REPORT ABOUT DIFFERENT TYPESOF 30 cm - APERTURE QUADRUPOLE LENSESSUMMARY

At the Meeting of the Study-group for secondary beams and PS-extracted beam facilities it has been suggested to compare by model measurements different types of 30 cm - aperture quadrupoles. The following types, all designed for a field - gradient  $\times$  iron length  $g \cdot L = 900 \left( \frac{G}{\text{cm}} \cdot \text{m} \right)$  and adapted to a CERN standard type III generator were investigated :

- a) the "Classical" type
- b) the Wilson "Figure of Eight" type
- c) the "CERN Eng Division" type
- d) the "Desy" type

This report gives the main parametres for these quadrupoles as well as the region with a magnetic field linearity deviation inferior to 1 o/o, using the pole pieces described in the figures.

It should be borne in mind, that only in the "CERN Eng. Div." design have special efforts been made to linearise the field by shaping the poles.

It is reasonable to assume that the region of good field (in which the deviation  $< 1$  o/o) for the "Desy" design can be made the same as that produced by the "CERN" design if special shims are attached to the edges of the pole-pieces.

The "CERN" type has the largest field uniformity region at a gradient  $g = 900 \frac{\text{G}}{\text{cm}}$ .

The "Figure of Eight" type has also a large field uniformity region, but attains a gradient of about only  $600 \frac{\text{G}}{\text{cm}}$ . The overall dimension of this quadrupole in one direction ( either height or width) is small.

With the "Classical" type a gradient of about  $g = 740 \frac{\text{G}}{\text{cm}}$  could be obtained. The field linearity is limited to a circle of 0,85 ... 0,9 times the geometrical aperture.

Due to their comparable iron weight and winding types, the costs for the quadrupoles a) ... c) would roughly be equal.

## RESULTS

The main parametres of the 4 considered quadrupole lenses are summarized in Table I :

Table I

"Classical"

| Field uniformity<br>curve on drawing         | 5,6                               | 7,8                               | 9,10                        | 11                                |

Fig. 1 ... 4 show what would be the cross-sections of these quadrupoles, while Fig. 5 ... 11 show the field uniformity curves, measured in the x and r directions as well as the region where the field linearity error is inferior to 1 o/o.

Presenting the results for four different quadrupoles, it is not the intention of this report to suggest the adoption of one or the other type. The relative usefulness of each of the four designs of quadrupole in collection from a target is not simply determined by the ratio of overall width to aperture, which would favour the "Figure of Eight" type. If the quadrupole forms part of a doublet the lower field gradient of the "Figure of Eight" design which necessitates a longer length of magnet may cause a severe reduction in the acceptance from the target.

It is hoped, that the present report will help the beam-layout specialists and physicists in showing what could be expected from various large aperture quadrupoles, which could still be powered from our standard generators.
