

Performance of ATLAS L1 Calorimeter trigger with data

Juraj Bracinik (University of Birmingham)
on behalf of the ATLAS Collaboration

TWEPP 2010, Aachen

- ◆ Introduction
- ◆ Calibration
- ◆ Experience from data taking
- ◆ Efficiency for physics objects

Life at hadronic colliders is not easy ...

Most of the time this!

Here it gets really exciting!

L1Calo - a major part of ATLAS L1 trigger

- ◆ Level-1
 - ➔ Custom built HW (ASICs and FPGAs)
 - ➔ Fixed latency $< 2.5 \mu\text{s}$, L1A $\sim 75 \text{ kHz}$
- ◆ Level-2
 - ➔ CPU's
 - ➔ Full granularity for areas of activity marked by L1 - Regions of Interest (RoI)
 - ➔ Latency $\sim 40 \text{ ms}$, L2A $\sim 2 \text{ kHz}$
- ◆ Event Filter (Level-3)
 - ➔ CPU's
 - ➔ Offline algorithms on full event
 - ➔ Latency $\sim 1 \text{ s}$, EFA $\sim 100 \text{ Hz}$
- ◆ Level-1 trigger:
 - ◆ L1-Muons
 - ◆ L1-Calorimeters (L1Calo)

Selection of interesting events

Hard final state objects in an event:

- e/γ and τ/h objects
- Jet candidates

Global event properties:

- E_T
- Missing E_T
- Jet sum E_T

• Sends to Central trigger:

- Multiplicity of electrons/photons, τ 's and jets passing thresholds
- Thresholds passed by Total and Missing E_T

• Sends to Level 2 trigger:

- position of RoIs \Rightarrow if L1 misses an object, it is lost also for L2!

Window 0.8 x 0.8

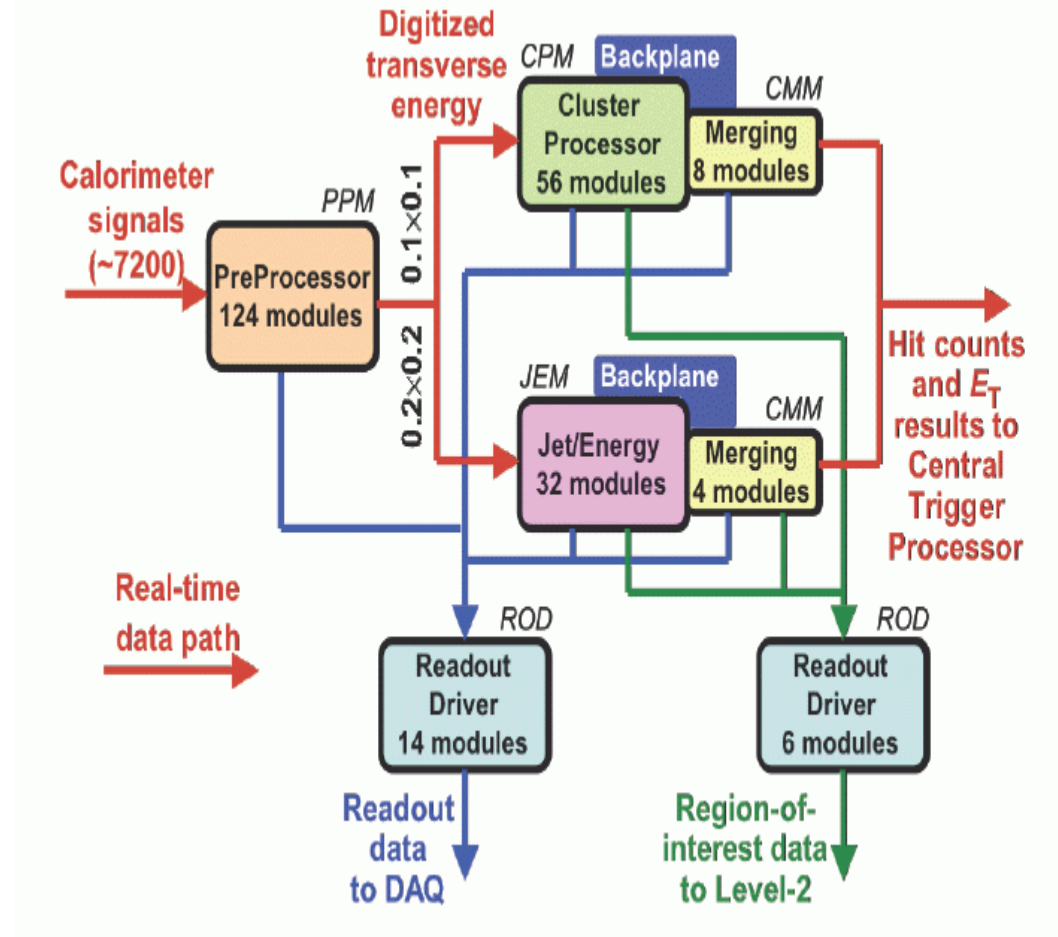

L1Calo - HW implementation

- ◆ Pipelined, synchronous system with fixed latency
- ◆ Many processing stages
- ◆ Highly parallel, mainly FPGA based
- ◆ Mainly custom electronics:
 - ➔ ~300 VME modules of 10 types housed in 17 crates

Main parts:

- ◆ Preprocessor:
 - ➔ Conditioning and calibration of analog signals, digitization, bunch cross identification
- ◆ Cluster processor:
 - ➔ Electrons/photons, taus
- ◆ Jet processor:
 - ➔ jets, E_T , Missing E_T

Full system installed in ATLAS cavern and running

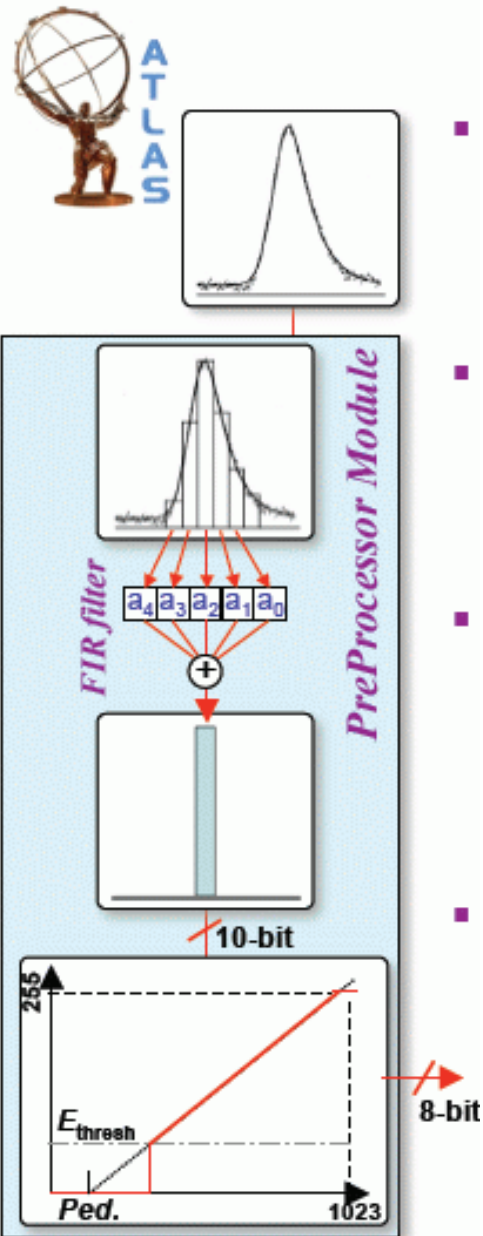

System installation and commissioning

- ◆ Most of the system installed end of 2007
- ◆ 2008, first part of 2009:
 - ◆ trigger commissioning with cosmics
 - fix digital links
 - repair faulty modules
 - ◆ First calibrations and timing with pulser
- ◆ Early data - end of 2009:
 - ◆ detailed checks of L1Calo performance
- ◆ Spring of 2010:
 - ◆ gradual increase in delivered luminosity
 - ◆ Stepwise updates of L1Calo calibrations
- ◆ Early July:
 - ◆ High Level Trigger rejects events (running in pass-through mode before)

Calibration of the trigger

Pulse conditioning and calibration

Analogue receivers:

- ◆ variable gain amplifier
- ◆ $E \rightarrow E_T$ conversion (where needed)
- ◆ first step in energy calibration ←

Digitization:

- ◆ 40 MHz, 10-bit FADCs
- ◆ timing at ns level ←
- ◆ $\sim 0.25 \text{ GeV/count}$

Bunch Crossing ID:

- ◆ assign signal to correct bunch crossing
- ◆ Linear digital filter ←
- ◆ special treatment of saturated pulses

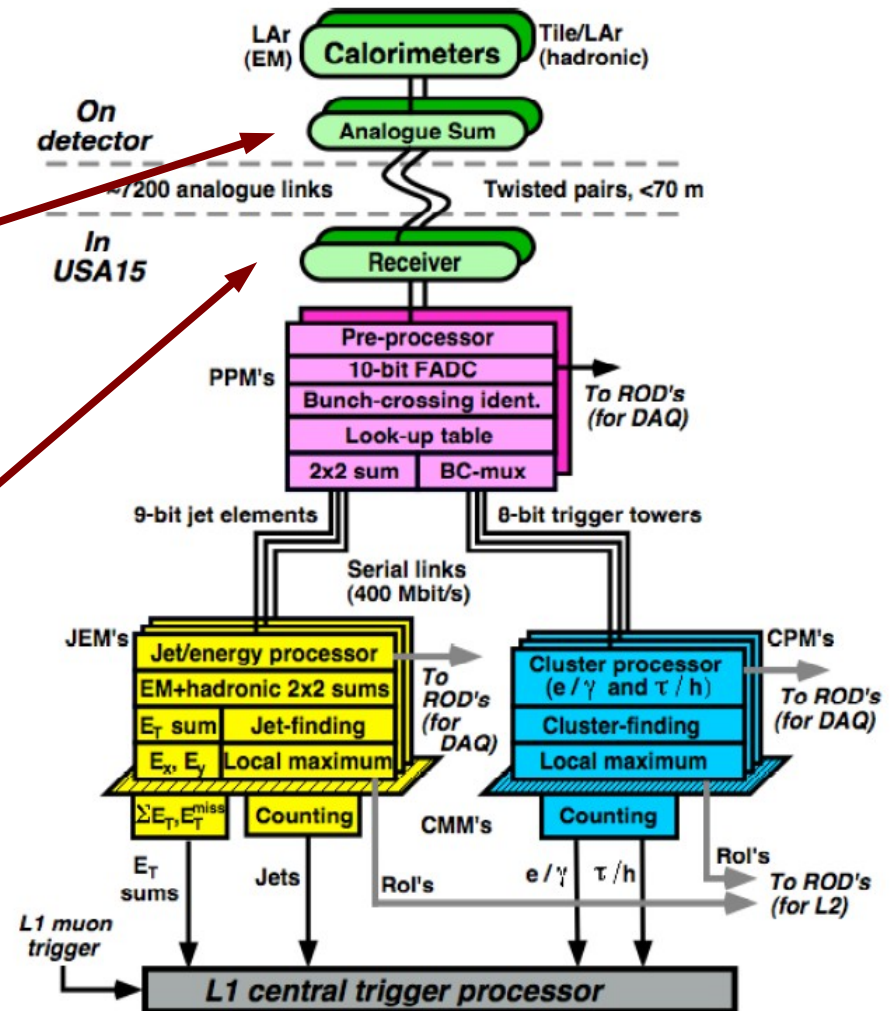

Look-up table (LUT):

- ◆ pedestal subtraction
- ◆ noise suppression
- ◆ killing of noisy channels
- ◆ final energy calibration
- ◆ 8-bit output for algorithms

Timing - Introduction

- ◆ Signals from individual calorimeter cells summed on detector into projective Trigger Towers
- ◆ Analogue signals routed using 30-70 m long twisted pair cables (4.76 ns/m)
- ◆ Signals at input of L1Calo need to be aligned in time
- ◆ Compensate for:
 - ➔ Different cable lengths
 - ➔ Individual channel variations
- ◆ If mistiming large, event lost
- ◆ Smaller mistiming means wrong energy measurement

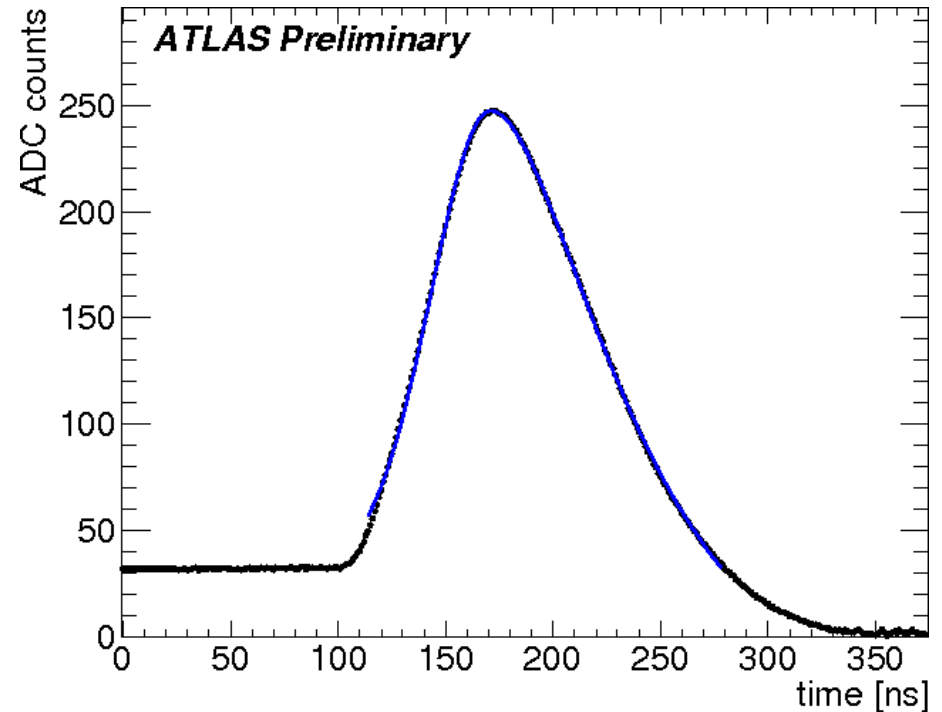

Timing with pulser

Several parameters available to adjust timing:

- ◆ Fine timing (PHOS4 chip) - 1 ns step
- ◆ Input delays (in input FIFO) - step of 1 BC
- ◆ Readout pointer - 1 BC step, used for the data readout of triggered events

First approximation done in dedicated runs with pulser (setup to mimic collisions):

- ◆ Adjust readout pointer such that signals are visible
- ◆ Align signals with BC precision using input timing
- ◆ Adjust fine timing to strobe at pulse maximum

Timing with splashes I

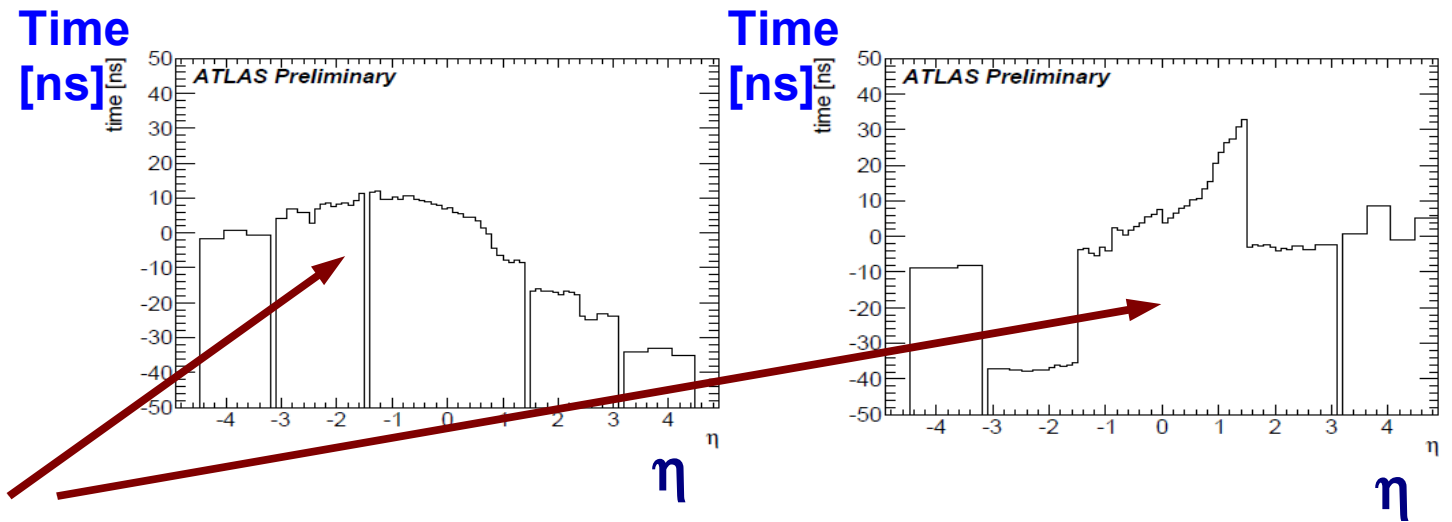

Splash events occur when beam is hitting collimator:

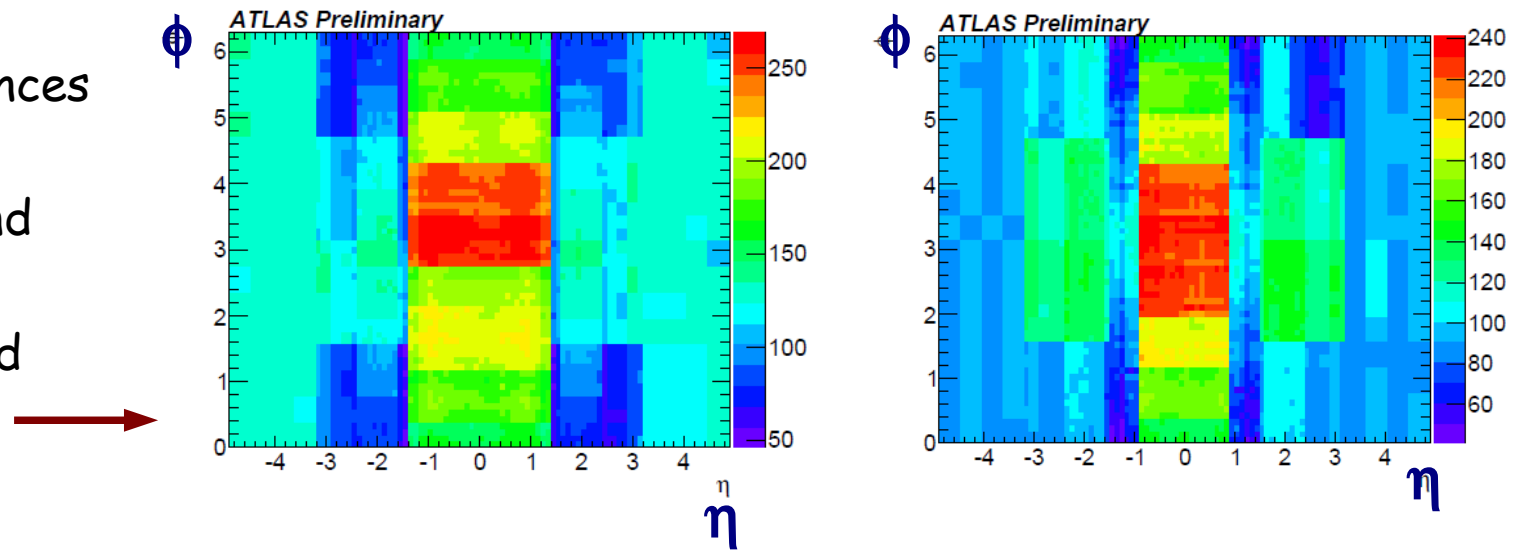

- ◆ Large signals in all towers
- ◆ Geometry of splashes different to collisions, need to correct for different time-of-flight effects:
 - ➔ ToF from collimator to Trigger Tower
 - ➔ ToF from beam vertex to Trigger Tower

Timing with splashes II

- Signals from splashes fitted by a function describing expected pulse shape
- Determine position of signal peak in time
- See time of flight for splashes nicely

- Correct for differences in time of flight between splashes and collisions
- timing delays as used for early data!

Timing with collisions

Final corrections are extracted from collision data:

- ◆ Good signals are selected
 - No hardware problems or noise
 - Coming from collisions
- ◆ Fit with function describing expected pulse shape
- Determine timing corrections for individual Trigger Towers
- After this correction timing known (for most towers) at the level of ± 2 ns

FIR filter I

- ▶ pulses are several bunch crossings wide
- ▶ Need to associate them with a single bunch crossing
- ▶ A 5-sample digital Finite Impulse Response (FIR) filter is applied:

$$S = \sum_{BC's} c_i FADC_i$$

- ▶ Maximum of filter output defines bunch crossing
- ▶ Value of filter output is input to LUT, output from LUT gives E_T
- ▶ Best performance expected for filter adjusted to the shape of pulse in each tower
- ▶ Studied using calibration pulses superimposed on realistic noise

FIR filter II

- ◆ Three sets of coefficients:
 - ➔ Matched to each tower
 - ➔ Common (one for EM layer, one for HAD, one in forward region)
 - ➔ Pass-through (only central sample in time is used)

- ◆ FIR filter clearly helps for:
 - ➔ Efficiency for small pulses
 - ➔ Noise rejection
 - ➔ Energy resolution

- ◆ Only marginal difference between matched and common
- ◆ Running with common filters now
- ◆ Next step- take into account differences between calibration and physics pulse shapes

Energy calibration with pulser I

- ◆ Number of ADC counts does not immediately translate to energy in GeV (1 FADC count \approx 0.250 GeV)
- ◆ need (energy) calibration
 - ➔ Implemented in receiver gains (and LUT slope)
- ◆ Use dedicated pulser runs
- ◆ Calibrate with respect to energy measured in calorimeter readout (more precise than trigger readout)
 - ➔ Several energy (pulse amplitude) steps
 - ➔ Compare energy seen in calo readout and in L1Calo Trigger Towers
 - ➔ Calibration factors determined in offline analysis

Energy calibration with pulser II

- ◆ Checks of the calibration done with collision data
- ◆ Compare E_T of large energy deposits seen in L1Calo readout with E_T seen in corresponding areas in calorimeters
- ◆ Correlation looks reasonable
- ◆ Next steps:
 - ➔ understand/fix problematic electronic channels
 - ➔ Use physical objects

Experience from datataking

Datataking performance I

Digital consistency:

- ◆ duplicated readout from several places in the system
- ➔ Good system in place to ensure that there are no digital inconsistencies!
- ◆ Trigger readout compared to bit-by-bit trigger simulation
 - ➔ Starting from FADC counts
 - ➔ Simulating (recalculating) response of the electronics

Zero tolerance to digital errors!

- ◆ Checked for each run
- ◆ Online (during data taking) for part of events
- ◆ Offline (when the data are reconstructed) for all events

Datataking performance II

Typical LHC fill:

- ◆ Smooth data taking, rate excursions are very rare!
- ◆ Rates of L1 electromagnetic triggers follow nicely luminosity profile of the fill
- ◆ High level trigger improves event selection, reducing rate to acceptable level

Datataking performance III

- ▶ Raw L1 rates as a function of instantaneous luminosity
- ▶ June 2010 (two colliding bunches)
- ▶ Nice linear dependence of L1Calo rates on luminosity
- ▶ Contribution of noise negligible, mainly QCD background
- ▶ Rate of Minimum Bias Trigger Scintillators (MBTS), used to trigger bulk of inelastic cross section saturates at high rates

Efficiency for triggering of physical objects

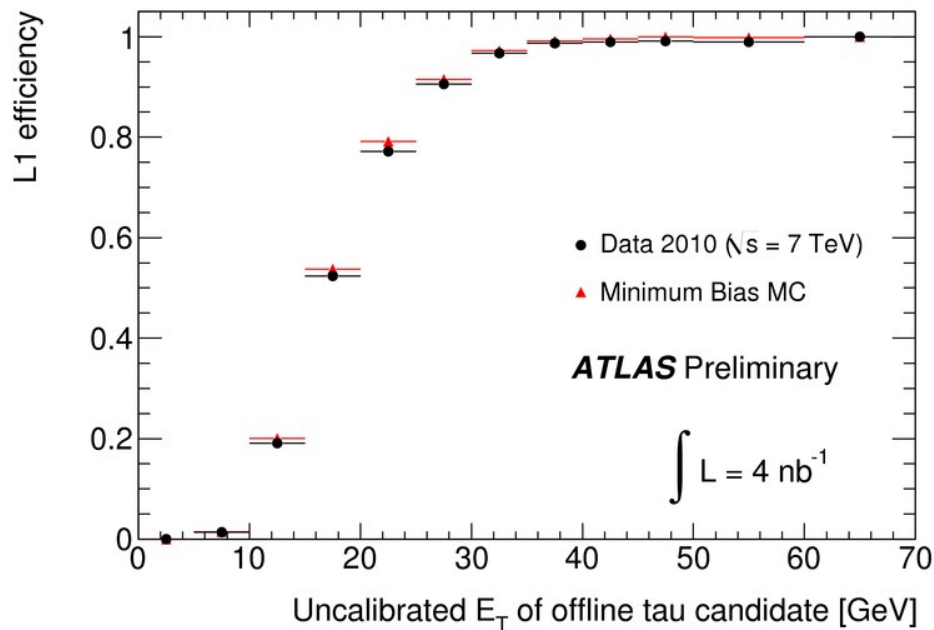

Efficiency for physics objects - EM clusters

- ◆ Data taken using independent trigger (MBTS) - checking efficiency ($\#triggered/\#all$) of electromagnetic L1Calo trigger for reconstructed offline clusters
- ◆ L1 threshold EM5:
 - ➔ Energy of cluster as seen by L1 should be larger than 5 counts (output of LUT)
 - ➔ roughly equivalent to 5 GeV
 - ➔ that is where efficiency curve starts to rise (trigger uses $E_T > \text{threshold}$ condition)
 - ➔ Full efficiency reached at 8 GeV

- ◆ Good agreement between data and MC !

Efficiency for physics objects - hadronic τ

- ◆ Trigger efficiency for reconstructed offline τ
- ◆ L1 threshold set to 5 (LUT) counts ($\sim 5 \text{ GeV}$)
- ◆ Efficiency rises up to 100% at τE_T of 30 GeV
 - ➔ L1 uses "raw" EM energy scale without dead material corrections
 - ➔ Part of τ energy may not be contained in L1 τ cluster
 - ➔ Noise cuts at L1 are harder than offline
- ◆ Both efficiency and E_T distribution of L1 τ candidates are well described by Monte Carlo!

Efficiency for physics objects - jets

- ▶ efficiency ($\# \text{triggered} / \# \text{all}$) for reconstructed offline jets
- ▶ L1 threshold set to 5 (LUT) counts ($\sim 5 \text{ GeV}$)
- ▶ Efficiency rises up to 100% at offline jet E_T of 40 GeV
 - ➔ L1 uses "raw" EM energy scale without dead material corrections
 - ➔ Often not whole offline jet energy gets collected into L1 object
 - ➔ Noise cuts at L1 are harder than offline
- ▶ Turn-on curve is well described by Monte Carlo !

Conclusions and plans

L1 Calorimeter trigger is an essential part of ATLAS trigger

- Based on custom hardware
- Optimized for speed
- As much parallel processing as possible

To run it efficiently is a challenge ...
(but getting there!)

Looking forward to wealth of LHC data !!!
