One-dimensional pion, kaon, and proton femtoscopy in Pb–Pb collisions at $\sqrt{s_{\text{NN}}} = 2.76 \text{ TeV}$

ALICE Collaboration*

Abstract

The size of the particle emission region in high-energy collisions can be deduced using the femtoscopic correlations of particle pairs at low relative momentum. Such correlations arise due to quantum statistics and Coulomb and strong final state interactions. In this paper, results are presented from femtoscopic analyses of $\pi^\pm\pi^\pm$, $K^\pm K^\pm$, $K_S^0 K_S^0$, pp, and $\bar{p}p$ correlations from Pb-Pb collisions at $\sqrt{s_{\text{NN}}} = 2.76 \text{ TeV}$ by the ALICE experiment at the LHC. One-dimensional radii of the system are extracted from correlation functions in terms of the invariant momentum difference of the pair. The comparison of the measured radii with the predictions from a hydrokinetic model is discussed. The pion and kaon source radii display a monotonic decrease with increasing average pair transverse mass m_T which is consistent with hydrodynamic model predictions for central collisions. The kaon and proton source sizes can be reasonably described by approximate m_T -scaling.

*See Appendix A for the list of collaboration members

1 Introduction

Two-particle correlations at low relative momenta (commonly referred to as *femtoscopy*), which are sensitive to quantum statistics (in the case of identical particles) as well as strong and Coulomb final-state interactions (FSI), are used to extract the space-time characteristics of the particle-emitting sources created in heavy-ion collisions [1–3]. The source radii extracted from these correlations describe the system at kinetic freeze-out, i.e. the last stage of particle interactions. Pion femtoscopy, which is the most common femtoscopic analysis, has shown signatures of hydrodynamic flow in heavy-ion collisions, manifesting as a decrease in the source radii with increasing transverse mass $m_T = \sqrt{k_T^2 + m^2}$ [4, 5], where $k_T = |\mathbf{p}_{T,1} + \mathbf{p}_{T,2}|/2$ is the average transverse momentum of the pair. This behavior can be interpreted as one of the signatures of the formation of deconfined quark matter in these collisions [6]. However, a necessary condition for collective behavior is for *all* particles created in the collision, not just pions, to experience hydrodynamic flow. Thus, femtoscopic studies with particles other than pions are also needed. It was shown that the hydrodynamic picture of nuclear collisions for the particular case of small transverse flow leads to the same m_T behavior of the longitudinal radii (R_{long}) for pions and kaons [7]. This common m_T -scaling for π and K is an indication that the thermal freeze-out occurs simultaneously for π and K and that these two particle species are subject to the same Lorentz boost. Previous kaon femtoscopy studies carried out in Pb–Pb collisions at the SPS by the NA44, NA49, and CERES Collaborations [8–10] reported the decrease of R_{long} with m_T as $\sim m_T^{-0.5}$ as a consequence of the boost-invariant longitudinal flow. Subsequent studies carried out in Au–Au collisions at RHIC [11–13] have shown the same level in the m_T -dependencies for π and K radii, consistent with a common freeze-out hyper-surface. Like the SPS analysis, no exact universal m_T -scaling for the 3D radii was observed at RHIC. In the case of the one-dimensional correlation radius R_{inv} , only approximate scaling with m_T is expected as an additional confirmation of hydrodynamic expansion [4]. In fact, R_{inv} source sizes as a function of m_T for different particle types (π , K, p...) follow the common curve with an accuracy of $\sim 10\%$.

The motivation for comparing femtoscopic analyses with different particle species is not limited to studying m_T dependence. The kaon analyses also offer a cleaner signal compared to pions, as they are less affected by resonance decays, while the proton analysis provides a possibility for checking if baryons are included in the collective motion. Studying charged and neutral kaon correlations together provides a convenient experimental consistency check, since they require different detection techniques (charged tracks vs. decay vertex reconstruction) and call for different final-state interaction fitting parametrizations (Coulomb-dominated vs. strong interaction-dominated), yet they are predicted to exhibit the same femtoscopic parameters [14]. In addition to the charged kaon analyses at the SPS and RHIC, neutral kaon correlations were studied in Au–Au collisions at RHIC [15], and ALICE has performed analyses on both charged and neutral kaons in pp collisions [16, 17]. Recent pion femtoscopic results were obtained at RHIC [18] and the LHC [5, 19–21], and proton femtoscopy has also been previously studied at RHIC [22].

This paper presents the results of femtoscopic studies of $\pi^\pm\pi^\pm$, $K^\pm K^\pm$, $K_S^0 K_S^0$, pp, and $\bar{p}\bar{p}$ correlations from Pb–Pb collisions at $\sqrt{s_{\text{NN}}} = 2.76$ TeV by the ALICE experiment at the LHC. The femtoscopic radii and λ parameters (the latter describe the decrease of the femtoscopic correlations due to e.g. long-lived resonances; see Sec. 3.1 and 4) are extracted from one-dimensional correlation functions in terms of the invariant momentum difference for a range of collision centralities and m_T values. A hydrokinetic model [14] is used to compare the kaon experimental results with hydrodynamic predictions.

The organization of the paper is as follows. In Sec. 2, we describe the data selection criteria. In Sec. 3, the details of the correlation functions and the fitting process are discussed. The results of the analysis are shown in Sec. 4, and a summary is provided in Sec. 5.

2 Data analysis

The dataset analyzed in this paper is from Pb–Pb collisions at $\sqrt{s_{\text{NN}}} = 2.76$ TeV at the LHC measured by the ALICE detector [23]. About 8 million events from 2010 and about 40 million events from 2011 were used (2010 data were analyzed in the pion and K_S^0 analyses only). Events were classified according to their centrality determined using the measured amplitudes in the V0 detectors [24]. Charged particle tracking is generally performed using the Time Projection Chamber (TPC) [25] and the Inner Tracking System (ITS) [23]. The ITS allows for high spatial resolution in determining the primary (collision) vertex. In the pion, charged kaon, and proton analyses, the determination of the momenta of the tracks was performed using tracks reconstructed with the TPC only and constrained to the primary vertex. Primary tracks were selected based on the distance of closest approach (DCA) to the primary vertex. Additional track selections based on the quality of the track reconstruction fit and the number of detected “hit” points in the TPC were used. Also, all primary pairs sharing more than 5% of TPC clusters were rejected. In the neutral kaon analysis, the secondary daughter tracks used global (TPC and ITS) track reconstruction and did not use any cuts based on track reconstruction quality or number of used or shared TPC clusters. The secondary vertex finder used to locate the neutral kaon decays employed the “on-the-fly” reconstruction method [26], which recalculates the daughter track momenta during the original tracking process under the assumption that the tracks came from a decay vertex instead of the primary vertex.

Particle identification (PID) for reconstructed tracks was carried out using both the TPC and the Time-of-Flight (TOF) detector [27] in the pseudorapidity range $|\eta| < 0.8$. For TPC PID, a parametrized Bethe-Bloch formula was used to calculate the specific energy loss (dE/dx) in the detector expected for a particle with a given mass and momentum. For PID with TOF, the particle mass was used to calculate the expected time-of-flight as a function of track length and momentum. For each PID method, a value N_σ was assigned to each track denoting the number of standard deviations between the measured track information and the calculations mentioned above. Different cut values of N_σ were chosen based on detector performance for the various particle types and track momentum (see Table 1 for specific values used in each analysis) [28].

The analysis details specific to each particle species used in this study are discussed separately below.

2.1 Pion selection

The main single-particle selection criteria used in the pion analysis are summarized in Table 1. Pion identification was performed using the TPC only. An overall purity of the pion candidate sample was estimated using TPC dE/dx distributions of the data and was found to be above 95%. The main source of contamination comes from e^\pm in the region where the dE/dx curves for pions and electrons intersect.

Femtoscopic correlation functions of identical particles are sensitive to the two-track reconstruction efficiency because the correlated particle pairs (i.e. those with small relative momentum) generally have close trajectories. The main two-track issues are splitting (two tracks reconstructed from one particle) and merging (one track reconstructed from two particles), which are generally avoided using a track separation cut. For pions, pairs were required to have a separation of $|\Delta\eta| > 0.016$ or $\sqrt{\Delta\eta^2 + \Delta\varphi^*{}^2} > 0.045$ measured at the radial distance 1.2 m. Here, η is the pseudorapidity, and φ^* is the azimuthal coordinate taking into account track bending due to the magnetic field.

2.2 Charged kaon selection

The main single-particle selection criteria used in the charged kaon analysis are listed in Table 1. K^\pm identification was performed using the TPC (for all momenta) and TOF (for $p > 0.5$ GeV/c) detectors. Figure 1 (a) shows the momentum dependence of the single kaon purity, defined as the fraction of accepted kaon tracks that correspond to true kaon particles. The purity values were obtained from TPC

Pion selection	
Transverse momentum p_T	$0.14 < p_T < 2.0 \text{ GeV}/c$
$ \eta $	< 0.8
Transverse DCA to primary vertex	$< 0.2 \text{ cm}$
Longitudinal DCA to primary vertex	$< 0.15 \text{ cm}$
$N_{\sigma,\text{TPC}}$	< 3
Charged kaon selection	
p_T	$0.15 < p_T < 1.5 \text{ GeV}/c$
$ \eta $	< 0.8
Transverse DCA to primary vertex	$< 2.4 \text{ cm}$
Longitudinal DCA to primary vertex	$< 3.0 \text{ cm}$
$N_{\sigma,\text{TPC}}$ (for $p < 0.5 \text{ GeV}/c$)	< 2
$N_{\sigma,\text{TPC}}$ (for $p > 0.5 \text{ GeV}/c$)	< 3
$N_{\sigma,\text{TOF}}$ (for $0.5 < p < 0.8 \text{ GeV}/c$)	< 2
$N_{\sigma,\text{TOF}}$ (for $0.8 < p < 1.0 \text{ GeV}/c$)	< 1.5
$N_{\sigma,\text{TOF}}$ (for $1.0 < p < 1.5 \text{ GeV}/c$)	< 1.0
Neutral kaon selection	
$ \eta $	< 0.8
Daughter-daughter DCA _{3D}	$< 0.3 \text{ cm}$
DCA _{3D} to primary vertex	$< 0.3 \text{ cm}$
Decay length	$< 30 \text{ cm}$
Cosine of pointing angle	> 0.99
Invariant mass	$0.480 < m_{\pi^+\pi^-} < 0.515 \text{ GeV}/c^2$
Daughter p_T	$> 0.15 \text{ GeV}/c$
Daughter $ \eta $	< 0.8
Daughter DCA _{3D} to primary vertex	$> 0.4 \text{ cm}$
Daughter $N_{\sigma,\text{TPC}}$	< 3
Daughter $N_{\sigma,\text{TOF}}$ (for $p > 0.8 \text{ GeV}/c$)	< 3
Proton selection	
p_T	$0.7 < p_T < 4.0 \text{ GeV}/c$
$ \eta $	< 0.8
Transverse DCA to primary vertex	$< 2.4 \text{ cm}$
Longitudinal DCA to primary vertex	$< 3.2 \text{ cm}$
$N_{\sigma,\text{TPC}}$ (for $p < 0.8 \text{ GeV}/c$)	< 3
$\sqrt{N_{\sigma,\text{TPC}}^2 + N_{\sigma,\text{TOF}}^2}$ (for $p > 0.8 \text{ GeV}/c$)	< 3

Table 1: Single particle selection criteria.

dE/dx distributions of the data and by studying HIJING [29] simulations using GEANT3 [30] to model particle transport through the detector. Like the pions, the dominant contamination for charged kaons in the momentum region $0.4 < p < 0.5 \text{ GeV}/c$ comes from e^\pm . The pair purity is calculated as a product of two single-particle purities, where the momenta are taken from the experimental distribution. The K^\pm pair purity as a function of k_T for three different centralities is shown in Fig.1(b).

Regarding two-track selection criteria, charged kaon pairs were required to have a separation of $|\Delta\eta| > 0.02$ or $|\Delta\varphi^*| > 0.017$ measured at the radial distance 1.6 m.

Fig. 1: (Color online) Single K^\pm purity (a) and K^\pm pair purity (b) for different centralities. In (b) the k_T values for different centrality intervals are slightly offset for clarity.

Fig. 2: (Color online) Invariant mass distribution of $\pi^+\pi^-$ pairs showing the K_S^0 peak for two centrality intervals. The 45-50% centrality is scaled so that both distributions have the same integral in the range $0.480 < m_{\pi^+\pi^-} < 0.515$ GeV/c 2 .

2.3 Neutral kaon selection

The decay channel $K_S^0 \rightarrow \pi^+\pi^-$ was used for the identification of neutral kaons. The single-particle cuts for parents (K_S^0) and daughters (π^\pm) used in the decay-vertex reconstruction are shown in Table 1. PID for the pion daughters was performed using both TPC (for all momenta) and TOF (for $p > 0.8$ GeV/c). Figure 2 shows an example of the $\pi^+\pi^-$ invariant mass distribution where the K_S^0 peak is seen. The cuts used in this analysis were chosen to balance statistics and signal purity. The neutral kaon purity (defined as $\text{Sig.}/[\text{Sig.} + \text{Bkg.}]$ for $0.480 < m_{\pi^+\pi^-} < 0.515$ GeV/c 2) was found to be greater than 0.95.

Two main two-particle cuts were used in the neutral kaon analysis. To resolve two-track inefficiencies associated with the daughter tracks, such as the splitting or merging of tracks discussed above, a separation cut was employed in the following way. For each kaon pair, the spatial separation between the same-sign pion daughters was tabulated at several points throughout the TPC (every 20 cm radially from 85 cm to 245 cm) and averaged. If the average separation of either pair of tracks was below 5 cm, the kaon pair was not used. Another cut was used to prevent two reconstructed kaons from using the same daughter track. If two kaons shared a daughter track, one of them was cut using a procedure which compared the two K_S^0 candidates and kept the candidate whose reconstructed parameters best matched those expected of a true K_S^0 particle in two of three categories (smaller K_S^0 DCA to primary vertex, smaller daughter-daughter DCA, and K_S^0 mass closer to the PDG value [31]). This procedure was shown, using HIJING+GEANT3 simulations, to have a success rate of about 95% in selecting a true K_S^0 particle over a fake one. More details about $K_S^0 K_S^0$ analysis can be found in Ref. [16, 32].

2.4 Proton selection

The single-particle cuts used in the proton analysis are summarized in Table 1. The proton analysis used tracks with $0.7 < p_T < 4.0$ GeV/c. The lower p_T cut is used to suppress protons coming from weak decays and interactions with the detector material. Particle identification for p and \bar{p} was performed using both TPC (for all momenta) and TOF (for $p > 0.8$ GeV/c). The proton purity was estimated using HIJING+GEANT3 simulations and was found to be greater than 95%. The used DCA criteria do not fully discriminate between primary protons and protons from weak decays. This may lead to a significant contamination from protons from lambda particles. The effect of this contamination is discussed in Sec. 3.4.

Regarding two-track selection criteria, pairs were required to have a separation of $|\Delta\eta| > 0.01$ or $|\Delta\varphi^*| > 0.045$ measured at the radial distance 1.2 m.

3 Construction of the correlation functions and fitting procedures

The experimental two-particle correlation function is defined as $C(\mathbf{q}) = A(\mathbf{q})/B(\mathbf{q})$, where $A(\mathbf{q})$ is the measured distribution of same-event pair momentum difference, $\mathbf{q} = \mathbf{p}_1 - \mathbf{p}_2$, and $B(\mathbf{q})$ is the reference distribution of pairs from mixed events. The pairs in the denominator distribution $B(\mathbf{q})$ are constructed by taking a particle from one event and pairing it with a particle from another event with a similar centrality and primary vertex position along the beam direction. Each event is mixed with five (ten) others for the K_S^0 (π^\pm , K^\pm , p) analysis. The available statistics of proton pairs with low q (< 0.2 GeV/c) allowed us to perform the analyses only for the one-dimensional correlation function $C(q)$, where $q = |\mathbf{q}|$ in the Pair Rest Frame (PRF). In the case of pions and kaons, the statistics were high enough for three-dimensional studies, but these are beyond the scope of this paper; here, only the one-dimensional analysis is presented in order to compare results with heavier particles. The numerator and denominator are normalized such that $C(q) \rightarrow 1$ as $q \rightarrow \infty$. Pair cuts have been applied in exactly the same way for the same-event (signal) and mixed-event (background) pairs.

All correlation functions have been corrected for momentum resolution effects. The correction factors were determined using HIJING events to build simulated correlation functions using theoretical correlation functions as weights. The ratio of the correlation functions using HIJING generated momenta to those using HIJING+GEANT3 reconstructed momenta forms the correction factor.

For the analyses presented in this paper, the theoretical femtoscopic correlation function is defined as the square of the two-particle wavefunction averaged over the relative distance \mathbf{r}^* of the emitters in the PRF. This is performed using the Koonin-Pratt equation [33, 34]

$$C(q) = \int S(\mathbf{r}^*) |\Psi(q, \mathbf{r}^*)|^2 d^3 \mathbf{r}^*. \quad (1)$$

For the one-dimensional analysis, we assume a spherically symmetric Gaussian distribution of the particle emitter spatial separation \mathbf{r}^* in the PRF with size R_{inv} [35],

$$S(\mathbf{r}^*) \sim \exp(-\mathbf{r}^{*2}/4R_{\text{inv}}^2). \quad (2)$$

The two-particle wavefunction is (anti-)symmetrized for identical bosons (fermions) and may include terms incorporating Coulomb or strong final-state interactions, depending on the type of particles being studied.

The methods used in constructing and fitting the various correlation functions are discussed separately below.

3.1 Pions

Pion correlation functions were fitted using the Bowler-Sinyukov formula [36, 37]:

$$C(q) = N \left[1 - \lambda + \lambda K(q) (1 + \exp(-R_{\text{inv}}^2 q^2)) \right], \quad (3)$$

where N is the normalization factor. The λ parameter (also used in the other analyses) can be affected by long-lived resonances, coherent sources [19, 38, 39], and non-Gaussian features of the particle-emission distribution. $K(q)$ is a symmetrized K -factor calculated according to Ref. [19, 37] as

$$K(q) = C(\text{QS} + \text{Coulomb})/C(\text{QS}), \quad (4)$$

where $C(\text{QS})$ and $C(\text{QS} + \text{Coulomb})$ are the theoretical correlation functions calculated with THERMINATOR 2 [40] using the quantum statistics (“QS”) and “QS+Coulomb” weights (i.e. squared wavefunction), respectively [41]. The effect of the strong interaction is neglected here, since for like-sign pions, the contribution is small for the expected source sizes [41]. Figure 3 shows an example $\pi^+ \pi^+$ correlation function with the corresponding line of best fit. More details about the pion analysis may be found in [42].

3.2 Charged kaons

Figure 4 shows an example $K^\pm K^\pm$ correlation function with the corresponding line of best fit. A purity correction was applied to the correlation function according to

$$C_{\text{corrected}} = (C_{\text{raw}} - 1 + P)/P, \quad (5)$$

where the pair purity P is taken from Fig. 1. $K^\pm K^\pm$ correlation functions were fitted using the Bowler-Sinyukov formula of Eq. 3; the procedure is essentially the same as for pions. There are no available experimental data for $K^\pm K^\pm$ strong FSI. The influence of the strong interaction to the correlation function was estimated with the s-wave scattering length calculated within the fully-dynamical lattice QCD [43]. The systematic uncertainty assigned to this effect was determined to be 4%.

3.3 Neutral kaons

Figure 5 shows an example $K_S^0 K_S^0$ correlation function with the corresponding line of best fit. $K_S^0 K_S^0$ correlation functions were fitted with a parametrization which includes Bose-Einstein statistics as well as strong final-state interactions (FSI) [15, 35],

$$C(q) = [1 - \lambda + \lambda C'(q)] (a + bq), \quad (6)$$

where

$$C'(q) = 1 + e^{-q^2 R^2} + C_{\text{strongFSI}}(q, R), \quad (7)$$

Fig. 3: (Color online) Example correlation function with fit for $\pi^+\pi^+$ for centrality 5-10% and $\langle k_T \rangle = 0.35 \text{ GeV}/c$. Statistical uncertainties are shown as thin lines.

Fig. 4: (Color online) Example correlation function with fit for $K^\pm K^\pm$ for centrality 0-10% and $\langle k_T \rangle = 0.35 \text{ GeV}/c$. Systematic uncertainties (boxes) are shown; statistical uncertainties are within the data markers. The main sources of systematic uncertainty are the momentum resolution correction and PID selection.

Fig. 5: (Color online) Example correlation function with fit for $K_S^0 K_S^0$ for centrality 0-10% and $\langle k_T \rangle = 0.48 \text{ GeV}/c$. Statistical (thin lines) and systematic (boxes) uncertainties are shown. The main source of systematic uncertainty is the variation of single-particle cuts.

Fig. 6: (Color online) Example correlation function with fit for $\bar{p}p$ for centrality 0-10% and $\langle k_T \rangle = 1.0 \text{ GeV}/c$. Statistical (thin lines) and systematic (boxes) uncertainties are shown. The main source of systematic uncertainty is the variation of two-track cuts.

$$C_{\text{strongFSI}}(q, R) = \frac{1}{2} \left[\left| \frac{f(q)}{R} \right|^2 + \frac{4\Re f(q)}{\sqrt{\pi}R} F_1(qR) - \frac{2\Im f(q)}{R} F_2(qR) \right], \quad (8)$$

and

$$F_1(z) = \int_0^z dx \frac{e^{x^2-z^2}}{z}; \quad F_2(z) = \frac{1-e^{-z^2}}{z}. \quad (9)$$

$f(q)$ is the s-wave scattering amplitude for the $K^0\bar{K}^0$ system; we neglect the scattering for K^0K^0 and $\bar{K}^0\bar{K}^0$ due to small scattering lengths ≈ 0.1 fm [15]. The factor of 1/2 in Eq. 8 is due to the fact that half of the $K_S^0 K_S^0$ pairs come from $K^0\bar{K}^0$. The strong FSI have a significant effect on the $K^0\bar{K}^0$ contribution to the $K_S^0 K_S^0$ correlation function due to the near-threshold resonances, $f_0(980)$ and $a_0(980)$. For the scattering amplitude, only s-wave contributions were taken into account; the higher-order corrections were small and therefore neglected [44]. The scattering amplitude $f(q)$ is calculated using a two-channel parametrization which accounts for the elastic transition $K^0\bar{K}^0 \rightarrow K^0\bar{K}^0$ and the inelastic transition $K^+K^- \rightarrow K^0\bar{K}^0$ (See Ref. [15] for more detailed expressions describing the fit function). Equation 6 also includes an additional factor to account for non-femtoscopic background correlations at large q , with a and b being free parameters in the fit.

3.4 Protons

Figure 6 shows an example $\bar{p}\bar{p}$ correlation function with the corresponding line of best fit. The femtoscopic correlations of $p p$ and $\bar{p}\bar{p}$ pairs are due to a combination of Fermi-Dirac statistics, Coulomb and strong FSI. A distinct maximum is seen at $q \approx 40$ MeV/c [35]; this enhancement is due to the strong interaction, as both quantum statistics and Coulomb interaction present a negative correlation. Due to the fact that feed-down from weak decays cannot be neglected in high-energy heavy-ion collisions, the effects of residual correlations related to the $p\Lambda$ system are taken into account. The proton daughter of a Λ decay has similar momentum to the Λ itself and may survive the experimental selection for primary protons. Thus, it may contribute to the measured correlations by forming a pair with a primary proton. As can be seen in Fig. 6, attempting to fit the measured correlation functions with the theoretical $p p$ ($\bar{p}\bar{p}$) functions alone was unsuccessful due to the additional positive correlation observed in the range $60 < q < 160$ MeV/c. Thus, a method of simultaneous fitting of $p p$ ($\bar{p}\bar{p}$) and $p\Lambda$ ($\bar{p}\bar{\Lambda}$) correlations was applied. Contributions from heavier baryon-baryon pairs are not taken into account since the original correlation between the parent particles is not known due to unknown interaction parameters, for example for the $\Lambda\Lambda$ pair. Moreover such residual correlations are more smeared compared with $p\Lambda$ because of larger decay momentum. In addition, the fraction of baryons heavier than Λ decaying to protons is smaller than the fraction of Λ 's. Finally, comparing with baryon-antibaryon pairs analysed in [45], the width of the correlation for baryon-baryon pairs is much smaller, and therefore the effect is much more smeared due to decay kinematics.

The experimental correlation function of $p p$ and $\bar{p}\bar{p}$ systems were fitted with [45]

$$C_{\text{meas}}(q_{pp}) = 1 + \lambda_{pp}(C_{pp}(q_{pp}; R) - 1) + \lambda_{p\Lambda}(C_{p\Lambda}(q_{pp}; R) - 1), \quad (10)$$

where λ_{pp} is the fraction of correlated $p p$ pairs where both particles are primary, and $\lambda_{p\Lambda}$ is the fraction of correlated $p p$ pairs where one particle is primary and the other is a daughter of Λ decay. The theoretical proton-proton correlation function was calculated as

$$C(q_{pp}) = \frac{1}{4} \left[\frac{\int S(\mathbf{r}^*) \frac{1}{2} |\Psi_{-\mathbf{q}_{pp}}^S(\mathbf{r}^*) + \Psi_{+\mathbf{q}_{pp}}^S(\mathbf{r}^*)|^2}{\int S(\mathbf{r}^*)} \right] + \frac{3}{4} \left[\frac{\int S(\mathbf{r}^*) \frac{1}{2} |\Psi_{-\mathbf{q}_{pp}}^T(\mathbf{r}^*) - \Psi_{+\mathbf{q}_{pp}}^T(\mathbf{r}^*)|^2}{\int S(\mathbf{r}^*)} \right]. \quad (11)$$

This formulation takes into account the necessary (anti-)symmetrization of the wavefunction for a $p p$ pair in the singlet (triplet) spin state with a corresponding weight of 1/4 (3/4). The $p p$ pair wavefunction

may be written as [44]

$$\Psi_{-\mathbf{q}_{\text{pp}}}(\mathbf{r}^*) = e^{i\delta_c} \sqrt{A_c(\eta)} \left[e^{-i\mathbf{q}_{\text{pp}} \cdot \mathbf{r}^*/2} F(-i\eta, 1, i\xi) + f_c(q_{\text{pp}}) \frac{\tilde{G}(\rho, \eta)}{|\mathbf{r}^*|} \right], \quad (12)$$

where \mathbf{r}^* is the spatial separation of particle emitters at generally different emission moments in the PRF, $\delta_c = \arg \Gamma(1 + i\eta)$ is the Coulomb s-wave phase shift, $A_c(\eta) = 2\pi\eta(e^{2\pi\eta} - 1)^{-1}$ is the Gamow factor (also referred to as Coulomb penetration factor), $\eta = (\frac{1}{2}aq_{\text{pp}})^{-1}$, $a = (\mu z_1 z_2 e^2)^{-1}$ is the two-particle Bohr radius taking into account the sign of the interaction ($a = 57.6$ fm for pp pair), F is the confluent hypergeometric function, $\xi = \frac{1}{2}q_{\text{pp}}r^*(1 + \cos\theta^*)$, θ^* is the angle between \mathbf{q}_{pp} and \mathbf{r}^* , \tilde{G} is the combination of the regular and singular s-wave Coulomb functions, and $\rho = \frac{1}{2}q_{\text{pp}}r^*$. The amplitude of the low-energy s-wave elastic scattering due to the short range interaction $f_c(q_{\text{pp}})$ may be expressed as

$$f_c(q_{\text{pp}}) = \left[\frac{1}{f_0} + \frac{d_0 q_{\text{pp}}^2}{8} - \frac{1}{2} i q_{\text{pp}} A_c(\eta) - \frac{2}{a} h(\eta) \right]^{-1}, \quad (13)$$

where f_0 is the scattering length, d_0 is the effective radius of the interaction, $h(\eta) = [\psi(i\eta) + \psi(-i\eta) - \ln(\eta^2)]/2$, and ψ is the digamma function. For the pp system in the singlet (triplet) state, f_0 and d_0 are 7.77 fm (-5.4 fm) and 2.77 fm (1.7 fm).

For the feed-down term, the theoretical pΛ correlation function for a given $R_{\text{p}\Lambda}$ transformed into the pp momentum space is obtained from the Lednicky-Lyuboshitz model [35] and calculated as

$$C_{\text{p}\Lambda}(q_{\text{pp}}; R_{\text{p}\Lambda}) = \sum_{q_{\text{p}\Lambda}} C_{\text{p}\Lambda}(q_{\text{p}\Lambda}; R_{\text{p}\Lambda}) T(q_{\text{pp}}, q_{\text{p}\Lambda}) / \sum_{q_{\text{p}\Lambda}} T(q_{\text{pp}}, q_{\text{p}\Lambda}), \quad (14)$$

where $C_{\text{p}\Lambda}(q_{\text{p}\Lambda}; R_{\text{p}\Lambda}) = 1 + C_{\text{strongFSI}}(q_{\text{p}\Lambda}; R_{\text{p}\Lambda})$, and $T(q_{\text{pp}}, q_{\text{p}\Lambda})$ are the transformation factors related to Λ decay kinematics, calculated with THERMINATOR 2 [40]. Here, a spin-dependent version of Eq. 8 is used [35]:

$$C_{\text{strongFSI}}(q, R) = \sum_S \rho_s \left[\frac{1}{2} \left| \frac{f^S(q)}{R} \right|^2 \left(1 - \frac{d_0^S}{2\sqrt{\pi}R} \right) + \frac{2\Re f^S(q)}{\sqrt{\pi}R} F_1(qR) - \frac{\Im f^S(q)}{R} F_2(qR) \right], \quad (15)$$

where $f^S(q)$ is the spin-dependent scattering amplitude, ρ_s is the fraction of pairs in each total spin state S , and d_0^S is the effective radius of the interaction. It is assumed that the radii of pp and pΛ sources are equal. Therefore, there are three free fit parameters in Eq. 10: λ_{pp} , $\lambda_{\text{p}\Lambda}$, and R . Theoretical pp and pΛ correlation functions were calculated using several values of the free parameters, and the fit function (for the set of parameters given during each fit iteration) was formed by a quadratic interpolation of the calculated correlation functions.

3.5 Systematic uncertainties

The effects of various sources of systematic uncertainty on the extracted fit parameters were studied as functions of centrality and k_T . Table 2 shows the minimum and maximum uncertainties from each source. The values of the total uncertainty are not necessarily equal to the sum of the individual uncertainties, as the latter can come from different centrality or k_T bins. All four analyses studied the effects of changing the selection criteria for the events, particles and pairs used (variation of cut values up to $\pm 25\%$) and varying the range of q values over which the fit is performed (variation of q limits up to $\pm 25\%$). Uncertainties associated with momentum resolution corrections are included in the π , K^\pm , and p analyses; the K_S^0 analysis also studied this and found the uncertainties to be negligible. The K^\pm , K_S^0 , and p analyses encountered uncertainties associated with the non-flat background seen at large- q for high- k_T pairs in peripheral collisions (estimated by using different parametrizations (linear or polynomial) to fit the large- q region). Strong FSI uncertainties affect both kaon analyses. For K_S^0 , the strong FSI uncertainty

	π^\pm		K^\pm		K_S^0		p	
	R_{inv}	λ	R_{inv}	λ	R_{inv}	λ	R_{inv}	λ

Table 2: Minimal and maximal uncertainty values for various sources of systematic uncertainty (in percent). The λ for the proton analysis refers to the sum of λ_{pp} and $\lambda_{p\Lambda}$. Please note that each value is the minimum (maximum) uncertainty from a specific source, but each can be from a different centrality or k_T bin. Thus, the minimum (maximum) total uncertainties are greater (smaller) than (or equal to) the sum of the minimum (maximum) individual uncertainties. 'n/a' denotes that the given descriptor of the systematic uncertainty is not applicable for the specific pair type, and '-' means that the contribution from the given source is negligible.

comes from the fact that several sets of $f_0(980)$ and $a_0(980)$ parameters are available [46–49]; each set is used to fit the data, the results are averaged, and the maximum difference was taken as the systematic error. The π and K^\pm analyses have uncertainties associated with the choice of the Coulomb function used in the fitting procedure. The K^\pm analysis had additional uncertainties due to the misidentification of particles and the associated purity correction. The p analysis also had uncertainties associated with the uncertainty in the $R_{pp}/R_{p\Lambda}$ ratio and attempts to fix the λ_{pp} parameter using the single-particle purity. All of the analyses were performed separately for the two different signs of the ALICE dipole magnetic field, but the resulting systematic uncertainty was found to be negligible in all cases.

Systematic uncertainties on correlation functions (Figs. 4, 5 and 6) were derived from the variation of single- and two-particle cuts.

4 Results

Figures 7 and 8 present the extracted fit parameters from $\pi^\pm\pi^\pm$, $K^\pm K^\pm$, $K_S^0 K_S^0$, and pp correlations for several intervals of centrality and transverse mass. Both statistical and systematic uncertainties are shown. The quality of the fits used to extract the shown parameters can be assessed using the χ^2/NDF values, which are in the ranges of 1.2-5.0, 0.8-3.5, 0.6-1.5, and 0.8-3.2 for the pion, charged kaon, neutral kaon, and proton analyses, respectively.

Figure 7 shows the extracted λ parameters vs. m_T for several centralities. The proton λ is the sum of λ_{pp} and $\lambda_{p\Lambda}$ from Eq. 10. The values for all species measured lie mostly in the range 0.3-0.7 and show no significant centrality dependence. The values of λ are less than unity due to long-lived resonances which dilute the correlation functions and also lead to non-Gaussian shapes of the correlation functions, especially in the one-dimensional case [20]. Results for kaons and protons are consistent with each other at similar m_T . Values of λ for pions are lower than for kaons due to the stronger influence of resonances; an additional cause could be a partial coherence of pions [19].

Figure 8 shows the extracted R_{inv} parameters vs. m_T for several centralities. For overlapping m_T , the radius parameters are mostly consistent with each other within uncertainties, though the pion radii are generally larger than the kaon radii. The K_S^0 radii are slightly higher than K^\pm radii for central collisions, but the difference is less than the systematic uncertainties. The radius parameters show increasing size

Fig. 7: (Color online) λ parameters ($\lambda_{pp} + \lambda_{pA}$ in case of (anti)proton pairs) vs. m_T for the three centralities considered for $\pi^\pm\pi^\pm$, $K^\pm K^\pm$, $K_S^0 K_S^0$, pp , and \overline{pp} . Statistical (thin lines) and systematic (boxes) uncertainties are shown. The m_T values for different centrality intervals are slightly offset for clarity.

Fig. 8: (Color online) R_{inv} parameters vs. m_T for the three centralities considered for $\pi^\pm\pi^\pm$, $K^\pm K^\pm$, $K_S^0 K_S^0$, pp , and \overline{pp} . Statistical (thin lines) and systematic (boxes) uncertainties are shown.

Fig. 9: (Color online) Comparison of the HKM model (see text) with measured kaon λ (a) and R_{inv} (b) parameters for 0-5% centrality. Statistical (thin lines) and systematic (boxes) uncertainties are shown.

with increasing centrality as would be expected from a simple geometric picture of the collisions. They also show a decreasing size with increasing m_T as would be expected in the presence of collective radial flow [6]. Both of these dependences can be seen in previous $\pi^\pm\pi^\pm$ femtoscopic measurements [4, 5] and also reinforce the interpretation that collective flow is present in these collisions for pions, kaons (neutral and charged), and protons alike. Deviations from exact m_T -scaling of R_{inv} can be explained as a consequence of the increase of the Lorentz factor with decreasing particle mass. In a hydrodynamic model [50], scaling is observed for the three-dimensional radii measured in the Longitudinally Co-Moving System (LCMS). The transformation from LCMS to PRF involves a boost along the outward direction only, where the boost value is proportional to the transverse velocity of the pair and inversely proportional to the particle mass (for similar m_T). Thus, a smaller mass leads to an increase in the boosted R_{out} and, subsequently, R_{inv} in the PRF. Indeed, we observe such an effect in the data, as pion radii are systematically higher than kaon radii at the same m_T .

A comparison of a hydrodynamic flow + kinetics model, HKM [14], with the measured R_{inv} and λ parameters for 0-5% centrality is shown in Fig. 9. The HKM values in Fig. 9 are specifically from $K^\pm K^\pm$, but the predictions for $K_S^0 K_S^0$ and $K^\pm K^\pm$ are consistent with each other. For R_{inv} , the charged kaon data show very good agreement with the predictions. The experimental data for the neutral kaons are again slightly higher than for the charged kaons, but this difference is still within systematic uncertainties. For λ , both sets of kaon data match the decreasing trend with increasing k_T exhibited by the HKM points, but the model slightly overpredicts the data. It is shown in [14] that the most important resonances for KK pairs, $K^*(890)$ and $\phi(1020)$, do not significantly influence the λ parameter (due to their low contribution), and the discrepancy between the model and experimental data can be explained by the lower experimental kaon purity and deviations of the experimental correlation function shape from a Gaussian distribution. For protons, the HKM prediction is compatible with the data. HKM calculations for one-dimensional pion radii are currently not available, but three-dimensional radii were reasonably reproduced by this model [51].

5 Summary

Results from femtoscopic studies of $\pi^\pm\pi^\pm$, $K^\pm K^\pm$, $K_S^0 K_S^0$, pp , and \bar{pp} correlations from Pb-Pb collisions at $\sqrt{s_{NN}} = 2.76$ TeV with ALICE at the LHC have been presented. The femtoscopic radii and λ parameters were extracted from one-dimensional correlation functions in terms of the invariant momentum difference. It was found that the emission source sizes of kaons and protons measured in these collisions exhibit transverse mass scaling within uncertainties, which is consistent with hydrodynamic model predictions assuming collective flow. The deviation from the scaling for the pions can be explained as a

consequence of the increase of the Lorentz factor with decreasing particle mass during the transformation from LCMS to PRF systems [50]. The extracted λ parameters are found to be less than unity, as is expected due to long-lived resonances and non-Gaussian correlation functions. The predictions of the hydrokinetic model (HKM) for the one-dimensional femtoscopic radii for charged and neutral kaons and protons coincide well with the observations.

Acknowledgements

The ALICE Collaboration would like to thank all its engineers and technicians for their invaluable contributions to the construction of the experiment and the CERN accelerator teams for the outstanding performance of the LHC complex. The ALICE Collaboration gratefully acknowledges the resources and support provided by all Grid centres and the Worldwide LHC Computing Grid (WLCG) collaboration. The ALICE Collaboration acknowledges the following funding agencies for their support in building and running the ALICE detector: State Committee of Science, World Federation of Scientists (WFS) and Swiss Fonds Kidagan, Armenia, Conselho Nacional de Desenvolvimento Científico e Tecnológico (CNPq), Financiadora de Estudos e Projetos (FINEP), Fundação de Amparo à Pesquisa do Estado de São Paulo (FAPESP); National Natural Science Foundation of China (NSFC), the Chinese Ministry of Education (CMOE) and the Ministry of Science and Technology of China (MSTC); Ministry of Education and Youth of the Czech Republic; Danish Natural Science Research Council, the Carlsberg Foundation and the Danish National Research Foundation; The European Research Council under the European Community's Seventh Framework Programme; Helsinki Institute of Physics and the Academy of Finland; French CNRS-IN2P3, the ‘Region Pays de Loire’, ‘Region Alsace’, ‘Region Auvergne’ and CEA, France; German Bundesministerium für Bildung, Wissenschaft, Forschung und Technologie (BMBF) and the Helmholtz Association; General Secretariat for Research and Technology, Ministry of Development, Greece; Hungarian Országos Tudományos Kutatási Alap (OTKA) and National Office for Research and Technology (NKTH); Department of Atomic Energy and Department of Science and Technology of the Government of India; Istituto Nazionale di Fisica Nucleare (INFN) and Centro Fermi - Museo Storico della Fisica e Centro Studi e Ricerche “Enrico Fermi”, Italy; MEXT Grant-in-Aid for Specially Promoted Research, Japan; Joint Institute for Nuclear Research, Dubna; National Research Foundation of Korea (NRF); Consejo Nacional de Ciencia y Tecnología (CONACYT), Dirección General de Asuntos del Personal Académico (DGAPA), México, Amerique Latine Formation académique - European Commission (ALFA-EC) and the EPLANET Program (European Particle Physics Latin American Network); Stichting voor Fundamenteel Onderzoek der Materie (FOM) and the Nederlandse Organisatie voor Wetenschappelijk Onderzoek (NWO), Netherlands; Research Council of Norway (NFR); National Science Centre, Poland; Ministry of National Education/Institute for Atomic Physics and National Council of Scientific Research in Higher Education (CNCSI-UEFISCDI), Romania; Ministry of Education and Science of Russian Federation, Russian Academy of Sciences, Russian Federal Agency of Atomic Energy, Russian Federal Agency for Science and Innovations and The Russian Foundation for Basic Research; Ministry of Education of Slovakia; Department of Science and Technology, South Africa; Centro de Investigaciones Energéticas, Medioambientales y Tecnológicas (CIEMAT), E-Infrastructure shared between Europe and Latin America (EELA), Ministerio de Economía y Competitividad (MINECO) of Spain, Xunta de Galicia (Consellería de Educación), Centro de Aplicaciones Tecnológicas y Desarrollo Nuclear (CEADEN), Cubaenergía, Cuba, and IAEA (International Atomic Energy Agency); Swedish Research Council (VR) and Knut & Alice Wallenberg Foundation (KAW); Ukraine Ministry of Education and Science; United Kingdom Science and Technology Facilities Council (STFC); The United States Department of Energy, the United States National Science Foundation, the State of Texas, and the State of Ohio; Ministry of Science, Education and Sports of Croatia and Unity through Knowledge Fund, Croatia; Council of Scientific and Industrial Research (CSIR), New Delhi, India.

¹⁹ Department of Physics, Aligarh Muslim University, Aligarh, India
²⁰ Department of Physics, Ohio State University, Columbus, Ohio, United States
²¹ Department of Physics, Sejong University, Seoul, South Korea
²² Department of Physics, University of Oslo, Oslo, Norway
²³ Dipartimento di Elettrotecnica ed Elettronica del Politecnico, Bari, Italy
²⁴ Dipartimento di Fisica dell’Università ‘La Sapienza’ and Sezione INFN Rome, Italy
²⁵ Dipartimento di Fisica dell’Università and Sezione INFN, Cagliari, Italy
²⁶ Dipartimento di Fisica dell’Università and Sezione INFN, Trieste, Italy
²⁷ Dipartimento di Fisica dell’Università and Sezione INFN, Turin, Italy
²⁸ Dipartimento di Fisica e Astronomia dell’Università and Sezione INFN, Bologna, Italy
²⁹ Dipartimento di Fisica e Astronomia dell’Università and Sezione INFN, Catania, Italy
³⁰ Dipartimento di Fisica e Astronomia dell’Università and Sezione INFN, Padova, Italy
³¹ Dipartimento di Fisica ‘E.R. Caianiello’ dell’Università and Gruppo Collegato INFN, Salerno, Italy
³² Dipartimento di Scienze e Innovazione Tecnologica dell’Università del Piemonte Orientale and Gruppo Collegato INFN, Alessandria, Italy
³³ Dipartimento Interateneo di Fisica ‘M. Merlin’ and Sezione INFN, Bari, Italy
³⁴ Division of Experimental High Energy Physics, University of Lund, Lund, Sweden
³⁵ Eberhard Karls Universität Tübingen, Tübingen, Germany
³⁶ European Organization for Nuclear Research (CERN), Geneva, Switzerland
³⁷ Excellence Cluster Universe, Technische Universität München, Munich, Germany
³⁸ Faculty of Engineering, Bergen University College, Bergen, Norway
³⁹ Faculty of Mathematics, Physics and Informatics, Comenius University, Bratislava, Slovakia
⁴⁰ Faculty of Nuclear Sciences and Physical Engineering, Czech Technical University in Prague, Prague, Czech Republic
⁴¹ Faculty of Science, P.J. Šafárik University, Košice, Slovakia
⁴² Faculty of Technology, Buskerud and Vestfold University College, Vestfold, Norway
⁴³ Frankfurt Institute for Advanced Studies, Johann Wolfgang Goethe-Universität Frankfurt, Frankfurt, Germany
⁴⁴ Gangneung-Wonju National University, Gangneung, South Korea
⁴⁵ Gauhati University, Department of Physics, Guwahati, India
⁴⁶ Helsinki Institute of Physics (HIP), Helsinki, Finland
⁴⁷ Hiroshima University, Hiroshima, Japan
⁴⁸ Indian Institute of Technology Bombay (IIT), Mumbai, India
⁴⁹ Indian Institute of Technology Indore, Indore (IITI), India
⁵⁰ Inha University, Incheon, South Korea
⁵¹ Institut de Physique Nucléaire d’Orsay (IPNO), Université Paris-Sud, CNRS-IN2P3, Orsay, France
⁵² Institut für Informatik, Johann Wolfgang Goethe-Universität Frankfurt, Frankfurt, Germany
⁵³ Institut für Kernphysik, Johann Wolfgang Goethe-Universität Frankfurt, Frankfurt, Germany
⁵⁴ Institut für Kernphysik, Westfälische Wilhelms-Universität Münster, Münster, Germany
⁵⁵ Institut Pluridisciplinaire Hubert Curien (IPHC), Université de Strasbourg, CNRS-IN2P3, Strasbourg, France
⁵⁶ Institute for Nuclear Research, Academy of Sciences, Moscow, Russia
⁵⁷ Institute for Subatomic Physics of Utrecht University, Utrecht, Netherlands
⁵⁸ Institute for Theoretical and Experimental Physics, Moscow, Russia
⁵⁹ Institute of Experimental Physics, Slovak Academy of Sciences, Košice, Slovakia
⁶⁰ Institute of Physics, Academy of Sciences of the Czech Republic, Prague, Czech Republic
⁶¹ Institute of Physics, Bhubaneswar, India
⁶² Institute of Space Science (ISS), Bucharest, Romania
⁶³ Instituto de Ciencias Nucleares, Universidad Nacional Autónoma de México, Mexico City, Mexico
⁶⁴ Instituto de Física, Universidad Nacional Autónoma de México, Mexico City, Mexico

- ⁶⁵ iThemba LABS, National Research Foundation, Somerset West, South Africa
⁶⁶ Joint Institute for Nuclear Research (JINR), Dubna, Russia
⁶⁷ Konkuk University, Seoul, South Korea
⁶⁸ Korea Institute of Science and Technology Information, Daejeon, South Korea
⁶⁹ KTO Karatay University, Konya, Turkey
⁷⁰ Laboratoire de Physique Corpusculaire (LPC), Clermont Université, Université Blaise Pascal, CNRS-IN2P3, Clermont-Ferrand, France
⁷¹ Laboratoire de Physique Subatomique et de Cosmologie, Université Grenoble-Alpes, CNRS-IN2P3, Grenoble, France
⁷² Laboratori Nazionali di Frascati, INFN, Frascati, Italy
⁷³ Laboratori Nazionali di Legnaro, INFN, Legnaro, Italy
⁷⁴ Lawrence Berkeley National Laboratory, Berkeley, California, United States
⁷⁵ Lawrence Livermore National Laboratory, Livermore, California, United States
⁷⁶ Moscow Engineering Physics Institute, Moscow, Russia
⁷⁷ National Centre for Nuclear Studies, Warsaw, Poland
⁷⁸ National Institute for Physics and Nuclear Engineering, Bucharest, Romania
⁷⁹ National Institute of Science Education and Research, Bhubaneswar, India
⁸⁰ Niels Bohr Institute, University of Copenhagen, Copenhagen, Denmark
⁸¹ Nikhef, Nationaal instituut voor subatomaire fysica, Amsterdam, Netherlands
⁸² Nuclear Physics Group, STFC Daresbury Laboratory, Daresbury, United Kingdom
⁸³ Nuclear Physics Institute, Academy of Sciences of the Czech Republic, Řež u Prahy, Czech Republic
⁸⁴ Oak Ridge National Laboratory, Oak Ridge, Tennessee, United States
⁸⁵ Petersburg Nuclear Physics Institute, Gatchina, Russia
⁸⁶ Physics Department, Creighton University, Omaha, Nebraska, United States
⁸⁷ Physics Department, Panjab University, Chandigarh, India
⁸⁸ Physics Department, University of Athens, Athens, Greece
⁸⁹ Physics Department, University of Cape Town, Cape Town, South Africa
⁹⁰ Physics Department, University of Jammu, Jammu, India
⁹¹ Physics Department, University of Rajasthan, Jaipur, India
⁹² Physik Department, Technische Universität München, Munich, Germany
⁹³ Physikalisches Institut, Ruprecht-Karls-Universität Heidelberg, Heidelberg, Germany
⁹⁴ Politecnico di Torino, Turin, Italy
⁹⁵ Purdue University, West Lafayette, Indiana, United States
⁹⁶ Pusan National University, Pusan, South Korea
⁹⁷ Research Division and ExtreMe Matter Institute EMMI, GSI Helmholtzzentrum für Schwerionenforschung, Darmstadt, Germany
⁹⁸ Rudjer Bošković Institute, Zagreb, Croatia
⁹⁹ Russian Federal Nuclear Center (VNIIEF), Sarov, Russia
¹⁰⁰ Russian Research Centre Kurchatov Institute, Moscow, Russia
¹⁰¹ Saha Institute of Nuclear Physics, Kolkata, India
¹⁰² School of Physics and Astronomy, University of Birmingham, Birmingham, United Kingdom
¹⁰³ Sección Física, Departamento de Ciencias, Pontificia Universidad Católica del Perú, Lima, Peru
¹⁰⁴ Sezione INFN, Bari, Italy
¹⁰⁵ Sezione INFN, Bologna, Italy
¹⁰⁶ Sezione INFN, Cagliari, Italy
¹⁰⁷ Sezione INFN, Catania, Italy
¹⁰⁸ Sezione INFN, Padova, Italy
¹⁰⁹ Sezione INFN, Rome, Italy
¹¹⁰ Sezione INFN, Trieste, Italy
¹¹¹ Sezione INFN, Turin, Italy
¹¹² SSC IHEP of NRC Kurchatov institute, Protvino, Russia
¹¹³ SUBATECH, Ecole des Mines de Nantes, Université de Nantes, CNRS-IN2P3, Nantes, France
¹¹⁴ Suranaree University of Technology, Nakhon Ratchasima, Thailand
¹¹⁵ Technical University of Košice, Košice, Slovakia
¹¹⁶ Technical University of Split FESB, Split, Croatia
¹¹⁷ The Henryk Niewodniczanski Institute of Nuclear Physics, Polish Academy of Sciences, Cracow, Poland

- ¹¹⁸ The University of Texas at Austin, Physics Department, Austin, Texas, USA
¹¹⁹ Universidad Autónoma de Sinaloa, Culiacán, Mexico
¹²⁰ Universidade de São Paulo (USP), São Paulo, Brazil
¹²¹ Universidade Estadual de Campinas (UNICAMP), Campinas, Brazil
¹²² University of Houston, Houston, Texas, United States
¹²³ University of Jyväskylä, Jyväskylä, Finland
¹²⁴ University of Liverpool, Liverpool, United Kingdom
¹²⁵ University of Tennessee, Knoxville, Tennessee, United States
¹²⁶ University of the Witwatersrand, Johannesburg, South Africa
¹²⁷ University of Tokyo, Tokyo, Japan
¹²⁸ University of Tsukuba, Tsukuba, Japan
¹²⁹ University of Zagreb, Zagreb, Croatia
¹³⁰ Université de Lyon, Université Lyon 1, CNRS/IN2P3, IPN-Lyon, Villeurbanne, France
¹³¹ V. Fock Institute for Physics, St. Petersburg State University, St. Petersburg, Russia
¹³² Variable Energy Cyclotron Centre, Kolkata, India
¹³³ Vinča Institute of Nuclear Sciences, Belgrade, Serbia
¹³⁴ Warsaw University of Technology, Warsaw, Poland
¹³⁵ Wayne State University, Detroit, Michigan, United States
¹³⁶ Wigner Research Centre for Physics, Hungarian Academy of Sciences, Budapest, Hungary
¹³⁷ Yale University, New Haven, Connecticut, United States
¹³⁸ Yonsei University, Seoul, South Korea
¹³⁹ Zentrum für Technologietransfer und Telekommunikation (ZTT), Fachhochschule Worms, Worms, Germany
