ABSTRACT: We apply the QCD factorization approach to exclusive, radiative B meson decays in the region of small invariant photon mass. We calculate factorizable and non-factorizable corrections to leading order in the heavy quark mass expansion and next-to-leading order in the strong coupling constant. Phenomenological consequences for the $B \rightarrow K^*\gamma$ decay rate and the $B \rightarrow K^*\ell^+\ell^-$ forward-backward asymmetry are discussed.

Radiative B -meson decays provide an important tool to test the standard model of electroweak interactions and to constrain various models of new physics. The theoretical description of *exclusive* channels has to deal with hadronic uncertainties related to the binding of quarks in the initial and final states. For the decays $B \rightarrow K^*\gamma$ and $B \rightarrow K^*\ell^+\ell^-$, that we are focusing on here, this is usually phrased as the need to know the hadronic form factors for the $B \rightarrow K^{(*)}$ transition, but there also exist “non-factorizable” strong interaction effects that do not correspond to form factors. They arise from the matrix elements of purely hadronic operators in the weak effective Hamiltonian with a photon radiated from one of the internal quarks. In Ref. `attr/Border [0 0 0] goto namebib1.9 .9 0 01` we have computed these non-factorizable corrections and demonstrated that exclusive, radiative decays can be treated in a similarly systematic manner as their inclusive counterparts. As a result we obtain the branching fractions for $B \rightarrow K^*\gamma$ and $B \rightarrow K^*\ell^+\ell^-$ for small invariant mass of the lepton pair to next-to-leading logarithmic (NLL) order in renormalization-group improved perturbation theory.

In the “naive” factorization approach, exclusive radiative B decays are described in terms of hadronic matrix elements of the electromagnetic penguin operator \mathcal{O}_7 and the semi-leptonic operators $\mathcal{O}_{9,10}$ `attr/Border [0 0 0] goto namebib2.9 .9 0 02`. These are parametrized in terms of the corresponding tensor, vector and axial-vector $B \rightarrow K^*$ transition form factors ($T_{1,2,3}(q^2)$, $V(q^2)$, $A_{0,1,2}(q^2)$). Factorizable quark-loop contributions

^{*}Speaker.

namefigure1 fith

Figure 1: LO contributions to $\langle \gamma^* \bar{K}^* | H_{\text{eff}} | \bar{B} \rangle$. The circled cross marks the possible insertions of the virtual photon line. In (a) and (b) the spectator line is not shown.

(Fig. attr/Border [0 0 0] goto nameref-fig1.9 .9 0 01b) with the four-quark operators \mathcal{O}_{1-6} are taken into account by using “effective” Wilson-coefficients, $C_7 \rightarrow C_7^{\text{eff}}$, $C_9 \rightarrow C_9^{\text{eff}}(q^2)$, renormalized at the scale $\mu = m_b$.

In order to include non-factorizable contributions as in Fig. attr/Border [0 0 0] goto nameref-fig1.9 .9 0 01c and Fig. attr/Border [0 0 0] goto nameref-fig2.9 .9 0 02 it is convenient to introduce generalized form factors $\mathcal{T}_i(q^2)$ for the transition into a *virtual* photon $B \rightarrow K^* \gamma^*$ as follows,

$$\begin{aligned} \langle \gamma^*(q, \mu) \bar{K}^*(p', \varepsilon^*) | H_{\text{eff}} | \bar{B}(p) \rangle &= -\frac{G_F}{\sqrt{2}} V_{ts}^* V_{tb} \frac{ig_{\text{em}} m_b}{4\pi^2} \\ &\left\{ 2 \mathcal{T}_1(q^2) \epsilon^{\mu\nu\rho\sigma} \varepsilon_\nu^* p_\rho p'_\sigma - i \mathcal{T}_2(q^2) [(M_B^2 - m_{K^*}^2) \varepsilon^{*\mu} - (\varepsilon^* \cdot q) (p^\mu + p'^\mu)] \right. \\ &\left. - i \mathcal{T}_3(q^2) (\varepsilon^* \cdot q) \left[q^\mu - \frac{q^2}{M_B^2 - m_{K^*}^2} (p^\mu + p'^\mu) \right] \right\} . \text{nameref - caltdef fith} \quad (1) \end{aligned}$$

In the “naive” factorization approach these new functions reduce to $\mathcal{T}_i(q^2) = C_7^{\text{eff}} T_i(q^2) + \dots$. Following the QCD factorization approach to exclusive B decays [attr/Border [0 0 0] goto namebib3.9 .9 0 03], factorizable and non-factorizable radiative corrections are calculable in the heavy quark mass limit and for small photon virtualities (in practice $q^2 < 4m_c^2$).

At leading order (LO) in the strong coupling constant, the generalized form factors read

$$\begin{aligned} \text{nameref - firstT fith} \mathcal{T}_1(q^2) &= C_7^{\text{eff}} T_1(q^2) + Y(q^2) \frac{q^2}{2m_b(M_B + m_{K^*})} V(q^2), \\ \mathcal{T}_2(q^2) &= C_7^{\text{eff}} T_2(q^2) + Y(q^2) \frac{q^2}{2m_b(M_B - m_{K^*})} A_1(q^2), \\ \mathcal{T}_3(q^2) &= C_7^{\text{eff}} T_3(q^2) + Y(q^2) \left[\frac{M_B - m_{K^*}}{2m_b} A_2(q^2) - \frac{M_B + m_{K^*}}{2m_b} A_1(q^2) \right] \\ &\quad - e_q (C_3 + 3C_4) \frac{8\pi^2 M_B f_B f_{K^*} m_{K^*}}{N_C m_b (M^2 - q^2)} \int d\omega \frac{\phi_{B,-}(\omega)}{\omega - q^2/M - i\epsilon} . \text{nameref - lastT fith} \end{aligned}$$

The function $Y(q^2)$, which is usually absorbed into $C_9^{\text{eff}}(q^2)$, arises from the quark loop in Fig. attr/Border [0 0 0] goto nameref-fig1.9 .9 0 01b. The last, “non-factorizable” term in $\mathcal{T}_3(q^2)$ comes from the annihilation graph in Fig. attr/Border [0 0 0] goto nameref-fig1.9 .9 0 01c when the photon is emitted from the light spectator in the B meson (all other graphs

Figure 3: Factorizable NLO corrections to the $B \rightarrow K^*$ form factors.

are sub-leading in the $1/m_b$ expansion). It introduces a new non-perturbative ingredient, namely one of the two light-cone distribution amplitudes of the B meson, $\phi_{B,\pm}(\omega)$, see [attr/Border [0 0 0] goto namebib1.9 .9 0 01, attr/Border [0 0 0] goto namebib4.9 .9 0 04] for details. Furthermore, for the considered values of q^2 , the recoil-energy of the out-going K^* meson is large, and the seven independent $B \rightarrow K^*$ form factors can be described in terms of only two universal form factors [attr/Border [0 0 0] goto namebib5.9 .9 0 05], which we denote as $\xi_{\perp}(q^2)$ and $\xi_{\parallel}(q^2)$ for transversely and longitudinally polarized K^* mesons, respectively [attr/Border [0 0 0] goto namebib4.9 .9 0 04].

Factorizable next-to-leading order (NLO) form factor corrections are derived from Fig. attr/Border [0 0 0] goto nameref-fig3.9 .9 0 03 after the corresponding infra-red divergent pieces are absorbed into the *soft* universal form factors ξ_{\perp} and ξ_{\parallel} , see [attr/Border [0 0 0] goto namebib4.9 .9 0 04] for details. The non-factorizable vertex corrections (Fig. attr/Border [0 0 0] goto nameref-fig2.9 .9 0 02c-e), are similar to the NLO calculation for the *inclusive* $b \rightarrow s\gamma^*$ transition, and the result for the two-loop diagrams in Fig. attr/Border [0 0 0] goto nameref-fig2.9 .9 0 02d+e are taken from Ref. [attr/Border [0 0 0] goto namebib6.9 .9 0 06]. For the vertex corrections we chose a renormalization scale $\mu = \mathcal{O}(m_b)$. The non-factorizable hard-scattering corrections in Fig. attr/Border [0 0 0] goto nameref-fig2.9 .9 0 02a+b and Fig. attr/Border [0 0 0] goto nameref-fig1.9 .9 0 01c involve the light-cone distribution amplitudes of both, B and K^* mesons. (For $q^2 = 0$ diagrams of this form have already been considered in [attr/Border [0 0 0] goto namebib7.9 .9 0 07], but using bound state model wave-functions, rather than light-cone distribution amplitudes.) Since in these class of diagrams the typical quark- and gluon-virtuality is of order $\sqrt{\Lambda_{\text{QCD}} m_b}$ we chose

a different renormalization scale μ' of that order. In principle, we also have to consider NLO order corrections to the annihilation graph in Fig. attr/Border [0 0 0] goto nameref-fig1.9 .9 0 01c. However, since this term is suppressed by small Wilson coefficients C_3 and C_4 and numerically small already at LO, we have neglected these effects. Notice however, that the annihilation topology is numerically more important for $B \rightarrow \rho\gamma$ decays [attr/Border [0 0 0] goto namebib8.9 .9 0 08, attr/Border [0 0 0] goto namebib9.9 .9 0 09].

The $B \rightarrow K^*\gamma$ decay rate is proportional to the function $|\mathcal{T}_1(0)|^2 = |\mathcal{T}_2(0)|^2$. In order to study the effect of NLO corrections it is convenient to define a generalized exclusive “Wilson” coefficient $\mathcal{C}_7 \equiv \mathcal{T}_1(0)/\xi_\perp(0)$. In Fig. attr/Border [0 0 0] goto nameref-fig4.9 .9 0 04 we have shown the μ -dependence of $|\mathcal{C}_7|^2$ at leading order (LO), including only next-to-leading order vertex corrections (NLO₁), and including all next-to-leading order corrections (NLO). As expected, the NLO₁ vertex corrections cancel the renormalization-scale dependence of the LO result to a great extent. (The hard-scattering corrections, arising at order α_s reintroduce a mild scale-dependence.) Most importantly, we observe that the NLO corrections significantly increase the theoretical prediction for $|\mathcal{C}_7|^2$. Numerically, we have $|\mathcal{C}_7|_{\text{NLO}}^2 \simeq 1.78 \cdot |\mathcal{C}_7|_{\text{LO}}^2$. From this we predict the branching ratio as

$$\text{Br}(\bar{B} \rightarrow \bar{K}^*\gamma) = (7.9_{-1.6}^{+1.8}) \cdot 10^{-5} \left(\frac{\tau_B}{1.6\text{ps}} \right) \left(\frac{m_{b,\text{PS}}}{4.6\text{GeV}} \right)^2 \left(\frac{\xi_\perp(0)}{0.35} \right)^2 \quad (3)$$

Comparing with the current experimental averages [attr/Border [0 0 0] goto namebib10.9 .9 0 010] $\text{Br}(\bar{B}^0 \rightarrow \bar{K}^{*0}\gamma)_{\text{exp}} = (4.54 \pm 0.37) \cdot 10^{-5}$, $\text{Br}(B^- \rightarrow \bar{K}^{*-}\gamma)_{\text{exp}} = (3.81 \pm 0.68) \cdot 10^{-5}$, and using the value $\xi_\perp(0) = 0.35$ from QCD sum rules [attr/Border [0 0 0] goto namebib11.9 .9 0 011], we observe that the central value of the theoretical prediction overshoots the data by nearly a factor of two. (An equivalent analysis with similar conclusions can be found in Ref. [attr/Border [0 0 0] goto namebib9.9 .9 0 09].) Possible explanations for this discrep-

nameref-fig4 fith

namefigure4 fith

Figure 4: $|\mathcal{C}_7|^2$ as a function of the renormalization scale μ , see text.

ancy are: i) new physics contributions (this is rather unlikely because of the good agreement between NLO theory and experiment for the *inclusive* counterpart, $B \rightarrow X_s\gamma$), ii) sizeable $1/m_b$ power-corrections (“chirally enhanced” corrections play a role for decays into light pseudoscalars [attr/Border [0 0 0] goto namebib12.9 .9 0 012]; in our case, however, we expect a less dramatic effect), iii) an insufficient understanding of the $B \rightarrow K^*$ form factors

namefigure5 fith

Figure 5: The FB asymmetry as a function of q^2 (left). The Wilson-coefficient C_9 as a function of the FB asymmetry zero (right). The error band refers to a variation of all input parameters and changing the renormalization scale between $m_b/2$ and $2m_b$. The dashed line is obtained from using the complete form factors from [attr/Border [0 0 0] goto namebib11.9 .9 0 011], see text. The grey band indicates the standard model value.

(a fit to the experimental data on the basis of our formalism yields a somewhat smaller value, $\xi_{\perp}(0) = 0.24 \pm 0.06$).

A quantity that is less sensitive to the precise value of $\xi_{\perp}(q^2)$ is provided by the $B \rightarrow K^*\ell^+\ell^-$ forward-backward asymmetry \mathcal{A}_{FB} . At LO the position of the asymmetry zero q_0^2 is determined by the implicit relation

$$C_9 + \text{Re}(Y(q_0^2)) = -\frac{2M_B m_b}{q_0^2} C_7^{\text{eff}}, \quad (4)$$

and does not depend on form factors at all [attr/Border [0 0 0] goto namebib13.9 .9 0 013]. As illustrated in Fig. attr/Border [0 0 0] goto nameref-fig5.9 .9 0 05 NLO corrections shift the position of the asymmetry zero from $q_0^2 = 3.4_{-0.5}^{+0.6} \text{ GeV}^2$ at LO to $q_0^2 = 4.39_{-0.35}^{+0.38} \text{ GeV}^2$. (A slightly different value $q_0^2 = 3.94 \text{ GeV}^2$ is found if one takes the complete form factors from QCD sum rules [attr/Border [0 0 0] goto namebib11.9 .9 0 011], instead of ξ_{\perp} and the factorizable NLO corrections from [attr/Border [0 0 0] goto namebib4.9 .9 0 04]). In any case, a measurement of the forward-backward asymmetry zero provide a clean test of the Wilson-coefficient C_9 in the standard model with a rather small theoretical uncertainty of about 10%.

In summary, we have shown that a systematic improvement of the theoretical description of exclusive radiative B meson decays is possible. This is because in the heavy quark limit decay amplitudes factorize into perturbatively calculable hard-scattering kernels and universal soft form factors or light-cone distribution amplitudes, respectively. The next-to-leading order corrections increase the branching ratio for the decay $B \rightarrow K^*\gamma$ by almost a factor of two (which is at variance with the current experimental data if “standard” values for the soft form factors are used). They also shift the position of the forward-backward asymmetry in the decay $B \rightarrow K^*\ell^+\ell^-$ towards $q_0^2 = 4.2 \pm 0.6 \text{ GeV}^2$ in the standard model.

In this case the precision of the prediction is sufficient to test the Wilson coefficient C_9 with only 10% theoretical uncertainty.
