Directed flow of charged particles at mid-rapidity relative to the spectator plane in Pb–Pb collisions at $\sqrt{s_{NN}} = 2.76$ TeV

ALICE Collaboration*

Abstract

The directed flow of charged particles at mid-rapidity is measured in Pb–Pb collisions at $\sqrt{s_{NN}} = 2.76$ TeV relative to the collision symmetry plane defined by the spectator nucleons. A negative slope of the rapidity-odd directed flow component with approximately 3 times smaller magnitude than found at the highest RHIC energy is observed. This suggests a smaller longitudinal tilt of the initial system and disfavors the strong fireball rotation predicted for the LHC energies. The rapidity-even directed flow component is measured for the first time with spectators and found to be independent of pseudorapidity with a sign change at transverse momenta p_T between 1.2 and 1.7 GeV/ c . Combined with the observation of a vanishing rapidity-even p_T shift along the spectator deflection this is strong evidence for dipole-like initial density fluctuations in the overlap zone of the nuclei. Similar trends in the rapidity-even directed flow and the estimate from two-particle correlations at mid-rapidity, which is larger by about a factor of 40, indicate a weak correlation between fluctuating participant and spectator symmetry planes. These observations open new possibilities for investigation of the initial conditions in heavy-ion collisions with spectator nucleons.

The goal of the heavy-ion program at the Large Hadron Collider (LHC) is to explore the properties of deconfined quark-gluon matter. Anisotropic transverse flow is sensitive to the early times of the collision, when the deconfined state of quarks and gluons is expected to dominate the collision dynamics (see reviews [1, 2, 3] and references therein), with a positive (in-plane) elliptic flow as first observed at the Alternating Gradient Synchrotron (AGS) [4, 5]. A much stronger flow was subsequently measured at the Super Proton Synchrotron (SPS) [6], Relativistic Heavy Ion Collider (RHIC) [7, 8, 9] and recently at the LHC [10, 11, 12]. Elliptic flow at RHIC and the LHC is reproduced by hydrodynamic model calculations with a small value of the ratio of shear viscosity to entropy density [13, 14, 15, 16]. Despite the success of hydrodynamics in describing the equilibrium phase of matter produced in a relativistic heavy-ion collision, there are still large theoretical uncertainties in determination of the initial conditions. Significant triangular flow measured recently at RHIC [17, 18] and LHC [19, 20, 12] energies has demonstrated [21, 22] that initial energy fluctuations play an important role in the development of the final momentum-space anisotropy of the distribution of produced particles.

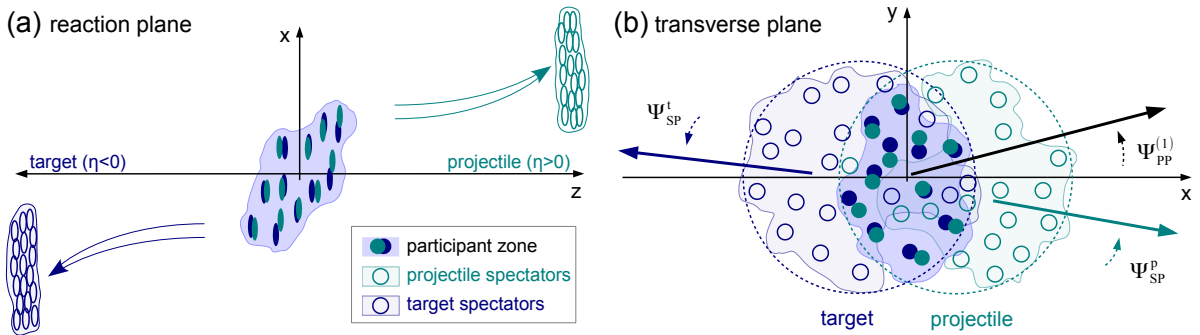

Fig. 1: (color online) Sketch of a non-central heavy-ion collision. See text for description of the figure.

The collision geometry is illustrated in Fig. 1 which depicts the participant overlap region and spectators as viewed in (a) the reaction plane and (b) the plane perpendicular to the beam. Figure 1(a) shows the projectile and target spectators repelled in the reaction (xz) plane from the center of the colliding system along the impact parameter (x) direction. An alternative scenario where spectators are attracted towards the center of the system is discussed in [23].

The directed flow is characterized by the first harmonic coefficient v_1 in a Fourier decomposition of the particle azimuthal distribution with respect to one of the collision symmetry planes, Ψ , as illustrated in Fig. 1(b) and discussed below

$$v_1(\eta, p_T)\{\Psi\} = \langle \cos(\phi - \Psi) \rangle. \quad (1)$$

Here $\eta = -\ln[\tan(\theta/2)]$, p_T , θ and ϕ are the particle pseudorapidity, transverse momentum, polar and azimuthal angles, respectively. The brackets " $\langle \dots \rangle$ " indicate an average over measured particles in all recorded events.

For a non-fluctuating nuclear matter distribution, the directed flow in the participant zone develops along the impact parameter direction. The collision symmetry requires that the directed flow be an anti-symmetric function of pseudorapidity, $v_1^{\text{odd}}(\eta) = -v_1^{\text{odd}}(-\eta)$. Due to event-by-event fluctuations in the initial energy density of the collision, the participant plane angle ($\Psi_{\text{PP}}^{(1)}$) defined by the dipole asymmetry of the initial energy density [24, 25] and that of projectile ($\Psi_{\text{SP}}^{\text{p}}$) and target ($\Psi_{\text{SP}}^{\text{t}}$) spectators are different from the geometrical reaction plane angle Ψ_{RP} (x -axis in Fig. 1(b)). As a consequence, the directed flow can develop [24, 25, 26, 27] a rapidity-symmetric component, $v_1^{\text{even}}(\eta) = v_1^{\text{even}}(-\eta)$, which does not vanish at mid-rapidity.

The slope of v_1^{odd} as a function of rapidity at AGS [5, 28] and SPS [29, 30] energies is driven by the difference between baryon and meson production and shadowing by the nuclear remnants. At higher

(RHIC) energies a multiple zero crossing of v_1^{odd} with rapidity outside the nuclear fragmentation regions was predicted as a signature of the deconfined phase transition [31, 32]. However, the RHIC measurements [33, 34, 35, 36] did not reveal such a structure. The magnitude of the directed flow depends on the amount of baryon stopping in the nuclear overlap zone [37]. The two can be related via realistic model calculations, making v_1^{odd} an important experimental probe of the initial conditions in a heavy-ion collision. The initial conditions assumed in model calculations of v_1^{odd} range from incomplete baryon stopping [37], with a positive space-momentum correlation, to full nucleon stopping with a tilted [32, 38] or rotating [39] source of matter produced in the overlap zone of the nuclei. Model calculations generally agree on the negative sign of the v_1^{odd} slope as a function of pseudorapidity at RHIC [33, 34, 35, 36]. The model predictions for v_1^{odd} at the LHC vary from having the same slope as at RHIC but with smaller magnitude [38] to an opposite (positive) slope with significantly larger magnitude [40, 39].

The v_1^{even} estimated from the two-particle azimuthal correlations at mid-rapidity for RHIC [41] (see also [25]) and LHC [42, 12, 20] energies is in approximate agreement with ideal hydrodynamic model calculations [26, 27] for dipole-like [24] energy fluctuations in the overlap zone of the nuclei. Interpretation of the two-particle correlations is complicated due to a possibly large bias from correlations unrelated to the initial geometry (non-flow) and due to the model dependence of the correction procedure for effects of momentum conservation [27]. The directed flow measured relative to the spectator deflection is free from such biases and provides a cleaner probe of the initial conditions in a heavy-ion collision. It also allows for a study of the main features of the dipole-like energy fluctuations such as a vanishing transverse momentum shift of the created system along the direction of the spectator deflection. Directed flow and its fluctuations also play an important role in understanding effects due to the strong magnetic field in heavy-ion collisions [24] and interpretation of the observed charge separation relative to the reaction plane [43] in terms of the chiral magnetic effect [44].

In this Letter, we report the charged particle directed flow measured relative to the deflection of spectator neutrons in Pb–Pb collisions at $\sqrt{s_{\text{NN}}} = 2.76$ TeV. About 13 million minimum-bias [10] collisions in the 5-80% centrality range were analyzed. For the most central (0-5%) collisions, the small number of spectators does not allow for a reliable reconstruction of their deflection. Two forward scintillator arrays (VZERO) [45] were used to determine the collision centrality. Charged particles reconstructed in the Time Projection Chamber (TPC) [46] with $p_{\text{T}} > 0.15$ GeV/c and $|\eta| < 0.8$ were selected for the analysis.

The deflection of neutron spectators was reconstructed using a pair of Zero Degree Calorimeters (ZDC) [47] with 2×2 segmentation installed 114 meters from the interaction point on each side, covering the $|\eta| > 8.78$ (beam rapidity) region. A typical energy measured by both ZDCs for 30-40% centrality is about 100 TeV [48]. The spectator deflection in the transverse plane was measured with a pair of two-dimensional vectors

$$\mathbf{Q}^{\text{t,p}} \equiv (\mathbf{Q}_x^{\text{t,p}}, \mathbf{Q}_y^{\text{t,p}}) = \frac{\sum_{i=1}^4 \mathbf{n}_i E_i^{\text{t,p}}}{\sum_{i=1}^4 E_i^{\text{t,p}}}, \quad (2)$$

where \mathbf{p} (t) denotes the ZDC on the $\eta > 0$ ($\eta < 0$) side of the interaction point, E_i is the measured signal and $\mathbf{n}_i = (x_i, y_i)$ are the coordinates of the i -th ZDC segment. An asymmetry of 0.1% [49] in energy calibration of the two ZDCs and an absolute energy scale uncertainty cancel in Eq. (2). To compensate for the run-dependent variation of the LHC beam crossing position, an event-by-event correction $\mathbf{Q}^{\text{t,p}} \rightarrow \mathbf{Q}^{\text{t,p}} - \langle \mathbf{Q}^{\text{t,p}} \rangle$ [3] was applied as a function of collision centrality and transverse position of the collision vertex relative to the center of the ALICE detector. Experimental values of the correction for the 30-40% centrality class are $\langle \mathbf{Q}_{x(y)}^{\text{p}} \rangle \approx 2.0$ (-1.5) mm and $\langle \mathbf{Q}_{x(y)}^{\text{t}} \rangle \approx -1.1$ (0.01) mm.

The directed flow is determined with the scalar product method [3, 50]

$$\begin{aligned} v_1\{\Psi_{\text{SP}}^{\text{p}}\} &= \frac{1}{\sqrt{2}} \left[\frac{\langle u_x Q_x^{\text{p}} \rangle}{\sqrt{|\langle Q_x^{\text{t}} Q_x^{\text{p}} \rangle|}} + \frac{\langle u_y Q_y^{\text{p}} \rangle}{\sqrt{|\langle Q_y^{\text{t}} Q_y^{\text{p}} \rangle|}} \right], \\ v_1\{\Psi_{\text{SP}}^{\text{t}}\} &= -\frac{1}{\sqrt{2}} \left[\frac{\langle u_x Q_x^{\text{t}} \rangle}{\sqrt{|\langle Q_x^{\text{t}} Q_x^{\text{p}} \rangle|}} + \frac{\langle u_y Q_y^{\text{t}} \rangle}{\sqrt{|\langle Q_y^{\text{t}} Q_y^{\text{p}} \rangle|}} \right] \end{aligned} \quad (3)$$

where $u_x = \cos\phi$ and $u_y = \sin\phi$ are defined for charged particles at midrapidity. The odd and even components of the directed flow relative to the spectator plane ($\Psi = \Psi_{\text{SP}}$ in Eq. (1)) are then calculated from the equations

$$v_1^{\text{odd}}\{\Psi_{\text{SP}}\} = [v_1\{\Psi_{\text{SP}}^{\text{p}}\} + v_1\{\Psi_{\text{SP}}^{\text{t}}\}]/2 \quad (4)$$

and

$$v_1^{\text{even}}\{\Psi_{\text{SP}}\} = [v_1\{\Psi_{\text{SP}}^{\text{p}}\} - v_1\{\Psi_{\text{SP}}^{\text{t}}\}]/2. \quad (5)$$

Equation (4) defines the sign of v_1^{odd} using the convention used at RHIC [33, 34] and implies a positive directed flow (or deflection along the positive x -axis direction in Fig. 1(a)) of the projectile spectators.

The negative correlations $\langle Q_x^{\text{t}} Q_x^{\text{p}} \rangle$ and $\langle Q_y^{\text{t}} Q_y^{\text{p}} \rangle$ [51] indicate a deflection of the projectile and target spectators in opposite directions. These correlations are sensitive to a combination of the spectator's directed flow relative to the reaction plane Ψ_{RP} and an additional contribution due to flow of spectators along the fluctuating $\Psi_{\text{SP}}^{\text{p}}$ and $\Psi_{\text{SP}}^{\text{t}}$ directions (see Fig. 1(b)). The two contributions are not separable using current experimental techniques and both should be considered in theoretical interpretations of the results derived from Eqs. (3)-(5). Given that the transverse deflection of spectators ($d_{\text{spec}} \approx \sqrt{(\langle Q_x^{\text{t}} Q_x^{\text{p}} \rangle + \langle Q_y^{\text{t}} Q_y^{\text{p}} \rangle) / 2}$) is tiny compared to the ZDC detector position $|z_{\text{ZDC}}| = 114$ m along the beam direction, one can make a rough estimate of the corresponding transverse momentum carried by an individual spectator: $p_{\text{T}}^{\text{spec}} \approx \sqrt{s_{\text{NN}}} (d_{\text{spec}} / z_{\text{ZDC}})$. The measured d_{spec} is about 0.67 (0.92) mm [51] for the 5-10% (30-40%) centrality class which yields $p_{\text{T}}^{\text{spec}} \sim 16$ (22) MeV/c. Correlations $\langle Q_x^{\text{t}} Q_y^{\text{p}} \rangle$ and $\langle Q_y^{\text{t}} Q_x^{\text{p}} \rangle$ in orthogonal directions, which can be non-zero due to residual detector effects, are less than 5% [51] of those in the aligned directions. The 10-20% [51] difference between $\langle Q_x^{\text{t}} Q_x^{\text{p}} \rangle$ and $\langle Q_y^{\text{t}} Q_y^{\text{p}} \rangle$ for mid-central collisions is mainly due to a different offset of the beam spot from the center of the ZDCs in-plane and perpendicular to the LHC accelerator ring. The corresponding dominant systematic uncertainty is evaluated from the spread of results for different terms in Eq. (3) and estimated to be below 20%. The results obtained with Eq. (3) are consistent with calculations using the event plane method [3]. The results with opposite polarity of the magnetic field of the ALICE detector are consistent within 5%. Variation of the results with the collision centrality estimated with the TPC, VZERO, and Silicon Pixel Detectors [47] and with narrowing the nominal ± 10 cm range of the collision vertex along the beam direction from the center of the ALICE detector to ± 7 cm is less than 5%. Altering the selection criteria for the tracks reconstructed with the TPC resulted in a 3-5% variation of the results. The systematic error evaluated for each of the sources listed above were added in quadrature to obtain the total systematic uncertainty of the measurement.

Figure 2(a) shows the charged particle directed flow as a function of pseudorapidity for 10-20%, 30-40%, and 10-60% centrality classes. The $v_1^{\text{even}}(\eta)$ component is found to be negative and independent of η . The $v_1^{\text{odd}}(\eta)$ component exhibits a negative slope as a function of pseudorapidity. This is in contrast to the positive slope expected from the model calculations [40, 39] with stronger rotation of the participant zone at the LHC than at RHIC. The $v_1^{\text{odd}}(\eta)$ at the highest RHIC energy [34] has the same sign of the slope and a factor of three larger magnitude. This is consistent with a smaller tilt of the participant zone in the x - z plane (see Fig. 1(a)) as predicted in [38] for LHC energies. Figure 2(c) compares v_1^{odd} with the STAR data [34] for Au-Au collisions at $\sqrt{s_{\text{NN}}} = 200$ (62) GeV downscaled by the ratio 0.37 (0.12) of the slope at the LHC to that at RHIC energy. These ratios indicate a strong violation by a factor of 1.82 (4.55) of the beam rapidity scaling discussed in [36].

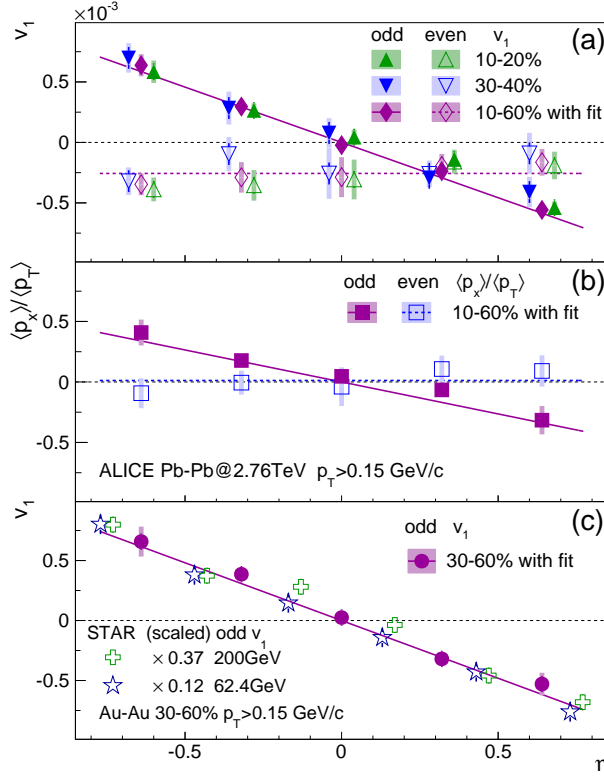

Fig. 2: (color online) (a) v_1 and (b) $\langle p_x \rangle / \langle p_T \rangle$ versus pseudorapidity in Pb–Pb collisions at $\sqrt{s_{NN}} = 2.76$ TeV. (c) v_1^{odd} compared to the STAR data [34] for Au–Au collisions at $\sqrt{s_{NN}} = 200$ (62.4) GeV downscaled by a factor 0.37 (0.12). The statistical (systematic) uncertainties are indicated by the error bars (shaded bands). Lines (to guide the eye) represent fits with a linear (constant) function for v_1^{odd} (v_1^{even}).

Figure 2(b) shows the relative momentum shift $\langle p_x \rangle / \langle p_T \rangle \equiv \langle p_T \cos(\phi - \Psi_{SP}) \rangle / \langle p_T \rangle$, along the spectator plane as a function of pseudorapidity. It is obtained by introducing a $p_T / \langle p_T \rangle$ weight in front of u_x and u_y in Eq. (3). The non-zero $\langle p_x \rangle^{\text{odd}} / \langle p_T \rangle$ shift has a smaller magnitude than v_1^{odd} . The $\langle p_x \rangle^{\text{even}}$ vanishes which is consistent with the dipole-like event-by-event fluctuations of the initial energy density in a system with zero net transverse momentum. Disappearance of $\langle p_x \rangle$ at $\eta \approx 0$ indicates that particles produced at mid-rapidity are not involved in balancing the transverse momentum carried away by spectators.

Figures 3(a) and 3(b) present v_1 and $\langle p_x \rangle / \langle p_T \rangle$ versus collision centrality. The odd components were calculated by taking values at negative η with an opposite sign. Both v_1 components have weak centrality dependence. The $\langle p_x \rangle^{\text{even}}$ component is zero at all centralities, while $\langle p_x \rangle^{\text{odd}} / \langle p_T \rangle$ is a steeper function of centrality than v_1^{odd} . This suggests that v_1^{odd} has two contributions. The first contribution has a similar origin as v_1^{even} due to asymmetric dipole-like initial energy fluctuations. The second contribution grows almost linearly from central to peripheral collisions and represents an effect of sideward collective motion of particles at non-zero rapidity due to expansion of the initially tilted source. This $\langle p_x \rangle$ is balanced by that of the particles produced at opposite rapidity and in very forward (spectator) regions. The magnitude of v_1^{odd} at the LHC is significantly smaller than at RHIC with a similar centrality dependence (see Fig. 3(c)).

Figure 4(a) presents v_1 as a function of p_T . Both components change sign around p_T between 1.2 – 1.7 GeV/c which is expected for the dipole-like energy fluctuations when the momentum of the low p_T particles is balanced by those at high p_T [24, 25, 26, 27]. The p_T dependence of v_1^{even} relative to Ψ_{SP} is similar to that of v_1^{even} relative to $\Psi_{pp}^{(1)}$ estimated from the Fourier fits of the two-particle correlations [42, 12, 20],

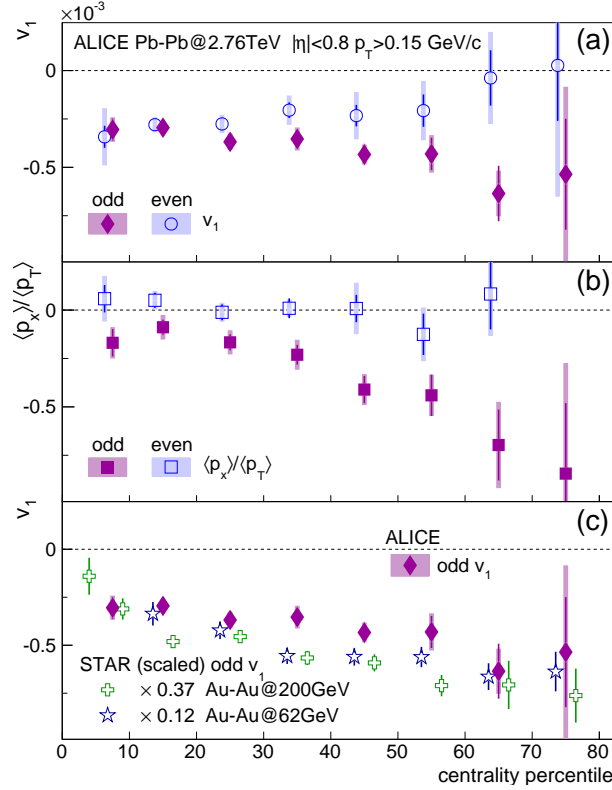

Fig. 3: (color online) (a) v_1 and (b) $\langle p_x \rangle / \langle p_T \rangle$ versus centrality. (c) v_1^{odd} comparison with STAR data [34]. See text and Fig. 2 for description of the data points.

while its magnitude is smaller by a factor of forty [27, 52]. This can be interpreted as a weak correlation, $\langle \cos(\Psi_{\text{PP}}^{(1)} - \Psi_{\text{SP}}) \rangle \ll 1$, between the orientation of the participant and spectator collision symmetry planes. Compared to the RHIC measurements in Fig. 4(b), v_1^{odd} shows a similar trend including the sign change around p_T of 1.5 GeV/c in central collisions and a negative value at all p_T for peripheral collisions.

According to hydrodynamic model calculations [53, 24, 27] particles with low p_T should flow in the direction opposite to the largest density gradient. This, together with the negative even and odd v_1 components relative to Ψ_{SP} measured for particles at mid-rapidity with low transverse momentum ($p_T \lesssim 1.2$ GeV/c) allows to determine if spectators deflect away from or towards the center of the system. However, a detailed theoretical calculation of the correlation between fluctuations in the spectator positions and energy density in the participant zone such as in [23] is required to provide a definitive answer to this question.

In summary, the v_1^{odd} and v_1^{even} components of charged particle directed flow at mid-rapidity, $|\eta| < 0.8$, are measured relative to the spectator plane for Pb–Pb collisions at $\sqrt{s_{\text{NN}}} = 2.76$ TeV. The v_1^{odd} has a negative slope as a function of pseudorapidity with a magnitude about three times smaller than at the highest RHIC energy. This suggests a smaller tilt of the medium created in the participant zone at the LHC, with insufficient rotation to alter the slope of $v_1^{\text{odd}}(\eta)$ as predicted in [40, 39]. As a function of p_T , v_1^{odd} and v_1^{even} cross zero at p_T between 1.2 – 1.7 GeV/c for semi-central collisions. Disappearance of $\langle p_x \rangle$ for particles produced close to zero rapidity suggest that they do not play a role in balancing the p_T kick of spectators. The shape of $v_1^{\text{even}}(p_T)$ and a vanishing $\langle p_x \rangle^{\text{even}}$ is consistent with dipole-like fluctuations of the initial energy density in the participant zone. A similar shape but with about forty times larger magnitude was observed for an estimate of $v_1^{\text{even}}(p_T)$ relative to the participant plane from the Fourier fits of the two-particle correlation [42, 12]. This indicates that fluctuating participant and

Fig. 4: (color online) (a) v_1 versus transverse momentum. (b) v_1^{odd} comparison with STAR data [34]. See text and Fig. 2 for description of the data points. Lines (to guide the eye) represent fits with a third order polynomial.

spectator collision symmetry planes are weakly correlated, which is important experimental input for modeling the ill-constrained initial conditions of a heavy-ion collision. Future studies of the directed flow at mid-rapidity using identified particles and extension of the v_1 measurements to forward rapidities should provide a stronger constraint on the effects of initial density fluctuations in the formation of directed flow.

Affiliation notes

- ⁱ Deceased
- ⁱⁱ Also at: M.V.Lomonosov Moscow State University, D.V.Skobeltzyn Institute of Nuclear Physics, Moscow, Russia
- ⁱⁱⁱ Also at: University of Belgrade, Faculty of Physics and "Vinča" Institute of Nuclear Sciences, Belgrade, Serbia
- ^{iv} Also at: Institute of Theoretical Physics, University of Wrocław, Wrocław, Poland

Collaboration Institutes

- ¹ Academy of Scientific Research and Technology (ASRT), Cairo, Egypt
- ² A. I. Alikhanyan National Science Laboratory (Yerevan Physics Institute) Foundation, Yerevan, Armenia
- ³ Benemérita Universidad Autónoma de Puebla, Puebla, Mexico
- ⁴ Bogolyubov Institute for Theoretical Physics, Kiev, Ukraine
- ⁵ Bose Institute, Department of Physics and Centre for Astroparticle Physics and Space Science (CAPSS), Kolkata, India
- ⁶ Budker Institute for Nuclear Physics, Novosibirsk, Russia
- ⁷ California Polytechnic State University, San Luis Obispo, California, United States
- ⁸ Central China Normal University, Wuhan, China

- ⁹ Centre de Calcul de l'IN2P3, Villeurbanne, France
- ¹⁰ Centro de Aplicaciones Tecnológicas y Desarrollo Nuclear (CEADEN), Havana, Cuba
- ¹¹ Centro de Investigaciones Energéticas Medioambientales y Tecnológicas (CIEMAT), Madrid, Spain
- ¹² Centro de Investigación y de Estudios Avanzados (CINVESTAV), Mexico City and Mérida, Mexico
- ¹³ Centro Fermi - Museo Storico della Fisica e Centro Studi e Ricerche "Enrico Fermi", Rome, Italy
- ¹⁴ Chicago State University, Chicago, United States
- ¹⁵ Commissariat à l'Energie Atomique, IRFU, Saclay, France
- ¹⁶ COMSATS Institute of Information Technology (CIIT), Islamabad, Pakistan
- ¹⁷ Departamento de Física de Partículas and IGFAE, Universidad de Santiago de Compostela, Santiago de Compostela, Spain
- ¹⁸ Department of Physics Aligarh Muslim University, Aligarh, India
- ¹⁹ Department of Physics and Technology, University of Bergen, Bergen, Norway
- ²⁰ Department of Physics, Ohio State University, Columbus, Ohio, United States
- ²¹ Department of Physics, Sejong University, Seoul, South Korea
- ²² Department of Physics, University of Oslo, Oslo, Norway
- ²³ Dipartimento di Fisica dell'Università and Sezione INFN, Trieste, Italy
- ²⁴ Dipartimento di Fisica dell'Università and Sezione INFN, Cagliari, Italy
- ²⁵ Dipartimento di Fisica dell'Università and Sezione INFN, Turin, Italy
- ²⁶ Dipartimento di Fisica dell'Università 'La Sapienza' and Sezione INFN, Rome, Italy
- ²⁷ Dipartimento di Fisica e Astronomia dell'Università and Sezione INFN, Catania, Italy
- ²⁸ Dipartimento di Fisica e Astronomia dell'Università and Sezione INFN, Bologna, Italy
- ²⁹ Dipartimento di Fisica e Astronomia dell'Università and Sezione INFN, Padova, Italy
- ³⁰ Dipartimento di Fisica 'E.R. Caianiello' dell'Università and Gruppo Collegato INFN, Salerno, Italy
- ³¹ Dipartimento di Scienze e Innovazione Tecnologica dell'Università del Piemonte Orientale and Gruppo Collegato INFN, Alessandria, Italy
- ³² Dipartimento Interateneo di Fisica 'M. Merlin' and Sezione INFN, Bari, Italy
- ³³ Division of Experimental High Energy Physics, University of Lund, Lund, Sweden
- ³⁴ European Organization for Nuclear Research (CERN), Geneva, Switzerland
- ³⁵ Fachhochschule Köln, Köln, Germany
- ³⁶ Faculty of Engineering, Bergen University College, Bergen, Norway
- ³⁷ Faculty of Mathematics, Physics and Informatics, Comenius University, Bratislava, Slovakia
- ³⁸ Faculty of Nuclear Sciences and Physical Engineering, Czech Technical University in Prague, Prague, Czech Republic
- ³⁹ Faculty of Science, P.J. Šafárik University, Košice, Slovakia
- ⁴⁰ Frankfurt Institute for Advanced Studies, Johann Wolfgang Goethe-Universität Frankfurt, Frankfurt, Germany
- ⁴¹ Gangneung-Wonju National University, Gangneung, South Korea
- ⁴² Gauhati University, Department of Physics, Guwahati, India
- ⁴³ Helsinki Institute of Physics (HIP) and University of Jyväskylä, Jyväskylä, Finland
- ⁴⁴ Hiroshima University, Hiroshima, Japan
- ⁴⁵ Indian Institute of Technology Bombay (IIT), Mumbai, India
- ⁴⁶ Indian Institute of Technology Indore, Indore, India (IITI)
- ⁴⁷ Institut de Physique Nucléaire d'Orsay (IPNO), Université Paris-Sud, CNRS-IN2P3, Orsay, France
- ⁴⁸ Institute for High Energy Physics, Protvino, Russia
- ⁴⁹ Institute for Nuclear Research, Academy of Sciences, Moscow, Russia
- ⁵⁰ Nikhef, National Institute for Subatomic Physics and Institute for Subatomic Physics of Utrecht University, Utrecht, Netherlands
- ⁵¹ Institute for Theoretical and Experimental Physics, Moscow, Russia
- ⁵² Institute of Experimental Physics, Slovak Academy of Sciences, Košice, Slovakia
- ⁵³ Institute of Physics, Bhubaneswar, India
- ⁵⁴ Institute of Physics, Academy of Sciences of the Czech Republic, Prague, Czech Republic
- ⁵⁵ Institute of Space Sciences (ISS), Bucharest, Romania
- ⁵⁶ Institut für Informatik, Johann Wolfgang Goethe-Universität Frankfurt, Frankfurt, Germany
- ⁵⁷ Institut für Kernphysik, Johann Wolfgang Goethe-Universität Frankfurt, Frankfurt, Germany
- ⁵⁸ Institut für Kernphysik, Technische Universität Darmstadt, Darmstadt, Germany
- ⁵⁹ Institut für Kernphysik, Westfälische Wilhelms-Universität Münster, Münster, Germany

- 60 Instituto de Ciencias Nucleares, Universidad Nacional Autónoma de México, Mexico City, Mexico
- 61 Instituto de Física, Universidad Nacional Autónoma de México, Mexico City, Mexico
- 62 Institut Pluridisciplinaire Hubert Curien (IPHC), Université de Strasbourg, CNRS-IN2P3, Strasbourg, France
- 63 Joint Institute for Nuclear Research (JINR), Dubna, Russia
- 64 Kirchhoff-Institut für Physik, Ruprecht-Karls-Universität Heidelberg, Heidelberg, Germany
- 65 Korea Institute of Science and Technology Information, Daejeon, South Korea
- 66 KTO Karatay University, Konya, Turkey
- 67 Laboratoire de Physique Corpusculaire (LPC), Clermont Université, Université Blaise Pascal, CNRS-IN2P3, Clermont-Ferrand, France
- 68 Laboratoire de Physique Subatomique et de Cosmologie (LPSC), Université Joseph Fourier, CNRS-IN2P3, Institut Polytechnique de Grenoble, Grenoble, France
- 69 Laboratori Nazionali di Frascati, INFN, Frascati, Italy
- 70 Laboratori Nazionali di Legnaro, INFN, Legnaro, Italy
- 71 Lawrence Berkeley National Laboratory, Berkeley, California, United States
- 72 Lawrence Livermore National Laboratory, Livermore, California, United States
- 73 Moscow Engineering Physics Institute, Moscow, Russia
- 74 National Centre for Nuclear Studies, Warsaw, Poland
- 75 National Institute for Physics and Nuclear Engineering, Bucharest, Romania
- 76 National Institute of Science Education and Research, Bhubaneswar, India
- 77 Niels Bohr Institute, University of Copenhagen, Copenhagen, Denmark
- 78 Nikhef, National Institute for Subatomic Physics, Amsterdam, Netherlands
- 79 Nuclear Physics Institute, Academy of Sciences of the Czech Republic, Řež u Prahy, Czech Republic
- 80 Oak Ridge National Laboratory, Oak Ridge, Tennessee, United States
