# Search for dijet resonances using events with three jets in proton-proton collisions at $\sqrt{s} = 13$ TeV

The CMS Collaboration<sup>\*</sup>

## Abstract

A search for a narrow resonance with a mass between 350 and 700 GeV, and decaying into a pair of jets, is performed using proton-proton collision events containing at least three jets. The data sample corresponds to an integrated luminosity of  $18.3 \text{ fb}^{-1}$  recorded at  $\sqrt{s} = 13$  TeV with the CMS detector. Data are collected with a technique known as “data scouting”, in which the events are reconstructed, selected, and recorded at a high rate in a compact form by the high-level trigger. The three-jet final state provides sensitivity to lower resonance masses than in previous searches using the data scouting technique. The spectrum of the dijet invariant mass, calculated from the two jets with the largest transverse momenta in the event, is used to search for a resonance. No significant excess over a smoothly falling background is found. Limits at 95% confidence level are set on the production cross section of a narrow dijet resonance. The corresponding upper limits on the coupling of a narrow vector resonance interacting only with quarks are between 0.10 and 0.15, depending on the resonance mass. These results represent the most stringent upper limits in the mass range between 350 and 450 GeV obtained with a search that is sensitive to the decay of the resonance into light-flavor quarks.

## 1 Introduction

Many models of new physics predict the existence of new massive particles coupled to quarks. The production and decay of these particles into two jets, known as dijets, have been searched for since the first high-energy hadron colliders came into operation [1–9]. In some models, these particles act as portals linking the standard model to new physics sectors containing dark matter (DM) particle candidates [10–13]. Therefore, the search for dijet resonances at hadron colliders can be interpreted as a search for a DM mediator and compared with searches for DM [14–39]. The search for dijet resonances is also sensitive to the signals predicted by other models [40–50].

Experiments at the CERN LHC have used various techniques to search for resonances in the dijet invariant mass spectrum. From searches where both jets are individually resolved, the ATLAS and CMS Collaborations have set limits for resonances with masses above 450 and 600 GeV, respectively, in  $\sqrt{s} = 13$  TeV proton-proton collisions [51–53], and above 250 and 500 GeV, respectively, in 8 TeV collisions [54, 55]. Another search by the ATLAS Collaboration at 13 TeV for dijet resonances, produced in association with a photon from initial-state radiation, has set limits in the mass region between 250 and 950 GeV [56]. A search by the CMS Collaboration at 8 TeV for resonances decaying into two bottom quarks, experimentally identified as b-tagged jets, has set limits in the mass range of 325–1200 GeV [57]. Finally, the ATLAS and CMS Collaborations have set limits in the mass range below 220 and 450 GeV, respectively, from searches for Lorentz-boosted resonances decaying into a quark-antiquark pair reconstructed as a single jet [58, 59].

This paper presents a search for a dijet resonance in three-jet events that is sensitive to narrow resonances with mass between 350 and 700 GeV. The search is based on data from pp collisions at  $\sqrt{s} = 13$  TeV collected in 2016, corresponding to an integrated luminosity of  $18.3 \text{ fb}^{-1}$ . To obtain a large trigger efficiency in the mass range of 350–700 GeV, we select a three-jet final state, where the third jet could come from initial state radiation, and utilize a special high-rate trigger with low jet  $p_T$  thresholds. This trigger uses a technique known as “data scouting” described in Section 3. This search is limited to data collected in the year 2016 in order to take advantage of the low trigger thresholds used in that data period. After 2016, these thresholds were raised in order to limit the trigger rate increase due to the larger instantaneous luminosity and pileup.

## 2 The CMS detector

A detailed description of the CMS detector, together with a definition of the coordinate system used and the relevant kinematic variables, can be found in Ref. [60]. The central feature of the CMS apparatus is a superconducting solenoid of 6 m internal diameter, providing a magnetic field of 3.8 T. Within the solenoid volume are a silicon pixel and strip tracker, a lead tungstate crystal electromagnetic calorimeter (ECAL), and a brass and scintillator hadron calorimeter (HCAL), each composed of a barrel and two endcap sections. Muons are detected in gas-ionization chambers embedded in the steel flux-return yoke outside the solenoid.

The jets used by this analysis are calorimeter-based jets that are reconstructed from the energy deposits in the calorimeter towers, clustered using the anti- $k_T$  algorithm [61, 62] with a distance parameter of 0.4. In this process, the contribution from each calorimeter tower is assigned a momentum, the absolute value and the direction of which are found from the energy measured in the tower, and the coordinates of the geometrical center of the tower. The raw jet energy is obtained from the sum of the tower energies, and the raw jet momentum by the vectorial sum

of the tower momenta. The raw jet energies are then corrected to establish a uniform relative response of the calorimeter in pseudorapidity  $\eta$  and a calibrated absolute response in transverse momentum  $p_T$ . The calorimetric jet energy resolution is typically 40% at a  $p_T$  of 10 GeV, 12% at 100 GeV, and 5% at 1 TeV. Events of interest are selected using a two-tiered trigger system [63]. The first level (L1), composed of custom hardware processors, uses information from the calorimeters and muon detectors to select events at a rate of around 100 kHz within a time interval of less than 4  $\mu$ s. The second level, known as the high-level trigger (HLT), consists of a farm of processors running a version of the full event reconstruction software optimized for fast processing, and reduces the event rate to around 1 kHz before data storage.

### 3 Data and simulated event samples

We selected events requiring  $H_T > 240$  GeV at the L1 trigger and  $H_T > 250$  GeV at the HLT, where  $H_T$  is the scalar  $p_T$  sum of jets with  $p_T > 40$  GeV and  $|\eta| < 2.5$ . The rate of this trigger was about 4 kHz at an instantaneous luminosity of  $1 \times 10^{34}$  cm $^{-2}$ s $^{-1}$ . The amount of data generated by such a high-rate trigger alone using the standard data-taking format would have saturated the computing and storage systems of the CMS experiment. For this reason, we used a special data-taking technique, which consisted of saving only the calorimeter-based jets reconstructed by the HLT, instead of the full detector readout. The size of this reduced data format is about 0.5% of the full event size. This technique is known as “data scouting” and was used in previous CMS dijet resonance searches [53, 55].

Data scouting allows the analysis of a very large rate of data passing the HLT trigger, only limited by the overall rate of the L1 trigger. To keep a constant rate, the L1 trigger  $H_T$  threshold was raised from 240 to 360 GeV as the instantaneous luminosity increased. This search is limited to data collected in 2016 with the lower L1 trigger threshold  $H_T > 240$  GeV, in order to obtain the maximum sensitivity for low mass resonances. From a sample of events collected with a minimum-bias trigger and passing the selection discussed below, we measured a trigger efficiency larger than 99% for a dijet invariant mass greater than 290 GeV.

Signal events corresponding to a narrow vector resonance decaying into quark-antiquark pairs were generated using the MADGRAPH5\_aMC@NLO version 2.2.2 generator at leading order [64, 65], with the PYTHIA 8.205 generator [66] incorporating the CUETP8M1 underlying event tune [67] providing the description of fragmentation and hadronization. The resonance width is negligible compared to the experimental dijet mass resolution. The detailed simulation of the CMS detector response is performed using the GEANT4 package [68]. The simulated signal events include multiple overlapping pp interactions per bunch crossing (pileup) as observed in the data. Additionally, to provide a framework for interpreting the results in terms of a DM mediator, signal cross sections were computed at leading order with MADGRAPH for a vector boson decaying into a quark-antiquark pair, with coupling to quarks  $g_q = 0.25$ , coupling to DM particles  $g_{\text{DM}} = 1.0$ , and the mass of DM particles 1 GeV. The NNPDF2.3LO [69] parton distribution functions were used.

### 4 Event reconstruction and selection

The discriminating variable in this analysis is the invariant mass of the two jets originating from the resonance decay. This variable is calculated using jets, reconstructed at the HLT from energy deposits in the calorimeter, and passing the selection  $p_T > 30$  GeV and  $|\eta| < 2.5$ . Spurious jets originating from instrumental noise are rejected by requiring each jet to be detected by both ECAL and HCAL, with at least 5% of the jet energy in each of the two types of cal-

orimeter. We form “wide jets”, by clustering the jets already reconstructed by the HLT, using the anti- $k_T$  algorithm with a distance parameter of 1.1. This algorithm improves the dijet mass resolution and the resonance search sensitivity, by recombining jets from hard final-state radiation to obtain a reduced number of wide jets. A similar algorithm using a merging distance of  $\Delta R = \sqrt{(\Delta\eta)^2 + (\Delta\varphi)^2} < 1.1$  was employed in previous CMS searches [53, 55], but it only reconstructed two wide jets per event. The wide-jet calibrations for the 2016 data scouting sample were already obtained in the low-mass dijet search of Ref. [53], and therefore we apply the same calibrations. We require at least three wide jets, each with  $p_T > 72$  GeV, in order to select events that have large  $H_T$  and pass the trigger selections. This requirement is particularly effective in selecting events with low dijet invariant mass, which would be rejected if only two jets were required. The  $p_T$  threshold of the three-jet selection has been chosen with a method that is explained in the next section. Finally, the two leading wide jets are required to have  $|\eta_1 - \eta_2| < 1.1$  to reduce the quantum chromodynamics multijet background, which is dominated by  $t$ -channel production of jets.

Since we require at least three wide jets in the event, there are multiple ways to select the dijet system, i.e., the pair of wide jets originating from the resonance decay. We select as the dijet the two wide jets with the largest  $p_T$  in the event. This selection is correct in 70(50)% of simulated signal events with a resonance mass of 700 (350) GeV. Wrong combinations arise because either an energetic initial-state radiation jet is included in the dijet selection, or an energetic jet from final-state radiation is emitted with a distance  $\Delta R > 1.1$  from the leading jets and therefore excluded from the reconstruction of the two leading wide jets. We investigated alternative criteria to select the dijet, such as choosing the jet pair with the largest norm of the vectorial sum  $p_T$ . We found that such alternative criteria do have better performance if the resonance  $p_T$  is greater than half the mass, but worse performance for this search. This is because, for accepted events, the  $p_T$  of the resonance is about 150 GeV, which is less than half the resonance mass considered in this search.

## 5 Dijet mass spectrum fit

Figure 1 shows the dijet mass ( $m_{jj}$ ) spectrum. The background is modeled with the following analytic function,

$$\frac{d\sigma}{dm_{jj}} = \frac{p_0(p_2x - 1)}{x^{p_1+p_3 \log x + p_4 \log^2 x}}, \quad (1)$$

where  $x$  is defined as  $m_{jj}/\sqrt{s}$ , and  $p_0$ ,  $p_1$ ,  $p_2$ ,  $p_3$ , and  $p_4$  are free parameters of the fit. This function is similar to that used by previous dijet searches [51–55], with a modification to the numerator. The new parameterization better fits the shape of the dijet mass spectrum for three-jet events, which includes the effect of a small inefficiency to pass the trigger for events at the lowest values of dijet mass. The function has been chosen from a pool of functions using a Fisher test [70] with a 95% confidence level (CL). The pool of functions is obtained by changing the number of degrees of freedom of the polylogarithmic function in the exponent of the denominator of Eq. (1). We perform a maximum likelihood fit of the function in Eq. (1) to our data in the mass range  $290 < m_{jj} < 1000$  GeV. The chi-square per number of degrees of freedom of the fit is  $\chi^2/\text{NDF} = 19.3/13$ , corresponding to a p-value of 0.11. Figure 1 also shows the expected dijet mass distributions of a resonance signal for three different values of resonance mass. The data is well modeled by the background parameterization and there is no evidence for a dijet resonance.

The dijet mass bin widths in Fig. 1 are the same as in the previous dijet searches, except for

Figure 1: Dijet mass spectrum (points) compared to a fitted parameterization of the background (solid curve), where the fit is performed in the range  $290 < m_{jj} < 1000 \text{ GeV}$ . The horizontal bars show the widths of each bin in dijet mass. The dashed lines represent the dijet mass distribution from 400, 550, and 700 GeV resonance signals expected to be excluded at 95% CL by this analysis. The lower panel shows the difference between the data and the fitted parametrization, divided by the statistical uncertainty of the data.

the first bin which is more narrow, starting at a dijet mass value of 290 GeV. This lower bound of the fit range and the jet  $p_T$  threshold for the three-jet selection are determined in the following way. We measure the distribution of the dijet mass in a signal-depleted region defined by replacing the requirement  $|\eta_1 - \eta_2| < 1.1$  with the requirement  $|\eta_1 + \eta_2| < 1.1$ . The dijet mass in the signal-depleted region is calculated after flipping the sign of  $\eta$  of the second jet—the sign of the  $z$  component of the momentum of the subleading jet is reversed and then the dijet mass is calculated. For background events, the dijet mass distribution in the signal-depleted region, so calculated, is closely similar to the dijet mass distribution in the signal region because the variables  $\eta_1 - \eta_2$  in the signal region and  $\eta_1 + \eta_2$  in the signal-depleted region have approximately the same uniform distribution between  $-1.1$  and  $1.1$ . The signal-depleted region contains about the same number of background events, 50% fewer signal events, and 35% of the observed events in the signal-depleted region are also in the signal region. Small data-driven corrections, which change the observed number of events by less than 5%, are applied to the dijet mass distribution in the signal-depleted region to make it the same as the background distribution in the signal region. These corrections, which are applied as a function of the product of the two largest values of jet  $p_T$  in the event, are obtained by fitting an analytic function describing this product to the ratio of the numbers of events passing the signal selection to the number of events passing the signal-depleted selection. The lower edge of dijet mass included in the search, 290 GeV, has been chosen to be the lowest value of the corrected dijet mass in the signal-depleted region for which the fit of the background parameterization has a Kolmogorov–Smirnov (KS) probability [71–73] larger than 33%. The  $p_T$  threshold of the three-jet selection, 72 GeV, has been chosen to obtain the lowest possible value for the corrected dijet mass in the signal-depleted region that could be included in the fit and satisfy the same KS test. We verified that an injected signal with a strength corresponding to the 95% CL expected upper limit does not change the choice of the fit range and the three-jet selection.

## 6 Systematic uncertainties

The asymptotic approximation [74] of the modified frequentist  $\text{CL}_s$  method [75, 76] is utilized to set upper limits on signal cross sections, following the prescription described in Ref. [77]. We use the profiled likelihood ratio as test statistic. The likelihood is the product of the Poisson probabilities for each of the bins in Fig. 1. The expected background yield of each bin is determined from the analytic function described in Eq. (1). The five parameters of the analytic function are profiled and their uncertainties from the fit to data are the dominant uncertainties. The shapes of the dijet mass distributions for signals are obtained from simulations. The systematic uncertainties affecting the signal shape and normalization are incorporated into the likelihood function via nuisance parameters with log-normal probability distributions. We account for the uncertainty of 2% in the jet energy scale [78] by shifting the dijet mass of the signal distribution by  $\pm 2\%$ . The effect of the jet energy resolution uncertainty is included by varying the width of the signal distribution by  $\pm 10\%$  [78]. The uncertainty due to the assumptions made in the simulation of the parton shower is estimated by modifying by a factor of two both the renormalization ( $\mu_R$ ) and the factorization scales ( $\mu_F$ ) using SysCalc [79]. This uncertainty has a negligible effect on the shape of the dijet mass distribution of a signal, and changes the normalization by 10%. The uncertainty in the integrated luminosity is 2.5% [80] and affects directly the signal normalization. The systematic uncertainty due to the choice of the background function has been estimated by measuring the signal yield in pseudo-data spectra generated using alternative background functions. The measured cross section in each case is the same as that of the injected signal, and this systematic uncertainty is found to be negligible. The systematic uncertainty related to pileup effects is also negligible.

## 7 Results

Figure 2 shows, as a function of resonance mass, observed and expected upper limits at 95% CL on the product of the cross section, branching fraction, and acceptance of a narrow vector resonance decaying to jets. Table 1 shows the acceptance calculated using signal simulations. Limits are presented for resonance masses between 350 and 700 GeV, for which the acceptance

Table 1: Acceptance for a vector resonance decaying into a dijet as a function of the resonance mass. The acceptance is calculated using signal simulations for the analysis selection, namely three wide jets with  $p_T > 72 \text{ GeV}$  and  $|\eta| < 2.5$ , and  $|\eta_1 - \eta_2| < 1.1$ . The errors are dominated by the uncertainties in the parton shower modeling used in signal simulations.

Resonance mass	300 GeV	400 GeV	500 GeV	600 GeV	800 GeV
Acceptance	$(4.0 \pm 0.4)\%$	$(6.7 \pm 0.7)\%$	$(9.2 \pm 0.9)\%$	$(10.9 \pm 1.1)\%$	$(13.6 \pm 1.4)\%$

of the dijet mass requirement  $290 < m_{jj} < 1000 \text{ GeV}$  is large enough to conduct the search. Figure 3 shows that the 95% CL upper limits on the coupling  $g'_q$  of a vector resonance that decays only to quarks, defined according to the convention of Ref. [81], are between 0.10 and 0.15. Figures 2 and 3 compare the upper limits on the cross section and the coupling  $g'_q$ , respectively, with the predictions of a model with a DM mediator that decays to DM particles with masses of 1 GeV, and also decays to quarks. This analysis excludes a benchmark model of such a DM mediator with coupling to quarks  $g_q = 0.25$  and coupling to DM particles  $g_{\text{DM}} = 1$ , over the complete mass range 350 to 700 GeV. In our notation,  $g'_q$  is the coupling for a model in which the resonance couples only to quarks, and  $g_q$  is the coupling to quarks for a model in which the resonance also couples to DM particles. A relationship between  $g_q$  and  $g'_q$  can be found in Ref. [53].

Figure 2: Upper limits at 95% CL on the product of the cross section, branching fraction, and acceptance as a function of resonance mass for a narrow vector resonance decaying into a pair of quark jets. The acceptance is calculated for the analysis selection, namely three wide jets with  $p_T > 72 \text{ GeV}$  and  $|\eta| < 2.5$ , and  $|\eta_1 - \eta_2| < 1.1$ . The observed limits (solid curve), expected limits (dashed curve) and their variation at the 1 and 2 standard deviation levels (shaded bands) are shown. The dashed-dotted curve shows the expected cross section times acceptance for a DM mediator (see text).

## 8 Summary

A search for a narrow vector resonance of mass between 350 and 700 GeV decaying into two jets has been performed in events containing at least three jets using proton-proton collision data at  $\sqrt{s} = 13 \text{ TeV}$  at the LHC corresponding to an integrated luminosity of  $18.3 \text{ fb}^{-1}$ . The dijet mass distribution of the two leading jets is smooth, and there is no evidence for a resonance. Upper limits at 95% confidence level are set on the product of the cross section, branching fraction, and acceptance as a function of resonance mass. This search excludes a simplified model of interactions between quarks and dark matter particles of mass 1 GeV, where the interactions are mediated by a vector particle with mass between 350 and 700 GeV, for coupling strengths of  $g_q = 0.25$  and  $g_{\text{DM}} = 1$ . Upper limits between 0.10 and 0.15 are also set on the coupling to quarks  $g'_q$  for a vector particle interacting only with quarks. These results represent the most stringent upper limits in the mass range between 350 and 450 GeV obtained with a search that is sensitive to the decay of the resonance into light-flavor quarks.

## Acknowledgments

We congratulate our colleagues in the CERN accelerator departments for the excellent performance of the LHC and thank the technical and administrative staffs at CERN and at other CMS institutes for their contributions to the success of the CMS effort. In addition, we gratefully acknowledge the computing centers and personnel of the Worldwide LHC Computing Grid for delivering so effectively the computing infrastructure essential to our analyses. Finally, we acknowledge the enduring support for the construction and operation of the LHC and the CMS detector provided by the following funding agencies: BMBWF and FWF (Austria); FNRS and FWO (Belgium); CNPq, CAPES, FAPERJ, FAPERGS, and FAPESP (Brazil); MES (Bulgaria); CERN; CAS, MoST, and NSFC (China); COLCIENCIAS (Colombia); MSES and CSF (Croatia);

Figure 3: Upper limits at 95% CL on the universal quark coupling  $g'_q$ , as a function of resonance mass, for a narrow vector resonance that only couples to quarks. The observed limits (solid curve), expected limits (dashed curve) and their variation at the 1 and 2 standard deviation levels (shaded bands) are shown. The dashed-dotted curve shows the coupling strength for which the cross section for dijet production in this model is the same as for a DM mediator (see text).

**Vanderbilt University, Nashville, USA**

S. Greene, A. Gurrola, R. Janjam, W. Johns, C. Maguire, A. Melo, H. Ni, K. Padeken, F. Romeo, P. Sheldon, S. Tuo, J. Velkovska, M. Verweij

**University of Virginia, Charlottesville, USA**

M.W. Arenton, P. Barria, B. Cox, G. Cummings, J. Hakala, R. Hirosky, M. Joyce, A. Ledovskoy, C. Neu, B. Tannenwald, Y. Wang, E. Wolfe, F. Xia

**Wayne State University, Detroit, USA**

R. Harr, P.E. Karchin, N. Poudyal, J. Sturdy, P. Thapa

**University of Wisconsin - Madison, Madison, WI, USA**

T. Bose, J. Buchanan, C. Caillol, D. Carlsmith, S. Dasu, I. De Bruyn, L. Dodd, C. Galloni, H. He, M. Herndon, A. Hervé, U. Hussain, A. Lanaro, A. Loeliger, K. Long, R. Loveless, J. Madhusudanan Sreekala, D. Pinna, T. Ruggles, A. Savin, V. Sharma, W.H. Smith, D. Teague, S. Trembath-reichert

†: Deceased

- 1: Also at Vienna University of Technology, Vienna, Austria
- 2: Also at IRFU, CEA, Université Paris-Saclay, Gif-sur-Yvette, France
- 3: Also at Universidade Estadual de Campinas, Campinas, Brazil
- 4: Also at Federal University of Rio Grande do Sul, Porto Alegre, Brazil
- 5: Also at UFMS, Nova Andradina, Brazil
- 6: Also at Universidade Federal de Pelotas, Pelotas, Brazil
- 7: Also at Université Libre de Bruxelles, Bruxelles, Belgium
- 8: Also at University of Chinese Academy of Sciences, Beijing, China
- 9: Also at Institute for Theoretical and Experimental Physics named by A.I. Alikhanov of NRC 'Kurchatov Institute', Moscow, Russia
- 10: Also at Joint Institute for Nuclear Research, Dubna, Russia
- 11: Also at Suez University, Suez, Egypt
- 12: Now at British University in Egypt, Cairo, Egypt
- 13: Also at Purdue University, West Lafayette, USA
- 14: Also at Université de Haute Alsace, Mulhouse, France
- 15: Also at Erzincan Binali Yildirim University, Erzincan, Turkey
- 16: Also at CERN, European Organization for Nuclear Research, Geneva, Switzerland
- 17: Also at RWTH Aachen University, III. Physikalisches Institut A, Aachen, Germany

- 18: Also at University of Hamburg, Hamburg, Germany  
19: Also at Brandenburg University of Technology, Cottbus, Germany  
20: Also at Institute of Physics, University of Debrecen, Debrecen, Hungary, Debrecen, Hungary  
21: Also at Institute of Nuclear Research ATOMKI, Debrecen, Hungary  
22: Also at MTA-ELTE Lendület CMS Particle and Nuclear Physics Group, Eötvös Loránd University, Budapest, Hungary, Budapest, Hungary  
23: Also at IIT Bhubaneswar, Bhubaneswar, India, Bhubaneswar, India  
24: Also at Institute of Physics, Bhubaneswar, India  
25: Also at Shoolini University, Solan, India  
26: Also at University of Hyderabad, Hyderabad, India  
27: Also at University of Visva-Bharati, Santiniketan, India  
28: Also at Isfahan University of Technology, Isfahan, Iran  
29: Now at INFN Sezione di Bari <sup>a</sup>, Università di Bari <sup>b</sup>, Politecnico di Bari <sup>c</sup>, Bari, Italy  
30: Also at Italian National Agency for New Technologies, Energy and Sustainable Economic Development, Bologna, Italy  
31: Also at Centro Siciliano di Fisica Nucleare e di Struttura Della Materia, Catania, Italy  
32: Also at Scuola Normale e Sezione dell'INFN, Pisa, Italy  
33: Also at Riga Technical University, Riga, Latvia, Riga, Latvia  
34: Also at Malaysian Nuclear Agency, MOSTI, Kajang, Malaysia  
35: Also at Consejo Nacional de Ciencia y Tecnología, Mexico City, Mexico  
36: Also at Warsaw University of Technology, Institute of Electronic Systems, Warsaw, Poland  
37: Also at Institute for Nuclear Research, Moscow, Russia  
38: Now at National Research Nuclear University 'Moscow Engineering Physics Institute' (MEPhI), Moscow, Russia  
39: Also at St. Petersburg State Polytechnical University, St. Petersburg, Russia  
40: Also at University of Florida, Gainesville, USA  
41: Also at Imperial College, London, United Kingdom  
42: Also at P.N. Lebedev Physical Institute, Moscow, Russia  
43: Also at California Institute of Technology, Pasadena, USA  
44: Also at Budker Institute of Nuclear Physics, Novosibirsk, Russia  
45: Also at Faculty of Physics, University of Belgrade, Belgrade, Serbia  
46: Also at Università degli Studi di Siena, Siena, Italy  
47: Also at INFN Sezione di Pavia <sup>a</sup>, Università di Pavia <sup>b</sup>, Pavia, Italy, Pavia, Italy  
48: Also at National and Kapodistrian University of Athens, Athens, Greece  
49: Also at Universität Zürich, Zurich, Switzerland  
50: Also at Stefan Meyer Institute for Subatomic Physics, Vienna, Austria, Vienna, Austria  
51: Also at Burdur Mehmet Akif Ersoy University, BURDUR, Turkey  
52: Also at Adiyaman University, Adiyaman, Turkey  
53: Also at Şırnak University, Sirnak, Turkey  
54: Also at Tsinghua University, Beijing, China  
55: Also at Beykent University, Istanbul, Turkey, Istanbul, Turkey  
56: Also at Istanbul Aydin University, Istanbul, Turkey  
57: Also at Mersin University, Mersin, Turkey  
58: Also at Piri Reis University, Istanbul, Turkey  
59: Also at Gaziosmanpasa University, Tokat, Turkey  
60: Also at Ozyegin University, Istanbul, Turkey  
61: Also at Izmir Institute of Technology, Izmir, Turkey  
62: Also at Marmara University, Istanbul, Turkey

- 63: Also at Kafkas University, Kars, Turkey
- 64: Also at Istanbul Bilgi University, Istanbul, Turkey
- 65: Also at Hacettepe University, Ankara, Turkey
- 66: Also at Vrije Universiteit Brussel, Brussel, Belgium
- 67: Also at School of Physics and Astronomy, University of Southampton, Southampton, United Kingdom
- 68: Also at IPPP Durham University, Durham, United Kingdom
- 69: Also at Monash University, Faculty of Science, Clayton, Australia
- 70: Also at Bethel University, St. Paul, Minneapolis, USA, St. Paul, USA
- 71: Also at Karamanoğlu Mehmetbey University, Karaman, Turkey
- 72: Also at Bingöl University, Bingöl, Turkey
- 73: Also at Georgian Technical University, Tbilisi, Georgia
- 74: Also at Sinop University, Sinop, Turkey
- 75: Also at Mimar Sinan University, Istanbul, Istanbul, Turkey
- 76: Also at Texas A&M University at Qatar, Doha, Qatar
- 77: Also at Kyungpook National University, Daegu, Korea, Daegu, Korea
