log q$ .

*Remark.* If  $\chi$  is merely assumed to be nonprincipal, then the bound [\(4\)](#page-0-1) still holds but with an extra factor of  $\sqrt{2}$  in front. One simply uses the Pólya-Vinogradov inequality stated in [\[7,](#page-23-5) page 139] in the proof.

*Proof of bound* [\(2\)](#page-0-3). Since  $|L(1/2+it, \chi)| = |L(1/2-it, \overline{\chi})|$  and the proof will apply symmetrically to  $L(1/2 + it, \chi)$  and  $L(1/2 + it, \overline{\chi})$ , we may assume that  $t \ge 0$ . Let  $n_1 = \lfloor \sqrt{qt/(2\pi)} \rfloor$ . Since  $qt \geq 2\pi$ , [\[4,](#page-23-1) Theorem 5.3] implies that

<span id="page-22-3"></span>(149) 
$$
|L(1/2+it,\chi)| \le (2+\delta_t) \left| \sum_{n=1}^{n_1} \frac{\chi(n)}{n^{1/2+it}} \right| + |\mathcal{R}(t,\chi)|,
$$

where<sup>[3](#page-22-1)</sup>  $\delta_t := e^{\frac{\pi}{24t} + \frac{1}{12t^2}} - 1$  and

<span id="page-22-4"></span>(150) 
$$
|\mathcal{R}(t,\chi)| \le \frac{264.72q^{1/4}\log q}{t^{1/4}} + \frac{11.39q^{3/4}}{t^{3/4}}e^{-0.78\sqrt{t/q}}.
$$

To prove this, we specialize [\[4,](#page-23-1) Theorem 5.3] to the critical line, taking  $X = Y$  with  $2\pi X^2 = qt$ , then appeal to well-known properties of Gauss sums. Put together, this yields

<span id="page-22-2"></span>(151) 
$$
L(1/2 + it, \chi) = \sum_{n \le X} \frac{\chi(n)}{n^{1/2+it}} + F(t, \chi) \sum_{n \le X} \frac{\overline{\chi(n)}}{n^{1/2-it}} + \mathcal{R}(t, \chi),
$$

where  $G(\chi, -1)$  is a Gauss sum and

(152) 
$$
F(t,\chi) := \frac{(2\pi i)^{1/2+it}q^{-1/2-it}G(\chi,-1)}{\Gamma(1/2+it)}
$$

(Here,  $(2\pi i)^{1/2+it}$  is defined using the principal branch of the logarithm.) We estimate  $\mathcal{R}(t, \chi)$  in [\(151\)](#page-22-2) using the case " $X \leq Y$ " in [\[4,](#page-23-1) Theorem 5.3]. Since we

.

<span id="page-22-1"></span><sup>&</sup>lt;sup>3</sup>The appearance of  $\delta_t$  in [\(149\)](#page-22-3) is due to a slight imperfection in the form of the approximate functional equation proved in [\[4\]](#page-23-1), and is not significant otherwise.

specialized  $X = \sqrt{qt/(2\pi)}$ , we obtain

(153) 
$$
|\mathcal{R}(t,\chi)| \leq \left(167.2(2\pi)^{1/4}\log q + \frac{2.87(2\pi)^{3/4}\sqrt{q}}{\sqrt{t}}e^{-\sqrt{\pi^3/50}\sqrt{t/q}}\right)\frac{q^{1/4}}{t^{1/4}}.
$$

The claimed estimate [\(150\)](#page-22-4) for  $\mathcal{R}(t, \chi)$  follows on noting that  $167.2(2\pi)^{1/4} < 264.72$ , 2.87( $2\pi$ )<sup>3/4</sup> < 11.39, and  $\pi^{3/2}/\sqrt{50}$  > 0.78.

To bound the factor  $1/\Gamma(1/2 + it)$  appearing in the definition of  $F(t)$ , we mimic the proof of [\[4,](#page-23-1) Lemma 2.1] with minor adjustments. This gives

<span id="page-23-11"></span>(154) 
$$
\frac{1}{|\Gamma(1/2+it)|} \le \frac{e^{\frac{\pi t}{2} + \frac{\pi}{24t} + \frac{1}{12t^2}}}{\sqrt{2\pi}}, \qquad (t > 0).
$$

Combining [\(154\)](#page-23-11) with the facts  $|G(\chi, -1)| = \sqrt{q}$  and  $|(2\pi i)^{1/2+it}| = \sqrt{2\pi}e^{-\pi t/2}$ gives  $|F(t,\chi)| \leq e^{\frac{\pi}{24t} + \frac{1}{12t^2}} = 1 + \delta_t$ . Since the second sum in the approximate functional equation [\(151\)](#page-22-2) is just the complex conjugate of the first sum there, this proves [\(149\)](#page-22-3).

Last, we trivially estimate the sum in [\(149\)](#page-22-3), then use the assumption  $t \geq \sqrt{q} \geq$  $\sqrt{2}$  and monotonicity to bound  $\mathcal{R}(t,\chi)$  and  $\delta_t$ . This gives (on noting that  $\log q \leq$  $\log \mathfrak{q}^{2/3}$ )

(155) 
$$
|L(1/2+it,\chi)| \le \left(\frac{2(1+\delta_{\sqrt{2}})}{(2\pi)^{1/4}}+11.39e^{-\frac{0.78}{2^{1/4}}}\right)\mathfrak{q}^{1/4}+264.72\mathfrak{q}^{1/12}\log\mathfrak{q}^{2/3}.
$$

Denote the r.h.s. above by (∗). Using Mathematica we verify that the equation (\*) =  $124.46q^{1/4}$  has no real solution if  $q \ge 10^9$ . Furthermore, (\*) is smaller than 124.46 $\mathfrak{q}^{1/4}$  when  $\mathfrak{q} = 10^9$ . Hence, (\*) ≤ 124.46 $\mathfrak{q}^{1/4}$  for all  $\mathfrak{q} \ge 10^9$ , as claimed.  $\Box$
