

Search for monotop signatures in proton-proton collisions at $\sqrt{s} = 8$ TeV

The CMS Collaboration*

Abstract

Results are presented from a search for new decaying massive particles whose presence is inferred from an imbalance in transverse momentum and which are produced in association with a single top quark that decays into a bottom quark and two light quarks. The measurement is performed using 19.7 fb^{-1} of data from proton-proton collisions at a center-of-mass energy of 8 TeV, collected with the CMS detector at the CERN LHC. No deviations from the standard model predictions are observed and lower limits are set on the masses of new invisible bosons. In particular, scalar and vector particles, with masses below 330 and 650 GeV, respectively, are excluded at 95% confidence level, thus substantially extending a previous limit published by the CDF Collaboration.

Submitted to Physical Review Letters

Extensions of theories beyond the standard model (BSM), such as those with universal extra dimensions [1] or supersymmetry [2, 3], predict the existence of neutral massive particles that are “invisible”, that is, they interact only weakly with matter. Such particles can be produced in collider experiments, but escape detection so that their existence can only be inferred by the presence of a large imbalance in transverse momentum (E_T^{miss}). Both the ATLAS [4] and CMS [5] Collaborations have performed searches for monojet [6, 7] and monophoton [8, 9] signatures that manifest themselves through the presence of a single jet or photon associated with large E_T^{miss} . These searches have not revealed any evidence for BSM monojet or monophoton final states, but the non-observation can be explained within a theory where new particles favor coupling to massive standard model (SM) particles such as the top quark. In this Letter we present a search for events in which an invisible BSM particle is produced in association with a top quark [10–20]. Such events, containing single top quarks and large E_T^{miss} , are referred to as “monotop” candidates.

At tree level a monotop system can be produced through two main mechanisms: it can originate either (i) from the decay of a heavy bosonic resonance, with E_T^{miss} arising from an invisible fermionic state (for instance, $\bar{d}\bar{s} \rightarrow \tilde{u}_i \rightarrow t\tilde{\chi}_1^0$, where \bar{d} and \bar{s} denote anti-d and anti-s quarks, \tilde{u}_i are any of the up-type squarks of R -parity violating supersymmetry [21], and t and $\tilde{\chi}_1^0$ are the top quark and neutralino), or (ii) through flavor-changing (FC) interactions mediated by a lighter up-type quark that produce an invisible bosonic state (for instance, $ug \rightarrow u^* \rightarrow tv$, where u , g , t , and v are an up quark, gluon, top quark, and invisible BSM particle, respectively) [10]. In both cases the new invisible particles are assumed to be either long-lived or strongly connected to a hidden sector that possibly contains a dark matter candidate. Consequently, even in the presence of non-vanishing couplings to SM particles, which enable the production of invisible particles in collider experiments, an E_T^{miss} signature is expected. The present study focuses on the second class of the above-mentioned processes, and, more precisely, it investigates the production of a bosonic invisible state yielding large E_T^{miss} in association with a single top quark that decays to a bottom quark and a W boson, the latter decaying into a pair of quarks.

The search is performed on data from proton-proton collisions recorded at a center-of-mass energy of 8 TeV, corresponding to an integrated luminosity of 19.7 fb^{-1} , and recorded with the CMS detector at the CERN LHC. The most important backgrounds for the event signature with three jets and large E_T^{miss} are Z +jets, W +jets, and $t\bar{t}$ processes. The Z +jets and W +jets backgrounds are estimated from data, and the signal yield is determined simultaneously with multijet background, using a likelihood approach based on the observed multiplicity of b -tagged jets.

We interpret the results within a simplified field theory [10, 11] where the invisible particle can be either a scalar (ϕ) or a vector (v) boson, with its Lagrangian given by

$$\mathcal{L} = \mathcal{L}_{\text{SM}} + \mathcal{L}_{\text{kin}} + a_{\text{FC}}^0 \phi \bar{u}u + a_{\text{FC}}^1 v_\mu \bar{u} \gamma^\mu u + \text{h.c.}, \quad (1)$$

where \mathcal{L}_{SM} denotes the SM Lagrangian, \mathcal{L}_{kin} kinetic terms for the ϕ and v fields, and the remaining terms model the interactions of the invisible states with up-type quarks. The coupling strengths are embedded in two 3×3 matrices in flavor space ($a_{\text{FC}}^{0,1}$), where only the elements connecting the first and third generations are non-vanishing and set to 0.1, as done in Ref. [10].

The central feature of the CMS apparatus is a superconducting solenoid of 6 m internal diameter, providing a magnetic field of 3.8 T. Within the superconducting solenoid volume are a silicon pixel and strip tracker, a lead tungstate crystal electromagnetic calorimeter, and a brass and scintillator hadron calorimeter, each composed of a barrel and two endcap sections.

Muons are measured in gas-ionization detectors embedded in the steel flux-return yoke outside the solenoid. Extensive forward calorimetry complements the coverage provided by the barrel and endcap detectors. A more detailed description of the CMS detector, together with a definition of the coordinate system used and the relevant kinematic variables, can be found in Ref. [5].

Events are recorded using a trigger requiring $E_T^{\text{miss}} > 150$ GeV. For the background estimation we use an independent control sample of events with an isolated single-muon trigger with a transverse momentum threshold of $p_T > 24$ GeV.

The monotop model is implemented within the FEYNRULES package [22, 23] and is interfaced [24, 25] with the MADGRAPH 5 event generator [26]. Simulated events are produced for masses of invisible particles from 0 to 0.2 TeV in steps of 0.05 TeV, and from 0.2 to 1 TeV in steps of 0.1 TeV. The production cross sections are calculated at leading order (LO) with MADGRAPH with the CTEQ6.1L [27] parton distribution functions (PDF).

The main backgrounds are generated using MADGRAPH. For W+jets and Z+jets processes, events are generated including up to four additional partons. For $Z(\rightarrow ee, \mu\mu, \tau\tau)$ +jets (with mass $m_{\ell\ell} > 50$ GeV) and $W(\rightarrow e\nu, \mu\nu, \tau\nu)$ + jets processes we use the next-to-next-to-leading order (NNLO) cross sections of 3.50 nb and 37.5 nb, respectively, as calculated using the FEWZ 3.1 program [28]. For the $Z(\rightarrow \nu\nu)$ + jets process we use events generated in four bins of H_T , the scalar sum of p_T of all of the generated jets in the process: $50 < H_T < 100$ GeV, $100 < H_T < 200$ GeV, $200 < H_T < 400$ GeV, and $H_T > 400$ GeV, with respective LO cross sections of 381, 160, 41.5, and 5.27 pb. The $t\bar{t}$ sample includes up to three additional partons at the matrix element level, and is rescaled to an inclusive NNLO cross section of 246 pb [29].

Other SM backgrounds arise from single top quark and diboson (WW, WZ, and ZZ) production. Single top quark production is modeled with POWHEG 1.0 [30–33], and diboson production is modeled with PYTHIA 6.4.22 [34]. All Monte Carlo (MC) generated events are evolved using PYTHIA and processed with a full simulation of the CMS detector implemented in the GEANT4 [35] package.

We require at least one reconstructed primary vertex and reject events with evidence of significant beam halo or events with a large amount of detector noise [36].

The CMS particle-flow (PF) algorithm [37–39] is used to reconstruct and identify each particle with an optimized combination of information from all the CMS subdetectors. The only charged PF particles considered in reconstructing an event are those associated with the main primary vertex, which is defined as the primary vertex with the largest sum of p_T^2 of all the associated tracks. Particles identified as originating from other collisions in the beam crossing (pileup) are removed from consideration.

The three jets from $t \rightarrow bW \rightarrow bq\bar{q}'$ decay are reconstructed using the anti- k_T clustering algorithm [40] with a distance parameter of 0.5. During jet reconstruction, the charged particles arising from pileup interactions are excluded, while the neutral pileup component is accounted for using the area-based energy subtraction procedure described in Refs. [41, 42]. Jet energy corrections used in this measurement rely on simulation and on studies performed in data [43]. Only jets with $p_T \geq 35$ GeV and $|\eta| < 2.4$ are considered, where η is the pseudorapidity. The two highest- p_T (leading) jets must have a $p_T > 60$ GeV, while the p_T of the jet with third highest p_T has to be above 40 GeV. The invariant mass of the three jets has to be less than 250 GeV. Events containing additional jets with a p_T above 35 GeV are rejected. We require one of the three jets to be identified as a candidate jet from a b quark. The identification algorithm is based on the reconstruction of a displaced secondary vertex [44]. A jet from a b quark is tagged

with $\approx 70\%$ efficiency. The probability to tag a light jet from u, d, or s quarks, or a gluon jet is 1–4% depending on the jet p_T . We also use events without b-tagged jets in order to define a background-enriched sample to extract the normalization for multijet background.

Signal-candidate events containing isolated muons or electrons are rejected. Muons are reconstructed by matching tracks from the outer muon detector to tracks reconstructed by the inner tracker [45]. Muons are required to have $p_T > 10$ GeV and $|\eta| < 2.4$. Electrons are reconstructed by associating tracks from the inner tracker to clustered energy depositions in the electromagnetic calorimeter [46]. Electrons are required to have $p_T > 20$ GeV and be within $|\eta| < 2.5$, excluding the transition region between barrel and endcap defined by $1.44 < |\eta| < 1.57$. Standard CMS muon and electron identification criteria [45, 46] are applied. The muon (electron) relative isolation variable I_{rel} is computed by first summing the transverse momenta of the reconstructed particles in a cone of $\Delta R = \sqrt{(\Delta\eta)^2 + (\Delta\phi)^2} < 0.4$ (0.3) around the muon (electron) direction, excluding the contribution of the lepton, and then dividing this sum by the transverse momentum of the lepton. The lepton candidates are rejected if they satisfy $I_{\text{rel}} < 0.2$.

The E_T^{miss} vector is defined by the negative vector sum of the transverse momenta of all the reconstructed particles in the event. The E_T^{miss} threshold of 350 GeV used in the analysis is optimized to give the most sensitive exclusion limit on the production cross section. This threshold is also nearly optimal for attaining best significance in the signal.

The dominant backgrounds after implementing the selection criteria are $t\bar{t}$ and V +jets events, with V being either a Z or a W boson. For electroweak vector boson production, additional jets originate from multijet processes and this can lead to large systematic uncertainties in the production of up to three additional jets. For this reason, we estimate the V +jets background using data.

The control region for W+jets and Z+jets backgrounds is defined with an alternative selection, requiring one or two isolated muons in addition to the three jets. A tighter selection is applied for muons, requiring them to satisfy $p_T \geq 40$ GeV and $|\eta| < 2.1$. In this case, the relative combined isolation variable in a cone of $\Delta R < 0.4$ must be below 0.12. As in the signal selection, the three jets are required to have $p_T > 60, 60, 40$ GeV respectively, and the invariant mass of the three jets has to be less than 250 GeV. Events with any additional jets with a p_T above 35 GeV, as well as events with additional isolated electrons or muons are rejected.

The $Z(\rightarrow \nu\nu)$ +jets background is estimated from events with two muons and three jets. In such events, we replace the requirement for $E_T^{\text{miss}} > 350$ GeV with the requirement for the vector sum of the p_T of the two muons and of E_T^{miss} to be greater than 350 GeV. We also eliminate most of the non-Z backgrounds by selecting events with $\mu^+\mu^-$ invariant mass between 60 and 120 GeV. The $Z(\rightarrow \nu\nu)$ +jets background is calculated using the following equation:

$$N(Z \rightarrow \nu\nu) = \frac{N^{\text{obs}}(\mu\mu)}{A \times \epsilon(\mu\mu)} \cdot \frac{\mathcal{B}(Z \rightarrow \nu\nu)}{\mathcal{B}(Z \rightarrow \mu\mu)} \quad (2)$$

where $N^{\text{obs}}(\mu\mu)$ is the number of observed events with two muons, $A \times \epsilon(\mu\mu)$ is the product of acceptance and efficiency to identify and select the two muons, as measured in simulation, and $\mathcal{B}(Z \rightarrow \nu\nu)/\mathcal{B}(Z \rightarrow \mu\mu) = 5.94$ [47] is the ratio of branching fractions for Z decays into two neutrinos and two muons. The accuracy of the background estimate is limited by the number of selected events with two muons. The estimated $Z(\rightarrow \nu\nu)$ +jets background is presented in Table 1.

The $W(\rightarrow \ell\nu)$ +jets background is calculated from events with a single muon and three jets. Just as in the selected signal events, E_T^{miss} has to be greater than 350 GeV. The transverse mass con-

structured with the muon- p_T and E_T^{miss} vectors has to be less than 180 GeV. From simulation we estimate the single-muon background that does not arise from W boson production (roughly a third of events), and subtract it from the observed number of events. The resulting number is divided by the acceptance and efficiency of the single-muon selection, providing thereby the number of $W(\rightarrow \mu\nu)$ +jets events. Assuming lepton universality, we use the same estimate for events with other lepton flavors. In the simulation, we calculate the probability that the $W(\rightarrow \ell\nu)$ +jets event can be present after applying the lepton veto that is used to select signal events. The resulting estimate of the $W(\rightarrow \ell\nu)$ +jets background is calculated as follows:

$$N(W \rightarrow \nu, \text{lost } \ell) = \frac{N^{\text{obs}}(\mu) - N_{\text{non-}W}^{\text{MC}}}{A \times \epsilon(\mu)} \sum_{\ell=e, \mu, \tau} \mathcal{P}(\text{lost } \ell) \quad (3)$$

where $N^{\text{obs}}(\mu)$ is the observed number of single muon events, $N_{\text{non-}W}^{\text{MC}}$ is the background that does not arise from W bosons, and is estimated through simulation, $A \times \epsilon(\mu)$ is the product of acceptance and efficiency to identify and select the muon, as measured in simulation, $\mathcal{P}(\text{lost } e)$ and $\mathcal{P}(\text{lost } \mu)$ are the probabilities that an electron or a muon from a W +jets event passes the lepton veto, and $\mathcal{P}(\text{lost } \tau)$ is the probability for a τ lepton to decay into hadrons and ν_τ , but not be rejected by the jet selections. The accuracy of the $W(\rightarrow \ell\nu)$ +jets background estimate is limited by the number of selected muon events and by the uncertainty in the simulation of background from other than W boson sources. The rate of W +jets events with one b-tagged jet is estimated by scaling the rate without b-tagged jets by the probability to have a b-tagged jet in simulated W +jets events. The estimated background from W +jets is given in Table 1.

The most important background after V +jets processes is from $t\bar{t}$ production, followed by single top quark and diboson production. These backgrounds are estimated through simulation. The leading systematic uncertainties arise in the simulated $t\bar{t}$ sample. They are related to the choice of the renormalization and factorization scales and the scale that determines the transition between modeling additional partons at matrix element level and at the level of parton showers. Other systematic uncertainties originate from jet energy scale and resolution, b-tagging efficiency and mistagging rate, choice of PDF, and accuracy of the luminosity measurement. The yields from background $t\bar{t}$, single top quark, and diboson sources, together with the systematic uncertainties are given in Table 1.

Figure 1 shows the distribution of the invariant mass of the three jets before requiring their invariant mass to be less than 250 GeV, in events with one b-tagged jet. We do not present a simulation of the multijet background, thus for the comparison between data and simulated backgrounds we suppress the potential contribution from this source with an additional cut on the opening azimuthal angle between the two leading jets: $|\phi^{\text{jet1}} - \phi^{\text{jet2}}| < 2.8$. The shaded areas represent the sum of the systematic uncertainties related to the renormalization and factorization scales for the $t\bar{t}$ and V +jets backgrounds, smoothed in a second-order polynomial fit, and taken in quadrature. Agreement is observed between data and background predictions. The dashed line in Fig. 1 indicates the prediction from a model based on a 700 GeV invisible vector boson.

The signal cross section, as well as the number of multijet background events, are measured in data using a likelihood approach, where each systematic source is treated as a nuisance parameter. The method is based on the observed number of events without and with just a single b-tagged jet accepted in selecting the signal. These two event categories contain untagged and tagged signal and background events as shown in the following system of equations:

$$\begin{cases} N^{0b} = \mathcal{P}_{\text{sig}}^{0b} \cdot N_{\text{sig}} + \mathcal{P}_{\text{MJ}}^{0b} \cdot N_{\text{MJ}} + N_{\text{other}}^{0b} \\ N^{1b} = \mathcal{P}_{\text{sig}}^{1b} \cdot N_{\text{sig}} + \mathcal{P}_{\text{MJ}}^{1b} \cdot N_{\text{MJ}} + N_{\text{other}}^{1b} \end{cases}, \quad (4)$$

Figure 1: The invariant mass of the three jets prior to the selection on their mass to be less than 250 GeV, for events with one b-tagged jet. Data are compared to the simulated backgrounds. The expectation from a model for an invisible vector particle with a mass of 700 GeV is represented by the dashed line.

where $\mathcal{P}_{\text{sig}}^{0\text{b}}$ and $\mathcal{P}_{\text{sig}}^{1\text{b}}$ are the probabilities to tag 0 or 1 jet as a b jet in the selected signal events, $\mathcal{P}_{\text{MJ}}^{0\text{b}}$ and $\mathcal{P}_{\text{MJ}}^{1\text{b}}$ are the corresponding probabilities for the selected multijet events in data, and $N_{\text{other}}^{0\text{b}}$ and $N_{\text{other}}^{1\text{b}}$ are the known contributions to 0 and 1 b-tagged event categories from other backgrounds. The $\mathcal{P}_{\text{sig,MJ}}^{0\text{b},1\text{b}}$ probabilities are obtained through simulation. The system above is solved to estimate the number of multijet (N_{MJ}) and signal (N_{sig}) events, by using a numerical minimization of the following likelihood:

$$\mathcal{L}(\sigma_{\text{sig}}, \nu) = \text{Poisson} \left(N_{\text{obs}}^{0\text{b}} | N^{0\text{b}} \right) \times \text{Poisson} \left(N_{\text{obs}}^{1\text{b}} | N^{1\text{b}} \right), \quad (5)$$

where σ_{sig} is the signal cross section, ν is the vector of the nuisance parameters describing uncertainties in the expected number of events from the Eq. (4), and $N_{\text{obs}}^{0\text{b}}$ and $N_{\text{obs}}^{1\text{b}}$ are, respectively, the total number of observed events in event categories without and with one b tag.

The number of expected SM background events is compared to the data after applying the final selections, and is presented in Table 1. Systematic uncertainties in the simulated backgrounds ($t\bar{t}$, single top, and VV') are presented as sums of the uncertainties from all of the respective sources, taken in quadrature. The multijet background is calculated using all the other backgrounds and data in Eq. (5). The uncertainty in the multijet background is determined by the uncertainties in the other backgrounds, and is therefore not included in the quadratic sum of background uncertainties.

Table 1: Total number of selected events in data compared to the background prediction. The background yields are given with statistical (first) and systematic (second) uncertainties. The multijet background is calculated using all the other backgrounds and therefore its uncertainty is not included in the quadratic sum of background uncertainties.

	No b tag	One b tag
$t\bar{t}$	6±0±5	12±0±12
W+jets	18±9±7	3±1±2
Z+jets	103±33±9	11±10±1
single top	2±1±1	1±1±1
VV'	5±0±0	0±0±0
multijet	6(±39)	1(±9)
total bkgd	140±36	28±16
data	143	30

No excess is observed above the background expectation, and limits are set at 95% confidence level (CL). The limits are calculated using the CL_s technique, which is based on statistical inference method jointly adopted by the ATLAS and CMS Collaborations for the Higgs boson searches [48]. The resulting limits are calculated using the expected signal and background predictions along with their uncertainties, and the likelihood given in Eq. (5). Statistical uncertainties, arising from number of observed events with one or two muons in the control regions are modeled with Poisson probabilities while all other uncertainties are modeled as log-normal distributions.

Figure 2 shows the 95% CL expected and observed limits on the product of the production cross section of the monotop and the branching ratio of the W decay to $q\bar{q}'$, as a function of mass of the invisible bosonic state, for scalar and vector fields.

In summary, a search has been performed by the CMS Collaboration for invisible particles produced in association with a single top quark that decays into three jets, one of which is b-tagged. The results are interpreted using a monotop model that predicts the existence of scalar

Figure 2: The 95% CL expected and observed CL_s limits as functions of the mass of a scalar (left) and vector (right) invisible particle. The expected magnitude of a signal as a function of mass, calculated at leading order, is shown by the dashed curve. The confidence intervals for the expected limit are given at 68% and 95% coverage probability.

or vector invisible particles. The signal and the backgrounds are extracted using a likelihood-based method. No excess of data over the standard model prediction is found and exclusion limits are set at 95% confidence level. The observed lower limits on mass for invisible scalar and vector particles are set at 330 GeV and 650 GeV, respectively. These results substantially extend a previous limit on monotop production of an invisible vector particle published by the CDF Collaboration [49].

Acknowledgments

We congratulate our colleagues in the CERN accelerator departments for the excellent performance of the LHC and thank the technical and administrative staffs at CERN and at other CMS institutes for their contributions to the success of the CMS effort. In addition, we gratefully acknowledge the computing centers and personnel of the Worldwide LHC Computing Grid for delivering so effectively the computing infrastructure essential to our analyses. Finally, we acknowledge the enduring support for the construction and operation of the LHC and the CMS detector provided by the following funding agencies: BMWFW and FWF (Austria); FNRS and FWO (Belgium); CNPq, CAPES, FAPERJ, and FAPESP (Brazil); MES (Bulgaria); CERN; CAS, MoST, and NSFC (China); COLCIENCIAS (Colombia); MSES and CSF (Croatia); RPF (Cyprus); MoER, ERC IUT and ERDF (Estonia); Academy of Finland, MEC, and HIP (Finland); CEA and CNRS/IN2P3 (France); BMBF, DFG, and HGF (Germany); GSRT (Greece); OTKA and NIH (Hungary); DAE and DST (India); IPM (Iran); SFI (Ireland); INFN (Italy); NRF and WCU (Republic of Korea); LAS (Lithuania); MOE and UM (Malaysia); CINVESTAV, CONACYT, SEP, and UASLP-FAI (Mexico); MBIE (New Zealand); PAEC (Pakistan); MSHE and NSC (Poland); FCT (Portugal); JINR (Dubna); MON, RosAtom, RAS and RFBR (Russia); MESTD (Serbia); SEIDI and CPAN (Spain); Swiss Funding Agencies (Switzerland); MST (Taipei); ThEPCenter, IPST, STAR and NSTDA (Thailand); TUBITAK and TAEK (Turkey); NASU and SFFR (Ukraine); STFC (United Kingdom); DOE and NSF (USA).

Ojalvo, T. Perry, G.A. Pierro, G. Polese, I. Ross, T. Sarangi, A. Savin, W.H. Smith, D. Taylor, P. Verwilligen, C. Vuosalo, N. Woods

†: Deceased

- 1: Also at Vienna University of Technology, Vienna, Austria
- 2: Also at CERN, European Organization for Nuclear Research, Geneva, Switzerland
- 3: Also at Institut Pluridisciplinaire Hubert Curien, Université de Strasbourg, Université de Haute Alsace Mulhouse, CNRS/IN2P3, Strasbourg, France
- 4: Also at National Institute of Chemical Physics and Biophysics, Tallinn, Estonia
- 5: Also at Skobeltsyn Institute of Nuclear Physics, Lomonosov Moscow State University, Moscow, Russia
- 6: Also at Universidade Estadual de Campinas, Campinas, Brazil
- 7: Also at Laboratoire Leprince-Ringuet, Ecole Polytechnique, IN2P3-CNRS, Palaiseau, France
- 8: Also at Joint Institute for Nuclear Research, Dubna, Russia
- 9: Also at Suez University, Suez, Egypt
- 10: Also at Cairo University, Cairo, Egypt
- 11: Also at Fayoum University, El-Fayoum, Egypt
- 12: Also at British University in Egypt, Cairo, Egypt
- 13: Now at Ain Shams University, Cairo, Egypt
- 14: Also at Université de Haute Alsace, Mulhouse, France
- 15: Also at Brandenburg University of Technology, Cottbus, Germany
- 16: Also at Institute of Nuclear Research ATOMKI, Debrecen, Hungary
- 17: Also at Eötvös Loránd University, Budapest, Hungary
- 18: Also at University of Debrecen, Debrecen, Hungary
- 19: Also at University of Visva-Bharati, Santiniketan, India
- 20: Now at King Abdulaziz University, Jeddah, Saudi Arabia
- 21: Also at University of Ruhuna, Matara, Sri Lanka
- 22: Also at Isfahan University of Technology, Isfahan, Iran
- 23: Also at Sharif University of Technology, Tehran, Iran
- 24: Also at Plasma Physics Research Center, Science and Research Branch, Islamic Azad University, Tehran, Iran
- 25: Also at Università degli Studi di Siena, Siena, Italy
- 26: Also at Centre National de la Recherche Scientifique (CNRS) - IN2P3, Paris, France
- 27: Also at Purdue University, West Lafayette, USA
- 28: Also at Universidad Michoacana de San Nicolas de Hidalgo, Morelia, Mexico
- 29: Also at Institute for Nuclear Research, Moscow, Russia
- 30: Also at St. Petersburg State Polytechnical University, St. Petersburg, Russia
- 31: Also at California Institute of Technology, Pasadena, USA
- 32: Also at Faculty of Physics, University of Belgrade, Belgrade, Serbia
- 33: Also at Facoltà Ingegneria, Università di Roma, Roma, Italy
- 34: Also at Scuola Normale e Sezione dell'INFN, Pisa, Italy
- 35: Also at University of Athens, Athens, Greece
- 36: Also at Paul Scherrer Institut, Villigen, Switzerland
- 37: Also at Institute for Theoretical and Experimental Physics, Moscow, Russia
- 38: Also at Albert Einstein Center for Fundamental Physics, Bern, Switzerland
- 39: Also at Gaziosmanpasa University, Tokat, Turkey
- 40: Also at Adiyaman University, Adiyaman, Turkey

- 41: Also at Cag University, Mersin, Turkey
- 42: Also at Izmir Institute of Technology, Izmir, Turkey
- 43: Also at Necmettin Erbakan University, Konya, Turkey
- 44: Also at Ozyegin University, Istanbul, Turkey
- 45: Also at Marmara University, Istanbul, Turkey
- 46: Also at Kafkas University, Kars, Turkey
- 47: Also at Rutherford Appleton Laboratory, Didcot, United Kingdom
- 48: Also at School of Physics and Astronomy, University of Southampton, Southampton, United Kingdom
- 49: Also at University of Belgrade, Faculty of Physics and Vinca Institute of Nuclear Sciences, Belgrade, Serbia
- 50: Also at Mimar Sinan University, Istanbul, Istanbul, Turkey
- 51: Also at Argonne National Laboratory, Argonne, USA
- 52: Also at Erzincan University, Erzincan, Turkey
- 53: Also at Yildiz Technical University, Istanbul, Turkey
- 54: Also at Texas A&M University at Qatar, Doha, Qatar
- 55: Also at Kyungpook National University, Daegu, Korea
