

Measurement of the total and differential Higgs boson production cross-sections at $\sqrt{s} = 13$ TeV with the ATLAS detector by combining the $H \rightarrow ZZ^* \rightarrow 4\ell$ and $H \rightarrow \gamma\gamma$ decay channels

The ATLAS Collaboration

The total and differential Higgs boson production cross-sections are measured through a combined statistical analysis of the $H \rightarrow ZZ^* \rightarrow 4\ell$ and $H \rightarrow \gamma\gamma$ decay channels. The results are based on a dataset of 139 fb^{-1} of proton–proton collisions at a centre-of-mass energy of 13 TeV, recorded by the ATLAS detector at the Large Hadron Collider. The measured total Higgs boson production cross-section is $55.5_{-3.8}^{+4.0} \text{ pb}$, consistent with the Standard Model prediction of $55.6 \pm 2.5 \text{ pb}$. All results from the two decay channels are compatible with each other, and their combination agrees with the Standard Model predictions. A combined statistical interpretation of the measured fiducial cross-sections as a function of the Higgs boson transverse momentum is performed in order to probe the Yukawa couplings to the bottom and charm quarks. A similar interpretation is performed by including also the constraints from the measurements of Higgs boson production in association with a W or Z boson in the $H \rightarrow b\bar{b}$ and $c\bar{c}$ decay channels.

1 Introduction

Following the discovery of a Higgs boson (H) with a mass around 125 GeV ten years ago [1, 2], by the ATLAS and CMS collaborations at the Large Hadron Collider (LHC) at CERN, an intense programme to measure the properties of this particle and compare them with those of the Higgs boson predicted by the Standard Model (SM) of particle physics [3, 4] has been carried out.

In particular, total and differential fiducial Higgs boson production cross-sections have been measured, probing the kinematic features of the Higgs boson and of the particles produced in association with it. Both the ATLAS and CMS collaborations have measured total and differential fiducial Higgs boson production cross-sections at a proton–proton (pp) centre-of-mass energy $\sqrt{s} = 13$ TeV in the $H \rightarrow ZZ^* \rightarrow 4\ell$ (where $\ell = e, \mu$) [5, 6], $H \rightarrow \gamma\gamma$ [7, 8], $H \rightarrow WW^* \rightarrow e\nu\mu\nu$ [9], and $H \rightarrow \tau\tau$ [10] decay channels. The collaborations have also performed combinations of some of the most sensitive results [11, 12]. The measurements are performed in fiducial phase spaces that closely match the selection requirements of the detector-level analysis after the event reconstruction. This approach significantly reduces the model dependence that would otherwise be introduced by relying on the acceptance factors predicted by the model under consideration to extrapolate the measured signal yields to the full phase space.

The most recent measurements of these cross-sections published by the ATLAS collaboration, exploiting 139 fb^{-1} [13, 14] of 13 TeV proton–proton collisions produced during the whole second data-taking phase of the LHC (Run 2, 2015–2018) and recorded by the ATLAS detector [15], have been performed using the $H \rightarrow ZZ^* \rightarrow 4\ell$ [5] and $H \rightarrow \gamma\gamma$ [7] final states.

The results of these two publications are combined in this article. The measurements are extrapolated to the full phase space and the measured cross-sections are compared with SM predictions. Additional

systematic uncertainties introduced by the extrapolation to the full phase space are counterbalanced by a significant reduction of the statistical uncertainty of the measurement, which is the main limitation to the precision of the measurements in the individual decay channels.

The measurements include the total production cross-section and one and two-dimensional differential production cross-sections as a function of the Higgs boson transverse momentum¹ p_T^H , sensitive to perturbative QCD calculations, and of the Higgs boson rapidity $|y_H|$, sensitive to the parton distribution functions (PDF). Furthermore, differential cross-sections for jet multiplicity N_{jets} and the transverse momentum of the highest- p_T jet $p_T^{\text{lead. jet}}$ are also measured. Both N_{jets} and $p_T^{\text{lead. jet}}$ observables probe the theoretical modelling of high- p_T QCD radiation in Higgs boson production. These distributions are also sensitive to the different Higgs boson production processes. The measurements provide a stringent test of the SM predictions and any deviations from these predictions can indicate the presence of physics beyond the SM (BSM).

This article also presents a combined statistical interpretation, in terms of the b - and c -quark Yukawa coupling strengths to the Higgs boson, of the fiducial differential cross-sections measured as a function of p_T^H in the two decay channels. Another interpretation, also including the constraints on the b and c Yukawa coupling strengths obtained from the measurements of Higgs boson production in association with a W or Z boson, with the Higgs boson decaying to b - or c -quark pairs [16, 17], is presented.

The results presented in this article update and supersede those of a previous publication [11] based on the same final states and a partial Run 2 dataset corresponding to an integrated luminosity of 36.1 fb^{-1} . With respect to the previous publication, both measurements included in this article use an improved jet reconstruction [18] and an improved unfolding procedure that is based on a detector response matrix included in the likelihood fit. Full descriptions of the measurements and the respective improvements in the $H \rightarrow ZZ^* \rightarrow 4\ell$ and $H \rightarrow \gamma\gamma$ decay channels used in this article are given in Refs. [5, 7]. In both decay channels, the cross-sections in the full phase space are obtained from these unfolded yields by taking into account the luminosity, detector effects, acceptance factors, and branching fractions. The SM values of the Higgs boson branching fractions are assumed, and the acceptance factors are based on SM predictions. The value of the Higgs boson mass is assumed to be 125.09 GeV [19].

The paper is organised as follows. Section 2 describes the simulated Higgs boson event samples and inclusive theory cross-section calculations used to obtain the total and fiducial cross-section predictions. The signal acceptance factors for extrapolating the results to the full phase space are detailed in Section 3. The statistical procedure for the combination of the two channels is illustrated in Section 4, yielding the results summarised in Section 5. The differential cross-sections measured as a function of p_T^H are then used to constrain the Yukawa couplings of the Higgs boson to the bottom and charm quarks in Section 6.

2 Higgs boson simulation samples and theoretical predictions

The Monte Carlo (MC) event generators used for the calculation of the acceptance factors and detector effects, and for the SM predictions, are described in detail in Refs. [5, 7]. Their main features are

¹ ATLAS uses a right-handed coordinate system with its origin at the nominal interaction point (IP) in the centre of the detector and the z -axis along the beam pipe. The x -axis points from the IP to the centre of the LHC ring, and the y -axis points upward. Cylindrical coordinates (r, ϕ) are used in the transverse plane, ϕ being the azimuthal angle around the z -axis. The pseudorapidity is defined in terms of the polar angle θ as $\eta = -\ln \tan(\theta/2)$. The rapidity of a particle of energy E and longitudinal momentum p_z is defined as $y = \frac{1}{2} \ln \left(\frac{E+p_z}{E-p_z} \right)$.

summarised in this section.

Gluon–gluon fusion (ggF) events are simulated using POWHEG NNLOPS [20–30] with the PDF4LHC15 next-to-next-to-leading order (NNLO) set of parton distribution functions [31], while other production modes are simulated with POWHEG [20–22] with the PDF4LHC15 next-to-leading order (NLO) set except for $b\bar{b}H$ and tH , which are simulated using MADGRAPH5_AMC@NLO [32, 33] with the NNPDF3.0 NLO PDF set [34]. These samples are generated assuming a Higgs boson with a mass $m_H = 125$ GeV and are normalised to cross-sections obtained from the best available predictions as provided by the LHC Higgs Working Group [35] for $m_H = 125.09$ GeV, which are 48.5 ± 2.4 pb, 3.78 ± 0.08 pb, 2.25 ± 0.06 pb, 0.49 ± 0.11 pb and 0.59 ± 0.05 pb for the ggF, VBF, VH , $b\bar{b}H$ and $t\bar{t}H + tH$ processes respectively. In the case of the ggF NNLOPS prediction, this corresponds to a rescaling to the fixed order N³LO cross-section by a global K -factor of 1.1. The impact of the 90 MeV difference between the values of m_H used in the simulation and in the analysis is negligible, as discussed in Section 3.

For all production mechanisms the PYTHIA 8.2 generator [36] is used to model the $H \rightarrow ZZ^* \rightarrow 4\ell$ and $H \rightarrow \gamma\gamma$ decays, as well as for the parton shower and the underlying event. The AZNLO set of tuned parameters [37] is used for ggF, VBF and VH production, while the A14 tune [38] is used for the other production modes. Alternative ggF, VBF, VH , $tH(t\bar{t}H)$ samples are produced by interfacing the nominal matrix element generator with HERWIG 7.1.3 (HERWIG 7.0.4) [39, 40], using the H7UE set of tuned parameters [40], in order to estimate uncertainties in the signal acceptance factors related to the modelling of the parton shower.

The measurements are also compared with an alternative prediction obtained by summing the expected cross-sections of non-ggF Higgs boson production processes described previously and an alternative SM ggF prediction obtained using MADGRAPH5_AMC@NLO (MG5 FxFx). This matrix-element generator provides NLO accuracy in QCD for zero, one, and two additional jets, using the FxFx merging scheme [32, 41], and includes the top and bottom quark mass effects [42–44]. The events are generated using the NNPDF30 NLO PDF set. The generator is interfaced to PYTHIA 8 for the modelling of the parton shower. The predicted cross-sections are scaled by a global N³LO K -factor of 1.47.

Uncertainties in the predicted ggF, VBF, VH and $t\bar{t}H$ cross-sections induced by PDF uncertainties are estimated by varying the PDF4LHC set according to its eigenvectors [31], and summing in quadrature the variations in the predictions. The effect of PDF variations on the tH and $b\bar{b}H$ cross-sections has a negligible impact on the total uncertainty and is not included.

Uncertainties due to missing higher-order QCD effects for the ggF NNLOPS, VBF, VH and $t\bar{t}H$ predicted cross-sections are estimated using the same scheme as in Refs. [5, 7]: parameters accounting for cross-section and migration effects across various Higgs boson kinematic and associated jet observables are used and their variations are summed in quadrature. For other production modes, uncertainties related to missing higher-order QCD effects are estimated by varying the renormalisation and factorisation scales by factors of 0.5 and 2.0, and computing the difference between the envelope of the alternative predictions and the nominal one.

The Higgs boson branching ratios for $m_H = 125.09$ GeV are assumed to be those of the SM, $(0.0125 \pm 0.0003)\%$ for the four-lepton final state and $(0.227 \pm 0.007)\%$ for the diphoton final state [35].

3 Acceptance factors

The acceptance factors that extrapolate at particle-level from the respective $H \rightarrow ZZ^* \rightarrow 4\ell$ and $H \rightarrow \gamma\gamma$ fiducial phase spaces to the full phase space are estimated using the simulated event samples and cross-sections described in Section 2. The definitions of the fiducial phase spaces are summarised in Table 1 and Table 2, with more details provided in Refs. [5, 7] respectively. The evaluation of the acceptance factors assumes SM Higgs boson production fractions and a Higgs boson mass of 125 GeV: the 90 MeV difference from the measured mass value of 125.09 GeV has a negligible impact on the Higgs boson kinematics.

Table 1: Summary of the particle-level fiducial definitions in the $H \rightarrow ZZ^* \rightarrow 4\ell$ analysis [5]. A lepton *quadruplet* is formed by two same-flavour, opposite-charge (SFOC) lepton pairs. Dressed leptons are leptons whose four-momenta have been modified by adding the four-momenta of photons within a cone of size $\Delta R = 0.1$ around the lepton to account for final state radiation. The invariant mass of the SFOC lepton pair that is closest to m_Z is denoted with m_{12} , while the invariant mass of the SFOC pair of remaining leptons that is closest to m_Z is denoted with m_{34} . The quadruplet satisfying the *lepton selection and pairing criteria* is labelled as the nominal quadruplet. If the nominal quadruplet fails the *event selection criteria*, no quadruplet is marked as the Higgs boson candidate. If the nominal quadruplet passes the selection and there is an additional lepton, the quadruplet with the largest ggF matrix element value is taken as the Higgs boson candidate. If no extra lepton is found, then the nominal quadruplet is taken as the Higgs boson candidate.

| Lepton and jet definitions | |
|-------------------------------------|---|
| Leptons | Dressed leptons not originating from hadron or τ decays $p_T > 5$ GeV, $ \eta < 2.7$ |
| Jets | $p_T > 30$ GeV, $ y < 4.4$ |
| Lepton selection and pairing | |
| Lepton kinematics | p_T threshold for three leading leptons: $> 20, 15, 10$ GeV |
| Leading pair (m_{12}) | SFOC lepton pair with smallest $ m_Z - m_{\ell\ell} $ |
| Subleading pair (m_{34}) | Remaining SFOC lepton pair with smallest $ m_Z - m_{\ell\ell} $ as nominal |
| Event selection | |
| Mass requirements | $50 \text{ GeV} < m_{12} < 106 \text{ GeV}$ and $12 \text{ GeV} < m_{34} < 115 \text{ GeV}$ |
| Lepton separation | $\Delta R(\ell_i, \ell_j) > 0.1$ |
| Lepton/Jet separation | $\Delta R(\ell_i, \text{jet}) > 0.1$ |
| J/ψ veto | $m(\ell_i, \ell_j) > 5$ GeV for all SFOC lepton pairs |
| Mass window | $105 \text{ GeV} < m_{4\ell} < 160 \text{ GeV}$ |
| If extra lepton with $p_T > 12$ GeV | Quadruplet with largest ggF matrix element value |

In the full phase space, the quantities p_T^H and $|y_H|$ are computed directly from the simulated Higgs boson momentum instead of its decay products, as in the fiducial analyses. The acceptance factors implicitly include the correction for this difference. Simulated particle-level jets are built from all stable particles with $c\tau > 10$ mm, including neutrinos, photons, and leptons from hadron decays or produced in the shower. All decay products from the Higgs boson decay and the leptonic decays of associated vector bosons are removed from the inputs to the jet algorithm. Jets are reconstructed using the anti- k_t algorithm [45] with a radius parameter $R = 0.4$, and are required to have $p_T > 30$ GeV.

Theory uncertainties related to the PDF, higher-order corrections, and the parton shower model are taken into account when evaluating acceptance factors. For each channel, the uncertainties in the acceptance

Table 2: Summary of the particle-level fiducial definitions in the $H \rightarrow \gamma\gamma$ analysis [7]. $E_T^{\text{iso}}(\Delta R, p_T, \text{charged})$ is the scalar sum of the transverse momenta of charged stable particles with a transverse momentum above the specified threshold within a ΔR cone centred on the photon direction.

| Photon and jet definitions | |
|-----------------------------------|--|
| Photons | Photons not originating from hadron decays $p_T > 15 \text{ GeV}$, $ \eta < 1.37$ or $1.52 < \eta < 2.37$ $E_T^{\text{iso}}(\Delta R < 0.2, p_T > 1 \text{ GeV}, \text{charged}) < 0.05 E_T$ |
| Jets | $p_T > 30 \text{ GeV}$, $ y < 4.4$ |
| Event selection | |
| Photon kinematics | p_T threshold for two leading photons: $p_T^{\gamma_1} > 0.35 m_{\gamma\gamma}$, $p_T^{\gamma_2} > 0.25 m_{\gamma\gamma}$ |
| Mass window | $105 \text{ GeV} < m_{\gamma\gamma} < 160 \text{ GeV}$ |

factors are correlated with the impact of these theoretical sources on the detector response matrix used in the unfolding. Due to this procedure, compared with the results in Ref. [7], the $H \rightarrow \gamma\gamma$ results presented in this article have these additional theoretical uncertainties in the detector response matrix. Uncertainties due to the PDF and missing higher-order corrections are estimated as described in Section 2. Uncertainties due to the parton shower model are evaluated by comparing the acceptance factors estimated using MC samples with the default PYTHIA8 showering with the acceptance factors computed using MC samples relying on the HERWIG7 showering model. To account for the uncertainties in the SM Higgs boson production cross-sections when calculating the total acceptance factor from the sum of the various production modes, the fractions of production modes are independently varied within their measured uncertainties taken from Ref. [46]. The total systematic uncertainties in the acceptance factors range between 0.5% and 7%, depending on the observable and bin, with the parton shower uncertainty being the dominant source.

The inclusive acceptance factors, relative to the full phase space, are about 50% for both the $H \rightarrow ZZ^* \rightarrow 4\ell$ and the $H \rightarrow \gamma\gamma$ channels. Figure 1 shows the acceptance factors and their systematic uncertainties as a function of p_T^H and N_{jets} . In the $H \rightarrow ZZ^* \rightarrow 4\ell$ channel, the acceptance factor drops in the highest p_T^H bin due to the lepton separation requirement, while the shape of the acceptance factor for the $H \rightarrow \gamma\gamma$ channel as a function of p_T^H is due to the p_T selection criteria on the photons.

4 Statistical procedure

A likelihood combination of the two decay channels is performed, following the method described in Ref. [11]. For some observables, such as p_T^H and $p_T^{\text{lead. jet}}$, the binning in the $H \rightarrow \gamma\gamma$ analysis is finer than that in the $H \rightarrow ZZ^* \rightarrow 4\ell$ analysis. Where needed, the sum of the consecutive $H \rightarrow \gamma\gamma$ sub-bins is combined with one $H \rightarrow ZZ^* \rightarrow 4\ell$ bin such that the measured bin boundaries match between the two results. A summary of the bin boundaries used in the combined results is presented in Table 3. Higgs boson events that are outside of the fiducial region but are reconstructed within the signal region are accounted for in the likelihood function by a small correction (around 1–2%) of the signal normalisation, as described in Refs. [5, 7].

Experimental and theoretical uncertainties that affect both channels are correlated via common nuisance parameters. The correlated experimental uncertainties include the uncertainties in the integrated luminosity,

Figure 1: Acceptance factors (solid lines), including systematic uncertainties (hatched bands), for the extrapolation from the fiducial to the full phase space for the $H \rightarrow ZZ^* \rightarrow 4\ell$ decay channel (blue) and the $H \rightarrow \gamma\gamma$ decay channel (magenta), as a function of variables characterising the Higgs boson kinematics: (a) Higgs boson transverse momentum p_T^H and (b) number of jets N_{jets} with $p_T > 30$ GeV.

Table 3: Bin boundaries used in the combination of the cross-section of various differential observables. For the $p_T^{\text{lead. jet}}$ distribution, the first bin contains all events with a leading jet with p_T less than 30 GeV, and corresponds exactly with the 0-jet bin in the N_{jets} differential distribution.

| Variable | Bin Edges | N_{bins} |
|--------------------------|--|-------------------|
| p_T^H | 0, 10, 20, 30, 45, 60, 80, 120, 200, 300, 650, 13000 GeV | 11 |
| $ y_H $ | 0, 0.15, 0.3, 0.45, 0.6, 0.75, 0.9, 1.2, 1.6, 2.0, 2.5 | 10 |
| N_{jets} | 0, 1, 2, ≥ 3 | 4 |
| $p_T^{\text{lead. jet}}$ | 0, 30, 60, 120, 350 GeV | 4 |
| p_T^H vs $ y_H $ | p_T^H : 0, 45, 120, 350 GeV; $ y_H $: 0, 0.5, 1.0, 1.5, 2.5 | 12 |

in the description of the pile-up in the simulation, in the jet reconstruction and calibration, in the common electron-photon energy scale, in the Higgs boson mass value, and in the contributions of the different Higgs boson production modes. Additionally, the common sources of theoretical uncertainty in the $H \rightarrow ZZ^* \rightarrow 4\ell$ and $H \rightarrow \gamma\gamma$ branching ratios (strong coupling constant, b and c quark masses, and partial decay widths to the main decay channels, such as two vector bosons, two gluons, or a $b\bar{b}$ pair) are also correlated. Finally, the theoretical uncertainties in the acceptance factor and response matrix due to missing higher-order QCD effects, PDF variations, variations of the modelling of the parton shower, and signal composition uncertainties are also correlated across the Higgs boson decay channels.

The asymptotic approximation [47] for the distribution of the profile likelihood ratio is assumed in the computation of uncertainties on all reported measurements. The validity of this approximation has been verified in previous analyses by performing pseudo-experiments.

5 Results

The total Higgs boson production cross-section at 13 TeV is measured to be $53.0^{+5.3}_{-5.1}$ pb ($^{+4.9}_{-4.8}$ (stat.) $^{+2.0}_{-1.7}$ (syst.)) using the $H \rightarrow ZZ^* \rightarrow 4\ell$ decay channel and $58.1^{+5.7}_{-5.4}$ pb (± 4.2 (stat.) $^{+3.9}_{-3.5}$ (syst.)) using the $H \rightarrow \gamma\gamma$ decay channel. The total cross-section obtained combining the two results is $55.5^{+4.0}_{-3.8}$ pb (± 3.2 (stat.) $^{+2.4}_{-2.2}$ (syst.)). All three results are in agreement with the SM prediction of 55.6 ± 2.5 pb. The measurements in the two decay channels are compatible with each other with a p -value of 49%, and the compatibility of the combined result with the SM prediction has a p -value of 98%. All compatibility checks are performed using a likelihood ratio approach, based on the test statistic variation under different hypotheses in the asymptotic approximation.

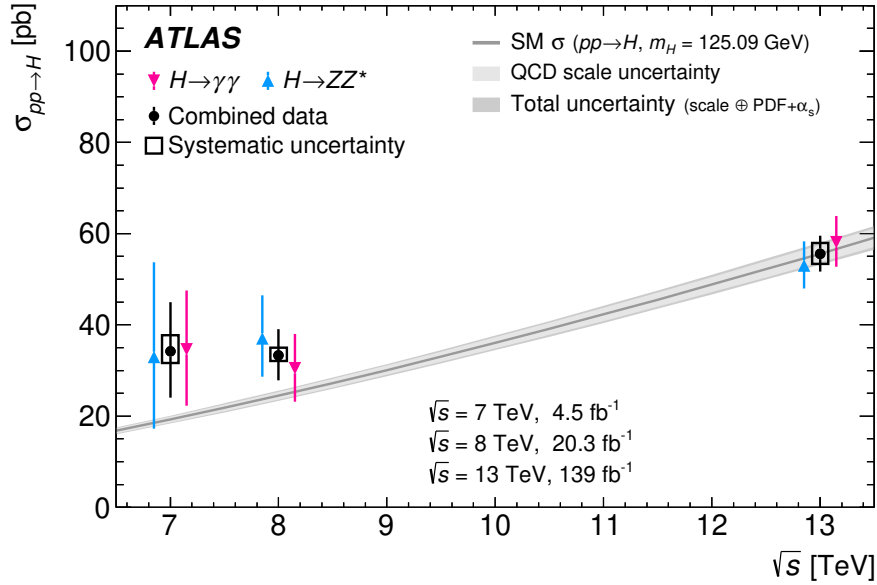

Figure 2: Total $pp \rightarrow H + X$ cross-sections measured at centre-of-mass energies of 7, 8 and 13 TeV, compared with Standard Model predictions taken from Ref. [35]. The measurements with the $H \rightarrow ZZ^* \rightarrow 4\ell$ channel (blue triangles), $H \rightarrow \gamma\gamma$ channel (magenta inverted triangles) and their combination (black dots) are shown. The individual channel results are offset along the x -axis for display purposes. The black boxes around the combined measurements represent the systematic uncertainty, while the error bars show the total uncertainty. The light grey band shows the uncertainty in the prediction due to missing QCD higher-order corrections. The dark grey band indicates the total theoretical uncertainty, corresponding to the dominant QCD higher-order-correction uncertainty summed in quadrature with the sum of the PDF and α_s uncertainties, and is partially correlated across values of the centre-of-mass energy.

The total cross-section measured using the two channels, their combination, and the SM prediction for a Higgs boson mass of 125.09 GeV are shown in Figure 2. The figure also includes the results of the measurements using data collected at a pp centre-of-mass energies of $\sqrt{s} = 8$ TeV and 7 TeV, and the corresponding theoretical expectations. The event samples, selections and the cross-section measurement techniques used for the 8 TeV measurements are described in Refs. [48, 49]; similar techniques are used to measure the cross-sections at 7 TeV as described in Refs. [50, 51]. For both the 7 and 8 TeV results, the signal yields in the two decay channels are measured inclusively and corrected for acceptance and detector effects. The results at each centre-of-mass energy are then combined using a likelihood-based technique described in Ref. [52]. The total Higgs boson production cross-section at 7 TeV is measured to be 33^{+21}_{-16} pb using the

$H \rightarrow ZZ^* \rightarrow 4\ell$ channel, 35_{-16}^{+13} pb using the $H \rightarrow \gamma\gamma$ decay channel, and 34_{-10}^{+11} pb (± 10 (stat.) $_{-2}^{+4}$ (syst.)) from their combination. This is to be compared with the SM expectation of 19.2 ± 0.9 pb. At 8 TeV, the total Higgs boson production cross-section is measured to be 37_{-8}^{+9} pb using the $H \rightarrow ZZ^* \rightarrow 4\ell$ channel, $30.5_{-7.4}^{+7.5}$ pb using the $H \rightarrow \gamma\gamma$ decay channel, and $33.3_{-5.4}^{+5.8}$ pb ($_{-5.3}^{+5.5}$ (stat.) $_{-1.3}^{+1.7}$ (syst.)) from their combination. This is to be compared with the SM expectation of 24.5 ± 1.1 pb. These results supersede the previously published ones, which used signal yield estimates, acceptance factors and SM Higgs boson branching ratios calculations based on a different value of the Higgs boson mass.

The differential cross-sections in bins of p_T^H , $|y_H|$, p_T^H vs $|y_H|$, N_{jets} and $p_T^{\text{lead. jet}}$ for the individual channels and their combination are shown in Figures 3 and 4. The uncertainty band around the SM prediction includes PDF and α_S uncertainties as well as those due to missing QCD higher-order corrections, obtained following the method described in Ref. [53]. When compared with the results from the individual channels, the total uncertainty for the combined results is lower by 20%–40% and the impact of uncorrelated systematic uncertainties is reduced by approximately 40%. The observed correlation matrices among the cross-sections measured in different bins of the same observable are shown in Appendix A. The correlations are small ($< 10\%$) for the Higgs-related observables (p_T^H , $|y_H|$), characterised by better experimental resolution, and larger (up to about 40%) for jet-related observables (N_{jets} and $p_T^{\text{lead. jet}}$) with worse resolution and larger migrations.

All combined measurements are dominated by statistical uncertainties. Significant systematic uncertainties affecting the total and all differential cross-sections arise from the background modelling in the $H \rightarrow \gamma\gamma$ signal extraction [7] (typical error of 2–5%) and the integrated luminosity (1.7%). For the N_{jets} and $p_T^{\text{lead. jet}}$ differential cross-section measurements, the uncertainties in the reconstruction of the jet energy scale and resolution are important as well, with impacts on the results typically in the range of 2–9%. The dominant theoretical source of uncertainty is the parton shower modelling for ggF signal and has an impact of 2–6%.

The p -values for the compatibility among the individual measurements are given in Table 4. The p -values for the compatibility of the measurements with various theoretical predictions are given in Table 5 for the differential cross-section results. For all observables, the measurements in the two channels are compatible with each other, with p -values ranging between 20% and 80%. The combined measurements are also in good agreement with the predictions, with p -values ranging between 20% and 98%. The prediction based on the NNLOPS simulation of gluon–gluon fusion events is lightly favoured over that based on the MG5 FxFx simulation.

Table 4: p -values for the compatibility of the individual $H \rightarrow ZZ^* \rightarrow 4\ell$ and $H \rightarrow \gamma\gamma$ results for the combined total and differential cross-sections.

| Observable | Total | p_T^H | $ y_H $ | p_T^H vs $ y_H $ | N_{jets} | $p_T^{\text{lead. jet}}$ |
|--------------------------|-------|---------|---------|--------------------|-------------------|--------------------------|
| Compatibility p -value | 49% | 20% | 23% | 69% | 80% | 37% |

Figure 3: Differential $pp \rightarrow H + X$ cross-sections, in the full phase space, as a function of variables characterising the Higgs boson kinematics: (a) Higgs boson transverse momentum p_T^H , (b) Higgs boson rapidity $|y_H|$, and (c) p_T^H vs $|y_H|$, compared with Standard Model predictions. The $H \rightarrow ZZ^* \rightarrow 4\ell$ (blue triangles), $H \rightarrow \gamma\gamma$ (magenta inverted triangles), and combined (black squares) measurements are shown. The error bars on the data points show the total uncertainties, while the systematic uncertainties are indicated by the boxes. The measurements are compared with two predictions, obtained by summing the ggF predictions of NNLOPS or MG5 FxFx, normalised to the fixed order N³LO total cross-section with the listed K -factors, and the MC predictions for the other production processes XH . The shaded bands indicate the relative impact of the PDF and scale systematic uncertainties in the prediction. These include the uncertainties related to the XH production modes. The dotted red histogram corresponds to the central value of the prediction that uses NNLOPS for the modelling of the ggF component. The bottom panels show the ratios between the predictions and the combined measurement. The grey area represents the total uncertainty of the measurement. For better visibility, all bins are shown as having the same size, independent of their numerical width.

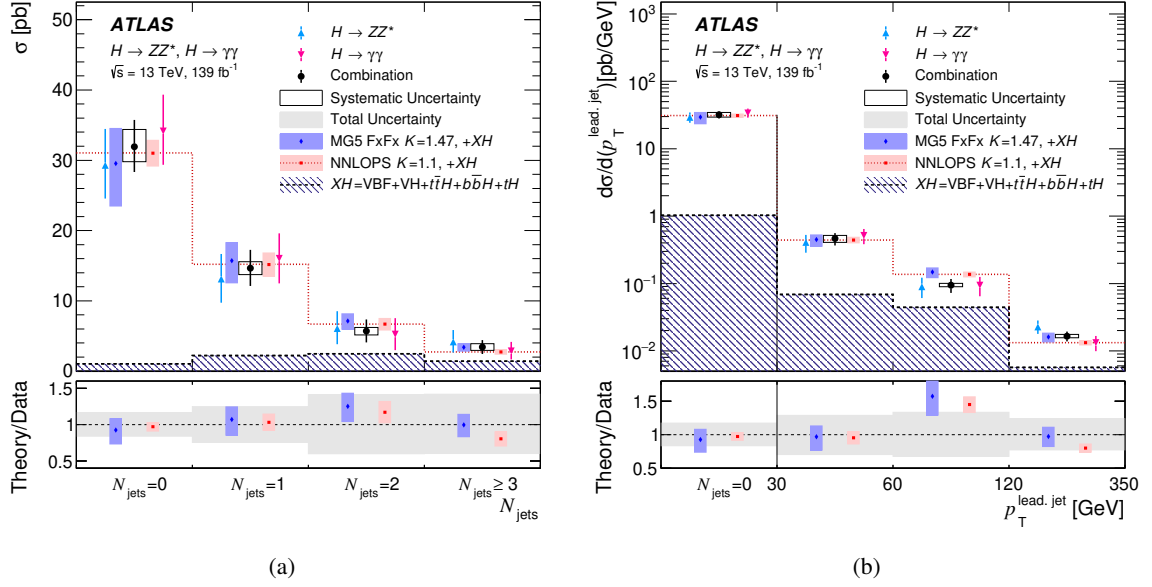

Figure 4: Differential $pp \rightarrow H + X$ cross-sections, in the full phase space, as a function of variables related to the jets produced in association with the Higgs boson, (a) number of jets and (b) p_T of the leading jet, compared with Standard Model predictions. The figure uses the same layout as Figure 3.

Table 5: p -values for the compatibility of the measured cross-sections with the SM predictions when the distributions for gluon–gluon fusion events obtained with either NNLOPS or MG5 FxFx, scaled to the fixed order $N^3\text{LO}$ total gluon–gluon fusion cross-section, are used. The uncertainties in the theoretical predictions are included when calculating the p -values.

| SM prediction | p_T^H | $ y_H $ | p_T^H vs $ y_H $ | N_{jets} | $p_T^{\text{lead.j}}$ |
|---------------|---------|---------|--------------------|-------------------|-----------------------|
| NNLOPS | 91% | 98% | 56% | 95% | 34% |

6 Constraints on the b - and c -quark Yukawa couplings

The observations of the Higgs boson decays to $b\bar{b}$ [16, 54] provided stringent constraints on the possible modification of the b -quark Yukawa coupling with respect to its SM prediction, whereas current searches for Higgs boson decays to charm final states [17, 55] still allow for a relatively large modification of the c -quark coupling. These measurements have been interpreted in terms of the Yukawa coupling modifiers for b - and c -quarks, κ_b and κ_c , defined as multipliers of the SM values of these couplings [35]. The measured value of κ_b agrees with the SM prediction of one with a precision of about 10% [56] to 20% [57], whereas the constraints on κ_c are significantly looser: $|\kappa_c| < 5.7$ [56] or $1.1 < |\kappa_c| < 5.5$ [58] at the 95% confidence level (CL).

The Higgs boson p_T distribution is sensitive to modifications of the Yukawa couplings of the Higgs boson to the b - and c -quarks [59]. This sensitivity is driven by the contributions of b - and c -quarks to the loop-induced ggF production and by the quark-initiated production of the Higgs boson. The former production mode includes an interference term between b - and c -quark loop-mediated amplitudes which is proportional to the product of the two couplings and is therefore sensitive to their relative sign. Modifications of the coupling strength to b - and c -quarks result in changes to both the overall cross-section and the shape of the p_T^H distribution. In addition, the branching ratio for the $H \rightarrow \gamma\gamma$ decay would be affected by corresponding changes to its partial decay width, and both the $H \rightarrow ZZ^* \rightarrow 4\ell$ and $H \rightarrow \gamma\gamma$ branching ratios would also be affected by the changes to the total Higgs boson decay width.

This section presents constraints on κ_b and κ_c , inferred from the measured p_T^H distributions. A combined interpretation is then performed in terms of κ_b and κ_c by including also the constraints from the measurement of Higgs bosons, produced in association with a vector boson, decaying to $b\bar{b}$ [16], and from the search for Higgs bosons produced in a similar way and decaying to $c\bar{c}$ [17]. All tree-level couplings of the Higgs boson to particles other than the b - or c -quarks are set to their SM values and loop-induced Higgs boson couplings are resolved to their SM expectation, with κ_b and κ_c as free parameters.

6.1 Constraints from the Higgs boson transverse momentum distributions

The constraints on κ_b and κ_c from the observed p_T^H distributions in the $H \rightarrow ZZ^* \rightarrow 4\ell$ and $H \rightarrow \gamma\gamma$ final states are derived in two scenarios: one in which only modification to the shape of the measured p_T^H distributions is considered (“*shape-only*”), and one in which the impact on the overall expected normalisation, through modifications of the total cross-sections, branching ratios and Higgs boson decay width, is also considered (“*shape+normalisation*”).

The theoretical predictions used for these interpretations are detailed in Ref. [7]. The predictions for κ_b and κ_c modifications of the ggF production are computed with SCET_{LIB} [60, 61]. For the $H \rightarrow \gamma\gamma$ decay channel, the calculations are performed directly after applying the particle-level requirements defining the $H \rightarrow \gamma\gamma$ fiducial phase space, while for the $H \rightarrow ZZ^* \rightarrow 4\ell$ decay channel, the calculations are performed in the full phase space and then extrapolated to the $H \rightarrow ZZ^* \rightarrow 4\ell$ fiducial phase space using the acceptance factors obtained from the NNLOPS ggF prediction. It has been verified that the dependence of the acceptance factors in each p_T^H bin on the b and c Yukawa coupling modifiers is negligible. The predictions for quark-initiated $b\bar{b} \rightarrow H$ and $c\bar{c} \rightarrow H$ production modes are computed with MADGRAPH5_AMC@NLO 2.7.3. The simulation of the Higgs boson decay, the parton shower, hadronisation and underlying event, is performed with PYTHIA 8 using a dedicated PDF set [62] and the A14 tune. The inclusive $b\bar{b} \rightarrow H$ and $c\bar{c} \rightarrow H$ cross-sections are then normalised to the state-of-the-art

NNLO computations available in Refs. [62, 63]. All the other Higgs boson production modes remain unchanged with κ_b and κ_c variations, and they are estimated as detailed in Section 2.

Theoretical uncertainties related to the QCD modelling and PDF uncertainties on the differential cross-sections are considered using the procedure detailed in Ref. [7]. For the theoretical calculation of the ggF process, uncertainties related to numerical integration, fixed-order scale, hard resummation phase, resummation scheme, matching scale and non-perturbative scheme are implemented [60]. For the b - and c -quark initiated processes, the uncertainty related to missing higher order QCD effects are estimated by varying the renormalisation, factorisation and merging scales; the uncertainties related to the PDF set are estimated by varying the mass and scale associated with the b -quark for the $b\bar{b} \rightarrow H$ process and by using the MC replicas of the nominal PDF set for the $c\bar{c} \rightarrow H$ process; the uncertainties due to the choice of the FxFx merging scale are estimated by using alternative values of this scale. Theoretical uncertainties in the other production modes that do not depend on κ_b or κ_c , from higher-order QCD effects, PDF and α_s , and the parton shower model, are estimated as described in Section 2.

The statistical interpretation is performed by first parameterising the fiducial cross-sections as a function of κ_b and κ_c for each decay channel. The two likelihood models are then jointly interpreted using the same procedure as detailed in Section 4.

Table 6: Observed and expected 95% confidence intervals for the Yukawa coupling modifiers when modifications to only the p_T^H shape are considered (*shape-only*), for the individual decay channels and their combination. The results for one coupling modifier are obtained while fixing the other one to the SM expectation ($\kappa = 1$).

| Channel | Parameter | Observed | Expected |
|--|------------|-------------------------|-------------------------|
| | | 95% confidence interval | 95% confidence interval |
| $H \rightarrow ZZ^* \rightarrow 4\ell$ | κ_b | [-1.8, 6.4] | [-3.3, 9.3] |
| | κ_c | [-7.7, 18.3] | [-12.3, 19.2] |
| $H \rightarrow \gamma\gamma$ | κ_b | [-3.5, 10.2] | [-2.5, 8.0] |
| | κ_c | [-12.6, 18.3] | [-10.1, 17.3] |
| Combined | κ_b | [-2.0, 7.4] | [-2.0, 7.4] |
| | κ_c | [-8.6, 17.3] | [-8.5, 15.9] |

The expected and observed 95% confidence intervals for κ_b and κ_c are shown in Tables 6 and 7 for the *shape-only* and *shape+normalisation* scenarios, respectively. The limits on a given κ parameter are determined with the other one fixed to SM prediction ($\kappa = 1$). If κ_b is unconstrained in the fit, the 95% confidence intervals for κ_c are about 10% (twice) larger than if κ_b is fixed to the SM value of one, in the *shape-only* (*shape+normalisation*) approach.

In the *shape-only* approach, the combined observed limits are less stringent than the individual $H \rightarrow ZZ^* \rightarrow 4\ell$ result. This is due to the quadratic dependency of the cross-section and the differential distribution on the κ parameters leading to a double minimum in the profile likelihood ratio, and due to the combined best-fit value for the κ_b parameter being further from the SM expectation when probing only the $H \rightarrow \gamma\gamma$ decay channel. For κ_c , the observed combined best-fit value is similar to the best-fit value in the $H \rightarrow ZZ^* \rightarrow 4\ell$ channel. However, due to the correlation between the κ_b and κ_c parameters, different best-fit κ_b observations between the channels, as well as the data fluctuations in some of the p_T^H bins, the 68% CL observed combined limits on κ_c are worse than the results from the $H \rightarrow ZZ^* \rightarrow 4\ell$ channel. The corresponding 95% CL limits are similar to those from the $H \rightarrow ZZ^* \rightarrow 4\ell$ channel.

In the *shape+normalisation* scenario the constraints on the coupling modifiers are tighter, since a large fraction of the allowed ranges for κ_b and κ_c from the *shape-only* approach lead to values of the total width and thus of the $H \rightarrow ZZ^* \rightarrow 4\ell$ and $H \rightarrow \gamma\gamma$ branching ratios and overall normalisation that are inconsistent with the data.

Two-dimensional confidence regions on κ_b and κ_c are also derived for both scenarios, as shown in Figure 5.

Table 7: Observed and expected 95% confidence intervals for the Yukawa coupling modifiers when modifications to both the p_T^H shape and normalisation are considered (*shape+normalisation*), for the individual decay channels and their combination. The results for one coupling modifier are obtained while fixing the other one to the SM expectation ($\kappa = 1$).

| Channel | Parameter | Observed 95% confidence interval | Expected 95% confidence interval |
|--|------------|-------------------------------------|-------------------------------------|
| $H \rightarrow ZZ^* \rightarrow 4\ell$ | κ_b | $[-1.14, -0.88] \cup [0.80, 1.17]$ | $[-1.23, -0.87] \cup [0.82, 1.20]$ |
| | κ_c | $[-2.94, 2.99]$ | $[-3.33, 3.14]$ |
| $H \rightarrow \gamma\gamma$ | κ_b | $[-1.12, -0.78] \cup [0.78, 1.07]$ | $[-1.18, -0.87] \cup [0.83, 1.19]$ |
| | κ_c | $[-2.46, 2.32]$ | $[-3.03, 3.09]$ |
| Combined | κ_b | $[-1.09, -0.86] \cup [0.81, 1.09]$ | $[-1.14, -0.92] \cup [0.86, 1.15]$ |
| | κ_c | $[-2.27, 2.27]$ | $[-2.77, 2.75]$ |

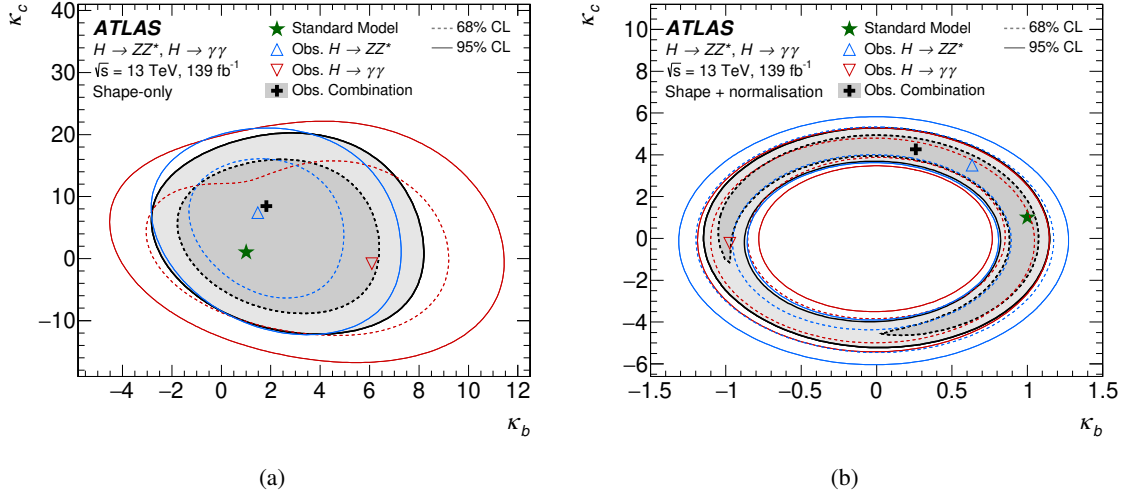

Figure 5: Observed limits at 95% CL on the Yukawa coupling modifiers κ_b and κ_c when (a) only the shape of the p_T^H differential cross-section (*shape-only*) or (b) also its normalisation (*shape+normalisation*) is used to constrain the parameters for the combined and individual decay channels results. The SM predictions (*) and the observed best-fit values (+) are indicated on the plots.

6.2 Combination with the constraints from $VH(b\bar{b})$ and $VH(c\bar{c})$ production

The measurement of Higgs boson decays to $b\bar{b}$ and the search for Higgs boson decays to $c\bar{c}$ in Higgsstrahlung events (VH) constrain the b - and c -quark coupling modifiers through the quadratic dependence on κ_b^2 and κ_c^2 of the partial widths of the Higgs boson to these two final states. This section describes the methodology and the results of a simultaneous fit to the Higgs boson transverse momentum distributions of the $H \rightarrow ZZ^* \rightarrow 4\ell$ and $H \rightarrow \gamma\gamma$ fiducial cross section measurements and to the multivariate discriminant used to measure the $VH(q\bar{q})$ ($q = b, c$) signal strength [16, 17].

Two scenarios are considered for this combination. The first scenario is the “*shape+normalisation*” scenario as described previously. In the second scenario, the Higgs boson is also allowed to decay to BSM particles and the associated partial width is included in the total width. The partial width for BSM decays is parameterised as $\Gamma_{\text{BSM}} = \Gamma \times B_{\text{BSM}} = \Gamma_{\text{SM}} \frac{B_{\text{BSM}}}{1 - B_{\text{BSM}}}$, where Γ is the Higgs boson total width, and B_{BSM} is its branching ratio to BSM particles. The second scenario reduces the assumptions of the model, at the cost of reduced sensitivity.

In the combination, most common experimental systematic uncertainties and signal theory uncertainties are modelled as correlated between the four channels ($H \rightarrow ZZ^* \rightarrow 4\ell$, $H \rightarrow \gamma\gamma$, $VH(b\bar{b})$, $VH(c\bar{c})$). Jet energy calibration and flavour tagging efficiency uncertainties are not modelled as correlated between the channels due to the use of different jet clustering algorithms.

The observed 68% and 95% CL contours in the 2D κ_b vs κ_c plane are shown in Figure 6(a) for the *shape+normalisation* scenario where B_{BSM} is fixed to zero and in Figure 6(b) for the case where B_{BSM} is a free parameter. The fit prefers a positive value of κ_b , but negative values are not excluded at 68% CL, leading to two disconnected allowed regions, corresponding to positive or negative values of κ_b . One-dimensional VH confidence intervals for κ_c with κ_b unconstrained in the fit are summarised in Table 8. Excluding the $VH(c\bar{c})$ channel would worsen the one-dimensional constraints on κ_c by about 10% for the $B_{\text{BSM}} = 0$ scenario, and by a factor two for the alternative scenario where B_{BSM} is not fixed to zero.

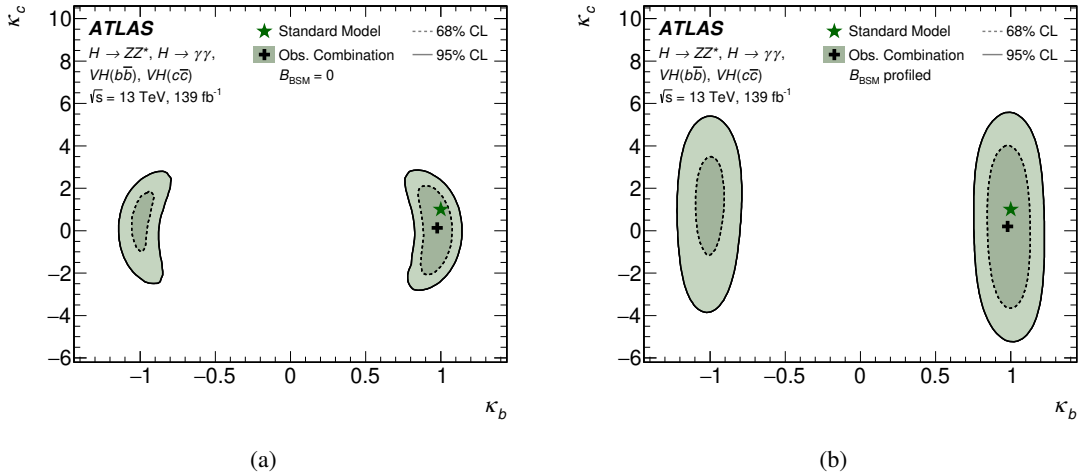

Figure 6: Observed 2D negative log likelihood contours for the κ_b and κ_c parameters from a simultaneous fit to the Higgs p_T fiducial cross-sections in $H \rightarrow \gamma\gamma$ and $H \rightarrow ZZ^* \rightarrow 4\ell$ and to multivariate discriminants used to identify VH events with Higgs bosons decaying to $b\bar{b}$ or $c\bar{c}$, for (a) $B_{\text{BSM}} = 0$ or (b) leaving B_{BSM} unconstrained.

Table 8: One-dimensional confidence intervals in κ_c , while profiling κ_b , at 68% and 95% CL, obtained from a simultaneous fit to fiducial cross-sections in $H \rightarrow ZZ^* \rightarrow 4\ell$ and $H \rightarrow \gamma\gamma$ in bins of the Higgs boson p_T and to VH data with Higgs bosons decaying to $b\bar{b}$ or $c\bar{c}$.

| Scenario | Observed | Observed |
|-----------------------------------|-------------------------|-------------------------|
| | 68% confidence interval | 95% confidence interval |
| $B_{\text{BSM}} = 0$ | [-1.61, 1.70] | [-2.47, 2.53] |
| No assumption on B_{BSM} | [-2.63, 3.01] | [-4.46, 4.81] |

7 Conclusions

A combined measurement of the total and differential Higgs production cross-sections in the $H \rightarrow \gamma\gamma$ and $H \rightarrow ZZ^* \rightarrow 4\ell$ decay channels was performed using 139 fb^{-1} of 13 TeV proton–proton collision recorded by the ATLAS detector during the LHC Run 2. Good agreement is observed when comparing the results from the two channels, after extrapolation to a common phase space. The total Higgs boson production cross-section is measured with an unprecedented precision of 7%, comparable to that of the best available Standard Model prediction which is 5%. The result, $55.5^{+4.0}_{-3.8} \text{ pb}$, agrees with the SM predicted value of $55.6 \pm 2.5 \text{ pb}$.

Differential cross-sections are measured as a function of the Higgs boson transverse momentum and rapidity, the number of jets produced together with the Higgs boson and the transverse momentum of the leading jet. The larger data set and the combination of the two decay channels result in measurement uncertainties that are significantly smaller than in previous results. Notably, the differential cross-section as a function of the Higgs boson transverse momentum is measured with 20–30% precision up to 300 GeV and about 60% precision in the 300–650 GeV range. The combined differential distributions agree with the Standard Model predictions.

The measured fiducial differential cross-sections as a function of p_T^H are used to derive limits on the bottom and charm-quark Yukawa couplings modifiers, κ_b and κ_c , assuming SM values of the other tree-level Higgs boson couplings. Fixing the value of κ_b to one, the 95% confidence interval for κ_c is [-8.6, 17.3] using only the observed shape of the p_T^H distribution, and [-2.27, 2.27] when considering also the impact of these couplings on the normalisation of the measured p_T^H fiducial cross-sections.

A combined fit with the ATLAS measurement of Higgs bosons produced in association with a W or Z boson and decaying to b - or c -quark pairs allows constraints to be set on the charm quark coupling modifier without any assumption on the bottom quark coupling. The 95% CL allowed range for κ_c when the Higgs boson is assumed to decay only to SM particles is [-2.47, 2.53] while in a more generic scenario in which BSM Higgs boson decays are allowed, the constraint is loosened to [-4.46, 4.81]. These represent the most stringent constraints on κ_c to date in these scenarios.

Acknowledgements

We thank CERN for the very successful operation of the LHC, as well as the support staff from our institutions without whom ATLAS could not be operated efficiently.

The crucial computing support from all WLCG partners is acknowledged gratefully, in particular from CERN, the ATLAS Tier-1 facilities at TRIUMF (Canada), NDGF (Denmark, Norway, Sweden), CC-IN2P3 (France), KIT/GridKA (Germany), INFN-CNAF (Italy), NL-T1 (Netherlands), PIC (Spain), ASGC (Taiwan), RAL (UK) and BNL (USA), the Tier-2 facilities worldwide and large non-WLCG resource providers. Major contributors of computing resources are listed in Ref. [64].

Appendix

A Correlation matrices between the measured cross-sections

Figure 7 and Figure 8 show the correlation matrices among the differential cross-sections measured in different bins of the same one-dimensional measurement.

(a)

(b)

(c)

Figure 7: Correlation matrices between the differential $pp \rightarrow H + X$ cross-sections measured in different bins of the same observable: (a) Higgs boson transverse momentum, (b) Higgs boson rapidity and (c) Higgs boson transverse momentum vs Higgs boson rapidity. The labels are defined as per the bin boundaries outlined in Table 3, with a higher label index corresponding to a higher bin for the given variable. For the correlation matrix for the Higgs boson transverse momentum vs Higgs boson rapidity, lower rapidity bins are labelled first with ascending bins in p_T^H .

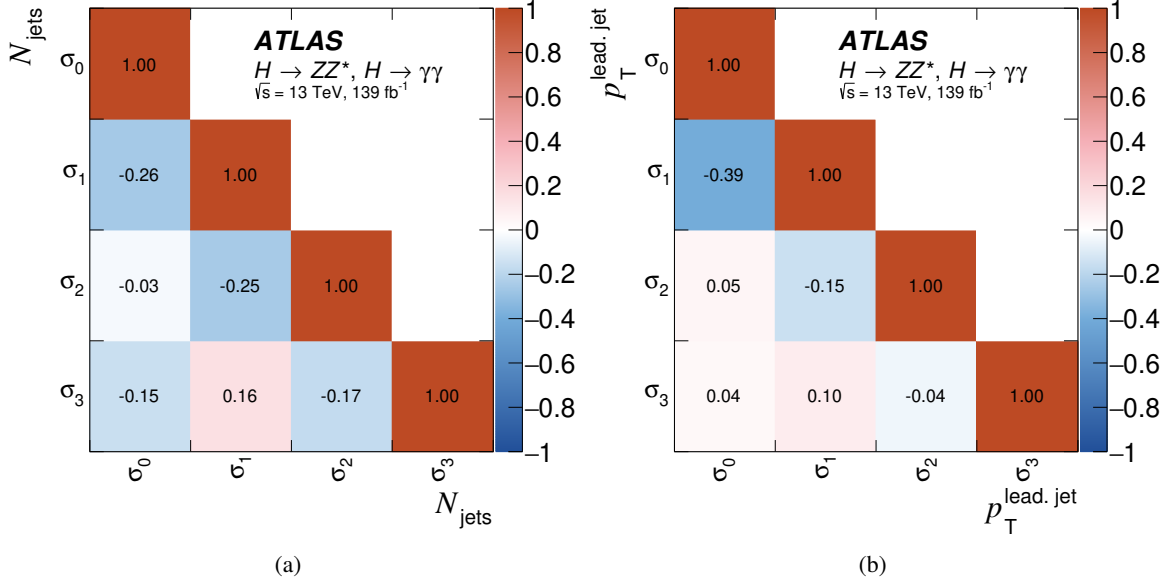

Figure 8: Correlation matrices between the differential $pp \rightarrow H + X$ cross-sections measured in different bins of the same observable: (a) number of jets and (b) p_T of the leading jet. The labels are defined as per the bin boundaries outlined in Table 3, with a higher label index corresponding to a higher bin for the given variable.

²⁸(^a)Faculty of Mathematics, Physics and Informatics, Comenius University, Bratislava; (^b)Department of Subnuclear Physics, Institute of Experimental Physics of the Slovak Academy of Sciences, Kosice; Slovak Republic.

²⁹Physics Department, Brookhaven National Laboratory, Upton NY; United States of America.

³⁰Universidad de Buenos Aires, Facultad de Ciencias Exactas y Naturales, Departamento de Física, y CONICET, Instituto de Física de Buenos Aires (IFIBA), Buenos Aires; Argentina.

³¹California State University, CA; United States of America.

³²Cavendish Laboratory, University of Cambridge, Cambridge; United Kingdom.

³³(^a)Department of Physics, University of Cape Town, Cape Town; (^b)iThemba Labs, Western Cape; (^c)Department of Mechanical Engineering Science, University of Johannesburg, Johannesburg; (^d)National Institute of Physics, University of the Philippines Diliman (Philippines); (^e)University of South Africa, Department of Physics, Pretoria; (^f)University of Zululand, KwaDlangezwa; (^g)School of Physics, University of the Witwatersrand, Johannesburg; South Africa.

³⁴Department of Physics, Carleton University, Ottawa ON; Canada.

³⁵(^a)Faculté des Sciences Ain Chock, Réseau Universitaire de Physique des Hautes Energies - Université Hassan II, Casablanca; (^b)Faculté des Sciences, Université Ibn-Tofail, Kénitra; (^c)Faculté des Sciences Semlalia, Université Cadi Ayyad, LPHEA-Marrakech; (^d)LPMR, Faculté des Sciences, Université Mohamed Premier, Oujda; (^e)Faculté des sciences, Université Mohammed V, Rabat; (^f)Institute of Applied Physics, Mohammed VI Polytechnic University, Ben Guerir; Morocco.

³⁶CERN, Geneva; Switzerland.

³⁷Affiliated with an institute covered by a cooperation agreement with CERN.

³⁸Affiliated with an international laboratory covered by a cooperation agreement with CERN.

³⁹Enrico Fermi Institute, University of Chicago, Chicago IL; United States of America.

⁴⁰LPC, Université Clermont Auvergne, CNRS/IN2P3, Clermont-Ferrand; France.

⁴¹Nevis Laboratory, Columbia University, Irvington NY; United States of America.

⁴²Niels Bohr Institute, University of Copenhagen, Copenhagen; Denmark.

⁴³(^a)Dipartimento di Fisica, Università della Calabria, Rende; (^b)INFN Gruppo Collegato di Cosenza,

Laboratori Nazionali di Frascati; Italy.

⁴⁴Physics Department, Southern Methodist University, Dallas TX; United States of America.

⁴⁵Physics Department, University of Texas at Dallas, Richardson TX; United States of America.

⁴⁶National Centre for Scientific Research "Demokritos", Agia Paraskevi; Greece.

⁴⁷(^a) Department of Physics, Stockholm University; (^b) Oskar Klein Centre, Stockholm; Sweden.

⁴⁸Deutsches Elektronen-Synchrotron DESY, Hamburg and Zeuthen; Germany.

⁴⁹Fakultät Physik, Technische Universität Dortmund, Dortmund; Germany.

⁵⁰Institut für Kern- und Teilchenphysik, Technische Universität Dresden, Dresden; Germany.

⁵¹Department of Physics, Duke University, Durham NC; United States of America.

⁵²SUPA - School of Physics and Astronomy, University of Edinburgh, Edinburgh; United Kingdom.

⁵³INFN e Laboratori Nazionali di Frascati, Frascati; Italy.

⁵⁴Physikalisches Institut, Albert-Ludwigs-Universität Freiburg, Freiburg; Germany.

⁵⁵II. Physikalisches Institut, Georg-August-Universität Göttingen, Göttingen; Germany.

⁵⁶Département de Physique Nucléaire et Corpusculaire, Université de Genève, Genève; Switzerland.

⁵⁷(^a) Dipartimento di Fisica, Università di Genova, Genova; (^b) INFN Sezione di Genova; Italy.

⁵⁸II. Physikalisches Institut, Justus-Liebig-Universität Giessen, Giessen; Germany.

⁵⁹SUPA - School of Physics and Astronomy, University of Glasgow, Glasgow; United Kingdom.

⁶⁰LPSC, Université Grenoble Alpes, CNRS/IN2P3, Grenoble INP, Grenoble; France.

⁶¹Laboratory for Particle Physics and Cosmology, Harvard University, Cambridge MA; United States of America.

⁶²(^a) Department of Modern Physics and State Key Laboratory of Particle Detection and Electronics, University of Science and Technology of China, Hefei; (^b) Institute of Frontier and Interdisciplinary Science and Key Laboratory of Particle Physics and Particle Irradiation (MOE), Shandong University, Qingdao; (^c) School of Physics and Astronomy, Shanghai Jiao Tong University, Key Laboratory for Particle Astrophysics and Cosmology (MOE), SKLPPC, Shanghai; (^d) Tsung-Dao Lee Institute, Shanghai; China.

⁶³(^a) Kirchhoff-Institut für Physik, Ruprecht-Karls-Universität Heidelberg, Heidelberg; (^b) Physikalisches Institut, Ruprecht-Karls-Universität Heidelberg, Heidelberg; Germany.

⁶⁴(^a) Department of Physics, Chinese University of Hong Kong, Shatin, N.T., Hong Kong; (^b) Department of Physics, University of Hong Kong, Hong Kong; (^c) Department of Physics and Institute for Advanced Study, Hong Kong University of Science and Technology, Clear Water Bay, Kowloon, Hong Kong; China.

⁶⁵Department of Physics, National Tsing Hua University, Hsinchu; Taiwan.

⁶⁶IJCLab, Université Paris-Saclay, CNRS/IN2P3, 91405, Orsay; France.

⁶⁷Department of Physics, Indiana University, Bloomington IN; United States of America.

⁶⁸(^a) INFN Gruppo Collegato di Udine, Sezione di Trieste, Udine; (^b) ICTP, Trieste; (^c) Dipartimento Politecnico di Ingegneria e Architettura, Università di Udine, Udine; Italy.

⁶⁹(^a) INFN Sezione di Lecce; (^b) Dipartimento di Matematica e Fisica, Università del Salento, Lecce; Italy.

⁷⁰(^a) INFN Sezione di Milano; (^b) Dipartimento di Fisica, Università di Milano, Milano; Italy.

⁷¹(^a) INFN Sezione di Napoli; (^b) Dipartimento di Fisica, Università di Napoli, Napoli; Italy.

⁷²(^a) INFN Sezione di Pavia; (^b) Dipartimento di Fisica, Università di Pavia, Pavia; Italy.

⁷³(^a) INFN Sezione di Pisa; (^b) Dipartimento di Fisica E. Fermi, Università di Pisa, Pisa; Italy.

⁷⁴(^a) INFN Sezione di Roma; (^b) Dipartimento di Fisica, Sapienza Università di Roma, Roma; Italy.

⁷⁵(^a) INFN Sezione di Roma Tor Vergata; (^b) Dipartimento di Fisica, Università di Roma Tor Vergata, Roma; Italy.

⁷⁶(^a) INFN Sezione di Roma Tre; (^b) Dipartimento di Matematica e Fisica, Università Roma Tre, Roma; Italy.

⁷⁷(^a) INFN-TIFPA; (^b) Università degli Studi di Trento, Trento; Italy.

⁷⁸Universität Innsbruck, Department of Astro and Particle Physics, Innsbruck; Austria.
