## Measurement of the Cross Section for Electromagnetic Dissociation with Neutron Emission in Pb-Pb Collisions at $\sqrt{s_{\text{NN}}} = 2.76 \text{ TeV}$

The ALICE Collaboration\*

### Abstract

The first measurement of neutron emission in electromagnetic dissociation of  $^{208}\text{Pb}$  nuclei at the LHC is presented. The measurement is performed using the neutron Zero Degree Calorimeters of the ALICE experiment, which detect neutral particles close to beam rapidity. The measured cross sections of single and mutual electromagnetic dissociation of Pb nuclei at  $\sqrt{s_{\text{NN}}} = 2.76 \text{ TeV}$  with neutron emission are  $\sigma_{\text{single EMD}} = 187.2 \pm 0.2 \text{ (stat.)} {}^{+13.8}_{-12.0} \text{ (syst.) b}$  and  $\sigma_{\text{mutual EMD}} = 6.2 \pm 0.1 \text{ (stat.)} \pm 0.4 \text{ (syst.) b}$  respectively. The experimental results are compared to the predictions from a relativistic electromagnetic dissociation model.

---

\*See Appendix A for the list of collaboration members

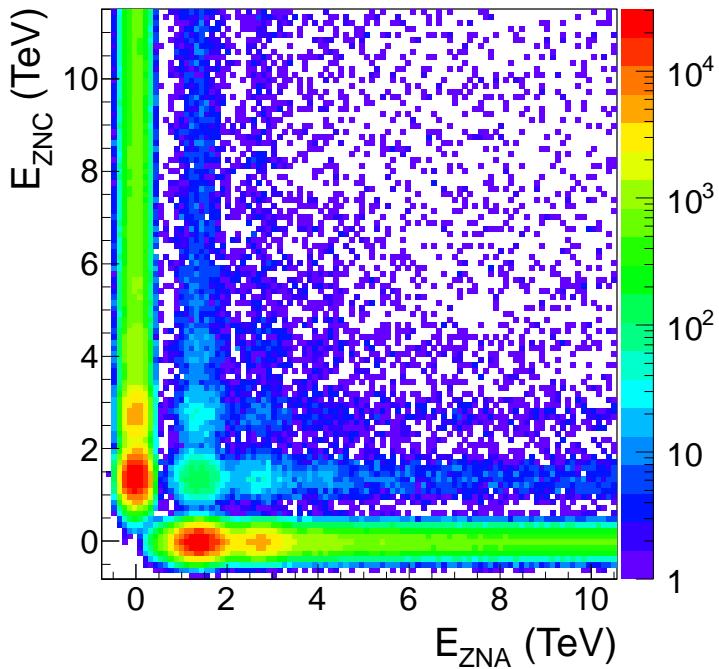

In ultra-peripheral collisions the two interacting nuclei collide at an impact parameter larger than the sum of the nuclear radii and hence the interaction is purely electromagnetic. The equivalent photon method, proposed by Fermi [1] in order to treat the moving electromagnetic field of a charged particle, was later extended by Weizsäcker and Williams to collisions of ultra-relativistic electrons and protons with nuclei [2, 3]. As beam energy increases, the photon spectrum hardens and the flux is enhanced, due to the increase of the Lorentz contraction of the Coulomb field. Moreover the photon flux is proportional to  $Z^2$ , with  $Z$  the charge number of the emitting nucleus. Therefore the electromagnetic interactions become dominant in ultra-relativistic collisions of heavy-ions. Two processes, the bound-free pair production and the electromagnetic dissociation (EMD), have attracted special attention in the last years, since they provide stringent limits on the beam lifetime in heavy-ion colliders [4]. As predicted [5], the excitation and subsequent decay of the Giant Dipole Resonance (GDR) via emission of one or two neutrons from colliding Pb nuclei occurs in  $\sim 60\%$  of EMD events at the LHC. This can be exploited to measure the luminosity at heavy-ion colliders by detecting forward neutrons [6].

This Letter reports the first measurement of the electromagnetic dissociation cross section of  $^{208}\text{Pb}$  nuclei at  $\sqrt{s_{\text{NN}}} = 2.76 \text{ TeV}$  via neutron emission, performed using the Zero Degree Calorimeters (ZDCs) of the ALICE experiment [7] at the Large Hadron Collider (LHC). The ZDCs are ideally suited to tag EMD interactions, since the resulting neutrons from the GDR decay are emitted very close to beam rapidity and are the most abundant particles produced in these processes. The data were collected using the neutron ZDCs (ZNA and ZNC), located 114 m away from the Interaction Point (IP) at the so-called A and C sides of the ALICE detector. Each ZN is placed at zero degree with respect to the LHC beam axis and is used to detect neutral particles at pseudo-rapidities  $|\eta| > 8.7$ . For the present analysis two small forward electromagnetic calorimeters (ZEM1 and ZEM2), placed on the A side at 7.35 m from the IP ( $4.8 \leq \eta \leq 5.7$ ), are also used to tag hadronic interactions.

The experimental results are presented and compared to theoretical predictions of the Relativistic ELectrone-magnetic DISSociation (RELDIS) model [5], which is designed to describe electromagnetic interactions between ultra-relativistic nuclei including single and double virtual photon absorption, excitation of giant resonances, intra-nuclear cascades of produced hadrons and statistical decay of excited residual nuclei. Above the GDR region photon-induced reactions become more complicated leading to multiple ( $> 3$ ) emission of neutrons [8]. RELDIS accurately reproduces this experimental observation and also predicts further increase of the mean number of neutrons and of the width of their multiplicity distribution as photon energy increases [9]. Calculations based on this model provide a good description of neutron emission in electromagnetic dissociation of Pb ions at the CERN SPS [10] and of Au ions at the Relativistic Heavy Ion Collider (RHIC) [11].

During the  $\sqrt{s_{\text{NN}}} = 2.76 \text{ TeV}$  Pb-Pb data taking in 2010, an EMD run was performed, requiring a minimum energy deposit in at least one of the two ZNs ( $\sim 3 \times 10^6$  events were collected). The energy thresholds were  $\sim 450 \text{ GeV}$  for ZNA and  $\sim 500 \text{ GeV}$  for ZNC and were placed approximately three standard deviations below the energy deposition of a 1.38 TeV neutron. In this dedicated run only the ZDCs were read-out. The trigger was set to tag neutrons emitted in EMD as well as hadronic interactions (see Figure 1). Following a common convention we define as single EMD a process where at least one neutron (1n) is emitted by a given Pb nucleus disregarding the fate of the other nucleus. Mutual EMD events, where at least 1n is emitted by both Pb nuclei, and hadronic events were selected offline requiring a minimum signal in both ZNs.

In the 2010 Pb-Pb run ZNs were used as the ALICE luminometer, providing different logical combinations of signals (ZDC triggers). In particular during a beam separation van der Meer (vdM) scan [12], a cross section  $\sigma_{\text{ZNA OR ZNC}}^{\text{vdM}} = 371.4 \pm 0.6 \text{ (stat.)}^{+24}_{-19} \text{ (syst.)} \text{ b}$  was measured for the (ZNA OR ZNC) trigger, tagging single EMD plus hadronic interactions. The systematic error of  $-5.2\% + 6.4\%$  can be decomposed as follows: 4.3% uncertainty coming from the vdM scan analysis [13], dominated by the calibration of the distance scale during the scan;  $-3\% + 4.7\%$  uncertainty coming from the measurement

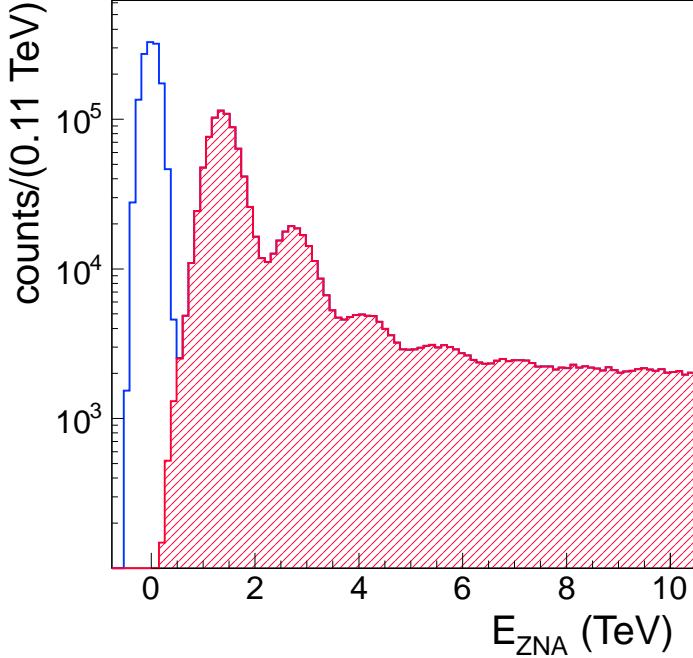

**Fig. 1:** Energy deposition in ZNC versus ZNA for single EMD plus hadronic events. The 1n signal is at 1.38 TeV. The events where at least 1n is detected by both ZNs are associated to mutual EMD and hadronic processes.

of the beam intensity, dominated by the beam current transformers scale [14] and by the non-colliding (ghost) charge fraction in the LHC beams [15, 16].

The energy spectrum for the ZNA is shown in Figure 2, for events in which there is a signal in at least one of the two ZNs (not filled area) or for events in which ZNA is fired (shaded area). The selection of events with signal in ZNA is performed offline using the timing information provided by a TDC. In the first case a pedestal peak centered at  $E = 0$  is visible, which corresponds to events where no signal is detected by the ZNA and the trigger is fired by the ZNC. As can be inferred in Figure 2 the TDC selection rejects only events in the pedestal. The width of the pedestal peak is related to the noise of electronic modules. In the energy spectrum a pronounced 1n peak at 1.38 TeV is present, but also 2n, 3n, 4n... peaks are clearly identified. The requirement of a signal in the TDC for the ZNA and the ZNC, respectively, allows to calculate two different estimates of the number of events from single EMD plus hadronic processes. The average of the two results is then calculated (the difference between the response of the ZNA and the ZNC is about 2%).

A second event selection requires a signal in one of the ZNs, but not in the other one. In this way hadronic events, which mostly lead to disintegration of both colliding nuclei, are rejected. In this case the mutual EMD events are also removed from the spectrum and therefore the selected process is the single EMD minus the mutual EMD. The energy spectrum is shown in Figure 3 together with the fit obtained by summing four Gaussians. The curve for the 1n peak has three free parameters, while the following Gaussians describing the  $i^{th}$  peak have a constraint both on the mean value  $\mu_{in}$  ( $\mu_{in} = i \times \mu_{1n}$ , where  $\mu_{in}$  is the mean value for  $i^{th}$  neutron peak) and on the width  $\sigma_{in}$  ( $\sigma_{in} = \sqrt{i \times (\sigma_{1n}^2 - \sigma_{ped}^2) + \sigma_{ped}^2}$ , where  $\sigma_{in}$  is the width of the  $i^{th}$  neutron peak and  $\sigma_{ped}$  is the width of the pedestal peak). The relative energy resolution  $\sigma_{1n}/\mu_{1n}$  of the 1n peak at 1.38 TeV is 21% for the ZNA and 20% for the ZNC, in agreement with expectations from beam tests at the CERN SPS [17] and Monte Carlo extrapolation to LHC energies. Similarly to the previous analysis we made the average of the ZNA and the ZNC results, which difference is about 2%. The contamination from beam-residual gas interactions, estimated via

the observed rates with non-colliding beams, is of the order of 2% and is considered in the systematic uncertainty.

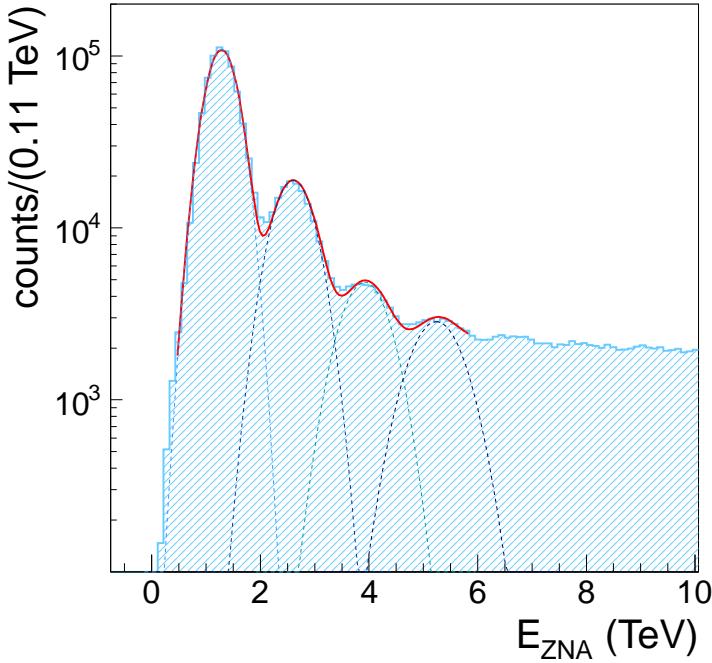

**Fig. 2:** ZNA energy spectrum requiring signal over threshold in ZNA or ZNC (not filled area) superimposed to ZNA energy spectrum requiring signal in ZNA (shaded area). The first peak centered at  $E = 0$  corresponds to pedestal events.

**Table 1:** Cross sections (barn) for  $\sqrt{s_{\text{NN}}} = 2.76$  TeV Pb-Pb interactions (systematic errors are dominated by the vdM cross section errors).

Physical Process	Data	RELDIS
single EMD + hadronic	$194.6 \pm 0.3 \text{ stat.}^{+14.1}_{-12.1} \text{ syst.}$	$192.9 \pm 9.2$
single EMD - mutual EMD	$181.2 \pm 0.3 \text{ stat.}^{+13.3}_{-11.4} \text{ syst.}$	$179.7 \pm 9.2$
mutual EMD	$6.2 \pm 0.1 \text{ stat.} \pm 0.4 \text{ syst.}$	$5.5 \pm 0.6$
hadronic	$7.5 \pm 0.1 \text{ stat.}^{+0.6}_{-0.5} \text{ syst.}$	$7.7 \pm 0.4$
single EMD	$187.2 \pm 0.2 \text{ stat.}^{+13.8}_{-12.0} \text{ syst.}$	$185.2 \pm 9.2$

The cross sections, listed in Table 1 (first two rows), are calculated using the (ZNA OR ZNC) cross section measured during the vdM scan:  $\sigma_{\text{proc}} = \sigma_{\text{ZNA OR ZNC}}^{\text{vdM}} \times N_{\text{proc}} / N_{\text{ZNA OR ZNC}}$ , where  $N_{\text{proc}}$  is the number of events in the sample of the selected process and  $N_{\text{ZNA OR ZNC}}$  is the number of events collected with the same trigger as used to determine  $\sigma_{\text{ZNA OR ZNC}}^{\text{vdM}}$ . The calculated values are corrected for the ZN detection probability ( $98.7\% \pm 0.04\%(\text{stat.}) \pm 0.1\%(\text{syst.})$ ), estimated from a Monte Carlo simulation using RELDIS as event generator. The systematic errors, dominated by the uncertainties of the cross sections measured during the vdM scan, take also into account the difference between the response of the ZNA and the ZNC (2%), the uncertainty due to the fits ( $\leq 1\%$ ) and the difference between the beam-gas background in the vdM fill with respect to the analysed fill ( $\leq 1\%$ ).

The predictions of the RELDIS model for  $\sqrt{s_{\text{NN}}} = 2.76$  TeV Pb-Pb EMD interactions are also shown in Table 1. The agreement between data and model predictions is remarkable. In calculations of the

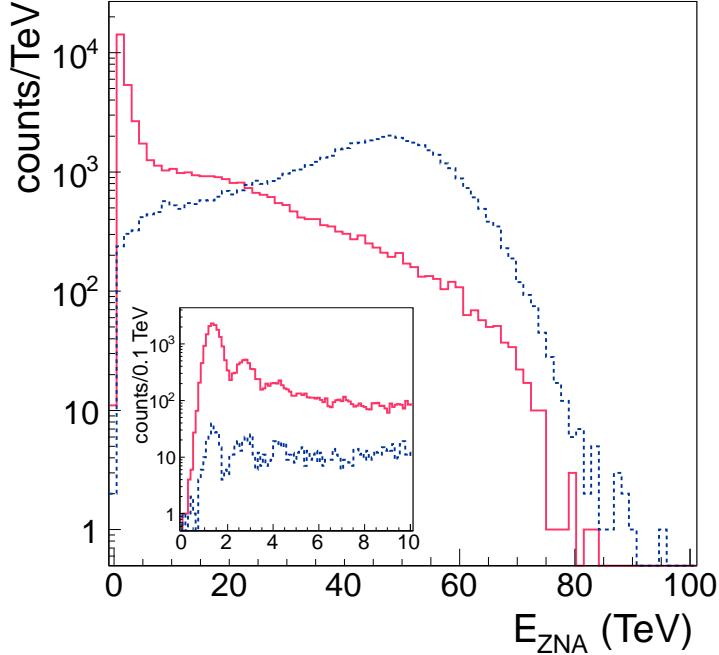

**Fig. 3:** ZNA energy spectrum requiring signal over threshold in ZNA but not in ZNC, rejecting thus neutron emission on the opposite side. The dashed lines represent the single fits of the different peaks (1n, 2n,...), while the continuous line is the sum of all the contributions.

EMD cross sections various approximations of the total photoabsorption cross sections on lead are used, leading to 5% uncertainties in the predicted values [5]. These errors include the difference between RELDIS and other theoretical predictions [18].

A third event selection is performed to select mutual EMD and hadronic events requiring a minimum energy deposition in both ZNs. To disentangle the two processes, the ZEMs are used to select events with no signal in any ZEM or a signal in at least one of the two ZEMs, respectively. The energy threshold for each ZEM is about 10 GeV. Figure 4 shows the ZNA energy spectrum for the mutual EMD (continuous line) and hadronic (dashed line) event selection. The measured cross section for the mutual EMD and hadronic processes are calculated, as in the previous analysis, using the vdM (ZNA OR ZNC) cross section. The contamination of hadronic events in the mutual EMD sample and of mutual EMD events in the hadronic sample is evaluated from simulations using, respectively, RELDIS and HIJING[19], combined with a simple fragmentation model as event generator [20]. The ZEM trigger efficiencies for mutual EMD and hadronic event selection are  $96.0\% \pm 0.1\text{(stat.)} \pm 0.6\text{(syst.)}$  and  $92.4\% \pm 0.3\text{(stat.)} \pm 1.0\text{(syst.)}$ . The measured cross sections and the ZEM trigger efficiencies for the two processes are inserted in a system of equations in two variables, where the unknowns are the true mutual EMD and the true hadronic cross sections, respectively. The extracted values are corrected for the estimated ZN detection probability for mutual EMD ( $95.7\% \pm 0.07\text{(stat.)} \pm 0.5\text{(syst.)}$ ) and for hadronic ( $97.0\% \pm 0.2\text{(stat.)} \pm 3\text{(syst.)}$ ) events. The final cross section results are summarized and compared to the RELDIS predictions in Table 1 (third and fourth rows).

The single EMD cross section listed in Table 1 (last row) is estimated from previous measurements, making an average of the (single EMD + hadronic) – hadronic and the (single EMD – mutual EMD) + mutual EMD cross sections.

For the single EMD minus mutual EMD event selection the measured fractions of 1n, 2n and 3n events with respect to the total number of events is estimated (Table 2). The table contains also the relevant

**Fig. 4:** ZNA energy spectrum for mutual EMD (no signal in any ZEM, continuous line) and hadronic (a signal in at least one of the two ZEMs, dashed line) event selection. The insert shows an expanded view of the low energy region.

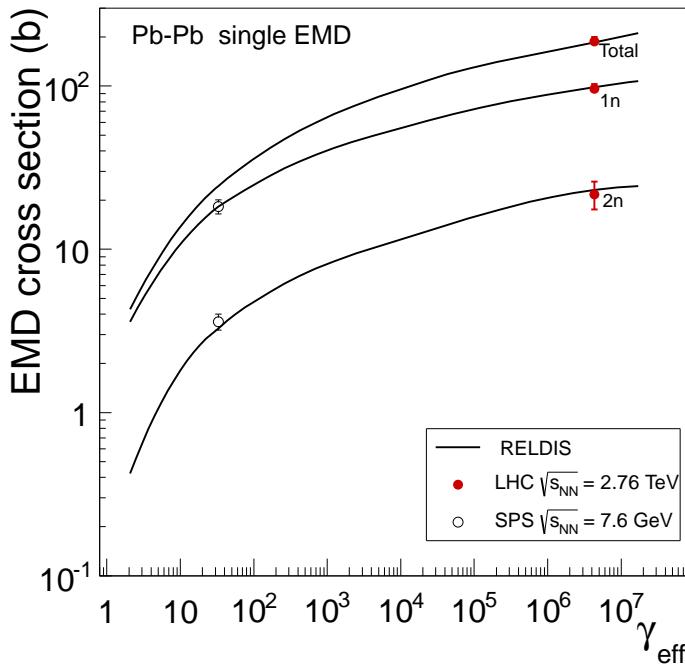

expectations for the ratios based on the calculations with the RELDIS model. The 1n and 2n emission channels give the main contribution (63%), confirming that EMD processes proceed predominantly via GDR excitation and subsequent decay by neutron emission. According to RELDIS, 3n emission is mostly induced by energetic ( $>40$  MeV) equivalent photons and frequently accompanied by emission of protons and pions. The measured 1n and 2n yields are much closer to RELDIS predictions compared to the 3n yields. This can be explained by the fact that RELDIS was already tuned by comparison with 1n and 2n data on photoabsorption on lead [5] and on EMD of 30 A GeV lead nuclei [10]. Unfortunately, the data on neutron emission induced by photons above 140 MeV are absent, while according to RELDIS almost half of 3n events is due to such energetic photons. In EMD calculations the native photonuclear reaction model of RELDIS can be replaced by the GNASH code [21], thus providing slightly different results for 1n and 2n yields. On the basis of this difference the theoretical uncertainties listed in Table 2 are estimated.

**Table 2:** Neutron emission fractions for single EMD minus mutual EMD process in  $\sqrt{s_{\text{NN}}} = 2.76$  TeV Pb-Pb interactions.

Ratio	Data(%)	RELDIS(%)
1n/ $N_{\text{tot}}$	$51.5 \pm 0.4$ stat. $\pm 0.2$ syst.	$54.2 \pm 2.4$
2n/ $N_{\text{tot}}$	$11.6 \pm 0.3$ stat. $\pm 0.5$ syst.	$12.7 \pm 0.8$
3n/ $N_{\text{tot}}$	$3.6 \pm 0.2$ stat. $\pm 0.2$ syst.	$5.4 \pm 0.7$
2n/1n	$22.5 \pm 0.5$ stat. $\pm 0.9$ syst.	$23.5 \pm 2.5$

Our 2n to 1n ratio of 22.5% in single EMD can be compared to the value of 19.7% reported for Pb-Pb collisions at 30 A GeV at the CERN SPS [10]. As predicted by RELDIS, the observed weak increase of the 2n to 1n ratio with collision energy is due to additional 2n events produced by more energetic equivalent photons at the LHC.

Finally, Figure 5 presents total and partial EMD cross sections for emission of one and two neutrons

**Fig. 5:** Total single EMD cross sections and partial EMD cross sections for emission of one and two neutrons as a function of the effective Lorentz factor  $\gamma_{\text{eff}}$ . The closed symbols are our data, while the open symbols represent the results obtained at CERN SPS [10] at 30 GeV. The RELDIS predictions [10] for total, 1n and 2n EMD cross sections are shown as solid lines.

measured by ALICE compared to CERN SPS data [10]. The results of the RELDIS model are also shown for a wide range of the projectile effective Lorentz-factor  $\gamma_{\text{eff}}$  calculated in the rest frame of the collision partner. As seen, both data sets are successfully described by the model despite of six orders-of-magnitude span of  $\gamma_{\text{eff}}$ .

In summary a first measurement of electromagnetic dissociation in  $\sqrt{s_{\text{NN}}} = 2.76$  TeV Pb-Pb collisions was performed at the LHC by detection of the emitted neutrons with the ALICE ZDCs. The measurement tests the theoretical predictions used for estimations of beam losses. The RELDIS model predictions are in a very good agreement with our experimental results. The measurements reported here establish experimentally the EMD cross section scale for the first time at LHC energy. We finally note that the ALICE ZDC detectors, calibrated through these results, provide the possibility of a direct absolute measurement of the LHC beam luminosity.

## Affiliation notes

<sup>i</sup> Also at: M.V.Lomonosov Moscow State University, D.V.Skobeltsyn Institute of Nuclear Physics, Moscow, Russia

<sup>ii</sup> Also at: "Vinča" Institute of Nuclear Sciences, Belgrade, Serbia

## Collaboration Institutes

<sup>1</sup> Benemérita Universidad Autónoma de Puebla, Puebla, Mexico

<sup>2</sup> Bogolyubov Institute for Theoretical Physics, Kiev, Ukraine

<sup>3</sup> Budker Institute for Nuclear Physics, Novosibirsk, Russia

<sup>4</sup> California Polytechnic State University, San Luis Obispo, California, United States

<sup>5</sup> Centre de Calcul de l'IN2P3, Villeurbanne, France

<sup>6</sup> Centro de Aplicaciones Tecnológicas y Desarrollo Nuclear (CEADEN), Havana, Cuba

<sup>7</sup> Centro de Investigaciones Energéticas Medioambientales y Tecnológicas (CIEMAT), Madrid, Spain

<sup>8</sup> Centro de Investigación y de Estudios Avanzados (CINVESTAV), Mexico City and Mérida, Mexico

<sup>9</sup> Centro Fermi – Centro Studi e Ricerche e Museo Storico della Fisica "Enrico Fermi", Rome, Italy

<sup>10</sup> Chicago State University, Chicago, United States

<sup>11</sup> Commissariat à l'Energie Atomique, IRFU, Saclay, France

<sup>12</sup> Departamento de Física de Partículas and IGFAE, Universidad de Santiago de Compostela, Santiago de Compostela, Spain

- 13 Department of Physics Aligarh Muslim University, Aligarh, India  
14 Department of Physics and Technology, University of Bergen, Bergen, Norway  
15 Department of Physics, Ohio State University, Columbus, Ohio, United States  
16 Department of Physics, Sejong University, Seoul, South Korea  
17 Department of Physics, University of Oslo, Oslo, Norway  
18 Dipartimento di Fisica dell’Università and Sezione INFN, Cagliari, Italy  
19 Dipartimento di Fisica dell’Università and Sezione INFN, Padova, Italy  
20 Dipartimento di Fisica dell’Università and Sezione INFN, Trieste, Italy  
21 Dipartimento di Fisica dell’Università and Sezione INFN, Bologna, Italy  
22 Dipartimento di Fisica dell’Università ‘La Sapienza’ and Sezione INFN, Rome, Italy  
23 Dipartimento di Fisica e Astronomia dell’Università and Sezione INFN, Catania, Italy  
24 Dipartimento di Fisica ‘E.R. Caianiello’ dell’Università and Gruppo Collegato INFN, Salerno, Italy  
25 Dipartimento di Fisica Sperimentale dell’Università and Sezione INFN, Turin, Italy  
26 Dipartimento di Scienze e Tecnologie Avanzate dell’Università del Piemonte Orientale and Gruppo Collegato INFN, Alessandria, Italy  
27 Dipartimento Interateneo di Fisica ‘M. Merlin’ and Sezione INFN, Bari, Italy  
28 Division of Experimental High Energy Physics, University of Lund, Lund, Sweden  
29 European Organization for Nuclear Research (CERN), Geneva, Switzerland  
30 Fachhochschule Köln, Köln, Germany  
31 Faculty of Engineering, Bergen University College, Bergen, Norway  
32 Faculty of Mathematics, Physics and Informatics, Comenius University, Bratislava, Slovakia  
33 Faculty of Nuclear Sciences and Physical Engineering, Czech Technical University in Prague, Prague, Czech Republic  
34 Faculty of Science, P.J. Šafárik University, Košice, Slovakia  
35 Frankfurt Institute for Advanced Studies, Johann Wolfgang Goethe-Universität Frankfurt, Frankfurt, Germany  
36 Gangneung-Wonju National University, Gangneung, South Korea  
37 Helsinki Institute of Physics (HIP) and University of Jyväskylä, Jyväskylä, Finland  
38 Hiroshima University, Hiroshima, Japan  
39 Hua-Zhong Normal University, Wuhan, China  
40 Indian Institute of Technology, Mumbai, India  
41 Indian Institute of Technology Indore (IIT), Indore, India  
42 Institut de Physique Nucléaire d’Orsay (IPNO), Université Paris-Sud, CNRS-IN2P3, Orsay, France  
43 Institute for High Energy Physics, Protvino, Russia  
44 Institute for Nuclear Research, Academy of Sciences, Moscow, Russia  
45 Nikhef, National Institute for Subatomic Physics and Institute for Subatomic Physics of Utrecht University, Utrecht, Netherlands  
46 Institute for Theoretical and Experimental Physics, Moscow, Russia  
47 Institute of Experimental Physics, Slovak Academy of Sciences, Košice, Slovakia  
48 Institute of Physics, Bhubaneswar, India  
49 Institute of Physics, Academy of Sciences of the Czech Republic, Prague, Czech Republic
