(Dated: September 2, 2013)

The first double diffractive cross-section measurement in the very forward region has been carried out by the TOTEM experiment at the LHC with center-of-mass energy of  $\sqrt{s} = 7$  TeV. By utilizing the very forward TOTEM tracking detectors T1 and T2, which extend up to  $|\eta|=6.5$ , a clean sample of double diffractive pp events was extracted. From these events, we measured the cross-section  $\sigma_{\rm DD} = (116 \pm 25) \ \mu \text{b}$  for events where both diffractive systems have  $4.7 < |\eta|_{min} < 6.5$ .

<sup>36</sup> which cannot be calculated with perturbative QCD. Var-37 ious model calculations predict diffractive cross-sections  $_{38}$  that are markedly different at the LHC energies [1–3].

Double diffraction (DD) is the process in which two 39 40 41 the interaction is mediated by an object with the quan- 58 Pot detectors to identify leading protons and T1 and T2 <sup>42</sup> tum numbers of the vacuum. Experimentally, DD events <sup>59</sup> telescopes to detect charged particles in the forward re-43 are typically associated with a rapidity gap that is large 60 gion. The most important detectors for this measure-<sup>44</sup> compared to random multiplicity fluctuations. Rapid- <sub>61</sub> ment are the T2 and T1 telescopes. T2 consists of Gas 45 ity gaps are exponentially suppressed in non-diffractive 62 Electron Multipliers that detect charged particles with  $_{46}$  (ND) events [4], however when a detector is not able to  $_{63}$   $p_T > 40$  MeV/c at pseudo-rapidities of 5.3< $|\eta| < 6.5$  [8].  $_{47}$  detect particles with the transverse momentum  $(p_T)$  of  $_{64}$  The T1 telescope consists of Cathode Strip Chambers 48 a few hundred MeV, the identification of double diffrac- 65 that measure charged particles with  $p_T > 100 \text{ MeV/c}$  at <sup>49</sup> tive events by means of rapidity gaps becomes very chal- <sup>66</sup>  $3.1 < |\eta| < 4.7$ .

Diffractive scattering represents a unique tool for inves- 50 lenging. The excellent  $p_T$  acceptance of the TOTEM  $_{34}$  tigating the dynamics of strong interactions and proton  $_{51}$  detectors makes the experiment favorable for the mea-35 structure. These events are dominated by soft processes 52 surement. Previous measurements of DD cross-section  $_{53}$  are described in [5, 6].

The TOTEM experiment [7] is a dedicated experiment 54 55 to study diffraction, total cross-section and elastic scat-<sup>56</sup> tering at the LHC. It has three subdetectors placed symcolliding hadrons dissociate into clusters of particles, and 57 metrically on both sides of the interaction point: Roman 67 section was determined in the forward region. 68 69 the minimum pseudorapidy of all primary particles pro- 129 sample corresponds to one signature type j. 73 duced in the diffractive system. Although these events  $_{\scriptscriptstyle 130}$ 74 75 76 77 78 <sup>79</sup> the  $\eta_{min}$  range was divided into two sub-regions on each 135 formula: side, providing four subcategories for the measurement. 80

The analysis is structured in three steps. In the first 81 step, the raw rate of double diffractive events is esti-82 mated: the selected sample is corrected for trigger ef-83 ficiency, pile-up and T1 multiplicity, and the amount of 84 background is determined. In the second step, the visible 85 cross-section is calculated by correcting the raw rate for <sup>87</sup> acceptance and efficiency to detect particles. In the last step, the visible cross-section is corrected so that both 88 diffractive systems have  $4.7 < |\eta|_{min} < 6.5$ . 89

This measurement uses data collected in October 2011 90 at  $\sqrt{s}=7$  TeV during a low pile-up run with a special 91  $\beta^*=90$  m optics. The data were collected with the T2 92 <sup>93</sup> minimum bias trigger. The trigger condition was that 3 <sup>94</sup> out of 10 superpads in the same  $r - \phi$  sector fired. A su-<sup>95</sup> perpad consists of 3 radial and 5 azimuthal neighbouring pads, and it is sufficient that one out of 15 pads registered 96 a signal for a superpad to be fired. 97

After the offline reconstruction [10], the DD events 98 were selected by requiring tracks in both T2 arms and 99 100 no tracks in either of the T1 arms (2T2+0T1). T2 tracks with a  $\chi^2$ -fit probability smaller than 2% and 101 tracks falling in the overlap region of two T2 quar-102 ters, i.e. tracks with  $80^{\circ} < \phi < 100^{\circ}$  or  $260^{\circ} < \phi < 280^{\circ}$ . 103 were removed. The tracks in the overlap region were 104 removed because simulation does not model well their 105 In the paper, this full selection for visiresponse. 106 ble cross-section is named  $I_{\rm track}.$  The four subcate-107 <sup>108</sup> gories for the visible cross-section measurement were de-109 fined by the T2 track with minimum  $|\eta|$  on each side, <sup>110</sup>  $|\eta^+_{track}|_{min}$  and  $|\eta^-_{track}|_{min}$ . The subcategory D11<sub>track</sub> <sup>111</sup> includes the events with 5.3< $|\eta^\pm_{track}|_{min}$ <5.9, D22<sub>track</sub> <sup>112</sup> the events with  $5.9 < |\eta_{track}^{\pm}|_{min} < 6.5$ , D12<sub>track</sub> the events <sup>113</sup> with 5.3< $|\eta^+_{track}|_{min}$ <5.9 and 5.9< $|\eta^-_{track}|_{min}$ <6.5, and <sup>114</sup> D21<sub>track</sub> the events with  $5.9 < |\eta^+_{track}|_{min} < 6.5$  and 115 5.3 <  $|\eta_{track}^{-}|_{min}$  < 5.9.

Two additional samples were extracted for background 116 <sup>117</sup> estimation. A control sample for single diffractive (SD) <sup>118</sup> events has at least one track in either of the T2 arms <sup>119</sup> and no tracks in the opposite side T2 arm nor in T1 <sup>167</sup> where  $N_{DD}^{2T2+2T1}$  and  $N_{SD}^{2T2+2T1}$  were taken from MC for <sup>120</sup> (1T2+0T1). A control sample for ND events has tracks <sup>168</sup> the first iteration. Pythia was used as the default gen-<sup>121</sup> in all arms of T2 and T1 detectors (2T2+2T1). Four <sup>169</sup> erator throughout the analysis. The ratio,  $R_{ND}^{I}$ , of ND  $_{122}$  additional exclusive data samples were defined for testing  $_{170}$  events expected in the sample j and in the control sam-

In this novel measurement, the double diffractive cross-<sup>123</sup> the background model validity: tracks in both arms of T2 The 124 and exactly in one arm of T1 (2T2+1T1), tracks in either method is as model-independent as possible. The DD 125 of T2 arms and in both T1 arms (1T2+2T1), tracks in  $_{126}$  events were selected by vetoing T1 tracks and requir- $_{126}$  T2 and T1 in one side of the interaction point (1T2+1T1 <sup>71</sup> ing tracks in T2, hence selecting events that have two <sup>127</sup> same side) and tracks in T2 and T1 in the opposite side  $_{72}$  diffractive systems with 4.7  $< |\eta|_{min} < 6.5$ , where  $\eta_{min}$  is  $_{128}$  of the interaction point (1T2+1T1 opposite side). Each

The number of selected data events was corrected for are only about 3% of the total  $\sigma_{DD}$ , they provide a pure 131 trigger efficiency and pile-up. The trigger efficiency corselection of DD events and the measurement is an impor- $_{132}$  rection  $c_t$  was calculated from zero-bias triggered sample tant step towards determining if there is a rich resonance 133 in the bins of number of tracks. It is described in detail structure in the low mass region [9]. To probe further, 134 in [11]. The pile-up correction was calculated using the

$$c_{pu}^{j} = \frac{1}{1 - \frac{2p_{pu}}{1 + p_{pu}} + \frac{2p_{pu}}{1 + p_{pu}} \cdot p^{j}}$$
(1)

<sup>136</sup> where j is the signature type,  $p_{pu} = (1.5 \pm 0.4)\%$  is the <sup>137</sup> pile-up correction factor for inelastic events [11], and <sup>138</sup>  $p^j$  is the correction for signature type changes due to <sup>139</sup> pile-up. The correction  $p^j$  was determined by creating <sup>140</sup> a MC study of pile-up. A pool of signature types was <sup>141</sup> created by weighting each type with their probability <sup>142</sup> in the data. Then a pair was randomly selected, and 143 their signatures were combined. After repeating the se-144 lection and combination, the correction was calculated 145 as  $p^j = N^j_{combined} / N^j_{original}$ .  $N^j_{combined}$  is the number of 146 selected combinations that have the combined signature <sup>147</sup> of j. The uncertainty in  $p^j$  was determined by taking the <sup>148</sup> event type weights from Pythia 8 [12] and recalculating <sup>149</sup>  $p^{j}$ . The corrected number of data events were calculated 150 with the formula  $N^j = c_t c_{pu}^j N_{raw}^j$ .

The simulated T1 track multiplicity distribution pre-151 152 dicts a lower number of zero-track events than what was <sup>153</sup> observed in the data. The number of T1 tracks in the <sup>154</sup> simulation was corrected to match with the data by ran-155 domly selecting 10% (2%) of one-(two-)track events and <sup>156</sup> changing them to zero-track events.

Three kinds of background were considered for the 157 <sup>158</sup> analysis: ND, SD and central diffraction (CD). ND and <sup>159</sup> SD background estimation methods were developed to <sup>160</sup> minimize the model dependence, and the values of esti-<sup>161</sup> mates were calculated iteratively. Since the CD back- $_{162}$  ground is significantly smaller than the ND and SD ones, its estimate  $(N_{CD})$  was taken from simulation, using the 163 acceptance and  $\sigma_{CD}=1.3$  mb from Phojet [13]. 164

The number of ND events in the ND dominated control 165 <sup>166</sup> sample, 2T2+2T1, has been determined as:

$$N_{ND}^{2T2+2T1} = N_{data}^{2T2+2T1} - N_{DD}^{2T2+2T1} - N_{SD}^{2T2+2T1} - N_{CD}^{2T2+2T1}$$
(2)

<sup>171</sup> ple, was calculated from MC as

$$R_{ND}^{j} = \frac{N_{ND,MC}^{j}}{N_{ND,MC}^{2T2+2T1}}.$$
(3)

<sup>172</sup> The number of ND events within the signal sample was 173 estimated as

$$N_{ND}^{j} = R_{ND}^{j} \cdot C^{j} \cdot N_{ND}^{2T2+2T1}, \qquad (4)$$

 $_{174}$  where  $C^{j}$  is the normalization factor deduced from the 175 relative mismatch between the data and the total Pythia <sup>176</sup> prediction in the signal sample:

$$C^{j} = \frac{N_{data}^{j}}{N_{MC}^{j}} \cdot \frac{N_{MC}^{2T2+2T1}}{N_{data}^{2T2+2T1}}.$$
 (5)

The SD background estimation starts from the calcu-177 178 lation of the number of SD events in the SD dominated <sup>179</sup> control sample, 1T2+0T1, by subtracting the number of 180 other kind of events from the number of data events:

$$N_{SD}^{1T2+0T1} = N_{data}^{1T2+0T1} - N_{DD}^{1T2+0T1} - N_{ND}^{1T2+0T1} - N_{CD}^{1T2+0T1} - N_{CD}^{1T2+0T1}$$
(6)

<sup>181</sup> where  $N_{ND}^{1T2+0T1}$  was calculated with the ND estimation <sup>182</sup> method and  $N_{DD}^{1T2+0T1}$  was taken from Pythia for the first 183 iteration. To scale the number of SD events to the signal <sup>184</sup> region, the ratio  $R_{SD}^{j}$  was calculated from data. The SD 185 dominated data events that were used in the calculation <sup>186</sup> of the ratio have exactly one leading proton seen by the 187 RPs, in addition to the sample selections based on T2 188 and T1 tracks. By using the ratio

$$R_{SD}^{j} = \frac{N_{data}^{j+1proton}}{N_{data}^{1T2+0T1+1proton}},$$
(7)

189 the expected number of background SD events was cal-190 culated as

$$N_{SD}^{j} = R_{SD}^{j} \cdot N_{SD}^{1T2+0T1}.$$
 (8)

191 <sup>192</sup> SD and CD background estimates described above. The <sup>210</sup> timate, the ratio  $R_{ND}^{j}$  was calculated from Phojet and <sup>193</sup> background estimations were repeated with redefined <sup>211</sup>  $N_{ND}^{j}$  estimated with it. A conservative uncertainty of <sup>194</sup> values of  $N_{DD}^{2T2+2T1}$ ,  $N_{SD}^{1T2+0T1}$ ,  $N_{ND}^{1T2+0T1}$ : <sup>212</sup> 50% was assigned for the CD estimate. <sup>195</sup> the numbers of DD events were scaled with the ratio <sup>213</sup> The visible DD cross-section was calculated using the  $_{196}$  of  $\sigma_{DD}^{measured}/\sigma_{DD}^{MC},$  and the numbers of SD and ND  $_{214}$  formula 197 events were calculated using their estimation methods. <sup>198</sup> Next, the three steps were repeated until  $N_{ND}^{2T2+0T1}$  and  $N_{SD}^{2T2+0T1}$  converged. The final numbers of estimates in  $_{200}$  the I<sub>track</sub> control samples are shown in Table I, and the  $_{215}$  where E is the experimental correction and the integrated <sub>201</sub> estimated numbers of background events in the signal <sub>216</sub> luminosity  $\mathcal{L}=(40.1\pm1.6) \mu b^{-1}$ . Trigger efficiency	2.1	1.2	1.0	0.9	0.9
Pile-up correction	2.4	2.1	0.4	1.1	1.0
T1 multiplicity	7.0	3.9	0.7	1.6	1.7
Luminosity	4.7	2.6	0.5	1.1	1.1
Acceptance	14.7	14.1	2.6	2.0	2.0
True $\eta_{min}$	15.4	11.0	1.5	2.9	2.9
Total uncertainty	24.8	19.6	4.8	5.1	4.9

TABLE III. Summary of statistical and systematic uncertainties  $(\mu b)$ .

TABLE IV. Double diffractive cross-section measurements ( $\mu$ b) in the forward region. Both visible and true  $\eta_{min}$  corrected cross-sections are given. The latter is compared to Pythia and Phojet predictions. Pythia estimate for total  $\sigma_{DD}=8.1$  mb and Phojet estimate  $\sigma_{DD}=3.9$  mb.

	$I_{track}$	$D11_{track}$	$D22_{track}$	$D12_{track}$	$D21_{track}$
Visible	$131 \pm 22$	$58 \pm 14$	$20{\pm}8$	$31\pm5$	$34 \pm 5$
	Ι	D11	D22	D12	D21
True $\eta_{min}$	$116 \pm 25$	$65 \pm 20$	$12 \pm 5$	$26\pm5$	$27 \pm 5$
Pythia true $\eta_{min}$	159	70	17	36	36
Phojet true $\eta_{min}$	101	44	12	23	23
