## Elliptic flow of muons from heavy-flavour hadron decays at forward rapidity in Pb–Pb collisions at $\sqrt{s_{NN}} = 2.76$ TeV

ALICE Collaboration\*

### Abstract

The elliptic flow,  $v_2$ , of muons from heavy-flavour hadron decays at forward rapidity ( $2.5 < y < 4$ ) is measured in Pb–Pb collisions at  $\sqrt{s_{NN}} = 2.76$  TeV with the ALICE detector at the LHC. The scalar product, two- and four-particle  $Q$  cumulants and Lee-Yang zeros methods are used. The dependence of the  $v_2$  of muons from heavy-flavour hadron decays on the collision centrality, in the range 0–40%, and on transverse momentum,  $p_T$ , is studied in the interval  $3 < p_T < 10$  GeV/ $c$ . A positive  $v_2$  is observed with the scalar product and two-particle  $Q$  cumulants in semi-central collisions (10–20% and 20–40% centrality classes) for the  $p_T$  interval from 3 to about 5 GeV/ $c$ . The  $v_2$  magnitude tends to decrease towards more central collisions and with increasing  $p_T$ . It becomes compatible with zero in the interval  $6 < p_T < 10$  GeV/ $c$ . The results are compared to models describing the interaction of heavy quarks and open heavy-flavour hadrons with the high-density medium formed in high-energy heavy-ion collisions. The model calculations describe the measured  $v_2$  within uncertainties.

## 1 Introduction

Experiments with ultra-relativistic heavy-ion collisions aim at investigating the properties of strongly-interacting matter at very high temperatures and energy densities. Quantum Chromodynamics (QCD) calculations on the lattice predict, under these conditions, the formation of a Quark-Gluon Plasma (QGP), where colour confinement vanishes and chiral symmetry is partially restored [1–5]. Heavy quarks (charm and beauty) are created in initial hard-scattering processes on a time scale shorter than the QGP formation time. Subsequently, they interact with the medium constituents via inelastic [6, 7] and elastic [8–10] processes. Therefore, heavy quarks are regarded as effective probes of the QGP properties.

Heavy-quark energy loss due to in-medium interactions can be studied by means of the nuclear modification factor  $R_{AA}$ , defined as the ratio of the yield of heavy-flavour particles measured in nucleus–nucleus (AA) collisions to that observed in proton–proton (pp) collisions scaled by the number of binary nucleon–nucleon collisions. The PHENIX and STAR Collaborations measured, in central Au–Au collisions at  $\sqrt{s_{NN}} = 200$  GeV, a strong suppression corresponding to a  $R_{AA}$  of about 0.2–0.3 for heavy-flavour decay electrons at mid-rapidity ( $y$ ) and transverse momentum  $p_T > 5$  GeV/ $c$  [11–17]. A similar suppression was also measured by the STAR Collaboration for mid-rapidity  $D^0$  mesons [18]. A significant suppression was also observed by the PHENIX Collaboration at forward rapidity for muons from heavy-flavour hadron decays in central Cu–Cu collisions at  $\sqrt{s_{NN}} = 200$  GeV [19]. At the LHC, the ALICE Collaboration reported a similar effect in central Pb–Pb collisions at  $\sqrt{s_{NN}} = 2.76$  TeV for D mesons at mid-rapidity [20] and muons from heavy-flavour hadron decays at forward rapidity [21] in the interval  $2 < p_T < 16$  GeV/ $c$  and  $4 < p_T < 10$  GeV/ $c$ , respectively. The CMS Collaboration measured a significant suppression of non-prompt  $J/\psi$  from beauty-hadron decays in the interval  $6.5 < p_T < 30$  GeV/ $c$  ( $3 < p_T < 30$  GeV/ $c$ ) and  $|y| < 2.4$  ( $1.6 < |y| < 2.4$ ) [22, 23]. A first measurement of non-prompt  $J/\psi$  by the ALICE Collaboration at mid-rapidity ( $|y| < 0.8$ ) and in the interval  $4.5 < p_T < 10$  GeV/ $c$  has been recently published [24].

Further insights into the QGP evolution and the in-medium interactions can be gained from the study of the azimuthal anisotropy of particles carrying heavy quarks which, in contrast to light quarks, have experienced the full system evolution. The study of azimuthal anisotropy is a field of intense experimental and theoretical investigations (see [25] and references therein). In non-central collisions, the initial spatial anisotropy of the overlap region, elongated in the direction perpendicular to the reaction plane, defined by the beam axis and the impact parameter of the collision, is converted into an anisotropy in momentum space through rescatterings [26]. Experimentally, the study of the particle azimuthal anisotropy is based on a Fourier expansion of azimuthal distributions given by:

$$\frac{d^2N}{dp_T d\varphi} = \frac{1}{2\pi} \frac{dN}{dp_T} \left( 1 + 2 \sum_{n=1}^{\infty} v_n(p_T) \cos[n(\varphi - \Psi_n)] \right), \quad (1)$$

where  $\varphi$  and  $p_T$  are the particle azimuthal angle and transverse momentum, respectively. The Fourier coefficients,  $v_n$ , characterize the anisotropy of produced particles and  $\Psi_n$  is the azimuthal angle of the initial-state symmetry plane for the  $n^{\text{th}}$  harmonic, introduced to account for the event-by-event fluctuations of the initial nucleon density profile. The second Fourier coefficient,  $v_2$ , which can also be expressed as  $v_2 = \langle \cos[2(\varphi - \Psi_2)] \rangle$ , is named elliptic flow.

The  $v_2$  of heavy-flavour hadrons is expected to provide information on the collective expansion and degree of thermalization of heavy quarks in the medium at low  $p_T$  ( $p_T < 2 - 3$  GeV/ $c$ ). The participation of heavy quarks in the collective expansion is expected to give a positive  $v_2$  [26]. Moving towards intermediate  $p_T$  ( $3 < p_T < 6$  GeV/ $c$ ), the  $v_2$  Fourier coefficient is also expected to be sensitive to the presence of recombination processes in the hadronization of heavy quarks [27, 28]. At high  $p_T$  ( $p_T > 6$  GeV/ $c$ ), the  $v_2$  measurement can constrain the path-length dependence of the in-medium parton energy loss, which becomes the dominant contribution to the azimuthal anisotropy and is also predicted to give a positive  $v_2$  [29, 30], thus complementing the  $R_{AA}$  measurement.

The PHENIX Collaboration reported a positive  $v_2$  of heavy-flavour decay electrons at mid-rapidity in Au–Au collisions at  $\sqrt{s_{NN}} = 200$  GeV, reaching a maximum value of about 0.15 at  $p_T = 1.5$  GeV/ $c$  in semi-central collisions [14, 15, 31]. A similar behaviour was also observed by the STAR Collaboration [32]. Recently, a  $v_2$  value significantly larger than zero was measured for D mesons at mid-rapidity in Pb–Pb collisions at  $\sqrt{s_{NN}} = 2.76$  TeV [33, 34]. A complementary measurement at the same energy, provided by the heavy-flavour decay muon elliptic flow at forward rapidity ( $2.5 < y < 4$ ), is of great interest in order to provide new constraints for models that implement the heavy-quark interactions with the medium. Finally, the measurement is also important for the interpretation of the  $J/\psi$  elliptic flow results at forward rapidity [35] in terms of a regeneration production from deconfined charm quarks in the medium.

In this Letter, we present the measurement of the elliptic flow of muons from heavy-flavour hadron decays at forward rapidity ( $2.5 < y < 4$ ) in Pb–Pb collisions at  $\sqrt{s_{NN}} = 2.76$  TeV recorded with the ALICE detector. The elliptic flow is measured using different methods: scalar product [36], two- and four-particle  $Q$  cumulants [37, 38] and Lee-Yang zeros [39–41]. These methods exhibit different sensitivities to flow fluctuations and correlations not related to the azimuthal asymmetry in the initial geometry (non-flow effects). The  $v_2$  coefficient is measured as a function of  $p_T$  in the interval  $3 < p_T < 10$  GeV/ $c$  and in three centrality classes in the range 0–40%. The centrality dependence of  $v_2$  is presented in the interval  $3 < p_T < 10$  GeV/ $c$ .

The Letter is organized as follows. The ALICE detector, with an emphasis on the muon spectrometer, and the data sample are presented in Section 2. The analysis details, the methods for the  $v_2$  measurement, the inclusive muon  $v_2$  determination, the procedure for the subtraction of the background of muons from decays of light-flavour hadrons and the study of systematic uncertainties, are described in Section 3. The  $v_2$  results for muons from heavy-flavour decays are presented in Section 4 and compared to model calculations in Section 5. Finally, conclusions are given in Section 6.

## 2 ALICE experiment and data sample

The ALICE detector is described in detail in [42, 43]. The apparatus is composed of a set of central barrel detectors (pseudo-rapidity coverage  $|\eta| < 0.9$ ) located inside a solenoid magnet that generates a field of 0.5 T parallel to the beam direction, a muon spectrometer ( $-4 < \eta < -2.5$ <sup>1</sup>) and a set of detectors for event characterization and triggering located in the forward and backward  $\eta$  regions. The muon spectrometer consists of a passive front absorber made of carbon, concrete and steel, a beam shield, a 3 T-m dipole magnet, tracking chambers, a muon filter (iron wall) and trigger chambers. The muon tracking system is composed of five stations, each including two planes of cathod pad chambers, with the third station inside the dipole magnet. The muon tracking system is completed by four trigger planes of resistive plate chambers downstream of the iron wall, which absorbs hadrons that punch through the front absorber, as well as secondary particles produced inside it and low momentum muons ( $p < 4$  GeV/ $c$ ). Two scintillator arrays (V0) covering the pseudo-rapidity intervals  $-3.7 < \eta < -1.7$  and  $2.8 < \eta < 5.1$  are used for triggering, for collision centrality determination and for beam-induced background rejection. The Zero Degree Calorimeters (ZDC), located at 114 m from the centre of the detector on both sides, can detect spectator protons and neutrons and are also used for the offline rejection of beam-induced background and electromagnetic interactions. The Silicon Pixel Detector (SPD), that composes the two innermost layers of the Inner Tracking System (ITS), is used for the interaction vertex reconstruction. The Time Projection Chamber (TPC), which measures charged-particle tracks with full azimuthal coverage in  $|\eta| < 0.9$ , is used in this analysis for the measurement of the reference particles (Section 3.1).

<sup>1</sup>In the ALICE reference frame, the muon spectrometer covers a negative  $\eta$  range and consequently a negative  $y$  range. In the following, given that the colliding system is symmetric, the results are presented with a positive  $y$  notation.

The results presented in this Letter are obtained from the data sample recorded with ALICE during the 2011 Pb–Pb run. The data were collected with a minimum-bias trigger requiring the coincidence of signals in the two V0 arrays in synchronization with the passage of two crossing bunches. In addition, the recorded event sample was enriched with central and semi-central Pb–Pb collisions by applying thresholds, at the trigger level, on the V0 signal amplitude. The beam-induced background (beam-gas interactions) was reduced by using the timing information from the V0 and ZDC detectors. Furthermore, a minimal energy deposit in the ZDC was required to reject the contribution from electromagnetic Pb–Pb interactions. Only events with a reconstructed primary vertex within  $\pm 10$  cm from the nominal position of the interaction vertex along the beam direction are analyzed. The Pb–Pb collisions are classified according to their degree of centrality by means of the sum of the amplitudes of the signals in the V0 detector and the centrality classes are defined as percentiles of the total hadronic Pb–Pb cross section [44]. The analysis is carried out in three centrality classes: 0–10%, 10–20% and 20–40%. The analysed data sample corresponds to an integrated luminosity of  $11.3 \mu\text{b}^{-1}$  in the 0–10% centrality class and of  $3.5 \mu\text{b}^{-1}$  in the other two centrality classes.

### 3 Data analysis

The elliptic flow of muons from heavy-flavour hadron decays,  $v_2^{\mu\leftarrow\text{HF}}$ , is obtained from the measurement of the inclusive muon elliptic flow,  $v_2^\mu$ , by subtracting the elliptic flow of muons from primary charged pion and kaon decays  $v_2^{\mu\leftarrow\pi,\text{K}}$  (Sections 3.1 and 3.4), as:

$$v_2^{\mu\leftarrow\text{HF}} = \frac{v_2^\mu - f^{\mu\leftarrow\pi,\text{K}} \cdot v_2^{\mu\leftarrow\pi,\text{K}}}{1 - f^{\mu\leftarrow\pi,\text{K}}}, \quad (2)$$

where  $f^{\mu\leftarrow\pi,\text{K}}$  is the muon background fraction, defined as the ratio of the yield of muons from primary charged pion and kaon decays to that of inclusive muons. The measurement of the  $v_2^{\mu\leftarrow\text{HF}}$  coefficient is carried out in the interval  $3 < p_T < 10$  GeV/ $c$  in order to limit the systematic uncertainty on the subtraction of the muon background contribution.

#### 3.1 Track selection

The selection criteria for particles of interest, muon tracks, are similar to those used in the previous analyses of pp collisions at  $\sqrt{s} = 2.76$  TeV and 7 TeV and Pb–Pb collisions at  $\sqrt{s_{\text{NN}}} = 2.76$  TeV [21, 45]. The tracks are required to be within the geometrical acceptance of the muon spectrometer, with  $-4 < \eta < -2.5$  and  $170^\circ < \theta_{\text{abs}} < 178^\circ$ , where  $\theta_{\text{abs}}$  is the polar angle measured at the end of the absorber. In order to improve the muon identification, a reconstructed track in the tracking chambers is required to match a track segment in the trigger chambers. This leads to a very efficient rejection of the background produced by charged hadrons, which are absorbed in the iron wall. Furthermore, a cut on the product  $p \cdot DCA$  of the track momentum  $p$  and distance of closest approach ( $DCA$ ) to the primary vertex is applied to remove the beam-induced background tracks and fake tracks coming from the superposition of several particles crossing the muon spectrometer. This cut is set to  $6\sigma$ , where  $\sigma$  is extracted from a Gaussian fit to the  $p \cdot DCA$  distribution measured in two intervals of  $\theta_{\text{abs}}$ , corresponding to different materials in the front absorber. After the cuts are applied, in the region  $p_T > 3$  GeV/ $c$  the residual background to heavy-flavour decay muons consists of muons from decays of primary charged pions and kaons<sup>2</sup> and it amounts to 5–15%, depending on  $p_T$  and on collision centrality (Section 3.4).

The mid-rapidity charged-particle tracks used to determine the flow vector  $\vec{Q}_n$  or the generating function (Section 3.2) are called in the following reference particles. They are defined as tracks measured in the TPC in  $|\eta| < 0.8$ . These are required to have at least 70 associated space points out of the maximum of

<sup>2</sup>Note that the contribution of muons from secondary light hadron decays produced inside the front absorber is negligible for  $p_T > 3$  GeV/ $c$  [45].

159, a  $\chi^2$  per degree of freedom (ndf) for the momentum fit in the range  $\chi^2/\text{ndf} < 2$  and a transverse momentum value in the interval  $0.2 < p_T < 5$  GeV/c. Additionally, tracks are rejected if their distance of closest approach to the primary vertex is larger than 3 cm in the plane transverse to the beam direction or in the longitudinal direction.

### 3.2 Flow analysis methods

The elliptic flow measurement is carried out using various methods that have different sensitivities to flow fluctuations and non-flow effects [46]. Flow fluctuations are mainly due to event-by-event fluctuations of the initial density profile, while non-flow effects correspond to correlations not related to the azimuthal anisotropy in the initial state, such as resonance decays, jets and Bose-Einstein correlations between identical particles. It is worth mentioning that, in the present analysis, most of these non-flow effects are strongly suppressed by introducing an  $\eta$  gap between reference particles and particles of interest [47]. In this analysis, the scalar product [36], two- and four-particle  $Q$  cumulants [37, 38] and Lee-Yang zeros [39–41] methods are employed. The description of these methods will be limited to the features specific to the present analysis. The following notations are introduced:  $v_2^{\mu(\mu \leftarrow \text{HF})}\{\text{SP}\}$ , refers to the measurement using the scalar product,  $v_2^{\mu(\mu \leftarrow \text{HF})}\{2\}$  and  $v_2^{\mu(\mu \leftarrow \text{HF})}\{4\}$  correspond to the ones using the two-particle  $Q$  cumulants and four-particle  $Q$  cumulants, while  $v_2^{\mu(\mu \leftarrow \text{HF})}\{\text{LYZ} - \text{Prod}\}$  and  $v_2^{\mu(\mu \leftarrow \text{HF})}\{\text{LYZ} - \text{Sum}\}$  are obtained using Lee-Yang zeros with product and sum generating functions. The superscripts  $\mu$  and  $\mu \leftarrow \text{HF}$  refer to inclusive muons and muons from heavy-flavour hadron decays, respectively. It is worth mentioning that these methods are more accurate than the standard event plane method, which yields a measurement lying between the event-averaged mean value and the root-mean-square value in the presence of flow fluctuations [48, 49]. Moreover, the multi-particle correlation methods (four-particle  $Q$  cumulants and Lee-Yang zeros) are less affected by non-flow correlations than two-particle correlation methods, but they cannot be used reliably when the muon flow magnitude is small and when the number of muons is small in the selected phase-space region e.g. in central and peripheral collisions, respectively [37, 39]. Under these conditions, the scalar product and two-particle cumulant methods provide a  $v_2$  measurement in a wider centrality range.

The scalar product method [36, 48], derived from the standard event plane technique [48], is based on the measurement of the flow vector  $\vec{Q}_n$  [36] computed from reference particles. In order to determine the elliptic flow, the  $\vec{Q}_2$  vector in a given event is expressed as:

$$\vec{Q}_2 = \left( \sum_{j=1}^N \cos 2\varphi_j, \sum_{j=1}^N \sin 2\varphi_j \right), \quad (3)$$

where  $\varphi_j$  is the particle azimuthal angle and  $N$  is the multiplicity of reference particles.

With this method the 2<sup>nd</sup> harmonic coefficient is given by:

$$v_2\{\text{SP}\} = \frac{\langle \vec{Q}_2 \cdot \vec{u}_{2,i}(\eta, p_T) \rangle}{2\sqrt{\langle \vec{Q}_2^A \cdot \vec{Q}_2^B \rangle}}, \quad (4)$$

where the brackets in the numerator indicate the average over muons at forward rapidity, in all events. The vector  $\vec{Q}_2$  is calculated from Eq. (3) and the vector  $\vec{u}_{2,i} = (\cos 2\varphi_i, \sin 2\varphi_i)$  is the unit vector of the  $i^{\text{th}}$  muon. In the denominator, each sample of reference particles used to compute  $\vec{Q}_2$  is divided into two sub-samples of same multiplicity in symmetrical  $\eta$  intervals,  $-0.8 < \eta < -0.5$  and  $0.5 < \eta < 0.8$ , separated by a  $\eta$  gap of one unit of pseudo-rapidity, labeled with the superscripts A and B and the brackets correspond to the average over events.

The cumulant technique [37, 38] is based on a cumulant expansion of multi-particle azimuthal correlations. Different order cumulants have different sensitivities to flow fluctuations. In the present analysis,

two- and four-particle cumulants are used to extract the muon elliptic flow. The results presented in the following are obtained from a direct calculation of multi-particle cumulants performed by using the  $Q$ -cumulant technique [38], which is based on the moments of the magnitude of the flow vector  $\vec{Q}_2$ . It is worth mentioning that in this approach the cumulants are not biased by the interferences between various harmonics. The reference elliptic flow values  $V_2$  evaluated from the 2<sup>nd</sup> order cumulant  $c_2\{2\}$  and 4<sup>th</sup> order cumulant  $c_2\{4\}$  with reference particles are given by  $V_2\{2\} = \sqrt{c_2\{2\}}$  and  $V_2\{4\} = \sqrt[4]{-c_2\{4\}}$ , respectively. Once the reference elliptic flow is estimated, the muon elliptic flow with respect to the reference elliptic flow is obtained from the 2<sup>nd</sup> and 4<sup>th</sup> order cumulants according to:

$$v_2\{2\} = \frac{d_2\{2\}}{V_2\{2\}} \text{ and } v_2\{4\} = \frac{d_2\{4\}}{V_2\{4\}^3}, \quad (5)$$

where  $d_2\{2\}$  and  $d_2\{4\}$  are the 2<sup>nd</sup> and 4<sup>th</sup> order cumulants of selected muons [38].

The Lee-Yang zeros method [39–41] relies on correlations involving all particles in the event. This is the limit of cumulants when the order of cumulants goes to infinity. The method is based on the location of the zeros in the complex plane, of a generating function of azimuthal correlations, which relates the position of the first minimum of the generating function to the magnitude of the reference elliptic flow  $V_2$  defined as:

$$V_2 \equiv \left\langle \sum_{j=1}^M \cos[2(\varphi_j - \Psi_2)] \right\rangle_{\text{events}}, \quad (6)$$

where  $M$  is the multiplicity of reference particles and the average is taken over all events. For this purpose, the following complex-valued generating function is evaluated as a function of a positive real variable  $r$  and few, typically five, equally spaced reference angles  $\vartheta$  (LYZ – Prod method):

$$G^\vartheta(ir) \equiv \left\langle \prod_{j=1}^M (1 + ir \cos[2(\varphi_j - \vartheta)]) \right\rangle_{\text{events}}. \quad (7)$$

The first positive minimum of  $|G^\vartheta(ir)|$ , denoted as  $r_0^\vartheta$ , allows one to estimate  $V_2^\vartheta$ , which can be written as  $V_2^\vartheta = j_{01}/r_0^\vartheta$ , where  $j_{01} \simeq 2.405$  is the first root of the Bessel function. Once the first minimum  $r_0^\vartheta$  is determined, the differential muon elliptic flow is estimated with respect to the reference flow  $V_2^\vartheta$  as detailed in [41]. Finally, the result is averaged over all  $\vartheta$  angles. An alternative form of the generating function provided with the LYZ – Sum method is:

$$G^\vartheta(ir) \equiv \left\langle \exp \left( ir \sum_{j=1}^M \cos[2(\varphi_j - \vartheta)] \right) \right\rangle_{\text{events}}. \quad (8)$$

The version of the method involving a product for the construction of the generation function (Eq. (7)) was designed to disentangle interferences between different harmonics, which is not the case with the generating function using a sum of the individual reference particle contributions. Both generating functions are used in this analysis.

Note that, for all methods, autocorrelation effects are avoided because the particles (muons) used in the determination of the flow are not included in the estimation of the reference flow.

### 3.3 Inclusive muon elliptic flow

The elliptic flow of inclusive muons,  $v_2^\mu$ , is studied with two-particle correlation methods (scalar product and two-particle  $Q$  cumulants) in the centrality intervals 0–10%, 10–20% and 20–40%. In the 20–40% centrality interval, the multi-particle correlation methods (four-particle  $Q$  cumulants and Lee-Yang zeros) are also used.

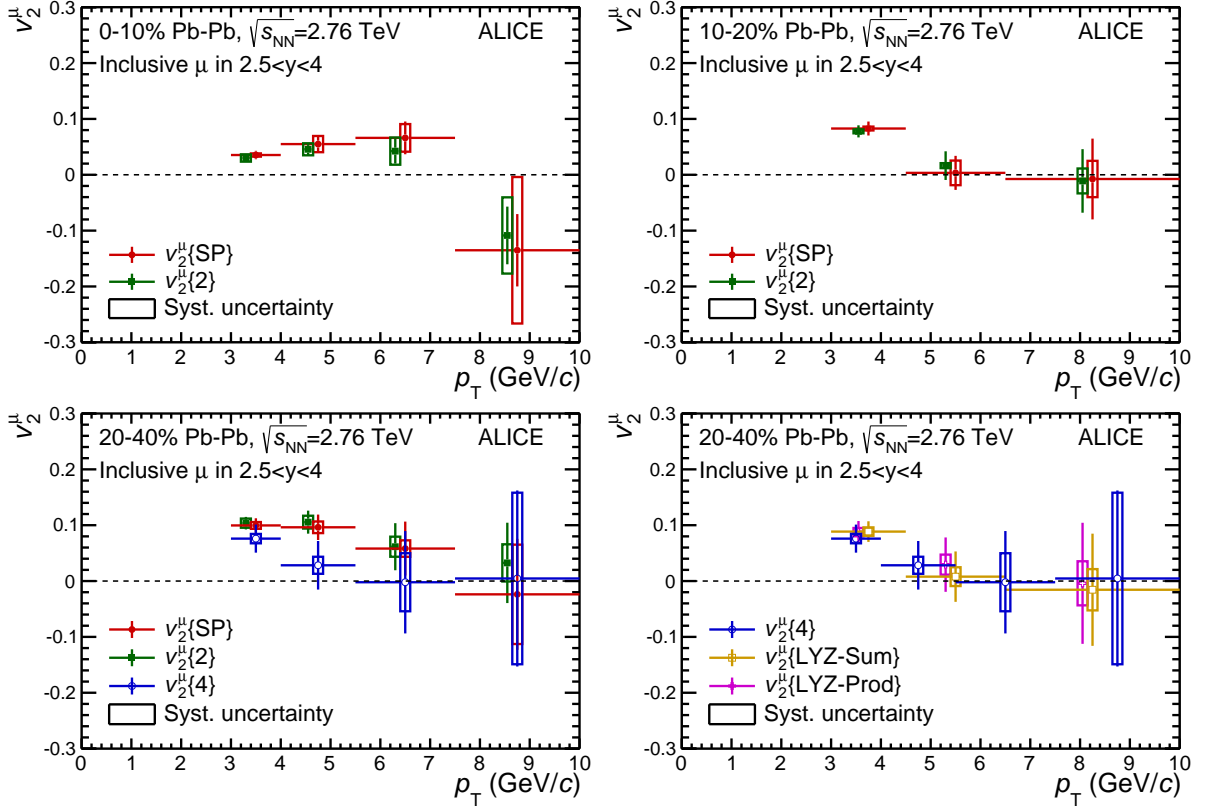

Several sources of systematic uncertainty affecting the muon elliptic flow measurement are considered. These take into account the changes due to the variations of the reference particle selection criteria as in [33, 34, 50], to allow us to check the robustness of the  $v_2^\mu$  measurement. Since the collision impact parameter distribution could slightly depend on the observable used for the centrality determination, a systematic uncertainty is estimated by repeating the analysis using the number of clusters in the outermost layer of the SPD and the number of tracks in the TPC as centrality estimators, instead of the V0 signal amplitude. The systematic uncertainty due to the effect of TPC tracks from different Pb–Pb collisions piled-up in the same recorded event is estimated by applying a tighter cut to remove outliers in the multiplicity distribution of reference particles. This is done by requiring that the centrality values determined using the V0 signal amplitude and the number of TPC tracks do not differ by more than 5%. An additional systematic uncertainty specific to the scalar product is evaluated by varying the  $\eta$  gap between the two sub-events from 1 to 0.8  $\eta$ -units (see Eq. (4) and [36]). The various systematic uncertainties are added in quadrature. They tend to increase with increasing  $p_T$  (see Fig. 1). A summary of the systematic uncertainties, in the interval  $3 < p_T < 4.5$  GeV/ $c$ , is presented in Table 1.

$v_2^\mu$ analysis	Source	Systematic uncertainty (%)		
		0–10%	10–20%	20–40%
$v_2^\mu\{\text{SP}\}$	Reference particles	3	1	3
	Centrality selection	6	1	4
	TPC pile-up	2	4	2
	$\eta$ gap	13	1	1
$v_2^\mu\{2\}$	Reference particles	13	3	2
	Centrality selection	14	3	6
	TPC pile-up	8	1	4
$v_2^\mu\{4\}$	Reference particles			10
	Centrality selection			1
	TPC pile-up			1
$v_2^\mu\{\text{LYZ} - \text{Sum}\}$	Reference particles			4
	Centrality selection			7
	TPC pile-up			2
$v_2^\mu\{\text{LYZ} - \text{Prod}\}$	Reference particles			2
	Centrality selection			8
	TPC pile-up			2

**Table 1:** Systematic uncertainty sources affecting the inclusive muon elliptic flow measurement in the 0–10%, 10–20% and 20–40% centrality classes for the interval  $3 < p_T < 4.5$  GeV/ $c$ . They are given as a percentage of the  $v_2$  value.

Figure 1 shows the  $p_T$ -differential muon elliptic flow ( $v_2^\mu$ ) in the 0–10%, 10–20% and 20–40% centrality classes as obtained using the various methods. The values of  $v_2^\mu$  slightly increase from central to semi-central collisions and this effect is more pronounced in the  $p_T$  interval  $2 < p_T < 4$  GeV/ $c$ . The two-particle correlation methods (scalar product and two-particle  $Q$  cumulants) give consistent results over the whole  $p_T$  range, indicating that these methods have a similar sensitivity to non-flow effects<sup>3</sup> and in particular to flow fluctuations. A similar agreement is found when comparing the multi-particle correlation methods (four-particle  $Q$  cumulants and Lee-Yang zeros) to each other. No significant difference between the  $v_2^\mu$  results extracted with Lee-Yang zeros using either the sum or product generating function is seen, hence indicating that interferences between harmonics are negligible [51]. The four-particle  $Q$  cumulants and Lee-Yang zeros are expected to be less affected by non-flow effects than scalar

<sup>3</sup>Note that, in this analysis, most non-flow correlations are suppressed, even with two-particle correlation methods since reference particles and inclusive muons are separated by at least 1.7  $\eta$ -units. However, it is worth mentioning that the main difference between the two methods is the  $\eta$  gap between the two sub-samples used to compute  $\bar{Q}_2$  (Eq. (4)) which also allows to partly remove non-flow effects.

**Fig. 1:**  $p_T$ -differential inclusive muon  $v_2$  in  $2.5 < y < 4$  and various centrality intervals, in Pb–Pb collisions at  $\sqrt{s_{NN}} = 2.76$  TeV. The symbols are placed at the centre of the  $p_T$  interval and, for visibility, the points from two-particle  $Q$  cumulants and Lee-Yang zeros with product generating function are shifted horizontally. The vertical error bars represent the statistical uncertainty, the horizontal error bars correspond to the width of the bin (not shown for the shifted data points) and the open boxes are the systematic uncertainties. The  $p_T$  intervals used with the Lee-Yang zeros method are different with respect to the other methods. Upper panels: results from two-particle correlation flow methods (scalar product and two-particle  $Q$  cumulants) in the 0–10% (left) and 10–20% (right) centrality intervals. Lower panels: results in the 20–40% centrality interval from two-particle correlation flow methods (scalar product and two-particle  $Q$  cumulants) and from four-particle  $Q$  cumulants (left), and from four-particle  $Q$  cumulants and Lee-Yang zeros (right).

product or two-particle  $Q$  cumulants [52]. Moreover, since four-particle  $Q$  cumulants give comparable results as Lee-Yang zeros, one can conclude that non-flow correlations are almost completely removed at the 4<sup>th</sup> order. Finally, the central values of  $v_2^\mu$  obtained with four-particle  $Q$  cumulants or Lee-Yang zeros are systematically smaller than with two-particle correlation methods, although compatible within uncertainties. Such differences may indicate that initial fluctuations play a role in the development of the final momentum-space anisotropy.

### 3.4 Muon background subtraction

The subtraction of the muon background contribution to the measured  $v_2^\mu$  requires an estimate of the elliptic flow of muons from charged pion and kaon decays,  $v_2^{\mu\leftarrow\pi,K}$ , and of the background fraction,  $f^{\mu\leftarrow\pi,K}$  (see Eq. (2)). The determination of the  $v_2^{\mu\leftarrow\pi,K}$  coefficient requires two steps. First, the  $p_T$ - and  $\eta$ -differential  $v_2$  of charged particles measured in  $|\eta| < 2.5$  by the ATLAS Collaboration in Pb–Pb collisions [53] and the  $p_T$  distributions of charged pions and kaons measured in  $|y| < 0.8$  by the ALICE Collaboration in pp and Pb–Pb collisions [54, 55] are extrapolated to forward rapidity. Then, the  $p_T$  distributions of muons from charged pion and kaon decays, needed to estimate  $f^{\mu\leftarrow\pi,K}$  and  $v_2^{\mu\leftarrow\pi,K}$ , are

generated according to a simulation taking into account the decay kinematics and the effect of the front absorber.

The  $p_T$ - and  $\eta$ -differential elliptic flow of charged particles in  $|\eta| < 2.5$ ,  $v_2^{\text{ch}}$ , is extrapolated to forward rapidity using:

$$v_2^{\text{ch}}(p_T, \eta) = F(\eta) \cdot v_2^{\text{ch}}(p_T, 2 < |\eta| < 2.5), \quad (9)$$

where  $v_2^{\text{ch}}(p_T, 2 < |\eta| < 2.5)$  is the measured charged-particle elliptic flow in  $2 < |\eta| < 2.5$  with the event plane method. Since the  $v_2^{\text{ch}}(p_T)$  measured by the ATLAS Collaboration is affected by statistical fluctuations, it is assumed that in the interval  $10 < p_T < 20$  GeV/c, needed to simulate the decay muons up to  $p_T = 10$  GeV/c,  $v_2^{\text{ch}}$  remains constant with a value given by the one measured in the interval  $10 < p_T < 12$  GeV/c. The extrapolation factor  $F(\eta)$  is calculated by parameterizing the  $\eta$ -differential  $v_2^{\text{ch}}$  measured by the ATLAS Collaboration in various  $p_T$  intervals with a second order polynomial. In the interval  $7 < p_T < 20$  GeV/c, the ATLAS  $v_2^{\text{ch}}$  does not show a dependence on  $\eta$  in  $|\eta| < 2.5$ . Therefore, for  $p_T > 7$  GeV/c,  $F(\eta)$  is computed as the average between a flat extrapolation function and the extrapolation factor obtained with the parabolic parameterization in  $4 < p_T < 7$  GeV/c.

The mid-rapidity charged pion and kaon  $p_T$  distributions measured in Pb–Pb collisions are extrapolated to forward rapidity using the same strategy as in [21] and summarized in the following. Assuming that the nuclear modification factor  $R_{\text{AA}}^{\pi, \text{K}}$  of charged pions and kaons in Pb–Pb collisions does not depend on rapidity up to  $y = 4$  [21, 56], the  $p_T$  distributions of charged pions and kaons at forward rapidity can be expressed as:

$$\frac{dN_{\text{PbPb}}^{\pi, \text{K}}}{dp_T dy} = \langle T_{\text{AA}} \rangle \cdot \frac{d\sigma_{\text{pp}}^{\pi, \text{K}}}{dp_T dy} \cdot [R_{\text{AA}}^{\pi, \text{K}}(p_T)]_{y=0}, \quad (10)$$

where  $\langle T_{\text{AA}} \rangle$  is the average nuclear overlap function in centrality classes under study, estimated as described in [57]. The systematic uncertainty introduced by the assumption on  $R_{\text{AA}}^{\pi, \text{K}}$  will be discussed later. The rapidity extrapolation of the mid-rapidity pion and kaon  $p_T$ -differential cross sections measured in pp collisions [21, 58] is done according to:

$$\frac{d^2\sigma_{\text{pp}}^{\pi, \text{K}}}{dp_T dy} = \left[ \frac{d^2\sigma_{\text{pp}}^{\pi, \text{K}}}{dp_T dy} \right]_{y=0} \cdot \exp\left(\frac{-y^2}{2\sigma_y^2}\right), \quad (11)$$

$\sigma_y$  being estimated from Monte-Carlo event generators (see [21] for details).

The elliptic flow of muons from charged pion and kaon decays,  $v_2^{\mu \leftarrow \pi, \text{K}}$ , in  $2.5 < y < 4$  and in various centrality classes<sup>4</sup>, is obtained by means of fast simulations using  $v_2^{\text{ch}}(\eta, p_T)$  given by Eq. (9) and charged pion and kaon  $p_T$  distributions as obtained from Eq. (10)–(11). The absorber effect is accounted for by rejecting the pions and kaons that do not decay within a distance corresponding to one interaction length from the beginning of the absorber. The simulation was repeated twice, considering that charged particles are either all pions or all kaons. The estimated  $v_2^{\mu \leftarrow \pi, \text{K}}$  decreases with increasing  $p_T$  from about 0.085 at  $p_T = 3$  GeV/c to 0.035 at  $p_T = 10$  GeV/c in the 10% most central collisions. In the 20–40% centrality interval, the  $v_2^{\mu \leftarrow \pi, \text{K}}$  values vary between 0.19 ( $p_T = 3$  GeV/c) and 0.08 ( $p_T = 10$  GeV/c).

The background fraction,  $f^{\mu \leftarrow \pi, \text{K}}$ , is calculated as the ratio of the  $p_T$ -differential yield of muons from charged pion and kaon decays in  $2.5 < y < 4$  obtained in the simulation to the measured  $p_T$ -differential yield of inclusive muons. It decreases as  $p_T$  increases, from about 12% (15%) at  $p_T = 3$  GeV/c to 5% (7%) at  $p_T = 10$  GeV/c in the 0–10% (20–40%) centrality class.

The systematic uncertainties affecting the estimated  $v_2^{\mu \leftarrow \pi, \text{K}}$  are summarized in Table 2. They originate from i) the method used to measure the charged-particle  $v_2^{\text{ch}}$  in ATLAS, ii) the  $\eta$  and  $p_T$  extrapolation of

<sup>4</sup>The  $v_2^{\mu \leftarrow \pi, \text{K}}$  of muons from charged pion and kaon decays in the 20–40% centrality class is then obtained from the mean of the charged-particle  $v_2$  in 20–30% and 30–40% centrality classes, with an additional systematic uncertainty provided by the difference with respect to the results in these two centrality classes.

$v_2^{\text{ch}}$  and iii) the treatment of the charged-particle  $v_2^{\text{ch}}$  in the fast simulation procedure. As the event plane method was used for the  $v_2^{\text{ch}}$  measurement in ATLAS, the results range between the mean ( $\langle v_2^{\text{ch}} \rangle$ ) and R.M.S. ( $\sqrt{\langle (v_2^{\text{ch}})^2 \rangle}$ ) of the true  $v_2^{\text{ch}}$  values due to fluctuations, depending on the event plane resolution which varies with the collision centrality [49]. According to a Monte-Carlo Glauber model [49], the ratio  $\sqrt{\langle (v_2^{\text{ch}})^2 \rangle} / \langle v_2^{\text{ch}} \rangle$  is expected to vary from about 1.06 to 1.15. Consequently, a conservative systematic uncertainty of 15% is applied to account for this bias and is propagated to  $v_2^{\mu\leftarrow\pi,K}$ . The systematic uncertainty due to the  $\eta$  extrapolation of  $v_2^{\text{ch}}$  is evaluated using several fit functions (first and third order polynomials, and Gaussian function) in the region  $p_T < 7$  GeV/c, and for larger  $p_T$  values an additional systematic uncertainty due to the extrapolation procedure is considered. The latter is determined by comparing the results obtained with the two extrapolation functions used in the interval  $p_T > 7$  GeV/c. The systematic uncertainty due to the assumption on  $v_2^{\text{ch}}$  in the region  $p_T > 10$  GeV/c is estimated by varying  $v_2^{\text{ch}}$  between 0 and the value in  $10 < p_T < 12$  GeV/c in the fast simulations. Such uncertainty affects mainly the high  $p_T$  region ( $p_T > 7$  GeV/c). Finally, the systematic uncertainty obtained by treating charged particles separately as pions and kaons is found to be negligible. The various systematic uncertainty sources are propagated to the estimated  $v_2^{\mu\leftarrow\pi,K}$  and added in quadrature.

Source	Systematic uncertainty (%)
Input $v_2^{\text{ch}}$ bias	9
$v_2^{\text{ch}}$ $\eta$ extrapolation	9–12
$v_2^{\text{ch}}$ high $p_T$ extrapolation	13–15
$\pi$ and K in fast simulations	< 1

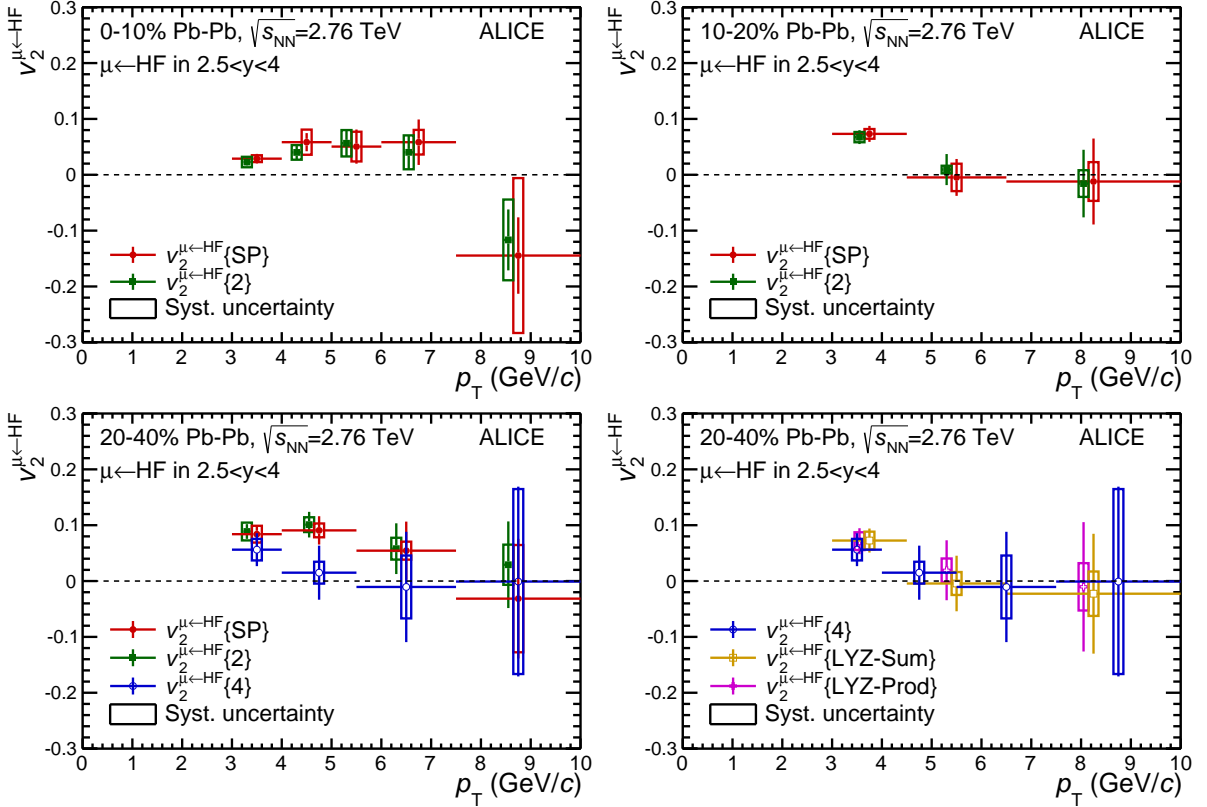

**Table 2:** Systematic uncertainty sources affecting the estimated  $v_2^{\mu\leftarrow\pi,K}$  for the interval  $3 < p_T < 10$  GeV/c. They are stated as a percentage of the  $v_2$  value. The given range reflects the dependence on the collision centrality.

The systematic uncertainty on  $f^{\mu\leftarrow\pi,K}$ , detailed in [21], includes the uncertainty on the generated  $p_T$  distributions of muons from charged pion and kaon decays, and the uncertainty on the measured inclusive muon  $p_T$  distributions. The former originates from the input charged pion and kaon distributions, the rapidity extrapolation and the absorber effect. The systematic uncertainty on the measured inclusive muon yields contains the systematic uncertainty on detector response, residual mis-alignment and centrality dependence of the efficiency. This gives a total systematic uncertainty on  $f^{\mu\leftarrow\pi,K}$  of about 21% in the interval  $3 < p_T < 4.5$  GeV/c with almost no dependence on the collision centrality. Finally, as done for the measurement of the heavy-flavour decay muon  $R_{AA}$  [21], the systematic uncertainty due to the unknown suppression of charged particles at forward rapidity is calculated by varying  $f^{\mu\leftarrow\pi,K}$  from 0 to two times the estimated value. This corresponds to a variation of  $R_{AA}^{\pi,K}(p_T)$  at forward rapidity from 0 up to two times  $[R_{AA}^{\pi,K}(p_T)]_{y=0}$ . This systematic uncertainty amounts to 10–30% in the interval  $3 < p_T < 4.5$  GeV/c, depending on the collision centrality and the flow analysis method.

Finally, the systematic uncertainty on the elliptic flow of muons from heavy-flavour decays,  $v_2^{\mu\leftarrow\text{HF}}$ , contains two contributions: the systematic uncertainties on  $v_2^\mu$ ,  $v_2^{\mu\leftarrow\pi,K}$  and  $f^{\mu\leftarrow\pi,K}$  propagated according to the definition of  $v_2^{\mu\leftarrow\text{HF}}$  given in Eq. (2), and the systematic uncertainty due to the unknown suppression of charged particles at forward rapidity. The final systematic uncertainty on  $v_2^{\mu\leftarrow\text{HF}}$  is obtained by adding in quadrature the two contributions. It amounts to about 12%–36% in the interval  $3 < p_T < 4.5$  GeV/c, depending on the collision centrality and the flow analysis method.

## 4 Results

Figure 2 presents the  $p_T$ -differential elliptic flow of muons from heavy-flavour hadron decays,  $v_2^{\mu\leftarrow\text{HF}}$ , calculated with Eq. (2). The results are shown for the 0–10% (upper, left), 10–20% (upper, right) and 20–40% (bottom) centrality classes using the same flow methods as for the measurement of the inclusive

**Fig. 2:**  $p_T$ -differential elliptic flow of muons from heavy-flavour decays,  $v_2^{\mu \leftarrow \text{HF}}$ , in  $2.5 < y < 4$  and various centrality intervals, in Pb–Pb collisions at  $\sqrt{s_{\text{NN}}} = 2.76$  TeV. The symbols are placed at the centre of the  $p_T$  interval and, for visibility, the points from two-particle  $Q$  cumulants and Lee-Yang zeros with product generating function are shifted horizontally. The meaning of the symbols is the same as in Fig. 1. The horizontal error bars are not plotted for shifted data points. The  $p_T$  intervals used with the Lee-Yang zeros method are different with respect to the other methods. Upper panels: results from two-particle correlation flow methods (scalar product and two-particle  $Q$  cumulants) in the 0–10% (left) and 10–20% (right) centrality intervals. Lower panels: results in the 20–40% centrality interval from two-particle correlation flow methods (scalar product and two-particle  $Q$  cumulants) and from four-particle  $Q$  cumulants (left), and from four-particle  $Q$  cumulants and Lee-Yang zeros (right). See the text for details.

muon elliptic flow (Fig. 1). When comparing the results to those obtained for inclusive muons (Fig. 1), one can notice that  $v_2^{\mu \leftarrow \text{HF}}$  and  $v_2^\mu$  are similar due to the small background fraction (5% to 15%) in the  $p_T$  interval 3–10 GeV/c. The differences between the various methods are similar to those discussed for the measurement of the inclusive muon  $v_2^\mu$  i.e. i) scalar product and two-particle  $Q$  cumulants give compatible results, ii) consistent results are also found with four-particle  $Q$  cumulants and Lee-Yang zeros, and iii) the  $v_2^{\mu \leftarrow \text{HF}}$  values extracted from these multi-particle correlation methods are smaller, although still compatible within uncertainties, than the ones obtained with two-particle correlation methods. As mentioned in Section 3.3, such differences are expected if initial-state fluctuations play a role in the development of the final momentum-space anisotropy.

A positive  $v_2^{\mu \leftarrow \text{HF}}$  is observed at intermediate  $p_T$  for the 20–40% and 10–20% centrality classes with a significance larger than  $3\sigma$  when combining statistical and systematic uncertainties. In the 20–40% centrality class, the values of the significance in the interval  $3 < p_T < 4$  GeV/c ( $4 < p_T < 5.5$  GeV/c) are  $4\sigma$  ( $3.2\sigma$ ) and  $4.3\sigma$  ( $3.8\sigma$ ) with scalar product and two-particle  $Q$  cumulants, respectively. In the 10–20% centrality class and in the interval  $3 < p_T < 4.5$  GeV/c, the values of the significance correspond to  $4.4\sigma$  both with scalar product and two-particle  $Q$  cumulants. This behaviour results from the interplay between the significant interaction of heavy quarks with the expanding medium and the path-length

**Fig. 3:** Elliptic flow of muons from heavy-flavour hadron decays as a function of the collision centrality in  $2.5 < y < 4$  and  $3 < p_T < 10$  GeV/c, in Pb–Pb collisions at  $\sqrt{s_{\text{NN}}} = 2.76$  TeV. The results are obtained with scalar product and two-particle  $Q$  cumulants. Vertical bars (open boxes) represent the statistical (systematic) uncertainty, the horizontal error bars correspond to the width of the centrality bin. For visibility, the points from scalar product are shifted horizontally and the horizontal error bars are not plotted

dependence of in-medium parton energy loss [29, 30]. The  $v_2^{\mu\leftarrow\text{HF}}$  of muons from heavy-flavour hadron decays decreases with increasing  $p_T$  and becomes compatible with zero in the high  $p_T$  region.

Figure 3 shows the centrality dependence of the  $p_T$ -integrated ( $3 < p_T < 10$  GeV/c) elliptic flow of muons from heavy-flavour hadron decays. It is investigated with scalar product and two-particle  $Q$  cumulants, which can be applied in a wider event-multiplicity (i.e. centrality) interval compared to multi-particle correlation methods. A significant decrease of the  $v_2$  magnitude towards central collisions is observed. This is expected from the decrease of the initial spatial anisotropy from semi-central to central collisions.

ALICE has measured the elliptic flow of prompt D mesons in  $|y| < 0.8$  in three centrality classes in the interval 0–50% with various two-particle correlation methods [33, 34]. Similar trends as those reported here for muons from heavy-flavour decays are observed, although in different  $p_T$  and rapidity intervals. In particular, a positive  $v_2$  was observed for D mesons in semi-central collisions in  $2 < p_T < 6$  GeV/c.

The positive elliptic flow of muons from heavy-flavour hadron decays has been observed in a  $p_T$  interval from 3 to about 5 GeV/c where the charm contribution is expected to be dominant with respect to the beauty component according to perturbative QCD calculations [21]. This measurement supports the interpretation of the  $J/\psi$  positive  $v_2$  at forward rapidity [35] in terms of a significant contribution to  $J/\psi$  production from recombination of flowing charm quarks in the deconfined medium.

## 5 Comparison with models

The results presented in this publication may constrain models describing the interactions of heavy quarks with the medium via elastic (collisional) and inelastic (radiative) processes, and in particular the parton energy loss dependence on the path-length within the medium.

**Fig. 4:** Left:  $p_T$ -differential elliptic flow of muons from heavy-flavour hadron decays in  $2.5 < y < 4$ , in Pb–Pb collisions at  $\sqrt{s_{\text{NN}}} = 2.76$  TeV for the centrality class 20–40% compared to various transport model predictions: MC@sHQ + EPOS [59–61], TAMU [62] and BAMPS [63–65]. The TAMU model is shown with a theoretical uncertainty band. Right:  $p_T$ -differential  $R_{\text{AA}}$  of muons from heavy-flavour hadron decays for the centrality class 0–10% from [21] compared to the same models as for  $v_2^{\mu\leftarrow\text{HF}}$ .

The elliptic flow coefficient and the nuclear modification factor of muons from heavy-flavour hadron decays [21] are compared to the following three models. The MC@sHQ + EPOS transport model [59] treats the propagation of heavy quarks in the medium including collisional and radiative energy loss, within a  $3 + 1$  dimensional fluid dynamical expansion based on the EPOS model [60, 61]. The hadronization of heavy quarks takes place at the transition temperature via recombination at low  $p_T$  and fragmentation at intermediate and high  $p_T$ . The final-state hadronic interactions are not included in the model. TAMU [62] is a transport model including only collisional processes via the Langevin equation. The hydrodynamical expansion is constrained by  $p_T$  spectra and elliptic flow data of light-flavour hadrons. The hadronization is modeled including a component of recombination of heavy quarks with light-flavour hadrons in the QGP. The diffusion of heavy-flavour mesons in the hadronic phase is also included. BAMPS [63–65] is a partonic transport model based on the Boltzmann approach to multi-parton scatterings. It includes collisional processes with a running strong coupling constant. The lack of radiative contributions is accounted for by scaling the binary cross section with a correction factor, tuned to describe the nuclear modification factor and elliptic flow results at RHIC energies. Vacuum fragmentation functions are used for the hadronization.

Figure 4 (left) shows that the  $p_T$ -differential elliptic flow of muons from heavy-flavour hadron decays in the 20–40% centrality class is described reasonably well by the three models. However, the BAMPS model tends to slightly underestimate the  $R_{\text{AA}}$  of muons from heavy-flavour decays in the 10% most central collisions, while the MC@sHQ+EPOS model tends to overestimate it. The TAMU model describes the  $R_{\text{AA}}$  measurement over the entire  $p_T$  interval within uncertainties and tends to slightly underestimate the  $v_2^{\mu\leftarrow\text{HF}}$  measurement in the low  $p_T$  region. This indicates that it is challenging to simultaneously describe the strong suppression of high- $p_T$  muons from heavy-flavour hadron decays in central collisions and the azimuthal anisotropy in semi-central collisions. Similar trends are also observed in the mid-rapidity region from the comparison of the  $R_{\text{AA}}$  and  $v_2$  of D mesons with model calculations [34].

## 6 Conclusions

In summary, we have reported on a measurement of the elliptic flow of muons from heavy-flavour hadron decays at forward rapidity in central and semi-central Pb–Pb collisions at  $\sqrt{s_{\text{NN}}} = 2.76$  TeV with the ALICE detector at the LHC.

Measurements have been carried out using several methods which exhibit different sensitivity to initial-

state fluctuations and non-flow correlations. The systematic comparison of scalar product, two- and four-particle  $Q$  cumulants and Lee-Yang zeros helps in understanding the processes that build up the observed differences between two-particle correlation methods and multi-particle correlation methods and suggests that flow fluctuations are significant.

The magnitude of the elliptic flow of muons from heavy-flavour hadron decays increases from central to semi-central collisions and decreases with increasing  $p_T$ , becoming compatible with zero at high  $p_T$ . The results indicate a positive elliptic flow with the scalar product and two-particle  $Q$  cumulants in semi-central collisions (10–20% and 20–40% centrality classes) for the  $p_T$  interval from 3 to about 5 GeV/ $c$  with a significance larger than  $3\sigma$ . The data are described by transport model calculations within uncertainties, although a simultaneous description of  $R_{AA}$  and  $v_2$  remains a challenge. The results reported in this Letter in various centrality classes may provide further important constraints to the models.

## Acknowledgements

The ALICE Collaboration would like to thank all its engineers and technicians for their invaluable contributions to the construction of the experiment and the CERN accelerator teams for the outstanding performance of the LHC complex. The ALICE Collaboration gratefully acknowledges the resources and support provided by all Grid centres and the Worldwide LHC Computing Grid (WLCG) collaboration. The ALICE Collaboration acknowledges the following funding agencies for their support in building and running the ALICE detector: State Committee of Science, World Federation of Scientists (WFS) and Swiss Fonds Kidagan, Armenia, Conselho Nacional de Desenvolvimento Científico e Tecnológico (CNPq), Financiadora de Estudos e Projetos (FINEP), Fundação de Amparo à Pesquisa do Estado de São Paulo (FAPESP); National Natural Science Foundation of China (NSFC), the Chinese Ministry of Education (CMOE) and the Ministry of Science and Technology of China (MSTC); Ministry of Education and Youth of the Czech Republic; Danish Natural Science Research Council, the Carlsberg Foundation and the Danish National Research Foundation; The European Research Council under the European Community's Seventh Framework Programme; Helsinki Institute of Physics and the Academy of Finland; French CNRS-IN2P3, the 'Region Pays de Loire', 'Region Alsace', 'Region Auvergne' and CEA, France; German Bundesministerium für Bildung, Wissenschaft, Forschung und Technologie (BMBF) and the Helmholtz Association; General Secretariat for Research and Technology, Ministry of Development, Greece; Hungarian Országos Tudományos Kutatási Alapprogramok (OTKA) and National Office for Research and Technology (NKTH); Department of Atomic Energy and Department of Science and Technology of the Government of India; Istituto Nazionale di Fisica Nucleare (INFN) and Centro Fermi - Museo Storico della Fisica e Centro Studi e Ricerche "Enrico Fermi", Italy; MEXT Grant-in-Aid for Specially Promoted Research, Japan; Joint Institute for Nuclear Research, Dubna; National Research Foundation of Korea (NRF); Consejo Nacional de Ciencia y Tecnología (CONACYT), Dirección General de Asuntos del Personal Académico (DGAPA), México; Amérique Latine Formation académique European Commission (ALFA-EC) and the EPLANET Program (European Particle Physics Latin American Network) Stichting voor Fundamenteel Onderzoek der Materie (FOM) and the Nederlandse Organisatie voor Wetenschappelijk Onderzoek (NWO), Netherlands; Research Council of Norway (NFR); National Science Centre, Poland; Ministry of National Education/Institute for Atomic Physics and Consiliul Național al Cercetării Științifice - Executive Agency for Higher Education Research Development and Innovation Funding (CNCS-UEFISCDI) - Romania; Ministry of Education and Science of Russian Federation, Russian Academy of Sciences, Russian Federal Agency of Atomic Energy, Russian Federal Agency for Science and Innovations and The Russian Foundation for Basic Research; Ministry of Education of Slovakia; Department of Science and Technology, South Africa; Centro de Investigaciones Energéticas, Medioambientales y Tecnológicas (CIEMAT), E-Infrastructure shared between Europe and Latin America (EELA), Ministerio de Economía y Competitividad (MINECO) of Spain, Xunta de Galicia (Consellería de Educación), Centro de Aplicaciones Tecnológicas y Desarrollo Nuclear (CEADEN),

## Affiliation notes

<sup>i</sup> Deceased

<sup>ii</sup> Also at: M.V. Lomonosov Moscow State University, D.V. Skobeltsyn Institute of Nuclear Physics, Moscow, Russia

<sup>iii</sup> Also at: University of Kansas, Lawrence, Kansas, United States

## Collaboration Institutes

- <sup>1</sup> A.I. Alikhanyan National Science Laboratory (Yerevan Physics Institute) Foundation, Yerevan, Armenia
- <sup>2</sup> Benemérita Universidad Autónoma de Puebla, Puebla, Mexico
- <sup>3</sup> Bogolyubov Institute for Theoretical Physics, Kiev, Ukraine
- <sup>4</sup> Bose Institute, Department of Physics and Centre for Astroparticle Physics and Space Science (CAPSS), Kolkata, India
- <sup>5</sup> Budker Institute for Nuclear Physics, Novosibirsk, Russia
- <sup>6</sup> California Polytechnic State University, San Luis Obispo, California, United States
- <sup>7</sup> Central China Normal University, Wuhan, China
- <sup>8</sup> Centre de Calcul de l'IN2P3, Villeurbanne, France
- <sup>9</sup> Centro de Aplicaciones Tecnológicas y Desarrollo Nuclear (CEADEN), Havana, Cuba
- <sup>10</sup> Centro de Investigaciones Energéticas Medioambientales y Tecnológicas (CIEMAT), Madrid, Spain
- <sup>11</sup> Centro de Investigación y de Estudios Avanzados (CINVESTAV), Mexico City and Mérida, Mexico

- 12 Centro Fermi - Museo Storico della Fisica e Centro Studi e Ricerche “Enrico Fermi”, Rome, Italy
- 13 Chicago State University, Chicago, Illinois, USA
- 14 China Institute of Atomic Energy, Beijing, China
- 15 Commissariat à l’Energie Atomique, IRFU, Saclay, France
- 16 COMSATS Institute of Information Technology (CIIT), Islamabad, Pakistan
- 17 Departamento de Física de Partículas and IGFAE, Universidad de Santiago de Compostela, Santiago de Compostela, Spain
- 18 Department of Physics and Technology, University of Bergen, Bergen, Norway
- 19 Department of Physics, Aligarh Muslim University, Aligarh, India
- 20 Department of Physics, Ohio State University, Columbus, Ohio, United States
- 21 Department of Physics, Sejong University, Seoul, South Korea
- 22 Department of Physics, University of Oslo, Oslo, Norway
- 23 Dipartimento di Elettrotecnica ed Elettronica del Politecnico, Bari, Italy
- 24 Dipartimento di Fisica dell’Università ‘La Sapienza’ and Sezione INFN Rome, Italy
- 25 Dipartimento di Fisica dell’Università and Sezione INFN, Cagliari, Italy
- 26 Dipartimento di Fisica dell’Università and Sezione INFN, Trieste, Italy
- 27 Dipartimento di Fisica dell’Università and Sezione INFN, Turin, Italy
- 28 Dipartimento di Fisica e Astronomia dell’Università and Sezione INFN, Bologna, Italy
- 29 Dipartimento di Fisica e Astronomia dell’Università and Sezione INFN, Catania, Italy
- 30 Dipartimento di Fisica e Astronomia dell’Università and Sezione INFN, Padova, Italy
- 31 Dipartimento di Fisica ‘E.R. Caianiello’ dell’Università and Gruppo Collegato INFN, Salerno, Italy
- 32 Dipartimento di Scienze e Innovazione Tecnologica dell’Università del Piemonte Orientale and Gruppo Collegato INFN, Alessandria, Italy
- 33 Dipartimento Interateneo di Fisica ‘M. Merlin’ and Sezione INFN, Bari, Italy
- 34 Division of Experimental High Energy Physics, University of Lund, Lund, Sweden
- 35 Eberhard Karls Universität Tübingen, Tübingen, Germany
- 36 European Organization for Nuclear Research (CERN), Geneva, Switzerland
- 37 Excellence Cluster Universe, Technische Universität München, Munich, Germany
- 38 Faculty of Engineering, Bergen University College, Bergen, Norway
- 39 Faculty of Mathematics, Physics and Informatics, Comenius University, Bratislava, Slovakia
- 40 Faculty of Nuclear Sciences and Physical Engineering, Czech Technical University in Prague, Prague, Czech Republic
- 41 Faculty of Science, P.J. Šafárik University, Košice, Slovakia
- 42 Faculty of Technology, Buskerud and Vestfold University College, Vestfold, Norway
- 43 Frankfurt Institute for Advanced Studies, Johann Wolfgang Goethe-Universität Frankfurt, Frankfurt, Germany
- 44 Gangneung-Wonju National University, Gangneung, South Korea
- 45 Gauhati University, Department of Physics, Guwahati, India
- 46 Helsinki Institute of Physics (HIP), Helsinki, Finland
- 47 Hiroshima University, Hiroshima, Japan
- 48 Indian Institute of Technology Bombay (IIT), Mumbai, India
- 49 Indian Institute of Technology Indore, Indore (IITI), India
- 50 Inha University, Incheon, South Korea
- 51 Institut de Physique Nucléaire d’Orsay (IPNO), Université Paris-Sud, CNRS-IN2P3, Orsay, France
- 52 Institut für Informatik, Johann Wolfgang Goethe-Universität Frankfurt, Frankfurt, Germany
- 53 Institut für Kernphysik, Johann Wolfgang Goethe-Universität Frankfurt, Frankfurt, Germany
- 54 Institut für Kernphysik, Westfälische Wilhelms-Universität Münster, Münster, Germany
- 55 Institut Pluridisciplinaire Hubert Curien (IPHC), Université de Strasbourg, CNRS-IN2P3, Strasbourg, France
- 56 Institute for Nuclear Research, Academy of Sciences, Moscow, Russia
- 57 Institute for Subatomic Physics of Utrecht University, Utrecht, Netherlands
- 58 Institute for Theoretical and Experimental Physics, Moscow, Russia
- 59 Institute of Experimental Physics, Slovak Academy of Sciences, Košice, Slovakia
- 60 Institute of Physics, Academy of Sciences of the Czech Republic, Prague, Czech Republic
- 61 Institute of Physics, Bhubaneswar, India
- 62 Institute of Space Science (ISS), Bucharest, Romania

- 63 Instituto de Ciencias Nucleares, Universidad Nacional Autónoma de México, Mexico City, Mexico
- 64 Instituto de Física, Universidad Nacional Autónoma de México, Mexico City, Mexico
- 65 iThemba LABS, National Research Foundation, Somerset West, South Africa
- 66 Joint Institute for Nuclear Research (JINR), Dubna, Russia
- 67 Konkuk University, Seoul, South Korea
- 68 Korea Institute of Science and Technology Information, Daejeon, South Korea
- 69 KTO Karatay University, Konya, Turkey
- 70 Laboratoire de Physique Corpusculaire (LPC), Clermont Université, Université Blaise Pascal, CNRS–IN2P3, Clermont-Ferrand, France
- 71 Laboratoire de Physique Subatomique et de Cosmologie, Université Grenoble-Alpes, CNRS-IN2P3, Grenoble, France
- 72 Laboratori Nazionali di Frascati, INFN, Frascati, Italy
- 73 Laboratori Nazionali di Legnaro, INFN, Legnaro, Italy
- 74 Lawrence Berkeley National Laboratory, Berkeley, California, United States
- 75 Lawrence Livermore National Laboratory, Livermore, California, United States
- 76 Moscow Engineering Physics Institute, Moscow, Russia
- 77 National Centre for Nuclear Studies, Warsaw, Poland
- 78 National Institute for Physics and Nuclear Engineering, Bucharest, Romania
- 79 National Institute of Science Education and Research, Bhubaneswar, India
- 80 Niels Bohr Institute, University of Copenhagen, Copenhagen, Denmark
- 81 Nikhef, Nationaal instituut voor subatomaire fysica, Amsterdam, Netherlands
- 82 Nuclear Physics Group, STFC Daresbury Laboratory, Daresbury, United Kingdom
- 83 Nuclear Physics Institute, Academy of Sciences of the Czech Republic, Řež u Prahy, Czech Republic
- 84 Oak Ridge National Laboratory, Oak Ridge, Tennessee, United States
- 85 Petersburg Nuclear Physics Institute, Gatchina, Russia
- 86 Physics Department, Creighton University, Omaha, Nebraska, United States
- 87 Physics Department, Panjab University, Chandigarh, India
- 88 Physics Department, University of Athens, Athens, Greece
- 89 Physics Department, University of Cape Town, Cape Town, South Africa
- 90 Physics Department, University of Jammu, Jammu, India
- 91 Physics Department, University of Rajasthan, Jaipur, India
- 92 Physik Department, Technische Universität München, Munich, Germany
- 93 Physikalisches Institut, Ruprecht-Karls-Universität Heidelberg, Heidelberg, Germany
- 94 Purdue University, West Lafayette, Indiana, United States
- 95 Pusan National University, Pusan, South Korea
- 96 Research Division and ExtreMe Matter Institute EMMI, GSI Helmholtzzentrum für Schwerionenforschung, Darmstadt, Germany
- 97 Rudjer Bošković Institute, Zagreb, Croatia
- 98 Russian Federal Nuclear Center (VNIIEF), Sarov, Russia
- 99 Russian Research Centre Kurchatov Institute, Moscow, Russia
- 100 Saha Institute of Nuclear Physics, Kolkata, India
- 101 School of Physics and Astronomy, University of Birmingham, Birmingham, United Kingdom
- 102 Sección Física, Departamento de Ciencias, Pontificia Universidad Católica del Perú, Lima, Peru
- 103 Sezione INFN, Bari, Italy
- 104 Sezione INFN, Bologna, Italy
- 105 Sezione INFN, Cagliari, Italy
- 106 Sezione INFN, Catania, Italy
- 107 Sezione INFN, Padova, Italy
- 108 Sezione INFN, Rome, Italy
- 109 Sezione INFN, Trieste, Italy
- 110 Sezione INFN, Turin, Italy
- 111 SSC IHEP of NRC Kurchatov institute, Protvino, Russia
- 112 SUBATECH, Ecole des Mines de Nantes, Université de Nantes, CNRS-IN2P3, Nantes, France
- 113 Suranaree University of Technology, Nakhon Ratchasima, Thailand
- 114 Technical University of Košice, Košice, Slovakia
- 115 Technical University of Split FESB, Split, Croatia

- 116 The Henryk Niewodniczanski Institute of Nuclear Physics, Polish Academy of Sciences, Cracow, Poland
- 117 The University of Texas at Austin, Physics Department, Austin, Texas, USA
- 118 Universidad Autónoma de Sinaloa, Culiacán, Mexico
- 119 Universidade de São Paulo (USP), São Paulo, Brazil
- 120 Universidade Estadual de Campinas (UNICAMP), Campinas, Brazil
- 121 University of Houston, Houston, Texas, United States
- 122 University of Jyväskylä, Jyväskylä, Finland
- 123 University of Liverpool, Liverpool, United Kingdom
- 124 University of Tennessee, Knoxville, Tennessee, United States
- 125 University of the Witwatersrand, Johannesburg, South Africa
- 126 University of Tokyo, Tokyo, Japan
- 127 University of Tsukuba, Tsukuba, Japan
- 128 University of Zagreb, Zagreb, Croatia
- 129 Université de Lyon, Université Lyon 1, CNRS/IN2P3, IPN-Lyon, Villeurbanne, France
- 130 V. Fock Institute for Physics, St. Petersburg State University, St. Petersburg, Russia
- 131 Variable Energy Cyclotron Centre, Kolkata, India
- 132 Warsaw University of Technology, Warsaw, Poland
- 133 Wayne State University, Detroit, Michigan, United States
- 134 Wigner Research Centre for Physics, Hungarian Academy of Sciences, Budapest, Hungary
- 135 Yale University, New Haven, Connecticut, United States
- 136 Yonsei University, Seoul, South Korea
- 137 Zentrum für Technologietransfer und Telekommunikation (ZTT), Fachhochschule Worms, Worms, Germany
