# Running of the top quark mass from proton-proton collisions at $\sqrt{s} = 13 \text{ TeV}$

The CMS Collaboration<sup>\*</sup>

## Abstract

The running of the top quark mass is experimentally investigated for the first time. The mass of the top quark in the modified minimal subtraction ( $\overline{\text{MS}}$ ) renormalization scheme is extracted from a comparison of the differential top quark-antiquark ( $t\bar{t}$ ) cross section as a function of the invariant mass of the  $t\bar{t}$  system to next-to-leading-order theoretical predictions. The differential cross section is determined at the parton level by means of a maximum-likelihood fit to distributions of final-state observables. The analysis is performed using  $t\bar{t}$  candidate events in the  $e^\pm\mu^\mp$  channel in proton-proton collision data at a centre-of-mass energy of 13 TeV recorded by the CMS detector at the CERN LHC in 2016, corresponding to an integrated luminosity of  $35.9 \text{ fb}^{-1}$ . The extracted running is found to be compatible with the scale dependence predicted by the corresponding renormalization group equation. In this analysis, the running is probed up to a scale of the order of 1 TeV.

*Submitted to Physics Letters B*

## 1 Introduction

Beyond leading order in perturbation theory, the fundamental parameters of the quantum chromodynamics (QCD) Lagrangian, i.e. the strong coupling constant  $\alpha_S$  and the quark masses, are subject to renormalization. As a result, these parameters depend on the scale at which they are evaluated. The evolution of  $\alpha_S$  and of the quark masses as a function of the scale, commonly referred to as running, is described by renormalization group equations (RGEs). The running of  $\alpha_S$  was experimentally verified on a wide range of scales using jet production in electron-proton, positron-proton, electron-positron, proton-antiproton, and proton-proton (pp) collisions, as summarized, e.g. in Refs. [1, 2]. In the modified minimal subtraction ( $\overline{\text{MS}}$ ) renormalization scheme, the dependence of a quark mass  $m$  on the scale  $\mu$  is described by the RGE

$$\mu^2 \frac{dm(\mu)}{d\mu^2} = -\gamma(\alpha_S(\mu)) m(\mu), \quad (1)$$

where  $\gamma(\alpha_S(\mu))$  is the mass anomalous dimension, which is known up to five-loop order in perturbative QCD [3, 4]. The solution of Eq. 1 can be used to obtain the quark mass at any scale  $\mu$  from the mass evaluated at an initial scale  $\mu_0$ . The running of the b quark mass was demonstrated [5] using data from various experiments at the CERN LEP [6–9], SLAC SLC [10], and DESY HERA [11]. Measurements of charm quark pair production in deep inelastic scattering at the DESY HERA were used to determine the running of the charm quark mass [12]. These measurements represent a powerful test of the validity of perturbative QCD. Furthermore, RGEs can be modified by contributions from physics beyond the standard model, e.g. in the context of supersymmetric theories [13].

This Letter describes the first experimental investigation of the running of the top quark mass,  $m_t$ , as defined in the  $\overline{\text{MS}}$  scheme. The running of  $m_t$  is extracted from a measurement of the differential top quark-antiquark pair production cross section,  $\sigma_{t\bar{t}}$ , as a function of the invariant mass of the  $t\bar{t}$  system,  $m_{t\bar{t}}$ . The differential cross section,  $d\sigma_{t\bar{t}}/dm_{t\bar{t}}$ , is determined at the parton level by means of a maximum-likelihood fit to distributions of final-state observables using  $t\bar{t}$  candidate events in the  $e^\pm\mu^\mp$  final state, extending the method described in Ref. [14]. This method allows the systematic uncertainties to be constrained simultaneously with the differential cross section in the visible phase space. In this analysis, the parton level is defined before QCD radiation from the parton shower, which allows a direct comparison with fixed-order theoretical predictions. The measurement is performed using pp collision data at  $\sqrt{s} = 13$  TeV recorded by the CMS detector at the CERN LHC in 2016, corresponding to an integrated luminosity of  $35.9 \text{ fb}^{-1}$ . The running mass,  $m_t(\mu)$ , is extracted at next-to-leading order (NLO) as a function of  $m_{t\bar{t}}$  by comparing fixed-order theoretical predictions at NLO to the measured  $d\sigma_{t\bar{t}}/dm_{t\bar{t}}$ . The running of  $m_t$  is probed up to a scale of the order of 1 TeV.

## 2 The CMS detector and Monte Carlo simulation

The central feature of the CMS apparatus is a superconducting solenoid of 6 m internal diameter, providing a magnetic field of 3.8 T. Within the solenoid volume are a silicon pixel and strip tracker, a lead tungstate crystal electromagnetic calorimeter (ECAL), and a brass and scintillator hadron calorimeter, each composed of a barrel and two endcap sections. Forward calorimeters extend the pseudorapidity coverage provided by the barrel and endcap detectors. Muons are detected in gas-ionization chambers embedded in the steel flux-return yoke outside the solenoid. A two-level trigger system selects events of interest for offline analysis [15]. A more detailed description of the CMS detector, together with a definition of the coordinate system used and the relevant kinematic variables, can be found in Ref. [16].

The particle-flow (PF) algorithm [17] aims to reconstruct and identify each individual particle in an event, with an optimized combination of information from the various elements of the CMS detector. The energy of electrons is determined from a combination of the electron momentum at the primary interaction vertex as determined by the tracker, the energy of the corresponding ECAL cluster, and the energy sum of all bremsstrahlung photons spatially compatible with originating from the electron track [18]. The energy of muons is obtained from the curvature of the corresponding track [19]. Jets are reconstructed from the PF candidates using the anti- $k_T$  clustering algorithm with a distance parameter of 0.4 [20, 21], and the jet momentum is determined as the vectorial sum of all particle momenta in the jet. The missing transverse momentum vector is computed as the negative vector sum of the transverse momenta ( $p_T$ ) of all the PF candidates in an event. Jets originating from the hadronization of b quarks (b jets) are identified (b tagged) using the combined secondary vertex [22] algorithm, using a working point that corresponds to an average b tagging efficiency of 41% and an average misidentification probability for light-flavour jets of 0.1% [22].

In this analysis, the same Monte Carlo (MC) simulations as in Ref. [14] are used. In particular,  $t\bar{t}$  events are simulated using the POWHEG v2 [23–26] NLO MC generator interfaced to PYTHIA 8.202 [27] for the modelling of the parton shower and using the CUETP8M2T4 underlying event tune [28, 29], and the proton structure is described by means of the NNPDF3.0 [30] parton distribution function (PDF) set. Background processes include single top quark production, Drell–Yan events, W+jets production, and diboson events, while the contribution from QCD multijet production is found to be negligible. Contributions from all background processes are estimated from simulation and are normalized to their predicted cross section. Details on the MC simulation of the backgrounds can be found in Ref. [14].

### 3 Event selection and systematic uncertainties

Events are collected using a combination of dilepton and single lepton triggers which require either one electron with  $p_T > 12 \text{ GeV}$  and one muon with  $p_T > 23 \text{ GeV}$ , or one electron with  $p_T > 23 \text{ GeV}$  and one muon with  $p_T > 8 \text{ GeV}$ , or one electron with  $p_T > 27 \text{ GeV}$ , or one muon with  $p_T > 24 \text{ GeV}$ . In the offline analysis, tight isolation requirements are applied to electrons and muons based on the ratio of the scalar sum of the  $p_T$  of neighbouring PF candidates to the  $p_T$  of the lepton candidate. Events are then required to contain at least one electron and one muon of opposite charge with  $p_T > 25 \text{ GeV}$  for the leading and  $p_T > 20 \text{ GeV}$  for the subleading lepton. In events with more than two leptons, the two leptons of opposite charge with the highest  $p_T$  are considered. Further details on the events selection can be found in Ref. [14].

In events with at least two jets with  $p_T > 30 \text{ GeV}$ , the kinematic properties of the  $t\bar{t}$  system are estimated by means of the analytic kinematic reconstruction algorithm described in Ref. [31]. The kinematic reconstruction algorithm examines all possible combinations of reconstructed jets and leptons and solves a system of equations under the assumptions that the invariant mass of the reconstructed W boson is  $80.4 \text{ GeV}$  and that the missing transverse momentum originates solely from the two neutrinos coming from the leptonic decays of the W bosons. In addition, the kinematic reconstruction algorithm requires an assumption on the value of the top quark mass,  $m_t^{\text{kin}}$ . Any possible bias due to the choice of this value is avoided by incorporating the dependence on  $m_t^{\text{kin}}$  in the fit described in Section 4. To estimate this dependence, the kinematic reconstruction and the event selection are repeated with three different choices of  $m_t^{\text{kin}}$ , corresponding to  $169.5$ ,  $172.5$ , and  $175.5 \text{ GeV}$ , and the top quark mass used in the MC simulation,  $m_t^{\text{MC}}$ , is varied accordingly. The parameter  $m_t^{\text{kin}} = m_t^{\text{MC}}$  is then treated as a free parameter of the fit.

The sources of systematic uncertainties can be classified as experimental and modelling uncertainties. Experimental uncertainties are related to the corrections applied to the MC simulation. These include uncertainties associated with trigger and lepton identification efficiencies, jet energy scale [32] and resolution [33], lepton energy scales, b tagging efficiencies [22], and the uncertainty in the integrated luminosity [34]. Modelling uncertainties are related to the simulation of the  $t\bar{t}$  signal, and include matrix-element scale variations in the POWHEG simulation [35, 36], scale variations in the parton shower [29], variations in the matching scale between the matrix element and the parton shower [28], uncertainties in the underlying event tune [28], the PDFs [37], the B hadron branching fraction and fragmentation function [38, 39], and uncertainties related to the choice of the colour reconnection model [40, 41]. In addition, an uncertainty that accounts for the different shape of the top quark  $p_T$  distribution in data and simulation observed in previous measurements [31, 42, 43] is derived by reweighting the  $t\bar{t}$  MC simulation to the observed spectrum. Other sources of uncertainty include the normalization of background processes and the modelling of the additional pp interactions within the same or nearby bunch crossings. Further details on the sources of systematic uncertainties and the considered variations can be found in Ref. [14].

The simulated  $t\bar{t}$  sample is split into four subsamples corresponding to bins of  $m_{t\bar{t}}$  at the parton level. Each subsample is treated as an independent signal and represents the  $t\bar{t}$  production at the scale  $\mu_k$ , which is chosen to be the centre-of-gravity of  $m_{t\bar{t}}$  in the bin  $k$ . The subsample corresponding to bin  $k$  is denoted with “Signal ( $\mu_k$ )”. The bins of  $m_{t\bar{t}}$ , the relative fraction of events in each bin, and the representative scales  $\mu_k$  are summarized in Table 1, where the values are estimated from the nominal POWHEG simulation. The bin width,  $\Delta m_{t\bar{t}}$ , is chosen taking into account the resolution in the reconstructed invariant mass of the  $t\bar{t}$  system,  $m_{t\bar{t}}^{\text{reco}}$ , in order to achieve high purity in each bin. Figure 1 shows the distribution of  $m_{t\bar{t}}^{\text{reco}}$  after the fit to the data, which is described in Section 4.

Table 1: Bins of  $m_{t\bar{t}}$ , the corresponding fraction of events in the POWHEG simulation, and the representative scale  $\mu_k$ .

Bin	$m_{t\bar{t}}$ [GeV]	Fraction [%]	$\mu_k$ [GeV]

3	550–810	24	644
4	>810	7	1024

## 4 Fit procedure and cross section results

The differential  $t\bar{t}$  cross section at the parton level is measured by means of a maximum-likelihood fit to distributions of final-state observables where the systematic uncertainties are treated as nuisance parameters. The likelihood function assumes that the number of events in each bin of any distribution of final-state observables follows a Poisson distribution. With  $\sigma_{t\bar{t}}^{(\mu_k)} = (d\sigma_{t\bar{t}}/dm_{t\bar{t}})\Delta m_{t\bar{t}}$  being the total  $t\bar{t}$  cross section in the bin  $k$  of  $m_{t\bar{t}}$ , the expected number of events in bin  $i$  of any of the considered final-state distributions, denoted with  $\nu_i$ , can be written as

$$\nu_i = \sum_{k=1}^4 s_i^k (\sigma_{t\bar{t}}^{(\mu_k)}, \vec{\lambda}, m_t^{\text{MC}}) + \sum_j b_i^j (\omega_j, \vec{\lambda}). \quad (2)$$

Here,  $s_i^k$  indicates the expected number of  $t\bar{t}$  events in the bin  $k$  of  $m_{t\bar{t}}$  and depends on  $\sigma_{t\bar{t}}^{(\mu_k)}$ ,  $m_t^{\text{MC}}$ , and the nuisance parameters  $\vec{\lambda}$ . Similarly,  $b_i^j$  represents the expected number of back-

ground events from a source  $j$  and depends on the respective background normalization parameter  $\omega_j$  and on the nuisance parameters  $\vec{\lambda}$ . Equation 2, which relates the various  $\sigma_{t\bar{t}}^{(\mu_k)}$  (and hence the parton-level differential cross section) to distributions of final-state observables, embeds the detector response and its fully parametrized dependence on the systematic uncertainties. Therefore, the maximization of the likelihood function provides results for  $\sigma_{t\bar{t}}^{(\mu_k)}$  that are automatically unfolded to the parton level. This method (described, e.g. in Ref. [44]) is also referred to as maximum-likelihood unfolding and, unlike other unfolding techniques, allows the nuisance parameters to be constrained simultaneously with the differential cross section. The unfolding problem was found to be well-conditioned, and therefore no regularization is needed. The expected signal and background distributions contributing to the fit are modelled with templates constructed using simulated samples. Selected events are categorized according to the number of b-tagged jets, as events with 1 b-tagged jet, 2 b-tagged jets, or a different amount of b-tagged jets (zero or more than two). With this categorization, the  $t\bar{t}$  topology can be used to determine the efficiency to reconstruct and identify a b jet. The number of events with one ( $S_{1b}^k$ ), two ( $S_{2b}^k$ ), or a different number of b-tagged jets ( $S_{\text{other}}^k$ ) in each bin of  $m_{t\bar{t}}$  can be expressed using multinomial probabilities:

$$\begin{aligned} S_{1b}^k &= \mathcal{L}\sigma_{t\bar{t}}^{(\mu_k)} A_{\text{sel}}^k \epsilon_{\text{sel}}^k 2\epsilon_b^k (1 - C_b^k \epsilon_b^k), \\ S_{2b}^k &= \mathcal{L}\sigma_{t\bar{t}}^{(\mu_k)} A_{\text{sel}}^k \epsilon_{\text{sel}}^k C_b^k (\epsilon_b^k)^2, \\ S_{\text{other}}^k &= \mathcal{L}\sigma_{t\bar{t}}^{(\mu_k)} A_{\text{sel}}^k \epsilon_{\text{sel}}^k \left[ 1 - 2\epsilon_b^k (1 - C_b^k \epsilon_b^k) - C_b^k (\epsilon_b^k)^2 \right]. \end{aligned}$$

Here,  $\mathcal{L}$  is the integrated luminosity,  $A_{\text{sel}}^k$  is the acceptance of the event selection in the  $m_{t\bar{t}}$  bin  $k$ , defined as the fraction of  $t\bar{t}$  events in bin  $k$  that decay into an electron and a muon of opposite charge which satisfy the selection criteria described in Section 3, and  $\epsilon_{\text{sel}}^k$  represents the efficiency for an event in the visible phase space to pass the full event selection. Furthermore,  $\epsilon_b^k$  represents the probability for a jet from the quark q in the  $t \rightarrow Wq$  decay, which is a b jet in the vast majority of the cases, to be b tagged. The parameter  $C_b^k$  accounts for any residual correlation between the tagging of two b jets in a  $t\bar{t}$  event. The quantities  $A_{\text{sel}}^k$ ,  $\epsilon_{\text{sel}}^k$ ,  $\epsilon_b^k$ , and  $C_b^k$  are determined from the signal simulation and are used in the fit to predict the number of events in the different categories of b-tagged jet multiplicity as a function of the nuisance parameters. However, they are not free parameters of the fit.

In order to constrain each individual  $\sigma_{t\bar{t}}^{(\mu_k)}$ , events with at least two jets are further divided into subcategories of  $m_{t\bar{t}}^{\text{reco}}$ , using the same binning as for  $m_{t\bar{t}}$  (Table 1). In order to mitigate the sensitivity of the measurement to the shape of the distributions of background processes, the total number of events is chosen as input to the fit for all subcategories with zero or more than two b-tagged jets, where the contribution of the background processes is the largest. The same choice is made for the subcategories corresponding to the last bin in  $m_{t\bar{t}}^{\text{reco}}$ , where the statistical uncertainty in both data and simulation is large, and for events with less than two jets, where the kinematic reconstruction cannot be performed. In the remaining subcategories with one b-tagged jet, the minimum invariant mass found when combining the reconstructed b jet and a lepton, referred to as the  $m_{t\bar{b}}^{\text{min}}$  distribution, is fitted. This distribution provides the sensitivity to constrain  $m_t^{\text{MC}}$  [45]. In the remaining subcategories with two b-tagged jets, the  $p_T$  spectrum of the softest selected jet in the event is used to constrain jet energy scale uncertainties at small values of  $p_T$ , the kinematic range where systematic uncertainties are the largest.

The efficiencies of the kinematic reconstruction in data and simulation have been investigated

in Ref. [31] and they were found to differ by 0.2%. Therefore, the efficiency in the simulation is corrected to match the one in data. An uncertainty of 0.2% is assigned to each bin of  $m_{t\bar{t}}$  independently. The same uncertainty is also assigned to  $t\bar{t}$  events with one or two b-tagged jets, independently. For  $t\bar{t}$  events with zero or more than two b-tagged jets, where the combinatorial background is larger, an uncertainty of 0.5% is conservatively assigned. The uncertainties are treated as uncorrelated to account for possible differences between the different  $m_{t\bar{t}}$  bins and categories of b-tagged jet multiplicity. Similarly, an uncertainty of 1% is assigned to the sum of the background processes, independently for each bin of  $m_{t\bar{t}}^{\text{reco}}$ , in order to reduce the correlation between the signal and the background templates. The impact of these uncertainties on the final results is found to be small compared to the total uncertainty.

The dependency of the various yields  $\nu_i$  on the nuisance parameters, on the background normalizations, and on  $m_t^{\text{MC}}$  is modelled using a second-order polynomial [14] and a Gaussian prior is assumed for all nuisance and normalization parameters. The negative log-likelihood is then minimized, using the MINUIT program [46], with respect to  $\sigma_{t\bar{t}}^{(\mu_k)}$ ,  $m_t^{\text{MC}}$ ,  $\vec{\omega}$ , and  $\vec{\lambda}$ . Finally, the fit uncertainties in the various  $\sigma_{t\bar{t}}^{(\mu_k)}$  are determined using MINOS [46]. Additional extrapolation uncertainties, which reflect the impact of modelling uncertainties on  $A_{\text{sel}}^k$ , are estimated without taking into account the constraints obtained in the visible phase space [14]. Moreover, an additional uncertainty arising from the limited statistical precision of the simulation is estimated using MC pseudo-experiments [14], where templates are varied within their statistical uncertainties taking the correlations between templates into account. The template dependencies are then rederived and the fit to the data is repeated over ten thousand times. For each parameter of interest, the root-mean-square of the best fit values obtained with this procedure is taken as an additional uncertainty and added in quadrature to the total uncertainty from the fit.

The measured  $\sigma_{t\bar{t}}^{(\mu_k)}$  are shown in Fig. 2 and compared to fixed-order theoretical predictions in the  $\overline{\text{MS}}$  scheme at NLO [47] implemented for the purpose of this analysis in the MCFM v6.8 program [48, 49]. In the calculation, the renormalization scale,  $\mu_r$ , and factorization scale,  $\mu_f$ , are both set to  $m_t$  and RGEs are assumed in the evolution of  $m_t$  and  $\alpha_S$  with five active flavours ( $n_f = 5$ ) and one-loop precision, corresponding to NLO. The  $\overline{\text{MS}}$  mass of the top quark evaluated at the scale  $m_t$  is denoted with  $m_t(m_t)$ . The calculation is interfaced with the ABMP16.5\_nlo PDF set [50], which is the only available PDF set where  $m_t$  is treated in the  $\overline{\text{MS}}$  scheme and where the correlations between the gluon PDF,  $\alpha_S$ , and  $m_t$  are taken into account. In the calculation, the value of  $\alpha_S$  at the Z boson mass,  $\alpha_S(m_Z)$ , is set to the value determined in the ABMP16.5\_nlo fit, which in the central PDF corresponds to 0.1191 [50]. In order to demonstrate the sensitivity to the top quark mass, predictions obtained with different values of  $m_t(m_t)$  are shown. Furthermore, it is worth noting that this method provides a cross section result with significantly improved precision compared to measurements that perform unfolding as a separate step, e.g. as the one described in Ref. [31].

## 5 Extraction of the running of the top quark mass

The measured  $\sigma_{t\bar{t}}^{(\mu_k)}$  are used to extract the running of the top quark  $\overline{\text{MS}}$  mass at NLO as a function of the scale  $\mu = m_{t\bar{t}}$ . The procedure is similar to the one used to extract the running of the charm quark mass [12]. The value of  $m_t(m_t)$  is determined independently in each bin of  $m_{t\bar{t}}$  from a  $\chi^2$  fit of fixed-order theoretical predictions at NLO to the data. The theoretical predictions are obtained as described in Section 4 for Fig. 2. The  $\chi^2$  definition follows the one

Figure 1: Distribution of  $m_{t\bar{t}}^{\text{reco}}$  after the fit to the data, with the same binning as used in the fit. The hatched band corresponds to the total uncertainty in the predicted yields and includes all correlations. The  $t\bar{t}$  MC sample is split into four subsamples, denoted with “Signal ( $\mu_k$ )”, corresponding to bins of  $m_{t\bar{t}}$  at the parton level. The first and last bins contain all events with  $m_{t\bar{t}}^{\text{reco}} < 420 \text{ GeV}$  and  $m_{t\bar{t}}^{\text{reco}} > 810 \text{ GeV}$ , respectively.

Figure 2: Measured values of  $\sigma_{t\bar{t}}^{(\mu_k)}$  (markers) and their uncertainties (vertical error bars) compared to NLO predictions in the  $\overline{\text{MS}}$  scheme obtained with different values of  $m_t(m_t)$  (horizontal lines of different styles). The values of  $\sigma_{t\bar{t}}^{(\mu_k)}$  are shown at the representative scale of the process  $\mu_k$ , defined as the centre-of-gravity of the  $m_{t\bar{t}}$  spectrum of each bin. The first and last bins contain all events with  $m_{t\bar{t}} < 420 \text{ GeV}$  and  $m_{t\bar{t}} > 810 \text{ GeV}$ , respectively.

described in Ref. [51], which accounts for asymmetries in the input uncertainties. The extracted  $m_t(m_t)$  are then converted to  $m_t(\mu_k)$  using the CRUNDEC v3.0 program [52], where  $\mu_k$  is the representative scale of the process in a given bin of  $m_{t\bar{t}}$ , as described in Section 3. The conversion is performed with one-loop precision assuming  $n_f = 5$  and  $\alpha_S(m_Z) = 0.1191$ , consistently with the calculation and the used PDF set. This procedure is equivalent to extracting directly  $m_t(\mu_k)$  in each bin. Furthermore, the result does not depend on the exact choice of  $\mu_k$ , since a change in  $\mu_k$  would correspond to a change in  $m_t(\mu_k)$  according to the RGE.

In order to benefit from the cancellation of correlated uncertainties in the measured  $\sigma_{t\bar{t}}^{(\mu_k)}$ , the ratios of the various  $m_t(\mu_k)$  to  $m_t(\mu_2)$  are considered. In particular, the quantities  $r_{12} = m_t(\mu_1)/m_t(\mu_2)$ ,  $r_{32} = m_t(\mu_3)/m_t(\mu_2)$ , and  $r_{42} = m_t(\mu_4)/m_t(\mu_2)$  are extracted. With this approach the running of  $m_t$ , i.e. the quantity predicted by the RGE (Eq. 1), is accessed directly. The measurement at the scale  $\mu_2$  is chosen as a reference in order to minimize the correlation between the extracted ratios.

Four different types of systematic uncertainty are considered for the ratios: the uncertainty in the various  $\sigma_{t\bar{t}}^{(\mu_k)}$  in the visible phase space (referred to as fit uncertainty), the extrapolation uncertainties, the uncertainties in the proton PDFs, and the uncertainty in the value of  $\alpha_S(m_Z)$ . The fit uncertainty includes experimental and modelling uncertainties described in Section 3. Scale variations in the MCFM predictions are not performed, since the scale dependence of  $m_t$  is being investigated at a fixed order in perturbation theory. In fact, scale variations in the hard scattering cross section are conventionally performed as a means of estimating the effect of missing higher order corrections and are therefore not applicable in this context.

Uncertainties in the proton PDFs affect the MCFM prediction and therefore the extracted values of the various  $m_t(\mu_k)$ . In order to estimate their impact, the calculation is repeated for each eigenvector of the PDF set and the differences in the extracted ratios are added in quadrature to yield the total PDF uncertainties. In the ABMP16.5\_nlo PDF set,  $\alpha_S(m_Z)$  is determined simultaneously with the PDFs, therefore its uncertainty is incorporated in that of the PDFs. However, the uncertainty in  $\alpha_S(m_Z)$  also affects the CRUNDEC conversion from  $m_t(m_t)$  to  $m_t(\mu_k)$ . This effect is estimated independently and is found to be negligible.

The impact of extrapolation uncertainties is estimated by varying the measured  $\sigma_{t\bar{t}}^{(\mu_k)}$  within their extrapolation uncertainty, separately for each source and simultaneously in the different bins in  $m_{t\bar{t}}$ , taking the correlations into account. The various contributions are added in quadrature to yield the total extrapolation uncertainty.

The correlations between the extracted masses arising from the fit uncertainty are estimated using MC pseudo-experiments, taking the correlations between the measured  $\sigma_{t\bar{t}}^{(\mu_k)}$  as inputs. The uncertainties are then propagated to the ratios using linear uncertainty propagation, taking the estimated correlations into account. The numerical values of the ratios are determined to be:

$$\begin{aligned} r_{12} &= 1.030 \pm 0.018 \text{ (fit)} \quad {}^{+0.003}_{-0.006} \text{ (PDF+}\alpha_S\text{)} \quad {}^{+0.003}_{-0.002} \text{ (extr)}, \\ r_{32} &= 0.982 \pm 0.025 \text{ (fit)} \quad {}^{+0.006}_{-0.005} \text{ (PDF+}\alpha_S\text{)} \pm 0.004 \text{ (extr)}, \\ r_{42} &= 0.904 \pm 0.050 \text{ (fit)} \quad {}^{+0.019}_{-0.017} \text{ (PDF+}\alpha_S\text{)} \quad {}^{+0.017}_{-0.013} \text{ (extr)}. \end{aligned}$$

Here, the fit uncertainty (fit), the combination of PDF and  $\alpha_S$  uncertainty (PDF+ $\alpha_S$ ), and the extrapolation uncertainty (extr) are given. The most relevant sources of experimental uncertainty are the integrated luminosity, the lepton identification efficiencies, and the jet energy scale and resolution. Among modelling uncertainties related to the POWHEG +PYTHIA 8 simulation of

the  $t\bar{t}$  signal, the largest contributions originate from the scale variations in the parton shower, the uncertainty in the shape of the  $p_T$  spectrum of the top quark, and the matching scale between the matrix element and the parton shower. The statistical uncertainties are found to be negligible. The correlations between the ratios arising from the fit uncertainty are investigated using a pseudo-experiment procedure which consists in repeating the extraction of the ratios using pseudo-measurements of  $\sigma_{t\bar{t}}^{(\mu_k)}$ , generated according to the corresponding fitted values, uncertainties, and correlations. With  $\rho_{ik}$  being the correlation between  $r_{i2}$  and  $r_{k2}$ , the results are  $\rho_{13} = 13\%$ ,  $\rho_{14} = -45\%$ , and  $\rho_{34} = 11\%$ .

The extracted ratios  $m_t(\mu_k)/m_t(\mu_2)$  are shown in Fig. 3 (left) together with the RGE prediction (Eq. 1) at one-loop precision. In the figure, the reference scale  $\mu_2$  is indicated with  $\mu_{\text{ref}}$ , and the RGE evolution is calculated from the initial scale  $\mu_0 = \mu_{\text{ref}}$ . Good agreement between the extracted running and the RGE prediction is observed.

For comparison, the  $\overline{\text{MS}}$  mass of the top quark is also extracted from the inclusive cross section measured in Ref. [14], using HATHOR 2.0 [53] predictions at NLO interfaced with the ABMP16\_5\_nlo PDF set, and is denoted with  $m_t^{\text{incl}}(m_t)$ . Fig. 3 (right) compares the extracted ratios  $m_t(\mu_k)/m_t(\mu_2)$  to the value of  $m_t^{\text{incl}}(m_t)/m_t(\mu_2)$ . The uncertainty in  $m_t^{\text{incl}}(m_t)$  includes fit, extrapolation, and PDF uncertainties, and is evolved to higher scales, while the value of  $m_t(\mu_2)$  in the ratio  $m_t^{\text{incl}}(m_t)/m_t(\mu_2)$  is taken without uncertainty. Here, the RGE evolution is calculated from the initial scale  $\mu_0 = m_t$ , which corresponds to 163 GeV.

Figure 3: Extracted running of the top quark mass  $m_t(\mu)/m_t(\mu_{\text{ref}})$  compared to the RGE prediction at one-loop precision ( $n_f = 5$ ) evolved from the initial scale  $\mu_0 = \mu_{\text{ref}} = 476$  GeV (left). The result is compared to the value of  $m_t^{\text{incl}}(m_t)/m_t(\mu_{\text{ref}})$ , where  $m_t^{\text{incl}}(m_t)$  is the value of  $m_t(m_t)$  extracted from the inclusive cross section measured in Ref. [14], which is based on the same data set. The uncertainty in  $m_t^{\text{incl}}(m_t)$  is evolved from the initial scale  $\mu_0 = m_t = 163$  GeV using the same RGE prediction (right).

Finally, the extracted running is parametrized with the function

$$f(x, \mu) = x [r(\mu) - 1] + 1, \quad (3)$$

where  $r(\mu) = m_t(\mu)/m_t(\mu_2)$  corresponds to the RGE prediction shown in Fig. 3 (left). In particular,  $f(x, \mu)$  corresponds to  $r(\mu)$  for  $x = 1$  and to 1, i.e. no running, for  $x = 0$ . The best fit value for  $x$ , denoted with  $x_{\min}$ , is determined via a  $\chi^2$  fit to the extracted ratios taking the correlations  $\rho_{ik}$  into account, and is found to be

$$x_{\min} = 2.05 \pm 0.61 \text{ (fit)} \begin{array}{l} +0.31 \\ -0.55 \end{array} \text{ (PDF + } \alpha_S \text{)} \begin{array}{l} +0.24 \\ -0.49 \end{array} \text{ (extr).}$$

The result shows agreement between the extracted running and the RGE prediction at one-loop precision within 1.1 standard deviations in the Gaussian approximation and excludes the no-running hypothesis at above 95% confidence level in the same approximation.

## 6 Summary

In this Letter, the first experimental investigation of the running of the top quark mass,  $m_t$ , is presented. The running is extracted from a measurement of the differential top quark-antiquark ( $t\bar{t}$ ) cross section as a function of the invariant mass of the  $t\bar{t}$  system,  $m_{t\bar{t}}$ . The differential  $t\bar{t}$  cross section,  $d\sigma_{t\bar{t}}/dm_{t\bar{t}}$ , is determined at the parton level using a maximum-likelihood fit to distributions of final-state observables, using  $t\bar{t}$  candidate events in the  $e^\pm\mu^\mp$  channel. This technique allows the nuisance parameters to be constrained simultaneously with the differential cross section in the visible phase space and therefore provides results with significantly improved precision compared to conventional procedures in which the unfolding is performed as a separate step. The analysis is performed using proton-proton collision data at a centre-of-mass energy of 13 TeV recorded by the CMS detector at the CERN LHC in 2016, corresponding to an integrated luminosity of  $35.9 \text{ fb}^{-1}$ .

The running mass  $m_t(\mu)$ , as defined in the modified minimal subtraction ( $\overline{\text{MS}}$ ) renormalization scheme, is extracted at next-to-leading order (NLO) as a function of  $m_{t\bar{t}}$  by comparing fixed-order theoretical predictions at NLO to the measured  $d\sigma_{t\bar{t}}/dm_{t\bar{t}}$ . The extracted running of  $m_t$  is found to be in agreement with the prediction of the corresponding renormalization group equation, within 1.1 standard deviations, and the no-running hypothesis is excluded at above 95% confidence level. The running of  $m_t$  is probed up to a scale of the order of 1 TeV.

## Acknowledgments

We congratulate our colleagues in the CERN accelerator departments for the excellent performance of the LHC and thank the technical and administrative staffs at CERN and at other CMS institutes for their contributions to the success of the CMS effort. In addition, we gratefully acknowledge the computing centres and personnel of the Worldwide LHC Computing Grid for delivering so effectively the computing infrastructure essential to our analyses. Finally, we acknowledge the enduring support for the construction and operation of the LHC and the CMS detector provided by the following funding agencies: BMBWF and FWF (Austria); FNRS and FWO (Belgium); CNPq, CAPES, FAPERJ, FAPERGS, and FAPESP (Brazil); MES (Bulgaria); CERN; CAS, MoST, and NSFC (China); COLCIENCIAS (Colombia); MSES and CSF (Croatia); RPF (Cyprus); SENESCYT (Ecuador); MoER, ERC IUT, PUT and ERDF (Estonia); Academy of Finland, MEC, and HIP (Finland); CEA and CNRS/IN2P3 (France); BMBF, DFG, and HGF (Germany); GSRT (Greece); NKFIA (Hungary); DAE and DST (India); IPM (Iran); SFI (Ireland); INFN (Italy); MSIP and NRF (Republic of Korea); MES (Latvia); LAS (Lithuania); MOE and UM (Malaysia); BUAP, CINVESTAV, CONACYT, LNS, SEP, and UASLP-FAI (Mexico); MOS (Montenegro); MBIE (New Zealand); PAEC (Pakistan); MSHE and NSC (Poland); FCT (Portugal); JINR (Dubna); MON, RosAtom, RAS, RFBR, and NRC KI (Russia); MESTD (Serbia); SEIDI, CPAN, PCTI, and FEDER (Spain); MOSTR (Sri Lanka); Swiss Funding Agencies (Switzerland); MST (Taipei); ThEPCenter, IPST, STAR, and NSTDA (Thailand); TUBITAK and TAEK (Turkey); NASU and SFFR (Ukraine); STFC (United Kingdom); DOE and NSF (USA).

Individuals have received support from the Marie-Curie programme and the European Research Council and Horizon 2020 Grant, contract Nos. 675440, 752730, and 765710 (Euro-

pean Union); the Leventis Foundation; the A.P. Sloan Foundation; the Alexander von Humboldt Foundation; the Belgian Federal Science Policy Office; the Fonds pour la Formation à la Recherche dans l'Industrie et dans l'Agriculture (FRIA-Belgium); the Agentschap voor Innovatie door Wetenschap en Technologie (IWT-Belgium); the F.R.S.-FNRS and FWO (Belgium) under the “Excellence of Science – EOS” – be.h project n. 30820817; the Beijing Municipal Science & Technology Commission, No. Z181100004218003; the Ministry of Education, Youth and Sports (MEYS) of the Czech Republic; the Lendület (“Momentum”) Programme and the János Bolyai Research Scholarship of the Hungarian Academy of Sciences, the New National Excellence Program ÚNKP, the NKFIA research grants 123842, 123959, 124845, 124850, 125105, 128713, 128786, and 129058 (Hungary); the Council of Science and Industrial Research, India; the HOMING PLUS programme of the Foundation for Polish Science, cofinanced from European Union, Regional Development Fund, the Mobility Plus programme of the Ministry of Science and Higher Education, the National Science Center (Poland), contracts Harmonia 2014/14/M/ST2/00428, Opus 2014/13/B/ST2/02543, 2014/15/B/ST2/03998, and 2015/19/B/ST2/02861, Sonata-bis 2012/07/E/ST2/01406; the National Priorities Research Program by Qatar National Research Fund; the Ministry of Science and Education, grant no. 3.2989.2017 (Russia); the Programa Estatal de Fomento de la Investigación Científica y Técnica de Excelencia María de Maeztu, grant MDM-2015-0509 and the Programa Severo Ochoa del Principado de Asturias; the Thalis and Aristeia programmes cofinanced by EU-ESF and the Greek NSRF; the Rachadapisek Sompot Fund for Postdoctoral Fellowship, Chulalongkorn University and the Chulalongkorn Academic into Its 2nd Century Project Advancement Project (Thailand); the Nvidia Corporation; the Welch Foundation, contract C-1845; and the Weston Havens Foundation (USA).

**Rutgers, The State University of New Jersey, Piscataway, USA**

B. Chiarito, J.P. Chou, A. Gandrakota, Y. Gershtein, E. Halkiadakis, A. Hart, M. Heindl, E. Hughes, S. Kaplan, I. Laflotte, A. Lath, R. Montalvo, K. Nash, M. Osherson, H. Saka, S. Salur, S. Schnetzer, S. Somalwar, R. Stone, S. Thomas

**University of Tennessee, Knoxville, USA**

H. Acharya, A.G. Delannoy, S. Spanier

**Texas A&M University, College Station, USA**

O. Bouhali<sup>77</sup>, M. Dalchenko, M. De Mattia, A. Delgado, S. Dildick, R. Eusebi, J. Gilmore, T. Huang, T. Kamon<sup>78</sup>, H. Kim, S. Luo, S. Malhotra, D. Marley, R. Mueller, D. Overton, L. Perniè, D. Rathjens, A. Safonov

**Texas Tech University, Lubbock, USA**

N. Akchurin, J. Damgov, F. De Guio, V. Hegde, S. Kunori, K. Lamichhane, S.W. Lee, T. Mengke, S. Muthumuni, T. Peltola, S. Undleeb, I. Volobouev, Z. Wang, A. Whitbeck

**Vanderbilt University, Nashville, USA**

S. Greene, A. Gurrola, R. Janjam, W. Johns, C. Maguire, A. Melo, H. Ni, K. Padeken, F. Romeo, P. Sheldon, S. Tuo, J. Velkovska, M. Verweij

**University of Virginia, Charlottesville, USA**

M.W. Arenton, P. Barria, B. Cox, G. Cummings, J. Hakala, R. Hirosky, M. Joyce, A. Ledovskoy, C. Neu, B. Tannenwald, Y. Wang, E. Wolfe, F. Xia

**Wayne State University, Detroit, USA**

R. Harr, P.E. Karchin, N. Poudyal, J. Sturdy, P. Thapa

**University of Wisconsin - Madison, Madison, WI, USA**

T. Bose, J. Buchanan, C. Caillol, D. Carlsmith, S. Dasu, I. De Bruyn, L. Dodd, C. Galloni, H. He, M. Herndon, A. Hervé, U. Hussain, P. Klabbers, A. Lanaro, A. Loeliger, K. Long, R. Loveless, J. Madhusudanan Sreekala, D. Pinna, T. Ruggles, A. Savin, V. Sharma, W.H. Smith, D. Teague, S. Trembath-reichert, N. Woods

†: Deceased

- 1: Also at Vienna University of Technology, Vienna, Austria
- 2: Also at IRFU, CEA, Université Paris-Saclay, Gif-sur-Yvette, France
- 3: Also at Universidade Estadual de Campinas, Campinas, Brazil
- 4: Also at Federal University of Rio Grande do Sul, Porto Alegre, Brazil
- 5: Also at UFMS, Nova Andradina, Brazil
- 6: Also at Universidade Federal de Pelotas, Pelotas, Brazil
- 7: Also at Université Libre de Bruxelles, Bruxelles, Belgium
- 8: Also at University of Chinese Academy of Sciences, Beijing, China
- 9: Also at Institute for Theoretical and Experimental Physics named by A.I. Alikhanov of NRC 'Kurchatov Institute', Moscow, Russia
- 10: Also at Joint Institute for Nuclear Research, Dubna, Russia
- 11: Also at Suez University, Suez, Egypt
- 12: Now at British University in Egypt, Cairo, Egypt
- 13: Also at Purdue University, West Lafayette, USA
- 14: Also at Université de Haute Alsace, Mulhouse, France

- 15: Also at Tbilisi State University, Tbilisi, Georgia
- 16: Also at Erzincan Binali Yildirim University, Erzincan, Turkey
- 17: Also at CERN, European Organization for Nuclear Research, Geneva, Switzerland
- 18: Also at RWTH Aachen University, III. Physikalisches Institut A, Aachen, Germany
- 19: Also at University of Hamburg, Hamburg, Germany
- 20: Also at Brandenburg University of Technology, Cottbus, Germany
- 21: Also at Institute of Physics, University of Debrecen, Debrecen, Hungary, Debrecen, Hungary
- 22: Also at Institute of Nuclear Research ATOMKI, Debrecen, Hungary
- 23: Also at MTA-ELTE Lendület CMS Particle and Nuclear Physics Group, Eötvös Loránd University, Budapest, Hungary, Budapest, Hungary
- 24: Also at IIT Bhubaneswar, Bhubaneswar, India, Bhubaneswar, India
- 25: Also at Institute of Physics, Bhubaneswar, India
- 26: Also at Shoolini University, Solan, India
- 27: Also at University of Hyderabad, Hyderabad, India
- 28: Also at University of Visva-Bharati, Santiniketan, India
- 29: Also at Isfahan University of Technology, Isfahan, Iran
- 30: Now at INFN Sezione di Bari <sup>a</sup>, Università di Bari <sup>b</sup>, Politecnico di Bari <sup>c</sup>, Bari, Italy
- 31: Also at Italian National Agency for New Technologies, Energy and Sustainable Economic Development, Bologna, Italy
- 32: Also at Centro Siciliano di Fisica Nucleare e di Struttura Della Materia, Catania, Italy
- 33: Also at Scuola Normale e Sezione dell'INFN, Pisa, Italy
- 34: Also at Riga Technical University, Riga, Latvia, Riga, Latvia
- 35: Also at Malaysian Nuclear Agency, MOSTI, Kajang, Malaysia
- 36: Also at Consejo Nacional de Ciencia y Tecnología, Mexico City, Mexico
- 37: Also at Warsaw University of Technology, Institute of Electronic Systems, Warsaw, Poland
- 38: Also at Institute for Nuclear Research, Moscow, Russia
- 39: Now at National Research Nuclear University 'Moscow Engineering Physics Institute' (MEPhI), Moscow, Russia
- 40: Also at St. Petersburg State Polytechnical University, St. Petersburg, Russia
- 41: Also at University of Florida, Gainesville, USA
- 42: Also at Imperial College, London, United Kingdom
- 43: Also at P.N. Lebedev Physical Institute, Moscow, Russia
- 44: Also at California Institute of Technology, Pasadena, USA
- 45: Also at Budker Institute of Nuclear Physics, Novosibirsk, Russia
- 46: Also at Faculty of Physics, University of Belgrade, Belgrade, Serbia
- 47: Also at Università degli Studi di Siena, Siena, Italy
- 48: Also at INFN Sezione di Pavia <sup>a</sup>, Università di Pavia <sup>b</sup>, Pavia, Italy, Pavia, Italy
- 49: Also at National and Kapodistrian University of Athens, Athens, Greece
- 50: Also at Universität Zürich, Zurich, Switzerland
- 51: Also at Stefan Meyer Institute for Subatomic Physics, Vienna, Austria, Vienna, Austria
- 52: Also at Burdur Mehmet Akif Ersoy University, BURDUR, Turkey
- 53: Also at Adiyaman University, Adiyaman, Turkey
- 54: Also at Şırnak University, Sırnak, Turkey
- 55: Also at Tsinghua University, Beijing, China
- 56: Also at Beykent University, Istanbul, Turkey, Istanbul, Turkey
- 57: Also at Istanbul Aydin University, Istanbul, Turkey
- 58: Also at Mersin University, Mersin, Turkey
- 59: Also at Piri Reis University, Istanbul, Turkey

- 
- 60: Also at Gaziosmanpasa University, Tokat, Turkey
  - 61: Also at Ozyegin University, Istanbul, Turkey
  - 62: Also at Izmir Institute of Technology, Izmir, Turkey
  - 63: Also at Marmara University, Istanbul, Turkey
  - 64: Also at Kafkas University, Kars, Turkey
  - 65: Also at Istanbul Bilgi University, Istanbul, Turkey
  - 66: Also at Hacettepe University, Ankara, Turkey
  - 67: Also at Vrije Universiteit Brussel, Brussel, Belgium
  - 68: Also at School of Physics and Astronomy, University of Southampton, Southampton, United Kingdom
  - 69: Also at IPPP Durham University, Durham, United Kingdom
  - 70: Also at Monash University, Faculty of Science, Clayton, Australia
  - 71: Also at Bethel University, St. Paul, Minneapolis, USA, St. Paul, USA
  - 72: Also at Karamanoğlu Mehmetbey University, Karaman, Turkey
  - 73: Also at Bingol University, Bingol, Turkey
  - 74: Also at Georgian Technical University, Tbilisi, Georgia
  - 75: Also at Sinop University, Sinop, Turkey
  - 76: Also at Mimar Sinan University, Istanbul, Istanbul, Turkey
  - 77: Also at Texas A&M University at Qatar, Doha, Qatar
  - 78: Also at Kyungpook National University, Daegu, Korea, Daegu, Korea
