List of labels. Note using `[[]]` returns a DataFrame.

```
>>> df.loc[['viper', 'sidewinder']]
```

|            | max_speed | shield |
|------------|-----------|--------|
| viper      | 4         | 5      |
| sidewinder | 7         | 8      |

Single label for row and column

```
>>> df.loc['cobra', 'shield']
2
```

Slice with labels for row and single label for column. As mentioned above, note that both the start and stop of the slice are included.

```
>>> df.loc['cobra':'viper', 'max_speed']
cobra    1
viper    4
Name: max_speed, dtype: int64
```

Boolean list with the same length as the row axis

```
>>> df.loc[[False, False, True]]
           max_speed  shield
sidewinder           7       8
```

Conditional that returns a boolean Series

```
>>> df.loc[df['shield'] > 6]
           max_speed  shield
sidewinder           7       8
```

Conditional that returns a boolean Series with column labels specified

```
>>> df.loc[df['shield'] > 6, ['max_speed']]
           max_speed
sidewinder           7
```

Callable that returns a boolean Series

```
>>> df.loc[lambda df: df['shield'] == 8]
           max_speed  shield
sidewinder           7       8
```

## Setting values

Set value for all items matching the list of labels

```
>>> df.loc[['viper', 'sidewinder'], ['shield']] = 50
>>> df
           max_speed  shield
cobra                1       2
viper                4      50
sidewinder           7      50
```

Set value for an entire row

```
>>> df.loc['cobra'] = 10
>>> df
           max_speed  shield
cobra            10      10
viper             4      50
sidewinder         7      50
```

Set value for an entire column

```
>>> df.loc[:, 'max_speed'] = 30
>>> df
           max_speed  shield
cobra              30      10
viper              30      50
sidewinder         30      50
```

Set value for rows matching callable condition

```
>>> df.loc[df['shield'] > 35] = 0
>>> df
           max_speed  shield
cobra              30      10
```

(continues on next page)

(continued from previous page)

|            |   |   |
|------------|---|---|
| viper      | 0 | 0 |
| sidewinder | 0 | 0 |

**Getting values on a DataFrame with an index that has integer labels**

Another example using integers for the index

```
>>> df = pd.DataFrame([[1, 2], [4, 5], [7, 8]],
...                     index=[7, 8, 9], columns=['max_speed', 'shield'])
>>> df
   max_speed  shield
7          1       2
8          4       5
9          7       8
```

Slice with integer labels for rows. As mentioned above, note that both the start and stop of the slice are included.

```
>>> df.loc[7:9]
   max_speed  shield
7          1       2
8          4       5
9          7       8
```

**Getting values with a MultiIndex**

A number of examples using a DataFrame with a MultiIndex

```
>>> tuples = [
...     ('cobra', 'mark i'), ('cobra', 'mark ii'),
...     ('sidewinder', 'mark i'), ('sidewinder', 'mark ii'),
...     ('viper', 'mark ii'), ('viper', 'mark iii')
... ]
>>> index = pd.MultiIndex.from_tuples(tuples)
>>> values = [[12, 2], [0, 4], [10, 20],
...            [1, 4], [7, 1], [16, 36]]
>>> df = pd.DataFrame(values, columns=['max_speed', 'shield'], index=index)
>>> df
               max_speed  shield
cobra  mark i          12       2
       mark ii         0       4
sidewinder mark i         10      20
          mark ii          1       4
viper    mark ii          7       1
          mark iii         16      36
```

Single label. Note this returns a DataFrame with a single index.

```
>>> df.loc['cobra']
   max_speed  shield
mark i          12       2
mark ii         0       4
```

Single index tuple. Note this returns a Series.

```
>>> df.loc[('cobra', 'mark ii')]
max_speed    0
```

(continues on next page)

(continued from previous page)

```
shield      4
Name: (cobra, mark ii), dtype: int64
```

Single label for row and column. Similar to passing in a tuple, this returns a Series.

```
>>> df.loc['cobra', 'mark i']
max_speed    12
shield       2
Name: (cobra, mark i), dtype: int64
```

Single tuple. Note using `[[]]` returns a DataFrame.

```
>>> df.loc[['cobra', 'mark ii']]
      max_speed  shield
cobra mark ii      0      4
```

Single tuple for the index with a single label for the column

```
>>> df.loc[('cobra', 'mark i'), 'shield']
2
```

Slice from index tuple to single label

```
>>> df.loc[('cobra', 'mark i'):'viper']
      max_speed  shield
cobra      mark i      12      2
           mark ii      0      4
sidewinder mark i      10     20
           mark ii      1      4
viper      mark ii      7      1
           mark iii     16     36
```

Slice from index tuple to index tuple

```
>>> df.loc[('cobra', 'mark i'):'viper', 'mark ii']
      max_speed  shield
cobra      mark i      12      2
           mark ii      0      4
sidewinder mark i      10     20
           mark ii      1      4
viper      mark ii      7      1
```

## pandas.Series.name

`Series.name`

Return name of the Series.

## pandas.Series.nbytes

`Series.nbytes`

Return the number of bytes in the underlying data.

### **pandas.Series.ndim**

**Series.ndim**

Number of dimensions of the underlying data, by definition 1.

### **pandas.Series.real**

**Series.real**

Return the real value of vector.

### **pandas.Series.shape**

**Series.shape**

Return a tuple of the shape of the underlying data.

### **pandas.Series.size**

**Series.size**

Return the number of elements in the underlying data.

### **pandas.Series.strides**

**Series.strides**

Return the strides of the underlying data.

### **pandas.Series.values**

**Series.values**

Return Series as ndarray or ndarray-like depending on the dtype.

**Warning:** We recommend using *Series.array* or *Series.to\_numpy()*, depending on whether you need a reference to the underlying data or a NumPy array.

#### **Returns**

**arr** [numpy.ndarray or ndarray-like]

#### **See also:**

**Series.array** Reference to the underlying data.

**Series.to\_numpy** A NumPy array representing the underlying data.

## Examples

```
>>> pd.Series([1, 2, 3]).values
array([1, 2, 3])
```

```
>>> pd.Series(list('aabc')).values
array(['a', 'a', 'b', 'c'], dtype=object)
```

```
>>> pd.Series(list('aabc')).astype('category').values
[a, a, b, c]
Categories (3, object): [a, b, c]
```

Timezone aware datetime data is converted to UTC:

```
>>> pd.Series(pd.date_range('20130101', periods=3,
...                          tz='US/Eastern')).values
array(['2013-01-01T05:00:00.000000000',
       '2013-01-02T05:00:00.000000000',
       '2013-01-03T05:00:00.000000000'], dtype='datetime64[ns]')
```

|           |  |
|-----------|--|
| empty     |  |
| timetuple |  |

## Methods

|                                                     |                                                                                     |
|-----------------------------------------------------|-------------------------------------------------------------------------------------|
| <i>abs()</i>                                        | Return a Series/DataFrame with absolute numeric value of each element.              |
| <i>add(other[, level, fill_value, axis])</i>        | Addition of series and other, element-wise (binary operator <i>add</i> ).           |
| <i>add_prefix(prefix)</i>                           | Prefix labels with string <i>prefix</i> .                                           |
| <i>add_suffix(suffix)</i>                           | Suffix labels with string <i>suffix</i> .                                           |
| <i>agg(func[, axis])</i>                            | Aggregate using one or more operations over the specified axis.                     |
| <i>aggregate(func[, axis])</i>                      | Aggregate using one or more operations over the specified axis.                     |
| <i>align(other[, join, axis, level, copy, ...])</i> | Align two objects on their axes with the specified join method for each axis Index. |
| <i>all([axis, bool_only, skipna, level])</i>        | Return whether all elements are True, potentially over an axis.                     |
| <i>any([axis, bool_only, skipna, level])</i>        | Return whether any element is True, potentially over an axis.                       |
| <i>append(to_append[, ignore_index, ...])</i>       | Concatenate two or more Series.                                                     |
| <i>apply(func[, convert_dtype, args])</i>           | Invoke function on values of Series.                                                |
| <i>argmax([axis, skipna])</i>                       | (DEPRECATED) Return the row label of the maximum value.                             |
| <i>argmin([axis, skipna])</i>                       | (DEPRECATED) Return the row label of the minimum value.                             |
| <i>argsort([axis, kind, order])</i>                 | Overrides ndarray.argsort.                                                          |

Table 27 – continued from previous page

|                                                          |                                                                                                           |
|----------------------------------------------------------|-----------------------------------------------------------------------------------------------------------|
| <code>as_blocks([copy])</code>                           | (DEPRECATED) Convert the frame to a dict of dtype -> Constructor Types that each has a homogeneous dtype. |
| <code>as_matrix([columns])</code>                        | (DEPRECATED) Convert the frame to its Numpy-array representation.                                         |
| <code>asfreq(freq[, method, how, normalize, ...])</code> | Convert TimeSeries to specified frequency.                                                                |
| <code>asof(where[, subset])</code>                       | Return the last row(s) without any NaNs before <i>where</i> .                                             |
| <code>astype(dtype[, copy, errors])</code>               | Cast a pandas object to a specified dtype <i>dtype</i> .                                                  |
| <code>at_time(time[, asof, axis])</code>                 | Select values at particular time of day (e.g.                                                             |
| <code>autocorr([lag])</code>                             | Compute the lag-N autocorrelation.                                                                        |
| <code>between(left, right[, inclusive])</code>           | Return boolean Series equivalent to <code>left &lt;= series &lt;= right</code> .                          |
| <code>between_time(start_time, end_time[, ...])</code>   | Select values between particular times of the day (e.g., 9:00-9:30 AM).                                   |
| <code>bfill([axis, inplace, limit, downcast])</code>     | Synonym for <code>DataFrame.fillna()</code> with <code>method='bfill'</code> .                            |
| <code>bool()</code>                                      | Return the bool of a single element PandasObject.                                                         |
| <code>cat</code>                                         | alias of <code>pandas.core.arrays.categorical.CategoricalAccessor</code>                                  |
| <code>clip([lower, upper, axis, inplace])</code>         | Trim values at input threshold(s).                                                                        |
| <code>clip_lower(threshold[, axis, inplace])</code>      | (DEPRECATED) Trim values below a given threshold.                                                         |
| <code>clip_upper(threshold[, axis, inplace])</code>      | (DEPRECATED) Trim values above a given threshold.                                                         |
| <code>combine(other, func[, fill_value])</code>          | Combine the Series with a Series or scalar according to <i>func</i> .                                     |
| <code>combine_first(other)</code>                        | Combine Series values, choosing the calling Series's values first.                                        |
| <code>compound([axis, skipna, level])</code>             | Return the compound percentage of the values for the requested axis.                                      |
| <code>compress(condition, *args, **kwargs)</code>        | (DEPRECATED) Return selected slices of an array along given axis as a Series.                             |
| <code>convert_objects([convert_dates, ...])</code>       | (DEPRECATED) Attempt to infer better dtype for object columns.                                            |
| <code>copy([deep])</code>                                | Make a copy of this object's indices and data.                                                            |
| <code>corr(other[, method, min_periods])</code>          | Compute correlation with <i>other</i> Series, excluding missing values.                                   |
| <code>count([level])</code>                              | Return number of non-NA/null observations in the Series.                                                  |
| <code>cov(other[, min_periods])</code>                   | Compute covariance with Series, excluding missing values.                                                 |
| <code>cummax([axis, skipna])</code>                      | Return cumulative maximum over a DataFrame or Series axis.                                                |
| <code>cummin([axis, skipna])</code>                      | Return cumulative minimum over a DataFrame or Series axis.                                                |
| <code>cumprod([axis, skipna])</code>                     | Return cumulative product over a DataFrame or Series axis.                                                |
| <code>cumsum([axis, skipna])</code>                      | Return cumulative sum over a DataFrame or Series axis.                                                    |

Continued on next page

Table 27 – continued from previous page

|                                                               |                                                                                                                                              |
|---------------------------------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------|
| <code>describe([percentiles, include, exclude])</code>        | Generate descriptive statistics that summarize the central tendency, dispersion and shape of a dataset's distribution, excluding NaN values. |
| <code>diff([periods])</code>                                  | First discrete difference of element.                                                                                                        |
| <code>div(other[, level, fill_value, axis])</code>            | Floating division of series and other, element-wise (binary operator <i>truediv</i> ).                                                       |
| <code>divide(other[, level, fill_value, axis])</code>         | Floating division of series and other, element-wise (binary operator <i>truediv</i> ).                                                       |
| <code>divmod(other[, level, fill_value, axis])</code>         | Integer division and modulo of series and other, element-wise (binary operator <i>divmod</i> ).                                              |
| <code>dot(other)</code>                                       | Compute the dot product between the Series and the columns of other.                                                                         |
| <code>drop([labels, axis, index, columns, level, ...])</code> | Return Series with specified index labels removed.                                                                                           |
| <code>drop_duplicates([keep, inplace])</code>                 | Return Series with duplicate values removed.                                                                                                 |
| <code>droplevel(level[, axis])</code>                         | Return DataFrame with requested index / column level(s) removed.                                                                             |
| <code>dropna([axis, inplace])</code>                          | Return a new Series with missing values removed.                                                                                             |
| <code>dt</code>                                               | alias of <code>pandas.core.indexes.accessors.CombinedDatetimelikeProperties</code>                                                           |
| <code>duplicated([keep])</code>                               | Indicate duplicate Series values.                                                                                                            |
| <code>eq(other[, level, fill_value, axis])</code>             | Equal to of series and other, element-wise (binary operator <i>eq</i> ).                                                                     |
| <code>equals(other)</code>                                    | Test whether two objects contain the same elements.                                                                                          |
| <code>ewm([com, span, halflife, alpha, ...])</code>           | Provides exponential weighted functions.                                                                                                     |
| <code>expanding([min_periods, center, axis])</code>           | Provides expanding transformations.                                                                                                          |
| <code>factorize([sort, na_sentinel])</code>                   | Encode the object as an enumerated type or categorical variable.                                                                             |
| <code>ffill([axis, inplace, limit, downcast])</code>          | Synonym for <code>DataFrame.fillna()</code> with <code>method='ffill'</code> .                                                               |
| <code>fillna([value, method, axis, inplace, ...])</code>      | Fill NA/NaN values using the specified method.                                                                                               |
| <code>filter([items, like, regex, axis])</code>               | Subset rows or columns of dataframe according to labels in the specified index.                                                              |
| <code>first(offset)</code>                                    | Convenience method for subsetting initial periods of time series data based on a date offset.                                                |
| <code>first_valid_index()</code>                              | Return index for first non-NA/null value.                                                                                                    |
| <code>floordiv(other[, level, fill_value, axis])</code>       | Integer division of series and other, element-wise (binary operator <i>floordiv</i> ).                                                       |
| <code>from_array(arr[, index, name, dtype, copy, ...])</code> | Construct Series from array.                                                                                                                 |
| <code>from_csv(path[, sep, parse_dates, header, ...])</code>  | (DEPRECATED) Read CSV file.                                                                                                                  |
| <code>ge(other[, level, fill_value, axis])</code>             | Greater than or equal to of series and other, element-wise (binary operator <i>ge</i> ).                                                     |
| <code>get(key[, default])</code>                              | Get item from object for given key (DataFrame column, Panel slice, etc.).                                                                    |
| <code>get_dtype_counts()</code>                               | Return counts of unique dtypes in this object.                                                                                               |
| <code>get_ftype_counts()</code>                               | (DEPRECATED) Return counts of unique ftypes in this object.                                                                                  |
| <code>get_value(label[, takeable])</code>                     | (DEPRECATED) Quickly retrieve single value at passed index label.                                                                            |
| <code>get_values()</code>                                     | Same as <code>values</code> (but handles sparseness conversions); is a view.                                                                 |

|                                                               |                                                                                                                 |
|---------------------------------------------------------------|-----------------------------------------------------------------------------------------------------------------|
| <code>groupby([by, axis, level, as_index, sort, ...])</code>  | Group DataFrame or Series using a mapper or by a Series of columns.                                             |
| <code>gt(other[, level, fill_value, axis])</code>             | Greater than of series and other, element-wise (binary operator <i>gt</i> ).                                    |
| <code>head([n])</code>                                        | Return the first <i>n</i> rows.                                                                                 |
| <code>hist([by, ax, grid, xlabelsize, xrot, ...])</code>      | Draw histogram of the input series using matplotlib.                                                            |
| <code>idxmax([axis, skipna])</code>                           | Return the row label of the maximum value.                                                                      |
| <code>idxmin([axis, skipna])</code>                           | Return the row label of the minimum value.                                                                      |
| <code>infer_objects()</code>                                  | Attempt to infer better dtypes for object columns.                                                              |
| <code>interpolate([method, axis, limit, inplace, ...])</code> | Interpolate values according to different methods.                                                              |
| <code>isin(values)</code>                                     | Check whether <i>values</i> are contained in Series.                                                            |
| <code>isna()</code>                                           | Detect missing values.                                                                                          |
| <code>isnull()</code>                                         | Detect missing values.                                                                                          |
| <code>item()</code>                                           | Return the first element of the underlying data as a python scalar.                                             |
| <code>items()</code>                                          | Lazily iterate over (index, value) tuples.                                                                      |
| <code>iteritems()</code>                                      | Lazily iterate over (index, value) tuples.                                                                      |
| <code>keys()</code>                                           | Alias for index.                                                                                                |
| <code>kurt([axis, skipna, level, numeric_only])</code>        | Return unbiased kurtosis over requested axis using Fisher's definition of kurtosis (kurtosis of normal == 0.0). |
| <code>kurtosis([axis, skipna, level, numeric_only])</code>    | Return unbiased kurtosis over requested axis using Fisher's definition of kurtosis (kurtosis of normal == 0.0). |
| <code>last(offset)</code>                                     | Convenience method for subsetting final periods of time series data based on a date offset.                     |
| <code>last_valid_index()</code>                               | Return index for last non-NA/null value.                                                                        |
| <code>le(other[, level, fill_value, axis])</code>             | Less than or equal to of series and other, element-wise (binary operator <i>le</i> ).                           |
| <code>lt(other[, level, fill_value, axis])</code>             | Less than of series and other, element-wise (binary operator <i>lt</i> ).                                       |
| <code>mad([axis, skipna, level])</code>                       | Return the mean absolute deviation of the values for the requested axis.                                        |
| <code>map(arg[, na_action])</code>                            | Map values of Series according to input correspondence.                                                         |
| <code>mask(cond[, other, inplace, axis, level, ...])</code>   | Replace values where the condition is True.                                                                     |
| <code>max([axis, skipna, level, numeric_only])</code>         | Return the maximum of the values for the requested axis.                                                        |
| <code>mean([axis, skipna, level, numeric_only])</code>        | Return the mean of the values for the requested axis.                                                           |
| <code>median([axis, skipna, level, numeric_only])</code>      | Return the median of the values for the requested axis.                                                         |
| <code>memory_usage([index, deep])</code>                      | Return the memory usage of the Series.                                                                          |
| <code>min([axis, skipna, level, numeric_only])</code>         | Return the minimum of the values for the requested axis.                                                        |
| <code>mod(other[, level, fill_value, axis])</code>            | Modulo of series and other, element-wise (binary operator <i>mod</i> ).                                         |
| <code>mode([dropna])</code>                                   | Return the mode(s) of the dataset.                                                                              |
| <code>mul(other[, level, fill_value, axis])</code>            | Multiplication of series and other, element-wise (binary operator <i>mul</i> ).                                 |
| <code>multiply(other[, level, fill_value, axis])</code>       | Multiplication of series and other, element-wise (binary operator <i>mul</i> ).                                 |

Table 27 – continued from previous page

|                                                                |                                                                                                                             |
|----------------------------------------------------------------|-----------------------------------------------------------------------------------------------------------------------------|
| <code>ne(other[, level, fill_value, axis])</code>              | Not equal to of series and other, element-wise (binary operator <i>ne</i> ).                                                |
| <code>nlargest([n, keep])</code>                               | Return the largest <i>n</i> elements.                                                                                       |
| <code>nonzero()</code>                                         | (DEPRECATED) Return the <i>integer</i> indices of the elements that are non-zero.                                           |
| <code>notna()</code>                                           | Detect existing (non-missing) values.                                                                                       |
| <code>notnull()</code>                                         | Detect existing (non-missing) values.                                                                                       |
| <code>nsmallest([n, keep])</code>                              | Return the smallest <i>n</i> elements.                                                                                      |
| <code>nunique([dropna])</code>                                 | Return number of unique elements in the object.                                                                             |
| <code>pct_change([periods, fill_method, limit, freq])</code>   | Percentage change between the current and a prior element.                                                                  |
| <code>pipe(func, *args, **kwargs)</code>                       | Apply <code>func(self, *args, **kwargs)</code> .                                                                            |
| <code>plot</code>                                              | alias of <code>pandas.plotting._core.SeriesPlotMethods</code>                                                               |
| <code>pop(item)</code>                                         | Return item and drop from frame.                                                                                            |
| <code>pow(other[, level, fill_value, axis])</code>             | Exponential power of series and other, element-wise (binary operator <i>pow</i> ).                                          |
| <code>prod([axis, skipna, level, numeric_only, ...])</code>    | Return the product of the values for the requested axis.                                                                    |
| <code>product([axis, skipna, level, numeric_only, ...])</code> | Return the product of the values for the requested axis.                                                                    |
| <code>ptp([axis, skipna, level, numeric_only])</code>          | (DEPRECATED) Returns the difference between the maximum value and the                                                       |
| <code>put(*args, **kwargs)</code>                              | Applies the <i>put</i> method to its <i>values</i> attribute if it has one.                                                 |
| <code>quantile([q, interpolation])</code>                      | Return value at the given quantile.                                                                                         |
| <code>radd(other[, level, fill_value, axis])</code>            | Addition of series and other, element-wise (binary operator <i>radd</i> ).                                                  |
| <code>rank([axis, method, numeric_only, ...])</code>           | Compute numerical data ranks (1 through <i>n</i> ) along axis.                                                              |
| <code>ravel([order])</code>                                    | Return the flattened underlying data as an ndarray.                                                                         |
| <code>rdiv(other[, level, fill_value, axis])</code>            | Floating division of series and other, element-wise (binary operator <i>rtruediv</i> ).                                     |
| <code>rdivmod(other[, level, fill_value, axis])</code>         | Integer division and modulo of series and other, element-wise (binary operator <i>rdivmod</i> ).                            |
| <code>reindex([index])</code>                                  | Conform Series to new index with optional filling logic, placing NA/NaN in locations having no value in the previous index. |
| <code>reindex_axis(labels[, axis])</code>                      | (DEPRECATED) Conform Series to new index with optional filling logic.                                                       |
| <code>reindex_like(other[, method, copy, limit, ...])</code>   | Return an object with matching indices as other object.                                                                     |
| <code>rename([index])</code>                                   | Alter Series index labels or name.                                                                                          |
| <code>rename_axis([mapper, index, columns, axis, ...])</code>  | Set the name of the axis for the index or columns.                                                                          |
| <code>reorder_levels(order)</code>                             | Rearrange index levels using input order.                                                                                   |
| <code>repeat(repeats[, axis])</code>                           | Repeat elements of a Series.                                                                                                |
| <code>replace([to_replace, value, inplace, limit, ...])</code> | Replace values given in <i>to_replace</i> with <i>value</i> .                                                               |
| <code>resample(rule[, how, axis, fill_method, ...])</code>     | Resample time-series data.                                                                                                  |
| <code>reset_index([level, drop, name, inplace])</code>         | Generate a new DataFrame or Series with the index reset.                                                                    |

Table 27 – continued from previous page

|                                                             |                                                                                         |
|-------------------------------------------------------------|-----------------------------------------------------------------------------------------|
| <code>rfloordiv(other[, level, fill_value, axis])</code>    | Integer division of series and other, element-wise (binary operator <i>rfloordiv</i> ). |
| <code>rmod(other[, level, fill_value, axis])</code>         | Modulo of series and other, element-wise (binary operator <i>rmod</i> ).                |
| <code>rmul(other[, level, fill_value, axis])</code>         | Multiplication of series and other, element-wise (binary operator <i>rmul</i> ).        |
| <code>rolling(window[, min_periods, center, ...])</code>    | Provides rolling window calculations.                                                   |
| <code>round([decimals])</code>                              | Round each value in a Series to the given number of decimals.                           |
| <code>rpow(other[, level, fill_value, axis])</code>         | Exponential power of series and other, element-wise (binary operator <i>rpow</i> ).     |
| <code>rsub(other[, level, fill_value, axis])</code>         | Subtraction of series and other, element-wise (binary operator <i>rsub</i> ).           |
| <code>rtruediv(other[, level, fill_value, axis])</code>     | Floating division of series and other, element-wise (binary operator <i>rtruediv</i> ). |
| <code>sample([n, frac, replace, weights, ...])</code>       | Return a random sample of items from an axis of object.                                 |
| <code>searchsorted(value[, side, sorter])</code>            | Find indices where elements should be inserted to maintain order.                       |
| <code>select(crit[, axis])</code>                           | (DEPRECATED) Return data corresponding to axis labels matching criteria.                |
| <code>sem([axis, skipna, level, ddof, numeric_only])</code> | Return unbiased standard error of the mean over requested axis.                         |
| <code>set_axis(labels[, axis, inplace])</code>              | Assign desired index to given axis.                                                     |
| <code>set_value(label, value[, takeable])</code>            | (DEPRECATED) Quickly set single value at passed label.                                  |
| <code>shift([periods, freq, axis, fill_value])</code>       | Shift index by desired number of periods with an optional time <i>freq</i> .            |
| <code>skew([axis, skipna, level, numeric_only])</code>      | Return unbiased skew over requested axis Normalized by N-1.                             |
| <code>slice_shift([periods, axis])</code>                   | Equivalent to <i>shift</i> without copying data.                                        |
| <code>sort_index([axis, level, ascending, ...])</code>      | Sort Series by index labels.                                                            |
| <code>sort_values([axis, ascending, inplace, ...])</code>   | Sort by the values.                                                                     |
| <code>sparse</code>                                         | alias of <code>pandas.core.arrays.sparse.SparseAccessor</code>                          |
| <code>squeeze([axis])</code>                                | Squeeze 1 dimensional axis objects into scalars.                                        |
| <code>std([axis, skipna, level, ddof, numeric_only])</code> | Return sample standard deviation over requested axis.                                   |
| <code>str</code>                                            | alias of <code>pandas.core.strings.StringMethods</code>                                 |
| <code>sub(other[, level, fill_value, axis])</code>          | Subtraction of series and other, element-wise (binary operator <i>sub</i> ).            |
| <code>subtract(other[, level, fill_value, axis])</code>     | Subtraction of series and other, element-wise (binary operator <i>sub</i> ).            |
| <code>sum([axis, skipna, level, numeric_only, ...])</code>  | Return the sum of the values for the requested axis.                                    |
| <code>swapaxes(axis1, axis2[, copy])</code>                 | Interchange axes and swap values axes appropriately.                                    |
| <code>swaplevel([i, j, copy])</code>                        | Swap levels i and j in a MultiIndex.                                                    |
| <code>tail([n])</code>                                      | Return the last <i>n</i> rows.                                                          |
| <code>take(indices[, axis, convert, is_copy])</code>        | Return the elements in the given <i>positional</i> indices along an axis.               |
| <code>to_clipboard([excel, sep])</code>                     | Copy object to the system clipboard.                                                    |

Table 27 – continued from previous page

|                                                                |                                                                                                                      |
|----------------------------------------------------------------|----------------------------------------------------------------------------------------------------------------------|
| <code>to_csv(*args, **kwargs)</code>                           | Write object to a comma-separated values (csv) file.                                                                 |
| <code>to_dense()</code>                                        | Return dense representation of NDFrame (as opposed to sparse).                                                       |
| <code>to_dict([into])</code>                                   | Convert Series to {label -> value} dict or dict-like object.                                                         |
| <code>to_excel(excel_writer[, sheet_name, na_rep, ...])</code> | Write object to an Excel sheet.                                                                                      |
| <code>to_frame([name])</code>                                  | Convert Series to DataFrame.                                                                                         |
| <code>to_hdf(path_or_buf, key, **kwargs)</code>                | Write the contained data to an HDF5 file using HDF-Store.                                                            |
| <code>to_json([path_or_buf, orient, date_format, ...])</code>  | Convert the object to a JSON string.                                                                                 |
| <code>to_latex([buf, columns, col_space, header, ...])</code>  | Render an object to a LaTeX tabular environment table.                                                               |
| <code>to_list()</code>                                         | Return a list of the values.                                                                                         |
| <code>to_msgpack([path_or_buf, encoding])</code>               | Serialize object to input file path using msgpack format.                                                            |
| <code>to_numpy([dtype, copy])</code>                           | A NumPy ndarray representing the values in this Series or Index.                                                     |
| <code>to_period([freq, copy])</code>                           | Convert Series from DatetimeIndex to PeriodIndex with desired frequency (inferred from index if not passed).         |
| <code>to_pickle(path[, compression, protocol])</code>          | Pickle (serialize) object to file.                                                                                   |
| <code>to_sparse([kind, fill_value])</code>                     | Convert Series to SparseSeries.                                                                                      |
| <code>to_sql(name, con[, schema, if_exists, ...])</code>       | Write records stored in a DataFrame to a SQL database.                                                               |
| <code>to_string([buf, na_rep, float_format, ...])</code>       | Render a string representation of the Series.                                                                        |
| <code>to_timestamp([freq, how, copy])</code>                   | Cast to DatetimeIndex of timestamps, at <i>beginning</i> of period.                                                  |
| <code>to_xarray()</code>                                       | Return an xarray object from the pandas object.                                                                      |
| <code>tolist()</code>                                          | Return a list of the values.                                                                                         |
| <code>transform(func[, axis])</code>                           | Call <code>func</code> on self producing a Series with transformed values and that has the same axis length as self. |
| <code>transpose(*args, **kwargs)</code>                        | Return the transpose, which is by definition self.                                                                   |
| <code>truediv(other[, level, fill_value, axis])</code>         | Floating division of series and other, element-wise (binary operator <i>truediv</i> ).                               |
| <code>truncate([before, after, axis, copy])</code>             | Truncate a Series or DataFrame before and after some index value.                                                    |
| <code>tshift([periods, freq, axis])</code>                     | Shift the time index, using the index's frequency if available.                                                      |
| <code>tz_convert(tz[, axis, level, copy])</code>               | Convert tz-aware axis to target time zone.                                                                           |
| <code>tz_localize(tz[, axis, level, copy, ...])</code>         | Localize tz-naive index of a Series or DataFrame to target time zone.                                                |
| <code>unique()</code>                                          | Return unique values of Series object.                                                                               |
| <code>unstack([level, fill_value])</code>                      | Unstack, a.k.a.                                                                                                      |
| <code>update(other)</code>                                     | Modify Series in place using non-NA values from passed Series.                                                       |
| <code>valid([inplace])</code>                                  | (DEPRECATED) Return Series without null values.                                                                      |
| <code>value_counts([normalize, sort, ascending, ...])</code>   | Return a Series containing counts of unique values.                                                                  |
| <code>var([axis, skipna, level, ddof, numeric_only])</code>    | Return unbiased variance over requested axis.                                                                        |
| <code>view([dtype])</code>                                     | Create a new view of the Series.                                                                                     |

|                                                              |                                                 |
|--------------------------------------------------------------|-------------------------------------------------|
| <code>where(cond[, other, inplace, axis, level, ...])</code> | Replace values where the condition is False.    |
| <code>xs(key[, axis, level, drop_level])</code>              | Return cross-section from the Series/DataFrame. |

**pandas.Series.abs**`Series.abs()`

Return a Series/DataFrame with absolute numeric value of each element.

This function only applies to elements that are all numeric.

**Returns****abs** Series/DataFrame containing the absolute value of each element.**See also:****numpy.absolute** Calculate the absolute value element-wise.**Notes**For complex inputs,  $1.2 + 1j$ , the absolute value is  $\sqrt{a^2 + b^2}$ .**Examples**

Absolute numeric values in a Series.

```
>>> s = pd.Series([-1.10, 2, -3.33, 4])
>>> s.abs()
0    1.10
1    2.00
2    3.33
3    4.00
dtype: float64
```

Absolute numeric values in a Series with complex numbers.

```
>>> s = pd.Series([1.2 + 1j])
>>> s.abs()
0    1.56205
dtype: float64
```

Absolute numeric values in a Series with a Timedelta element.

```
>>> s = pd.Series([pd.Timedelta('1 days')])
>>> s.abs()
0    1 days
dtype: timedelta64[ns]
```

Select rows with data closest to certain value using `argsort` (from [StackOverflow](#)).

```
>>> df = pd.DataFrame({
...     'a': [4, 5, 6, 7],
...     'b': [10, 20, 30, 40],
...     'c': [100, 50, -30, -50]
```

(continues on next page)

(continued from previous page)

```

... })
>>> df
   a    b    c
0   4   10  100
1   5   20   50
2   6   30  -30
3   7   40  -50
>>> df.loc[(df.c - 43).abs().argsort()]
   a    b    c
1   5   20   50
0   4   10  100
2   6   30  -30
3   7   40  -50

```

## pandas.Series.add

`Series.add(other, level=None, fill_value=None, axis=0)`

Addition of series and other, element-wise (binary operator *add*).

Equivalent to `series + other`, but with support to substitute a `fill_value` for missing data in one of the inputs.

### Parameters

**other** [Series or scalar value]

**fill\_value** [None or float value, default None (NaN)] Fill existing missing (NaN) values, and any new element needed for successful Series alignment, with this value before computation. If data in both corresponding Series locations is missing the result will be missing

**level** [int or name] Broadcast across a level, matching Index values on the passed MultiIndex level

### Returns

**result** [Series]

### See also:

`Series.radd`

## Examples

```

>>> a = pd.Series([1, 1, 1, np.nan], index=['a', 'b', 'c', 'd'])
>>> a
a    1.0
b    1.0
c    1.0
d    NaN
dtype: float64
>>> b = pd.Series([1, np.nan, 1, np.nan], index=['a', 'b', 'd', 'e'])
>>> b
a    1.0
b    NaN
d    1.0
e    NaN

```

(continues on next page)

(continued from previous page)

```
dtype: float64
>>> a.add(b, fill_value=0)
a      2.0
b      1.0
c      1.0
d      1.0
e      NaN
dtype: float64
```

### pandas.Series.add\_prefix

**Series.add\_prefix** (*prefix*)

Prefix labels with string *prefix*.

For Series, the row labels are prefixed. For DataFrame, the column labels are prefixed.

#### Parameters

**prefix** [str] The string to add before each label.

#### Returns

**Series or DataFrame** New Series or DataFrame with updated labels.

#### See also:

**Series.add\_suffix** Suffix row labels with string *suffix*.

**DataFrame.add\_suffix** Suffix column labels with string *suffix*.

### Examples

```
>>> s = pd.Series([1, 2, 3, 4])
>>> s
0      1
1      2
2      3
3      4
dtype: int64
```

```
>>> s.add_prefix('item_')
item_0      1
item_1      2
item_2      3
item_3      4
dtype: int64
```

```
>>> df = pd.DataFrame({'A': [1, 2, 3, 4], 'B': [3, 4, 5, 6]})
>>> df
   A  B
0  1  3
1  2  4
2  3  5
3  4  6
```

```
>>> df.add_prefix('col_')
      col_A  col_B
0         1     3
1         2     4
2         3     5
3         4     6
```

## pandas.Series.add\_suffix

**Series.add\_suffix** (*suffix*)  
Suffix labels with string *suffix*.

For Series, the row labels are suffixed. For DataFrame, the column labels are suffixed.

### Parameters

**suffix** [str] The string to add after each label.

### Returns

**Series or DataFrame** New Series or DataFrame with updated labels.

**See also:**

**Series.add\_prefix** Prefix row labels with string *prefix*.

**DataFrame.add\_prefix** Prefix column labels with string *prefix*.

## Examples

```
>>> s = pd.Series([1, 2, 3, 4])
>>> s
0    1
1    2
2    3
3    4
dtype: int64
```

```
>>> s.add_suffix('_item')
0_item    1
1_item    2
2_item    3
3_item    4
dtype: int64
```

```
>>> df = pd.DataFrame({'A': [1, 2, 3, 4], 'B': [3, 4, 5, 6]})
>>> df
   A  B
0  1  3
1  2  4
2  3  5
3  4  6
```

```
>>> df.add_suffix('_col')
   A_col  B_col
0       1     3
1       2     4
2       3     5
3       4     6
```

## pandas.Series.agg

`Series.agg(func, axis=0, *args, **kwargs)`

Aggregate using one or more operations over the specified axis.

New in version 0.20.0.

### Parameters

**func** [function, str, list or dict] Function to use for aggregating the data. If a function, must either work when passed a Series or when passed to Series.apply.

Accepted combinations are:

- function
- string function name
- list of functions and/or function names, e.g. `[np.sum, 'mean']`
- dict of axis labels -> functions, function names or list of such.

**axis** [{0 or 'index'}] Parameter needed for compatibility with DataFrame.

**\*args** Positional arguments to pass to *func*.

**\*\*kwargs** Keyword arguments to pass to *func*.

### Returns

**DataFrame, Series or scalar** if DataFrame.agg is called with a single function, returns a Series if DataFrame.agg is called with several functions, returns a DataFrame if Series.agg is called with single function, returns a scalar if Series.agg is called with several functions, returns a Series

**See also:**

**Series.apply** Invoke function on a Series.

**Series.transform** Transform function producing a Series with like indexes.

## Notes

*agg* is an alias for *aggregate*. Use the alias.

A passed user-defined-function will be passed a Series for evaluation.

## Examples

```
>>> s = pd.Series([1, 2, 3, 4])
>>> s
0    1
1    2
2    3
3    4
dtype: int64
```

```
>>> s.agg('min')
1
```

```
>>> s.agg(['min', 'max'])
min    1
max    4
dtype: int64
```

## pandas.Series.aggregate

**Series.aggregate** (*func*, *axis=0*, *\*args*, *\*\*kwargs*)

Aggregate using one or more operations over the specified axis.

New in version 0.20.0.

### Parameters

**func** [function, str, list or dict] Function to use for aggregating the data. If a function, must either work when passed a Series or when passed to Series.apply.

Accepted combinations are:

- function
- string function name
- list of functions and/or function names, e.g. `[np.sum, 'mean']`
- dict of axis labels -> functions, function names or list of such.

**axis** [{0 or 'index'}] Parameter needed for compatibility with DataFrame.

**\*args** Positional arguments to pass to *func*.

**\*\*kwargs** Keyword arguments to pass to *func*.

### Returns

**DataFrame, Series or scalar** if DataFrame.agg is called with a single function, returns a Series if DataFrame.agg is called with several functions, returns a DataFrame if Series.agg is called with single function, returns a scalar if Series.agg is called with several functions, returns a Series

See also:

**Series.apply** Invoke function on a Series.

**Series.transform** Transform function producing a Series with like indexes.

## Notes

*agg* is an alias for *aggregate*. Use the alias.

A passed user-defined-function will be passed a Series for evaluation.

## Examples

```
>>> s = pd.Series([1, 2, 3, 4])
>>> s
0    1
1    2
2    3
3    4
dtype: int64
```

```
>>> s.agg('min')
1
```

```
>>> s.agg(['min', 'max'])
min    1
max    4
dtype: int64
```

## pandas.Series.align

`Series.align(other, join='outer', axis=None, level=None, copy=True, fill_value=None, method=None, limit=None, fill_axis=0, broadcast_axis=None)`

Align two objects on their axes with the specified join method for each axis Index.

### Parameters

**other** [DataFrame or Series]

**join** [{ 'outer', 'inner', 'left', 'right' }, default 'outer']

**axis** [allowed axis of the other object, default None] Align on index (0), columns (1), or both (None)

**level** [int or level name, default None] Broadcast across a level, matching Index values on the passed MultiIndex level

**copy** [boolean, default True] Always returns new objects. If copy=False and no reindexing is required then original objects are returned.

**fill\_value** [scalar, default np.NaN] Value to use for missing values. Defaults to NaN, but can be any “compatible” value

**method** [{ 'backfill', 'bfill', 'pad', 'ffill', None }, default None] Method to use for filling holes in reindexed Series pad / ffill: propagate last valid observation forward to next valid backfill / bfill: use NEXT valid observation to fill gap

**limit** [int, default None] If method is specified, this is the maximum number of consecutive NaN values to forward/backward fill. In other words, if there is a gap with more than this number of consecutive NaNs, it will only be partially filled. If method is not specified, this is the maximum number of entries along the entire axis where NaNs will be filled. Must be greater than 0 if not None.

**fill\_axis** [{0 or 'index'}, default 0] Filling axis, method and limit

**broadcast\_axis** [{0 or 'index'}, default None] Broadcast values along this axis, if aligning two objects of different dimensions

### Returns

**(left, right)** [(Series, type of other)] Aligned objects

## pandas.Series.all

`Series.all` (*axis=0, bool\_only=None, skipna=True, level=None, \*\*kwargs*)

Return whether all elements are True, potentially over an axis.

Returns True unless there at least one element within a series or along a Dataframe axis that is False or equivalent (e.g. zero or empty).

### Parameters

**axis** [{0 or 'index', 1 or 'columns', None}, default 0] Indicate which axis or axes should be reduced.

- 0 / 'index' : reduce the index, return a Series whose index is the original column labels.
- 1 / 'columns' : reduce the columns, return a Series whose index is the original index.
- None : reduce all axes, return a scalar.

**bool\_only** [bool, default None] Include only boolean columns. If None, will attempt to use everything, then use only boolean data. Not implemented for Series.

**skipna** [bool, default True] Exclude NA/null values. If the entire row/column is NA and skipna is True, then the result will be True, as for an empty row/column. If skipna is False, then NA are treated as True, because these are not equal to zero.

**level** [int or level name, default None] If the axis is a MultiIndex (hierarchical), count along a particular level, collapsing into a scalar.

**\*\*kwargs** [any, default None] Additional keywords have no effect but might be accepted for compatibility with NumPy.

### Returns

**scalar or Series** If level is specified, then, Series is returned; otherwise, scalar is returned.

### See also:

**Series.all** Return True if all elements are True.

**DataFrame.any** Return True if one (or more) elements are True.

## Examples

### Series

```
>>> pd.Series([True, True]).all()
True
>>> pd.Series([True, False]).all()
False
>>> pd.Series([]).all()
True
```

(continues on next page)

(continued from previous page)

```
>>> pd.Series([np.nan]).all()
True
>>> pd.Series([np.nan]).all(skipna=False)
True
```

## DataFrames

Create a dataframe from a dictionary.

```
>>> df = pd.DataFrame({'col1': [True, True], 'col2': [True, False]})
>>> df
   col1  col2
0  True  True
1  True False
```

Default behaviour checks if column-wise values all return True.

```
>>> df.all()
col1    True
col2   False
dtype: bool
```

Specify `axis='columns'` to check if row-wise values all return True.

```
>>> df.all(axis='columns')
0    True
1   False
dtype: bool
```

Or `axis=None` for whether every value is True.

```
>>> df.all(axis=None)
False
```

## pandas.Series.any

`Series.any` (*axis=0, bool\_only=None, skipna=True, level=None, \*\*kwargs*)

Return whether any element is True, potentially over an axis.

Returns False unless there at least one element within a series or along a Dataframe axis that is True or equivalent (e.g. non-zero or non-empty).

### Parameters

**axis** [{0 or 'index', 1 or 'columns', None}, default 0] Indicate which axis or axes should be reduced.

- 0 / 'index' : reduce the index, return a Series whose index is the original column labels.
- 1 / 'columns' : reduce the columns, return a Series whose index is the original index.
- None : reduce all axes, return a scalar.

**bool\_only** [bool, default None] Include only boolean columns. If None, will attempt to use everything, then use only boolean data. Not implemented for Series.

**skipna** [bool, default True] Exclude NA/null values. If the entire row/column is NA and skipna is True, then the result will be False, as for an empty row/column. If skipna is False, then NA are treated as True, because these are not equal to zero.

**level** [int or level name, default None] If the axis is a MultiIndex (hierarchical), count along a particular level, collapsing into a scalar.

**\*\*kwargs** [any, default None] Additional keywords have no effect but might be accepted for compatibility with NumPy.

### Returns

**scalar or Series** If level is specified, then, Series is returned; otherwise, scalar is returned.

### See also:

**numpy.any** Numpy version of this method.

**Series.any** Return whether any element is True.

**Series.all** Return whether all elements are True.

**DataFrame.any** Return whether any element is True over requested axis.

**DataFrame.all** Return whether all elements are True over requested axis.

## Examples

### Series

For Series input, the output is a scalar indicating whether any element is True.

```
>>> pd.Series([False, False]).any()
False
>>> pd.Series([True, False]).any()
True
>>> pd.Series([]).any()
False
>>> pd.Series([np.nan]).any()
False
>>> pd.Series([np.nan]).any(skipna=False)
True
```

### DataFrame

Whether each column contains at least one True element (the default).

```
>>> df = pd.DataFrame({"A": [1, 2], "B": [0, 2], "C": [0, 0]})
>>> df
   A  B  C
0  1  0  0
1  2  2  0
```

```
>>> df.any()
A      True
B      True
C     False
dtype: bool
```

Aggregating over the columns.

```
>>> df = pd.DataFrame({"A": [True, False], "B": [1, 2]})
>>> df
   A  B
0  True  1
1 False  2
```

```
>>> df.any(axis='columns')
0    True
1    True
dtype: bool
```

```
>>> df = pd.DataFrame({"A": [True, False], "B": [1, 0]})
>>> df
   A  B
0  True  1
1 False  0
```

```
>>> df.any(axis='columns')
0    True
1   False
dtype: bool
```

Aggregating over the entire DataFrame with `axis=None`.

```
>>> df.any(axis=None)
True
```

`any` for an empty DataFrame is an empty Series.

```
>>> pd.DataFrame([]).any()
Series([], dtype: bool)
```

## pandas.Series.append

`Series.append(to_append, ignore_index=False, verify_integrity=False)`

Concatenate two or more Series.

### Parameters

**to\_append** [Series or list/tuple of Series]

**ignore\_index** [boolean, default False] If True, do not use the index labels.

New in version 0.19.0.

**verify\_integrity** [boolean, default False] If True, raise Exception on creating index with duplicates

### Returns

**appended** [Series]

**See also:**

**concat** General function to concatenate DataFrame, Series or Panel objects.

## Notes

Iteratively appending to a Series can be more computationally intensive than a single concatenate. A better solution is to append values to a list and then concatenate the list with the original Series all at once.

## Examples

```
>>> s1 = pd.Series([1, 2, 3])
>>> s2 = pd.Series([4, 5, 6])
>>> s3 = pd.Series([4, 5, 6], index=[3, 4, 5])
>>> s1.append(s2)
0    1
1    2
2    3
0    4
1    5
2    6
dtype: int64
```

```
>>> s1.append(s3)
0    1
1    2
2    3
3    4
4    5
5    6
dtype: int64
```

With *ignore\_index* set to True:

```
>>> s1.append(s2, ignore_index=True)
0    1
1    2
2    3
3    4
4    5
5    6
dtype: int64
```

With *verify\_integrity* set to True:

```
>>> s1.append(s2, verify_integrity=True)
Traceback (most recent call last):
...
ValueError: Indexes have overlapping values: [0, 1, 2]
```

## pandas.Series.apply

`Series.apply(func, convert_dtype=True, args=(), **kwargs)`

Invoke function on values of Series.

Can be ufunc (a NumPy function that applies to the entire Series) or a Python function that only works on single values.

### Parameters

**func** [function] Python function or NumPy ufunc to apply.

**convert\_dtype** [bool, default True] Try to find better dtype for elementwise function results.  
If False, leave as dtype=object.

**args** [tuple] Positional arguments passed to func after the series value.

**\*\*kwargs** Additional keyword arguments passed to func.

### Returns

**Series or DataFrame** If func returns a Series object the result will be a DataFrame.

### See also:

**Series.map** For element-wise operations.

**Series.agg** Only perform aggregating type operations.

**Series.transform** Only perform transforming type operations.

### Examples

Create a series with typical summer temperatures for each city.

```
>>> s = pd.Series([20, 21, 12],
...                index=['London', 'New York', 'Helsinki'])
>>> s
London      20
New York    21
Helsinki    12
dtype: int64
```

Square the values by defining a function and passing it as an argument to `apply()`.

```
>>> def square(x):
...     return x ** 2
>>> s.apply(square)
London      400
New York    441
Helsinki    144
dtype: int64
```

Square the values by passing an anonymous function as an argument to `apply()`.

```
>>> s.apply(lambda x: x ** 2)
London      400
New York    441
Helsinki    144
dtype: int64
```

Define a custom function that needs additional positional arguments and pass these additional arguments using the `args` keyword.

```
>>> def subtract_custom_value(x, custom_value):
...     return x - custom_value
```

```
>>> s.apply(subtract_custom_value, args=(5,))
London      15
New York    16
Helsinki     7
dtype: int64
```

Define a custom function that takes keyword arguments and pass these arguments to `apply`.

```
>>> def add_custom_values(x, **kwargs):
...     for month in kwargs:
...         x += kwargs[month]
...     return x
```

```
>>> s.apply(add_custom_values, june=30, july=20, august=25)
London      95
New York    96
Helsinki    87
dtype: int64
```

Use a function from the Numpy library.

```
>>> s.apply(np.log)
London      2.995732
New York    3.044522
Helsinki    2.484907
dtype: float64
```

## pandas.Series.argmax

`Series.argmax` (*axis=0, skipna=True, \*args, \*\*kwargs*)

Return the row label of the maximum value.

Deprecated since version 0.21.0.

The current behaviour of ‘Series.argmax’ is deprecated, use ‘idxmax’ instead. The behavior of ‘argmax’ will be corrected to return the positional maximum in the future. For now, use ‘series.values.argmax’ or ‘np.argmax(np.array(values))’ to get the position of the maximum row.

If multiple values equal the maximum, the first row label with that value is returned.

### Parameters

**skipna** [boolean, default True] Exclude NA/null values. If the entire Series is NA, the result will be NA.

**axis** [int, default 0] For compatibility with `DataFrame.idxmax`. Redundant for application on Series.

**\*args, \*\*kwargs** Additional keywords have no effect but might be accepted for compatibility with NumPy.

### Returns

**idxmax** [Index of maximum of values.]

### Raises

**ValueError** If the Series is empty.

See also:

**numpy.argmax** Return indices of the maximum values along the given axis.

**DataFrame.idxmax** Return index of first occurrence of maximum over requested axis.

**Series.idxmin** Return index *label* of the first occurrence of minimum of values.

## Notes

This method is the Series version of `ndarray.argmax`. This method returns the label of the maximum, while `ndarray.argmax` returns the position. To get the position, use `series.values.argmax()`.

## Examples

```
>>> s = pd.Series(data=[1, None, 4, 3, 4],
...                 index=['A', 'B', 'C', 'D', 'E'])
>>> s
A    1.0
B    NaN
C    4.0
D    3.0
E    4.0
dtype: float64
```

```
>>> s.idxmax()
'C'
```

If *skipna* is False and there is an NA value in the data, the function returns nan.

```
>>> s.idxmax(skipna=False)
nan
```

## pandas.Series.argmin

**Series.argmin** (*axis=0, skipna=True, \*args, \*\*kwargs*)

Return the row label of the minimum value.

Deprecated since version 0.21.0.

The current behaviour of ‘Series.argmin’ is deprecated, use ‘idxmin’ instead. The behavior of ‘argmin’ will be corrected to return the positional minimum in the future. For now, use ‘series.values.argmin’ or ‘np.argmin(np.array(values))’ to get the position of the minimum row.

If multiple values equal the minimum, the first row label with that value is returned.

### Parameters

**skipna** [boolean, default True] Exclude NA/null values. If the entire Series is NA, the result will be NA.

**axis** [int, default 0] For compatibility with DataFrame.idxmin. Redundant for application on Series.

**\*args, \*\*kwargs** Additional keywords have no effect but might be accepted for compatibility with NumPy.

### Returns

**idxmin** [Index of minimum of values.]

**Raises**

**ValueError** If the Series is empty.

**See also:**

**numpy.argmax** Return indices of the minimum values along the given axis.

**DataFrame.idxmin** Return index of first occurrence of minimum over requested axis.

**Series.idxmax** Return index *label* of the first occurrence of maximum of values.

## Notes

This method is the Series version of `ndarray.argmax`. This method returns the label of the minimum, while `ndarray.argmax` returns the position. To get the position, use `series.values.argmax()`.

## Examples

```
>>> s = pd.Series(data=[1, None, 4, 1],
...               index=['A', 'B', 'C', 'D'])
>>> s
A    1.0
B    NaN
C    4.0
D    1.0
dtype: float64
```

```
>>> s.idxmin()
'A'
```

If *skipna* is False and there is an NA value in the data, the function returns nan.

```
>>> s.idxmin(skipna=False)
nan
```

## pandas.Series.argsort

**Series.argsort** (*axis=0, kind='quicksort', order=None*)

Overrides `ndarray.argsort`. Argsorts the value, omitting NA/null values, and places the result in the same locations as the non-NA values.

**Parameters**

**axis** [int (can only be zero)]

**kind** [{‘mergesort’, ‘quicksort’, ‘heapsort’}, default ‘quicksort’] Choice of sorting algorithm. See `np.sort` for more information. ‘mergesort’ is the only stable algorithm

**order** [ignored]

**Returns**

**argsorted** [Series, with -1 indicated where nan values are present]

See also:

`numpy.ndarray.argsort`

### **pandas.Series.as\_blocks**

`Series.as_blocks (copy=True)`

Convert the frame to a dict of dtype -> Constructor Types that each has a homogeneous dtype.

Deprecated since version 0.21.0.

**NOTE: the dtypes of the blocks WILL BE PRESERVED HERE (unlike in `as_matrix`)**

#### **Parameters**

**copy** [boolean, default True]

#### **Returns**

**values** [a dict of dtype -> Constructor Types]

### **pandas.Series.as\_matrix**

`Series.as_matrix (columns=None)`

Convert the frame to its Numpy-array representation.

Deprecated since version 0.23.0: Use `DataFrame.values()` instead.

#### **Parameters**

**columns** [list, optional, default:None] If None, return all columns, otherwise, returns specified columns.

#### **Returns**

**values** [ndarray] If the caller is heterogeneous and contains booleans or objects, the result will be of dtype=object. See Notes.

See also:

`DataFrame.values`

### **Notes**

Return is NOT a Numpy-matrix, rather, a Numpy-array.

The dtype will be a lower-common-denominator dtype (implicit upcasting); that is to say if the dtypes (even of numeric types) are mixed, the one that accommodates all will be chosen. Use this with care if you are not dealing with the blocks.

e.g. If the dtypes are float16 and float32, dtype will be upcast to float32. If dtypes are int32 and uint8, dtype will be upcase to int32. By `numpy.find_common_type` convention, mixing int64 and uint64 will result in a float64 dtype.

This method is provided for backwards compatibility. Generally, it is recommended to use `'values'`.

## pandas.Series.asfreq

`Series.asfreq(freq, method=None, how=None, normalize=False, fill_value=None)`

Convert TimeSeries to specified frequency.

Optionally provide filling method to pad/backfill missing values.

Returns the original data conformed to a new index with the specified frequency. `resample` is more appropriate if an operation, such as summarization, is necessary to represent the data at the new frequency.

### Parameters

**freq** [DateOffset object, or string]

**method** [{ 'backfill'/'bfill', 'pad'/'ffill' }, default None] Method to use for filling holes in reindexed Series (note this does not fill NaNs that already were present):

- 'pad' / 'ffill': propagate last valid observation forward to next valid
- 'backfill' / 'bfill': use NEXT valid observation to fill

**how** [{ 'start', 'end' }, default end] For PeriodIndex only, see PeriodIndex.asfreq

**normalize** [bool, default False] Whether to reset output index to midnight

**fill\_value** [scalar, optional] Value to use for missing values, applied during upsampling (note this does not fill NaNs that already were present).

New in version 0.20.0.

### Returns

**converted** [same type as caller]

See also:

*reindex*

## Notes

To learn more about the frequency strings, please see [this link](#).

## Examples

Start by creating a series with 4 one minute timestamps.

```
>>> index = pd.date_range('1/1/2000', periods=4, freq='T')
>>> series = pd.Series([0.0, None, 2.0, 3.0], index=index)
>>> df = pd.DataFrame({'s':series})
>>> df
```

|                     | s   |
|---------------------|-----|
| 2000-01-01 00:00:00 | 0.0 |
| 2000-01-01 00:01:00 | NaN |
| 2000-01-01 00:02:00 | 2.0 |
| 2000-01-01 00:03:00 | 3.0 |

Upsample the series into 30 second bins.

```
>>> df.ashfreq(freq='30S')
      S
2000-01-01 00:00:00    0.0
2000-01-01 00:00:30   NaN
2000-01-01 00:01:00   NaN
2000-01-01 00:01:30   NaN
2000-01-01 00:02:00    2.0
2000-01-01 00:02:30   NaN
2000-01-01 00:03:00    3.0
```

Upsample again, providing a fill value.

```
>>> df.ashfreq(freq='30S', fill_value=9.0)
      S
2000-01-01 00:00:00    0.0
2000-01-01 00:00:30    9.0
2000-01-01 00:01:00   NaN
2000-01-01 00:01:30    9.0
2000-01-01 00:02:00    2.0
2000-01-01 00:02:30    9.0
2000-01-01 00:03:00    3.0
```

Upsample again, providing a method.

```
>>> df.ashfreq(freq='30S', method='bfill')
      S
2000-01-01 00:00:00    0.0
2000-01-01 00:00:30   NaN
2000-01-01 00:01:00   NaN
2000-01-01 00:01:30    2.0
2000-01-01 00:02:00    2.0
2000-01-01 00:02:30    3.0
2000-01-01 00:03:00    3.0
```

## pandas.Series.asof

`Series.asof` (*where*, *subset=None*)

Return the last row(s) without any NaNs before *where*.

The last row (for each element in *where*, if list) without any NaN is taken. In case of a *DataFrame*, the last row without NaN considering only the subset of columns (if not *None*)

New in version 0.19.0: For *DataFrame*

If there is no good value, NaN is returned for a *Series* or a *Series* of NaN values for a *DataFrame*

### Parameters

**where** [date or array-like of dates] Date(s) before which the last row(s) are returned.

**subset** [str or array-like of str, default *None*] For *DataFrame*, if not *None*, only use these columns to check for NaNs.

### Returns

**scalar, Series, or DataFrame**

- scalar : when *self* is a *Series* and *where* is a scalar

- Series: when *self* is a Series and *where* is an array-like, or when *self* is a DataFrame and *where* is a scalar
- DataFrame : when *self* is a DataFrame and *where* is an array-like

See also:

**`merge_asof`** Perform an asof merge. Similar to left join.

## Notes

Dates are assumed to be sorted. Raises if this is not the case.

## Examples

A Series and a scalar *where*.

```
>>> s = pd.Series([1, 2, np.nan, 4], index=[10, 20, 30, 40])
>>> s
10    1.0
20    2.0
30    NaN
40    4.0
dtype: float64
```

```
>>> s.asof(20)
2.0
```

For a sequence *where*, a Series is returned. The first value is NaN, because the first element of *where* is before the first index value.

```
>>> s.asof([5, 20])
5      NaN
20     2.0
dtype: float64
```

Missing values are not considered. The following is 2.0, not NaN, even though NaN is at the index location for 30.

```
>>> s.asof(30)
2.0
```

Take all columns into consideration

```
>>> df = pd.DataFrame({'a': [10, 20, 30, 40, 50],
...                     'b': [None, None, None, None, 500]},
...                    index=pd.DatetimeIndex(['2018-02-27 09:01:00',
...                                             '2018-02-27 09:02:00',
...                                             '2018-02-27 09:03:00',
...                                             '2018-02-27 09:04:00',
...                                             '2018-02-27 09:05:00']))
>>> df.asof(pd.DatetimeIndex(['2018-02-27 09:03:30',
...                           '2018-02-27 09:04:30']))
               a    b
2018-02-27 09:03:30  NaN  NaN
2018-02-27 09:04:30  NaN  NaN
```

Take a single column into consideration

```
>>> df.asof(pd.DatetimeIndex(['2018-02-27 09:03:30',
...                           '2018-02-27 09:04:30']),
...         subset=['a'])
              a    b
2018-02-27 09:03:30  30.0 NaN
2018-02-27 09:04:30  40.0 NaN
```

## pandas.Series.astype

`Series.astype(dtype, copy=True, errors='raise', **kwargs)`

Cast a pandas object to a specified dtype dtype.

### Parameters

**dtype** [data type, or dict of column name -> data type] Use a numpy.dtype or Python type to cast entire pandas object to the same type. Alternatively, use {col: dtype, ...}, where col is a column label and dtype is a numpy.dtype or Python type to cast one or more of the DataFrame's columns to column-specific types.

**copy** [bool, default True] Return a copy when copy=True (be very careful setting copy=False as changes to values then may propagate to other pandas objects).

**errors** [{ 'raise', 'ignore' }, default 'raise'] Control raising of exceptions on invalid data for provided dtype.

- `raise` : allow exceptions to be raised
- `ignore` : suppress exceptions. On error return original object

New in version 0.20.0.

**kwargs** [keyword arguments to pass on to the constructor]

### Returns

**casted** [same type as caller]

See also:

**to\_datetime** Convert argument to datetime.

**to\_timedelta** Convert argument to timedelta.

**to\_numeric** Convert argument to a numeric type.

**numpy.ndarray.astype** Cast a numpy array to a specified type.

## Examples

```
>>> ser = pd.Series([1, 2], dtype='int32')
>>> ser
0    1
1    2
dtype: int32
>>> ser.astype('int64')
0    1
1    2
dtype: int64
```

Convert to categorical type:

```
>>> ser.astype('category')
0    1
1    2
dtype: category
Categories (2, int64): [1, 2]
```

Convert to ordered categorical type with custom ordering:

```
>>> cat_dtype = pd.api.types.CategoricalDtype(
...     categories=[2, 1], ordered=True)
>>> ser.astype(cat_dtype)
0    1
1    2
dtype: category
Categories (2, int64): [2 < 1]
```

Note that using `copy=False` and changing data on a new pandas object may propagate changes:

```
>>> s1 = pd.Series([1,2])
>>> s2 = s1.astype('int64', copy=False)
>>> s2[0] = 10
>>> s1 # note that s1[0] has changed too
0    10
1     2
dtype: int64
```

## pandas.Series.at\_time

`Series.at_time` (*time*, *asof=False*, *axis=None*)

Select values at particular time of day (e.g. 9:30AM).

### Parameters

**time** [datetime.time or string]

**axis** [{0 or 'index', 1 or 'columns'}], default 0] New in version 0.24.0.

### Returns

**values\_at\_time** [same type as caller]

### Raises

**TypeError** If the index is not a *DatetimeIndex*

See also:

**between\_time** Select values between particular times of the day.

**first** Select initial periods of time series based on a date offset.

**last** Select final periods of time series based on a date offset.

**DatetimeIndex.indexer\_at\_time** Get just the index locations for values at particular time of the day.

## Examples

```
>>> i = pd.date_range('2018-04-09', periods=4, freq='12H')
>>> ts = pd.DataFrame({'A': [1,2,3,4]}, index=i)
>>> ts
```

|                     | A |
|---------------------|---|
| 2018-04-09 00:00:00 | 1 |
| 2018-04-09 12:00:00 | 2 |
| 2018-04-10 00:00:00 | 3 |
| 2018-04-10 12:00:00 | 4 |

```
>>> ts.at_time('12:00')
```

|                     | A |
|---------------------|---|
| 2018-04-09 12:00:00 | 2 |
| 2018-04-10 12:00:00 | 4 |

## pandas.Series.autocorr

**Series.autocorr** (*lag=1*)

Compute the lag-N autocorrelation.

This method computes the Pearson correlation between the Series and its shifted self.

### Parameters

**lag** [int, default 1] Number of lags to apply before performing autocorrelation.

### Returns

**float** The Pearson correlation between self and self.shift(lag).

### See also:

**Series.corr** Compute the correlation between two Series.

**Series.shift** Shift index by desired number of periods.

**DataFrame.corr** Compute pairwise correlation of columns.

**DataFrame.corrwith** Compute pairwise correlation between rows or columns of two DataFrame objects.

## Notes

If the Pearson correlation is not well defined return 'NaN'.

## Examples

```
>>> s = pd.Series([0.25, 0.5, 0.2, -0.05])
>>> s.autocorr() # doctest: +ELLIPSIS
0.10355...
>>> s.autocorr(lag=2) # doctest: +ELLIPSIS
-0.99999...
```

If the Pearson correlation is not well defined, then 'NaN' is returned.

```
>>> s = pd.Series([1, 0, 0, 0])
>>> s.autocorr()
nan
```

## pandas.Series.between

`Series.between` (*left*, *right*, *inclusive=True*)

Return boolean Series equivalent to `left <= series <= right`.

This function returns a boolean vector containing *True* wherever the corresponding Series element is between the boundary values *left* and *right*. NA values are treated as *False*.

### Parameters

**left** [scalar] Left boundary.

**right** [scalar] Right boundary.

**inclusive** [bool, default True] Include boundaries.

### Returns

**Series** Each element will be a boolean.

### See also:

***Series.gt*** Greater than of series and other.

***Series.lt*** Less than of series and other.

### Notes

This function is equivalent to `(left <= ser) & (ser <= right)`

### Examples

```
>>> s = pd.Series([2, 0, 4, 8, np.nan])
```

Boundary values are included by default:

```
>>> s.between(1, 4)
0      True
1     False
2      True
3     False
4     False
dtype: bool
```

With *inclusive* set to *False* boundary values are excluded:

```
>>> s.between(1, 4, inclusive=False)
0      True
1     False
2     False
3     False
```

(continues on next page)

(continued from previous page)

```
4    False
dtype: bool
```

*left* and *right* can be any scalar value:

```
>>> s = pd.Series(['Alice', 'Bob', 'Carol', 'Eve'])
>>> s.between('Anna', 'Daniel')
0    False
1     True
2     True
3    False
dtype: bool
```

### pandas.Series.between\_time

`Series.between_time(start_time, end_time, include_start=True, include_end=True, axis=None)`

Select values between particular times of the day (e.g., 9:00-9:30 AM).

By setting `start_time` to be later than `end_time`, you can get the times that are *not* between the two times.

#### Parameters

**start\_time** [datetime.time or string]

**end\_time** [datetime.time or string]

**include\_start** [boolean, default True]

**include\_end** [boolean, default True]

**axis** [{0 or 'index', 1 or 'columns'}, default 0] New in version 0.24.0.

#### Returns

**values\_between\_time** [same type as caller]

#### Raises

**TypeError** If the index is not a *DatetimeIndex*

#### See also:

**at\_time** Select values at a particular time of the day.

**first** Select initial periods of time series based on a date offset.

**last** Select final periods of time series based on a date offset.

**DatetimeIndex.indexer\_between\_time** Get just the index locations for values between particular times of the day.

### Examples

```
>>> i = pd.date_range('2018-04-09', periods=4, freq='1D20min')
>>> ts = pd.DataFrame({'A': [1,2,3,4]}, index=i)
>>> ts
```

A

(continues on next page)

(continued from previous page)

```

2018-04-09 00:00:00 1
2018-04-10 00:20:00 2
2018-04-11 00:40:00 3
2018-04-12 01:00:00 4

```

```

>>> ts.between_time('0:15', '0:45')
A
2018-04-10 00:20:00 2
2018-04-11 00:40:00 3

```

You get the times that are *not* between two times by setting `start_time` later than `end_time`:

```

>>> ts.between_time('0:45', '0:15')
A
2018-04-09 00:00:00 1
2018-04-12 01:00:00 4

```

## pandas.Series.bfill

`Series.bfill` (*axis=None, inplace=False, limit=None, downcast=None*)  
 Synonym for `DataFrame.fillna()` with `method='bfill'`.

## pandas.Series.bool

`Series.bool()`

Return the bool of a single element `PandasObject`.

This must be a boolean scalar value, either `True` or `False`. Raise a `ValueError` if the `PandasObject` does not have exactly 1 element, or that element is not boolean

## pandas.Series.cat

`Series.cat()`

Accessor object for categorical properties of the Series values.

Be aware that assigning to `categories` is an inplace operation, while all methods return new categorical data per default (but can be called with `inplace=True`).

### Parameters

**data** [Series or CategoricalIndex]

### Examples

```

>>> s.cat.categories
>>> s.cat.categories = list('abc')
>>> s.cat.rename_categories(list('cab'))
>>> s.cat.reorder_categories(list('cab'))
>>> s.cat.add_categories(['d', 'e'])
>>> s.cat.remove_categories(['d'])
>>> s.cat.remove_unused_categories()

```

(continues on next page)

(continued from previous page)

```
>>> s.cat.set_categories(list('abcde'))
>>> s.cat.as_ordered()
>>> s.cat.as_unordered()
```

**pandas.Series.clip**

`Series.clip` (*lower=None, upper=None, axis=None, inplace=False, \*args, \*\*kwargs*)

Trim values at input threshold(s).

Assigns values outside boundary to boundary values. Thresholds can be singular values or array like, and in the latter case the clipping is performed element-wise in the specified axis.

**Parameters**

**lower** [float or array\_like, default None] Minimum threshold value. All values below this threshold will be set to it.

**upper** [float or array\_like, default None] Maximum threshold value. All values above this threshold will be set to it.

**axis** [int or string axis name, optional] Align object with lower and upper along the given axis.

**inplace** [boolean, default False] Whether to perform the operation in place on the data.

New in version 0.21.0.

**\*args, \*\*kwargs** Additional keywords have no effect but might be accepted for compatibility with numpy.

**Returns**

**Series or DataFrame** Same type as calling object with the values outside the clip boundaries replaced

**Examples**

```
>>> data = {'col_0': [9, -3, 0, -1, 5], 'col_1': [-2, -7, 6, 8, -5]}
>>> df = pd.DataFrame(data)
>>> df
   col_0  col_1
0      9     -2
1     -3     -7
2      0      6
3     -1      8
4      5     -5
```

Clips per column using lower and upper thresholds:

```
>>> df.clip(-4, 6)
   col_0  col_1
0      6     -2
1     -3     -4
2      0      6
3     -1      6
4      5     -4
```

Clips using specific lower and upper thresholds per column element:

```
>>> t = pd.Series([2, -4, -1, 6, 3])
>>> t
0    2
1   -4
2   -1
3    6
4    3
dtype: int64
```

```
>>> df.clip(t, t + 4, axis=0)
   col_0  col_1
0      6      2
1     -3     -4
2      0      3
3      6      8
4      5      3
```

### pandas.Series.clip\_lower

`Series.clip_lower(threshold, axis=None, inplace=False)`

Trim values below a given threshold.

Deprecated since version 0.24.0: Use `clip(lower=threshold)` instead.

Elements below the *threshold* will be changed to match the *threshold* value(s). Threshold can be a single value or an array, in the latter case it performs the truncation element-wise.

#### Parameters

**threshold** [numeric or array-like] Minimum value allowed. All values below threshold will be set to this value.

- float : every value is compared to *threshold*.
- array-like : The shape of *threshold* should match the object it's compared to. When *self* is a Series, *threshold* should be the length. When *self* is a DataFrame, *threshold* should be 2-D and the same shape as *self* for `axis=None`, or 1-D and the same length as the axis being compared.

**axis** [{0 or 'index', 1 or 'columns'}, default 0] Align *self* with *threshold* along the given axis.

**inplace** [boolean, default False] Whether to perform the operation in place on the data.

New in version 0.21.0.

#### Returns

**Series or DataFrame** Original data with values trimmed.

**See also:**

**Series.clip** General purpose method to trim Series values to given threshold(s).

**DataFrame.clip** General purpose method to trim DataFrame values to given threshold(s).

## Examples

Series single threshold clipping:

```
>>> s = pd.Series([5, 6, 7, 8, 9])
>>> s.clip(lower=8)
0      8
1      8
2      8
3      8
4      9
dtype: int64
```

Series clipping element-wise using an array of thresholds. *threshold* should be the same length as the Series.

```
>>> elemwise_thresholds = [4, 8, 7, 2, 5]
>>> s.clip(lower=elemwise_thresholds)
0      5
1      8
2      7
3      8
4      9
dtype: int64
```

DataFrames can be compared to a scalar.

```
>>> df = pd.DataFrame({"A": [1, 3, 5], "B": [2, 4, 6]})
>>> df
   A  B
0  1  2
1  3  4
2  5  6
```

```
>>> df.clip(lower=3)
   A  B
0  3  3
1  3  4
2  5  6
```

Or to an array of values. By default, *threshold* should be the same shape as the DataFrame.

```
>>> df.clip(lower=np.array([[3, 4], [2, 2], [6, 2]]))
   A  B
0  3  4
1  3  4
2  6  6
```

Control how *threshold* is broadcast with *axis*. In this case *threshold* should be the same length as the axis specified by *axis*.

```
>>> df.clip(lower=[3, 3, 5], axis='index')
   A  B
0  3  3
1  3  4
2  5  6
```

```
>>> df.clip(lower=[4, 5], axis='columns')
   A  B
0  4  5
1  4  5
2  5  6
```

## pandas.Series.clip\_upper

`Series.clip_upper` (*threshold*, *axis=None*, *inplace=False*)

Trim values above a given threshold.

Deprecated since version 0.24.0: Use `clip(upper=threshold)` instead.

Elements above the *threshold* will be changed to match the *threshold* value(s). Threshold can be a single value or an array, in the latter case it performs the truncation element-wise.

### Parameters

**threshold** [numeric or array-like] Maximum value allowed. All values above threshold will be set to this value.

- float : every value is compared to *threshold*.
- array-like : The shape of *threshold* should match the object it's compared to. When *self* is a Series, *threshold* should be the length. When *self* is a DataFrame, *threshold* should be 2-D and the same shape as *self* for *axis=None*, or 1-D and the same length as the axis being compared.

**axis** [{0 or 'index', 1 or 'columns'}], default 0] Align object with *threshold* along the given axis.

**inplace** [boolean, default False] Whether to perform the operation in place on the data.

New in version 0.21.0.

### Returns

**Series or DataFrame** Original data with values trimmed.

See also:

**Series.clip** General purpose method to trim Series values to given threshold(s).

**DataFrame.clip** General purpose method to trim DataFrame values to given threshold(s).

## Examples

```
>>> s = pd.Series([1, 2, 3, 4, 5])
>>> s
0    1
1    2
2    3
3    4
4    5
dtype: int64
```

```
>>> s.clip(upper=3)
0    1
1    2
2    3
3    3
4    3
dtype: int64
```

```
>>> elemwise_thresholds = [5, 4, 3, 2, 1]
>>> elemwise_thresholds
[5, 4, 3, 2, 1]
```

```
>>> s.clip(upper=elemwise_thresholds)
0    1
1    2
2    3
3    2
4    1
dtype: int64
```

## pandas.Series.combine

**Series.combine** (*other, func, fill\_value=None*)

Combine the Series with a Series or scalar according to *func*.

Combine the Series and *other* using *func* to perform elementwise selection for combined Series. *fill\_value* is assumed when value is missing at some index from one of the two objects being combined.

### Parameters

**other** [Series or scalar] The value(s) to be combined with the *Series*.

**func** [function] Function that takes two scalars as inputs and returns an element.

**fill\_value** [scalar, optional] The value to assume when an index is missing from one Series or the other. The default specifies to use the appropriate NaN value for the underlying dtype of the Series.

### Returns

**Series** The result of combining the Series with the other object.

### See also:

**Series.combine\_first** Combine Series values, choosing the calling Series' values first.

## Examples

Consider 2 Datasets *s1* and *s2* containing highest clocked speeds of different birds.

```
>>> s1 = pd.Series({'falcon': 330.0, 'eagle': 160.0})
>>> s1
falcon    330.0
eagle     160.0
dtype: float64
>>> s2 = pd.Series({'falcon': 345.0, 'eagle': 200.0, 'duck': 30.0})
```

(continues on next page)

(continued from previous page)

```
>>> s2
falcon      345.0
eagle       200.0
duck        30.0
dtype: float64
```

Now, to combine the two datasets and view the highest speeds of the birds across the two datasets

```
>>> s1.combine(s2, max)
duck      NaN
eagle     200.0
falcon    345.0
dtype: float64
```

In the previous example, the resulting value for duck is missing, because the maximum of a NaN and a float is a NaN. So, in the example, we set `fill_value=0`, so the maximum value returned will be the value from some dataset.

```
>>> s1.combine(s2, max, fill_value=0)
duck      30.0
eagle     200.0
falcon    345.0
dtype: float64
```

## pandas.Series.combine\_first

`Series.combine_first(other)`

Combine Series values, choosing the calling Series's values first.

### Parameters

**other** [Series] The value(s) to be combined with the *Series*.

### Returns

**Series** The result of combining the Series with the other object.

**See also:**

***Series.combine*** Perform elementwise operation on two Series using a given function.

## Notes

Result index will be the union of the two indexes.

## Examples

```
>>> s1 = pd.Series([1, np.nan])
>>> s2 = pd.Series([3, 4])
>>> s1.combine_first(s2)
0    1.0
1    4.0
dtype: float64
```

### pandas.Series.compound

`Series.compound` (*axis=None, skipna=None, level=None*)

Return the compound percentage of the values for the requested axis.

#### Parameters

**axis** [{index (0)}] Axis for the function to be applied on.

**skipna** [bool, default True] Exclude NA/null values when computing the result.

**level** [int or level name, default None] If the axis is a MultiIndex (hierarchical), count along a particular level, collapsing into a scalar.

**numeric\_only** [bool, default None] Include only float, int, boolean columns. If None, will attempt to use everything, then use only numeric data. Not implemented for Series.

**\*\*kwargs** Additional keyword arguments to be passed to the function.

#### Returns

**compounded** [scalar or Series (if level specified)]

### pandas.Series.compress

`Series.compress` (*condition, \*args, \*\*kwargs*)

Return selected slices of an array along given axis as a Series.

Deprecated since version 0.24.0.

#### See also:

`numpy.ndarray.compress`

### pandas.Series.convert\_objects

`Series.convert_objects` (*convert\_dates=True, convert\_numeric=False, convert\_timedeltas=True, copy=True*)

Attempt to infer better dtype for object columns.

Deprecated since version 0.21.0.

#### Parameters

**convert\_dates** [boolean, default True] If True, convert to date where possible. If 'coerce', force conversion, with unconvertible values becoming NaT.

**convert\_numeric** [boolean, default False] If True, attempt to coerce to numbers (including strings), with unconvertible values becoming NaN.

**convert\_timedeltas** [boolean, default True] If True, convert to timedelta where possible. If 'coerce', force conversion, with unconvertible values becoming NaT.

**copy** [boolean, default True] If True, return a copy even if no copy is necessary (e.g. no conversion was done). Note: This is meant for internal use, and should not be confused with inplace.

#### Returns

**converted** [same as input object]

#### See also:

**to\_datetime** Convert argument to datetime.

**to\_timedelta** Convert argument to timedelta.

**to\_numeric** Convert argument to numeric type.

## pandas.Series.copy

`Series.copy(deep=True)`

Make a copy of this object's indices and data.

When `deep=True` (default), a new object will be created with a copy of the calling object's data and indices. Modifications to the data or indices of the copy will not be reflected in the original object (see notes below).

When `deep=False`, a new object will be created without copying the calling object's data or index (only references to the data and index are copied). Any changes to the data of the original will be reflected in the shallow copy (and vice versa).

### Parameters

**deep** [bool, default True] Make a deep copy, including a copy of the data and the indices.  
With `deep=False` neither the indices nor the data are copied.

### Returns

**copy** [Series, DataFrame or Panel] Object type matches caller.

## Notes

When `deep=True`, data is copied but actual Python objects will not be copied recursively, only the reference to the object. This is in contrast to `copy.deepcopy` in the Standard Library, which recursively copies object data (see examples below).

While `Index` objects are copied when `deep=True`, the underlying numpy array is not copied for performance reasons. Since `Index` is immutable, the underlying data can be safely shared and a copy is not needed.

## Examples

```
>>> s = pd.Series([1, 2], index=["a", "b"])
>>> s
a    1
b    2
dtype: int64
```

```
>>> s_copy = s.copy()
>>> s_copy
a    1
b    2
dtype: int64
```

**Shallow copy versus default (deep) copy:**

```
>>> s = pd.Series([1, 2], index=["a", "b"])
>>> deep = s.copy()
>>> shallow = s.copy(deep=False)
```

Shallow copy shares data and index with original.

```
>>> s is shallow
False
>>> s.values is shallow.values and s.index is shallow.index
True
```

Deep copy has own copy of data and index.

```
>>> s is deep
False
>>> s.values is deep.values or s.index is deep.index
False
```

Updates to the data shared by shallow copy and original is reflected in both; deep copy remains unchanged.

```
>>> s[0] = 3
>>> shallow[1] = 4
>>> s
a    3
b    4
dtype: int64
>>> shallow
a    3
b    4
dtype: int64
>>> deep
a    1
b    2
dtype: int64
```

Note that when copying an object containing Python objects, a deep copy will copy the data, but will not do so recursively. Updating a nested data object will be reflected in the deep copy.

```
>>> s = pd.Series([[1, 2], [3, 4]])
>>> deep = s.copy()
>>> s[0][0] = 10
>>> s
0    [10, 2]
1     [3, 4]
dtype: object
>>> deep
0    [10, 2]
1     [3, 4]
dtype: object
```

## pandas.Series.corr

`Series.corr` (*other*, *method*='pearson', *min\_periods*=None)  
 Compute correlation with *other* Series, excluding missing values.

### Parameters

**other** [Series]

**method** [{ 'pearson', 'kendall', 'spearman' } or callable]

- pearson : standard correlation coefficient
- kendall : Kendall Tau correlation coefficient
- spearman : Spearman rank correlation
- **callable:** callable with input two 1d ndarray and returning a float .. versionadded:: 0.24.0

**min\_periods** [int, optional] Minimum number of observations needed to have a valid result

#### Returns

**correlation** [float]

#### Examples

```
>>> histogram_intersection = lambda a, b: np.minimum(a, b
... ).sum().round(decimals=1)
>>> s1 = pd.Series([.2, .0, .6, .2])
>>> s2 = pd.Series([.3, .6, .0, .1])
>>> s1.corr(s2, method=histogram_intersection)
0.3
```

### pandas.Series.count

`Series.count (level=None)`

Return number of non-NA/null observations in the Series.

#### Parameters

**level** [int or level name, default None] If the axis is a MultiIndex (hierarchical), count along a particular level, collapsing into a smaller Series

#### Returns

**nobs** [int or Series (if level specified)]

### pandas.Series.cov

`Series.cov (other, min_periods=None)`

Compute covariance with Series, excluding missing values.

#### Parameters

**other** [Series]

**min\_periods** [int, optional] Minimum number of observations needed to have a valid result

#### Returns

**covariance** [float]

**Normalized by N-1 (unbiased estimator).**

**pandas.Series.cummax**

`Series.cummax` (*axis=None*, *skipna=True*, *\*args*, *\*\*kwargs*)

Return cumulative maximum over a DataFrame or Series axis.

Returns a DataFrame or Series of the same size containing the cumulative maximum.

**Parameters**

**axis** [{0 or 'index', 1 or 'columns'}, default 0] The index or the name of the axis. 0 is equivalent to None or 'index'.

**skipna** [boolean, default True] Exclude NA/null values. If an entire row/column is NA, the result will be NA.

**\*args, \*\*kwargs** : Additional keywords have no effect but might be accepted for compatibility with NumPy.

**Returns**

**cummax** [scalar or Series]

See also:

**core.window.Expanding.max** Similar functionality but ignores NaN values.

**Series.max** Return the maximum over Series axis.

**Series.cummax** Return cumulative maximum over Series axis.

**Series.cummin** Return cumulative minimum over Series axis.

**Series.cumsum** Return cumulative sum over Series axis.

**Series.cumprod** Return cumulative product over Series axis.

**Examples****Series**

```
>>> s = pd.Series([2, np.nan, 5, -1, 0])
>>> s
0    2.0
1    NaN
2    5.0
3   -1.0
4    0.0
dtype: float64
```

By default, NA values are ignored.

```
>>> s.cummax()
0    2.0
1    NaN
2    5.0
3    5.0
4    5.0
dtype: float64
```

To include NA values in the operation, use `skipna=False`

```
>>> s.cummax(skipna=False)
0    2.0
1    NaN
2    NaN
3    NaN
4    NaN
dtype: float64
```

### DataFrame

```
>>> df = pd.DataFrame([[2.0, 1.0],
...                    [3.0, np.nan],
...                    [1.0, 0.0]],
...                    columns=list('AB'))
>>> df
   A    B
0  2.0  1.0
1  3.0  NaN
2  1.0  0.0
```

By default, iterates over rows and finds the maximum in each column. This is equivalent to `axis=None` or `axis='index'`.

```
>>> df.cummax()
   A    B
0  2.0  1.0
1  3.0  NaN
2  3.0  1.0
```

To iterate over columns and find the maximum in each row, use `axis=1`

```
>>> df.cummax(axis=1)
   A    B
0  2.0  2.0
1  3.0  NaN
2  1.0  1.0
```

## pandas.Series.cummin

`Series.cummin(axis=None, skipna=True, *args, **kwargs)`

Return cumulative minimum over a DataFrame or Series axis.

Returns a DataFrame or Series of the same size containing the cumulative minimum.

### Parameters

**axis** [{0 or 'index', 1 or 'columns'}, default 0] The index or the name of the axis. 0 is equivalent to None or 'index'.

**skipna** [boolean, default True] Exclude NA/null values. If an entire row/column is NA, the result will be NA.

**\*args, \*\*kwargs**: Additional keywords have no effect but might be accepted for compatibility with NumPy.

### Returns

**cummin** [scalar or Series]

See also:

**`core.window.Expanding.min`** Similar functionality but ignores NaN values.

**`Series.min`** Return the minimum over Series axis.

**`Series.cummax`** Return cumulative maximum over Series axis.

**`Series.cummin`** Return cumulative minimum over Series axis.

**`Series.cumsum`** Return cumulative sum over Series axis.

**`Series.cumprod`** Return cumulative product over Series axis.

## Examples

### Series

```
>>> s = pd.Series([2, np.nan, 5, -1, 0])
>>> s
0    2.0
1    NaN
2    5.0
3   -1.0
4    0.0
dtype: float64
```

By default, NA values are ignored.

```
>>> s.cummin()
0    2.0
1    NaN
2    2.0
3   -1.0
4   -1.0
dtype: float64
```

To include NA values in the operation, use `skipna=False`

```
>>> s.cummin(skipna=False)
0    2.0
1    NaN
2    NaN
3    NaN
4    NaN
dtype: float64
```

### DataFrame

```
>>> df = pd.DataFrame([[2.0, 1.0],
...                    [3.0, np.nan],
...                    [1.0, 0.0]],
...                    columns=list('AB'))
>>> df
   A    B
0  2.0  1.0
1  3.0  NaN
2  1.0  0.0
```

By default, iterates over rows and finds the minimum in each column. This is equivalent to `axis=None` or `axis='index'`.

```
>>> df.cummin()
      A      B
0  2.0  1.0
1  2.0  NaN
2  1.0  0.0
```

To iterate over columns and find the minimum in each row, use `axis=1`

```
>>> df.cummin(axis=1)
      A      B
0  2.0  1.0
1  3.0  NaN
2  1.0  0.0
```

## pandas.Series.cumprod

`Series.cumprod(axis=None, skipna=True, *args, **kwargs)`

Return cumulative product over a DataFrame or Series axis.

Returns a DataFrame or Series of the same size containing the cumulative product.

### Parameters

**axis** [{0 or 'index', 1 or 'columns'}, default 0] The index or the name of the axis. 0 is equivalent to None or 'index'.

**skipna** [boolean, default True] Exclude NA/null values. If an entire row/column is NA, the result will be NA.

**\*args, \*\*kwargs** : Additional keywords have no effect but might be accepted for compatibility with NumPy.

### Returns

**cumprod** [scalar or Series]

See also:

**core.window.Expanding.prod** Similar functionality but ignores NaN values.

**Series.prod** Return the product over Series axis.

**Series.cummax** Return cumulative maximum over Series axis.

**Series.cummin** Return cumulative minimum over Series axis.

**Series.cumsum** Return cumulative sum over Series axis.

**Series.cumprod** Return cumulative product over Series axis.

## Examples

Series

```
>>> s = pd.Series([2, np.nan, 5, -1, 0])
>>> s
0    2.0
1    NaN
2    5.0
3   -1.0
4    0.0
dtype: float64
```

By default, NA values are ignored.

```
>>> s.cumprod()
0    2.0
1    NaN
2   10.0
3  -10.0
4   -0.0
dtype: float64
```

To include NA values in the operation, use `skipna=False`

```
>>> s.cumprod(skipna=False)
0    2.0
1    NaN
2    NaN
3    NaN
4    NaN
dtype: float64
```

### DataFrame

```
>>> df = pd.DataFrame([[2.0, 1.0],
...                    [3.0, np.nan],
...                    [1.0, 0.0]],
...                    columns=list('AB'))
>>> df
   A  B
0  2.0  1.0
1  3.0 NaN
2  1.0  0.0
```

By default, iterates over rows and finds the product in each column. This is equivalent to `axis=None` or `axis='index'`.

```
>>> df.cumprod()
   A  B
0  2.0  1.0
1  6.0 NaN
2  6.0  0.0
```

To iterate over columns and find the product in each row, use `axis=1`

```
>>> df.cumprod(axis=1)
   A  B
0  2.0  2.0
1  3.0 NaN
2  1.0  0.0
```

## pandas.Series.cumsum

`Series.cumsum(axis=None, skipna=True, *args, **kwargs)`

Return cumulative sum over a DataFrame or Series axis.

Returns a DataFrame or Series of the same size containing the cumulative sum.

### Parameters

**axis** [{0 or 'index', 1 or 'columns'}, default 0] The index or the name of the axis. 0 is equivalent to None or 'index'.

**skipna** [boolean, default True] Exclude NA/null values. If an entire row/column is NA, the result will be NA.

**\*args, \*\*kwargs** : Additional keywords have no effect but might be accepted for compatibility with NumPy.

### Returns

**cumsum** [scalar or Series]

See also:

**core.window.Expanding.sum** Similar functionality but ignores NaN values.

**Series.sum** Return the sum over Series axis.

**Series.cummax** Return cumulative maximum over Series axis.

**Series.cummin** Return cumulative minimum over Series axis.

**Series.cumsum** Return cumulative sum over Series axis.

**Series.cumprod** Return cumulative product over Series axis.

## Examples

### Series

```
>>> s = pd.Series([2, np.nan, 5, -1, 0])
>>> s
0    2.0
1    NaN
2    5.0
3   -1.0
4    0.0
dtype: float64
```

By default, NA values are ignored.

```
>>> s.cumsum()
0    2.0
1    NaN
2    7.0
3    6.0
4    6.0
dtype: float64
```

To include NA values in the operation, use `skipna=False`

```
>>> s.cumsum(skipna=False)
0    2.0
1    NaN
2    NaN
3    NaN
4    NaN
dtype: float64
```

### DataFrame

```
>>> df = pd.DataFrame([[2.0, 1.0],
...                    [3.0, np.nan],
...                    [1.0, 0.0]],
...                    columns=list('AB'))
>>> df
   A    B
0  2.0  1.0
1  3.0  NaN
2  1.0  0.0
```

By default, iterates over rows and finds the sum in each column. This is equivalent to `axis=None` or `axis='index'`.

```
>>> df.cumsum()
   A    B
0  2.0  1.0
1  5.0  NaN
2  6.0  1.0
```

To iterate over columns and find the sum in each row, use `axis=1`

```
>>> df.cumsum(axis=1)
   A    B
0  2.0  3.0
1  3.0  NaN
2  1.0  1.0
```

## pandas.Series.describe

`Series.describe` (*percentiles=None, include=None, exclude=None*)

Generate descriptive statistics that summarize the central tendency, dispersion and shape of a dataset's distribution, excluding NaN values.

Analyzes both numeric and object series, as well as `DataFrame` column sets of mixed data types. The output will vary depending on what is provided. Refer to the notes below for more detail.

### Parameters

**percentiles** [list-like of numbers, optional] The percentiles to include in the output. All should fall between 0 and 1. The default is `[.25, .5, .75]`, which returns the 25th, 50th, and 75th percentiles.

**include** ['all', list-like of dtypes or None (default), optional] A white list of data types to include in the result. Ignored for `Series`. Here are the options:

- 'all' : All columns of the input will be included in the output.

- A list-like of dtypes : Limits the results to the provided data types. To limit the result to numeric types submit `numpy.number`. To limit it instead to object columns submit the `numpy.object` data type. Strings can also be used in the style of `select_dtypes` (e.g. `df.describe(include=['O'])`). To select pandas categorical columns, use `'category'`
- None (default) : The result will include all numeric columns.

**exclude** [list-like of dtypes or None (default), optional,] A black list of data types to omit from the result. Ignored for `Series`. Here are the options:

- A list-like of dtypes : Excludes the provided data types from the result. To exclude numeric types submit `numpy.number`. To exclude object columns submit the data type `numpy.object`. Strings can also be used in the style of `select_dtypes` (e.g. `df.describe(include=['O'])`). To exclude pandas categorical columns, use `'category'`
- None (default) : The result will exclude nothing.

### Returns

**Series or DataFrame** Summary statistics of the Series or Dataframe provided.

See also:

**DataFrame.count** Count number of non-NA/null observations.

**DataFrame.max** Maximum of the values in the object.

**DataFrame.min** Minimum of the values in the object.

**DataFrame.mean** Mean of the values.

**DataFrame.std** Standard deviation of the observations.

**DataFrame.select\_dtypes** Subset of a DataFrame including/excluding columns based on their dtype.

### Notes

For numeric data, the result's index will include `count`, `mean`, `std`, `min`, `max` as well as lower, 50 and upper percentiles. By default the lower percentile is 25 and the upper percentile is 75. The 50 percentile is the same as the median.

For object data (e.g. strings or timestamps), the result's index will include `count`, `unique`, `top`, and `freq`. The `top` is the most common value. The `freq` is the most common value's frequency. Timestamps also include the `first` and `last` items.

If multiple object values have the highest count, then the `count` and `top` results will be arbitrarily chosen from among those with the highest count.

For mixed data types provided via a `DataFrame`, the default is to return only an analysis of numeric columns. If the dataframe consists only of object and categorical data without any numeric columns, the default is to return an analysis of both the object and categorical columns. If `include='all'` is provided as an option, the result will include a union of attributes of each type.

The `include` and `exclude` parameters can be used to limit which columns in a `DataFrame` are analyzed for the output. The parameters are ignored when analyzing a `Series`.

## Examples

Describing a numeric Series.

```
>>> s = pd.Series([1, 2, 3])
>>> s.describe()
count      3.0
mean       2.0
std        1.0
min        1.0
25%        1.5
50%        2.0
75%        2.5
max        3.0
dtype: float64
```

Describing a categorical Series.

```
>>> s = pd.Series(['a', 'a', 'b', 'c'])
>>> s.describe()
count      4
unique      3
top         a
freq        2
dtype: object
```

Describing a timestamp Series.

```
>>> s = pd.Series([
...     np.datetime64("2000-01-01"),
...     np.datetime64("2010-01-01"),
...     np.datetime64("2010-01-01")
... ])
>>> s.describe()
count              3
unique             2
top      2010-01-01 00:00:00
freq              2
first    2000-01-01 00:00:00
last     2010-01-01 00:00:00
dtype: object
```

Describing a DataFrame. By default only numeric fields are returned.

```
>>> df = pd.DataFrame({'categorical': pd.Categorical(['d', 'e', 'f']),
...                    'numeric': [1, 2, 3],
...                    'object': ['a', 'b', 'c']
...                    })
>>> df.describe()
      numeric
count      3.0
mean       2.0
std        1.0
min        1.0
25%        1.5
50%        2.0
75%        2.5
max        3.0
```

Describing all columns of a DataFrame regardless of data type.

```
>>> df.describe(include='all')
      categorical  numeric  object
count           3        3.0      3
unique          3        NaN      3
top             f        NaN      c
freq           1        NaN      1
mean           NaN        2.0     NaN
std            NaN        1.0     NaN
min            NaN        1.0     NaN
25%            NaN        1.5     NaN
50%            NaN        2.0     NaN
75%            NaN        2.5     NaN
max            NaN        3.0     NaN
```

Describing a column from a DataFrame by accessing it as an attribute.

```
>>> df.numeric.describe()
count      3.0
mean       2.0
std        1.0
min        1.0
25%        1.5
50%        2.0
75%        2.5
max        3.0
Name: numeric, dtype: float64
```

Including only numeric columns in a DataFrame description.

```
>>> df.describe(include=[np.number])
      numeric
count      3.0
mean       2.0
std        1.0
min        1.0
25%        1.5
50%        2.0
75%        2.5
max        3.0
```

Including only string columns in a DataFrame description.

```
>>> df.describe(include=[np.object])
      object
count      3
unique      3
top        c
freq       1
```

Including only categorical columns from a DataFrame description.

```
>>> df.describe(include=['category'])
      categorical
count           3
unique          3
```

(continues on next page)

(continued from previous page)

|      |   |
|------|---|
| top  | f |
| freq | 1 |

Excluding numeric columns from a DataFrame description.

```
>>> df.describe(exclude=[np.number])
           categorical  object
count              3      3
unique             3      3
top               f      c
freq             1      1
```

Excluding object columns from a DataFrame description.

```
>>> df.describe(exclude=[np.object])
           categorical  numeric
count              3      3.0
unique             3      NaN
top               f      NaN
freq             1      NaN
mean             NaN      2.0
std              NaN      1.0
min              NaN      1.0
25%              NaN      1.5
50%              NaN      2.0
75%              NaN      2.5
max              NaN      3.0
```

## pandas.Series.diff

**Series.diff** (*periods=1*)

First discrete difference of element.

Calculates the difference of a Series element compared with another element in the Series (default is element in previous row).

### Parameters

**periods** [int, default 1] Periods to shift for calculating difference, accepts negative values.

### Returns

**diffed** [Series]

See also:

**Series.pct\_change** Percent change over given number of periods.

**Series.shift** Shift index by desired number of periods with an optional time freq.

**DataFrame.diff** First discrete difference of object.

## Examples

Difference with previous row

```
>>> s = pd.Series([1, 1, 2, 3, 5, 8])
>>> s.diff()
0      NaN
1      0.0
2      1.0
3      1.0
4      2.0
5      3.0
dtype: float64
```

Difference with 3rd previous row

```
>>> s.diff(periods=3)
0      NaN
1      NaN
2      NaN
3      2.0
4      4.0
5      6.0
dtype: float64
```

Difference with following row

```
>>> s.diff(periods=-1)
0      0.0
1     -1.0
2     -1.0
3     -2.0
4     -3.0
5      NaN
dtype: float64
```

## pandas.Series.div

`Series.div` (*other*, *level=None*, *fill\_value=None*, *axis=0*)

Floating division of series and other, element-wise (binary operator *truediv*).

Equivalent to `series / other`, but with support to substitute a `fill_value` for missing data in one of the inputs.

### Parameters

**other** [Series or scalar value]

**fill\_value** [None or float value, default None (NaN)] Fill existing missing (NaN) values, and any new element needed for successful Series alignment, with this value before computation. If data in both corresponding Series locations is missing the result will be missing

**level** [int or name] Broadcast across a level, matching Index values on the passed Multi-Index level

### Returns

**result** [Series]

**See also:**

`Series.rtruediv`

## Examples

```

>>> a = pd.Series([1, 1, 1, np.nan], index=['a', 'b', 'c', 'd'])
>>> a
a    1.0
b    1.0
c    1.0
d    NaN
dtype: float64
>>> b = pd.Series([1, np.nan, 1, np.nan], index=['a', 'b', 'd', 'e'])
>>> b
a    1.0
b    NaN
d    1.0
e    NaN
dtype: float64
>>> a.add(b, fill_value=0)
a    2.0
b    1.0
c    1.0
d    1.0
e    NaN
dtype: float64

```

## pandas.Series.divide

`Series.divide` (*other*, *level=None*, *fill\_value=None*, *axis=0*)

Floating division of series and other, element-wise (binary operator *truediv*).

Equivalent to `series / other`, but with support to substitute a `fill_value` for missing data in one of the inputs.

### Parameters

**other** [Series or scalar value]

**fill\_value** [None or float value, default None (NaN)] Fill existing missing (NaN) values, and any new element needed for successful Series alignment, with this value before computation. If data in both corresponding Series locations is missing the result will be missing

**level** [int or name] Broadcast across a level, matching Index values on the passed Multi-Index level

### Returns

**result** [Series]

### See also:

`Series.rtruediv`

## Examples

```

>>> a = pd.Series([1, 1, 1, np.nan], index=['a', 'b', 'c', 'd'])
>>> a
a    1.0

```

(continues on next page)

(continued from previous page)

```

b    1.0
c    1.0
d    NaN
dtype: float64
>>> b = pd.Series([1, np.nan, 1, np.nan], index=['a', 'b', 'd', 'e'])
>>> b
a    1.0
b    NaN
d    1.0
e    NaN
dtype: float64
>>> a.add(b, fill_value=0)
a    2.0
b    1.0
c    1.0
d    1.0
e    NaN
dtype: float64

```

### pandas.Series.divmod

`Series.divmod(other, level=None, fill_value=None, axis=0)`

Integer division and modulo of series and other, element-wise (binary operator *divmod*).

Equivalent to `series divmod other`, but with support to substitute a `fill_value` for missing data in one of the inputs.

#### Parameters

**other** [Series or scalar value]

**fill\_value** [None or float value, default None (NaN)] Fill existing missing (NaN) values, and any new element needed for successful Series alignment, with this value before computation. If data in both corresponding Series locations is missing the result will be missing

**level** [int or name] Broadcast across a level, matching Index values on the passed Multi-Index level

#### Returns

**result** [Series]

#### See also:

`Series.rdivmod`

### Examples

```

>>> a = pd.Series([1, 1, 1, np.nan], index=['a', 'b', 'c', 'd'])
>>> a
a    1.0
b    1.0
c    1.0
d    NaN
dtype: float64

```

(continues on next page)

(continued from previous page)

```

>>> b = pd.Series([1, np.nan, 1, np.nan], index=['a', 'b', 'd', 'e'])
>>> b
a    1.0
b    NaN
d    1.0
e    NaN
dtype: float64
>>> a.add(b, fill_value=0)
a    2.0
b    1.0
c    1.0
d    1.0
e    NaN
dtype: float64

```

## pandas.Series.dot

`Series.dot(other)`

Compute the dot product between the Series and the columns of other.

This method computes the dot product between the Series and another one, or the Series and each columns of a DataFrame, or the Series and each columns of an array.

It can also be called using *self @ other* in Python >= 3.5.

### Parameters

**other** [Series, DataFrame or array-like] The other object to compute the dot product with its columns.

### Returns

**scalar, Series or numpy.ndarray** Return the dot product of the Series and other if other is a Series, the Series of the dot product of Series and each rows of other if other is a DataFrame or a numpy.ndarray between the Series and each columns of the numpy array.

### See also:

**DataFrame.dot** Compute the matrix product with the DataFrame.

**Series.mul** Multiplication of series and other, element-wise.

## Notes

The Series and other has to share the same index if other is a Series or a DataFrame.

## Examples

```

>>> s = pd.Series([0, 1, 2, 3])
>>> other = pd.Series([-1, 2, -3, 4])
>>> s.dot(other)
8
>>> s @ other

```

(continues on next page)

(continued from previous page)

```

8
>>> df = pd.DataFrame([[0, 1], [-2, 3], [4, -5], [6, 7]])
>>> s.dot(df)
0    24
1    14
dtype: int64
>>> arr = np.array([[0, 1], [-2, 3], [4, -5], [6, 7]])
>>> s.dot(arr)
array([24, 14])

```

## pandas.Series.drop

**Series.drop** (*labels=None, axis=0, index=None, columns=None, level=None, inplace=False, errors='raise'*)

Return Series with specified index labels removed.

Remove elements of a Series based on specifying the index labels. When using a multi-index, labels on different levels can be removed by specifying the level.

### Parameters

**labels** [single label or list-like] Index labels to drop.

**axis** [0, default 0] Redundant for application on Series.

**index, columns** [None] Redundant for application on Series, but index can be used instead of labels.

New in version 0.21.0.

**level** [int or level name, optional] For MultiIndex, level for which the labels will be removed.

**inplace** [bool, default False] If True, do operation inplace and return None.

**errors** [{ 'ignore', 'raise' }, default 'raise'] If 'ignore', suppress error and only existing labels are dropped.

### Returns

**dropped** [pandas.Series]

### Raises

**KeyError** If none of the labels are found in the index.

See also:

**Series.reindex** Return only specified index labels of Series.

**Series.dropna** Return series without null values.

**Series.drop\_duplicates** Return Series with duplicate values removed.

**DataFrame.drop** Drop specified labels from rows or columns.

## Examples

```
>>> s = pd.Series(data=np.arange(3), index=['A', 'B', 'C'])
>>> s
A    0
B    1
C    2
dtype: int64
```

Drop labels B en C

```
>>> s.drop(labels=['B', 'C'])
A    0
dtype: int64
```

Drop 2nd level label in MultiIndex Series

```
>>> midx = pd.MultiIndex(levels=[['lama', 'cow', 'falcon'],
...                               ['speed', 'weight', 'length']],
...                       codes=[[0, 0, 0, 1, 1, 1, 2, 2, 2],
...                               [0, 1, 2, 0, 1, 2, 0, 1, 2]])
>>> s = pd.Series([45, 200, 1.2, 30, 250, 1.5, 320, 1, 0.3],
...               index=midx)
>>> s
lama    speed    45.0
        weight   200.0
        length    1.2
cow     speed    30.0
        weight   250.0
        length    1.5
falcon  speed    320.0
        weight    1.0
        length    0.3
dtype: float64
```

```
>>> s.drop(labels='weight', level=1)
lama    speed    45.0
        length    1.2
cow     speed    30.0
        length    1.5
falcon  speed    320.0
        length    0.3
dtype: float64
```

## pandas.Series.drop\_duplicates

`Series.drop_duplicates` (*keep='first', inplace=False*)

Return Series with duplicate values removed.

### Parameters

**keep** [{‘first’, ‘last’, False}, default ‘first’]

- ‘first’ : Drop duplicates except for the first occurrence.
- ‘last’ : Drop duplicates except for the last occurrence.
- False : Drop all duplicates.

**inplace** [boolean, default False] If True, performs operation inplace and returns None.

**Returns****deduplicated** [Series]**See also:****Index.drop\_duplicates** Equivalent method on Index.**DataFrame.drop\_duplicates** Equivalent method on DataFrame.**Series.duplicated** Related method on Series, indicating duplicate Series values.**Examples**

Generate an Series with duplicated entries.

```
>>> s = pd.Series(['lama', 'cow', 'lama', 'beetle', 'lama', 'hippo'],
...               name='animal')
>>> s
0      lama
1       cow
2      lama
3    beetle
4      lama
5     hippo
Name: animal, dtype: object
```

With the ‘keep’ parameter, the selection behaviour of duplicated values can be changed. The value ‘first’ keeps the first occurrence for each set of duplicated entries. The default value of keep is ‘first’.

```
>>> s.drop_duplicates()
0      lama
1       cow
3    beetle
5     hippo
Name: animal, dtype: object
```

The value ‘last’ for parameter ‘keep’ keeps the last occurrence for each set of duplicated entries.

```
>>> s.drop_duplicates(keep='last')
1       cow
3    beetle
4      lama
5     hippo
Name: animal, dtype: object
```

The value False for parameter ‘keep’ discards all sets of duplicated entries. Setting the value of ‘inplace’ to True performs the operation inplace and returns None.

```
>>> s.drop_duplicates(keep=False, inplace=True)
>>> s
1       cow
3    beetle
5     hippo
Name: animal, dtype: object
```

**pandas.Series.droplevel****Series.droplevel** (*level*, *axis=0*)

Return DataFrame with requested index / column level(s) removed.

New in version 0.24.0.

**Parameters****level** [int, str, or list-like] If a string is given, must be the name of a level If list-like, elements must be names or positional indexes of levels.**axis** [{0 or 'index', 1 or 'columns'}, default 0]**Returns****DataFrame.droplevel()****Examples**

```
>>> df = pd.DataFrame([
...     [1, 2, 3, 4],
...     [5, 6, 7, 8],
...     [9, 10, 11, 12]
... ]).set_index([0, 1]).rename_axis(['a', 'b'])
```

```
>>> df.columns = pd.MultiIndex.from_tuples([
...     ('c', 'e'), ('d', 'f')
... ], names=['level_1', 'level_2'])
```

```
>>> df
level_1  c  d
level_2  e  f
a b
1 2      3  4
5 6      7  8
9 10     11 12
```

```
>>> df.droplevel('a')
level_1  c  d
level_2  e  f
b
2      3  4
6      7  8
10     11 12
```

```
>>> df.droplevel('level2', axis=1)
level_1  c  d
a b
1 2      3  4
5 6      7  8
9 10     11 12
```

## pandas.Series.dropna

`Series.dropna(axis=0, inplace=False, **kwargs)`

Return a new Series with missing values removed.

See the *User Guide* for more on which values are considered missing, and how to work with missing data.

### Parameters

**axis** [{0 or 'index'}, default 0] There is only one axis to drop values from.

**inplace** [bool, default False] If True, do operation inplace and return None.

**\*\*kwargs** Not in use.

### Returns

**Series** Series with NA entries dropped from it.

See also:

**Series.isna** Indicate missing values.

**Series.notna** Indicate existing (non-missing) values.

**Series.fillna** Replace missing values.

**DataFrame.dropna** Drop rows or columns which contain NA values.

**Index.dropna** Drop missing indices.

## Examples

```
>>> ser = pd.Series([1., 2., np.nan])
>>> ser
0    1.0
1    2.0
2     NaN
dtype: float64
```

Drop NA values from a Series.

```
>>> ser.dropna()
0    1.0
1    2.0
dtype: float64
```

Keep the Series with valid entries in the same variable.

```
>>> ser.dropna(inplace=True)
>>> ser
0    1.0
1    2.0
dtype: float64
```

Empty strings are not considered NA values. None is considered an NA value.

```
>>> ser = pd.Series([np.NaN, 2, pd.NaT, '', None, 'I stay'])
>>> ser
0     NaN
```

(continues on next page)

(continued from previous page)

```

1      2
2      NaT
3
4      None
5      I stay
dtype: object
>>> ser.dropna()
1      2
3
5      I stay
dtype: object

```

## pandas.Series.dt

`Series.dt()`

Accessor object for datetimelike properties of the Series values.

### Examples

```

>>> s.dt.hour
>>> s.dt.second
>>> s.dt.quarter

```

Returns a Series indexed like the original Series. Raises `TypeError` if the Series does not contain date-timelike values.

## pandas.Series.duplicated

`Series.duplicated(keep='first')`

Indicate duplicate Series values.

Duplicated values are indicated as `True` values in the resulting Series. Either all duplicates, all except the first or all except the last occurrence of duplicates can be indicated.

### Parameters

**keep** [{ 'first', 'last', False }, default 'first']

- 'first' : Mark duplicates as `True` except for the first occurrence.
- 'last' : Mark duplicates as `True` except for the last occurrence.
- `False` : Mark all duplicates as `True`.

### Returns

`pandas.core.series.Series`

See also:

***Index.duplicated*** Equivalent method on `pandas.Index`.

***DataFrame.duplicated*** Equivalent method on `pandas.DataFrame`.

***Series.drop\_duplicates*** Remove duplicate values from Series.

## Examples

By default, for each set of duplicated values, the first occurrence is set on False and all others on True:

```
>>> animals = pd.Series(['lama', 'cow', 'lama', 'beetle', 'lama'])
>>> animals.duplicated()
0    False
1    False
2     True
3    False
4     True
dtype: bool
```

which is equivalent to

```
>>> animals.duplicated(keep='first')
0    False
1    False
2     True
3    False
4     True
dtype: bool
```

By using 'last', the last occurrence of each set of duplicated values is set on False and all others on True:

```
>>> animals.duplicated(keep='last')
0     True
1    False
2     True
3    False
4    False
dtype: bool
```

By setting keep on False, all duplicates are True:

```
>>> animals.duplicated(keep=False)
0     True
1    False
2     True
3    False
4     True
dtype: bool
```

## pandas.Series.eq

`Series.eq(other, level=None, fill_value=None, axis=0)`

Equal to of series and other, element-wise (binary operator *eq*).

Equivalent to `series == other`, but with support to substitute a `fill_value` for missing data in one of the inputs.

### Parameters

**other** [Series or scalar value]

**fill\_value** [None or float value, default None (NaN)] Fill existing missing (NaN) values, and any new element needed for successful Series alignment, with this value before

computation. If data in both corresponding Series locations is missing the result will be missing

**level** [int or name] Broadcast across a level, matching Index values on the passed Multi-Index level

### Returns

**result** [Series]

### See also:

Series.None

### Examples

```
>>> a = pd.Series([1, 1, 1, np.nan], index=['a', 'b', 'c', 'd'])
>>> a
a    1.0
b    1.0
c    1.0
d    NaN
dtype: float64
>>> b = pd.Series([1, np.nan, 1, np.nan], index=['a', 'b', 'd', 'e'])
>>> b
a    1.0
b    NaN
d    1.0
e    NaN
dtype: float64
>>> a.add(b, fill_value=0)
a    2.0
b    1.0
c    1.0
d    1.0
e    NaN
dtype: float64
```

## pandas.Series.equals

Series.equals(*other*)

Test whether two objects contain the same elements.

This function allows two Series or DataFrames to be compared against each other to see if they have the same shape and elements. NaNs in the same location are considered equal. The column headers do not need to have the same type, but the elements within the columns must be the same dtype.

### Parameters

**other** [Series or DataFrame] The other Series or DataFrame to be compared with the first.

### Returns

**bool** True if all elements are the same in both objects, False otherwise.

### See also:

**Series.eq** Compare two Series objects of the same length and return a Series where each element is True if the element in each Series is equal, False otherwise.

**DataFrame.eq** Compare two DataFrame objects of the same shape and return a DataFrame where each element is True if the respective element in each DataFrame is equal, False otherwise.

**assert\_series\_equal** Return True if left and right Series are equal, False otherwise.

**assert\_frame\_equal** Return True if left and right DataFrames are equal, False otherwise.

**numpy.array\_equal** Return True if two arrays have the same shape and elements, False otherwise.

## Notes

This function requires that the elements have the same dtype as their respective elements in the other Series or DataFrame. However, the column labels do not need to have the same type, as long as they are still considered equal.

## Examples

```
>>> df = pd.DataFrame({'1': [10], 2: [20]})
>>> df
   1  2
0 10 20
```

DataFrames df and exactly\_equal have the same types and values for their elements and column labels, which will return True.

```
>>> exactly_equal = pd.DataFrame({'1': [10], 2: [20]})
>>> exactly_equal
   1  2
0 10 20
>>> df.equals(exactly_equal)
True
```

DataFrames df and different\_column\_type have the same element types and values, but have different types for the column labels, which will still return True.

```
>>> different_column_type = pd.DataFrame({'1.0': [10], 2.0: [20]})
>>> different_column_type
   1.0  2.0
0   10   20
>>> df.equals(different_column_type)
True
```

DataFrames df and different\_data\_type have different types for the same values for their elements, and will return False even though their column labels are the same values and types.

```
>>> different_data_type = pd.DataFrame({'1': [10.0], 2: [20.0]})
>>> different_data_type
   1    2
0 10.0 20.0
>>> df.equals(different_data_type)
False
```

**pandas.Series.ewm**

`Series.ewm(com=None, span=None, halflife=None, alpha=None, min_periods=0, adjust=True, ignore_na=False, axis=0)`

Provides exponential weighted functions.

New in version 0.18.0.

**Parameters**

**com** [float, optional] Specify decay in terms of center of mass,  $\alpha = 1/(1 + com)$ , for  $com \geq 0$

**span** [float, optional] Specify decay in terms of span,  $\alpha = 2/(span + 1)$ , for  $span \geq 1$

**halflife** [float, optional] Specify decay in terms of half-life,  $\alpha = 1 - \exp(\log(0.5)/halflife)$ , for  $halflife > 0$

**alpha** [float, optional] Specify smoothing factor  $\alpha$  directly,  $0 < \alpha \leq 1$

New in version 0.18.0.

**min\_periods** [int, default 0] Minimum number of observations in window required to have a value (otherwise result is NA).

**adjust** [bool, default True] Divide by decaying adjustment factor in beginning periods to account for imbalance in relative weightings (viewing EWMA as a moving average)

**ignore\_na** [bool, default False] Ignore missing values when calculating weights; specify True to reproduce pre-0.15.0 behavior

**Returns**

a Window sub-classed for the particular operation

See also:

**rolling** Provides rolling window calculations.

**expanding** Provides expanding transformations.

**Notes**

Exactly one of center of mass, span, half-life, and alpha must be provided. Allowed values and relationship between the parameters are specified in the parameter descriptions above; see the link at the end of this section for a detailed explanation.

When `adjust` is `True` (default), weighted averages are calculated using weights  $(1-\alpha)^{(n-1)}$ ,  $(1-\alpha)^{(n-2)}$ , ...,  $1-\alpha$ , 1.

**When `adjust` is `False`, weighted averages are calculated recursively as:** `weighted_average[0] = arg[0]`; `weighted_average[i] = (1-alpha)*weighted_average[i-1] + alpha*arg[i]`.

When `ignore_na` is `False` (default), weights are based on absolute positions. For example, the weights of `x` and `y` used in calculating the final weighted average of `[x, None, y]` are  $(1-\alpha)^2$  and 1 (if `adjust` is `True`), and  $(1-\alpha)^2$  and  $\alpha$  (if `adjust` is `False`).

When `ignore_na` is `True` (reproducing pre-0.15.0 behavior), weights are based on relative positions. For example, the weights of `x` and `y` used in calculating the final weighted average of `[x, None, y]` are  $1-\alpha$  and 1 (if `adjust` is `True`), and  $1-\alpha$  and  $\alpha$  (if `adjust` is `False`).

More details can be found at <http://pandas.pydata.org/pandas-docs/stable/computation.html#exponentially-weighted-windows>

## Examples

```
>>> df = pd.DataFrame({'B': [0, 1, 2, np.nan, 4]})
      B
0  0.0
1  1.0
2  2.0
3  NaN
4  4.0
```

```
>>> df.ewm(com=0.5).mean()
      B
0  0.000000
1  0.750000
2  1.615385
3  1.615385
4  3.670213
```

## pandas.Series.expanding

`Series.expanding` (*min\_periods=1, center=False, axis=0*)

Provides expanding transformations.

New in version 0.18.0.

### Parameters

**min\_periods** [int, default 1] Minimum number of observations in window required to have a value (otherwise result is NA).

**center** [bool, default False] Set the labels at the center of the window.

**axis** [int or str, default 0]

### Returns

a **Window** sub-classed for the particular operation

See also:

**rolling** Provides rolling window calculations.

**ewm** Provides exponential weighted functions.

## Notes

By default, the result is set to the right edge of the window. This can be changed to the center of the window by setting `center=True`.

## Examples

```
>>> df = pd.DataFrame({'B': [0, 1, 2, np.nan, 4]})
      B
0  0.0
1  1.0
```

(continues on next page)

(continued from previous page)

```
2  2.0
3  NaN
4  4.0
```

```
>>> df.expanding(2).sum()
      B
0  NaN
1  1.0
2  3.0
3  3.0
4  7.0
```

## pandas.Series.factorize

`Series.factorize (sort=False, na_sentinel=-1)`

Encode the object as an enumerated type or categorical variable.

This method is useful for obtaining a numeric representation of an array when all that matters is identifying distinct values. *factorize* is available as both a top-level function `pandas.factorize()`, and as a method `Series.factorize()` and `Index.factorize()`.

### Parameters

**sort** [boolean, default False] Sort *uniques* and shuffle *labels* to maintain the relationship.

**na\_sentinel** [int, default -1] Value to mark “not found”.

### Returns

**labels** [ndarray] An integer ndarray that’s an indexer into *uniques*. `uniques.take(labels)` will have the same values as *values*.

**uniques** [ndarray, Index, or Categorical] The unique valid values. When *values* is Categorical, *uniques* is a Categorical. When *values* is some other pandas object, an *Index* is returned. Otherwise, a 1-D ndarray is returned.

---

**Note:** Even if there’s a missing value in *values*, *uniques* will *not* contain an entry for it.

---

### See also:

**cut** Discretize continuous-valued array.

**unique** Find the unique value in an array.

## Examples

These examples all show *factorize* as a top-level method like `pd.factorize(values)`. The results are identical for methods like `Series.factorize()`.

```
>>> labels, uniques = pd.factorize(['b', 'b', 'a', 'c', 'b'])
>>> labels
array([0, 0, 1, 2, 0])
```

(continues on next page)

(continued from previous page)

```
>>> uniques
array(['b', 'a', 'c'], dtype=object)
```

With `sort=True`, the *uniques* will be sorted, and *labels* will be shuffled so that the relationship is the maintained.

```
>>> labels, uniques = pd.factorize(['b', 'b', 'a', 'c', 'b'], sort=True)
>>> labels
array([1, 1, 0, 2, 1])
>>> uniques
array(['a', 'b', 'c'], dtype=object)
```

Missing values are indicated in *labels* with *na\_sentinel* (-1 by default). Note that missing values are never included in *uniques*.

```
>>> labels, uniques = pd.factorize(['b', None, 'a', 'c', 'b'])
>>> labels
array([ 0, -1,  1,  2,  0])
>>> uniques
array(['b', 'a', 'c'], dtype=object)
```

Thus far, we've only factorized lists (which are internally coerced to NumPy arrays). When factorizing pandas objects, the type of *uniques* will differ. For Categoricals, a *Categorical* is returned.

```
>>> cat = pd.Categorical(['a', 'a', 'c'], categories=['a', 'b', 'c'])
>>> labels, uniques = pd.factorize(cat)
>>> labels
array([0, 0, 1])
>>> uniques
[a, c]
Categories (3, object): [a, b, c]
```

Notice that 'b' is in `uniques.categories`, despite not being present in `cat.values`.

For all other pandas objects, an Index of the appropriate type is returned.

```
>>> cat = pd.Series(['a', 'a', 'c'])
>>> labels, uniques = pd.factorize(cat)
>>> labels
array([0, 0, 1])
>>> uniques
Index(['a', 'c'], dtype='object')
```

## pandas.Series.ffill

`Series.ffi11` (*axis=None, inplace=False, limit=None, downcast=None*)  
 Synonym for `DataFrame.fillna()` with `method='ffill'`.

## pandas.Series.fillna

`Series.fillna` (*value=None, method=None, axis=None, inplace=False, limit=None, downcast=None, \*\*kwargs*)  
 Fill NA/NaN values using the specified method.

### Parameters

**value** [scalar, dict, Series, or DataFrame] Value to use to fill holes (e.g. 0), alternately a dict/Series/DataFrame of values specifying which value to use for each index (for a Series) or column (for a DataFrame). (values not in the dict/Series/DataFrame will not be filled). This value cannot be a list.

**method** [{ 'backfill', 'bfill', 'pad', 'ffill', None }, default None] Method to use for filling holes in reindexed Series pad / ffill: propagate last valid observation forward to next valid backfill / bfill: use NEXT valid observation to fill gap

**axis** [{0 or 'index' }]

**inplace** [boolean, default False] If True, fill in place. Note: this will modify any other views on this object, (e.g. a no-copy slice for a column in a DataFrame).

**limit** [int, default None] If method is specified, this is the maximum number of consecutive NaN values to forward/backward fill. In other words, if there is a gap with more than this number of consecutive NaNs, it will only be partially filled. If method is not specified, this is the maximum number of entries along the entire axis where NaNs will be filled. Must be greater than 0 if not None.

**downcast** [dict, default is None] a dict of item->dtype of what to downcast if possible, or the string 'infer' which will try to downcast to an appropriate equal type (e.g. float64 to int64 if possible)

### Returns

**filled** [Series]

See also:

**interpolate** Fill NaN values using interpolation.

*reindex, asfreq*

### Examples

```
>>> df = pd.DataFrame([[np.nan, 2, np.nan, 0],
...                    [3, 4, np.nan, 1],
...                    [np.nan, np.nan, np.nan, 5],
...                    [np.nan, 3, np.nan, 4]],
...                    columns=list('ABCD'))
>>> df
   A    B    C    D
0 NaN  2.0 NaN   0
1  3.0  4.0 NaN   1
2 NaN  NaN NaN   5
3 NaN  3.0 NaN   4
```

Replace all NaN elements with 0s.

```
>>> df.fillna(0)
   A    B    C    D
0  0.0  2.0  0.0  0
1  3.0  4.0  0.0  1
2  0.0  0.0  0.0  5
3  0.0  3.0  0.0  4
```

We can also propagate non-null values forward or backward.

```
>>> df.fillna(method='ffill')
   A    B    C    D
0  NaN  2.0  NaN  0
1  3.0  4.0  NaN  1
2  3.0  4.0  NaN  5
3  3.0  3.0  NaN  4
```

Replace all NaN elements in column 'A', 'B', 'C', and 'D', with 0, 1, 2, and 3 respectively.

```
>>> values = {'A': 0, 'B': 1, 'C': 2, 'D': 3}
>>> df.fillna(value=values)
   A    B    C    D
0  0.0  2.0  2.0  0
1  3.0  4.0  2.0  1
2  0.0  1.0  2.0  5
3  0.0  3.0  2.0  4
```

Only replace the first NaN element.

```
>>> df.fillna(value=values, limit=1)
   A    B    C    D
0  0.0  2.0  2.0  0
1  3.0  4.0  NaN  1
2  NaN  1.0  NaN  5
3  NaN  3.0  NaN  4
```

## pandas.Series.filter

`Series.filter` (*items=None, like=None, regex=None, axis=None*)

Subset rows or columns of dataframe according to labels in the specified index.

Note that this routine does not filter a dataframe on its contents. The filter is applied to the labels of the index.

### Parameters

**items** [list-like] List of axis to restrict to (must not all be present).

**like** [string] Keep axis where “arg in col == True”.

**regex** [string (regular expression)] Keep axis with `re.search(regex, col) == True`.

**axis** [int or string axis name] The axis to filter on. By default this is the info axis, ‘index’ for Series, ‘columns’ for DataFrame.

### Returns

same type as input object

See also:

`DataFrame.loc`

### Notes

The `items`, `like`, and `regex` parameters are enforced to be mutually exclusive.

`axis` defaults to the info axis that is used when indexing with `[]`.

## Examples

```
>>> df = pd.DataFrame(np.array([[1,2,3], [4,5,6]]),
...                    index=['mouse', 'rabbit'],
...                    columns=['one', 'two', 'three'])
```

```
>>> # select columns by name
>>> df.filter(items=['one', 'three'])
      one  three
mouse    1     3
rabbit    4     6
```

```
>>> # select columns by regular expression
>>> df.filter(regex='e$', axis=1)
      one  three
mouse    1     3
rabbit    4     6
```

```
>>> # select rows containing 'bbi'
>>> df.filter(like='bbi', axis=0)
      one two three
rabbit    4   5     6
```

## pandas.Series.first

**Series.first** (*offset*)

Convenience method for subsetting initial periods of time series data based on a date offset.

### Parameters

**offset** [string, DateOffset, dateutil.relativedelta]

### Returns

**subset** [same type as caller]

### Raises

**TypeError** If the index is not a *DatetimeIndex*

**See also:**

**last** Select final periods of time series based on a date offset.

**at\_time** Select values at a particular time of the day.

**between\_time** Select values between particular times of the day.

## Examples

```
>>> i = pd.date_range('2018-04-09', periods=4, freq='2D')
>>> ts = pd.DataFrame({'A': [1,2,3,4]}, index=i)
>>> ts
              A
2018-04-09    1
2018-04-11    2
```

(continues on next page)

(continued from previous page)

```
2018-04-13    3
2018-04-15    4
```

Get the rows for the first 3 days:

```
>>> ts.first('3D')
      A
2018-04-09    1
2018-04-11    2
```

Notice the data for 3 first calendar days were returned, not the first 3 days observed in the dataset, and therefore data for 2018-04-13 was not returned.

### **pandas.Series.first\_valid\_index**

**Series.first\_valid\_index()**  
Return index for first non-NA/null value.

#### **Returns**

**scalar** [type of index]

#### **Notes**

If all elements are non-NA/null, returns None. Also returns None for empty NDFrame.

### **pandas.Series.floordiv**

**Series.floordiv** (*other*, *level=None*, *fill\_value=None*, *axis=0*)  
Integer division of series and other, element-wise (binary operator *floordiv*).

Equivalent to `series // other`, but with support to substitute a *fill\_value* for missing data in one of the inputs.

#### **Parameters**

**other** [Series or scalar value]

**fill\_value** [None or float value, default None (NaN)] Fill existing missing (NaN) values, and any new element needed for successful Series alignment, with this value before computation. If data in both corresponding Series locations is missing the result will be missing

**level** [int or name] Broadcast across a level, matching Index values on the passed Multi-Index level

#### **Returns**

**result** [Series]

**See also:**

*Series.rfloordiv*

## Examples

```
>>> a = pd.Series([1, 1, 1, np.nan], index=['a', 'b', 'c', 'd'])
>>> a
a    1.0
b    1.0
c    1.0
d    NaN
dtype: float64
>>> b = pd.Series([1, np.nan, 1, np.nan], index=['a', 'b', 'd', 'e'])
>>> b
a    1.0
b    NaN
d    1.0
e    NaN
dtype: float64
>>> a.add(b, fill_value=0)
a    2.0
b    1.0
c    1.0
d    1.0
e    NaN
dtype: float64
```

### pandas.Series.from\_array

**classmethod** `Series.from_array(arr, index=None, name=None, dtype=None, copy=False, fastpath=False)`

Construct Series from array.

Deprecated since version 0.23.0: Use `pd.Series(..)` constructor instead.

### pandas.Series.from\_csv

**classmethod** `Series.from_csv(path, sep=',', parse_dates=True, header=None, index_col=0, encoding=None, infer_datetime_format=False)`

Read CSV file.

Deprecated since version 0.21.0: Use `pandas.read_csv()` instead.

It is preferable to use the more powerful `pandas.read_csv()` for most general purposes, but `from_csv` makes for an easy roundtrip to and from a file (the exact counterpart of `to_csv`), especially with a time Series.

This method only differs from `pandas.read_csv()` in some defaults:

- `index_col` is 0 instead of None (take first column as index by default)
- `header` is None instead of 0 (the first row is not used as the column names)
- `parse_dates` is True instead of False (try parsing the index as datetime by default)

With `pandas.read_csv()`, the option `squeeze=True` can be used to return a Series like `from_csv`.

#### Parameters

**path** [string file path or file handle / StringIO]

**sep** [string, default ‘,’] Field delimiter

**parse\_dates** [boolean, default True] Parse dates. Different default from `read_table`

**header** [int, default None] Row to use as header (skip prior rows)

**index\_col** [int or sequence, default 0] Column to use for index. If a sequence is given, a MultiIndex is used. Different default from `read_table`

**encoding** [string, optional] a string representing the encoding to use if the contents are non-ascii, for python versions prior to 3

**infer\_datetime\_format** [boolean, default False] If True and *parse\_dates* is True for a column, try to infer the datetime format based on the first datetime string. If the format can be inferred, there often will be a large parsing speed-up.

#### Returns

**y** [Series]

#### See also:

`read_csv`

### pandas.Series.ge

`Series.ge(other, level=None, fill_value=None, axis=0)`

Greater than or equal to of series and other, element-wise (binary operator *ge*).

Equivalent to `series >= other`, but with support to substitute a *fill\_value* for missing data in one of the inputs.

#### Parameters

**other** [Series or scalar value]

**fill\_value** [None or float value, default None (NaN)] Fill existing missing (NaN) values, and any new element needed for successful Series alignment, with this value before computation. If data in both corresponding Series locations is missing the result will be missing

**level** [int or name] Broadcast across a level, matching Index values on the passed Multi-Index level

#### Returns

**result** [Series]

#### See also:

`Series.None`

### Examples

```
>>> a = pd.Series([1, 1, 1, np.nan], index=['a', 'b', 'c', 'd'])
>>> a
a    1.0
b    1.0
c    1.0
d     NaN
dtype: float64
```

(continues on next page)

(continued from previous page)

```

>>> b = pd.Series([1, np.nan, 1, np.nan], index=['a', 'b', 'd', 'e'])
>>> b
a    1.0
b    NaN
d    1.0
e    NaN
dtype: float64
>>> a.add(b, fill_value=0)
a    2.0
b    1.0
c    1.0
d    1.0
e    NaN
dtype: float64

```

### pandas.Series.get

`Series.get(key, default=None)`

Get item from object for given key (DataFrame column, Panel slice, etc.). Returns default value if not found.

#### Parameters

**key** [object]

#### Returns

**value** [same type as items contained in object]

### pandas.Series.get\_dtype\_counts

`Series.get_dtype_counts()`

Return counts of unique dtypes in this object.

#### Returns

**dtype** [Series] Series with the count of columns with each dtype.

#### See also:

**dtypes** Return the dtypes in this object.

### Examples

```

>>> a = [['a', 1, 1.0], ['b', 2, 2.0], ['c', 3, 3.0]]
>>> df = pd.DataFrame(a, columns=['str', 'int', 'float'])
>>> df
   str  int  float
0   a     1    1.0
1   b     2    2.0
2   c     3    3.0

```

```
>>> df.get_dtype_counts()
float64    1
int64      1
object     1
dtype: int64
```

## pandas.Series.get\_ftype\_counts

`Series.get_ftype_counts()`

Return counts of unique ftypes in this object.

Deprecated since version 0.23.0.

This is useful for SparseDataFrame or for DataFrames containing sparse arrays.

### Returns

**dtype** [Series] Series with the count of columns with each type and sparsity (dense/sparse)

### See also:

**ftypes** Return ftypes (indication of sparse/dense and dtype) in this object.

## Examples

```
>>> a = [['a', 1, 1.0], ['b', 2, 2.0], ['c', 3, 3.0]]
>>> df = pd.DataFrame(a, columns=['str', 'int', 'float'])
>>> df
   str  int  float
0   a    1    1.0
1   b    2    2.0
2   c    3    3.0
```

```
>>> df.get_ftype_counts() # doctest: +SKIP
float64:dense    1
int64:dense      1
object:dense     1
dtype: int64
```

## pandas.Series.get\_value

`Series.get_value(label, takeable=False)`

Quickly retrieve single value at passed index label.

Deprecated since version 0.21.0: Please use `.at[]` or `.iat[]` accessors.

### Parameters

**label** [object]

**takeable** [interpret the index as indexers, default False]

### Returns

**value** [scalar value]

## pandas.Series.get\_values

`Series.get_values()`

Same as `values` (but handles sparseness conversions); is a view.

## pandas.Series.groupby

`Series.groupby` (*by=None, axis=0, level=None, as\_index=True, sort=True, group\_keys=True, squeeze=False, observed=False, \*\*kwargs*)

Group DataFrame or Series using a mapper or by a Series of columns.

A groupby operation involves some combination of splitting the object, applying a function, and combining the results. This can be used to group large amounts of data and compute operations on these groups.

### Parameters

**by** [mapping, function, label, or list of labels] Used to determine the groups for the groupby. If `by` is a function, it's called on each value of the object's index. If a dict or Series is passed, the Series or dict VALUES will be used to determine the groups (the Series' values are first aligned; see `.align()` method). If an ndarray is passed, the values are used as-is determine the groups. A label or list of labels may be passed to group by the columns in `self`. Notice that a tuple is interpreted a (single) key.

**axis** [{0 or 'index', 1 or 'columns'}, default 0] Split along rows (0) or columns (1).

**level** [int, level name, or sequence of such, default None] If the axis is a MultiIndex (hierarchical), group by a particular level or levels.

**as\_index** [bool, default True] For aggregated output, return object with group labels as the index. Only relevant for DataFrame input. `as_index=False` is effectively "SQL-style" grouped output.

**sort** [bool, default True] Sort group keys. Get better performance by turning this off. Note this does not influence the order of observations within each group. Groupby preserves the order of rows within each group.

**group\_keys** [bool, default True] When calling `apply`, add group keys to index to identify pieces.

**squeeze** [bool, default False] Reduce the dimensionality of the return type if possible, otherwise return a consistent type.

**observed** [bool, default False] This only applies if any of the groupers are Categoricals. If True: only show observed values for categorical groupers. If False: show all values for categorical groupers.

New in version 0.23.0.

**\*\*kwargs** Optional, only accepts keyword argument 'mutated' and is passed to groupby.

### Returns

**DataFrameGroupBy or SeriesGroupBy** Depends on the calling object and returns groupby object that contains information about the groups.

See also:

**resample** Convenience method for frequency conversion and resampling of time series.

## Notes

See the [user guide](#) for more.

## Examples

```
>>> df = pd.DataFrame({'Animal' : ['Falcon', 'Falcon',  
...                               'Parrot', 'Parrot'],  
...                   'Max Speed' : [380., 370., 24., 26.]})  
>>> df  
   Animal  Max Speed  
0  Falcon    380.0  
1  Falcon    370.0  
2  Parrot     24.0  
3  Parrot     26.0  
>>> df.groupby(['Animal']).mean()  
      Max Speed  
Animal  
Falcon    375.0  
Parrot     25.0
```

## Hierarchical Indexes

We can groupby different levels of a hierarchical index using the *level* parameter:

```
>>> arrays = [['Falcon', 'Falcon', 'Parrot', 'Parrot'],  
...          ['Capitve', 'Wild', 'Capitve', 'Wild']]  
>>> index = pd.MultiIndex.from_arrays(arrays, names=('Animal', 'Type'))  
>>> df = pd.DataFrame({'Max Speed' : [390., 350., 30., 20.]},  
...                   index=index)  
>>> df  
      Max Speed  
Animal Type  
Falcon Capitve    390.0  
      Wild       350.0  
Parrot Capitve     30.0  
      Wild       20.0  
>>> df.groupby(level=0).mean()  
      Max Speed  
Animal  
Falcon    370.0  
Parrot     25.0  
>>> df.groupby(level=1).mean()  
      Max Speed  
Type  
Capitve    210.0  
Wild       185.0
```

## pandas.Series.gt

`Series.gt` (*other*, *level=None*, *fill\_value=None*, *axis=0*)

Greater than of series and other, element-wise (binary operator *gt*).

Equivalent to `series > other`, but with support to substitute a *fill\_value* for missing data in one of the inputs.

**Parameters****other** [Series or scalar value]**fill\_value** [None or float value, default None (NaN)] Fill existing missing (NaN) values, and any new element needed for successful Series alignment, with this value before computation. If data in both corresponding Series locations is missing the result will be missing**level** [int or name] Broadcast across a level, matching Index values on the passed Multi-Index level**Returns****result** [Series]**See also:**

Series.None

**Examples**

```

>>> a = pd.Series([1, 1, 1, np.nan], index=['a', 'b', 'c', 'd'])
>>> a
a    1.0
b    1.0
c    1.0
d    NaN
dtype: float64
>>> b = pd.Series([1, np.nan, 1, np.nan], index=['a', 'b', 'd', 'e'])
>>> b
a    1.0
b    NaN
d    1.0
e    NaN
dtype: float64
>>> a.add(b, fill_value=0)
a    2.0
b    1.0
c    1.0
d    1.0
e    NaN
dtype: float64

```

**pandas.Series.head**Series.head(*n*=5)Return the first *n* rows.

This function returns the first *n* rows for the object based on position. It is useful for quickly testing if your object has the right type of data in it.

**Parameters****n** [int, default 5] Number of rows to select.**Returns****obj\_head** [same type as caller] The first *n* rows of the caller object.

See also:

**DataFrame.tail** Returns the last *n* rows.

## Examples

```
>>> df = pd.DataFrame({'animal': ['alligator', 'bee', 'falcon', 'lion',  
...                               'monkey', 'parrot', 'shark', 'whale', 'zebra']})  
>>> df  
   animal  
0  alligator  
1      bee  
2    falcon  
3      lion  
4    monkey  
5    parrot  
6     shark  
7     whale  
8     zebra
```

Viewing the first 5 lines

```
>>> df.head()  
   animal  
0  alligator  
1      bee  
2    falcon  
3      lion  
4    monkey
```

Viewing the first *n* lines (three in this case)

```
>>> df.head(3)  
   animal  
0  alligator  
1      bee  
2    falcon
```

## pandas.Series.hist

**Series.hist** (*by=None, ax=None, grid=True, xlabelsize=None, xrot=None, ylabelsize=None, yrot=None, figsize=None, bins=10, \*\*kwargs*)

Draw histogram of the input series using matplotlib.

### Parameters

**by** [object, optional] If passed, then used to form histograms for separate groups

**ax** [matplotlib axis object] If not passed, uses gca()

**grid** [boolean, default True] Whether to show axis grid lines

**xlabelsize** [int, default None] If specified changes the x-axis label size

**xrot** [float, default None] rotation of x axis labels

**ylabelsize** [int, default None] If specified changes the y-axis label size

**yrot** [float, default None] rotation of y axis labels

**figsize** [tuple, default None] figure size in inches by default

**bins** [integer or sequence, default 10] Number of histogram bins to be used. If an integer is given, bins + 1 bin edges are calculated and returned. If bins is a sequence, gives bin edges, including left edge of first bin and right edge of last bin. In this case, bins is returned unmodified.

**bins** [integer, default 10] Number of histogram bins to be used

**\*\*kwargs** [keywords] To be passed to the actual plotting function

See also:

`matplotlib.axes.Axes.hist` Plot a histogram using matplotlib.

### pandas.Series.idxmax

`Series.idxmax(axis=0, skipna=True, *args, **kwargs)`

Return the row label of the maximum value.

If multiple values equal the maximum, the first row label with that value is returned.

#### Parameters

**skipna** [boolean, default True] Exclude NA/null values. If the entire Series is NA, the result will be NA.

**axis** [int, default 0] For compatibility with `DataFrame.idxmax`. Redundant for application on Series.

**\*args, \*\*kwargs** Additional keywords have no effect but might be accepted for compatibility with NumPy.

#### Returns

**idxmax** [Index of maximum of values.]

#### Raises

**ValueError** If the Series is empty.

See also:

`numpy.argmax` Return indices of the maximum values along the given axis.

`DataFrame.idxmax` Return index of first occurrence of maximum over requested axis.

`Series.idxmin` Return index *label* of the first occurrence of minimum of values.

### Notes

This method is the Series version of `ndarray.argmax`. This method returns the label of the maximum, while `ndarray.argmax` returns the position. To get the position, use `series.values.argmax()`.

### Examples

```
>>> s = pd.Series(data=[1, None, 4, 3, 4],
...               index=['A', 'B', 'C', 'D', 'E'])
>>> s
A    1.0
B    NaN
C    4.0
D    3.0
E    4.0
dtype: float64
```

```
>>> s.idxmax()
'C'
```

If *skipna* is False and there is an NA value in the data, the function returns nan.

```
>>> s.idxmax(skipna=False)
nan
```

## pandas.Series.idxmin

`Series.idxmin(axis=0, skipna=True, *args, **kwargs)`

Return the row label of the minimum value.

If multiple values equal the minimum, the first row label with that value is returned.

### Parameters

**skipna** [boolean, default True] Exclude NA/null values. If the entire Series is NA, the result will be NA.

**axis** [int, default 0] For compatibility with DataFrame.idxmin. Redundant for application on Series.

**\*args, \*\*kwargs** Additional keywords have no effect but might be accepted for compatibility with NumPy.

### Returns

**idxmin** [Index of minimum of values.]

### Raises

**ValueError** If the Series is empty.

See also:

**numpy.argmax** Return indices of the minimum values along the given axis.

**DataFrame.idxmin** Return index of first occurrence of minimum over requested axis.

**Series.idxmax** Return index *label* of the first occurrence of maximum of values.

## Notes

This method is the Series version of `ndarray.argmax`. This method returns the label of the minimum, while `ndarray.argmax` returns the position. To get the position, use `series.values.argmax()`.

## Examples

```
>>> s = pd.Series(data=[1, None, 4, 1],
...                 index=['A', 'B', 'C', 'D'])
>>> s
A    1.0
B    NaN
C    4.0
D    1.0
dtype: float64
```

```
>>> s.idxmin()
'A'
```

If *skipna* is False and there is an NA value in the data, the function returns nan.

```
>>> s.idxmin(skipna=False)
nan
```

## pandas.Series.infer\_objects

`Series.infer_objects()`

Attempt to infer better dtypes for object columns.

Attempts soft conversion of object-dtyped columns, leaving non-object and unconvertible columns unchanged. The inference rules are the same as during normal Series/DataFrame construction.

New in version 0.21.0.

### Returns

**converted** [same type as input object]

**See also:**

**to\_datetime** Convert argument to datetime.

**to\_timedelta** Convert argument to timedelta.

**to\_numeric** Convert argument to numeric type.

## Examples

```
>>> df = pd.DataFrame({"A": ["a", 1, 2, 3]})
>>> df = df.iloc[1:]
>>> df
   A
1  1
2  2
3  3
```

```
>>> df.dtypes
A    object
dtype: object
```

```
>>> df.infer_objects().dtypes
A      int64
dtype: object
```

## pandas.Series.interpolate

`Series.interpolate` (*method='linear', axis=0, limit=None, inplace=False, limit\_direction='forward', limit\_area=None, downcast=None, \*\*kwargs*)  
Interpolate values according to different methods.

Please note that only `method='linear'` is supported for DataFrame/Series with a MultiIndex.

### Parameters

**method** [str, default 'linear'] Interpolation technique to use. One of:

- 'linear': Ignore the index and treat the values as equally spaced. This is the only method supported on MultiIndexes.
- 'time': Works on daily and higher resolution data to interpolate given length of interval.
- 'index', 'values': use the actual numerical values of the index.
- 'pad': Fill in NaNs using existing values.
- 'nearest', 'zero', 'slinear', 'quadratic', 'cubic', 'spline', 'barycentric', 'polynomial': Passed to `scipy.interpolate.interp1d`. Both 'polynomial' and 'spline' require that you also specify an *order* (int), e.g. `df.interpolate(method='polynomial', order=4)`. These use the numerical values of the index.
- 'krogh', 'piecewise\_polynomial', 'spline', 'pchip', 'akima': Wrappers around the SciPy interpolation methods of similar names. See *Notes*.
- 'from\_derivatives': Refers to `scipy.interpolate.BPoly.from_derivatives` which replaces 'piecewise\_polynomial' interpolation method in scipy 0.18.

New in version 0.18.1: Added support for the 'akima' method. Added interpolate method 'from\_derivatives' which replaces 'piecewise\_polynomial' in SciPy 0.18; backwards-compatible with SciPy < 0.18

**axis** [{0 or 'index', 1 or 'columns', None}, default None] Axis to interpolate along.

**limit** [int, optional] Maximum number of consecutive NaNs to fill. Must be greater than 0.

**inplace** [bool, default False] Update the data in place if possible.

**limit\_direction** [{ 'forward', 'backward', 'both' }, default 'forward'] If limit is specified, consecutive NaNs will be filled in this direction.

**limit\_area** [{None, 'inside', 'outside'}, default None] If limit is specified, consecutive NaNs will be filled with this restriction.

- None: No fill restriction.
- 'inside': Only fill NaNs surrounded by valid values (interpolate).
- 'outside': Only fill NaNs outside valid values (extrapolate).

New in version 0.21.0.

**downcast** [optional, 'infer' or None, defaults to None] Downcast dtypes if possible.

**\*\*kwargs** Keyword arguments to pass on to the interpolating function.

### Returns

**Series or DataFrame** Returns the same object type as the caller, interpolated at some or all NaN values

### See also:

**fillna** Fill missing values using different methods.

**scipy.interpolate.Akima1DInterpolator** Piecewise cubic polynomials (Akima interpolator).

**scipy.interpolate.BPoly.from\_derivatives** Piecewise polynomial in the Bernstein basis.

**scipy.interpolate.interpld** Interpolate a 1-D function.

**scipy.interpolate.KroghInterpolator** Interpolate polynomial (Krogh interpolator).

**scipy.interpolate.PchipInterpolator** PCHIP 1-d monotonic cubic interpolation.

**scipy.interpolate.CubicSpline** Cubic spline data interpolator.

### Notes

The 'krogh', 'piecewise\_polynomial', 'spline', 'pchip' and 'akima' methods are wrappers around the respective SciPy implementations of similar names. These use the actual numerical values of the index. For more information on their behavior, see the [SciPy documentation](#) and [SciPy tutorial](#).

### Examples

Filling in NaN in a *Series* via linear interpolation.

```
>>> s = pd.Series([0, 1, np.nan, 3])
>>> s
0    0.0
1    1.0
2    NaN
3    3.0
dtype: float64
>>> s.interpolate()
0    0.0
1    1.0
2    2.0
3    3.0
dtype: float64
```

Filling in NaN in a *Series* by padding, but filling at most two consecutive NaN at a time.

```
>>> s = pd.Series([np.nan, "single_one", np.nan,
...                 "fill_two_more", np.nan, np.nan, np.nan,
...                 4.71, np.nan])
>>> s
0          NaN
1    single_one
```

(continues on next page)

(continued from previous page)

```

2          NaN
3    fill_two_more
4          NaN
5          NaN
6          NaN
7          4.71
8          NaN
dtype: object
>>> s.interpolate(method='pad', limit=2)
0          NaN
1    single_one
2    single_one
3    fill_two_more
4    fill_two_more
5    fill_two_more
6          NaN
7          4.71
8          4.71
dtype: object

```

Filling in NaN in a Series via polynomial interpolation or splines: Both 'polynomial' and 'spline' methods require that you also specify an order (int).

```

>>> s = pd.Series([0, 2, np.nan, 8])
>>> s.interpolate(method='polynomial', order=2)
0    0.000000
1    2.000000
2    4.666667
3    8.000000
dtype: float64

```

Fill the DataFrame forward (that is, going down) along each column using linear interpolation.

Note how the last entry in column 'a' is interpolated differently, because there is no entry after it to use for interpolation. Note how the first entry in column 'b' remains NaN, because there is no entry before it to use for interpolation.

```

>>> df = pd.DataFrame([(0.0, np.nan, -1.0, 1.0),
...                     (np.nan, 2.0, np.nan, np.nan),
...                     (2.0, 3.0, np.nan, 9.0),
...                     (np.nan, 4.0, -4.0, 16.0)],
...                     columns=list('abcd'))
>>> df
   a    b    c    d
0  0.0 NaN -1.0  1.0
1 NaN  2.0 NaN  NaN
2  2.0  3.0 NaN  9.0
3 NaN  4.0 -4.0 16.0
>>> df.interpolate(method='linear', limit_direction='forward', axis=0)
   a    b    c    d
0  0.0 NaN -1.0  1.0
1  1.0  2.0 -2.0  5.0
2  2.0  3.0 -3.0  9.0
3  2.0  4.0 -4.0 16.0

```

Using polynomial interpolation.

```
>>> df['d'].interpolate(method='polynomial', order=2)
0      1.0
1      4.0
2      9.0
3     16.0
Name: d, dtype: float64
```

## pandas.Series.isin

`Series.isin(values)`

Check whether *values* are contained in Series.

Return a boolean Series showing whether each element in the Series matches an element in the passed sequence of *values* exactly.

### Parameters

**values** [set or list-like] The sequence of values to test. Passing in a single string will raise a `TypeError`. Instead, turn a single string into a list of one element.

New in version 0.18.1: Support for values as a set.

### Returns

**isin** [Series (bool dtype)]

### Raises

#### TypeError

- If *values* is a string

**See also:**

**DataFrame.isin** Equivalent method on DataFrame.

## Examples

```
>>> s = pd.Series(['lama', 'cow', 'lama', 'beetle', 'lama',
...               'hippo'], name='animal')
>>> s.isin(['cow', 'lama'])
0      True
1      True
2      True
3     False
4      True
5     False
Name: animal, dtype: bool
```

Passing a single string as `s.isin('lama')` will raise an error. Use a list of one element instead:

```
>>> s.isin(['lama'])
0      True
1     False
2      True
3     False
4      True
```

(continues on next page)

(continued from previous page)

```
5    False
Name: animal, dtype: bool
```

**pandas.Series.isna****Series.isna()**

Detect missing values.

Return a boolean same-sized object indicating if the values are NA. NA values, such as `None` or `numpy.NaN`, gets mapped to `True` values. Everything else gets mapped to `False` values. Characters such as empty strings `' '` or `numpy.inf` are not considered NA values (unless you set `pandas.options.mode.use_inf_as_na = True`).

**Returns**

**Series** Mask of bool values for each element in Series that indicates whether an element is not an NA value.

**See also:**

**Series.isnull** Alias of `isna`.

**Series.notna** Boolean inverse of `isna`.

**Series.dropna** Omit axes labels with missing values.

**isna** Top-level `isna`.

**Examples**

Show which entries in a DataFrame are NA.

```
>>> df = pd.DataFrame({'age': [5, 6, np.NaN],
...                    'born': [pd.NaT, pd.Timestamp('1939-05-27'),
...                             pd.Timestamp('1940-04-25')],
...                    'name': ['Alfred', 'Batman', ''],
...                    'toy': [None, 'Batmobile', 'Joker']})
>>> df
   age      born    name    toy
0  5.0      NaT  Alfred    None
1  6.0  1939-05-27  Batman  Batmobile
2  NaN  1940-04-25      Joker
```

```
>>> df.isna()
   age  born  name  toy
0  False  True  False  True
1  False False  False False
2   True False  False False
```

Show which entries in a Series are NA.

```
>>> ser = pd.Series([5, 6, np.NaN])
>>> ser
0    5.0
1    6.0
```

(continues on next page)

(continued from previous page)

```
2    NaN
dtype: float64
```

```
>>> ser.isna()
0    False
1    False
2     True
dtype: bool
```

## pandas.Series.isnull

**Series.isnull()**

Detect missing values.

Return a boolean same-sized object indicating if the values are NA. NA values, such as `None` or `numpy.NaN`, gets mapped to `True` values. Everything else gets mapped to `False` values. Characters such as empty strings `' '` or `numpy.inf` are not considered NA values (unless you set `pandas.options.mode.use_inf_as_na = True`).

### Returns

**Series** Mask of bool values for each element in Series that indicates whether an element is not an NA value.

### See also:

**Series.isnull** Alias of `isna`.

**Series.notna** Boolean inverse of `isna`.

**Series.dropna** Omit axes labels with missing values.

**isna** Top-level `isna`.

## Examples

Show which entries in a DataFrame are NA.

```
>>> df = pd.DataFrame({'age': [5, 6, np.NaN],
...                     'born': [pd.NaT, pd.Timestamp('1939-05-27'),
...                               pd.Timestamp('1940-04-25')],
...                     'name': ['Alfred', 'Batman', ''],
...                     'toy': [None, 'Batmobile', 'Joker']})
>>> df
   age      born    name    toy
0  5.0      NaT  Alfred   None
1  6.0  1939-05-27  Batman  Batmobile
2  NaN  1940-04-25      Joker
```

```
>>> df.isna()
   age  born  name  toy
0  False  True  False  True
1  False  False  False  False
2   True  False  False  False
```

Show which entries in a Series are NA.

```
>>> ser = pd.Series([5, 6, np.NaN])
>>> ser
0    5.0
1    6.0
2    NaN
dtype: float64
```

```
>>> ser.isna()
0    False
1    False
2     True
dtype: bool
```

### pandas.Series.item

`Series.item()`

Return the first element of the underlying data as a python scalar.

### pandas.Series.items

`Series.items()`

Lazily iterate over (index, value) tuples.

### pandas.Series.iteritems

`Series.iteritems()`

Lazily iterate over (index, value) tuples.

### pandas.Series.keys

`Series.keys()`

Alias for index.

### pandas.Series.kurt

`Series.kurt(axis=None, skipna=None, level=None, numeric_only=None, **kwargs)`

Return unbiased kurtosis over requested axis using Fisher's definition of kurtosis (kurtosis of normal == 0.0). Normalized by N-1.

#### Parameters

**axis** [{index (0)}] Axis for the function to be applied on.

**skipna** [bool, default True] Exclude NA/null values when computing the result.

**level** [int or level name, default None] If the axis is a MultiIndex (hierarchical), count along a particular level, collapsing into a scalar.

**numeric\_only** [bool, default None] Include only float, int, boolean columns. If None, will attempt to use everything, then use only numeric data. Not implemented for Series.

**\*\*kwargs** Additional keyword arguments to be passed to the function.

#### Returns

**kurt** [scalar or Series (if level specified)]

### pandas.Series.kurtosis

`Series.kurtosis` (*axis=None, skipna=None, level=None, numeric\_only=None, \*\*kwargs*)

Return unbiased kurtosis over requested axis using Fisher's definition of kurtosis (kurtosis of normal == 0.0). Normalized by N-1.

#### Parameters

**axis** [{index (0)}] Axis for the function to be applied on.

**skipna** [bool, default True] Exclude NA/null values when computing the result.

**level** [int or level name, default None] If the axis is a MultiIndex (hierarchical), count along a particular level, collapsing into a scalar.

**numeric\_only** [bool, default None] Include only float, int, boolean columns. If None, will attempt to use everything, then use only numeric data. Not implemented for Series.

**\*\*kwargs** Additional keyword arguments to be passed to the function.

#### Returns

**kurt** [scalar or Series (if level specified)]

### pandas.Series.last

`Series.last` (*offset*)

Convenience method for subsetting final periods of time series data based on a date offset.

#### Parameters

**offset** [string, DateOffset, dateutil.relativedelta]

#### Returns

**subset** [same type as caller]

#### Raises

**TypeError** If the index is not a *DatetimeIndex*

See also:

**first** Select initial periods of time series based on a date offset.

**at\_time** Select values at a particular time of the day.

**between\_time** Select values between particular times of the day.

## Examples

```
>>> i = pd.date_range('2018-04-09', periods=4, freq='2D')
>>> ts = pd.DataFrame({'A': [1,2,3,4]}, index=i)
>>> ts
```

|            | A |
|------------|---|
| 2018-04-09 | 1 |
| 2018-04-11 | 2 |
| 2018-04-13 | 3 |
| 2018-04-15 | 4 |

Get the rows for the last 3 days:

```
>>> ts.last('3D')
```

|            | A |
|------------|---|
| 2018-04-13 | 3 |
| 2018-04-15 | 4 |

Notice the data for 3 last calendar days were returned, not the last 3 observed days in the dataset, and therefore data for 2018-04-11 was not returned.

## pandas.Series.last\_valid\_index

`Series.last_valid_index()`  
Return index for last non-NA/null value.

### Returns

**scalar** [type of index]

## Notes

If all elements are non-NA/null, returns None. Also returns None for empty NDFrame.

## pandas.Series.le

`Series.le(other, level=None, fill_value=None, axis=0)`  
Less than or equal to of series and other, element-wise (binary operator *le*).

Equivalent to `series <= other`, but with support to substitute a `fill_value` for missing data in one of the inputs.

### Parameters

**other** [Series or scalar value]

**fill\_value** [None or float value, default None (NaN)] Fill existing missing (NaN) values, and any new element needed for successful Series alignment, with this value before computation. If data in both corresponding Series locations is missing the result will be missing

**level** [int or name] Broadcast across a level, matching Index values on the passed Multi-Index level

### Returns

**result** [Series]

**See also:**

Series.None

**Examples**

```

>>> a = pd.Series([1, 1, 1, np.nan], index=['a', 'b', 'c', 'd'])
>>> a
a    1.0
b    1.0
c    1.0
d    NaN
dtype: float64
>>> b = pd.Series([1, np.nan, 1, np.nan], index=['a', 'b', 'd', 'e'])
>>> b
a    1.0
b    NaN
d    1.0
e    NaN
dtype: float64
>>> a.add(b, fill_value=0)
a    2.0
b    1.0
c    1.0
d    1.0
e    NaN
dtype: float64

```

**pandas.Series.lt**

Series.lt (other, level=None, fill\_value=None, axis=0)

Less than of series and other, element-wise (binary operator *lt*).Equivalent to `series < other`, but with support to substitute a `fill_value` for missing data in one of the inputs.**Parameters****other** [Series or scalar value]**fill\_value** [None or float value, default None (NaN)] Fill existing missing (NaN) values, and any new element needed for successful Series alignment, with this value before computation. If data in both corresponding Series locations is missing the result will be missing**level** [int or name] Broadcast across a level, matching Index values on the passed Multi-Index level**Returns****result** [Series]**See also:**

Series.None

## Examples

```
>>> a = pd.Series([1, 1, 1, np.nan], index=['a', 'b', 'c', 'd'])
>>> a
a    1.0
b    1.0
c    1.0
d    NaN
dtype: float64
>>> b = pd.Series([1, np.nan, 1, np.nan], index=['a', 'b', 'd', 'e'])
>>> b
a    1.0
b    NaN
d    1.0
e    NaN
dtype: float64
>>> a.add(b, fill_value=0)
a    2.0
b    1.0
c    1.0
d    1.0
e    NaN
dtype: float64
```

## pandas.Series.mad

`Series.mad` (*axis=None, skipna=None, level=None*)

Return the mean absolute deviation of the values for the requested axis.

### Parameters

**axis** [{index (0)}] Axis for the function to be applied on.

**skipna** [bool, default True] Exclude NA/null values when computing the result.

**level** [int or level name, default None] If the axis is a MultiIndex (hierarchical), count along a particular level, collapsing into a scalar.

**numeric\_only** [bool, default None] Include only float, int, boolean columns. If None, will attempt to use everything, then use only numeric data. Not implemented for Series.

**\*\*kwargs** Additional keyword arguments to be passed to the function.

### Returns

**mad** [scalar or Series (if level specified)]

## pandas.Series.map

`Series.map` (*arg, na\_action=None*)

Map values of Series according to input correspondence.

Used for substituting each value in a Series with another value, that may be derived from a function, a dict or a *Series*.

### Parameters

**arg** [function, dict, or Series] Mapping correspondence.

**na\_action** [{None, 'ignore'}, default None] If 'ignore', propagate NaN values, without passing them to the mapping correspondence.

### Returns

**Series** Same index as caller.

### See also:

**Series.apply** For applying more complex functions on a Series.

**DataFrame.apply** Apply a function row-/column-wise.

**DataFrame.applymap** Apply a function elementwise on a whole DataFrame.

### Notes

When `arg` is a dictionary, values in Series that are not in the dictionary (as keys) are converted to NaN. However, if the dictionary is a `dict` subclass that defines `__missing__` (i.e. provides a method for default values), then this default is used rather than NaN.

### Examples

```
>>> s = pd.Series(['cat', 'dog', np.nan, 'rabbit'])
>>> s
0      cat
1      dog
2      NaN
3  rabbit
dtype: object
```

`map` accepts a dict or a Series. Values that are not found in the dict are converted to NaN, unless the dict has a default value (e.g. `defaultdict`):

```
>>> s.map({'cat': 'kitten', 'dog': 'puppy'})
0  kitten
1  puppy
2    NaN
3    NaN
dtype: object
```

It also accepts a function:

```
>>> s.map('I am a {}'.format)
0      I am a cat
1      I am a dog
2      I am a nan
3  I am a rabbit
dtype: object
```

To avoid applying the function to missing values (and keep them as NaN) `na_action='ignore'` can be used:

```
>>> s.map('I am a {}'.format, na_action='ignore')
0      I am a cat
1      I am a dog
2              NaN
3  I am a rabbit
dtype: object
```

## pandas.Series.mask

`Series.mask(cond, other=nan, inplace=False, axis=None, level=None, errors='raise', try_cast=False, raise_on_error=None)`  
Replace values where the condition is True.

### Parameters

**cond** [boolean NDFrame, array-like, or callable] Where *cond* is False, keep the original value. Where True, replace with corresponding value from *other*. If *cond* is callable, it is computed on the NDFrame and should return boolean NDFrame or array. The callable must not change input NDFrame (though pandas doesn't check it).

New in version 0.18.1: A callable can be used as *cond*.

**other** [scalar, NDFrame, or callable] Entries where *cond* is True are replaced with corresponding value from *other*. If *other* is callable, it is computed on the NDFrame and should return scalar or NDFrame. The callable must not change input NDFrame (though pandas doesn't check it).

New in version 0.18.1: A callable can be used as *other*.

**inplace** [boolean, default False] Whether to perform the operation in place on the data.

**axis** [int, default None] Alignment axis if needed.

**level** [int, default None] Alignment level if needed.

**errors** [str, {'raise', 'ignore'}, default *raise*] Note that currently this parameter won't affect the results and will always coerce to a suitable dtype.

- *raise* : allow exceptions to be raised.
- *ignore* : suppress exceptions. On error return original object.

**try\_cast** [boolean, default False] Try to cast the result back to the input type (if possible).

**raise\_on\_error** [boolean, default True] Whether to raise on invalid data types (e.g. trying to where on strings).

Deprecated since version 0.21.0: Use *errors*.

### Returns

**wh** [same type as caller]

See also:

**DataFrame.where()** Return an object of same shape as self.

## Notes

The mask method is an application of the if-then idiom. For each element in the calling DataFrame, if `cond` is `False` the element is used; otherwise the corresponding element from the DataFrame `other` is used.

The signature for `DataFrame.where()` differs from `numpy.where()`. Roughly `df1.where(m, df2)` is equivalent to `np.where(m, df1, df2)`.

For further details and examples see the mask documentation in *indexing*.

## Examples

```
>>> s = pd.Series(range(5))
>>> s.where(s > 0)
0    NaN
1    1.0
2    2.0
3    3.0
4    4.0
dtype: float64
```

```
>>> s.mask(s > 0)
0    0.0
1    NaN
2    NaN
3    NaN
4    NaN
dtype: float64
```

```
>>> s.where(s > 1, 10)
0    10
1    10
2     2
3     3
4     4
dtype: int64
```

```
>>> df = pd.DataFrame(np.arange(10).reshape(-1, 2), columns=['A', 'B'])
>>> m = df % 3 == 0
>>> df.where(m, -df)
   A  B
0  0 -1
1 -2  3
2 -4 -5
3  6 -7
4 -8  9
>>> df.where(m, -df) == np.where(m, df, -df)
   A      B
0  True  True
1  True  True
2  True  True
3  True  True
4  True  True
>>> df.where(m, -df) == df.mask(~m, -df)
   A      B
```

(continues on next page)

(continued from previous page)

```
0  True  True
1  True  True
2  True  True
3  True  True
4  True  True
```

## pandas.Series.max

`Series.max` (*axis=None, skipna=None, level=None, numeric\_only=None, \*\*kwargs*)

Return the maximum of the values for the requested axis.

If you want the *index* of the maximum, use `idxmax`. This is the equivalent of the `numpy.ndarray` method `argmax`.

### Parameters

**axis** [{index (0)}] Axis for the function to be applied on.

**skipna** [bool, default True] Exclude NA/null values when computing the result.

**level** [int or level name, default None] If the axis is a MultiIndex (hierarchical), count along a particular level, collapsing into a scalar.

**numeric\_only** [bool, default None] Include only float, int, boolean columns. If None, will attempt to use everything, then use only numeric data. Not implemented for Series.

**\*\*kwargs** Additional keyword arguments to be passed to the function.

### Returns

**max** [scalar or Series (if level specified)]

### See also:

**Series.sum** Return the sum.

**Series.min** Return the minimum.

**Series.max** Return the maximum.

**Series.idxmin** Return the index of the minimum.

**Series.idxmax** Return the index of the maximum.

**DataFrame.min** Return the sum over the requested axis.

**DataFrame.min** Return the minimum over the requested axis.

**DataFrame.max** Return the maximum over the requested axis.

**DataFrame.idxmin** Return the index of the minimum over the requested axis.

**DataFrame.idxmax** Return the index of the maximum over the requested axis.

## Examples

```
>>> idx = pd.MultiIndex.from_arrays([
...     ['warm', 'warm', 'cold', 'cold'],
...     ['dog', 'falcon', 'fish', 'spider']],
...     names=['blooded', 'animal'])
>>> s = pd.Series([4, 2, 0, 8], name='legs', index=idx)
>>> s
blooded  animal
warm     dog      4
         falcon   2
cold     fish     0
         spider   8
Name: legs, dtype: int64
```

```
>>> s.max()
8
```

Max using level names, as well as indices.

```
>>> s.max(level='blooded')
blooded
warm     4
cold     8
Name: legs, dtype: int64
```

```
>>> s.max(level=0)
blooded
warm     4
cold     8
Name: legs, dtype: int64
```

## pandas.Series.mean

`Series.mean` (*axis=None, skipna=None, level=None, numeric\_only=None, \*\*kwargs*)

Return the mean of the values for the requested axis.

### Parameters

**axis** [{index (0)}] Axis for the function to be applied on.

**skipna** [bool, default True] Exclude NA/null values when computing the result.

**level** [int or level name, default None] If the axis is a MultiIndex (hierarchical), count along a particular level, collapsing into a scalar.

**numeric\_only** [bool, default None] Include only float, int, boolean columns. If None, will attempt to use everything, then use only numeric data. Not implemented for Series.

**\*\*kwargs** Additional keyword arguments to be passed to the function.

### Returns

**mean** [scalar or Series (if level specified)]

## pandas.Series.median

`Series.median` (*axis=None, skipna=None, level=None, numeric\_only=None, \*\*kwargs*)

Return the median of the values for the requested axis.

### Parameters

**axis** [{index (0)}] Axis for the function to be applied on.

**skipna** [bool, default True] Exclude NA/null values when computing the result.

**level** [int or level name, default None] If the axis is a MultiIndex (hierarchical), count along a particular level, collapsing into a scalar.

**numeric\_only** [bool, default None] Include only float, int, boolean columns. If None, will attempt to use everything, then use only numeric data. Not implemented for Series.

**\*\*kwargs** Additional keyword arguments to be passed to the function.

### Returns

**median** [scalar or Series (if level specified)]

## pandas.Series.memory\_usage

`Series.memory_usage` (*index=True, deep=False*)

Return the memory usage of the Series.

The memory usage can optionally include the contribution of the index and of elements of *object* dtype.

### Parameters

**index** [bool, default True] Specifies whether to include the memory usage of the Series index.

**deep** [bool, default False] If True, introspect the data deeply by interrogating *object* dtypes for system-level memory consumption, and include it in the returned value.

### Returns

**int** Bytes of memory consumed.

See also:

**numpy.ndarray.nbytes** Total bytes consumed by the elements of the array.

**DataFrame.memory\_usage** Bytes consumed by a DataFrame.

## Examples

```
>>> s = pd.Series(range(3))
>>> s.memory_usage()
104
```

Not including the index gives the size of the rest of the data, which is necessarily smaller:

```
>>> s.memory_usage(index=False)
24
```

The memory footprint of *object* values is ignored by default:

```
>>> s = pd.Series(["a", "b"])
>>> s.values
array(['a', 'b'], dtype=object)
>>> s.memory_usage()
96
>>> s.memory_usage(deep=True)
212
```

## pandas.Series.min

`Series.min` (*axis=None, skipna=None, level=None, numeric\_only=None, \*\*kwargs*)

Return the minimum of the values for the requested axis.

If you want the *index* of the minimum, use `idxmin`. This is the equivalent of the `numpy.ndarray` method `argmin`.

### Parameters

**axis** [{index (0)}] Axis for the function to be applied on.

**skipna** [bool, default True] Exclude NA/null values when computing the result.

**level** [int or level name, default None] If the axis is a MultiIndex (hierarchical), count along a particular level, collapsing into a scalar.

**numeric\_only** [bool, default None] Include only float, int, boolean columns. If None, will attempt to use everything, then use only numeric data. Not implemented for Series.

**\*\*kwargs** Additional keyword arguments to be passed to the function.

### Returns

**min** [scalar or Series (if level specified)]

See also:

**Series.sum** Return the sum.

**Series.min** Return the minimum.

**Series.max** Return the maximum.

**Series.idxmin** Return the index of the minimum.

**Series.idxmax** Return the index of the maximum.

**DataFrame.min** Return the sum over the requested axis.

**DataFrame.min** Return the minimum over the requested axis.

**DataFrame.max** Return the maximum over the requested axis.

**DataFrame.idxmin** Return the index of the minimum over the requested axis.

**DataFrame.idxmax** Return the index of the maximum over the requested axis.

## Examples

```
>>> idx = pd.MultiIndex.from_arrays([
...     ['warm', 'warm', 'cold', 'cold'],
...     ['dog', 'falcon', 'fish', 'spider']],
...     names=['blooded', 'animal'])
>>> s = pd.Series([4, 2, 0, 8], name='legs', index=idx)
>>> s
blooded  animal
warm     dog      4
         falcon   2
cold     fish     0
         spider   8
Name: legs, dtype: int64
```

```
>>> s.min()
0
```

Min using level names, as well as indices.

```
>>> s.min(level='blooded')
blooded
warm     2
cold     0
Name: legs, dtype: int64
```

```
>>> s.min(level=0)
blooded
warm     2
cold     0
Name: legs, dtype: int64
```

## pandas.Series.mod

`Series.mod(other, level=None, fill_value=None, axis=0)`

Modulo of series and other, element-wise (binary operator *mod*).

Equivalent to `series % other`, but with support to substitute a `fill_value` for missing data in one of the inputs.

### Parameters

**other** [Series or scalar value]

**fill\_value** [None or float value, default None (NaN)] Fill existing missing (NaN) values, and any new element needed for successful Series alignment, with this value before computation. If data in both corresponding Series locations is missing the result will be missing

**level** [int or name] Broadcast across a level, matching Index values on the passed Multi-Index level

### Returns

**result** [Series]

See also:

*Series.rmod*

## Examples

```

>>> a = pd.Series([1, 1, 1, np.nan], index=['a', 'b', 'c', 'd'])
>>> a
a    1.0
b    1.0
c    1.0
d    NaN
dtype: float64
>>> b = pd.Series([1, np.nan, 1, np.nan], index=['a', 'b', 'd', 'e'])
>>> b
a    1.0
b    NaN
d    1.0
e    NaN
dtype: float64
>>> a.add(b, fill_value=0)
a    2.0
b    1.0
c    1.0
d    1.0
e    NaN
dtype: float64

```

## pandas.Series.mode

*Series.mode (dropna=True)*

Return the mode(s) of the dataset.

Always returns Series even if only one value is returned.

### Parameters

**dropna** [boolean, default True] Don't consider counts of NaN/NaT.

New in version 0.24.0.

### Returns

**modes** [Series (sorted)]

## pandas.Series.mul

*Series.mul (other, level=None, fill\_value=None, axis=0)*Multiplication of series and other, element-wise (binary operator *mul*).Equivalent to `series * other`, but with support to substitute a `fill_value` for missing data in one of the inputs.

### Parameters

**other** [Series or scalar value]**fill\_value** [None or float value, default None (NaN)] Fill existing missing (NaN) values, and any new element needed for successful Series alignment, with this value before

computation. If data in both corresponding Series locations is missing the result will be missing

**level** [int or name] Broadcast across a level, matching Index values on the passed Multi-Index level

### Returns

**result** [Series]

### See also:

*Series.rmul*

### Examples

```
>>> a = pd.Series([1, 1, 1, np.nan], index=['a', 'b', 'c', 'd'])
>>> a
a    1.0
b    1.0
c    1.0
d     NaN
dtype: float64
>>> b = pd.Series([1, np.nan, 1, np.nan], index=['a', 'b', 'd', 'e'])
>>> b
a    1.0
b     NaN
d    1.0
e     NaN
dtype: float64
>>> a.add(b, fill_value=0)
a    2.0
b    1.0
c    1.0
d    1.0
e     NaN
dtype: float64
```

## pandas.Series.multiply

`Series.multiply` (*other*, *level=None*, *fill\_value=None*, *axis=0*)

Multiplication of series and other, element-wise (binary operator *mul*).

Equivalent to `series * other`, but with support to substitute a *fill\_value* for missing data in one of the inputs.

### Parameters

**other** [Series or scalar value]

**fill\_value** [None or float value, default None (NaN)] Fill existing missing (NaN) values, and any new element needed for successful Series alignment, with this value before computation. If data in both corresponding Series locations is missing the result will be missing

**level** [int or name] Broadcast across a level, matching Index values on the passed Multi-Index level

### Returns

**result** [Series]**See also:**`Series.rmul`

## Examples

```

>>> a = pd.Series([1, 1, 1, np.nan], index=['a', 'b', 'c', 'd'])
>>> a
a    1.0
b    1.0
c    1.0
d    NaN
dtype: float64
>>> b = pd.Series([1, np.nan, 1, np.nan], index=['a', 'b', 'd', 'e'])
>>> b
a    1.0
b    NaN
d    1.0
e    NaN
dtype: float64
>>> a.add(b, fill_value=0)
a    2.0
b    1.0
c    1.0
d    1.0
e    NaN
dtype: float64

```

## pandas.Series.ne

`Series.ne` (*other*, *level=None*, *fill\_value=None*, *axis=0*)Not equal to of series and other, element-wise (binary operator *ne*).Equivalent to `series != other`, but with support to substitute a *fill\_value* for missing data in one of the inputs.

### Parameters

**other** [Series or scalar value]**fill\_value** [None or float value, default None (NaN)] Fill existing missing (NaN) values, and any new element needed for successful Series alignment, with this value before computation. If data in both corresponding Series locations is missing the result will be missing**level** [int or name] Broadcast across a level, matching Index values on the passed Multi-Index level

### Returns

**result** [Series]**See also:**`Series.None`

## Examples

```
>>> a = pd.Series([1, 1, 1, np.nan], index=['a', 'b', 'c', 'd'])
>>> a
a    1.0
b    1.0
c    1.0
d    NaN
dtype: float64
>>> b = pd.Series([1, np.nan, 1, np.nan], index=['a', 'b', 'd', 'e'])
>>> b
a    1.0
b    NaN
d    1.0
e    NaN
dtype: float64
>>> a.add(b, fill_value=0)
a    2.0
b    1.0
c    1.0
d    1.0
e    NaN
dtype: float64
```

## pandas.Series.nlargest

`Series.nlargest` (*n=5, keep='first'*)

Return the largest *n* elements.

### Parameters

**n** [int, default 5] Return this many descending sorted values.

**keep** [{‘first’, ‘last’, ‘all’}, default ‘first’] When there are duplicate values that cannot all fit in a Series of *n* elements:

- **first** : take the first occurrences based on the index order
- **last** : take the last occurrences based on the index order
- **all** [keep all occurrences. This can result in a Series of] size larger than *n*.

### Returns

**Series** The *n* largest values in the Series, sorted in decreasing order.

See also:

**Series.nsmallest** Get the *n* smallest elements.

**Series.sort\_values** Sort Series by values.

**Series.head** Return the first *n* rows.

## Notes

Faster than `.sort_values(ascending=False).head(n)` for small *n* relative to the size of the Series object.

## Examples

```
>>> countries_population = {"Italy": 59000000, "France": 65000000,
...                          "Malta": 434000, "Maldives": 434000,
...                          "Brunei": 434000, "Iceland": 337000,
...                          "Nauru": 11300, "Tuvalu": 11300,
...                          "Anguilla": 11300, "Monserat": 5200}
>>> s = pd.Series(countries_population)
>>> s
Italy      59000000
France     65000000
Malta       434000
Maldives    434000
Brunei      434000
Iceland     337000
Nauru        11300
Tuvalu       11300
Anguilla     11300
Monserat      5200
dtype: int64
```

The  $n$  largest elements where  $n=5$  by default.

```
>>> s.nlargest()
France      65000000
Italy       59000000
Malta        434000
Maldives     434000
Brunei       434000
dtype: int64
```

The  $n$  largest elements where  $n=3$ . Default *keep* value is 'first' so Malta will be kept.

```
>>> s.nlargest(3)
France      65000000
Italy       59000000
Malta        434000
dtype: int64
```

The  $n$  largest elements where  $n=3$  and keeping the last duplicates. Brunei will be kept since it is the last with value 434000 based on the index order.

```
>>> s.nlargest(3, keep='last')
France      65000000
Italy       59000000
Brunei       434000
dtype: int64
```

The  $n$  largest elements where  $n=3$  with all duplicates kept. Note that the returned Series has five elements due to the three duplicates.

```
>>> s.nlargest(3, keep='all')
France      65000000
Italy       59000000
Malta        434000
Maldives     434000
Brunei       434000
dtype: int64
```

## pandas.Series.nonzero

`Series.nonzero()`

Return the *integer* indices of the elements that are non-zero.

Deprecated since version 0.24.0: Please use `.to_numpy().nonzero()` as a replacement.

This method is equivalent to calling *numpy.nonzero* on the series data. For compatibility with NumPy, the return value is the same (a tuple with an array of indices for each dimension), but it will always be a one-item tuple because series only have one dimension.

**See also:**

`numpy.nonzero`

## Examples

```
>>> s = pd.Series([0, 3, 0, 4])
>>> s.nonzero()
(array([1, 3]),)
>>> s.iloc[s.nonzero()[0]]
1      3
3      4
dtype: int64
```

```
>>> s = pd.Series([0, 3, 0, 4], index=['a', 'b', 'c', 'd'])
# same return although index of s is different
>>> s.nonzero()
(array([1, 3]),)
>>> s.iloc[s.nonzero()[0]]
b      3
d      4
dtype: int64
```

## pandas.Series.notna

`Series.notna()`

Detect existing (non-missing) values.

Return a boolean same-sized object indicating if the values are not NA. Non-missing values get mapped to True. Characters such as empty strings `' '` or `numpy.inf` are not considered NA values (unless you set `pandas.options.mode.use_inf_as_na = True`). NA values, such as `None` or `numpy.NaN`, get mapped to False values.

### Returns

**Series** Mask of bool values for each element in Series that indicates whether an element is not an NA value.

**See also:**

**Series.notnull** Alias of `notna`.

**Series.isna** Boolean inverse of `notna`.

**Series.dropna** Omit axes labels with missing values.

**notna** Top-level `notna`.

## Examples

Show which entries in a DataFrame are not NA.

```
>>> df = pd.DataFrame({'age': [5, 6, np.NaN],
...                     'born': [pd.NaT, pd.Timestamp('1939-05-27'),
...                             pd.Timestamp('1940-04-25')],
...                     'name': ['Alfred', 'Batman', ''],
...                     'toy': [None, 'Batmobile', 'Joker']})
>>> df
   age      born    name    toy
0  5.0      NaT  Alfred   None
1  6.0 1939-05-27  Batman Batmobile
2  NaN 1940-04-25      Joker
```

```
>>> df.notna()
   age  born  name  toy
0  True False  True False
1  True  True  True  True
2  False  True  True  True
```

Show which entries in a Series are not NA.

```
>>> ser = pd.Series([5, 6, np.NaN])
>>> ser
0    5.0
1    6.0
2    NaN
dtype: float64
```

```
>>> ser.notna()
0    True
1    True
2    False
dtype: bool
```

## pandas.Series.notnull

`Series.notnull()`

Detect existing (non-missing) values.

Return a boolean same-sized object indicating if the values are not NA. Non-missing values get mapped to True. Characters such as empty strings '' or `numpy.inf` are not considered NA values (unless you set `pandas.options.mode.use_inf_as_na = True`). NA values, such as `None` or `numpy.NaN`, get mapped to False values.

### Returns

**Series** Mask of bool values for each element in Series that indicates whether an element is not an NA value.

See also:

**Series.notnull** Alias of `notna`.

**Series.isna** Boolean inverse of `notna`.

**Series.dropna** Omit axes labels with missing values.

**notna** Top-level notna.

## Examples

Show which entries in a DataFrame are not NA.

```
>>> df = pd.DataFrame({'age': [5, 6, np.NaN],
...                     'born': [pd.NaT, pd.Timestamp('1939-05-27'),
...                               pd.Timestamp('1940-04-25')],
...                     'name': ['Alfred', 'Batman', ''],
...                     'toy': [None, 'Batmobile', 'Joker']})
>>> df
   age      born   name    toy
0  5.0      NaT  Alfred   None
1  6.0 1939-05-27  Batman Batmobile
2  NaN 1940-04-25     Joker    Joker
```

```
>>> df.notna()
   age  born  name  toy
0  True False  True False
1  True  True  True  True
2 False  True  True  True
```

Show which entries in a Series are not NA.

```
>>> ser = pd.Series([5, 6, np.NaN])
>>> ser
0    5.0
1    6.0
2    NaN
dtype: float64
```

```
>>> ser.notna()
0     True
1     True
2    False
dtype: bool
```

## pandas.Series.nsmallest

**Series.nsmallest** (*n=5, keep='first'*)

Return the smallest *n* elements.

### Parameters

**n** [int, default 5] Return this many ascending sorted values.

**keep** [{‘first’, ‘last’, ‘all’}, default ‘first’] When there are duplicate values that cannot all fit in a Series of *n* elements:

- **first** : take the first occurrences based on the index order
- **last** : take the last occurrences based on the index order
- **all** [keep all occurrences. This can result in a Series of] size larger than *n*.

### Returns

**Series** The  $n$  smallest values in the Series, sorted in increasing order.

**See also:**

***Series.nlargest*** Get the  $n$  largest elements.

***Series.sort\_values*** Sort Series by values.

***Series.head*** Return the first  $n$  rows.

### Notes

Faster than `.sort_values().head(n)` for small  $n$  relative to the size of the Series object.

### Examples

```
>>> countries_population = {"Italy": 59000000, "France": 65000000,
...                          "Brunei": 434000, "Malta": 434000,
...                          "Maldives": 434000, "Iceland": 337000,
...                          "Nauru": 11300, "Tuvalu": 11300,
...                          "Anguilla": 11300, "Monserat": 5200}
>>> s = pd.Series(countries_population)
>>> s
Italy          59000000
France         65000000
Brunei          434000
Malta           434000
Maldives        434000
Iceland         337000
Nauru            11300
Tuvalu           11300
Anguilla         11300
Monserat          5200
dtype: int64
```

The  $n$  largest elements where  $n=5$  by default.

```
>>> s.nsmallest()
Monserat          5200
Nauru             11300
Tuvalu            11300
Anguilla          11300
Iceland           337000
dtype: int64
```

The  $n$  smallest elements where  $n=3$ . Default *keep* value is 'first' so Nauru and Tuvalu will be kept.

```
>>> s.nsmallest(3)
Monserat          5200
Nauru             11300
Tuvalu            11300
dtype: int64
```

The  $n$  smallest elements where  $n=3$  and keeping the last duplicates. Anguilla and Tuvalu will be kept since they are the last with value 11300 based on the index order.

```
>>> s.nsmallest(3, keep='last')
Monserat      5200
Anguilla      11300
Tuvalu        11300
dtype: int64
```

The  $n$  smallest elements where  $n=3$  with all duplicates kept. Note that the returned Series has four elements due to the three duplicates.

```
>>> s.nsmallest(3, keep='all')
Monserat      5200
Nauru         11300
Tuvalu        11300
Anguilla      11300
dtype: int64
```

### pandas.Series.nunique

`Series.nunique(dropna=True)`

Return number of unique elements in the object.

Excludes NA values by default.

#### Parameters

**dropna** [boolean, default True] Don't include NaN in the count.

#### Returns

**nunique** [int]

### pandas.Series.pct\_change

`Series.pct_change(periods=1, fill_method='pad', limit=None, freq=None, **kwargs)`

Percentage change between the current and a prior element.

Computes the percentage change from the immediately previous row by default. This is useful in comparing the percentage of change in a time series of elements.

#### Parameters

**periods** [int, default 1] Periods to shift for forming percent change.

**fill\_method** [str, default 'pad'] How to handle NAs before computing percent changes.

**limit** [int, default None] The number of consecutive NAs to fill before stopping.

**freq** [DateOffset, timedelta, or offset alias string, optional] Increment to use from time series API (e.g. 'M' or BDay()).

**\*\*kwargs** Additional keyword arguments are passed into *DataFrame.shift* or *Series.shift*.

#### Returns

**chg** [Series or DataFrame] The same type as the calling object.

See also:

**Series.diff** Compute the difference of two elements in a Series.

**DataFrame.diff** Compute the difference of two elements in a DataFrame.

**Series.shift** Shift the index by some number of periods.

**DataFrame.shift** Shift the index by some number of periods.

## Examples

### Series

```
>>> s = pd.Series([90, 91, 85])
>>> s
0    90
1    91
2    85
dtype: int64
```

```
>>> s.pct_change()
0      NaN
1    0.011111
2   -0.065934
dtype: float64
```

```
>>> s.pct_change(periods=2)
0      NaN
1      NaN
2   -0.055556
dtype: float64
```

See the percentage change in a Series where filling NAs with last valid observation forward to next valid.

```
>>> s = pd.Series([90, 91, None, 85])
>>> s
0    90.0
1    91.0
2     NaN
3    85.0
dtype: float64
```

```
>>> s.pct_change(fill_method='ffill')
0      NaN
1    0.011111
2    0.000000
3   -0.065934
dtype: float64
```

### DataFrame

Percentage change in French franc, Deutsche Mark, and Italian lira from 1980-01-01 to 1980-03-01.

```
>>> df = pd.DataFrame({
...     'FR': [4.0405, 4.0963, 4.3149],
...     'GR': [1.7246, 1.7482, 1.8519],
...     'IT': [804.74, 810.01, 860.13]},
...     index=['1980-01-01', '1980-02-01', '1980-03-01'])
>>> df
```

|            | FR     | GR     | IT     |
|------------|--------|--------|--------|
| 1980-01-01 | 4.0405 | 1.7246 | 804.74 |
| 1980-02-01 | 4.0963 | 1.7482 | 810.01 |
| 1980-03-01 | 4.3149 | 1.8519 | 860.13 |

(continues on next page)

(continued from previous page)

|            |        |        |        |
|------------|--------|--------|--------|
| 1980-01-01 | 4.0405 | 1.7246 | 804.74 |
| 1980-02-01 | 4.0963 | 1.7482 | 810.01 |
| 1980-03-01 | 4.3149 | 1.8519 | 860.13 |

```
>>> df.pct_change()
              FR          GR          IT

1980-03-01  0.053365  0.059318  0.061876
```

Percentage of change in GOOG and APPL stock volume. Shows computing the percentage change between columns.

```
>>> df = pd.DataFrame({
...     '2016': [1769950, 30586265],
...     '2015': [1500923, 40912316],
...     '2014': [1371819, 41403351]},
...     index=['GOOG', 'APPL'])
>>> df
              2016          2015          2014
GOOG    1769950    1500923    1371819
APPL    30586265    40912316    41403351
```

```
>>> df.pct_change(axis='columns')
              2016          2015          2014
GOOG      NaN -0.151997 -0.086016
APPL      NaN  0.337604  0.012002
```

## pandas.Series.pipe

`Series.pipe(func, *args, **kwargs)`  
Apply `func(self, *args, **kwargs)`.

### Parameters

**func** [function] function to apply to the NDFrame. `args`, and `kwargs` are passed into `func`. Alternatively a (callable, `data_keyword`) tuple where `data_keyword` is a string indicating the keyword of callable that expects the NDFrame.

**args** [iterable, optional] positional arguments passed into `func`.

**kwargs** [mapping, optional] a dictionary of keyword arguments passed into `func`.

### Returns

**object** [the return type of `func`.]

### See also:

`DataFrame.apply`, `DataFrame.applymap`, `Series.map`

## Notes

Use `.pipe` when chaining together functions that expect Series, DataFrames or GroupBy objects. Instead of writing

```
>>> f(g(h(df), arg1=a), arg2=b, arg3=c)
```

You can write

```
>>> (df.pipe(h)
...   .pipe(g, arg1=a)
...   .pipe(f, arg2=b, arg3=c)
... )
```

If you have a function that takes the data as (say) the second argument, pass a tuple indicating which keyword expects the data. For example, suppose `f` takes its data as `arg2`:

```
>>> (df.pipe(h)
...   .pipe(g, arg1=a)
...   .pipe((f, 'arg2'), arg1=a, arg3=c)
... )
```

## pandas.Series.plot

`Series.plot` (*kind='line', ax=None, figsize=None, use\_index=True, title=None, grid=None, legend=False, style=None, logx=False, logy=False, loglog=False, xticks=None, yticks=None, xlim=None, ylim=None, rot=None, fontsize=None, colormap=None, table=False, yerr=None, xerr=None, label=None, secondary\_y=False, \*\*kwargs*)

Make plots of Series using matplotlib / pylab.

*New in version 0.17.0:* Each plot kind has a corresponding method on the `Series.plot` accessor: `s.plot(kind='line')` is equivalent to `s.plot.line()`.

### Parameters

**data** [Series]

**kind** [str]

- 'line' : line plot (default)
- 'bar' : vertical bar plot
- 'barh' : horizontal bar plot
- 'hist' : histogram
- 'box' : boxplot
- 'kde' : Kernel Density Estimation plot
- 'density' : same as 'kde'
- 'area' : area plot
- 'pie' : pie plot

**ax** [matplotlib axes object] If not passed, uses `gca()`

**figsize** [a tuple (width, height) in inches]

**use\_index** [boolean, default True] Use index as ticks for x axis

**title** [string or list] Title to use for the plot. If a string is passed, print the string at the top of the figure. If a list is passed and *subplots* is True, print each item in the list above the corresponding subplot.

**grid** [boolean, default None (matlab style default)] Axis grid lines

**legend** [False/True/'reverse'] Place legend on axis subplots

**style** [list or dict] matplotlib line style per column

**logx** [boolean, default False] Use log scaling on x axis

**logy** [boolean, default False] Use log scaling on y axis

**loglog** [boolean, default False] Use log scaling on both x and y axes

**xticks** [sequence] Values to use for the xticks

**yticks** [sequence] Values to use for the yticks

**xlim** [2-tuple/list]

**ylim** [2-tuple/list]

**rot** [int, default None] Rotation for ticks (xticks for vertical, yticks for horizontal plots)

**fontsize** [int, default None] Font size for xticks and yticks

**colormap** [str or matplotlib colormap object, default None] Colormap to select colors from. If string, load colormap with that name from matplotlib.

**colorbar** [boolean, optional] If True, plot colorbar (only relevant for 'scatter' and 'hexbin' plots)

**position** [float] Specify relative alignments for bar plot layout. From 0 (left/bottom-end) to 1 (right/top-end). Default is 0.5 (center)

**table** [boolean, Series or DataFrame, default False] If True, draw a table using the data in the DataFrame and the data will be transposed to meet matplotlib's default layout. If a Series or DataFrame is passed, use passed data to draw a table.

**yerr** [DataFrame, Series, array-like, dict and str] See *Plotting with Error Bars* for detail.

**xerr** [same types as yerr.]

**label** [label argument to provide to plot]

**secondary\_y** [boolean or sequence of ints, default False] If True then y-axis will be on the right

**mark\_right** [boolean, default True] When using a secondary\_y axis, automatically mark the column labels with "(right)" in the legend

**\*\*\*kwds** [keywords] Options to pass to matplotlib plotting method

#### Returns

**axes** [matplotlib.axes.Axes or numpy.ndarray of them]

#### Notes

- See matplotlib documentation online for more on this subject
- If *kind* = 'bar' or 'barh', you can specify relative alignments for bar plot layout by *position* keyword. From 0 (left/bottom-end) to 1 (right/top-end). Default is 0.5 (center)

## pandas.Series.pop

`Series.pop(item)`

Return item and drop from frame. Raise `KeyError` if not found.

### Parameters

**item** [str] Column label to be popped

### Returns

**popped** [Series]

## Examples

```
>>> df = pd.DataFrame([('falcon', 'bird', 389.0),
...                     ('parrot', 'bird', 24.0),
...                     ('lion', 'mammal', 80.5),
...                     ('monkey', 'mammal', np.nan)],
...                     columns=('name', 'class', 'max_speed'))
>>> df
```

|   | name   | class  | max_speed |
|---|--------|--------|-----------|
| 0 | falcon | bird   | 389.0     |
| 1 | parrot | bird   | 24.0      |
| 2 | lion   | mammal | 80.5      |
| 3 | monkey | mammal | NaN       |

```
>>> df.pop('class')
0      bird
1      bird
2    mammal
3    mammal
Name: class, dtype: object
```

```
>>> df
```

|   | name   | max_speed |
|---|--------|-----------|
| 0 | falcon | 389.0     |
| 1 | parrot | 24.0      |
| 2 | lion   | 80.5      |
| 3 | monkey | NaN       |

## pandas.Series.pow

`Series.pow(other, level=None, fill_value=None, axis=0)`

Exponential power of series and other, element-wise (binary operator *pow*).

Equivalent to `series ** other`, but with support to substitute a `fill_value` for missing data in one of the inputs.

### Parameters

**other** [Series or scalar value]

**fill\_value** [None or float value, default None (NaN)] Fill existing missing (NaN) values, and any new element needed for successful Series alignment, with this value before computation. If data in both corresponding Series locations is missing the result will be missing

**level** [int or name] Broadcast across a level, matching Index values on the passed Multi-Index level

### Returns

**result** [Series]

### See also:

*Series.rpow*

### Examples

```
>>> a = pd.Series([1, 1, 1, np.nan], index=['a', 'b', 'c', 'd'])
>>> a
a    1.0
b    1.0
c    1.0
d    NaN
dtype: float64
>>> b = pd.Series([1, np.nan, 1, np.nan], index=['a', 'b', 'd', 'e'])
>>> b
a    1.0
b    NaN
d    1.0
e    NaN
dtype: float64
>>> a.add(b, fill_value=0)
a    2.0
b    1.0
c    1.0
d    1.0
e    NaN
dtype: float64
```

## pandas.Series.prod

`Series.prod(axis=None, skipna=None, level=None, numeric_only=None, min_count=0, **kwargs)`

Return the product of the values for the requested axis.

### Parameters

**axis** [{index (0)}] Axis for the function to be applied on.

**skipna** [bool, default True] Exclude NA/null values when computing the result.

**level** [int or level name, default None] If the axis is a MultiIndex (hierarchical), count along a particular level, collapsing into a scalar.

**numeric\_only** [bool, default None] Include only float, int, boolean columns. If None, will attempt to use everything, then use only numeric data. Not implemented for Series.

**min\_count** [int, default 0] The required number of valid values to perform the operation. If fewer than `min_count` non-NA values are present the result will be NA.

New in version 0.22.0: Added with the default being 0. This means the sum of an all-NA or empty Series is 0, and the product of an all-NA or empty Series is 1.

**\*\*kwargs** Additional keyword arguments to be passed to the function.

### Returns

**prod** [scalar or Series (if level specified)]

### Examples

By default, the product of an empty or all-NA Series is 1

```
>>> pd.Series([]).prod()
1.0
```

This can be controlled with the `min_count` parameter

```
>>> pd.Series([]).prod(min_count=1)
nan
```

Thanks to the `skipna` parameter, `min_count` handles all-NA and empty series identically.

```
>>> pd.Series([np.nan]).prod()
1.0
```

```
>>> pd.Series([np.nan]).prod(min_count=1)
nan
```

## pandas.Series.product

`Series.product` (*axis=None*, *skipna=None*, *level=None*, *numeric\_only=None*, *min\_count=0*, **\*\*kwargs**)

Return the product of the values for the requested axis.

### Parameters

**axis** [{index (0)}] Axis for the function to be applied on.

**skipna** [bool, default True] Exclude NA/null values when computing the result.

**level** [int or level name, default None] If the axis is a MultiIndex (hierarchical), count along a particular level, collapsing into a scalar.

**numeric\_only** [bool, default None] Include only float, int, boolean columns. If None, will attempt to use everything, then use only numeric data. Not implemented for Series.

**min\_count** [int, default 0] The required number of valid values to perform the operation. If fewer than `min_count` non-NA values are present the result will be NA.

New in version 0.22.0: Added with the default being 0. This means the sum of an all-NA or empty Series is 0, and the product of an all-NA or empty Series is 1.

**\*\*kwargs** Additional keyword arguments to be passed to the function.

### Returns

**prod** [scalar or Series (if level specified)]

## Examples

By default, the product of an empty or all-NA Series is 1

```
>>> pd.Series([]).prod()
1.0
```

This can be controlled with the `min_count` parameter

```
>>> pd.Series([]).prod(min_count=1)
nan
```

Thanks to the `skipna` parameter, `min_count` handles all-NA and empty series identically.

```
>>> pd.Series([np.nan]).prod()
1.0
```

```
>>> pd.Series([np.nan]).prod(min_count=1)
nan
```

## pandas.Series.ptp

`Series.ptp` (*axis=None, skipna=None, level=None, numeric\_only=None, \*\*kwargs*)

**Returns the difference between the maximum value and the** minimum value in the object. This is the equivalent of the `numpy.ndarray` method `ptp`.

Deprecated since version 0.24.0: Use `numpy.ptp` instead

### Parameters

**axis** [{index (0)}] Axis for the function to be applied on.

**skipna** [bool, default True] Exclude NA/null values when computing the result.

**level** [int or level name, default None] If the axis is a MultiIndex (hierarchical), count along a particular level, collapsing into a scalar.

**numeric\_only** [bool, default None] Include only float, int, boolean columns. If None, will attempt to use everything, then use only numeric data. Not implemented for Series.

**\*\*kwargs** Additional keyword arguments to be passed to the function.

### Returns

**ptp** [scalar or Series (if level specified)]

## pandas.Series.put

`Series.put` (*\*args, \*\*kwargs*)

Applies the `put` method to its *values* attribute if it has one.

**See also:**

`numpy.ndarray.put`

## pandas.Series.quantile

`Series.quantile` (*q=0.5, interpolation='linear'*)

Return value at the given quantile.

### Parameters

**q** [float or array-like, default 0.5 (50% quantile)] 0 <= q <= 1, the quantile(s) to compute

**interpolation** [{ 'linear', 'lower', 'higher', 'midpoint', 'nearest' }] New in version 0.18.0.

This optional parameter specifies the interpolation method to use, when the desired quantile lies between two data points *i* and *j*:

- linear:  $i + (j - i) * fraction$ , where *fraction* is the fractional part of the index surrounded by *i* and *j*.
- lower: *i*.
- higher: *j*.
- nearest: *i* or *j* whichever is nearest.
- midpoint:  $(i + j) / 2$ .

### Returns

**quantile** [float or Series] if *q* is an array, a Series will be returned where the index is *q* and the values are the quantiles.

### See also:

`core.window.Rolling.quantile`, `numpy.percentile`

### Examples

```
>>> s = pd.Series([1, 2, 3, 4])
>>> s.quantile(.5)
2.5
>>> s.quantile([.25, .5, .75])
0.25    1.75
0.50    2.50
0.75    3.25
dtype: float64
```

## pandas.Series.radd

`Series.radd` (*other, level=None, fill\_value=None, axis=0*)

Addition of series and other, element-wise (binary operator *radd*).

Equivalent to `other + series`, but with support to substitute a *fill\_value* for missing data in one of the inputs.

### Parameters

**other** [Series or scalar value]

**fill\_value** [None or float value, default None (NaN)] Fill existing missing (NaN) values, and any new element needed for successful Series alignment, with this value before

computation. If data in both corresponding Series locations is missing the result will be missing

**level** [int or name] Broadcast across a level, matching Index values on the passed Multi-Index level

### Returns

**result** [Series]

### See also:

`Series.add`

### Examples

```
>>> a = pd.Series([1, 1, 1, np.nan], index=['a', 'b', 'c', 'd'])
>>> a
a    1.0
b    1.0
c    1.0
d    NaN
dtype: float64
>>> b = pd.Series([1, np.nan, 1, np.nan], index=['a', 'b', 'd', 'e'])
>>> b
a    1.0
b    NaN
d    1.0
e    NaN
dtype: float64
>>> a.add(b, fill_value=0)
a    2.0
b    1.0
c    1.0
d    1.0
e    NaN
dtype: float64
```

## pandas.Series.rank

`Series.rank` (*axis=0, method='average', numeric\_only=None, na\_option='keep', ascending=True, pct=False*)

Compute numerical data ranks (1 through n) along axis. Equal values are assigned a rank that is the average of the ranks of those values.

### Parameters

**axis** [{0 or 'index', 1 or 'columns'}], default 0] index to direct ranking

**method** [{‘average’, ‘min’, ‘max’, ‘first’, ‘dense’}]

- average: average rank of group
- min: lowest rank in group
- max: highest rank in group
- first: ranks assigned in order they appear in the array
- dense: like ‘min’, but rank always increases by 1 between groups

**numeric\_only** [boolean, default None] Include only float, int, boolean data. Valid only for DataFrame or Panel objects

**na\_option** [{ 'keep', 'top', 'bottom' }]

- keep: leave NA values where they are
- top: smallest rank if ascending
- bottom: smallest rank if descending

**ascending** [boolean, default True] False for ranks by high (1) to low (N)

**pct** [boolean, default False] Computes percentage rank of data

#### Returns

**ranks** [same type as caller]

### pandas.Series.ravel

`Series.ravel (order='C')`

Return the flattened underlying data as an ndarray.

**See also:**

`numpy.ndarray.ravel`

### pandas.Series.rdiv

`Series.rdiv (other, level=None, fill_value=None, axis=0)`

Floating division of series and other, element-wise (binary operator *rtruediv*).

Equivalent to `other / series`, but with support to substitute a `fill_value` for missing data in one of the inputs.

#### Parameters

**other** [Series or scalar value]

**fill\_value** [None or float value, default None (NaN)] Fill existing missing (NaN) values, and any new element needed for successful Series alignment, with this value before computation. If data in both corresponding Series locations is missing the result will be missing

**level** [int or name] Broadcast across a level, matching Index values on the passed Multi-Index level

#### Returns

**result** [Series]

**See also:**

`Series.truediv`

### Examples

```
>>> a = pd.Series([1, 1, 1, np.nan], index=['a', 'b', 'c', 'd'])
>>> a
a    1.0
b    1.0
c    1.0
d    NaN
dtype: float64
>>> b = pd.Series([1, np.nan, 1, np.nan], index=['a', 'b', 'd', 'e'])
>>> b
a    1.0
b    NaN
d    1.0
e    NaN
dtype: float64
>>> a.add(b, fill_value=0)
a    2.0
b    1.0
c    1.0
d    1.0
e    NaN
dtype: float64
```

### pandas.Series.rdivmod

`Series.rdivmod(other, level=None, fill_value=None, axis=0)`

Integer division and modulo of series and other, element-wise (binary operator *rdivmod*).

Equivalent to `other.divmod(series)`, but with support to substitute a `fill_value` for missing data in one of the inputs.

#### Parameters

**other** [Series or scalar value]

**fill\_value** [None or float value, default None (NaN)] Fill existing missing (NaN) values, and any new element needed for successful Series alignment, with this value before computation. If data in both corresponding Series locations is missing the result will be missing

**level** [int or name] Broadcast across a level, matching Index values on the passed Multi-Index level

#### Returns

**result** [Series]

#### See also:

`Series.divmod`

### Examples

```
>>> a = pd.Series([1, 1, 1, np.nan], index=['a', 'b', 'c', 'd'])
>>> a
a    1.0
b    1.0
c    1.0
```

(continues on next page)

(continued from previous page)

```

d      NaN
dtype: float64
>>> b = pd.Series([1, np.nan, 1, np.nan], index=['a', 'b', 'd', 'e'])
>>> b
a      1.0
b      NaN
d      1.0
e      NaN
dtype: float64
>>> a.add(b, fill_value=0)
a      2.0
b      1.0
c      1.0
d      1.0
e      NaN
dtype: float64

```

### pandas.Series.reindex

`Series.reindex` (*index=None, \*\*kwargs*)

Conform Series to new index with optional filling logic, placing NA/NaN in locations having no value in the previous index. A new object is produced unless the new index is equivalent to the current one and `copy=False`.

#### Parameters

**index** [array-like, optional] New labels / index to conform to, should be specified using keywords. Preferably an Index object to avoid duplicating data

**method** [{None, 'backfill'/'bfill', 'pad'/'ffill', 'nearest'}] Method to use for filling holes in reindexed DataFrame. Please note: this is only applicable to DataFrames/Series with a monotonically increasing/decreasing index.

- None (default): don't fill gaps
- pad / ffill: propagate last valid observation forward to next valid
- backfill / bfill: use next valid observation to fill gap
- nearest: use nearest valid observations to fill gap

**copy** [bool, default True] Return a new object, even if the passed indexes are the same.

**level** [int or name] Broadcast across a level, matching Index values on the passed Multi-Index level.

**fill\_value** [scalar, default np.NaN] Value to use for missing values. Defaults to NaN, but can be any "compatible" value.

**limit** [int, default None] Maximum number of consecutive elements to forward or backward fill.

**tolerance** [optional] Maximum distance between original and new labels for inexact matches. The values of the index at the matching locations must satisfy the equation `abs(index[indexer] - target) <= tolerance`.

Tolerance may be a scalar value, which applies the same tolerance to all values, or list-like, which applies variable tolerance per element. List-like includes list, tuple,

array, Series, and must be the same size as the index and its dtype must exactly match the index's type.

New in version 0.21.0: (list-like tolerance)

### Returns

**Series with changed index.**

See also:

**DataFrame.set\_index** Set row labels.

**DataFrame.reset\_index** Remove row labels or move them to new columns.

**DataFrame.reindex\_like** Change to same indices as other DataFrame.

### Examples

DataFrame.reindex supports two calling conventions

- (index=index\_labels, columns=column\_labels, ...)
- (labels, axis={'index', 'columns'}, ...)

We *highly* recommend using keyword arguments to clarify your intent.

Create a dataframe with some fictional data.

```
>>> index = ['Firefox', 'Chrome', 'Safari', 'IE10', 'Konqueror']
>>> df = pd.DataFrame({
...     'http_status': [200, 200, 404, 404, 301],
...     'response_time': [0.04, 0.02, 0.07, 0.08, 1.0]},
...     index=index)
>>> df
```

|           | http_status | response_time |
|-----------|-------------|---------------|
| Firefox   | 200         | 0.04          |
| Chrome    | 200         | 0.02          |
| Safari    | 404         | 0.07          |
| IE10      | 404         | 0.08          |
| Konqueror | 301         | 1.00          |

Create a new index and reindex the dataframe. By default values in the new index that do not have corresponding records in the dataframe are assigned NaN.

```
>>> new_index= ['Safari', 'Iceweasel', 'Comodo Dragon', 'IE10',
...             'Chrome']
>>> df.reindex(new_index)
```

|               | http_status | response_time |
|---------------|-------------|---------------|
| Safari        | 404.0       | 0.07          |
| Iceweasel     | NaN         | NaN           |
| Comodo Dragon | NaN         | NaN           |
| IE10          | 404.0       | 0.08          |
| Chrome        | 200.0       | 0.02          |

We can fill in the missing values by passing a value to the keyword `fill_value`. Because the index is not monotonically increasing or decreasing, we cannot use arguments to the keyword `method` to fill the NaN values.

```
>>> df.reindex(new_index, fill_value=0)
           http_status  response_time
Safari                404            0.07
Iceweasel              0            0.00
Comodo Dragon          0            0.00
IE10                  404            0.08
Chrome                200            0.02
```

```
>>> df.reindex(new_index, fill_value='missing')
           http_status  response_time
Safari                404            0.07
Iceweasel            missing          missing
Comodo Dragon        missing          missing
IE10                 404            0.08
Chrome              200            0.02
```

We can also reindex the columns.

```
>>> df.reindex(columns=['http_status', 'user_agent'])
           http_status  user_agent
Firefox             200         NaN
Chrome              200         NaN
Safari              404         NaN
IE10                404         NaN
Konqueror           301         NaN
```

Or we can use “axis-style” keyword arguments

```
>>> df.reindex(['http_status', 'user_agent'], axis="columns")
           http_status  user_agent
Firefox             200         NaN
Chrome              200         NaN
Safari              404         NaN
IE10                404         NaN
Konqueror           301         NaN
```

To further illustrate the filling functionality in `reindex`, we will create a dataframe with a monotonically increasing index (for example, a sequence of dates).

```
>>> date_index = pd.date_range('1/1/2010', periods=6, freq='D')
>>> df2 = pd.DataFrame({"prices": [100, 101, np.nan, 100, 89, 88]},
...                    index=date_index)
>>> df2
           prices
2010-01-01    100.0
2010-01-02    101.0
2010-01-03         NaN
2010-01-04    100.0
2010-01-05     89.0
2010-01-06     88.0
```

Suppose we decide to expand the dataframe to cover a wider date range.

```
>>> date_index2 = pd.date_range('12/29/2009', periods=10, freq='D')
>>> df2.reindex(date_index2)
           prices
2009-12-29     NaN
```

(continues on next page)

(continued from previous page)

|            |       |
|------------|-------|
| 2009-12-30 | NaN   |
| 2009-12-31 | NaN   |
| 2010-01-01 | 100.0 |
| 2010-01-02 | 101.0 |
| 2010-01-03 | NaN   |
| 2010-01-04 | 100.0 |
| 2010-01-05 | 89.0  |
| 2010-01-06 | 88.0  |
| 2010-01-07 | NaN   |

The index entries that did not have a value in the original data frame (for example, '2009-12-29') are by default filled with NaN. If desired, we can fill in the missing values using one of several options.

For example, to back-propagate the last valid value to fill the NaN values, pass `bfill` as an argument to the `method` keyword.

```
>>> df2.reindex(date_index2, method='bfill')
prices
2009-12-29    100.0
2009-12-30    100.0
2009-12-31    100.0
2010-01-01    100.0
2010-01-02    101.0
2010-01-03     NaN
2010-01-04    100.0
2010-01-05     89.0
2010-01-06     88.0
2010-01-07     NaN
```

Please note that the NaN value present in the original dataframe (at index value 2010-01-03) will not be filled by any of the value propagation schemes. This is because filling while reindexing does not look at dataframe values, but only compares the original and desired indexes. If you do want to fill in the NaN values present in the original dataframe, use the `fillna()` method.

See the *user guide* for more.

## pandas.Series.reindex\_axis

`Series.reindex_axis(labels, axis=0, **kwargs)`

Conform Series to new index with optional filling logic.

Deprecated since version 0.21.0: Use `Series.reindex` instead.

## pandas.Series.reindex\_like

`Series.reindex_like(other, method=None, copy=True, limit=None, tolerance=None)`

Return an object with matching indices as other object.

Conform the object to the same index on all axes. Optional filling logic, placing NaN in locations having no value in the previous index. A new object is produced unless the new index is equivalent to the current one and `copy=False`.

### Parameters

**other** [Object of the same data type] Its row and column indices are used to define the new indices of this object.

**method** [{None, 'backfill'/'bfill', 'pad'/'ffill', 'nearest'}] Method to use for filling holes in reindexed DataFrame. Please note: this is only applicable to DataFrames/Series with a monotonically increasing/decreasing index.

- None (default): don't fill gaps
- pad / ffill: propagate last valid observation forward to next valid
- backfill / bfill: use next valid observation to fill gap
- nearest: use nearest valid observations to fill gap

**copy** [bool, default True] Return a new object, even if the passed indexes are the same.

**limit** [int, default None] Maximum number of consecutive labels to fill for inexact matches.

**tolerance** [optional] Maximum distance between original and new labels for inexact matches. The values of the index at the matching locations must satisfy the equation  $\text{abs}(\text{index}[\text{indexer}] - \text{target}) \leq \text{tolerance}$ .

Tolerance may be a scalar value, which applies the same tolerance to all values, or list-like, which applies variable tolerance per element. List-like includes list, tuple, array, Series, and must be the same size as the index and its dtype must exactly match the index's type.

New in version 0.21.0: (list-like tolerance)

### Returns

**Series or DataFrame** Same type as caller, but with changed indices on each axis.

See also:

**DataFrame.set\_index** Set row labels.

**DataFrame.reset\_index** Remove row labels or move them to new columns.

**DataFrame.reindex** Change to new indices or expand indices.

### Notes

Same as calling `.reindex(index=other.index, columns=other.columns, ...)`.

### Examples

```
>>> df1 = pd.DataFrame([[24.3, 75.7, 'high'],
...                     [31, 87.8, 'high'],
...                     [22, 71.6, 'medium'],
...                     [35, 95, 'medium']],
...                     columns=['temp_celsius', 'temp_fahrenheit', 'windspeed'],
...                     index=pd.date_range(start='2014-02-12',
...                                         end='2014-02-15', freq='D'))
```

```
>>> df1
           temp_celsius  temp_fahrenheit  windspeed
2014-02-12          24.3             75.7         high
2014-02-13          31.0             87.8         high
2014-02-14          22.0             71.6        medium
2014-02-15          35.0             95.0        medium
```

```
>>> df2 = pd.DataFrame([[28, 'low'],
...                     [30, 'low'],
...                     [35.1, 'medium']],
...                     columns=['temp_celsius', 'windspeed'],
...                     index=pd.DatetimeIndex(['2014-02-12', '2014-02-13',
...                                             '2014-02-15']))
```

```
>>> df2
           temp_celsius windspeed
2014-02-12          28.0        low
2014-02-13          30.0        low
2014-02-15          35.1    medium
```

```
>>> df2.reindex_like(df1)
           temp_celsius  temp_fahrenheit windspeed
2014-02-12          28.0              NaN        low
2014-02-13          30.0              NaN        low
2014-02-14           NaN              NaN        NaN
2014-02-15          35.1              NaN    medium
```

## pandas.Series.rename

`Series.rename(index=None, **kwargs)`

Alter Series index labels or name.

Function / dict values must be unique (1-to-1). Labels not contained in a dict / Series will be left as-is. Extra labels listed don't throw an error.

Alternatively, change `Series.name` with a scalar value.

See the *user guide* for more.

### Parameters

**index** [scalar, hashable sequence, dict-like or function, optional] dict-like or functions are transformations to apply to the index. Scalar or hashable sequence-like will alter the `Series.name` attribute.

**copy** [bool, default True] Also copy underlying data

**inplace** [bool, default False] Whether to return a new Series. If True then value of copy is ignored.

**level** [int or level name, default None] In case of a MultiIndex, only rename labels in the specified level.

### Returns

**renamed** [Series (new object)]

See also:

`Series.rename_axis`

## Examples

```

>>> s = pd.Series([1, 2, 3])
>>> s
0    1
1    2
2    3
dtype: int64
>>> s.rename("my_name") # scalar, changes Series.name
0    1
1    2
2    3
Name: my_name, dtype: int64
>>> s.rename(lambda x: x ** 2) # function, changes labels
0    1
1    2
4    3
dtype: int64
>>> s.rename({1: 3, 2: 5}) # mapping, changes labels
0    1
3    2
5    3
dtype: int64

```

### pandas.Series.rename\_axis

**Series.rename\_axis** (*mapper=None, index=None, columns=None, axis=None, copy=True, inplace=False*)

Set the name of the axis for the index or columns.

#### Parameters

**mapper** [scalar, list-like, optional] Value to set the axis name attribute.

**index, columns** [scalar, list-like, dict-like or function, optional] A scalar, list-like, dict-like or functions transformations to apply to that axis' values.

Use either **mapper** and **axis** to specify the axis to target with **mapper**, or **index** and/or **columns**.

Changed in version 0.24.0.

**axis** [{0 or 'index', 1 or 'columns'}, default 0] The axis to rename.

**copy** [bool, default True] Also copy underlying data.

**inplace** [bool, default False] Modifies the object directly, instead of creating a new Series or DataFrame.

#### Returns

**Series, DataFrame, or None** The same type as the caller or None if *inplace* is True.

See also:

**Series.rename** Alter Series index labels or name.

**DataFrame.rename** Alter DataFrame index labels or name.

**Index.rename** Set new names on index.

## Notes

Prior to version 0.21.0, `rename_axis` could also be used to change the axis *labels* by passing a mapping or scalar. This behavior is deprecated and will be removed in a future version. Use `rename` instead.

`DataFrame.rename_axis` supports two calling conventions

- `(index=index_mapper, columns=columns_mapper, ...)`
- `(mapper, axis={'index', 'columns'}, ...)`

The first calling convention will only modify the names of the index and/or the names of the Index object that is the columns. In this case, the parameter `copy` is ignored.

The second calling convention will modify the names of the the corresponding index if `mapper` is a list or a scalar. However, if `mapper` is dict-like or a function, it will use the deprecated behavior of modifying the axis *labels*.

We *highly* recommend using keyword arguments to clarify your intent.

## Examples

### Series

```
>>> s = pd.Series(["dog", "cat", "monkey"])
>>> s
0      dog
1      cat
2    monkey
dtype: object
>>> s.rename_axis("animal")
animal
0      dog
1      cat
2    monkey
dtype: object
```

### DataFrame

```
>>> df = pd.DataFrame({"num_legs": [4, 4, 2],
...                    "num_arms": [0, 0, 2]},
...                    ["dog", "cat", "monkey"])
>>> df
   num_legs  num_arms
dog         4         0
cat         4         0
monkey      2         2
>>> df = df.rename_axis("animal")
>>> df
   num_legs  num_arms
animal
dog         4         0
cat         4         0
monkey      2         2
>>> df = df.rename_axis("limbs", axis="columns")
>>> df
limbs  num_legs  num_arms
animal
```

(continues on next page)

(continued from previous page)

|        |   |   |
|--------|---|---|
| dog    | 4 | 0 |
| cat    | 4 | 0 |
| monkey | 2 | 2 |

**MultiIndex**

```
>>> df.index = pd.MultiIndex.from_product(['mammal'],
...                                       ['dog', 'cat', 'monkey']),
...                                       names=['type', 'name'])
>>> df
```

| limbs  |        | num_legs | num_arms |
|--------|--------|----------|----------|
| type   | name   |          |          |
| mammal | dog    | 4        | 0        |
|        | cat    | 4        | 0        |
|        | monkey | 2        | 2        |

```
>>> df.rename_axis(index={'type': 'class'})
```

| limbs  |        | num_legs | num_arms |
|--------|--------|----------|----------|
| class  | name   |          |          |
| mammal | dog    | 4        | 0        |
|        | cat    | 4        | 0        |
|        | monkey | 2        | 2        |

```
>>> df.rename_axis(columns=str.upper)
```

| LIMBS  |        | num_legs | num_arms |
|--------|--------|----------|----------|
| type   | name   |          |          |
| mammal | dog    | 4        | 0        |
|        | cat    | 4        | 0        |
|        | monkey | 2        | 2        |

**pandas.Series.reorder\_levels****Series.reorder\_levels** (*order*)

Rearrange index levels using input order.

May not drop or duplicate levels.

**Parameters****order** [list of int representing new level order] (reference level by number or key)**Returns****type of caller (new object)****pandas.Series.repeat****Series.repeat** (*repeats*, *axis=None*)

Repeat elements of a Series.

Returns a new Series where each element of the current Series is repeated consecutively a given number of times.

**Parameters**

**repeats** [int or array of ints] The number of repetitions for each element. This should be a non-negative integer. Repeating 0 times will return an empty Series.

**axis** [None] Must be `None`. Has no effect but is accepted for compatibility with numpy.

#### Returns

**repeated\_series** [Series] Newly created Series with repeated elements.

See also:

**Index.repeat** Equivalent function for Index.

**numpy.repeat** Similar method for `numpy.ndarray`.

#### Examples

```
>>> s = pd.Series(['a', 'b', 'c'])
>>> s
0    a
1    b
2    c
dtype: object
>>> s.repeat(2)
0    a
0    a
1    b
1    b
2    c
2    c
dtype: object
>>> s.repeat([1, 2, 3])
0    a
1    b
1    b
2    c
2    c
2    c
dtype: object
```

#### pandas.Series.replace

`Series.replace(to_replace=None, value=None, inplace=False, limit=None, regex=False, method='pad')`

Replace values given in *to\_replace* with *value*.

Values of the Series are replaced with other values dynamically. This differs from updating with `.loc` or `.iloc`, which require you to specify a location to update with some value.

#### Parameters

**to\_replace** [str, regex, list, dict, Series, int, float, or None] How to find the values that will be replaced.

- numeric, str or regex:
  - numeric: numeric values equal to *to\_replace* will be replaced with *value*
  - str: string exactly matching *to\_replace* will be replaced with *value*

- regex: regexs matching *to\_replace* will be replaced with *value*
- list of str, regex, or numeric:
  - First, if *to\_replace* and *value* are both lists, they **must** be the same length.
  - Second, if *regex=True* then all of the strings in **both** lists will be interpreted as regexs otherwise they will match directly. This doesn't matter much for *value* since there are only a few possible substitution regexes you can use.
  - str, regex and numeric rules apply as above.
- dict:
  - Dicts can be used to specify different replacement values for different existing values. For example, `{ 'a': 'b', 'y': 'z' }` replaces the value 'a' with 'b' and 'y' with 'z'. To use a dict in this way the *value* parameter should be *None*.
  - For a DataFrame a dict can specify that different values should be replaced in different columns. For example, `{ 'a': 1, 'b': 'z' }` looks for the value 1 in column 'a' and the value 'z' in column 'b' and replaces these values with whatever is specified in *value*. The *value* parameter should not be *None* in this case. You can treat this as a special case of passing two lists except that you are specifying the column to search in.
  - For a DataFrame nested dictionaries, e.g., `{ 'a': { 'b': np.nan } }`, are read as follows: look in column 'a' for the value 'b' and replace it with NaN. The *value* parameter should be *None* to use a nested dict in this way. You can nest regular expressions as well. Note that column names (the top-level dictionary keys in a nested dictionary) **cannot** be regular expressions.
- None:
  - This means that the *regex* argument must be a string, compiled regular expression, or list, dict, ndarray or Series of such elements. If *value* is also *None* then this **must** be a nested dictionary or Series.

See the examples section for examples of each of these.

**value** [scalar, dict, list, str, regex, default None] Value to replace any values matching *to\_replace* with. For a DataFrame a dict of values can be used to specify which value to use for each column (columns not in the dict will not be filled). Regular expressions, strings and lists or dicts of such objects are also allowed.

**inplace** [bool, default False] If True, in place. Note: this will modify any other views on this object (e.g. a column from a DataFrame). Returns the caller if this is True.

**limit** [int, default None] Maximum size gap to forward or backward fill.

**regex** [bool or same types as *to\_replace*, default False] Whether to interpret *to\_replace* and/or *value* as regular expressions. If this is *True* then *to\_replace* *must* be a string. Alternatively, this could be a regular expression or a list, dict, or array of regular expressions in which case *to\_replace* *must* be *None*.

**method** [{ 'pad', 'ffill', 'bfill', *None* }] The method to use when for replacement, when *to\_replace* is a scalar, list or tuple and *value* is *None*.

Changed in version 0.23.0: Added to DataFrame.

## Returns

**Series** Object after replacement.

**Raises****AssertionError**

- If *regex* is not a `bool` and *to\_replace* is not `None`.

**TypeError**

- If *to\_replace* is a `dict` and *value* is not a `list`, `dict`, `ndarray`, or `Series`
- If *to\_replace* is `None` and *regex* is not compilable into a regular expression or is a `list`, `dict`, `ndarray`, or `Series`.
- When replacing multiple `bool` or `datetime64` objects and the arguments to *to\_replace* does not match the type of the value being replaced

**ValueError**

- If a `list` or an `ndarray` is passed to *to\_replace* and *value* but they are not the same length.

**See also:**

***Series.fillna*** Fill NA values.

***Series.where*** Replace values based on boolean condition.

***Series.str.replace*** Simple string replacement.

**Notes**

- Regex substitution is performed under the hood with `re.sub`. The rules for substitution for `re.sub` are the same.
- Regular expressions will only substitute on strings, meaning you cannot provide, for example, a regular expression matching floating point numbers and expect the columns in your frame that have a numeric dtype to be matched. However, if those floating point numbers *are* strings, then you can do this.
- This method has *a lot* of options. You are encouraged to experiment and play with this method to gain intuition about how it works.
- When `dict` is used as the *to\_replace* value, it is like `key(s)` in the `dict` are the *to\_replace* part and `value(s)` in the `dict` are the *value* parameter.

**Examples****Scalar ‘to\_replace’ and ‘value’**

```
>>> s = pd.Series([0, 1, 2, 3, 4])
>>> s.replace(0, 5)
0    5
1    1
2    2
3    3
4    4
dtype: int64
```

```
>>> df = pd.DataFrame({'A': [0, 1, 2, 3, 4],
...                     'B': [5, 6, 7, 8, 9],
...                     'C': ['a', 'b', 'c', 'd', 'e']})
>>> df.replace(0, 5)
   A  B  C
0  5  5  a
1  1  6  b
2  2  7  c
3  3  8  d
4  4  9  e
```

**List-like ‘to\_replace’**

```
>>> df.replace([0, 1, 2, 3], 4)
   A  B  C
0  4  5  a
1  4  6  b
2  4  7  c
3  4  8  d
4  4  9  e
```

```
>>> df.replace([0, 1, 2, 3], [4, 3, 2, 1])
   A  B  C
0  4  5  a
1  3  6  b
2  2  7  c
3  1  8  d
4  4  9  e
```

```
>>> s.replace([1, 2], method='bfill')
0    0
1    3
2    3
3    3
4    4
dtype: int64
```

**dict-like ‘to\_replace’**

```
>>> df.replace({0: 10, 1: 100})
   A  B  C
0  10  5  a
1 100  6  b
2   2  7  c
3   3  8  d
4   4  9  e
```

```
>>> df.replace({'A': 0, 'B': 5}, 100)
   A   B  C
0 100 100  a
1   1   6  b
2   2   7  c
3   3   8  d
4   4   9  e
```

```
>>> df.replace({'A': {0: 100, 4: 400}})
   A  B  C
0 100  5  a
1   1  6  b
2   2  7  c
3   3  8  d
4 400  9  e
```

**Regular expression ‘to\_replace’**

```
>>> df = pd.DataFrame({'A': ['bat', 'foo', 'bait'],
...                     'B': ['abc', 'bar', 'xyz']})
>>> df.replace(to_replace=r'^ba.$', value='new', regex=True)
   A  B
0  new abc
1  foo new
2  bait xyz
```

```
>>> df.replace({'A': r'^ba.$'}, {'A': 'new'}, regex=True)
   A  B
0  new abc
1  foo bar
2  bait xyz
```

```
>>> df.replace(regex=r'^ba.$', value='new')
   A  B
0  new abc
1  foo new
2  bait xyz
```

```
>>> df.replace(regex={'r'^ba.$': 'new', 'foo': 'xyz'})
   A  B
0  new abc
1  xyz new
2  bait xyz
```

```
>>> df.replace(regex=[r'^ba.$', 'foo'], value='new')
   A  B
0  new abc
1  new new
2  bait xyz
```

Note that when replacing multiple bool or datetime64 objects, the data types in the *to\_replace* parameter must match the data type of the value being replaced:

```
>>> df = pd.DataFrame({'A': [True, False, True],
...                     'B': [False, True, False]})
>>> df.replace({'a string': 'new value', True: False}) # raises
Traceback (most recent call last):
...
TypeError: Cannot compare types 'ndarray(dtype=bool)' and 'str'
```

This raises a `TypeError` because one of the dict keys is not of the correct type for replacement.

Compare the behavior of `s.replace({'a': None})` and `s.replace('a', None)` to understand the peculiarities of the *to\_replace* parameter:

```
>>> s = pd.Series([10, 'a', 'a', 'b', 'a'])
```

When one uses a dict as the *to\_replace* value, it is like the value(s) in the dict are equal to the *value* parameter. `s.replace({'a': None})` is equivalent to `s.replace(to_replace={'a': None}, value=None, method=None)`:

```
>>> s.replace({'a': None})
0      10
1     None
2     None
3        b
4     None
dtype: object
```

When *value=None* and *to\_replace* is a scalar, list or tuple, *replace* uses the *method* parameter (default 'pad') to do the replacement. So this is why the 'a' values are being replaced by 10 in rows 1 and 2 and 'b' in row 4 in this case. The command `s.replace('a', None)` is actually equivalent to `s.replace(to_replace='a', value=None, method='pad')`:

```
>>> s.replace('a', None)
0      10
1      10
2      10
3        b
4        b
dtype: object
```

## pandas.Series.resample

`Series.resample(rule, how=None, axis=0, fill_method=None, closed=None, label=None, convention='start', kind=None, loffset=None, limit=None, base=0, on=None, level=None)`

Resample time-series data.

Convenience method for frequency conversion and resampling of time series. Object must have a datetime-like index (*DatetimeIndex*, *PeriodIndex*, or *TimedeltaIndex*), or pass datetime-like values to the *on* or *level* keyword.

### Parameters

**rule** [str] The offset string or object representing target conversion.

**how** [str] Method for down/re-sampling, default to 'mean' for downsampling.

Deprecated since version 0.18.0: The new syntax is `.resample(...).mean()`, or `.resample(...).apply(<func>)`

**axis** [{0 or 'index', 1 or 'columns'}, default 0] Which axis to use for up- or down-sampling. For *Series* this will default to 0, i.e. along the rows. Must be *DatetimeIndex*, *TimedeltaIndex* or *PeriodIndex*.

**fill\_method** [str, default None] Filling method for upsampling.

Deprecated since version 0.18.0: The new syntax is `.resample(...).<func>()`, e.g. `.resample(...).pad()`

**closed** [{‘right’, ‘left’}, default None] Which side of bin interval is closed. The default is ‘left’ for all frequency offsets except for ‘M’, ‘A’, ‘Q’, ‘BM’, ‘BA’, ‘BQ’, and ‘W’ which all have a default of ‘right’.

**label** [{‘right’, ‘left’}, default None] Which bin edge label to label bucket with. The default is ‘left’ for all frequency offsets except for ‘M’, ‘A’, ‘Q’, ‘BM’, ‘BA’, ‘BQ’, and ‘W’ which all have a default of ‘right’.

**convention** [{‘start’, ‘end’, ‘s’, ‘e’}, default ‘start’] For *PeriodIndex* only, controls whether to use the start or end of *rule*.

**kind** [{‘timestamp’, ‘period’}, optional, default None] Pass ‘timestamp’ to convert the resulting index to a *DateTimeIndex* or ‘period’ to convert it to a *PeriodIndex*. By default the input representation is retained.

**loffset** [timedelta, default None] Adjust the resampled time labels.

**limit** [int, default None] Maximum size gap when reindexing with *fill\_method*.

Deprecated since version 0.18.0.

**base** [int, default 0] For frequencies that evenly subdivide 1 day, the “origin” of the aggregated intervals. For example, for ‘5min’ frequency, base could range from 0 through 4. Defaults to 0.

**on** [str, optional] For a DataFrame, column to use instead of index for resampling. Column must be datetime-like.

New in version 0.19.0.

**level** [str or int, optional] For a MultiIndex, level (name or number) to use for resampling. *level* must be datetime-like.

New in version 0.19.0.

## Returns

### Resampler object

See also:

**groupby** Group by mapping, function, label, or list of labels.

**Series.resample** Resample a Series.

**DataFrame.resample** Resample a DataFrame.

## Notes

See the [user guide](#) for more.

To learn more about the offset strings, please see [this link](#).

## Examples

Start by creating a series with 9 one minute timestamps.

```
>>> index = pd.date_range('1/1/2000', periods=9, freq='T')
>>> series = pd.Series(range(9), index=index)
>>> series
2000-01-01 00:00:00    0
```

(continues on next page)

(continued from previous page)

```

2000-01-01 00:01:00    1
2000-01-01 00:02:00    2
2000-01-01 00:03:00    3
2000-01-01 00:04:00    4
2000-01-01 00:05:00    5
2000-01-01 00:06:00    6
2000-01-01 00:07:00    7
2000-01-01 00:08:00    8
Freq: T, dtype: int64

```

Downsample the series into 3 minute bins and sum the values of the timestamps falling into a bin.

```

>>> series.resample('3T').sum()
2000-01-01 00:00:00    3
2000-01-01 00:03:00   12
2000-01-01 00:06:00   21
Freq: 3T, dtype: int64

```

Downsample the series into 3 minute bins as above, but label each bin using the right edge instead of the left. Please note that the value in the bucket used as the label is not included in the bucket, which it labels. For example, in the original series the bucket 2000-01-01 00:03:00 contains the value 3, but the summed value in the resampled bucket with the label 2000-01-01 00:03:00 does not include 3 (if it did, the summed value would be 6, not 3). To include this value close the right side of the bin interval as illustrated in the example below this one.

```

>>> series.resample('3T', label='right').sum()
2000-01-01 00:03:00    3
2000-01-01 00:06:00   12
2000-01-01 00:09:00   21
Freq: 3T, dtype: int64

```

Downsample the series into 3 minute bins as above, but close the right side of the bin interval.

```

>>> series.resample('3T', label='right', closed='right').sum()
2000-01-01 00:00:00    0
2000-01-01 00:03:00    6
2000-01-01 00:06:00   15
2000-01-01 00:09:00   15
Freq: 3T, dtype: int64

```

Upsample the series into 30 second bins.

```

>>> series.resample('30S').asfreq()[0:5]    # Select first 5 rows
2000-01-01 00:00:00    0.0
2000-01-01 00:00:30   NaN
2000-01-01 00:01:00    1.0
2000-01-01 00:01:30   NaN
2000-01-01 00:02:00    2.0
Freq: 30S, dtype: float64

```

Upsample the series into 30 second bins and fill the NaN values using the pad method.

```

>>> series.resample('30S').pad()[0:5]
2000-01-01 00:00:00    0
2000-01-01 00:00:30    0
2000-01-01 00:01:00    1

```

(continues on next page)

(continued from previous page)

```

2000-01-01 00:01:30    1
2000-01-01 00:02:00    2
Freq: 30S, dtype: int64

```

Upsample the series into 30 second bins and fill the NaN values using the `bfill` method.

```

>>> series.resample('30S').bfill()[0:5]
2000-01-01 00:00:00    0
2000-01-01 00:00:30    1
2000-01-01 00:01:00    1
2000-01-01 00:01:30    2
2000-01-01 00:02:00    2
Freq: 30S, dtype: int64

```

Pass a custom function via `apply`

```

>>> def custom_resampler(array_like):
...     return np.sum(array_like) + 5
...
>>> series.resample('3T').apply(custom_resampler)
2000-01-01 00:00:00     8
2000-01-01 00:03:00    17
2000-01-01 00:06:00    26
Freq: 3T, dtype: int64

```

For a Series with a PeriodIndex, the keyword *convention* can be used to control whether to use the start or end of *rule*.

Resample a year by quarter using ‘start’ *convention*. Values are assigned to the first quarter of the period.

```

>>> s = pd.Series([1, 2], index=pd.period_range('2012-01-01',
...                                             freq='A',
...                                             periods=2))
>>> s
2012    1
2013    2
Freq: A-DEC, dtype: int64
>>> s.resample('Q', convention='start').asfreq()
2012Q1    1.0
2012Q2    NaN
2012Q3    NaN
2012Q4    NaN
2013Q1    2.0
2013Q2    NaN
2013Q3    NaN
2013Q4    NaN
Freq: Q-DEC, dtype: float64

```

Resample quarters by month using ‘end’ *convention*. Values are assigned to the last month of the period.

```

>>> q = pd.Series([1, 2, 3, 4], index=pd.period_range('2018-01-01',
...                                             freq='Q',
...                                             periods=4))
>>> q
2018Q1    1
2018Q2    2
2018Q3    3

```

(continues on next page)

(continued from previous page)

```

2018Q4      4
Freq: Q-DEC, dtype: int64
>>> q.resample('M', convention='end').asfreq()
2018-03      1.0
2018-04      NaN
2018-05      NaN
2018-06      2.0
2018-07      NaN
2018-08      NaN
2018-09      3.0
2018-10      NaN
2018-11      NaN
2018-12      4.0
Freq: M, dtype: float64

```

For DataFrame objects, the keyword *on* can be used to specify the column instead of the index for resampling.

```

>>> d = dict({'price': [10, 11, 9, 13, 14, 18, 17, 19],
...          'volume': [50, 60, 40, 100, 50, 100, 40, 50]})
>>> df = pd.DataFrame(d)
>>> df['week_starting'] = pd.date_range('01/01/2018',
...                                     periods=8,
...                                     freq='W')
>>> df
   price  volume week_starting
0     10     50   2018-01-07
1     11     60   2018-01-14
2      9     40   2018-01-21
3     13    100   2018-01-28
4     14     50   2018-02-04
5     18    100   2018-02-11
6     17     40   2018-02-18
7     19     50   2018-02-25
>>> df.resample('M', on='week_starting').mean()
           price  volume
week_starting
2018-01-31    10.75    62.5
2018-02-28    17.00    60.0

```

For a DataFrame with MultiIndex, the keyword *level* can be used to specify on which level the resampling needs to take place.

```

>>> days = pd.date_range('1/1/2000', periods=4, freq='D')
>>> d2 = dict({'price': [10, 11, 9, 13, 14, 18, 17, 19],
...          'volume': [50, 60, 40, 100, 50, 100, 40, 50]})
>>> df2 = pd.DataFrame(d2,
...                    index=pd.MultiIndex.from_product([days,
...                                                       ['morning',
...                                                        'afternoon']])
>>> df2
           price  volume
2000-01-01 morning      10      50
           afternoon     11      60
2000-01-02 morning       9      40

```

(continues on next page)

(continued from previous page)

```

                afternoon    13    100
2000-01-03 morning    14     50
                afternoon    18    100
2000-01-04 morning    17     40
                afternoon    19     50
>>> df2.resample('D', level=0).sum()
           price  volume
2000-01-01     21     110
2000-01-02     22     140
2000-01-03     32     150
2000-01-04     36      90

```

## pandas.Series.reset\_index

`Series.reset_index` (*level=None, drop=False, name=None, inplace=False*)

Generate a new DataFrame or Series with the index reset.

This is useful when the index needs to be treated as a column, or when the index is meaningless and needs to be reset to the default before another operation.

### Parameters

**level** [int, str, tuple, or list, default optional] For a Series with a MultiIndex, only remove the specified levels from the index. Removes all levels by default.

**drop** [bool, default False] Just reset the index, without inserting it as a column in the new DataFrame.

**name** [object, optional] The name to use for the column containing the original Series values. Uses `self.name` by default. This argument is ignored when *drop* is True.

**inplace** [bool, default False] Modify the Series in place (do not create a new object).

### Returns

**Series or DataFrame** When *drop* is False (the default), a DataFrame is returned. The newly created columns will come first in the DataFrame, followed by the original Series values. When *drop* is True, a *Series* is returned. In either case, if *inplace=True*, no value is returned.

See also:

**DataFrame.reset\_index** Analogous function for DataFrame.

## Examples

```

>>> s = pd.Series([1, 2, 3, 4], name='foo',
...               index=pd.Index(['a', 'b', 'c', 'd'], name='idx'))

```

Generate a DataFrame with default index.

```

>>> s.reset_index()
   idx  foo
0    a    1
1    b    2

```

(continues on next page)

(continued from previous page)

|   |   |   |
|---|---|---|
| 2 | c | 3 |
| 3 | d | 4 |

To specify the name of the new column use *name*.

```
>>> s.reset_index(name='values')
   idx  values
0    a      1
1    b      2
2    c      3
3    d      4
```

To generate a new Series with the default set *drop* to True.

```
>>> s.reset_index(drop=True)
0    1
1    2
2    3
3    4
Name: foo, dtype: int64
```

To update the Series in place, without generating a new one set *inplace* to True. Note that it also requires *drop=True*.

```
>>> s.reset_index(inplace=True, drop=True)
>>> s
0    1
1    2
2    3
3    4
Name: foo, dtype: int64
```

The *level* parameter is interesting for Series with a multi-level index.

```
>>> arrays = [np.array(['bar', 'bar', 'baz', 'baz']),
...           np.array(['one', 'two', 'one', 'two'])]
>>> s2 = pd.Series(
...     range(4), name='foo',
...     index=pd.MultiIndex.from_arrays(arrays,
...                                     names=['a', 'b']))
```

To remove a specific level from the Index, use *level*.

```
>>> s2.reset_index(level='a')
   a  foo
b
one bar    0
two bar    1
one baz    2
two baz    3
```

If *level* is not set, all levels are removed from the Index.

```
>>> s2.reset_index()
   a  b  foo
0  bar one  0
```

(continues on next page)

(continued from previous page)

|   |     |     |   |
|---|-----|-----|---|
| 1 | bar | two | 1 |
| 2 | baz | one | 2 |
| 3 | baz | two | 3 |

**pandas.Series.rfloordiv****Series.rfloordiv** (*other*, *level=None*, *fill\_value=None*, *axis=0*)Integer division of series and other, element-wise (binary operator *rfloordiv*).Equivalent to `other // series`, but with support to substitute a `fill_value` for missing data in one of the inputs.**Parameters****other** [Series or scalar value]**fill\_value** [None or float value, default None (NaN)] Fill existing missing (NaN) values, and any new element needed for successful Series alignment, with this value before computation. If data in both corresponding Series locations is missing the result will be missing**level** [int or name] Broadcast across a level, matching Index values on the passed Multi-Index level**Returns****result** [Series]**See also:***Series.floordiv***Examples**

```
>>> a = pd.Series([1, 1, 1, np.nan], index=['a', 'b', 'c', 'd'])
>>> a
a    1.0
b    1.0
c    1.0
d    NaN
dtype: float64
>>> b = pd.Series([1, np.nan, 1, np.nan], index=['a', 'b', 'd', 'e'])
>>> b
a    1.0
b    NaN
d    1.0
e    NaN
dtype: float64
>>> a.add(b, fill_value=0)
a    2.0
b    1.0
c    1.0
d    1.0
e    NaN
dtype: float64
```

## pandas.Series.rmod

`Series.rmod` (*other*, *level=None*, *fill\_value=None*, *axis=0*)

Modulo of series and other, element-wise (binary operator *rmod*).

Equivalent to `other % series`, but with support to substitute a *fill\_value* for missing data in one of the inputs.

### Parameters

**other** [Series or scalar value]

**fill\_value** [None or float value, default None (NaN)] Fill existing missing (NaN) values, and any new element needed for successful Series alignment, with this value before computation. If data in both corresponding Series locations is missing the result will be missing

**level** [int or name] Broadcast across a level, matching Index values on the passed Multi-Index level

### Returns

**result** [Series]

**See also:**

`Series.mod`

## Examples

```

>>> a = pd.Series([1, 1, 1, np.nan], index=['a', 'b', 'c', 'd'])
>>> a
a    1.0
b    1.0
c    1.0
d    NaN
dtype: float64
>>> b = pd.Series([1, np.nan, 1, np.nan], index=['a', 'b', 'd', 'e'])
>>> b
a    1.0
b    NaN
d    1.0
e    NaN
dtype: float64
>>> a.add(b, fill_value=0)
a    2.0
b    1.0
c    1.0
d    1.0
e    NaN
dtype: float64

```

## pandas.Series.rmul

`Series.rmul` (*other*, *level=None*, *fill\_value=None*, *axis=0*)

Multiplication of series and other, element-wise (binary operator *rmul*).

Equivalent to `other * series`, but with support to substitute a `fill_value` for missing data in one of the inputs.

#### Parameters

**other** [Series or scalar value]

**fill\_value** [None or float value, default None (NaN)] Fill existing missing (NaN) values, and any new element needed for successful Series alignment, with this value before computation. If data in both corresponding Series locations is missing the result will be missing

**level** [int or name] Broadcast across a level, matching Index values on the passed Multi-Index level

#### Returns

**result** [Series]

#### See also:

`Series.mul`

#### Examples

```
>>> a = pd.Series([1, 1, 1, np.nan], index=['a', 'b', 'c', 'd'])
>>> a
a    1.0
b    1.0
c    1.0
d    NaN
dtype: float64
>>> b = pd.Series([1, np.nan, 1, np.nan], index=['a', 'b', 'd', 'e'])
>>> b
a    1.0
b    NaN
d    1.0
e    NaN
dtype: float64
>>> a.add(b, fill_value=0)
a    2.0
b    1.0
c    1.0
d    1.0
e    NaN
dtype: float64
```

### pandas.Series.rolling

`Series.rolling(window, min_periods=None, center=False, win_type=None, on=None, axis=0, closed=None)`

Provides rolling window calculations.

New in version 0.18.0.

#### Parameters

**window** [int, or offset] Size of the moving window. This is the number of observations used for calculating the statistic. Each window will be a fixed size.

If its an offset then this will be the time period of each window. Each window will be a variable sized based on the observations included in the time-period. This is only valid for datetimelike indexes. This is new in 0.19.0

**min\_periods** [int, default None] Minimum number of observations in window required to have a value (otherwise result is NA). For a window that is specified by an offset, *min\_periods* will default to 1. Otherwise, *min\_periods* will default to the size of the window.

**center** [bool, default False] Set the labels at the center of the window.

**win\_type** [str, default None] Provide a window type. If `None`, all points are evenly weighted. See the notes below for further information.

**on** [str, optional] For a DataFrame, column on which to calculate the rolling window, rather than the index

**axis** [int or str, default 0]

**closed** [str, default None] Make the interval closed on the 'right', 'left', 'both' or 'neither' endpoints. For offset-based windows, it defaults to 'right'. For fixed windows, defaults to 'both'. Remaining cases not implemented for fixed windows.

New in version 0.20.0.

### Returns

a Window or Rolling sub-classed for the particular operation

See also:

**expanding** Provides expanding transformations.

**ewm** Provides exponential weighted functions.

### Notes

By default, the result is set to the right edge of the window. This can be changed to the center of the window by setting `center=True`.

To learn more about the offsets & frequency strings, please see [this link](#).

The recognized win\_types are:

- boxcar
- triang
- blackman
- hamming
- bartlett
- parzen
- bohman
- blackmanharris
- nuttall
- barthann
- kaiser (needs beta)

- gaussian (needs std)
- general\_gaussian (needs power, width)
- slepian (needs width).

If `win_type=None` all points are evenly weighted. To learn more about different window types see [scipy.signal window functions](#).

## Examples

```
>>> df = pd.DataFrame({'B': [0, 1, 2, np.nan, 4]})
>>> df
   B
0  0.0
1  1.0
2  2.0
3  NaN
4  4.0
```

Rolling sum with a window length of 2, using the 'triang' window type.

```
>>> df.rolling(2, win_type='triang').sum()
   B
0  NaN
1  1.0
2  2.5
3  NaN
4  NaN
```

Rolling sum with a window length of 2, `min_periods` defaults to the window length.

```
>>> df.rolling(2).sum()
   B
0  NaN
1  1.0
2  3.0
3  NaN
4  NaN
```

Same as above, but explicitly set the `min_periods`

```
>>> df.rolling(2, min_periods=1).sum()
   B
0  0.0
1  1.0
2  3.0
3  2.0
4  4.0
```

A ragged (meaning not-a-regular frequency), time-indexed DataFrame

```
>>> df = pd.DataFrame({'B': [0, 1, 2, np.nan, 4]},
...                     index = [pd.Timestamp('20130101 09:00:00'),
...                               pd.Timestamp('20130101 09:00:02'),
...                               pd.Timestamp('20130101 09:00:03'),
...                               pd.Timestamp('20130101 09:00:05'),
...                               pd.Timestamp('20130101 09:00:06')])
```

```
>>> df
                B
2013-01-01 09:00:00  0.0
2013-01-01 09:00:02  1.0
2013-01-01 09:00:03  2.0
2013-01-01 09:00:05  NaN
2013-01-01 09:00:06  4.0
```

Contrasting to an integer rolling window, this will roll a variable length window corresponding to the time period. The default for `min_periods` is 1.

```
>>> df.rolling('2s').sum()
                B
2013-01-01 09:00:00  0.0
2013-01-01 09:00:02  1.0
2013-01-01 09:00:03  3.0
2013-01-01 09:00:05  NaN
2013-01-01 09:00:06  4.0
```

## pandas.Series.round

`Series.round(decimals=0, *args, **kwargs)`

Round each value in a Series to the given number of decimals.

### Parameters

**decimals** [int] Number of decimal places to round to (default: 0). If decimals is negative, it specifies the number of positions to the left of the decimal point.

### Returns

Series object

See also:

`numpy.around`, `DataFrame.round`

## pandas.Series.rpow

`Series.rpow(other, level=None, fill_value=None, axis=0)`

Exponential power of series and other, element-wise (binary operator *rpow*).

Equivalent to `other ** series`, but with support to substitute a `fill_value` for missing data in one of the inputs.

### Parameters

**other** [Series or scalar value]

**fill\_value** [None or float value, default None (NaN)] Fill existing missing (NaN) values, and any new element needed for successful Series alignment, with this value before computation. If data in both corresponding Series locations is missing the result will be missing

**level** [int or name] Broadcast across a level, matching Index values on the passed Multi-Index level

### Returns

**result** [Series]

**See also:**

*Series.pow*

## Examples

```
>>> a = pd.Series([1, 1, 1, np.nan], index=['a', 'b', 'c', 'd'])
>>> a
a    1.0
b    1.0
c    1.0
d    NaN
dtype: float64
>>> b = pd.Series([1, np.nan, 1, np.nan], index=['a', 'b', 'd', 'e'])
>>> b
a    1.0
b    NaN
d    1.0
e    NaN
dtype: float64
>>> a.add(b, fill_value=0)
a    2.0
b    1.0
c    1.0
d    1.0
e    NaN
dtype: float64
```

## pandas.Series.rsub

`Series.rsub` (*other*, *level=None*, *fill\_value=None*, *axis=0*)

Subtraction of series and other, element-wise (binary operator *rsub*).

Equivalent to `other - series`, but with support to substitute a *fill\_value* for missing data in one of the inputs.

### Parameters

**other** [Series or scalar value]

**fill\_value** [None or float value, default None (NaN)] Fill existing missing (NaN) values, and any new element needed for successful Series alignment, with this value before computation. If data in both corresponding Series locations is missing the result will be missing

**level** [int or name] Broadcast across a level, matching Index values on the passed Multi-Index level

### Returns

**result** [Series]

**See also:**

*Series.sub*

## Examples

```

>>> a = pd.Series([1, 1, 1, np.nan], index=['a', 'b', 'c', 'd'])
>>> a
a    1.0
b    1.0
c    1.0
d    NaN
dtype: float64
>>> b = pd.Series([1, np.nan, 1, np.nan], index=['a', 'b', 'd', 'e'])
>>> b
a    1.0
b    NaN
d    1.0
e    NaN
dtype: float64
>>> a.add(b, fill_value=0)
a    2.0
b    1.0
c    1.0
d    1.0
e    NaN
dtype: float64

```

## pandas.Series.rtruediv

`Series.rtruediv` (*other*, *level=None*, *fill\_value=None*, *axis=0*)

Floating division of series and other, element-wise (binary operator *rtruediv*).

Equivalent to `other / series`, but with support to substitute a `fill_value` for missing data in one of the inputs.

### Parameters

**other** [Series or scalar value]

**fill\_value** [None or float value, default None (NaN)] Fill existing missing (NaN) values, and any new element needed for successful Series alignment, with this value before computation. If data in both corresponding Series locations is missing the result will be missing

**level** [int or name] Broadcast across a level, matching Index values on the passed Multi-Index level

### Returns

**result** [Series]

### See also:

`Series.truediv`

## Examples

```

>>> a = pd.Series([1, 1, 1, np.nan], index=['a', 'b', 'c', 'd'])
>>> a
a    1.0

```

(continues on next page)

(continued from previous page)

```

b    1.0
c    1.0
d    NaN
dtype: float64
>>> b = pd.Series([1, np.nan, 1, np.nan], index=['a', 'b', 'd', 'e'])
>>> b
a    1.0
b    NaN
d    1.0
e    NaN
dtype: float64
>>> a.add(b, fill_value=0)
a    2.0
b    1.0
c    1.0
d    1.0
e    NaN
dtype: float64

```

### pandas.Series.sample

`Series.sample` (*n=None*, *frac=None*, *replace=False*, *weights=None*, *random\_state=None*, *axis=None*)

Return a random sample of items from an axis of object.

You can use *random\_state* for reproducibility.

#### Parameters

**n** [int, optional] Number of items from axis to return. Cannot be used with *frac*. Default = 1 if *frac* = None.

**frac** [float, optional] Fraction of axis items to return. Cannot be used with *n*.

**replace** [bool, default False] Sample with or without replacement.

**weights** [str or ndarray-like, optional] Default 'None' results in equal probability weighting. If passed a Series, will align with target object on index. Index values in weights not found in sampled object will be ignored and index values in sampled object not in weights will be assigned weights of zero. If called on a DataFrame, will accept the name of a column when *axis* = 0. Unless weights are a Series, weights must be same length as axis being sampled. If weights do not sum to 1, they will be normalized to sum to 1. Missing values in the weights column will be treated as zero. Infinite values not allowed.

**random\_state** [int or numpy.random.RandomState, optional] Seed for the random number generator (if int), or numpy RandomState object.

**axis** [int or string, optional] Axis to sample. Accepts axis number or name. Default is stat axis for given data type (0 for Series and DataFrames, 1 for Panels).

#### Returns

**Series or DataFrame** A new object of same type as caller containing *n* items randomly sampled from the caller object.

See also:

`numpy.random.choice` Generates a random sample from a given 1-D numpy array.

## Examples

```
>>> df = pd.DataFrame({'num_legs': [2, 4, 8, 0],
...                     'num_wings': [2, 0, 0, 0],
...                     'num_specimen_seen': [10, 2, 1, 8]},
...                     index=['falcon', 'dog', 'spider', 'fish'])
>>> df
```

|        | num_legs | num_wings | num_specimen_seen |
|--------|----------|-----------|-------------------|
| falcon | 2        | 2         | 10                |
| dog    | 4        | 0         | 2                 |
| spider | 8        | 0         | 1                 |
| fish   | 0        | 0         | 8                 |

Extract 3 random elements from the Series `df['num_legs']`: Note that we use *random\_state* to ensure the reproducibility of the examples.

```
>>> df['num_legs'].sample(n=3, random_state=1)
fish      0
spider    8
falcon    2
Name: num_legs, dtype: int64
```

A random 50% sample of the DataFrame with replacement:

```
>>> df.sample(frac=0.5, replace=True, random_state=1)
```

|      | num_legs | num_wings | num_specimen_seen |
|------|----------|-----------|-------------------|
| dog  | 4        | 0         | 2                 |
| fish | 0        | 0         | 8                 |

Using a DataFrame column as weights. Rows with larger value in the *num\_specimen\_seen* column are more likely to be sampled.

```
>>> df.sample(n=2, weights='num_specimen_seen', random_state=1)
```

|        | num_legs | num_wings | num_specimen_seen |
|--------|----------|-----------|-------------------|
| falcon | 2        | 2         | 10                |
| fish   | 0        | 0         | 8                 |

## pandas.Series.searchsorted

`Series.searchsorted(value, side='left', sorter=None)`

Find indices where elements should be inserted to maintain order.

Find the indices into a sorted Series *self* such that, if the corresponding elements in *value* were inserted before the indices, the order of *self* would be preserved.

### Parameters

**value** [array\_like] Values to insert into *self*.

**side** [{‘left’, ‘right’}, optional] If ‘left’, the index of the first suitable location found is given. If ‘right’, return the last such index. If there is no suitable index, return either 0 or N (where N is the length of *self*).

**sorter** [1-D array\_like, optional] Optional array of integer indices that sort *self* into ascending order. They are typically the result of `np.argsort`.

### Returns

**int or array of int** A scalar or array of insertion points with the same shape as *value*.

Changed in version 0.24.0: If *value* is a scalar, an int is now always returned. Previously, scalar inputs returned an 1-item array for *Series* and *Categorical*.

### See also:

`numpy.searchsorted`

### Notes

Binary search is used to find the required insertion points.

### Examples

```
>>> x = pd.Series([1, 2, 3])
>>> x
0    1
1    2
2    3
dtype: int64
```

```
>>> x.searchsorted(4)
3
```

```
>>> x.searchsorted([0, 4])
array([0, 3])
```

```
>>> x.searchsorted([1, 3], side='left')
array([0, 2])
```

```
>>> x.searchsorted([1, 3], side='right')
array([1, 3])
```

```
>>> x = pd.Categorical(['apple', 'bread', 'bread',
                        'cheese', 'milk'], ordered=True)
[apple, bread, bread, cheese, milk]
Categories (4, object): [apple < bread < cheese < milk]
```

```
>>> x.searchsorted('bread')
1
```

```
>>> x.searchsorted(['bread'], side='right')
array([3])
```

### `pandas.Series.select`

`Series.select` (*crit*, *axis=0*)

Return data corresponding to axis labels matching criteria.

Deprecated since version 0.21.0: Use `df.loc[df.index.map(crit)]` to select via labels

**Parameters**

**crit** [function] To be called on each index (label). Should return True or False

**axis** [int]

**Returns**

**selection** [same type as caller]

**pandas.Series.sem**

`Series.sem(axis=None, skipna=None, level=None, ddof=1, numeric_only=None, **kwargs)`

Return unbiased standard error of the mean over requested axis.

Normalized by N-1 by default. This can be changed using the ddof argument

**Parameters**

**axis** [{index (0)}]

**skipna** [boolean, default True] Exclude NA/null values. If an entire row/column is NA, the result will be NA

**level** [int or level name, default None] If the axis is a MultiIndex (hierarchical), count along a particular level, collapsing into a scalar

**ddof** [int, default 1] Delta Degrees of Freedom. The divisor used in calculations is N - ddof, where N represents the number of elements.

**numeric\_only** [boolean, default None] Include only float, int, boolean columns. If None, will attempt to use everything, then use only numeric data. Not implemented for Series.

**Returns**

**sem** [scalar or Series (if level specified)]

**pandas.Series.set\_axis**

`Series.set_axis(labels, axis=0, inplace=None)`

Assign desired index to given axis.

Indexes for column or row labels can be changed by assigning a list-like or Index.

Changed in version 0.21.0: The signature is now *labels* and *axis*, consistent with the rest of pandas API. Previously, the *axis* and *labels* arguments were respectively the first and second positional arguments.

**Parameters**

**labels** [list-like, Index] The values for the new index.

**axis** [{0 or 'index', 1 or 'columns'}, default 0] The axis to update. The value 0 identifies the rows, and 1 identifies the columns.

**inplace** [boolean, default None] Whether to return a new %(klass)s instance.

**Warning:** `inplace=None` currently falls back to `True`, but in a future version, will default to `False`. Use `inplace=True` explicitly rather than relying on the default.

### Returns

**renamed** [% (klass)s or None] An object of same type as caller if inplace=False, None otherwise.

### See also:

**DataFrame.rename\_axis** Alter the name of the index or columns.

## Examples

### Series

```
>>> s = pd.Series([1, 2, 3])
>>> s
0    1
1    2
2    3
dtype: int64
```

```
>>> s.set_axis(['a', 'b', 'c'], axis=0, inplace=False)
a    1
b    2
c    3
dtype: int64
```

The original object is not modified.

```
>>> s
0    1
1    2
2    3
dtype: int64
```

### DataFrame

```
>>> df = pd.DataFrame({"A": [1, 2, 3], "B": [4, 5, 6]})
```

Change the row labels.

```
>>> df.set_axis(['a', 'b', 'c'], axis='index', inplace=False)
   A  B
a  1  4
b  2  5
c  3  6
```

Change the column labels.

```
>>> df.set_axis(['I', 'II'], axis='columns', inplace=False)
   I  II
0  1   4
1  2   5
2  3   6
```

Now, update the labels inplace.

```
>>> df.set_axis(['i', 'ii'], axis='columns', inplace=True)
>>> df
   i  ii
0  1   4
1  2   5
2  3   6
```

### pandas.Series.set\_value

`Series.set_value` (*label, value, takeable=False*)

Quickly set single value at passed label.

Deprecated since version 0.21.0: Please use `.at[]` or `.iat[]` accessors.

If label is not contained, a new object is created with the label placed at the end of the result index.

#### Parameters

**label** [object] Partial indexing with MultiIndex not allowed

**value** [object] Scalar value

**takeable** [interpret the index as indexers, default False]

#### Returns

**series** [Series] If label is contained, will be reference to calling Series, otherwise a new object

### pandas.Series.shift

`Series.shift` (*periods=1, freq=None, axis=0, fill\_value=None*)

Shift index by desired number of periods with an optional time *freq*.

When *freq* is not passed, shift the index without realigning the data. If *freq* is passed (in this case, the index must be date or datetime, or it will raise a *NotImplementedError*), the index will be increased using the periods and the *freq*.

#### Parameters

**periods** [int] Number of periods to shift. Can be positive or negative.

**freq** [DateOffset, tseries.offsets, timedelta, or str, optional] Offset to use from the tseries module or time rule (e.g. 'EOM'). If *freq* is specified then the index values are shifted but the data is not realigned. That is, use *freq* if you would like to extend the index when shifting and preserve the original data.

**axis** [{0 or 'index', 1 or 'columns', None}, default None] Shift direction.

**fill\_value** [object, optional] The scalar value to use for newly introduced missing values. the default depends on the dtype of *self*. For numeric data, `np.nan` is used. For datetime, timedelta, or period data, etc. `NaT` is used. For extension dtypes, `self.dtype.na_value` is used.

Changed in version 0.24.0.

#### Returns

**Series** Copy of input object, shifted.

See also:

**`Index.shift`** Shift values of Index.

**`DatetimeIndex.shift`** Shift values of DatetimeIndex.

**`PeriodIndex.shift`** Shift values of PeriodIndex.

**`tshift`** Shift the time index, using the index's frequency if available.

## Examples

```
>>> df = pd.DataFrame({'Col1': [10, 20, 15, 30, 45],
...                    'Col2': [13, 23, 18, 33, 48],
...                    'Col3': [17, 27, 22, 37, 52]})
```

```
>>> df.shift(periods=3)
   Col1  Col2  Col3
0   NaN   NaN   NaN
1   NaN   NaN   NaN
2   NaN   NaN   NaN
3  10.0  13.0  17.0
4  20.0  23.0  27.0
```

```
>>> df.shift(periods=1, axis='columns')
   Col1  Col2  Col3
0   NaN  10.0  13.0
1   NaN  20.0  23.0
2   NaN  15.0  18.0
3   NaN  30.0  33.0
4   NaN  45.0  48.0
```

```
>>> df.shift(periods=3, fill_value=0)
   Col1  Col2  Col3
0     0     0     0
1     0     0     0
2     0     0     0
3    10    13    17
4    20    23    27
```

## pandas.Series.skew

**`Series.skew`** (*axis=None, skipna=None, level=None, numeric\_only=None, \*\*kwargs*)

Return unbiased skew over requested axis Normalized by N-1.

### Parameters

**`axis`** [{index (0)}] Axis for the function to be applied on.

**`skipna`** [bool, default True] Exclude NA/null values when computing the result.

**`level`** [int or level name, default None] If the axis is a MultiIndex (hierarchical), count along a particular level, collapsing into a scalar.

**`numeric_only`** [bool, default None] Include only float, int, boolean columns. If None, will attempt to use everything, then use only numeric data. Not implemented for Series.

**\*\*kwargs** Additional keyword arguments to be passed to the function.

#### Returns

**skew** [scalar or Series (if level specified)]

### pandas.Series.slice\_shift

`Series.slice_shift` (*periods=1, axis=0*)

Equivalent to *shift* without copying data. The shifted data will not include the dropped periods and the shifted axis will be smaller than the original.

#### Parameters

**periods** [int] Number of periods to move, can be positive or negative

#### Returns

**shifted** [same type as caller]

#### Notes

While the *slice\_shift* is faster than *shift*, you may pay for it later during alignment.

### pandas.Series.sort\_index

`Series.sort_index` (*axis=0, level=None, ascending=True, inplace=False, kind='quicksort', na\_position='last', sort\_remaining=True*)

Sort Series by index labels.

Returns a new Series sorted by label if *inplace* argument is `False`, otherwise updates the original series and returns `None`.

#### Parameters

**axis** [int, default 0] Axis to direct sorting. This can only be 0 for Series.

**level** [int, optional] If not `None`, sort on values in specified index level(s).

**ascending** [bool, default `true`] Sort ascending vs. descending.

**inplace** [bool, default `False`] If `True`, perform operation in-place.

**kind** [{`'quicksort'`, `'mergesort'`, `'heapsort'`}, default `'quicksort'`] Choice of sorting algorithm. See also `numpy.sort()` for more information. `'mergesort'` is the only stable algorithm. For DataFrames, this option is only applied when sorting on a single column or label.

**na\_position** [{`'first'`, `'last'`}, default `'last'`] If `'first'` puts NaNs at the beginning, `'last'` puts NaNs at the end. Not implemented for MultiIndex.

**sort\_remaining** [bool, default `True`] If `true` and sorting by level and index is multilevel, sort by other levels too (in order) after sorting by specified level.

#### Returns

**pandas.Series** The original Series sorted by the labels

See also:

**DataFrame.sort\_index** Sort DataFrame by the index.

**DataFrame.sort\_values** Sort DataFrame by the value.

**Series.sort\_values** Sort Series by the value.

## Examples

```
>>> s = pd.Series(['a', 'b', 'c', 'd'], index=[3, 2, 1, 4])
>>> s.sort_index()
1    c
2    b
3    a
4    d
dtype: object
```

### Sort Descending

```
>>> s.sort_index(ascending=False)
4    d
3    a
2    b
1    c
dtype: object
```

### Sort Inplace

```
>>> s.sort_index(inplace=True)
>>> s
1    c
2    b
3    a
4    d
dtype: object
```

By default NaNs are put at the end, but use *na\_position* to place them at the beginning

```
>>> s = pd.Series(['a', 'b', 'c', 'd'], index=[3, 2, 1, np.nan])
>>> s.sort_index(na_position='first')
NaN    d
1.0    c
2.0    b
3.0    a
dtype: object
```

### Specify index level to sort

```
>>> arrays = [np.array(['qux', 'qux', 'foo', 'foo',
...                     'baz', 'baz', 'bar', 'bar']),
...           np.array(['two', 'one', 'two', 'one',
...                     'two', 'one', 'two', 'one'])]
>>> s = pd.Series([1, 2, 3, 4, 5, 6, 7, 8], index=arrays)
>>> s.sort_index(level=1)
bar one    8
baz one    6
foo one    4
qux one    2
```

(continues on next page)

(continued from previous page)

```

bar two 7
baz two 5
foo two 3
qux two 1
dtype: int64

```

Does not sort by remaining levels when sorting by levels

```

>>> s.sort_index(level=1, sort_remaining=False)
qux one 2
foo one 4
baz one 6
bar one 8
qux two 1
foo two 3
baz two 5
bar two 7
dtype: int64

```

### pandas.Series.sort\_values

**Series.sort\_values** (*axis=0*, *ascending=True*, *inplace=False*, *kind='quicksort'*, *na\_position='last'*)

Sort by the values.

Sort a Series in ascending or descending order by some criterion.

#### Parameters

**axis** [{0 or 'index'}, default 0] Axis to direct sorting. The value 'index' is accepted for compatibility with `DataFrame.sort_values`.

**ascending** [bool, default True] If True, sort values in ascending order, otherwise descending.

**inplace** [bool, default False] If True, perform operation in-place.

**kind** [{ 'quicksort', 'mergesort' or 'heapsort' }, default 'quicksort'] Choice of sorting algorithm. See also `numpy.sort()` for more information. 'mergesort' is the only stable algorithm.

**na\_position** [{ 'first' or 'last' }, default 'last'] Argument 'first' puts NaNs at the beginning, 'last' puts NaNs at the end.

#### Returns

**Series** Series ordered by values.

See also:

**Series.sort\_index** Sort by the Series indices.

**DataFrame.sort\_values** Sort DataFrame by the values along either axis.

**DataFrame.sort\_index** Sort DataFrame by indices.

## Examples

```
>>> s = pd.Series([np.nan, 1, 3, 10, 5])
>>> s
0      NaN
1       1.0
2       3.0
3      10.0
4       5.0
dtype: float64
```

Sort values ascending order (default behaviour)

```
>>> s.sort_values(ascending=True)
1       1.0
2       3.0
4       5.0
3      10.0
0      NaN
dtype: float64
```

Sort values descending order

```
>>> s.sort_values(ascending=False)
3      10.0
4       5.0
2       3.0
1       1.0
0      NaN
dtype: float64
```

Sort values inplace

```
>>> s.sort_values(ascending=False, inplace=True)
>>> s
3      10.0
4       5.0
2       3.0
1       1.0
0      NaN
dtype: float64
```

Sort values putting NAs first

```
>>> s.sort_values(na_position='first')
0      NaN
1       1.0
2       3.0
4       5.0
3      10.0
dtype: float64
```

Sort a series of strings

```
>>> s = pd.Series(['z', 'b', 'd', 'a', 'c'])
>>> s
0      z
```

(continues on next page)

(continued from previous page)

```
1    b
2    d
3    a
4    c
dtype: object
```

```
>>> s.sort_values()
3    a
1    b
4    c
2    d
0    z
dtype: object
```

## pandas.Series.squeeze

`Series.squeeze (axis=None)`

Squeeze 1 dimensional axis objects into scalars.

Series or DataFrames with a single element are squeezed to a scalar. DataFrames with a single column or a single row are squeezed to a Series. Otherwise the object is unchanged.

This method is most useful when you don't know if your object is a Series or DataFrame, but you do know it has just a single column. In that case you can safely call *squeeze* to ensure you have a Series.

### Parameters

**axis** [{0 or 'index', 1 or 'columns', None}, default None] A specific axis to squeeze. By default, all length-1 axes are squeezed.

New in version 0.20.0.

### Returns

**DataFrame, Series, or scalar** The projection after squeezing *axis* or all the axes.

**See also:**

***Series.iloc*** Integer-location based indexing for selecting scalars.

***DataFrame.iloc*** Integer-location based indexing for selecting Series.

***Series.to\_frame*** Inverse of *DataFrame.squeeze* for a single-column DataFrame.

## Examples

```
>>> primes = pd.Series([2, 3, 5, 7])
```

Slicing might produce a Series with a single value:

```
>>> even_primes = primes[primes % 2 == 0]
>>> even_primes
0    2
dtype: int64
```

```
>>> even_primes.squeeze()
2
```

Squeezing objects with more than one value in every axis does nothing:

```
>>> odd_primes = primes[primes % 2 == 1]
>>> odd_primes
1    3
2    5
3    7
dtype: int64
```

```
>>> odd_primes.squeeze()
1    3
2    5
3    7
dtype: int64
```

Squeezing is even more effective when used with DataFrames.

```
>>> df = pd.DataFrame([[1, 2], [3, 4]], columns=['a', 'b'])
>>> df
   a  b
0  1  2
1  3  4
```

Slicing a single column will produce a DataFrame with the columns having only one value:

```
>>> df_a = df[['a']]
>>> df_a
   a
0  1
1  3
```

So the columns can be squeezed down, resulting in a Series:

```
>>> df_a.squeeze('columns')
0    1
1    3
Name: a, dtype: int64
```

Slicing a single row from a single column will produce a single scalar DataFrame:

```
>>> df_0a = df.loc[df.index < 1, ['a']]
>>> df_0a
   a
0  1
```

Squeezing the rows produces a single scalar Series:

```
>>> df_0a.squeeze('rows')
a    1
Name: 0, dtype: int64
```

Squeezing all axes will project directly into a scalar:

```
>>> df_0a.squeeze()
1
```

### pandas.Series.std

`Series.std` (*axis=None, skipna=None, level=None, ddof=1, numeric\_only=None, \*\*kwargs*)

Return sample standard deviation over requested axis.

Normalized by N-1 by default. This can be changed using the `ddof` argument

#### Parameters

**axis** [{index (0)}]

**skipna** [boolean, default True] Exclude NA/null values. If an entire row/column is NA, the result will be NA

**level** [int or level name, default None] If the axis is a MultiIndex (hierarchical), count along a particular level, collapsing into a scalar

**ddof** [int, default 1] Delta Degrees of Freedom. The divisor used in calculations is  $N - \text{ddof}$ , where  $N$  represents the number of elements.

**numeric\_only** [boolean, default None] Include only float, int, boolean columns. If None, will attempt to use everything, then use only numeric data. Not implemented for Series.

#### Returns

**std** [scalar or Series (if level specified)]

### pandas.Series.str

`Series.str` ()

Vectorized string functions for Series and Index. NAs stay NA unless handled otherwise by a particular method. Patterned after Python's string methods, with some inspiration from R's stringr package.

#### Examples

```
>>> s.str.split('_')
>>> s.str.replace('_', '')
```

### pandas.Series.sub

`Series.sub` (*other, level=None, fill\_value=None, axis=0*)

Subtraction of series and other, element-wise (binary operator *sub*).

Equivalent to `series - other`, but with support to substitute a `fill_value` for missing data in one of the inputs.

#### Parameters

**other** [Series or scalar value]

**fill\_value** [None or float value, default None (NaN)] Fill existing missing (NaN) values, and any new element needed for successful Series alignment, with this value before computation. If data in both corresponding Series locations is missing the result will be missing

**level** [int or name] Broadcast across a level, matching Index values on the passed Multi-Index level

### Returns

**result** [Series]

### See also:

*Series.rsub*

### Examples

```
>>> a = pd.Series([1, 1, 1, np.nan], index=['a', 'b', 'c', 'd'])
>>> a
a    1.0
b    1.0
c    1.0
d    NaN
dtype: float64
>>> b = pd.Series([1, np.nan, 1, np.nan], index=['a', 'b', 'd', 'e'])
>>> b
a    1.0
b    NaN
d    1.0
e    NaN
dtype: float64
>>> a.add(b, fill_value=0)
a    2.0
b    1.0
c    1.0
d    1.0
e    NaN
dtype: float64
```

## pandas.Series.subtract

`Series.subtract` (*other*, *level=None*, *fill\_value=None*, *axis=0*)

Subtraction of series and other, element-wise (binary operator *sub*).

Equivalent to `series - other`, but with support to substitute a `fill_value` for missing data in one of the inputs.

### Parameters

**other** [Series or scalar value]

**fill\_value** [None or float value, default None (NaN)] Fill existing missing (NaN) values, and any new element needed for successful Series alignment, with this value before computation. If data in both corresponding Series locations is missing the result will be missing

**level** [int or name] Broadcast across a level, matching Index values on the passed Multi-Index level

### Returns

**result** [Series]

### See also:

*Series.rsub*

### Examples

```
>>> a = pd.Series([1, 1, 1, np.nan], index=['a', 'b', 'c', 'd'])
>>> a
a    1.0
b    1.0
c    1.0
d    NaN
dtype: float64
>>> b = pd.Series([1, np.nan, 1, np.nan], index=['a', 'b', 'd', 'e'])
>>> b
a    1.0
b    NaN
d    1.0
e    NaN
dtype: float64
>>> a.add(b, fill_value=0)
a    2.0
b    1.0
c    1.0
d    1.0
e    NaN
dtype: float64
```

## pandas.Series.sum

`Series.sum(axis=None, skipna=None, level=None, numeric_only=None, min_count=0, **kwargs)`

Return the sum of the values for the requested axis.

This is equivalent to the method `numpy.sum`.

### Parameters

**axis** [{index (0)}] Axis for the function to be applied on.

**skipna** [bool, default True] Exclude NA/null values when computing the result.

**level** [int or level name, default None] If the axis is a MultiIndex (hierarchical), count along a particular level, collapsing into a scalar.

**numeric\_only** [bool, default None] Include only float, int, boolean columns. If None, will attempt to use everything, then use only numeric data. Not implemented for Series.

**min\_count** [int, default 0] The required number of valid values to perform the operation. If fewer than `min_count` non-NA values are present the result will be NA.

New in version 0.22.0: Added with the default being 0. This means the sum of an all-NA or empty Series is 0, and the product of an all-NA or empty Series is 1.

**\*\*kwargs** Additional keyword arguments to be passed to the function.

### Returns

**sum** [scalar or Series (if level specified)]

### See also:

**Series.sum** Return the sum.

**Series.min** Return the minimum.

**Series.max** Return the maximum.

**Series.idxmin** Return the index of the minimum.

**Series.idxmax** Return the index of the maximum.

**DataFrame.min** Return the sum over the requested axis.

**DataFrame.min** Return the minimum over the requested axis.

**DataFrame.max** Return the maximum over the requested axis.

**DataFrame.idxmin** Return the index of the minimum over the requested axis.

**DataFrame.idxmax** Return the index of the maximum over the requested axis.

### Examples

```
>>> idx = pd.MultiIndex.from_arrays([
...     ['warm', 'warm', 'cold', 'cold'],
...     ['dog', 'falcon', 'fish', 'spider']],
...     names=['blooded', 'animal'])
>>> s = pd.Series([4, 2, 0, 8], name='legs', index=idx)
>>> s
blooded  animal
warm     dog      4
         falcon   2
cold     fish     0
         spider   8
Name: legs, dtype: int64
```

```
>>> s.sum()
14
```

Sum using level names, as well as indices.

```
>>> s.sum(level='blooded')
blooded
warm     6
cold     8
Name: legs, dtype: int64
```

```
>>> s.sum(level=0)
blooded
warm      6
cold      8
Name: legs, dtype: int64
```

By default, the sum of an empty or all-NA Series is 0.

```
>>> pd.Series([]).sum() # min_count=0 is the default
0.0
```

This can be controlled with the `min_count` parameter. For example, if you'd like the sum of an empty series to be NaN, pass `min_count=1`.

```
>>> pd.Series([]).sum(min_count=1)
nan
```

Thanks to the `skipna` parameter, `min_count` handles all-NA and empty series identically.

```
>>> pd.Series([np.nan]).sum()
0.0
```

```
>>> pd.Series([np.nan]).sum(min_count=1)
nan
```

## pandas.Series.swapaxes

`Series.swapaxes` (*axis1*, *axis2*, *copy=True*)

Interchange axes and swap values axes appropriately.

### Returns

**y** [same as input]

## pandas.Series.swaplevel

`Series.swaplevel` (*i=-2*, *j=-1*, *copy=True*)

Swap levels *i* and *j* in a MultiIndex.

### Parameters

**i, j** [int, string (can be mixed)] Level of index to be swapped. Can pass level name as string.

### Returns

**swapped** [Series]

.. **versionchanged:: 0.18.1** The indexes *i* and *j* are now optional, and default to the two innermost levels of the index.

## pandas.Series.tail

`Series.tail` (*n=5*)

Return the last *n* rows.

This function returns last  $n$  rows from the object based on position. It is useful for quickly verifying data, for example, after sorting or appending rows.

#### Parameters

**n** [int, default 5] Number of rows to select.

#### Returns

**type of caller** The last  $n$  rows of the caller object.

**See also:**

**DataFrame.head** The first  $n$  rows of the caller object.

### Examples

```
>>> df = pd.DataFrame({'animal': ['alligator', 'bee', 'falcon', 'lion',
...                               'monkey', 'parrot', 'shark', 'whale', 'zebra']})
>>> df
   animal
0  alligator
1      bee
2   falcon
3     lion
4   monkey
5   parrot
6    shark
7   whale
8   zebra
```

Viewing the last 5 lines

```
>>> df.tail()
   animal
4  monkey
5  parrot
6   shark
7   whale
8   zebra
```

Viewing the last  $n$  lines (three in this case)

```
>>> df.tail(3)
   animal
6   shark
7   whale
8   zebra
```

### pandas.Series.take

**Series.take** (*indices*, *axis=0*, *convert=None*, *is\_copy=True*, *\*\*kwargs*)

Return the elements in the given *positional* indices along an axis.

This means that we are not indexing according to actual values in the index attribute of the object. We are indexing according to the actual position of the element in the object.

**Parameters**

**indices** [array-like] An array of ints indicating which positions to take.

**axis** [{0 or 'index', 1 or 'columns', None}, default 0] The axis on which to select elements. 0 means that we are selecting rows, 1 means that we are selecting columns.

**convert** [bool, default True] Whether to convert negative indices into positive ones. For example, -1 would map to the `len(axis) - 1`. The conversions are similar to the behavior of indexing a regular Python list.

Deprecated since version 0.21.0: In the future, negative indices will always be converted.

**is\_copy** [bool, default True] Whether to return a copy of the original object or not.

**\*\*kwargs** For compatibility with `numpy.take()`. Has no effect on the output.

**Returns**

**taken** [same type as caller] An array-like containing the elements taken from the object.

**See also:**

**DataFrame.loc** Select a subset of a DataFrame by labels.

**DataFrame.iloc** Select a subset of a DataFrame by positions.

**numpy.take** Take elements from an array along an axis.

**Examples**

```
>>> df = pd.DataFrame([('falcon', 'bird', 389.0),
...                     ('parrot', 'bird', 24.0),
...                     ('lion', 'mammal', 80.5),
...                     ('monkey', 'mammal', np.nan)],
...                     columns=['name', 'class', 'max_speed'],
...                     index=[0, 2, 3, 1])
>>> df
   name  class  max_speed
0  falcon   bird    389.0
2  parrot   bird     24.0
3   lion  mammal     80.5
1  monkey  mammal      NaN
```

Take elements at positions 0 and 3 along the axis 0 (default).

Note how the actual indices selected (0 and 1) do not correspond to our selected indices 0 and 3. That's because we are selecting the 0th and 3rd rows, not rows whose indices equal 0 and 3.

```
>>> df.take([0, 3])
   name  class  max_speed
0  falcon   bird    389.0
1  monkey  mammal      NaN
```

Take elements at indices 1 and 2 along the axis 1 (column selection).

```
>>> df.take([1, 2], axis=1)
   class  max_speed
0   bird    389.0
```

(continues on next page)

(continued from previous page)

|   |        |      |
|---|--------|------|
| 2 | bird   | 24.0 |
| 3 | mammal | 80.5 |
| 1 | mammal | NaN  |

We may take elements using negative integers for positive indices, starting from the end of the object, just like with Python lists.

```
>>> df.take([-1, -2])
      name  class  max_speed
1  monkey  mammal         NaN
3    lion  mammal        80.5
```

## pandas.Series.to\_clipboard

`Series.to_clipboard(excel=True, sep=None, **kwargs)`

Copy object to the system clipboard.

Write a text representation of object to the system clipboard. This can be pasted into Excel, for example.

### Parameters

**excel** [bool, default True]

- True, use the provided separator, writing in a csv format for allowing easy pasting into excel.
- False, write a string representation of the object to the clipboard.

**sep** [str, default '\t'] Field delimiter.

**\*\*kwargs** These parameters will be passed to `DataFrame.to_csv`.

See also:

**DataFrame.to\_csv** Write a DataFrame to a comma-separated values (csv) file.

**read\_clipboard** Read text from clipboard and pass to `read_table`.

## Notes

Requirements for your platform.

- Linux : *xclip*, or *xsel* (with *gtk* or *PyQt4* modules)
- Windows : none
- OS X : none

## Examples

Copy the contents of a DataFrame to the clipboard.

```
>>> df = pd.DataFrame([[1, 2, 3], [4, 5, 6]], columns=['A', 'B', 'C'])
>>> df.to_clipboard(sep=',')
... # Wrote the following to the system clipboard:
... # ,A,B,C
```

(continues on next page)

(continued from previous page)

```
... # 0,1,2,3
... # 1,4,5,6
```

We can omit the the index by passing the keyword *index* and setting it to false.

```
>>> df.to_clipboard(sep=',', index=False)
... # Wrote the following to the system clipboard:
... # A,B,C
... # 1,2,3
... # 4,5,6
```

## pandas.Series.to\_csv

`Series.to_csv(*args, **kwargs)`

Write object to a comma-separated values (csv) file.

Changed in version 0.24.0: The order of arguments for Series was changed.

### Parameters

**path\_or\_buf** [str or file handle, default None] File path or object, if None is provided the result is returned as a string.

Changed in version 0.24.0: Was previously named “path” for Series.

**sep** [str, default ‘,’] String of length 1. Field delimiter for the output file.

**na\_rep** [str, default ‘’] Missing data representation.

**float\_format** [str, default None] Format string for floating point numbers.

**columns** [sequence, optional] Columns to write.

**header** [bool or list of str, default True] Write out the column names. If a list of strings is given it is assumed to be aliases for the column names.

Changed in version 0.24.0: Previously defaulted to False for Series.

**index** [bool, default True] Write row names (index).

**index\_label** [str or sequence, or False, default None] Column label for index column(s) if desired. If None is given, and *header* and *index* are True, then the index names are used. A sequence should be given if the object uses MultiIndex. If False do not print fields for index names. Use *index\_label=False* for easier importing in R.

**mode** [str] Python write mode, default ‘w’.

**encoding** [str, optional] A string representing the encoding to use in the output file, defaults to ‘ascii’ on Python 2 and ‘utf-8’ on Python 3.

**compression** [str, default ‘infer’] Compression mode among the following possible values: {‘infer’, ‘gzip’, ‘bz2’, ‘zip’, ‘xz’, None}. If ‘infer’ and *path\_or\_buf* is path-like, then detect compression from the following extensions: ‘.gz’, ‘.bz2’, ‘.zip’ or ‘.xz’. (otherwise no compression).

Changed in version 0.24.0: ‘infer’ option added and set to default.

**quoting** [optional constant from csv module] Defaults to csv.QUOTE\_MINIMAL. If you have set a *float\_format* then floats are converted to strings and thus csv.QUOTE\_NONNUMERIC will treat them as non-numeric.

**quotechar** [str, default `''`] String of length 1. Character used to quote fields.

**line\_terminator** [string, optional] The newline character or character sequence to use in the output file. Defaults to `os.linesep`, which depends on the OS in which this method is called (`'n'` for linux, `'rn'` for Windows, i.e.).

Changed in version 0.24.0.

**chunksize** [int or None] Rows to write at a time.

**tupleize\_cols** [bool, default False] Write MultiIndex columns as a list of tuples (if True) or in the new, expanded format, where each MultiIndex column is a row in the CSV (if False).

Deprecated since version 0.21.0: This argument will be removed and will always write each row of the multi-index as a separate row in the CSV file.

**date\_format** [str, default None] Format string for datetime objects.

**doublequote** [bool, default True] Control quoting of *quotechar* inside a field.

**escapechar** [str, default None] String of length 1. Character used to escape *sep* and *quotechar* when appropriate.

**decimal** [str, default `'.'`] Character recognized as decimal separator. E.g. use `','` for European data.

#### Returns

**None or str** If `path_or_buf` is None, returns the resulting csv format as a string. Otherwise returns None.

See also:

**`read_csv`** Load a CSV file into a DataFrame.

**`to_excel`** Load an Excel file into a DataFrame.

#### Examples

```
>>> df = pd.DataFrame({'name': ['Raphael', 'Donatello'],
...                   'mask': ['red', 'purple'],
...                   'weapon': ['sai', 'bo staff']})
>>> df.to_csv(index=False)
'name,mask,weapon\nRaphael,red,sai\nDonatello,purple,bo staff\n'
```

### pandas.Series.to\_dense

`Series.to_dense()`

Return dense representation of NDFrame (as opposed to sparse).

### pandas.Series.to\_dict

`Series.to_dict(into=<class 'dict'>)`

Convert Series to {label -> value} dict or dict-like object.

#### Parameters

**into** [class, default dict] The collections.Mapping subclass to use as the return object. Can be the actual class or an empty instance of the mapping type you want. If you want a collections.defaultdict, you must pass it initialized.

New in version 0.21.0.

### Returns

**value\_dict** [collections.Mapping]

### Examples

```
>>> s = pd.Series([1, 2, 3, 4])
>>> s.to_dict()
{0: 1, 1: 2, 2: 3, 3: 4}
>>> from collections import OrderedDict, defaultdict
>>> s.to_dict(OrderedDict)
OrderedDict([(0, 1), (1, 2), (2, 3), (3, 4)])
>>> dd = defaultdict(list)
>>> s.to_dict(dd)
defaultdict(<type 'list'>, {0: 1, 1: 2, 2: 3, 3: 4})
```

### pandas.Series.to\_excel

**Series.to\_excel** (*excel\_writer*, *sheet\_name*='Sheet1', *na\_rep*="", *float\_format*=None, *columns*=None, *header*=True, *index*=True, *index\_label*=None, *startrow*=0, *startcol*=0, *engine*=None, *merge\_cells*=True, *encoding*=None, *inf\_rep*='inf', *verbose*=True, *freeze\_panes*=None)

Write object to an Excel sheet.

To write a single object to an Excel .xlsx file it is only necessary to specify a target file name. To write to multiple sheets it is necessary to create an *ExcelWriter* object with a target file name, and specify a sheet in the file to write to.

Multiple sheets may be written to by specifying unique *sheet\_name*. With all data written to the file it is necessary to save the changes. Note that creating an *ExcelWriter* object with a file name that already exists will result in the contents of the existing file being erased.

### Parameters

**excel\_writer** [str or ExcelWriter object] File path or existing ExcelWriter.

**sheet\_name** [str, default 'Sheet1'] Name of sheet which will contain DataFrame.

**na\_rep** [str, default ''] Missing data representation.

**float\_format** [str, optional] Format string for floating point numbers. For example `float_format="% .2f"` will format 0.1234 to 0.12.

**columns** [sequence or list of str, optional] Columns to write.

**header** [bool or list of str, default True] Write out the column names. If a list of string is given it is assumed to be aliases for the column names.

**index** [bool, default True] Write row names (index).

**index\_label** [str or sequence, optional] Column label for index column(s) if desired. If not specified, and *header* and *index* are True, then the index names are used. A sequence should be given if the DataFrame uses MultiIndex.

**startrow** [int, default 0] Upper left cell row to dump data frame.

**startcol** [int, default 0] Upper left cell column to dump data frame.

**engine** [str, optional] Write engine to use, 'openpyxl' or 'xlsxwriter'. You can also set this via the options `io.excel.xlsx.writer`, `io.excel.xls.writer`, and `io.excel.xlsm.writer`.

**merge\_cells** [bool, default True] Write MultiIndex and Hierarchical Rows as merged cells.

**encoding** [str, optional] Encoding of the resulting excel file. Only necessary for xlwt, other writers support unicode natively.

**inf\_rep** [str, default 'inf'] Representation for infinity (there is no native representation for infinity in Excel).

**verbose** [bool, default True] Display more information in the error logs.

**freeze\_panes** [tuple of int (length 2), optional] Specifies the one-based bottommost row and rightmost column that is to be frozen.

New in version 0.20.0..

#### See also:

**to\_csv** Write DataFrame to a comma-separated values (csv) file.

**ExcelWriter** Class for writing DataFrame objects into excel sheets.

**read\_excel** Read an Excel file into a pandas DataFrame.

**read\_csv** Read a comma-separated values (csv) file into DataFrame.

## Notes

For compatibility with `to_csv()`, `to_excel` serializes lists and dicts to strings before writing.

Once a workbook has been saved it is not possible write further data without rewriting the whole workbook.

## Examples

Create, write to and save a workbook:

```
>>> df1 = pd.DataFrame([[ 'a', 'b'], [ 'c', 'd']],
...                     index=[ 'row 1', 'row 2'],
...                     columns=[ 'col 1', 'col 2'])
>>> df1.to_excel("output.xlsx") # doctest: +SKIP
```

To specify the sheet name:

```
>>> df1.to_excel("output.xlsx",
...              sheet_name='Sheet_name_1') # doctest: +SKIP
```

If you wish to write to more than one sheet in the workbook, it is necessary to specify an `ExcelWriter` object:

```
>>> df2 = df1.copy()
>>> with pd.ExcelWriter('output.xlsx') as writer: # doctest: +SKIP
...     df1.to_excel(writer, sheet_name='Sheet_name_1')
...     df2.to_excel(writer, sheet_name='Sheet_name_2')
```

To set the library that is used to write the Excel file, you can pass the *engine* keyword (the default engine is automatically chosen depending on the file extension):

```
>>> df1.to_excel('output1.xlsx', engine='xlsxwriter') # doctest: +SKIP
```

### pandas.Series.to\_frame

**Series.to\_frame** (*name=None*)  
Convert Series to DataFrame.

#### Parameters

**name** [object, default None] The passed name should substitute for the series name (if it has one).

#### Returns

**data\_frame** [DataFrame]

### pandas.Series.to\_hdf

**Series.to\_hdf** (*path\_or\_buf, key, \*\*kwargs*)  
Write the contained data to an HDF5 file using HDFStore.

Hierarchical Data Format (HDF) is self-describing, allowing an application to interpret the structure and contents of a file with no outside information. One HDF file can hold a mix of related objects which can be accessed as a group or as individual objects.

In order to add another DataFrame or Series to an existing HDF file please use append mode and a different a key.

For more information see the *user guide*.

#### Parameters

**path\_or\_buf** [str or pandas.HDFStore] File path or HDFStore object.

**key** [str] Identifier for the group in the store.

**mode** [{ 'a', 'w', 'r+' }, default 'a'] Mode to open file:

- 'w': write, a new file is created (an existing file with the same name would be deleted).
- 'a': append, an existing file is opened for reading and writing, and if the file does not exist it is created.
- 'r+': similar to 'a', but the file must already exist.

**format** [{ 'fixed', 'table' }, default 'fixed'] Possible values:

- 'fixed': Fixed format. Fast writing/reading. Not-appendable, nor searchable.

- **'table'**: Table format. Write as a PyTables Table structure which may perform worse but allow more flexible operations like searching / selecting subsets of the data.

**append** [bool, default False] For Table formats, append the input data to the existing.

**data\_columns** [list of columns or True, optional] List of columns to create as indexed data columns for on-disk queries, or True to use all columns. By default only the axes of the object are indexed. See *Query via Data Columns*. Applicable only to format='table'.

**complevel** [{0-9}, optional] Specifies a compression level for data. A value of 0 disables compression.

**complib** [{ 'zlib', 'lzo', 'bzip2', 'blosc' }, default 'zlib'] Specifies the compression library to be used. As of v0.20.2 these additional compressors for Blosc are supported (default if no compressor specified: 'blosc:blosclz'): { 'blosc:blosclz', 'blosc:lz4', 'blosc:lz4hc', 'blosc:snappy', 'blosc:zlib', 'blosc:zstd' }. Specifying a compression library which is not available issues a ValueError.

**fletcher32** [bool, default False] If applying compression use the fletcher32 checksum.

**dropna** [bool, default False] If true, ALL nan rows will not be written to store.

**errors** [str, default 'strict'] Specifies how encoding and decoding errors are to be handled. See the errors argument for `open()` for a full list of options.

See also:

**DataFrame.read\_hdf** Read from HDF file.

**DataFrame.to\_parquet** Write a DataFrame to the binary parquet format.

**DataFrame.to\_sql** Write to a sql table.

**DataFrame.to\_feather** Write out feather-format for DataFrames.

**DataFrame.to\_csv** Write out to a csv file.

## Examples

```
>>> df = pd.DataFrame({'A': [1, 2, 3], 'B': [4, 5, 6]},
...                    index=['a', 'b', 'c'])
>>> df.to_hdf('data.h5', key='df', mode='w')
```

We can add another object to the same file:

```
>>> s = pd.Series([1, 2, 3, 4])
>>> s.to_hdf('data.h5', key='s')
```

Reading from HDF file:

```
>>> pd.read_hdf('data.h5', 'df')
A  B
a  1  4
b  2  5
c  3  6
>>> pd.read_hdf('data.h5', 's')
0    1
1    2
```

(continues on next page)

(continued from previous page)

```
2    3
3    4
dtype: int64
```

Deleting file with data:

```
>>> import os
>>> os.remove('data.h5')
```

## pandas.Series.to\_json

`Series.to_json` (*path\_or\_buf=None, orient=None, date\_format=None, double\_precision=10, force\_ascii=True, date\_unit='ms', default\_handler=None, lines=False, compression='infer', index=True*)

Convert the object to a JSON string.

Note NaN's and None will be converted to null and datetime objects will be converted to UNIX timestamps.

### Parameters

**path\_or\_buf** [string or file handle, optional] File path or object. If not specified, the result is returned as a string.

**orient** [string] Indication of expected JSON string format.

- Series
  - default is 'index'
  - allowed values are: {'split','records','index','table'}
- DataFrame
  - default is 'columns'
  - allowed values are: {'split','records','index','columns','values','table'}
- The format of the JSON string
  - 'split' : dict like {'index' -> [index], 'columns' -> [columns], 'data' -> [values]}
  - 'records' : list like [{column -> value}, ... , {column -> value}]
  - 'index' : dict like {index -> {column -> value}}
  - 'columns' : dict like {column -> {index -> value}}
  - 'values' : just the values array
  - 'table' : dict like {'schema': {schema}, 'data': {data}} describing the data, and the data component is like `orient='records'`.

Changed in version 0.20.0.

**date\_format** [{None, 'epoch', 'iso'}] Type of date conversion. 'epoch' = epoch milliseconds, 'iso' = ISO8601. The default depends on the *orient*. For `orient='table'`, the default is 'iso'. For all other orients, the default is 'epoch'.

**double\_precision** [int, default 10] The number of decimal places to use when encoding floating point values.

**force\_ascii** [bool, default True] Force encoded string to be ASCII.

**date\_unit** [string, default 'ms' (milliseconds)] The time unit to encode to, governs timestamp and ISO8601 precision. One of 's', 'ms', 'us', 'ns' for second, millisecond, microsecond, and nanosecond respectively.

**default\_handler** [callable, default None] Handler to call if object cannot otherwise be converted to a suitable format for JSON. Should receive a single argument which is the object to convert and return a serialisable object.

**lines** [bool, default False] If 'orient' is 'records' write out line delimited json format. Will throw ValueError if incorrect 'orient' since others are not list like.

New in version 0.19.0.

**compression** [{ 'infer', 'gzip', 'bz2', 'zip', 'xz', None}] A string representing the compression to use in the output file, only used when the first argument is a filename. By default, the compression is inferred from the filename.

New in version 0.21.0.

Changed in version 0.24.0: 'infer' option added and set to default

**index** [bool, default True] Whether to include the index values in the JSON string. Not including the index (index=False) is only supported when orient is 'split' or 'table'.

New in version 0.23.0.

#### See also:

*read\_json*

#### Examples

```
>>> df = pd.DataFrame([[ 'a', 'b'], [ 'c', 'd']],
...                    index=[ 'row 1', 'row 2'],
...                    columns=[ 'col 1', 'col 2'])
>>> df.to_json(orient='split')
'{"columns":["col 1","col 2"],
  "index":["row 1","row 2"],
  "data":[["a","b"],["c","d"]]]'
```

Encoding/decoding a Dataframe using 'records' formatted JSON. Note that index labels are not preserved with this encoding.

```
>>> df.to_json(orient='records')
'[{"col 1":"a","col 2":"b"}, {"col 1":"c","col 2":"d"}]'
```

Encoding/decoding a Dataframe using 'index' formatted JSON:

```
>>> df.to_json(orient='index')
'{"row 1":{"col 1":"a","col 2":"b"},"row 2":{"col 1":"c","col 2":"d"}}'
```

Encoding/decoding a Dataframe using 'columns' formatted JSON:

```
>>> df.to_json(orient='columns')
'{"col 1":{"row 1":"a","row 2":"c"},"col 2":{"row 1":"b","row 2":"d"}}'
```

Encoding/decoding a Dataframe using 'values' formatted JSON:

```
>>> df.to_json(orient='values')
'[[{"a", "b"}, {"c", "d"}]'
```

### Encoding with Table Schema

```
>>> df.to_json(orient='table')
'{"schema": {"fields": [{"name": "index", "type": "string"},
                        {"name": "col 1", "type": "string"},
                        {"name": "col 2", "type": "string"}],
  "primaryKey": "index",
  "pandas_version": "0.20.0"},
 "data": [{"index": "row 1", "col 1": "a", "col 2": "b"},
           {"index": "row 2", "col 1": "c", "col 2": "d"}]}'
```

## pandas.Series.to\_latex

`Series.to_latex`(*buf=None, columns=None, col\_space=None, header=True, index=True, na\_rep='NaN', formatters=None, float\_format=None, sparsify=None, index\_names=True, bold\_rows=False, column\_format=None, longtable=None, escape=None, encoding=None, decimal='.', multicolumn=None, multirow=None*)

Render an object to a LaTeX tabular environment table.

Render an object to a tabular environment table. You can splice this into a LaTeX document. Requires `usepackage{booktabs}`.

Changed in version 0.20.2: Added to Series

### Parameters

- buf** [file descriptor or None] Buffer to write to. If None, the output is returned as a string.
- columns** [list of label, optional] The subset of columns to write. Writes all columns by default.
- col\_space** [int, optional] The minimum width of each column.
- header** [bool or list of str, default True] Write out the column names. If a list of strings is given, it is assumed to be aliases for the column names.
- index** [bool, default True] Write row names (index).
- na\_rep** [str, default 'NaN'] Missing data representation.
- formatters** [list of functions or dict of {str: function}, optional] Formatter functions to apply to columns' elements by position or name. The result of each function must be a unicode string. List must be of length equal to the number of columns.
- float\_format** [str, optional] Format string for floating point numbers.
- sparsify** [bool, optional] Set to False for a DataFrame with a hierarchical index to print every multiindex key at each row. By default, the value will be read from the config module.
- index\_names** [bool, default True] Prints the names of the indexes.
- bold\_rows** [bool, default False] Make the row labels bold in the output.
- column\_format** [str, optional] The columns format as specified in [LaTeX table format](#) e.g. 'rcl' for 3 columns. By default, 'l' will be used for all columns except columns of numbers, which default to 'r'.

**longtable** [bool, optional] By default, the value will be read from the pandas config module. Use a longtable environment instead of tabular. Requires adding a usepackage{longtable} to your LaTeX preamble.

**escape** [bool, optional] By default, the value will be read from the pandas config module. When set to False prevents from escaping latex special characters in column names.

**encoding** [str, optional] A string representing the encoding to use in the output file, defaults to 'ascii' on Python 2 and 'utf-8' on Python 3.

**decimal** [str, default '.'] Character recognized as decimal separator, e.g. ',' in Europe. .. versionadded:: 0.18.0

**multicolumn** [bool, default True] Use multicolumn to enhance MultiIndex columns. The default will be read from the config module. .. versionadded:: 0.20.0

**multicolumn\_format** [str, default 'l'] The alignment for multicolumns, similar to *column\_format* The default will be read from the config module. .. versionadded:: 0.20.0

**multirow** [bool, default False] Use multirow to enhance MultiIndex rows. Requires adding a usepackage{multirow} to your LaTeX preamble. Will print centered labels (instead of top-aligned) across the contained rows, separating groups via clines. The default will be read from the pandas config module. .. versionadded:: 0.20.0

### Returns

**str or None** If buf is None, returns the resulting LaTeX format as a string. Otherwise returns None.

### See also:

**DataFrame.to\_string** Render a DataFrame to a console-friendly tabular output.

**DataFrame.to\_html** Render a DataFrame as an HTML table.

### Examples

```
>>> df = pd.DataFrame({'name': ['Raphael', 'Donatello'],
...                    'mask': ['red', 'purple'],
...                    'weapon': ['sai', 'bo staff']})
>>> df.to_latex(index=False) # doctest: +NORMALIZE_WHITESPACE
'\begin{tabular}{lll}\n\toprule\n      name & mask & weapon\n\\\\\n\midrule\n  Raphael & red & sai \\\n\n Donatello & purple & bo staff \\\n\n\bottomrule\n\end{tabular}\n'
```

### pandas.Series.to\_list

**Series.to\_list()**

Return a list of the values.

These are each a scalar type, which is a Python scalar (for str, int, float) or a pandas scalar (for Timestamp/Timedelta/Interval/Period)

### See also:

`numpy.ndarray.tolist`

### pandas.Series.to\_msgpack

`Series.to_msgpack` (*path\_or\_buf=None*, *encoding='utf-8'*, *\*\*kwargs*)

Serialize object to input file path using msgpack format.

THIS IS AN EXPERIMENTAL LIBRARY and the storage format may not be stable until a future release.

#### Parameters

**path** [string File path, buffer-like, or None] if None, return generated string

**append** [bool whether to append to an existing msgpack] (default is False)

**compress** [type of compressor (zlib or blosc), default to None (no) compression]

### pandas.Series.to\_numpy

`Series.to_numpy` (*dtype=None*, *copy=False*)

A NumPy ndarray representing the values in this Series or Index.

New in version 0.24.0.

#### Parameters

**dtype** [str or numpy.dtype, optional] The dtype to pass to `numpy.asarray()`

**copy** [bool, default False] Whether to ensure that the returned value is a not a view on another array. Note that `copy=False` does not *ensure* that `to_numpy()` is no-copy. Rather, `copy=True` ensure that a copy is made, even if not strictly necessary.

#### Returns

`numpy.ndarray`

See also:

**Series.array** Get the actual data stored within.

**Index.array** Get the actual data stored within.

**DataFrame.to\_numpy** Similar method for DataFrame.

### Notes

The returned array will be the same up to equality (values equal in *self* will be equal in the returned array; likewise for values that are not equal). When *self* contains an `ExtensionArray`, the dtype may be different. For example, for a category-dtype Series, `to_numpy()` will return a NumPy array and the categorical dtype will be lost.

For NumPy dtypes, this will be a reference to the actual data stored in this Series or Index (assuming `copy=False`). Modifying the result in place will modify the data stored in the Series or Index (not that we recommend doing that).

For extension types, `to_numpy()` *may* require copying data and coercing the result to a NumPy type (possibly object), which may be expensive. When you need a no-copy reference to the underlying data, `Series.array` should be used instead.

This table lays out the different dtypes and default return types of `to_numpy()` for various dtypes within pandas.

| dtype              | array type                       |
|--------------------|----------------------------------|
| category[T]        | ndarray[T] (same dtype as input) |
| period             | ndarray[object] (Periods)        |
| interval           | ndarray[object] (Intervals)      |
| IntegerNA          | ndarray[object]                  |
| datetime64[ns]     | datetime64[ns]                   |
| datetime64[ns, tz] | ndarray[object] (Timestamps)     |

## Examples

```
>>> ser = pd.Series(pd.Categorical(['a', 'b', 'a']))
>>> ser.to_numpy()
array(['a', 'b', 'a'], dtype=object)
```

Specify the *dtype* to control how datetime-aware data is represented. Use `dtype=object` to return an ndarray of pandas *Timestamp* objects, each with the correct `tz`.

```
>>> ser = pd.Series(pd.date_range('2000', periods=2, tz="CET"))
>>> ser.to_numpy(dtype=object)
array([Timestamp('2000-01-01 00:00:00+0100', tz='CET', freq='D'),
       Timestamp('2000-01-02 00:00:00+0100', tz='CET', freq='D')],
      dtype=object)
```

Or `dtype='datetime64[ns]'` to return an ndarray of native `datetime64` values. The values are converted to UTC and the timezone info is dropped.

```
>>> ser.to_numpy(dtype="datetime64[ns]")
... # doctest: +ELLIPSIS
array(['1999-12-31T23:00:00.000000000', '2000-01-01T23:00:00...'],
      dtype='datetime64[ns]')
```

## pandas.Series.to\_period

`Series.to_period(freq=None, copy=True)`

Convert Series from `DatetimeIndex` to `PeriodIndex` with desired frequency (inferred from index if not passed).

### Parameters

**freq** [string, default]

### Returns

**ts** [Series with `PeriodIndex`]

## pandas.Series.to\_pickle

`Series.to_pickle(path, compression='infer', protocol=4)`

Pickle (serialize) object to file.

### Parameters

**path** [str] File path where the pickled object will be stored.

**compression** [{‘infer’, ‘gzip’, ‘bz2’, ‘zip’, ‘xz’, None}, default ‘infer’] A string representing the compression to use in the output file. By default, infers from the file extension in specified path.

New in version 0.20.0.

**protocol** [int] Int which indicates which protocol should be used by the pickler, default HIGHEST\_PROTOCOL (see [?] paragraph 12.1.2). The possible values for this parameter depend on the version of Python. For Python 2.x, possible values are 0, 1, 2. For Python >=3.0, 3 is a valid value. For Python >= 3.4, 4 is a valid value. A negative value for the protocol parameter is equivalent to setting its value to HIGHEST\_PROTOCOL.

New in version 0.21.0.

See also:

**read\_pickle** Load pickled pandas object (or any object) from file.

**DataFrame.to\_hdf** Write DataFrame to an HDF5 file.

**DataFrame.to\_sql** Write DataFrame to a SQL database.

**DataFrame.to\_parquet** Write a DataFrame to the binary parquet format.

## Examples

```
>>> original_df = pd.DataFrame({"foo": range(5), "bar": range(5, 10)})
>>> original_df
   foo  bar
0    0    5
1    1    6
2    2    7
3    3    8
4    4    9
>>> original_df.to_pickle("./dummy.pkl")
```

```
>>> unpickled_df = pd.read_pickle("./dummy.pkl")
>>> unpickled_df
   foo  bar
0    0    5
1    1    6
2    2    7
3    3    8
4    4    9
```

```
>>> import os
>>> os.remove("./dummy.pkl")
```

## pandas.Series.to\_sparse

**Series.to\_sparse** (*kind*=‘block’, *fill\_value*=None)

Convert Series to SparseSeries.

### Parameters

**kind** [{‘block’, ‘integer’}]

**fill\_value** [float, defaults to NaN (missing)]

### Returns

**sp** [SparseSeries]

## pandas.Series.to\_sql

`Series.to_sql(name, con, schema=None, if_exists='fail', index=True, index_label=None, chunksize=None, dtype=None, method=None)`

Write records stored in a DataFrame to a SQL database.

Databases supported by SQLAlchemy [?] are supported. Tables can be newly created, appended to, or overwritten.

### Parameters

**name** [string] Name of SQL table.

**con** [sqlalchemy.engine.Engine or sqlite3.Connection] Using SQLAlchemy makes it possible to use any DB supported by that library. Legacy support is provided for sqlite3.Connection objects.

**schema** [string, optional] Specify the schema (if database flavor supports this). If None, use default schema.

**if\_exists** [{ 'fail', 'replace', 'append' }, default 'fail'] How to behave if the table already exists.

- fail: Raise a ValueError.
- replace: Drop the table before inserting new values.
- append: Insert new values to the existing table.

**index** [bool, default True] Write DataFrame index as a column. Uses *index\_label* as the column name in the table.

**index\_label** [string or sequence, default None] Column label for index column(s). If None is given (default) and *index* is True, then the index names are used. A sequence should be given if the DataFrame uses MultiIndex.

**chunksize** [int, optional] Rows will be written in batches of this size at a time. By default, all rows will be written at once.

**dtype** [dict, optional] Specifying the datatype for columns. The keys should be the column names and the values should be the SQLAlchemy types or strings for the sqlite3 legacy mode.

**method** [{None, 'multi', callable}, default None] Controls the SQL insertion clause used:

- None : Uses standard SQL INSERT clause (one per row).
- 'multi': Pass multiple values in a single INSERT clause.
- callable with signature (pd\_table, conn, keys, data\_iter).

Details and a sample callable implementation can be found in the section *insert method*.

New in version 0.24.0.

### Raises

**ValueError** When the table already exists and *if\_exists* is 'fail' (the default).

See also:

**`read_sql`** Read a DataFrame from a table.

## Notes

Timezone aware datetime columns will be written as `Timestamp` with `timezone` type with SQLAlchemy if supported by the database. Otherwise, the datetimes will be stored as timezone unaware timestamps local to the original timezone.

New in version 0.24.0.

## References

[?], [?]

## Examples

Create an in-memory SQLite database.

```
>>> from sqlalchemy import create_engine
>>> engine = create_engine('sqlite://', echo=False)
```

Create a table from scratch with 3 rows.

```
>>> df = pd.DataFrame({'name' : ['User 1', 'User 2', 'User 3']})
>>> df
   name
0  User 1
1  User 2
2  User 3
```

```
>>> df.to_sql('users', con=engine)
>>> engine.execute("SELECT * FROM users").fetchall()
[(0, 'User 1'), (1, 'User 2'), (2, 'User 3')]
```

```
>>> df1 = pd.DataFrame({'name' : ['User 4', 'User 5']})
>>> df1.to_sql('users', con=engine, if_exists='append')
>>> engine.execute("SELECT * FROM users").fetchall()
[(0, 'User 1'), (1, 'User 2'), (2, 'User 3'),
 (0, 'User 4'), (1, 'User 5')]
```

Overwrite the table with just df1.

```
>>> df1.to_sql('users', con=engine, if_exists='replace',
...           index_label='id')
>>> engine.execute("SELECT * FROM users").fetchall()
[(0, 'User 4'), (1, 'User 5')]
```

Specify the dtype (especially useful for integers with missing values). Notice that while pandas is forced to store the data as floating point, the database supports nullable integers. When fetching the data with Python, we get back integer scalars.

```
>>> df = pd.DataFrame({"A": [1, None, 2]})
>>> df
   A
0  1.0
1  NaN
2  2.0

>>> from sqlalchemy.types import Integer
>>> df.to_sql('integers', con=engine, index=False,
...         dtype={"A": Integer()})

>>> engine.execute("SELECT * FROM integers").fetchall()
[(1,), (None,), (2,)]
```

### pandas.Series.to\_string

`Series.to_string` (*buf=None*, *na\_rep='NaN'*, *float\_format=None*, *header=True*, *index=True*, *length=False*, *dtype=False*, *name=False*, *max\_rows=None*)

Render a string representation of the Series.

#### Parameters

- buf** [StringIO-like, optional] buffer to write to
- na\_rep** [string, optional] string representation of NAN to use, default 'NaN'
- float\_format** [one-parameter function, optional] formatter function to apply to columns' elements if they are floats default None
- header** [boolean, default True] Add the Series header (index name)
- index** [bool, optional] Add index (row) labels, default True
- length** [boolean, default False] Add the Series length
- dtype** [boolean, default False] Add the Series dtype
- name** [boolean, default False] Add the Series name if not None
- max\_rows** [int, optional] Maximum number of rows to show before truncating. If None, show all.

#### Returns

- formatted** [string (if not buffer passed)]

### pandas.Series.to\_timestamp

`Series.to_timestamp` (*freq=None*, *how='start'*, *copy=True*)

Cast to DatetimeIndex of timestamps, at *beginning* of period.

#### Parameters

- freq** [string, default frequency of PeriodIndex] Desired frequency
- how** [{ 's', 'e', 'start', 'end' }] Convention for converting period to timestamp; start of period vs. end

#### Returns

`ts` [Series with DatetimeIndex]

## pandas.Series.to\_xarray

`Series.to_xarray()`

Return an xarray object from the pandas object.

### Returns

**xarray.DataArray or xarray.Dataset** Data in the pandas structure converted to Dataset if the object is a DataFrame, or a DataArray if the object is a Series.

### See also:

**DataFrame.to\_hdf** Write DataFrame to an HDF5 file.

**DataFrame.to\_parquet** Write a DataFrame to the binary parquet format.

## Notes

See the [xarray docs](#)

## Examples

```
>>> df = pd.DataFrame([('falcon', 'bird', 389.0, 2),
...                     ('parrot', 'bird', 24.0, 2),
...                     ('lion', 'mammal', 80.5, 4),
...                     ('monkey', 'mammal', np.nan, 4)],
...                     columns=['name', 'class', 'max_speed',
...                               'num_legs'])
>>> df
   name  class  max_speed  num_legs
0  falcon   bird     389.0         2
1  parrot   bird      24.0         2
2   lion  mammal     80.5         4
3  monkey  mammal      NaN         4
```

```
>>> df.to_xarray()
<xarray.Dataset>
Dimensions:      (index: 4)
Coordinates:
  * index        (index) int64 0 1 2 3
Data variables:
  name           (index) object 'falcon' 'parrot' 'lion' 'monkey'
  class          (index) object 'bird' 'bird' 'mammal' 'mammal'
  max_speed      (index) float64 389.0 24.0 80.5 nan
  num_legs       (index) int64 2 2 4 4
```

```
>>> df['max_speed'].to_xarray()
<xarray.DataArray 'max_speed' (index: 4)>
array([389. ,  24. ,  80.5,   nan])
Coordinates:
  * index        (index) int64 0 1 2 3
```

```
>>> dates = pd.to_datetime(['2018-01-01', '2018-01-01',
...                          '2018-01-02', '2018-01-02'])
>>> df_multiindex = pd.DataFrame({'date': dates,
...                               'animal': ['falcon', 'parrot', 'falcon',
...                                         'parrot'],
...                               'speed': [350, 18, 361, 15]}).set_index(['date',
...                               'animal'])
>>> df_multiindex
```

|            |        | speed |
|------------|--------|-------|
| date       | animal |       |
| 2018-01-01 | falcon | 350   |
|            | parrot | 18    |
| 2018-01-02 | falcon | 361   |
|            | parrot | 15    |

```
>>> df_multiindex.to_xarray()
<xarray.Dataset>
Dimensions:  (animal: 2, date: 2)
Coordinates:
  * date      (date) datetime64[ns] 2018-01-01 2018-01-02
  * animal    (animal) object 'falcon' 'parrot'
Data variables:
  speed      (date, animal) int64 350 18 361 15
```

## pandas.Series.tolist

`Series.tolist()`

Return a list of the values.

These are each a scalar type, which is a Python scalar (for str, int, float) or a pandas scalar (for Timestamp/Timedelta/Interval/Period)

**See also:**

`numpy.ndarray.tolist`

## pandas.Series.transform

`Series.transform(func, axis=0, *args, **kwargs)`

Call `func` on self producing a Series with transformed values and that has the same axis length as self.

New in version 0.20.0.

### Parameters

**func** [function, str, list or dict] Function to use for transforming the data. If a function, must either work when passed a Series or when passed to `Series.apply`.

Accepted combinations are:

- function
- string function name
- list of functions and/or function names, e.g. `[np.exp, 'sqrt']`
- dict of axis labels -> functions, function names or list of such.

**axis** [{0 or 'index'}] Parameter needed for compatibility with DataFrame.

**\*args** Positional arguments to pass to *func*.

**\*\*kwargs** Keyword arguments to pass to *func*.

### Returns

**Series** A Series that must have the same length as self.

### Raises

**ValueError** [If the returned Series has a different length than self.]

### See also:

**Series.agg** Only perform aggregating type operations.

**Series.apply** Invoke function on a Series.

### Examples

```
>>> df = pd.DataFrame({'A': range(3), 'B': range(1, 4)})
>>> df
   A  B
0  0  1
1  1  2
2  2  3
>>> df.transform(lambda x: x + 1)
   A  B
0  1  2
1  2  3
2  3  4
```

Even though the resulting Series must have the same length as the input Series, it is possible to provide several input functions:

```
>>> s = pd.Series(range(3))
>>> s
0    0
1    1
2    2
dtype: int64
>>> s.transform([np.sqrt, np.exp])
      sqrt      exp
0  0.000000  1.000000
1  1.000000  2.718282
2  1.414214  7.389056
```

## pandas.Series.transpose

**Series.transpose** (\*args, \*\*kwargs)

Return the transpose, which is by definition self.

## pandas.Series.truediv

Series.**truediv** (*other*, *level=None*, *fill\_value=None*, *axis=0*)

Floating division of series and other, element-wise (binary operator *truediv*).

Equivalent to `series / other`, but with support to substitute a `fill_value` for missing data in one of the inputs.

### Parameters

**other** [Series or scalar value]

**fill\_value** [None or float value, default None (NaN)] Fill existing missing (NaN) values, and any new element needed for successful Series alignment, with this value before computation. If data in both corresponding Series locations is missing the result will be missing

**level** [int or name] Broadcast across a level, matching Index values on the passed Multi-Index level

### Returns

**result** [Series]

### See also:

`Series.rtruediv`

## Examples

```
>>> a = pd.Series([1, 1, 1, np.nan], index=['a', 'b', 'c', 'd'])
>>> a
a    1.0
b    1.0
c    1.0
d    NaN
dtype: float64
>>> b = pd.Series([1, np.nan, 1, np.nan], index=['a', 'b', 'd', 'e'])
>>> b
a    1.0
b    NaN
d    1.0
e    NaN
dtype: float64
>>> a.add(b, fill_value=0)
a    2.0
b    1.0
c    1.0
d    1.0
e    NaN
dtype: float64
```

## pandas.Series.truncate

Series.**truncate** (*before=None*, *after=None*, *axis=None*, *copy=True*)

Truncate a Series or DataFrame before and after some index value.

This is a useful shorthand for boolean indexing based on index values above or below certain thresholds.

**Parameters**

**before** [date, string, int] Truncate all rows before this index value.

**after** [date, string, int] Truncate all rows after this index value.

**axis** [{0 or 'index', 1 or 'columns'}, optional] Axis to truncate. Truncates the index (rows) by default.

**copy** [boolean, default is True,] Return a copy of the truncated section.

**Returns**

**type of caller** The truncated Series or DataFrame.

**See also:**

**DataFrame.loc** Select a subset of a DataFrame by label.

**DataFrame.iloc** Select a subset of a DataFrame by position.

**Notes**

If the index being truncated contains only datetime values, *before* and *after* may be specified as strings instead of Timestamps.

**Examples**

```
>>> df = pd.DataFrame({'A': ['a', 'b', 'c', 'd', 'e'],
...                    'B': ['f', 'g', 'h', 'i', 'j'],
...                    'C': ['k', 'l', 'm', 'n', 'o']},
...                    index=[1, 2, 3, 4, 5])
>>> df
   A  B  C
1  a  f  k
2  b  g  l
3  c  h  m
4  d  i  n
5  e  j  o
```

```
>>> df.truncate(before=2, after=4)
   A  B  C
2  b  g  l
3  c  h  m
4  d  i  n
```

The columns of a DataFrame can be truncated.

```
>>> df.truncate(before="A", after="B", axis="columns")
   A  B
1  a  f
2  b  g
3  c  h
4  d  i
5  e  j
```

For Series, only rows can be truncated.

```
>>> df['A'].truncate(before=2, after=4)
2      b
3      c
4      d
Name: A, dtype: object
```

The index values in `truncate` can be datetimes or string dates.

```
>>> dates = pd.date_range('2016-01-01', '2016-02-01', freq='s')
>>> df = pd.DataFrame(index=dates, data={'A': 1})
>>> df.tail()
                A
2016-01-31 23:59:56  1
2016-01-31 23:59:57  1
2016-01-31 23:59:58  1
2016-01-31 23:59:59  1
2016-02-01 00:00:00  1
```

```
>>> df.truncate(before=pd.Timestamp('2016-01-05'),
...             after=pd.Timestamp('2016-01-10')).tail()
                A
2016-01-09 23:59:56  1
2016-01-09 23:59:57  1
2016-01-09 23:59:58  1
2016-01-09 23:59:59  1
2016-01-10 00:00:00  1
```

Because the index is a `DatetimeIndex` containing only dates, we can specify *before* and *after* as strings. They will be coerced to `Timestamps` before truncation.

```
>>> df.truncate('2016-01-05', '2016-01-10').tail()
                A
2016-01-09 23:59:56  1
2016-01-09 23:59:57  1
2016-01-09 23:59:58  1
2016-01-09 23:59:59  1
2016-01-10 00:00:00  1
```

Note that `truncate` assumes a 0 value for any unspecified time component (midnight). This differs from partial string slicing, which returns any partially matching dates.

```
>>> df.loc['2016-01-05':'2016-01-10', :].tail()
                A
2016-01-10 23:59:55  1
2016-01-10 23:59:56  1
2016-01-10 23:59:57  1
2016-01-10 23:59:58  1
2016-01-10 23:59:59  1
```

## pandas.Series.tshift

`Series.tshift` (*periods=1, freq=None, axis=0*)

Shift the time index, using the index's frequency if available.

### Parameters

**periods** [int] Number of periods to move, can be positive or negative

**freq** [DateOffset, timedelta, or time rule string, default None] Increment to use from the tseries module or time rule (e.g. 'EOM')

**axis** [int or basestring] Corresponds to the axis that contains the Index

#### Returns

**shifted** [NDFrame]

#### Notes

If freq is not specified then tries to use the freq or inferred\_freq attributes of the index. If neither of those attributes exist, a ValueError is thrown

### pandas.Series.tz\_convert

`Series.tz_convert(tz, axis=0, level=None, copy=True)`

Convert tz-aware axis to target time zone.

#### Parameters

**tz** [string or pytz.timezone object]

**axis** [the axis to convert]

**level** [int, str, default None] If axis is a MultiIndex, convert a specific level. Otherwise must be None

**copy** [boolean, default True] Also make a copy of the underlying data

#### Raises

**TypeError** If the axis is tz-naive.

### pandas.Series.tz\_localize

`Series.tz_localize(tz, axis=0, level=None, copy=True, ambiguous='raise', nonexistent='raise')`

Localize tz-naive index of a Series or DataFrame to target time zone.

This operation localizes the Index. To localize the values in a timezone-naive Series, use `Series.dt.tz_localize()`.

#### Parameters

**tz** [string or pytz.timezone object]

**axis** [the axis to localize]

**level** [int, str, default None] If axis is a MultiIndex, localize a specific level. Otherwise must be None

**copy** [boolean, default True] Also make a copy of the underlying data

**ambiguous** ['infer', bool-ndarray, 'NaT', default 'raise'] When clocks moved backward due to DST, ambiguous times may arise. For example in Central European Time (UTC+01), when going from 03:00 DST to 02:00 non-DST, 02:30:00 local time occurs both at 00:30:00 UTC and at 01:30:00 UTC. In such a situation, the *ambiguous* parameter dictates how ambiguous times should be handled.

- ‘infer’ will attempt to infer fall dst-transition hours based on order
- bool-ndarray where True signifies a DST time, False designates a non-DST time (note that this flag is only applicable for ambiguous times)
- ‘NaT’ will return NaT where there are ambiguous times
- ‘raise’ will raise an AmbiguousTimeError if there are ambiguous times

**nonexistent** [str, default ‘raise’] A nonexistent time does not exist in a particular timezone where clocks moved forward due to DST. Valid values are:

- ‘shift\_forward’ will shift the nonexistent time forward to the closest existing time
- ‘shift\_backward’ will shift the nonexistent time backward to the closest existing time
- ‘NaT’ will return NaT where there are nonexistent times
- timedelta objects will shift nonexistent times by the timedelta
- ‘raise’ will raise a NonExistentTimeError if there are nonexistent times

New in version 0.24.0.

### Returns

**Series or DataFrame** Same type as the input.

### Raises

**TypeError** If the TimeSeries is tz-aware and tz is not None.

## Examples

Localize local times:

```
>>> s = pd.Series([1],
... index=pd.DatetimeIndex(['2018-09-15 01:30:00']))
>>> s.tz_localize('CET')
2018-09-15 01:30:00+02:00    1
dtype: int64
```

Be careful with DST changes. When there is sequential data, pandas can infer the DST time:

```
>>> s = pd.Series(range(7), index=pd.DatetimeIndex([
... '2018-10-28 01:30:00',
... '2018-10-28 02:00:00',
... '2018-10-28 02:30:00',
... '2018-10-28 02:00:00',
... '2018-10-28 02:30:00',
... '2018-10-28 03:00:00',
... '2018-10-28 03:30:00']))
>>> s.tz_localize('CET', ambiguous='infer')
2018-10-28 01:30:00+02:00    0
2018-10-28 02:00:00+02:00    1
2018-10-28 02:30:00+02:00    2
2018-10-28 02:00:00+01:00    3
2018-10-28 02:30:00+01:00    4
2018-10-28 03:00:00+01:00    5
2018-10-28 03:30:00+01:00    6
dtype: int64
```

In some cases, inferring the DST is impossible. In such cases, you can pass an ndarray to the ambiguous parameter to set the DST explicitly

```
>>> s = pd.Series(range(3), index=pd.DatetimeIndex([
...     '2018-10-28 01:20:00',
...     '2018-10-28 02:36:00',
...     '2018-10-28 03:46:00']))
>>> s.tz_localize('CET', ambiguous=np.array([True, True, False]))
2018-10-28 01:20:00+02:00    0
2018-10-28 02:36:00+02:00    1
2018-10-28 03:46:00+01:00    2
dtype: int64
```

If the DST transition causes nonexistent times, you can shift these dates forward or backwards with a timedelta object or `'shift_forward'` or `'shift_backwards'`. `>>> s = pd.Series(range(2), index=pd.DatetimeIndex([ ... '2015-03-29 02:30:00', ... '2015-03-29 03:30:00']))` `>>> s.tz_localize('Europe/Warsaw', nonexistent='shift_forward')` 2015-03-29 03:00:00+02:00 0 2015-03-29 03:30:00+02:00 1 dtype: int64 `>>> s.tz_localize('Europe/Warsaw', nonexistent='shift_backward')` 2015-03-29 01:59:59.999999999+01:00 0 2015-03-29 03:30:00+02:00 1 dtype: int64 `>>> s.tz_localize('Europe/Warsaw', nonexistent=pd.Timedelta('1H'))` 2015-03-29 03:30:00+02:00 0 2015-03-29 03:30:00+02:00 1 dtype: int64

## pandas.Series.unique

`Series.unique()`

Return unique values of Series object.

Uniques are returned in order of appearance. Hash table-based unique, therefore does NOT sort.

### Returns

**ndarray or ExtensionArray** The unique values returned as a NumPy array. In case of an extension-array backed Series, a new *ExtensionArray* of that type with just the unique values is returned. This includes

- Categorical
- Period
- Datetime with Timezone
- Interval
- Sparse
- IntegerNA

**See also:**

**unique** Top-level unique method for any 1-d array-like object.

**Index.unique** Return Index with unique values from an Index object.

## Examples

```
>>> pd.Series([2, 1, 3, 3], name='A').unique()
array([2, 1, 3])
```

```
>>> pd.Series([pd.Timestamp('2016-01-01') for _ in range(3)]).unique()
array(['2016-01-01T00:00:00.000000000'], dtype='datetime64[ns]')
```

```
>>> pd.Series([pd.Timestamp('2016-01-01', tz='US/Eastern')
...           for _ in range(3)]).unique()
<DatetimeArray>
['2016-01-01 00:00:00-05:00']
Length: 1, dtype: datetime64[ns, US/Eastern]
```

An unordered Categorical will return categories in the order of appearance.

```
>>> pd.Series(pd.Categorical(list('baabc'))).unique()
[b, a, c]
Categories (3, object): [b, a, c]
```

An ordered Categorical preserves the category ordering.

```
>>> pd.Series(pd.Categorical(list('baabc'), categories=list('abc'),
...                           ordered=True)).unique()
[b, a, c]
Categories (3, object): [a < b < c]
```

## pandas.Series.unstack

`Series.unstack (level=-1, fill_value=None)`

Unstack, a.k.a. pivot, Series with MultiIndex to produce DataFrame. The level involved will automatically get sorted.

### Parameters

**level** [int, string, or list of these, default last level] Level(s) to unstack, can pass level name

**fill\_value** [replace NaN with this value if the unstack produces] missing values

New in version 0.18.0.

### Returns

**unstacked** [DataFrame]

## Examples

```
>>> s = pd.Series([1, 2, 3, 4],
...               index=pd.MultiIndex.from_product([['one', 'two'], ['a', 'b']]))
>>> s
one  a    1
     b    2
two  a    3
     b    4
dtype: int64
```

```
>>> s.unstack(level=-1)
   a  b
one 1  2
two 3  4
```

```
>>> s.unstack(level=0)
      one  two
a      1    3
b      2    4
```

## pandas.Series.update

`Series.update(other)`

Modify Series in place using non-NA values from passed Series. Aligns on index.

### Parameters

**other** [Series]

### Examples

```
>>> s = pd.Series([1, 2, 3])
>>> s.update(pd.Series([4, 5, 6]))
>>> s
0    4
1    5
2    6
dtype: int64
```

```
>>> s = pd.Series(['a', 'b', 'c'])
>>> s.update(pd.Series(['d', 'e'], index=[0, 2]))
>>> s
0    d
1    b
2    e
dtype: object
```

```
>>> s = pd.Series([1, 2, 3])
>>> s.update(pd.Series([4, 5, 6, 7, 8]))
>>> s
0    4
1    5
2    6
dtype: int64
```

If other contains NaNs the corresponding values are not updated in the original Series.

```
>>> s = pd.Series([1, 2, 3])
>>> s.update(pd.Series([4, np.nan, 6]))
>>> s
0    4
1    2
2    6
dtype: int64
```

## pandas.Series.valid

`Series.valid` (*inplace=False, \*\*kwargs*)

Return Series without null values.

Deprecated since version 0.23.0: Use `Series.dropna()` instead.

## pandas.Series.value\_counts

`Series.value_counts` (*normalize=False, sort=True, ascending=False, bins=None, dropna=True*)

Return a Series containing counts of unique values.

The resulting object will be in descending order so that the first element is the most frequently-occurring element. Excludes NA values by default.

### Parameters

**normalize** [boolean, default False] If True then the object returned will contain the relative frequencies of the unique values.

**sort** [boolean, default True] Sort by values.

**ascending** [boolean, default False] Sort in ascending order.

**bins** [integer, optional] Rather than count values, group them into half-open bins, a convenience for `pd.cut`, only works with numeric data.

**dropna** [boolean, default True] Don't include counts of NaN.

### Returns

**counts** [Series]

See also:

**Series.count** Number of non-NA elements in a Series.

**DataFrame.count** Number of non-NA elements in a DataFrame.

## Examples

```
>>> index = pd.Index([3, 1, 2, 3, 4, np.nan])
>>> index.value_counts()
3.0    2
4.0    1
2.0    1
1.0    1
dtype: int64
```

With *normalize* set to *True*, returns the relative frequency by dividing all values by the sum of values.

```
>>> s = pd.Series([3, 1, 2, 3, 4, np.nan])
>>> s.value_counts(normalize=True)
3.0    0.4
4.0    0.2
2.0    0.2
1.0    0.2
dtype: float64
```

**bins**

Bins can be useful for going from a continuous variable to a categorical variable; instead of counting unique apparitions of values, divide the index in the specified number of half-open bins.

```
>>> s.value_counts(bins=3)
(2.0, 3.0]      2
(0.996, 2.0]     2
(3.0, 4.0]      1
dtype: int64
```

**dropna**

With *dropna* set to *False* we can also see NaN index values.

```
>>> s.value_counts(dropna=False)
3.0      2
NaN      1
4.0      1
2.0      1
1.0      1
dtype: int64
```

**pandas.Series.var**

`Series.var` (*axis=None, skipna=None, level=None, ddof=1, numeric\_only=None, \*\*kwargs*)

Return unbiased variance over requested axis.

Normalized by N-1 by default. This can be changed using the *ddof* argument

**Parameters**

**axis** [{index (0)}]

**skipna** [boolean, default True] Exclude NA/null values. If an entire row/column is NA, the result will be NA

**level** [int or level name, default None] If the axis is a MultiIndex (hierarchical), count along a particular level, collapsing into a scalar

**ddof** [int, default 1] Delta Degrees of Freedom. The divisor used in calculations is N - ddof, where N represents the number of elements.

**numeric\_only** [boolean, default None] Include only float, int, boolean columns. If None, will attempt to use everything, then use only numeric data. Not implemented for Series.

**Returns**

**var** [scalar or Series (if level specified)]

**pandas.Series.view**

`Series.view` (*dtype=None*)

Create a new view of the Series.

This function will return a new Series with a view of the same underlying values in memory, optionally reinterpreted with a new data type. The new data type must preserve the same size in bytes as to not cause index misalignment.

**Parameters**

**dtype** [data type] Data type object or one of their string representations.

**Returns**

**Series** A new Series object as a view of the same data in memory.

**See also:**

**numpy.ndarray.view** Equivalent numpy function to create a new view of the same data in memory.

**Notes**

Series are instantiated with `dtype=float64` by default. While `numpy.ndarray.view()` will return a view with the same data type as the original array, `Series.view()` (without specified dtype) will try using `float64` and may fail if the original data type size in bytes is not the same.

**Examples**

```
>>> s = pd.Series([-2, -1, 0, 1, 2], dtype='int8')
>>> s
0    -2
1    -1
2     0
3     1
4     2
dtype: int8
```

The 8 bit signed integer representation of `-1` is `0b11111111`, but the same bytes represent 255 if read as an 8 bit unsigned integer:

```
>>> us = s.view('uint8')
>>> us
0    254
1    255
2     0
3     1
4     2
dtype: uint8
```

The views share the same underlying values:

```
>>> us[0] = 128
>>> s
0   -128
1     -1
2      0
3      1
4      2
dtype: int8
```

## pandas.Series.where

`Series.where(cond, other=nan, inplace=False, axis=None, level=None, errors='raise', try_cast=False, raise_on_error=None)`

Replace values where the condition is False.

### Parameters

**cond** [boolean NDFrame, array-like, or callable] Where *cond* is True, keep the original value. Where False, replace with corresponding value from *other*. If *cond* is callable, it is computed on the NDFrame and should return boolean NDFrame or array. The callable must not change input NDFrame (though pandas doesn't check it).

New in version 0.18.1: A callable can be used as *cond*.

**other** [scalar, NDFrame, or callable] Entries where *cond* is False are replaced with corresponding value from *other*. If *other* is callable, it is computed on the NDFrame and should return scalar or NDFrame. The callable must not change input NDFrame (though pandas doesn't check it).

New in version 0.18.1: A callable can be used as *other*.

**inplace** [boolean, default False] Whether to perform the operation in place on the data.

**axis** [int, default None] Alignment axis if needed.

**level** [int, default None] Alignment level if needed.

**errors** [str, {'raise', 'ignore'}, default *raise*] Note that currently this parameter won't affect the results and will always coerce to a suitable dtype.

- *raise* : allow exceptions to be raised.
- *ignore* : suppress exceptions. On error return original object.

**try\_cast** [boolean, default False] Try to cast the result back to the input type (if possible).

**raise\_on\_error** [boolean, default True] Whether to raise on invalid data types (e.g. trying to where on strings).

Deprecated since version 0.21.0: Use *errors*.

### Returns

**wh** [same type as caller]

See also:

**DataFrame.mask()** Return an object of same shape as self.

### Notes

The where method is an application of the if-then idiom. For each element in the calling DataFrame, if *cond* is True the element is used; otherwise the corresponding element from the DataFrame *other* is used.

The signature for `DataFrame.where()` differs from `numpy.where()`. Roughly `df1.where(m, df2)` is equivalent to `np.where(m, df1, df2)`.

For further details and examples see the `where` documentation in *indexing*.

## Examples

```
>>> s = pd.Series(range(5))
>>> s.where(s > 0)
0    NaN
1    1.0
2    2.0
3    3.0
4    4.0
dtype: float64
```

```
>>> s.mask(s > 0)
0    0.0
1    NaN
2    NaN
3    NaN
4    NaN
dtype: float64
```

```
>>> s.where(s > 1, 10)
0    10
1    10
2     2
3     3
4     4
dtype: int64
```

```
>>> df = pd.DataFrame(np.arange(10).reshape(-1, 2), columns=['A', 'B'])
>>> m = df % 3 == 0
>>> df.where(m, -df)
   A  B
0  0 -1
1 -2  3
2 -4 -5
3  6 -7
4 -8  9
>>> df.where(m, -df) == np.where(m, df, -df)
   A      B
0  True  True
1  True  True
2  True  True
3  True  True
4  True  True
>>> df.where(m, -df) == df.mask(~m, -df)
   A      B
0  True  True
1  True  True
2  True  True
3  True  True
4  True  True
```

## pandas.Series.xs

Series.**xs** (*key, axis=0, level=None, drop\_level=True*)  
Return cross-section from the Series/DataFrame.

This method takes a *key* argument to select data at a particular level of a MultiIndex.

#### Parameters

- key** [label or tuple of label] Label contained in the index, or partially in a MultiIndex.
- axis** [{0 or 'index', 1 or 'columns'}, default 0] Axis to retrieve cross-section on.
- level** [object, defaults to first n levels (n=1 or len(key))] In case of a key partially contained in a MultiIndex, indicate which levels are used. Levels can be referred by label or position.
- drop\_level** [bool, default True] If False, returns object with same levels as self.

#### Returns

**Series or DataFrame** Cross-section from the original Series or DataFrame corresponding to the selected index levels.

See also:

**DataFrame.loc** Access a group of rows and columns by label(s) or a boolean array.

**DataFrame.iloc** Purely integer-location based indexing for selection by position.

#### Notes

*xs* can not be used to set values.

MultiIndex Slicers is a generic way to get/set values on any level or levels. It is a superset of *xs* functionality, see *MultiIndex Slicers*.

#### Examples

```
>>> d = {'num_legs': [4, 4, 2, 2],
...      'num_wings': [0, 0, 2, 2],
...      'class': ['mammal', 'mammal', 'mammal', 'bird'],
...      'animal': ['cat', 'dog', 'bat', 'penguin'],
...      'locomotion': ['walks', 'walks', 'flies', 'walks']}
>>> df = pd.DataFrame(data=d)
>>> df = df.set_index(['class', 'animal', 'locomotion'])
>>> df
```

|        |         |            | num_legs | num_wings |
|--------|---------|------------|----------|-----------|
| class  | animal  | locomotion |          |           |
| mammal | cat     | walks      | 4        | 0         |
|        | dog     | walks      | 4        | 0         |
|        | bat     | flies      | 2        | 2         |
| bird   | penguin | walks      | 2        | 2         |

Get values at specified index

```
>>> df.xs('mammal')
           num_legs  num_wings
animal locomotion
cat      walks      4          0
dog      walks      4          0
bat      flies      2          2
```

Get values at several indexes

```
>>> df.xs(('mammal', 'dog'))
           num_legs  num_wings
locomotion
walks              4          0
```

Get values at specified index and level

```
>>> df.xs('cat', level=1)
           num_legs  num_wings
class locomotion
mammal walks              4          0
```

Get values at several indexes and levels

```
>>> df.xs(('bird', 'walks'),
...       level=[0, 'locomotion'])
           num_legs  num_wings
animal
penguin              2          2
```

Get values at specified column and axis

```
>>> df.xs('num_wings', axis=1)
class  animal  locomotion
mammal  cat    walks          0
         dog    walks          0
         bat    flies          2
bird    penguin walks          2
Name: num_wings, dtype: int64
```

### 35.3.2 Attributes

#### Axes

|                        |                                                                        |
|------------------------|------------------------------------------------------------------------|
| <i>Series.index</i>    | The index (axis labels) of the Series.                                 |
| <i>Series.array</i>    | The ExtensionArray of the data backing this Series or Index.           |
| <i>Series.values</i>   | Return Series as ndarray or ndarray-like depending on the dtype.       |
| <i>Series.dtype</i>    | Return the dtype object of the underlying data.                        |
| <i>Series.ftype</i>    | Return if the data is sparsedense.                                     |
| <i>Series.shape</i>    | Return a tuple of the shape of the underlying data.                    |
| <i>Series.nbytes</i>   | Return the number of bytes in the underlying data.                     |
| <i>Series.ndim</i>     | Number of dimensions of the underlying data, by definition 1.          |
| <i>Series.size</i>     | Return the number of elements in the underlying data.                  |
| <i>Series.strides</i>  | Return the strides of the underlying data.                             |
| <i>Series.itemsize</i> | Return the size of the dtype of the item of the underlying data.       |
| <i>Series.base</i>     | Return the base object if the memory of the underlying data is shared. |

Continued on next page

Table 29 – continued from previous page

|                                            |                                                                             |
|--------------------------------------------|-----------------------------------------------------------------------------|
| <i>Series.T</i>                            | Return the transpose, which is by definition self.                          |
| <i>Series.memory_usage</i> ([index, deep]) | Return the memory usage of the Series.                                      |
| <i>Series.hasnans</i>                      | Return if I have any nans; enables various perf speedups.                   |
| <i>Series.flags</i>                        |                                                                             |
| <i>Series.empty</i>                        |                                                                             |
| <i>Series.dtypes</i>                       | Return the dtype object of the underlying data.                             |
| <i>Series.ftypes</i>                       | Return if the data is sparseldense.                                         |
| <i>Series.data</i>                         | Return the data pointer of the underlying data.                             |
| <i>Series.is_copy</i>                      | Return the copy.                                                            |
| <i>Series.name</i>                         | Return name of the Series.                                                  |
| <i>Series.put</i> (*args, **kwargs)        | Applies the <i>put</i> method to its <i>values</i> attribute if it has one. |

### 35.3.2.1 pandas.Series.empty

`Series.empty`

## 35.3.3 Conversion

|                                                      |                                                                                                              |
|------------------------------------------------------|--------------------------------------------------------------------------------------------------------------|
| <i>Series.astype</i> (dtype[, copy, errors])         | Cast a pandas object to a specified dtype <i>dtype</i> .                                                     |
| <i>Series.infer_objects</i> ()                       | Attempt to infer better dtypes for object columns.                                                           |
| <i>Series.convert_objects</i> ([convert_dates, ...]) | (DEPRECATED) Attempt to infer better dtype for object columns.                                               |
| <i>Series.copy</i> ([deep])                          | Make a copy of this object's indices and data.                                                               |
| <i>Series.bool</i> ()                                | Return the bool of a single element PandasObject.                                                            |
| <i>Series.to_numpy</i> ([dtype, copy])               | A NumPy ndarray representing the values in this Series or Index.                                             |
| <i>Series.to_period</i> ([freq, copy])               | Convert Series from DatetimeIndex to PeriodIndex with desired frequency (inferred from index if not passed). |
| <i>Series.to_timestamp</i> ([freq, how, copy])       | Cast to datetimeindex of timestamps, at <i>beginning</i> of period.                                          |
| <i>Series.to_list</i> ()                             | Return a list of the values.                                                                                 |
| <i>Series.get_values</i> ()                          | Same as values (but handles sparseness conversions); is a view.                                              |
| <i>Series.__array__</i> ([dtype])                    | Return the values as a NumPy array.                                                                          |

### 35.3.3.1 pandas.Series.\_\_array\_\_

`Series.__array__` (*dtype=None*)  
Return the values as a NumPy array.

Users should not call this directly. Rather, it is invoked by `numpy.array()` and `numpy.asarray()`.

#### Parameters

**dtype** [str or numpy.dtype, optional] The dtype to use for the resulting NumPy array. By default, the dtype is inferred from the data.

#### Returns

**numpy.ndarray** The values in the series converted to a `numpy.ndarray` with the specified *dtype*.

See also:

**pandas.array** Create a new array from data.

**Series.array** Zero-copy view to the array backing the Series.

**Series.to\_numpy** Series method for similar behavior.

## Examples

```
>>> ser = pd.Series([1, 2, 3])
>>> np.asarray(ser)
array([1, 2, 3])
```

For timezone-aware data, the timezones may be retained with `dtype='object'`

```
>>> tzser = pd.Series(pd.date_range('2000', periods=2, tz="CET"))
>>> np.asarray(tzser, dtype="object")
array([Timestamp('2000-01-01 00:00:00+0100', tz='CET', freq='D'),
       Timestamp('2000-01-02 00:00:00+0100', tz='CET', freq='D')],
      dtype=object)
```

Or the values may be localized to UTC and the tzinfo discarded with `dtype='datetime64[ns]'`

```
>>> np.asarray(tzser, dtype="datetime64[ns]") # doctest: +ELLIPSIS
array(['1999-12-31T23:00:00.000000000', ...],
      dtype='datetime64[ns]')
```

### 35.3.4 Indexing, iteration

|                                                        |                                                                           |
|--------------------------------------------------------|---------------------------------------------------------------------------|
| <code>Series.get(key[, default])</code>                | Get item from object for given key (DataFrame column, Panel slice, etc.). |
| <code>Series.at</code>                                 | Access a single value for a row/column label pair.                        |
| <code>Series.iat</code>                                | Access a single value for a row/column pair by integer position.          |
| <code>Series.loc</code>                                | Access a group of rows and columns by label(s) or a boolean array.        |
| <code>Series.iloc</code>                               | Purely integer-location based indexing for selection by position.         |
| <code>Series.__iter__()</code>                         | Return an iterator of the values.                                         |
| <code>Series.iteritems()</code>                        | Lazily iterate over (index, value) tuples.                                |
| <code>Series.items()</code>                            | Lazily iterate over (index, value) tuples.                                |
| <code>Series.keys()</code>                             | Alias for index.                                                          |
| <code>Series.pop(item)</code>                          | Return item and drop from frame.                                          |
| <code>Series.item()</code>                             | Return the first element of the underlying data as a python scalar.       |
| <code>Series.xs(key[, axis, level, drop_level])</code> | Return cross-section from the Series/DataFrame.                           |

### 35.3.4.1 pandas.Series.\_\_iter\_\_

`Series.__iter__()`

Return an iterator of the values.

These are each a scalar type, which is a Python scalar (for str, int, float) or a pandas scalar (for Timestamp/Timedelta/Interval/Period)

For more information on `.at`, `.iat`, `.loc`, and `.iloc`, see the *indexing documentation*.

### 35.3.5 Binary operator functions

|                                                                |                                                                                         |
|----------------------------------------------------------------|-----------------------------------------------------------------------------------------|
| <code>Series.add(other[, level, fill_value, axis])</code>      | Addition of series and other, element-wise (binary operator <i>add</i> ).               |
| <code>Series.sub(other[, level, fill_value, axis])</code>      | Subtraction of series and other, element-wise (binary operator <i>sub</i> ).            |
| <code>Series.mul(other[, level, fill_value, axis])</code>      | Multiplication of series and other, element-wise (binary operator <i>mul</i> ).         |
| <code>Series.div(other[, level, fill_value, axis])</code>      | Floating division of series and other, element-wise (binary operator <i>truediv</i> ).  |
| <code>Series.truediv(other[, level, fill_value, axis])</code>  | Floating division of series and other, element-wise (binary operator <i>truediv</i> ).  |
| <code>Series.floordiv(other[, level, fill_value, axis])</code> | Integer division of series and other, element-wise (binary operator <i>floordiv</i> ).  |
| <code>Series.mod(other[, level, fill_value, axis])</code>      | Modulo of series and other, element-wise (binary operator <i>mod</i> ).                 |
| <code>Series.pow(other[, level, fill_value, axis])</code>      | Exponential power of series and other, element-wise (binary operator <i>pow</i> ).      |
| <code>Series.radd(other[, level, fill_value, axis])</code>     | Addition of series and other, element-wise (binary operator <i>radd</i> ).              |
| <code>Series.rsub(other[, level, fill_value, axis])</code>     | Subtraction of series and other, element-wise (binary operator <i>rsub</i> ).           |
| <code>Series.rmul(other[, level, fill_value, axis])</code>     | Multiplication of series and other, element-wise (binary operator <i>rmul</i> ).        |
| <code>Series.rdiv(other[, level, fill_value, axis])</code>     | Floating division of series and other, element-wise (binary operator <i>rtruediv</i> ). |
| <code>Series.rtruediv(other[, level, fill_value, axis])</code> | Floating division of series and other, element-wise (binary operator <i>rtruediv</i> ). |
| <code>Series.rfloordiv(other[, level, fill_value, ...])</code> | Integer division of series and other, element-wise (binary operator <i>rfloordiv</i> ). |
| <code>Series.rmod(other[, level, fill_value, axis])</code>     | Modulo of series and other, element-wise (binary operator <i>rmod</i> ).                |
| <code>Series.rpow(other[, level, fill_value, axis])</code>     | Exponential power of series and other, element-wise (binary operator <i>rpow</i> ).     |
| <code>Series.combine(other, func[, fill_value])</code>         | Combine the Series with a Series or scalar according to <i>func</i> .                   |
| <code>Series.combine_first(other)</code>                       | Combine Series values, choosing the calling Series's values first.                      |
| <code>Series.round([decimals])</code>                          | Round each value in a Series to the given number of decimals.                           |
| <code>Series.lt(other[, level, fill_value, axis])</code>       | Less than of series and other, element-wise (binary operator <i>lt</i> ).               |

Continued on next page

Table 32 – continued from previous page

|                                                          |                                                                                          |
|----------------------------------------------------------|------------------------------------------------------------------------------------------|
| <code>Series.gt(other[, level, fill_value, axis])</code> | Greater than of series and other, element-wise (binary operator <i>gt</i> ).             |
| <code>Series.le(other[, level, fill_value, axis])</code> | Less than or equal to of series and other, element-wise (binary operator <i>le</i> ).    |
| <code>Series.ge(other[, level, fill_value, axis])</code> | Greater than or equal to of series and other, element-wise (binary operator <i>ge</i> ). |
| <code>Series.ne(other[, level, fill_value, axis])</code> | Not equal to of series and other, element-wise (binary operator <i>ne</i> ).             |
| <code>Series.eq(other[, level, fill_value, axis])</code> | Equal to of series and other, element-wise (binary operator <i>eq</i> ).                 |
| <code>Series.product([axis, skipna, level, ...])</code>  | Return the product of the values for the requested axis.                                 |
| <code>Series.dot(other)</code>                           | Compute the dot product between the Series and the columns of other.                     |

### 35.3.6 Function application, GroupBy & Window

|                                                               |                                                                                                                      |
|---------------------------------------------------------------|----------------------------------------------------------------------------------------------------------------------|
| <code>Series.apply(func[, convert_dtype, args])</code>        | Invoke function on values of Series.                                                                                 |
| <code>Series.agg(func[, axis])</code>                         | Aggregate using one or more operations over the specified axis.                                                      |
| <code>Series.aggregate(func[, axis])</code>                   | Aggregate using one or more operations over the specified axis.                                                      |
| <code>Series.transform(func[, axis])</code>                   | Call <code>func</code> on self producing a Series with transformed values and that has the same axis length as self. |
| <code>Series.map(arg[, na_action])</code>                     | Map values of Series according to input correspondence.                                                              |
| <code>Series.groupby([by, axis, level, as_index, ...])</code> | Group DataFrame or Series using a mapper or by a Series of columns.                                                  |
| <code>Series.rolling(window[, min_periods, ...])</code>       | Provides rolling window calculations.                                                                                |
| <code>Series.expanding([min_periods, center, axis])</code>    | Provides expanding transformations.                                                                                  |
| <code>Series.ewm([com, span, halflife, alpha, ...])</code>    | Provides exponential weighted functions.                                                                             |
| <code>Series.pipe(func, *args, **kwargs)</code>               | Apply <code>func(self, *args, **kwargs)</code> .                                                                     |

### 35.3.7 Computations / Descriptive Stats

|                                                            |                                                                                  |
|------------------------------------------------------------|----------------------------------------------------------------------------------|
| <code>Series.abs()</code>                                  | Return a Series/DataFrame with absolute numeric value of each element.           |
| <code>Series.all([axis, bool_only, skipna, level])</code>  | Return whether all elements are True, potentially over an axis.                  |
| <code>Series.any([axis, bool_only, skipna, level])</code>  | Return whether any element is True, potentially over an axis.                    |
| <code>Series.autocorr([lag])</code>                        | Compute the lag-N autocorrelation.                                               |
| <code>Series.between(left, right[, inclusive])</code>      | Return boolean Series equivalent to <code>left &lt;= series &lt;= right</code> . |
| <code>Series.clip([lower, upper, axis, inplace])</code>    | Trim values at input threshold(s).                                               |
| <code>Series.clip_lower(threshold[, axis, inplace])</code> | (DEPRECATED) Trim values below a given threshold.                                |
| <code>Series.clip_upper(threshold[, axis, inplace])</code> | (DEPRECATED) Trim values above a given threshold.                                |
| <code>Series.corr(other[, method, min_periods])</code>     | Compute correlation with <i>other</i> Series, excluding missing values.          |

Table 34 – continued from previous page

|                                                          |                                                                                                                                              |
|----------------------------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------|
| <i>Series.count</i> ([level])                            | Return number of non-NA/null observations in the Series.                                                                                     |
| <i>Series.cov</i> (other[, min_periods])                 | Compute covariance with Series, excluding missing values.                                                                                    |
| <i>Series.cummax</i> ([axis, skipna])                    | Return cumulative maximum over a DataFrame or Series axis.                                                                                   |
| <i>Series.cummin</i> ([axis, skipna])                    | Return cumulative minimum over a DataFrame or Series axis.                                                                                   |
| <i>Series.cumprod</i> ([axis, skipna])                   | Return cumulative product over a DataFrame or Series axis.                                                                                   |
| <i>Series.cumsum</i> ([axis, skipna])                    | Return cumulative sum over a DataFrame or Series axis.                                                                                       |
| <i>Series.describe</i> ([percentiles, include, exclude]) | Generate descriptive statistics that summarize the central tendency, dispersion and shape of a dataset's distribution, excluding NaN values. |
| <i>Series.diff</i> ([periods])                           | First discrete difference of element.                                                                                                        |
| <i>Series.factorize</i> ([sort, na_sentinel])            | Encode the object as an enumerated type or categorical variable.                                                                             |
| <i>Series.kurt</i> ([axis, skipna, level, numeric_only]) | Return unbiased kurtosis over requested axis using Fisher's definition of kurtosis (kurtosis of normal == 0.0).                              |
| <i>Series.mad</i> ([axis, skipna, level])                | Return the mean absolute deviation of the values for the requested axis.                                                                     |
| <i>Series.max</i> ([axis, skipna, level, numeric_only])  | Return the maximum of the values for the requested axis.                                                                                     |
| <i>Series.mean</i> ([axis, skipna, level, numeric_only]) | Return the mean of the values for the requested axis.                                                                                        |
| <i>Series.median</i> ([axis, skipna, level, ...])        | Return the median of the values for the requested axis.                                                                                      |
| <i>Series.min</i> ([axis, skipna, level, numeric_only])  | Return the minimum of the values for the requested axis.                                                                                     |
| <i>Series.mode</i> ([dropna])                            | Return the mode(s) of the dataset.                                                                                                           |
| <i>Series.nlargest</i> ([n, keep])                       | Return the largest <i>n</i> elements.                                                                                                        |
| <i>Series.nsmallest</i> ([n, keep])                      | Return the smallest <i>n</i> elements.                                                                                                       |
| <i>Series.pct_change</i> ([periods, fill_method, ...])   | Percentage change between the current and a prior element.                                                                                   |
| <i>Series.prod</i> ([axis, skipna, level, ...])          | Return the product of the values for the requested axis.                                                                                     |
| <i>Series.quantile</i> ([q, interpolation])              | Return value at the given quantile.                                                                                                          |
| <i>Series.rank</i> ([axis, method, numeric_only, ...])   | Compute numerical data ranks (1 through <i>n</i> ) along axis.                                                                               |
| <i>Series.sem</i> ([axis, skipna, level, ddof, ...])     | Return unbiased standard error of the mean over requested axis.                                                                              |
| <i>Series.skew</i> ([axis, skipna, level, numeric_only]) | Return unbiased skew over requested axis Normalized by <i>N</i> -1.                                                                          |
| <i>Series.std</i> ([axis, skipna, level, ddof, ...])     | Return sample standard deviation over requested axis.                                                                                        |
| <i>Series.sum</i> ([axis, skipna, level, ...])           | Return the sum of the values for the requested axis.                                                                                         |
| <i>Series.var</i> ([axis, skipna, level, ddof, ...])     | Return unbiased variance over requested axis.                                                                                                |
| <i>Series.kurtosis</i> ([axis, skipna, level, ...])      | Return unbiased kurtosis over requested axis using Fisher's definition of kurtosis (kurtosis of normal == 0.0).                              |
| <i>Series.unique</i> ()                                  | Return unique values of Series object.                                                                                                       |
| <i>Series.nunique</i> ([dropna])                         | Return number of unique elements in the object.                                                                                              |
| <i>Series.is_unique</i>                                  | Return boolean if values in the object are unique.                                                                                           |
| <i>Series.is_monotonic</i>                               | Return boolean if values in the object are monotonic_increasing.                                                                             |

Continued on next page

Table 34 – continued from previous page

|                                                          |                                                                      |
|----------------------------------------------------------|----------------------------------------------------------------------|
| <code>Series.is_monotonic_increasing</code>              | Return boolean if values in the object are monotonic_increasing.     |
| <code>Series.is_monotonic_decreasing</code>              | Return boolean if values in the object are monotonic_decreasing.     |
| <code>Series.value_counts([normalize, sort, ...])</code> | Return a Series containing counts of unique values.                  |
| <code>Series.compound([axis, skipna, level])</code>      | Return the compound percentage of the values for the requested axis. |

### 35.3.8 Reindexing / Selection / Label manipulation

|                                                                |                                                                                                                             |
|----------------------------------------------------------------|-----------------------------------------------------------------------------------------------------------------------------|
| <code>Series.align(other[, join, axis, level, ...])</code>     | Align two objects on their axes with the specified join method for each axis Index.                                         |
| <code>Series.drop([labels, axis, index, columns, ...])</code>  | Return Series with specified index labels removed.                                                                          |
| <code>Series.droplevel(level[, axis])</code>                   | Return DataFrame with requested index / column level(s) removed.                                                            |
| <code>Series.drop_duplicates([keep, inplace])</code>           | Return Series with duplicate values removed.                                                                                |
| <code>Series.duplicated([keep])</code>                         | Indicate duplicate Series values.                                                                                           |
| <code>Series.equals(other)</code>                              | Test whether two objects contain the same elements.                                                                         |
| <code>Series.first(offset)</code>                              | Convenience method for subsetting initial periods of time series data based on a date offset.                               |
| <code>Series.head([n])</code>                                  | Return the first <i>n</i> rows.                                                                                             |
| <code>Series.idxmax([axis, skipna])</code>                     | Return the row label of the maximum value.                                                                                  |
| <code>Series.idxmin([axis, skipna])</code>                     | Return the row label of the minimum value.                                                                                  |
| <code>Series.isin(values)</code>                               | Check whether <i>values</i> are contained in Series.                                                                        |
| <code>Series.last(offset)</code>                               | Convenience method for subsetting final periods of time series data based on a date offset.                                 |
| <code>Series.reindex([index])</code>                           | Conform Series to new index with optional filling logic, placing NA/NaN in locations having no value in the previous index. |
| <code>Series.reindex_like(other[, method, copy, ...])</code>   | Return an object with matching indices as other object.                                                                     |
| <code>Series.rename([index])</code>                            | Alter Series index labels or name.                                                                                          |
| <code>Series.rename_axis([mapper, index, columns, ...])</code> | Set the name of the axis for the index or columns.                                                                          |
| <code>Series.reset_index([level, drop, name, inplace])</code>  | Generate a new DataFrame or Series with the index reset.                                                                    |
| <code>Series.sample([n, frac, replace, weights, ...])</code>   | Return a random sample of items from an axis of object.                                                                     |
| <code>Series.select(crit[, axis])</code>                       | (DEPRECATED) Return data corresponding to axis labels matching criteria.                                                    |
| <code>Series.set_axis(labels[, axis, inplace])</code>          | Assign desired index to given axis.                                                                                         |
| <code>Series.take(indices[, axis, convert, is_copy])</code>    | Return the elements in the given <i>positional</i> indices along an axis.                                                   |
| <code>Series.tail([n])</code>                                  | Return the last <i>n</i> rows.                                                                                              |
| <code>Series.truncate([before, after, axis, copy])</code>      | Truncate a Series or DataFrame before and after some index value.                                                           |
| <code>Series.where(cond[, other, inplace, axis, ...])</code>   | Replace values where the condition is False.                                                                                |
| <code>Series.mask(cond[, other, inplace, axis, ...])</code>    | Replace values where the condition is True.                                                                                 |
| <code>Series.add_prefix(prefix)</code>                         | Prefix labels with string <i>prefix</i> .                                                                                   |
| <code>Series.add_suffix(suffix)</code>                         | Suffix labels with string <i>suffix</i> .                                                                                   |
| <code>Series.filter([items, like, regex, axis])</code>         | Subset rows or columns of dataframe according to labels in the specified index.                                             |

### 35.3.9 Missing data handling

|                                                             |                                                    |
|-------------------------------------------------------------|----------------------------------------------------|
| <code>Series.isna()</code>                                  | Detect missing values.                             |
| <code>Series.notna()</code>                                 | Detect existing (non-missing) values.              |
| <code>Series.dropna([axis, inplace])</code>                 | Return a new Series with missing values removed.   |
| <code>Series.fillna([value, method, axis, ...])</code>      | Fill NA/NaN values using the specified method.     |
| <code>Series.interpolate([method, axis, limit, ...])</code> | Interpolate values according to different methods. |

### 35.3.10 Reshaping, sorting

|                                                               |                                                                   |
|---------------------------------------------------------------|-------------------------------------------------------------------|
| <code>Series.argsort([axis, kind, order])</code>              | Overrides ndarray.argsort.                                        |
| <code>Series.argmin([axis, skipna])</code>                    | (DEPRECATED) Return the row label of the minimum value.           |
| <code>Series.argmax([axis, skipna])</code>                    | (DEPRECATED) Return the row label of the maximum value.           |
| <code>Series.reorder_levels(order)</code>                     | Rearrange index levels using input order.                         |
| <code>Series.sort_values([axis, ascending, ...])</code>       | Sort by the values.                                               |
| <code>Series.sort_index([axis, level, ascending, ...])</code> | Sort Series by index labels.                                      |
| <code>Series.swaplevel([i, j, copy])</code>                   | Swap levels i and j in a MultiIndex.                              |
| <code>Series.unstack([level, fill_value])</code>              | Unstack, a.k.a.                                                   |
| <code>Series.searchsorted(value[, side, sorter])</code>       | Find indices where elements should be inserted to maintain order. |
| <code>Series.ravel([order])</code>                            | Return the flattened underlying data as an ndarray.               |
| <code>Series.repeat(repeats[, axis])</code>                   | Repeat elements of a Series.                                      |
| <code>Series.squeeze([axis])</code>                           | Squeeze 1 dimensional axis objects into scalars.                  |
| <code>Series.view([dtype])</code>                             | Create a new view of the Series.                                  |

### 35.3.11 Combining / joining / merging

|                                                                |                                                                |
|----------------------------------------------------------------|----------------------------------------------------------------|
| <code>Series.append(to_append[, ignore_index, ...])</code>     | Concatenate two or more Series.                                |
| <code>Series.replace([to_replace, value, inplace, ...])</code> | Replace values given in <i>to_replace</i> with <i>value</i> .  |
| <code>Series.update(other)</code>                              | Modify Series in place using non-NA values from passed Series. |

### 35.3.12 Time series-related

|                                                               |                                                                              |
|---------------------------------------------------------------|------------------------------------------------------------------------------|
| <code>Series.asfreq(freq[, method, how, ...])</code>          | Convert TimeSeries to specified frequency.                                   |
| <code>Series.asof(where[, subset])</code>                     | Return the last row(s) without any NaNs before <i>where</i> .                |
| <code>Series.shift([periods, freq, axis, fill_value])</code>  | Shift index by desired number of periods with an optional time <i>freq</i> . |
| <code>Series.first_valid_index()</code>                       | Return index for first non-NA/null value.                                    |
| <code>Series.last_valid_index()</code>                        | Return index for last non-NA/null value.                                     |
| <code>Series.resample(rule[, how, axis, ...])</code>          | Resample time-series data.                                                   |
| <code>Series.tz_convert(tz[, axis, level, copy])</code>       | Convert tz-aware axis to target time zone.                                   |
| <code>Series.tz_localize(tz[, axis, level, copy, ...])</code> | Localize tz-naive index of a Series or DataFrame to target time zone.        |
| <code>Series.at_time(time[, asof, axis])</code>               | Select values at particular time of day (e.g.                                |

Continued on next page

Table 39 – continued from previous page

|                                                               |                                                                         |
|---------------------------------------------------------------|-------------------------------------------------------------------------|
| <code>Series.between_time(start_time, end_time[, ...])</code> | Select values between particular times of the day (e.g., 9:00-9:30 AM). |
| <code>Series.tshift([periods, freq, axis])</code>             | Shift the time index, using the index's frequency if available.         |
| <code>Series.slice_shift([periods, axis])</code>              | Equivalent to <i>shift</i> without copying data.                        |

### 35.3.13 Accessors

Pandas provides dtype-specific methods under various accessors. These are separate namespaces within *Series* that only apply to specific data types.

| Data Type                   | Accessor      |
|-----------------------------|---------------|
| Datetime, Timedelta, Period | <i>dt</i>     |
| String                      | <i>str</i>    |
| Categorical                 | <i>cat</i>    |
| Sparse                      | <i>sparse</i> |

#### 35.3.13.1 Datetimelike Properties

`Series.dt` can be used to access the values of the series as datetimelike and return several properties. These can be accessed like `Series.dt.<property>`.

#### Datetime Properties

|                                         |                                                                                                                         |
|-----------------------------------------|-------------------------------------------------------------------------------------------------------------------------|
| <code>Series.dt.date</code>             | Returns numpy array of python datetime.date objects (namely, the date part of Timestamps without timezone information). |
| <code>Series.dt.time</code>             | Returns numpy array of datetime.time.                                                                                   |
| <code>Series.dt.timetz</code>           | Returns numpy array of datetime.time also containing timezone information.                                              |
| <code>Series.dt.year</code>             | The year of the datetime.                                                                                               |
| <code>Series.dt.month</code>            | The month as January=1, December=12.                                                                                    |
| <code>Series.dt.day</code>              | The days of the datetime.                                                                                               |
| <code>Series.dt.hour</code>             | The hours of the datetime.                                                                                              |
| <code>Series.dt.minute</code>           | The minutes of the datetime.                                                                                            |
| <code>Series.dt.second</code>           | The seconds of the datetime.                                                                                            |
| <code>Series.dt.microsecond</code>      | The microseconds of the datetime.                                                                                       |
| <code>Series.dt.nanosecond</code>       | The nanoseconds of the datetime.                                                                                        |
| <code>Series.dt.week</code>             | The week ordinal of the year.                                                                                           |
| <code>Series.dt.weekofyear</code>       | The week ordinal of the year.                                                                                           |
| <code>Series.dt.dayofweek</code>        | The day of the week with Monday=0, Sunday=6.                                                                            |
| <code>Series.dt.weekday</code>          | The day of the week with Monday=0, Sunday=6.                                                                            |
| <code>Series.dt.dayofyear</code>        | The ordinal day of the year.                                                                                            |
| <code>Series.dt.quarter</code>          | The quarter of the date.                                                                                                |
| <code>Series.dt.is_month_start</code>   | Indicates whether the date is the first day of the month.                                                               |
| <code>Series.dt.is_month_end</code>     | Indicates whether the date is the last day of the month.                                                                |
| <code>Series.dt.is_quarter_start</code> | Indicator for whether the date is the first day of a quarter.                                                           |
| <code>Series.dt.is_quarter_end</code>   | Indicator for whether the date is the last day of a quarter.                                                            |

Table 40 – continued from previous page

|                                |                                                        |
|--------------------------------|--------------------------------------------------------|
| <i>Series.dt.is_year_start</i> | Indicate whether the date is the first day of a year.  |
| <i>Series.dt.is_year_end</i>   | Indicate whether the date is the last day of the year. |
| <i>Series.dt.is_leap_year</i>  | Boolean indicator if the date belongs to a leap year.  |
| <i>Series.dt.daysinmonth</i>   | The number of days in the month.                       |
| <i>Series.dt.days_in_month</i> | The number of days in the month.                       |
| <i>Series.dt.tz</i>            | Return timezone, if any.                               |
| <i>Series.dt.freq</i>          |                                                        |

**pandas.Series.dt.date****Series.dt.date**

Returns numpy array of python datetime.date objects (namely, the date part of Timestamps without timezone information).

**pandas.Series.dt.time****Series.dt.time**

Returns numpy array of datetime.time. The time part of the Timestamps.

**pandas.Series.dt.timetz****Series.dt.timetz**

Returns numpy array of datetime.time also containing timezone information. The time part of the Timestamps.

**pandas.Series.dt.year****Series.dt.year**

The year of the datetime.

**pandas.Series.dt.month****Series.dt.month**

The month as January=1, December=12.

**pandas.Series.dt.day****Series.dt.day**

The days of the datetime.

**pandas.Series.dt.hour****Series.dt.hour**

The hours of the datetime.

### **pandas.Series.dt.minute**

`Series.dt.minute`

The minutes of the datetime.

### **pandas.Series.dt.second**

`Series.dt.second`

The seconds of the datetime.

### **pandas.Series.dt.microsecond**

`Series.dt.microsecond`

The microseconds of the datetime.

### **pandas.Series.dt.nanosecond**

`Series.dt.nanosecond`

The nanoseconds of the datetime.

### **pandas.Series.dt.week**

`Series.dt.week`

The week ordinal of the year.

### **pandas.Series.dt.weekofyear**

`Series.dt.weekofyear`

The week ordinal of the year.

### **pandas.Series.dt.dayofweek**

`Series.dt.dayofweek`

The day of the week with Monday=0, Sunday=6.

Return the day of the week. It is assumed the week starts on Monday, which is denoted by 0 and ends on Sunday which is denoted by 6. This method is available on both Series with datetime values (using the *dt* accessor) or DatetimeIndex.

#### **Returns**

**Series or Index** Containing integers indicating the day number.

See also:

**`Series.dt.dayofweek`** Alias.

**`Series.dt.weekday`** Alias.

**`Series.dt.day_name`** Returns the name of the day of the week.

## Examples

```
>>> s = pd.date_range('2016-12-31', '2017-01-08', freq='D').to_series()
>>> s.dt.dayofweek
2016-12-31    5
2017-01-01    6
2017-01-02    0
2017-01-03    1
2017-01-04    2
2017-01-05    3
2017-01-06    4
2017-01-07    5
2017-01-08    6
Freq: D, dtype: int64
```

## pandas.Series.dt.weekday

### Series.dt.weekday

The day of the week with Monday=0, Sunday=6.

Return the day of the week. It is assumed the week starts on Monday, which is denoted by 0 and ends on Sunday which is denoted by 6. This method is available on both Series with datetime values (using the *dt* accessor) or DatetimeIndex.

#### Returns

**Series or Index** Containing integers indicating the day number.

See also:

**Series.dt.dayofweek** Alias.

**Series.dt.weekday** Alias.

**Series.dt.day\_name** Returns the name of the day of the week.

## Examples

```
>>> s = pd.date_range('2016-12-31', '2017-01-08', freq='D').to_series()
>>> s.dt.dayofweek
2016-12-31    5
2017-01-01    6
2017-01-02    0
2017-01-03    1
2017-01-04    2
2017-01-05    3
2017-01-06    4
2017-01-07    5
2017-01-08    6
Freq: D, dtype: int64
```

## pandas.Series.dt.dayofyear

### Series.dt.dayofyear

The ordinal day of the year.

## pandas.Series.dt.quarter

Series.dt.**quarter**

The quarter of the date.

## pandas.Series.dt.is\_month\_start

Series.dt.**is\_month\_start**

Indicates whether the date is the first day of the month.

### Returns

**Series or array** For Series, returns a Series with boolean values. For DatetimeIndex, returns a boolean array.

**See also:**

**is\_month\_start** Return a boolean indicating whether the date is the first day of the month.

**is\_month\_end** Return a boolean indicating whether the date is the last day of the month.

## Examples

This method is available on Series with datetime values under the `.dt` accessor, and directly on DatetimeIndex.

```
>>> s = pd.Series(pd.date_range("2018-02-27", periods=3))
>>> s
0    2018-02-27
1    2018-02-28
2    2018-03-01
dtype: datetime64[ns]
>>> s.dt.is_month_start
0    False
1    False
2     True
dtype: bool
>>> s.dt.is_month_end
0    False
1     True
2    False
dtype: bool
```

```
>>> idx = pd.date_range("2018-02-27", periods=3)
>>> idx.is_month_start
array([False, False,  True])
>>> idx.is_month_end
array([False,  True, False])
```

## pandas.Series.dt.is\_month\_end

Series.dt.**is\_month\_end**

Indicates whether the date is the last day of the month.

### Returns

**Series or array** For Series, returns a Series with boolean values. For DatetimeIndex, returns a boolean array.

**See also:**

**`is_month_start`** Return a boolean indicating whether the date is the first day of the month.

**`is_month_end`** Return a boolean indicating whether the date is the last day of the month.

## Examples

This method is available on Series with datetime values under the `.dt` accessor, and directly on DatetimeIndex.

```
>>> s = pd.Series(pd.date_range("2018-02-27", periods=3))
>>> s
0    2018-02-27
1    2018-02-28
2    2018-03-01
dtype: datetime64[ns]
>>> s.dt.is_month_start
0    False
1    False
2     True
dtype: bool
>>> s.dt.is_month_end
0    False
1     True
2    False
dtype: bool
```

```
>>> idx = pd.date_range("2018-02-27", periods=3)
>>> idx.is_month_start
array([False, False,  True])
>>> idx.is_month_end
array([False,  True, False])
```

## pandas.Series.dt.is\_quarter\_start

**Series.dt.is\_quarter\_start**

Indicator for whether the date is the first day of a quarter.

### Returns

**`is_quarter_start`** [Series or DatetimeIndex] The same type as the original data with boolean values. Series will have the same name and index. DatetimeIndex will have the same name.

**See also:**

**`quarter`** Return the quarter of the date.

**`is_quarter_end`** Similar property for indicating the quarter start.

## Examples

This method is available on Series with datetime values under the `.dt` accessor, and directly on DatetimeIndex.

```
>>> df = pd.DataFrame({'dates': pd.date_range("2017-03-30",
...                                           periods=4)})
>>> df.assign(quarter=df.dates.dt.quarter,
...           is_quarter_start=df.dates.dt.is_quarter_start)
   dates  quarter  is_quarter_start
0 2017-03-30      1             False
1 2017-03-31      1             False
2 2017-04-01      2              True
3 2017-04-02      2             False
```

```
>>> idx = pd.date_range('2017-03-30', periods=4)
>>> idx
DatetimeIndex(['2017-03-30', '2017-03-31', '2017-04-01', '2017-04-02'],
              dtype='datetime64[ns]', freq='D')
```

```
>>> idx.is_quarter_start
array([False, False,  True, False])
```

## pandas.Series.dt.is\_quarter\_end

### Series.dt.is\_quarter\_end

Indicator for whether the date is the last day of a quarter.

#### Returns

**is\_quarter\_end** [Series or DatetimeIndex] The same type as the original data with boolean values. Series will have the same name and index. DatetimeIndex will have the same name.

**See also:**

**quarter** Return the quarter of the date.

**is\_quarter\_start** Similar property indicating the quarter start.

## Examples

This method is available on Series with datetime values under the `.dt` accessor, and directly on DatetimeIndex.

```
>>> df = pd.DataFrame({'dates': pd.date_range("2017-03-30",
...                                           periods=4)})
>>> df.assign(quarter=df.dates.dt.quarter,
...           is_quarter_end=df.dates.dt.is_quarter_end)
   dates  quarter  is_quarter_end
0 2017-03-30      1             False
1 2017-03-31      1              True
2 2017-04-01      2             False
3 2017-04-02      2             False
```

```
>>> idx = pd.date_range('2017-03-30', periods=4)
>>> idx
DatetimeIndex(['2017-03-30', '2017-03-31', '2017-04-01', '2017-04-02'],
              dtype='datetime64[ns]', freq='D')
```

```
>>> idx.is_quarter_end
array([False,  True, False, False])
```

## pandas.Series.dt.is\_year\_start

### Series.dt.is\_year\_start

Indicate whether the date is the first day of a year.

#### Returns

**Series or DatetimeIndex** The same type as the original data with boolean values. Series will have the same name and index. DatetimeIndex will have the same name.

See also:

**is\_year\_end** Similar property indicating the last day of the year.

## Examples

This method is available on Series with datetime values under the `.dt` accessor, and directly on DatetimeIndex.

```
>>> dates = pd.Series(pd.date_range("2017-12-30", periods=3))
>>> dates
0    2017-12-30
1    2017-12-31
2    2018-01-01
dtype: datetime64[ns]
```

```
>>> dates.dt.is_year_start
0    False
1    False
2     True
dtype: bool
```

```
>>> idx = pd.date_range("2017-12-30", periods=3)
>>> idx
DatetimeIndex(['2017-12-30', '2017-12-31', '2018-01-01'],
              dtype='datetime64[ns]', freq='D')
```

```
>>> idx.is_year_start
array([False, False,  True])
```

## pandas.Series.dt.is\_year\_end

### Series.dt.is\_year\_end

Indicate whether the date is the last day of the year.

#### Returns

**Series or DatetimeIndex** The same type as the original data with boolean values. Series will have the same name and index. DatetimeIndex will have the same name.

See also:

**`is_year_start`** Similar property indicating the start of the year.

## Examples

This method is available on Series with datetime values under the `.dt` accessor, and directly on DatetimeIndex.

```
>>> dates = pd.Series(pd.date_range("2017-12-30", periods=3))
>>> dates
0    2017-12-30
1    2017-12-31
2    2018-01-01
dtype: datetime64[ns]
```

```
>>> dates.dt.is_year_end
0    False
1     True
2    False
dtype: bool
```

```
>>> idx = pd.date_range("2017-12-30", periods=3)
>>> idx
DatetimeIndex(['2017-12-30', '2017-12-31', '2018-01-01'],
              dtype='datetime64[ns]', freq='D')
```

```
>>> idx.is_year_end
array([False,  True, False])
```

## pandas.Series.dt.is\_leap\_year

### Series.dt.is\_leap\_year

Boolean indicator if the date belongs to a leap year.

A leap year is a year, which has 366 days (instead of 365) including 29th of February as an intercalary day. Leap years are years which are multiples of four with the exception of years divisible by 100 but not by 400.

#### Returns

**Series or ndarray** Booleans indicating if dates belong to a leap year.

## Examples

This method is available on Series with datetime values under the `.dt` accessor, and directly on DatetimeIndex.

```
>>> idx = pd.date_range("2012-01-01", "2015-01-01", freq="Y")
>>> idx
DatetimeIndex(['2012-12-31', '2013-12-31', '2014-12-31'],
              dtype='datetime64[ns]', freq='A-DEC')
>>> idx.is_leap_year
array([ True, False, False], dtype=bool)
```

```
>>> dates = pd.Series(idx)
>>> dates_series
0    2012-12-31
```

(continues on next page)

(continued from previous page)

```

1    2013-12-31
2    2014-12-31
dtype: datetime64[ns]
>>> dates_series.dt.is_leap_year
0     True
1    False
2    False
dtype: bool

```

**pandas.Series.dt.daysinmonth****Series.dt.daysinmonth**

The number of days in the month.

**pandas.Series.dt.days\_in\_month****Series.dt.days\_in\_month**

The number of days in the month.

**pandas.Series.dt.tz****Series.dt.tz**

Return timezone, if any.

**Returns****datetime.tzinfo, pytz.tzinfo.BaseTZInfo, dateutil.tz.tz.tzfile, or None** Returns None when the array is tz-naive.**pandas.Series.dt.freq****Series.dt.freq****Datetime Methods**

|                                               |                                                                          |
|-----------------------------------------------|--------------------------------------------------------------------------|
| <i>Series.dt.to_period(*args, **kwargs)</i>   | Cast to PeriodArray/Index at a particular frequency.                     |
| <i>Series.dt.to_pydatetime()</i>              | Return the data as an array of native Python datetime objects.           |

|----------------------------------------------------|--------------------------------------------------------------------|
| <code>Series.dt.ceil(*args, **kwargs)</code>       | Perform ceil operation on the data to the specified <i>freq</i> .  |
| <code>Series.dt.month_name(*args, **kwargs)</code> | Return the month names of the DateTimeIndex with specified locale. |
| <code>Series.dt.day_name(*args, **kwargs)</code>   | Return the day names of the DateTimeIndex with specified locale.   |

## pandas.Series.dt.to\_period

`Series.dt.to_period(*args, **kwargs)`

Cast to PeriodArray/Index at a particular frequency.

Converts DatetimeArray/Index to PeriodArray/Index.

### Parameters

**freq** [string or Offset, optional] One of pandas' *offset strings* or an Offset object. Will be inferred by default.

### Returns

**PeriodArray/Index**

### Raises

**ValueError** When converting a DatetimeArray/Index with non-regular values, so that a frequency cannot be inferred.

See also:

**PeriodIndex** Immutable ndarray holding ordinal values.

**DatetimeIndex.to\_pydatetime** Return DatetimeIndex as object.

## Examples

```
>>> df = pd.DataFrame({"y": [1,2,3]},
...                    index=pd.to_datetime(["2000-03-31 00:00:00",
...                                          "2000-05-31 00:00:00",
...                                          "2000-08-31 00:00:00"]))
>>> df.index.to_period("M")
PeriodIndex(['2000-03', '2000-05', '2000-08'],
            dtype='period[M]', freq='M')
```

Infer the daily frequency

```
>>> idx = pd.date_range("2017-01-01", periods=2)
>>> idx.to_period()
PeriodIndex(['2017-01-01', '2017-01-02'],
            dtype='period[D]', freq='D')
```

## pandas.Series.dt.to\_pydatetime

`Series.dt.to_pydatetime()`

Return the data as an array of native Python datetime objects.

Timezone information is retained if present.

**Warning:** Python's datetime uses microsecond resolution, which is lower than pandas (nanosecond). The values are truncated.

### Returns

`numpy.ndarray` object dtype array containing native Python datetime objects.

### See also:

`datetime.datetime` Standard library value for a datetime.

### Examples

```
>>> s = pd.Series(pd.date_range('20180310', periods=2))
>>> s
0    2018-03-10
1    2018-03-11
dtype: datetime64[ns]
```

```
>>> s.dt.to_pydatetime()
array([datetime.datetime(2018, 3, 10, 0, 0),
       datetime.datetime(2018, 3, 11, 0, 0)], dtype=object)
```

pandas' nanosecond precision is truncated to microseconds.

```
>>> s = pd.Series(pd.date_range('20180310', periods=2, freq='ns'))
>>> s
0    2018-03-10 00:00:00.000000000
1    2018-03-10 00:00:00.000000001
dtype: datetime64[ns]
```

```
>>> s.dt.to_pydatetime()
array([datetime.datetime(2018, 3, 10, 0, 0),
       datetime.datetime(2018, 3, 10, 0, 0)], dtype=object)
```

## pandas.Series.dt.tz\_localize

`Series.dt.tz_localize(*args, **kwargs)`

Localize tz-naive Datetime Array/Index to tz-aware Datetime Array/Index.

This method takes a time zone (tz) naive Datetime Array/Index object and makes this time zone aware. It does not move the time to another time zone. Time zone localization helps to switch from time zone aware to time zone unaware objects.

### Parameters

**tz** [string, `pytz.timezone`, `dateutil.tz.tzfile` or `None`] Time zone to convert timestamps to. Passing `None` will remove the time zone information preserving local time.

**ambiguous** ['infer', 'NaT', bool array, default 'raise'] When clocks moved backward due to DST, ambiguous times may arise. For example in Central European Time (UTC+01), when going from 03:00 DST to 02:00 non-DST, 02:30:00 local time occurs both at 00:30:00 UTC and at 01:30:00 UTC. In such a situation, the *ambiguous* parameter dictates how ambiguous times should be handled.

- 'infer' will attempt to infer fall dst-transition hours based on order
- bool-ndarray where True signifies a DST time, False signifies a non-DST time (note that this flag is only applicable for ambiguous times)
- 'NaT' will return NaT where there are ambiguous times
- 'raise' will raise an AmbiguousTimeError if there are ambiguous times

**nonexistent** ['shift\_forward', 'shift\_backward', 'NaT', timedelta,]

default 'raise'

A nonexistent time does not exist in a particular timezone where clocks moved forward due to DST.

- 'shift\_forward' will shift the nonexistent time forward to the closest existing time
- 'shift\_backward' will shift the nonexistent time backward to the closest existing time
- 'NaT' will return NaT where there are nonexistent times
- timedelta objects will shift nonexistent times by the timedelta
- 'raise' will raise an NonExistentTimeError if there are nonexistent times

New in version 0.24.0.

**errors** [{ 'raise', 'coerce' }, default None]

- 'raise' will raise a NonExistentTimeError if a timestamp is not valid in the specified time zone (e.g. due to a transition from or to DST time). Use nonexistent='raise' instead.
- 'coerce' will return NaT if the timestamp can not be converted to the specified time zone. Use nonexistent='NaT' instead.

Deprecated since version 0.24.0.

### Returns

**result** [same type as self] Array/Index converted to the specified time zone.

### Raises

**TypeError** If the Datetime Array/Index is tz-aware and tz is not None.

See also:

**DatetimeIndex.tz\_convert** Convert tz-aware DatetimeIndex from one time zone to another.

### Examples

```
>>> tz_naive = pd.date_range('2018-03-01 09:00', periods=3)
>>> tz_naive
DatetimeIndex(['2018-03-01 09:00:00', '2018-03-02 09:00:00',
               '2018-03-03 09:00:00'],
              dtype='datetime64[ns]', freq='D')
```

Localize DatetimeIndex in US/Eastern time zone:

```
>>> tz_aware = tz_naive.tz_localize(tz='US/Eastern')
>>> tz_aware
DatetimeIndex(['2018-03-01 09:00:00-05:00',
               '2018-03-02 09:00:00-05:00',
               '2018-03-03 09:00:00-05:00'],
              dtype='datetime64[ns, US/Eastern]', freq='D')
```

With the `tz=None`, we can remove the time zone information while keeping the local time (not converted to UTC):

```
>>> tz_aware.tz_localize(None)
DatetimeIndex(['2018-03-01 09:00:00', '2018-03-02 09:00:00',
               '2018-03-03 09:00:00'],
              dtype='datetime64[ns]', freq='D')
```

Be careful with DST changes. When there is sequential data, pandas can infer the DST time: `>>> s = pd.to_datetime(pd.Series([ ... '2018-10-28 01:30:00', ... '2018-10-28 02:00:00', ... '2018-10-28 02:30:00', ... '2018-10-28 02:00:00', ... '2018-10-28 02:30:00', ... '2018-10-28 03:00:00', ... '2018-10-28 03:30:00']))` `>>> s.dt.tz_localize('CET', ambiguous='infer')` 2018-10-28 01:30:00+02:00 0 2018-10-28 02:00:00+02:00 1 2018-10-28 02:30:00+02:00 2 2018-10-28 02:00:00+01:00 3 2018-10-28 02:30:00+01:00 4 2018-10-28 03:00:00+01:00 5 2018-10-28 03:30:00+01:00 6 dtype: int64

In some cases, inferring the DST is impossible. In such cases, you can pass an ndarray to the `ambiguous` parameter to set the DST explicitly

```
>>> s = pd.to_datetime(pd.Series([
... '2018-10-28 01:20:00',
... '2018-10-28 02:36:00',
... '2018-10-28 03:46:00']))
>>> s.dt.tz_localize('CET', ambiguous=np.array([True, True, False]))
0 2018-10-28 01:20:00+02:00
1 2018-10-28 02:36:00+02:00
2 2018-10-28 03:46:00+01:00
dtype: datetime64[ns, CET]
```

If the DST transition causes nonexistent times, you can shift these dates forward or backwards with a `timedelta` object or `'shift_forward'` or `'shift_backwards'`. `>>> s = pd.to_datetime(pd.Series([ ... '2015-03-29 02:30:00', ... '2015-03-29 03:30:00']))` `>>> s.dt.tz_localize('Europe/Warsaw', nonexistent='shift_forward')` 0 2015-03-29 03:00:00+02:00 1 2015-03-29 03:30:00+02:00 dtype: datetime64[ns, 'Europe/Warsaw'] `>>> s.dt.tz_localize('Europe/Warsaw', nonexistent='shift_backward')` 0 2015-03-29 01:59:59.999999999+01:00 1 2015-03-29 03:30:00+02:00 dtype: datetime64[ns, 'Europe/Warsaw'] `>>> s.dt.tz_localize('Europe/Warsaw', nonexistent=pd.Timedelta('1H'))` 0 2015-03-29 03:30:00+02:00 1 2015-03-29 03:30:00+02:00 dtype: datetime64[ns, 'Europe/Warsaw']

### pandas.Series.dt.tz\_convert

`Series.dt.tz_convert(*args, **kwargs)`

Convert tz-aware Datetime Array/Index from one time zone to another.

#### Parameters

**tz** [string, `pytz.timezone`, `dateutil.tz.tzfile` or `None`] Time zone for time. Corresponding timestamps would be converted to this time zone of the Datetime Array/Index. A `tz` of `None` will convert to UTC and remove the timezone information.

#### Returns

**normalized** [same type as self]

**Raises**

**TypeError** If Datetime Array/Index is tz-naive.

See also:

**DatetimeIndex.tz** A timezone that has a variable offset from UTC.

**DatetimeIndex.tz\_localize** Localize tz-naive DatetimeIndex to a given time zone, or remove time-zone from a tz-aware DatetimeIndex.

## Examples

With the `tz` parameter, we can change the DatetimeIndex to other time zones:

```
>>> dti = pd.date_range(start='2014-08-01 09:00',
...                      freq='H', periods=3, tz='Europe/Berlin')
```

```
>>> dti
DatetimeIndex(['2014-08-01 09:00:00+02:00',
              '2014-08-01 10:00:00+02:00',
              '2014-08-01 11:00:00+02:00'],
              dtype='datetime64[ns, Europe/Berlin]', freq='H')
```

```
>>> dti.tz_convert('US/Central')
DatetimeIndex(['2014-08-01 02:00:00-05:00',
              '2014-08-01 03:00:00-05:00',
              '2014-08-01 04:00:00-05:00'],
              dtype='datetime64[ns, US/Central]', freq='H')
```

With the `tz=None`, we can remove the timezone (after converting to UTC if necessary):

```
>>> dti = pd.date_range(start='2014-08-01 09:00', freq='H',
...                      periods=3, tz='Europe/Berlin')
```

```
>>> dti
DatetimeIndex(['2014-08-01 09:00:00+02:00',
              '2014-08-01 10:00:00+02:00',
              '2014-08-01 11:00:00+02:00'],
              dtype='datetime64[ns, Europe/Berlin]', freq='H')
```

```
>>> dti.tz_convert(None)
DatetimeIndex(['2014-08-01 07:00:00',
              '2014-08-01 08:00:00',
              '2014-08-01 09:00:00'],
              dtype='datetime64[ns]', freq='H')
```

## pandas.Series.dt.normalize

`Series.dt.normalize(*args, **kwargs)`

Convert times to midnight.

The time component of the date-time is converted to midnight i.e. 00:00:00. This is useful in cases, when the time does not matter. Length is unaltered. The timezones are unaffected.

This method is available on Series with datetime values under the `.dt` accessor, and directly on Datetime Array/Index.

#### Returns

**DatetimeArray, DatetimeIndex or Series** The same type as the original data. Series will have the same name and index. DatetimeIndex will have the same name.

#### See also:

***floor*** Floor the datetimes to the specified freq.

***ceil*** Ceil the datetimes to the specified freq.

***round*** Round the datetimes to the specified freq.

#### Examples

```
>>> idx = pd.date_range(start='2014-08-01 10:00', freq='H',
...                      periods=3, tz='Asia/Calcutta')
>>> idx
DatetimeIndex(['2014-08-01 10:00:00+05:30',
               '2014-08-01 11:00:00+05:30',
               '2014-08-01 12:00:00+05:30'],
              dtype='datetime64[ns, Asia/Calcutta]', freq='H')
>>> idx.normalize()
DatetimeIndex(['2014-08-01 00:00:00+05:30',
               '2014-08-01 00:00:00+05:30',
               '2014-08-01 00:00:00+05:30'],
              dtype='datetime64[ns, Asia/Calcutta]', freq=None)
```

### pandas.Series.dt.strftime

`Series.dt.strftime(*args, **kwargs)`

Convert to Index using specified date\_format.

Return an Index of formatted strings specified by date\_format, which supports the same string format as the python standard library. Details of the string format can be found in [python string format doc](#)

#### Parameters

**date\_format** [str] Date format string (e.g. “%Y-%m-%d”).

#### Returns

**Index** Index of formatted strings

#### See also:

***to\_datetime*** Convert the given argument to datetime.

***DatetimeIndex.normalize*** Return DatetimeIndex with times to midnight.

***DatetimeIndex.round*** Round the DatetimeIndex to the specified freq.

***DatetimeIndex.floor*** Floor the DatetimeIndex to the specified freq.

## Examples

```
>>> rng = pd.date_range(pd.Timestamp("2018-03-10 09:00"),
...                      periods=3, freq='s')
>>> rng.strftime('%B %d, %Y, %r')
Index(['March 10, 2018, 09:00:00 AM', 'March 10, 2018, 09:00:01 AM',
      'March 10, 2018, 09:00:02 AM'],
      dtype='object')
```

## pandas.Series.dt.round

`Series.dt.round(*args, **kwargs)`

Perform round operation on the data to the specified *freq*.

### Parameters

**freq** [str or Offset] The frequency level to round the index to. Must be a fixed frequency like ‘S’ (second) not ‘ME’ (month end). See *frequency aliases* for a list of possible *freq* values.

**ambiguous** [‘infer’, bool-ndarray, ‘NaT’, default ‘raise’] Only relevant for DatetimeIndex:

- ‘infer’ will attempt to infer fall dst-transition hours based on order
- bool-ndarray where True signifies a DST time, False designates a non-DST time (note that this flag is only applicable for ambiguous times)
- ‘NaT’ will return NaT where there are ambiguous times
- ‘raise’ will raise an AmbiguousTimeError if there are ambiguous times

New in version 0.24.0.

**nonexistent** [‘shift\_forward’, ‘shift\_backward’, ‘NaT’, timedelta,]

default ‘raise’

A nonexistent time does not exist in a particular timezone where clocks moved forward due to DST.

- ‘shift\_forward’ will shift the nonexistent time forward to the closest existing time
- ‘shift\_backward’ will shift the nonexistent time backward to the closest existing time
- ‘NaT’ will return NaT where there are nonexistent times
- timedelta objects will shift nonexistent times by the timedelta
- ‘raise’ will raise a NonExistentTimeError if there are nonexistent times

New in version 0.24.0.

### Returns

**DatetimeIndex, TimedeltaIndex, or Series** Index of the same type for a DatetimeIndex or TimedeltaIndex, or a Series with the same index for a Series.

### Raises

**ValueError** if the ‘freq’ cannot be converted.

## Examples

### DatetimeIndex

```
>>> rng = pd.date_range('1/1/2018 11:59:00', periods=3, freq='min')
>>> rng
DatetimeIndex(['2018-01-01 11:59:00', '2018-01-01 12:00:00',
              '2018-01-01 12:01:00'],
              dtype='datetime64[ns]', freq='T')
>>> rng.round('H')
DatetimeIndex(['2018-01-01 12:00:00', '2018-01-01 12:00:00',
              '2018-01-01 12:00:00'],
              dtype='datetime64[ns]', freq=None)
```

### Series

```
>>> pd.Series(rng).dt.round("H")
0    2018-01-01 12:00:00
1    2018-01-01 12:00:00
2    2018-01-01 12:00:00
dtype: datetime64[ns]
```

## pandas.Series.dt.floor

`Series.dt.floor(*args, **kwargs)`

Perform floor operation on the data to the specified *freq*.

### Parameters

**freq** [str or Offset] The frequency level to floor the index to. Must be a fixed frequency like ‘S’ (second) not ‘ME’ (month end). See *frequency aliases* for a list of possible *freq* values.

**ambiguous** [‘infer’, bool-ndarray, ‘NaT’, default ‘raise’] Only relevant for DatetimeIndex:

- ‘infer’ will attempt to infer fall dst-transition hours based on order
- bool-ndarray where True signifies a DST time, False designates a non-DST time (note that this flag is only applicable for ambiguous times)
- ‘NaT’ will return NaT where there are ambiguous times
- ‘raise’ will raise an AmbiguousTimeError if there are ambiguous times

New in version 0.24.0.

**nonexistent** [‘shift\_forward’, ‘shift\_backward’, ‘NaT’, timedelta,]  
default ‘raise’

A nonexistent time does not exist in a particular timezone where clocks moved forward due to DST.

- ‘shift\_forward’ will shift the nonexistent time forward to the closest existing time
- ‘shift\_backward’ will shift the nonexistent time backward to the closest existing time
- ‘NaT’ will return NaT where there are nonexistent times
- timedelta objects will shift nonexistent times by the timedelta
- ‘raise’ will raise an NonExistentTimeError if there are nonexistent times

New in version 0.24.0.

### Returns

**DatetimeIndex, TimedeltaIndex, or Series** Index of the same type for a DatetimeIndex or TimedeltaIndex, or a Series with the same index for a Series.

### Raises

**ValueError** if the ‘freq’ cannot be converted.

## Examples

### DatetimeIndex

```
>>> rng = pd.date_range('1/1/2018 11:59:00', periods=3, freq='min')
>>> rng
DatetimeIndex(['2018-01-01 11:59:00', '2018-01-01 12:00:00',
              '2018-01-01 12:01:00'],
              dtype='datetime64[ns]', freq='T')
>>> rng.floor('H')
DatetimeIndex(['2018-01-01 11:00:00', '2018-01-01 12:00:00',
              '2018-01-01 12:00:00'],
              dtype='datetime64[ns]', freq=None)
```

### Series

```
>>> pd.Series(rng).dt.floor("H")
0    2018-01-01 11:00:00
1    2018-01-01 12:00:00
2    2018-01-01 12:00:00
dtype: datetime64[ns]
```

## pandas.Series.dt.ceil

`Series.dt.ceil(*args, **kwargs)`

Perform ceil operation on the data to the specified *freq*.

### Parameters

**freq** [str or Offset] The frequency level to ceil the index to. Must be a fixed frequency like ‘S’ (second) not ‘ME’ (month end). See *frequency aliases* for a list of possible *freq* values.

**ambiguous** [‘infer’, bool-ndarray, ‘NaT’, default ‘raise’] Only relevant for DatetimeIndex:

- ‘infer’ will attempt to infer fall dst-transition hours based on order
- bool-ndarray where True signifies a DST time, False designates a non-DST time (note that this flag is only applicable for ambiguous times)
- ‘NaT’ will return NaT where there are ambiguous times
- ‘raise’ will raise an AmbiguousTimeError if there are ambiguous times

New in version 0.24.0.

**nonexistent** [‘shift\_forward’, ‘shift\_backward’, ‘NaT’, timedelta,]  
default ‘raise’

A nonexistent time does not exist in a particular timezone where clocks moved forward due to DST.

- 'shift\_forward' will shift the nonexistent time forward to the closest existing time
- 'shift\_backward' will shift the nonexistent time backward to the closest existing time
- 'NaT' will return NaT where there are nonexistent times
- timedelta objects will shift nonexistent times by the timedelta
- 'raise' will raise a NonExistentTimeError if there are nonexistent times

New in version 0.24.0.

#### Returns

**DatetimeIndex, TimedeltaIndex, or Series** Index of the same type for a DatetimeIndex or TimedeltaIndex, or a Series with the same index for a Series.

#### Raises

**ValueError** if the 'freq' cannot be converted.

### Examples

#### DatetimeIndex

```
>>> rng = pd.date_range('1/1/2018 11:59:00', periods=3, freq='min')
>>> rng
DatetimeIndex(['2018-01-01 11:59:00', '2018-01-01 12:00:00',
              '2018-01-01 12:01:00'],
              dtype='datetime64[ns]', freq='T')
>>> rng.ceil('H')
DatetimeIndex(['2018-01-01 12:00:00', '2018-01-01 12:00:00',
              '2018-01-01 13:00:00'],
              dtype='datetime64[ns]', freq=None)
```

#### Series

```
>>> pd.Series(rng).dt.ceil("H")
0    2018-01-01 12:00:00
1    2018-01-01 12:00:00
2    2018-01-01 13:00:00
dtype: datetime64[ns]
```

### pandas.Series.dt.month\_name

`Series.dt.month_name(*args, **kwargs)`

Return the month names of the DateTimeIndex with specified locale.

New in version 0.23.0.

#### Parameters

**locale** [str, optional] Locale determining the language in which to return the month name. Default is English locale.

#### Returns

**Index** Index of month names.

## Examples

```
>>> idx = pd.date_range(start='2018-01', freq='M', periods=3)
>>> idx
DatetimeIndex(['2018-01-31', '2018-02-28', '2018-03-31'],
              dtype='datetime64[ns]', freq='M')
>>> idx.month_name()
Index(['January', 'February', 'March'], dtype='object')
```

## pandas.Series.dt.day\_name

`Series.dt.day_name(*args, **kwargs)`

Return the day names of the DateTimeIndex with specified locale.

New in version 0.23.0.

### Parameters

**locale** [str, optional] Locale determining the language in which to return the day name. Default is English locale.

### Returns

**Index** Index of day names.

## Examples

```
>>> idx = pd.date_range(start='2018-01-01', freq='D', periods=3)
>>> idx
DatetimeIndex(['2018-01-01', '2018-01-02', '2018-01-03'],
              dtype='datetime64[ns]', freq='D')
>>> idx.day_name()
Index(['Monday', 'Tuesday', 'Wednesday'], dtype='object')
```

|                                     |                                                                                 |
|-------------------------------------|---------------------------------------------------------------------------------|
| <code>Series.dt.days</code>         | Number of days for each element.                                                |
| <code>Series.dt.seconds</code>      | Number of seconds ( $\geq 0$ and less than 1 day) for each element.             |
| <code>Series.dt.microseconds</code> | Number of microseconds ( $\geq 0$ and less than 1 second) for each element.     |
| <code>Series.dt.nanoseconds</code>  | Number of nanoseconds ( $\geq 0$ and less than 1 microsecond) for each element. |
| <code>Series.dt.components</code>   | Return a Dataframe of the components of the Timedeltas.                         |

**pandas.Series.dt.days**`Series.dt.days`

Number of days for each element.

**pandas.Series.dt.seconds**`Series.dt.seconds`Number of seconds ( $\geq 0$  and less than 1 day) for each element.**pandas.Series.dt.microseconds**`Series.dt.microseconds`Number of microseconds ( $\geq 0$  and less than 1 second) for each element.**pandas.Series.dt.nanoseconds**`Series.dt.nanoseconds`Number of nanoseconds ( $\geq 0$  and less than 1 microsecond) for each element.**pandas.Series.dt.components**`Series.dt.components`

Return a Dataframe of the components of the Timedeltas.

**Returns****DataFrame**

## Examples

```
>>> s = pd.Series(pd.to_timedelta(np.arange(5), unit='s'))
>>> s
0    00:00:00
1    00:00:01
2    00:00:02
3    00:00:03
4    00:00:04
dtype: timedelta64[ns]
>>> s.dt.components
   days  hours  minutes  seconds  milliseconds  microseconds  nanoseconds
0     0     0         0         0              0              0              0
1     0     0         0         1              0              0              0
2     0     0         0         2              0              0              0
3     0     0         0         3              0              0              0
4     0     0         0         4              0              0              0
```

## Timedelta Methods

|                                                       |                                                              |
|-------------------------------------------------------|--------------------------------------------------------------|
| <code>Series.dt.to_pytimedelta()</code>               | Return an array of native <i>datetime.timedelta</i> objects. |
| <code>Series.dt.total_seconds(*args, **kwargs)</code> | Return total duration of each element expressed in seconds.  |

## pandas.Series.dt.to\_pytimedelta

`Series.dt.to_pytimedelta()`

Return an array of native *datetime.timedelta* objects.

Python's standard *datetime* library uses a different representation *timedelta*'s. This method converts a Series of pandas Timedeltas to *datetime.timedelta* format with the same length as the original Series.

### Returns

**a** [numpy.ndarray] 1D array containing data with *datetime.timedelta* type.

### See also:

`datetime.timedelta`

## Examples

```
>>> s = pd.Series(pd.to_timedelta(np.arange(5), unit='d'))
>>> s
0    0 days
1    1 days
2    2 days
3    3 days
4    4 days
dtype: timedelta64[ns]
```

```
>>> s.dt.to_pytimedelta()
array([datetime.timedelta(0), datetime.timedelta(1),
```

(continues on next page)

(continued from previous page)

```
datetime.timedelta(2), datetime.timedelta(3),
datetime.timedelta(4)], dtype=object)
```

## pandas.Series.dt.total\_seconds

`Series.dt.total_seconds(*args, **kwargs)`

Return total duration of each element expressed in seconds.

This method is available directly on `TimedeltaArray`, `TimedeltaIndex` and on `Series` containing `timedelta` values under the `.dt` namespace.

### Returns

**seconds** [[ndarray, Float64Index, Series]] When the calling object is a `TimedeltaArray`, the return type is `ndarray`. When the calling object is a `TimedeltaIndex`, the return type is a `Float64Index`. When the calling object is a `Series`, the return type is `Series` of type `float64` whose index is the same as the original.

See also:

`datetime.timedelta.total_seconds` Standard library version of this method.

**`TimedeltaIndex.components`** Return a `DataFrame` with components of each `Timedelta`.

## Examples

### Series

```
>>> s = pd.Series(pd.to_timedelta(np.arange(5), unit='d'))
>>> s
0    0 days
1    1 days
2    2 days
3    3 days
4    4 days
dtype: timedelta64[ns]
```

```
>>> s.dt.total_seconds()
0         0.0
1    86400.0
2   172800.0
3   259200.0
4   345600.0
dtype: float64
```

### TimedeltaIndex

```
>>> idx = pd.to_timedelta(np.arange(5), unit='d')
>>> idx
TimedeltaIndex(['0 days', '1 days', '2 days', '3 days', '4 days'],
               dtype='timedelta64[ns]', freq=None)
```

```
>>> idx.total_seconds()
Float64Index([0.0, 86400.0, 172800.0, 259200.000000000003, 345600.0],
             dtype='float64')
```

### 35.3.13.2 String handling

`Series.str` can be used to access the values of the series as strings and apply several methods to it. These can be accessed like `Series.str.<function/property>`.

|                                                               |                                                                                                                        |
|---------------------------------------------------------------|------------------------------------------------------------------------------------------------------------------------|
| <code>Series.str.capitalize()</code>                          | Convert strings in the Series/Index to be capitalized.                                                                 |
| <code>Series.str.cat([others, sep, na_rep, join])</code>      | Concatenate strings in the Series/Index with given separator.                                                          |
| <code>Series.str.center(width[, fillchar])</code>             | Filling left and right side of strings in the Series/Index with an additional character.                               |
| <code>Series.str.contains(pat[, case, flags, na, ...])</code> | Test if pattern or regex is contained within a string of a Series or Index.                                            |
| <code>Series.str.count(pat[, flags])</code>                   | Count occurrences of pattern in each string of the Series/Index.                                                       |
| <code>Series.str.decode(encoding[, errors])</code>            | Decode character string in the Series/Index using indicated encoding.                                                  |
| <code>Series.str.encode(encoding[, errors])</code>            | Encode character string in the Series/Index using indicated encoding.                                                  |
| <code>Series.str.endswith(pat[, na])</code>                   | Test if the end of each string element matches a pattern.                                                              |
| <code>Series.str.extract(pat[, flags, expand])</code>         | Extract capture groups in the regex <i>pat</i> as columns in a DataFrame.                                              |
| <code>Series.str.extractall(pat[, flags])</code>              | For each subject string in the Series, extract groups from all matches of regular expression <i>pat</i> .              |
| <code>Series.str.find(sub[, start, end])</code>               | Return lowest indexes in each strings in the Series/Index where the substring is fully contained between [start:end].  |
| <code>Series.str.findall(pat[, flags])</code>                 | Find all occurrences of pattern or regular expression in the Series/Index.                                             |
| <code>Series.str.get(i)</code>                                | Extract element from each component at specified position.                                                             |
| <code>Series.str.index(sub[, start, end])</code>              | Return lowest indexes in each strings where the substring is fully contained between [start:end].                      |
| <code>Series.str.join(sep)</code>                             | Join lists contained as elements in the Series/Index with passed delimiter.                                            |
| <code>Series.str.len()</code>                                 | Computes the length of each element in the Series/Index.                                                               |
| <code>Series.str.ljust(width[, fillchar])</code>              | Filling right side of strings in the Series/Index with an additional character.                                        |
| <code>Series.str.lower()</code>                               | Convert strings in the Series/Index to lowercase.                                                                      |
| <code>Series.str.lstrip([to_strip])</code>                    | Remove leading and trailing characters.                                                                                |
| <code>Series.str.match(pat[, case, flags, na])</code>         | Determine if each string matches a regular expression.                                                                 |
| <code>Series.str.normalize(form)</code>                       | Return the Unicode normal form for the strings in the Series/Index.                                                    |
| <code>Series.str.pad(width[, side, fillchar])</code>          | Pad strings in the Series/Index up to width.                                                                           |
| <code>Series.str.partition([sep, expand])</code>              | Split the string at the first occurrence of <i>sep</i> .                                                               |
| <code>Series.str.repeat(repeats)</code>                       | Duplicate each string in the Series or Index.                                                                          |
| <code>Series.str.replace(pat, repl[, n, case, ...])</code>    | Replace occurrences of pattern/regex in the Series/Index with some other string.                                       |
| <code>Series.str.rfind(sub[, start, end])</code>              | Return highest indexes in each strings in the Series/Index where the substring is fully contained between [start:end]. |

Table 45 – continued from previous page

|                                                            |                                                                                                          |
|------------------------------------------------------------|----------------------------------------------------------------------------------------------------------|
| <code>Series.str.rindex(sub[, start, end])</code>          | Return highest indexes in each strings where the substring is fully contained between [start:end].       |
| <code>Series.str.rjust(width[, fillchar])</code>           | Filling left side of strings in the Series/Index with an additional character.                           |
| <code>Series.str.rpartition([sep, expand])</code>          | Split the string at the last occurrence of <i>sep</i> .                                                  |
| <code>Series.str.rstrip([to_strip])</code>                 | Remove leading and trailing characters.                                                                  |
| <code>Series.str.slice([start, stop, step])</code>         | Slice substrings from each element in the Series or Index.                                               |
| <code>Series.str.slice_replace([start, stop, repl])</code> | Replace a positional slice of a string with another value.                                               |
| <code>Series.str.split([pat, n, expand])</code>            | Split strings around given separator/delimiter.                                                          |
| <code>Series.str.rsplit([pat, n, expand])</code>           | Split strings around given separator/delimiter.                                                          |
| <code>Series.str.startswith(pat[, na])</code>              | Test if the start of each string element matches a pattern.                                              |
| <code>Series.str.strip([to_strip])</code>                  | Remove leading and trailing characters.                                                                  |
| <code>Series.str.swapcase()</code>                         | Convert strings in the Series/Index to be swapcased.                                                     |
| <code>Series.str.title()</code>                            | Convert strings in the Series/Index to titlecase.                                                        |
| <code>Series.str.translate(table[, deletechars])</code>    | Map all characters in the string through the given mapping table.                                        |
| <code>Series.str.upper()</code>                            | Convert strings in the Series/Index to uppercase.                                                        |
| <code>Series.str.wrap(width, **kwargs)</code>              | Wrap long strings in the Series/Index to be formatted in paragraphs with length less than a given width. |
| <code>Series.str.zfill(width)</code>                       | Pad strings in the Series/Index by prepending '0' characters.                                            |
| <code>Series.str.isalnum()</code>                          | Check whether all characters in each string are alphanumeric.                                            |
| <code>Series.str.isalpha()</code>                          | Check whether all characters in each string are alphabetic.                                              |
| <code>Series.str.isdigit()</code>                          | Check whether all characters in each string are digits.                                                  |
| <code>Series.str.isspace()</code>                          | Check whether all characters in each string are whitespace.                                              |
| <code>Series.str.islower()</code>                          | Check whether all characters in each string are lowercase.                                               |
| <code>Series.str.isupper()</code>                          | Check whether all characters in each string are uppercase.                                               |
| <code>Series.str.istitle()</code>                          | Check whether all characters in each string are titlecase.                                               |
| <code>Series.str.isnumeric()</code>                        | Check whether all characters in each string are numeric.                                                 |
| <code>Series.str.isdecimal()</code>                        | Check whether all characters in each string are decimal.                                                 |
| <code>Series.str.get_dummies([sep])</code>                 | Split each string in the Series by <i>sep</i> and return a frame of dummy/indicator variables.           |

**pandas.Series.str.capitalize****Series.str.capitalize()**

Convert strings in the Series/Index to be capitalized.

Equivalent to `str.capitalize()`.**Returns****Series/Index of objects****See also:****Series.str.lower** Converts all characters to lowercase.

***Series.str.upper*** Converts all characters to uppercase.

***Series.str.title*** Converts first character of each word to uppercase and remaining to lowercase.

***Series.str.capitalize*** Converts first character to uppercase and remaining to lowercase.

***Series.str.swapcase*** Converts uppercase to lowercase and lowercase to uppercase.

## Examples

```
>>> s = pd.Series(['lower', 'CAPITALS', 'this is a sentence', 'SwApCaSe'])
>>> s
0          lower
1        CAPITALS
2    this is a sentence
3        SwApCaSe
dtype: object
```

```
>>> s.str.lower()
0          lower
1        capitals
2    this is a sentence
3        swapcase
dtype: object
```

```
>>> s.str.upper()
0          LOWER
1        CAPITALS
2    THIS IS A SENTENCE
3        SWAPCASE
dtype: object
```

```
>>> s.str.title()
0          Lower
1        Capitals
2    This Is A Sentence
3        Swapcase
dtype: object
```

```
>>> s.str.capitalize()
0          Lower
1        Capitals
2    This is a sentence
3        Swapcase
dtype: object
```

```
>>> s.str.swapcase()
0          LOWER
1        capitals
2    THIS IS A SENTENCE
3        sWaPcAsE
dtype: object
```

**pandas.Series.str.cat**`Series.str.cat` (*others=None, sep=None, na\_rep=None, join=None*)

Concatenate strings in the Series/Index with given separator.

If *others* is specified, this function concatenates the Series/Index and elements of *others* element-wise. If *others* is not passed, then all values in the Series/Index are concatenated into a single string with a given *sep*.

**Parameters**

**others** [Series, Index, DataFrame, np.ndarray or list-like] Series, Index, DataFrame, np.ndarray (one- or two-dimensional) and other list-likes of strings must have the same length as the calling Series/Index, with the exception of indexed objects (i.e. Series/Index/DataFrame) if *join* is not None.

If *others* is a list-like that contains a combination of Series, Index or np.ndarray (1-dim), then all elements will be unpacked and must satisfy the above criteria individually.

If *others* is None, the method returns the concatenation of all strings in the calling Series/Index.

**sep** [str, default “”] The separator between the different elements/columns. By default the empty string “” is used.

**na\_rep** [str or None, default None] Representation that is inserted for all missing values:

- If *na\_rep* is None, and *others* is None, missing values in the Series/Index are omitted from the result.
- If *na\_rep* is None, and *others* is not None, a row containing a missing value in any of the columns (before concatenation) will have a missing value in the result.

**join** [{‘left’, ‘right’, ‘outer’, ‘inner’}, default None] Determines the join-style between the calling Series/Index and any Series/Index/DataFrame in *others* (objects without an index need to match the length of the calling Series/Index). If None, alignment is disabled, but this option will be removed in a future version of pandas and replaced with a default of ‘left’. To disable alignment, use *.values* on any Series/Index/DataFrame in *others*.

New in version 0.23.0.

**Returns**

**concat** [str or Series/Index of objects] If *others* is None, *str* is returned, otherwise a *Series/Index* (same type as caller) of objects is returned.

See also:

**split** Split each string in the Series/Index.

**join** Join lists contained as elements in the Series/Index.

**Examples**

When not passing *others*, all values are concatenated into a single string:

```
>>> s = pd.Series(['a', 'b', np.nan, 'd'])
>>> s.str.cat(sep=' ')
'a b d'
```

By default, NA values in the Series are ignored. Using *na\_rep*, they can be given a representation:

```
>>> s.str.cat(sep=' ', na_rep='?')
'a b ? d'
```

If *others* is specified, corresponding values are concatenated with the separator. Result will be a Series of strings.

```
>>> s.str.cat(['A', 'B', 'C', 'D'], sep=',')
0    a,A
1    b,B
2    NaN
3    d,D
dtype: object
```

Missing values will remain missing in the result, but can again be represented using *na\_rep*

```
>>> s.str.cat(['A', 'B', 'C', 'D'], sep=',', na_rep='-')
0    a,A
1    b,B
2    -,C
3    d,D
dtype: object
```

If *sep* is not specified, the values are concatenated without separation.

```
>>> s.str.cat(['A', 'B', 'C', 'D'], na_rep='-')
0    aA
1    bB
2    -C
3    dD
dtype: object
```

Series with different indexes can be aligned before concatenation. The *join*-keyword works as in other methods.

```
>>> t = pd.Series(['d', 'a', 'e', 'c'], index=[3, 0, 4, 2])
>>> s.str.cat(t, join='left', na_rep='-')
0    aa
1    b-
2    -c
3    dd
dtype: object
>>>
>>> s.str.cat(t, join='outer', na_rep='-')
0    aa
1    b-
2    -c
3    dd
4    -e
dtype: object
>>>
>>> s.str.cat(t, join='inner', na_rep='-')
0    aa
2    -c
3    dd
dtype: object
>>>
>>> s.str.cat(t, join='right', na_rep='-')
3    dd
0    aa
```

(continues on next page)

(continued from previous page)

```
4    -e
2    -c
dtype: object
```

For more examples, see *here*.

### pandas.Series.str.center

`Series.str.center(width, fillchar='')`

Filling left and right side of strings in the Series/Index with an additional character. Equivalent to `str.center()`.

#### Parameters

**width** [int] Minimum width of resulting string; additional characters will be filled with `fillchar`

**fillchar** [str] Additional character for filling, default is whitespace

#### Returns

**filled** [Series/Index of objects]

### pandas.Series.str.contains

`Series.str.contains(pat, case=True, flags=0, na=nan, regex=True)`

Test if pattern or regex is contained within a string of a Series or Index.

Return boolean Series or Index based on whether a given pattern or regex is contained within a string of a Series or Index.

#### Parameters

**pat** [str] Character sequence or regular expression.

**case** [bool, default True] If True, case sensitive.

**flags** [int, default 0 (no flags)] Flags to pass through to the re module, e.g. `re.IGNORECASE`.

**na** [default NaN] Fill value for missing values.

**regex** [bool, default True] If True, assumes the `pat` is a regular expression.

If False, treats the `pat` as a literal string.

#### Returns

**Series or Index of boolean values** A Series or Index of boolean values indicating whether the given pattern is contained within the string of each element of the Series or Index.

See also:

**match** Analogous, but stricter, relying on `re.match` instead of `re.search`.

**Series.str.startswith** Test if the start of each string element matches a pattern.

**Series.str.endswith** Same as `startswith`, but tests the end of string.

## Examples

Returning a Series of booleans using only a literal pattern.

```
>>> s1 = pd.Series(['Mouse', 'dog', 'house and parrot', '23', np.NaN])
>>> s1.str.contains('og', regex=False)
0    False
1     True
2    False
3    False
4     NaN
dtype: object
```

Returning an Index of booleans using only a literal pattern.

```
>>> ind = pd.Index(['Mouse', 'dog', 'house and parrot', '23.0', np.NaN])
>>> ind.str.contains('23', regex=False)
Index([False, False, False, True, nan], dtype='object')
```

Specifying case sensitivity using *case*.

```
>>> s1.str.contains('oG', case=True, regex=True)
0    False
1    False
2    False
3    False
4     NaN
dtype: object
```

Specifying *na* to be *False* instead of *NaN* replaces NaN values with *False*. If Series or Index does not contain NaN values the resultant dtype will be *bool*, otherwise, an *object* dtype.

```
>>> s1.str.contains('og', na=False, regex=True)
0    False
1     True
2    False
3    False
4    False
dtype: bool
```

Returning 'house' or 'dog' when either expression occurs in a string.

```
>>> s1.str.contains('house|dog', regex=True)
0    False
1     True
2     True
3    False
4     NaN
dtype: object
```

Ignoring case sensitivity using *flags* with regex.

```
>>> import re
>>> s1.str.contains('PARROT', flags=re.IGNORECASE, regex=True)
0    False
1    False
2     True
```

(continues on next page)

(continued from previous page)

```

3     False
4         NaN
dtype: object

```

Returning any digit using regular expression.

```

>>> s1.str.contains('\d', regex=True)
0     False
1     False
2     False
3      True
4         NaN
dtype: object

```

Ensure *pat* is not a literal pattern when *regex* is set to *True*. Note in the following example one might expect only *s2[1]* and *s2[3]* to return *True*. However, *'0'* as a regex matches any character followed by a 0.

```

>>> s2 = pd.Series(['40', '40.0', '41', '41.0', '35'])
>>> s2.str.contains('.0', regex=True)
0      True
1      True
2     False
3      True
4     False
dtype: bool

```

## pandas.Series.str.count

`Series.str.count` (*pat*, *flags=0*, *\*\*kwargs*)

Count occurrences of pattern in each string of the Series/Index.

This function is used to count the number of times a particular regex pattern is repeated in each of the string elements of the *Series*.

### Parameters

**pat** [str] Valid regular expression.

**flags** [int, default 0, meaning no flags] Flags for the *re* module. For a complete list, [see here](#).

**\*\*kwargs** For compatibility with other string methods. Not used.

### Returns

**counts** [Series or Index] Same type as the calling object containing the integer counts.

See also:

**re** Standard library module for regular expressions.

**str.count** Standard library version, without regular expression support.

## Notes

Some characters need to be escaped when passing in *pat*. eg. *'\$'* has a special meaning in regex and must be escaped when finding this literal character.

## Examples

```
>>> s = pd.Series(['A', 'B', 'Aaba', 'Baca', np.nan, 'CABA', 'cat'])
>>> s.str.count('a')
0      0.0
1      0.0
2      2.0
3      2.0
4      NaN
5      0.0
6      1.0
dtype: float64
```

Escape '\$' to find the literal dollar sign.

```
>>> s = pd.Series(['$', 'B', 'Aab$', '$$ca', 'C$B$', 'cat'])
>>> s.str.count('\$')
0      1
1      0
2      1
3      2
4      2
5      0
dtype: int64
```

This is also available on Index

```
>>> pd.Index(['A', 'A', 'Aaba', 'cat']).str.count('a')
Int64Index([0, 0, 2, 1], dtype='int64')
```

## pandas.Series.str.decode

`Series.str.decode(encoding, errors='strict')`

Decode character string in the Series/Index using indicated encoding. Equivalent to `str.decode()` in python2 and `bytes.decode()` in python3.

### Parameters

**encoding** [str]

**errors** [str, optional]

### Returns

**decoded** [Series/Index of objects]

## pandas.Series.str.encode

`Series.str.encode(encoding, errors='strict')`

Encode character string in the Series/Index using indicated encoding. Equivalent to `str.encode()`.

### Parameters

**encoding** [str]

**errors** [str, optional]

### Returns

**encoded** [Series/Index of objects]

## pandas.Series.str.endswith

`Series.str.endswith(pat, na=nan)`

Test if the end of each string element matches a pattern.

Equivalent to `str.endswith()`.

### Parameters

**pat** [str] Character sequence. Regular expressions are not accepted.

**na** [object, default NaN] Object shown if element tested is not a string.

### Returns

**Series or Index of bool** A Series of booleans indicating whether the given pattern matches the end of each string element.

See also:

**str.endswith** Python standard library string method.

**Series.str.startswith** Same as `endswith`, but tests the start of string.

**Series.str.contains** Tests if string element contains a pattern.

## Examples

```
>>> s = pd.Series(['bat', 'bear', 'caT', np.nan])
>>> s
0    bat
1    bear
2    caT
3    NaN
dtype: object
```

```
>>> s.str.endswith('t')
0     True
1    False
2    False
3     NaN
dtype: object
```

Specifying *na* to be *False* instead of *NaN*.

```
>>> s.str.endswith('t', na=False)
0     True
1    False
2    False
3    False
dtype: bool
```

## pandas.Series.str.extract

`Series.str.extract` (*pat*, *flags=0*, *expand=True*)

Extract capture groups in the regex *pat* as columns in a DataFrame.

For each subject string in the Series, extract groups from the first match of regular expression *pat*.

### Parameters

**pat** [string] Regular expression pattern with capturing groups.

**flags** [int, default 0 (no flags)] Flags from the `re` module, e.g. `re.IGNORECASE`, that modify regular expression matching for things like case, spaces, etc. For more details, see `re`.

**expand** [bool, default True] If True, return DataFrame with one column per capture group. If False, return a Series/Index if there is one capture group or DataFrame if there are multiple capture groups.

New in version 0.18.0.

### Returns

**DataFrame or Series or Index** A DataFrame with one row for each subject string, and one column for each group. Any capture group names in regular expression *pat* will be used for column names; otherwise capture group numbers will be used. The dtype of each result column is always object, even when no match is found. If `expand=False` and *pat* has only one capture group, then return a Series (if subject is a Series) or Index (if subject is an Index).

See also:

**`extractall`** Returns all matches (not just the first match).

## Examples

A pattern with two groups will return a DataFrame with two columns. Non-matches will be NaN.

```
>>> s = pd.Series(['a1', 'b2', 'c3'])
>>> s.str.extract(r'([ab])(\d)')
   0  1
0  a  1
1  b  2
2 NaN NaN
```

A pattern may contain optional groups.

```
>>> s.str.extract(r'([ab])?(\d)')
   0  1
0  a  1
1  b  2
2 NaN 3
```

Named groups will become column names in the result.

```
>>> s.str.extract(r'(?P<letter>[ab])(?P<digit>\d)')
   letter digit
0      a      1
```

(continues on next page)

(continued from previous page)

|   |     |     |
|---|-----|-----|
| 1 | b   | 2   |
| 2 | NaN | NaN |

A pattern with one group will return a DataFrame with one column if `expand=True`.

```
>>> s.str.extract(r'[ab](\d)', expand=True)
      0
0      1
1      2
2    NaN
```

A pattern with one group will return a Series if `expand=False`.

```
>>> s.str.extract(r'[ab](\d)', expand=False)
0      1
1      2
2    NaN
dtype: object
```

## pandas.Series.str.extractall

`Series.str.extractall(pat, flags=0)`

For each subject string in the Series, extract groups from all matches of regular expression `pat`. When each subject string in the Series has exactly one match, `extractall(pat).xs(0, level='match')` is the same as `extract(pat)`.

New in version 0.18.0.

### Parameters

**pat** [str] Regular expression pattern with capturing groups.

**flags** [int, default 0 (no flags)] A `re` module flag, for example `re.IGNORECASE`. These allow to modify regular expression matching for things like case, spaces, etc. Multiple flags can be combined with the bitwise OR operator, for example `re.IGNORECASE | re.MULTILINE`.

### Returns

**DataFrame** A `DataFrame` with one row for each match, and one column for each group. Its rows have a `MultiIndex` with first levels that come from the subject `Series`. The last level is named 'match' and indexes the matches in each item of the `Series`. Any capture group names in regular expression `pat` will be used for column names; otherwise capture group numbers will be used.

**See also:**

**extract** Returns first match only (not all matches).

## Examples

A pattern with one group will return a `DataFrame` with one column. Indices with no matches will not appear in the result.

```
>>> s = pd.Series(["a1a2", "b1", "c1"], index=["A", "B", "C"])
>>> s.str.extractall(r"[ab](\d)")
      0
match
A 0    1
  1    2
B 0    1
```

Capture group names are used for column names of the result.

```
>>> s.str.extractall(r"[ab](?P<digit>\d)")
      digit
match
A 0        1
  1        2
B 0        1
```

A pattern with two groups will return a DataFrame with two columns.

```
>>> s.str.extractall(r"(?P<letter>[ab])(?P<digit>\d)")
      letter digit
match
A 0         a     1
  1         a     2
B 0         b     1
```

Optional groups that do not match are NaN in the result.

```
>>> s.str.extractall(r"(?P<letter>[ab])?(?P<digit>\d)")
      letter digit
match
A 0         a     1
  1         a     2
B 0         b     1
C 0        NaN     1
```

## pandas.Series.str.find

`Series.str.find(sub, start=0, end=None)`

Return lowest indexes in each strings in the Series/Index where the substring is fully contained between [start:end]. Return -1 on failure. Equivalent to standard `str.find()`.

### Parameters

**sub** [str] Substring being searched

**start** [int] Left edge index

**end** [int] Right edge index

### Returns

**found** [Series/Index of integer values]

See also:

**rfind** Return highest indexes in each strings.

**pandas.Series.str.findall****Series.str.findall** (*pat*, *flags=0*, *\*\*kwargs*)

Find all occurrences of pattern or regular expression in the Series/Index.

Equivalent to applying `re.findall()` to all the elements in the Series/Index.**Parameters****pat** [string] Pattern or regular expression.**flags** [int, default 0] re module flags, e.g. `re.IGNORECASE` (default is 0, which means no flags).**Returns****Series/Index of lists of strings** All non-overlapping matches of pattern or regular expression in each string of this Series/Index.**See also:****count** Count occurrences of pattern or regular expression in each string of the Series/Index.**extractall** For each string in the Series, extract groups from all matches of regular expression and return a DataFrame with one row for each match and one column for each group.**re.findall** The equivalent re function to all non-overlapping matches of pattern or regular expression in string, as a list of strings.**Examples**

```
>>> s = pd.Series(['Lion', 'Monkey', 'Rabbit'])
```

The search for the pattern 'Monkey' returns one match:

```
>>> s.str.findall('Monkey')
0      []
1  [Monkey]
2      []
dtype: object
```

On the other hand, the search for the pattern 'MONKEY' doesn't return any match:

```
>>> s.str.findall('MONKEY')
0      []
1      []
2      []
dtype: object
```

Flags can be added to the pattern or regular expression. For instance, to find the pattern 'MONKEY' ignoring the case:

```
>>> import re
>>> s.str.findall('MONKEY', flags=re.IGNORECASE)
0      []
1  [Monkey]
2      []
dtype: object
```

When the pattern matches more than one string in the Series, all matches are returned:

```
>>> s.str.findall('on')
0      [on]
1      [on]
2      []
dtype: object
```

Regular expressions are supported too. For instance, the search for all the strings ending with the word 'on' is shown next:

```
>>> s.str.findall('on$')
0      [on]
1      []
2      []
dtype: object
```

If the pattern is found more than once in the same string, then a list of multiple strings is returned:

```
>>> s.str.findall('b')
0      []
1      []
2      [b, b]
dtype: object
```

## pandas.Series.str.get

`Series.str.get(i)`

Extract element from each component at specified position.

Extract element from lists, tuples, or strings in each element in the Series/Index.

### Parameters

**i** [int] Position of element to extract.

### Returns

**items** [Series/Index of objects]

## Examples

```
>>> s = pd.Series(["String",
                  (1, 2, 3),
                  ["a", "b", "c"],
                  123, -456,
                  {1:"Hello", "2":"World"}])

>>> s
0      String
1      (1, 2, 3)
2      [a, b, c]
3      123
4      -456
5      {1: 'Hello', '2': 'World'}
dtype: object
```

```
>>> s.str.get(1)
0      t
1      2
2      b
3     NaN
4     NaN
5    Hello
dtype: object
```

```
>>> s.str.get(-1)
0      g
1      3
2      c
3     NaN
4     NaN
5     NaN
dtype: object
```

### pandas.Series.str.index

`Series.str.index(sub, start=0, end=None)`

Return lowest indexes in each strings where the substring is fully contained between [start:end]. This is the same as `str.find` except instead of returning -1, it raises a `ValueError` when the substring is not found. Equivalent to standard `str.index`.

#### Parameters

**sub** [str] Substring being searched  
**start** [int] Left edge index  
**end** [int] Right edge index

#### Returns

**found** [Series/Index of objects]

See also:

**rindex** Return highest indexes in each strings.

### pandas.Series.str.join

`Series.str.join(sep)`

Join lists contained as elements in the Series/Index with passed delimiter.

If the elements of a Series are lists themselves, join the content of these lists using the delimiter passed to the function. This function is an equivalent to `str.join()`.

#### Parameters

**sep** [str] Delimiter to use between list entries.

#### Returns

**Series/Index: object** The list entries concatenated by intervening occurrences of the delimiter.

### Raises

**AttributeError** If the supplied Series contains neither strings nor lists.

See also:

**str.join** Standard library version of this method.

**Series.str.split** Split strings around given separator/delimiter.

### Notes

If any of the list items is not a string object, the result of the join will be *NaN*.

### Examples

Example with a list that contains non-string elements.

```
>>> s = pd.Series([[ 'lion', 'elephant', 'zebra'],
...                [1.1, 2.2, 3.3],
...                [ 'cat', np.nan, 'dog'],
...                [ 'cow', 4.5, 'goat'],
...                [ 'duck', [ 'swan', 'fish'], 'guppy']])
>>> s
0      [lion, elephant, zebra]
1      [1.1, 2.2, 3.3]
2      [cat, nan, dog]
3      [cow, 4.5, goat]
4      [duck, [swan, fish], guppy]
dtype: object
```

Join all lists using a '-'. The lists containing object(s) of types other than str will produce a NaN.

```
>>> s.str.join('-')
0      lion-elephant-zebra
1                        NaN
2                        NaN
3                        NaN
4                        NaN
dtype: object
```

## pandas.Series.str.len

**Series.str.len()**

Computes the length of each element in the Series/Index. The element may be a sequence (such as a string, tuple or list) or a collection (such as a dictionary).

### Returns

**Series or Index of int** A Series or Index of integer values indicating the length of each element in the Series or Index.

See also:

**str.len** Python built-in function returning the length of an object.

**Series.size** Returns the length of the Series.

## Examples

Returns the length (number of characters) in a string. Returns the number of entries for dictionaries, lists or tuples.

```
>>> s = pd.Series(['dog',
...                '',
...                5,
...                {'foo': 'bar'},
...                [2, 3, 5, 7],
...                ('one', 'two', 'three')])
>>> s
0          dog
1
2          5
3    {'foo': 'bar'}
4      [2, 3, 5, 7]
5    (one, two, three)
dtype: object
>>> s.str.len()
0      3.0
1      0.0
2     NaN
3      1.0
4      4.0
5      3.0
dtype: float64
```

## pandas.Series.str.ljust

`Series.str.ljust (width, fillchar=' ')`

Filling right side of strings in the Series/Index with an additional character. Equivalent to `str.ljust()`.

### Parameters

**width** [int] Minimum width of resulting string; additional characters will be filled with `fillchar`

**fillchar** [str] Additional character for filling, default is whitespace

### Returns

**filled** [Series/Index of objects]

## pandas.Series.str.lower

`Series.str.lower ()`

Convert strings in the Series/Index to lowercase.

Equivalent to `str.lower()`.

### Returns

**Series/Index of objects**

See also:

**`Series.str.lower`** Converts all characters to lowercase.

***Series.str.upper*** Converts all characters to uppercase.

***Series.str.title*** Converts first character of each word to uppercase and remaining to lowercase.

***Series.str.capitalize*** Converts first character to uppercase and remaining to lowercase.

***Series.str.swapcase*** Converts uppercase to lowercase and lowercase to uppercase.

## Examples

```
>>> s = pd.Series(['lower', 'CAPITALS', 'this is a sentence', 'SwApCaSe'])
>>> s
0          lower
1        CAPITALS
2  this is a sentence
3        SwApCaSe
dtype: object
```

```
>>> s.str.lower()
0          lower
1        capitals
2  this is a sentence
3        swapcase
dtype: object
```

```
>>> s.str.upper()
0          LOWER
1        CAPITALS
2  THIS IS A SENTENCE
3        SWAPCASE
dtype: object
```

```
>>> s.str.title()
0          Lower
1        Capitals
2  This Is A Sentence
3        Swapcase
dtype: object
```

```
>>> s.str.capitalize()
0          Lower
1        Capitals
2  This is a sentence
3        Swapcase
dtype: object
```

```
>>> s.str.swapcase()
0          LOWER
1        capitals
2  THIS IS A SENTENCE
3        sWaPcAsE
dtype: object
```

## pandas.Series.str.lstrip

`Series.str.lstrip(to_strip=None)`

Remove leading and trailing characters.

Strip whitespaces (including newlines) or a set of specified characters from each string in the Series/Index from left side. Equivalent to `str.lstrip()`.

### Parameters

**to\_strip** [str or None, default None] Specifying the set of characters to be removed. All combinations of this set of characters will be stripped. If None then whitespaces are removed.

### Returns

Series/Index of objects

See also:

**Series.str.strip** Remove leading and trailing characters in Series/Index.

**Series.str.lstrip** Remove leading characters in Series/Index.

**Series.str.rstrip** Remove trailing characters in Series/Index.

## Examples

```
>>> s = pd.Series(['1. Ant. ', '2. Bee!\n', '3. Cat?\t', np.nan])
>>> s
0    1. Ant.
1    2. Bee!\n
2    3. Cat?\t
3         NaN
dtype: object
```

```
>>> s.str.strip()
0    1. Ant.
1    2. Bee!
2    3. Cat?
3         NaN
dtype: object
```

```
>>> s.str.lstrip('123.')
0    Ant.
1    Bee!\n
2    Cat?\t
3         NaN
dtype: object
```

```
>>> s.str.rstrip('!.? \n\t')
0    1. Ant
1    2. Bee
2    3. Cat
3         NaN
dtype: object
```

```
>>> s.str.strip('123.!? \n\t')
0    Ant
1    Bee
2    Cat
3    NaN
dtype: object
```

## pandas.Series.str.match

`Series.str.match(pat, case=True, flags=0, na=nan)`

Determine if each string matches a regular expression.

### Parameters

**pat** [string] Character sequence or regular expression

**case** [boolean, default True] If True, case sensitive

**flags** [int, default 0 (no flags)] re module flags, e.g. re.IGNORECASE

**na** [default NaN, fill value for missing values]

### Returns

Series/array of boolean values

See also:

**contains** Analogous, but less strict, relying on re.search instead of re.match.

**extract** Extract matched groups.

## pandas.Series.str.normalize

`Series.str.normalize(form)`

Return the Unicode normal form for the strings in the Series/Index. For more information on the forms, see the `unicodedata.normalize()`.

### Parameters

**form** [{ 'NFC', 'NFKC', 'NFD', 'NFKD' }] Unicode form

### Returns

**normalized** [Series/Index of objects]

## pandas.Series.str.pad

`Series.str.pad(width, side='left', fillchar=' ')`

Pad strings in the Series/Index up to width.

### Parameters

**width** [int] Minimum width of resulting string; additional characters will be filled with character defined in *fillchar*.

**side** [{ 'left', 'right', 'both' }, default 'left'] Side from which to fill resulting string.

**fillchar** [str, default ' '] Additional character for filling, default is whitespace.

### Returns

**Series or Index of object** Returns Series or Index with minimum number of char in object.

See also:

**Series.str.rjust** Fills the left side of strings with an arbitrary character. Equivalent to `Series.str.pad(side='left')`.

**Series.str.ljust** Fills the right side of strings with an arbitrary character. Equivalent to `Series.str.pad(side='right')`.

**Series.str.center** Fills boths sides of strings with an arbitrary character. Equivalent to `Series.str.pad(side='both')`.

**Series.str.zfill** Pad strings in the Series/Index by prepending '0' character. Equivalent to `Series.str.pad(side='left', fillchar='0')`.

### Examples

```
>>> s = pd.Series(["caribou", "tiger"])
>>> s
0    caribou
1     tiger
dtype: object
```

```
>>> s.str.pad(width=10)
0    caribou
1     tiger
dtype: object
```

```
>>> s.str.pad(width=10, side='right', fillchar='-')
0    caribou---
1    tiger-----
dtype: object
```

```
>>> s.str.pad(width=10, side='both', fillchar='-')
0    -caribou--
1    --tiger---
dtype: object
```

### pandas.Series.str.partition

`Series.str.partition(sep=' ', expand=True)`

Split the string at the first occurrence of *sep*.

This method splits the string at the first occurrence of *sep*, and returns 3 elements containing the part before the separator, the separator itself, and the part after the separator. If the separator is not found, return 3 elements containing the string itself, followed by two empty strings.

#### Parameters

**sep** [str, default whitespace] String to split on.

**pat** [str, default whitespace] Deprecated since version 0.24.0: Use *sep* instead

**expand** [bool, default True] If True, return DataFrame/MultiIndex expanding dimensionality.  
If False, return Series/Index.

### Returns

**DataFrame/MultiIndex or Series/Index of objects**

See also:

**rpartition** Split the string at the last occurrence of *sep*.

**Series.str.split** Split strings around given separators.

**str.partition** Standard library version.

### Examples

```
>>> s = pd.Series(['Linda van der Berg', 'George Pitt-Rivers'])
>>> s
0    Linda van der Berg
1    George Pitt-Rivers
dtype: object
```

```
>>> s.str.partition()
      0 1      2
0  Linda  van der Berg
1  George  Pitt-Rivers
```

To partition by the last space instead of the first one:

```
>>> s.str.rpartition()
      0 1      2
0  Linda van der      Berg
1      George  Pitt-Rivers
```

To partition by something different than a space:

```
>>> s.str.partition('-')
      0 1      2
0  Linda van der Berg
1      George Pitt  -  Rivers
```

To return a Series containing tuples instead of a DataFrame:

```
>>> s.str.partition('-', expand=False)
0    (Linda van der Berg, , )
1    (George Pitt, -, Rivers)
dtype: object
```

Also available on indices:

```
>>> idx = pd.Index(['X 123', 'Y 999'])
>>> idx
Index(['X 123', 'Y 999'], dtype='object')
```

Which will create a MultiIndex:

```
>>> idx.str.partition()
MultiIndex(levels=[['X', 'Y'], [' ', ''], ['123', '999']],
            labels=[[0, 1], [0, 0], [0, 1]])
```

Or an index with tuples with `expand=False`:

```
>>> idx.str.partition(expand=False)
Index(['X', ' ', '123'), ('Y', ' ', '999')], dtype='object')
```

## pandas.Series.str.repeat

`Series.str.repeat` (*repeats*)

Duplicate each string in the Series or Index.

### Parameters

**repeats** [int or sequence of int] Same value for all (int) or different value per (sequence).

### Returns

**Series or Index of object** Series or Index of repeated string objects specified by input parameter repeats.

## Examples

```
>>> s = pd.Series(['a', 'b', 'c'])
>>> s
0    a
1    b
2    c
```

Single int repeats string in Series

```
>>> s.str.repeat(repeats=2)
0    aa
1    bb
2    cc
```

Sequence of int repeats corresponding string in Series

```
>>> s.str.repeat(repeats=[1, 2, 3])
0    a
1    bb
2    ccc
```

## pandas.Series.str.replace

`Series.str.replace` (*pat, repl, n=-1, case=None, flags=0, regex=True*)

Replace occurrences of pattern/regex in the Series/Index with some other string. Equivalent to `str.replace()` or `re.sub()`.

### Parameters

**pat** [string or compiled regex] String can be a character sequence or regular expression.

New in version 0.20.0: *pat* also accepts a compiled regex.

**repl** [string or callable] Replacement string or a callable. The callable is passed the regex match object and must return a replacement string to be used. See `re.sub()`.

New in version 0.20.0: *repl* also accepts a callable.

**n** [int, default -1 (all)] Number of replacements to make from start

**case** [boolean, default None]

- If True, case sensitive (the default if *pat* is a string)
- Set to False for case insensitive
- Cannot be set if *pat* is a compiled regex

**flags** [int, default 0 (no flags)]

- re module flags, e.g. `re.IGNORECASE`
- Cannot be set if *pat* is a compiled regex

**regex** [boolean, default True]

- If True, assumes the passed-in pattern is a regular expression.
- If False, treats the pattern as a literal string
- Cannot be set to False if *pat* is a compiled regex or *repl* is a callable.

New in version 0.23.0.

## Returns

**Series or Index of object** A copy of the object with all matching occurrences of *pat* replaced by *repl*.

## Raises

### ValueError

- if *regex* is False and *repl* is a callable or *pat* is a compiled regex
- if *pat* is a compiled regex and *case* or *flags* is set

## Notes

When *pat* is a compiled regex, all flags should be included in the compiled regex. Use of *case*, *flags*, or *regex=False* with a compiled regex will raise an error.

## Examples

When *pat* is a string and *regex* is True (the default), the given *pat* is compiled as a regex. When *repl* is a string, it replaces matching regex patterns as with `re.sub()`. NaN value(s) in the Series are left as is:

```
>>> pd.Series(['foo', 'fuz', np.nan]).str.replace('f.', 'ba', regex=True)
0    bao
1    baz
2    NaN
dtype: object
```

When *pat* is a string and *regex* is False, every *pat* is replaced with *repl* as with `str.replace()`:

```
>>> pd.Series(['f.o', 'fuz', np.nan]).str.replace('f.', 'ba', regex=False)
0    bao
1    fuz
2    NaN
dtype: object
```

When *repl* is a callable, it is called on every *pat* using `re.sub()`. The callable should expect one positional argument (a regex object) and return a string.

To get the idea:

```
>>> pd.Series(['foo', 'fuz', np.nan]).str.replace('f', repr)
0    <_sre.SRE_Match object; span=(0, 1), match='f'>oo
1    <_sre.SRE_Match object; span=(0, 1), match='f'>uz
2    NaN
dtype: object
```

Reverse every lowercase alphabetic word:

```
>>> repl = lambda m: m.group(0)[::-1]
>>> pd.Series(['foo 123', 'bar baz', np.nan]).str.replace(r'[a-z]+', repl)
0    oof 123
1    rab zab
2    NaN
dtype: object
```

Using regex groups (extract second group and swap case):

```
>>> pat = r"(?P<one>\w+) (?P<two>\w+) (?P<three>\w+)"
>>> repl = lambda m: m.group('two').swapcase()
>>> pd.Series(['One Two Three', 'Foo Bar Baz']).str.replace(pat, repl)
0    tWO
1    bAR
dtype: object
```

Using a compiled regex with flags

```
>>> regex_pat = re.compile(r'FUZ', flags=re.IGNORECASE)
>>> pd.Series(['foo', 'fuz', np.nan]).str.replace(regex_pat, 'bar')
0    foo
1    bar
2    NaN
dtype: object
```

## pandas.Series.str.rfind

`Series.str.rfind(sub, start=0, end=None)`

Return highest indexes in each strings in the Series/Index where the substring is fully contained between [start:end]. Return -1 on failure. Equivalent to standard `str.rfind()`.

### Parameters

**sub** [str] Substring being searched

**start** [int] Left edge index

**end** [int] Right edge index

**Returns**

**found** [Series/Index of integer values]

**See also:**

**find** Return lowest indexes in each strings.

## pandas.Series.str.rindex

`Series.str.rindex(sub, start=0, end=None)`

Return highest indexes in each strings where the substring is fully contained between [start:end]. This is the same as `str.rfind` except instead of returning -1, it raises a `ValueError` when the substring is not found. Equivalent to standard `str.rindex`.

**Parameters**

**sub** [str] Substring being searched

**start** [int] Left edge index

**end** [int] Right edge index

**Returns**

**found** [Series/Index of objects]

**See also:**

**index** Return lowest indexes in each strings.

## pandas.Series.str.rjust

`Series.str.rjust(width, fillchar='')`

Filling left side of strings in the Series/Index with an additional character. Equivalent to `str.rjust()`.

**Parameters**

**width** [int] Minimum width of resulting string; additional characters will be filled with `fillchar`

**fillchar** [str] Additional character for filling, default is whitespace

**Returns**

**filled** [Series/Index of objects]

## pandas.Series.str.rpartition

`Series.str.rpartition(sep='', expand=True)`

Split the string at the last occurrence of `sep`.

This method splits the string at the last occurrence of `sep`, and returns 3 elements containing the part before the separator, the separator itself, and the part after the separator. If the separator is not found, return 3 elements containing two empty strings, followed by the string itself.

**Parameters**

**sep** [str, default whitespace] String to split on.

**pat** [str, default whitespace] Deprecated since version 0.24.0: Use `sep` instead

**expand** [bool, default True] If True, return DataFrame/MultiIndex expanding dimensionality.  
If False, return Series/Index.

### Returns

**DataFrame/MultiIndex or Series/Index of objects**

See also:

**partition** Split the string at the first occurrence of *sep*.

**Series.str.split** Split strings around given separators.

**str.partition** Standard library version.

### Examples

```
>>> s = pd.Series(['Linda van der Berg', 'George Pitt-Rivers'])
>>> s
0    Linda van der Berg
1    George Pitt-Rivers
dtype: object
```

```
>>> s.str.partition()
      0  1      2
0  Linda  van der Berg
1  George  Pitt-Rivers
```

To partition by the last space instead of the first one:

```
>>> s.str.rpartition()
      0  1      2
0  Linda van der      Berg
1      George  Pitt-Rivers
```

To partition by something different than a space:

```
>>> s.str.partition('-')
      0  1      2
0  Linda van der Berg
1      George Pitt  -  Rivers
```

To return a Series containing tuples instead of a DataFrame:

```
>>> s.str.partition('-', expand=False)
0    (Linda van der Berg, , )
1    (George Pitt, -, Rivers)
dtype: object
```

Also available on indices:

```
>>> idx = pd.Index(['X 123', 'Y 999'])
>>> idx
Index(['X 123', 'Y 999'], dtype='object')
```

Which will create a MultiIndex:

```
>>> idx.str.partition()
MultiIndex(levels=[['X', 'Y'], [' '], ['123', '999']],
            labels=[[0, 1], [0, 0], [0, 1]])
```

Or an index with tuples with `expand=False`:

```
>>> idx.str.partition(expand=False)
Index([('X', ' ', '123'), ('Y', ' ', '999')], dtype='object')
```

## pandas.Series.str.rstrip

`Series.str.rstrip` (*to\_strip=None*)

Remove leading and trailing characters.

Strip whitespaces (including newlines) or a set of specified characters from each string in the Series/Index from right side. Equivalent to `str.rstrip()`.

### Parameters

**to\_strip** [str or None, default None] Specifying the set of characters to be removed. All combinations of this set of characters will be stripped. If None then whitespaces are removed.

### Returns

Series/Index of objects

See also:

**Series.str.strip** Remove leading and trailing characters in Series/Index.

**Series.str.lstrip** Remove leading characters in Series/Index.

**Series.str.rstrip** Remove trailing characters in Series/Index.

## Examples

```
>>> s = pd.Series(['1. Ant. ', '2. Bee!\n', '3. Cat?\t', np.nan])
>>> s
0    1. Ant.
1    2. Bee!\n
2    3. Cat?\t
3         NaN
dtype: object
```

```
>>> s.str.strip()
0    1. Ant.
1    2. Bee!
2    3. Cat?
3         NaN
dtype: object
```

```
>>> s.str.lstrip('123.')
0    Ant.
1    Bee!\n
2    Cat?\t
3      NaN
dtype: object
```

```
>>> s.str.rstrip('.!? \n\t')
0    1. Ant
1    2. Bee
2    3. Cat
3      NaN
dtype: object
```

```
>>> s.str.strip('123.!? \n\t')
0    Ant
1    Bee
2    Cat
3    NaN
dtype: object
```

## pandas.Series.str.slice

**Series.str.slice** (*start=None, stop=None, step=None*)

Slice substrings from each element in the Series or Index.

### Parameters

**start** [int, optional] Start position for slice operation.

**stop** [int, optional] Stop position for slice operation.

**step** [int, optional] Step size for slice operation.

### Returns

**Series or Index of object** Series or Index from sliced substring from original string object.

**See also:**

**Series.str.slice\_replace** Replace a slice with a string.

**Series.str.get** Return element at position. Equivalent to *Series.str.slice(start=i, stop=i+1)* with *i* being the position.

## Examples

```
>>> s = pd.Series(["koala", "fox", "chameleon"])
>>> s
0    koala
1     fox
2  chameleon
dtype: object
```

```
>>> s.str.slice(start=1)
0      oala
1       ox
2  hameleon
dtype: object
```

```
>>> s.str.slice(stop=2)
0    ko
1   fo
2   ch
dtype: object
```

```
>>> s.str.slice(step=2)
0    kaa
1    fx
2  caeen
dtype: object
```

```
>>> s.str.slice(start=0, stop=5, step=3)
0    kl
1    f
2    cm
dtype: object
```

Equivalent behaviour to:

```
>>> s.str[0:5:3]
0    kl
1    f
2    cm
dtype: object
```

## pandas.Series.str.slice\_replace

`Series.str.slice_replace` (*start=None, stop=None, repl=None*)

Replace a positional slice of a string with another value.

### Parameters

**start** [int, optional] Left index position to use for the slice. If not specified (None), the slice is unbounded on the left, i.e. slice from the start of the string.

**stop** [int, optional] Right index position to use for the slice. If not specified (None), the slice is unbounded on the right, i.e. slice until the end of the string.

**repl** [str, optional] String for replacement. If not specified (None), the sliced region is replaced with an empty string.

### Returns

**replaced** [Series or Index] Same type as the original object.

See also:

**Series.str.slice** Just slicing without replacement.

## Examples

```
>>> s = pd.Series(['a', 'ab', 'abc', 'abdc', 'abcde'])
>>> s
0      a
1     ab
2    abc
3   abdc
4  abcde
dtype: object
```

Specify just *start*, meaning replace *start* until the end of the string with *repl*.

```
>>> s.str.slice_replace(1, repl='X')
0    aX
1    aX
2    aX
3    aX
4    aX
dtype: object
```

Specify just *stop*, meaning the start of the string to *stop* is replaced with *repl*, and the rest of the string is included.

```
>>> s.str.slice_replace(stop=2, repl='X')
0      X
1      X
2     Xc
3    Xdc
4   Xcde
dtype: object
```

Specify *start* and *stop*, meaning the slice from *start* to *stop* is replaced with *repl*. Everything before or after *start* and *stop* is included as is.

```
>>> s.str.slice_replace(start=1, stop=3, repl='X')
0    aX
1    aX
2    aX
3   aXc
4  aXde
dtype: object
```

## pandas.Series.str.split

`Series.str.split` (*pat=None, n=-1, expand=False*)

Split strings around given separator/delimiter.

Splits the string in the Series/Index from the beginning, at the specified delimiter string. Equivalent to `str.split()`.

### Parameters

**pat** [str, optional] String or regular expression to split on. If not specified, split on whitespace.

**n** [int, default -1 (all)] Limit number of splits in output. None, 0 and -1 will be interpreted as return all splits.

**expand** [bool, default False] Expand the splitted strings into separate columns.

- If `True`, return `DataFrame`/`MultiIndex` expanding dimensionality.
- If `False`, return `Series`/`Index`, containing lists of strings.

### Returns

**Series, Index, DataFrame or MultiIndex** Type matches caller unless `expand=True` (see Notes).

See also:

**`Series.str.split`** Split strings around given separator/delimiter.

**`Series.str.rsplit`** Splits string around given separator/delimiter, starting from the right.

**`Series.str.join`** Join lists contained as elements in the `Series`/`Index` with passed delimiter.

**`str.split`** Standard library version for split.

**`str.rsplit`** Standard library version for rsplit.

### Notes

The handling of the `n` keyword depends on the number of found splits:

- If found splits  $> n$ , make first  $n$  splits only
- If found splits  $\leq n$ , make all splits
- If for a certain row the number of found splits  $< n$ , append `None` for padding up to  $n$  if `expand=True`

If using `expand=True`, `Series` and `Index` callers return `DataFrame` and `MultiIndex` objects, respectively.

### Examples

```
>>> s = pd.Series(["this is a regular sentence",  
"https://docs.python.org/3/tutorial/index.html", np.nan])
```

In the default setting, the string is split by whitespace.

```
>>> s.str.split()  
0          [this, is, a, regular, sentence]  
1  [https://docs.python.org/3/tutorial/index.html]  
2                                     NaN  
dtype: object
```

Without the `n` parameter, the outputs of `rsplit` and `split` are identical.

```
>>> s.str.rsplit()  
0          [this, is, a, regular, sentence]  
1  [https://docs.python.org/3/tutorial/index.html]  
2                                     NaN  
dtype: object
```

The `n` parameter can be used to limit the number of splits on the delimiter. The outputs of `split` and `rsplit` are different.

```
>>> s.str.split(n=2)
0          [this, is, a regular sentence]
1  [https://docs.python.org/3/tutorial/index.html]
2                                     NaN
dtype: object
```

```
>>> s.str.rsplit(n=2)
0          [this is a, regular, sentence]
1  [https://docs.python.org/3/tutorial/index.html]
2                                     NaN
dtype: object
```

The *pat* parameter can be used to split by other characters.

```
>>> s.str.split(pat = "/")
0          [this is a regular sentence]
1  [https:, , docs.python.org, 3, tutorial, index...]
2                                     NaN
dtype: object
```

When using `expand=True`, the split elements will expand out into separate columns. If NaN is present, it is propagated throughout the columns during the split.

```
>>> s.str.split(expand=True)
           0      1      2      3
0          this   is    a  regular
1  https://docs.python.org/3/tutorial/index.html  None  None    None
2                                     NaN   NaN   NaN   NaN

           4
0      sentence
1          None
2          NaN
```

For slightly more complex use cases like splitting the html document name from a url, a combination of parameter settings can be used.

```
>>> s.str.rsplit("/", n=1, expand=True)
           0      1
0          this is a regular sentence  None
1  https://docs.python.org/3/tutorial  index.html
2                                     NaN   NaN
```

## pandas.Series.str.rsplit

`Series.str.rsplit(pat=None, n=-1, expand=False)`

Split strings around given separator/delimiter.

Splits the string in the Series/Index from the end, at the specified delimiter string. Equivalent to `str.rsplit()`.

### Parameters

**pat** [str, optional] String or regular expression to split on. If not specified, split on whitespace.

**n** [int, default -1 (all)] Limit number of splits in output. None, 0 and -1 will be interpreted as return all splits.

**expand** [bool, default False] Expand the splitted strings into separate columns.

- If `True`, return `DataFrame`/`MultiIndex` expanding dimensionality.
- If `False`, return `Series`/`Index`, containing lists of strings.

### Returns

**Series, Index, DataFrame or MultiIndex** Type matches caller unless `expand=True` (see Notes).

See also:

**`Series.str.split`** Split strings around given separator/delimiter.

**`Series.str.rspl`** Splits string around given separator/delimiter, starting from the right.

**`Series.str.join`** Join lists contained as elements in the `Series`/`Index` with passed delimiter.

**`str.split`** Standard library version for split.

**`str.rspl`** Standard library version for `rspl`.

### Notes

The handling of the *n* keyword depends on the number of found splits:

- If found splits > *n*, make first *n* splits only
- If found splits <= *n*, make all splits
- If for a certain row the number of found splits < *n*, append *None* for padding up to *n* if `expand=True`

If using `expand=True`, `Series` and `Index` callers return `DataFrame` and `MultiIndex` objects, respectively.

### Examples

```
>>> s = pd.Series(["this is a regular sentence",
                  "https://docs.python.org/3/tutorial/index.html", np.nan])
```

In the default setting, the string is split by whitespace.

```
>>> s.str.split()
0          [this, is, a, regular, sentence]
1    [https://docs.python.org/3/tutorial/index.html]
2                                           NaN
dtype: object
```

Without the *n* parameter, the outputs of *rsplit* and *split* are identical.

```
>>> s.str.rspl()
0          [this, is, a, regular, sentence]
1    [https://docs.python.org/3/tutorial/index.html]
2                                           NaN
dtype: object
```

The *n* parameter can be used to limit the number of splits on the delimiter. The outputs of *split* and *rsplit* are different.

```
>>> s.str.split(n=2)
0          [this, is, a regular sentence]
1  [https://docs.python.org/3/tutorial/index.html]
2                                           NaN
dtype: object
```

```
>>> s.str.rsplit(n=2)
0          [this is a, regular, sentence]
1  [https://docs.python.org/3/tutorial/index.html]
2                                           NaN
dtype: object
```

The *pat* parameter can be used to split by other characters.

```
>>> s.str.split(pat = "/")
0          [this is a regular sentence]
1  [https:, , docs.python.org, 3, tutorial, index...]
2                                           NaN
dtype: object
```

When using `expand=True`, the split elements will expand out into separate columns. If NaN is present, it is propagated throughout the columns during the split.

```
>>> s.str.split(expand=True)
           0      1      2      3
0          this   is    a  regular
1  https://docs.python.org/3/tutorial/index.html  None  None    None
2          NaN   NaN   NaN    NaN

           4
0      sentence
1          None
2          NaN
```

For slightly more complex use cases like splitting the html document name from a url, a combination of parameter settings can be used.

```
>>> s.str.rsplit("/", n=1, expand=True)
           0      1
0          this is a regular sentence  None
1  https://docs.python.org/3/tutorial  index.html
2          NaN          NaN
```

## pandas.Series.str.startswith

`Series.str.startswith(pat, na=nan)`

Test if the start of each string element matches a pattern.

Equivalent to `str.startswith()`.

### Parameters

**pat** [str] Character sequence. Regular expressions are not accepted.

**na** [object, default NaN] Object shown if element tested is not a string.

### Returns

**Series or Index of bool** A Series of booleans indicating whether the given pattern matches the start of each string element.

See also:

**str.startswith** Python standard library string method.

**Series.str.endswith** Same as startswith, but tests the end of string.

**Series.str.contains** Tests if string element contains a pattern.

## Examples

```
>>> s = pd.Series(['bat', 'Bear', 'cat', np.nan])
>>> s
0    bat
1   Bear
2    cat
3   NaN
dtype: object
```

```
>>> s.str.startswith('b')
0    True
1   False
2   False
3    NaN
dtype: object
```

Specifying *na* to be *False* instead of *NaN*.

```
>>> s.str.startswith('b', na=False)
0    True
1   False
2   False
3   False
dtype: bool
```

## pandas.Series.str.strip

**Series.str.strip** (*to\_strip=None*)

Remove leading and trailing characters.

Strip whitespaces (including newlines) or a set of specified characters from each string in the Series/Index from left and right sides. Equivalent to `str.strip()`.

### Parameters

**to\_strip** [str or None, default None] Specifying the set of characters to be removed. All combinations of this set of characters will be stripped. If None then whitespaces are removed.

### Returns

**Series/Index of objects**

See also:

**Series.str.strip** Remove leading and trailing characters in Series/Index.

**`Series.str.lstrip`** Remove leading characters in Series/Index.

**`Series.str.rstrip`** Remove trailing characters in Series/Index.

### Examples

```
>>> s = pd.Series(['1. Ant. ', '2. Bee!\n', '3. Cat?\t', np.nan])
>>> s
0    1. Ant.
1    2. Bee!\n
2    3. Cat?\t
3         NaN
dtype: object
```

```
>>> s.str.strip()
0    1. Ant.
1    2. Bee!
2    3. Cat?
3         NaN
dtype: object
```

```
>>> s.str.lstrip('123.')
0    Ant.
1    Bee!\n
2    Cat?\t
3         NaN
dtype: object
```

```
>>> s.str.rstrip('!?\n\t')
0    1. Ant
1    2. Bee
2    3. Cat
3         NaN
dtype: object
```

```
>>> s.str.strip('123.!?\n\t')
0    Ant
1    Bee
2    Cat
3    NaN
dtype: object
```

### pandas.Series.str.swapcase

`Series.str.swapcase()`

Convert strings in the Series/Index to be swapcased.

Equivalent to `str.swapcase()`.

#### Returns

Series/Index of objects

See also:

**`Series.str.lower`** Converts all characters to lowercase.

***Series.str.upper*** Converts all characters to uppercase.

***Series.str.title*** Converts first character of each word to uppercase and remaining to lowercase.

***Series.str.capitalize*** Converts first character to uppercase and remaining to lowercase.

***Series.str.swapcase*** Converts uppercase to lowercase and lowercase to uppercase.

## Examples

```
>>> s = pd.Series(['lower', 'CAPITALS', 'this is a sentence', 'SwApCaSe'])
>>> s
0          lower
1        CAPITALS
2  this is a sentence
3        SwApCaSe
dtype: object
```

```
>>> s.str.lower()
0          lower
1        capitals
2  this is a sentence
3        swapcase
dtype: object
```

```
>>> s.str.upper()
0          LOWER
1        CAPITALS
2  THIS IS A SENTENCE
3        SWAPCASE
dtype: object
```

```
>>> s.str.title()
0          Lower
1        Capitals
2  This Is A Sentence
3        Swapcase
dtype: object
```

```
>>> s.str.capitalize()
0          Lower
1        Capitals
2  This is a sentence
3        Swapcase
dtype: object
```

```
>>> s.str.swapcase()
0          LOWER
1        capitals
2  THIS IS A SENTENCE
3        sWaPcAsE
dtype: object
```

**pandas.Series.str.title**`Series.str.title()`

Convert strings in the Series/Index to titlecase.

Equivalent to `str.title()`.**Returns****Series/Index of objects****See also:*****Series.str.lower*** Converts all characters to lowercase.***Series.str.upper*** Converts all characters to uppercase.***Series.str.title*** Converts first character of each word to uppercase and remaining to lowercase.***Series.str.capitalize*** Converts first character to uppercase and remaining to lowercase.***Series.str.swapcase*** Converts uppercase to lowercase and lowercase to uppercase.**Examples**

```
>>> s = pd.Series(['lower', 'CAPITALS', 'this is a sentence', 'SwApCaSe'])
>>> s
0          lower
1        CAPITALS
2    this is a sentence
3        SwApCaSe
dtype: object
```

```
>>> s.str.lower()
0          lower
1        capitals
2    this is a sentence
3        swapcase
dtype: object
```

```
>>> s.str.upper()
0          LOWER
1        CAPITALS
2    THIS IS A SENTENCE
3        SWAPCASE
dtype: object
```

```
>>> s.str.title()
0          Lower
1        Capitals
2    This Is A Sentence
3        Swapcase
dtype: object
```

```
>>> s.str.capitalize()
0          Lower
1        Capitals
```

(continues on next page)

(continued from previous page)

```
2    This is a sentence
3                Swapcase
dtype: object
```

```
>>> s.str.swapcase()
0                LOWER
1            capitals
2    THIS IS A SENTENCE
3            sWaPcAsE
dtype: object
```

## pandas.Series.str.translate

`Series.str.translate` (*table*, *deletechars=None*)

Map all characters in the string through the given mapping table. Equivalent to standard `str.translate()`. Note that the optional argument `deletechars` is only valid if you are using python 2. For python 3, character deletion should be specified via the `table` argument.

### Parameters

**table** [dict (python 3), str or None (python 2)] In python 3, `table` is a mapping of Unicode ordinals to Unicode ordinals, strings, or None. Unmapped characters are left untouched. Characters mapped to None are deleted. `str.maketrans()` is a helper function for making translation tables. In python 2, `table` is either a string of length 256 or None. If the `table` argument is None, no translation is applied and the operation simply removes the characters in `deletechars`. `string.maketrans()` is a helper function for making translation tables.

**deletechars** [str, optional (python 2)] A string of characters to delete. This argument is only valid in python 2.

### Returns

**translated** [Series/Index of objects]

## pandas.Series.str.upper

`Series.str.upper` ()

Convert strings in the Series/Index to uppercase.

Equivalent to `str.upper()`.

### Returns

**Series/Index of objects**

See also:

**Series.str.lower** Converts all characters to lowercase.

**Series.str.upper** Converts all characters to uppercase.

**Series.str.title** Converts first character of each word to uppercase and remaining to lowercase.

**Series.str.capitalize** Converts first character to uppercase and remaining to lowercase.

**Series.str.swapcase** Converts uppercase to lowercase and lowercase to uppercase.

## Examples

```
>>> s = pd.Series(['lower', 'CAPITALS', 'this is a sentence', 'SwApCaSe'])
>>> s
0          lower
1        CAPITALS
2    this is a sentence
3        SwApCaSe
dtype: object
```

```
>>> s.str.lower()
0          lower
1        capitals
2    this is a sentence
3        swapcase
dtype: object
```

```
>>> s.str.upper()
0          LOWER
1        CAPITALS
2    THIS IS A SENTENCE
3        SWAPCASE
dtype: object
```

```
>>> s.str.title()
0          Lower
1        Capitals
2    This Is A Sentence
3        Swapcase
dtype: object
```

```
>>> s.str.capitalize()
0          Lower
1        Capitals
2    This is a sentence
3        Swapcase
dtype: object
```

```
>>> s.str.swapcase()
0          LOWER
1        capitals
2    THIS IS A SENTENCE
3        sWaPcAsE
dtype: object
```

## pandas.Series.str.wrap

`Series.str.wrap(width, **kwargs)`

Wrap long strings in the Series/Index to be formatted in paragraphs with length less than a given width.

This method has the same keyword parameters and defaults as `textwrap.TextWrapper`.

### Parameters

**width** [int] Maximum line-width

**expand\_tabs** [bool, optional] If true, tab characters will be expanded to spaces (default: True)

**replace\_whitespace** [bool, optional] If true, each whitespace character (as defined by `string.whitespace`) remaining after tab expansion will be replaced by a single space (default: True)

**drop\_whitespace** [bool, optional] If true, whitespace that, after wrapping, happens to end up at the beginning or end of a line is dropped (default: True)

**break\_long\_words** [bool, optional] If true, then words longer than width will be broken in order to ensure that no lines are longer than width. If it is false, long words will not be broken, and some lines may be longer than width. (default: True)

**break\_on\_hyphens** [bool, optional] If true, wrapping will occur preferably on whitespace and right after hyphens in compound words, as it is customary in English. If false, only whitespaces will be considered as potentially good places for line breaks, but you need to set `break_long_words` to false if you want truly insecable words. (default: True)

### Returns

**wrapped** [Series/Index of objects]

### Notes

Internally, this method uses a `textwrap.TextWrapper` instance with default settings. To achieve behavior matching R's `stringr` library `str_wrap` function, use the arguments:

- `expand_tabs = False`
- `replace_whitespace = True`
- `drop_whitespace = True`
- `break_long_words = False`
- `break_on_hyphens = False`

### Examples

```
>>> s = pd.Series(['line to be wrapped', 'another line to be wrapped'])
>>> s.str.wrap(12)
0          line to be\nwrapped
1  another line\nto be\nwrapped
```

## pandas.Series.str.zfill

`Series.str.zfill` (*width*)

Pad strings in the Series/Index by prepending '0' characters.

Strings in the Series/Index are padded with '0' characters on the left of the string to reach a total string length *width*. Strings in the Series/Index with length greater or equal to *width* are unchanged.

### Parameters

**width** [int] Minimum length of resulting string; strings with length less than *width* be prepended with '0' characters.

### Returns

**Series/Index of objects**

See also:

***Series.str.rjust*** Fills the left side of strings with an arbitrary character.

***Series.str.ljust*** Fills the right side of strings with an arbitrary character.

***Series.str.pad*** Fills the specified sides of strings with an arbitrary character.

***Series.str.center*** Fills both sides of strings with an arbitrary character.

**Notes**

Differs from `str.zfill()` which has special handling for '+'/'-' in the string.

**Examples**

```
>>> s = pd.Series(['-1', '1', '1000', 10, np.nan])
>>> s
0      -1
1       1
2    1000
3      10
4     NaN
dtype: object
```

Note that 10 and NaN are not strings, therefore they are converted to NaN. The minus sign in '-1' is treated as a regular character and the zero is added to the left of it (`str.zfill()` would have moved it to the left). 1000 remains unchanged as it is longer than *width*.

```
>>> s.str.zfill(3)
0    0-1
1    001
2   1000
3    NaN
4    NaN
dtype: object
```

**pandas.Series.str.isalnum**

**Series.str.isalnum()**

Check whether all characters in each string are alphanumeric.

This is equivalent to running the Python string method `str.isalnum()` for each element of the Series/Index. If a string has zero characters, `False` is returned for that check.

**Returns**

**Series or Index of bool** Series or Index of boolean values with the same length as the original Series/Index.

See also:

***Series.str.isalpha*** Check whether all characters are alphabetic.

***Series.str.isnumeric*** Check whether all characters are numeric.

**`Series.str.isalnum`** Check whether all characters are alphanumeric.

**`Series.str.isdigit`** Check whether all characters are digits.

**`Series.str.isdecimal`** Check whether all characters are decimal.

**`Series.str.isspace`** Check whether all characters are whitespace.

**`Series.str.islower`** Check whether all characters are lowercase.

**`Series.str.isupper`** Check whether all characters are uppercase.

**`Series.str.istitle`** Check whether all characters are titlecase.

## Examples

### Checks for Alphabetic and Numeric Characters

```
>>> s1 = pd.Series(['one', 'one1', '1', ''])
```

```
>>> s1.str.isalpha()
0      True
1     False
2     False
3     False
dtype: bool
```

```
>>> s1.str.isnumeric()
0     False
1     False
2      True
3     False
dtype: bool
```

```
>>> s1.str.isalnum()
0      True
1      True
2      True
3     False
dtype: bool
```

Note that checks against characters mixed with any additional punctuation or whitespace will evaluate to false for an alphanumeric check.

```
>>> s2 = pd.Series(['A B', '1.5', '3,000'])
>>> s2.str.isalnum()
0     False
1     False
2     False
dtype: bool
```

### More Detailed Checks for Numeric Characters

There are several different but overlapping sets of numeric characters that can be checked for.

```
>>> s3 = pd.Series(['23', '3', '', ''])
```

The `s3.str.isdecimal` method checks for characters used to form numbers in base 10.

```
>>> s3.str.isdecimal()
0      True
1     False
2     False
3     False
dtype: bool
```

The `s.str.isdigit` method is the same as `s3.str.isdecimal` but also includes special digits, like superscripted and subscripted digits in unicode.

```
>>> s3.str.isdigit()
0      True
1      True
2     False
3     False
dtype: bool
```

The `s.str.isnumeric` method is the same as `s3.str.isdigit` but also includes other characters that can represent quantities such as unicode fractions.

```
>>> s3.str.isnumeric()
0      True
1      True
2      True
3     False
dtype: bool
```

### Checks for Whitespace

```
>>> s4 = pd.Series([' ', '\t\r\n ', ''])
>>> s4.str.isspace()
0      True
1      True
2     False
dtype: bool
```

### Checks for Character Case

```
>>> s5 = pd.Series(['leopard', 'Golden Eagle', 'SNAKE', ''])
```

```
>>> s5.str.islower()
0      True
1     False
2     False
3     False
dtype: bool
```

```
>>> s5.str.isupper()
0     False
1     False
2      True
3     False
dtype: bool
```

The `s5.str.istitle` method checks for whether all words are in title case (whether only the first letter of each word is capitalized). Words are assumed to be as any sequence of non-numeric characters separated by whitespace characters.

```
>>> s5.str.istitle()
0    False
1     True
2    False
3    False
dtype: bool
```

## pandas.Series.str.isalpha

`Series.str.isalpha()`

Check whether all characters in each string are alphabetic.

This is equivalent to running the Python string method `str.isalpha()` for each element of the Series/Index. If a string has zero characters, `False` is returned for that check.

### Returns

**Series or Index of bool** Series or Index of boolean values with the same length as the original Series/Index.

See also:

***Series.str.isalpha*** Check whether all characters are alphabetic.

***Series.str.isnumeric*** Check whether all characters are numeric.

***Series.str.isalnum*** Check whether all characters are alphanumeric.

***Series.str.isdigit*** Check whether all characters are digits.

***Series.str.isdecimal*** Check whether all characters are decimal.

***Series.str.isspace*** Check whether all characters are whitespace.

***Series.str.islower*** Check whether all characters are lowercase.

***Series.str.isupper*** Check whether all characters are uppercase.

***Series.str.istitle*** Check whether all characters are titlecase.

## Examples

### Checks for Alphabetic and Numeric Characters

```
>>> s1 = pd.Series(['one', 'one1', '1', ''])
```

```
>>> s1.str.isalpha()
0     True
1    False
2    False
3    False
dtype: bool
```

```
>>> s1.str.isnumeric()
0    False
1    False
2     True
```

(continues on next page)

(continued from previous page)

```
3    False
dtype: bool
```

```
>>> s1.str.isalnum()
0     True
1     True
2     True
3    False
dtype: bool
```

Note that checks against characters mixed with any additional punctuation or whitespace will evaluate to false for an alphanumeric check.

```
>>> s2 = pd.Series(['A B', '1.5', '3,000'])
>>> s2.str.isalnum()
0    False
1    False
2    False
dtype: bool
```

### More Detailed Checks for Numeric Characters

There are several different but overlapping sets of numeric characters that can be checked for.

```
>>> s3 = pd.Series(['23', '³', ' ', ''])
```

The `s3.str.isdecimal` method checks for characters used to form numbers in base 10.

```
>>> s3.str.isdecimal()
0     True
1    False
2    False
3    False
dtype: bool
```

The `s.str.isdigit` method is the same as `s3.str.isdecimal` but also includes special digits, like superscripted and subscripted digits in unicode.

```
>>> s3.str.isdigit()
0     True
1     True
2    False
3    False
dtype: bool
```

The `s.str.isnumeric` method is the same as `s3.str.isdigit` but also includes other characters that can represent quantities such as unicode fractions.

```
>>> s3.str.isnumeric()
0     True
1     True
2     True
3    False
dtype: bool
```

### Checks for Whitespace

```
>>> s4 = pd.Series([' ', '\t\r\n ', ''])
>>> s4.str.isspace()
0      True
1      True
2     False
dtype: bool
```

### Checks for Character Case

```
>>> s5 = pd.Series(['leopard', 'Golden Eagle', 'SNAKE', ''])
```

```
>>> s5.str.islower()
0      True
1     False
2     False
3     False
dtype: bool
```

```
>>> s5.str.isupper()
0     False
1     False
2      True
3     False
dtype: bool
```

The `s5.str.istitle` method checks for whether all words are in title case (whether only the first letter of each word is capitalized). Words are assumed to be as any sequence of non-numeric characters separated by whitespace characters.

```
>>> s5.str.istitle()
0     False
1      True
2     False
3     False
dtype: bool
```

## pandas.Series.str.isdigit

`Series.str.isdigit()`

Check whether all characters in each string are digits.

This is equivalent to running the Python string method `str.isdigit()` for each element of the Series/Index. If a string has zero characters, `False` is returned for that check.

### Returns

**Series or Index of bool** Series or Index of boolean values with the same length as the original Series/Index.

See also:

***Series.str.isalpha*** Check whether all characters are alphabetic.

***Series.str.isnumeric*** Check whether all characters are numeric.

***Series.str.isalnum*** Check whether all characters are alphanumeric.

**`Series.str.isdigit`** Check whether all characters are digits.

**`Series.str.isdecimal`** Check whether all characters are decimal.

**`Series.str.isspace`** Check whether all characters are whitespace.

**`Series.str.islower`** Check whether all characters are lowercase.

**`Series.str.isupper`** Check whether all characters are uppercase.

**`Series.str.istitle`** Check whether all characters are titlecase.

## Examples

### Checks for Alphabetic and Numeric Characters

```
>>> s1 = pd.Series(['one', 'one1', '1', ''])
```

```
>>> s1.str.isalpha()
0      True
1     False
2     False
3     False
dtype: bool
```

```
>>> s1.str.isnumeric()
0     False
1     False
2       True
3     False
dtype: bool
```

```
>>> s1.str.isalnum()
0      True
1      True
2      True
3     False
dtype: bool
```

Note that checks against characters mixed with any additional punctuation or whitespace will evaluate to false for an alphanumeric check.

```
>>> s2 = pd.Series(['A B', '1.5', '3,000'])
>>> s2.str.isalnum()
0     False
1     False
2     False
dtype: bool
```

### More Detailed Checks for Numeric Characters

There are several different but overlapping sets of numeric characters that can be checked for.

```
>>> s3 = pd.Series(['23', '3', '', ''])
```

The `s3.str.isdecimal` method checks for characters used to form numbers in base 10.

```
>>> s3.str.isdecimal()
0      True
1     False
2     False
3     False
dtype: bool
```

The `s.str.isdigit` method is the same as `s3.str.isdecimal` but also includes special digits, like superscripted and subscripted digits in unicode.

```
>>> s3.str.isdigit()
0      True
1      True
2     False
3     False
dtype: bool
```

The `s.str.isnumeric` method is the same as `s3.str.isdigit` but also includes other characters that can represent quantities such as unicode fractions.

```
>>> s3.str.isnumeric()
0      True
1      True
2      True
3     False
dtype: bool
```

### Checks for Whitespace

```
>>> s4 = pd.Series([' ', '\t\r\n ', ''])
>>> s4.str.isspace()
0      True
1      True
2     False
dtype: bool
```

### Checks for Character Case

```
>>> s5 = pd.Series(['leopard', 'Golden Eagle', 'SNAKE', ''])
```

```
>>> s5.str.islower()
0      True
1     False
2     False
3     False
dtype: bool
```

```
>>> s5.str.isupper()
0     False
1     False
2      True
3     False
dtype: bool
```

The `s5.str.istitle` method checks for whether all words are in title case (whether only the first letter of each word is capitalized). Words are assumed to be as any sequence of non-numeric characters separated by whitespace characters.

```
>>> s5.str.istitle()
0    False
1     True
2    False
3    False
dtype: bool
```

## pandas.Series.str.isspace

`Series.str.isspace()`

Check whether all characters in each string are whitespace.

This is equivalent to running the Python string method `str.isspace()` for each element of the Series/Index. If a string has zero characters, `False` is returned for that check.

### Returns

**Series or Index of bool** Series or Index of boolean values with the same length as the original Series/Index.

See also:

***Series.str.isalpha*** Check whether all characters are alphabetic.

***Series.str.isnumeric*** Check whether all characters are numeric.

***Series.str.isalnum*** Check whether all characters are alphanumeric.

***Series.str.isdigit*** Check whether all characters are digits.

***Series.str.isdecimal*** Check whether all characters are decimal.

***Series.str.isspace*** Check whether all characters are whitespace.

***Series.str.islower*** Check whether all characters are lowercase.

***Series.str.isupper*** Check whether all characters are uppercase.

***Series.str.istitle*** Check whether all characters are titlecase.

## Examples

### Checks for Alphabetic and Numeric Characters

```
>>> s1 = pd.Series(['one', 'one1', '1', ''])
```

```
>>> s1.str.isalpha()
0     True
1    False
2    False
3    False
dtype: bool
```

```
>>> s1.str.isnumeric()
0    False
1    False
2     True
```

(continues on next page)

(continued from previous page)

```
3    False
dtype: bool
```

```
>>> s1.str.isalnum()
0     True
1     True
2     True
3    False
dtype: bool
```

Note that checks against characters mixed with any additional punctuation or whitespace will evaluate to false for an alphanumeric check.

```
>>> s2 = pd.Series(['A B', '1.5', '3,000'])
>>> s2.str.isalnum()
0    False
1    False
2    False
dtype: bool
```

### More Detailed Checks for Numeric Characters

There are several different but overlapping sets of numeric characters that can be checked for.

```
>>> s3 = pd.Series(['23', '³', ' ', ''])
```

The `s3.str.isdecimal` method checks for characters used to form numbers in base 10.

```
>>> s3.str.isdecimal()
0     True
1    False
2    False
3    False
dtype: bool
```

The `s.str.isdigit` method is the same as `s3.str.isdecimal` but also includes special digits, like superscripted and subscripted digits in unicode.

```
>>> s3.str.isdigit()
0     True
1     True
2    False
3    False
dtype: bool
```

The `s.str.isnumeric` method is the same as `s3.str.isdigit` but also includes other characters that can represent quantities such as unicode fractions.

```
>>> s3.str.isnumeric()
0     True
1     True
2     True
3    False
dtype: bool
```

### Checks for Whitespace

```
>>> s4 = pd.Series([' ', '\t\r\n ', ''])
>>> s4.str.isspace()
0      True
1      True
2     False
dtype: bool
```

### Checks for Character Case

```
>>> s5 = pd.Series(['leopard', 'Golden Eagle', 'SNAKE', ''])
```

```
>>> s5.str.islower()
0      True
1     False
2     False
3     False
dtype: bool
```

```
>>> s5.str.isupper()
0     False
1     False
2      True
3     False
dtype: bool
```

The `s5.str.istitle` method checks for whether all words are in title case (whether only the first letter of each word is capitalized). Words are assumed to be as any sequence of non-numeric characters separated by whitespace characters.

```
>>> s5.str.istitle()
0     False
1      True
2     False
3     False
dtype: bool
```

## pandas.Series.str.islower

`Series.str.islower()`

Check whether all characters in each string are lowercase.

This is equivalent to running the Python string method `str.islower()` for each element of the Series/Index. If a string has zero characters, `False` is returned for that check.

### Returns

**Series or Index of bool** Series or Index of boolean values with the same length as the original Series/Index.

See also:

***Series.str.isalpha*** Check whether all characters are alphabetic.

***Series.str.isnumeric*** Check whether all characters are numeric.

***Series.str.isalnum*** Check whether all characters are alphanumeric.

***Series.str.isdigit*** Check whether all characters are digits.

***Series.str.isdecimal*** Check whether all characters are decimal.

***Series.str.isspace*** Check whether all characters are whitespace.

***Series.str.islower*** Check whether all characters are lowercase.

***Series.str.isupper*** Check whether all characters are uppercase.

***Series.str.istitle*** Check whether all characters are titlecase.

## Examples

### Checks for Alphabetic and Numeric Characters

```
>>> s1 = pd.Series(['one', 'one1', '1', ''])
```

```
>>> s1.str.isalpha()
0      True
1     False
2     False
3     False
dtype: bool
```

```
>>> s1.str.isnumeric()
0     False
1     False
2       True
3     False
dtype: bool
```

```
>>> s1.str.isalnum()
0      True
1      True
2      True
3     False
dtype: bool
```

Note that checks against characters mixed with any additional punctuation or whitespace will evaluate to false for an alphanumeric check.

```
>>> s2 = pd.Series(['A B', '1.5', '3,000'])
>>> s2.str.isalnum()
0     False
1     False
2     False
dtype: bool
```

### More Detailed Checks for Numeric Characters

There are several different but overlapping sets of numeric characters that can be checked for.

```
>>> s3 = pd.Series(['23', '3', '', ''])
```

The `s3.str.isdecimal` method checks for characters used to form numbers in base 10.

```
>>> s3.str.isdecimal()
0      True
1     False
2     False
3     False
dtype: bool
```

The `s.str.isdigit` method is the same as `s3.str.isdecimal` but also includes special digits, like superscripted and subscripted digits in unicode.

```
>>> s3.str.isdigit()
0      True
1      True
2     False
3     False
dtype: bool
```

The `s.str.isnumeric` method is the same as `s3.str.isdigit` but also includes other characters that can represent quantities such as unicode fractions.

```
>>> s3.str.isnumeric()
0      True
1      True
2      True
3     False
dtype: bool
```

### Checks for Whitespace

```
>>> s4 = pd.Series([' ', '\t\r\n ', ''])
>>> s4.str.isspace()
0      True
1      True
2     False
dtype: bool
```

### Checks for Character Case

```
>>> s5 = pd.Series(['leopard', 'Golden Eagle', 'SNAKE', ''])
```

```
>>> s5.str.islower()
0      True
1     False
2     False
3     False
dtype: bool
```

```
>>> s5.str.isupper()
0     False
1     False
2      True
3     False
dtype: bool
```

The `s5.str.istitle` method checks for whether all words are in title case (whether only the first letter of each word is capitalized). Words are assumed to be as any sequence of non-numeric characters separated by whitespace characters.

```
>>> s5.str.istitle()
0    False
1     True
2    False
3    False
dtype: bool
```

## pandas.Series.str.isupper

`Series.str.isupper()`

Check whether all characters in each string are uppercase.

This is equivalent to running the Python string method `str.isupper()` for each element of the Series/Index. If a string has zero characters, `False` is returned for that check.

### Returns

**Series or Index of bool** Series or Index of boolean values with the same length as the original Series/Index.

See also:

**`Series.str.isdecimal`** Check whether all characters are decimal.

**`Series.str.isspace`** Check whether all characters are whitespace.

**`Series.str.islower`** Check whether all characters are lowercase.

**`Series.str.isupper`** Check whether all characters are uppercase.

**`Series.str.istitle`** Check whether all characters are titlecase.

## Examples

### Checks for Alphabetic and Numeric Characters

```
>>> s1 = pd.Series(['one', 'one1', '1', ''])
```

```
>>> s1.str.isalpha()
0     True
1    False
2    False
3    False
dtype: bool
```

```
>>> s1.str.isnumeric()
0    False
1    False
2     True
```

(continues on next page)

(continued from previous page)

```
3    False
dtype: bool
```

```
>>> s1.str.isalnum()
0     True
1     True
2     True
3    False
dtype: bool
```

Note that checks against characters mixed with any additional punctuation or whitespace will evaluate to false for an alphanumeric check.

```
>>> s2 = pd.Series(['A B', '1.5', '3,000'])
>>> s2.str.isalnum()
0    False
1    False
2    False
dtype: bool
```

### More Detailed Checks for Numeric Characters

There are several different but overlapping sets of numeric characters that can be checked for.

```
>>> s3 = pd.Series(['23', '³', ' ', ''])
```

The `s3.str.isdecimal` method checks for characters used to form numbers in base 10.

```
>>> s3.str.isdecimal()
0     True
1    False
2    False
3    False
dtype: bool
```

The `s.str.isdigit` method is the same as `s3.str.isdecimal` but also includes special digits, like superscripted and subscripted digits in unicode.

```
>>> s3.str.isdigit()
0     True
1     True
2    False
3    False
dtype: bool
```

The `s.str.isnumeric` method is the same as `s3.str.isdigit` but also includes other characters that can represent quantities such as unicode fractions.

```
>>> s3.str.isnumeric()
0     True
1     True
2     True
3    False
dtype: bool
```

### Checks for Whitespace

```

***Series.str.isdecimal*** Check whether all characters are decimal.  
***Series.str.isspace*** Check whether all characters are whitespace.  
***Series.str.islower*** Check whether all characters are lowercase.  
***Series.str.isupper*** Check whether all characters are uppercase.  
***Series.str.istitle*** Check whether all characters are titlecase.

## Examples

### Checks for Alphabetic and Numeric Characters

```
>>> s1 = pd.Series(['one', 'one1', '1', ''])
```

```
>>> s1.str.isalpha()
0      True
1     False
2     False
3     False
dtype: bool
```

```
>>> s1.str.isnumeric()
0     False
1     False
2       True
3     False
dtype: bool
```

```
>>> s1.str.isalnum()
0      True
1      True
2      True
3     False
dtype: bool
```

Note that checks against characters mixed with any additional punctuation or whitespace will evaluate to false for an alphanumeric check.

```
>>> s2 = pd.Series(['A B', '1.5', '3,000'])
>>> s2.str.isalnum()
0     False
1     False
2     False
dtype: bool
```

### More Detailed Checks for Numeric Characters

There are several different but overlapping sets of numeric characters that can be checked for.

```
>>> s3 = pd.Series(['23', '3', '', ''])
```

The `s3.str.isdecimal` method checks for characters used to form numbers in base 10.

```
>>> s3.str.isdecimal()
0      True
1     False
2     False
3     False
dtype: bool
```

The `s.str.isdigit` method is the same as `s3.str.isdecimal` but also includes special digits, like superscripted and subscripted digits in unicode.

```
>>> s3.str.isdigit()
0      True
1      True
2     False
3     False
dtype: bool
```

The `s.str.isnumeric` method is the same as `s3.str.isdigit` but also includes other characters that can represent quantities such as unicode fractions.

```
>>> s3.str.isnumeric()
0      True
1      True
2      True
3     False
dtype: bool
```

### Checks for Whitespace

```
>>> s4 = pd.Series([' ', '\t\r\n ', ''])
>>> s4.str.isspace()
0      True
1      True
2     False
dtype: bool
```

### Checks for Character Case

```
>>> s5 = pd.Series(['leopard', 'Golden Eagle', 'SNAKE', ''])
```

```
>>> s5.str.islower()
0      True
1     False
2     False
3     False
dtype: bool
```

```
>>> s5.str.isupper()
0     False
1     False
2      True
3     False
dtype: bool
```

The `s5.str.istitle` method checks for whether all words are in title case (whether only the first letter of each word is capitalized). Words are assumed to be as any sequence of non-numeric characters separated by whitespace characters.

```
>>> s5.str.istitle()
0    False
1     True
2    False
3    False
dtype: bool
```

### pandas.Series.str.get\_dummies

`Series.str.get_dummies(sep='|')`

Split each string in the Series by sep and return a frame of dummy/indicator variables.

#### Parameters

**sep** [string, default “|”] String to split on.

#### Returns

**dummies** [DataFrame]

#### See also:

`get_dummies`

### Examples

```
>>> pd.Series(['a|b', 'a', 'a|c']).str.get_dummies()
   a  b  c
0  1  1  0
1  1  0  0
2  1  0  1
```

```
>>> pd.Series(['a|b', np.nan, 'a|c']).str.get_dummies()
   a  b  c
0  1  1  0
1  0  0  0
2  1  0  1
```

### 35.3.13.3 Categorical Accessor

Categorical-dtype specific methods and attributes are available under the `Series.cat` accessor.

|                                    |                                                      |
|------------------------------------|------------------------------------------------------|
| <code>Series.cat.categories</code> | The categories of this categorical.                  |
| <code>Series.cat.ordered</code>    | Whether the categories have an ordered relationship. |
| <code>Series.cat.codes</code>      | Return Series of codes as well as the index.         |

### pandas.Series.cat.categories

`Series.cat.categories`

The categories of this categorical.

Setting assigns new values to each category (effectively a rename of each individual category).

The assigned value has to be a list-like object. All items must be unique and the number of items in the new categories must be the same as the number of items in the old categories.

Assigning to *categories* is a inplace operation!

#### Raises

**ValueError** If the new categories do not validate as categories or if the number of new categories is unequal the number of old categories

#### See also:

*rename\_categories*, *reorder\_categories*, *add\_categories*, *remove\_categories*, *remove\_unused\_categories*, *set\_categories*

### pandas.Series.cat.ordered

`Series.cat.ordered`

Whether the categories have an ordered relationship.

### pandas.Series.cat.codes

`Series.cat.codes`

Return Series of codes as well as the index.

|                                                                   |                                                      |
|-------------------------------------------------------------------|------------------------------------------------------|
| <code>Series.cat.rename_categories(*args, **kwargs)</code>        | Renames categories.                                  |
| <code>Series.cat.reorder_categories(*args, **kwargs)</code>       | Reorders categories as specified in new_categories.  |
| <code>Series.cat.add_categories(*args, **kwargs)</code>           | Add new categories.                                  |
| <code>Series.cat.remove_categories(*args, **kwargs)</code>        | Removes the specified categories.                    |
| <code>Series.cat.remove_unused_categories(*args, **kwargs)</code> | Removes categories which are not used.               |
| <code>Series.cat.set_categories(*args, **kwargs)</code>           | Sets the categories to the specified new_categories. |
| <code>Series.cat.as_ordered(*args, **kwargs)</code>               | Set the Categorical to be ordered.                   |
| <code>Series.cat.as_unordered(*args, **kwargs)</code>             | Set the Categorical to be unordered.                 |

### pandas.Series.cat.rename\_categories

`Series.cat.rename_categories(*args, **kwargs)`

Renames categories.

#### Parameters

**new\_categories** [list-like, dict-like or callable]

- list-like: all items must be unique and the number of items in the new categories must match the existing number of categories.
- dict-like: specifies a mapping from old categories to new. Categories not contained in the mapping are passed through and extra categories in the mapping are ignored.

New in version 0.21.0.

- `callable` : a callable that is called on all items in the old categories and whose return values comprise the new categories.

New in version 0.23.0.

**Warning:** Currently, Series are considered list like. In a future version of pandas they'll be considered dict-like.

**inplace** [boolean (default: False)] Whether or not to rename the categories inplace or return a copy of this categorical with renamed categories.

#### Returns

**cat** [Categorical or None] With `inplace=False`, the new categorical is returned. With `inplace=True`, there is no return value.

#### Raises

**ValueError** If new categories are list-like and do not have the same number of items than the current categories or do not validate as categories

#### See also:

`reorder_categories`, `add_categories`, `remove_categories`,  
`remove_unused_categories`, `set_categories`

#### Examples

```
>>> c = pd.Categorical(['a', 'a', 'b'])
>>> c.rename_categories([0, 1])
[0, 0, 1]
Categories (2, int64): [0, 1]
```

For dict-like `new_categories`, extra keys are ignored and categories not in the dictionary are passed through

```
>>> c.rename_categories({'a': 'A', 'c': 'C'})
[A, A, b]
Categories (2, object): [A, b]
```

You may also provide a callable to create the new categories

```
>>> c.rename_categories(lambda x: x.upper())
[A, A, B]
Categories (2, object): [A, B]
```

### pandas.Series.cat.reorder\_categories

`Series.cat.reorder_categories(*args, **kwargs)`

Reorders categories as specified in `new_categories`.

`new_categories` need to include all old categories and no new category items.

#### Parameters

**new\_categories** [Index-like] The categories in new order.

**ordered** [boolean, optional] Whether or not the categorical is treated as a ordered categorical.  
If not given, do not change the ordered information.

**inplace** [boolean (default: False)] Whether or not to reorder the categories inplace or return  
a copy of this categorical with reordered categories.

#### Returns

**cat** [Categorical with reordered categories or None if inplace.]

#### Raises

**ValueError** If the new categories do not contain all old category items or any new ones

#### See also:

*rename\_categories*, *add\_categories*, *remove\_categories*,  
*remove\_unused\_categories*, *set\_categories*

### pandas.Series.cat.add\_categories

`Series.cat.add_categories(*args, **kwargs)`

Add new categories.

*new\_categories* will be included at the last/highest place in the categories and will be unused directly after this call.

#### Parameters

**new\_categories** [category or list-like of category] The new categories to be included.

**inplace** [boolean (default: False)] Whether or not to add the categories inplace or return a  
copy of this categorical with added categories.

#### Returns

**cat** [Categorical with new categories added or None if inplace.]

#### Raises

**ValueError** If the new categories include old categories or do not validate as categories

#### See also:

*rename\_categories*, *reorder\_categories*, *remove\_categories*,  
*remove\_unused\_categories*, *set\_categories*

### pandas.Series.cat.remove\_categories

`Series.cat.remove_categories(*args, **kwargs)`

Removes the specified categories.

*removals* must be included in the old categories. Values which were in the removed categories will be set to NaN

#### Parameters

**removals** [category or list of categories] The categories which should be removed.

**inplace** [boolean (default: False)] Whether or not to remove the categories inplace or return  
a copy of this categorical with removed categories.

#### Returns

**cat** [Categorical with removed categories or None if inplace.]

**Raises**

**ValueError** If the removals are not contained in the categories

**See also:**

*rename\_categories*, *reorder\_categories*, *add\_categories*,  
*remove\_unused\_categories*, *set\_categories*

### pandas.Series.cat.remove\_unused\_categories

`Series.cat.remove_unused_categories(*args, **kwargs)`

Removes categories which are not used.

**Parameters**

**inplace** [boolean (default: False)] Whether or not to drop unused categories inplace or return a copy of this categorical with unused categories dropped.

**Returns**

**cat** [Categorical with unused categories dropped or None if inplace.]

**See also:**

*rename\_categories*, *reorder\_categories*, *add\_categories*, *remove\_categories*,  
*set\_categories*

### pandas.Series.cat.set\_categories

`Series.cat.set_categories(*args, **kwargs)`

Sets the categories to the specified new\_categories.

*new\_categories* can include new categories (which will result in unused categories) or remove old categories (which results in values set to NaN). If *rename==True*, the categories will simply be renamed (less or more items than in old categories will result in values set to NaN or in unused categories respectively).

This method can be used to perform more than one action of adding, removing, and reordering simultaneously and is therefore faster than performing the individual steps via the more specialised methods.

On the other hand this method does not do checks (e.g., whether the old categories are included in the new categories on a reorder), which can result in surprising changes, for example when using special string dtypes on python3, which does not consider a S1 string equal to a single char python string.

**Parameters**

**new\_categories** [Index-like] The categories in new order.

**ordered** [boolean, (default: False)] Whether or not the categorical is treated as an ordered categorical. If not given, do not change the ordered information.

**rename** [boolean (default: False)] Whether or not the new\_categories should be considered as a rename of the old categories or as reordered categories.

**inplace** [boolean (default: False)] Whether or not to reorder the categories inplace or return a copy of this categorical with reordered categories.

**Returns**

**cat** [Categorical with reordered categories or None if inplace.]

**Raises****ValueError** If `new_categories` does not validate as categories**See also:**

`rename_categories`, `reorder_categories`, `add_categories`, `remove_categories`,  
`remove_unused_categories`

**pandas.Series.cat.as\_ordered**`Series.cat.as_ordered(*args, **kwargs)`

Set the Categorical to be ordered.

**Parameters**

**inplace** [boolean (default: False)] Whether or not to set the ordered attribute inplace or return a copy of this categorical with ordered set to True

**pandas.Series.cat.as\_unordered**`Series.cat.as_unordered(*args, **kwargs)`

Set the Categorical to be unordered.

**Parameters**

**inplace** [boolean (default: False)] Whether or not to set the ordered attribute inplace or return a copy of this categorical with ordered set to False

**35.3.13.4 Sparse Accessor**Sparse-dtype specific methods and attributes are provided under the `Series.sparse` accessor.

|                                       |                                                                    |
|---------------------------------------|--------------------------------------------------------------------|
| <code>Series.sparse.npoints</code>    | The number of non- <code>fill_value</code> points.                 |
| <code>Series.sparse.density</code>    | The percent of non- <code>fill_value</code> points, as decimal.    |
| <code>Series.sparse.fill_value</code> | Elements in <i>data</i> that are <i>fill_value</i> are not stored. |
| <code>Series.sparse.sp_values</code>  | An ndarray containing the non- <code>fill_value</code> values.     |

**pandas.Series.sparse.npoints**`Series.sparse.npoints`The number of non- `fill_value` points.**Examples**

```
>>> s = SparseArray([0, 0, 1, 1, 1], fill_value=0)
>>> s.npoints
3
```

## pandas.Series.sparse.density

### Series.sparse.density

The percent of non- *fill\_value* points, as decimal.

#### Examples

```
>>> s = SparseArray([0, 0, 1, 1, 1], fill_value=0)
>>> s.density
0.6
```

## pandas.Series.sparse.fill\_value

### Series.sparse.fill\_value

Elements in *data* that are *fill\_value* are not stored.

For memory savings, this should be the most common value in the array.

## pandas.Series.sparse.sp\_values

### Series.sparse.sp\_values

An ndarray containing the non- *fill\_value* values.

#### Examples

```
>>> s = SparseArray([0, 0, 1, 0, 2], fill_value=0)
>>> s.sp_values
array([1, 2])
```

---

*Series.sparse.from\_coo*(A[, dense\_index])

Create a SparseSeries from a `scipy.sparse.coo_matrix`.

*Series.sparse.to\_coo*([row\_levels, ...])

Create a `scipy.sparse.coo_matrix` from a SparseSeries with MultiIndex.

---

## pandas.Series.sparse.from\_coo

**classmethod** `sparse.from_coo` (A, dense\_index=False)

Create a SparseSeries from a `scipy.sparse.coo_matrix`.

#### Parameters

**A** [`scipy.sparse.coo_matrix`]

**dense\_index** [bool, default False] If False (default), the SparseSeries index consists of only the coords of the non-null entries of the original `coo_matrix`. If True, the SparseSeries index consists of the full sorted (row, col) coordinates of the `coo_matrix`.

#### Returns

**s** [SparseSeries]

## Examples

```
>>> from scipy import sparse
>>> A = sparse.coo_matrix(([3.0, 1.0, 2.0], ([1, 0, 0], [0, 2, 3])),
                          shape=(3, 4))
>>> A
<3x4 sparse matrix of type '<class 'numpy.float64'>'
  with 3 stored elements in COOrdinate format>
>>> A.todense()
matrix([[ 0.,  0.,  1.,  2.],
        [ 3.,  0.,  0.,  0.],
        [ 0.,  0.,  0.,  0.]])
>>> ss = pd.SparseSeries.from_coo(A)
>>> ss
0 2 1
  3 2
1 0 3
dtype: float64
BlockIndex
Block locations: array([0], dtype=int32)
Block lengths: array([3], dtype=int32)
```

## pandas.Series.sparse.to\_coo

`sparse.to_coo(row_levels=(0, ), column_levels=(1, ), sort_labels=False)`

Create a `scipy.sparse.coo_matrix` from a `SparseSeries` with `MultiIndex`.

Use `row_levels` and `column_levels` to determine the row and column coordinates respectively. `row_levels` and `column_levels` are the names (labels) or numbers of the levels. `{row_levels, column_levels}` must be a partition of the `MultiIndex` level names (or numbers).

### Parameters

**row\_levels** [tuple/list]

**column\_levels** [tuple/list]

**sort\_labels** [bool, default False] Sort the row and column labels before forming the sparse matrix.

### Returns

**y** [`scipy.sparse.coo_matrix`]

**rows** [list (row labels)]

**columns** [list (column labels)]

## Examples

```
>>> s = pd.Series([3.0, np.nan, 1.0, 3.0, np.nan, np.nan])
>>> s.index = pd.MultiIndex.from_tuples([(1, 2, 'a', 0),
                                         (1, 2, 'a', 1),
                                         (1, 1, 'b', 0),
                                         (1, 1, 'b', 1),
                                         (2, 1, 'b', 0),
                                         (2, 1, 'b', 1)],
```

(continues on next page)

(continued from previous page)

```

names=['A', 'B', 'C', 'D'])
>>> ss = s.to_sparse()
>>> A, rows, columns = ss.to_coo(row_levels=['A', 'B'],
                                column_levels=['C', 'D'],
                                sort_labels=True)

>>> A
<3x4 sparse matrix of type '<class 'numpy.float64'>'
  with 3 stored elements in COOrdinate format>
>>> A.todense()
matrix([[ 0.,  0.,  1.,  3.],
 [ 3.,  0.,  0.,  0.],
 [ 0.,  0.,  0.,  0.]])
>>> rows
[(1, 1), (1, 2), (2, 1)]
>>> columns
[('a', 0), ('a', 1), ('b', 0), ('b', 1)]

```

### 35.3.14 Plotting

`Series.plot` is both a callable method and a namespace attribute for specific plotting methods of the form `Series.plot.<kind>`.

|                                                    |                                                               |
|----------------------------------------------------|---------------------------------------------------------------|
| <code>Series.plot([kind, ax, figsize, ...])</code> | Series plotting accessor and method                           |
| <code>Series.plot.area(**kwargs)</code>            | Area plot.                                                    |
| <code>Series.plot.bar(**kwargs)</code>             | Vertical bar plot.                                            |
| <code>Series.plot.barh(**kwargs)</code>            | Horizontal bar plot.                                          |
| <code>Series.plot.box(**kwargs)</code>             | Boxplot.                                                      |
| <code>Series.plot.density([bw_method, ind])</code> | Generate Kernel Density Estimate plot using Gaussian kernels. |
| <code>Series.plot.hist([bins])</code>              | Histogram.                                                    |
| <code>Series.plot.kde([bw_method, ind])</code>     | Generate Kernel Density Estimate plot using Gaussian kernels. |
| <code>Series.plot.line(**kwargs)</code>            | Line plot.                                                    |
| <code>Series.plot.pie(**kwargs)</code>             | Pie chart.                                                    |

#### 35.3.14.1 pandas.Series.plot.area

`Series.plot.area(**kwargs)`  
Area plot.

##### Parameters

**‘\*\*kwargs’** [optional] Additional keyword arguments are documented in `pandas.Series.plot()`.

##### Returns

**axes** [`matplotlib.axes.Axes` or `numpy.ndarray` of them]

### 35.3.14.2 pandas.Series.plot.bar

`Series.plot.bar(**kws)`  
Vertical bar plot.

#### Parameters

**‘\*\*kws’** [optional] Additional keyword arguments are documented in `pandas.Series.plot()`.

#### Returns

**axes** [`matplotlib.axes.Axes` or `numpy.ndarray` of them]

### 35.3.14.3 pandas.Series.plot.barh

`Series.plot.barh(**kws)`  
Horizontal bar plot.

#### Parameters

**‘\*\*kws’** [optional] Additional keyword arguments are documented in `pandas.Series.plot()`.

#### Returns

**axes** [`matplotlib.axes.Axes` or `numpy.ndarray` of them]

### 35.3.14.4 pandas.Series.plot.box

`Series.plot.box(**kws)`  
Boxplot.

#### Parameters

**‘\*\*kws’** [optional] Additional keyword arguments are documented in `pandas.Series.plot()`.

#### Returns

**axes** [`matplotlib.axes.Axes` or `numpy.ndarray` of them]

### 35.3.14.5 pandas.Series.plot.density

`Series.plot.density(bw_method=None, ind=None, **kws)`  
Generate Kernel Density Estimate plot using Gaussian kernels.

In statistics, [kernel density estimation](#) (KDE) is a non-parametric way to estimate the probability density function (PDF) of a random variable. This function uses Gaussian kernels and includes automatic bandwidth determination.

#### Parameters

**bw\_method** [str, scalar or callable, optional] The method used to calculate the estimator bandwidth. This can be ‘scott’, ‘silverman’, a scalar constant or a callable. If None (default), ‘scott’ is used. See `scipy.stats.gaussian_kde` for more information.

**ind** [NumPy array or integer, optional] Evaluation points for the estimated PDF. If None (default), 1000 equally spaced points are used. If *ind* is a NumPy array, the KDE is evaluated at the points passed. If *ind* is an integer, *ind* number of equally spaced points are used.

**\*\*kwargs** [optional] Additional keyword arguments are documented in `pandas.Series.plot()`.

#### Returns

**axes** [matplotlib.axes.Axes or numpy.ndarray of them]

See also:

**scipy.stats.gaussian\_kde** Representation of a kernel-density estimate using Gaussian kernels. This is the function used internally to estimate the PDF.

**DataFrame.plot.kde** Generate a KDE plot for a DataFrame.

#### Examples

Given a Series of points randomly sampled from an unknown distribution, estimate its PDF using KDE with automatic bandwidth determination and plot the results, evaluating them at 1000 equally spaced points (default):

```
>>> s = pd.Series([1, 2, 2.5, 3, 3.5, 4, 5])
>>> ax = s.plot.kde()
```

A scalar bandwidth can be specified. Using a small bandwidth value can lead to over-fitting, while using a large bandwidth value may result in under-fitting:

```
>>> ax = s.plot.kde(bw_method=0.3)
```

```
>>> ax = s.plot.kde(bw_method=3)
```

Finally, the *ind* parameter determines the evaluation points for the plot of the estimated PDF:

```
>>> ax = s.plot.kde(ind=[1, 2, 3, 4, 5])
```

#### 35.3.14.6 pandas.Series.plot.hist

`Series.plot.hist` (*bins=10, \*\*kwargs*)

Histogram.

##### Parameters

**bins** [integer, default 10] Number of histogram bins to be used

**\*\*kwargs** [optional] Additional keyword arguments are documented in `pandas.Series.plot()`.

##### Returns

**axes** [matplotlib.axes.Axes or numpy.ndarray of them]

### 35.3.14.7 pandas.Series.plot.kde

`Series.plot.kde` (*bw\_method=None, ind=None, \*\*kws*)

Generate Kernel Density Estimate plot using Gaussian kernels.

In statistics, [kernel density estimation](#) (KDE) is a non-parametric way to estimate the probability density function (PDF) of a random variable. This function uses Gaussian kernels and includes automatic bandwidth determination.

#### Parameters

**bw\_method** [str, scalar or callable, optional] The method used to calculate the estimator bandwidth. This can be 'scott', 'silverman', a scalar constant or a callable. If None (default), 'scott' is used. See [scipy.stats.gaussian\\_kde](#) for more information.

**ind** [NumPy array or integer, optional] Evaluation points for the estimated PDF. If None (default), 1000 equally spaced points are used. If *ind* is a NumPy array, the KDE is evaluated at the points passed. If *ind* is an integer, *ind* number of equally spaced points are used.

**\*\*kws** [optional] Additional keyword arguments are documented in `pandas.Series.plot()`.

#### Returns

**axes** [matplotlib.axes.Axes or numpy.ndarray of them]

See also:

[scipy.stats.gaussian\\_kde](#) Representation of a kernel-density estimate using Gaussian kernels. This is the function used internally to estimate the PDF.

**DataFrame.plot.kde** Generate a KDE plot for a DataFrame.

#### Examples

Given a Series of points randomly sampled from an unknown distribution, estimate its PDF using KDE with automatic bandwidth determination and plot the results, evaluating them at 1000 equally spaced points (default):

```
>>> s = pd.Series([1, 2, 2.5, 3, 3.5, 4, 5])
>>> ax = s.plot.kde()
```

A scalar bandwidth can be specified. Using a small bandwidth value can lead to over-fitting, while using a large bandwidth value may result in under-fitting:

```
>>> ax = s.plot.kde(bw_method=0.3)
```

```
>>> ax = s.plot.kde(bw_method=3)
```

Finally, the *ind* parameter determines the evaluation points for the plot of the estimated PDF:

```
>>> ax = s.plot.kde(ind=[1, 2, 3, 4, 5])
```

### 35.3.14.8 pandas.Series.plot.line

`Series.plot.line` (*\*\*kws*)

Line plot.

**Parameters**

**\*\*kwargs** [optional] Additional keyword arguments are documented in `pandas.Series.plot()`.

**Returns**

**axes** [`matplotlib.axes.Axes` or `numpy.ndarray` of them]

**Examples**

```
>>> s = pd.Series([1, 3, 2])
>>> s.plot.line()
```

**35.3.14.9 pandas.Series.plot.pie**

`Series.plot.pie(**kwargs)`

Pie chart.

**Parameters**

**\*\*kwargs** [optional] Additional keyword arguments are documented in `pandas.Series.plot()`.

**Returns**

**axes** [`matplotlib.axes.Axes` or `numpy.ndarray` of them]

---

|                                                           |                                                      |
|-----------------------------------------------------------|------------------------------------------------------|
| <code>Series.hist([by, ax, grid, xlabelsize, ...])</code> | Draw histogram of the input series using matplotlib. |
|-----------------------------------------------------------|------------------------------------------------------|

---

**35.3.15 Serialization / IO / Conversion**

|                                                               |                                                                |
|---------------------------------------------------------------|----------------------------------------------------------------|
| <code>Series.to_pickle(path[, compression, protocol])</code>  | Pickle (serialize) object to file.                             |
| <code>Series.to_csv(*args, **kwargs)</code>                   | Write object to a comma-separated values (csv) file.           |
| <code>Series.to_dict(into)</code>                             | Convert Series to {label -> value} dict or dict-like object.   |
| <code>Series.to_excel(excel_writer[, sheet_name, ...])</code> | Write object to an Excel sheet.                                |
| <code>Series.to_frame([name])</code>                          | Convert Series to DataFrame.                                   |
| <code>Series.to_xarray()</code>                               | Return an xarray object from the pandas object.                |
| <code>Series.to_hdf(path_or_buf, key, **kwargs)</code>        | Write the contained data to an HDF5 file using HDFStore.       |
| <code>Series.to_sql(name, con[, schema, ...])</code>          | Write records stored in a DataFrame to a SQL database.         |
| <code>Series.to_msgpack([path_or_buf, encoding])</code>       | Serialize object to input file path using msgpack format.      |
| <code>Series.to_json([path_or_buf, orient, ...])</code>       | Convert the object to a JSON string.                           |
| <code>Series.to_sparse([kind, fill_value])</code>             | Convert Series to SparseSeries.                                |
| <code>Series.to_dense()</code>                                | Return dense representation of NDFrame (as opposed to sparse). |
| <code>Series.to_string([buf, na_rep, ...])</code>             | Render a string representation of the Series.                  |
| <code>Series.to_clipboard([excel, sep])</code>                | Copy object to the system clipboard.                           |
| <code>Series.to_latex([buf, columns, col_space, ...])</code>  | Render an object to a LaTeX tabular environment table.         |

### 35.3.16 Sparse

|                                                     |                                                                                                               |
|-----------------------------------------------------|---------------------------------------------------------------------------------------------------------------|
| <code>SparseSeries.to_coo([row_levels,...])</code>  | Create a <code>scipy.sparse.coo_matrix</code> from a <code>SparseSeries</code> with <code>MultiIndex</code> . |
| <code>SparseSeries.from_coo(A[,dense_index])</code> | Create a <code>SparseSeries</code> from a <code>scipy.sparse.coo_matrix</code> .                              |

#### 35.3.16.1 pandas.SparseSeries.to\_coo

`SparseSeries.to_coo(row_levels=(0, ), column_levels=(1, ), sort_labels=False)`

Create a `scipy.sparse.coo_matrix` from a `SparseSeries` with `MultiIndex`.

Use `row_levels` and `column_levels` to determine the row and column coordinates respectively. `row_levels` and `column_levels` are the names (labels) or numbers of the levels. `{row_levels, column_levels}` must be a partition of the `MultiIndex` level names (or numbers).

##### Parameters

**row\_levels** [tuple/list]

**column\_levels** [tuple/list]

**sort\_labels** [bool, default False] Sort the row and column labels before forming the sparse matrix.

##### Returns

**y** [`scipy.sparse.coo_matrix`]

**rows** [list (row labels)]

**columns** [list (column labels)]

#### Examples

```
>>> s = pd.Series([3.0, np.nan, 1.0, 3.0, np.nan, np.nan])
>>> s.index = pd.MultiIndex.from_tuples([(1, 2, 'a', 0),
                                         (1, 2, 'a', 1),
                                         (1, 1, 'b', 0),
                                         (1, 1, 'b', 1),
                                         (2, 1, 'b', 0),
                                         (2, 1, 'b', 1)],
                                         names=['A', 'B', 'C', 'D'])

>>> ss = s.to_sparse()
>>> A, rows, columns = ss.to_coo(row_levels=['A', 'B'],
                                column_levels=['C', 'D'],
                                sort_labels=True)

>>> A
<3x4 sparse matrix of type '<class 'numpy.float64'>'
  with 3 stored elements in COOrdinate format>
>>> A.todense()
matrix([[ 0.,  0.,  1.,  3.],
 [ 3.,  0.,  0.,  0.],
 [ 0.,  0.,  0.,  0.]])
>>> rows
[(1, 1), (1, 2), (2, 1)]
>>> columns
[('a', 0), ('a', 1), ('b', 0), ('b', 1)]
```

### 35.3.16.2 pandas.SparseSeries.from\_coo

**classmethod** `SparseSeries.from_coo` (*A*, *dense\_index=False*)

Create a `SparseSeries` from a `scipy.sparse.coo_matrix`.

#### Parameters

**A** [`scipy.sparse.coo_matrix`]

**dense\_index** [`bool`, default `False`] If `False` (default), the `SparseSeries` index consists of only the coords of the non-null entries of the original `coo_matrix`. If `True`, the `SparseSeries` index consists of the full sorted (row, col) coordinates of the `coo_matrix`.

#### Returns

**s** [`SparseSeries`]

#### Examples

```
>>> from scipy import sparse
>>> A = sparse.coo_matrix(([3.0, 1.0, 2.0], ([1, 0, 0], [0, 2, 3])),
                          shape=(3, 4))
>>> A
<3x4 sparse matrix of type '<class 'numpy.float64'>'
  with 3 stored elements in COOrdinate format>
>>> A.todense()
matrix([[ 0.,  0.,  1.,  2.],
        [ 3.,  0.,  0.,  0.],
        [ 0.,  0.,  0.,  0.]])
>>> ss = pd.SparseSeries.from_coo(A)
>>> ss
0 2 1
 3 2
1 0 3
dtype: float64
BlockIndex
Block locations: array([0], dtype=int32)
Block lengths: array([3], dtype=int32)
```

{{ header }}

## 35.4 DataFrame

### 35.4.1 Constructor

`DataFrame`(*[data, index, columns, dtype, copy]*)

Two-dimensional size-mutable, potentially heterogeneous tabular data structure with labeled axes (rows and columns).

#### 35.4.1.1 pandas.DataFrame

**class** `pandas.DataFrame` (*data=None, index=None, columns=None, dtype=None, copy=False*)

Two-dimensional size-mutable, potentially heterogeneous tabular data structure with labeled axes (rows and columns). Arithmetic operations align on both row and column labels. Can be thought of as a dict-like container

for Series objects. The primary pandas data structure.

### Parameters

**data** [ndarray (structured or homogeneous), Iterable, dict, or DataFrame] Dict can contain Series, arrays, constants, or list-like objects

Changed in version 0.23.0: If data is a dict, argument order is maintained for Python 3.6 and later.

**index** [Index or array-like] Index to use for resulting frame. Will default to RangeIndex if no indexing information part of input data and no index provided

**columns** [Index or array-like] Column labels to use for resulting frame. Will default to RangeIndex (0, 1, 2, ..., n) if no column labels are provided

**dtype** [dtype, default None] Data type to force. Only a single dtype is allowed. If None, infer

**copy** [boolean, default False] Copy data from inputs. Only affects DataFrame / 2d ndarray input

See also:

**DataFrame.from\_records** Constructor from tuples, also record arrays.

**DataFrame.from\_dict** From dicts of Series, arrays, or dicts.

**DataFrame.from\_items** From sequence of (key, value) pairs pandas.read\_csv, pandas.read\_table, pandas.read\_clipboard.

### Examples

Constructing DataFrame from a dictionary.

```
>>> d = {'col1': [1, 2], 'col2': [3, 4]}
>>> df = pd.DataFrame(data=d)
>>> df
   col1  col2
0     1     3
1     2     4
```

Notice that the inferred dtype is int64.

```
>>> df.dtypes
col1    int64
col2    int64
dtype: object
```

To enforce a single dtype:

```
>>> df = pd.DataFrame(data=d, dtype=np.int8)
>>> df.dtypes
col1    int8
col2    int8
dtype: object
```

Constructing DataFrame from numpy ndarray:

```
>>> df2 = pd.DataFrame(np.array([[1, 2, 3], [4, 5, 6], [7, 8, 9]]),
...                      columns=['a', 'b', 'c'])
>>> df2
   a  b  c
0  1  2  3
1  4  5  6
2  7  8  9
```

## Attributes

|                |                                                                                                                   |
|----------------|-------------------------------------------------------------------------------------------------------------------|
| <i>T</i>       | Transpose index and columns.                                                                                      |
| <i>at</i>      | Access a single value for a row/column label pair.                                                                |
| <i>axes</i>    | Return a list representing the axes of the DataFrame.                                                             |
| <i>blocks</i>  | (DEPRECATED) Internal property, property synonym for <i>as_blocks()</i> .                                         |
| <i>columns</i> | The column labels of the DataFrame.                                                                               |
| <i>dtypes</i>  | Return the dtypes in the DataFrame.                                                                               |
| <i>empty</i>   | Indicator whether DataFrame is empty.                                                                             |
| <i>ftypes</i>  | Return the ftypes (indication of sparse/dense and dtype) in DataFrame.                                            |
| <i>iat</i>     | Access a single value for a row/column pair by integer position.                                                  |
| <i>iloc</i>    | Purely integer-location based indexing for selection by position.                                                 |
| <i>index</i>   | The index (row labels) of the DataFrame.                                                                          |
| <i>is_copy</i> | Return the copy.                                                                                                  |
| <i>ix</i>      | A primarily label-location based indexer, with integer position fallback.                                         |
| <i>loc</i>     | Access a group of rows and columns by label(s) or a boolean array.                                                |
| <i>ndim</i>    | Return an int representing the number of axes / array dimensions.                                                 |
| <i>shape</i>   | Return a tuple representing the dimensionality of the DataFrame.                                                  |
| <i>size</i>    | Return an int representing the number of elements in this object.                                                 |
| <i>style</i>   | Property returning a Styler object containing methods for building a styled HTML representation fo the DataFrame. |
| <i>values</i>  | Return a Numpy representation of the DataFrame.                                                                   |

## pandas.DataFrame.T

`DataFrame.T`

Transpose index and columns.

Reflect the DataFrame over its main diagonal by writing rows as columns and vice-versa. The property *T* is an accessor to the method *transpose()*.

### Parameters

**copy** [bool, default False] If True, the underlying data is copied. Otherwise (default), no

copy is made if possible.

**\*args, \*\*kwargs** Additional keywords have no effect but might be accepted for compatibility with numpy.

### Returns

**DataFrame** The transposed DataFrame.

### See also:

**numpy.transpose** Permute the dimensions of a given array.

### Notes

Transposing a DataFrame with mixed dtypes will result in a homogeneous DataFrame with the *object* dtype. In such a case, a copy of the data is always made.

### Examples

#### Square DataFrame with homogeneous dtype

```
>>> d1 = {'col1': [1, 2], 'col2': [3, 4]}
>>> df1 = pd.DataFrame(data=d1)
>>> df1
   col1  col2
0     1     3
1     2     4
```

```
>>> df1_transposed = df1.T # or df1.transpose()
>>> df1_transposed
   0  1
col1 1  2
col2 3  4
```

When the dtype is homogeneous in the original DataFrame, we get a transposed DataFrame with the same dtype:

```
>>> df1.dtypes
col1    int64
col2    int64
dtype: object
>>> df1_transposed.dtypes
0    int64
1    int64
dtype: object
```

#### Non-square DataFrame with mixed dtypes

```
>>> d2 = {'name': ['Alice', 'Bob'],
...       'score': [9.5, 8],
...       'employed': [False, True],
...       'kids': [0, 0]}
>>> df2 = pd.DataFrame(data=d2)
>>> df2
   name  score  employed  kids
```

(continues on next page)

(continued from previous page)

|   |       |     |       |   |
|---|-------|-----|-------|---|
| 0 | Alice | 9.5 | False | 0 |
| 1 | Bob   | 8.0 | True  | 0 |

```
>>> df2_transposed = df2.T # or df2.transpose()
>>> df2_transposed
      0      1
name  Alice  Bob
score   9.5    8
employed False  True
kids      0    0
```

When the DataFrame has mixed dtypes, we get a transposed DataFrame with the *object* dtype:

```
>>> df2.dtypes
name          object
score        float64
employed       bool
kids          int64
dtype: object
>>> df2_transposed.dtypes
0      object
1      object
dtype: object
```

## pandas.DataFrame.at

### DataFrame.at

Access a single value for a row/column label pair.

Similar to `loc`, in that both provide label-based lookups. Use `at` if you only need to get or set a single value in a DataFrame or Series.

#### Raises

**KeyError** When label does not exist in DataFrame

#### See also:

**DataFrame.iat** Access a single value for a row/column pair by integer position.

**DataFrame.loc** Access a group of rows and columns by label(s).

**Series.at** Access a single value using a label.

## Examples

```
>>> df = pd.DataFrame([[0, 2, 3], [0, 4, 1], [10, 20, 30]],
...                    index=[4, 5, 6], columns=['A', 'B', 'C'])
>>> df
   A  B  C
4  0  2  3
5  0  4  1
6 10 20 30
```

Get value at specified row/column pair

```
>>> df.at[4, 'B']
2
```

Set value at specified row/column pair

```
>>> df.at[4, 'B'] = 10
>>> df.at[4, 'B']
10
```

Get value within a Series

```
>>> df.loc[5].at['B']
4
```

## pandas.DataFrame.axes

**DataFrame.axes**

Return a list representing the axes of the DataFrame.

It has the row axis labels and column axis labels as the only members. They are returned in that order.

### Examples

```
>>> df = pd.DataFrame({'col1': [1, 2], 'col2': [3, 4]})
>>> df.axes
[RangeIndex(start=0, stop=2, step=1), Index(['col1', 'col2'],
dtype='object')]
```

## pandas.DataFrame.blocks

**DataFrame.blocks**

Internal property, property synonym for `as_blocks()`.

Deprecated since version 0.21.0.

## pandas.DataFrame.columns

**DataFrame.columns**

The column labels of the DataFrame.

## pandas.DataFrame.dtypes

**DataFrame.dtypes**

Return the dtypes in the DataFrame.

This returns a Series with the data type of each column. The result's index is the original DataFrame's columns. Columns with mixed types are stored with the `object` dtype. See *the User Guide* for more.

### Returns

**pandas.Series** The data type of each column.

See also:

**`pandas.DataFrame.ftypes`** Dtype and sparsity information.

## Examples

```
>>> df = pd.DataFrame({'float': [1.0],
...                    'int': [1],
...                    'datetime': [pd.Timestamp('20180310')],
...                    'string': ['foo']})
>>> df.dtypes
float          float64
int            int64
datetime      datetime64[ns]
string         object
dtype: object
```

## **`pandas.DataFrame.empty`**

**`DataFrame.empty`**

Indicator whether DataFrame is empty.

True if DataFrame is entirely empty (no items), meaning any of the axes are of length 0.

### Returns

**bool** If DataFrame is empty, return True, if not return False.

See also:

*`pandas.Series.dropna`, `pandas.DataFrame.dropna`*

## Notes

If DataFrame contains only NaNs, it is still not considered empty. See the example below.

## Examples

An example of an actual empty DataFrame. Notice the index is empty:

```
>>> df_empty = pd.DataFrame({'A' : []})
>>> df_empty
Empty DataFrame
Columns: [A]
Index: []
>>> df_empty.empty
True
```

If we only have NaNs in our DataFrame, it is not considered empty! We will need to drop the NaNs to make the DataFrame empty:

```

>>> df = pd.DataFrame({'A' : [np.nan]})
>>> df
   A
0 NaN
>>> df.empty
False
>>> df.dropna().empty
True

```

## pandas.DataFrame.ftypes

### DataFrame.ftypes

Return the ftypes (indication of sparse/dense and dtype) in DataFrame.

This returns a Series with the data type of each column. The result's index is the original DataFrame's columns. Columns with mixed types are stored with the `object` dtype. See *the User Guide* for more.

#### Returns

**pandas.Series** The data type and indication of sparse/dense of each column.

See also:

**pandas.DataFrame.dtypes** Series with just dtype information.

**pandas.SparseDataFrame** Container for sparse tabular data.

## Notes

Sparse data should have the same dtypes as its dense representation.

## Examples

```

>>> arr = np.random.RandomState(0).randn(100, 4)
>>> arr[arr < .8] = np.nan
>>> pd.DataFrame(arr).ftypes
0    float64:dense
1    float64:dense
2    float64:dense
3    float64:dense
dtype: object

```

```

>>> pd.SparseDataFrame(arr).ftypes
0    float64:sparse
1    float64:sparse
2    float64:sparse
3    float64:sparse
dtype: object

```

## pandas.DataFrame.iat

### DataFrame.iat

Access a single value for a row/column pair by integer position.

Similar to `iloc`, in that both provide integer-based lookups. Use `iat` if you only need to get or set a single value in a `DataFrame` or `Series`.

#### Raises

**IndexError** When integer position is out of bounds

See also:

**`DataFrame.at`** Access a single value for a row/column label pair.

**`DataFrame.loc`** Access a group of rows and columns by label(s).

**`DataFrame.iloc`** Access a group of rows and columns by integer position(s).

### Examples

```
>>> df = pd.DataFrame([[0, 2, 3], [0, 4, 1], [10, 20, 30]],
...                    columns=['A', 'B', 'C'])
>>> df
   A  B  C
0  0  2  3
1  0  4  1
2 10 20 30
```

Get value at specified row/column pair

```
>>> df.iat[1, 2]
1
```

Set value at specified row/column pair

```
>>> df.iat[1, 2] = 10
>>> df.iat[1, 2]
10
```

Get value within a series

```
>>> df.loc[0].iat[1]
2
```

## pandas.DataFrame.iloc

### `DataFrame.iloc`

Purely integer-location based indexing for selection by position.

`.iloc[]` is primarily integer position based (from 0 to `length-1` of the axis), but may also be used with a boolean array.

Allowed inputs are:

- An integer, e.g. 5.
- A list or array of integers, e.g. `[4, 3, 0]`.
- A slice object with ints, e.g. `1:7`.
- A boolean array.

- A callable function with one argument (the calling Series, DataFrame or Panel) and that returns valid output for indexing (one of the above). This is useful in method chains, when you don't have a reference to the calling object, but would like to base your selection on some value.

`.iloc` will raise `IndexError` if a requested indexer is out-of-bounds, except *slice* indexers which allow out-of-bounds indexing (this conforms with python/numpy *slice* semantics).

See more at [ref:Selection by Position <indexing.integer>](#).

See also:

**DataFrame.iat** Fast integer location scalar accessor.

**DataFrame.loc** Purely label-location based indexer for selection by label.

**Series.iloc** Purely integer-location based indexing for selection by position.

## Examples

```
>>> mydict = [{'a': 1, 'b': 2, 'c': 3, 'd': 4},
...           {'a': 100, 'b': 200, 'c': 300, 'd': 400},
...           {'a': 1000, 'b': 2000, 'c': 3000, 'd': 4000}]
>>> df = pd.DataFrame(mydict)
>>> df
   a    b    c    d
0   1    2    3    4
1 100  200  300  400
2 1000 2000 3000 4000
```

### Indexing just the rows

With a scalar integer.

```
>>> type(df.iloc[0])
<class 'pandas.core.series.Series'>
>>> df.iloc[0]
a    1
b    2
c    3
d    4
Name: 0, dtype: int64
```

With a list of integers.

```
>>> df.iloc[[0]]
   a  b  c  d
0  1  2  3  4
>>> type(df.iloc[[0]])
<class 'pandas.core.frame.DataFrame'>
```

```
>>> df.iloc[[0, 1]]
   a  b  c  d
0  1  2  3  4
1 100 200 300 400
```

With a *slice* object.

```
>>> df.iloc[:3]
   a    b    c    d
0   1    2    3    4
1  100  200  300  400
2 1000 2000 3000 4000
```

With a boolean mask the same length as the index.

```
>>> df.iloc[[True, False, True]]
   a    b    c    d
0   1    2    3    4
2 1000 2000 3000 4000
```

With a callable, useful in method chains. The *x* passed to the `lambda` is the `DataFrame` being sliced. This selects the rows whose index label even.

```
>>> df.iloc[lambda x: x.index % 2 == 0]
   a    b    c    d
0   1    2    3    4
2 1000 2000 3000 4000
```

### Indexing both axes

You can mix the indexer types for the index and columns. Use `:` to select the entire axis.

With scalar integers.

```
>>> df.iloc[0, 1]
2
```

With lists of integers.

```
>>> df.iloc[[0, 2], [1, 3]]
   b    d
0   2    4
2 2000 4000
```

With *slice* objects.

```
>>> df.iloc[1:3, 0:3]
   a    b    c
1  100  200  300
2 1000 2000 3000
```

With a boolean array whose length matches the columns.

```
>>> df.iloc[:, [True, False, True, False]]
   a    c
0   1    3
1  100  300
2 1000 3000
```

With a callable function that expects the `Series` or `DataFrame`.

```
>>> df.iloc[:, lambda df: [0, 2]]
   a    c
0   1    3
```

(continued from previous page)

|   |      |      |
|---|------|------|
| 1 | 100  | 300  |
| 2 | 1000 | 3000 |

**pandas.DataFrame.index****DataFrame.index**

The index (row labels) of the DataFrame.

**pandas.DataFrame.is\_copy****DataFrame.is\_copy**

Return the copy.

**pandas.DataFrame.ix****DataFrame.ix**

A primarily label-location based indexer, with integer position fallback.

Warning: Starting in 0.20.0, the `.ix` indexer is deprecated, in favor of the more strict `.iloc` and `.loc` indexers.

`.ix[]` supports mixed integer and label based access. It is primarily label based, but will fall back to integer positional access unless the corresponding axis is of integer type.

`.ix` is the most general indexer and will support any of the inputs in `.loc` and `.iloc`. `.ix` also supports floating point label schemes. `.ix` is exceptionally useful when dealing with mixed positional and label based hierarchical indexes.

However, when an axis is integer based, **ONLY** label based access and not positional access is supported. Thus, in such cases, it's usually better to be explicit and use `.iloc` or `.loc`.

See more at *Advanced Indexing*.

**pandas.DataFrame.loc****DataFrame.loc**

Access a group of rows and columns by label(s) or a boolean array.

`.loc[]` is primarily label based, but may also be used with a boolean array.

Allowed inputs are:

- A single label, e.g. 5 or 'a', (note that 5 is interpreted as a *label* of the index, and **never** as an integer position along the index).
- A list or array of labels, e.g. ['a', 'b', 'c'].
- A slice object with labels, e.g. 'a':'f'.

|                                                                                                                   |
|-------------------------------------------------------------------------------------------------------------------|
| <p><b>Warning:</b> Note that contrary to usual python slices, <b>both</b> the start and the stop are included</p> |
|-------------------------------------------------------------------------------------------------------------------|

- A boolean array of the same length as the axis being sliced, e.g. [True, False, True].

- A callable function with one argument (the calling Series, DataFrame or Panel) and that returns valid output for indexing (one of the above)

See more at *Selection by Label*

### Raises

**KeyError:** when any items are not found

See also:

**DataFrame.at** Access a single value for a row/column label pair.

**DataFrame.iloc** Access group of rows and columns by integer position(s).

**DataFrame.xs** Returns a cross-section (row(s) or column(s)) from the Series/DataFrame.

**Series.loc** Access group of values using labels.

## Examples

### Getting values

```
>>> df = pd.DataFrame([[1, 2], [4, 5], [7, 8]],
...                     index=['cobra', 'viper', 'sidewinder'],
...                     columns=['max_speed', 'shield'])
>>> df
```

|            | max_speed | shield |
|------------|-----------|--------|
| cobra      | 1         | 2      |
| viper      | 4         | 5      |
| sidewinder | 7         | 8      |

Single label. Note this returns the row as a Series.

```
>>> df.loc['viper']
max_speed    4
shield       5
Name: viper, dtype: int64
```

List of labels. Note using `[[]]` returns a DataFrame.

```
>>> df.loc[['viper', 'sidewinder']]
```

|            | max_speed | shield |
|------------|-----------|--------|
| viper      | 4         | 5      |
| sidewinder | 7         | 8      |

Single label for row and column

```
>>> df.loc['cobra', 'shield']
2
```

Slice with labels for row and single label for column. As mentioned above, note that both the start and stop of the slice are included.

```
>>> df.loc['cobra':'viper', 'max_speed']
cobra    1
viper    4
Name: max_speed, dtype: int64
```

Boolean list with the same length as the row axis

```
>>> df.loc[[False, False, True]]
           max_speed  shield
sidewinder           7       8
```

Conditional that returns a boolean Series

```
>>> df.loc[df['shield'] > 6]
           max_speed  shield
sidewinder           7       8
```

Conditional that returns a boolean Series with column labels specified

```
>>> df.loc[df['shield'] > 6, ['max_speed']]
           max_speed
sidewinder           7
```

Callable that returns a boolean Series

```
>>> df.loc[lambda df: df['shield'] == 8]
           max_speed  shield
sidewinder           7       8
```

### Setting values

Set value for all items matching the list of labels

```
>>> df.loc[['viper', 'sidewinder'], ['shield']] = 50
>>> df
           max_speed  shield
cobra                1       2
viper                4      50
sidewinder           7      50
```

Set value for an entire row

```
>>> df.loc['cobra'] = 10
>>> df
           max_speed  shield
cobra            10      10
viper             4      50
sidewinder         7      50
```

Set value for an entire column

```
>>> df.loc[:, 'max_speed'] = 30
>>> df
           max_speed  shield
cobra              30      10
viper              30      50
sidewinder          30      50
```

Set value for rows matching callable condition

```
>>> df.loc[df['shield'] > 35] = 0
>>> df
           max_speed  shield
cobra              30      10
```

(continues on next page)

(continued from previous page)

|            |   |   |
|------------|---|---|
| viper      | 0 | 0 |
| sidewinder | 0 | 0 |

**Getting values on a DataFrame with an index that has integer labels**

Another example using integers for the index

```
>>> df = pd.DataFrame([[1, 2], [4, 5], [7, 8]],
...                     index=[7, 8, 9], columns=['max_speed', 'shield'])
>>> df
```

|   | max_speed | shield |
|---|-----------|--------|
| 7 | 1         | 2      |
| 8 | 4         | 5      |
| 9 | 7         | 8      |

Slice with integer labels for rows. As mentioned above, note that both the start and stop of the slice are included.

```
>>> df.loc[7:9]
```

|   | max_speed | shield |
|---|-----------|--------|
| 7 | 1         | 2      |
| 8 | 4         | 5      |
| 9 | 7         | 8      |

**Getting values with a MultiIndex**

A number of examples using a DataFrame with a MultiIndex

```
>>> tuples = [
...     ('cobra', 'mark i'), ('cobra', 'mark ii'),
...     ('sidewinder', 'mark i'), ('sidewinder', 'mark ii'),
...     ('viper', 'mark ii'), ('viper', 'mark iii')
... ]
>>> index = pd.MultiIndex.from_tuples(tuples)
>>> values = [[12, 2], [0, 4], [10, 20],
...           [1, 4], [7, 1], [16, 36]]
>>> df = pd.DataFrame(values, columns=['max_speed', 'shield'], index=index)
>>> df
```

|            |          | max_speed | shield |
|------------|----------|-----------|--------|
| cobra      | mark i   | 12        | 2      |
|            | mark ii  | 0         | 4      |
| sidewinder | mark i   | 10        | 20     |
|            | mark ii  | 1         | 4      |
| viper      | mark ii  | 7         | 1      |
|            | mark iii | 16        | 36     |

Single label. Note this returns a DataFrame with a single index.

```
>>> df.loc['cobra']
```

|         | max_speed | shield |
|---------|-----------|--------|
| mark i  | 12        | 2      |
| mark ii | 0         | 4      |

Single index tuple. Note this returns a Series.

```
>>> df.loc[('cobra', 'mark ii')]
max_speed    0
```

(continues on next page)

(continued from previous page)

```
shield      4
Name: (cobra, mark ii), dtype: int64
```

Single label for row and column. Similar to passing in a tuple, this returns a Series.

```
>>> df.loc['cobra', 'mark i']
max_speed    12
shield       2
Name: (cobra, mark i), dtype: int64
```

Single tuple. Note using `[[]]` returns a DataFrame.

```
>>> df.loc[['cobra', 'mark ii']]
      max_speed  shield
cobra mark ii      0      4
```

Single tuple for the index with a single label for the column

```
>>> df.loc[('cobra', 'mark i'), 'shield']
2
```

Slice from index tuple to single label

```
>>> df.loc[('cobra', 'mark i'):'viper']
      max_speed  shield
cobra      mark i      12      2
           mark ii      0      4
sidewinder mark i      10     20
           mark ii      1      4
viper      mark ii      7      1
           mark iii     16     36
```

Slice from index tuple to index tuple

```
>>> df.loc[('cobra', 'mark i'):'viper', 'mark ii']
      max_speed  shield
cobra      mark ii      0      4
sidewinder mark ii      1      4
viper      mark ii      7      1
```

## pandas.DataFrame.ndim

`DataFrame.ndim`

Return an int representing the number of axes / array dimensions.

Return 1 if Series. Otherwise return 2 if DataFrame.

**See also:**

`ndarray.ndim` Number of array dimensions.

## Examples

```
>>> s = pd.Series({'a': 1, 'b': 2, 'c': 3})
>>> s.ndim
1
```

```
>>> df = pd.DataFrame({'col1': [1, 2], 'col2': [3, 4]})
>>> df.ndim
2
```

## pandas.DataFrame.shape

### DataFrame.shape

Return a tuple representing the dimensionality of the DataFrame.

#### See also:

`ndarray.shape`

## Examples

```
>>> df = pd.DataFrame({'col1': [1, 2], 'col2': [3, 4]})
>>> df.shape
(2, 2)
```

```
>>> df = pd.DataFrame({'col1': [1, 2], 'col2': [3, 4],
...                   'col3': [5, 6]})
>>> df.shape
(2, 3)
```

## pandas.DataFrame.size

### DataFrame.size

Return an int representing the number of elements in this object.

Return the number of rows if Series. Otherwise return the number of rows times number of columns if DataFrame.

#### See also:

**`ndarray.size`** Number of elements in the array.

## Examples

```
>>> s = pd.Series({'a': 1, 'b': 2, 'c': 3})
>>> s.size
3
```

```
>>> df = pd.DataFrame({'col1': [1, 2], 'col2': [3, 4]})
>>> df.size
4
```

## pandas.DataFrame.style

### DataFrame.style

Property returning a Styler object containing methods for building a styled HTML representation for the DataFrame.

#### See also:

`pandas.io.formats.style.Styler`

## pandas.DataFrame.values

### DataFrame.values

Return a Numpy representation of the DataFrame.

**Warning:** We recommend using `DataFrame.to_numpy()` instead.

Only the values in the DataFrame will be returned, the axes labels will be removed.

#### Returns

**numpy.ndarray** The values of the DataFrame.

#### See also:

**DataFrame.to\_numpy** Recommended alternative to this method.

**pandas.DataFrame.index** Retrieve the index labels.

**pandas.DataFrame.columns** Retrieving the column names.

## Notes

The dtype will be a lower-common-denominator dtype (implicit upcasting); that is to say if the dtypes (even of numeric types) are mixed, the one that accommodates all will be chosen. Use this with care if you are not dealing with the blocks.

e.g. If the dtypes are float16 and float32, dtype will be upcast to float32. If dtypes are int32 and uint8, dtype will be upcast to int32. By `numpy.find_common_type()` convention, mixing int64 and uint64 will result in a float64 dtype.

## Examples

A DataFrame where all columns are the same type (e.g., int64) results in an array of the same type.

```

>>> df = pd.DataFrame({'age':    [ 3,   29],
...                    'height': [94, 170],
...                    'weight': [31, 115]})
>>> df
   age  height  weight
0    3     94     31
1   29    170    115
>>> df.dtypes
age      int64

```

(continues on next page)

(continued from previous page)

```

height    int64
weight    int64
dtype: object
>>> df.values
array([[ 3,  94,  31],
       [29, 170, 115]], dtype=int64)

```

A DataFrame with mixed type columns(e.g., str/object, int64, float32) results in an ndarray of the broadest type that accommodates these mixed types (e.g., object).

```

>>> df2 = pd.DataFrame([('parrot', 24.0, 'second'),
...                      ('lion', 80.5, 1),
...                      ('monkey', np.nan, None)],
...                      columns=('name', 'max_speed', 'rank'))
>>> df2.dtypes
name          object
max_speed     float64
rank          object
dtype: object
>>> df2.values
array([['parrot', 24.0, 'second'],
       ['lion', 80.5, 1],
       ['monkey', nan, None]], dtype=object)

```

timetuple

## Methods

|                                                         |                                                                                                           |
|---------------------------------------------------------|-----------------------------------------------------------------------------------------------------------|
| <i>abs()</i>                                            | Return a Series/DataFrame with absolute numeric value of each element.                                    |
| <i>add(other[, axis, level, fill_value])</i>            | Addition of dataframe and other, element-wise (binary operator <i>add</i> ).                              |
| <i>add_prefix(prefix)</i>                               | Prefix labels with string <i>prefix</i> .                                                                 |
| <i>add_suffix(suffix)</i>                               | Suffix labels with string <i>suffix</i> .                                                                 |
| <i>agg(func[, axis])</i>                                | Aggregate using one or more operations over the specified axis.                                           |
| <i>aggregate(func[, axis])</i>                          | Aggregate using one or more operations over the specified axis.                                           |
| <i>align(other[, join, axis, level, copy, ...])</i>     | Align two objects on their axes with the specified join method for each axis Index.                       |
| <i>all([axis, bool_only, skipna, level])</i>            | Return whether all elements are True, potentially over an axis.                                           |
| <i>any([axis, bool_only, skipna, level])</i>            | Return whether any element is True, potentially over an axis.                                             |
| <i>append(other[, ignore_index, ...])</i>               | Append rows of <i>other</i> to the end of caller, returning a new object.                                 |
| <i>apply(func[, axis, broadcast, raw, reduce, ...])</i> | Apply a function along an axis of the DataFrame.                                                          |
| <i>applymap(func)</i>                                   | Apply a function to a Dataframe elementwise.                                                              |
| <i>as_blocks([copy])</i>                                | (DEPRECATED) Convert the frame to a dict of dtype -> Constructor Types that each has a homogeneous dtype. |

Table 57 – continued from previous page

|                                                            |                                                                                                                                              |
|------------------------------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------|
| <code>as_matrix([columns])</code>                          | (DEPRECATED) Convert the frame to its Numpy-array representation.                                                                            |
| <code>asfreq(freq[, method, how, normalize, ...])</code>   | Convert TimeSeries to specified frequency.                                                                                                   |
| <code>asof(where[, subset])</code>                         | Return the last row(s) without any NaNs before <i>where</i> .                                                                                |
| <code>assign(**kwargs)</code>                              | Assign new columns to a DataFrame.                                                                                                           |
| <code>astype(dtype[, copy, errors])</code>                 | Cast a pandas object to a specified dtype <code>dtype</code> .                                                                               |
| <code>at_time(time[, asof, axis])</code>                   | Select values at particular time of day (e.g.                                                                                                |
| <code>between_time(start_time, end_time[, ...])</code>     | Select values between particular times of the day (e.g., 9:00-9:30 AM).                                                                      |
| <code>bfill([axis, inplace, limit, downcast])</code>       | Synonym for <code>DataFrame.fillna()</code> with <code>method='bfill'</code> .                                                               |
| <code>bool()</code>                                        | Return the bool of a single element PandasObject.                                                                                            |
| <code>boxplot([column, by, ax, fontsize, rot, ...])</code> | Make a box plot from DataFrame columns.                                                                                                      |
| <code>clip([lower, upper, axis, inplace])</code>           | Trim values at input threshold(s).                                                                                                           |
| <code>clip_lower(threshold[, axis, inplace])</code>        | (DEPRECATED) Trim values below a given threshold.                                                                                            |
| <code>clip_upper(threshold[, axis, inplace])</code>        | (DEPRECATED) Trim values above a given threshold.                                                                                            |
| <code>combine(other, func[, fill_value, overwrite])</code> | Perform column-wise combine with another DataFrame based on a passed function.                                                               |
| <code>combine_first(other)</code>                          | Update null elements with value in the same location in <i>other</i> .                                                                       |
| <code>compound([axis, skipna, level])</code>               | Return the compound percentage of the values for the requested axis.                                                                         |
| <code>convert_objects([convert_dates, ...])</code>         | (DEPRECATED) Attempt to infer better dtype for object columns.                                                                               |
| <code>copy([deep])</code>                                  | Make a copy of this object's indices and data.                                                                                               |
| <code>corr([method, min_periods])</code>                   | Compute pairwise correlation of columns, excluding NA/null values.                                                                           |
| <code>corrwith(other[, axis, drop, method])</code>         | Compute pairwise correlation between rows or columns of DataFrame with rows or columns of Series or DataFrame.                               |
| <code>count([axis, level, numeric_only])</code>            | Count non-NA cells for each column or row.                                                                                                   |
| <code>cov([min_periods])</code>                            | Compute pairwise covariance of columns, excluding NA/null values.                                                                            |
| <code>cummax([axis, skipna])</code>                        | Return cumulative maximum over a DataFrame or Series axis.                                                                                   |
| <code>cummin([axis, skipna])</code>                        | Return cumulative minimum over a DataFrame or Series axis.                                                                                   |
| <code>cumprod([axis, skipna])</code>                       | Return cumulative product over a DataFrame or Series axis.                                                                                   |
| <code>cumsum([axis, skipna])</code>                        | Return cumulative sum over a DataFrame or Series axis.                                                                                       |
| <code>describe([percentiles, include, exclude])</code>     | Generate descriptive statistics that summarize the central tendency, dispersion and shape of a dataset's distribution, excluding NaN values. |
| <code>diff([periods, axis])</code>                         | First discrete difference of element.                                                                                                        |
| <code>div(other[, axis, level, fill_value])</code>         | Floating division of dataframe and other, element-wise (binary operator <i>truediv</i> ).                                                    |

|                                                               |                                                                                               |
|---------------------------------------------------------------|-----------------------------------------------------------------------------------------------|
| <code>divide(other[, axis, level, fill_value])</code>         | Floating division of dataframe and other, element-wise (binary operator <i>truediv</i> ).     |
| <code>dot(other)</code>                                       | Compute the matrix multiplication between the DataFrame and other.                            |
| <code>drop([labels, axis, index, columns, level, ...])</code> | Drop specified labels from rows or columns.                                                   |
| <code>drop_duplicates([subset, keep, inplace])</code>         | Return DataFrame with duplicate rows removed, optionally only considering certain columns.    |
| <code>droplevel(level[, axis])</code>                         | Return DataFrame with requested index / column level(s) removed.                              |
| <code>dropna([axis, how, thresh, subset, inplace])</code>     | Remove missing values.                                                                        |
| <code>duplicated([subset, keep])</code>                       | Return boolean Series denoting duplicate rows, optionally only considering certain columns.   |
| <code>eq(other[, axis, level])</code>                         | Equal to of dataframe and other, element-wise (binary operator <i>eq</i> ).                   |
| <code>equals(other)</code>                                    | Test whether two objects contain the same elements.                                           |
| <code>eval(expr[, inplace])</code>                            | Evaluate a string describing operations on DataFrame columns.                                 |
| <code>ewm([com, span, halflife, alpha, ...])</code>           | Provides exponential weighted functions.                                                      |
| <code>expanding([min_periods, center, axis])</code>           | Provides expanding transformations.                                                           |
| <code>ffill([axis, inplace, limit, downcast])</code>          | Synonym for <code>DataFrame.fillna()</code> with method='ffill'.                              |
| <code>fillna([value, method, axis, inplace, ...])</code>      | Fill NA/NaN values using the specified method.                                                |
| <code>filter([items, like, regex, axis])</code>               | Subset rows or columns of dataframe according to labels in the specified index.               |
| <code>first(offset)</code>                                    | Convenience method for subsetting initial periods of time series data based on a date offset. |
| <code>first_valid_index()</code>                              | Return index for first non-NA/null value.                                                     |
| <code>floordiv(other[, axis, level, fill_value])</code>       | Integer division of dataframe and other, element-wise (binary operator <i>floordiv</i> ).     |
| <code>from_csv(path[, header, sep, index_col, ...])</code>    | (DEPRECATED) Read CSV file.                                                                   |
| <code>from_dict(data[, orient, dtype, columns])</code>        | Construct DataFrame from dict of array-like or dicts.                                         |
| <code>from_items(items[, columns, orient])</code>             | (DEPRECATED) Construct a DataFrame from a list of tuples.                                     |
| <code>from_records(data[, index, exclude, ...])</code>        | Convert structured or record ndarray to DataFrame.                                            |
| <code>ge(other[, axis, level])</code>                         | Greater than or equal to of dataframe and other, element-wise (binary operator <i>ge</i> ).   |
| <code>get(key[, default])</code>                              | Get item from object for given key (DataFrame column, Panel slice, etc.).                     |
| <code>get_dtype_counts()</code>                               | Return counts of unique dtypes in this object.                                                |
| <code>get_ftype_counts()</code>                               | (DEPRECATED) Return counts of unique ftypes in this object.                                   |
| <code>get_value(index, col[, takeable])</code>                | (DEPRECATED) Quickly retrieve single value at passed column and index.                        |
| <code>get_values()</code>                                     | Return an ndarray after converting sparse values to dense.                                    |
| <code>groupby([by, axis, level, as_index, sort, ...])</code>  | Group DataFrame or Series using a mapper or by a Series of columns.                           |
| <code>gt(other[, axis, level])</code>                         | Greater than of dataframe and other, element-wise (binary operator <i>gt</i> ).               |
| <code>head([n])</code>                                        | Return the first <i>n</i> rows.                                                               |
| <code>hist([column, by, grid, xlabelsize, xrot, ...])</code>  | Make a histogram of the DataFrame's.                                                          |

Table 57 – continued from previous page

|                                                           |                                                                                                                 |
|-----------------------------------------------------------|-----------------------------------------------------------------------------------------------------------------|
| <i>idxmax</i> ([axis, skipna])                            | Return index of first occurrence of maximum over requested axis.                                                |
| <i>idxmin</i> ([axis, skipna])                            | Return index of first occurrence of minimum over requested axis.                                                |
| <i>infer_objects</i> ()                                   | Attempt to infer better dtypes for object columns.                                                              |
| <i>info</i> ([verbose, buf, max_cols, memory_usage, ...]) | Print a concise summary of a DataFrame.                                                                         |
| <i>insert</i> (loc, column, value[, allow_duplicates])    | Insert column into DataFrame at specified location.                                                             |
| <i>interpolate</i> ([method, axis, limit, inplace, ...])  | Interpolate values according to different methods.                                                              |
| <i>isin</i> (values)                                      | Whether each element in the DataFrame is contained in values.                                                   |
| <i>isna</i> ()                                            | Detect missing values.                                                                                          |
| <i>isnull</i> ()                                          | Detect missing values.                                                                                          |
| <i>items</i> ()                                           | Iterator over (column name, Series) pairs.                                                                      |
| <i>iteritems</i> ()                                       | Iterator over (column name, Series) pairs.                                                                      |
| <i>iterrows</i> ()                                        | Iterate over DataFrame rows as (index, Series) pairs.                                                           |
| <i>itertuples</i> ([index, name])                         | Iterate over DataFrame rows as namedtuples.                                                                     |
| <i>join</i> (other[, on, how, lsuffix, rsuffix, sort])    | Join columns of another DataFrame.                                                                              |
| <i>keys</i> ()                                            | Get the ‘info axis’ (see Indexing for more)                                                                     |
| <i>kurt</i> ([axis, skipna, level, numeric_only])         | Return unbiased kurtosis over requested axis using Fisher’s definition of kurtosis (kurtosis of normal == 0.0). |
| <i>kurtosis</i> ([axis, skipna, level, numeric_only])     | Return unbiased kurtosis over requested axis using Fisher’s definition of kurtosis (kurtosis of normal == 0.0). |
| <i>last</i> (offset)                                      | Convenience method for subsetting final periods of time series data based on a date offset.                     |
| <i>last_valid_index</i> ()                                | Return index for last non-NA/null value.                                                                        |
| <i>le</i> (other[, axis, level])                          | Less than or equal to of dataframe and other, element-wise (binary operator <i>le</i> ).                        |
| <i>lookup</i> (row_labels, col_labels)                    | Label-based “fancy indexing” function for DataFrame.                                                            |
| <i>lt</i> (other[, axis, level])                          | Less than of dataframe and other, element-wise (binary operator <i>lt</i> ).                                    |
| <i>mad</i> ([axis, skipna, level])                        | Return the mean absolute deviation of the values for the requested axis.                                        |
| <i>mask</i> (cond[, other, inplace, axis, level, ...])    | Replace values where the condition is True.                                                                     |
| <i>max</i> ([axis, skipna, level, numeric_only])          | Return the maximum of the values for the requested axis.                                                        |
| <i>mean</i> ([axis, skipna, level, numeric_only])         | Return the mean of the values for the requested axis.                                                           |
| <i>median</i> ([axis, skipna, level, numeric_only])       | Return the median of the values for the requested axis.                                                         |
| <i>melt</i> ([id_vars, value_vars, var_name, ...])        | Unpivots a DataFrame from wide format to long format, optionally leaving identifier variables set.              |
| <i>memory_usage</i> ([index, deep])                       | Return the memory usage of each column in bytes.                                                                |
| <i>merge</i> (right[, how, on, left_on, right_on, ...])   | Merge DataFrame or named Series objects with a database-style join.                                             |
| <i>min</i> ([axis, skipna, level, numeric_only])          | Return the minimum of the values for the requested axis.                                                        |
| <i>mod</i> (other[, axis, level, fill_value])             | Modulo of dataframe and other, element-wise (binary operator <i>mod</i> ).                                      |

|                                                                |                                                                                                                                |
|----------------------------------------------------------------|--------------------------------------------------------------------------------------------------------------------------------|
| <code>mode([axis, numeric_only, dropna])</code>                | Get the mode(s) of each element along the selected axis.                                                                       |
| <code>mul(other[, axis, level, fill_value])</code>             | Multiplication of dataframe and other, element-wise (binary operator <i>mul</i> ).                                             |
| <code>multiply(other[, axis, level, fill_value])</code>        | Multiplication of dataframe and other, element-wise (binary operator <i>mul</i> ).                                             |
| <code>ne(other[, axis, level])</code>                          | Not equal to of dataframe and other, element-wise (binary operator <i>ne</i> ).                                                |
| <code>nlargest(n, columns[, keep])</code>                      | Return the first <i>n</i> rows ordered by <i>columns</i> in descending order.                                                  |
| <code>notna()</code>                                           | Detect existing (non-missing) values.                                                                                          |
| <code>notnull()</code>                                         | Detect existing (non-missing) values.                                                                                          |
| <code>nsmallest(n, columns[, keep])</code>                     | Return the first <i>n</i> rows ordered by <i>columns</i> in ascending order.                                                   |
| <code>nunique([axis, dropna])</code>                           | Count distinct observations over requested axis.                                                                               |
| <code>pct_change([periods, fill_method, limit, freq])</code>   | Percentage change between the current and a prior element.                                                                     |
| <code>pipe(func, *args, **kwargs)</code>                       | Apply <code>func(self, *args, **kwargs)</code> .                                                                               |
| <code>pivot([index, columns, values])</code>                   | Return reshaped DataFrame organized by given index / column values.                                                            |
| <code>pivot_table([values, index, columns, ...])</code>        | Create a spreadsheet-style pivot table as a DataFrame.                                                                         |
| <code>plot</code>                                              | alias of <code>pandas.plotting._core.FramePlotMethods</code>                                                                   |
| <code>pop(item)</code>                                         | Return item and drop from frame.                                                                                               |
| <code>pow(other[, axis, level, fill_value])</code>             | Exponential power of dataframe and other, element-wise (binary operator <i>pow</i> ).                                          |
| <code>prod([axis, skipna, level, numeric_only, ...])</code>    | Return the product of the values for the requested axis.                                                                       |
| <code>product([axis, skipna, level, numeric_only, ...])</code> | Return the product of the values for the requested axis.                                                                       |
| <code>quantile([q, axis, numeric_only, interpolation])</code>  | Return values at the given quantile over requested axis.                                                                       |
| <code>query(expr[, inplace])</code>                            | Query the columns of a DataFrame with a boolean expression.                                                                    |
| <code>radd(other[, axis, level, fill_value])</code>            | Addition of dataframe and other, element-wise (binary operator <i>radd</i> ).                                                  |
| <code>rank([axis, method, numeric_only, ...])</code>           | Compute numerical data ranks (1 through <i>n</i> ) along axis.                                                                 |
| <code>rdiv(other[, axis, level, fill_value])</code>            | Floating division of dataframe and other, element-wise (binary operator <i>rtruediv</i> ).                                     |
| <code>reindex([labels, index, columns, axis, ...])</code>      | Conform DataFrame to new index with optional filling logic, placing NA/NaN in locations having no value in the previous index. |
| <code>reindex_axis(labels[, axis, method, level, ...])</code>  | (DEPRECATED) Conform input object to new index.                                                                                |
| <code>reindex_like(other[, method, copy, limit, ...])</code>   | Return an object with matching indices as other object.                                                                        |
| <code>rename([mapper, index, columns, axis, copy, ...])</code> | Alter axes labels.                                                                                                             |
| <code>rename_axis([mapper, index, columns, axis, ...])</code>  | Set the name of the axis for the index or columns.                                                                             |

Table 57 – continued from previous page

|                                                                |                                                                                            |
|----------------------------------------------------------------|--------------------------------------------------------------------------------------------|
| <code>reorder_levels(order[, axis])</code>                     | Rearrange index levels using input order.                                                  |
| <code>replace([to_replace, value, inplace, limit, ...])</code> | Replace values given in <i>to_replace</i> with <i>value</i> .                              |
| <code>resample(rule[, how, axis, fill_method, ...])</code>     | Resample time-series data.                                                                 |
| <code>reset_index([level, drop, inplace, ...])</code>          | Reset the index, or a level of it.                                                         |
| <code>rfloordiv(other[, axis, level, fill_value])</code>       | Integer division of dataframe and other, element-wise (binary operator <i>rfloordiv</i> ). |
| <code>rmod(other[, axis, level, fill_value])</code>            | Modulo of dataframe and other, element-wise (binary operator <i>rmod</i> ).                |
| <code>rmul(other[, axis, level, fill_value])</code>            | Multiplication of dataframe and other, element-wise (binary operator <i>rmul</i> ).        |
| <code>rolling(window[, min_periods, center, ...])</code>       | Provides rolling window calculations.                                                      |
| <code>round([decimals])</code>                                 | Round a DataFrame to a variable number of decimal places.                                  |
| <code>rpow(other[, axis, level, fill_value])</code>            | Exponential power of dataframe and other, element-wise (binary operator <i>rpow</i> ).     |
| <code>rsub(other[, axis, level, fill_value])</code>            | Subtraction of dataframe and other, element-wise (binary operator <i>rsub</i> ).           |
| <code>rtruediv(other[, axis, level, fill_value])</code>        | Floating division of dataframe and other, element-wise (binary operator <i>rtruediv</i> ). |
| <code>sample([n, frac, replace, weights, ...])</code>          | Return a random sample of items from an axis of object.                                    |
| <code>select(crit[, axis])</code>                              | (DEPRECATED) Return data corresponding to axis labels matching criteria.                   |
| <code>select_dtypes([include, exclude])</code>                 | Return a subset of the DataFrame's columns based on the column dtypes.                     |
| <code>sem([axis, skipna, level, ddof, numeric_only])</code>    | Return unbiased standard error of the mean over requested axis.                            |
| <code>set_axis(labels[, axis, inplace])</code>                 | Assign desired index to given axis.                                                        |
| <code>set_index(keys[, drop, append, inplace, ...])</code>     | Set the DataFrame index using existing columns.                                            |
| <code>set_value(index, col, value[, takeable])</code>          | (DEPRECATED) Put single value at passed column and index.                                  |
| <code>shift([periods, freq, axis, fill_value])</code>          | Shift index by desired number of periods with an optional time <i>freq</i> .               |
| <code>skew([axis, skipna, level, numeric_only])</code>         | Return unbiased skew over requested axis Normalized by N-1.                                |
| <code>slice_shift([periods, axis])</code>                      | Equivalent to <i>shift</i> without copying data.                                           |
| <code>sort_index([axis, level, ascending, ...])</code>         | Sort object by labels (along an axis)                                                      |
| <code>sort_values(by[, axis, ascending, inplace, ...])</code>  | Sort by the values along either axis                                                       |
| <code>squeeze([axis])</code>                                   | Squeeze 1 dimensional axis objects into scalars.                                           |
| <code>stack([level, dropna])</code>                            | Stack the prescribed level(s) from columns to index.                                       |
| <code>std([axis, skipna, level, ddof, numeric_only])</code>    | Return sample standard deviation over requested axis.                                      |
| <code>sub(other[, axis, level, fill_value])</code>             | Subtraction of dataframe and other, element-wise (binary operator <i>sub</i> ).            |
| <code>subtract(other[, axis, level, fill_value])</code>        | Subtraction of dataframe and other, element-wise (binary operator <i>sub</i> ).            |
| <code>sum([axis, skipna, level, numeric_only, ...])</code>     | Return the sum of the values for the requested axis.                                       |
| <code>swapaxes(axis1, axis2[, copy])</code>                    | Interchange axes and swap values axes appropriately.                                       |
| <code>swaplevel([i, j, axis])</code>                           | Swap levels i and j in a MultiIndex on a particular axis.                                  |
| <code>tail([n])</code>                                         | Return the last <i>n</i> rows.                                                             |

Table 57 – continued from previous page

|                                                                |                                                                                                                         |
|----------------------------------------------------------------|-------------------------------------------------------------------------------------------------------------------------|
| <code>take(indices[, axis, convert, is_copy])</code>           | Return the elements in the given <i>positional</i> indices along an axis.                                               |
| <code>to_clipboard([excel, sep])</code>                        | Copy object to the system clipboard.                                                                                    |
| <code>to_csv([path_or_buf, sep, na_rep, ...])</code>           | Write object to a comma-separated values (csv) file.                                                                    |
| <code>to_dense()</code>                                        | Return dense representation of NDFrame (as opposed to sparse).                                                          |
| <code>to_dict([orient, into])</code>                           | Convert the DataFrame to a dictionary.                                                                                  |
| <code>to_excel(excel_writer[, sheet_name, na_rep, ...])</code> | Write object to an Excel sheet.                                                                                         |
| <code>to_feather(fname)</code>                                 | Write out the binary feather-format for DataFrames.                                                                     |
| <code>to_gbq(destination_table[, project_id, ...])</code>      | Write a DataFrame to a Google BigQuery table.                                                                           |
| <code>to_hdf(path_or_buf, key, **kwargs)</code>                | Write the contained data to an HDF5 file using HDF-Store.                                                               |
| <code>to_html([buf, columns, col_space, header, ...])</code>   | Render a DataFrame as an HTML table.                                                                                    |
| <code>to_json([path_or_buf, orient, date_format, ...])</code>  | Convert the object to a JSON string.                                                                                    |
| <code>to_latex([buf, columns, col_space, header, ...])</code>  | Render an object to a LaTeX tabular environment table.                                                                  |
| <code>to_msgpack([path_or_buf, encoding])</code>               | Serialize object to input file path using msgpack format.                                                               |
| <code>to_numpy([dtype, copy])</code>                           | Convert the DataFrame to a NumPy array.                                                                                 |
| <code>to_panel()</code>                                        | (DEPRECATED) Transform long (stacked) format (DataFrame) into wide (3D, Panel) format.                                  |
| <code>to_parquet(fname[, engine, compression, ...])</code>     | Write a DataFrame to the binary parquet format.                                                                         |
| <code>to_period([freq, axis, copy])</code>                     | Convert DataFrame from DatetimeIndex to PeriodIndex with desired frequency (inferred from index if not passed).         |
| <code>to_pickle(path[, compression, protocol])</code>          | Pickle (serialize) object to file.                                                                                      |
| <code>to_records([index, convert_datetime64, ...])</code>      | Convert DataFrame to a NumPy record array.                                                                              |
| <code>to_sparse([fill_value, kind])</code>                     | Convert to SparseDataFrame.                                                                                             |
| <code>to_sql(name, con[, schema, if_exists, ...])</code>       | Write records stored in a DataFrame to a SQL database.                                                                  |
| <code>to_stata(fname[, convert_dates, ...])</code>             | Export DataFrame object to Stata dta format.                                                                            |
| <code>to_string([buf, columns, col_space, header, ...])</code> | Render a DataFrame to a console-friendly tabular output.                                                                |
| <code>to_timestamp([freq, how, axis, copy])</code>             | Cast to DatetimeIndex of timestamps, at <i>beginning</i> of period.                                                     |
| <code>to_xarray()</code>                                       | Return an xarray object from the pandas object.                                                                         |
| <code>transform(func[, axis])</code>                           | Call <code>func</code> on self producing a DataFrame with transformed values and that has the same axis length as self. |
| <code>transpose(*args, **kwargs)</code>                        | Transpose index and columns.                                                                                            |
| <code>truediv(other[, axis, level, fill_value])</code>         | Floating division of dataframe and other, element-wise (binary operator <i>truediv</i> ).                               |
| <code>truncate([before, after, axis, copy])</code>             | Truncate a Series or DataFrame before and after some index value.                                                       |
| <code>tshift([periods, freq, axis])</code>                     | Shift the time index, using the index's frequency if available.                                                         |
| <code>tz_convert(tz[, axis, level, copy])</code>               | Convert tz-aware axis to target time zone.                                                                              |
| <code>tz_localize(tz[, axis, level, copy, ...])</code>         | Localize tz-naive index of a Series or DataFrame to target time zone.                                                   |

Table 57 – continued from previous page

|                                                              |                                                                                                                                                                                      |
|--------------------------------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>unstack([level, fill_value])</code>                    | Pivot a level of the (necessarily hierarchical) index labels, returning a DataFrame having a new level of column labels whose inner-most level consists of the pivoted index labels. |
| <code>update(other[, join, overwrite, ...])</code>           | Modify in place using non-NA values from another DataFrame.                                                                                                                          |
| <code>var([axis, skipna, level, ddof, numeric_only])</code>  | Return unbiased variance over requested axis.                                                                                                                                        |
| <code>where(cond[, other, inplace, axis, level, ...])</code> | Replace values where the condition is False.                                                                                                                                         |
| <code>xs(key[, axis, level, drop_level])</code>              | Return cross-section from the Series/DataFrame.                                                                                                                                      |

**pandas.DataFrame.abs**`DataFrame.abs()`

Return a Series/DataFrame with absolute numeric value of each element.

This function only applies to elements that are all numeric.

**Returns****abs** Series/DataFrame containing the absolute value of each element.**See also:**`numpy.absolute` Calculate the absolute value element-wise.**Notes**For complex inputs,  $1.2 + 1j$ , the absolute value is  $\sqrt{a^2 + b^2}$ .**Examples**

Absolute numeric values in a Series.

```
>>> s = pd.Series([-1.10, 2, -3.33, 4])
>>> s.abs()
0    1.10
1    2.00
2    3.33
3    4.00
dtype: float64
```

Absolute numeric values in a Series with complex numbers.

```
>>> s = pd.Series([1.2 + 1j])
>>> s.abs()
0    1.56205
dtype: float64
```

Absolute numeric values in a Series with a Timedelta element.

```
>>> s = pd.Series([pd.Timedelta('1 days')])
>>> s.abs()
0    1 days
dtype: timedelta64[ns]
```

Select rows with data closest to certain value using `argsort` (from [StackOverflow](#)).

```
>>> df = pd.DataFrame({
...     'a': [4, 5, 6, 7],
...     'b': [10, 20, 30, 40],
...     'c': [100, 50, -30, -50]
... })
>>> df
   a  b  c
0  4 10 100
1  5 20  50
2  6 30 -30
3  7 40 -50
>>> df.loc[(df.c - 43).abs().argsort()]
   a  b  c
1  5 20  50
0  4 10 100
2  6 30 -30
3  7 40 -50
```

## pandas.DataFrame.add

`DataFrame.add` (*other*, *axis*='columns', *level*=None, *fill\_value*=None)

Addition of dataframe and other, element-wise (binary operator *add*).

Equivalent to `dataframe + other`, but with support to substitute a *fill\_value* for missing data in one of the inputs. With reverse version, *radd*.

Among flexible wrappers (*add*, *sub*, *mul*, *div*, *mod*, *pow*) to arithmetic operators: `+`, `-`, `*`, `/`, `//`, `%`, `**`.

### Parameters

**other** [scalar, sequence, Series, or DataFrame] Any single or multiple element data structure, or list-like object.

**axis** [{0 or 'index', 1 or 'columns'}] Whether to compare by the index (0 or 'index') or columns (1 or 'columns'). For Series input, axis to match Series index on.

**level** [int or label] Broadcast across a level, matching Index values on the passed Multi-Index level.

**fill\_value** [float or None, default None] Fill existing missing (NaN) values, and any new element needed for successful DataFrame alignment, with this value before computation. If data in both corresponding DataFrame locations is missing the result will be missing.

### Returns

**DataFrame** Result of the arithmetic operation.

See also:

**DataFrame.add** Add DataFrames.

**DataFrame.sub** Subtract DataFrames.

**DataFrame.mul** Multiply DataFrames.

**DataFrame.div** Divide DataFrames (float division).

**DataFrame.truediv** Divide DataFrames (float division).

**DataFrame.floordiv** Divide DataFrames (integer division).

**DataFrame.mod** Calculate modulo (remainder after division).

**DataFrame.pow** Calculate exponential power.

## Notes

Mismatched indices will be unioned together.

## Examples

```
>>> df = pd.DataFrame({'angles': [0, 3, 4],
...                     'degrees': [360, 180, 360]},
...                     index=['circle', 'triangle', 'rectangle'])
>>> df
```

|           | angles | degrees |
|-----------|--------|---------|
| circle    | 0      | 360     |
| triangle  | 3      | 180     |
| rectangle | 4      | 360     |

Add a scalar with operator version which return the same results.

```
>>> df + 1
```

|           | angles | degrees |
|-----------|--------|---------|
| circle    | 1      | 361     |
| triangle  | 4      | 181     |
| rectangle | 5      | 361     |

```
>>> df.add(1)
```

|           | angles | degrees |
|-----------|--------|---------|
| circle    | 1      | 361     |
| triangle  | 4      | 181     |
| rectangle | 5      | 361     |

Divide by constant with reverse version.

```
>>> df.div(10)
```

|           | angles | degrees |
|-----------|--------|---------|
| circle    | 0.0    | 36.0    |
| triangle  | 0.3    | 18.0    |
| rectangle | 0.4    | 36.0    |

```
>>> df.rdiv(10)
```

|           | angles   | degrees  |
|-----------|----------|----------|
| circle    | inf      | 0.027778 |
| triangle  | 3.333333 | 0.055556 |
| rectangle | 2.500000 | 0.027778 |

Subtract a list and Series by axis with operator version.

```
>>> df - [1, 2]
```

|           | angles | degrees |
|-----------|--------|---------|
| circle    | -1     | 358     |
| triangle  | 2      | 178     |
| rectangle | 3      | 358     |

```
>>> df.sub([1, 2], axis='columns')
          angles  degrees
circle         -1     358
triangle        2     178
rectangle       3     358
```

```
>>> df.sub(pd.Series([1, 1, 1], index=['circle', 'triangle', 'rectangle']),
...        axis='index')
          angles  degrees
circle         -1     359
triangle        2     179
rectangle       3     359
```

Multiply a DataFrame of different shape with operator version.

```
>>> other = pd.DataFrame({'angles': [0, 3, 4]},
...                       index=['circle', 'triangle', 'rectangle'])
>>> other
          angles
circle         0
triangle        3
rectangle       4
```

```
>>> df * other
          angles  degrees
circle         0      NaN
triangle        9      NaN
rectangle       16      NaN
```

```
>>> df.mul(other, fill_value=0)
          angles  degrees
circle         0      0.0
triangle        9      0.0
rectangle       16      0.0
```

Divide by a MultiIndex by level.

```
>>> df_multindex = pd.DataFrame({'angles': [0, 3, 4, 4, 5, 6],
...                               'degrees': [360, 180, 360, 360, 540, 720]},
...                              index=[['A', 'A', 'A', 'B', 'B', 'B'],
...                                     ['circle', 'triangle', 'rectangle',
...                                      'square', 'pentagon', 'hexagon']])
>>> df_multindex
          angles  degrees
A circle         0     360
  triangle        3     180
  rectangle        4     360
B square         4     360
  pentagon        5     540
  hexagon         6     720
```

```
>>> df.div(df_multindex, level=1, fill_value=0)
          angles  degrees
A circle      NaN      1.0
  triangle    1.0      1.0
  rectangle    1.0      1.0
```

(continues on next page)

(continued from previous page)

|          |     |     |
|----------|-----|-----|
| B square | 0.0 | 0.0 |
| pentagon | 0.0 | 0.0 |
| hexagon  | 0.0 | 0.0 |

**pandas.DataFrame.add\_prefix**`DataFrame.add_prefix` (*prefix*)Prefix labels with string *prefix*.

For Series, the row labels are prefixed. For DataFrame, the column labels are prefixed.

**Parameters****prefix** [str] The string to add before each label.**Returns****Series or DataFrame** New Series or DataFrame with updated labels.**See also:****`Series.add_suffix`** Suffix row labels with string *suffix*.**`DataFrame.add_suffix`** Suffix column labels with string *suffix*.**Examples**

```
>>> s = pd.Series([1, 2, 3, 4])
>>> s
0    1
1    2
2    3
3    4
dtype: int64
```

```
>>> s.add_prefix('item_')
item_0    1
item_1    2
item_2    3
item_3    4
dtype: int64
```

```
>>> df = pd.DataFrame({'A': [1, 2, 3, 4], 'B': [3, 4, 5, 6]})
>>> df
   A  B
0  1  3
1  2  4
2  3  5
3  4  6
```

```
>>> df.add_prefix('col_')
   col_A  col_B
0      1      3
1      2      4
```

## **pandas.DataFrame.add\_suffix**

`DataFrame.add_suffix(suffix)`

Suffix labels with string *suffix*.

For Series, the row labels are suffixed. For DataFrame, the column labels are suffixed.

### **Parameters**

**suffix** [str] The string to add after each label.

### **Returns**

**Series or DataFrame** New Series or DataFrame with updated labels.

**See also:**

***Series.add\_prefix*** Prefix row labels with string *prefix*.

***DataFrame.add\_prefix*** Prefix column labels with string *prefix*.

## **Examples**

```
>>> s = pd.Series([1, 2, 3, 4])
>>> s
0    1
1    2
2    3
3    4
dtype: int64
```

```
>>> s.add_suffix('_item')
0_item    1
1_item    2
2_item    3
3_item    4
dtype: int64
```

```
>>> df = pd.DataFrame({'A': [1, 2, 3, 4], 'B': [3, 4, 5, 6]})
>>> df
   A  B
0  1  3
1  2  4
2  3  5
3  4  6
```

```
>>> df.add_suffix('_col')
   A_col  B_col
0     1     3
1     2     4
2     3     5
3     4     6
```

**pandas.DataFrame.agg**`DataFrame.agg` (*func*, *axis=0*, *\*args*, *\*\*kwargs*)

Aggregate using one or more operations over the specified axis.

New in version 0.20.0.

**Parameters****func** [function, str, list or dict] Function to use for aggregating the data. If a function, must either work when passed a DataFrame or when passed to DataFrame.apply.

Accepted combinations are:

- function
- string function name
- list of functions and/or function names, e.g. `[np.sum, 'mean']`
- dict of axis labels -> functions, function names or list of such.

**axis** [{0 or 'index', 1 or 'columns'}, default 0] If 0 or 'index': apply function to each column. If 1 or 'columns': apply function to each row.**\*args** Positional arguments to pass to *func*.**\*\*kwargs** Keyword arguments to pass to *func*.**Returns****DataFrame, Series or scalar** if DataFrame.agg is called with a single function, returns a Series if DataFrame.agg is called with several functions, returns a DataFrame if Series.agg is called with single function, returns a scalar if Series.agg is called with several functions, returns a Series

The aggregation operations are always performed over an axis, either the index (default) or the column axis. This behavior is different from 'numpy' aggregation functions ('mean', 'median', 'prod', 'sum', 'std', 'var'), where the default is to compute the aggregation of the flattened array, e.g., `"numpy.mean(arr_2d)"` as opposed to `"numpy.mean(arr_2d, axis=0)"`.

'agg' is an alias for 'aggregate'. Use the alias.

See also:

**DataFrame.apply** Perform any type of operations.**DataFrame.transform** Perform transformation type operations.**pandas.core.groupby.GroupBy** Perform operations over groups.**pandas.core.resample.Resampler** Perform operations over resampled bins.**pandas.core.window.Rolling** Perform operations over rolling window.**pandas.core.window.Expanding** Perform operations over expanding window.**pandas.core.window.EWM** Perform operation over exponential weighted window.

## Notes

*agg* is an alias for *aggregate*. Use the alias.

A passed user-defined-function will be passed a Series for evaluation.

## Examples

```
>>> df = pd.DataFrame([[1, 2, 3],
...                    [4, 5, 6],
...                    [7, 8, 9],
...                    [np.nan, np.nan, np.nan]],
...                   columns=['A', 'B', 'C'])
```

Aggregate these functions over the rows.

```
>>> df.agg(['sum', 'min'])
      A      B      C
sum  12.0  15.0  18.0
min   1.0   2.0   3.0
```

Different aggregations per column.

```
>>> df.agg({'A' : ['sum', 'min'], 'B' : ['min', 'max']})
      A      B
max   NaN   8.0
min   1.0   2.0
sum  12.0   NaN
```

Aggregate over the columns.

```
>>> df.agg("mean", axis="columns")
0      2.0
1      5.0
2      8.0
3      NaN
dtype: float64
```

## pandas.DataFrame.aggregate

`DataFrame.aggregate` (*func*, *axis=0*, *\*args*, *\*\*kwargs*)

Aggregate using one or more operations over the specified axis.

New in version 0.20.0.

### Parameters

**func** [function, str, list or dict] Function to use for aggregating the data. If a function, must either work when passed a DataFrame or when passed to DataFrame.apply.

Accepted combinations are:

- function
- string function name
- list of functions and/or function names, e.g. `[np.sum, 'mean']`

- dict of axis labels -> functions, function names or list of such.

**axis** [{0 or 'index', 1 or 'columns'}, default 0] If 0 or 'index': apply function to each column. If 1 or 'columns': apply function to each row.

**\*args** Positional arguments to pass to *func*.

**\*\*kwargs** Keyword arguments to pass to *func*.

### Returns

**DataFrame, Series or scalar** if DataFrame.agg is called with a single function, returns a Series if DataFrame.agg is called with several functions, returns a DataFrame if Series.agg is called with single function, returns a scalar if Series.agg is called with several functions, returns a Series

The aggregation operations are always performed over an axis, either the index (default) or the column axis. This behavior is different from 'numpy' aggregation functions ('mean', 'median', 'prod', 'sum', 'std', 'var'), where the default is to compute the aggregation of the flattened array, e.g., "numpy.mean(arr\_2d)" as opposed to "numpy.mean(arr\_2d, axis=0)".

'agg' is an alias for 'aggregate'. Use the alias.

See also:

**DataFrame.apply** Perform any type of operations.

**DataFrame.transform** Perform transformation type operations.

**pandas.core.groupby.GroupBy** Perform operations over groups.

**pandas.core.resample.Resampler** Perform operations over resampled bins.

**pandas.core.window.Rolling** Perform operations over rolling window.

**pandas.core.window.Expanding** Perform operations over expanding window.

**pandas.core.window.EWM** Perform operation over exponential weighted window.

### Notes

agg is an alias for aggregate. Use the alias.

A passed user-defined-function will be passed a Series for evaluation.

### Examples

```
>>> df = pd.DataFrame([[1, 2, 3],
...                    [4, 5, 6],
...                    [7, 8, 9],
...                    [np.nan, np.nan, np.nan]],
...                   columns=['A', 'B', 'C'])
```

Aggregate these functions over the rows.

```
>>> df.agg(['sum', 'min'])
      A      B      C
sum  12.0  15.0  18.0
min   1.0   2.0   3.0
```

Different aggregations per column.

```
>>> df.agg({'A' : ['sum', 'min'], 'B' : ['min', 'max']})
      A      B
max   NaN   8.0
min    1.0   2.0
sum   12.0   NaN
```

Aggregate over the columns.

```
>>> df.agg("mean", axis="columns")
0      2.0
1      5.0
2      8.0
3      NaN
dtype: float64
```

## pandas.DataFrame.align

`DataFrame.align(other, join='outer', axis=None, level=None, copy=True, fill_value=None, method=None, limit=None, fill_axis=0, broadcast_axis=None)`

Align two objects on their axes with the specified join method for each axis Index.

### Parameters

**other** [DataFrame or Series]

**join** [{‘outer’, ‘inner’, ‘left’, ‘right’}, default ‘outer’]

**axis** [allowed axis of the other object, default None] Align on index (0), columns (1), or both (None)

**level** [int or level name, default None] Broadcast across a level, matching Index values on the passed MultiIndex level

**copy** [boolean, default True] Always returns new objects. If copy=False and no reindexing is required then original objects are returned.

**fill\_value** [scalar, default np.NaN] Value to use for missing values. Defaults to NaN, but can be any “compatible” value

**method** [{‘backfill’, ‘bfill’, ‘pad’, ‘ffill’, None}, default None] Method to use for filling holes in reindexed Series pad / ffill: propagate last valid observation forward to next valid backfill / bfill: use NEXT valid observation to fill gap

**limit** [int, default None] If method is specified, this is the maximum number of consecutive NaN values to forward/backward fill. In other words, if there is a gap with more than this number of consecutive NaNs, it will only be partially filled. If method is not specified, this is the maximum number of entries along the entire axis where NaNs will be filled. Must be greater than 0 if not None.

**fill\_axis** [{0 or ‘index’, 1 or ‘columns’}, default 0] Filling axis, method and limit

**broadcast\_axis** [{0 or 'index', 1 or 'columns'}, default None] Broadcast values along this axis, if aligning two objects of different dimensions

### Returns

**(left, right)** [(DataFrame, type of other)] Aligned objects

## pandas.DataFrame.all

`DataFrame.all` (*axis=0, bool\_only=None, skipna=True, level=None, \*\*kwargs*)

Return whether all elements are True, potentially over an axis.

Returns True unless there at least one element within a series or along a Dataframe axis that is False or equivalent (e.g. zero or empty).

### Parameters

**axis** [{0 or 'index', 1 or 'columns', None}, default 0] Indicate which axis or axes should be reduced.

- 0 / 'index' : reduce the index, return a Series whose index is the original column labels.
- 1 / 'columns' : reduce the columns, return a Series whose index is the original index.
- None : reduce all axes, return a scalar.

**bool\_only** [bool, default None] Include only boolean columns. If None, will attempt to use everything, then use only boolean data. Not implemented for Series.

**skipna** [bool, default True] Exclude NA/null values. If the entire row/column is NA and skipna is True, then the result will be True, as for an empty row/column. If skipna is False, then NA are treated as True, because these are not equal to zero.

**level** [int or level name, default None] If the axis is a MultiIndex (hierarchical), count along a particular level, collapsing into a Series.

**\*\*kwargs** [any, default None] Additional keywords have no effect but might be accepted for compatibility with NumPy.

### Returns

**Series or DataFrame** If level is specified, then, DataFrame is returned; otherwise, Series is returned.

### See also:

**Series.all** Return True if all elements are True.

**DataFrame.any** Return True if one (or more) elements are True.

## Examples

### Series

```
>>> pd.Series([True, True]).all()
True
>>> pd.Series([True, False]).all()
False
```

(continues on next page)

(continued from previous page)

```
>>> pd.Series([]).all()
True
>>> pd.Series([np.nan]).all()
True
>>> pd.Series([np.nan]).all(skipna=False)
True
```

## DataFrames

Create a dataframe from a dictionary.

```
>>> df = pd.DataFrame({'col1': [True, True], 'col2': [True, False]})
>>> df
   col1  col2
0  True   True
1  True  False
```

Default behaviour checks if column-wise values all return True.

```
>>> df.all()
col1    True
col2   False
dtype: bool
```

Specify `axis='columns'` to check if row-wise values all return True.

```
>>> df.all(axis='columns')
0    True
1   False
dtype: bool
```

Or `axis=None` for whether every value is True.

```
>>> df.all(axis=None)
False
```

## pandas.DataFrame.any

`DataFrame.any` (*axis=0*, *bool\_only=None*, *skipna=True*, *level=None*, *\*\*kwargs*)

Return whether any element is True, potentially over an axis.

Returns False unless there at least one element within a series or along a Dataframe axis that is True or equivalent (e.g. non-zero or non-empty).

### Parameters

**axis** [{0 or 'index', 1 or 'columns', None}, default 0] Indicate which axis or axes should be reduced.

- 0 / 'index' : reduce the index, return a Series whose index is the original column labels.
- 1 / 'columns' : reduce the columns, return a Series whose index is the original index.
- None : reduce all axes, return a scalar.

**bool\_only** [bool, default None] Include only boolean columns. If None, will attempt to use everything, then use only boolean data. Not implemented for Series.

**skipna** [bool, default True] Exclude NA/null values. If the entire row/column is NA and skipna is True, then the result will be False, as for an empty row/column. If skipna is False, then NA are treated as True, because these are not equal to zero.

**level** [int or level name, default None] If the axis is a MultiIndex (hierarchical), count along a particular level, collapsing into a Series.

**\*\*kwargs** [any, default None] Additional keywords have no effect but might be accepted for compatibility with NumPy.

### Returns

**Series or DataFrame** If level is specified, then, DataFrame is returned; otherwise, Series is returned.

See also:

**numpy.any** Numpy version of this method.

**Series.any** Return whether any element is True.

**Series.all** Return whether all elements are True.

**DataFrame.any** Return whether any element is True over requested axis.

**DataFrame.all** Return whether all elements are True over requested axis.

## Examples

### Series

For Series input, the output is a scalar indicating whether any element is True.

```
>>> pd.Series([False, False]).any()
False
>>> pd.Series([True, False]).any()
True
>>> pd.Series([]).any()
False
>>> pd.Series([np.nan]).any()
False
>>> pd.Series([np.nan]).any(skipna=False)
True
```

### DataFrame

Whether each column contains at least one True element (the default).

```
>>> df = pd.DataFrame({"A": [1, 2], "B": [0, 2], "C": [0, 0]})
>>> df
   A  B  C
0  1  0  0
1  2  2  0
```

```
>>> df.any()
A    True
B    True
```

(continues on next page)

(continued from previous page)

```
C    False
dtype: bool
```

Aggregating over the columns.

```
>>> df = pd.DataFrame({"A": [True, False], "B": [1, 2]})
>>> df
   A  B
0  True  1
1  False 2
```

```
>>> df.any(axis='columns')
0    True
1    True
dtype: bool
```

```
>>> df = pd.DataFrame({"A": [True, False], "B": [1, 0]})
>>> df
   A  B
0  True  1
1  False 0
```

```
>>> df.any(axis='columns')
0    True
1    False
dtype: bool
```

Aggregating over the entire DataFrame with `axis=None`.

```
>>> df.any(axis=None)
True
```

`any` for an empty DataFrame is an empty Series.

```
>>> pd.DataFrame([]).any()
Series([], dtype: bool)
```

## pandas.DataFrame.append

`DataFrame.append(other, ignore_index=False, verify_integrity=False, sort=None)`

Append rows of *other* to the end of caller, returning a new object.

Columns in *other* that are not in the caller are added as new columns.

### Parameters

**other** [DataFrame or Series/dict-like object, or list of these] The data to append.

**ignore\_index** [boolean, default False] If True, do not use the index labels.

**verify\_integrity** [boolean, default False] If True, raise `ValueError` on creating index with duplicates.

**sort** [boolean, default None] Sort columns if the columns of *self* and *other* are not aligned. The default sorting is deprecated and will change to not-sorting in a fu-

ture version of pandas. Explicitly pass `sort=True` to silence the warning and sort. Explicitly pass `sort=False` to silence the warning and not sort.

New in version 0.23.0.

### Returns

**appended** [DataFrame]

### See also:

**`pandas.concat`** General function to concatenate DataFrame, Series or Panel objects.

### Notes

If a list of dict/series is passed and the keys are all contained in the DataFrame's index, the order of the columns in the resulting DataFrame will be unchanged.

Iteratively appending rows to a DataFrame can be more computationally intensive than a single concatenate. A better solution is to append those rows to a list and then concatenate the list with the original DataFrame all at once.

### Examples

```
>>> df = pd.DataFrame([[1, 2], [3, 4]], columns=list('AB'))
>>> df
   A  B
0  1  2
1  3  4
>>> df2 = pd.DataFrame([[5, 6], [7, 8]], columns=list('AB'))
>>> df.append(df2)
   A  B
0  1  2
1  3  4
0  5  6
1  7  8
```

With `ignore_index` set to `True`:

```
>>> df.append(df2, ignore_index=True)
   A  B
0  1  2
1  3  4
2  5  6
3  7  8
```

The following, while not recommended methods for generating DataFrames, show two ways to generate a DataFrame from multiple data sources.

Less efficient:

```
>>> df = pd.DataFrame(columns=['A'])
>>> for i in range(5):
...     df = df.append({'A': i}, ignore_index=True)
>>> df
   A
0  0
```

(continues on next page)

(continued from previous page)

```
1  1
2  2
3  3
4  4
```

More efficient:

```
>>> pd.concat([pd.DataFrame([i], columns=['A']) for i in range(5)],
...            ignore_index=True)
   A
0  0
1  1
2  2
3  3
4  4
```

## pandas.DataFrame.apply

**DataFrame.apply** (*func*, *axis=0*, *broadcast=None*, *raw=False*, *reduce=None*, *result\_type=None*, *args=()*, *\*\*kwargs*)

Apply a function along an axis of the DataFrame.

Objects passed to the function are Series objects whose index is either the DataFrame's index (*axis=0*) or the DataFrame's columns (*axis=1*). By default (*result\_type=None*), the final return type is inferred from the return type of the applied function. Otherwise, it depends on the *result\_type* argument.

### Parameters

**func** [function] Function to apply to each column or row.

**axis** [{0 or 'index', 1 or 'columns'}, default 0] Axis along which the function is applied:

- 0 or 'index': apply function to each column.
- 1 or 'columns': apply function to each row.

**broadcast** [bool, optional] Only relevant for aggregation functions:

- `False` or `None` : returns a Series whose length is the length of the index or the number of columns (based on the *axis* parameter)
- `True` : results will be broadcast to the original shape of the frame, the original index and columns will be retained.

Deprecated since version 0.23.0: This argument will be removed in a future version, replaced by *result\_type='broadcast'*.

**raw** [bool, default False]

- `False` : passes each row or column as a Series to the function.
- `True` : the passed function will receive ndarray objects instead. If you are just applying a NumPy reduction function this will achieve much better performance.

**reduce** [bool or None, default None] Try to apply reduction procedures. If the DataFrame is empty, *apply* will use *reduce* to determine whether the result should be a Series or a DataFrame. If *reduce=None* (the default), *apply*'s return value will be guessed by calling *func* on an empty Series (note: while guessing, exceptions raised by *func* will be ignored). If *reduce=True* a Series will always be returned, and if *reduce=False* a DataFrame will always be returned.

Deprecated since version 0.23.0: This argument will be removed in a future version, replaced by `result_type='reduce'`.

**result\_type** [{‘expand’, ‘reduce’, ‘broadcast’, None}, default None] These only act when `axis=1` (columns):

- ‘expand’ : list-like results will be turned into columns.
- ‘reduce’ : returns a Series if possible rather than expanding list-like results. This is the opposite of ‘expand’.
- ‘broadcast’ : results will be broadcast to the original shape of the DataFrame, the original index and columns will be retained.

The default behaviour (None) depends on the return value of the applied function: list-like results will be returned as a Series of those. However if the apply function returns a Series these are expanded to columns.

New in version 0.23.0.

**args** [tuple] Positional arguments to pass to *func* in addition to the array/series.

**\*\*kwargs** Additional keyword arguments to pass as keywords arguments to *func*.

### Returns

**applied** [Series or DataFrame]

See also:

**DataFrame.applymap** For elementwise operations.

**DataFrame.aggregate** Only perform aggregating type operations.

**DataFrame.transform** Only perform transforming type operations.

### Notes

In the current implementation `apply` calls *func* twice on the first column/row to decide whether it can take a fast or slow code path. This can lead to unexpected behavior if *func* has side-effects, as they will take effect twice for the first column/row.

### Examples

```
>>> df = pd.DataFrame([[4, 9],] * 3, columns=['A', 'B'])
>>> df
   A  B
0  4  9
1  4  9
2  4  9
```

Using a numpy universal function (in this case the same as `np.sqrt(df)`):

```
>>> df.apply(np.sqrt)
   A  B
0  2.0  3.0
1  2.0  3.0
2  2.0  3.0
```

Using a reducing function on either axis

```
>>> df.apply(np.sum, axis=0)
A    12
B    27
dtype: int64
```

```
>>> df.apply(np.sum, axis=1)
0    13
1    13
2    13
dtype: int64
```

Returning a list-like will result in a Series

```
>>> df.apply(lambda x: [1, 2], axis=1)
0    [1, 2]
1    [1, 2]
2    [1, 2]
dtype: object
```

Passing `result_type='expand'` will expand list-like results to columns of a DataFrame

```
>>> df.apply(lambda x: [1, 2], axis=1, result_type='expand')
   0  1
0  1  2
1  1  2
2  1  2
```

Returning a Series inside the function is similar to passing `result_type='expand'`. The resulting column names will be the Series index.

```
>>> df.apply(lambda x: pd.Series([1, 2], index=['foo', 'bar']), axis=1)
   foo  bar
0    1    2
1    1    2
2    1    2
```

Passing `result_type='broadcast'` will ensure the same shape result, whether list-like or scalar is returned by the function, and broadcast it along the axis. The resulting column names will be the originals.

```
>>> df.apply(lambda x: [1, 2], axis=1, result_type='broadcast')
   A  B
0  1  2
1  1  2
2  1  2
```

## pandas.DataFrame.applymap

`DataFrame.applymap(func)`

Apply a function to a DataFrame elementwise.

This method applies a function that accepts and returns a scalar to every element of a DataFrame.

### Parameters

**func** [callable] Python function, returns a single value from a single value.

### Returns

**DataFrame** Transformed DataFrame.

See also:

**DataFrame.apply** Apply a function along input axis of DataFrame.

## Notes

In the current implementation `applymap` calls *func* twice on the first column/row to decide whether it can take a fast or slow code path. This can lead to unexpected behavior if *func* has side-effects, as they will take effect twice for the first column/row.

## Examples

```
>>> df = pd.DataFrame([[1, 2.12], [3.356, 4.567]])
>>> df
   0      1
0  1.000  2.120
1  3.356  4.567
```

```
>>> df.applymap(lambda x: len(str(x)))
   0  1
0  3  4
1  5  5
```

Note that a vectorized version of *func* often exists, which will be much faster. You could square each number elementwise.

```
>>> df.applymap(lambda x: x**2)
   0      1
0  1.000000  4.494400
1  11.262736  20.857489
```

But it's better to avoid `applymap` in that case.

```
>>> df ** 2
   0      1
0  1.000000  4.494400
1  11.262736  20.857489
```

## pandas.DataFrame.as\_blocks

`DataFrame.as_blocks(copy=True)`

Convert the frame to a dict of dtype -> Constructor Types that each has a homogeneous dtype.

Deprecated since version 0.21.0.

**NOTE: the dtypes of the blocks WILL BE PRESERVED HERE (unlike in `as_matrix`)**

### Parameters

**copy** [boolean, default True]

### Returns

**values** [a dict of dtype -> Constructor Types]

### pandas.DataFrame.as\_matrix

`DataFrame.as_matrix(columns=None)`

Convert the frame to its Numpy-array representation.

Deprecated since version 0.23.0: Use `DataFrame.values()` instead.

#### Parameters

**columns** [list, optional, default:None] If None, return all columns, otherwise, returns specified columns.

#### Returns

**values** [ndarray] If the caller is heterogeneous and contains booleans or objects, the result will be of dtype=object. See Notes.

#### See also:

`DataFrame.values`

#### Notes

Return is NOT a Numpy-matrix, rather, a Numpy-array.

The dtype will be a lower-common-denominator dtype (implicit upcasting); that is to say if the dtypes (even of numeric types) are mixed, the one that accommodates all will be chosen. Use this with care if you are not dealing with the blocks.

e.g. If the dtypes are float16 and float32, dtype will be upcast to float32. If dtypes are int32 and uint8, dtype will be upcase to int32. By `numpy.find_common_type` convention, mixing int64 and uint64 will result in a float64 dtype.

This method is provided for backwards compatibility. Generally, it is recommended to use `‘.values’`.

### pandas.DataFrame.asfreq

`DataFrame.asfreq(freq, method=None, how=None, normalize=False, fill_value=None)`

Convert TimeSeries to specified frequency.

Optionally provide filling method to pad/backfill missing values.

Returns the original data conformed to a new index with the specified frequency. `resample` is more appropriate if an operation, such as summarization, is necessary to represent the data at the new frequency.

#### Parameters

**freq** [DateOffset object, or string]

**method** [{‘backfill’/‘bfill’, ‘pad’/‘ffill’}, default None] Method to use for filling holes in reindexed Series (note this does not fill NaNs that already were present):

- ‘pad’ / ‘ffill’: propagate last valid observation forward to next valid
- ‘backfill’ / ‘bfill’: use NEXT valid observation to fill

**how** [{‘start’, ‘end’}, default end] For PeriodIndex only, see `PeriodIndex.asfreq`

**normalize** [bool, default False] Whether to reset output index to midnight

**fill\_value** [scalar, optional] Value to use for missing values, applied during upsampling (note this does not fill NaNs that already were present).

New in version 0.20.0.

### Returns

**converted** [same type as caller]

### See also:

*reindex*

### Notes

To learn more about the frequency strings, please see [this link](#).

### Examples

Start by creating a series with 4 one minute timestamps.

```
>>> index = pd.date_range('1/1/2000', periods=4, freq='T')
>>> series = pd.Series([0.0, None, 2.0, 3.0], index=index)
>>> df = pd.DataFrame({'s':series})
>>> df
```

|                     | s   |
|---------------------|-----|
| 2000-01-01 00:00:00 | 0.0 |
| 2000-01-01 00:01:00 | NaN |
| 2000-01-01 00:02:00 | 2.0 |
| 2000-01-01 00:03:00 | 3.0 |

Upsample the series into 30 second bins.

```
>>> df.asfreq(freq='30S')
s
2000-01-01 00:00:00    0.0
2000-01-01 00:00:30    NaN
2000-01-01 00:01:00    NaN
2000-01-01 00:01:30    NaN
2000-01-01 00:02:00    2.0
2000-01-01 00:02:30    NaN
2000-01-01 00:03:00    3.0
```

Upsample again, providing a fill value.

```
>>> df.asfreq(freq='30S', fill_value=9.0)
s
2000-01-01 00:00:00    0.0
2000-01-01 00:00:30    9.0
2000-01-01 00:01:00    NaN
2000-01-01 00:01:30    9.0
2000-01-01 00:02:00    2.0
2000-01-01 00:02:30    9.0
2000-01-01 00:03:00    3.0
```

Upsample again, providing a method.

```
>>> df.asfreq(freq='30S', method='bfill')
              s
2000-01-01 00:00:00    0.0
2000-01-01 00:00:30   NaN
2000-01-01 00:01:00   NaN
2000-01-01 00:01:30    2.0
2000-01-01 00:02:00    2.0
2000-01-01 00:02:30    3.0
2000-01-01 00:03:00    3.0
```

## pandas.DataFrame.asof

`DataFrame.asof` (*where*, *subset=None*)

Return the last row(s) without any NaNs before *where*.

The last row (for each element in *where*, if list) without any NaN is taken. In case of a *DataFrame*, the last row without NaN considering only the subset of columns (if not *None*)

New in version 0.19.0: For *DataFrame*

If there is no good value, NaN is returned for a *Series* or a *Series* of NaN values for a *DataFrame*

### Parameters

**where** [date or array-like of dates] Date(s) before which the last row(s) are returned.

**subset** [str or array-like of str, default *None*] For *DataFrame*, if not *None*, only use these columns to check for NaNs.

### Returns

**scalar, Series, or DataFrame**

- scalar : when *self* is a *Series* and *where* is a scalar
- Series: when *self* is a *Series* and *where* is an array-like, or when *self* is a *DataFrame* and *where* is a scalar
- DataFrame : when *self* is a *DataFrame* and *where* is an array-like

**See also:**

**`merge_asof`** Perform an asof merge. Similar to left join.

## Notes

Dates are assumed to be sorted. Raises if this is not the case.

## Examples

A *Series* and a scalar *where*.

```
>>> s = pd.Series([1, 2, np.nan, 4], index=[10, 20, 30, 40])
>>> s
10    1.0
20    2.0
30    NaN
```

(continues on next page)

(continued from previous page)

```
40      4.0
dtype: float64
```

```
>>> s.asof(20)
2.0
```

For a sequence *where*, a Series is returned. The first value is NaN, because the first element of *where* is before the first index value.

```
>>> s.asof([5, 20])
5      NaN
20     2.0
dtype: float64
```

Missing values are not considered. The following is 2.0, not NaN, even though NaN is at the index location for 30.

```
>>> s.asof(30)
2.0
```

Take all columns into consideration

```
>>> df = pd.DataFrame({'a': [10, 20, 30, 40, 50],
...                    'b': [None, None, None, None, 500]},
...                    index=pd.DatetimeIndex(['2018-02-27 09:01:00',
...                                             '2018-02-27 09:02:00',
...                                             '2018-02-27 09:03:00',
...                                             '2018-02-27 09:04:00',
...                                             '2018-02-27 09:05:00']))
>>> df.asof(pd.DatetimeIndex(['2018-02-27 09:03:30',
...                           '2018-02-27 09:04:30']))
...
           a      b
2018-02-27 09:03:30 NaN NaN
2018-02-27 09:04:30 NaN NaN
```

Take a single column into consideration

```
>>> df.asof(pd.DatetimeIndex(['2018-02-27 09:03:30',
...                           '2018-02-27 09:04:30']),
...         subset=['a'])
...
           a      b
2018-02-27 09:03:30  30.0 NaN
2018-02-27 09:04:30  40.0 NaN
```

## pandas.DataFrame.assign

`DataFrame.assign(**kwargs)`

Assign new columns to a DataFrame.

Returns a new object with all original columns in addition to new ones. Existing columns that are re-assigned will be overwritten.

### Parameters

**\*\*kwargs** [dict of {str: callable or Series}] The column names are keywords. If the values are callable, they are computed on the DataFrame and assigned to the new

columns. The callable must not change input DataFrame (though pandas doesn't check it). If the values are not callable, (e.g. a Series, scalar, or array), they are simply assigned.

### Returns

**DataFrame** A new DataFrame with the new columns in addition to all the existing columns.

### Notes

Assigning multiple columns within the same `assign` is possible. For Python 3.6 and above, later items in `**kwargs` may refer to newly created or modified columns in `'df'`; items are computed and assigned into `'df'` in order. For Python 3.5 and below, the order of keyword arguments is not specified, you cannot refer to newly created or modified columns. All items are computed first, and then assigned in alphabetical order.

Changed in version 0.23.0: Keyword argument order is maintained for Python 3.6 and later.

### Examples

```
>>> df = pd.DataFrame({'temp_c': [17.0, 25.0]},
...                    index=['Portland', 'Berkeley'])
>>> df
```

|          | temp_c |
|----------|--------|
| Portland | 17.0   |
| Berkeley | 25.0   |

Where the value is a callable, evaluated on `df`:

```
>>> df.assign(temp_f=lambda x: x.temp_c * 9 / 5 + 32)
```

|          | temp_c | temp_f |
|----------|--------|--------|
| Portland | 17.0   | 62.6   |
| Berkeley | 25.0   | 77.0   |

Alternatively, the same behavior can be achieved by directly referencing an existing Series or sequence:

```
>>> df.assign(temp_f=df['temp_c'] * 9 / 5 + 32)
```

|          | temp_c | temp_f |
|----------|--------|--------|
| Portland | 17.0   | 62.6   |
| Berkeley | 25.0   | 77.0   |

In Python 3.6+, you can create multiple columns within the same assign where one of the columns depends on another one defined within the same assign:

```
>>> df.assign(temp_f=lambda x: x['temp_c'] * 9 / 5 + 32,
...          temp_k=lambda x: (x['temp_f'] + 459.67) * 5 / 9)
```

|          | temp_c | temp_f | temp_k |
|----------|--------|--------|--------|
| Portland | 17.0   | 62.6   | 290.15 |
| Berkeley | 25.0   | 77.0   | 298.15 |

## pandas.DataFrame.astype

`DataFrame.astype(dtype, copy=True, errors='raise', **kwargs)`

Cast a pandas object to a specified dtype `dtype`.

**Parameters**

**dtype** [data type, or dict of column name -> data type] Use a `numpy.dtype` or Python type to cast entire pandas object to the same type. Alternatively, use `{col: dtype, ...}`, where `col` is a column label and `dtype` is a `numpy.dtype` or Python type to cast one or more of the DataFrame's columns to column-specific types.

**copy** [bool, default True] Return a copy when `copy=True` (be very careful setting `copy=False` as changes to values then may propagate to other pandas objects).

**errors** [{`'raise'`, `'ignore'`}, default `'raise'`] Control raising of exceptions on invalid data for provided dtype.

- `raise` : allow exceptions to be raised
- `ignore` : suppress exceptions. On error return original object

New in version 0.20.0.

**kwargs** [keyword arguments to pass on to the constructor]

**Returns**

**casted** [same type as caller]

See also:

**`to_datetime`** Convert argument to datetime.

**`to_timedelta`** Convert argument to timedelta.

**`to_numeric`** Convert argument to a numeric type.

**`numpy.ndarray.astype`** Cast a numpy array to a specified type.

**Examples**

```
>>> ser = pd.Series([1, 2], dtype='int32')
>>> ser
0    1
1    2
dtype: int32
>>> ser.astype('int64')
0    1
1    2
dtype: int64
```

Convert to categorical type:

```
>>> ser.astype('category')
0    1
1    2
dtype: category
Categories (2, int64): [1, 2]
```

Convert to ordered categorical type with custom ordering:

```
>>> cat_dtype = pd.api.types.CategoricalDtype(
...     categories=[2, 1], ordered=True)
>>> ser.astype(cat_dtype)
```

(continues on next page)

(continued from previous page)

```

0    1
1    2
dtype: category
Categories (2, int64): [2 < 1]

```

Note that using `copy=False` and changing data on a new pandas object may propagate changes:

```

>>> s1 = pd.Series([1,2])
>>> s2 = s1.astype('int64', copy=False)
>>> s2[0] = 10
>>> s1 # note that s1[0] has changed too
0    10
1     2
dtype: int64

```

## pandas.DataFrame.at\_time

`DataFrame.at_time` (*time*, *asof=False*, *axis=None*)

Select values at particular time of day (e.g. 9:30AM).

### Parameters

**time** [datetime.time or string]

**axis** [{0 or 'index', 1 or 'columns'}, default 0] New in version 0.24.0.

### Returns

**values\_at\_time** [same type as caller]

### Raises

**TypeError** If the index is not a *DatetimeIndex*

See also:

**between\_time** Select values between particular times of the day.

**first** Select initial periods of time series based on a date offset.

**last** Select final periods of time series based on a date offset.

**DatetimeIndex.indexer\_at\_time** Get just the index locations for values at particular time of the day.

## Examples

```

>>> i = pd.date_range('2018-04-09', periods=4, freq='12H')
>>> ts = pd.DataFrame({'A': [1,2,3,4]}, index=i)
>>> ts

```

|                     | A |
|---------------------|---|
| 2018-04-09 00:00:00 | 1 |
| 2018-04-09 12:00:00 | 2 |
| 2018-04-10 00:00:00 | 3 |
| 2018-04-10 12:00:00 | 4 |

```
>>> ts.at_time('12:00')
      A
2018-04-09 12:00:00    2
2018-04-10 12:00:00    4
```

## pandas.DataFrame.between\_time

`DataFrame.between_time(start_time, end_time, include_start=True, include_end=True, axis=None)`

Select values between particular times of the day (e.g., 9:00-9:30 AM).

By setting `start_time` to be later than `end_time`, you can get the times that are *not* between the two times.

### Parameters

**start\_time** [datetime.time or string]

**end\_time** [datetime.time or string]

**include\_start** [boolean, default True]

**include\_end** [boolean, default True]

**axis** [{0 or 'index', 1 or 'columns'}, default 0] New in version 0.24.0.

### Returns

**values\_between\_time** [same type as caller]

### Raises

**TypeError** If the index is not a *DatetimeIndex*

### See also:

**at\_time** Select values at a particular time of the day.

**first** Select initial periods of time series based on a date offset.

**last** Select final periods of time series based on a date offset.

**DatetimeIndex.indexer\_between\_time** Get just the index locations for values between particular times of the day.

## Examples

```
>>> i = pd.date_range('2018-04-09', periods=4, freq='1D20min')
>>> ts = pd.DataFrame({'A': [1, 2, 3, 4]}, index=i)
>>> ts
      A
2018-04-09 00:00:00    1
2018-04-10 00:20:00    2
2018-04-11 00:40:00    3
2018-04-12 01:00:00    4
```

```
>>> ts.between_time('0:15', '0:45')
A
2018-04-10 00:20:00    2
2018-04-11 00:40:00    3
```

You get the times that are *not* between two times by setting `start_time` later than `end_time`:

```
>>> ts.between_time('0:45', '0:15')
A
2018-04-09 00:00:00    1
2018-04-12 01:00:00    4
```

### pandas.DataFrame.bfill

`DataFrame.bfill` (*axis=None, inplace=False, limit=None, downcast=None*)

Synonym for `DataFrame.fillna()` with `method='bfill'`.

### pandas.DataFrame.bool

`DataFrame.bool()`

Return the bool of a single element `PandasObject`.

This must be a boolean scalar value, either `True` or `False`. Raise a `ValueError` if the `PandasObject` does not have exactly 1 element, or that element is not boolean

### pandas.DataFrame.boxplot

`DataFrame.boxplot` (*column=None, by=None, ax=None, fontsize=None, rot=0, grid=True, figsize=None, layout=None, return\_type=None, \*\*kwargs*)

Make a box plot from `DataFrame` columns.

Make a box-and-whisker plot from `DataFrame` columns, optionally grouped by some other columns. A box plot is a method for graphically depicting groups of numerical data through their quartiles. The box extends from the Q1 to Q3 quartile values of the data, with a line at the median (Q2). The whiskers extend from the edges of box to show the range of the data. The position of the whiskers is set by default to  $1.5 * IQR$  ( $IQR = Q3 - Q1$ ) from the edges of the box. Outlier points are those past the end of the whiskers.

For further details see Wikipedia's entry for [boxplot](#).

#### Parameters

**column** [str or list of str, optional] Column name or list of names, or vector. Can be any valid input to `pandas.DataFrame.groupby()`.

**by** [str or array-like, optional] Column in the `DataFrame` to `pandas.DataFrame.groupby()`. One box-plot will be done per value of columns in `by`.

**ax** [object of class `matplotlib.axes.Axes`, optional] The `matplotlib` axes to be used by `boxplot`.

**fontsize** [float or str] Tick label font size in points or as a string (e.g., *large*).

**rot** [int or float, default 0] The rotation angle of labels (in degrees) with respect to the screen coordinate system.

**grid** [boolean, default True] Setting this to `True` will show the grid.

**figsize** [A tuple (width, height) in inches] The size of the figure to create in matplotlib.

**layout** [tuple (rows, columns), optional] For example, (3, 5) will display the subplots using 3 columns and 5 rows, starting from the top-left.

**return\_type** [{ 'axes', 'dict', 'both' } or None, default 'axes'] The kind of object to return. The default is `axes`.

- 'axes' returns the matplotlib axes the boxplot is drawn on.
- 'dict' returns a dictionary whose values are the matplotlib Lines of the boxplot.
- 'both' returns a namedtuple with the axes and dict.
- when grouping with `by`, a Series mapping columns to `return_type` is returned.

If `return_type` is `None`, a NumPy array of axes with the same shape as `layout` is returned.

**\*\*kwargs** All other plotting keyword arguments to be passed to `matplotlib.pyplot.boxplot()`.

### Returns

**result** : The return type depends on the `return_type` parameter:

- 'axes' : object of class `matplotlib.axes.Axes`
- 'dict' : dict of `matplotlib.lines.Line2D` objects
- 'both' : a namedtuple with structure (ax, lines)

For data grouped with `by`:

- `Series`
- array (for `return_type = None`)

See also:

**`Series.plot.hist`** Make a histogram.

**`matplotlib.pyplot.boxplot`** Matplotlib equivalent plot.

### Notes

Use `return_type='dict'` when you want to tweak the appearance of the lines after plotting. In this case a dict containing the Lines making up the boxes, caps, fliers, medians, and whiskers is returned.

### Examples

Boxplots can be created for every column in the dataframe by `df.boxplot()` or indicating the columns to be used:

```
>>> np.random.seed(1234)
>>> df = pd.DataFrame(np.random.randn(10,4),
...                    columns=['Col1', 'Col2', 'Col3', 'Col4'])
>>> boxplot = df.boxplot(column=['Col1', 'Col2', 'Col3'])
```

Boxplots of variables distributions grouped by the values of a third variable can be created using the option `by`. For instance:

```
>>> df = pd.DataFrame(np.random.randn(10, 2),
...                    columns=['Col1', 'Col2'])
>>> df['X'] = pd.Series(['A', 'A', 'A', 'A', 'A',
...                     'B', 'B', 'B', 'B', 'B'])
>>> boxplot = df.boxplot(by='X')
```

A list of strings (i.e. ['X', 'Y']) can be passed to `boxplot` in order to group the data by combination of the variables in the x-axis:

```
>>> df = pd.DataFrame(np.random.randn(10, 3),
...                    columns=['Col1', 'Col2', 'Col3'])
>>> df['X'] = pd.Series(['A', 'A', 'A', 'A', 'A',
...                     'B', 'B', 'B', 'B', 'B'])
>>> df['Y'] = pd.Series(['A', 'B', 'A', 'B', 'A',
...                     'B', 'A', 'B', 'A', 'B'])
>>> boxplot = df.boxplot(column=['Col1', 'Col2'], by=['X', 'Y'])
```

The layout of `boxplot` can be adjusted giving a tuple to `layout`:

```
>>> boxplot = df.boxplot(column=['Col1', 'Col2'], by='X',
...                       layout=(2, 1))
```

Additional formatting can be done to the boxplot, like suppressing the grid (`grid=False`), rotating the labels in the x-axis (i.e. `rot=45`) or changing the fontsize (i.e. `fontsize=15`):

```
>>> boxplot = df.boxplot(grid=False, rot=45, fontsize=15)
```

The parameter `return_type` can be used to select the type of element returned by `boxplot`. When `return_type='axes'` is selected, the matplotlib axes on which the boxplot is drawn are returned:

```
>>> boxplot = df.boxplot(column=['Col1', 'Col2'], return_type='axes')
>>> type(boxplot)
<class 'matplotlib.axes._subplots.AxesSubplot'>
```

When grouping with `by`, a Series mapping columns to `return_type` is returned:

```
>>> boxplot = df.boxplot(column=['Col1', 'Col2'], by='X',
...                       return_type='axes')
>>> type(boxplot)
<class 'pandas.core.series.Series'>
```

If `return_type` is `None`, a NumPy array of axes with the same shape as `layout` is returned:

```
>>> boxplot = df.boxplot(column=['Col1', 'Col2'], by='X',
...                       return_type=None)
>>> type(boxplot)
<class 'numpy.ndarray'>
```

## pandas.DataFrame.clip

`DataFrame.clip` (*lower=None, upper=None, axis=None, inplace=False, \*args, \*\*kwargs*)

Trim values at input threshold(s).

Assigns values outside boundary to boundary values. Thresholds can be singular values or array like, and in the latter case the clipping is performed element-wise in the specified axis.

**Parameters**

**lower** [float or array\_like, default None] Minimum threshold value. All values below this threshold will be set to it.

**upper** [float or array\_like, default None] Maximum threshold value. All values above this threshold will be set to it.

**axis** [int or string axis name, optional] Align object with lower and upper along the given axis.

**inplace** [boolean, default False] Whether to perform the operation in place on the data.

New in version 0.21.0.

**\*args, \*\*kwargs** Additional keywords have no effect but might be accepted for compatibility with numpy.

**Returns**

**Series or DataFrame** Same type as calling object with the values outside the clip boundaries replaced

**Examples**

```
>>> data = {'col_0': [9, -3, 0, -1, 5], 'col_1': [-2, -7, 6, 8, -5]}
>>> df = pd.DataFrame(data)
>>> df
   col_0  col_1
0      9     -2
1     -3     -7
2      0      6
3     -1      8
4      5     -5
```

Clips per column using lower and upper thresholds:

```
>>> df.clip(-4, 6)
   col_0  col_1
0      6     -2
1     -3     -4
2      0      6
3     -1      6
4      5     -4
```

Clips using specific lower and upper thresholds per column element:

```
>>> t = pd.Series([2, -4, -1, 6, 3])
>>> t
0      2
1     -4
2     -1
3      6
4      3
dtype: int64
```

```
>>> df.clip(t, t + 4, axis=0)
   col_0  col_1
```

(continues on next page)

(continued from previous page)

|   |    |    |
|---|----|----|
| 0 | 6  | 2  |
| 1 | -3 | -4 |
| 2 | 0  | 3  |
| 3 | 6  | 8  |
| 4 | 5  | 3  |

### pandas.DataFrame.clip\_lower

`DataFrame.clip_lower(threshold, axis=None, inplace=False)`

Trim values below a given threshold.

Deprecated since version 0.24.0: Use `clip(lower=threshold)` instead.

Elements below the *threshold* will be changed to match the *threshold* value(s). Threshold can be a single value or an array, in the latter case it performs the truncation element-wise.

#### Parameters

**threshold** [numeric or array-like] Minimum value allowed. All values below threshold will be set to this value.

- float : every value is compared to *threshold*.
- array-like : The shape of *threshold* should match the object it's compared to. When *self* is a Series, *threshold* should be the length. When *self* is a DataFrame, *threshold* should be 2-D and the same shape as *self* for `axis=None`, or 1-D and the same length as the axis being compared.

**axis** [{0 or 'index', 1 or 'columns'}], default 0] Align *self* with *threshold* along the given axis.

**inplace** [boolean, default False] Whether to perform the operation in place on the data.

New in version 0.21.0.

#### Returns

**Series or DataFrame** Original data with values trimmed.

See also:

**Series.clip** General purpose method to trim Series values to given threshold(s).

**DataFrame.clip** General purpose method to trim DataFrame values to given threshold(s).

### Examples

Series single threshold clipping:

```
>>> s = pd.Series([5, 6, 7, 8, 9])
>>> s.clip(lower=8)
0    8
1    8
2    8
3    8
4    9
dtype: int64
```

Series clipping element-wise using an array of thresholds. *threshold* should be the same length as the Series.

```
>>> elemwise_thresholds = [4, 8, 7, 2, 5]
>>> s.clip(lower=elemwise_thresholds)
0    5
1    8
2    7
3    8
4    9
dtype: int64
```

DataFrames can be compared to a scalar.

```
>>> df = pd.DataFrame({"A": [1, 3, 5], "B": [2, 4, 6]})
>>> df
   A  B
0  1  2
1  3  4
2  5  6
```

```
>>> df.clip(lower=3)
   A  B
0  3  3
1  3  4
2  5  6
```

Or to an array of values. By default, *threshold* should be the same shape as the DataFrame.

```
>>> df.clip(lower=np.array([[3, 4], [2, 2], [6, 2]]))
   A  B
0  3  4
1  3  4
2  6  6
```

Control how *threshold* is broadcast with *axis*. In this case *threshold* should be the same length as the axis specified by *axis*.

```
>>> df.clip(lower=[3, 3, 5], axis='index')
   A  B
0  3  3
1  3  4
2  5  6
```

```
>>> df.clip(lower=[4, 5], axis='columns')
   A  B
0  4  5
1  4  5
2  5  6
```

### pandas.DataFrame.clip\_upper

`DataFrame.clip_upper(threshold, axis=None, inplace=False)`

Trim values above a given threshold.

Deprecated since version 0.24.0: Use `clip(upper=threshold)` instead.

Elements above the *threshold* will be changed to match the *threshold* value(s). Threshold can be a single value or an array, in the latter case it performs the truncation element-wise.

### Parameters

**threshold** [numeric or array-like] Maximum value allowed. All values above threshold will be set to this value.

- float : every value is compared to *threshold*.
- array-like : The shape of *threshold* should match the object it's compared to. When *self* is a Series, *threshold* should be the length. When *self* is a DataFrame, *threshold* should 2-D and the same shape as *self* for `axis=None`, or 1-D and the same length as the axis being compared.

**axis** [{0 or 'index', 1 or 'columns'}, default 0] Align object with *threshold* along the given axis.

**inplace** [boolean, default False] Whether to perform the operation in place on the data.

New in version 0.21.0.

### Returns

**Series or DataFrame** Original data with values trimmed.

See also:

***Series.clip*** General purpose method to trim Series values to given threshold(s).

***DataFrame.clip*** General purpose method to trim DataFrame values to given threshold(s).

### Examples

```
>>> s = pd.Series([1, 2, 3, 4, 5])
>>> s
0    1
1    2
2    3
3    4
4    5
dtype: int64
```

```
>>> s.clip(upper=3)
0    1
1    2
2    3
3    3
4    3
dtype: int64
```

```
>>> elemwise_thresholds = [5, 4, 3, 2, 1]
>>> elemwise_thresholds
[5, 4, 3, 2, 1]
```

```
>>> s.clip(upper=elemwise_thresholds)
0    1
1    2
2    3
```

(continues on next page)

(continued from previous page)

```

3      2
4      1
dtype: int64

```

## pandas.DataFrame.combine

`DataFrame.combine` (*other*, *func*, *fill\_value=None*, *overwrite=True*)

Perform column-wise combine with another DataFrame based on a passed function.

Combines a DataFrame with *other* DataFrame using *func* to element-wise combine columns. The row and column indexes of the resulting DataFrame will be the union of the two.

### Parameters

**other** [DataFrame] The DataFrame to merge column-wise.

**func** [function] Function that takes two series as inputs and return a Series or a scalar.  
Used to merge the two dataframes column by columns.

**fill\_value** [scalar value, default None] The value to fill NaNs with prior to passing any column to the merge func.

**overwrite** [boolean, default True] If True, columns in *self* that do not exist in *other* will be overwritten with NaNs.

### Returns

**result** [DataFrame]

### See also:

**DataFrame.combine\_first** Combine two DataFrame objects and default to non-null values in frame calling the method.

## Examples

Combine using a simple function that chooses the smaller column.

```

>>> df1 = pd.DataFrame({'A': [0, 0], 'B': [4, 4]})
>>> df2 = pd.DataFrame({'A': [1, 1], 'B': [3, 3]})
>>> take_smaller = lambda s1, s2: s1 if s1.sum() < s2.sum() else s2
>>> df1.combine(df2, take_smaller)
   A  B
0  0  3
1  0  3

```

Example using a true element-wise combine function.

```

>>> df1 = pd.DataFrame({'A': [5, 0], 'B': [2, 4]})
>>> df2 = pd.DataFrame({'A': [1, 1], 'B': [3, 3]})
>>> df1.combine(df2, np.minimum)
   A  B
0  1  2
1  0  3

```

Using *fill\_value* fills Nones prior to passing the column to the merge function.

```
>>> df1 = pd.DataFrame({'A': [0, 0], 'B': [None, 4]})
>>> df2 = pd.DataFrame({'A': [1, 1], 'B': [3, 3]})
>>> df1.combine(df2, take_smaller, fill_value=-5)
   A    B
0  0 -5.0
1  0  4.0
```

However, if the same element in both dataframes is None, that None is preserved

```
>>> df1 = pd.DataFrame({'A': [0, 0], 'B': [None, 4]})
>>> df2 = pd.DataFrame({'A': [1, 1], 'B': [None, 3]})
>>> df1.combine(df2, take_smaller, fill_value=-5)
   A    B
0  0  NaN
1  0  3.0
```

Example that demonstrates the use of *overwrite* and behavior when the axis differ between the dataframes.

```
>>> df1 = pd.DataFrame({'A': [0, 0], 'B': [4, 4]})
>>> df2 = pd.DataFrame({'B': [3, 3], 'C': [-10, 1]}, index=[1, 2])
>>> df1.combine(df2, take_smaller)
   A    B    C
0  NaN  NaN  NaN
1  NaN  3.0 -10.0
2  NaN  3.0  1.0
```

```
>>> df1.combine(df2, take_smaller, overwrite=False)
   A    B    C
0  0.0  NaN  NaN
1  0.0  3.0 -10.0
2  NaN  3.0  1.0
```

Demonstrating the preference of the passed in dataframe.

```
>>> df2 = pd.DataFrame({'B': [3, 3], 'C': [1, 1]}, index=[1, 2])
>>> df2.combine(df1, take_smaller)
   A    B    C
0  0.0  NaN  NaN
1  0.0  3.0  NaN
2  NaN  3.0  NaN
```

```
>>> df2.combine(df1, take_smaller, overwrite=False)
   A    B    C
0  0.0  NaN  NaN
1  0.0  3.0  1.0
2  NaN  3.0  1.0
```

## pandas.DataFrame.combine\_first

`DataFrame.combine_first(other)`

Update null elements with value in the same location in *other*.

Combine two DataFrame objects by filling null values in one DataFrame with non-null values from other DataFrame. The row and column indexes of the resulting DataFrame will be the union of the two.

### Parameters

**other** [DataFrame] Provided DataFrame to use to fill null values.

### Returns

**combined** [DataFrame]

See also:

**DataFrame.combine** Perform series-wise operation on two DataFrames using a given function.

### Examples

```
>>> df1 = pd.DataFrame({'A': [None, 0], 'B': [None, 4]})
>>> df2 = pd.DataFrame({'A': [1, 1], 'B': [3, 3]})
>>> df1.combine_first(df2)
   A  B
0  1.0 3.0
1  0.0 4.0
```

Null values still persist if the location of that null value does not exist in *other*

```
>>> df1 = pd.DataFrame({'A': [None, 0], 'B': [4, None]})
>>> df2 = pd.DataFrame({'B': [3, 3], 'C': [1, 1]}, index=[1, 2])
>>> df1.combine_first(df2)
   A  B  C
0  NaN 4.0 NaN
1  0.0 3.0 1.0
2  NaN 3.0 1.0
```

## pandas.DataFrame.compound

**DataFrame.compound** (*axis=None, skipna=None, level=None*)

Return the compound percentage of the values for the requested axis.

### Parameters

**axis** [{index (0), columns (1)}] Axis for the function to be applied on.

**skipna** [bool, default True] Exclude NA/null values when computing the result.

**level** [int or level name, default None] If the axis is a MultiIndex (hierarchical), count along a particular level, collapsing into a Series.

**numeric\_only** [bool, default None] Include only float, int, boolean columns. If None, will attempt to use everything, then use only numeric data. Not implemented for Series.

**\*\*kwargs** Additional keyword arguments to be passed to the function.

### Returns

**compounded** [Series or DataFrame (if level specified)]

## pandas.DataFrame.convert\_objects

**DataFrame.convert\_objects** (*convert\_dates=True, convert\_numeric=False, convert\_timedeltas=True, copy=True*)

Attempt to infer better dtype for object columns.

Deprecated since version 0.21.0.

#### Parameters

**convert\_dates** [boolean, default True] If True, convert to date where possible. If 'coerce', force conversion, with unconvertible values becoming NaT.

**convert\_numeric** [boolean, default False] If True, attempt to coerce to numbers (including strings), with unconvertible values becoming NaN.

**convert\_timedeltas** [boolean, default True] If True, convert to timedelta where possible. If 'coerce', force conversion, with unconvertible values becoming NaT.

**copy** [boolean, default True] If True, return a copy even if no copy is necessary (e.g. no conversion was done). Note: This is meant for internal use, and should not be confused with inplace.

#### Returns

**converted** [same as input object]

See also:

**to\_datetime** Convert argument to datetime.

**to\_timedelta** Convert argument to timedelta.

**to\_numeric** Convert argument to numeric type.

### pandas.DataFrame.copy

`DataFrame.copy(deep=True)`

Make a copy of this object's indices and data.

When `deep=True` (default), a new object will be created with a copy of the calling object's data and indices. Modifications to the data or indices of the copy will not be reflected in the original object (see notes below).

When `deep=False`, a new object will be created without copying the calling object's data or index (only references to the data and index are copied). Any changes to the data of the original will be reflected in the shallow copy (and vice versa).

#### Parameters

**deep** [bool, default True] Make a deep copy, including a copy of the data and the indices. With `deep=False` neither the indices nor the data are copied.

#### Returns

**copy** [Series, DataFrame or Panel] Object type matches caller.

### Notes

When `deep=True`, data is copied but actual Python objects will not be copied recursively, only the reference to the object. This is in contrast to `copy.deepcopy` in the Standard Library, which recursively copies object data (see examples below).

While `Index` objects are copied when `deep=True`, the underlying numpy array is not copied for performance reasons. Since `Index` is immutable, the underlying data can be safely shared and a copy is not needed.

## Examples

```
>>> s = pd.Series([1, 2], index=["a", "b"])
>>> s
a    1
b    2
dtype: int64
```

```
>>> s_copy = s.copy()
>>> s_copy
a    1
b    2
dtype: int64
```

### Shallow copy versus default (deep) copy:

```
>>> s = pd.Series([1, 2], index=["a", "b"])
>>> deep = s.copy()
>>> shallow = s.copy(deep=False)
```

Shallow copy shares data and index with original.

```
>>> s is shallow
False
>>> s.values is shallow.values and s.index is shallow.index
True
```

Deep copy has own copy of data and index.

```
>>> s is deep
False
>>> s.values is deep.values or s.index is deep.index
False
```

Updates to the data shared by shallow copy and original is reflected in both; deep copy remains unchanged.

```
>>> s[0] = 3
>>> shallow[1] = 4
>>> s
a    3
b    4
dtype: int64
>>> shallow
a    3
b    4
dtype: int64
>>> deep
a    1
b    2
dtype: int64
```

Note that when copying an object containing Python objects, a deep copy will copy the data, but will not do so recursively. Updating a nested data object will be reflected in the deep copy.

```
>>> s = pd.Series([[1, 2], [3, 4]])
>>> deep = s.copy()
>>> s[0][0] = 10
```

(continues on next page)

(continued from previous page)

```
>>> s
0    [10, 2]
1    [3, 4]
dtype: object
>>> deep
0    [10, 2]
1    [3, 4]
dtype: object
```

## pandas.DataFrame.corr

`DataFrame.corr` (*method='pearson', min\_periods=1*)

Compute pairwise correlation of columns, excluding NA/null values.

### Parameters

**method** [{‘pearson’, ‘kendall’, ‘spearman’} or callable]

- **pearson** : standard correlation coefficient
- **kendall** : Kendall Tau correlation coefficient
- **spearman** : Spearman rank correlation
- **callable**: callable with input two 1d ndarrays and returning a float .. version-added:: 0.24.0

**min\_periods** [int, optional] Minimum number of observations required per pair of columns to have a valid result. Currently only available for pearson and spearman correlation

### Returns

**y** [DataFrame]

### See also:

`DataFrame.corrwith`, `Series.corr`

## Examples

```
>>> histogram_intersection = lambda a, b: np.minimum(a, b
... ).sum().round(decimals=1)
>>> df = pd.DataFrame([(0.2, 0.3), (0.0, 0.6), (0.6, 0.0), (0.2, 0.1)],
...                     columns=['dogs', 'cats'])
>>> df.corr(method=histogram_intersection)
      dogs cats
dogs    1.0  0.3
cats    0.3  1.0
```

## pandas.DataFrame.corrwith

`DataFrame.corrwith` (*other, axis=0, drop=False, method='pearson'*)

Compute pairwise correlation between rows or columns of DataFrame with rows or columns of Series or DataFrame. DataFrames are first aligned along both axes before computing the correlations.

**Parameters****other** [DataFrame, Series]**axis** [{0 or 'index', 1 or 'columns'}, default 0] 0 or 'index' to compute column-wise, 1 or 'columns' for row-wise**drop** [boolean, default False] Drop missing indices from result**method** [{ 'pearson', 'kendall', 'spearman' } or callable]

- **pearson** : standard correlation coefficient
- **kendall** : Kendall Tau correlation coefficient
- **spearman** : Spearman rank correlation
- **callable**: **callable with input two 1d ndarrays** and returning a float

New in version 0.24.0.

**Returns****correls** [Series]**See Also**

———

**DataFrame.corr****pandas.DataFrame.count**`DataFrame.count` (*axis=0, level=None, numeric\_only=False*)

Count non-NA cells for each column or row.

The values *None*, *NaN*, *NaT*, and optionally *numpy.inf* (depending on *pandas.options.mode.use\_inf\_as\_na*) are considered NA.**Parameters****axis** [{0 or 'index', 1 or 'columns'}, default 0] If 0 or 'index' counts are generated for each column. If 1 or 'columns' counts are generated for each **row**.**level** [int or str, optional] If the axis is a *MultiIndex* (hierarchical), count along a particular *level*, collapsing into a *DataFrame*. A *str* specifies the level name.**numeric\_only** [boolean, default False] Include only *float*, *int* or *boolean* data.**Returns****Series or DataFrame** For each column/row the number of non-NA/null entries. If *level* is specified returns a *DataFrame*.**See also:****Series.count** Number of non-NA elements in a Series.**DataFrame.shape** Number of DataFrame rows and columns (including NA elements).**DataFrame.isna** Boolean same-sized DataFrame showing places of NA elements.

## Examples

Constructing DataFrame from a dictionary:

```
>>> df = pd.DataFrame({"Person":
...                     ["John", "Myla", "Lewis", "John", "Myla"],
...                     "Age": [24., np.nan, 21., 33, 26],
...                     "Single": [False, True, True, True, False]})
>>> df
   Person  Age  Single
0   John  24.0  False
1   Myla   NaN   True
2  Lewis  21.0   True
3   John  33.0   True
4   Myla  26.0  False
```

Notice the uncounted NA values:

```
>>> df.count()
Person      5
Age         4
Single      5
dtype: int64
```

Counts for each row:

```
>>> df.count(axis='columns')
0      3
1      2
2      3
3      3
4      3
dtype: int64
```

Counts for one level of a *MultiIndex*:

```
>>> df.set_index(["Person", "Single"]).count(level="Person")
      Age
Person
John      2
Lewis     1
Myla      1
```

## pandas.DataFrame.cov

`DataFrame.cov` (*min\_periods=None*)

Compute pairwise covariance of columns, excluding NA/null values.

Compute the pairwise covariance among the series of a DataFrame. The returned data frame is the **covariance matrix** of the columns of the DataFrame.

Both NA and null values are automatically excluded from the calculation. (See the note below about bias from missing values.) A threshold can be set for the minimum number of observations for each value created. Comparisons with observations below this threshold will be returned as NaN.

This method is generally used for the analysis of time series data to understand the relationship between different measures across time.

**Parameters**

**min\_periods** [int, optional] Minimum number of observations required per pair of columns to have a valid result.

**Returns**

**DataFrame** The covariance matrix of the series of the DataFrame.

See also:

**pandas.Series.cov** Compute covariance with another Series.

**pandas.core.window.EWM.cov** Exponential weighted sample covariance.

**pandas.core.window.Expanding.cov** Expanding sample covariance.

**pandas.core.window.Rolling.cov** Rolling sample covariance.

**Notes**

Returns the covariance matrix of the DataFrame's time series. The covariance is normalized by N-1.

For DataFrames that have Series that are missing data (assuming that data is [missing at random](#)) the returned covariance matrix will be an unbiased estimate of the variance and covariance between the member Series.

However, for many applications this estimate may not be acceptable because the estimate covariance matrix is not guaranteed to be positive semi-definite. This could lead to estimate correlations having absolute values which are greater than one, and/or a non-invertible covariance matrix. See [Estimation of covariance matrices](#) for more details.

**Examples**

```
>>> df = pd.DataFrame([(1, 2), (0, 3), (2, 0), (1, 1)],
...                    columns=['dogs', 'cats'])
>>> df.cov()
           dogs      cats
dogs  0.666667 -1.000000
cats -1.000000  1.666667
```

```
>>> np.random.seed(42)
>>> df = pd.DataFrame(np.random.randn(1000, 5),
...                    columns=['a', 'b', 'c', 'd', 'e'])
>>> df.cov()
           a         b         c         d         e
a  0.998438 -0.020161  0.059277 -0.008943  0.014144
b -0.020161  1.059352 -0.008543 -0.024738  0.009826
c  0.059277 -0.008543  1.010670 -0.001486 -0.000271
d -0.008943 -0.024738 -0.001486  0.921297 -0.013692
e  0.014144  0.009826 -0.000271 -0.013692  0.977795
```

**Minimum number of periods**

This method also supports an optional `min_periods` keyword that specifies the required minimum number of non-NA observations for each column pair in order to have a valid result:

```
>>> np.random.seed(42)
>>> df = pd.DataFrame(np.random.randn(20, 3),
...                    columns=['a', 'b', 'c'])
>>> df.loc[df.index[:5], 'a'] = np.nan
>>> df.loc[df.index[5:10], 'b'] = np.nan
>>> df.cov(min_periods=12)
           a         b         c
a  0.316741      NaN -0.150812
b      NaN  1.248003  0.191417
c -0.150812  0.191417  0.895202
```

## pandas.DataFrame.cummax

`DataFrame.cummax` (*axis=None, skipna=True, \*args, \*\*kwargs*)

Return cumulative maximum over a DataFrame or Series axis.

Returns a DataFrame or Series of the same size containing the cumulative maximum.

### Parameters

**axis** [{0 or 'index', 1 or 'columns'}, default 0] The index or the name of the axis. 0 is equivalent to None or 'index'.

**skipna** [boolean, default True] Exclude NA/null values. If an entire row/column is NA, the result will be NA.

**\*args, \*\*kwargs** : Additional keywords have no effect but might be accepted for compatibility with NumPy.

### Returns

**cummax** [Series or DataFrame]

See also:

**core.window.Expanding.max** Similar functionality but ignores NaN values.

**DataFrame.max** Return the maximum over DataFrame axis.

**DataFrame.cummax** Return cumulative maximum over DataFrame axis.

**DataFrame.cummin** Return cumulative minimum over DataFrame axis.

**DataFrame.cumsum** Return cumulative sum over DataFrame axis.

**DataFrame.cumprod** Return cumulative product over DataFrame axis.

## Examples

### Series

```
>>> s = pd.Series([2, np.nan, 5, -1, 0])
>>> s
0    2.0
1    NaN
2    5.0
3   -1.0
4    0.0
dtype: float64
```

By default, NA values are ignored.

```
>>> s.cummax()
0    2.0
1    NaN
2    5.0
3    5.0
4    5.0
dtype: float64
```

To include NA values in the operation, use `skipna=False`

```
>>> s.cummax(skipna=False)
0    2.0
1    NaN
2    NaN
3    NaN
4    NaN
dtype: float64
```

### DataFrame

```
>>> df = pd.DataFrame([[2.0, 1.0],
...                    [3.0, np.nan],
...                    [1.0, 0.0]],
...                    columns=list('AB'))
>>> df
   A    B
0  2.0  1.0
1  3.0  NaN
2  1.0  0.0
```

By default, iterates over rows and finds the maximum in each column. This is equivalent to `axis=None` or `axis='index'`.

```
>>> df.cummax()
   A    B
0  2.0  1.0
1  3.0  NaN
2  3.0  1.0
```

To iterate over columns and find the maximum in each row, use `axis=1`

```
>>> df.cummax(axis=1)
   A    B
0  2.0  2.0
1  3.0  NaN
2  1.0  1.0
```

### pandas.DataFrame.cummin

`DataFrame.cummin` (*axis=None, skipna=True, \*args, \*\*kwargs*)

Return cumulative minimum over a DataFrame or Series axis.

Returns a DataFrame or Series of the same size containing the cumulative minimum.

#### Parameters

**axis** [{0 or 'index', 1 or 'columns'}, default 0] The index or the name of the axis. 0 is equivalent to None or 'index'.

**skipna** [boolean, default True] Exclude NA/null values. If an entire row/column is NA, the result will be NA.

**\*args, \*\*kwargs** : Additional keywords have no effect but might be accepted for compatibility with NumPy.

### Returns

**cummin** [Series or DataFrame]

### See also:

**core.window.Expanding.min** Similar functionality but ignores NaN values.

**DataFrame.min** Return the minimum over DataFrame axis.

**DataFrame.cummax** Return cumulative maximum over DataFrame axis.

**DataFrame.cummin** Return cumulative minimum over DataFrame axis.

**DataFrame.cumsum** Return cumulative sum over DataFrame axis.

**DataFrame.cumprod** Return cumulative product over DataFrame axis.

## Examples

### Series

```
>>> s = pd.Series([2, np.nan, 5, -1, 0])
>>> s
0      2.0
1      NaN
2      5.0
3     -1.0
4      0.0
dtype: float64
```

By default, NA values are ignored.

```
>>> s.cummin()
0      2.0
1      NaN
2      2.0
3     -1.0
4     -1.0
dtype: float64
```

To include NA values in the operation, use `skipna=False`

```
>>> s.cummin(skipna=False)
0      2.0
1      NaN
2      NaN
3      NaN
4      NaN
dtype: float64
```

### DataFrame

```
>>> df = pd.DataFrame([[2.0, 1.0],
...                    [3.0, np.nan],
...                    [1.0, 0.0]],
...                    columns=list('AB'))
>>> df
   A    B
0  2.0  1.0
1  3.0  NaN
2  1.0  0.0
```

By default, iterates over rows and finds the minimum in each column. This is equivalent to `axis=None` or `axis='index'`.

```
>>> df.cummin()
   A    B
0  2.0  1.0
1  2.0  NaN
2  1.0  0.0
```

To iterate over columns and find the minimum in each row, use `axis=1`

```
>>> df.cummin(axis=1)
   A    B
0  2.0  1.0
1  3.0  NaN
2  1.0  0.0
```

## pandas.DataFrame.cumprod

`DataFrame.cumprod` (*axis=None*, *skipna=True*, *\*args*, *\*\*kwargs*)

Return cumulative product over a DataFrame or Series axis.

Returns a DataFrame or Series of the same size containing the cumulative product.

### Parameters

**axis** [{0 or 'index', 1 or 'columns'}, default 0] The index or the name of the axis. 0 is equivalent to None or 'index'.

**skipna** [boolean, default True] Exclude NA/null values. If an entire row/column is NA, the result will be NA.

**\*args, \*\*kwargs** : Additional keywords have no effect but might be accepted for compatibility with NumPy.

### Returns

**cumprod** [Series or DataFrame]

See also:

**core.window.Expanding.prod** Similar functionality but ignores NaN values.

**DataFrame.prod** Return the product over DataFrame axis.

**DataFrame.cummax** Return cumulative maximum over DataFrame axis.

**DataFrame.cummin** Return cumulative minimum over DataFrame axis.

**DataFrame.cumsum** Return cumulative sum over DataFrame axis.

**DataFrame.cumprod** Return cumulative product over DataFrame axis.

## Examples

### Series

```
>>> s = pd.Series([2, np.nan, 5, -1, 0])
>>> s
0    2.0
1    NaN
2    5.0
3   -1.0
4    0.0
dtype: float64
```

By default, NA values are ignored.

```
>>> s.cumprod()
0    2.0
1    NaN
2   10.0
3  -10.0
4   -0.0
dtype: float64
```

To include NA values in the operation, use `skipna=False`

```
>>> s.cumprod(skipna=False)
0    2.0
1    NaN
2    NaN
3    NaN
4    NaN
dtype: float64
```

### DataFrame

```
>>> df = pd.DataFrame([[2.0, 1.0],
...                    [3.0, np.nan],
...                    [1.0, 0.0]],
...                    columns=list('AB'))
>>> df
   A  B
0  2.0  1.0
1  3.0 NaN
2  1.0  0.0
```

By default, iterates over rows and finds the product in each column. This is equivalent to `axis=None` or `axis='index'`.

```
>>> df.cumprod()
   A  B
0  2.0  1.0
1  6.0 NaN
2  6.0  0.0
```

To iterate over columns and find the product in each row, use `axis=1`

```
>>> df.cumprod(axis=1)
   A      B
0  2.0  2.0
1  3.0  NaN
2  1.0  0.0
```

## pandas.DataFrame.cumsum

`DataFrame.cumsum(axis=None, skipna=True, *args, **kwargs)`

Return cumulative sum over a DataFrame or Series axis.

Returns a DataFrame or Series of the same size containing the cumulative sum.

### Parameters

**axis** [{0 or 'index', 1 or 'columns'}, default 0] The index or the name of the axis. 0 is equivalent to None or 'index'.

**skipna** [boolean, default True] Exclude NA/null values. If an entire row/column is NA, the result will be NA.

**\*args, \*\*kwargs** : Additional keywords have no effect but might be accepted for compatibility with NumPy.

### Returns

**cumsum** [Series or DataFrame]

See also:

**core.window.Expanding.sum** Similar functionality but ignores NaN values.

**DataFrame.sum** Return the sum over DataFrame axis.

**DataFrame.cummax** Return cumulative maximum over DataFrame axis.

**DataFrame.cummin** Return cumulative minimum over DataFrame axis.

**DataFrame.cumsum** Return cumulative sum over DataFrame axis.

**DataFrame.cumprod** Return cumulative product over DataFrame axis.

## Examples

### Series

```
>>> s = pd.Series([2, np.nan, 5, -1, 0])
>>> s
0    2.0
1    NaN
2    5.0
3   -1.0
4    0.0
dtype: float64
```

By default, NA values are ignored.

```
>>> s.cumsum()
0    2.0
1    NaN
2    7.0
3    6.0
4    6.0
dtype: float64
```

To include NA values in the operation, use `skipna=False`

```
>>> s.cumsum(skipna=False)
0    2.0
1    NaN
2    NaN
3    NaN
4    NaN
dtype: float64
```

### DataFrame

```
>>> df = pd.DataFrame([[2.0, 1.0],
...                    [3.0, np.nan],
...                    [1.0, 0.0]],
...                    columns=list('AB'))
>>> df
   A  B
0  2.0 1.0
1  3.0 NaN
2  1.0 0.0
```

By default, iterates over rows and finds the sum in each column. This is equivalent to `axis=None` or `axis='index'`.

```
>>> df.cumsum()
   A  B
0  2.0 1.0
1  5.0 NaN
2  6.0 1.0
```

To iterate over columns and find the sum in each row, use `axis=1`

```
>>> df.cumsum(axis=1)
   A  B
0  2.0 3.0
1  3.0 NaN
2  1.0 1.0
```

## pandas.DataFrame.describe

`DataFrame.describe` (*percentiles=None, include=None, exclude=None*)

Generate descriptive statistics that summarize the central tendency, dispersion and shape of a dataset's distribution, excluding NaN values.

Analyzes both numeric and object series, as well as `DataFrame` column sets of mixed data types. The output will vary depending on what is provided. Refer to the notes below for more detail.

### Parameters

**percentiles** [list-like of numbers, optional] The percentiles to include in the output. All should fall between 0 and 1. The default is `[.25, .5, .75]`, which returns the 25th, 50th, and 75th percentiles.

**include** ['all', list-like of dtypes or None (default), optional] A white list of data types to include in the result. Ignored for `Series`. Here are the options:

- 'all' : All columns of the input will be included in the output.
- A list-like of dtypes : Limits the results to the provided data types. To limit the result to numeric types submit `numpy.number`. To limit it instead to object columns submit the `numpy.object` data type. Strings can also be used in the style of `select_dtypes` (e.g. `df.describe(include=['O'])`). To select pandas categorical columns, use `'category'`
- None (default) : The result will include all numeric columns.

**exclude** [list-like of dtypes or None (default), optional] A black list of data types to omit from the result. Ignored for `Series`. Here are the options:

- A list-like of dtypes : Excludes the provided data types from the result. To exclude numeric types submit `numpy.number`. To exclude object columns submit the data type `numpy.object`. Strings can also be used in the style of `select_dtypes` (e.g. `df.describe(include=['O'])`). To exclude pandas categorical columns, use `'category'`
- None (default) : The result will exclude nothing.

### Returns

**Series or DataFrame** Summary statistics of the Series or Dataframe provided.

See also:

**DataFrame.count** Count number of non-NA/null observations.

**DataFrame.max** Maximum of the values in the object.

**DataFrame.min** Minimum of the values in the object.

**DataFrame.mean** Mean of the values.

**DataFrame.std** Standard deviation of the observations.

**DataFrame.select\_dtypes** Subset of a DataFrame including/excluding columns based on their dtype.

### Notes

For numeric data, the result's index will include `count`, `mean`, `std`, `min`, `max` as well as `lower`, 50 and upper percentiles. By default the lower percentile is 25 and the upper percentile is 75. The 50 percentile is the same as the median.

For object data (e.g. strings or timestamps), the result's index will include `count`, `unique`, `top`, and `freq`. The `top` is the most common value. The `freq` is the most common value's frequency. Timestamps also include the `first` and `last` items.

If multiple object values have the highest count, then the `count` and `top` results will be arbitrarily chosen from among those with the highest count.

For mixed data types provided via a `DataFrame`, the default is to return only an analysis of numeric columns. If the dataframe consists only of object and categorical data without any numeric columns,

the default is to return an analysis of both the object and categorical columns. If `include='all'` is provided as an option, the result will include a union of attributes of each type.

The *include* and *exclude* parameters can be used to limit which columns in a `DataFrame` are analyzed for the output. The parameters are ignored when analyzing a `Series`.

## Examples

Describing a numeric `Series`.

```
>>> s = pd.Series([1, 2, 3])
>>> s.describe()
count      3.0
mean       2.0
std        1.0
min        1.0
25%        1.5
50%        2.0
75%        2.5
max        3.0
dtype: float64
```

Describing a categorical `Series`.

```
>>> s = pd.Series(['a', 'a', 'b', 'c'])
>>> s.describe()
count      4
unique     3
top        a
freq       2
dtype: object
```

Describing a timestamp `Series`.

```
>>> s = pd.Series([
...     np.datetime64("2000-01-01"),
...     np.datetime64("2010-01-01"),
...     np.datetime64("2010-01-01")
... ])
>>> s.describe()
count      3
unique     2
top      2010-01-01 00:00:00
freq       2
first      2000-01-01 00:00:00
last       2010-01-01 00:00:00
dtype: object
```

Describing a `DataFrame`. By default only numeric fields are returned.

```
>>> df = pd.DataFrame({'categorical': pd.Categorical(['d', 'e', 'f']),
...                    'numeric': [1, 2, 3],
...                    'object': ['a', 'b', 'c']
...                    })
>>> df.describe()
           numeric
count      3.0
```

(continues on next page)

(continued from previous page)

|      |     |
|------|-----|
| mean | 2.0 |
| std  | 1.0 |
| min  | 1.0 |
| 25%  | 1.5 |
| 50%  | 2.0 |
| 75%  | 2.5 |
| max  | 3.0 |

Describing all columns of a DataFrame regardless of data type.

```
>>> df.describe(include='all')
      categorical  numeric  object
count           3        3.0      3
unique           3        NaN      3
top              f        NaN      c
freq            1        NaN      1
mean            NaN        2.0     NaN
std             NaN        1.0     NaN
min             NaN        1.0     NaN
25%             NaN        1.5     NaN
50%             NaN        2.0     NaN
75%             NaN        2.5     NaN
max             NaN        3.0     NaN
```

Describing a column from a DataFrame by accessing it as an attribute.

```
>>> df.numeric.describe()
count    3.0
mean     2.0
std      1.0
min      1.0
25%     1.5
50%     2.0
75%     2.5
max      3.0
Name: numeric, dtype: float64
```

Including only numeric columns in a DataFrame description.

```
>>> df.describe(include=[np.number])
      numeric
count      3.0
mean       2.0
std        1.0
min        1.0
25%        1.5
50%        2.0
75%        2.5
max        3.0
```

Including only string columns in a DataFrame description.

```
>>> df.describe(include=[np.object])
      object
count      3
unique      3
```

(continues on next page)

(continued from previous page)

|      |   |
|------|---|
| top  | c |
| freq | 1 |

Including only categorical columns from a DataFrame description.

```
>>> df.describe(include=['category'])
      categorical
count          3
unique          3
top            f
freq           1
```

Excluding numeric columns from a DataFrame description.

```
>>> df.describe(exclude=[np.number])
      categorical  object
count           3      3
unique           3      3
top             f      c
freq            1      1
```

Excluding object columns from a DataFrame description.

```
>>> df.describe(exclude=[np.object])
      categorical  numeric
count           3      3.0
unique           3      NaN
top             f      NaN
freq            1      NaN
mean            NaN      2.0
std             NaN      1.0
min             NaN      1.0
25%             NaN      1.5
50%             NaN      2.0
75%             NaN      2.5
max             NaN      3.0
```

## pandas.DataFrame.diff

DataFrame.**diff** (*periods=1, axis=0*)

First discrete difference of element.

Calculates the difference of a DataFrame element compared with another element in the DataFrame (default is the element in the same column of the previous row).

### Parameters

**periods** [int, default 1] Periods to shift for calculating difference, accepts negative values.

**axis** [{0 or 'index', 1 or 'columns'}, default 0] Take difference over rows (0) or columns (1).

New in version 0.16.1..

### Returns

**diffed** [DataFrame]

See also:

**Series.diff** First discrete difference for a Series.

**DataFrame.pct\_change** Percent change over given number of periods.

**DataFrame.shift** Shift index by desired number of periods with an optional time freq.

## Examples

Difference with previous row

```
>>> df = pd.DataFrame({'a': [1, 2, 3, 4, 5, 6],
...                     'b': [1, 1, 2, 3, 5, 8],
...                     'c': [1, 4, 9, 16, 25, 36]})
>>> df
   a  b  c
0  1  1  1
1  2  1  4
2  3  2  9
3  4  3 16
4  5  5 25
5  6  8 36
```

```
>>> df.diff()
   a  b  c
0 NaN NaN NaN
1 1.0 0.0 3.0
2 1.0 1.0 5.0
3 1.0 1.0 7.0
4 1.0 2.0 9.0
5 1.0 3.0 11.0
```

Difference with previous column

```
>>> df.diff(axis=1)
   a  b  c
0 NaN 0.0 0.0
1 NaN -1.0 3.0
2 NaN -1.0 7.0
3 NaN -1.0 13.0
4 NaN 0.0 20.0
5 NaN 2.0 28.0
```

Difference with 3rd previous row

```
>>> df.diff(periods=3)
   a  b  c
0 NaN NaN NaN
1 NaN NaN NaN
2 NaN NaN NaN
3 3.0 2.0 15.0
4 3.0 4.0 21.0
5 3.0 6.0 27.0
```

Difference with following row

```
>>> df.diff( periods=-1)
      a      b      c
0 -1.0  0.0 -3.0
1 -1.0 -1.0 -5.0
2 -1.0 -1.0 -7.0
3 -1.0 -2.0 -9.0
4 -1.0 -3.0 -11.0
5  NaN  NaN  NaN
```

## pandas.DataFrame.div

`DataFrame.div` (*other*, *axis*=*'columns'*, *level*=*None*, *fill\_value*=*None*)

Floating division of dataframe and other, element-wise (binary operator *truediv*).

Equivalent to `dataframe / other`, but with support to substitute a *fill\_value* for missing data in one of the inputs. With reverse version, *rtruediv*.

Among flexible wrappers (*add*, *sub*, *mul*, *div*, *mod*, *pow*) to arithmetic operators: *+*, *-*, *\**, */*, *//*, *%*, *\*\**.

### Parameters

**other** [scalar, sequence, Series, or DataFrame] Any single or multiple element data structure, or list-like object.

**axis** [{0 or *'index'*, 1 or *'columns'*}] Whether to compare by the index (0 or *'index'*) or columns (1 or *'columns'*). For Series input, axis to match Series index on.

**level** [int or label] Broadcast across a level, matching Index values on the passed Multi-Index level.

**fill\_value** [float or None, default None] Fill existing missing (NaN) values, and any new element needed for successful DataFrame alignment, with this value before computation. If data in both corresponding DataFrame locations is missing the result will be missing.

### Returns

**DataFrame** Result of the arithmetic operation.

See also:

**DataFrame.add** Add DataFrames.

**DataFrame.sub** Subtract DataFrames.

**DataFrame.mul** Multiply DataFrames.

**DataFrame.div** Divide DataFrames (float division).

**DataFrame.truediv** Divide DataFrames (float division).

**DataFrame.floordiv** Divide DataFrames (integer division).

**DataFrame.mod** Calculate modulo (remainder after division).

**DataFrame.pow** Calculate exponential power.

### Notes

Mismatched indices will be unioned together.

## Examples

```
>>> df = pd.DataFrame({'angles': [0, 3, 4],
...                     'degrees': [360, 180, 360]},
...                     index=['circle', 'triangle', 'rectangle'])
>>> df
```

|           | angles | degrees |
|-----------|--------|---------|
| circle    | 0      | 360     |
| triangle  | 3      | 180     |
| rectangle | 4      | 360     |

Add a scalar with operator version which return the same results.

```
>>> df + 1
```

|           | angles | degrees |
|-----------|--------|---------|
| circle    | 1      | 361     |
| triangle  | 4      | 181     |
| rectangle | 5      | 361     |

```
>>> df.add(1)
```

|           | angles | degrees |
|-----------|--------|---------|
| circle    | 1      | 361     |
| triangle  | 4      | 181     |
| rectangle | 5      | 361     |

Divide by constant with reverse version.

```
>>> df.div(10)
```

|           | angles | degrees |
|-----------|--------|---------|
| circle    | 0.0    | 36.0    |
| triangle  | 0.3    | 18.0    |
| rectangle | 0.4    | 36.0    |

```
>>> df.rdiv(10)
```

|           | angles   | degrees  |
|-----------|----------|----------|
| circle    | inf      | 0.027778 |
| triangle  | 3.333333 | 0.055556 |
| rectangle | 2.500000 | 0.027778 |

Subtract a list and Series by axis with operator version.

```
>>> df - [1, 2]
```

|           | angles | degrees |
|-----------|--------|---------|
| circle    | -1     | 358     |
| triangle  | 2      | 178     |
| rectangle | 3      | 358     |

```
>>> df.sub([1, 2], axis='columns')
```

|           | angles | degrees |
|-----------|--------|---------|
| circle    | -1     | 358     |
| triangle  | 2      | 178     |
| rectangle | 3      | 358     |

```
>>> df.sub(pd.Series([1, 1, 1], index=['circle', 'triangle', 'rectangle']),
...        axis='index')
```

|           | angles | degrees |
|-----------|--------|---------|
| circle    | -1     | 359     |
| triangle  | 2      | 179     |
| rectangle | 3      | 359     |

(continues on next page)

(continued from previous page)

|           |    |     |
|-----------|----|-----|
| circle    | -1 | 359 |
| triangle  | 2  | 179 |
| rectangle | 3  | 359 |

Multiply a DataFrame of different shape with operator version.

```
>>> other = pd.DataFrame({'angles': [0, 3, 4]},
...                        index=['circle', 'triangle', 'rectangle'])
>>> other
```

|           | angles |
|-----------|--------|
| circle    | 0      |
| triangle  | 3      |
| rectangle | 4      |

```
>>> df * other
```

|           | angles | degrees |
|-----------|--------|---------|
| circle    | 0      | NaN     |
| triangle  | 9      | NaN     |
| rectangle | 16     | NaN     |

```
>>> df.mul(other, fill_value=0)
```

|           | angles | degrees |
|-----------|--------|---------|
| circle    | 0      | 0.0     |
| triangle  | 9      | 0.0     |
| rectangle | 16     | 0.0     |

Divide by a MultiIndex by level.

```
>>> df_multindex = pd.DataFrame({'angles': [0, 3, 4, 4, 5, 6],
...                               'degrees': [360, 180, 360, 360, 540, 720]},
...                               index=[['A', 'A', 'A', 'B', 'B', 'B'],
...                                       ['circle', 'triangle', 'rectangle',
...                                        'square', 'pentagon', 'hexagon']])
>>> df_multindex
```

|   |           | angles | degrees |
|---|-----------|--------|---------|
| A | circle    | 0      | 360     |
|   | triangle  | 3      | 180     |
|   | rectangle | 4      | 360     |
| B | square    | 4      | 360     |
|   | pentagon  | 5      | 540     |
|   | hexagon   | 6      | 720     |

```
>>> df.div(df_multindex, level=1, fill_value=0)
```

|   |           | angles | degrees |
|---|-----------|--------|---------|
| A | circle    | NaN    | 1.0     |
|   | triangle  | 1.0    | 1.0     |
|   | rectangle | 1.0    | 1.0     |
| B | square    | 0.0    | 0.0     |
|   | pentagon  | 0.0    | 0.0     |
|   | hexagon   | 0.0    | 0.0     |

**pandas.DataFrame.divide**

`DataFrame.divide` (*other*, *axis*='columns', *level*=None, *fill\_value*=None)

Floating division of dataframe and other, element-wise (binary operator *truediv*).

Equivalent to `dataframe / other`, but with support to substitute a *fill\_value* for missing data in one of the inputs. With reverse version, *rtruediv*.

Among flexible wrappers (*add*, *sub*, *mul*, *div*, *mod*, *pow*) to arithmetic operators: `+`, `-`, `*`, `/`, `//`, `%`, `**`.

**Parameters**

**other** [scalar, sequence, Series, or DataFrame] Any single or multiple element data structure, or list-like object.

**axis** [{0 or 'index', 1 or 'columns'}] Whether to compare by the index (0 or 'index') or columns (1 or 'columns'). For Series input, axis to match Series index on.

**level** [int or label] Broadcast across a level, matching Index values on the passed Multi-Index level.

**fill\_value** [float or None, default None] Fill existing missing (NaN) values, and any new element needed for successful DataFrame alignment, with this value before computation. If data in both corresponding DataFrame locations is missing the result will be missing.

**Returns**

**DataFrame** Result of the arithmetic operation.

See also:

**DataFrame.add** Add DataFrames.

**DataFrame.sub** Subtract DataFrames.

**DataFrame.mul** Multiply DataFrames.

**DataFrame.div** Divide DataFrames (float division).

**DataFrame.truediv** Divide DataFrames (float division).

**DataFrame.floordiv** Divide DataFrames (integer division).

**DataFrame.mod** Calculate modulo (remainder after division).

**DataFrame.pow** Calculate exponential power.

**Notes**

Mismatched indices will be unioned together.

**Examples**

```
>>> df = pd.DataFrame({'angles': [0, 3, 4],
...                     'degrees': [360, 180, 360]},
...                     index=['circle', 'triangle', 'rectangle'])
>>> df
      angles  degrees
circle      0     360
```

(continued from previous page)

|           |   |     |
|-----------|---|-----|
| triangle  | 3 | 180 |
| rectangle | 4 | 360 |

Add a scalar with operator version which return the same results.

```
>>> df + 1
```

|           | angles | degrees |
|-----------|--------|---------|
| circle    | 1      | 361     |
| triangle  | 4      | 181     |
| rectangle | 5      | 361     |

```
>>> df.add(1)
```

|           | angles | degrees |
|-----------|--------|---------|
| circle    | 1      | 361     |
| triangle  | 4      | 181     |
| rectangle | 5      | 361     |

Divide by constant with reverse version.

```
>>> df.div(10)
```

|           | angles | degrees |
|-----------|--------|---------|
| circle    | 0.0    | 36.0    |
| triangle  | 0.3    | 18.0    |
| rectangle | 0.4    | 36.0    |

```
>>> df.rdiv(10)
```

|           | angles   | degrees  |
|-----------|----------|----------|
| circle    | inf      | 0.027778 |
| triangle  | 3.333333 | 0.055556 |
| rectangle | 2.500000 | 0.027778 |

Subtract a list and Series by axis with operator version.

```
>>> df - [1, 2]
```

|           | angles | degrees |
|-----------|--------|---------|
| circle    | -1     | 358     |
| triangle  | 2      | 178     |
| rectangle | 3      | 358     |

```
>>> df.sub([1, 2], axis='columns')
```

|           | angles | degrees |
|-----------|--------|---------|
| circle    | -1     | 358     |
| triangle  | 2      | 178     |
| rectangle | 3      | 358     |

```
>>> df.sub(pd.Series([1, 1, 1], index=['circle', 'triangle', 'rectangle']),  
...        axis='index')
```

|           | angles | degrees |
|-----------|--------|---------|
| circle    | -1     | 359     |
| triangle  | 2      | 179     |
| rectangle | 3      | 359     |

Multiply a DataFrame of different shape with operator version.

```
>>> other = pd.DataFrame({'angles': [0, 3, 4]},
...                        index=['circle', 'triangle', 'rectangle'])
>>> other
```

|           | angles |
|-----------|--------|
| circle    | 0      |
| triangle  | 3      |
| rectangle | 4      |

```
>>> df * other
```

|           | angles | degrees |
|-----------|--------|---------|
| circle    | 0      | NaN     |
| triangle  | 9      | NaN     |

```
>>> df.mul(other, fill_value=0)
```

|           | angles | degrees |
|-----------|--------|---------|
| circle    | 0      | 0.0     |
| triangle  | 9      | 0.0     |
| rectangle | 16     | 0.0     |

Divide by a MultiIndex by level.

```
>>> df_multindex = pd.DataFrame({'angles': [0, 3, 4, 4, 5, 6],
...                               'degrees': [360, 180, 360, 360, 540, 720]},
...                              index=[['A', 'A', 'A', 'B', 'B', 'B'],
...                                     ['circle', 'triangle', 'rectangle',
...                                      'square', 'pentagon', 'hexagon']])
>>> df_multindex
```

|   |           | angles | degrees |
|---|-----------|--------|---------|
| A | circle    | 0      | 360     |
|   | triangle  | 3      | 180     |
|   | rectangle | 4      | 360     |
| B | square    | 4      | 360     |
|   | pentagon  | 5      | 540     |
|   | hexagon   | 6      | 720     |

```
>>> df.div(df_multindex, level=1, fill_value=0)
```

|   |           | angles | degrees |
|---|-----------|--------|---------|
| A | circle    | NaN    | 1.0     |
|   | triangle  | 1.0    | 1.0     |
|   | rectangle | 1.0    | 1.0     |
| B | square    | 0.0    | 0.0     |
|   | pentagon  | 0.0    | 0.0     |
|   | hexagon   | 0.0    | 0.0     |

## pandas.DataFrame.dot

`DataFrame.dot(other)`

Compute the matrix multiplication between the DataFrame and other.

This method computes the matrix product between the DataFrame and the values of an other Series, DataFrame or a numpy array.

It can also be called using `self @ other` in Python `>= 3.5`.

### Parameters

**other** [Series, DataFrame or array-like] The other object to compute the matrix product with.

### Returns

**Series or DataFrame** If other is a Series, return the matrix product between self and other as a Serie. If other is a DataFrame or a numpy.array, return the matrix product of self and other in a DataFrame of a np.array.

### See also:

**Series.dot** Similar method for Series.

### Notes

The dimensions of DataFrame and other must be compatible in order to compute the matrix multiplication.

The dot method for Series computes the inner product, instead of the matrix product here.

### Examples

Here we multiply a DataFrame with a Series.

```
>>> df = pd.DataFrame([[0, 1, -2, -1], [1, 1, 1, 1]])
>>> s = pd.Series([1, 1, 2, 1])
>>> df.dot(s)
0    -4
1     5
dtype: int64
```

Here we multiply a DataFrame with another DataFrame.

```
>>> other = pd.DataFrame([[0, 1], [1, 2], [-1, -1], [2, 0]])
>>> df.dot(other)
0    1
0    1    4
1    2    2
```

Note that the dot method give the same result as @

```
>>> df @ other
0    1
0    1    4
1    2    2
```

The dot method works also if other is an np.array.

```
>>> arr = np.array([[0, 1], [1, 2], [-1, -1], [2, 0]])
>>> df.dot(arr)
0    1
0    1    4
1    2    2
```

**pandas.DataFrame.drop**

`DataFrame.drop` (*labels=None, axis=0, index=None, columns=None, level=None, inplace=False, errors='raise'*)

Drop specified labels from rows or columns.

Remove rows or columns by specifying label names and corresponding axis, or by specifying directly index or column names. When using a multi-index, labels on different levels can be removed by specifying the level.

**Parameters**

**labels** [single label or list-like] Index or column labels to drop.

**axis** [{0 or 'index', 1 or 'columns'}, default 0] Whether to drop labels from the index (0 or 'index') or columns (1 or 'columns').

**index, columns** [single label or list-like] Alternative to specifying axis (*labels*, *axis=1* is equivalent to *columns=labels*).

New in version 0.21.0.

**level** [int or level name, optional] For MultiIndex, level from which the labels will be removed.

**inplace** [bool, default False] If True, do operation inplace and return None.

**errors** [{ 'ignore', 'raise' }, default 'raise'] If 'ignore', suppress error and only existing labels are dropped.

**Returns**

**dropped** [pandas.DataFrame]

**Raises**

**KeyError** If none of the labels are found in the selected axis

See also:

**DataFrame.loc** Label-location based indexer for selection by label.

**DataFrame.dropna** Return DataFrame with labels on given axis omitted where (all or any) data are missing.

**DataFrame.drop\_duplicates** Return DataFrame with duplicate rows removed, optionally only considering certain columns.

**Series.drop** Return Series with specified index labels removed.

**Examples**

```
>>> df = pd.DataFrame(np.arange(12).reshape(3,4),
...                    columns=['A', 'B', 'C', 'D'])
>>> df
   A  B  C  D
0  0  1  2  3
1  4  5  6  7
2  8  9 10 11
```

Drop columns

```
>>> df.drop(['B', 'C'], axis=1)
   A  D
0  0  3
1  4  7
2  8 11
```

```
>>> df.drop(columns=['B', 'C'])
   A  D
0  0  3
1  4  7
2  8 11
```

Drop a row by index

```
>>> df.drop([0, 1])
   A  B  C  D
2  8  9 10 11
```

Drop columns and/or rows of MultiIndex DataFrame

```
>>> midx = pd.MultiIndex(levels=[['lama', 'cow', 'falcon'],
...                               ['speed', 'weight', 'length']],
...                       codes=[[0, 0, 0, 1, 1, 1, 2, 2, 2],
...                               [0, 1, 2, 0, 1, 2, 0, 1, 2]])
>>> df = pd.DataFrame(index=midx, columns=['big', 'small'],
...                     data=[[45, 30], [200, 100], [1.5, 1], [30, 20],
...                               [250, 150], [1.5, 0.8], [320, 250],
...                               [1, 0.8], [0.3, 0.2]])
>>> df
```

|        |        |       |       |
|--------|--------|-------|-------|
|        |        | big   | small |
| lama   | speed  | 45.0  | 30.0  |
|        | weight | 200.0 | 100.0 |
|        | length | 1.5   | 1.0   |
| cow    | speed  | 30.0  | 20.0  |
|        | weight | 250.0 | 150.0 |
|        | length | 1.5   | 0.8   |
| falcon | speed  | 320.0 | 250.0 |
|        | weight | 1.0   | 0.8   |
|        | length | 0.3   | 0.2   |

```
>>> df.drop(index='cow', columns='small')
           big
lama  speed  45.0
      weight 200.0
      length  1.5
falcon speed 320.0
      weight  1.0
      length  0.3
```

```
>>> df.drop(index='length', level=1)
           big  small
lama  speed  45.0  30.0
      weight 200.0 100.0
cow    speed  30.0  20.0
      weight 250.0 150.0
falcon speed 320.0 250.0
      weight  1.0   0.8
```

**pandas.DataFrame.drop\_duplicates**`DataFrame.drop_duplicates` (*subset=None, keep='first', inplace=False*)

Return DataFrame with duplicate rows removed, optionally only considering certain columns.

**Parameters****subset** [column label or sequence of labels, optional] Only consider certain columns for identifying duplicates, by default use all of the columns**keep** [{ 'first', 'last', False }, default 'first']

- `first` : Drop duplicates except for the first occurrence.
- `last` : Drop duplicates except for the last occurrence.
- `False` : Drop all duplicates.

**inplace** [boolean, default False] Whether to drop duplicates in place or to return a copy**Returns****deduplicated** [DataFrame]**pandas.DataFrame.droplevel**`DataFrame.droplevel` (*level, axis=0*)

Return DataFrame with requested index / column level(s) removed.

New in version 0.24.0.

**Parameters****level** [int, str, or list-like] If a string is given, must be the name of a level If list-like, elements must be names or positional indexes of levels.**axis** [{0 or 'index', 1 or 'columns'}, default 0]**Returns****DataFrame.droplevel()****Examples**

```
>>> df = pd.DataFrame([
...     [1, 2, 3, 4],
...     [5, 6, 7, 8],
...     [9, 10, 11, 12]
... ]).set_index([0, 1]).rename_axis(['a', 'b'])
```

```
>>> df.columns = pd.MultiIndex.from_tuples([
...     ('c', 'e'), ('d', 'f')
... ], names=['level_1', 'level_2'])
```

```
>>> df
level_1  c  d
level_2  e  f
a b
1 2      3  4
```

(continues on next page)

(continued from previous page)

```
5 6      7      8
9 10     11     12
```

```
>>> df.droplevel('a')
level_1  c    d
level_2  e    f
b
2         3    4
6         7    8
10        11   12
```

```
>>> df.droplevel('level2', axis=1)
level_1  c    d
a b
1 2      3    4
5 6      7    8
9 10     11   12
```

## pandas.DataFrame.dropna

`DataFrame.dropna` (*axis=0*, *how='any'*, *thresh=None*, *subset=None*, *inplace=False*)

Remove missing values.

See the *User Guide* for more on which values are considered missing, and how to work with missing data.

### Parameters

**axis** [{0 or 'index', 1 or 'columns'}, default 0] Determine if rows or columns which contain missing values are removed.

- 0, or 'index' : Drop rows which contain missing values.
- 1, or 'columns' : Drop columns which contain missing value.

Deprecated since version 0.23.0: Pass tuple or list to drop on multiple axes. Only a single axis is allowed.

**how** [{ 'any', 'all' }, default 'any'] Determine if row or column is removed from DataFrame, when we have at least one NA or all NA.

- 'any' : If any NA values are present, drop that row or column.
- 'all' : If all values are NA, drop that row or column.

**thresh** [int, optional] Require that many non-NA values.

**subset** [array-like, optional] Labels along other axis to consider, e.g. if you are dropping rows these would be a list of columns to include.

**inplace** [bool, default False] If True, do operation inplace and return None.

### Returns

**DataFrame** DataFrame with NA entries dropped from it.

See also:

**DataFrame.isna** Indicate missing values.

**DataFrame.notna** Indicate existing (non-missing) values.

**DataFrame.fillna** Replace missing values.

**Series.dropna** Drop missing values.

**Index.dropna** Drop missing indices.

## Examples

```
>>> df = pd.DataFrame({"name": ['Alfred', 'Batman', 'Catwoman'],
...                     "toy": [np.nan, 'Batmobile', 'Bullwhip'],
...                     "born": [pd.NaT, pd.Timestamp("1940-04-25"),
...                               pd.NaT]})
>>> df
```

|   | name     | toy       | born       |
|---|----------|-----------|------------|
| 0 | Alfred   | NaN       | NaT        |
| 1 | Batman   | Batmobile | 1940-04-25 |
| 2 | Catwoman | Bullwhip  | NaT        |

Drop the rows where at least one element is missing.

```
>>> df.dropna()
      name      toy      born
1  Batman  Batmobile  1940-04-25
```

Drop the columns where at least one element is missing.

```
>>> df.dropna(axis='columns')
      name
0  Alfred
1  Batman
2  Catwoman
```

Drop the rows where all elements are missing.

```
>>> df.dropna(how='all')
      name      toy      born
0  Alfred      NaN      NaT
1  Batman  Batmobile  1940-04-25
2  Catwoman  Bullwhip      NaT
```

Keep only the rows with at least 2 non-NA values.

```
>>> df.dropna(thresh=2)
      name      toy      born
1  Batman  Batmobile  1940-04-25
2  Catwoman  Bullwhip      NaT
```

Define in which columns to look for missing values.

```
>>> df.dropna(subset=['name', 'born'])
      name      toy      born
1  Batman  Batmobile  1940-04-25
```

Keep the DataFrame with valid entries in the same variable.

```
>>> df.dropna(inplace=True)
>>> df
```

(continues on next page)

(continued from previous page)

|   | name   | toy       | born       |
|---|--------|-----------|------------|
| 1 | Batman | Batmobile | 1940-04-25 |

## pandas.DataFrame.duplicated

`DataFrame.duplicated` (*subset=None, keep='first'*)

Return boolean Series denoting duplicate rows, optionally only considering certain columns.

### Parameters

**subset** [column label or sequence of labels, optional] Only consider certain columns for identifying duplicates, by default use all of the columns

**keep** [{ 'first', 'last', False }, default 'first']

- `first` : Mark duplicates as `True` except for the first occurrence.
- `last` : Mark duplicates as `True` except for the last occurrence.
- `False` : Mark all duplicates as `True`.

### Returns

**duplicated** [Series]

## pandas.DataFrame.eq

`DataFrame.eq` (*other, axis='columns', level=None*)

Equal to of dataframe and other, element-wise (binary operator *eq*).

Among flexible wrappers (*eq, ne, le, lt, ge, gt*) to comparison operators.

Equivalent to `==`, `!=`, `<=`, `<`, `>=`, `>` with support to choose axis (rows or columns) and level for comparison.

### Parameters

**other** [scalar, sequence, Series, or DataFrame] Any single or multiple element data structure, or list-like object.

**axis** [{0 or 'index', 1 or 'columns'}, default 'columns'] Whether to compare by the index (0 or 'index') or columns (1 or 'columns').

**level** [int or label] Broadcast across a level, matching Index values on the passed Multi-Index level.

### Returns

**DataFrame of bool** Result of the comparison.

See also:

**DataFrame.eq** Compare DataFrames for equality elementwise.

**DataFrame.ne** Compare DataFrames for inequality elementwise.

**DataFrame.le** Compare DataFrames for less than inequality or equality elementwise.

**DataFrame.lt** Compare DataFrames for strictly less than inequality elementwise.

**DataFrame.ge** Compare DataFrames for greater than inequality or equality elementwise.

**DataFrame.gt** Compare DataFrames for strictly greater than inequality elementwise.

## Notes

Mismatched indices will be unioned together. *NaN* values are considered different (i.e. *NaN* != *NaN*).

## Examples

```
>>> df = pd.DataFrame({'cost': [250, 150, 100],
...                     'revenue': [100, 250, 300]},
...                     index=['A', 'B', 'C'])
>>> df
```

|   | cost | revenue |
|---|------|---------|
| A | 250  | 100     |
| B | 150  | 250     |
| C | 100  | 300     |

Compare to a scalar and operator version which return the same results.

```
>>> df == 100
```

|   | cost  | revenue |
|---|-------|---------|
| A | False | True    |
| B | False | False   |
| C | True  | False   |

```
>>> df.eq(100)
```

|   | cost  | revenue |
|---|-------|---------|
| A | False | True    |
| B | False | False   |
| C | True  | False   |

Compare to a list and Series by axis and operator version. As shown, for list axis is by default 'index', but for Series axis is by default 'columns'.

```
>>> df != [100, 250, 300]
```

|   | cost | revenue |
|---|------|---------|
| A | True | False   |
| B | True | False   |
| C | True | False   |

```
>>> df.ne([100, 250, 300], axis='index')
```

|   | cost | revenue |
|---|------|---------|
| A | True | False   |
| B | True | False   |
| C | True | False   |

```
>>> df != pd.Series([100, 250, 300])
```

|   | cost | revenue | 0    | 1    | 2    |
|---|------|---------|------|------|------|
| A | True | True    | True | True | True |
| B | True | True    | True | True | True |
| C | True | True    | True | True | True |

```
>>> df.ne(pd.Series([100, 250, 300]), axis='columns')
      cost  revenue    0    1    2
A  True      True  True  True  True
B  True      True  True  True  True
C  True      True  True  True  True
```

Compare to a DataFrame of different shape.

```
>>> other = pd.DataFrame({'revenue': [300, 250, 100, 150]},
...                        index=['A', 'B', 'C', 'D'])
>>> other
      revenue
A         300
B         250
C         100
D         150
```

```
>>> df.gt(other)
      cost  revenue
A  False   False
B  False   False
C  False    True
D  False   False
```

Compare to a MultiIndex by level.

```
>>> df_multindex = pd.DataFrame({'cost': [250, 150, 100, 150, 300, 220],
...                               'revenue': [100, 250, 300, 200, 175, 225]},
...                              index=[['Q1', 'Q1', 'Q1', 'Q2', 'Q2', 'Q2'],
...                                     ['A', 'B', 'C', 'A', 'B', 'C']])
>>> df_multindex
      cost  revenue
Q1 A    250     100
   B    150     250
   C    100     300
Q2 A    150     200
   B    300     175
   C    220     225
```

```
>>> df.le(df_multindex, level=1)
      cost  revenue
Q1 A   True     True
   B   True     True
   C   True     True
Q2 A  False     True
   B   True     False
   C   True     False
```

## pandas.DataFrame.equals

`DataFrame.equals` (*other*)

Test whether two objects contain the same elements.

This function allows two Series or DataFrames to be compared against each other to see if they have the same shape and elements. NaNs in the same location are considered equal. The column headers do not need to have the same type, but the elements within the columns must be the same dtype.

**Parameters**

**other** [Series or DataFrame] The other Series or DataFrame to be compared with the first.

**Returns**

**bool** True if all elements are the same in both objects, False otherwise.

**See also:**

**Series.eq** Compare two Series objects of the same length and return a Series where each element is True if the element in each Series is equal, False otherwise.

**DataFrame.eq** Compare two DataFrame objects of the same shape and return a DataFrame where each element is True if the respective element in each DataFrame is equal, False otherwise.

**assert\_series\_equal** Return True if left and right Series are equal, False otherwise.

**assert\_frame\_equal** Return True if left and right DataFrames are equal, False otherwise.

**numpy.array\_equal** Return True if two arrays have the same shape and elements, False otherwise.

**Notes**

This function requires that the elements have the same dtype as their respective elements in the other Series or DataFrame. However, the column labels do not need to have the same type, as long as they are still considered equal.

**Examples**

```
>>> df = pd.DataFrame({1: [10], 2: [20]})
>>> df
   1  2
0 10 20
```

DataFrames `df` and `exactly_equal` have the same types and values for their elements and column labels, which will return True.

```
>>> exactly_equal = pd.DataFrame({1: [10], 2: [20]})
>>> exactly_equal
   1  2
0 10 20
>>> df.equals(exactly_equal)
True
```

DataFrames `df` and `different_column_type` have the same element types and values, but have different types for the column labels, which will still return True.

```
>>> different_column_type = pd.DataFrame({1.0: [10], 2.0: [20]})
>>> different_column_type
   1.0  2.0
0   10   20
>>> df.equals(different_column_type)
True
```

DataFrames `df` and `different_data_type` have different types for the same values for their elements, and will return False even though their column labels are the same values and types.

```
>>> different_data_type = pd.DataFrame({1: [10.0], 2: [20.0]})
>>> different_data_type
   1      2
0 10.0  20.0
>>> df.equals(different_data_type)
False
```

## pandas.DataFrame.eval

`DataFrame.eval` (*expr*, *inplace=False*, *\*\*kwargs*)

Evaluate a string describing operations on DataFrame columns.

Operates on columns only, not specific rows or elements. This allows *eval* to run arbitrary code, which can make you vulnerable to code injection if you pass user input to this function.

### Parameters

**expr** [str] The expression string to evaluate.

**inplace** [bool, default False] If the expression contains an assignment, whether to perform the operation inplace and mutate the existing DataFrame. Otherwise, a new DataFrame is returned.

New in version 0.18.0..

**kwargs** [dict] See the documentation for *eval()* for complete details on the keyword arguments accepted by *query()*.

### Returns

**ndarray, scalar, or pandas object** The result of the evaluation.

See also:

**DataFrame.query** Evaluates a boolean expression to query the columns of a frame.

**DataFrame.assign** Can evaluate an expression or function to create new values for a column.

**pandas.eval** Evaluate a Python expression as a string using various backends.

## Notes

For more details see the API documentation for *eval()*. For detailed examples see *enhancing performance with eval*.

## Examples

```
>>> df = pd.DataFrame({'A': range(1, 6), 'B': range(10, 0, -2)})
>>> df
   A  B
0  1 10
1  2  8
2  3  6
3  4  4
4  5  2
>>> df.eval('A + B')
```

(continues on next page)

(continued from previous page)

```

0      11
1      10
2       9
3       8
4       7
dtype: int64

```

Assignment is allowed though by default the original DataFrame is not modified.

```

>>> df.eval('C = A + B')
   A  B  C
0  1 10 11
1  2  8 10
2  3  6  9
3  4  4  8
4  5  2  7
>>> df
   A  B
0  1 10
1  2  8
2  3  6
3  4  4
4  5  2

```

Use `inplace=True` to modify the original DataFrame.

```

>>> df.eval('C = A + B', inplace=True)
>>> df
   A  B  C
0  1 10 11
1  2  8 10
2  3  6  9
3  4  4  8
4  5  2  7

```

## pandas.DataFrame.ewm

`DataFrame.ewm` (*com=None, span=None, halflife=None, alpha=None, min\_periods=0, adjust=True, ignore\_na=False, axis=0*)

Provides exponential weighted functions.

New in version 0.18.0.

### Parameters

**com** [float, optional] Specify decay in terms of center of mass,  $\alpha = 1/(1 + com)$ , for  $com \geq 0$

**span** [float, optional] Specify decay in terms of span,  $\alpha = 2/(span + 1)$ , for  $span \geq 1$

**halflife** [float, optional] Specify decay in terms of half-life,  $\alpha = 1 - \exp(\log(0.5)/halflife)$ , for  $halflife > 0$

**alpha** [float, optional] Specify smoothing factor  $\alpha$  directly,  $0 < \alpha \leq 1$

New in version 0.18.0.

**min\_periods** [int, default 0] Minimum number of observations in window required to have a value (otherwise result is NA).

**adjust** [bool, default True] Divide by decaying adjustment factor in beginning periods to account for imbalance in relative weightings (viewing EWMA as a moving average)

**ignore\_na** [bool, default False] Ignore missing values when calculating weights; specify True to reproduce pre-0.15.0 behavior

### Returns

a Window sub-classed for the particular operation

See also:

**rolling** Provides rolling window calculations.

**expanding** Provides expanding transformations.

### Notes

Exactly one of center of mass, span, half-life, and alpha must be provided. Allowed values and relationship between the parameters are specified in the parameter descriptions above; see the link at the end of this section for a detailed explanation.

When **adjust** is True (default), weighted averages are calculated using weights  $(1-\alpha)^{(n-1)}$ ,  $(1-\alpha)^{(n-2)}$ , ...,  $1-\alpha$ , 1.

**When **adjust** is False, weighted averages are calculated recursively as:**  $\text{weighted\_average}[0] = \text{arg}[0]$ ;  $\text{weighted\_average}[i] = (1-\alpha)*\text{weighted\_average}[i-1] + \alpha*\text{arg}[i]$ .

When **ignore\_na** is False (default), weights are based on absolute positions. For example, the weights of *x* and *y* used in calculating the final weighted average of [*x*, None, *y*] are  $(1-\alpha)^{**2}$  and 1 (if **adjust** is True), and  $(1-\alpha)^{**2}$  and  $\alpha$  (if **adjust** is False).

When **ignore\_na** is True (reproducing pre-0.15.0 behavior), weights are based on relative positions. For example, the weights of *x* and *y* used in calculating the final weighted average of [*x*, None, *y*] are  $1-\alpha$  and 1 (if **adjust** is True), and  $1-\alpha$  and  $\alpha$  (if **adjust** is False).

More details can be found at <http://pandas.pydata.org/pandas-docs/stable/computation.html#exponentially-weighted-windows>

### Examples

```
>>> df = pd.DataFrame({'B': [0, 1, 2, np.nan, 4]})
      B
0  0.0
1  1.0
2  2.0
3  NaN
4  4.0
```

```
>>> df.ewm(com=0.5).mean()
      B
0  0.000000
1  0.750000
2  1.615385
```

(continues on next page)

(continued from previous page)

```
3  1.615385
4  3.670213
```

**pandas.DataFrame.expanding**`DataFrame.expanding` (*min\_periods=1, center=False, axis=0*)

Provides expanding transformations.

New in version 0.18.0.

**Parameters****min\_periods** [int, default 1] Minimum number of observations in window required to have a value (otherwise result is NA).**center** [bool, default False] Set the labels at the center of the window.**axis** [int or str, default 0]**Returns****a Window sub-classed for the particular operation****See also:****rolling** Provides rolling window calculations.**ewm** Provides exponential weighted functions.**Notes**By default, the result is set to the right edge of the window. This can be changed to the center of the window by setting `center=True`.**Examples**

```
>>> df = pd.DataFrame({'B': [0, 1, 2, np.nan, 4]})
      B
0  0.0
1  1.0
2  2.0
3  NaN
4  4.0
```

```
>>> df.expanding(2).sum()
      B
0  NaN
1  1.0
2  3.0
3  3.0
4  7.0
```

**pandas.DataFrame.fffll**

`DataFrame.fffll` (*axis=None, inplace=False, limit=None, downcast=None*)

Synonym for `DataFrame.fillna()` with `method='fffll'`.

**pandas.DataFrame.fillna**

`DataFrame.fillna` (*value=None, method=None, axis=None, inplace=False, limit=None, downcast=None, \*\*kwargs*)

Fill NA/NaN values using the specified method.

**Parameters**

**value** [scalar, dict, Series, or DataFrame] Value to use to fill holes (e.g. 0), alternately a dict/Series/DataFrame of values specifying which value to use for each index (for a Series) or column (for a DataFrame). (values not in the dict/Series/DataFrame will not be filled). This value cannot be a list.

**method** [{‘backfill’, ‘bfill’, ‘pad’, ‘fffll’, None}, default None] Method to use for filling holes in reindexed Series `pad` / `fffll`: propagate last valid observation forward to next valid `backfill` / `bfill`: use NEXT valid observation to fill gap

**axis** [{0 or ‘index’, 1 or ‘columns’}]

**inplace** [boolean, default False] If True, fill in place. Note: this will modify any other views on this object, (e.g. a no-copy slice for a column in a DataFrame).

**limit** [int, default None] If method is specified, this is the maximum number of consecutive NaN values to forward/backward fill. In other words, if there is a gap with more than this number of consecutive NaNs, it will only be partially filled. If method is not specified, this is the maximum number of entries along the entire axis where NaNs will be filled. Must be greater than 0 if not None.

**downcast** [dict, default is None] a dict of item->dtype of what to downcast if possible, or the string ‘infer’ which will try to downcast to an appropriate equal type (e.g. float64 to int64 if possible)

**Returns**

**filled** [DataFrame]

See also:

**interpolate** Fill NaN values using interpolation.

*reindex, asfreq*

**Examples**

```
>>> df = pd.DataFrame([[np.nan, 2, np.nan, 0],
...                     [3, 4, np.nan, 1],
...                     [np.nan, np.nan, np.nan, 5],
...                     [np.nan, 3, np.nan, 4]],
...                     columns=list('ABCD'))
>>> df
   A    B    C    D
0 NaN  2.0 NaN   0
```

(continues on next page)

(continued from previous page)

|   |     |     |     |   |
|---|-----|-----|-----|---|
| 1 | 3.0 | 4.0 | NaN | 1 |
| 2 | NaN | NaN | NaN | 5 |
| 3 | NaN | 3.0 | NaN | 4 |

Replace all NaN elements with 0s.

```
>>> df.fillna(0)
   A    B    C    D
0  0.0  2.0  0.0  0
1  3.0  4.0  0.0  1
2  0.0  0.0  0.0  5
3  0.0  3.0  0.0  4
```

We can also propagate non-null values forward or backward.

```
>>> df.fillna(method='ffill')
   A    B    C    D
0  NaN  2.0  NaN  0
1  3.0  4.0  NaN  1
2  3.0  4.0  NaN  5
3  3.0  3.0  NaN  4
```

Replace all NaN elements in column 'A', 'B', 'C', and 'D', with 0, 1, 2, and 3 respectively.

```
>>> values = {'A': 0, 'B': 1, 'C': 2, 'D': 3}
>>> df.fillna(value=values)
   A    B    C    D
0  0.0  2.0  2.0  0
1  3.0  4.0  2.0  1
2  0.0  1.0  2.0  5
3  0.0  3.0  2.0  4
```

Only replace the first NaN element.

```
>>> df.fillna(value=values, limit=1)
   A    B    C    D
0  0.0  2.0  2.0  0
1  3.0  4.0  NaN  1
2  NaN  1.0  NaN  5
3  NaN  3.0  NaN  4
```

## pandas.DataFrame.filter

`DataFrame.filter` (*items=None, like=None, regex=None, axis=None*)

Subset rows or columns of dataframe according to labels in the specified index.

Note that this routine does not filter a dataframe on its contents. The filter is applied to the labels of the index.

### Parameters

**items** [list-like] List of axis to restrict to (must not all be present).

**like** [string] Keep axis where “arg in col == True”.

**regex** [string (regular expression)] Keep axis with `re.search(regex, col) == True`.

**axis** [int or string axis name] The axis to filter on. By default this is the info axis, ‘index’ for Series, ‘columns’ for DataFrame.

### Returns

same type as input object

### See also:

`DataFrame.loc`

### Notes

The `items`, `like`, and `regex` parameters are enforced to be mutually exclusive.

`axis` defaults to the info axis that is used when indexing with `[]`.

### Examples

```
>>> df = pd.DataFrame(np.array([[1,2,3], [4,5,6]]),
...                    index=['mouse', 'rabbit'],
...                    columns=['one', 'two', 'three'])
```

```
>>> # select columns by name
>>> df.filter(items=['one', 'three'])
      one  three
mouse    1     3
rabbit    4     6
```

```
>>> # select columns by regular expression
>>> df.filter(regex='e$', axis=1)
      one  three
mouse    1     3
rabbit    4     6
```

```
>>> # select rows containing 'bbi'
>>> df.filter(like='bbi', axis=0)
      one  two  three
rabbit    4    5     6
```

## pandas.DataFrame.first

`DataFrame.first` (*offset*)

Convenience method for subsetting initial periods of time series data based on a date offset.

### Parameters

**offset** [string, `DateOffset`, `dateutil.relativedelta`]

### Returns

**subset** [same type as caller]

### Raises

**TypeError** If the index is not a `DatetimeIndex`

See also:

**last** Select final periods of time series based on a date offset.

**at\_time** Select values at a particular time of the day.

**between\_time** Select values between particular times of the day.

## Examples

```
>>> i = pd.date_range('2018-04-09', periods=4, freq='2D')
>>> ts = pd.DataFrame({'A': [1,2,3,4]}, index=i)
>>> ts
```

|            | A |
|------------|---|
| 2018-04-09 | 1 |
| 2018-04-11 | 2 |
| 2018-04-13 | 3 |
| 2018-04-15 | 4 |

Get the rows for the first 3 days:

```
>>> ts.first('3D')
```

|            | A |
|------------|---|
| 2018-04-09 | 1 |
| 2018-04-11 | 2 |

Notice the data for 3 first calendar days were returned, not the first 3 days observed in the dataset, and therefore data for 2018-04-13 was not returned.

## pandas.DataFrame.first\_valid\_index

`DataFrame.first_valid_index()`

Return index for first non-NA/null value.

### Returns

**scalar** [type of index]

### Notes

If all elements are non-NA/null, returns None. Also returns None for empty NDFrame.

## pandas.DataFrame.floordiv

`DataFrame.floordiv(other, axis='columns', level=None, fill_value=None)`

Integer division of dataframe and other, element-wise (binary operator *floordiv*).

Equivalent to `dataframe // other`, but with support to substitute a `fill_value` for missing data in one of the inputs. With reverse version, *rfloordiv*.

Among flexible wrappers (*add*, *sub*, *mul*, *div*, *mod*, *pow*) to arithmetic operators: `+`, `-`, `*`, `/`, `//`, `%`, `**`.

### Parameters

**other** [scalar, sequence, Series, or DataFrame] Any single or multiple element data structure, or list-like object.

**axis** [{0 or 'index', 1 or 'columns'}] Whether to compare by the index (0 or 'index') or columns (1 or 'columns'). For Series input, axis to match Series index on.

**level** [int or label] Broadcast across a level, matching Index values on the passed Multi-Index level.

**fill\_value** [float or None, default None] Fill existing missing (NaN) values, and any new element needed for successful DataFrame alignment, with this value before computation. If data in both corresponding DataFrame locations is missing the result will be missing.

### Returns

**DataFrame** Result of the arithmetic operation.

See also:

**DataFrame.add** Add DataFrames.

**DataFrame.sub** Subtract DataFrames.

**DataFrame.mul** Multiply DataFrames.

**DataFrame.div** Divide DataFrames (float division).

**DataFrame.truediv** Divide DataFrames (float division).

**DataFrame.floordiv** Divide DataFrames (integer division).

**DataFrame.mod** Calculate modulo (remainder after division).

**DataFrame.pow** Calculate exponential power.

### Notes

Mismatched indices will be unioned together.

### Examples

```
>>> df = pd.DataFrame({'angles': [0, 3, 4],
...                     'degrees': [360, 180, 360]},
...                    index=['circle', 'triangle', 'rectangle'])
>>> df
```

|           | angles | degrees |
|-----------|--------|---------|
| circle    | 0      | 360     |
| triangle  | 3      | 180     |
| rectangle | 4      | 360     |

Add a scalar with operator version which return the same results.

```
>>> df + 1
```

|           | angles | degrees |
|-----------|--------|---------|
| circle    | 1      | 361     |
| triangle  | 4      | 181     |
| rectangle | 5      | 361     |

```
>>> df.add(1)
      angles  degrees
circle      1     361
triangle    4     181
rectangle   5     361
```

Divide by constant with reverse version.

```
>>> df.div(10)
      angles  degrees
circle    0.0    36.0
triangle  0.3    18.0
rectangle 0.4    36.0
```

```
>>> df.rdiv(10)
      angles  degrees
circle      inf  0.027778
triangle  3.333333  0.055556
rectangle  2.500000  0.027778
```

Subtract a list and Series by axis with operator version.

```
>>> df - [1, 2]
      angles  degrees
circle     -1     358
triangle    2     178
rectangle    3     358
```

```
>>> df.sub([1, 2], axis='columns')
      angles  degrees
circle     -1     358
triangle    2     178
rectangle    3     358
```

```
>>> df.sub(pd.Series([1, 1, 1], index=['circle', 'triangle', 'rectangle']),
...        axis='index')
      angles  degrees
circle     -1     359
triangle    2     179
rectangle    3     359
```

Multiply a DataFrame of different shape with operator version.

```
>>> other = pd.DataFrame({'angles': [0, 3, 4]},
...                       index=['circle', 'triangle', 'rectangle'])
>>> other
      angles
circle      0
triangle     3
rectangle     4
```

```
>>> df * other
      angles  degrees
circle      0      NaN
triangle     9      NaN
rectangle   16      NaN
```

```
>>> df.mul(other, fill_value=0)
           angles  degrees
circle          0      0.0
triangle         9      0.0
rectangle       16      0.0
```

Divide by a MultiIndex by level.

```
>>> df_multindex = pd.DataFrame({'angles': [0, 3, 4, 4, 5, 6],
...                               'degrees': [360, 180, 360, 360, 540, 720]},
...                               index=[['A', 'A', 'A', 'B', 'B', 'B'],
...                                       ['circle', 'triangle', 'rectangle',
...                                        'square', 'pentagon', 'hexagon']])
>>> df_multindex
           angles  degrees
A circle          0      360
  triangle         3      180
  rectangle         4      360
B square          4      360
  pentagon         5      540
  hexagon          6      720
```

```
>>> df.div(df_multindex, level=1, fill_value=0)
           angles  degrees
A circle        NaN      1.0
  triangle        1.0      1.0
  rectangle        1.0      1.0
B square         0.0      0.0
  pentagon         0.0      0.0
  hexagon         0.0      0.0
```

## pandas.DataFrame.from\_csv

**classmethod** `DataFrame.from_csv` (*path*, *header=0*, *sep=','*, *index\_col=0*, *parse\_dates=True*, *encoding=None*, *tupleize\_cols=None*, *infer\_datetime\_format=False*)

Read CSV file.

Deprecated since version 0.21.0: Use `pandas.read_csv()` instead.

It is preferable to use the more powerful `pandas.read_csv()` for most general purposes, but `from_csv` makes for an easy roundtrip to and from a file (the exact counterpart of `to_csv`), especially with a `DataFrame` of time series data.

This method only differs from the preferred `pandas.read_csv()` in some defaults:

- *index\_col* is 0 instead of None (take first column as index by default)
- *parse\_dates* is True instead of False (try parsing the index as datetime by default)

So a `pd.DataFrame.from_csv(path)` can be replaced by `pd.read_csv(path, index_col=0, parse_dates=True)`.

### Parameters

**path** [string file path or file handle / StringIO]

**header** [int, default 0] Row to use as header (skip prior rows)

**sep** [string, default ‘,’] Field delimiter

**index\_col** [int or sequence, default 0] Column to use for index. If a sequence is given, a MultiIndex is used. Different default from read\_table

**parse\_dates** [boolean, default True] Parse dates. Different default from read\_table

**tupleize\_cols** [boolean, default False] write multi\_index columns as a list of tuples (if True) or new (expanded format) if False)

**infer\_datetime\_format** [boolean, default False] If True and *parse\_dates* is True for a column, try to infer the datetime format based on the first datetime string. If the format can be inferred, there often will be a large parsing speed-up.

#### Returns

**y** [DataFrame]

#### See also:

*pandas.read\_csv*

### pandas.DataFrame.from\_dict

**classmethod** `DataFrame.from_dict` (*data*, *orient*=‘columns’, *dtype*=None, *columns*=None)

Construct DataFrame from dict of array-like or dicts.

Creates DataFrame object from dictionary by columns or by index allowing dtype specification.

#### Parameters

**data** [dict] Of the form {field : array-like} or {field : dict}.

**orient** [{‘columns’, ‘index’}, default ‘columns’] The “orientation” of the data. If the keys of the passed dict should be the columns of the resulting DataFrame, pass ‘columns’ (default). Otherwise if the keys should be rows, pass ‘index’.

**dtype** [dtype, default None] Data type to force, otherwise infer.

**columns** [list, default None] Column labels to use when *orient*=‘index’. Raises a ValueError if used with *orient*=‘columns’.

New in version 0.23.0.

#### Returns

**pandas.DataFrame**

#### See also:

**DataFrame.from\_records** DataFrame from ndarray (structured dtype), list of tuples, dict, or DataFrame.

**DataFrame** DataFrame object creation using constructor.

### Examples

By default the keys of the dict become the DataFrame columns:

```
>>> data = {'col_1': [3, 2, 1, 0], 'col_2': ['a', 'b', 'c', 'd']}
>>> pd.DataFrame.from_dict(data)
   col_1 col_2
0      3    a
1      2    b
2      1    c
3      0    d
```

Specify `orient='index'` to create the DataFrame using dictionary keys as rows:

```
>>> data = {'row_1': [3, 2, 1, 0], 'row_2': ['a', 'b', 'c', 'd']}
>>> pd.DataFrame.from_dict(data, orient='index')
   row_1 row_2
0      3    a
1      2    b
2      1    c
3      0    d
```

When using the ‘index’ orientation, the column names can be specified manually:

```
>>> pd.DataFrame.from_dict(data, orient='index',
...                          columns=['A', 'B', 'C', 'D'])
   row_1 A  B  C  D
0      3  3  2  1  0
1      2  3  2  1  0
2      1  3  2  1  0
3      0  3  2  1  0
```

## pandas.DataFrame.from\_items

**classmethod** `DataFrame.from_items` (*items*, *columns=None*, *orient='columns'*)

Construct a DataFrame from a list of tuples.

Deprecated since version 0.23.0: *from\_items* is deprecated and will be removed in a future version. Use *DataFrame.from\_dict(dict(items))* instead. *DataFrame.from\_dict(OrderedDict(items))* may be used to preserve the key order.

Convert (key, value) pairs to DataFrame. The keys will be the axis index (usually the columns, but depends on the specified orientation). The values should be arrays or Series.

### Parameters

**items** [sequence of (key, value) pairs] Values should be arrays or Series.

**columns** [sequence of column labels, optional] Must be passed if `orient='index'`.

**orient** [{‘columns’, ‘index’}, default ‘columns’] The “orientation” of the data. If the keys of the input correspond to column labels, pass ‘columns’ (default). Otherwise if the keys correspond to the index, pass ‘index’.

### Returns

**frame** [DataFrame]

## pandas.DataFrame.from\_records

**classmethod** `DataFrame.from_records` (*data*, *index=None*, *exclude=None*, *columns=None*, *coerce\_float=False*, *nrows=None*)

Convert structured or record ndarray to DataFrame.

### Parameters

**data** [ndarray (structured dtype), list of tuples, dict, or DataFrame]

**index** [string, list of fields, array-like] Field of array to use as the index, alternately a specific set of input labels to use

**exclude** [sequence, default None] Columns or fields to exclude

**columns** [sequence, default None] Column names to use. If the passed data do not have names associated with them, this argument provides names for the columns. Otherwise this argument indicates the order of the columns in the result (any names not found in the data will become all-NA columns)

**coerce\_float** [boolean, default False] Attempt to convert values of non-string, non-numeric objects (like decimal.Decimal) to floating point, useful for SQL result sets

**nrows** [int, default None] Number of rows to read if data is an iterator

**Returns**

**df** [DataFrame]

**pandas.DataFrame.ge**

`DataFrame.ge` (*other*, *axis*=*'columns'*, *level*=*None*)

Greater than or equal to of dataframe and other, element-wise (binary operator *ge*).

Among flexible wrappers (*eq*, *ne*, *le*, *lt*, *ge*, *gt*) to comparison operators.

Equivalent to `==`, `!=`, `<=`, `<`, `>=`, `>` with support to choose axis (rows or columns) and level for comparison.

**Parameters**

**other** [scalar, sequence, Series, or DataFrame] Any single or multiple element data structure, or list-like object.

**axis** [{0 or *'index'*, 1 or *'columns'*}, default *'columns'*] Whether to compare by the index (0 or *'index'*) or columns (1 or *'columns'*).

**level** [int or label] Broadcast across a level, matching Index values on the passed Multi-Index level.

**Returns**

**DataFrame of bool** Result of the comparison.

See also:

**DataFrame.eq** Compare DataFrames for equality elementwise.

**DataFrame.ne** Compare DataFrames for inequality elementwise.

**DataFrame.le** Compare DataFrames for less than inequality or equality elementwise.

**DataFrame.lt** Compare DataFrames for strictly less than inequality elementwise.

**DataFrame.ge** Compare DataFrames for greater than inequality or equality elementwise.

**DataFrame.gt** Compare DataFrames for strictly greater than inequality elementwise.

**Notes**

Mismatched indices will be unioned together. *NaN* values are considered different (i.e. *NaN* != *NaN*).

## Examples

```
>>> df = pd.DataFrame({'cost': [250, 150, 100],
...                     'revenue': [100, 250, 300]},
...                     index=['A', 'B', 'C'])
>>> df
   cost  revenue
A   250     100
B   150     250
C   100     300
```

Compare to a scalar and operator version which return the same results.

```
>>> df == 100
   cost  revenue
A  False     True
B  False    False
C   True    False
```

```
>>> df.eq(100)
   cost  revenue
A  False     True
B  False    False
C   True    False
```

Compare to a list and Series by axis and operator version. As shown, for list axis is by default 'index', but for Series axis is by default 'columns'.

```
>>> df != [100, 250, 300]
   cost  revenue
A   True    False
B   True    False
C   True    False
```

```
>>> df.ne([100, 250, 300], axis='index')
   cost  revenue
A   True    False
B   True    False
C   True    False
```

```
>>> df != pd.Series([100, 250, 300])
   cost  revenue    0    1    2
A   True     True  True  True  True
B   True     True  True  True  True
C   True     True  True  True  True
```

```
>>> df.ne(pd.Series([100, 250, 300]), axis='columns')
   cost  revenue    0    1    2
A   True     True  True  True  True
B   True     True  True  True  True
C   True     True  True  True  True
```

Compare to a DataFrame of different shape.

```
>>> other = pd.DataFrame({'revenue': [300, 250, 100, 150]},
...                       index=['A', 'B', 'C', 'D'])
```

(continues on next page)

(continued from previous page)

```
>>> other
      revenue
A         300
B         250
C         100
D         150
```

```
>>> df.gt(other)
      cost  revenue
A  False   False
B  False   False
C  False    True
D  False   False
```

Compare to a MultiIndex by level.

```
>>> df_multindex = pd.DataFrame({'cost': [250, 150, 100, 150, 300, 220],
...                               'revenue': [100, 250, 300, 200, 175, 225]},
...                               index=[['Q1', 'Q1', 'Q1', 'Q2', 'Q2', 'Q2'],
...                                       ['A', 'B', 'C', 'A', 'B', 'C']])
>>> df_multindex
      cost  revenue
Q1 A    250     100
   B    150     250
   C    100     300
Q2 A    150     200
   B    300     175
   C    220     225
```

```
>>> df.le(df_multindex, level=1)
      cost  revenue
Q1 A    True     True
   B    True     True
   C    True     True
Q2 A   False     True
   B    True    False
   C    True    False
```

## pandas.DataFrame.get

`DataFrame.get(key, default=None)`

Get item from object for given key (DataFrame column, Panel slice, etc.). Returns default value if not found.

### Parameters

**key** [object]

### Returns

**value** [same type as items contained in object]

## pandas.DataFrame.get\_dtype\_counts

`DataFrame.get_dtype_counts()`  
Return counts of unique dtypes in this object.

### Returns

**dtype** [Series] Series with the count of columns with each dtype.

### See also:

**dtypes** Return the dtypes in this object.

### Examples

```
>>> a = [['a', 1, 1.0], ['b', 2, 2.0], ['c', 3, 3.0]]
>>> df = pd.DataFrame(a, columns=['str', 'int', 'float'])
>>> df
   str  int  float
0   a    1    1.0
1   b    2    2.0
2   c    3    3.0
```

```
>>> df.get_dtype_counts()
float64    1
int64      1
object     1
dtype: int64
```

## pandas.DataFrame.get\_ftype\_counts

`DataFrame.get_ftype_counts()`  
Return counts of unique ftypes in this object.

Deprecated since version 0.23.0.

This is useful for `SparseDataFrame` or for `DataFrames` containing sparse arrays.

### Returns

**dtype** [Series] Series with the count of columns with each type and sparsity (dense/sparse)

### See also:

**ftypes** Return ftypes (indication of sparse/dense and dtype) in this object.

### Examples

```
>>> a = [['a', 1, 1.0], ['b', 2, 2.0], ['c', 3, 3.0]]
>>> df = pd.DataFrame(a, columns=['str', 'int', 'float'])
>>> df
   str  int  float
0   a    1    1.0
```

(continues on next page)

(continued from previous page)

|   |   |   |     |
|---|---|---|-----|
| 1 | b | 2 | 2.0 |
| 2 | c | 3 | 3.0 |

```
>>> df.get_ftype_counts() # doctest: +SKIP
float64:dense    1
int64:dense      1
object:dense     1
dtype: int64
```

### pandas.DataFrame.get\_value

DataFrame.**get\_value**(*index*, *col*, *takeable=False*)

Quickly retrieve single value at passed column and index.

Deprecated since version 0.21.0: Use .at[] or .iat[] accessors instead.

#### Parameters

**index** [row label]

**col** [column label]

**takeable** [interpret the index/col as indexers, default False]

#### Returns

**value** [scalar value]

### pandas.DataFrame.get\_values

DataFrame.**get\_values**()

Return an ndarray after converting sparse values to dense.

This is the same as `.values` for non-sparse data. For sparse data contained in a *pandas.SparseArray*, the data are first converted to a dense representation.

#### Returns

**numpy.ndarray** Numpy representation of DataFrame

See also:

**values** Numpy representation of DataFrame.

**pandas.SparseArray** Container for sparse data.

### Examples

```
>>> df = pd.DataFrame({'a': [1, 2], 'b': [True, False],
...                    'c': [1.0, 2.0]})
>>> df
   a    b    c
0  1  True  1.0
1  2 False  2.0
```

```
>>> df.get_values()
array([[1, True, 1.0], [2, False, 2.0]], dtype=object)
```

```
>>> df = pd.DataFrame({"a": pd.SparseArray([1, None, None]),
...                    "c": [1.0, 2.0, 3.0]})
>>> df
   a    c
0  1.0  1.0
1  NaN  2.0
2  NaN  3.0
```

```
>>> df.get_values()
array([[ 1.,  1.],
       [nan,  2.],
       [nan,  3.]])
```

## pandas.DataFrame.groupby

`DataFrame.groupby` (*by=None, axis=0, level=None, as\_index=True, sort=True, group\_keys=True, squeeze=False, observed=False, \*\*kwargs*)

Group DataFrame or Series using a mapper or by a Series of columns.

A groupby operation involves some combination of splitting the object, applying a function, and combining the results. This can be used to group large amounts of data and compute operations on these groups.

### Parameters

**by** [mapping, function, label, or list of labels] Used to determine the groups for the groupby. If *by* is a function, it's called on each value of the object's index. If a dict or Series is passed, the Series or dict VALUES will be used to determine the groups (the Series' values are first aligned; see `.align()` method). If an ndarray is passed, the values are used as-is determine the groups. A label or list of labels may be passed to group by the columns in *self*. Notice that a tuple is interpreted a (single) key.

**axis** [{0 or 'index', 1 or 'columns'}, default 0] Split along rows (0) or columns (1).

**level** [int, level name, or sequence of such, default None] If the axis is a MultiIndex (hierarchical), group by a particular level or levels.

**as\_index** [bool, default True] For aggregated output, return object with group labels as the index. Only relevant for DataFrame input. *as\_index=False* is effectively "SQL-style" grouped output.

**sort** [bool, default True] Sort group keys. Get better performance by turning this off. Note this does not influence the order of observations within each group. Groupby preserves the order of rows within each group.

**group\_keys** [bool, default True] When calling `apply`, add group keys to index to identify pieces.

**squeeze** [bool, default False] Reduce the dimensionality of the return type if possible, otherwise return a consistent type.

**observed** [bool, default False] This only applies if any of the groupers are Categoricals. If True: only show observed values for categorical groupers. If False: show all values for categorical groupers.

New in version 0.23.0.

**\*\*kwargs** Optional, only accepts keyword argument 'mutated' and is passed to groupby.

### Returns

**DataFrameGroupBy or SeriesGroupBy** Depends on the calling object and returns groupby object that contains information about the groups.

### See also:

**resample** Convenience method for frequency conversion and resampling of time series.

### Notes

See the [user guide](#) for more.

### Examples

```
>>> df = pd.DataFrame({'Animal' : ['Falcon', 'Falcon',
...                               'Parrot', 'Parrot'],
...                    'Max Speed' : [380., 370., 24., 26.]})
>>> df
   Animal  Max Speed
0  Falcon    380.0
1  Falcon    370.0
2  Parrot     24.0
3  Parrot     26.0
>>> df.groupby(['Animal']).mean()
      Max Speed
Animal
Falcon    375.0
Parrot     25.0
```

### Hierarchical Indexes

We can groupby different levels of a hierarchical index using the *level* parameter:

```
>>> arrays = [['Falcon', 'Falcon', 'Parrot', 'Parrot'],
...           ['Capitve', 'Wild', 'Capitve', 'Wild']]
>>> index = pd.MultiIndex.from_arrays(arrays, names=('Animal', 'Type'))
>>> df = pd.DataFrame({'Max Speed' : [390., 350., 30., 20.]},
...                    index=index)
>>> df
      Max Speed
Animal Type
Falcon Capitve    390.0
      Wild       350.0
Parrot Capitve     30.0
      Wild       20.0
>>> df.groupby(level=0).mean()
      Max Speed
Animal
Falcon    370.0
Parrot     25.0
>>> df.groupby(level=1).mean()
      Max Speed
```

(continues on next page)

(continued from previous page)

|         |       |
|---------|-------|
| Type    |       |
| Capitve | 210.0 |
| Wild    | 185.0 |

**pandas.DataFrame.gt**`DataFrame.gt` (*other*, *axis*='columns', *level*=None)Greater than of dataframe and other, element-wise (binary operator *gt*).Among flexible wrappers (*eq*, *ne*, *le*, *lt*, *ge*, *gt*) to comparison operators.Equivalent to `==`, `!=`, `<=`, `<`, `>=`, `>` with support to choose axis (rows or columns) and level for comparison.**Parameters****other** [scalar, sequence, Series, or DataFrame] Any single or multiple element data structure, or list-like object.**axis** [{0 or 'index', 1 or 'columns'}, default 'columns'] Whether to compare by the index (0 or 'index') or columns (1 or 'columns').**level** [int or label] Broadcast across a level, matching Index values on the passed Multi-Index level.**Returns****DataFrame of bool** Result of the comparison.

```
>>> df = pd.DataFrame({'cost': [250, 150, 100],
...                    'revenue': [100, 250, 300]},
...                    index=['A', 'B', 'C'])
>>> df
   cost  revenue
A   250     100
B   150     250
C   100     300
```

Compare to a scalar and operator version which return the same results.

```
>>> df == 100
      cost  revenue
A  False     True
B  False     False
C   True     False
```

```
>>> df.eq(100)
      cost  revenue
A  False     True
B  False     False
C   True     False
```

Compare to a list and Series by axis and operator version. As shown, for list axis is by default 'index', but for Series axis is by default 'columns'.

```
>>> df != [100, 250, 300]
      cost  revenue
A   True     False
B   True     False
C   True     False
```

```

```

```
>>> df != pd.Series([100, 250, 300])
      cost  revenue  0    1    2
A   True     True  True  True  True
B   True     True  True  True  True
C   True     True  True  True  True
```

```
>>> df.ne(pd.Series([100, 250, 300]), axis='columns')
      cost  revenue  0    1    2
A   True     True  True  True  True
B   True     True  True  True  True
C   True     True  True  True  True
```

Compare to a DataFrame of different shape.

```
>>> other = pd.DataFrame({'revenue': [300, 250, 100, 150]},
...                        index=['A', 'B', 'C', 'D'])
>>> other
      revenue
A         300
B         250
C         100
D         150
```

```
>>> df.gt(other)
      cost  revenue
A  False     False
B  False     False
```

(continues on next page)

(continued from previous page)

```
C False      True
D False      False
```

Compare to a MultiIndex by level.

```
>>> df_multindex = pd.DataFrame({'cost': [250, 150, 100, 150, 300, 220],
...                               'revenue': [100, 250, 300, 200, 175, 225]},
...                               index=[['Q1', 'Q1', 'Q1', 'Q2', 'Q2', 'Q2'],
...                                       ['A', 'B', 'C', 'A', 'B', 'C']])
>>> df_multindex
      cost  revenue
Q1 A    250     100
   B    150     250
   C    100     300
Q2 A    150     200
   B    300     175
   C    220     225
```

```
>>> df.le(df_multindex, level=1)
      cost  revenue
Q1 A    True     True
   B    True     True
   C    True     True
Q2 A   False     True
   B    True    False
   C    True    False
```

## pandas.DataFrame.head

`DataFrame.head(n=5)`

Return the first  $n$  rows.

This function returns the first  $n$  rows for the object based on position. It is useful for quickly testing if your object has the right type of data in it.

### Parameters

**n** [int, default 5] Number of rows to select.

### Returns

**obj\_head** [same type as caller] The first  $n$  rows of the caller object.

**See also:**

**DataFrame.tail** Returns the last  $n$  rows.

## Examples

```
>>> df = pd.DataFrame({'animal': ['alligator', 'bee', 'falcon', 'lion',
...                               'monkey', 'parrot', 'shark', 'whale', 'zebra']})
>>> df
      animal
0 alligator
1        bee
```

(continues on next page)

(continued from previous page)

```

2    falcon
3     lion
4    monkey
5    parrot
6     shark
7     whale
8     zebra

```

Viewing the first 5 lines

```

>>> df.head()
   animal
0  alligator
1     bee
2    falcon
3     lion
4    monkey

```

Viewing the first  $n$  lines (three in this case)

```

>>> df.head(3)
   animal
0  alligator
1     bee
2    falcon

```

## pandas.DataFrame.hist

`DataFrame.hist` (*column=None, by=None, grid=True, xlabelsize=None, xrot=None, ylabelsize=None, yrot=None, ax=None, sharex=False, sharey=False, figsize=None, layout=None, bins=10, \*\*kwargs*)

Make a histogram of the DataFrame's.

A **histogram** is a representation of the distribution of data. This function calls `matplotlib.pyplot.hist()`, on each series in the DataFrame, resulting in one histogram per column.

### Parameters

**data** [DataFrame] The pandas object holding the data.

**column** [string or sequence] If passed, will be used to limit data to a subset of columns.

**by** [object, optional] If passed, then used to form histograms for separate groups.

**grid** [boolean, default True] Whether to show axis grid lines.

**xlabelsize** [int, default None] If specified changes the x-axis label size.

**xrot** [float, default None] Rotation of x axis labels. For example, a value of 90 displays the x labels rotated 90 degrees clockwise.

**ylabelsize** [int, default None] If specified changes the y-axis label size.

**yrot** [float, default None] Rotation of y axis labels. For example, a value of 90 displays the y labels rotated 90 degrees clockwise.

**ax** [Matplotlib axes object, default None] The axes to plot the histogram on.

**sharex** [boolean, default True if ax is None else False] In case subplots=True, share x axis and set some x axis labels to invisible; defaults to True if ax is None otherwise False if an ax is passed in. Note that passing in both an ax and sharex=True will alter all x axis labels for all subplots in a figure.

**sharey** [boolean, default False] In case subplots=True, share y axis and set some y axis labels to invisible.

**figsize** [tuple] The size in inches of the figure to create. Uses the value in *matplotlib.rcParams* by default.

**layout** [tuple, optional] Tuple of (rows, columns) for the layout of the histograms.

**bins** [integer or sequence, default 10] Number of histogram bins to be used. If an integer is given, bins + 1 bin edges are calculated and returned. If bins is a sequence, gives bin edges, including left edge of first bin and right edge of last bin. In this case, bins is returned unmodified.

**\*\*kwargs** All other plotting keyword arguments to be passed to `matplotlib.pyplot.hist()`.

### Returns

**axes** [matplotlib.AxesSubplot or numpy.ndarray of them]

See also:

`matplotlib.pyplot.hist` Plot a histogram using matplotlib.

### Examples

This example draws a histogram based on the length and width of some animals, displayed in three bins

```
>>> df = pd.DataFrame({
...     'length': [1.5, 0.5, 1.2, 0.9, 3],
...     'width': [0.7, 0.2, 0.15, 0.2, 1.1]
... }, index= ['pig', 'rabbit', 'duck', 'chicken', 'horse'])
>>> hist = df.hist(bins=3)
```

### pandas.DataFrame.idxmax

`DataFrame.idxmax` (*axis=0, skipna=True*)

Return index of first occurrence of maximum over requested axis. NA/null values are excluded.

#### Parameters

**axis** [{0 or 'index', 1 or 'columns'}, default 0] 0 or 'index' for row-wise, 1 or 'columns' for column-wise

**skipna** [boolean, default True] Exclude NA/null values. If an entire row/column is NA, the result will be NA.

#### Returns

**idxmax** [Series]

#### Raises

**ValueError**

- If the row/column is empty

**See also:**

*Series.idxmax*

**Notes**

This method is the DataFrame version of `ndarray.argmax`.

**pandas.DataFrame.idxmin**

`DataFrame.idxmin (axis=0, skipna=True)`

Return index of first occurrence of minimum over requested axis. NA/null values are excluded.

**Parameters**

**axis** [{0 or 'index', 1 or 'columns'}, default 0] 0 or 'index' for row-wise, 1 or 'columns' for column-wise

**skipna** [boolean, default True] Exclude NA/null values. If an entire row/column is NA, the result will be NA.

**Returns**

**idxmin** [Series]

**Raises****ValueError**

- If the row/column is empty

**See also:**

*Series.idxmin*

**Notes**

This method is the DataFrame version of `ndarray.argmin`.

**pandas.DataFrame.infer\_objects**

`DataFrame.infer_objects ()`

Attempt to infer better dtypes for object columns.

Attempts soft conversion of object-dtyped columns, leaving non-object and unconvertible columns unchanged. The inference rules are the same as during normal Series/DataFrame construction.

New in version 0.21.0.

**Returns**

**converted** [same type as input object]

**See also:**

**to\_datetime** Convert argument to datetime.

**to\_timedelta** Convert argument to timedelta.

**to\_numeric** Convert argument to numeric type.

### Examples

```
>>> df = pd.DataFrame({"A": ["a", 1, 2, 3]})
>>> df = df.iloc[1:]
>>> df
   A
1  1
2  2
3  3
```

```
>>> df.dtypes
A    object
dtype: object
```

```
>>> df.infer_objects().dtypes
A    int64
dtype: object
```

### pandas.DataFrame.info

`DataFrame.info(verbose=None, buf=None, max_cols=None, memory_usage=None, null_counts=None)`

Print a concise summary of a DataFrame.

This method prints information about a DataFrame including the index dtype and column dtypes, non-null values and memory usage.

#### Parameters

**verbose** [bool, optional] Whether to print the full summary. By default, the setting in `pandas.options.display.max_info_columns` is followed.

**buf** [writable buffer, defaults to `sys.stdout`] Where to send the output. By default, the output is printed to `sys.stdout`. Pass a writable buffer if you need to further process the output.

**max\_cols** [int, optional] When to switch from the verbose to the truncated output. If the DataFrame has more than `max_cols` columns, the truncated output is used. By default, the setting in `pandas.options.display.max_info_columns` is used.

**memory\_usage** [bool, str, optional] Specifies whether total memory usage of the DataFrame elements (including the index) should be displayed. By default, this follows the `pandas.options.display.memory_usage` setting.

True always show memory usage. False never shows memory usage. A value of 'deep' is equivalent to "True with deep introspection". Memory usage is shown in human-readable units (base-2 representation). Without deep introspection a memory estimation is made based in column dtype and number of rows assuming values consume the same memory amount for corresponding dtypes. With deep memory introspection, a real memory usage calculation is performed at the cost of computational resources.

**null\_counts** [bool, optional] Whether to show the non-null counts. By default, this is shown only if the frame is smaller than `pandas.options.display.max_info_rows` and `pandas.options.display.max_info_columns`. A value of True always shows the counts, and False never shows the counts.

### Returns

**None** This method prints a summary of a DataFrame and returns None.

### See also:

**DataFrame.describe** Generate descriptive statistics of DataFrame columns.

**DataFrame.memory\_usage** Memory usage of DataFrame columns.

### Examples

```
>>> int_values = [1, 2, 3, 4, 5]
>>> text_values = ['alpha', 'beta', 'gamma', 'delta', 'epsilon']
>>> float_values = [0.0, 0.25, 0.5, 0.75, 1.0]
>>> df = pd.DataFrame({"int_col": int_values, "text_col": text_values,
...                     "float_col": float_values})
>>> df
   int_col text_col float_col
0         1   alpha      0.00
1         2    beta      0.25
2         3   gamma      0.50
3         4    delta      0.75
4         5  epsilon      1.00
```

Prints information of all columns:

```
>>> df.info(verbose=True)
<class 'pandas.core.frame.DataFrame'>
RangeIndex: 5 entries, 0 to 4
Data columns (total 3 columns):
int_col      5 non-null int64
text_col     5 non-null object
float_col    5 non-null float64
dtypes: float64(1), int64(1), object(1)
memory usage: 200.0+ bytes
```

Prints a summary of columns count and its dtypes but not per column information:

```
>>> df.info(verbose=False)
<class 'pandas.core.frame.DataFrame'>
RangeIndex: 5 entries, 0 to 4
Columns: 3 entries, int_col to float_col
dtypes: float64(1), int64(1), object(1)
memory usage: 200.0+ bytes
```

Pipe output of DataFrame.info to buffer instead of sys.stdout, get buffer content and writes to a text file:

```
>>> import io
>>> buffer = io.StringIO()
>>> df.info(buf=buffer)
>>> s = buffer.getvalue()
```

(continues on next page)

(continued from previous page)

```
>>> with open("df_info.txt", "w",
...           encoding="utf-8") as f: # doctest: +SKIP
...     f.write(s)
260
```

The `memory_usage` parameter allows deep introspection mode, specially useful for big DataFrames and fine-tune memory optimization:

```
>>> random_strings_array = np.random.choice(['a', 'b', 'c'], 10 ** 6)
>>> df = pd.DataFrame({
...     'column_1': np.random.choice(['a', 'b', 'c'], 10 ** 6),
...     'column_2': np.random.choice(['a', 'b', 'c'], 10 ** 6),
...     'column_3': np.random.choice(['a', 'b', 'c'], 10 ** 6)
... })
>>> df.info()
<class 'pandas.core.frame.DataFrame'>
RangeIndex: 1000000 entries, 0 to 999999
Data columns (total 3 columns):
column_1    1000000 non-null object
column_2    1000000 non-null object
column_3    1000000 non-null object
dtypes: object(3)
memory usage: 22.9+ MB
```

```
>>> df.info(memory_usage='deep')
<class 'pandas.core.frame.DataFrame'>
RangeIndex: 1000000 entries, 0 to 999999
Data columns (total 3 columns):
column_1    1000000 non-null object
column_2    1000000 non-null object
column_3    1000000 non-null object
dtypes: object(3)
memory usage: 188.8 MB
```

## pandas.DataFrame.insert

`DataFrame.insert` (*loc*, *column*, *value*, *allow\_duplicates=False*)

Insert column into DataFrame at specified location.

Raises a `ValueError` if *column* is already contained in the DataFrame, unless *allow\_duplicates* is set to `True`.

### Parameters

**loc** [int] Insertion index. Must verify  $0 \leq \text{loc} \leq \text{len}(\text{columns})$

**column** [string, number, or hashable object] label of the inserted column

**value** [int, Series, or array-like]

**allow\_duplicates** [bool, optional]

**pandas.DataFrame.interpolate**

```
DataFrame.interpolate (method='linear', axis=0, limit=None, inplace=False,
                        limit_direction='forward', limit_area=None, downcast=None,
                        **kwargs)
```

Interpolate values according to different methods.

Please note that only `method='linear'` is supported for DataFrame/Series with a MultiIndex.

**Parameters**

**method** [str, default 'linear'] Interpolation technique to use. One of:

- 'linear': Ignore the index and treat the values as equally spaced. This is the only method supported on MultiIndexes.
- 'time': Works on daily and higher resolution data to interpolate given length of interval.
- 'index', 'values': use the actual numerical values of the index.
- 'pad': Fill in NaNs using existing values.
- 'nearest', 'zero', 'slinear', 'quadratic', 'cubic', 'spline', 'barycentric', 'polynomial': Passed to `scipy.interpolate.interp1d`. Both 'polynomial' and 'spline' require that you also specify an *order* (int), e.g. `df.interpolate(method='polynomial', order=4)`. These use the numerical values of the index.
- 'krogh', 'piecewise\_polynomial', 'spline', 'pchip', 'akima': Wrappers around the SciPy interpolation methods of similar names. See *Notes*.
- 'from\_derivatives': Refers to `scipy.interpolate.BPoly.from_derivatives` which replaces 'piecewise\_polynomial' interpolation method in scipy 0.18.

New in version 0.18.1: Added support for the 'akima' method. Added interpolate method 'from\_derivatives' which replaces 'piecewise\_polynomial' in SciPy 0.18; backwards-compatible with SciPy < 0.18

**axis** [{0 or 'index', 1 or 'columns', None}, default None] Axis to interpolate along.

**limit** [int, optional] Maximum number of consecutive NaNs to fill. Must be greater than 0.

**inplace** [bool, default False] Update the data in place if possible.

**limit\_direction** [{ 'forward', 'backward', 'both' }, default 'forward'] If limit is specified, consecutive NaNs will be filled in this direction.

**limit\_area** [{None, 'inside', 'outside'}, default None] If limit is specified, consecutive NaNs will be filled with this restriction.

- None: No fill restriction.
- 'inside': Only fill NaNs surrounded by valid values (interpolate).
- 'outside': Only fill NaNs outside valid values (extrapolate).

New in version 0.21.0.

**downcast** [optional, 'infer' or None, defaults to None] Downcast dtypes if possible.

**\*\*kwargs** Keyword arguments to pass on to the interpolating function.

**Returns**

**Series or DataFrame** Returns the same object type as the caller, interpolated at some or all NaN values

**See also:**

***fillna*** Fill missing values using different methods.

**`scipy.interpolate.Akima1DInterpolator`** Piecewise cubic polynomials (Akima interpolator).

**`scipy.interpolate.BPoly.from_derivatives`** Piecewise polynomial in the Bernstein basis.

**`scipy.interpolate.interpld`** Interpolate a 1-D function.

**`scipy.interpolate.KroghInterpolator`** Interpolate polynomial (Krogh interpolator).

**`scipy.interpolate.PchipInterpolator`** PCHIP 1-d monotonic cubic interpolation.

**`scipy.interpolate.CubicSpline`** Cubic spline data interpolator.

## Notes

The ‘krogh’, ‘piecewise\_polynomial’, ‘spline’, ‘pchip’ and ‘akima’ methods are wrappers around the respective SciPy implementations of similar names. These use the actual numerical values of the index. For more information on their behavior, see the [SciPy documentation](#) and [SciPy tutorial](#).

## Examples

Filling in NaN in a *Series* via linear interpolation.

```
>>> s = pd.Series([0, 1, np.nan, 3])
>>> s
0    0.0
1    1.0
2    NaN
3    3.0
dtype: float64
>>> s.interpolate()
0    0.0
1    1.0
2    2.0
3    3.0
dtype: float64
```

Filling in NaN in a *Series* by padding, but filling at most two consecutive NaN at a time.

```
>>> s = pd.Series([np.nan, "single_one", np.nan,
...                "fill_two_more", np.nan, np.nan, np.nan,
...                4.71, np.nan])
>>> s
0      NaN
1  single_one
2      NaN
3  fill_two_more
4      NaN
5      NaN
6      NaN
```

(continues on next page)

(continued from previous page)

```

7          4.71
8          NaN
dtype: object
>>> s.interpolate(method='pad', limit=2)
0          NaN
1    single_one
2    single_one
3    fill_two_more
4    fill_two_more
5    fill_two_more
6          NaN
7          4.71
8          4.71
dtype: object

```

Filling in NaN in a Series via polynomial interpolation or splines: Both ‘polynomial’ and ‘spline’ methods require that you also specify an `order` (int).

```

>>> s = pd.Series([0, 2, np.nan, 8])
>>> s.interpolate(method='polynomial', order=2)
0    0.000000
1    2.000000
2    4.666667
3    8.000000
dtype: float64

```

Fill the DataFrame forward (that is, going down) along each column using linear interpolation.

Note how the last entry in column ‘a’ is interpolated differently, because there is no entry after it to use for interpolation. Note how the first entry in column ‘b’ remains NaN, because there is no entry before it to use for interpolation.

```

>>> df = pd.DataFrame([(0.0, np.nan, -1.0, 1.0),
...                     (np.nan, 2.0, np.nan, np.nan),
...                     (2.0, 3.0, np.nan, 9.0),
...                     (np.nan, 4.0, -4.0, 16.0)],
...                     columns=list('abcd'))
>>> df
   a    b    c    d
0  0.0 NaN -1.0  1.0
1 NaN  2.0 NaN  NaN
2  2.0  3.0 NaN  9.0
3 NaN  4.0 -4.0 16.0
>>> df.interpolate(method='linear', limit_direction='forward', axis=0)
   a    b    c    d
0  0.0 NaN -1.0  1.0
1  1.0  2.0 -2.0  5.0
2  2.0  3.0 -3.0  9.0
3  2.0  4.0 -4.0 16.0

```

Using polynomial interpolation.

```

>>> df['d'].interpolate(method='polynomial', order=2)
0    1.0
1    4.0
2    9.0

```

(continues on next page)

(continued from previous page)

```
3      16.0
Name: d, dtype: float64
```

## pandas.DataFrame.isin

`DataFrame.isin(values)`

Whether each element in the DataFrame is contained in values.

### Parameters

**values** [iterable, Series, DataFrame or dict] The result will only be true at a location if all the labels match. If *values* is a Series, that's the index. If *values* is a dict, the keys must be the column names, which must match. If *values* is a DataFrame, then both the index and column labels must match.

### Returns

**DataFrame** DataFrame of booleans showing whether each element in the DataFrame is contained in values.

See also:

**DataFrame.eq** Equality test for DataFrame.

**Series.isin** Equivalent method on Series.

**Series.str.contains** Test if pattern or regex is contained within a string of a Series or Index.

## Examples

```
>>> df = pd.DataFrame({'num_legs': [2, 4], 'num_wings': [2, 0]},
...                    index=['falcon', 'dog'])
>>> df
```

|        | num_legs | num_wings |
|--------|----------|-----------|
| falcon | 2        | 2         |
| dog    | 4        | 0         |

When *values* is a list check whether every value in the DataFrame is present in the list (which animals have 0 or 2 legs or wings)

```
>>> df.isin([0, 2])
```

|        | num_legs | num_wings |
|--------|----------|-----------|
| falcon | True     | True      |
| dog    | False    | True      |

When *values* is a dict, we can pass values to check for each column separately:

```
>>> df.isin({'num_wings': [0, 3]})
```

|        | num_legs | num_wings |
|--------|----------|-----------|
| falcon | False    | False     |
| dog    | False    | True      |

When *values* is a Series or DataFrame the index and column must match. Note that 'falcon' does not match based on the number of legs in df2.

```
>>> other = pd.DataFrame({'num_legs': [8, 2], 'num_wings': [0, 2]},
...                       index=['spider', 'falcon'])
>>> df.isin(other)
      num_legs  num_wings
falcon      True        True
dog         False       False
```

## pandas.DataFrame.isna

`DataFrame.isna()`

Detect missing values.

Return a boolean same-sized object indicating if the values are NA. NA values, such as `None` or `numpy.NaN`, gets mapped to `True` values. Everything else gets mapped to `False` values. Characters such as empty strings `' '` or `numpy.inf` are not considered NA values (unless you set `pandas.options.mode.use_inf_as_na = True`).

### Returns

**DataFrame** Mask of bool values for each element in `DataFrame` that indicates whether an element is not an NA value.

See also:

**DataFrame.isnull** Alias of `isna`.

**DataFrame.notna** Boolean inverse of `isna`.

**DataFrame.dropna** Omit axes labels with missing values.

**isna** Top-level `isna`.

## Examples

Show which entries in a `DataFrame` are NA.

```
>>> df = pd.DataFrame({'age': [5, 6, np.NaN],
...                    'born': [pd.NaT, pd.Timestamp('1939-05-27'),
...                             pd.Timestamp('1940-04-25')],
...                    'name': ['Alfred', 'Batman', ''],
...                    'toy': [None, 'Batmobile', 'Joker']})
>>> df
   age      born    name    toy
0  5.0      NaT  Alfred   None
1  6.0 1939-05-27  Batman Batmobile
2  NaN 1940-04-25      Joker
```

```
>>> df.isna()
   age  born  name  toy
0 False  True False  True
1 False False False False
2  True False False False
```

Show which entries in a `Series` are NA.

```
>>> ser = pd.Series([5, 6, np.NaN])
>>> ser
0    5.0
1    6.0
2    NaN
dtype: float64
```

```
>>> ser.isna()
0    False
1    False
2     True
dtype: bool
```

## pandas.DataFrame.isnull

`DataFrame.isnull()`

Detect missing values.

Return a boolean same-sized object indicating if the values are NA. NA values, such as `None` or `numpy.NaN`, gets mapped to `True` values. Everything else gets mapped to `False` values. Characters such as empty strings `' '` or `numpy.inf` are not considered NA values (unless you set `pandas.options.mode.use_inf_as_na = True`).

### Returns

**DataFrame** Mask of bool values for each element in `DataFrame` that indicates whether an element is not an NA value.

See also:

**DataFrame.isnull** Alias of `isna`.

**DataFrame.notna** Boolean inverse of `isna`.

**DataFrame.dropna** Omit axes labels with missing values.

**isna** Top-level `isna`.

## Examples

Show which entries in a `DataFrame` are NA.

```
>>> df = pd.DataFrame({'age': [5, 6, np.NaN],
...                    'born': [pd.NaT, pd.Timestamp('1939-05-27'),
...                             pd.Timestamp('1940-04-25')],
...                    'name': ['Alfred', 'Batman', ''],
...                    'toy': [None, 'Batmobile', 'Joker']})
>>> df
   age      born    name    toy
0  5.0      NaT  Alfred   None
1  6.0  1939-05-27  Batman  Batmobile
2  NaN  1940-04-25      Joker
```

```
>>> df.isna()
   age      born    name    toy
```

(continues on next page)

(continued from previous page)

```

0  False    True  False    True
1  False   False  False   False
2    True   False  False   False

```

Show which entries in a Series are NA.

```

>>> ser = pd.Series([5, 6, np.NaN])
>>> ser
0    5.0
1    6.0
2    NaN
dtype: float64

```

```

>>> ser.isna()
0    False
1    False
2     True
dtype: bool

```

## pandas.DataFrame.items

`DataFrame.items()`

Iterator over (column name, Series) pairs.

Iterates over the DataFrame columns, returning a tuple with the column name and the content as a Series.

### Yields

**label** [object] The column names for the DataFrame being iterated over.

**content** [Series] The column entries belonging to each label, as a Series.

See also:

**DataFrame.iterrows** Iterate over DataFrame rows as (index, Series) pairs.

**DataFrame.itertuples** Iterate over DataFrame rows as namedtuples of the values.

## Examples

```

>>> df = pd.DataFrame({'species': ['bear', 'bear', 'marsupial'],
...                     'population': [1864, 22000, 80000]},
...                     index=['panda', 'polar', 'koala'])
>>> df
   species  population
panda   bear       1864
polar   bear      22000
koala  marsupial  80000
>>> for label, content in df.iteritems():
...     print('label:', label)
...     print('content:', content, sep='\n')
...
label: species
content:
panda      bear

```

(continues on next page)

(continued from previous page)

```

polar      bear
koala      marsupial
Name: species, dtype: object
label: population
content:
panda      1864
polar      22000
koala      80000
Name: population, dtype: int64

```

**pandas.DataFrame.iteritems****DataFrame.iteritems()**

Iterator over (column name, Series) pairs.

Iterates over the DataFrame columns, returning a tuple with the column name and the content as a Series.

**Yields****label** [object] The column names for the DataFrame being iterated over.**content** [Series] The column entries belonging to each label, as a Series.**See also:****DataFrame.iterrows** Iterate over DataFrame rows as (index, Series) pairs.**DataFrame.itertuples** Iterate over DataFrame rows as namedtuples of the values.**Examples**

```

>>> df = pd.DataFrame({'species': ['bear', 'bear', 'marsupial'],
...                     'population': [1864, 22000, 80000]},
...                     index=['panda', 'polar', 'koala'])
>>> df
   species  population
panda   bear      1864
polar   bear     22000
koala  marsupial   80000
>>> for label, content in df.iteritems():
...     print('label:', label)
...     print('content:', content, sep='\n')
...
label: species
content:
panda      bear
polar      bear
koala  marsupial
Name: species, dtype: object
label: population
content:
panda      1864
polar     22000
koala     80000
Name: population, dtype: int64

```

**pandas.DataFrame.iterrows**`DataFrame.iterrows()`

Iterate over DataFrame rows as (index, Series) pairs.

**Yields****index** [label or tuple of label] The index of the row. A tuple for a *MultiIndex*.**data** [Series] The data of the row as a Series.**it** [generator] A generator that iterates over the rows of the frame.**See also:****itertuples** Iterate over DataFrame rows as namedtuples of the values.**iteritems** Iterate over (column name, Series) pairs.**Notes**

1. Because `iterrows` returns a Series for each row, it does **not** preserve dtypes across the rows (dtypes are preserved across columns for DataFrames). For example,

```
>>> df = pd.DataFrame([[1, 1.5]], columns=['int', 'float'])
>>> row = next(df.iterrows())[1]
>>> row
int      1.0
float    1.5
Name: 0, dtype: float64
>>> print(row['int'].dtype)
float64
>>> print(df['int'].dtype)
int64
```

To preserve dtypes while iterating over the rows, it is better to use `itertuples()` which returns namedtuples of the values and which is generally faster than `iterrows`.

2. You should **never modify** something you are iterating over. This is not guaranteed to work in all cases. Depending on the data types, the iterator returns a copy and not a view, and writing to it will have no effect.

**pandas.DataFrame.itertuples**`DataFrame.itertuples(index=True, name='Pandas')`

Iterate over DataFrame rows as namedtuples.

**Parameters****index** [bool, default True] If True, return the index as the first element of the tuple.**name** [str, default "Pandas"] The name of the returned namedtuples or None to return regular tuples.**Yields****collections.namedtuple** Yields a namedtuple for each row in the DataFrame with the first field possibly being the index and following fields being the column values.

See also:

**DataFrame.iterrows** Iterate over DataFrame rows as (index, Series) pairs.

**DataFrame.iteritems** Iterate over (column name, Series) pairs.

## Notes

The column names will be renamed to positional names if they are invalid Python identifiers, repeated, or start with an underscore. With a large number of columns (>255), regular tuples are returned.

## Examples

```
>>> df = pd.DataFrame({'num_legs': [4, 2], 'num_wings': [0, 2]},
...                    index=['dog', 'hawk'])
>>> df
   num_legs  num_wings
dog         4         0
hawk        2         2
>>> for row in df.itertuples():
...     print(row)
...
Pandas(Index='dog', num_legs=4, num_wings=0)
Pandas(Index='hawk', num_legs=2, num_wings=2)
```

By setting the *index* parameter to `False` we can remove the index as the first element of the tuple:

```
>>> for row in df.itertuples(index=False):
...     print(row)
...
Pandas(num_legs=4, num_wings=0)
Pandas(num_legs=2, num_wings=2)
```

With the *name* parameter set we set a custom name for the yielded namedtuples:

```
>>> for row in df.itertuples(name='Animal'):
...     print(row)
...
Animal(Index='dog', num_legs=4, num_wings=0)
Animal(Index='hawk', num_legs=2, num_wings=2)
```

## pandas.DataFrame.join

`DataFrame.join(other, on=None, how='left', lsuffix="", rsuffix="", sort=False)`

Join columns of another DataFrame.

Join columns with *other* DataFrame either on index or on a key column. Efficiently join multiple DataFrame objects by index at once by passing a list.

### Parameters

**other** [DataFrame, Series, or list of DataFrame] Index should be similar to one of the columns in this one. If a Series is passed, its name attribute must be set, and that will be used as the column name in the resulting joined DataFrame.

**on** [str, list of str, or array-like, optional] Column or index level name(s) in the caller to join on the index in *other*, otherwise joins index-on-index. If multiple values given, the *other* DataFrame must have a MultiIndex. Can pass an array as the join key if it is not already contained in the calling DataFrame. Like an Excel VLOOKUP operation.

**how** [{ 'left', 'right', 'outer', 'inner' }, default 'left'] How to handle the operation of the two objects.

- left: use calling frame's index (or column if on is specified)
- right: use *other*'s index.
- outer: form union of calling frame's index (or column if on is specified) with *other*'s index, and sort it. lexicographically.
- inner: form intersection of calling frame's index (or column if on is specified) with *other*'s index, preserving the order of the calling's one.

**lsuffix** [str, default ''] Suffix to use from left frame's overlapping columns.

**rsuffix** [str, default ''] Suffix to use from right frame's overlapping columns.

**sort** [bool, default False] Order result DataFrame lexicographically by the join key. If False, the order of the join key depends on the join type (how keyword).

### Returns

**DataFrame** A dataframe containing columns from both the caller and *other*.

See also:

**DataFrame.merge** For column(s)-on-columns(s) operations.

### Notes

Parameters *on*, *lsuffix*, and *rsuffix* are not supported when passing a list of *DataFrame* objects.

Support for specifying index levels as the *on* parameter was added in version 0.23.0.

### Examples

```
>>> df = pd.DataFrame({'key': ['K0', 'K1', 'K2', 'K3', 'K4', 'K5'],
...                    'A': ['A0', 'A1', 'A2', 'A3', 'A4', 'A5']})
```

```
>>> df
   key  A
0  K0  A0
1  K1  A1
2  K2  A2
3  K3  A3
4  K4  A4
5  K5  A5
```

```
>>> other = pd.DataFrame({'key': ['K0', 'K1', 'K2'],
...                       'B': ['B0', 'B1', 'B2']})
```

```
>>> other
   key  B
0  K0  B0
1  K1  B1
2  K2  B2
```

Join DataFrames using their indexes.

```
>>> df.join(other, lsuffix='_caller', rsuffix='_other')
   key_caller  A key_other  B
0          K0  A0        K0  B0
1          K1  A1        K1  B1
2          K2  A2        K2  B2
3          K3  A3        NaN NaN
4          K4  A4        NaN NaN
5          K5  A5        NaN NaN
```

If we want to join using the key columns, we need to set key to be the index in both *df* and *other*. The joined DataFrame will have key as its index.

```
>>> df.set_index('key').join(other.set_index('key'))
   A  B
key
K0  A0  B0
K1  A1  B1
K2  A2  B2
K3  A3  NaN
K4  A4  NaN
K5  A5  NaN
```

Another option to join using the key columns is to use the *on* parameter. DataFrame.join always uses *other*'s index but we can use any column in *df*. This method preserves the original DataFrame's index in the result.

```
>>> df.join(other.set_index('key'), on='key')
   key  A  B
0  K0  A0  B0
1  K1  A1  B1
2  K2  A2  B2
3  K3  A3  NaN
4  K4  A4  NaN
5  K5  A5  NaN
```

## pandas.DataFrame.keys

DataFrame.**keys**()

Get the 'info axis' (see Indexing for more)

This is index for Series, columns for DataFrame and major\_axis for Panel.

## pandas.DataFrame.kurt

DataFrame.**kurt** (axis=None, skipna=None, level=None, numeric\_only=None, \*\*kwargs)

Return unbiased kurtosis over requested axis using Fisher's definition of kurtosis (kurtosis of normal == 0.0). Normalized by N-1.

**Parameters**

- axis** [{index (0), columns (1)}] Axis for the function to be applied on.
- skipna** [bool, default True] Exclude NA/null values when computing the result.
- level** [int or level name, default None] If the axis is a MultiIndex (hierarchical), count along a particular level, collapsing into a Series.
- numeric\_only** [bool, default None] Include only float, int, boolean columns. If None, will attempt to use everything, then use only numeric data. Not implemented for Series.
- \*\*kwargs** Additional keyword arguments to be passed to the function.

**Returns**

**kurt** [Series or DataFrame (if level specified)]

**pandas.DataFrame.kurtosis**

`DataFrame.kurtosis` (*axis=None, skipna=None, level=None, numeric\_only=None, \*\*kwargs*)  
Return unbiased kurtosis over requested axis using Fisher's definition of kurtosis (kurtosis of normal == 0.0). Normalized by N-1.

**Parameters**

- axis** [{index (0), columns (1)}] Axis for the function to be applied on.
- skipna** [bool, default True] Exclude NA/null values when computing the result.
- level** [int or level name, default None] If the axis is a MultiIndex (hierarchical), count along a particular level, collapsing into a Series.
- numeric\_only** [bool, default None] Include only float, int, boolean columns. If None, will attempt to use everything, then use only numeric data. Not implemented for Series.
- \*\*kwargs** Additional keyword arguments to be passed to the function.

**Returns**

**kurt** [Series or DataFrame (if level specified)]

**pandas.DataFrame.last**

`DataFrame.last` (*offset*)  
Convenience method for subsetting final periods of time series data based on a date offset.

**Parameters**

**offset** [string, DateOffset, dateutil.relativedelta]

**Returns**

**subset** [same type as caller]

**Raises**

**TypeError** If the index is not a *DatetimeIndex*

See also:

**first** Select initial periods of time series based on a date offset.

**at\_time** Select values at a particular time of the day.

**between\_time** Select values between particular times of the day.

## Examples

```
>>> i = pd.date_range('2018-04-09', periods=4, freq='2D')
>>> ts = pd.DataFrame({'A': [1,2,3,4]}, index=i)
>>> ts
```

|            | A |
|------------|---|
| 2018-04-09 | 1 |
| 2018-04-11 | 2 |
| 2018-04-13 | 3 |
| 2018-04-15 | 4 |

Get the rows for the last 3 days:

```
>>> ts.last('3D')
```

|            | A |
|------------|---|
| 2018-04-13 | 3 |
| 2018-04-15 | 4 |

Notice the data for 3 last calendar days were returned, not the last 3 observed days in the dataset, and therefore data for 2018-04-11 was not returned.

## pandas.DataFrame.last\_valid\_index

`DataFrame.last_valid_index()`  
Return index for last non-NA/null value.

### Returns

**scalar** [type of index]

## Notes

If all elements are non-NA/null, returns None. Also returns None for empty NDFrame.

## pandas.DataFrame.le

`DataFrame.le(other, axis='columns', level=None)`

Less than or equal to of dataframe and other, element-wise (binary operator *le*).

Among flexible wrappers (*eq*, *ne*, *le*, *lt*, *ge*, *gt*) to comparison operators.

Equivalent to `==`, `!=`, `<=`, `<`, `>=`, `>` with support to choose axis (rows or columns) and level for comparison.

### Parameters

**other** [scalar, sequence, Series, or DataFrame] Any single or multiple element data structure, or list-like object.

**axis** [{0 or 'index', 1 or 'columns'}, default 'columns'] Whether to compare by the index (0 or 'index') or columns (1 or 'columns').

**level** [int or label] Broadcast across a level, matching Index values on the passed Multi-Index level.

### Returns

**DataFrame of bool** Result of the comparison.

See also:

**DataFrame.eq** Compare DataFrames for equality elementwise.

**DataFrame.ne** Compare DataFrames for inequality elementwise.

**DataFrame.le** Compare DataFrames for less than inequality or equality elementwise.

**DataFrame.lt** Compare DataFrames for strictly less than inequality elementwise.

**DataFrame.ge** Compare DataFrames for greater than inequality or equality elementwise.

**DataFrame.gt** Compare DataFrames for strictly greater than inequality elementwise.

### Notes

Mismatched indices will be unioned together. *NaN* values are considered different (i.e. *NaN* != *NaN*).

### Examples

```
>>> df = pd.DataFrame({'cost': [250, 150, 100],
...                    'revenue': [100, 250, 300]},
...                    index=['A', 'B', 'C'])
>>> df
   cost  revenue
A   250     100
B   150     250
C   100     300
```

Compare to a scalar and operator version which return the same results.

```
>>> df == 100
   cost  revenue
A  False     True
B  False     False
C   True     False
```

```
>>> df.eq(100)
   cost  revenue
A  False     True
B  False     False
C   True     False
```

Compare to a list and Series by axis and operator version. As shown, for list axis is by default 'index', but for Series axis is by default 'columns'.

```
>>> df != [100, 250, 300]
cost revenue
A True False
B True False
C True False
```

```
>>> df.ne([100, 250, 300], axis='index')
cost revenue
A True False
B True False
C True False
```

```
>>> df != pd.Series([100, 250, 300])
cost revenue 0 1 2
A True True True True True
B True True True True True
C True True True True True
```

```
>>> df.ne(pd.Series([100, 250, 300]), axis='columns')
cost revenue 0 1 2
A True True True True True
B True True True True True
C True True True True True
```

Compare to a DataFrame of different shape.

```
>>> other = pd.DataFrame({'revenue': [300, 250, 100, 150]},
...                        index=['A', 'B', 'C', 'D'])
>>> other
revenue
A      300
B      250
C      100
D      150
```

```
>>> df.gt(other)
cost revenue
A False False
B False False
C False True
D False False
```

Compare to a MultiIndex by level.

```
>>> df_multindex = pd.DataFrame({'cost': [250, 150, 100, 150, 300, 220],
...                               'revenue': [100, 250, 300, 200, 175, 225]},
...                               index=[['Q1', 'Q1', 'Q1', 'Q2', 'Q2', 'Q2'],
...                                       ['A', 'B', 'C', 'A', 'B', 'C']])
>>> df_multindex
cost revenue
Q1 A 250 100
   B 150 250
   C 100 300
Q2 A 150 200
   B 300 175
   C 220 225
```

```
>>> df.le(df_multindex, level=1)
      cost  revenue
Q1 A   True     True
   B   True     True
   C   True     True
Q2 A  False     True
   B   True    False
   C   True    False
```

## pandas.DataFrame.lookup

`DataFrame.lookup` (*row\_labels*, *col\_labels*)

Label-based “fancy indexing” function for DataFrame.

Given equal-length arrays of row and column labels, return an array of the values corresponding to each (row, col) pair.

### Parameters

**row\_labels** [sequence] The row labels to use for lookup

**col\_labels** [sequence] The column labels to use for lookup

### Notes

Akin to:

```
result = [df.get_value(row, col)
          for row, col in zip(row_labels, col_labels)]
```

## Examples

**values** [ndarray] The found values

## pandas.DataFrame.lt

`DataFrame.lt` (*other*, *axis*=‘columns’, *level*=None)

Less than of dataframe and other, element-wise (binary operator *lt*).

Among flexible wrappers (*eq*, *ne*, *le*, *lt*, *ge*, *gt*) to comparison operators.

Equivalent to `==`, `!=`, `<=`, `<`, `>=`, `>` with support to choose axis (rows or columns) and level for comparison.

### Parameters

**other** [scalar, sequence, Series, or DataFrame] Any single or multiple element data structure, or list-like object.

**axis** [{0 or ‘index’, 1 or ‘columns’}, default ‘columns’] Whether to compare by the index (0 or ‘index’) or columns (1 or ‘columns’).

**level** [int or label] Broadcast across a level, matching Index values on the passed Multi-Index level.

### Returns

**DataFrame of bool** Result of the comparison.

See also:

**DataFrame.eq** Compare DataFrames for equality elementwise.

**DataFrame.ne** Compare DataFrames for inequality elementwise.

**DataFrame.le** Compare DataFrames for less than inequality or equality elementwise.

**DataFrame.lt** Compare DataFrames for strictly less than inequality elementwise.

**DataFrame.ge** Compare DataFrames for greater than inequality or equality elementwise.

**DataFrame.gt** Compare DataFrames for strictly greater than inequality elementwise.

## Notes

Mismatched indices will be unioned together. *NaN* values are considered different (i.e. *NaN* != *NaN*).

## Examples

```
>>> df = pd.DataFrame({'cost': [250, 150, 100],
...                    'revenue': [100, 250, 300]},
...                    index=['A', 'B', 'C'])
>>> df
   cost  revenue
A   250     100
B   150     250
C   100     300
```

Compare to a scalar and operator version which return the same results.

```
>>> df == 100
   cost  revenue
A  False     True
B  False     False
C   True     False
```

```
>>> df.eq(100)
   cost  revenue
A  False     True
B  False     False
C   True     False
```

Compare to a list and Series by axis and operator version. As shown, for list axis is by default 'index', but for Series axis is by default 'columns'.

```
>>> df != [100, 250, 300]
   cost  revenue
A   True     False
B   True     False
C   True     False
```

```
>>> df.ne([100, 250, 300], axis='index')
      cost  revenue
A  True    False
B  True    False
C  True    False
```

```
>>> df != pd.Series([100, 250, 300])
      cost  revenue    0    1    2
A  True    True  True  True  True
B  True    True  True  True  True
C  True    True  True  True  True
```

```
>>> df.ne(pd.Series([100, 250, 300]), axis='columns')
      cost  revenue    0    1    2
A  True    True  True  True  True
B  True    True  True  True  True
C  True    True  True  True  True
```

Compare to a DataFrame of different shape.

```
>>> other = pd.DataFrame({'revenue': [300, 250, 100, 150]},
...                        index=['A', 'B', 'C', 'D'])
>>> other
      revenue
A         300
B         250
C         100
D         150
```

```
>>> df.gt(other)
      cost  revenue
A  False    False
B  False    False
C  False     True
D  False    False
```

Compare to a MultiIndex by level.

```
>>> df_multindex = pd.DataFrame({'cost': [250, 150, 100, 150, 300, 220],
...                               'revenue': [100, 250, 300, 200, 175, 225]},
...                               index=[['Q1', 'Q1', 'Q1', 'Q2', 'Q2', 'Q2'],
...                                       ['A', 'B', 'C', 'A', 'B', 'C']])
>>> df_multindex
      cost  revenue
Q1 A    250     100
   B    150     250
   C    100     300
Q2 A    150     200
   B    300     175
   C    220     225
```

```
>>> df.le(df_multindex, level=1)
      cost  revenue
Q1 A  True    True
   B  True    True
   C  True    True
```

(continues on next page)

(continued from previous page)

|    |   |       |       |

|    | B | True  | False |
|    | C | True  | False |

### pandas.DataFrame.mad

DataFrame.**mad** (*axis=None, skipna=None, level=None*)

Return the mean absolute deviation of the values for the requested axis.

#### Parameters

**axis** [{index (0), columns (1)}] Axis for the function to be applied on.

**skipna** [bool, default True] Exclude NA/null values when computing the result.

**level** [int or level name, default None] If the axis is a MultiIndex (hierarchical), count along a particular level, collapsing into a Series.

**numeric\_only** [bool, default None] Include only float, int, boolean columns. If None, will attempt to use everything, then use only numeric data. Not implemented for Series.

**\*\*kwargs** Additional keyword arguments to be passed to the function.

#### Returns

**mad** [Series or DataFrame (if level specified)]

### pandas.DataFrame.mask

DataFrame.**mask** (*cond, other=nan, inplace=False, axis=None, level=None, errors='raise', try\_cast=False, raise\_on\_error=None*)

Replace values where the condition is True.

#### Parameters

**cond** [boolean NDFrame, array-like, or callable] Where *cond* is False, keep the original value. Where True, replace with corresponding value from *other*. If *cond* is callable, it is computed on the NDFrame and should return boolean NDFrame or array. The callable must not change input NDFrame (though pandas doesn't check it).

New in version 0.18.1: A callable can be used as cond.

**other** [scalar, NDFrame, or callable] Entries where *cond* is True are replaced with corresponding value from *other*. If *other* is callable, it is computed on the NDFrame and should return scalar or NDFrame. The callable must not change input NDFrame (though pandas doesn't check it).

New in version 0.18.1: A callable can be used as other.

**inplace** [boolean, default False] Whether to perform the operation in place on the data.

**axis** [int, default None] Alignment axis if needed.

**level** [int, default None] Alignment level if needed.

**errors** [str, {'raise', 'ignore'}, default *raise*] Note that currently this parameter won't affect the results and will always coerce to a suitable dtype.

- *raise* : allow exceptions to be raised.

- *ignore* : suppress exceptions. On error return original object.

**try\_cast** [boolean, default False] Try to cast the result back to the input type (if possible).

**raise\_on\_error** [boolean, default True] Whether to raise on invalid data types (e.g. trying to where on strings).

Deprecated since version 0.21.0: Use *errors*.

### Returns

**wh** [same type as caller]

See also:

**DataFrame.where()** Return an object of same shape as self.

### Notes

The mask method is an application of the if-then idiom. For each element in the calling DataFrame, if *cond* is *False* the element is used; otherwise the corresponding element from the DataFrame *other* is used.

The signature for *DataFrame.where()* differs from *numpy.where()*. Roughly *df1.where(m, df2)* is equivalent to *np.where(m, df1, df2)*.

For further details and examples see the *mask* documentation in *indexing*.

### Examples

```
>>> s = pd.Series(range(5))
>>> s.where(s > 0)
0    NaN
1     1.0
2     2.0
3     3.0
4     4.0
dtype: float64
```

```
>>> s.mask(s > 0)
0     0.0
1     NaN
2     NaN
3     NaN
4     NaN
dtype: float64
```

```
>>> s.where(s > 1, 10)
0     10
1     10
2      2
3      3
4      4
dtype: int64
```

```
>>> df = pd.DataFrame(np.arange(10).reshape(-1, 2), columns=['A', 'B'])
>>> m = df % 3 == 0
>>> df.where(m, -df)
   A  B
0  0 -1
1 -2  3
2 -4 -5
3  6 -7
4 -8  9
>>> df.where(m, -df) == np.where(m, df, -df)
   A      B
0  True  True
1  True  True
2  True  True
3  True  True
4  True  True
>>> df.where(m, -df) == df.mask(~m, -df)
   A      B
0  True  True
1  True  True
2  True  True
3  True  True
4  True  True
```

## pandas.DataFrame.max

DataFrame.**max** (*axis=None, skipna=None, level=None, numeric\_only=None, \*\*kwargs*)

Return the maximum of the values for the requested axis.

If you want the *index* of the maximum, use `idxmax`. This is the equivalent of the `numpy.ndarray` method `argmax`.

### Parameters

**axis** [{index (0), columns (1)}] Axis for the function to be applied on.

**skipna** [bool, default True] Exclude NA/null values when computing the result.

**level** [int or level name, default None] If the axis is a MultiIndex (hierarchical), count along a particular level, collapsing into a Series.

**numeric\_only** [bool, default None] Include only float, int, boolean columns. If None, will attempt to use everything, then use only numeric data. Not implemented for Series.

**\*\*kwargs** Additional keyword arguments to be passed to the function.

### Returns

**max** [Series or DataFrame (if level specified)]

### See also:

**Series.sum** Return the sum.

**Series.min** Return the minimum.

**Series.max** Return the maximum.

**Series.idxmin** Return the index of the minimum.

**Series.idxmax** Return the index of the maximum.

**DataFrame.min** Return the sum over the requested axis.

**DataFrame.min** Return the minimum over the requested axis.

**DataFrame.max** Return the maximum over the requested axis.

**DataFrame.idxmin** Return the index of the minimum over the requested axis.

**DataFrame.idxmax** Return the index of the maximum over the requested axis.

## Examples

```
>>> idx = pd.MultiIndex.from_arrays([
...     ['warm', 'warm', 'cold', 'cold'],
...     ['dog', 'falcon', 'fish', 'spider']],
...     names=['blooded', 'animal'])
>>> s = pd.Series([4, 2, 0, 8], name='legs', index=idx)
>>> s
blooded  animal
warm     dog      4
         falcon   2
cold     fish     0
         spider   8
Name: legs, dtype: int64
```

```
>>> s.max()
8
```

Max using level names, as well as indices.

```
>>> s.max(level='blooded')
blooded
warm     4
cold     8
Name: legs, dtype: int64
```

```
>>> s.max(level=0)
blooded
warm     4
cold     8
Name: legs, dtype: int64
```

## pandas.DataFrame.mean

**DataFrame.mean** (*axis=None, skipna=None, level=None, numeric\_only=None, \*\*kwargs*)  
Return the mean of the values for the requested axis.

### Parameters

**axis** [{index (0), columns (1)}] Axis for the function to be applied on.

**skipna** [bool, default True] Exclude NA/null values when computing the result.

**level** [int or level name, default None] If the axis is a MultiIndex (hierarchical), count along a particular level, collapsing into a Series.

**numeric\_only** [bool, default None] Include only float, int, boolean columns. If None, will attempt to use everything, then use only numeric data. Not implemented for Series.

**\*\*kwargs** Additional keyword arguments to be passed to the function.

#### Returns

**mean** [Series or DataFrame (if level specified)]

### pandas.DataFrame.median

`DataFrame.median` (*axis=None, skipna=None, level=None, numeric\_only=None, \*\*kwargs*)

Return the median of the values for the requested axis.

#### Parameters

**axis** [{index (0), columns (1)}] Axis for the function to be applied on.

**skipna** [bool, default True] Exclude NA/null values when computing the result.

**level** [int or level name, default None] If the axis is a MultiIndex (hierarchical), count along a particular level, collapsing into a Series.

**numeric\_only** [bool, default None] Include only float, int, boolean columns. If None, will attempt to use everything, then use only numeric data. Not implemented for Series.

**\*\*kwargs** Additional keyword arguments to be passed to the function.

#### Returns

**median** [Series or DataFrame (if level specified)]

### pandas.DataFrame.melt

`DataFrame.melt` (*id\_vars=None, value\_vars=None, var\_name=None, value\_name='value', col\_level=None*)

Unpivots a DataFrame from wide format to long format, optionally leaving identifier variables set.

This function is useful to massage a DataFrame into a format where one or more columns are identifier variables (*id\_vars*), while all other columns, considered measured variables (*value\_vars*), are “unpivoted” to the row axis, leaving just two non-identifier columns, ‘variable’ and ‘value’.

New in version 0.20.0.

#### Parameters

**frame** [DataFrame]

**id\_vars** [tuple, list, or ndarray, optional] Column(s) to use as identifier variables.

**value\_vars** [tuple, list, or ndarray, optional] Column(s) to unpivot. If not specified, uses all columns that are not set as *id\_vars*.

**var\_name** [scalar] Name to use for the ‘variable’ column. If None it uses `frame.columns.name` or ‘variable’.

**value\_name** [scalar, default ‘value’] Name to use for the ‘value’ column.

**col\_level** [int or string, optional] If columns are a MultiIndex then use this level to melt.

**See also:**

*melt, pivot\_table, DataFrame.pivot*

## Examples

```
>>> df = pd.DataFrame({'A': {0: 'a', 1: 'b', 2: 'c'},
...                    'B': {0: 1, 1: 3, 2: 5},
...                    'C': {0: 2, 1: 4, 2: 6}})
>>> df
```

|   | A | B | C |
|---|---|---|---|
| 0 | a | 1 | 2 |
| 1 | b | 3 | 4 |
| 2 | c | 5 | 6 |

```
>>> df.melt(id_vars=['A'], value_vars=['B'])
```

|   | A | variable | value |
|---|---|----------|-------|
| 0 | a | B        | 1     |
| 1 | b | B        | 3     |
| 2 | c | B        | 5     |

```
>>> df.melt(id_vars=['A'], value_vars=['B', 'C'])
```

|   | A | variable | value |
|---|---|----------|-------|
| 0 | a | B        | 1     |
| 1 | b | B        | 3     |
| 2 | c | B        | 5     |
| 3 | a | C        | 2     |
| 4 | b | C        | 4     |
| 5 | c | C        | 6     |

The names of ‘variable’ and ‘value’ columns can be customized:

```
>>> df.melt(id_vars=['A'], value_vars=['B'],
...         var_name='myVarname', value_name='myValname')
```

|   | A | myVarname | myValname |
|---|---|-----------|-----------|
| 0 | a | B         | 1         |
| 1 | b | B         | 3         |
| 2 | c | B         | 5         |

If you have multi-index columns:

```
>>> df.columns = [list('ABC'), list('DEF')]
>>> df
```

|   | A | B | C |
|---|---|---|---|
|   | D | E | F |
| 0 | a | 1 | 2 |
| 1 | b | 3 | 4 |
| 2 | c | 5 | 6 |

```
>>> df.melt(col_level=0, id_vars=['A'], value_vars=['B'])
```

|   | A | variable | value |
|---|---|----------|-------|
| 0 | a | B        | 1     |
| 1 | b | B        | 3     |
| 2 | c | B        | 5     |

```
>>> df.melt(id_vars=[('A', 'D')], value_vars=[('B', 'E')])
(A, D) variable_0 variable_1 value
0      a          B          E      1
1      b          B          E      3
2      c          B          E      5
```

## pandas.DataFrame.memory\_usage

`DataFrame.memory_usage(index=True, deep=False)`

Return the memory usage of each column in bytes.

The memory usage can optionally include the contribution of the index and elements of *object* dtype.

This value is displayed in `DataFrame.info` by default. This can be suppressed by setting `pandas.options.display.memory_usage` to `False`.

### Parameters

**index** [bool, default True] Specifies whether to include the memory usage of the DataFrame's index in returned Series. If `index=True` the memory usage of the index the first item in the output.

**deep** [bool, default False] If True, introspect the data deeply by interrogating *object* dtypes for system-level memory consumption, and include it in the returned values.

### Returns

**sizes** [Series] A Series whose index is the original column names and whose values is the memory usage of each column in bytes.

See also:

**numpy.ndarray.nbytes** Total bytes consumed by the elements of an ndarray.

**Series.memory\_usage** Bytes consumed by a Series.

**pandas.Categorical** Memory-efficient array for string values with many repeated values.

**DataFrame.info** Concise summary of a DataFrame.

## Examples

```
>>> dtypes = ['int64', 'float64', 'complex128', 'object', 'bool']
>>> data = dict([(t, np.ones(shape=5000).astype(t))
...              for t in dtypes])
>>> df = pd.DataFrame(data)
>>> df.head()
   int64  float64  complex128  object  bool
0      1      1.0      (1+0j)      1  True
1      1      1.0      (1+0j)      1  True
2      1      1.0      (1+0j)      1  True
3      1      1.0      (1+0j)      1  True
4      1      1.0      (1+0j)      1  True
```

```
>>> df.memory_usage()
Index      80
int64     40000
```

(continues on next page)

(continued from previous page)

```
float64      40000
complex128    80000
object        40000
bool          5000
dtype: int64
```

```
>>> df.memory_usage(index=False)
int64      40000
float64     40000
complex128  80000
object      40000
bool        5000
dtype: int64
```

The memory footprint of *object* dtype columns is ignored by default:

```
>>> df.memory_usage(deep=True)
Index      80
int64      40000
float64     40000
complex128  80000
object     160000
bool        5000
dtype: int64
```

Use a Categorical for efficient storage of an object-dtype column with many repeated values.

```
>>> df['object'].astype('category').memory_usage(deep=True)
5168
```

## pandas.DataFrame.merge

`DataFrame.merge(right, how='inner', on=None, left_on=None, right_on=None, left_index=False, right_index=False, sort=False, suffixes=('_x', '_y'), copy=True, indicator=False, validate=None)`

Merge DataFrame or named Series objects with a database-style join.

The join is done on columns or indexes. If joining columns on columns, the DataFrame indexes *will be ignored*. Otherwise if joining indexes on indexes or indexes on a column or columns, the index will be passed on.

### Parameters

**right** [DataFrame or named Series] Object to merge with.

**how** [{ 'left', 'right', 'outer', 'inner' }, default 'inner'] Type of merge to be performed.

- left: use only keys from left frame, similar to a SQL left outer join; preserve key order.
- right: use only keys from right frame, similar to a SQL right outer join; preserve key order.
- outer: use union of keys from both frames, similar to a SQL full outer join; sort keys lexicographically.
- inner: use intersection of keys from both frames, similar to a SQL inner join; preserve the order of the left keys.

**on** [label or list] Column or index level names to join on. These must be found in both DataFrames. If *on* is None and not merging on indexes then this defaults to the intersection of the columns in both DataFrames.

**left\_on** [label or list, or array-like] Column or index level names to join on in the left DataFrame. Can also be an array or list of arrays of the length of the left DataFrame. These arrays are treated as if they are columns.

**right\_on** [label or list, or array-like] Column or index level names to join on in the right DataFrame. Can also be an array or list of arrays of the length of the right DataFrame. These arrays are treated as if they are columns.

**left\_index** [bool, default False] Use the index from the left DataFrame as the join key(s). If it is a MultiIndex, the number of keys in the other DataFrame (either the index or a number of columns) must match the number of levels.

**right\_index** [bool, default False] Use the index from the right DataFrame as the join key. Same caveats as *left\_index*.

**sort** [bool, default False] Sort the join keys lexicographically in the result DataFrame. If False, the order of the join keys depends on the join type (how keyword).

**suffixes** [tuple of (str, str), default ('\_x', '\_y')] Suffix to apply to overlapping column names in the left and right side, respectively. To raise an exception on overlapping columns use (False, False).

**copy** [bool, default True] If False, avoid copy if possible.

**indicator** [bool or str, default False] If True, adds a column to output DataFrame called “\_merge” with information on the source of each row. If string, column with information on source of each row will be added to output DataFrame, and column will be named value of string. Information column is Categorical-type and takes on a value of “left\_only” for observations whose merge key only appears in ‘left’ DataFrame, “right\_only” for observations whose merge key only appears in ‘right’ DataFrame, and “both” if the observation’s merge key is found in both.

**validate** [str, optional] If specified, checks if merge is of specified type.

- “one\_to\_one” or “1:1”: check if merge keys are unique in both left and right datasets.
- “one\_to\_many” or “1:m”: check if merge keys are unique in left dataset.
- “many\_to\_one” or “m:1”: check if merge keys are unique in right dataset.
- “many\_to\_many” or “m:m”: allowed, but does not result in checks.

New in version 0.21.0.

### Returns

**DataFrame** A DataFrame of the two merged objects.

See also:

***merge\_ordered*** Merge with optional filling/interpolation.

***merge\_asof*** Merge on nearest keys.

***DataFrame.join*** Similar method using indices.

## Notes

Support for specifying index levels as the *on*, *left\_on*, and *right\_on* parameters was added in version 0.23.0  
 Support for merging named Series objects was added in version 0.24.0

## Examples

```
>>> df1 = pd.DataFrame({'lkey': ['foo', 'bar', 'baz', 'foo'],
...                     'value': [1, 2, 3, 5]})
>>> df2 = pd.DataFrame({'rkey': ['foo', 'bar', 'baz', 'foo'],
...                     'value': [5, 6, 7, 8]})
>>> df1
   lkey  value
0   foo      1
1   bar      2
2   baz      3
3   foo      5
>>> df2
   rkey  value
0   foo      5
1   bar      6
2   baz      7
3   foo      8
```

Merge df1 and df2 on the lkey and rkey columns. The value columns have the default suffixes, *\_x* and *\_y*, appended.

```
>>> df1.merge(df2, left_on='lkey', right_on='rkey')
   lkey  value_x rkey  value_y
0   foo      1   foo      5
1   foo      1   foo      8
2   foo      5   foo      5
3   foo      5   foo      8
4   bar      2   bar      6
5   baz      3   baz      7
```

Merge DataFrames df1 and df2 with specified left and right suffixes appended to any overlapping columns.

```
>>> df1.merge(df2, left_on='lkey', right_on='rkey',
...           suffixes=('_left', '_right'))
   lkey  value_left rkey  value_right
0   foo      1     foo      5
1   foo      1     foo      8
2   foo      5     foo      5
3   foo      5     foo      8
4   bar      2     bar      6
5   baz      3     baz      7
```

Merge DataFrames df1 and df2, but raise an exception if the DataFrames have any overlapping columns.

```
>>> df1.merge(df2, left_on='lkey', right_on='rkey', suffixes=(False, False))
Traceback (most recent call last):
...
ValueError: columns overlap but no suffix specified:
   Index(['value'], dtype='object')
```

## pandas.DataFrame.min

`DataFrame.min` (*axis=None, skipna=None, level=None, numeric\_only=None, \*\*kwargs*)

Return the minimum of the values for the requested axis.

If you want the *index* of the minimum, use `idxmin`. This is the equivalent of the `numpy.ndarray` method `argmin`.

### Parameters

**axis** [{index (0), columns (1)}] Axis for the function to be applied on.

**skipna** [bool, default True] Exclude NA/null values when computing the result.

**level** [int or level name, default None] If the axis is a `MultiIndex` (hierarchical), count along a particular level, collapsing into a `Series`.

**numeric\_only** [bool, default None] Include only float, int, boolean columns. If None, will attempt to use everything, then use only numeric data. Not implemented for `Series`.

**\*\*kwargs** Additional keyword arguments to be passed to the function.

### Returns

**min** [Series or DataFrame (if level specified)]

See also:

**Series.sum** Return the sum.

**Series.min** Return the minimum.

**Series.max** Return the maximum.

**Series.idxmin** Return the index of the minimum.

**Series.idxmax** Return the index of the maximum.

**DataFrame.min** Return the sum over the requested axis.

**DataFrame.min** Return the minimum over the requested axis.

**DataFrame.max** Return the maximum over the requested axis.

**DataFrame.idxmin** Return the index of the minimum over the requested axis.

**DataFrame.idxmax** Return the index of the maximum over the requested axis.

### Examples

```
>>> idx = pd.MultiIndex.from_arrays([
...     ['warm', 'warm', 'cold', 'cold'],
...     ['dog', 'falcon', 'fish', 'spider']],
...     names=['blooded', 'animal'])
>>> s = pd.Series([4, 2, 0, 8], name='legs', index=idx)
>>> s
blooded  animal
warm     dog      4
         falcon   2
cold     fish     0
```

(continues on next page)

(continued from previous page)

```

        spider      8
Name: legs, dtype: int64

```

```

>>> s.min()
0

```

Min using level names, as well as indices.

```

>>> s.min(level='blooded')
blooded
warm      2
cold      0
Name: legs, dtype: int64

```

```

>>> s.min(level=0)
blooded
warm      2
cold      0
Name: legs, dtype: int64

```

## pandas.DataFrame.mod

`DataFrame.mod(other, axis='columns', level=None, fill_value=None)`

Modulo of dataframe and other, element-wise (binary operator *mod*).

Equivalent to `dataframe % other`, but with support to substitute a `fill_value` for missing data in one of the inputs. With reverse version, *rmod*.

Among flexible wrappers (*add*, *sub*, *mul*, *div*, *mod*, *pow*) to arithmetic operators: `+`, `-`, `*`, `/`, `//`, `%`, `**`.

### Parameters

**other** [scalar, sequence, Series, or DataFrame] Any single or multiple element data structure, or list-like object.

**axis** [{0 or 'index', 1 or 'columns'}] Whether to compare by the index (0 or 'index') or columns (1 or 'columns'). For Series input, axis to match Series index on.

**level** [int or label] Broadcast across a level, matching Index values on the passed Multi-Index level.

**fill\_value** [float or None, default None] Fill existing missing (NaN) values, and any new element needed for successful DataFrame alignment, with this value before computation. If data in both corresponding DataFrame locations is missing the result will be missing.

### Returns

**DataFrame** Result of the arithmetic operation.

See also:

**DataFrame.add** Add DataFrames.

**DataFrame.sub** Subtract DataFrames.

**DataFrame.mul** Multiply DataFrames.

**DataFrame.div** Divide DataFrames (float division).

**DataFrame.truediv** Divide DataFrames (float division).

**DataFrame.floordiv** Divide DataFrames (integer division).

**DataFrame.mod** Calculate modulo (remainder after division).

**DataFrame.pow** Calculate exponential power.

## Notes

Mismatched indices will be unioned together.

## Examples

```
>>> df = pd.DataFrame({'angles': [0, 3, 4],
...                     'degrees': [360, 180, 360]},
...                     index=['circle', 'triangle', 'rectangle'])
>>> df
```

|           | angles | degrees |
|-----------|--------|---------|
| circle    | 0      | 360     |
| triangle  | 3      | 180     |
| rectangle | 4      | 360     |

Add a scalar with operator version which return the same results.

```
>>> df + 1
```

|           | angles | degrees |
|-----------|--------|---------|
| circle    | 1      | 361     |
| triangle  | 4      | 181     |
| rectangle | 5      | 361     |

```
>>> df.add(1)
```

|           | angles | degrees |
|-----------|--------|---------|
| circle    | 1      | 361     |
| triangle  | 4      | 181     |
| rectangle | 5      | 361     |

Divide by constant with reverse version.

```
>>> df.div(10)
```

|           | angles | degrees |
|-----------|--------|---------|
| circle    | 0.0    | 36.0    |
| triangle  | 0.3    | 18.0    |
| rectangle | 0.4    | 36.0    |

```
>>> df.rdiv(10)
```

|           | angles   | degrees  |
|-----------|----------|----------|
| circle    | inf      | 0.027778 |
| triangle  | 3.333333 | 0.055556 |
| rectangle | 2.500000 | 0.027778 |

Subtract a list and Series by axis with operator version.

```
>>> df - [1, 2]
      angles  degrees
circle      -1     358
triangle     2     178
rectangle    3     358
```

```
>>> df.sub([1, 2], axis='columns')
      angles  degrees
circle      -1     358
triangle     2     178
rectangle    3     358
```

```
>>> df.sub(pd.Series([1, 1, 1], index=['circle', 'triangle', 'rectangle']),
...        axis='index')
      angles  degrees
circle      -1     359
triangle     2     179
rectangle    3     359
```

Multiply a DataFrame of different shape with operator version.

```
>>> other = pd.DataFrame({'angles': [0, 3, 4]},
...                       index=['circle', 'triangle', 'rectangle'])
>>> other
      angles
circle      0
triangle     3
rectangle    4
```

```
>>> df * other
      angles  degrees
circle      0      NaN
triangle     9      NaN
rectangle   16      NaN
```

```
>>> df.mul(other, fill_value=0)
      angles  degrees
circle      0      0.0
triangle     9      0.0
rectangle   16      0.0
```

Divide by a MultiIndex by level.

```
>>> df_multindex = pd.DataFrame({'angles': [0, 3, 4, 4, 5, 6],
...                              'degrees': [360, 180, 360, 360, 540, 720]},
...                              index=[['A', 'A', 'A', 'B', 'B', 'B'],
...                                    ['circle', 'triangle', 'rectangle',
...                                     'square', 'pentagon', 'hexagon']])
>>> df_multindex
      angles  degrees
A circle      0     360
  triangle     3     180
  rectangle     4     360
B square      4     360
  pentagon     5     540
  hexagon      6     720
```

```
>>> df.div(df_multindex, level=1, fill_value=0)
      angles  degrees
A circle    NaN     1.0
  triangle    1.0     1.0
  rectangle    1.0     1.0
B square     0.0     0.0
  pentagon    0.0     0.0
  hexagon     0.0     0.0
```

## pandas.DataFrame.mode

`DataFrame.mode(axis=0, numeric_only=False, dropna=True)`

Get the mode(s) of each element along the selected axis.

The mode of a set of values is the value that appears most often. It can be multiple values.

### Parameters

**axis** [{0 or 'index', 1 or 'columns'}, default 0] The axis to iterate over while searching for the mode:

- 0 or 'index' : get mode of each column
- 1 or 'columns' : get mode of each row

**numeric\_only** [bool, default False] If True, only apply to numeric columns.

**dropna** [bool, default True] Don't consider counts of NaN/NaT.

New in version 0.24.0.

### Returns

**DataFrame** The modes of each column or row.

See also:

**Series.mode** Return the highest frequency value in a Series.

**Series.value\_counts** Return the counts of values in a Series.

## Examples

```
>>> df = pd.DataFrame([('bird', 2, 2),
...                    ('mammal', 4, np.nan),
...                    ('arthropod', 8, 0),
...                    ('bird', 2, np.nan)],
...                    index=('falcon', 'horse', 'spider', 'ostrich'),
...                    columns=('species', 'legs', 'wings'))
>>> df
      species  legs  wings
falcon    bird     2    2.0
horse    mammal     4    NaN
spider  arthropod     8    0.0
ostrich    bird     2    NaN
```

By default, missing values are not considered, and the mode of wings are both 0 and 2. The second row of species and legs contains NaN, because they have only one mode, but the DataFrame has two rows.

```
>>> df.mode()
   species  legs  wings
0    bird    2.0    0.0
1     NaN    NaN    2.0
```

Setting `dropna=False` NaN values are considered and they can be the mode (like for wings).

```
>>> df.mode(dropna=False)
   species  legs  wings
0    bird    2    NaN
```

Setting `numeric_only=True`, only the mode of numeric columns is computed, and columns of other types are ignored.

```
>>> df.mode(numeric_only=True)
   legs  wings
0    2.0    0.0
1    NaN    2.0
```

To compute the mode over columns and not rows, use the `axis` parameter:

```
>>> df.mode(axis='columns', numeric_only=True)
      0      1
falcon  2.0  NaN
horse   4.0  NaN
spider  0.0  8.0
ostrich  2.0  NaN
```

## pandas.DataFrame.mul

`DataFrame.mul` (*other*, *axis*='columns', *level*=None, *fill\_value*=None)

Multiplication of dataframe and other, element-wise (binary operator *mul*).

Equivalent to `dataframe * other`, but with support to substitute a `fill_value` for missing data in one of the inputs. With reverse version, *rmul*.

Among flexible wrappers (*add*, *sub*, *mul*, *div*, *mod*, *pow*) to arithmetic operators: `+`, `-`, `*`, `/`, `//`, `%`, `**`.

### Parameters

**other** [scalar, sequence, Series, or DataFrame] Any single or multiple element data structure, or list-like object.

**axis** [{0 or 'index', 1 or 'columns'}] Whether to compare by the index (0 or 'index') or columns (1 or 'columns'). For Series input, axis to match Series index on.

**level** [int or label] Broadcast across a level, matching Index values on the passed Multi-Index level.

**fill\_value** [float or None, default None] Fill existing missing (NaN) values, and any new element needed for successful DataFrame alignment, with this value before computation. If data in both corresponding DataFrame locations is missing the result will be missing.

### Returns

**DataFrame** Result of the arithmetic operation.

See also:

**DataFrame.add** Add DataFrames.

**DataFrame.sub** Subtract DataFrames.

**DataFrame.mul** Multiply DataFrames.

**DataFrame.div** Divide DataFrames (float division).

**DataFrame.truediv** Divide DataFrames (float division).

**DataFrame.floordiv** Divide DataFrames (integer division).

**DataFrame.mod** Calculate modulo (remainder after division).

**DataFrame.pow** Calculate exponential power.

## Notes

Mismatched indices will be unioned together.

## Examples

```
>>> df = pd.DataFrame({'angles': [0, 3, 4],
...                     'degrees': [360, 180, 360]},
...                     index=['circle', 'triangle', 'rectangle'])
>>> df
```

|           | angles | degrees |
|-----------|--------|---------|
| circle    | 0      | 360     |
| triangle  | 3      | 180     |
| rectangle | 4      | 360     |

Add a scalar with operator version which return the same results.

```
>>> df + 1
```

|           | angles | degrees |
|-----------|--------|---------|
| circle    | 1      | 361     |
| triangle  | 4      | 181     |
| rectangle | 5      | 361     |

```
>>> df.add(1)
```

|           | angles | degrees |
|-----------|--------|---------|
| circle    | 1      | 361     |
| triangle  | 4      | 181     |
| rectangle | 5      | 361     |

Divide by constant with reverse version.

```
>>> df.div(10)
```

|           | angles | degrees |
|-----------|--------|---------|
| circle    | 0.0    | 36.0    |
| triangle  | 0.3    | 18.0    |
| rectangle | 0.4    | 36.0    |

```
>>> df.rdiv(10)
```

|           | angles   | degrees  |
|-----------|----------|----------|
| circle    | inf      | 0.027778 |
| triangle  | 3.333333 | 0.055556 |
| rectangle | 2.500000 | 0.027778 |

Subtract a list and Series by axis with operator version.

```
>>> df - [1, 2]
      angles  degrees
circle      -1     358
triangle     2     178
rectangle    3     358
```

```
>>> df.sub([1, 2], axis='columns')
      angles  degrees
circle      -1     358
triangle     2     178
rectangle    3     358
```

```
>>> df.sub(pd.Series([1, 1, 1], index=['circle', 'triangle', 'rectangle']),
...        axis='index')
      angles  degrees
circle      -1     359
triangle     2     179
rectangle    3     359
```

Multiply a DataFrame of different shape with operator version.

```
>>> other = pd.DataFrame({'angles': [0, 3, 4]},
...                       index=['circle', 'triangle', 'rectangle'])
>>> other
      angles
circle      0
triangle     3
rectangle    4
```

```
>>> df * other
      angles  degrees
circle      0      NaN
triangle     9      NaN
rectangle   16      NaN
```

```
>>> df.mul(other, fill_value=0)
      angles  degrees
circle      0      0.0
triangle     9      0.0
rectangle   16      0.0
```

Divide by a MultiIndex by level.

```
>>> df_multindex = pd.DataFrame({'angles': [0, 3, 4, 4, 5, 6],
...                               'degrees': [360, 180, 360, 360, 540, 720]},
...                              index=[['A', 'A', 'A', 'B', 'B', 'B'],
...                                      ['circle', 'triangle', 'rectangle',
...                                       'square', 'pentagon', 'hexagon']])
>>> df_multindex
      angles  degrees
A circle      0     360
  triangle     3     180
  rectangle     4     360
B square      4     360
```

(continues on next page)

(continued from previous page)

|          |   |     |
|----------|---|-----|
| pentagon | 5 | 540 |
| hexagon  | 6 | 720 |

```

>>> df.div(df_multindex, level=1, fill_value=0)
      angles  degrees
A circle   NaN     1.0
  triangle  1.0     1.0
 rectangle  1.0     1.0
B square   0.0     0.0
  pentagon  0.0     0.0
  hexagon   0.0     0.0

```

### pandas.DataFrame.multiply

`DataFrame.multiply` (*other*, *axis*=*'columns'*, *level*=*None*, *fill\_value*=*None*)

Multiplication of dataframe and other, element-wise (binary operator *mul*).

Equivalent to `dataframe * other`, but with support to substitute a *fill\_value* for missing data in one of the inputs. With reverse version, *rmul*.

Among flexible wrappers (*add*, *sub*, *mul*, *div*, *mod*, *pow*) to arithmetic operators: *+*, *-*, *\**, */*, *//*, *%*, *\*\**.

#### Parameters

**other** [scalar, sequence, Series, or DataFrame] Any single or multiple element data structure, or list-like object.

**axis** [{0 or 'index', 1 or 'columns'}] Whether to compare by the index (0 or 'index') or columns (1 or 'columns'). For Series input, axis to match Series index on.

**level** [int or label] Broadcast across a level, matching Index values on the passed Multi-Index level.

**fill\_value** [float or None, default None] Fill existing missing (NaN) values, and any new element needed for successful DataFrame alignment, with this value before computation. If data in both corresponding DataFrame locations is missing the result will be missing.

#### Returns

**DataFrame** Result of the arithmetic operation.

See also:

**DataFrame.add** Add DataFrames.

**DataFrame.sub** Subtract DataFrames.

**DataFrame.mul** Multiply DataFrames.

**DataFrame.div** Divide DataFrames (float division).

**DataFrame.truediv** Divide DataFrames (float division).

**DataFrame.floordiv** Divide DataFrames (integer division).

**DataFrame.mod** Calculate modulo (remainder after division).

**DataFrame.pow** Calculate exponential power.

## Notes

Mismatched indices will be unioned together.

## Examples

```
>>> df = pd.DataFrame({'angles': [0, 3, 4],
...                     'degrees': [360, 180, 360]},
...                    index=['circle', 'triangle', 'rectangle'])
>>> df
```

|           | angles | degrees |
|-----------|--------|---------|
| circle    | 0      | 360     |
| triangle  | 3      | 180     |
| rectangle | 4      | 360     |

Add a scalar with operator version which return the same results.

```
>>> df + 1
```

|           | angles | degrees |
|-----------|--------|---------|
| circle    | 1      | 361     |
| triangle  | 4      | 181     |
| rectangle | 5      | 361     |

```
>>> df.add(1)
```

|           | angles | degrees |
|-----------|--------|---------|
| circle    | 1      | 361     |
| triangle  | 4      | 181     |
| rectangle | 5      | 361     |

Divide by constant with reverse version.

```
>>> df.div(10)
```

|           | angles | degrees |
|-----------|--------|---------|
| circle    | 0.0    | 36.0    |
| triangle  | 0.3    | 18.0    |
| rectangle | 0.4    | 36.0    |

```
>>> df.rdiv(10)
```

|           | angles   | degrees  |
|-----------|----------|----------|
| circle    | inf      | 0.027778 |
| triangle  | 3.333333 | 0.055556 |
| rectangle | 2.500000 | 0.027778 |

Subtract a list and Series by axis with operator version.

```
>>> df - [1, 2]
```

|           | angles | degrees |
|-----------|--------|---------|
| circle    | -1     | 358     |
| triangle  | 2      | 178     |
| rectangle | 3      | 358     |

```
>>> df.sub([1, 2], axis='columns')
```

|           | angles | degrees |
|-----------|--------|---------|
| circle    | -1     | 358     |
| triangle  | 2      | 178     |
| rectangle | 3      | 358     |

```
>>> df.sub(pd.Series([1, 1, 1], index=['circle', 'triangle', 'rectangle']),
...         axis='index')
      angles  degrees
circle      -1     359
triangle     2     179
rectangle    3     359
```

Multiply a DataFrame of different shape with operator version.

```
>>> other = pd.DataFrame({'angles': [0, 3, 4]},
...                       index=['circle', 'triangle', 'rectangle'])
>>> other
      angles
circle      0
triangle     3
rectangle    4
```

```
>>> df * other
      angles  degrees
circle      0      NaN
triangle     9      NaN
rectangle   16      NaN
```

```
>>> df.mul(other, fill_value=0)
      angles  degrees
circle      0      0.0
triangle     9      0.0
rectangle   16      0.0
```

Divide by a MultiIndex by level.

```
>>> df_multindex = pd.DataFrame({'angles': [0, 3, 4, 4, 5, 6],
...                               'degrees': [360, 180, 360, 360, 540, 720]},
...                              index=[['A', 'A', 'A', 'B', 'B', 'B'],
...                                      ['circle', 'triangle', 'rectangle',
...                                       'square', 'pentagon', 'hexagon']])
>>> df_multindex
      angles  degrees
A circle      0     360
  triangle     3     180
  rectangle     4     360
B square      4     360
  pentagon     5     540
  hexagon      6     720
```

```
>>> df.div(df_multindex, level=1, fill_value=0)
      angles  degrees
A circle      NaN     1.0
  triangle     1.0     1.0
  rectangle     1.0     1.0
B square      0.0     0.0
  pentagon     0.0     0.0
  hexagon      0.0     0.0
```

## pandas.DataFrame.ne

`DataFrame.ne` (*other*, *axis*=*'columns'*, *level*=*None*)

Not equal to of dataframe and other, element-wise (binary operator *ne*).

Among flexible wrappers (*eq*, *ne*, *le*, *lt*, *ge*, *gt*) to comparison operators.

Equivalent to `==`, `!=`, `<=`, `<`, `>=`, `>` with support to choose axis (rows or columns) and level for comparison.

### Parameters

**other** [scalar, sequence, Series, or DataFrame] Any single or multiple element data structure, or list-like object.

**axis** [{0 or 'index', 1 or 'columns'}], default 'columns' Whether to compare by the index (0 or 'index') or columns (1 or 'columns').

**level** [int or label] Broadcast across a level, matching Index values on the passed Multi-Index level.

### Returns

**DataFrame of bool** Result of the comparison.

See also:

**DataFrame.eq** Compare DataFrames for equality elementwise.

**DataFrame.ne** Compare DataFrames for inequality elementwise.

**DataFrame.le** Compare DataFrames for less than inequality or equality elementwise.

**DataFrame.lt** Compare DataFrames for strictly less than inequality elementwise.

**DataFrame.ge** Compare DataFrames for greater than inequality or equality elementwise.

**DataFrame.gt** Compare DataFrames for strictly greater than inequality elementwise.

### Notes

Mismatched indices will be unioned together. *NaN* values are considered different (i.e. *NaN* != *NaN*).

### Examples

```
>>> df = pd.DataFrame({'cost': [250, 150, 100],
...                    'revenue': [100, 250, 300]},
...                    index=['A', 'B', 'C'])
>>> df
   cost  revenue
A   250     100
B   150     250
C   100     300
```

Compare to a scalar and operator version which return the same results.

```
>>> df == 100
   cost  revenue
A  False     True
```

(continues on next page)

(continued from previous page)

```
B False    False
C   True    False
```

```
>>> df.eq(100)
      cost  revenue
A False     True
B False     False
C   True     False
```

Compare to a list and Series by axis and operator version. As shown, for list axis is by default 'index', but for Series axis is by default 'columns'.

```
>>> df != [100, 250, 300]
      cost  revenue
A   True     False
B   True     False
C   True     False
```

```
>>> df.ne([100, 250, 300], axis='index')
      cost  revenue
A   True     False
B   True     False
C   True     False
```

```
>>> df != pd.Series([100, 250, 300])
      cost  revenue  0    1    2
A   True     True  True True True
B   True     True  True True True
C   True     True  True True True
```

```
>>> df.ne(pd.Series([100, 250, 300]), axis='columns')
      cost  revenue  0    1    2
A   True     True  True True True
B   True     True  True True True
C   True     True  True True True
```

Compare to a DataFrame of different shape.

```
>>> other = pd.DataFrame({'revenue': [300, 250, 100, 150]},
...                        index=['A', 'B', 'C', 'D'])
>>> other
      revenue
A         300
B         250
C         100
D         150
```

```
>>> df.gt(other)
      cost  revenue
A False     False
B False     False
C False      True
D False     False
```

Compare to a MultiIndex by level.

```
>>> df_multindex = pd.DataFrame({'cost': [250, 150, 100, 150, 300, 220],
...                               'revenue': [100, 250, 300, 200, 175, 225]},
...                               index=[['Q1', 'Q1', 'Q1', 'Q2', 'Q2', 'Q2'],
...                                       ['A', 'B', 'C', 'A', 'B', 'C']])
>>> df_multindex
      cost  revenue
Q1 A    250     100
   B    150     250
   C    100     300
Q2 A    150     200
   B    300     175
   C    220     225
```

```
>>> df.le(df_multindex, level=1)
      cost  revenue
Q1 A    True     True
   B    True     True
   C    True     True
Q2 A    False    True
   B    True     False
   C    True     False
```

## pandas.DataFrame.nlargest

`DataFrame.nlargest` (*n*, *columns*, *keep*='first')

Return the first *n* rows ordered by *columns* in descending order.

Return the first *n* rows with the largest values in *columns*, in descending order. The columns that are not specified are returned as well, but not used for ordering.

This method is equivalent to `df.sort_values(columns, ascending=False).head(n)`, but more performant.

### Parameters

**n** [int] Number of rows to return.

**columns** [label or list of labels] Column label(s) to order by.

**keep** [{ 'first', 'last', 'all' }, default 'first'] Where there are duplicate values:

- *first* : prioritize the first occurrence(s)
- *last* : prioritize the last occurrence(s)
- **all** [do not drop any duplicates, even it means] selecting more than *n* items.

New in version 0.24.0.

### Returns

**DataFrame** The first *n* rows ordered by the given columns in descending order.

See also:

**DataFrame.nsmallest** Return the first *n* rows ordered by *columns* in ascending order.

**DataFrame.sort\_values** Sort DataFrame by the values.

**DataFrame.head** Return the first *n* rows without re-ordering.

## Notes

This function cannot be used with all column types. For example, when specifying columns with *object* or *category* dtypes, `TypeError` is raised.

## Examples

```
>>> df = pd.DataFrame({'population': [59000000, 65000000, 434000,
...                                   434000, 434000, 337000, 11300,
...                                   11300, 11300],
...                    'GDP': [1937894, 2583560, 12011, 4520, 12128,
...                             17036, 182, 38, 311],
...                    'alpha-2': ["IT", "FR", "MT", "MV", "BN",
...                                 "IS", "NR", "TV", "AI"]},
...                    index=["Italy", "France", "Malta",
...                             "Maldives", "Brunei", "Iceland",
...                             "Nauru", "Tuvalu", "Anguilla"])
>>> df
```

|          | population | GDP     | alpha-2 |
|----------|------------|---------|---------|
| Italy    | 59000000   | 1937894 | IT      |
| France   | 65000000   | 2583560 | FR      |
| Malta    | 434000     | 12011   | MT      |
| Maldives | 434000     | 4520    | MV      |
| Brunei   | 434000     | 12128   | BN      |
| Iceland  | 337000     | 17036   | IS      |
| Nauru    | 11300      | 182     | NR      |
| Tuvalu   | 11300      | 38      | TV      |
| Anguilla | 11300      | 311     | AI      |

In the following example, we will use `nlargest` to select the three rows having the largest values in column “population”.

```
>>> df.nlargest(3, 'population')
```

|        | population | GDP     | alpha-2 |
|--------|------------|---------|---------|
| France | 65000000   | 2583560 | FR      |
| Italy  | 59000000   | 1937894 | IT      |
| Malta  | 434000     | 12011   | MT      |

When using `keep='last'`, ties are resolved in reverse order:

```
>>> df.nlargest(3, 'population', keep='last')
```

|        | population | GDP     | alpha-2 |
|--------|------------|---------|---------|
| France | 65000000   | 2583560 | FR      |
| Italy  | 59000000   | 1937894 | IT      |
| Brunei | 434000     | 12128   | BN      |

When using `keep='all'`, all duplicate items are maintained:

```
>>> df.nlargest(3, 'population', keep='all')
```

|          | population | GDP     | alpha-2 |
|----------|------------|---------|---------|
| France   | 65000000   | 2583560 | FR      |
| Italy    | 59000000   | 1937894 | IT      |
| Malta    | 434000     | 12011   | MT      |
| Maldives | 434000     | 4520    | MV      |
| Brunei   | 434000     | 12128   | BN      |

To order by the largest values in column “population” and then “GDP”, we can specify multiple columns like in the next example.

```
>>> df.nlargest(3, ['population', 'GDP'])
```

|        | population | GDP     | alpha-2 |
|--------|------------|---------|---------|
| France | 65000000   | 2583560 | FR      |
| Italy  | 59000000   | 1937894 | IT      |
| Brunei | 434000     | 12128   | BN      |

## pandas.DataFrame.notna

`DataFrame.notna()`

Detect existing (non-missing) values.

Return a boolean same-sized object indicating if the values are not NA. Non-missing values get mapped to True. Characters such as empty strings '' or `numpy.inf` are not considered NA values (unless you set `pandas.options.mode.use_inf_as_na = True`). NA values, such as `None` or `numpy.NaN`, get mapped to False values.

### Returns

**DataFrame** Mask of bool values for each element in DataFrame that indicates whether an element is not an NA value.

See also:

**DataFrame.notnull** Alias of `notna`.

**DataFrame.isna** Boolean inverse of `notna`.

**DataFrame.dropna** Omit axes labels with missing values.

**notna** Top-level `notna`.

## Examples

Show which entries in a DataFrame are not NA.

```
>>> df = pd.DataFrame({'age': [5, 6, np.NaN],
...                     'born': [pd.NaT, pd.Timestamp('1939-05-27'),
...                               pd.Timestamp('1940-04-25')],
...                     'name': ['Alfred', 'Batman', ''],
...                     'toy': [None, 'Batmobile', 'Joker']})
>>> df
```

|   | age | born       | name   | toy       |
|---|-----|------------|--------|-----------|
| 0 | 5.0 | NaT        | Alfred | None      |
| 1 | 6.0 | 1939-05-27 | Batman | Batmobile |
| 2 | NaN | 1940-04-25 |        | Joker     |

```
>>> df.notna()
```

|   | age   | born  | name | toy   |
|---|-------|-------|------|-------|
| 0 | True  | False | True | False |
| 1 | True  | True  | True | True  |
| 2 | False | True  | True | True  |

Show which entries in a Series are not NA.

```
>>> ser = pd.Series([5, 6, np.NaN])
>>> ser
0    5.0
1    6.0
2    NaN
dtype: float64
```

```
>>> ser.notna()
0    True
1    True
2   False
dtype: bool
```

## pandas.DataFrame.notnull

`DataFrame.notnull()`

Detect existing (non-missing) values.

Return a boolean same-sized object indicating if the values are not NA. Non-missing values get mapped to True. Characters such as empty strings '' or `numpy.inf` are not considered NA values (unless you set `pandas.options.mode.use_inf_as_na = True`). NA values, such as `None` or `numpy.NaN`, get mapped to False values.

### Returns

**DataFrame** Mask of bool values for each element in DataFrame that indicates whether an element is not an NA value.

See also:

**DataFrame.notnull** Alias of `notna`.

**DataFrame.isna** Boolean inverse of `notna`.

**DataFrame.dropna** Omit axes labels with missing values.

**notna** Top-level `notna`.

## Examples

Show which entries in a DataFrame are not NA.

```
>>> df = pd.DataFrame({'age': [5, 6, np.NaN],
...                    'born': [pd.NaT, pd.Timestamp('1939-05-27'),
...                             pd.Timestamp('1940-04-25')],
...                    'name': ['Alfred', 'Batman', ''],
...                    'toy': [None, 'Batmobile', 'Joker']})
>>> df
   age      born    name      toy
0  5.0      NaT  Alfred     None
1  6.0  1939-05-27  Batman  Batmobile
2  NaN  1940-04-25      Joker
```

```
>>> df.notna()
   age      born    name      toy
```

(continues on next page)

(continued from previous page)

```

0    True  False  True  False
1    True   True  True   True
2   False   True  True   True

```

Show which entries in a Series are not NA.

```

>>> ser = pd.Series([5, 6, np.NaN])
>>> ser
0    5.0
1    6.0
2    NaN
dtype: float64

```

```

>>> ser.notna()
0    True
1    True
2   False
dtype: bool

```

## pandas.DataFrame.nsmallest

`DataFrame.nsmallest` (*n*, *columns*, *keep*='first')

Return the first *n* rows ordered by *columns* in ascending order.

Return the first *n* rows with the smallest values in *columns*, in ascending order. The columns that are not specified are returned as well, but not used for ordering.

This method is equivalent to `df.sort_values(columns, ascending=True).head(n)`, but more performant.

### Parameters

**n** [int] Number of items to retrieve.

**columns** [list or str] Column name or names to order by.

**keep** [{ 'first', 'last', 'all' }, default 'first'] Where there are duplicate values:

- `first` : take the first occurrence.
- `last` : take the last occurrence.
- `all` : do not drop any duplicates, even it means selecting more than *n* items.

New in version 0.24.0.

### Returns

**DataFrame**

See also:

**DataFrame.nlargest** Return the first *n* rows ordered by *columns* in descending order.

**DataFrame.sort\_values** Sort DataFrame by the values.

**DataFrame.head** Return the first *n* rows without re-ordering.

## Examples

```
>>> df = pd.DataFrame({'population': [59000000, 65000000, 434000,
...                                   434000, 434000, 337000, 11300,
...                                   11300, 11300],
...                    'GDP': [1937894, 2583560, 12011, 4520, 12128,
...                             17036, 182, 38, 311],
...                    'alpha-2': ["IT", "FR", "MT", "MV", "BN",
...                                 "IS", "NR", "TV", "AI"]},
...                    index=["Italy", "France", "Malta",
...                             "Maldives", "Brunei", "Iceland",
...                             "Nauru", "Tuvalu", "Anguilla"])
>>> df
```

|          | population | GDP     | alpha-2 |
|----------|------------|---------|---------|
| Italy    | 59000000   | 1937894 | IT      |
| France   | 65000000   | 2583560 | FR      |
| Malta    | 434000     | 12011   | MT      |
| Maldives | 434000     | 4520    | MV      |
| Brunei   | 434000     | 12128   | BN      |
| Iceland  | 337000     | 17036   | IS      |
| Nauru    | 11300      | 182     | NR      |
| Tuvalu   | 11300      | 38      | TV      |
| Anguilla | 11300      | 311     | AI      |

In the following example, we will use `nsmallest` to select the three rows having the smallest values in column “a”.

```
>>> df.nsmallest(3, 'population')
```

|          | population | GDP | alpha-2 |
|----------|------------|-----|---------|
| Nauru    | 11300      | 182 | NR      |
| Tuvalu   | 11300      | 38  | TV      |
| Anguilla | 11300      | 311 | AI      |

When using `keep='last'`, ties are resolved in reverse order:

```
>>> df.nsmallest(3, 'population', keep='last')
```

|          | population | GDP | alpha-2 |
|----------|------------|-----|---------|
| Anguilla | 11300      | 311 | AI      |
| Tuvalu   | 11300      | 38  | TV      |
| Nauru    | 11300      | 182 | NR      |

When using `keep='all'`, all duplicate items are maintained:

```
>>> df.nsmallest(3, 'population', keep='all')
```

|          | population | GDP | alpha-2 |
|----------|------------|-----|---------|
| Nauru    | 11300      | 182 | NR      |
| Tuvalu   | 11300      | 38  | TV      |
| Anguilla | 11300      | 311 | AI      |

To order by the largest values in column “a” and then “c”, we can specify multiple columns like in the next example.

```
>>> df.nsmallest(3, ['population', 'GDP'])
```

|          | population | GDP | alpha-2 |
|----------|------------|-----|---------|
| Tuvalu   | 11300      | 38  | TV      |
| Nauru    | 11300      | 182 | NR      |
| Anguilla | 11300      | 311 | AI      |

**pandas.DataFrame.nunique**`DataFrame.nunique` (*axis=0, dropna=True*)

Count distinct observations over requested axis.

Return Series with number of distinct observations. Can ignore NaN values.

New in version 0.20.0.

**Parameters****axis** [{0 or 'index', 1 or 'columns'}, default 0] The axis to use. 0 or 'index' for row-wise, 1 or 'columns' for column-wise.**dropna** [bool, default True] Don't include NaN in the counts.**Returns****nunique** [Series]**See also:****Series.nunique** Method nunique for Series.**DataFrame.count** Count non-NA cells for each column or row.**Examples**

```
>>> df = pd.DataFrame({'A': [1, 2, 3], 'B': [1, 1, 1]})
>>> df.nunique()
A      3
B      1
dtype: int64
```

```
>>> df.nunique(axis=1)
0      1
1      2
2      2
dtype: int64
```

**pandas.DataFrame.pct\_change**`DataFrame.pct_change` (*periods=1, fill\_method='pad', limit=None, freq=None, \*\*kwargs*)

Percentage change between the current and a prior element.

Computes the percentage change from the immediately previous row by default. This is useful in comparing the percentage of change in a time series of elements.

**Parameters****periods** [int, default 1] Periods to shift for forming percent change.**fill\_method** [str, default 'pad'] How to handle NAs before computing percent changes.**limit** [int, default None] The number of consecutive NAs to fill before stopping.**freq** [DateOffset, timedelta, or offset alias string, optional] Increment to use from time series API (e.g. 'M' or BDay()).**\*\*kwargs** Additional keyword arguments are passed into `DataFrame.shift` or `Series.shift`.

**Returns**

**chg** [Series or DataFrame] The same type as the calling object.

**See also:**

**Series.diff** Compute the difference of two elements in a Series.

**DataFrame.diff** Compute the difference of two elements in a DataFrame.

**Series.shift** Shift the index by some number of periods.

**DataFrame.shift** Shift the index by some number of periods.

**Examples****Series**

```
>>> s = pd.Series([90, 91, 85])
>>> s
0    90
1    91
2    85
dtype: int64
```

```
>>> s.pct_change()
0      NaN
1    0.011111
2   -0.065934
dtype: float64
```

```
>>> s.pct_change(periods=2)
0      NaN
1      NaN
2   -0.055556
dtype: float64
```

See the percentage change in a Series where filling NAs with last valid observation forward to next valid.

```
>>> s = pd.Series([90, 91, None, 85])
>>> s
0    90.0
1    91.0
2     NaN
3    85.0
dtype: float64
```

```
>>> s.pct_change(fill_method='ffill')
0      NaN
1    0.011111
2    0.000000
3   -0.065934
dtype: float64
```

**DataFrame**

Percentage change in French franc, Deutsche Mark, and Italian lira from 1980-01-01 to 1980-03-01.

```
>>> df = pd.DataFrame({
...     'FR': [4.0405, 4.0963, 4.3149],
...     'GR': [1.7246, 1.7482, 1.8519],
...     'IT': [804.74, 810.01, 860.13]},
...     index=['1980-01-01', '1980-02-01', '1980-03-01'])
>>> df
```

|            | FR     | GR     | IT     |
|------------|--------|--------|--------|
| 1980-01-01 | 4.0405 | 1.7246 | 804.74 |
| 1980-02-01 | 4.0963 | 1.7482 | 810.01 |
| 1980-03-01 | 4.3149 | 1.8519 | 860.13 |

```
>>> df.pct_change()
```

|            | FR       | GR       | IT       |
|------------|----------|----------|----------|
| 1980-01-01 | NaN      | NaN      | NaN      |
| 1980-02-01 | 0.013810 | 0.013684 | 0.006549 |
| 1980-03-01 | 0.053365 | 0.059318 | 0.061876 |

Percentage of change in GOOG and APPL stock volume. Shows computing the percentage change between columns.

```
>>> df = pd.DataFrame({
...     '2016': [1769950, 30586265],
...     '2015': [1500923, 40912316],
...     '2014': [1371819, 41403351]},
...     index=['GOOG', 'APPL'])
>>> df
```

|      | 2016     | 2015     | 2014     |
|------|----------|----------|----------|
| GOOG | 1769950  | 1500923  | 1371819  |
| APPL | 30586265 | 40912316 | 41403351 |

```
>>> df.pct_change(axis='columns')
```

|      | 2016 | 2015      | 2014      |
|------|------|-----------|-----------|

| APPL | NaN  | 0.337604  | 0.012002  |

## pandas.DataFrame.pipe

`DataFrame.pipe(func, *args, **kwargs)`

Apply func(self, \*args, \*\*kwargs).

### Parameters

**func** [function] function to apply to the NDFrame. `args`, and `kwargs` are passed into `func`. Alternatively a (callable, `data_keyword`) tuple where `data_keyword` is a string indicating the keyword of callable that expects the NDFrame.

**args** [iterable, optional] positional arguments passed into `func`.

**kwargs** [mapping, optional] a dictionary of keyword arguments passed into `func`.

### Returns

**object** [the return type of `func`.]

See also:

`DataFrame.apply`, `DataFrame.applymap`, `Series.map`

## Notes

Use `.pipe` when chaining together functions that expect Series, DataFrames or GroupBy objects. Instead of writing

```
>>> f(g(h(df), arg1=a), arg2=b, arg3=c)
```

You can write

```
>>> (df.pipe(h)
...   .pipe(g, arg1=a)
...   .pipe(f, arg2=b, arg3=c)
... )
```

If you have a function that takes the data as (say) the second argument, pass a tuple indicating which keyword expects the data. For example, suppose `f` takes its data as `arg2`:

```
>>> (df.pipe(h)
...   .pipe(g, arg1=a)
...   .pipe((f, 'arg2'), arg1=a, arg3=c)
... )
```

## pandas.DataFrame.pivot

`DataFrame.pivot` (*index=None, columns=None, values=None*)

Return reshaped DataFrame organized by given index / column values.

Reshape data (produce a “pivot” table) based on column values. Uses unique values from specified *index* / *columns* to form axes of the resulting DataFrame. This function does not support data aggregation, multiple values will result in a MultiIndex in the columns. See the *User Guide* for more on reshaping.

### Parameters

**index** [string or object, optional] Column to use to make new frame’s index. If None, uses existing index.

**columns** [string or object] Column to use to make new frame’s columns.

**values** [string, object or a list of the previous, optional] Column(s) to use for populating new frame’s values. If not specified, all remaining columns will be used and the result will have hierarchically indexed columns.

Changed in version 0.23.0: Also accept list of column names.

### Returns

**DataFrame** Returns reshaped DataFrame.

### Raises

**ValueError:** When there are any *index*, *columns* combinations with multiple values.  
*DataFrame.pivot\_table* when you need to aggregate.

See also:

**DataFrame.pivot\_table** Generalization of pivot that can handle duplicate values for one index/column pair.

**DataFrame.unstack** Pivot based on the index values instead of a column.

## Notes

For finer-tuned control, see hierarchical indexing documentation along with the related `stack/unstack` methods.

## Examples

```
>>> df = pd.DataFrame({'foo': ['one', 'one', 'one', 'two', 'two',
...                             'two'],
...                    'bar': ['A', 'B', 'C', 'A', 'B', 'C'],
...                    'baz': [1, 2, 3, 4, 5, 6],
...                    'zoo': ['x', 'y', 'z', 'q', 'w', 't']})
>>> df
   foo bar baz zoo
0  one  A   1   x
1  one  B   2   y
2  one  C   3   z
3  two  A   4   q
4  two  B   5   w
5  two  C   6   t
```

```
>>> df.pivot(index='foo', columns='bar', values='baz')
bar A  B  C
foo
one 1  2  3
two 4  5  6
```

```
>>> df.pivot(index='foo', columns='bar')['baz']
bar A  B  C
foo
one 1  2  3
two 4  5  6
```

```
>>> df.pivot(index='foo', columns='bar', values=['baz', 'zoo'])
      baz      zoo
bar  A B C  A B C
foo
one  1 2 3  x y z
two  4 5 6  q w t
```

A `ValueError` is raised if there are any duplicates.

```
>>> df = pd.DataFrame({"foo": ['one', 'one', 'two', 'two'],
...                    "bar": ['A', 'A', 'B', 'C'],
...                    "baz": [1, 2, 3, 4]})
>>> df
   foo bar baz
0  one  A   1
1  one  A   2
2  two  B   3
3  two  C   4
```

Notice that the first two rows are the same for our *index* and *columns* arguments.

```
>>> df.pivot(index='foo', columns='bar', values='baz')
Traceback (most recent call last):
...
ValueError: Index contains duplicate entries, cannot reshape
```

## pandas.DataFrame.pivot\_table

`DataFrame.pivot_table` (*values=None, index=None, columns=None, aggfunc='mean', fill\_value=None, margins=False, dropna=True, margins\_name='All'*)  
 Create a spreadsheet-style pivot table as a DataFrame. The levels in the pivot table will be stored in MultiIndex objects (hierarchical indexes) on the index and columns of the result DataFrame.

### Parameters

- values** [column to aggregate, optional]
- index** [column, Grouper, array, or list of the previous] If an array is passed, it must be the same length as the data. The list can contain any of the other types (except list). Keys to group by on the pivot table index. If an array is passed, it is being used as the same manner as column values.
- columns** [column, Grouper, array, or list of the previous] If an array is passed, it must be the same length as the data. The list can contain any of the other types (except list). Keys to group by on the pivot table column. If an array is passed, it is being used as the same manner as column values.
- aggfunc** [function, list of functions, dict, default `numpy.mean`] If list of functions passed, the resulting pivot table will have hierarchical columns whose top level are the function names (inferred from the function objects themselves) If dict is passed, the key is column to aggregate and value is function or list of functions
- fill\_value** [scalar, default `None`] Value to replace missing values with
- margins** [boolean, default `False`] Add all row / columns (e.g. for subtotal / grand totals)
- dropna** [boolean, default `True`] Do not include columns whose entries are all `NaN`
- margins\_name** [string, default `'All'`] Name of the row / column that will contain the totals when margins is `True`.

### Returns

**table** [DataFrame]

See also:

**DataFrame.pivot** Pivot without aggregation that can handle non-numeric data.

## Examples

```
>>> df = pd.DataFrame({"A": ["foo", "foo", "foo", "foo", "foo",
...                           "bar", "bar", "bar", "bar"],
...                    "B": ["one", "one", "one", "two", "two",
...                           "one", "one", "two", "two"],
...                    "C": ["small", "large", "large", "small",
...                           "small", "large", "small", "small",
...                           "large"]})
```

(continues on next page)

(continued from previous page)

```

...         "D": [1, 2, 2, 3, 3, 4, 5, 6, 7],
...         "E": [2, 4, 5, 5, 6, 6, 8, 9, 9]})
>>> df
   A    B    C  D  E
0  foo one  small  1  2
1  foo one  large  2  4
2  foo one  large  2  5
3  foo two  small  3  5
4  foo two  small  3  6
5  bar one  large  4  6
6  bar one  small  5  8
7  bar two  small  6  9
8  bar two  large  7  9

```

This first example aggregates values by taking the sum.

```

>>> table = pivot_table(df, values='D', index=['A', 'B'],
...                      columns=['C'], aggfunc=np.sum)
>>> table
C      large  small
A  B
bar one      4      5
   two      7      6
foo one      4      1
   two    NaN      6

```

We can also fill missing values using the *fill\_value* parameter.

```

>>> table = pivot_table(df, values='D', index=['A', 'B'],
...                      columns=['C'], aggfunc=np.sum, fill_value=0)
>>> table
C      large  small
A  B
bar one      4      5
   two      7      6
foo one      4      1
   two      0      6

```

The next example aggregates by taking the mean across multiple columns.

```

>>> table = pivot_table(df, values=['D', 'E'], index=['A', 'C'],
...                      aggfunc={'D': np.mean,
...                               'E': np.mean})
>>> table
      D      E
      mean  mean
A  C
bar large  5.500000  7.500000
   small  5.500000  8.500000
foo large  2.000000  4.500000
   small  2.333333  4.333333

```

We can also calculate multiple types of aggregations for any given value column.

```

>>> table = pivot_table(df, values=['D', 'E'], index=['A', 'C'],
...                      aggfunc={'D': np.mean,

```

(continues on next page)

(continued from previous page)

```

...                                     'E': [min, max, np.mean]})
>>> table
      D  E
      mean max  mean min
A  C
bar large 5.500000 9  7.500000 6
    small 5.500000 9  8.500000 8
foo large 2.000000 5  4.500000 4
    small 2.333333 6  4.333333 2

```

**pandas.DataFrame.plot**

`DataFrame.plot` (*x=None, y=None, kind='line', ax=None, subplots=False, sharex=None, sharey=False, layout=None, figsize=None, use\_index=True, title=None, grid=None, legend=True, style=None, logx=False, logy=False, loglog=False, xticks=None, yticks=None, xlim=None, ylim=None, rot=None, fontsize=None, colormap=None, table=False, yerr=None, xerr=None, secondary\_y=False, sort\_columns=False, \*\*kwds*)

Make plots of DataFrame using matplotlib / pylab.

*New in version 0.17.0:* Each plot kind has a corresponding method on the `DataFrame.plot` accessor: `df.plot(kind='line')` is equivalent to `df.plot.line()`.

**Parameters**

**data** [DataFrame]

**x** [label or position, default None]

**y** [label, position or list of label, positions, default None] Allows plotting of one column versus another

**kind** [str]

- 'line' : line plot (default)
- 'bar' : vertical bar plot
- 'barh' : horizontal bar plot
- 'hist' : histogram
- 'box' : boxplot
- 'kde' : Kernel Density Estimation plot
- 'density' : same as 'kde'
- 'area' : area plot
- 'pie' : pie plot
- 'scatter' : scatter plot
- 'hexbin' : hexbin plot

**ax** [matplotlib axes object, default None]

**subplots** [boolean, default False] Make separate subplots for each column

**sharex** [boolean, default True if ax is None else False] In case subplots=True, share x axis and set some x axis labels to invisible; defaults to True if ax is None otherwise

False if an ax is passed in; Be aware, that passing in both an ax and sharex=True will alter all x axis labels for all axis in a figure!

**sharey** [boolean, default False] In case subplots=True, share y axis and set some y axis labels to invisible

**layout** [tuple (optional)] (rows, columns) for the layout of subplots

**figsize** [a tuple (width, height) in inches]

**use\_index** [boolean, default True] Use index as ticks for x axis

**title** [string or list] Title to use for the plot. If a string is passed, print the string at the top of the figure. If a list is passed and *subplots* is True, print each item in the list above the corresponding subplot.

**grid** [boolean, default None (matlab style default)] Axis grid lines

**legend** [False/True/'reverse'] Place legend on axis subplots

**style** [list or dict] matplotlib line style per column

**logx** [boolean, default False] Use log scaling on x axis

**logy** [boolean, default False] Use log scaling on y axis

**loglog** [boolean, default False] Use log scaling on both x and y axes

**xticks** [sequence] Values to use for the xticks

**yticks** [sequence] Values to use for the yticks

**xlim** [2-tuple/list]

**ylim** [2-tuple/list]

**rot** [int, default None] Rotation for ticks (xticks for vertical, yticks for horizontal plots)

**fontsize** [int, default None] Font size for xticks and yticks

**colormap** [str or matplotlib colormap object, default None] Colormap to select colors from. If string, load colormap with that name from matplotlib.

**colorbar** [boolean, optional] If True, plot colorbar (only relevant for 'scatter' and 'hexbin' plots)

**position** [float] Specify relative alignments for bar plot layout. From 0 (left/bottom-end) to 1 (right/top-end). Default is 0.5 (center)

**table** [boolean, Series or DataFrame, default False] If True, draw a table using the data in the DataFrame and the data will be transposed to meet matplotlib's default layout. If a Series or DataFrame is passed, use passed data to draw a table.

**yerr** [DataFrame, Series, array-like, dict and str] See *Plotting with Error Bars* for detail.

**xerr** [same types as yerr.]

**stacked** [boolean, default False in line and] bar plots, and True in area plot. If True, create stacked plot.

**sort\_columns** [boolean, default False] Sort column names to determine plot ordering

**secondary\_y** [boolean or sequence, default False] Whether to plot on the secondary y-axis If a list/tuple, which columns to plot on secondary y-axis

**mark\_right** [boolean, default True] When using a secondary\_y axis, automatically mark the column labels with "(right)" in the legend

**\*\*kwargs** [keywords] Options to pass to matplotlib plotting method

### Returns

**axes** [matplotlib.axes.Axes or numpy.ndarray of them]

### Notes

- See matplotlib documentation online for more on this subject
- If *kind* = 'bar' or 'barh', you can specify relative alignments for bar plot layout by *position* keyword. From 0 (left/bottom-end) to 1 (right/top-end). Default is 0.5 (center)
- If *kind* = 'scatter' and the argument *c* is the name of a dataframe column, the values of that column are used to color each point.
- If *kind* = 'hexbin', you can control the size of the bins with the *gridsize* argument. By default, a histogram of the counts around each (*x*, *y*) point is computed. You can specify alternative aggregations by passing values to the *C* and *reduce\_C\_function* arguments. *C* specifies the value at each (*x*, *y*) point and *reduce\_C\_function* is a function of one argument that reduces all the values in a bin to a single number (e.g. *mean*, *max*, *sum*, *std*).

## pandas.DataFrame.pop

DataFrame.**pop** (*item*)

Return item and drop from frame. Raise KeyError if not found.

### Parameters

**item** [str] Column label to be popped

### Returns

**popped** [Series]

### Examples

```
>>> df = pd.DataFrame([('falcon', 'bird', 389.0),
...                    ('parrot', 'bird', 24.0),
...                    ('lion', 'mammal', 80.5),
...                    ('monkey', 'mammal', np.nan)],
...                    columns=('name', 'class', 'max_speed'))
>>> df
   name  class  max_speed
0  falcon   bird    389.0
1  parrot   bird     24.0
2   lion  mammal     80.5
3  monkey  mammal      NaN
```

```
>>> df.pop('class')
0    bird
1    bird
2  mammal
3  mammal
Name: class, dtype: object
```

```
>>> df
   name  max_speed
0  falcon      389.0
1  parrot       24.0
2   lion       80.5
3  monkey        NaN
```

## pandas.DataFrame.pow

`DataFrame.pow(other, axis='columns', level=None, fill_value=None)`

Exponential power of dataframe and other, element-wise (binary operator *pow*).

Equivalent to `dataframe ** other`, but with support to substitute a `fill_value` for missing data in one of the inputs. With reverse version, *rpow*.

Among flexible wrappers (*add*, *sub*, *mul*, *div*, *mod*, *pow*) to arithmetic operators: `+`, `-`, `*`, `/`, `//`, `%`, `**`.

### Parameters

**other** [scalar, sequence, Series, or DataFrame] Any single or multiple element data structure, or list-like object.

**axis** [{0 or 'index', 1 or 'columns'}] Whether to compare by the index (0 or 'index') or columns (1 or 'columns'). For Series input, axis to match Series index on.

**level** [int or label] Broadcast across a level, matching Index values on the passed Multi-Index level.

**fill\_value** [float or None, default None] Fill existing missing (NaN) values, and any new element needed for successful DataFrame alignment, with this value before computation. If data in both corresponding DataFrame locations is missing the result will be missing.

### Returns

**DataFrame** Result of the arithmetic operation.

See also:

**DataFrame.add** Add DataFrames.

**DataFrame.sub** Subtract DataFrames.

**DataFrame.mul** Multiply DataFrames.

**DataFrame.div** Divide DataFrames (float division).

**DataFrame.truediv** Divide DataFrames (float division).

**DataFrame.floordiv** Divide DataFrames (integer division).

**DataFrame.mod** Calculate modulo (remainder after division).

**DataFrame.pow** Calculate exponential power.

### Notes

Mismatched indices will be unioned together.

## Examples

```
>>> df = pd.DataFrame({'angles': [0, 3, 4],
...                     'degrees': [360, 180, 360]},
...                     index=['circle', 'triangle', 'rectangle'])
>>> df
```

|           | angles | degrees |
|-----------|--------|---------|
| circle    | 0      | 360     |
| triangle  | 3      | 180     |
| rectangle | 4      | 360     |

Add a scalar with operator version which return the same results.

```
>>> df + 1
```

|           | angles | degrees |
|-----------|--------|---------|
| circle    | 1      | 361     |
| triangle  | 4      | 181     |
| rectangle | 5      | 361     |

```
>>> df.add(1)
```

|           | angles | degrees |
|-----------|--------|---------|
| circle    | 1      | 361     |
| triangle  | 4      | 181     |
| rectangle | 5      | 361     |

Divide by constant with reverse version.

```
>>> df.div(10)
```

|           | angles | degrees |
|-----------|--------|---------|
| circle    | 0.0    | 36.0    |
| triangle  | 0.3    | 18.0    |
| rectangle | 0.4    | 36.0    |

```
>>> df.rdiv(10)
```

|           | angles   | degrees  |
|-----------|----------|----------|
| circle    | inf      | 0.027778 |
| triangle  | 3.333333 | 0.055556 |
| rectangle | 2.500000 | 0.027778 |

Subtract a list and Series by axis with operator version.

```
>>> df - [1, 2]
```

|           | angles | degrees |
|-----------|--------|---------|
| circle    | -1     | 358     |
| triangle  | 2      | 178     |
| rectangle | 3      | 358     |

```
>>> df.sub([1, 2], axis='columns')
```

|           | angles | degrees |
|-----------|--------|---------|
| circle    | -1     | 358     |
| triangle  | 2      | 178     |
| rectangle | 3      | 358     |

```
>>> df.sub(pd.Series([1, 1, 1], index=['circle', 'triangle', 'rectangle']),
...        axis='index')
```

|           | angles | degrees |
|-----------|--------|---------|
| circle    | -1     | 359     |
| triangle  | 2      | 179     |
| rectangle | 3      | 359     |

(continues on next page)

(continued from previous page)

|           |    |     |
|-----------|----|-----|
| circle    | -1 | 359 |
| triangle  | 2  | 179 |
| rectangle | 3  | 359 |

Multiply a DataFrame of different shape with operator version.

```
>>> other = pd.DataFrame({'angles': [0, 3, 4]},
...                        index=['circle', 'triangle', 'rectangle'])
>>> other
```

|           | angles |
|-----------|--------|
| circle    | 0      |
| triangle  | 3      |
| rectangle | 4      |

```
>>> df * other
```

|           | angles | degrees |
|-----------|--------|---------|
| circle    | 0      | NaN     |
| triangle  | 9      | NaN     |
| rectangle | 16     | NaN     |

```
>>> df.mul(other, fill_value=0)
```

|           | angles | degrees |
|-----------|--------|---------|
| circle    | 0      | 0.0     |
| triangle  | 9      | 0.0     |
| rectangle | 16     | 0.0     |

Divide by a MultiIndex by level.

```
>>> df_multindex = pd.DataFrame({'angles': [0, 3, 4, 4, 5, 6],
...                               'degrees': [360, 180, 360, 360, 540, 720]},
...                               index=[['A', 'A', 'A', 'B', 'B', 'B'],
...                                       ['circle', 'triangle', 'rectangle',
...                                        'square', 'pentagon', 'hexagon']])
>>> df_multindex
```

|   |           | angles | degrees |
|---|-----------|--------|---------|
| A | circle    | 0      | 360     |
|   | triangle  | 3      | 180     |
|   | rectangle | 4      | 360     |
| B | square    | 4      | 360     |
|   | pentagon  | 5      | 540     |
|   | hexagon   | 6      | 720     |

```
>>> df.div(df_multindex, level=1, fill_value=0)
```

|   |           | angles | degrees |
|---|-----------|--------|---------|
| A | circle    | NaN    | 1.0     |
|   | triangle  | 1.0    | 1.0     |
|   | rectangle | 1.0    | 1.0     |

## pandas.DataFrame.prod

`DataFrame.prod` (*axis=None*, *skipna=None*, *level=None*, *numeric\_only=None*, *min\_count=0*, *\*\*kwargs*)

Return the product of the values for the requested axis.

### Parameters

**axis** [{index (0), columns (1)}] Axis for the function to be applied on.

**skipna** [bool, default True] Exclude NA/null values when computing the result.

**level** [int or level name, default None] If the axis is a MultiIndex (hierarchical), count along a particular level, collapsing into a Series.

**numeric\_only** [bool, default None] Include only float, int, boolean columns. If None, will attempt to use everything, then use only numeric data. Not implemented for Series.

**min\_count** [int, default 0] The required number of valid values to perform the operation. If fewer than `min_count` non-NA values are present the result will be NA.

New in version 0.22.0: Added with the default being 0. This means the sum of an all-NA or empty Series is 0, and the product of an all-NA or empty Series is 1.

**\*\*kwargs** Additional keyword arguments to be passed to the function.

### Returns

**prod** [Series or DataFrame (if level specified)]

## Examples

By default, the product of an empty or all-NA Series is 1

```
>>> pd.Series([]).prod()
1.0
```

This can be controlled with the `min_count` parameter

```
>>> pd.Series([]).prod(min_count=1)
nan
```

Thanks to the `skipna` parameter, `min_count` handles all-NA and empty series identically.

```
>>> pd.Series([np.nan]).prod()
1.0
```

```
>>> pd.Series([np.nan]).prod(min_count=1)
nan
```

## pandas.DataFrame.product

`DataFrame.product` (*axis=None*, *skipna=None*, *level=None*, *numeric\_only=None*, *min\_count=0*, *\*\*kwargs*)

Return the product of the values for the requested axis.

### Parameters

**axis** [{index (0), columns (1)}] Axis for the function to be applied on.

**skipna** [bool, default True] Exclude NA/null values when computing the result.

**level** [int or level name, default None] If the axis is a MultiIndex (hierarchical), count along a particular level, collapsing into a Series.

**numeric\_only** [bool, default None] Include only float, int, boolean columns. If None, will attempt to use everything, then use only numeric data. Not implemented for Series.

**min\_count** [int, default 0] The required number of valid values to perform the operation. If fewer than `min_count` non-NA values are present the result will be NA.

New in version 0.22.0: Added with the default being 0. This means the sum of an all-NA or empty Series is 0, and the product of an all-NA or empty Series is 1.

**\*\*kwargs** Additional keyword arguments to be passed to the function.

### Returns

**prod** [Series or DataFrame (if level specified)]

### Examples

By default, the product of an empty or all-NA Series is 1

```
>>> pd.Series([]).prod()
1.0
```

This can be controlled with the `min_count` parameter

```
>>> pd.Series([]).prod(min_count=1)
nan
```

Thanks to the `skipna` parameter, `min_count` handles all-NA and empty series identically.

```
>>> pd.Series([np.nan]).prod()
1.0
```

```
>>> pd.Series([np.nan]).prod(min_count=1)
nan
```

## pandas.DataFrame.quantile

`DataFrame.quantile` (*q=0.5, axis=0, numeric\_only=True, interpolation='linear'*)

Return values at the given quantile over requested axis.

### Parameters

**q** [float or array-like, default 0.5 (50% quantile)] Value between  $0 \leq q \leq 1$ , the quantile(s) to compute.

**axis** [{0, 1, 'index', 'columns'} (default 0)] Equals 0 or 'index' for row-wise, 1 or 'columns' for column-wise.

**numeric\_only** [bool, default True] If False, the quantile of datetime and timedelta data will be computed as well.

**interpolation** [{ 'linear', 'lower', 'higher', 'midpoint', 'nearest' }] This optional parameter specifies the interpolation method to use, when the desired quantile lies between two data points  $i$  and  $j$ :

- linear:  $i + (j - i) * \text{fraction}$ , where *fraction* is the fractional part of the index surrounded by  $i$  and  $j$ .
- lower:  $i$ .
- higher:  $j$ .
- nearest:  $i$  or  $j$  whichever is nearest.
- midpoint:  $(i + j) / 2$ .

New in version 0.18.0.

### Returns

**quantiles** [Series or DataFrame]

- If  $q$  is an array, a DataFrame will be returned where the index is  $q$ , the columns are the columns of self, and the values are the quantiles.
- If  $q$  is a float, a Series will be returned where the index is the columns of self and the values are the quantiles.

See also:

**core.window.Rolling.quantile** Rolling quantile.

**numpy.percentile** Numpy function to compute the percentile.

### Examples

```
>>> df = pd.DataFrame(np.array([[1, 1], [2, 10], [3, 100], [4, 100]]),
...                    columns=['a', 'b'])
>>> df.quantile(.1)
a    1.3
b    3.7
Name: 0.1, dtype: float64
>>> df.quantile([.1, .5])
      a    b
0.1  1.3  3.7
0.5  2.5 55.0
```

Specifying *numeric\_only=False* will also compute the quantile of datetime and timedelta data.

```
>>> df = pd.DataFrame({'A': [1, 2],
...                    'B': [pd.Timestamp('2010'),
...                          pd.Timestamp('2011')],
...                    'C': [pd.Timedelta('1 days'),
...                          pd.Timedelta('2 days')]}))
>>> df.quantile(0.5, numeric_only=False)
A          1.5
B    2010-07-02 12:00:00
C          1 days 12:00:00
Name: 0.5, dtype: object
```

**pandas.DataFrame.query**`DataFrame.query` (*expr*, *inplace=False*, *\*\*kwargs*)

Query the columns of a DataFrame with a boolean expression.

**Parameters****expr** [string] The query string to evaluate. You can refer to variables in the environment by prefixing them with an '@' character like @a + b.**inplace** [bool] Whether the query should modify the data in place or return a modified copy

New in version 0.18.0.

**kwargs** [dict] See the documentation for `pandas.eval()` for complete details on the keyword arguments accepted by `DataFrame.query()`.**Returns****q** [DataFrame]**See also:**`pandas.eval`, `DataFrame.eval`**Notes**

The result of the evaluation of this expression is first passed to `DataFrame.loc` and if that fails because of a multidimensional key (e.g., a DataFrame) then the result will be passed to `DataFrame.__getitem__()`.

This method uses the top-level `pandas.eval()` function to evaluate the passed query.

The `query()` method uses a slightly modified Python syntax by default. For example, the `&` and `|` (bitwise) operators have the precedence of their boolean cousins, `and` and `or`. This *is* syntactically valid Python, however the semantics are different.

You can change the semantics of the expression by passing the keyword argument `parser='python'`. This enforces the same semantics as evaluation in Python space. Likewise, you can pass `engine='python'` to evaluate an expression using Python itself as a backend. This is not recommended as it is inefficient compared to using `numexpr` as the engine.

The `DataFrame.index` and `DataFrame.columns` attributes of the `DataFrame` instance are placed in the query namespace by default, which allows you to treat both the index and columns of the frame as a column in the frame. The identifier `index` is used for the frame index; you can also use the name of the index to identify it in a query. Please note that Python keywords may not be used as identifiers.

For further details and examples see the `query` documentation in *indexing*.

**Examples**

```
>>> df = pd.DataFrame(np.random.randn(10, 2), columns=list('ab'))
>>> df.query('a > b')
>>> df[df.a > df.b] # same result as the previous expression
```

## pandas.DataFrame.radd

`DataFrame.radd(other, axis='columns', level=None, fill_value=None)`

Addition of dataframe and other, element-wise (binary operator *radd*).

Equivalent to `other + dataframe`, but with support to substitute a `fill_value` for missing data in one of the inputs. With reverse version, *add*.

Among flexible wrappers (*add*, *sub*, *mul*, *div*, *mod*, *pow*) to arithmetic operators: `+`, `-`, `*`, `/`, `//`, `%`, `**`.

### Parameters

**other** [scalar, sequence, Series, or DataFrame] Any single or multiple element data structure, or list-like object.

**axis** [{0 or 'index', 1 or 'columns'}] Whether to compare by the index (0 or 'index') or columns (1 or 'columns'). For Series input, axis to match Series index on.

**level** [int or label] Broadcast across a level, matching Index values on the passed Multi-Index level.

**fill\_value** [float or None, default None] Fill existing missing (NaN) values, and any new element needed for successful DataFrame alignment, with this value before computation. If data in both corresponding DataFrame locations is missing the result will be missing.

### Returns

**DataFrame** Result of the arithmetic operation.

See also:

**DataFrame.add** Add DataFrames.

**DataFrame.sub** Subtract DataFrames.

**DataFrame.mul** Multiply DataFrames.

**DataFrame.div** Divide DataFrames (float division).

**DataFrame.truediv** Divide DataFrames (float division).

**DataFrame.floordiv** Divide DataFrames (integer division).

**DataFrame.mod** Calculate modulo (remainder after division).

**DataFrame.pow** Calculate exponential power.

### Notes

Mismatched indices will be unioned together.

### Examples

```
>>> df = pd.DataFrame({'angles': [0, 3, 4],
...                    'degrees': [360, 180, 360]},
...                    index=['circle', 'triangle', 'rectangle'])
>>> df
      angles  degrees
circle      0     360
```

(continues on next page)

(continued from previous page)

|           |   |     |
|-----------|---|-----|
| triangle  | 3 | 180 |
| rectangle | 4 | 360 |

Add a scalar with operator version which return the same results.

```
>>> df + 1
```

|           | angles | degrees |
|-----------|--------|---------|
| circle    | 1      | 361     |

```

|   |           | angles | degrees |
|---|-----------|--------|---------|
| A | circle    | NaN    | 1.0     |
|   | triangle  | 1.0    | 1.0     |
|   | rectangle | 1.0    | 1.0     |
| B | square    | 0.0    | 0.0     |
|   | pentagon  | 0.0    | 0.0     |
|   | hexagon   | 0.0    | 0.0     |

## pandas.DataFrame.rank

`DataFrame.rank` (*axis=0*, *method='average'*, *numeric\_only=None*, *na\_option='keep'*, *ascending=True*, *pct=False*)

Compute numerical data ranks (1 through n) along axis. Equal values are assigned a rank that is the average of the ranks of those values.

### Parameters

**axis** [{0 or 'index', 1 or 'columns'}], default 0] index to direct ranking

**method** [{‘average’, ‘min’, ‘max’, ‘first’, ‘dense’}]

- average: average rank of group
- min: lowest rank in group
- max: highest rank in group
- first: ranks assigned in order they appear in the array
- dense: like ‘min’, but rank always increases by 1 between groups

**numeric\_only** [boolean, default None] Include only float, int, boolean data. Valid only for DataFrame or Panel objects

**na\_option** [{‘keep’, ‘top’, ‘bottom’}]

- keep: leave NA values where they are
- top: smallest rank if ascending
- bottom: smallest rank if descending

**ascending** [boolean, default True] False for ranks by high (1) to low (N)

**pct** [boolean, default False] Computes percentage rank of data

#### Returns

**ranks** [same type as caller]

### pandas.DataFrame.rdiv

`DataFrame.rdiv(other, axis='columns', level=None, fill_value=None)`

Floating division of dataframe and other, element-wise (binary operator *rtruediv*).

Equivalent to `other / dataframe`, but with support to substitute a `fill_value` for missing data in one of the inputs. With reverse version, *truediv*.

Among flexible wrappers (*add*, *sub*, *mul*, *div*, *mod*, *pow*) to arithmetic operators: `+`, `-`, `*`, `/`, `//`, `%`, `**`.

#### Parameters

**other** [scalar, sequence, Series, or DataFrame] Any single or multiple element data structure, or list-like object.

**axis** [{0 or ‘index’, 1 or ‘columns’}] Whether to compare by the index (0 or ‘index’) or columns (1 or ‘columns’). For Series input, axis to match Series index on.

**level** [int or label] Broadcast across a level, matching Index values on the passed Multi-Index level.

**fill\_value** [float or None, default None] Fill existing missing (NaN) values, and any new element needed for successful DataFrame alignment, with this value before computation. If data in both corresponding DataFrame locations is missing the result will be missing.

#### Returns

**DataFrame** Result of the arithmetic operation.

See also:

**DataFrame.add** Add DataFrames.

**DataFrame.sub** Subtract DataFrames.

**DataFrame.mul** Multiply DataFrames.

**DataFrame.div** Divide DataFrames (float division).

**DataFrame.truediv** Divide DataFrames (float division).

**DataFrame.floordiv** Divide DataFrames (integer division).

**DataFrame.mod** Calculate modulo (remainder after division).

**DataFrame.pow** Calculate exponential power.

## Notes

Mismatched indices will be unioned together.

## Examples

```
>>> df = pd.DataFrame({'angles': [0, 3, 4],
...                     'degrees': [360, 180, 360]},
...                     index=['circle', 'triangle', 'rectangle'])
>>> df
```

|           | angles | degrees |
|-----------|--------|---------|
| circle    | 0      | 360     |
| triangle  | 3      | 180     |
| rectangle | 4      | 360     |

Add a scalar with operator version which return the same results.

```
>>> df + 1
```

|           | angles | degrees |
|-----------|--------|---------|
| circle    | 1      | 361     |
| triangle  | 4      | 181     |
| rectangle | 5      | 361     |

```
>>> df.add(1)
```

|           | angles | degrees |
|-----------|--------|---------|
| circle    | 1      | 361     |
| triangle  | 4      | 181     |
| rectangle | 5      | 361     |

Divide by constant with reverse version.

```
>>> df.div(10)
```

|           | angles | degrees |
|-----------|--------|---------|
| circle    | 0.0    | 36.0    |
| triangle  | 0.3    | 18.0    |
| rectangle | 0.4    | 36.0    |

```
>>> df.rdiv(10)
```

|           | angles   | degrees  |
|-----------|----------|----------|
| circle    | inf      | 0.027778 |
| triangle  | 3.333333 | 0.055556 |
| rectangle | 2.500000 | 0.027778 |

Subtract a list and Series by axis with operator version.

```
>>> df - [1, 2]
      angles  degrees
circle      -1     358
triangle     2     178
rectangle    3     358
```

```
>>> df.sub([1, 2], axis='columns')
      angles  degrees
circle      -1     358
triangle     2     178
rectangle    3     358
```

```
>>> df.sub(pd.Series([1, 1, 1], index=['circle', 'triangle', 'rectangle']),
...        axis='index')
      angles  degrees
circle      -1     359
triangle     2     179
rectangle    3     359
```

Multiply a DataFrame of different shape with operator version.

```
>>> other = pd.DataFrame({'angles': [0, 3, 4]},
...                       index=['circle', 'triangle', 'rectangle'])
>>> other
      angles
circle      0
triangle     3
rectangle    4
```

```
>>> df * other
      angles  degrees
circle      0      NaN
triangle     9      NaN
rectangle   16      NaN
```

```
>>> df.mul(other, fill_value=0)
      angles  degrees
circle      0      0.0
triangle     9      0.0
rectangle   16      0.0
```

Divide by a MultiIndex by level.

```
>>> df_multindex = pd.DataFrame({'angles': [0, 3, 4, 4, 5, 6],
...                              'degrees': [360, 180, 360, 360, 540, 720]},
...                              index=[['A', 'A', 'A', 'B', 'B', 'B'],
...                                      ['circle', 'triangle', 'rectangle',
...                                       'square', 'pentagon', 'hexagon']])
>>> df_multindex
      angles  degrees
A circle      0     360
  triangle     3     180
  rectangle     4     360
B square      4     360
```

(continues on next page)

(continued from previous page)

|          |   |     |
|----------|---|-----|
| pentagon | 5 | 540 |
| hexagon  | 6 | 720 |

```

>>> df.div(df_multindex, level=1, fill_value=0)
      angles  degrees
A circle    NaN    1.0
  triangle    1.0    1.0
 rectangle    1.0    1.0
B square     0.0    0.0
  pentagon    0.0    0.0
  hexagon     0.0    0.0

```

**pandas.DataFrame.reindex**

`DataFrame.reindex` (*labels=None, index=None, columns=None, axis=None, method=None, copy=True, level=None, fill\_value=nan, limit=None, tolerance=None*)

Conform `DataFrame` to new index with optional filling logic, placing NA/NaN in locations having no value in the previous index. A new object is produced unless the new index is equivalent to the current one and `copy=False`.

**Parameters**

**labels** [array-like, optional] New labels / index to conform the axis specified by ‘axis’ to.

**index, columns** [array-like, optional] New labels / index to conform to, should be specified using keywords. Preferably an Index object to avoid duplicating data

**axis** [int or str, optional] Axis to target. Can be either the axis name (‘index’, ‘columns’) or number (0, 1).

**method** [{None, ‘backfill’/‘bfill’, ‘pad’/‘ffill’, ‘nearest’}] Method to use for filling holes in reindexed `DataFrame`. Please note: this is only applicable to `DataFrames/Series` with a monotonically increasing/decreasing index.

- None (default): don’t fill gaps
- pad / ffill: propagate last valid observation forward to next valid
- backfill / bfill: use next valid observation to fill gap
- nearest: use nearest valid observations to fill gap

**copy** [bool, default True] Return a new object, even if the passed indexes are the same.

**level** [int or name] Broadcast across a level, matching Index values on the passed Multi-Index level.

**fill\_value** [scalar, default np.NaN] Value to use for missing values. Defaults to NaN, but can be any “compatible” value.

**limit** [int, default None] Maximum number of consecutive elements to forward or backward fill.

**tolerance** [optional] Maximum distance between original and new labels for inexact matches. The values of the index at the matching locations must satisfy the equation `abs(index[indexer] - target) <= tolerance`.

Tolerance may be a scalar value, which applies the same tolerance to all values, or list-like, which applies variable tolerance per element. List-like includes list, tuple,

array, Series, and must be the same size as the index and its dtype must exactly match the index's type.

New in version 0.21.0: (list-like tolerance)

### Returns

**DataFrame with changed index.**

See also:

**DataFrame.set\_index** Set row labels.

**DataFrame.reset\_index** Remove row labels or move them to new columns.

**DataFrame.reindex\_like** Change to same indices as other DataFrame.

### Examples

DataFrame.reindex supports two calling conventions

- (index=index\_labels, columns=column\_labels, ...)
- (labels, axis={'index', 'columns'}, ...)

We *highly* recommend using keyword arguments to clarify your intent.

Create a dataframe with some fictional data.

```
>>> index = ['Firefox', 'Chrome', 'Safari', 'IE10', 'Konqueror']
>>> df = pd.DataFrame({
...     'http_status': [200, 200, 404, 404, 301],
...     'response_time': [0.04, 0.02, 0.07, 0.08, 1.0]},
...     index=index)
>>> df
```

|           | http_status | response_time |
|-----------|-------------|---------------|
| Firefox   | 200         | 0.04          |
| Chrome    | 200         | 0.02          |
| Safari    | 404         | 0.07          |
| IE10      | 404         | 0.08          |
| Konqueror | 301         | 1.00          |

Create a new index and reindex the dataframe. By default values in the new index that do not have corresponding records in the dataframe are assigned NaN.

```
>>> new_index= ['Safari', 'Iceweasel', 'Comodo Dragon', 'IE10',
...             'Chrome']
>>> df.reindex(new_index)
```

|               | http_status | response_time |
|---------------|-------------|---------------|
| Safari        | 404.0       | 0.07          |
| Iceweasel     | NaN         | NaN           |
| Comodo Dragon | NaN         | NaN           |
| IE10          | 404.0       | 0.08          |
| Chrome        | 200.0       | 0.02          |

We can fill in the missing values by passing a value to the keyword `fill_value`. Because the index is not monotonically increasing or decreasing, we cannot use arguments to the keyword `method` to fill the NaN values.

```
>>> df.reindex(new_index, fill_value=0)
           http_status  response_time
Safari              404             0.07
Iceweasel            0             0.00
Comodo Dragon        0             0.00
IE10                 404             0.08
Chrome              200             0.02
```

```
>>> df.reindex(new_index, fill_value='missing')
           http_status  response_time
Safari              404             0.07
Iceweasel        missing          missing
Comodo Dragon    missing          missing
IE10              404             0.08
Chrome           200             0.02
```

We can also reindex the columns.

```
>>> df.reindex(columns=['http_status', 'user_agent'])
           http_status  user_agent
Firefox              200         NaN
Chrome               200         NaN
Safari               404         NaN
IE10                 404         NaN
Konqueror            301         NaN
```

Or we can use “axis-style” keyword arguments

```
>>> df.reindex(['http_status', 'user_agent'], axis="columns")
           http_status  user_agent
Firefox              200         NaN
Chrome               200         NaN
Safari               404         NaN
IE10                 404         NaN
Konqueror            301         NaN
```

To further illustrate the filling functionality in `reindex`, we will create a dataframe with a monotonically increasing index (for example, a sequence of dates).

```
>>> date_index = pd.date_range('1/1/2010', periods=6, freq='D')
>>> df2 = pd.DataFrame({"prices": [100, 101, np.nan, 100, 89, 88]},
...                     index=date_index)
>>> df2
           prices
2010-01-01  100.0
2010-01-02  101.0
2010-01-03    NaN
2010-01-04  100.0
2010-01-05   89.0
2010-01-06   88.0
```

Suppose we decide to expand the dataframe to cover a wider date range.

```
>>> date_index2 = pd.date_range('12/29/2009', periods=10, freq='D')
>>> df2.reindex(date_index2)
           prices
2009-12-29    NaN
```

(continues on next page)

(continued from previous page)

|            |       |
|------------|-------|
| 2009-12-30 | NaN   |
| 2009-12-31 | NaN   |
| 2010-01-01 | 100.0 |
| 2010-01-02 | 101.0 |
| 2010-01-03 | NaN   |
| 2010-01-04 | 100.0 |
| 2010-01-05 | 89.0  |
| 2010-01-06 | 88.0  |
| 2010-01-07 | NaN   |

The index entries that did not have a value in the original data frame (for example, '2009-12-29') are by default filled with NaN. If desired, we can fill in the missing values using one of several options.

For example, to back-propagate the last valid value to fill the NaN values, pass `bfill` as an argument to the `method` keyword.

```
>>> df2.reindex(date_index2, method='bfill')
           prices
2009-12-29  100.0
2009-12-30  100.0
2009-12-31  100.0
2010-01-01  100.0
2010-01-02  101.0
2010-01-03   NaN
2010-01-04  100.0
2010-01-05   89.0
2010-01-06   88.0
2010-01-07   NaN
```

Please note that the NaN value present in the original dataframe (at index value 2010-01-03) will not be filled by any of the value propagation schemes. This is because filling while reindexing does not look at dataframe values, but only compares the original and desired indexes. If you do want to fill in the NaN values present in the original dataframe, use the `fillna()` method.

See the *user guide* for more.

## pandas.DataFrame.reindex\_axis

`DataFrame.reindex_axis(labels, axis=0, method=None, level=None, copy=True, limit=None, fill_value=nan)`

Conform input object to new index.

Deprecated since version 0.21.0: Use `reindex` instead.

By default, places NaN in locations having no value in the previous index. A new object is produced unless the new index is equivalent to the current one and `copy=False`.

### Parameters

**labels** [array-like] New labels / index to conform to. Preferably an Index object to avoid duplicating data.

**axis** [{0 or 'index', 1 or 'columns'}] Indicate whether to use rows or columns.

**method** [{None, 'backfill'/'bfill', 'pad'/'ffill', 'nearest'}, optional] Method to use for filling holes in reindexed DataFrame:

- default: don't fill gaps.

- `pad / ffill`: propagate last valid observation forward to next valid.
- `backfill / bfill`: use next valid observation to fill gap.
- `nearest`: use nearest valid observations to fill gap.

**level** [int or str] Broadcast across a level, matching Index values on the passed MultiIndex level.

**copy** [bool, default True] Return a new object, even if the passed indexes are the same.

**limit** [int, optional] Maximum number of consecutive elements to forward or backward fill.

**fill\_value** [float, default NaN] Value used to fill in locations having no value in the previous index.

New in version 0.21.0: (list-like tolerance)

### Returns

**DataFrame** Returns a new DataFrame object with new indices, unless the new index is equivalent to the current one and `copy=False`.

### See also:

**DataFrame.set\_index** Set row labels.

**DataFrame.reset\_index** Remove row labels or move them to new columns.

**DataFrame.reindex** Change to new indices or expand indices.

**DataFrame.reindex\_like** Change to same indices as other DataFrame.

### Examples

```
>>> df = pd.DataFrame({'num_legs': [4, 2], 'num_wings': [0, 2]},
...                    index=['dog', 'hawk'])
>>> df
   num_legs  num_wings
dog         4         0
hawk        2         2
>>> df.reindex(['num_wings', 'num_legs', 'num_heads'],
...            axis='columns')
   num_wings  num_legs  num_heads
dog         0         4        NaN
hawk        2         2        NaN
```

### pandas.DataFrame.reindex\_like

**DataFrame.reindex\_like** (*other, method=None, copy=True, limit=None, tolerance=None*)

Return an object with matching indices as other object.

Conform the object to the same index on all axes. Optional filling logic, placing NaN in locations having no value in the previous index. A new object is produced unless the new index is equivalent to the current one and `copy=False`.

### Parameters

**other** [Object of the same data type] Its row and column indices are used to define the new indices of this object.

**method** [{None, 'backfill'/'bfill', 'pad'/'ffill', 'nearest'}] Method to use for filling holes in reindexed DataFrame. Please note: this is only applicable to DataFrames/Series with a monotonically increasing/decreasing index.

- None (default): don't fill gaps
- pad / ffill: propagate last valid observation forward to next valid
- backfill / bfill: use next valid observation to fill gap
- nearest: use nearest valid observations to fill gap

**copy** [bool, default True] Return a new object, even if the passed indexes are the same.

**limit** [int, default None] Maximum number of consecutive labels to fill for inexact matches.

**tolerance** [optional] Maximum distance between original and new labels for inexact matches. The values of the index at the matching locations must satisfy the equation  $\text{abs}(\text{index}[\text{indexer}] - \text{target}) \leq \text{tolerance}$ .

Tolerance may be a scalar value, which applies the same tolerance to all values, or list-like, which applies variable tolerance per element. List-like includes list, tuple, array, Series, and must be the same size as the index and its dtype must exactly match the index's type.

New in version 0.21.0: (list-like tolerance)

### Returns

**Series or DataFrame** Same type as caller, but with changed indices on each axis.

See also:

**DataFrame.set\_index** Set row labels.

**DataFrame.reset\_index** Remove row labels or move them to new columns.

**DataFrame.reindex** Change to new indices or expand indices.

### Notes

Same as calling `.reindex(index=other.index, columns=other.columns, ...)`.

### Examples

```
>>> df1 = pd.DataFrame([[24.3, 75.7, 'high'],
...                     [31, 87.8, 'high'],
...                     [22, 71.6, 'medium'],
...                     [35, 95, 'medium']],
...                     columns=['temp_celsius', 'temp_fahrenheit', 'windspeed'],
...                     index=pd.date_range(start='2014-02-12',
...                                         end='2014-02-15', freq='D'))
```

```
>>> df1
      temp_celsius  temp_fahrenheit  windspeed
2014-02-12      24.3             75.7        high
2014-02-13      31.0             87.8        high
2014-02-14      22.0             71.6    medium
2014-02-15      35.0             95.0    medium
```

```
>>> df2 = pd.DataFrame([[28, 'low'],
...                      [30, 'low'],
...                      [35.1, 'medium']],
...                     columns=['temp_celsius', 'windspeed'],
...                     index=pd.DatetimeIndex(['2014-02-12', '2014-02-13',
...                                             '2014-02-15']))
```

```
>>> df2
      temp_celsius  windspeed
2014-02-12      28.0        low
2014-02-13      30.0        low
2014-02-15      35.1    medium
```

```
>>> df2.reindex_like(df1)
      temp_celsius  temp_fahrenheit  windspeed
2014-02-12      28.0             NaN        low
2014-02-13      30.0             NaN        low
2014-02-14      NaN             NaN        NaN
2014-02-15      35.1             NaN    medium
```

## pandas.DataFrame.rename

`DataFrame.rename` (*mapper=None, index=None, columns=None, axis=None, copy=True, inplace=False, level=None*)

Alter axes labels.

Function / dict values must be unique (1-to-1). Labels not contained in a dict / Series will be left as-is. Extra labels listed don't throw an error.

See the *user guide* for more.

### Parameters

**mapper, index, columns** [dict-like or function, optional] dict-like or functions transformations to apply to that axis' values. Use either `mapper` and `axis` to specify the axis to target with `mapper`, or `index` and `columns`.

**axis** [int or str, optional] Axis to target with `mapper`. Can be either the axis name ('index', 'columns') or number (0, 1). The default is 'index'.

**copy** [boolean, default True] Also copy underlying data

**inplace** [boolean, default False] Whether to return a new DataFrame. If True then value of `copy` is ignored.

**level** [int or level name, default None] In case of a MultiIndex, only rename labels in the specified level.

### Returns

**renamed** [DataFrame]

**See also:**`pandas.DataFrame.rename_axis`**Examples**`DataFrame.rename` supports two calling conventions

- `(index=index_mapper, columns=columns_mapper, ...)`
- `(mapper, axis={'index', 'columns'}, ...)`

We *highly* recommend using keyword arguments to clarify your intent.

```
>>> df = pd.DataFrame({"A": [1, 2, 3], "B": [4, 5, 6]})
>>> df.rename(index=str, columns={"A": "a", "B": "c"})
```

|   | a | c |
|---|---|---|
| 0 | 1 | 4 |
| 1 | 2 | 5 |
| 2 | 3 | 6 |

```
>>> df.rename(index=str, columns={"A": "a", "C": "c"})
```

|   | a | B |
|---|---|---|
| 0 | 1 | 4 |
| 1 | 2 | 5 |
| 2 | 3 | 6 |

**Using axis-style parameters**

```
>>> df.rename(str.lower, axis='columns')
```

|   | a | b |
|---|---|---|
| 0 | 1 | 4 |
| 1 | 2 | 5 |
| 2 | 3 | 6 |

```
>>> df.rename({1: 2, 2: 4}, axis='index')
```

|   | A | B |
|---|---|---|
| 0 | 1 | 4 |
| 2 | 2 | 5 |
| 4 | 3 | 6 |

**pandas.DataFrame.rename\_axis**

`DataFrame.rename_axis` (*mapper=None, index=None, columns=None, axis=None, copy=True, inplace=False*)

Set the name of the axis for the index or columns.

**Parameters****mapper** [scalar, list-like, optional] Value to set the axis name attribute.**index, columns** [scalar, list-like, dict-like or function, optional] A scalar, list-like, dict-like or functions transformations to apply to that axis' values.Use either `mapper` and `axis` to specify the axis to target with `mapper`, or `index` and/or `columns`.

Changed in version 0.24.0.

**axis** [{0 or 'index', 1 or 'columns'}, default 0] The axis to rename.

**copy** [bool, default True] Also copy underlying data.

**inplace** [bool, default False] Modifies the object directly, instead of creating a new Series or DataFrame.

### Returns

**Series, DataFrame, or None** The same type as the caller or None if *inplace* is True.

See also:

**Series.rename** Alter Series index labels or name.

**DataFrame.rename** Alter DataFrame index labels or name.

**Index.rename** Set new names on index.

### Notes

Prior to version 0.21.0, `rename_axis` could also be used to change the axis *labels* by passing a mapping or scalar. This behavior is deprecated and will be removed in a future version. Use `rename` instead.

`DataFrame.rename_axis` supports two calling conventions

- `(index=index_mapper, columns=columns_mapper, ...)`
- `(mapper, axis={'index', 'columns'}, ...)`

The first calling convention will only modify the names of the index and/or the names of the Index object that is the columns. In this case, the parameter `copy` is ignored.

The second calling convention will modify the names of the the corresponding index if `mapper` is a list or a scalar. However, if `mapper` is dict-like or a function, it will use the deprecated behavior of modifying the axis *labels*.

We *highly* recommend using keyword arguments to clarify your intent.

### Examples

#### Series

```
>>> s = pd.Series(["dog", "cat", "monkey"])
>>> s
0      dog
1      cat
2  monkey
dtype: object
>>> s.rename_axis("animal")
animal
0      dog
1      cat
2  monkey
dtype: object
```

#### DataFrame

```

>>> df = pd.DataFrame({"num_legs": [4, 4, 2],
...                     "num_arms": [0, 0, 2]},
...                     ["dog", "cat", "monkey"])
>>> df
   num_legs  num_arms
dog         4         0
cat         4         0
monkey      2         2
>>> df = df.rename_axis("animal")
>>> df
   num_legs  num_arms
animal
dog         4         0
cat         4         0
monkey      2         2
>>> df = df.rename_axis("limbs", axis="columns")
>>> df
limbs  num_legs  num_arms
animal
dog         4         0
cat         4         0
monkey      2         2

```

### MultiIndex

```

>>> df.index = pd.MultiIndex.from_product([['mammal'],
...                                         ['dog', 'cat', 'monkey']],
...                                         names=['type', 'name'])
>>> df
limbs      num_legs  num_arms
type  name
mammal dog         4         0
      cat         4         0
      monkey      2         2

```

```

>>> df.rename_axis(index={'type': 'class'})
limbs      num_legs  num_arms
class  name
mammal dog         4         0
      cat         4         0
      monkey      2         2

```

```

>>> df.rename_axis(columns=str.upper)
LIMBS      num_legs  num_arms
type  name
mammal dog         4         0
      cat         4         0
      monkey      2         2

```

### pandas.DataFrame.reorder\_levels

`DataFrame.reorder_levels` (*order*, *axis=0*)

Rearrange index levels using input order. May not drop or duplicate levels.

#### Parameters

**order** [list of int or list of str] List representing new level order. Reference level by number (position) or by key (label).

**axis** [int] Where to reorder levels.

### Returns

**type of caller (new object)**

## pandas.DataFrame.replace

`DataFrame.replace` (*to\_replace=None*, *value=None*, *inplace=False*, *limit=None*, *regex=False*, *method='pad'*)

Replace values given in *to\_replace* with *value*.

Values of the DataFrame are replaced with other values dynamically. This differs from updating with `.loc` or `.iloc`, which require you to specify a location to update with some value.

### Parameters

**to\_replace** [str, regex, list, dict, Series, int, float, or None] How to find the values that will be replaced.

- numeric, str or regex:
  - numeric: numeric values equal to *to\_replace* will be replaced with *value*
  - str: string exactly matching *to\_replace* will be replaced with *value*
  - regex: regexs matching *to\_replace* will be replaced with *value*
- list of str, regex, or numeric:
  - First, if *to\_replace* and *value* are both lists, they **must** be the same length.
  - Second, if `regex=True` then all of the strings in **both** lists will be interpreted as regexs otherwise they will match directly. This doesn't matter much for *value* since there are only a few possible substitution regexes you can use.
  - str, regex and numeric rules apply as above.
- dict:
  - Dicts can be used to specify different replacement values for different existing values. For example, `{ 'a': 'b', 'y': 'z' }` replaces the value 'a' with 'b' and 'y' with 'z'. To use a dict in this way the *value* parameter should be *None*.
  - For a DataFrame a dict can specify that different values should be replaced in different columns. For example, `{ 'a': 1, 'b': 'z' }` looks for the value 1 in column 'a' and the value 'z' in column 'b' and replaces these values with whatever is specified in *value*. The *value* parameter should not be *None* in this case. You can treat this as a special case of passing two lists except that you are specifying the column to search in.
  - For a DataFrame nested dictionaries, e.g., `{ 'a': { 'b': np.nan } }`, are read as follows: look in column 'a' for the value 'b' and replace it with NaN. The *value* parameter should be *None* to use a nested dict in this way. You can nest regular expressions as well. Note that column names (the top-level dictionary keys in a nested dictionary) **cannot** be regular expressions.
- None:

- This means that the *regex* argument must be a string, compiled regular expression, or list, dict, ndarray or Series of such elements. If *value* is also `None` then this **must** be a nested dictionary or Series.

See the examples section for examples of each of these.

**value** [scalar, dict, list, str, regex, default `None`] Value to replace any values matching *to\_replace* with. For a `DataFrame` a dict of values can be used to specify which value to use for each column (columns not in the dict will not be filled). Regular expressions, strings and lists or dicts of such objects are also allowed.

**inplace** [bool, default `False`] If `True`, in place. Note: this will modify any other views on this object (e.g. a column from a `DataFrame`). Returns the caller if this is `True`.

**limit** [int, default `None`] Maximum size gap to forward or backward fill.

**regex** [bool or same types as *to\_replace*, default `False`] Whether to interpret *to\_replace* and/or *value* as regular expressions. If this is `True` then *to\_replace* must be a string. Alternatively, this could be a regular expression or a list, dict, or array of regular expressions in which case *to\_replace* must be `None`.

**method** [{`'pad'`, `'ffill'`, `'bfill'`, `None`}] The method to use when for replacement, when *to\_replace* is a scalar, list or tuple and *value* is `None`.

Changed in version 0.23.0: Added to `DataFrame`.

#### Returns

**DataFrame** Object after replacement.

#### Raises

##### **AssertionError**

- If *regex* is not a `bool` and *to\_replace* is not `None`.

##### **TypeError**

- If *to\_replace* is a `dict` and *value* is not a `list`, `dict`, `ndarray`, or `Series`
- If *to\_replace* is `None` and *regex* is not compilable into a regular expression or is a `list`, `dict`, `ndarray`, or `Series`.
- When replacing multiple `bool` or `datetime64` objects and the arguments to *to\_replace* does not match the type of the value being replaced

##### **ValueError**

- If a `list` or an `ndarray` is passed to *to\_replace* and *value* but they are not the same length.

#### See also:

**`DataFrame.fillna`** Fill NA values.

**`DataFrame.where`** Replace values based on boolean condition.

**`Series.str.replace`** Simple string replacement.

#### Notes

- Regex substitution is performed under the hood with `re.sub`. The rules for substitution for `re.sub` are the same.

- Regular expressions will only substitute on strings, meaning you cannot provide, for example, a regular expression matching floating point numbers and expect the columns in your frame that have a numeric dtype to be matched. However, if those floating point numbers *are* strings, then you can do this.
- This method has *a lot* of options. You are encouraged to experiment and play with this method to gain intuition about how it works.
- When dict is used as the *to\_replace* value, it is like key(s) in the dict are the *to\_replace* part and value(s) in the dict are the *value* parameter.

## Examples

### Scalar ‘to\_replace’ and ‘value’

```
>>> s = pd.Series([0, 1, 2, 3, 4])
>>> s.replace(0, 5)
0    5
1    1
2    2
3    3
4    4
dtype: int64
```

```
>>> df = pd.DataFrame({'A': [0, 1, 2, 3, 4],
...                    'B': [5, 6, 7, 8, 9],
...                    'C': ['a', 'b', 'c', 'd', 'e']})
>>> df.replace(0, 5)
   A  B  C
0  5  5  a
1  1  6  b
2  2  7  c
3  3  8  d
4  4  9  e
```

### List-like ‘to\_replace’

```
>>> df.replace([0, 1, 2, 3], 4)
   A  B  C
0  4  5  a
1  4  6  b
2  4  7  c
3  4  8  d
4  4  9  e
```

```
>>> df.replace([0, 1, 2, 3], [4, 3, 2, 1])
   A  B  C
0  4  5  a
1  3  6  b
2  2  7  c
3  1  8  d
4  4  9  e
```

```
>>> s.replace([1, 2], method='bfill')
0    0
1    3
```

(continues on next page)

(continued from previous page)

```

2      3
3      3
4      4
dtype: int64

```

**dict-like ‘to\_replace’**

```

>>> df.replace({0: 10, 1: 100})
   A  B  C
0  10  5  a
1 100  6  b
2   2  7  c
3   3  8  d
4   4  9  e

```

```

>>> df.replace({'A': 0, 'B': 5}, 100)
   A  B  C
0 100 100  a
1   1   6  b
2   2   7  c
3   3   8  d
4   4   9  e

```

```

>>> df.replace({'A': {0: 100, 4: 400}})
   A  B  C
0 100  5  a
1   1  6  b
2   2  7  c
3   3  8  d
4 400  9  e

```

**Regular expression ‘to\_replace’**

```

>>> df = pd.DataFrame({'A': ['bat', 'foo', 'bait'],
...                     'B': ['abc', 'bar', 'xyz']})
>>> df.replace(to_replace=r'^ba.$', value='new', regex=True)
   A  B
0  new abc
1  foo new
2  bait xyz

```

```

>>> df.replace({'A': r'^ba.$'}, {'A': 'new'}, regex=True)
   A  B
0  new abc
1  foo bar
2  bait xyz

```

```

>>> df.replace(regex=r'^ba.$', value='new')
   A  B
0  new abc
1  foo new
2  bait xyz

```

```

>>> df.replace(regex={r'^ba.$': 'new', 'foo': 'xyz'})
   A  B

```

(continues on next page)

(continued from previous page)

```

0   new  abc
1   xyz  new
2  bait  xyz

```

```

>>> df.replace(regex=[r'^ba.$', 'foo'], value='new')
   A  B
0  new  abc
1  new  new
2  bait  xyz

```

Note that when replacing multiple bool or datetime64 objects, the data types in the *to\_replace* parameter must match the data type of the value being replaced:

```

>>> df = pd.DataFrame({'A': [True, False, True],
...                    'B': [False, True, False]})
>>> df.replace({'a string': 'new value', True: False}) # raises
Traceback (most recent call last):
...
TypeError: Cannot compare types 'ndarray(dtype=bool)' and 'str'

```

This raises a `TypeError` because one of the dict keys is not of the correct type for replacement.

Compare the behavior of `s.replace({'a': None})` and `s.replace('a', None)` to understand the peculiarities of the *to\_replace* parameter:

```

>>> s = pd.Series([10, 'a', 'a', 'b', 'a'])

```

When one uses a dict as the *to\_replace* value, it is like the value(s) in the dict are equal to the *value* parameter. `s.replace({'a': None})` is equivalent to `s.replace(to_replace={'a': None}, value=None, method=None)`:

```

>>> s.replace({'a': None})
0      10
1     None
2     None
3        b
4     None
dtype: object

```

When `value=None` and *to\_replace* is a scalar, list or tuple, *replace* uses the *method* parameter (default 'pad') to do the replacement. So this is why the 'a' values are being replaced by 10 in rows 1 and 2 and 'b' in row 4 in this case. The command `s.replace('a', None)` is actually equivalent to `s.replace(to_replace='a', value=None, method='pad')`:

```

>>> s.replace('a', None)
0      10
1      10
2      10
3        b
4        b
dtype: object

```

**pandas.DataFrame.resample**

`DataFrame.resample` (*rule*, *how=None*, *axis=0*, *fill\_method=None*, *closed=None*, *label=None*, *convention='start'*, *kind=None*, *loffset=None*, *limit=None*, *base=0*, *on=None*, *level=None*)

Resample time-series data.

Convenience method for frequency conversion and resampling of time series. Object must have a datetime-like index (*DatetimeIndex*, *PeriodIndex*, or *TimedeltaIndex*), or pass datetime-like values to the *on* or *level* keyword.

**Parameters**

**rule** [str] The offset string or object representing target conversion.

**how** [str] Method for down/re-sampling, default to 'mean' for downsampling.

Deprecated since version 0.18.0: The new syntax is `.resample(...).mean()`, or `.resample(...).apply(<func>)`

**axis** [{0 or 'index', 1 or 'columns'}, default 0] Which axis to use for up- or down-sampling. For *Series* this will default to 0, i.e. along the rows. Must be *DatetimeIndex*, *TimedeltaIndex* or *PeriodIndex*.

**fill\_method** [str, default None] Filling method for upsampling.

Deprecated since version 0.18.0: The new syntax is `.resample(...).<func>()`, e.g. `.resample(...).pad()`

**closed** [{ 'right', 'left' }, default None] Which side of bin interval is closed. The default is 'left' for all frequency offsets except for 'M', 'A', 'Q', 'BM', 'BA', 'BQ', and 'W' which all have a default of 'right'.

**label** [{ 'right', 'left' }, default None] Which bin edge label to label bucket with. The default is 'left' for all frequency offsets except for 'M', 'A', 'Q', 'BM', 'BA', 'BQ', and 'W' which all have a default of 'right'.

**convention** [{ 'start', 'end', 's', 'e' }, default 'start'] For *PeriodIndex* only, controls whether to use the start or end of *rule*.

**kind** [{ 'timestamp', 'period' }, optional, default None] Pass 'timestamp' to convert the resulting index to a *DateTimeIndex* or 'period' to convert it to a *PeriodIndex*. By default the input representation is retained.

**loffset** [timedelta, default None] Adjust the resampled time labels.

**limit** [int, default None] Maximum size gap when reindexing with *fill\_method*.

Deprecated since version 0.18.0.

**base** [int, default 0] For frequencies that evenly subdivide 1 day, the "origin" of the aggregated intervals. For example, for '5min' frequency, base could range from 0 through 4. Defaults to 0.

**on** [str, optional] For a *DataFrame*, column to use instead of index for resampling. Column must be datetime-like.

New in version 0.19.0.

**level** [str or int, optional] For a *MultiIndex*, level (name or number) to use for resampling. *level* must be datetime-like.

New in version 0.19.0.

## Returns

### Resampler object

See also:

**groupby** Group by mapping, function, label, or list of labels.

**Series.resample** Resample a Series.

**DataFrame.resample** Resample a DataFrame.

## Notes

See the [user guide](#) for more.

To learn more about the offset strings, please see [this link](#).

## Examples

Start by creating a series with 9 one minute timestamps.

```
>>> index = pd.date_range('1/1/2000', periods=9, freq='T')
>>> series = pd.Series(range(9), index=index)
>>> series
2000-01-01 00:00:00    0
2000-01-01 00:01:00    1
2000-01-01 00:02:00    2
2000-01-01 00:03:00    3
2000-01-01 00:04:00    4
2000-01-01 00:05:00    5
2000-01-01 00:06:00    6
2000-01-01 00:07:00    7
2000-01-01 00:08:00    8
Freq: T, dtype: int64
```

Downsample the series into 3 minute bins and sum the values of the timestamps falling into a bin.

```
>>> series.resample('3T').sum()
2000-01-01 00:00:00    3
2000-01-01 00:03:00   12
2000-01-01 00:06:00   21
Freq: 3T, dtype: int64
```

Downsample the series into 3 minute bins as above, but label each bin using the right edge instead of the left. Please note that the value in the bucket used as the label is not included in the bucket, which it labels. For example, in the original series the bucket 2000-01-01 00:03:00 contains the value 3, but the summed value in the resampled bucket with the label 2000-01-01 00:03:00 does not include 3 (if it did, the summed value would be 6, not 3). To include this value close the right side of the bin interval as illustrated in the example below this one.

```
>>> series.resample('3T', label='right').sum()
2000-01-01 00:03:00    3
2000-01-01 00:06:00   12
2000-01-01 00:09:00   21
Freq: 3T, dtype: int64
```

Downsample the series into 3 minute bins as above, but close the right side of the bin interval.

```
>>> series.resample('3T', label='right', closed='right').sum()
2000-01-01 00:00:00    0
2000-01-01 00:03:00    6
2000-01-01 00:06:00   15
2000-01-01 00:09:00   15
Freq: 3T, dtype: int64
```

Upsample the series into 30 second bins.

```
>>> series.resample('30S').asfreq()[0:5] # Select first 5 rows
2000-01-01 00:00:00    0.0
2000-01-01 00:00:30   NaN
2000-01-01 00:01:00    1.0
2000-01-01 00:01:30   NaN
2000-01-01 00:02:00    2.0
Freq: 30S, dtype: float64
```

Upsample the series into 30 second bins and fill the NaN values using the pad method.

```
>>> series.resample('30S').pad()[0:5]
2000-01-01 00:00:00    0
2000-01-01 00:00:30    0
2000-01-01 00:01:00    1
2000-01-01 00:01:30    1
2000-01-01 00:02:00    2
Freq: 30S, dtype: int64
```

Upsample the series into 30 second bins and fill the NaN values using the bfill method.

```
>>> series.resample('30S').bfill()[0:5]
2000-01-01 00:00:00    0
2000-01-01 00:00:30    1
2000-01-01 00:01:00    1
2000-01-01 00:01:30    2
2000-01-01 00:02:00    2
Freq: 30S, dtype: int64
```

Pass a custom function via apply

```
>>> def custom_resampler(array_like):
...     return np.sum(array_like) + 5
...
>>> series.resample('3T').apply(custom_resampler)
2000-01-01 00:00:00    8
2000-01-01 00:03:00   17
2000-01-01 00:06:00   26
Freq: 3T, dtype: int64
```

For a Series with a PeriodIndex, the keyword *convention* can be used to control whether to use the start or end of *rule*.

Resample a year by quarter using 'start' *convention*. Values are assigned to the first quarter of the period.

```
>>> s = pd.Series([1, 2], index=pd.period_range('2012-01-01',
...                                             freq='A',
...                                             periods=2))
>>> s
```

(continues on next page)

(continued from previous page)

```

2012    1
2013    2
Freq: A-DEC, dtype: int64
>>> s.resample('Q', convention='start').asfreq()
2012Q1    1.0
2012Q2    NaN
2012Q3    NaN
2012Q4    NaN
2013Q1    2.0
2013Q2    NaN
2013Q3    NaN
2013Q4    NaN
Freq: Q-DEC, dtype: float64

```

Resample quarters by month using ‘end’ convention. Values are assigned to the last month of the period.

```

>>> q = pd.Series([1, 2, 3, 4], index=pd.period_range('2018-01-01',
...                                                freq='Q',
...                                                periods=4))
>>> q
2018Q1    1
2018Q2    2
2018Q3    3
2018Q4    4
Freq: Q-DEC, dtype: int64
>>> q.resample('M', convention='end').asfreq()
2018-03    1.0
2018-04    NaN
2018-05    NaN
2018-06    2.0
2018-07    NaN
2018-08    NaN
2018-09    3.0
2018-10    NaN
2018-11    NaN
2018-12    4.0
Freq: M, dtype: float64

```

For DataFrame objects, the keyword *on* can be used to specify the column instead of the index for resampling.

```

>>> d = dict({'price': [10, 11, 9, 13, 14, 18, 17, 19],
...          'volume': [50, 60, 40, 100, 50, 100, 40, 50]})
>>> df = pd.DataFrame(d)
>>> df['week_starting'] = pd.date_range('01/01/2018',
...                                     periods=8,
...                                     freq='W')
>>> df
   price  volume week_starting
0     10     50   2018-01-07
1     11     60   2018-01-14
2      9     40   2018-01-21
3     13    100   2018-01-28
4     14     50   2018-02-04
5     18    100   2018-02-11
6     17     40   2018-02-18

```

(continues on next page)

(continued from previous page)

```

7      19      50      2018-02-25
>>> df.resample('M', on='week_starting').mean()
           price  volume
week_starting
2018-01-31      10.75    62.5
2018-02-28      17.00    60.0

```

For a DataFrame with MultiIndex, the keyword *level* can be used to specify on which level the resampling needs to take place.

```

>>> days = pd.date_range('1/1/2000', periods=4, freq='D')
>>> d2 = dict({'price': [10, 11, 9, 13, 14, 18, 17, 19],
...          'volume': [50, 60, 40, 100, 50, 100, 40, 50]})
>>> df2 = pd.DataFrame(d2,
...                    index=pd.MultiIndex.from_product([days,
...                                                    ['morning',
...                                                    'afternoon']])
>>> df2
           price  volume
2000-01-01 morning      10      50
           afternoon    11      60
2000-01-02 morning      9      40
           afternoon    13     100
2000-01-03 morning     14      50
           afternoon    18     100
2000-01-04 morning     17      40
           afternoon    19      50
>>> df2.resample('D', level=0).sum()
           price  volume
2000-01-01     21     110
2000-01-02     22     140
2000-01-03     32     150
2000-01-04     36      90

```

## pandas.DataFrame.reset\_index

`DataFrame.reset_index(level=None, drop=False, inplace=False, col_level=0, col_fill="")`

Reset the index, or a level of it.

Reset the index of the DataFrame, and use the default one instead. If the DataFrame has a MultiIndex, this method can remove one or more levels.

### Parameters

**level** [int, str, tuple, or list, default None] Only remove the given levels from the index. Removes all levels by default.

**drop** [bool, default False] Do not try to insert index into dataframe columns. This resets the index to the default integer index.

**inplace** [bool, default False] Modify the DataFrame in place (do not create a new object).

**col\_level** [int or str, default 0] If the columns have multiple levels, determines which level the labels are inserted into. By default it is inserted into the first level.

**col\_fill** [object, default “”] If the columns have multiple levels, determines how the other levels are named. If None then the index name is repeated.

### Returns

**DataFrame** DataFrame with the new index.

### See also:

**DataFrame.set\_index** Opposite of reset\_index.

**DataFrame.reindex** Change to new indices or expand indices.

**DataFrame.reindex\_like** Change to same indices as other DataFrame.

## Examples

```
>>> df = pd.DataFrame([('bird', 389.0),
...                     ('bird', 24.0),
...                     ('mammal', 80.5),
...                     ('mammal', np.nan)],
...                     index=['falcon', 'parrot', 'lion', 'monkey'],
...                     columns=('class', 'max_speed'))
>>> df
```

|        | class  | max_speed |
|--------|--------|-----------|
| falcon | bird   | 389.0     |
| parrot | bird   | 24.0      |
| lion   | mammal | 80.5      |
| monkey | mammal | NaN       |

When we reset the index, the old index is added as a column, and a new sequential index is used:

```
>>> df.reset_index()
   index  class  max_speed
0  falcon   bird    389.0
1  parrot   bird    24.0
2    lion  mammal    80.5
3  monkey  mammal     NaN
```

We can use the *drop* parameter to avoid the old index being added as a column:

```
>>> df.reset_index(drop=True)
   class  max_speed
0   bird    389.0
1   bird    24.0
2  mammal    80.5
3  mammal     NaN
```

You can also use *reset\_index* with *MultiIndex*.

```
>>> index = pd.MultiIndex.from_tuples([('bird', 'falcon'),
...                                   ('bird', 'parrot'),
...                                   ('mammal', 'lion'),
...                                   ('mammal', 'monkey')],
...                                   names=['class', 'name'])
>>> columns = pd.MultiIndex.from_tuples([('speed', 'max'),
...                                      ('species', 'type')])
>>> df = pd.DataFrame([(389.0, 'fly'),
```

(continues on next page)

(continued from previous page)

```

...         ( 24.0, 'fly'),
...         ( 80.5, 'run'),
...         (np.nan, 'jump')],
...         index=index,
...         columns=columns)
>>> df

```

|        |        | speed | species |
|--------|--------|-------|---------|
|        |        | max   | type    |
| class  | name   |       |         |
| bird   | falcon | 389.0 | fly     |
|        | parrot | 24.0  | fly     |
| mammal | lion   | 80.5  | run     |
|        | monkey | NaN   | jump    |

If the index has multiple levels, we can reset a subset of them:

```

>>> df.reset_index(level='class')

```

|        | class  | speed | species |
|--------|--------|-------|---------|
|        |        | max   | type    |
| name   |        |       |         |
| falcon | bird   | 389.0 | fly     |
| parrot | bird   | 24.0  | fly     |
| lion   | mammal | 80.5  | run     |
| monkey | mammal | NaN   | jump    |

If we are not dropping the index, by default, it is placed in the top level. We can place it in another level:

```

>>> df.reset_index(level='class', col_level=1)

```

|        |        | speed | species |
|--------|--------|-------|---------|
|        | class  | max   | type    |
| name   |        |       |         |
| falcon | bird   | 389.0 | fly     |
| parrot | bird   | 24.0  | fly     |
| lion   | mammal | 80.5  | run     |
| monkey | mammal | NaN   | jump    |

When the index is inserted under another level, we can specify under which one with the parameter *col\_fill*:

```

>>> df.reset_index(level='class', col_level=1, col_fill='species')

```

|        |        | species | speed | species |
|--------|--------|---------|-------|---------|
|        | class  |         | max   | type    |
| name   |        |         |       |         |
| falcon | bird   |         | 389.0 | fly     |
| parrot | bird   |         | 24.0  | fly     |
| lion   | mammal |         | 80.5  | run     |
| monkey | mammal |         | NaN   | jump    |

If we specify a nonexistent level for *col\_fill*, it is created:

```

>>> df.reset_index(level='class', col_level=1, col_fill='genus')

```

|        |       | genus | speed | species |
|--------|-------|-------|-------|---------|
|        | class |       | max   | type    |
| name   |       |       |       |         |
| falcon | bird  |       | 389.0 | fly     |
| parrot | bird  |       | 24.0  | fly     |

(continues on next page)

(continued from previous page)

|        |        |      |      |
|--------|--------|------|------|
| lion   | mammal | 80.5 | run  |
| monkey | mammal | NaN  | jump |

## **pandas.DataFrame.rfloordiv**

`DataFrame.rfloordiv(other, axis='columns', level=None, fill_value=None)`

Integer division of dataframe and other, element-wise (binary operator *rfloordiv*).

Equivalent to `other // dataframe`, but with support to substitute a `fill_value` for missing data in one of the inputs. With reverse version, *floordiv*.

Among flexible wrappers (*add*, *sub*, *mul*, *div*, *mod*, *pow*) to arithmetic operators: `+`, `-`, `*`, `/`, `//`, `%`, `**`.

### **Parameters**

**other** [scalar, sequence, Series, or DataFrame] Any single or multiple element data structure, or list-like object.

**axis** [{0 or 'index', 1 or 'columns'}] Whether to compare by the index (0 or 'index') or columns (1 or 'columns'). For Series input, axis to match Series index on.

**level** [int or label] Broadcast across a level, matching Index values on the passed Multi-Index level.

**fill\_value** [float or None, default None] Fill existing missing (NaN) values, and any new element needed for successful DataFrame alignment, with this value before computation. If data in both corresponding DataFrame locations is missing the result will be missing.

### **Returns**

**DataFrame** Result of the arithmetic operation.

See also:

**DataFrame.add** Add DataFrames.

**DataFrame.sub** Subtract DataFrames.

**DataFrame.mul** Multiply DataFrames.

**DataFrame.div** Divide DataFrames (float division).

**DataFrame.truediv** Divide DataFrames (float division).

**DataFrame.floordiv** Divide DataFrames (integer division).

**DataFrame.mod** Calculate modulo (remainder after division).

**DataFrame.pow** Calculate exponential power.

### **Notes**

Mismatched indices will be unioned together.

## Examples

```
>>> df = pd.DataFrame({'angles': [0, 3, 4],
...                     'degrees': [360, 180, 360]},
...                     index=['circle', 'triangle', 'rectangle'])
>>> df
```

|           | angles | degrees |
|-----------|--------|---------|
| circle    | 0      | 360     |
| triangle  | 3      | 180     |
| rectangle | 4      | 360     |

Add a scalar with operator version which return the same results.

```
>>> df + 1
```

|           | angles | degrees |
|-----------|--------|---------|
| circle    | 1      | 361     |
| triangle  | 4      | 181     |
| rectangle | 5      | 361     |

```
>>> df.add(1)
```

|           | angles | degrees |
|-----------|--------|---------|
| circle    | 1      | 361     |
| triangle  | 4      | 181     |
| rectangle | 5      | 361     |

Divide by constant with reverse version.

```
>>> df.div(10)
```

|           | angles | degrees |
|-----------|--------|---------|
| circle    | 0.0    | 36.0    |
| triangle  | 0.3    | 18.0    |
| rectangle | 0.4    | 36.0    |

```
>>> df.rdiv(10)
```

|           | angles   | degrees  |
|-----------|----------|----------|
| circle    | inf      | 0.027778 |
| triangle  | 3.333333 | 0.055556 |
| rectangle | 2.500000 | 0.027778 |

Subtract a list and Series by axis with operator version.

```
>>> df - [1, 2]
```

|           | angles | degrees |
|-----------|--------|---------|
| circle    | -1     | 358     |
| triangle  | 2      | 178     |
| rectangle | 3      | 358     |

```
>>> df.sub([1, 2], axis='columns')
```

|           | angles | degrees |
|-----------|--------|---------|
| circle    | -1     | 358     |
| triangle  | 2      | 178     |
| rectangle | 3      | 358     |

```
>>> df.sub(pd.Series([1, 1, 1], index=['circle', 'triangle', 'rectangle']),
...        axis='index')
```

|           | angles | degrees |
|-----------|--------|---------|
| circle    | -1     | 359     |
| triangle  | 2      | 179     |
| rectangle | 3      | 359     |

(continues on next page)

(continued from previous page)

|           |    |     |
|-----------|----|-----|
| circle    | -1 | 359 |
| triangle  | 2  | 179 |
| rectangle | 3  | 359 |

Multiply a DataFrame of different shape with operator version.

```
>>> other = pd.DataFrame({'angles': [0, 3, 4]},
...                        index=['circle', 'triangle', 'rectangle'])
>>> other
```

|           | angles |
|-----------|--------|
| circle    | 0      |
| triangle  | 3      |
| rectangle | 4      |

```
>>> df * other
```

|           | angles | degrees |
|-----------|--------|---------|
| circle    | 0      | NaN     |
| triangle  | 9      | NaN     |
| rectangle | 16     | NaN     |

```
>>> df.mul(other, fill_value=0)
```

|           | angles | degrees |
|-----------|--------|---------|
| circle    | 0      | 0.0     |
| triangle  | 9      | 0.0     |
| rectangle | 16     | 0.0     |

Divide by a MultiIndex by level.

```
>>> df_multindex = pd.DataFrame({'angles': [0, 3, 4, 4, 5, 6],
...                               'degrees': [360, 180, 360, 360, 540, 720]},
...                               index=[['A', 'A', 'A', 'B', 'B', 'B'],
...                                       ['circle', 'triangle', 'rectangle',
...                                        'square', 'pentagon', 'hexagon']])
>>> df_multindex
```

|   |           | angles | degrees |
|---|-----------|--------|---------|
| A | circle    | 0      | 360     |
|   | triangle  | 3      | 180     |
|   | rectangle | 4      | 360     |
| B | square    | 4      | 360     |
|   | pentagon  | 5      | 540     |
|   | hexagon   | 6      | 720     |

```
>>> df.div(df_multindex, level=1, fill_value=0)
```

|   |           | angles | degrees |
|---|-----------|--------|---------|
| A | circle    | NaN    | 1.0     |
|   | triangle  | 1.0    | 1.0     |
|   | rectangle | 1.0    | 1.0     |
| B | square    | 0.0    | 0.0     |
|   | pentagon  | 0.0    | 0.0     |
|   | hexagon   | 0.0    | 0.0     |

**pandas.DataFrame.rmod**

`DataFrame.rmod(other, axis='columns', level=None, fill_value=None)`

Modulo of dataframe and other, element-wise (binary operator *rmod*).

Equivalent to `other % dataframe`, but with support to substitute a `fill_value` for missing data in one of the inputs. With reverse version, *mod*.

Among flexible wrappers (*add*, *sub*, *mul*, *div*, *mod*, *pow*) to arithmetic operators: `+`, `-`, `*`, `/`, `//`, `%`, `**`.

**Parameters**

**other** [scalar, sequence, Series, or DataFrame] Any single or multiple element data structure, or list-like object.

**axis** [{0 or 'index', 1 or 'columns'}] Whether to compare by the index (0 or 'index') or columns (1 or 'columns'). For Series input, axis to match Series index on.

**level** [int or label] Broadcast across a level, matching Index values on the passed Multi-Index level.

**fill\_value** [float or None, default None] Fill existing missing (NaN) values, and any new element needed for successful DataFrame alignment, with this value before computation. If data in both corresponding DataFrame locations is missing the result will be missing.

**Returns**

**DataFrame** Result of the arithmetic operation.

```

|           | angles | degrees |
|-----------|--------|---------|
| circle    | -1     | 358     |
| triangle  | 2      | 178     |
| rectangle | 3      | 358     |

```
>>> df.sub(pd.Series([1, 1, 1], index=['circle', 'triangle', 'rectangle']),  
...        axis='index')
```

|           | angles | degrees |
|-----------|--------|---------|
| circle    | -1     | 359     |
| triangle  | 2      | 179     |
| rectangle | 3      | 359     |

Multiply a DataFrame of different shape with operator version.

```
>>> other = pd.DataFrame({'angles': [0, 3, 4]},
...                        index=['circle', 'triangle', 'rectangle'])
>>> other
```

|           | angles |
|-----------|--------|
| circle    | 0      |
| triangle  | 3      |
| rectangle | 4      |

```
>>> df * other
```

|           | angles | degrees |
|-----------|--------|---------|
| circle    | 0      | NaN     |
| triangle  | 9      | NaN     |
| rectangle | 16     | NaN     |

```
>>> df.mul(other, fill_value=0)
```

|           | angles | degrees |
|-----------|--------|---------|
| circle    | 0      | 0.0     |
| triangle  | 9      | 0.0     |
| rectangle | 16     | 0.0     |

Divide by a MultiIndex by level.

```
>>> df_multindex = pd.DataFrame({'angles': [0, 3, 4, 4, 5, 6],
...                               'degrees': [360, 180, 360, 360, 540, 720]},
...                              index=[['A', 'A', 'A', 'B', 'B', 'B'],
...                                     ['circle', 'triangle', 'rectangle',
...                                      'square', 'pentagon', 'hexagon']])
>>> df_multindex
```

|   |           | angles | degrees |
|---|-----------|--------|---------|
| A | circle    | 0      | 360     |
|   | triangle  | 3      | 180     |
|   | rectangle | 4      | 360     |
| B | square    | 4      | 360     |
|   | pentagon  | 5      | 540     |
|   | hexagon   | 6      | 720     |

```
>>> df.div(df_multindex, level=1, fill_value=0)
```

|   |           | angles | degrees |
|---|-----------|--------|---------|
| A | circle    | NaN    | 1.0     |
|   | triangle  | 1.0    | 1.0     |
|   | rectangle | 1.0    | 1.0     |
| B | square    | 0.0    | 0.0     |
|   | pentagon  | 0.0    | 0.0     |
|   | hexagon   | 0.0    | 0.0     |

## pandas.DataFrame.rmul

`DataFrame.rmul(other, axis='columns', level=None, fill_value=None)`

Multiplication of dataframe and other, element-wise (binary operator *rmul*).

Equivalent to `other * dataframe`, but with support to substitute a `fill_value` for missing data in one of the inputs. With reverse version, *mul*.

Among flexible wrappers (*add*, *sub*, *mul*, *div*, *mod*, *pow*) to arithmetic operators: `+`, `-`, `*`, `/`, `//`, `%`, `**`.

### Parameters

- other** [scalar, sequence, Series, or DataFrame] Any single or multiple element data structure, or list-like object.
- axis** [{0 or 'index', 1 or 'columns'}] Whether to compare by the index (0 or 'index') or columns (1 or 'columns'). For Series input, axis to match Series index on.
- level** [int or label] Broadcast across a level, matching Index values on the passed Multi-Index level.
- fill\_value** [float or None, default None] Fill existing missing (NaN) values, and any new element needed for successful DataFrame alignment, with this value before computation. If data in both corresponding DataFrame locations is missing the result will be missing.

### Returns

**DataFrame** Result of the arithmetic operation.

See also:

**DataFrame.add** Add DataFrames.

**DataFrame.sub** Subtract DataFrames.

**DataFrame.mul** Multiply DataFrames.

**DataFrame.div** Divide DataFrames (float division).

**DataFrame.truediv** Divide DataFrames (float division).

**DataFrame.floordiv** Divide DataFrames (integer division).

**DataFrame.mod** Calculate modulo (remainder after division).

**DataFrame.pow** Calculate exponential power.

### Notes

Mismatched indices will be unioned together.

### Examples

```
>>> df = pd.DataFrame({'angles': [0, 3, 4],
...                     'degrees': [360, 180, 360]},
...                     index=['circle', 'triangle', 'rectangle'])
>>> df
```

|           | angles | degrees |
|-----------|--------|---------|
| circle    | 0      | 360     |
| triangle  | 3      | 180     |
| rectangle | 4      | 360     |

Add a scalar with operator version which return the same results.

```
>>> df + 1
```

|           | angles | degrees |
|-----------|--------|---------|
| circle    | 1      | 361     |
| triangle  | 4      | 181     |
| rectangle | 5      | 361     |

```
>>> df.add(1)
      angles  degrees
circle      1     361
triangle    4     181
rectangle   5     361
```

Divide by constant with reverse version.

```
>>> df.div(10)
      angles  degrees
circle    0.0     36.0
triangle  0.3     18.0
rectangle 0.4     36.0
```

```
>>> df.rdiv(10)
      angles  degrees
circle      inf  0.027778
triangle  3.333333  0.055556
rectangle 2.500000  0.027778
```

Subtract a list and Series by axis with operator version.

```
>>> df - [1, 2]
      angles  degrees
circle     -1     358
triangle    2     178
rectangle    3     358
```

```
>>> df.sub([1, 2], axis='columns')
      angles  degrees
circle     -1     358
triangle    2     178
rectangle    3     358
```

```
>>> df.sub(pd.Series([1, 1, 1], index=['circle', 'triangle', 'rectangle']),
...         axis='index')
      angles  degrees
circle     -1     359
triangle    2     179
rectangle    3     359
```

Multiply a DataFrame of different shape with operator version.

```
>>> other = pd.DataFrame({'angles': [0, 3, 4]},
...                       index=['circle', 'triangle', 'rectangle'])
>>> other
      angles
circle      0
triangle    3
rectangle    4
```

```
>>> df * other
      angles  degrees
circle      0      NaN
triangle     9      NaN
rectangle   16      NaN
```

```
>>> df.mul(other, fill_value=0)
          angles  degrees
circle         0      0.0
triangle        9      0.0
rectangle      16      0.0
```

Divide by a MultiIndex by level.

```
>>> df_multindex = pd.DataFrame({'angles': [0, 3, 4, 4, 5, 6],
...                               'degrees': [360, 180, 360, 360, 540, 720]},
...                               index=[['A', 'A', 'A', 'B', 'B', 'B'],
...                                       ['circle', 'triangle', 'rectangle',
...                                        'square', 'pentagon', 'hexagon']])
>>> df_multindex
          angles  degrees
A circle         0      360
  triangle         3      180
  rectangle         4      360
B square          4      360
  pentagon         5      540
  hexagon          6      720
```

```
>>> df.div(df_multindex, level=1, fill_value=0)
          angles  degrees
A circle      NaN       1.0
  triangle     1.0       1.0
  rectangle     1.0       1.0
B square       0.0       0.0
  pentagon     0.0       0.0
  hexagon      0.0       0.0
```

## pandas.DataFrame.rolling

`DataFrame.rolling(window, min_periods=None, center=False, win_type=None, on=None, axis=0, closed=None)`

Provides rolling window calculations.

New in version 0.18.0.

### Parameters

**window** [int, or offset] Size of the moving window. This is the number of observations used for calculating the statistic. Each window will be a fixed size.

If its an offset then this will be the time period of each window. Each window will be a variable sized based on the observations included in the time-period. This is only valid for datetimelike indexes. This is new in 0.19.0

**min\_periods** [int, default None] Minimum number of observations in window required to have a value (otherwise result is NA). For a window that is specified by an offset, *min\_periods* will default to 1. Otherwise, *min\_periods* will default to the size of the window.

**center** [bool, default False] Set the labels at the center of the window.

**win\_type** [str, default None] Provide a window type. If *None*, all points are evenly weighted. See the notes below for further information.

**on** [str, optional] For a DataFrame, column on which to calculate the rolling window, rather than the index

**axis** [int or str, default 0]

**closed** [str, default None] Make the interval closed on the 'right', 'left', 'both' or 'neither' endpoints. For offset-based windows, it defaults to 'right'. For fixed windows, defaults to 'both'. Remaining cases not implemented for fixed windows.

New in version 0.20.0.

### Returns

a Window or Rolling sub-classed for the particular operation

See also:

***expanding*** Provides expanding transformations.

***ewm*** Provides exponential weighted functions.

### Notes

By default, the result is set to the right edge of the window. This can be changed to the center of the window by setting `center=True`.

To learn more about the offsets & frequency strings, please see [this link](#).

The recognized win\_types are:

- boxcar
- triang
- blackman
- hamming
- bartlett
- parzen
- bohman
- blackmanharris
- nuttall
- barthann
- kaiser (needs beta)
- gaussian (needs std)
- general\_gaussian (needs power, width)
- slepian (needs width).

If `win_type=None` all points are evenly weighted. To learn more about different window types see [scipy.signal window functions](#).

## Examples

```
>>> df = pd.DataFrame({'B': [0, 1, 2, np.nan, 4]})
>>> df
   B
0  0.0
1  1.0
2  2.0
3  NaN
4  4.0
```

Rolling sum with a window length of 2, using the 'triang' window type.

```
>>> df.rolling(2, win_type='triang').sum()
   B
0  NaN
1  1.0
2  2.5
3  NaN
4  NaN
```

Rolling sum with a window length of 2, min\_periods defaults to the window length.

```
>>> df.rolling(2).sum()
   B
0  NaN
1  1.0
2  3.0
3  NaN
4  NaN
```

Same as above, but explicitly set the min\_periods

```
>>> df.rolling(2, min_periods=1).sum()
   B
0  0.0
1  1.0
2  3.0
3  2.0
4  4.0
```

A ragged (meaning not-a-regular frequency), time-indexed DataFrame

```
>>> df = pd.DataFrame({'B': [0, 1, 2, np.nan, 4]},
...                     index = [pd.Timestamp('20130101 09:00:00'),
...                               pd.Timestamp('20130101 09:00:02'),
...                               pd.Timestamp('20130101 09:00:03'),
...                               pd.Timestamp('20130101 09:00:05'),
...                               pd.Timestamp('20130101 09:00:06')])
```

```
>>> df
                B
2013-01-01 09:00:00  0.0
2013-01-01 09:00:02  1.0
2013-01-01 09:00:03  2.0
2013-01-01 09:00:05  NaN
2013-01-01 09:00:06  4.0
```

Contrasting to an integer rolling window, this will roll a variable length window corresponding to the time period. The default for `min_periods` is 1.

```
>>> df.rolling('2s').sum()
      B
2013-01-01 09:00:00  0.0
2013-01-01 09:00:02  1.0
2013-01-01 09:00:03  3.0
2013-01-01 09:00:05  NaN
2013-01-01 09:00:06  4.0
```

## pandas.DataFrame.round

`DataFrame.round(decimals=0, *args, **kwargs)`

Round a DataFrame to a variable number of decimal places.

### Parameters

**decimals** [int, dict, Series] Number of decimal places to round each column to. If an int is given, round each column to the same number of places. Otherwise dict and Series round to variable numbers of places. Column names should be in the keys if *decimals* is a dict-like, or in the index if *decimals* is a Series. Any columns not included in *decimals* will be left as is. Elements of *decimals* which are not columns of the input will be ignored.

### Returns

**DataFrame**

See also:

`numpy.around`, `Series.round`

## Examples

```
>>> df = pd.DataFrame(np.random.random([3, 3]),
...                    columns=['A', 'B', 'C'], index=['first', 'second', 'third'])
>>> df
      A      B      C
first 0.028208 0.992815 0.173891
second 0.038683 0.645646 0.577595
third 0.877076 0.149370 0.491027
>>> df.round(2)
      A      B      C
first 0.03 0.99 0.17
second 0.04 0.65 0.58
third 0.88 0.15 0.49
>>> df.round({'A': 1, 'C': 2})
      A      B      C
first 0.0 0.992815 0.17
second 0.0 0.645646 0.58
third 0.9 0.149370 0.49
>>> decimals = pd.Series([1, 0, 2], index=['A', 'B', 'C'])
>>> df.round(decimals)
      A B      C
first 0.0 1 0.17
```

(continues on next page)

(continued from previous page)

|        |     |   |      |
|--------|-----|---|------|
| second | 0.0 | 1 | 0.58 |
| third  | 0.9 | 0 | 0.49 |

## **pandas.DataFrame.rpow**

`DataFrame.rpow` (*other*, *axis*='columns', *level*=None, *fill\_value*=None)

Exponential power of dataframe and other, element-wise (binary operator *rpow*).

Equivalent to `other ** dataframe`, but with support to substitute a *fill\_value* for missing data in one of the inputs. With reverse version, *pow*.

Among flexible wrappers (*add*, *sub*, *mul*, *div*, *mod*, *pow*) to arithmetic operators: `+`, `-`, `*`, `/`, `//`, `%`, `**`.

### **Parameters**

**other** [scalar, sequence, Series, or DataFrame] Any single or multiple element data structure, or list-like object.

**axis** [{0 or 'index', 1 or 'columns'}] Whether to compare by the index (0 or 'index') or columns (1 or 'columns'). For Series input, axis to match Series index on.

**level** [int or label] Broadcast across a level, matching Index values on the passed Multi-Index level.

**fill\_value** [float or None, default None] Fill existing missing (NaN) values, and any new element needed for successful DataFrame alignment, with this value before computation. If data in both corresponding DataFrame locations is missing the result will be missing.

### **Returns**

**DataFrame** Result of the arithmetic operation.

See also:

**DataFrame.add** Add DataFrames.

**DataFrame.sub** Subtract DataFrames.

**DataFrame.mul** Multiply DataFrames.

**DataFrame.div** Divide DataFrames (float division).

**DataFrame.truediv** Divide DataFrames (float division).

**DataFrame.floordiv** Divide DataFrames (integer division).

**DataFrame.mod** Calculate modulo (remainder after division).

**DataFrame.pow** Calculate exponential power.

### **Notes**

Mismatched indices will be unioned together.

## Examples

```
>>> df = pd.DataFrame({'angles': [0, 3, 4],
...                     'degrees': [360, 180, 360]},
...                     index=['circle', 'triangle', 'rectangle'])
>>> df
```

|           | angles | degrees |
|-----------|--------|---------|
| circle    | 0      | 360     |
| triangle  | 3      | 180     |
| rectangle | 4      | 360     |

Add a scalar with operator version which return the same results.

```
>>> df + 1
```

|           | angles | degrees |
|-----------|--------|---------|
| circle    | 1      | 361     |
| triangle  | 4      | 181     |
| rectangle | 5      | 361     |

```
>>> df.add(1)
```

|           | angles | degrees |
|-----------|--------|---------|
| circle    | 1      | 361     |
| triangle  | 4      | 181     |
| rectangle | 5      | 361     |

Divide by constant with reverse version.

```
>>> df.div(10)
```

|           | angles | degrees |
|-----------|--------|---------|
| circle    | 0.0    | 36.0    |
| triangle  | 0.3    | 18.0    |
| rectangle | 0.4    | 36.0    |

```
>>> df.rdiv(10)
```

|           | angles   | degrees  |
|-----------|----------|----------|
| circle    | inf      | 0.027778 |
| triangle  | 3.333333 | 0.055556 |
| rectangle | 2.500000 | 0.027778 |

Subtract a list and Series by axis with operator version.

```
>>> df - [1, 2]
```

|           | angles | degrees |
|-----------|--------|---------|
| circle    | -1     | 358     |
| triangle  | 2      | 178     |
| rectangle | 3      | 358     |

```
>>> df.sub([1, 2], axis='columns')
```

|           | angles | degrees |
|-----------|--------|---------|
| circle    | -1     | 358     |
| triangle  | 2      | 178     |
| rectangle | 3      | 358     |

```
>>> df.sub(pd.Series([1, 1, 1], index=['circle', 'triangle', 'rectangle']),
...        axis='index')
```

|           | angles | degrees |
|-----------|--------|---------|
| circle    | -1     | 359     |
| triangle  | 2      | 179     |
| rectangle | 3      | 359     |

(continues on next page)

(continued from previous page)

|           |    |     |
|-----------|----|-----|
| circle    | -1 | 359 |
| triangle  | 2  | 179 |
| rectangle | 3  | 359 |

Multiply a DataFrame of different shape with operator version.

```
>>> other = pd.DataFrame({'angles': [0, 3, 4]},
...                        index=['circle', 'triangle', 'rectangle'])
>>> other
```

|           | angles |
|-----------|--------|
| circle    | 0      |
| triangle  | 3      |
| rectangle | 4      |

```
>>> df * other
```

|           | angles | degrees |
|-----------|--------|---------|
| circle    | 0      | NaN     |
| triangle  | 9      | NaN     |
| rectangle | 16     | NaN     |

```
>>> df.mul(other, fill_value=0)
```

|           | angles | degrees |
|-----------|--------|---------|
| circle    | 0      | 0.0     |
| triangle  | 9      | 0.0     |
| rectangle | 16     | 0.0     |

Divide by a MultiIndex by level.

```
>>> df_multindex = pd.DataFrame({'angles': [0, 3, 4, 4, 5, 6],
...                               'degrees': [360, 180, 360, 360, 540, 720]},
...                               index=[['A', 'A', 'A', 'B', 'B', 'B'],
...                                       ['circle', 'triangle', 'rectangle',
...                                        'square', 'pentagon', 'hexagon']])
>>> df_multindex
```

|   |           | angles | degrees |
|---|-----------|--------|---------|
| A | circle    | 0      | 360     |
|   | triangle  | 3      | 180     |
|   | rectangle | 4      | 360     |
| B | square    | 4      | 360     |
|   | pentagon  | 5      | 540     |
|   | hexagon   | 6      | 720     |

```
>>> df.div(df_multindex, level=1, fill_value=0)
```

|   |           | angles | degrees |
|---|-----------|--------|---------|
| A | circle    | NaN    | 1.0     |
|   | triangle  | 1.0    | 1.0     |
|   | rectangle | 1.0    | 1.0     |
| B | square    | 0.0    | 0.0     |
|   | pentagon  | 0.0    | 0.0     |
|   | hexagon   | 0.0    | 0.0     |

## pandas.DataFrame.rsub

`DataFrame.rsub` (*other*, *axis*='columns', *level*=None, *fill\_value*=None)

Subtraction of dataframe and other, element-wise (binary operator *rsub*).

Equivalent to `other - dataframe`, but with support to substitute a *fill\_value* for missing data in one of the inputs. With reverse version, *sub*.

Among flexible wrappers (*add*, *sub*, *mul*, *div*, *mod*, *pow*) to arithmetic operators: `+`, `-`, `*`, `/`, `//`, `%`, `**`.

### Parameters

**other** [scalar, sequence, Series, or DataFrame] Any single or multiple element data structure, or list-like object.

**axis** [{0 or 'index', 1 or 'columns'}] Whether to compare by the index (0 or 'index') or columns (1 or 'columns'). For Series input, axis to match Series index on.

**level** [int or label] Broadcast across a level, matching Index values on the passed Multi-Index level.

**fill\_value** [float or None, default None] Fill existing missing (NaN) values, and any new element needed for successful DataFrame alignment, with this value before computation. If data in both corresponding DataFrame locations is missing the result will be missing.

### Returns

**DataFrame** Result of the arithmetic operation.

See also:

**DataFrame.add** Add DataFrames.

**DataFrame.sub** Subtract DataFrames.

**DataFrame.mul** Multiply DataFrames.

**DataFrame.div** Divide DataFrames (float division).

**DataFrame.truediv** Divide DataFrames (float division).

**DataFrame.floordiv** Divide DataFrames (integer division).

**DataFrame.mod** Calculate modulo (remainder after division).

**DataFrame.pow** Calculate exponential power.

### Notes

Mismatched indices will be unioned together.

### Examples

```

>>> df = pd.DataFrame({'angles': [0, 3, 4],
...                     'degrees': [360, 180, 360]},
...                     index=['circle', 'triangle', 'rectangle'])
>>> df

```

|        | angles | degrees |
|--------|--------|---------|
| circle | 0      | 360     |

(continues on next page)

(continued from previous page)

|           |   |     |
|-----------|---|-----|
| triangle  | 3 | 180 |
| rectangle | 4 | 360 |

Add a scalar with operator version which return the same results.

```
>>> df + 1
```

|           | angles | degrees |
|-----------|--------|---------|
| circle    | 1      | 361     |
| triangle  | 4      | 181     |
| rectangle | 5      | 361     |

```
>>> df.add(1)
```

|           | angles | degrees |
|-----------|--------|---------|
| circle    | 1      | 361     |
| triangle  | 4      | 181     |
| rectangle | 5      | 361     |

Divide by constant with reverse version.

```
>>> df.div(10)
```

|           | angles | degrees |
|-----------|--------|---------|
| circle    | 0.0    | 36.0    |
| triangle  | 0.3    | 18.0    |
| rectangle | 0.4    | 36.0    |

```
>>> df.rdiv(10)
```

|           | angles   | degrees  |
|-----------|----------|----------|
| circle    | inf      | 0.027778 |
| triangle  | 3.333333 | 0.055556 |
| rectangle | 2.500000 | 0.027778 |

Subtract a list and Series by axis with operator version.

```
>>> df - [1, 2]
```

|           | angles | degrees |
|-----------|--------|---------|
| circle    | -1     | 358     |
| triangle  | 2      | 178     |
| rectangle | 3      | 358     |

```
>>> df.sub([1, 2], axis='columns')
```

|           | angles | degrees |
|-----------|--------|---------|
| circle    | -1     | 358     |
| triangle  | 2      | 178     |
| rectangle | 3      | 358     |

```
>>> df.sub(pd.Series([1, 1, 1], index=['circle', 'triangle', 'rectangle']),
...        axis='index')
```

|           | angles | degrees |
|-----------|--------|---------|
| circle    | -1     | 359     |
| triangle  | 2      | 179     |
| rectangle | 3      | 359     |

Multiply a DataFrame of different shape with operator version.

```
>>> other = pd.DataFrame({'angles': [0, 3, 4]},
...                        index=['circle', 'triangle', 'rectangle'])
>>> other
```

|           | angles |
|-----------|--------|
| circle    | 0      |
| triangle  | 3      |
| rectangle | 4      |

```
>>> df * other
```

|           | angles | degrees |
|-----------|--------|---------|
| circle    | 0      | NaN     |
| triangle  | 9      | NaN     |
| rectangle | 16     | NaN     |

```
>>> df.mul(other, fill_value=0)
```

|           | angles | degrees |
|-----------|--------|---------|
| circle    | 0      | 0.0     |
| triangle  | 9      | 0.0     |
| rectangle | 16     | 0.0     |

Divide by a MultiIndex by level.

```
>>> df_multindex = pd.DataFrame({'angles': [0, 3, 4, 4, 5, 6],
...                               'degrees': [360, 180, 360, 360, 540, 720]},
...                              index=[['A', 'A', 'A', 'B', 'B', 'B'],
...                                     ['circle', 'triangle', 'rectangle',
...                                      'square', 'pentagon', 'hexagon']])
>>> df_multindex
```

|   |           | angles | degrees |
|---|-----------|--------|---------|
| A | circle    | 0      | 360     |
|   | triangle  | 3      | 180     |
|   | rectangle | 4      | 360     |
| B | square    | 4      | 360     |
|   | pentagon  | 5      | 540     |
|   | hexagon   | 6      | 720     |

```
>>> df.div(df_multindex, level=1, fill_value=0)
```

|   |           | angles | degrees |
|---|-----------|--------|---------|
| A | circle    | NaN    | 1.0     |
|   | triangle  | 1.0    | 1.0     |
|   | rectangle | 1.0    | 1.0     |
| B | square    | 0.0    | 0.0     |
|   | pentagon  | 0.0    | 0.0     |
|   | hexagon   | 0.0    | 0.0     |

### pandas.DataFrame.rtruediv

`DataFrame.rtruediv(other, axis='columns', level=None, fill_value=None)`

Floating division of dataframe and other, element-wise (binary operator *rtruediv*).

Equivalent to `other / dataframe`, but with support to substitute a `fill_value` for missing data in one of the inputs. With reverse version, *truediv*.

Among flexible wrappers (*add*, *sub*, *mul*, *div*, *mod*, *pow*) to arithmetic operators: `+`, `-`, `*`, `/`, `//`, `%`, `**`.

#### Parameters

**other** [scalar, sequence, Series, or DataFrame] Any single or multiple element data structure, or list-like object.

**axis** [{0 or 'index', 1 or 'columns'}] Whether to compare by the index (0 or 'index') or columns (1 or 'columns'). For Series input, axis to match Series index on.

**level** [int or label] Broadcast across a level, matching Index values on the passed Multi-Index level.

**fill\_value** [float or None, default None] Fill existing missing (NaN) values, and any new element needed for successful DataFrame alignment, with this value before computation. If data in both corresponding DataFrame locations is missing the result will be missing.

### Returns

**DataFrame** Result of the arithmetic operation.

See also:

**DataFrame.add** Add DataFrames.

**DataFrame.sub** Subtract DataFrames.

**DataFrame.mul** Multiply DataFrames.

**DataFrame.div** Divide DataFrames (float division).

**DataFrame.truediv** Divide DataFrames (float division).

**DataFrame.floordiv** Divide DataFrames (integer division).

**DataFrame.mod** Calculate modulo (remainder after division).

**DataFrame.pow** Calculate exponential power.

### Notes

Mismatched indices will be unioned together.

### Examples

```
>>> df = pd.DataFrame({'angles': [0, 3, 4],
...                     'degrees': [360, 180, 360]},
...                     index=['circle', 'triangle', 'rectangle'])
>>> df
```

|           | angles | degrees |
|-----------|--------|---------|
| circle    | 0      | 360     |
| triangle  | 3      | 180     |
| rectangle | 4      | 360     |

Add a scalar with operator version which return the same results.

```
>>> df + 1
```

|           | angles | degrees |
|-----------|--------|---------|
| circle    | 1      | 361     |
| triangle  | 4      | 181     |
| rectangle | 5      | 361     |

```
>>> df.add(1)
      angles  degrees
circle      1     361
triangle    4     181
rectangle   5     361
```

Divide by constant with reverse version.

```
>>> df.div(10)
      angles  degrees
circle    0.0     36.0
triangle  0.3     18.0
rectangle 0.4     36.0
```

```
>>> df.rdiv(10)
      angles  degrees
circle      inf  0.027778
triangle  3.333333  0.055556
rectangle 2.500000  0.027778
```

Subtract a list and Series by axis with operator version.

```
>>> df - [1, 2]
      angles  degrees
circle     -1     358
triangle    2     178
rectangle    3     358
```

```
>>> df.sub([1, 2], axis='columns')
      angles  degrees
circle     -1     358
triangle    2     178
rectangle    3     358
```

```
>>> df.sub(pd.Series([1, 1, 1], index=['circle', 'triangle', 'rectangle']),
...        axis='index')
      angles  degrees
circle     -1     359
triangle    2     179
rectangle    3     359
```

Multiply a DataFrame of different shape with operator version.

```
>>> other = pd.DataFrame({'angles': [0, 3, 4]},
...                       index=['circle', 'triangle', 'rectangle'])
>>> other
      angles
circle      0
triangle     3
rectangle    4
```

```
>>> df * other
      angles  degrees
circle      0      NaN
triangle     9      NaN
rectangle   16      NaN
```

```
>>> df.mul(other, fill_value=0)
           angles  degrees
circle          0      0.0
triangle         9      0.0
rectangle       16      0.0
```

Divide by a MultiIndex by level.

```
>>> df_multindex = pd.DataFrame({'angles': [0, 3, 4, 4, 5, 6],
...                               'degrees': [360, 180, 360, 360, 540, 720]},
...                               index=[['A', 'A', 'A', 'B', 'B', 'B'],
...                                       ['circle', 'triangle', 'rectangle',
...                                        'square', 'pentagon', 'hexagon']])
>>> df_multindex
           angles  degrees
A circle          0      360
  triangle          3      180
  rectangle          4      360
B square           4      360
  pentagon          5      540
  hexagon           6      720
```

```
>>> df.div(df_multindex, level=1, fill_value=0)
           angles  degrees
A circle        NaN      1.0
  triangle        1.0      1.0
  rectangle        1.0      1.0
B square         0.0      0.0
  pentagon         0.0      0.0
  hexagon         0.0      0.0
```

## pandas.DataFrame.sample

`DataFrame.sample` (*n=None*, *frac=None*, *replace=False*, *weights=None*, *random\_state=None*, *axis=None*)

Return a random sample of items from an axis of object.

You can use *random\_state* for reproducibility.

### Parameters

**n** [int, optional] Number of items from axis to return. Cannot be used with *frac*. Default = 1 if *frac* = None.

**frac** [float, optional] Fraction of axis items to return. Cannot be used with *n*.

**replace** [bool, default False] Sample with or without replacement.

**weights** [str or ndarray-like, optional] Default 'None' results in equal probability weighting. If passed a Series, will align with target object on index. Index values in weights not found in sampled object will be ignored and index values in sampled object not in weights will be assigned weights of zero. If called on a DataFrame, will accept the name of a column when *axis* = 0. Unless weights are a Series, weights must be same length as axis being sampled. If weights do not sum to 1, they will be normalized to sum to 1. Missing values in the weights column will be treated as zero. Infinite values not allowed.

**random\_state** [int or numpy.random.RandomState, optional] Seed for the random number generator (if int), or numpy RandomState object.

**axis** [int or string, optional] Axis to sample. Accepts axis number or name. Default is stat axis for given data type (0 for Series and DataFrames, 1 for Panels).

### Returns

**Series or DataFrame** A new object of same type as caller containing *n* items randomly sampled from the caller object.

See also:

**numpy.random.choice** Generates a random sample from a given 1-D numpy array.

### Examples

```
>>> df = pd.DataFrame({'num_legs': [2, 4, 8, 0],
...                     'num_wings': [2, 0, 0, 0],
...                     'num_specimen_seen': [10, 2, 1, 8]},
...                     index=['falcon', 'dog', 'spider', 'fish'])
>>> df
```

|        | num_legs | num_wings | num_specimen_seen |
|--------|----------|-----------|-------------------|
| falcon | 2        | 2         | 10                |
| dog    | 4        | 0         | 2                 |
| spider | 8        | 0         | 1                 |
| fish   | 0        | 0         | 8                 |

Extract 3 random elements from the Series `df['num_legs']`: Note that we use *random\_state* to ensure the reproducibility of the examples.

```
>>> df['num_legs'].sample(n=3, random_state=1)
fish      0
spider    8
falcon    2
Name: num_legs, dtype: int64
```

A random 50% sample of the DataFrame with replacement:

```
>>> df.sample(frac=0.5, replace=True, random_state=1)
```

|      | num_legs | num_wings | num_specimen_seen |
|------|----------|-----------|-------------------|
| dog  | 4        | 0         | 2                 |
| fish | 0        | 0         | 8                 |

Using a DataFrame column as weights. Rows with larger value in the *num\_specimen\_seen* column are more likely to be sampled.

```
>>> df.sample(n=2, weights='num_specimen_seen', random_state=1)
```

|        | num_legs | num_wings | num_specimen_seen |
|--------|----------|-----------|-------------------|
| falcon | 2        | 2         | 10                |
| fish   | 0        | 0         | 8                 |

## pandas.DataFrame.select

`DataFrame.select` (*crit*, *axis=0*)

Return data corresponding to axis labels matching criteria.

Deprecated since version 0.21.0: Use `df.loc[df.index.map(crit)]` to select via labels

#### Parameters

**crit** [function] To be called on each index (label). Should return True or False

**axis** [int]

#### Returns

**selection** [same type as caller]

### `pandas.DataFrame.select_dtypes`

`DataFrame.select_dtypes` (*include=None, exclude=None*)

Return a subset of the DataFrame's columns based on the column dtypes.

#### Parameters

**include, exclude** [scalar or list-like] A selection of dtypes or strings to be included/excluded. At least one of these parameters must be supplied.

#### Returns

**subset** [DataFrame] The subset of the frame including the dtypes in *include* and excluding the dtypes in *exclude*.

#### Raises

##### **ValueError**

- If both of *include* and *exclude* are empty
- If *include* and *exclude* have overlapping elements
- If any kind of string dtype is passed in.

### Notes

- To select all *numeric* types, use `np.number` or `'number'`
- To select strings you must use the `object` dtype, but note that this will return *all* object dtype columns
- See the [numpy dtype hierarchy](#)
- To select datetimes, use `np.datetime64`, `'datetime'` or `'datetime64'`
- To select timedeltas, use `np.timedelta64`, `'timedelta'` or `'timedelta64'`
- To select Pandas categorical dtypes, use `'category'`
- To select Pandas datetimetz dtypes, use `'datetimetz'` (new in 0.20.0) or `'datetime64[ns, tz]'`

### Examples

```
>>> df = pd.DataFrame({'a': [1, 2] * 3,
...                     'b': [True, False] * 3,
...                     'c': [1.0, 2.0] * 3})
>>> df
```

|   | a | b     | c   |
|---|---|-------|-----|
| 0 | 1 | True  | 1.0 |
| 1 | 2 | False | 2.0 |
| 2 | 1 | True  | 1.0 |
| 3 | 2 | False | 2.0 |
| 4 | 1 | True  | 1.0 |
| 5 | 2 | False | 2.0 |

```
>>> df.select_dtypes(include='bool')
b
0  True
1  False
2  True
3  False
4  True
5  False
```

```
>>> df.select_dtypes(include=['float64'])
c
0  1.0
1  2.0
2  1.0
3  2.0
4  1.0
5  2.0
```

```
>>> df.select_dtypes(exclude=['int'])
b    c
0  True  1.0
1  False 2.0
2  True  1.0
3  False 2.0
4  True  1.0
5  False 2.0
```

### pandas.DataFrame.sem

DataFrame.**sem**(axis=None, skipna=None, level=None, ddof=1, numeric\_only=None, \*\*kwargs)

Return unbiased standard error of the mean over requested axis.

Normalized by N-1 by default. This can be changed using the ddof argument

#### Parameters

**axis** [{index (0), columns (1)}]

**skipna** [boolean, default True] Exclude NA/null values. If an entire row/column is NA, the result will be NA

**level** [int or level name, default None] If the axis is a MultiIndex (hierarchical), count along a particular level, collapsing into a Series

**ddof** [int, default 1] Delta Degrees of Freedom. The divisor used in calculations is  $N - \text{ddof}$ , where  $N$  represents the number of elements.

**numeric\_only** [boolean, default None] Include only float, int, boolean columns. If None, will attempt to use everything, then use only numeric data. Not implemented for Series.

#### Returns

**sem** [Series or DataFrame (if level specified)]

### pandas.DataFrame.set\_axis

`DataFrame.set_axis(labels, axis=0, inplace=None)`

Assign desired index to given axis.

Indexes for column or row labels can be changed by assigning a list-like or Index.

Changed in version 0.21.0: The signature is now *labels* and *axis*, consistent with the rest of pandas API. Previously, the *axis* and *labels* arguments were respectively the first and second positional arguments.

#### Parameters

**labels** [list-like, Index] The values for the new index.

**axis** [{0 or 'index', 1 or 'columns'}, default 0] The axis to update. The value 0 identifies the rows, and 1 identifies the columns.

**inplace** [boolean, default None] Whether to return a new *%(klass)s* instance.

**Warning:** `inplace=None` currently falls back to `True`, but in a future version, will default to `False`. Use `inplace=True` explicitly rather than relying on the default.

#### Returns

**renamed** [*%(klass)s* or None] An object of same type as caller if `inplace=False`, None otherwise.

#### See also:

**DataFrame.rename\_axis** Alter the name of the index or columns.

### Examples

#### Series

```
>>> s = pd.Series([1, 2, 3])
>>> s
0    1
1    2
2    3
dtype: int64
```

```
>>> s.set_axis(['a', 'b', 'c'], axis=0, inplace=False)
a    1
b    2
c    3
dtype: int64
```

The original object is not modified.

```
>>> s
0    1
1    2
2    3
dtype: int64
```

### DataFrame

```
>>> df = pd.DataFrame({"A": [1, 2, 3], "B": [4, 5, 6]})
```

Change the row labels.

```
>>> df.set_axis(['a', 'b', 'c'], axis='index', inplace=False)
   A  B
a  1  4
b  2  5
c  3  6
```

Change the column labels.

```
>>> df.set_axis(['I', 'II'], axis='columns', inplace=False)
   I  II
0  1   4
1  2   5
2  3   6
```

Now, update the labels inplace.

```
>>> df.set_axis(['i', 'ii'], axis='columns', inplace=True)
>>> df
   i  ii
0  1   4
1  2   5
2  3   6
```

### pandas.DataFrame.set\_index

`DataFrame.set_index(keys, drop=True, append=False, inplace=False, verify_integrity=False)`

Set the DataFrame index using existing columns.

Set the DataFrame index (row labels) using one or more existing columns. The index can replace the existing index or expand on it.

#### Parameters

**keys** [label or list of label] Name or names of the columns that will be used as the index.

**drop** [bool, default True] Delete columns to be used as the new index.

**append** [bool, default False] Whether to append columns to existing index.

**inplace** [bool, default False] Modify the DataFrame in place (do not create a new object).

**verify\_integrity** [bool, default False] Check the new index for duplicates. Otherwise defer the check until necessary. Setting to False will improve the performance of this method.

### Returns

**DataFrame** Changed row labels.

### See also:

**DataFrame.reset\_index** Opposite of set\_index.

**DataFrame.reindex** Change to new indices or expand indices.

**DataFrame.reindex\_like** Change to same indices as other DataFrame.

### Examples

```
>>> df = pd.DataFrame({'month': [1, 4, 7, 10],
...                     'year': [2012, 2014, 2013, 2014],
...                     'sale': [55, 40, 84, 31]})
>>> df
   month  year  sale
0      1  2012    55
1      4  2014    40
2      7  2013    84
3     10  2014    31
```

Set the index to become the ‘month’ column:

```
>>> df.set_index('month')
   year  sale
month
1     2012    55
4     2014    40
7     2013    84
10    2014    31
```

Create a multi-index using columns ‘year’ and ‘month’:

```
>>> df.set_index(['year', 'month'])
   sale
year month
2012  1     55
2014  4     40
2013  7     84
2014 10     31
```

Create a multi-index using a set of values and a column:

```
>>> df.set_index([[1, 2, 3, 4], 'year'])
   month  sale
year
1  2012  1     55
2  2014  4     40
3  2013  7     84
4  2014 10     31
```

## pandas.DataFrame.set\_value

`DataFrame.set_value(index, col, value, takeable=False)`

Put single value at passed column and index.

Deprecated since version 0.21.0: Use `.at[]` or `.iat[]` accessors instead.

### Parameters

**index** [row label]

**col** [column label]

**value** [scalar value]

**takeable** [interpret the index/col as indexers, default False]

### Returns

**frame** [DataFrame] If label pair is contained, will be reference to calling DataFrame, otherwise a new object

## pandas.DataFrame.shift

`DataFrame.shift(periods=1, freq=None, axis=0, fill_value=None)`

Shift index by desired number of periods with an optional time *freq*.

When *freq* is not passed, shift the index without realigning the data. If *freq* is passed (in this case, the index must be date or datetime, or it will raise a *NotImplementedError*), the index will be increased using the periods and the *freq*.

### Parameters

**periods** [int] Number of periods to shift. Can be positive or negative.

**freq** [DateOffset, tseries.offsets, timedelta, or str, optional] Offset to use from the tseries module or time rule (e.g. 'EOM'). If *freq* is specified then the index values are shifted but the data is not realigned. That is, use *freq* if you would like to extend the index when shifting and preserve the original data.

**axis** [{0 or 'index', 1 or 'columns', None}, default None] Shift direction.

**fill\_value** [object, optional] The scalar value to use for newly introduced missing values. the default depends on the dtype of *self*. For numeric data, `np.nan` is used. For datetime, timedelta, or period data, etc. `NaT` is used. For extension dtypes, `self.dtype.na_value` is used.

Changed in version 0.24.0.

### Returns

**DataFrame** Copy of input object, shifted.

See also:

**Index.shift** Shift values of Index.

**DatetimeIndex.shift** Shift values of DatetimeIndex.

**PeriodIndex.shift** Shift values of PeriodIndex.

**tshift** Shift the time index, using the index's frequency if available.

## Examples

```
>>> df = pd.DataFrame({'Col1': [10, 20, 15, 30, 45],
...                     'Col2': [13, 23, 18, 33, 48],
...                     'Col3': [17, 27, 22, 37, 52]})
```

```
>>> df.shift(periods=3)
   Col1  Col2  Col3
0   NaN   NaN   NaN
1   NaN   NaN   NaN
2   NaN   NaN   NaN
3  10.0  13.0  17.0
4  20.0  23.0  27.0
```

```
>>> df.shift(periods=1, axis='columns')
   Col1  Col2  Col3
0   NaN  10.0  13.0
1   NaN  20.0  23.0
2   NaN  15.0  18.0
3   NaN  30.0  33.0
4   NaN  45.0  48.0
```

```
>>> df.shift(periods=3, fill_value=0)
   Col1  Col2  Col3
0     0     0     0
1     0     0     0
2     0     0     0
3    10    13    17
4    20    23    27
```

## pandas.DataFrame.skew

`DataFrame.skew` (*axis=None, skipna=None, level=None, numeric\_only=None, \*\*kwargs*)

Return unbiased skew over requested axis Normalized by N-1.

### Parameters

**axis** [{index (0), columns (1)}] Axis for the function to be applied on.

**skipna** [bool, default True] Exclude NA/null values when computing the result.

**level** [int or level name, default None] If the axis is a MultiIndex (hierarchical), count along a particular level, collapsing into a Series.

**numeric\_only** [bool, default None] Include only float, int, boolean columns. If None, will attempt to use everything, then use only numeric data. Not implemented for Series.

**\*\*kwargs** Additional keyword arguments to be passed to the function.

### Returns

**skew** [Series or DataFrame (if level specified)]

**pandas.DataFrame.slice\_shift**`DataFrame.slice_shift` (*periods=1, axis=0*)

Equivalent to *shift* without copying data. The shifted data will not include the dropped periods and the shifted axis will be smaller than the original.

**Parameters**

**periods** [int] Number of periods to move, can be positive or negative

**Returns**

**shifted** [same type as caller]

**Notes**

While the *slice\_shift* is faster than *shift*, you may pay for it later during alignment.

**pandas.DataFrame.sort\_index**

`DataFrame.sort_index` (*axis=0, level=None, ascending=True, inplace=False, kind='quicksort', na\_position='last', sort\_remaining=True, by=None*)

Sort object by labels (along an axis)

**Parameters**

**axis** [index, columns to direct sorting]

**level** [int or level name or list of ints or list of level names] if not None, sort on values in specified index level(s)

**ascending** [boolean, default True] Sort ascending vs. descending

**inplace** [bool, default False] if True, perform operation in-place

**kind** [{ 'quicksort', 'mergesort', 'heapsort' }, default 'quicksort'] Choice of sorting algorithm. See also `ndarray.sort` for more information. *mergesort* is the only stable algorithm. For DataFrames, this option is only applied when sorting on a single column or label.

**na\_position** [{ 'first', 'last' }, default 'last'] *first* puts NaNs at the beginning, *last* puts NaNs at the end. Not implemented for MultiIndex.

**sort\_remaining** [bool, default True] if true and sorting by level and index is multilevel, sort by other levels too (in order) after sorting by specified level

**Returns**

**sorted\_obj** [DataFrame]

**pandas.DataFrame.sort\_values**

`DataFrame.sort_values` (*by, axis=0, ascending=True, inplace=False, kind='quicksort', na\_position='last'*)

Sort by the values along either axis

**Parameters**

**by** [str or list of str] Name or list of names to sort by.

- if *axis* is 0 or *'index'* then *by* may contain index levels and/or column labels
- if *axis* is 1 or *'columns'* then *by* may contain column levels and/or index labels

Changed in version 0.23.0: Allow specifying index or column level names.

**axis** [{0 or *'index'*, 1 or *'columns'*}, default 0] Axis to be sorted

**ascending** [bool or list of bool, default True] Sort ascending vs. descending. Specify list for multiple sort orders. If this is a list of bools, must match the length of the *by*.

**inplace** [bool, default False] if True, perform operation in-place

**kind** [{*'quicksort'*, *'mergesort'*, *'heapsort'*}, default *'quicksort'*] Choice of sorting algorithm. See also `ndarray.sort` for more information. *mergesort* is the only stable algorithm. For DataFrames, this option is only applied when sorting on a single column or label.

**na\_position** [{*'first'*, *'last'*}, default *'last'*] *first* puts NaNs at the beginning, *last* puts NaNs at the end

### Returns

**sorted\_obj** [DataFrame]

### Examples

```
>>> df = pd.DataFrame({
...     'col1' : ['A', 'A', 'B', np.nan, 'D', 'C'],
...     'col2' : [2, 1, 9, 8, 7, 4],
...     'col3': [0, 1, 9, 4, 2, 3],
... })
>>> df
   col1  col2  col3
0    A     2     0
1    A     1     1
2    B     9     9
3  NaN     8     4
4    D     7     2
5    C     4     3
```

#### Sort by col1

```
>>> df.sort_values(by=['col1'])
   col1  col2  col3
0    A     2     0
1    A     1     1
2    B     9     9
5    C     4     3
4    D     7     2
3  NaN     8     4
```

#### Sort by multiple columns

```
>>> df.sort_values(by=['col1', 'col2'])
   col1  col2  col3
1    A     1     1
0    A     2     0
2    B     9     9
```

(continues on next page)

(continued from previous page)

|   |     |   |   |
|---|-----|---|---|
| 5 | C   | 4 | 3 |
| 4 | D   | 7 | 2 |
| 3 | NaN | 8 | 4 |

### Sort Descending

```
>>> df.sort_values(by='col1', ascending=False)
   col1 col2 col3
4    D     7     2
5    C     4     3
2    B     9     9
0    A     2     0
1    A     1     1
3  NaN     8     4
```

### Putting NAs first

```
>>> df.sort_values(by='col1', ascending=False, na_position='first')
   col1 col2 col3
3  NaN     8     4
4    D     7     2
5    C     4     3
2    B     9     9
0    A     2     0
1    A     1     1
```

## pandas.DataFrame.squeeze

`DataFrame.squeeze` (*axis=None*)

Squeeze 1 dimensional axis objects into scalars.

Series or DataFrames with a single element are squeezed to a scalar. DataFrames with a single column or a single row are squeezed to a Series. Otherwise the object is unchanged.

This method is most useful when you don't know if your object is a Series or DataFrame, but you do know it has just a single column. In that case you can safely call *squeeze* to ensure you have a Series.

### Parameters

**axis** [{0 or 'index', 1 or 'columns', None}, default None] A specific axis to squeeze. By default, all length-1 axes are squeezed.

New in version 0.20.0.

### Returns

**DataFrame, Series, or scalar** The projection after squeezing *axis* or all the axes.

### See also:

**Series.iloc** Integer-location based indexing for selecting scalars.

**DataFrame.iloc** Integer-location based indexing for selecting Series.

**Series.to\_frame** Inverse of DataFrame.squeeze for a single-column DataFrame.

## Examples

```
>>> primes = pd.Series([2, 3, 5, 7])
```

Slicing might produce a Series with a single value:

```
>>> even_primes = primes[primes % 2 == 0]
>>> even_primes
0    2
dtype: int64
```

```
>>> even_primes.squeeze()
2
```

Squeezing objects with more than one value in every axis does nothing:

```
>>> odd_primes = primes[primes % 2 == 1]
>>> odd_primes
1    3
2    5
3    7
dtype: int64
```

```
>>> odd_primes.squeeze()
1    3
2    5
3    7
dtype: int64
```

Squeezing is even more effective when used with DataFrames.

```
>>> df = pd.DataFrame([[1, 2], [3, 4]], columns=['a', 'b'])
>>> df
   a  b
0  1  2
1  3  4
```

Slicing a single column will produce a DataFrame with the columns having only one value:

```
>>> df_a = df[['a']]
>>> df_a
   a
0  1
1  3
```

So the columns can be squeezed down, resulting in a Series:

```
>>> df_a.squeeze('columns')
0    1
1    3
Name: a, dtype: int64
```

Slicing a single row from a single column will produce a single scalar DataFrame:

```
>>> df_0a = df.loc[df.index < 1, ['a']]
>>> df_0a
```

(continues on next page)

(continued from previous page)

```
a
0  1
```

Squeezing the rows produces a single scalar Series:

```
>>> df_0a.squeeze('rows')
a      1
Name: 0, dtype: int64
```

Squeezing all axes will project directly into a scalar:

```
>>> df_0a.squeeze()
1
```

## pandas.DataFrame.stack

`DataFrame.stack` (*level=-1, dropna=True*)

Stack the prescribed level(s) from columns to index.

Return a reshaped DataFrame or Series having a multi-level index with one or more new inner-most levels compared to the current DataFrame. The new inner-most levels are created by pivoting the columns of the current dataframe:

- if the columns have a single level, the output is a Series;
- if the columns have multiple levels, the new index level(s) is (are) taken from the prescribed level(s) and the output is a DataFrame.

The new index levels are sorted.

### Parameters

**level** [int, str, list, default -1] Level(s) to stack from the column axis onto the index axis, defined as one index or label, or a list of indices or labels.

**dropna** [bool, default True] Whether to drop rows in the resulting Frame/Series with missing values. Stacking a column level onto the index axis can create combinations of index and column values that are missing from the original dataframe. See Examples section.

### Returns

**DataFrame or Series** Stacked dataframe or series.

See also:

**DataFrame.unstack** Unstack prescribed level(s) from index axis onto column axis.

**DataFrame.pivot** Reshape dataframe from long format to wide format.

**DataFrame.pivot\_table** Create a spreadsheet-style pivot table as a DataFrame.

## Notes

The function is named by analogy with a collection of books being re-organised from being side by side on a horizontal position (the columns of the dataframe) to being stacked vertically on top of each other (in the index of the dataframe).

## Examples

### Single level columns

```
>>> df_single_level_cols = pd.DataFrame([[0, 1], [2, 3]],
...                                     index=['cat', 'dog'],
...                                     columns=['weight', 'height'])
```

Stacking a dataframe with a single level column axis returns a Series:

```
>>> df_single_level_cols
   weight height
cat      0      1
dog      2      3
>>> df_single_level_cols.stack()
cat weight      0
   height      1
dog weight      2
   height      3
dtype: int64
```

### Multi level columns: simple case

```
>>> multicol1 = pd.MultiIndex.from_tuples([('weight', 'kg'),
...                                       ('weight', 'pounds')])
>>> df_multi_level_cols1 = pd.DataFrame([[1, 2], [2, 4]],
...                                     index=['cat', 'dog'],
...                                     columns=multicol1)
```

Stacking a dataframe with a multi-level column axis:

```
>>> df_multi_level_cols1
   weight
   kg    pounds
cat    1         2
dog    2         4
>>> df_multi_level_cols1.stack()
   weight
cat kg      1
   pounds      2
dog kg      2
   pounds      4
```

### Missing values

```
>>> multicol2 = pd.MultiIndex.from_tuples([('weight', 'kg'),
...                                       ('height', 'm')])
>>> df_multi_level_cols2 = pd.DataFrame([[1.0, 2.0], [3.0, 4.0]],
...                                     index=['cat', 'dog'],
...                                     columns=multicol2)
```

It is common to have missing values when stacking a dataframe with multi-level columns, as the stacked dataframe typically has more values than the original dataframe. Missing values are filled with NaNs:

```
>>> df_multi_level_cols2
   weight height
   kg      m
```

(continues on next page)

(continued from previous page)

```

cat    1.0    2.0
dog    3.0    4.0
>>> df_multi_level_cols2.stack()
      height  weight
cat kg      NaN    1.0
   m      2.0    NaN
dog kg      NaN    3.0
   m      4.0    NaN

```

**Prescribing the level(s) to be stacked**

The first parameter controls which level or levels are stacked:

```

>>> df_multi_level_cols2.stack(0)
      kg      m
cat height NaN  2.0
   weight 1.0 NaN
dog height NaN  4.0
   weight 3.0 NaN
>>> df_multi_level_cols2.stack([0, 1])
cat height m      2.0
   weight kg      1.0
dog height m      4.0
   weight kg      3.0
dtype: float64

```

**Dropping missing values**

```

>>> df_multi_level_cols3 = pd.DataFrame([[None, 1.0], [2.0, 3.0]],
...                                     index=['cat', 'dog'],
...                                     columns=multicol2)

```

Note that rows where all values are missing are dropped by default but this behaviour can be controlled via the `dropna` keyword parameter:

```

>>> df_multi_level_cols3
      weight height
      kg      m
cat    NaN    1.0
dog    2.0    3.0
>>> df_multi_level_cols3.stack(dropna=False)
      height  weight
cat kg      NaN    NaN
   m      1.0    NaN
dog kg      NaN    2.0
   m      3.0    NaN
>>> df_multi_level_cols3.stack(dropna=True)
      height  weight
cat m      1.0    NaN
dog kg      NaN    2.0
   m      3.0    NaN

```

**pandas.DataFrame.std**

`DataFrame.std` (*axis=None, skipna=None, level=None, ddof=1, numeric\_only=None, \*\*kwargs*)  
 Return sample standard deviation over requested axis.

Normalized by N-1 by default. This can be changed using the `ddof` argument

#### Parameters

**axis** [{index (0), columns (1)}]

**skipna** [boolean, default True] Exclude NA/null values. If an entire row/column is NA, the result will be NA

**level** [int or level name, default None] If the axis is a MultiIndex (hierarchical), count along a particular level, collapsing into a Series

**ddof** [int, default 1] Delta Degrees of Freedom. The divisor used in calculations is N - ddof, where N represents the number of elements.

**numeric\_only** [boolean, default None] Include only float, int, boolean columns. If None, will attempt to use everything, then use only numeric data. Not implemented for Series.

#### Returns

**std** [Series or DataFrame (if level specified)]

### pandas.DataFrame.sub

`DataFrame.sub(other, axis='columns', level=None, fill_value=None)`

Subtraction of dataframe and other, element-wise (binary operator *sub*).

Equivalent to `dataframe - other`, but with support to substitute a `fill_value` for missing data in one of the inputs. With reverse version, *rsub*.

Among flexible wrappers (*add*, *sub*, *mul*, *div*, *mod*, *pow*) to arithmetic operators: `+`, `-`, `*`, `/`, `//`, `%`, `**`.

#### Parameters

**other** [scalar, sequence, Series, or DataFrame] Any single or multiple element data structure, or list-like object.

**axis** [{0 or 'index', 1 or 'columns'}] Whether to compare by the index (0 or 'index') or columns (1 or 'columns'). For Series input, axis to match Series index on.

**level** [int or label] Broadcast across a level, matching Index values on the passed Multi-Index level.

**fill\_value** [float or None, default None] Fill existing missing (NaN) values, and any new element needed for successful DataFrame alignment, with this value before computation. If data in both corresponding DataFrame locations is missing the result will be missing.

#### Returns

**DataFrame** Result of the arithmetic operation.

See also:

**DataFrame.add** Add DataFrames.

**DataFrame.sub** Subtract DataFrames.

**DataFrame.mul** Multiply DataFrames.

**DataFrame.div** Divide DataFrames (float division).

**DataFrame.truediv** Divide DataFrames (float division).

**DataFrame.floordiv** Divide DataFrames (integer division).

**DataFrame.mod** Calculate modulo (remainder after division).

**DataFrame.pow** Calculate exponential power.

## Notes

Mismatched indices will be unioned together.

## Examples

```
>>> df = pd.DataFrame({'angles': [0, 3, 4],
...                     'degrees': [360, 180, 360]},
...                     index=['circle', 'triangle', 'rectangle'])
>>> df
```

|           | angles | degrees |
|-----------|--------|---------|
| circle    | 0      | 360     |
| triangle  | 3      | 180     |
| rectangle | 4      | 360     |

Add a scalar with operator version which return the same results.

```
>>> df + 1
```

|           | angles | degrees |
|-----------|--------|---------|
| circle    | 1      | 361     |
| triangle  | 4      | 181     |
| rectangle | 5      | 361     |

```
>>> df.add(1)
```

|           | angles | degrees |
|-----------|--------|---------|
| circle    | 1      | 361     |
| triangle  | 4      | 181     |
| rectangle | 5      | 361     |

Divide by constant with reverse version.

```
>>> df.div(10)
```

|           | angles | degrees |
|-----------|--------|---------|
| circle    | 0.0    | 36.0    |
| triangle  | 0.3    | 18.0    |
| rectangle | 0.4    | 36.0    |

```
>>> df.rdiv(10)
```

|           | angles   | degrees  |
|-----------|----------|----------|
| circle    | inf      | 0.027778 |
| triangle  | 3.333333 | 0.055556 |
| rectangle | 2.500000 | 0.027778 |

Subtract a list and Series by axis with operator version.

```
>>> df - [1, 2]
```

|           | angles | degrees |
|-----------|--------|---------|
| circle    | -1     | 358     |
| triangle  | 2      | 178     |
| rectangle | 3      | 358     |

```
>>> df.sub([1, 2], axis='columns')
      angles  degrees
circle      -1     358
triangle     2     178
rectangle    3     358
```

```
>>> df.sub(pd.Series([1, 1, 1], index=['circle', 'triangle', 'rectangle']),
...        axis='index')
      angles  degrees
circle      -1     359
triangle     2     179
rectangle    3     359
```

Multiply a DataFrame of different shape with operator version.

```
>>> other = pd.DataFrame({'angles': [0, 3, 4]},
...                        index=['circle', 'triangle', 'rectangle'])
>>> other
      angles
circle      0
triangle     3
rectangle    4
```

```
>>> df * other
      angles  degrees
circle      0      NaN
triangle     9      NaN
rectangle   16      NaN
```

```
>>> df.mul(other, fill_value=0)
      angles  degrees
circle      0      0.0
triangle     9      0.0
rectangle   16      0.0
```

Divide by a MultiIndex by level.

```
>>> df_multindex = pd.DataFrame({'angles': [0, 3, 4, 4, 5, 6],
...                               'degrees': [360, 180, 360, 360, 540, 720]},
...                               index=[['A', 'A', 'A', 'B', 'B', 'B'],
...                                       ['circle', 'triangle', 'rectangle',
...                                        'square', 'pentagon', 'hexagon']])
>>> df_multindex
      angles  degrees
A circle      0     360
  triangle     3     180
  rectangle     4     360
B square      4     360
  pentagon     5     540
  hexagon      6     720
```

```
>>> df.div(df_multindex, level=1, fill_value=0)
      angles  degrees
A circle      NaN     1.0
  triangle     1.0     1.0
  rectangle     1.0     1.0
```

(continues on next page)

(continued from previous page)

|          |     |     |
|----------|-----|-----|
| B square | 0.0 | 0.0 |
| pentagon | 0.0 | 0.0 |
| hexagon  | 0.0 | 0.0 |

**pandas.DataFrame.subtract**`DataFrame.subtract` (*other*, *axis*='columns', *level*=None, *fill\_value*=None)Subtraction of dataframe and other, element-wise (binary operator *sub*).Equivalent to `dataframe - other`, but with support to substitute a *fill\_value* for missing data in one of the inputs. With reverse version, *rsub*.Among flexible wrappers (*add*, *sub*, *mul*, *div*, *mod*, *pow*) to arithmetic operators: +, -, \*, /, //, %, \*\*.**Parameters****other** [scalar, sequence, Series, or DataFrame] Any single or multiple element data structure, or list-like object.**axis** [{0 or 'index', 1 or 'columns'}] Whether to compare by the index (0 or 'index') or columns (1 or 'columns'). ## Examples

```
>>> df = pd.DataFrame({'angles': [0, 3, 4],
...                     'degrees': [360, 180, 360]},
...                     index=['circle', 'triangle', 'rectangle'])
>>> df
```

|           | angles | degrees |
|-----------|--------|---------|
| circle    | 0      | 360     |
| triangle  | 3      | 180     |
| rectangle | 4      | 360     |

Add a scalar with operator version which return the same results.

```
>>> df + 1
```

|           | angles | degrees |
|-----------|--------|---------|
| circle    | 1      | 361     |
| triangle  | 4      | 181     |
| rectangle | 5      | 361     |

```
>>> df.add(1)
```

|           | angles | degrees |
|-----------|--------|---------|
| circle    | 1      | 361     |
| triangle  | 4      | 181     |
| rectangle | 5      | 361     |

Divide by constant with reverse version.

```
>>> df.div(10)
```

|           | angles | degrees |
|-----------|--------|---------|
| circle    | 0.0    | 36.0    |
| triangle  | 0.3    | 18.0    |
| rectangle | 0.4    | 36.0    |

```
>>> df.rdiv(10)
```

|           | angles   | degrees  |
|-----------|----------|----------|
| circle    | inf      | 0.027778 |
| triangle  | 3.333333 | 0.055556 |
| rectangle | 2.500000 | 0.027778 |

Subtract a list and Series by axis with operator version.

```
>>> df - [1, 2]
```

|           | angles | degrees |
|-----------|--------|---------|
| circle    | -1     | 358     |
| triangle  | 2      | 178     |
| rectangle | 3      | 358     |

```
>>> df.sub([1, 2], axis='columns')
```

|           | angles | degrees |
|-----------|--------|---------|
| circle    | -1     | 358     |
| triangle  | 2      | 178     |
| rectangle | 3      | 358     |

```
>>> df.sub(pd.Series([1, 1, 1], index=['circle', 'triangle', 'rectangle']),
...        axis='index')
```

|  | angles | degrees |
|--|--------|---------|
|--|--------|---------|

(continues on next page)

(continued from previous page)

|           |    |     |
|-----------|----|-----|
| circle    | -1 | 359 |
| triangle  | 2  | 179 |
| rectangle | 3  | 359 |

Multiply a DataFrame of different shape with operator version.

```
>>> other = pd.DataFrame({'angles': [0, 3, 4]},
...                        index=['circle', 'triangle', 'rectangle'])
>>> other
```

|           | angles |
|-----------|--------|
| circle    | 0      |
| triangle  | 3      |
| rectangle | 4      |

```
>>> df * other
```

|           | angles | degrees |
|-----------|--------|---------|
| circle    | 0      | NaN     |
| triangle  | 9      | NaN     |
| rectangle | 16     | NaN     |

```
>>> df.mul(other, fill_value=0)
```

|           | angles | degrees |
|-----------|--------|---------|
| circle    | 0      | 0.0     |
| triangle  | 9      | 0.0     |
| rectangle | 16     | 0.0     |

Divide by a MultiIndex by level.

```
>>> df_multindex = pd.DataFrame({'angles': [0, 3, 4, 4, 5, 6],
...                              'degrees': [360, 180, 360, 360, 540, 720]},
...                              index=[['A', 'A', 'A', 'B', 'B', 'B'],
...                                    ['circle', 'triangle', 'rectangle',
...                                     'square', 'pentagon', 'hexagon']])
>>> df_multindex
```

|   |           | angles | degrees |
|---|-----------|--------|---------|
| A | circle    | 0      | 360     |
|   | triangle  | 3      | 180     |
|   | rectangle | 4      | 360     |
| B | square    | 4      | 360     |
|   | pentagon  | 5      | 540     |
|   | hexagon   | 6      | 720     |

```
>>> df.div(df_multindex, level=1, fill_value=0)
```

|   |           | angles | degrees |
|---|-----------|--------|---------|
| A | circle    | NaN    | 1.0     |
|   | triangle  | 1.0    | 1.0     |
|   | rectangle | 1.0    | 1.0     |
| B | square    | 0.0    | 0.0     |
|   | pentagon  | 0.0    | 0.0     |
|   | hexagon   | 0.0    | 0.0     |

## pandas.DataFrame.sum

`DataFrame.sum(axis=None, skipna=None, level=None, numeric_only=None, min_count=0, **kwargs)`

Return the sum of the values for the requested axis.

This is equivalent to the method `numpy.sum`.

### Parameters

**axis** [{index (0), columns (1)}] Axis for the function to be applied on.

**skipna** [bool, default True] Exclude NA/null values when computing the result.

**level** [int or level name, default None] If the axis is a MultiIndex (hierarchical), count along a particular level, collapsing into a Series.

**numeric\_only** [bool, default None] Include only float, int, boolean columns. If None, will attempt to use everything, then use only numeric data. Not implemented for Series.

**min\_count** [int, default 0] The required number of valid values to perform the operation. If fewer than `min_count` non-NA values are present the result will be NA.

New in version 0.22.0: Added with the default being 0. This means the sum of an all-NA or empty Series is 0, and the product of an all-NA or empty Series is 1.

**\*\*kwargs** Additional keyword arguments to be passed to the function.

### Returns

**sum** [Series or DataFrame (if level specified)]

See also:

**Series.sum** Return the sum.

**Series.min** Return the minimum.

**Series.max** Return the maximum.

**Series.idxmin** Return the index of the minimum.

**Series.idxmax** Return the index of the maximum.

**DataFrame.min** Return the sum over the requested axis.

**DataFrame.min** Return the minimum over the requested axis.

**DataFrame.max** Return the maximum over the requested axis.

**DataFrame.idxmin** Return the index of the minimum over the requested axis.

**DataFrame.idxmax** Return the index of the maximum over the requested axis.

### Examples

```
>>> idx = pd.MultiIndex.from_arrays([
...     ['warm', 'warm', 'cold', 'cold'],
...     ['dog', 'falcon', 'fish', 'spider']],
...     names=['blooded', 'animal'])
>>> s = pd.Series([4, 2, 0, 8], name='legs', index=idx)
```

(continues on next page)

(continued from previous page)

```
>>> s
blooded  animal
warm     dog      4
         falcon   2
cold     fish     0
         spider   8
Name: legs, dtype: int64
```

```
>>> s.sum()
14
```

Sum using level names, as well as indices.

```
>>> s.sum(level='blooded')
blooded
warm     6
cold     8
Name: legs, dtype: int64
```

```
>>> s.sum(level=0)
blooded
warm     6
cold     8
Name: legs, dtype: int64
```

By default, the sum of an empty or all-NA Series is 0.

```
>>> pd.Series([]).sum() # min_count=0 is the default
0.0
```

This can be controlled with the `min_count` parameter. For example, if you'd like the sum of an empty series to be NaN, pass `min_count=1`.

```
>>> pd.Series([]).sum(min_count=1)
nan
```

Thanks to the `skipna` parameter, `min_count` handles all-NA and empty series identically.

```
>>> pd.Series([np.nan]).sum()
0.0
```

```
>>> pd.Series([np.nan]).sum(min_count=1)
nan
```

## pandas.DataFrame.swapaxes

`DataFrame.swapaxes` (*axis1*, *axis2*, *copy=True*)

Interchange axes and swap values axes appropriately.

### Returns

**y** [same as input]

## pandas.DataFrame.swaplevel

`DataFrame.swaplevel` (*i*=-2, *j*=-1, *axis*=0)

Swap levels *i* and *j* in a MultiIndex on a particular axis.

### Parameters

**i, j** [int, string (can be mixed)] Level of index to be swapped. Can pass level name as string.

### Returns

**swapped** [same type as caller (new object)]

.. **versionchanged:: 0.18.1** The indexes *i* and *j* are now optional, and default to the two innermost levels of the index.

## pandas.DataFrame.tail

`DataFrame.tail` (*n*=5)

Return the last *n* rows.

This function returns last *n* rows from the object based on position. It is useful for quickly verifying data, for example, after sorting or appending rows.

### Parameters

**n** [int, default 5] Number of rows to select.

### Returns

**type of caller** The last *n* rows of the caller object.

**See also:**

**DataFrame.head** The first *n* rows of the caller object.

## Examples

```
>>> df = pd.DataFrame({'animal': ['alligator', 'bee', 'falcon', 'lion',
...                               'monkey', 'parrot', 'shark', 'whale', 'zebra']})
>>> df
   animal
0  alligator
1      bee
2   falcon
3     lion
4   monkey
5   parrot
6    shark
7    whale
8    zebra
```

Viewing the last 5 lines

```
>>> df.tail()
   animal
4  monkey
```

(continues on next page)

(continued from previous page)

```

5  parrot
6  shark
7  whale
8  zebra

```

Viewing the last  $n$  lines (three in this case)

```

>>> df.tail(3)
      animal
6    shark
7    whale
8    zebra

```

## pandas.DataFrame.take

`DataFrame.take` (*indices*, *axis=0*, *convert=None*, *is\_copy=True*, *\*\*kwargs*)

Return the elements in the given *positional* indices along an axis.

This means that we are not indexing according to actual values in the index attribute of the object. We are indexing according to the actual position of the element in the object.

### Parameters

**indices** [array-like] An array of ints indicating which positions to take.

**axis** [{0 or 'index', 1 or 'columns', None}, default 0] The axis on which to select elements. 0 means that we are selecting rows, 1 means that we are selecting columns.

**convert** [bool, default True] Whether to convert negative indices into positive ones. For example,  $-1$  would map to the `len(axis) - 1`. The conversions are similar to the behavior of indexing a regular Python list.

Deprecated since version 0.21.0: In the future, negative indices will always be converted.

**is\_copy** [bool, default True] Whether to return a copy of the original object or not.

**\*\*kwargs** For compatibility with `numpy.take()`. Has no effect on the output.

### Returns

**taken** [same type as caller] An array-like containing the elements taken from the object.

See also:

**DataFrame.loc** Select a subset of a DataFrame by labels.

**DataFrame.iloc** Select a subset of a DataFrame by positions.

**numpy.take** Take elements from an array along an axis.

## Examples

```

>>> df = pd.DataFrame([('falcon', 'bird', 389.0),
...                     ('parrot', 'bird', 24.0),
...                     ('lion', 'mammal', 80.5),
...                     ('monkey', 'mammal', np.nan)],

```

(continues on next page)

(continued from previous page)

```

...         columns=['name', 'class', 'max_speed'],
...         index=[0, 2, 3, 1])
>>> df
   name  class  max_speed
0  falcon   bird    389.0
2  parrot   bird     24.0
3   lion  mammal     80.5
1  monkey  mammal      NaN

```

Take elements at positions 0 and 3 along the axis 0 (default).

Note how the actual indices selected (0 and 1) do not correspond to our selected indices 0 and 3. That's because we are selecting the 0th and 3rd rows, not rows whose indices equal 0 and 3.

```

>>> df.take([0, 3])
   name  class  max_speed
0  falcon   bird    389.0
1  monkey  mammal      NaN

```

Take elements at indices 1 and 2 along the axis 1 (column selection).

```

>>> df.take([1, 2], axis=1)
   class  max_speed
0   bird    389.0
2   bird     24.0
3  mammal     80.5
1  mammal      NaN

```

We may take elements using negative integers for positive indices, starting from the end of the object, just like with Python lists.

```

>>> df.take([-1, -2])
   name  class  max_speed
1  monkey  mammal      NaN
3   lion  mammal     80.5

```

## pandas.DataFrame.to\_clipboard

`DataFrame.to_clipboard(excel=True, sep=None, **kwargs)`

Copy object to the system clipboard.

Write a text representation of object to the system clipboard. This can be pasted into Excel, for example.

### Parameters

**excel** [bool, default True]

- True, use the provided separator, writing in a csv format for allowing easy pasting into excel.
- False, write a string representation of the object to the clipboard.

**sep** [str, default '\t'] Field delimiter.

**\*\*kwargs** These parameters will be passed to `DataFrame.to_csv`.

See also:

**DataFrame.to\_csv** Write a DataFrame to a comma-separated values (csv) file.

**read\_clipboard** Read text from clipboard and pass to read\_table.

## Notes

Requirements for your platform.

- Linux : *xclip*, or *xsel* (with *gtk* or *PyQt4* modules)
- Windows : none
- OS X : none

## Examples

Copy the contents of a DataFrame to the clipboard.

```
>>> df = pd.DataFrame([[1, 2, 3], [4, 5, 6]], columns=['A', 'B', 'C'])
>>> df.to_clipboard(sep=',')
... # Wrote the following to the system clipboard:
... # ,A,B,C
... # 0,1,2,3
... # 1,4,5,6
```

We can omit the the index by passing the keyword *index* and setting it to false.

```
>>> df.to_clipboard(sep=',', index=False)
... # Wrote the following to the system clipboard:
... # A,B,C
... # 1,2,3
... # 4,5,6
```

## pandas.DataFrame.to\_csv

**DataFrame.to\_csv** (*path\_or\_buf=None*, *sep=','*, *na\_rep=""*, *float\_format=None*, *columns=None*, *header=True*, *index=True*, *index\_label=None*, *mode='w'*, *encoding=None*, *compression='infer'*, *quoting=None*, *quotechar='"'*, *line\_terminator=None*, *chunksize=None*, *tupleize\_cols=None*, *date\_format=None*, *doublequote=True*, *escapechar=None*, *decimal='.'*)

Write object to a comma-separated values (csv) file.

Changed in version 0.24.0: The order of arguments for Series was changed.

### Parameters

**path\_or\_buf** [str or file handle, default None] File path or object, if None is provided the result is returned as a string.

Changed in version 0.24.0: Was previously named “path” for Series.

**sep** [str, default ','] String of length 1. Field delimiter for the output file.

**na\_rep** [str, default ''] Missing data representation.

**float\_format** [str, default None] Format string for floating point numbers.

**columns** [sequence, optional] Columns to write.

**header** [bool or list of str, default True] Write out the column names. If a list of strings is given it is assumed to be aliases for the column names.

Changed in version 0.24.0: Previously defaulted to False for Series.

**index** [bool, default True] Write row names (index).

**index\_label** [str or sequence, or False, default None] Column label for index column(s) if desired. If None is given, and *header* and *index* are True, then the index names are used. A sequence should be given if the object uses MultiIndex. If False do not print fields for index names. Use *index\_label=False* for easier importing in R.

**mode** [str] Python write mode, default 'w'.

**encoding** [str, optional] A string representing the encoding to use in the output file, defaults to 'ascii' on Python 2 and 'utf-8' on Python 3.

**compression** [str, default 'infer'] Compression mode among the following possible values: {'infer', 'gzip', 'bz2', 'zip', 'xz', None}. If 'infer' and *path\_or\_buf* is path-like, then detect compression from the following extensions: '.gz', '.bz2', '.zip' or '.xz'. (otherwise no compression).

Changed in version 0.24.0: 'infer' option added and set to default.

**quoting** [optional constant from csv module] Defaults to csv.QUOTE\_MINIMAL. If you have set a *float\_format* then floats are converted to strings and thus csv.QUOTE\_NONNUMERIC will treat them as non-numeric.

**quotechar** [str, default '"'] String of length 1. Character used to quote fields.

**line\_terminator** [string, optional] The newline character or character sequence to use in the output file. Defaults to *os.linesep*, which depends on the OS in which this method is called ('n' for linux, 'rn' for Windows, i.e.).

Changed in version 0.24.0.

**chunksize** [int or None] Rows to write at a time.

**tupleize\_cols** [bool, default False] Write MultiIndex columns as a list of tuples (if True) or in the new, expanded format, where each MultiIndex column is a row in the CSV (if False).

Deprecated since version 0.21.0: This argument will be removed and will always write each row of the multi-index as a separate row in the CSV file.

**date\_format** [str, default None] Format string for datetime objects.

**doublequote** [bool, default True] Control quoting of *quotechar* inside a field.

**escapechar** [str, default None] String of length 1. Character used to escape *sep* and *quotechar* when appropriate.

**decimal** [str, default '.'] Character recognized as decimal separator. E.g. use ',' for European data.

### Returns

**None or str** If *path\_or\_buf* is None, returns the resulting csv format as a string. Otherwise returns None.

See also:

**read\_csv** Load a CSV file into a DataFrame.

**to\_excel** Load an Excel file into a DataFrame.

## Examples

```
>>> df = pd.DataFrame({'name': ['Raphael', 'Donatello'],
...                     'mask': ['red', 'purple'],
...                     'weapon': ['sai', 'bo staff']})
>>> df.to_csv(index=False)
'name,mask,weapon\nRaphael,red,sai\nDonatello,purple,bo staff\n'
```

## pandas.DataFrame.to\_dense

`DataFrame.to_dense()`

Return dense representation of NDFrame (as opposed to sparse).

## pandas.DataFrame.to\_dict

`DataFrame.to_dict(orient='dict', into=<class 'dict'>)`

Convert the DataFrame to a dictionary.

The type of the key-value pairs can be customized with the parameters (see below).

### Parameters

**orient** [str {'dict', 'list', 'series', 'split', 'records', 'index'}] Determines the type of the values of the dictionary.

- 'dict' (default) : dict like {column -> {index -> value}}
- 'list' : dict like {column -> [values]}
- 'series' : dict like {column -> Series(values)}
- 'split' : dict like {'index' -> [index], 'columns' -> [columns], 'data' -> [values]}
- 'records' : list like [{column -> value}, ... , {column -> value}]
- 'index' : dict like {index -> {column -> value}}

Abbreviations are allowed. *s* indicates *series* and *sp* indicates *split*.

**into** [class, default dict] The collections.Mapping subclass used for all Mappings in the return value. Can be the actual class or an empty instance of the mapping type you want. If you want a collections.defaultdict, you must pass it initialized.

New in version 0.21.0.

### Returns

**dict, list or collections.Mapping** Return a collections.Mapping object representing the DataFrame. The resulting transformation depends on the *orient* parameter.

See also:

**DataFrame.from\_dict** Create a DataFrame from a dictionary.

**DataFrame.to\_json** Convert a DataFrame to JSON format.

## Examples

```
>>> df = pd.DataFrame({'col1': [1, 2],
...                     'col2': [0.5, 0.75]},
...                     index=['row1', 'row2'])
>>> df
   col1  col2
row1    1  0.50
row2    2  0.75
>>> df.to_dict()
{'col1': {'row1': 1, 'row2': 2}, 'col2': {'row1': 0.5, 'row2': 0.75}}
```

You can specify the return orientation.

```
>>> df.to_dict('series')
{'col1': row1    1
         row2    2
Name: col1, dtype: int64,
 'col2': row1    0.50
         row2    0.75
Name: col2, dtype: float64}
```

```
>>> df.to_dict('split')
{'index': ['row1', 'row2'], 'columns': ['col1', 'col2'],
 'data': [[1, 0.5], [2, 0.75]]}
```

```
>>> df.to_dict('records')
[{'col1': 1, 'col2': 0.5}, {'col1': 2, 'col2': 0.75}]
```

```
>>> df.to_dict('index')
{'row1': {'col1': 1, 'col2': 0.5}, 'row2': {'col1': 2, 'col2': 0.75}}
```

You can also specify the mapping type.

```
>>> from collections import OrderedDict, defaultdict
>>> df.to_dict(into=OrderedDict)
OrderedDict([('col1', OrderedDict([('row1', 1), ('row2', 2)])),
            ('col2', OrderedDict([('row1', 0.5), ('row2', 0.75)]))])
```

If you want a *defaultdict*, you need to initialize it:

```
>>> dd = defaultdict(list)
>>> df.to_dict('records', into=dd)
[defaultdict(<class 'list'>, {'col1': 1, 'col2': 0.5}),
 defaultdict(<class 'list'>, {'col1': 2, 'col2': 0.75})]
```

## pandas.DataFrame.to\_excel

```
DataFrame.to_excel(excel_writer, sheet_name='Sheet1', na_rep="", float_format=None,
                   columns=None, header=True, index=True, index_label=None,
                   startrow=0, startcol=0, engine=None, merge_cells=True, encoding=None,
                   inf_rep='inf', verbose=True, freeze_panes=None)
```

Write object to an Excel sheet.

To write a single object to an Excel .xlsx file it is only necessary to specify a target file name. To write to multiple sheets it is necessary to create an *ExcelWriter* object with a target file name, and specify a sheet in the file to write to.

Multiple sheets may be written to by specifying unique *sheet\_name*. With all data written to the file it is necessary to save the changes. Note that creating an *ExcelWriter* object with a file name that already exists will result in the contents of the existing file being erased.

#### Parameters

- excel\_writer** [str or ExcelWriter object] File path or existing ExcelWriter.
- sheet\_name** [str, default 'Sheet1'] Name of sheet which will contain DataFrame.
- na\_rep** [str, default ''] Missing data representation.
- float\_format** [str, optional] Format string for floating point numbers. For example `float_format="% .2f"` will format 0.1234 to 0.12.
- columns** [sequence or list of str, optional] Columns to write.
- header** [bool or list of str, default True] Write out the column names. If a list of string is given it is assumed to be aliases for the column names.
- index** [bool, default True] Write row names (index).
- index\_label** [str or sequence, optional] Column label for index column(s) if desired. If not specified, and *header* and *index* are True, then the index names are used. A sequence should be given if the DataFrame uses MultiIndex.
- startrow** [int, default 0] Upper left cell row to dump data frame.
- startcol** [int, default 0] Upper left cell column to dump data frame.
- engine** [str, optional] Write engine to use, 'openpyxl' or 'xlsxwriter'. You can also set this via the options `io.excel.xlsx.writer`, `io.excel.xls.writer`, and `io.excel.xlsm.writer`.
- merge\_cells** [bool, default True] Write MultiIndex and Hierarchical Rows as merged cells.
- encoding** [str, optional] Encoding of the resulting excel file. Only necessary for xlwt, other writers support unicode natively.
- inf\_rep** [str, default 'inf'] Representation for infinity (there is no native representation for infinity in Excel).
- verbose** [bool, default True] Display more information in the error logs.
- freeze\_panes** [tuple of int (length 2), optional] Specifies the one-based bottommost row and rightmost column that is to be frozen.

New in version 0.20.0..

#### See also:

- to\_csv** Write DataFrame to a comma-separated values (csv) file.
- ExcelWriter** Class for writing DataFrame objects into excel sheets.
- read\_excel** Read an Excel file into a pandas DataFrame.
- read\_csv** Read a comma-separated values (csv) file into DataFrame.

## Notes

For compatibility with `to_csv()`, `to_excel` serializes lists and dicts to strings before writing.

Once a workbook has been saved it is not possible write further data without rewriting the whole workbook.

## Examples

Create, write to and save a workbook:

```
>>> df1 = pd.DataFrame([[ 'a', 'b'], [ 'c', 'd']],
...                     index=[ 'row 1', 'row 2'],
...                     columns=[ 'col 1', 'col 2'])
>>> df1.to_excel("output.xlsx") # doctest: +SKIP
```

To specify the sheet name:

```
>>> df1.to_excel("output.xlsx",
...              sheet_name='Sheet_name_1') # doctest: +SKIP
```

If you wish to write to more than one sheet in the workbook, it is necessary to specify an `ExcelWriter` object:

```
>>> df2 = df1.copy()
>>> with pd.ExcelWriter('output.xlsx') as writer: # doctest: +SKIP
...     df1.to_excel(writer, sheet_name='Sheet_name_1')
...     df2.to_excel(writer, sheet_name='Sheet_name_2')
```

To set the library that is used to write the Excel file, you can pass the `engine` keyword (the default engine is automatically chosen depending on the file extension):

```
>>> df1.to_excel('output1.xlsx', engine='xlsxwriter') # doctest: +SKIP
```

## pandas.DataFrame.to\_feather

`DataFrame.to_feather(fname)`

Write out the binary feather-format for DataFrames.

New in version 0.20.0.

### Parameters

**fname** [str] string file path

## pandas.DataFrame.to\_gbq

`DataFrame.to_gbq(destination_table, project_id=None, chunksize=None, reauth=False, if_exists='fail', auth_local_webserver=False, table_schema=None, location=None, progress_bar=True, credentials=None, verbose=None, private_key=None)`

Write a DataFrame to a Google BigQuery table.

This function requires the `pandas-gbq` package.

See the [How to authenticate with Google BigQuery](#) guide for authentication instructions.

## Parameters

**destination\_table** [str] Name of table to be written, in the form `dataset.tablename`.

**project\_id** [str, optional] Google BigQuery Account project ID. Optional when available from the environment.

**chunksize** [int, optional] Number of rows to be inserted in each chunk from the dataframe. Set to `None` to load the whole dataframe at once.

**reauth** [bool, default False] Force Google BigQuery to re-authenticate the user. This is useful if multiple accounts are used.

**if\_exists** [str, default 'fail'] Behavior when the destination table exists. Value can be one of:

**'fail'** If table exists, do nothing.

**'replace'** If table exists, drop it, recreate it, and insert data.

**'append'** If table exists, insert data. Create if does not exist.

**auth\_local\_webserver** [bool, default False] Use the [local webserver flow](#) instead of the [console flow](#) when getting user credentials.

*New in version 0.2.0 of pandas-gbq.*

**table\_schema** [list of dicts, optional] List of BigQuery table fields to which according DataFrame columns conform to, e.g. `[{'name': 'col1', 'type': 'STRING'}, ...]`. If schema is not provided, it will be generated according to dtypes of DataFrame columns. See BigQuery API documentation on available names of a field.

*New in version 0.3.1 of pandas-gbq.*

**location** [str, optional] Location where the load job should run. See the [BigQuery locations documentation](#) for a list of available locations. The location must match that of the target dataset.

*New in version 0.5.0 of pandas-gbq.*

**progress\_bar** [bool, default True] Use the library *tqdm* to show the progress bar for the upload, chunk by chunk.

*New in version 0.5.0 of pandas-gbq.*

**credentials** [google.auth.credentials.Credentials, optional] Credentials for accessing Google APIs. Use this parameter to override default credentials, such as to use Compute Engine `google.auth.compute_engine.Credentials` or Service Account `google.oauth2.service_account.Credentials` directly.

*New in version 0.8.0 of pandas-gbq.*

New in version 0.24.0.

**verbose** [bool, deprecated] Deprecated in pandas-gbq version 0.4.0. Use the [logging module to adjust verbosity instead](#).

**private\_key** [str, deprecated] Deprecated in pandas-gbq version 0.8.0. Use the `credentials` parameter and `google.oauth2.service_account.Credentials.from_service_account_info()` or `google.oauth2.service_account.Credentials.from_service_account_file()` instead.

Service account private key in JSON format. Can be file path or string contents. This is useful for remote server authentication (eg. Jupyter/IPython notebook on remote host).

See also:

`pandas_gbq.to_gbq` This function in the pandas-gbq library.

`pandas.read_gbq` Read a DataFrame from Google BigQuery.

## pandas.DataFrame.to\_hdf

`DataFrame.to_hdf` (*path\_or\_buf*, *key*, *\*\*kwargs*)

Write the contained data to an HDF5 file using HDFStore.

Hierarchical Data Format (HDF) is self-describing, allowing an application to interpret the structure and contents of a file with no outside information. One HDF file can hold a mix of related objects which can be accessed as a group or as individual objects.

In order to add another DataFrame or Series to an existing HDF file please use append mode and a different a key.

For more information see the *user guide*.

### Parameters

**path\_or\_buf** [str or pandas.HDFStore] File path or HDFStore object.

**key** [str] Identifier for the group in the store.

**mode** [{ 'a', 'w', 'r+' }, default 'a'] Mode to open file:

- 'w': write, a new file is created (an existing file with the same name would be deleted).
- 'a': append, an existing file is opened for reading and writing, and if the file does not exist it is created.
- 'r+': similar to 'a', but the file must already exist.

**format** [{ 'fixed', 'table' }, default 'fixed'] Possible values:

- 'fixed': Fixed format. Fast writing/reading. Not-appendable, nor searchable.
- 'table': Table format. Write as a PyTables Table structure which may perform worse but allow more flexible operations like searching / selecting subsets of the data.

**append** [bool, default False] For Table formats, append the input data to the existing.

**data\_columns** [list of columns or True, optional] List of columns to create as indexed data columns for on-disk queries, or True to use all columns. By default only the axes of the object are indexed. See *Query via Data Columns*. Applicable only to format='table'.

**complevel** [{0-9}, optional] Specifies a compression level for data. A value of 0 disables compression.

**complib** [{ 'zlib', 'lzo', 'bzip2', 'blosc' }, default 'zlib'] Specifies the compression library to be used. As of v0.20.2 these additional compressors for Blosc are supported (default if no compressor specified: 'blosc:blosclz'): { 'blosc:blosclz', 'blosc:lz4',

'blosc:lz4hc', 'blosc:snappy', 'blosc:zlib', 'blosc:zstd'}. Specifying a compression library which is not available issues a `ValueError`.

**fletcher32** [bool, default False] If applying compression use the fletcher32 checksum.

**dropna** [bool, default False] If true, ALL nan rows will not be written to store.

**errors** [str, default 'strict'] Specifies how encoding and decoding errors are to be handled.

See the `errors` argument for `open()` for a full list of options.

See also:

**DataFrame.read\_hdf** Read from HDF file.

**DataFrame.to\_parquet** Write a DataFrame to the binary parquet format.

**DataFrame.to\_sql** Write to a sql table.

**DataFrame.to\_feather** Write out feather-format for DataFrames.

**DataFrame.to\_csv** Write out to a csv file.

## Examples

```
>>> df = pd.DataFrame({'A': [1, 2, 3], 'B': [4, 5, 6]},
...                    index=['a', 'b', 'c'])
>>> df.to_hdf('data.h5', key='df', mode='w')
```

We can add another object to the same file:

```
>>> s = pd.Series([1, 2, 3, 4])
>>> s.to_hdf('data.h5', key='s')
```

Reading from HDF file:

```
>>> pd.read_hdf('data.h5', 'df')
A  B
a  1  4
b  2  5
c  3  6
>>> pd.read_hdf('data.h5', 's')
0    1
1    2
2    3
3    4
dtype: int64
```

Deleting file with data:

```
>>> import os
>>> os.remove('data.h5')
```

## pandas.DataFrame.to\_html

```
DataFrame.to_html (buf=None, columns=None, col_space=None, header=True, index=True,  
                  na_rep='NaN', formatters=None, float_format=None, sparsify=None,  
                  index_names=True, justify=None, max_rows=None, max_cols=None,  
                  show_dimensions=False, decimal='.', bold_rows=True, classes=None,  
                  escape=True, notebook=False, border=None, table_id=None, ren-  
                  der_links=False)
```

Render a DataFrame as an HTML table.

### Parameters

**buf** [StringIO-like, optional] Buffer to write to.

**columns** [sequence, optional, default None] The subset of columns to write. Writes all columns by default.

**col\_space** [int, optional] The minimum width of each column.

**header** [bool, optional] Whether to print column labels, default True.

**index** [bool, optional, default True] Whether to print index (row) labels.

**na\_rep** [str, optional, default 'NaN'] String representation of NAN to use.

**formatters** [list or dict of one-param. functions, optional] Formatter functions to apply to columns' elements by position or name. The result of each function must be a unicode string. List must be of length equal to the number of columns.

**float\_format** [one-parameter function, optional, default None] Formatter function to apply to columns' elements if they are floats. The result of this function must be a unicode string.

**sparsify** [bool, optional, default True] Set to False for a DataFrame with a hierarchical index to print every multiindex key at each row.

**index\_names** [bool, optional, default True] Prints the names of the indexes.

**justify** [str, default None] How to justify the column labels. If None uses the option from the print configuration (controlled by set\_option), 'right' out of the box. Valid values are

- left
- right
- center
- justify
- justify-all
- start
- end
- inherit
- match-parent
- initial
- unset.

**max\_rows** [int, optional] Maximum number of rows to display in the console.

**max\_cols** [int, optional] Maximum number of columns to display in the console.

**show\_dimensions** [bool, default False] Display DataFrame dimensions (number of rows by number of columns).

**decimal** [str, default '.'] Character recognized as decimal separator, e.g. ',' in Europe.  
New in version 0.18.0.

**bold\_rows** [bool, default True] Make the row labels bold in the output.

**classes** [str or list or tuple, default None] CSS class(es) to apply to the resulting html table.

**escape** [bool, default True] Convert the characters <, >, and & to HTML-safe sequences.

**notebook** [{True, False}, default False] Whether the generated HTML is for IPython Notebook.

**border** [int] A border=border attribute is included in the opening <table> tag. Default `pd.options.html.border`.  
New in version 0.19.0.

**table\_id** [str, optional] A css id is included in the opening <table> tag if specified.  
New in version 0.23.0.

**render\_links** [bool, default False] Convert URLs to HTML links.  
New in version 0.24.0.

#### Returns

**str (or unicode, depending on data and options)** String representation of the dataframe.

#### See also:

**to\_string** Convert DataFrame to a string.

### pandas.DataFrame.to\_json

`DataFrame.to_json` (*path\_or\_buf=None, orient=None, date\_format=None, double\_precision=10, force\_ascii=True, date\_unit='ms', default\_handler=None, lines=False, compression='infer', index=True*)

Convert the object to a JSON string.

Note NaN's and None will be converted to null and datetime objects will be converted to UNIX timestamps.

#### Parameters

**path\_or\_buf** [string or file handle, optional] File path or object. If not specified, the result is returned as a string.

**orient** [string] Indication of expected JSON string format.

- Series
  - default is 'index'
  - allowed values are: {'split','records','index','table'}
- DataFrame

- default is ‘columns’
- allowed values are: { ‘split’, ‘records’, ‘index’, ‘columns’, ‘values’, ‘table’ }
- The format of the JSON string
  - ‘split’ : dict like { ‘index’ -> [index], ‘columns’ -> [columns], ‘data’ -> [values] }
  - ‘records’ : list like [ {column -> value}, ... , {column -> value} ]
  - ‘index’ : dict like {index -> {column -> value} }
  - ‘columns’ : dict like {column -> {index -> value} }
  - ‘values’ : just the values array
  - ‘table’ : dict like { ‘schema’: {schema}, ‘data’: {data} } describing the data, and the data component is like `orient=‘records’`.

Changed in version 0.20.0.

**date\_format** [{None, ‘epoch’, ‘iso’}] Type of date conversion. ‘epoch’ = epoch milliseconds, ‘iso’ = ISO8601. The default depends on the *orient*. For `orient=‘table’`, the default is ‘iso’. For all other orients, the default is ‘epoch’.

**double\_precision** [int, default 10] The number of decimal places to use when encoding floating point values.

**force\_ascii** [bool, default True] Force encoded string to be ASCII.

**date\_unit** [string, default ‘ms’ (milliseconds)] The time unit to encode to, governs timestamp and ISO8601 precision. One of ‘s’, ‘ms’, ‘us’, ‘ns’ for second, millisecond, microsecond, and nanosecond respectively.

**default\_handler** [callable, default None] Handler to call if object cannot otherwise be converted to a suitable format for JSON. Should receive a single argument which is the object to convert and return a serialisable object.

**lines** [bool, default False] If ‘orient’ is ‘records’ write out line delimited json format. Will throw `ValueError` if incorrect ‘orient’ since others are not list like.

New in version 0.19.0.

**compression** [{ ‘infer’, ‘gzip’, ‘bz2’, ‘zip’, ‘xz’, None}] A string representing the compression to use in the output file, only used when the first argument is a filename. By default, the compression is inferred from the filename.

New in version 0.21.0.

Changed in version 0.24.0: ‘infer’ option added and set to default

**index** [bool, default True] Whether to include the index values in the JSON string. Not including the index (`index=False`) is only supported when orient is ‘split’ or ‘table’.

New in version 0.23.0.

**See also:**

`read_json`

## Examples

```
>>> df = pd.DataFrame([[ 'a', 'b'], [ 'c', 'd']],
...                    index=[ 'row 1', 'row 2'],
...                    columns=[ 'col 1', 'col 2'])
>>> df.to_json(orient='split')
'{"columns":["col 1","col 2"],
  "index":["row 1","row 2"],
  "data":[["a","b"],["c","d"]]]'
```

Encoding/decoding a Dataframe using 'records' formatted JSON. Note that index labels are not preserved with this encoding.

```
>>> df.to_json(orient='records')
'[{"col 1":"a","col 2":"b"}, {"col 1":"c","col 2":"d"}]'
```

Encoding/decoding a Dataframe using 'index' formatted JSON:

```
>>> df.to_json(orient='index')
'{"row 1":{"col 1":"a","col 2":"b"},"row 2":{"col 1":"c","col 2":"d"}}'
```

Encoding/decoding a Dataframe using 'columns' formatted JSON:

```
>>> df.to_json(orient='columns')
'{"col 1":{"row 1":"a","row 2":"c"},"col 2":{"row 1":"b","row 2":"d"}}'
```

Encoding/decoding a Dataframe using 'values' formatted JSON:

```
>>> df.to_json(orient='values')
'[["a","b"],["c","d"]]
```

Encoding with Table Schema

```
>>> df.to_json(orient='table')
'{"schema": {"fields": [{"name": "index", "type": "string"},
                        {"name": "col 1", "type": "string"},
                        {"name": "col 2", "type": "string"}],
  "primaryKey": "index",
  "pandas_version": "0.20.0"},
  "data": [{"index": "row 1", "col 1": "a", "col 2": "b"},
            {"index": "row 2", "col 1": "c", "col 2": "d"}]}'
```

## pandas.DataFrame.to\_latex

`DataFrame.to_latex` (*buf=None, columns=None, col\_space=None, header=True, index=True, na\_rep='NaN', formatters=None, float\_format=None, sparsify=None, index\_names=True, bold\_rows=False, column\_format=None, longtable=None, escape=None, encoding=None, decimal='.', multicolumn=None, multicolumn\_format=None, multirow=None*)

Render an object to a LaTeX tabular environment table.

Render an object to a tabular environment table. You can splice this into a LaTeX document. Requires `usepackage{booktabs}`.

Changed in version 0.20.2: Added to Series

### Parameters

**buf** [file descriptor or None] Buffer to write to. If None, the output is returned as a string.

**columns** [list of label, optional] The subset of columns to write. Writes all columns by default.

**col\_space** [int, optional] The minimum width of each column.

**header** [bool or list of str, default True] Write out the column names. If a list of strings is given, it is assumed to be aliases for the column names.

**index** [bool, default True] Write row names (index).

**na\_rep** [str, default 'NaN'] Missing data representation.

**formatters** [list of functions or dict of {str: function}, optional] Formatter functions to apply to columns' elements by position or name. The result of each function must be a unicode string. List must be of length equal to the number of columns.

**float\_format** [str, optional] Format string for floating point numbers.

**sparsify** [bool, optional] Set to False for a DataFrame with a hierarchical index to print every multiindex key at each row. By default, the value will be read from the config module.

**index\_names** [bool, default True] Prints the names of the indexes.

**bold\_rows** [bool, default False] Make the row labels bold in the output.

**column\_format** [str, optional] The columns format as specified in [LaTeX table format](#) e.g. 'rcl' for 3 columns. By default, 'l' will be used for all columns except columns of numbers, which default to 'r'.

**longtable** [bool, optional] By default, the value will be read from the pandas config module. Use a longtable environment instead of tabular. Requires adding a `usepackage{longtable}` to your LaTeX preamble.

**escape** [bool, optional] By default, the value will be read from the pandas config module. When set to False prevents from escaping latex special characters in column names.

**encoding** [str, optional] A string representing the encoding to use in the output file, defaults to 'ascii' on Python 2 and 'utf-8' on Python 3.

**decimal** [str, default '.'] Character recognized as decimal separator, e.g. ',' in Europe. .. versionadded:: 0.18.0

**multicolumn** [bool, default True] Use multicolumn to enhance MultiIndex columns. The default will be read from the config module. .. versionadded:: 0.20.0

**multicolumn\_format** [str, default 'l'] The alignment for multicolumns, similar to *column\_format* The default will be read from the config module. .. versionadded:: 0.20.0

**multirow** [bool, default False] Use multirow to enhance MultiIndex rows. Requires adding a `usepackage{multirow}` to your LaTeX preamble. Will print centered labels (instead of top-aligned) across the contained rows, separating groups via clines. The default will be read from the pandas config module. .. versionadded:: 0.20.0

### Returns

**str or None** If buf is None, returns the resulting LaTeX format as a string. Otherwise returns None.

### See also:

**DataFrame.to\_string** Render a DataFrame to a console-friendly tabular output.

**DataFrame.to\_html** Render a DataFrame as an HTML table.

### Examples

```
>>> df = pd.DataFrame({'name': ['Raphael', 'Donatello'],
...                    'mask': ['red', 'purple'],
...                    'weapon': ['sai', 'bo staff']})
>>> df.to_latex(index=False) # doctest: +NORMALIZE_WHITESPACE
'\\begin{tabular}{lll}\\n\\toprule\\n      name &      mask &      weapon
\\\\\\n\\midrule\\n      Raphael &      red &      sai \\\\\\n Donatello &
purple & bo staff \\\\\\n\\bottomrule\\n\\end{tabular}\\n'
```

### pandas.DataFrame.to\_msgpack

**DataFrame.to\_msgpack** (*path\_or\_buf=None, encoding='utf-8', \*\*kwargs*)

Serialize object to input file path using msgpack format.

THIS IS AN EXPERIMENTAL LIBRARY and the storage format may not be stable until a future release.

#### Parameters

**path** [string File path, buffer-like, or None] if None, return generated string

**append** [bool whether to append to an existing msgpack] (default is False)

**compress** [type of compressor (zlib or blosc), default to None (no) compression]

### pandas.DataFrame.to\_numpy

**DataFrame.to\_numpy** (*dtype=None, copy=False*)

Convert the DataFrame to a NumPy array.

New in version 0.24.0.

By default, the dtype of the returned array will be the common NumPy dtype of all types in the DataFrame. For example, if the dtypes are `float16` and `float32`, the results dtype will be `float32`. This may require copying data and coercing values, which may be expensive.

#### Parameters

**dtype** [str or numpy.dtype, optional] The dtype to pass to `numpy.asarray()`

**copy** [bool, default False] Whether to ensure that the returned value is a not a view on another array. Note that `copy=False` does not *ensure* that `to_numpy()` is no-copy. Rather, `copy=True` ensure that a copy is made, even if not strictly necessary.

#### Returns

**array** [numpy.ndarray]

See also:

**Series.to\_numpy** Similar method for Series.

## Examples

```
>>> pd.DataFrame({"A": [1, 2], "B": [3, 4]}).to_numpy()
array([[1, 3],
       [2, 4]])
```

With heterogenous data, the lowest common type will have to be used.

```
>>> df = pd.DataFrame({"A": [1, 2], "B": [3.0, 4.5]})
>>> df.to_numpy()
array([[1. , 3. ],
       [2. , 4.5]])
```

For a mix of numeric and non-numeric types, the output array will have object dtype.

```
>>> df['C'] = pd.date_range('2000', periods=2)
>>> df.to_numpy()
array([[1, 3.0, Timestamp('2000-01-01 00:00:00')],
       [2, 4.5, Timestamp('2000-01-02 00:00:00')]], dtype=object)
```

## pandas.DataFrame.to\_panel

`DataFrame.to_panel()`

Transform long (stacked) format (DataFrame) into wide (3D, Panel) format.

Deprecated since version 0.20.0.

Currently the index of the DataFrame must be a 2-level MultiIndex. This may be generalized later

### Returns

**panel** [Panel]

## pandas.DataFrame.to\_parquet

`DataFrame.to_parquet(fname, engine='auto', compression='snappy', index=None, partition_cols=None, **kwargs)`

Write a DataFrame to the binary parquet format.

New in version 0.21.0.

This function writes the dataframe as a [parquet file](#). You can choose different parquet backends, and have the option of compression. See *the user guide* for more details.

### Parameters

**fname** [str] File path or Root Directory path. Will be used as Root Directory path while writing a partitioned dataset.

Changed in version 0.24.0.

**engine** [{ 'auto', 'pyarrow', 'fastparquet' }, default 'auto'] Parquet library to use. If 'auto', then the option `io.parquet.engine` is used. The default `io.parquet.engine` behavior is to try 'pyarrow', falling back to 'fastparquet' if 'pyarrow' is unavailable.

**compression** [{ 'snappy', 'gzip', 'brotli', None }, default 'snappy'] Name of the compression to use. Use None for no compression.

**index** [bool, default None] If `True`, include the dataframe's index(es) in the file output. If `False`, they will not be written to the file. If `None`, the behavior depends on the chosen engine.

New in version 0.24.0.

**partition\_cols** [list, optional, default None] Column names by which to partition the dataset Columns are partitioned in the order they are given

New in version 0.24.0.

**\*\*kwargs** Additional arguments passed to the parquet library. See *pandas io* for more details.

See also:

**read\_parquet** Read a parquet file.

**DataFrame.to\_csv** Write a csv file.

**DataFrame.to\_sql** Write to a sql table.

**DataFrame.to\_hdf** Write to hdf.

## Notes

This function requires either the `fastparquet` or `pyarrow` library.

## Examples

```
>>> df = pd.DataFrame(data={'col1': [1, 2], 'col2': [3, 4]})
>>> df.to_parquet('df.parquet.gz',
...               compression='gzip') # doctest: +SKIP
>>> pd.read_parquet('df.parquet.gz') # doctest: +SKIP
   col1  col2
0     1     3
1     2     4
```

## pandas.DataFrame.to\_period

**DataFrame.to\_period** (*freq=None, axis=0, copy=True*)

Convert DataFrame from DatetimeIndex to PeriodIndex with desired frequency (inferred from index if not passed).

### Parameters

**freq** [string, default]

**axis** [{0 or 'index', 1 or 'columns'}, default 0] The axis to convert (the index by default)

**copy** [boolean, default True] If False then underlying input data is not copied

### Returns

**ts** [TimeSeries with PeriodIndex]

## pandas.DataFrame.to\_pickle

`DataFrame.to_pickle` (*path*, *compression*='infer', *protocol*=4)

Pickle (serialize) object to file.

### Parameters

**path** [str] File path where the pickled object will be stored.

**compression** [{ 'infer', 'gzip', 'bz2', 'zip', 'xz', None }, default 'infer'] A string representing the compression to use in the output file. By default, infers from the file extension in specified path.

New in version 0.20.0.

**protocol** [int] Int which indicates which protocol should be used by the pickler, default HIGHEST\_PROTOCOL (see [?] paragraph 12.1.2). The possible values for this parameter depend on the version of Python. For Python 2.x, possible values are 0, 1, 2. For Python >= 3.0, 3 is a valid value. For Python >= 3.4, 4 is a valid value. A negative value for the protocol parameter is equivalent to setting its value to HIGHEST\_PROTOCOL.

New in version 0.21.0.

### See also:

**read\_pickle** Load pickled pandas object (or any object) from file.

**DataFrame.to\_hdf** Write DataFrame to an HDF5 file.

**DataFrame.to\_sql** Write DataFrame to a SQL database.

**DataFrame.to\_parquet** Write a DataFrame to the binary parquet format.

### Examples

```
>>> original_df = pd.DataFrame({"foo": range(5), "bar": range(5, 10)})
>>> original_df
   foo  bar
0    0    5
1    1    6
2    2    7
3    3    8
4    4    9
>>> original_df.to_pickle("./dummy.pkl")
```

```
>>> unpickled_df = pd.read_pickle("./dummy.pkl")
>>> unpickled_df
   foo  bar
0    0    5
1    1    6
2    2    7
3    3    8
4    4    9
```

```
>>> import os
>>> os.remove("./dummy.pkl")
```

**pandas.DataFrame.to\_records**

`DataFrame.to_records` (*index=True*, *convert\_datetime64=None*, *column\_dtypes=None*, *index\_dtypes=None*)

Convert DataFrame to a NumPy record array.

Index will be included as the first field of the record array if requested.

**Parameters**

**index** [bool, default True] Include index in resulting record array, stored in ‘index’ field or using the index label, if set.

**convert\_datetime64** [bool, default None] Deprecated since version 0.23.0.

Whether to convert the index to datetime.datetime if it is a DatetimeIndex.

**column\_dtypes** [str, type, dict, default None] New in version 0.24.0.

If a string or type, the data type to store all columns. If a dictionary, a mapping of column names and indices (zero-indexed) to specific data types.

**index\_dtypes** [str, type, dict, default None] New in version 0.24.0.

If a string or type, the data type to store all index levels. If a dictionary, a mapping of index level names and indices (zero-indexed) to specific data types.

This mapping is applied only if *index=True*.

**Returns**

**numpy.recarray** NumPy ndarray with the DataFrame labels as fields and each row of the DataFrame as entries.

**See also:**

**DataFrame.from\_records** Convert structured or record ndarray to DataFrame.

**numpy.recarray** An ndarray that allows field access using attributes, analogous to typed columns in a spreadsheet.

**Examples**

```
>>> df = pd.DataFrame({'A': [1, 2], 'B': [0.5, 0.75]},
...                    index=['a', 'b'])
>>> df
   A    B
a  1  0.5
b  2  0.75
>>> df.to_records()
rec.array([( 'a', 1, 0.5 ), ( 'b', 2, 0.75)],
          dtype=[('index', 'O'), ('A', '<i8'), ('B', '<f8')])
```

If the DataFrame index has no label then the recarray field name is set to ‘index’. If the index has a label then this is used as the field name:

```
>>> df.index = df.index.rename("I")
>>> df.to_records()
rec.array([( 'I', 1, 0.5 ), ( 'b', 2, 0.75)],
          dtype=[('I', 'O'), ('A', '<i8'), ('B', '<f8')])
```

The index can be excluded from the record array:

```
>>> df.to_records(index=False)
rec.array([(1, 0.5 ), (2, 0.75)],
          dtype=[('A', '<i8'), ('B', '<f8')])
```

Data types can be specified for the columns:

```
>>> df.to_records(column_dtypes={"A": "int32"})
rec.array([(b'a', 1, 0.5 ), (b'b', 2, 0.75)],
          dtype=[('I', 'O'), ('A', '<i4'), ('B', '<f8')])
```

As well as for the index:

```
>>> df.to_records(index_dtypes="<S2")
rec.array([(b'a', 1, 0.5 ), (b'b', 2, 0.75)],
          dtype=[('I', 'S2'), ('A', '<i8'), ('B', '<f8')])
```

```
>>> index_dtypes = "<S{}".format(df.index.str.len().max())
>>> df.to_records(index_dtypes=index_dtypes)
rec.array([(b'a', 1, 0.5 ), (b'b', 2, 0.75)],
          dtype=[('I', 'S1'), ('A', '<i8'), ('B', '<f8')])
```

## pandas.DataFrame.to\_sparse

`DataFrame.to_sparse` (*fill\_value=None, kind='block'*)

Convert to SparseDataFrame.

Implement the sparse version of the DataFrame meaning that any data matching a specific value it's omitted in the representation. The sparse DataFrame allows for a more efficient storage.

### Parameters

**fill\_value** [float, default None] The specific value that should be omitted in the representation.

**kind** [{ 'block', 'integer' }, default 'block'] The kind of the SparseIndex tracking where data is not equal to the fill value:

- 'block' tracks only the locations and sizes of blocks of data.
- 'integer' keeps an array with all the locations of the data.

In most cases 'block' is recommended, since it's more memory efficient.

### Returns

**SparseDataFrame** The sparse representation of the DataFrame.

See also:

**DataFrame.to\_dense** Converts the DataFrame back to the its dense form.

## Examples

```

>>> df = pd.DataFrame([(np.nan, np.nan),
...                     (1., np.nan),
...                     (np.nan, 1.)])
>>> df
   0    1
0 NaN NaN
1 1.0 NaN
2 NaN 1.0
>>> type(df)
<class 'pandas.core.frame.DataFrame'>

>>> sdf = df.to_sparse()
>>> sdf
   0    1
0 NaN NaN
1 1.0 NaN
2 NaN 1.0
>>> type(sdf)
<class 'pandas.core.sparse.frame.SparseDataFrame'>

```

## pandas.DataFrame.to\_sql

`DataFrame.to_sql(name, con, schema=None, if_exists='fail', index=True, index_label=None, chunksize=None, dtype=None, method=None)`

Write records stored in a DataFrame to a SQL database.

Databases supported by SQLAlchemy [?] are supported. Tables can be newly created, appended to, or overwritten.

### Parameters

**name** [string] Name of SQL table.

**con** [sqlalchemy.engine.Engine or sqlite3.Connection] Using SQLAlchemy makes it possible to use any DB supported by that library. Legacy support is provided for sqlite3.Connection objects.

**schema** [string, optional] Specify the schema (if database flavor supports this). If None, use default schema.

**if\_exists** [{ 'fail', 'replace', 'append' }, default 'fail'] How to behave if the table already exists.

- fail: Raise a ValueError.
- replace: Drop the table before inserting new values.
- append: Insert new values to the existing table.

**index** [bool, default True] Write DataFrame index as a column. Uses *index\_label* as the column name in the table.

**index\_label** [string or sequence, default None] Column label for index column(s). If None is given (default) and *index* is True, then the index names are used. A sequence should be given if the DataFrame uses MultiIndex.

**chunksize** [int, optional] Rows will be written in batches of this size at a time. By default, all rows will be written at once.

**dtype** [dict, optional] Specifying the datatype for columns. The keys should be the column names and the values should be the SQLAlchemy types or strings for the sqlite3 legacy mode.

**method** [{None, 'multi', callable}, default None] Controls the SQL insertion clause used:

- None : Uses standard SQL INSERT clause (one per row).
- 'multi': Pass multiple values in a single INSERT clause.
- callable with signature (pd\_table, conn, keys, data\_iter).

Details and a sample callable implementation can be found in the section *insert method*.

New in version 0.24.0.

### Raises

**ValueError** When the table already exists and *if\_exists* is 'fail' (the default).

**See also:**

**read\_sql** Read a DataFrame from a table.

### Notes

Timezone aware datetime columns will be written as Timestamp with timezone type with SQLAlchemy if supported by the database. Otherwise, the datetimes will be stored as timezone unaware timestamps local to the original timezone.

New in version 0.24.0.

### References

[?], [?]

### Examples

Create an in-memory SQLite database.

```
>>> from sqlalchemy import create_engine
>>> engine = create_engine('sqlite://', echo=False)
```

Create a table from scratch with 3 rows.

```
>>> df = pd.DataFrame({'name' : ['User 1', 'User 2', 'User 3']})
>>> df
   name
0  User 1
1  User 2
2  User 3
```

```
>>> df.to_sql('users', con=engine)
>>> engine.execute("SELECT * FROM users").fetchall()
[(0, 'User 1'), (1, 'User 2'), (2, 'User 3')]
```

```
>>> df1 = pd.DataFrame({'name' : ['User 4', 'User 5']})
>>> df1.to_sql('users', con=engine, if_exists='append')
>>> engine.execute("SELECT * FROM users").fetchall()
[(0, 'User 1'), (1, 'User 2'), (2, 'User 3'),
 (0, 'User 4'), (1, 'User 5')]
```

Overwrite the table with just df1.

```
>>> df1.to_sql('users', con=engine, if_exists='replace',
...           index_label='id')
>>> engine.execute("SELECT * FROM users").fetchall()
[(0, 'User 4'), (1, 'User 5')]
```

Specify the dtype (especially useful for integers with missing values). Notice that while pandas is forced to store the data as floating point, the database supports nullable integers. When fetching the data with Python, we get back integer scalars.

```
>>> df = pd.DataFrame({"A": [1, None, 2]})
>>> df
   A
0  1.0
1  NaN
2  2.0
```

```
>>> from sqlalchemy.types import Integer
>>> df.to_sql('integers', con=engine, index=False,
...          dtype={"A": Integer()})
```

```
>>> engine.execute("SELECT * FROM integers").fetchall()
[(1,), (None,), (2,)]
```

## pandas.DataFrame.to\_stata

`DataFrame.to_stata` (*fname*, *convert\_dates=None*, *write\_index=True*, *encoding='latin-1'*, *byte-order=None*, *time\_stamp=None*, *data\_label=None*, *variable\_labels=None*, *version=114*, *convert\_strl=None*)

Export DataFrame object to Stata dta format.

Writes the DataFrame to a Stata dataset file. “dta” files contain a Stata dataset.

### Parameters

**fname** [str, buffer or path object] String, path object (pathlib.Path or py\_path.local.LocalPath) or object implementing a binary write() function. If using a buffer then the buffer will not be automatically closed after the file data has been written.

**convert\_dates** [dict] Dictionary mapping columns containing datetime types to stata internal format to use when writing the dates. Options are ‘tc’, ‘td’, ‘tm’, ‘tw’, ‘th’, ‘tq’, ‘ty’. Column can be either an integer or a name. Datetime columns that do not have a conversion type specified will be converted to ‘tc’. Raises NotImplementedError if a datetime column has timezone information.

**write\_index** [bool] Write the index to Stata dataset.

**encoding** [str] Default is latin-1. Unicode is not supported.

**byteorder** [str] Can be “>”, “<”, “little”, or “big”. default is *sys.byteorder*.

**time\_stamp** [datetime] A datetime to use as file creation date. Default is the current time.

**data\_label** [str, optional] A label for the data set. Must be 80 characters or smaller.

**variable\_labels** [dict] Dictionary containing columns as keys and variable labels as values. Each label must be 80 characters or smaller.

New in version 0.19.0.

**version** [{114, 117}, default 114] Version to use in the output dta file. Version 114 can be used read by Stata 10 and later. Version 117 can be read by Stata 13 or later. Version 114 limits string variables to 244 characters or fewer while 117 allows strings with lengths up to 2,000,000 characters.

New in version 0.23.0.

**convert\_strl** [list, optional] List of column names to convert to string columns to Stata StrL format. Only available if version is 117. Storing strings in the StrL format can produce smaller dta files if strings have more than 8 characters and values are repeated.

New in version 0.23.0.

### Raises

#### NotImplementedError

- If datetimes contain timezone information
- Column dtype is not representable in Stata

#### ValueError

- Columns listed in `convert_dates` are neither `datetime64[ns]` or `datetime.datetime`
- Column listed in `convert_dates` is not in `DataFrame`
- Categorical label contains more than 32,000 characters

New in version 0.19.0.

### See also:

**`read_stata`** Import Stata data files.

**`io.stata.StataWriter`** Low-level writer for Stata data files.

**`io.stata.StataWriter117`** Low-level writer for version 117 files.

### Examples

```
>>> df = pd.DataFrame({'animal': ['falcon', 'parrot', 'falcon',  
...                               'parrot'],  
...                   'speed': [350, 18, 361, 15]})  
>>> df.to_stata('animals.dta') # doctest: +SKIP
```

**pandas.DataFrame.to\_string**

`DataFrame.to_string` (*buf=None, columns=None, col\_space=None, header=True, index=True, na\_rep='NaN', formatters=None, float\_format=None, sparsify=None, index\_names=True, justify=None, max\_rows=None, max\_cols=None, show\_dimensions=False, decimal='.', line\_width=None*)

Render a DataFrame to a console-friendly tabular output.

**Parameters**

**buf** [StringIO-like, optional] Buffer to write to.

**columns** [sequence, optional, default None] The subset of columns to write. Writes all columns by default.

**col\_space** [int, optional] The minimum width of each column.

**header** [bool, optional] Write out the column names. If a list of strings is given, it is assumed to be aliases for the column names.

**index** [bool, optional, default True] Whether to print index (row) labels.

**na\_rep** [str, optional, default 'NaN'] String representation of NAN to use.

**formatters** [list or dict of one-param. functions, optional] Formatter functions to apply to columns' elements by position or name. The result of each function must be a unicode string. List must be of length equal to the number of columns.

**float\_format** [one-parameter function, optional, default None] Formatter function to apply to columns' elements if they are floats. The result of this function must be a unicode string.

**sparsify** [bool, optional, default True] Set to False for a DataFrame with a hierarchical index to print every multiindex key at each row.

**index\_names** [bool, optional, default True] Prints the names of the indexes.

**justify** [str, default None] How to justify the column labels. If None uses the option from the print configuration (controlled by `set_option`), 'right' out of the box. Valid values are

- left
- right
- center
- justify
- justify-all
- start
- end
- inherit
- match-parent
- initial
- unset.

**max\_rows** [int, optional] Maximum number of rows to display in the console.

**max\_cols** [int, optional] Maximum number of columns to display in the console.

**show\_dimensions** [bool, default False] Display DataFrame dimensions (number of rows by number of columns).

**decimal** [str, default '.'] Character recognized as decimal separator, e.g. ',' in Europe.

New in version 0.18.0.

**line\_width** [int, optional] Width to wrap a line in characters.

#### Returns

**str (or unicode, depending on data and options)** String representation of the dataframe.

#### See also:

**to\_html** Convert DataFrame to HTML.

#### Examples

```
>>> d = {'col1': [1, 2, 3], 'col2': [4, 5, 6]}
>>> df = pd.DataFrame(d)
>>> print(df.to_string())
   col1  col2
0      1     4
1      2     5
2      3     6
```

### pandas.DataFrame.to\_timestamp

`DataFrame.to_timestamp(freq=None, how='start', axis=0, copy=True)`

Cast to DatetimeIndex of timestamps, at *beginning* of period.

#### Parameters

**freq** [string, default frequency of PeriodIndex] Desired frequency

**how** [{ 's', 'e', 'start', 'end' }] Convention for converting period to timestamp; start of period vs. end

**axis** [{0 or 'index', 1 or 'columns'}, default 0] The axis to convert (the index by default)

**copy** [boolean, default True] If false then underlying input data is not copied

#### Returns

**df** [DataFrame with DatetimeIndex]

### pandas.DataFrame.to\_xarray

`DataFrame.to_xarray()`

Return an xarray object from the pandas object.

#### Returns

**xarray.DataArray or xarray.Dataset** Data in the pandas structure converted to Dataset if the object is a DataFrame, or a DataArray if the object is a Series.

#### See also:

**DataFrame.to\_hdf** Write DataFrame to an HDF5 file.

**DataFrame.to\_parquet** Write a DataFrame to the binary parquet format.

## Notes

See the [xarray docs](#)

## Examples

```
>>> df = pd.DataFrame([('falcon', 'bird', 389.0, 2),
...                     ('parrot', 'bird', 24.0, 2),
...                     ('lion', 'mammal', 80.5, 4),
...                     ('monkey', 'mammal', np.nan, 4)],
...                     columns=['name', 'class', 'max_speed',
...                               'num_legs'])
>>> df
```

|   | name   | class  | max_speed | num_legs |
|---|--------|--------|-----------|----------|
| 0 | falcon | bird   | 389.0     | 2        |
| 1 | parrot | bird   | 24.0      | 2        |
| 2 | lion   | mammal | 80.5      | 4        |
| 3 | monkey | mammal | NaN       | 4        |

```
>>> df.to_xarray()
<xarray.Dataset>
Dimensions:      (index: 4)
Coordinates:
  * index        (index) int64 0 1 2 3
Data variables:
  name           (index) object 'falcon' 'parrot' 'lion' 'monkey'
  class          (index) object 'bird' 'bird' 'mammal' 'mammal'
  max_speed      (index) float64 389.0 24.0 80.5 nan
  num_legs       (index) int64 2 2 4 4
```

```
>>> df['max_speed'].to_xarray()
<xarray.DataArray 'max_speed' (index: 4)>
array([389. , 24. , 80.5,  nan])
Coordinates:
  * index        (index) int64 0 1 2 3
```

```
>>> dates = pd.to_datetime(['2018-01-01', '2018-01-01',
...                          '2018-01-02', '2018-01-02'])
>>> df_multiindex = pd.DataFrame({'date': dates,
...                                'animal': ['falcon', 'parrot', 'falcon',
...                                           'parrot'],
...                                'speed': [350, 18, 361, 15]}).set_index(['date',
...                                                                           'animal'])
>>> df_multiindex
```

|  | date       | animal | speed |
|--|------------|--------|-------|
|  | 2018-01-01 | falcon | 350   |
|  |            | parrot | 18    |
|  | 2018-01-02 | falcon | 361   |
|  |            | parrot | 15    |

```
>>> df_multiindex.to_xarray()
<xarray.Dataset>
Dimensions:  (animal: 2, date: 2)
Coordinates:
  * date      (date) datetime64[ns] 2018-01-01 2018-01-02
  * animal    (animal) object 'falcon' 'parrot'
Data variables:
  speed      (date, animal) int64 350 18 361 15
```

## pandas.DataFrame.transform

`DataFrame.transform(func, axis=0, *args, **kwargs)`

Call `func` on self producing a `DataFrame` with transformed values and that has the same axis length as self.

New in version 0.20.0.

### Parameters

**func** [function, str, list or dict] Function to use for transforming the data. If a function, must either work when passed a `DataFrame` or when passed to `DataFrame.apply`.

Accepted combinations are:

- function
- string function name
- list of functions and/or function names, e.g. `[np.exp, 'sqrt']`
- dict of axis labels -> functions, function names or list of such.

**axis** [{0 or 'index', 1 or 'columns'}, default 0] If 0 or 'index': apply function to each column. If 1 or 'columns': apply function to each row.

**\*args** Positional arguments to pass to `func`.

**\*\*kwargs** Keyword arguments to pass to `func`.

### Returns

**DataFrame** A `DataFrame` that must have the same length as self.

### Raises

**ValueError** [If the returned `DataFrame` has a different length than self.]

See also:

**DataFrame.agg** Only perform aggregating type operations.

**DataFrame.apply** Invoke function on a `DataFrame`.

## Examples

```
>>> df = pd.DataFrame({'A': range(3), 'B': range(1, 4)})
>>> df
   A  B
0  0  1
1  1  2
```

(continues on next page)

(continued from previous page)

```

2  2  3
>>> df.transform(lambda x: x + 1)
   A  B
0  1  2
1  2  3
2  3  4

```

Even though the resulting DataFrame must have the same length as the input DataFrame, it is possible to provide several input functions:

```

>>> s = pd.Series(range(3))
>>> s
0    0
1    1
2    2
dtype: int64
>>> s.transform([np.sqrt, np.exp])
      sqrt      exp
0  0.000000  1.000000
1  1.000000  2.718282
2  1.414214  7.389056

```

## pandas.DataFrame.transpose

`DataFrame.transpose(*args, **kwargs)`

Transpose index and columns.

Reflect the DataFrame over its main diagonal by writing rows as columns and vice-versa. The property *T* is an accessor to the method *transpose()*.

### Parameters

**copy** [bool, default False] If True, the underlying data is copied. Otherwise (default), no copy is made if possible.

**\*args, \*\*kwargs** Additional keywords have no effect but might be accepted for compatibility with numpy.

### Returns

**DataFrame** The transposed DataFrame.

See also:

**numpy.transpose** Permute the dimensions of a given array.

### Notes

Transposing a DataFrame with mixed dtypes will result in a homogeneous DataFrame with the *object* dtype. In such a case, a copy of the data is always made.

## Examples

**Square DataFrame with homogeneous dtype**

```
>>> d1 = {'col1': [1, 2], 'col2': [3, 4]}
>>> df1 = pd.DataFrame(data=d1)
>>> df1
   col1  col2
0     1     3
1     2     4
```

```
>>> df1_transposed = df1.T # or df1.transpose()
>>> df1_transposed
      0  1
col1  1  2
col2  3  4
```

When the dtype is homogeneous in the original DataFrame, we get a transposed DataFrame with the same dtype:

```
>>> df1.dtypes
col1    int64
col2    int64
dtype: object
>>> df1_transposed.dtypes
0    int64
1    int64
dtype: object
```

### Non-square DataFrame with mixed dtypes

```
>>> d2 = {'name': ['Alice', 'Bob'],
...       'score': [9.5, 8],
...       'employed': [False, True],
...       'kids': [0, 0]}
>>> df2 = pd.DataFrame(data=d2)
>>> df2
   name  score  employed  kids
0  Alice   9.5     False     0
1   Bob    8.0      True     0
```

```
>>> df2_transposed = df2.T # or df2.transpose()
>>> df2_transposed
      0  1
name   Alice  Bob
score    9.5    8
employed False  True
kids       0    0
```

When the DataFrame has mixed dtypes, we get a transposed DataFrame with the *object* dtype:

```
>>> df2.dtypes
name      object
score    float64
employed    bool
kids      int64
dtype: object
>>> df2_transposed.dtypes
0    object
1    object
dtype: object
```

**pandas.DataFrame.truediv**

`DataFrame.truediv` (*other*, *axis*='columns', *level*=None, *fill\_value*=None)

Floating division of dataframe and other, element-wise (binary operator *truediv*).

Equivalent to `dataframe / other`, but with support to substitute a *fill\_value* for missing data in one of the inputs. With reverse version, *rtruediv*.

Among flexible wrappers (*add*, *sub*, *mul*, *div*, *mod*, *pow*) to arithmetic operators: `+`, `-`, `*`, `/`, `//`, `%`, `**`.

**Parameters**

**other** [scalar, sequence, Series, or DataFrame] Any single or multiple element data structure, or list-like object.

**axis** [{0 or 'index', 1 or 'columns'}] Whether to compare by the index (0 or 'index') or columns (1 or 'columns'). For Series input, axis to match Series index on.

**level** [int or label] Broadcast across a level, matching Index values on the passed Multi-Index level.

**fill\_value** [float or None, default None] Fill existing missing (NaN) values, and any new element needed for successful DataFrame alignment, with this value before computation. If data in both corresponding DataFrame locations is missing the result will be missing.

**Returns**

**DataFrame** Result of the arithmetic operation.

See also:

**DataFrame.add** Add DataFrames.

**DataFrame.sub** Subtract DataFrames.

**DataFrame.mul** Multiply DataFrames.

**DataFrame.div** Divide DataFrames (float division).

**DataFrame.truediv** Divide DataFrames (float division).

**DataFrame.floordiv** Divide DataFrames (integer division).

**DataFrame.mod** Calculate modulo (remainder after division).

**DataFrame.pow** Calculate exponential power.

**Notes**

Mismatched indices will be unioned together.

**Examples**

```
>>> df = pd.DataFrame({'angles': [0, 3, 4],
...                     'degrees': [360, 180, 360]},
...                     index=['circle', 'triangle', 'rectangle'])
>>> df
      angles  degrees
circle      0     360
```

(continues on next page)

(continued from previous page)

|           |   |     |
|-----------|---|-----|
| triangle  | 3 | 180 |
| rectangle | 4 | 360 |

Add a scalar with operator version which return the same results.

```
>>> df + 1
```

|           | angles | degrees |
|-----------|--------|---------|
| circle    | 1      | 361     |
| triangle  | 4      | 181     |
| rectangle | 5      | 361     |

```
>>> df.add(1)
```

|           | angles | degrees |
|-----------|--------|---------|
| circle    | 1      | 361     |
| triangle  | 4      | 181     |
| rectangle | 5      | 361     |

Divide by constant with reverse version.

```
>>> df.div(10)
```

|           | angles | degrees |
|-----------|--------|---------|
| circle    | 0.0    | 36.0    |
| triangle  | 0.3    | 18.0    |
| rectangle | 0.4    | 36.0    |

```
>>> df.rdiv(10)
```

|           | angles   | degrees  |
|-----------|----------|----------|
| circle    | inf      | 0.027778 |
| triangle  | 3.333333 | 0.055556 |
| rectangle | 2.500000 | 0.027778 |

Subtract a list and Series by axis with operator version.

```
>>> df - [1, 2]
```

|           | angles | degrees |
|-----------|--------|---------|
| circle    | -1     | 358     |
| triangle  | 2      | 178     |
| rectangle | 3      | 358     |

```
>>> df.sub([1, 2], axis='columns')
```

|           | angles | degrees |
|-----------|--------|---------|
| circle    | -1     | 358     |
| triangle  | 2      | 178     |
| rectangle | 3      | 358     |

```
>>> df.sub(pd.Series([1, 1, 1], index=['circle', 'triangle', 'rectangle']),  
...        axis='index')
```

|           | angles | degrees |
|-----------|--------|---------|
| circle    | -1     | 359     |
| triangle  | 2      | 179     |
| rectangle | 3      | 359     |

Multiply a DataFrame of different shape with operator version.

```
>>> other = pd.DataFrame({'angles': [0, 3, 4]},
...                        index=['circle', 'triangle', 'rectangle'])
>>> other
```

|           | angles |
|-----------|--------|
| circle    | 0      |
| triangle  | 3      |
| rectangle | 4      |

```
>>> df * other
```

|           | angles | degrees |
|-----------|--------|---------|
| circle    | 0      | NaN     |
| triangle  | 9      | NaN     |
| rectangle | 16     | NaN     |

```
>>> df.mul(other, fill_value=0)
```

|           | angles | degrees |
|-----------|--------|---------|
| circle    | 0      | 0.0     |
| triangle  | 9      | 0.0     |
| rectangle | 16     | 0.0     |

Divide by a MultiIndex by level.

```
>>> df_multindex = pd.DataFrame({'angles': [0, 3, 4, 4, 5, 6],
...                               'degrees': [360, 180, 360, 360, 540, 720]},
...                              index=[['A', 'A', 'A', 'B', 'B', 'B'],
...                                     ['circle', 'triangle', 'rectangle',
...                                      'square', 'pentagon', 'hexagon']])
>>> df_multindex
```

|   |           | angles | degrees |
|---|-----------|--------|---------|
| A | circle    | 0      | 360     |
|   | triangle  | 3      | 180     |
|   | rectangle | 4      | 360     |
| B | square    | 4      | 360     |
|   | pentagon  | 5      | 540     |
|   | hexagon   | 6      | 720     |

```
>>> df.div(df_multindex, level=1, fill_value=0)
```

|   |           | angles | degrees |
|---|-----------|--------|---------|
| A | circle    | NaN    | 1.0     |
|   | triangle  | 1.0    | 1.0     |
|   | rectangle | 1.0    | 1.0     |
| B | square    | 0.0    | 0.0     |
|   | pentagon  | 0.0    | 0.0     |
|   | hexagon   | 0.0    | 0.0     |

### pandas.DataFrame.truncate

`DataFrame.truncate` (*before=None, after=None, axis=None, copy=True*)

Truncate a Series or DataFrame before and after some index value.

This is a useful shorthand for boolean indexing based on index values above or below certain thresholds.

#### Parameters

**before** [date, string, int] Truncate all rows before this index value.

**after** [date, string, int] Truncate all rows after this index value.

**axis** [{0 or 'index', 1 or 'columns'}, optional] Axis to truncate. Truncates the index (rows) by default.

**copy** [boolean, default is True,] Return a copy of the truncated section.

### Returns

**type of caller** The truncated Series or DataFrame.

### See also:

**DataFrame.loc** Select a subset of a DataFrame by label.

**DataFrame.iloc** Select a subset of a DataFrame by position.

### Notes

If the index being truncated contains only datetime values, *before* and *after* may be specified as strings instead of Timestamps.

### Examples

```
>>> df = pd.DataFrame({'A': ['a', 'b', 'c', 'd', 'e'],
...                    'B': ['f', 'g', 'h', 'i', 'j'],
...                    'C': ['k', 'l', 'm', 'n', 'o']},
...                    index=[1, 2, 3, 4, 5])
>>> df
   A  B  C
1  a  f  k
2  b  g  l
3  c  h  m
4  d  i  n
5  e  j  o
```

```
>>> df.truncate(before=2, after=4)
   A  B  C
2  b  g  l
3  c  h  m
4  d  i  n
```

The columns of a DataFrame can be truncated.

```
>>> df.truncate(before="A", after="B", axis="columns")
   A  B
1  a  f
2  b  g
3  c  h
4  d  i
5  e  j
```

For Series, only rows can be truncated.

```
>>> df['A'].truncate(before=2, after=4)
2    b
3    c
```

(continues on next page)

(continued from previous page)

```
4      d
Name: A, dtype: object
```

The index values in `truncate` can be datetimes or string dates.

```
>>> dates = pd.date_range('2016-01-01', '2016-02-01', freq='s')
>>> df = pd.DataFrame(index=dates, data={'A': 1})
>>> df.tail()
                A
2016-01-31 23:59:56  1
2016-01-31 23:59:57  1
2016-01-31 23:59:58  1
2016-01-31 23:59:59  1
2016-02-01 00:00:00  1
```

```
>>> df.truncate(before=pd.Timestamp('2016-01-05'),
...             after=pd.Timestamp('2016-01-10')).tail()
                A
2016-01-09 23:59:56  1
2016-01-09 23:59:57  1
2016-01-09 23:59:58  1
2016-01-09 23:59:59  1
2016-01-10 00:00:00  1
```

Because the index is a `DatetimeIndex` containing only dates, we can specify *before* and *after* as strings. They will be coerced to `Timestamps` before truncation.

```
>>> df.truncate('2016-01-05', '2016-01-10').tail()
                A
2016-01-09 23:59:56  1
2016-01-09 23:59:57  1
2016-01-09 23:59:58  1
2016-01-09 23:59:59  1
2016-01-10 00:00:00  1
```

Note that `truncate` assumes a 0 value for any unspecified time component (midnight). This differs from partial string slicing, which returns any partially matching dates.

```
>>> df.loc['2016-01-05':'2016-01-10', :].tail()
                A
2016-01-10 23:59:55  1
2016-01-10 23:59:56  1
2016-01-10 23:59:57  1
2016-01-10 23:59:58  1
2016-01-10 23:59:59  1
```

## pandas.DataFrame.tshift

`DataFrame.tshift` (*periods=1, freq=None, axis=0*)

Shift the time index, using the index's frequency if available.

### Parameters

**periods** [int] Number of periods to move, can be positive or negative

**freq** [DateOffset, timedelta, or time rule string, default None] Increment to use from the tseries module or time rule (e.g. 'EOM')

**axis** [int or basestring] Corresponds to the axis that contains the Index

#### Returns

**shifted** [NDFrame]

#### Notes

If freq is not specified then tries to use the freq or inferred\_freq attributes of the index. If neither of those attributes exist, a ValueError is thrown

### pandas.DataFrame.tz\_convert

`DataFrame.tz_convert(tz, axis=0, level=None, copy=True)`

Convert tz-aware axis to target time zone.

#### Parameters

**tz** [string or pytz.timezone object]

**axis** [the axis to convert]

**level** [int, str, default None] If axis is a MultiIndex, convert a specific level. Otherwise must be None

**copy** [boolean, default True] Also make a copy of the underlying data

#### Raises

**TypeError** If the axis is tz-naive.

### pandas.DataFrame.tz\_localize

`DataFrame.tz_localize(tz, axis=0, level=None, copy=True, ambiguous='raise', nonexistent='raise')`

Localize tz-naive index of a Series or DataFrame to target time zone.

This operation localizes the Index. To localize the values in a timezone-naive Series, use `Series.dt.tz_localize()`.

#### Parameters

**tz** [string or pytz.timezone object]

**axis** [the axis to localize]

**level** [int, str, default None] If axis is a MultiIndex, localize a specific level. Otherwise must be None

**copy** [boolean, default True] Also make a copy of the underlying data

**ambiguous** ['infer', bool-ndarray, 'NaT', default 'raise'] When clocks moved backward due to DST, ambiguous times may arise. For example in Central European Time (UTC+01), when going from 03:00 DST to 02:00 non-DST, 02:30:00 local time occurs both at 00:30:00 UTC and at 01:30:00 UTC. In such a situation, the *ambiguous* parameter dictates how ambiguous times should be handled.

- ‘infer’ will attempt to infer fall dst-transition hours based on order
- bool-ndarray where True signifies a DST time, False designates a non-DST time (note that this flag is only applicable for ambiguous times)
- ‘NaT’ will return NaT where there are ambiguous times
- ‘raise’ will raise an AmbiguousTimeError if there are ambiguous times

**nonexistent** [str, default ‘raise’] A nonexistent time does not exist in a particular timezone where clocks moved forward due to DST. Valid values are:

- ‘shift\_forward’ will shift the nonexistent time forward to the closest existing time
- ‘shift\_backward’ will shift the nonexistent time backward to the closest existing time
- ‘NaT’ will return NaT where there are nonexistent times
- timedelta objects will shift nonexistent times by the timedelta
- ‘raise’ will raise a NonExistentTimeError if there are nonexistent times

New in version 0.24.0.

### Returns

**Series or DataFrame** Same type as the input.

### Raises

**TypeError** If the TimeSeries is tz-aware and tz is not None.

## Examples

Localize local times:

```
>>> s = pd.Series([1],
... index=pd.DatetimeIndex(['2018-09-15 01:30:00']))
>>> s.tz_localize('CET')
2018-09-15 01:30:00+02:00    1
dtype: int64
```

Be careful with DST changes. When there is sequential data, pandas can infer the DST time:

```
>>> s = pd.Series(range(7), index=pd.DatetimeIndex([
... '2018-10-28 01:30:00',
... '2018-10-28 02:00:00',
... '2018-10-28 02:30:00',
... '2018-10-28 02:00:00',
... '2018-10-28 02:30:00',
... '2018-10-28 03:00:00',
... '2018-10-28 03:30:00']))
>>> s.tz_localize('CET', ambiguous='infer')
2018-10-28 01:30:00+02:00    0
2018-10-28 02:00:00+02:00    1
2018-10-28 02:30:00+02:00    2
2018-10-28 02:00:00+01:00    3
2018-10-28 02:30:00+01:00    4
2018-10-28 03:00:00+01:00    5
2018-10-28 03:30:00+01:00    6
dtype: int64
```

In some cases, inferring the DST is impossible. In such cases, you can pass an ndarray to the ambiguous parameter to set the DST explicitly

```
>>> s = pd.Series(range(3), index=pd.DatetimeIndex([
...     '2018-10-28 01:20:00',
...     '2018-10-28 02:36:00',
...     '2018-10-28 03:46:00']))
>>> s.tz_localize('CET', ambiguous=np.array([True, True, False]))
2018-10-28 01:20:00+02:00    0
2018-10-28 02:36:00+02:00    1
2018-10-28 03:46:00+01:00    2
dtype: int64
```

If the DST transition causes nonexistent times, you can shift these dates forward or backwards with a timedelta object or `'shift_forward'` or `'shift_backwards'`. `>>> s = pd.Series(range(2), index=pd.DatetimeIndex([ ... '2015-03-29 02:30:00', ... '2015-03-29 03:30:00'])) >>> s.tz_localize('Europe/Warsaw', nonexistent='shift_forward')` 2015-03-29 03:00:00+02:00 0 2015-03-29 03:30:00+02:00 1 dtype: int64 `>>> s.tz_localize('Europe/Warsaw', nonexistent='shift_backward')` 2015-03-29 01:59:59.999999999+01:00 0 2015-03-29 03:30:00+02:00 1 dtype: int64 `>>> s.tz_localize('Europe/Warsaw', nonexistent=pd.Timedelta('1H'))` 2015-03-29 03:30:00+02:00 0 2015-03-29 03:30:00+02:00 1 dtype: int64

## pandas.DataFrame.unstack

`DataFrame.unstack (level=-1, fill_value=None)`

Pivot a level of the (necessarily hierarchical) index labels, returning a DataFrame having a new level of column labels whose inner-most level consists of the pivoted index labels.

If the index is not a MultiIndex, the output will be a Series (the analogue of stack when the columns are not a MultiIndex).

The level involved will automatically get sorted.

### Parameters

**level** [int, string, or list of these, default -1 (last level)] Level(s) of index to unstack, can pass level name

**fill\_value** [replace NaN with this value if the unstack produces] missing values

New in version 0.18.0.

### Returns

**unstacked** [DataFrame or Series]

See also:

**DataFrame.pivot** Pivot a table based on column values.

**DataFrame.stack** Pivot a level of the column labels (inverse operation from *unstack*).

## Examples

```
>>> index = pd.MultiIndex.from_tuples([('one', 'a'), ('one', 'b'),
...                                   ('two', 'a'), ('two', 'b')])
>>> s = pd.Series(np.arange(1.0, 5.0), index=index)
```

(continues on next page)

(continued from previous page)

```
>>> s
one  a    1.0
     b    2.0
two  a    3.0
     b    4.0
dtype: float64
```

```
>>> s.unstack(level=-1)
     a    b
one  1.0  2.0
two  3.0  4.0
```

```
>>> s.unstack(level=0)
     one  two
a    1.0   3.0
b    2.0   4.0
```

```
>>> df = s.unstack(level=0)
>>> df.unstack()
one  a    1.0
     b    2.0
two  a    3.0
     b    4.0
dtype: float64
```

## pandas.DataFrame.update

`DataFrame.update(other, join='left', overwrite=True, filter_func=None, errors='ignore')`

Modify in place using non-NA values from another DataFrame.

Aligns on indices. There is no return value.

### Parameters

**other** [DataFrame, or object coercible into a DataFrame] Should have at least one matching index/column label with the original DataFrame. If a Series is passed, its name attribute must be set, and that will be used as the column name to align with the original DataFrame.

**join** [{ 'left' }, default 'left'] Only left join is implemented, keeping the index and columns of the original object.

**overwrite** [bool, default True] How to handle non-NA values for overlapping keys:

- True: overwrite original DataFrame's values with values from *other*.
- False: only update values that are NA in the original DataFrame.

**filter\_func** [callable(1d-array) -> bool 1d-array, optional] Can choose to replace values other than NA. Return True for values that should be updated.

**errors** [{ 'raise', 'ignore' }, default 'ignore'] If 'raise', will raise a ValueError if the DataFrame and *other* both contain non-NA data in the same place.

Changed in version 0.24.0: Changed from `raise_conflict=False|True` to `errors='ignore'|'raise'`.

### Returns

**None** [method directly changes calling object]

### Raises

#### ValueError

- When `errors='raise'` and there's overlapping non-NA data.
- When `errors` is not either `'ignore'` or `'raise'`

#### NotImplementedError

- If `join != 'left'`

### See also:

`dict.update` Similar method for dictionaries.

`DataFrame.merge` For column(s)-on-columns(s) operations.

### Examples

```
>>> df = pd.DataFrame({'A': [1, 2, 3],
...                     'B': [400, 500, 600]})
>>> new_df = pd.DataFrame({'B': [4, 5, 6],
...                         'C': [7, 8, 9]})
>>> df.update(new_df)
>>> df
   A  B
0  1  4
1  2  5
2  3  6
```

The `DataFrame`'s length does not increase as a result of the update, only values at matching index/column labels are updated.

```
>>> df = pd.DataFrame({'A': ['a', 'b', 'c'],
...                     'B': ['x', 'y', 'z']})
>>> new_df = pd.DataFrame({'B': ['d', 'e', 'f', 'g', 'h', 'i']})
>>> df.update(new_df)
>>> df
   A  B
0  a  d
1  b  e
2  c  f
```

For `Series`, it's `name` attribute must be set.

```
>>> df = pd.DataFrame({'A': ['a', 'b', 'c'],
...                     'B': ['x', 'y', 'z']})
>>> new_column = pd.Series(['d', 'e'], name='B', index=[0, 2])
>>> df.update(new_column)
>>> df
   A  B
0  a  d
1  b  y
2  c  e
>>> df = pd.DataFrame({'A': ['a', 'b', 'c'],
...                     'B': ['x', 'y', 'z']})
```

(continues on next page)

(continued from previous page)

```
>>> new_df = pd.DataFrame({'B': ['d', 'e']}, index=[1, 2])
>>> df.update(new_df)
>>> df
   A  B
0  a  x
1  b  d
2  c  e
```

If *other* contains NaNs the corresponding values are not updated in the original dataframe.

```
>>> df = pd.DataFrame({'A': [1, 2, 3],
...                    'B': [400, 500, 600]})
>>> new_df = pd.DataFrame({'B': [4, np.nan, 6]})
>>> df.update(new_df)
>>> df
   A      B
0  1    4.0
1  2  500.0
2  3    6.0
```

### pandas.DataFrame.var

`DataFrame.var` (*axis=None, skipna=None, level=None, ddof=1, numeric\_only=None, \*\*kwargs*)

Return unbiased variance over requested axis.

Normalized by N-1 by default. This can be changed using the `ddof` argument

#### Parameters

**axis** [{index (0), columns (1)}]

**skipna** [boolean, default True] Exclude NA/null values. If an entire row/column is NA, the result will be NA

**level** [int or level name, default None] If the axis is a MultiIndex (hierarchical), count along a particular level, collapsing into a Series

**ddof** [int, default 1] Delta Degrees of Freedom. The divisor used in calculations is N - ddof, where N represents the number of elements.

**numeric\_only** [boolean, default None] Include only float, int, boolean columns. If None, will attempt to use everything, then use only numeric data. Not implemented for Series.

#### Returns

**var** [Series or DataFrame (if level specified)]

### pandas.DataFrame.where

`DataFrame.where` (*cond, other=nan, inplace=False, axis=None, level=None, errors='raise', try\_cast=False, raise\_on\_error=None*)

Replace values where the condition is False.

#### Parameters

**cond** [boolean NDFrame, array-like, or callable] Where *cond* is True, keep the original value. Where False, replace with corresponding value from *other*. If *cond* is callable, it is computed on the NDFrame and should return boolean NDFrame or array. The callable must not change input NDFrame (though pandas doesn't check it).

New in version 0.18.1: A callable can be used as *cond*.

**other** [scalar, NDFrame, or callable] Entries where *cond* is False are replaced with corresponding value from *other*. If *other* is callable, it is computed on the NDFrame and should return scalar or NDFrame. The callable must not change input NDFrame (though pandas doesn't check it).

New in version 0.18.1: A callable can be used as *other*.

**inplace** [boolean, default False] Whether to perform the operation in place on the data.

**axis** [int, default None] Alignment axis if needed.

**level** [int, default None] Alignment level if needed.

**errors** [str, {'raise', 'ignore'}, default *raise*] Note that currently this parameter won't affect the results and will always coerce to a suitable dtype.

- *raise* : allow exceptions to be raised.
- *ignore* : suppress exceptions. On error return original object.

**try\_cast** [boolean, default False] Try to cast the result back to the input type (if possible).

**raise\_on\_error** [boolean, default True] Whether to raise on invalid data types (e.g. trying to where on strings).

Deprecated since version 0.21.0: Use *errors*.

### Returns

**wh** [same type as caller]

See also:

**DataFrame.mask()** Return an object of same shape as self.

### Notes

The *where* method is an application of the if-then idiom. For each element in the calling DataFrame, if *cond* is True the element is used; otherwise the corresponding element from the DataFrame *other* is used.

The signature for *DataFrame.where()* differs from *numpy.where()*. Roughly *df1.where(m, df2)* is equivalent to *np.where(m, df1, df2)*.

For further details and examples see the *where* documentation in *indexing*.

### Examples

```
>>> s = pd.Series(range(5))
>>> s.where(s > 0)
0    NaN
1    1.0
2    2.0
```

(continues on next page)

(continued from previous page)

```
3    3.0
4    4.0
dtype: float64
```

```
>>> s.mask(s > 0)
0    0.0
1    NaN
2    NaN
3    NaN
4    NaN
dtype: float64
```

```
>>> s.where(s > 1, 10)
0    10
1    10
2     2
3     3
4     4
dtype: int64
```

```
>>> df = pd.DataFrame(np.arange(10).reshape(-1, 2), columns=['A', 'B'])
>>> m = df % 3 == 0
>>> df.where(m, -df)
   A  B
0  0 -1
1 -2  3
2 -4 -5
3  6 -7
4 -8  9
>>> df.where(m, -df) == np.where(m, df, -df)
   A      B
0  True  True
1  True  True
2  True  True
3  True  True
4  True  True
>>> df.where(m, -df) == df.mask(~m, -df)
   A      B
0  True  True
1  True  True
2  True  True
3  True  True
4  True  True
```

### pandas.DataFrame.xs

DataFrame.**xs** (*key*, *axis=0*, *level=None*, *drop\_level=True*)

Return cross-section from the Series/DataFrame.

This method takes a *key* argument to select data at a particular level of a MultiIndex.

#### Parameters

**key** [label or tuple of label] Label contained in the index, or partially in a MultiIndex.

**axis** [{0 or 'index', 1 or 'columns'}, default 0] Axis to retrieve cross-section on.

**level** [object, defaults to first n levels (n=1 or len(key))] In case of a key partially contained in a MultiIndex, indicate which levels are used. Levels can be referred by label or position.

**drop\_level** [bool, default True] If False, returns object with same levels as self.

### Returns

**Series or DataFrame** Cross-section from the original Series or DataFrame corresponding to the selected index levels.

### See also:

**DataFrame.loc** Access a group of rows and columns by label(s) or a boolean array.

**DataFrame.iloc** Purely integer-location based indexing for selection by position.

### Notes

*xs* can not be used to set values.

MultiIndex Slicers is a generic way to get/set values on any level or levels. It is a superset of *xs* functionality, see *MultiIndex Slicers*.

### Examples

```
>>> d = {'num_legs': [4, 4, 2, 2],
...      'num_wings': [0, 0, 2, 2],
...      'class': ['mammal', 'mammal', 'mammal', 'bird'],
...      'animal': ['cat', 'dog', 'bat', 'penguin'],
...      'locomotion': ['walks', 'walks', 'flies', 'walks']}
>>> df = pd.DataFrame(data=d)
>>> df = df.set_index(['class', 'animal', 'locomotion'])
>>> df
```

|        |         |            | num_legs | num_wings |
|--------|---------|------------|----------|-----------|
| class  | animal  | locomotion |          |           |
| mammal | cat     | walks      | 4        | 0         |
|        | dog     | walks      | 4        | 0         |
|        | bat     | flies      | 2        | 2         |
| bird   | penguin | walks      | 2        | 2         |

#### Get values at specified index

```
>>> df.xs('mammal')
```

|        |            | num_legs | num_wings |
|--------|------------|----------|-----------|
| animal | locomotion |          |           |
| cat    | walks      | 4        | 0         |
| dog    | walks      | 4        | 0         |
| bat    | flies      | 2        | 2         |

#### Get values at several indexes

```
>>> df.xs(('mammal', 'dog'))
```

|            | num_legs | num_wings |
|------------|----------|-----------|
| locomotion |          |           |
| walks      | 4        | 0         |

#### Get values at specified index and level

```
>>> df.xs('cat', level=1)
               num_legs  num_wings
class locomotion
mammal walks           4          0
```

Get values at several indexes and levels

```
>>> df.xs(('bird', 'walks'),
...       level=[0, 'locomotion'])
               num_legs  num_wings
animal
penguin           2          2
```

Get values at specified column and axis

```
>>> df.xs('num_wings', axis=1)
class animal locomotion
mammal cat      walks      0
        dog      walks      0
        bat      flies      2
bird   penguin  walks      2
Name: num_wings, dtype: int64
```

## 35.4.2 Attributes and underlying data

### Axes

|                                                          |                                                                        |
|----------------------------------------------------------|------------------------------------------------------------------------|
| <code>DataFrame.index</code>                             | The index (row labels) of the DataFrame.                               |
| <code>DataFrame.columns</code>                           | The column labels of the DataFrame.                                    |
| <code>DataFrame.dtypes</code>                            | Return the dtypes in the DataFrame.                                    |
| <code>DataFrame.ftypes</code>                            | Return the ftypes (indication of sparse/dense and dtype) in DataFrame. |
| <code>DataFrame.get_dtype_counts()</code>                | Return counts of unique dtypes in this object.                         |
| <code>DataFrame.get_ftype_counts()</code>                | (DEPRECATED) Return counts of unique ftypes in this object.            |
| <code>DataFrame.select_dtypes([include, exclude])</code> | Return a subset of the DataFrame's columns based on the column dtypes. |
| <code>DataFrame.values</code>                            | Return a Numpy representation of the DataFrame.                        |
| <code>DataFrame.get_values()</code>                      | Return an ndarray after converting sparse values to dense.             |
| <code>DataFrame.axes</code>                              | Return a list representing the axes of the DataFrame.                  |
| <code>DataFrame.ndim</code>                              | Return an int representing the number of axes / array dimensions.      |
| <code>DataFrame.size</code>                              | Return an int representing the number of elements in this object.      |
| <code>DataFrame.shape</code>                             | Return a tuple representing the dimensionality of the DataFrame.       |
| <code>DataFrame.memory_usage([index, deep])</code>       | Return the memory usage of each column in bytes.                       |
| <code>DataFrame.empty</code>                             | Indicator whether DataFrame is empty.                                  |
| <code>DataFrame.is_copy</code>                           | Return the copy.                                                       |

### 35.4.3 Conversion

|                                                              |                                                                |
|--------------------------------------------------------------|----------------------------------------------------------------|
| <code>DataFrame.astype(dtype[, copy, errors])</code>         | Cast a pandas object to a specified dtype <code>dtype</code> . |
| <code>DataFrame.convert_objects([convert_dates, ...])</code> | (DEPRECATED) Attempt to infer better dtype for object columns. |
| <code>DataFrame.infer_objects()</code>                       | Attempt to infer better dtypes for object columns.             |
| <code>DataFrame.copy([deep])</code>                          | Make a copy of this object's indices and data.                 |
| <code>DataFrame.isna()</code>                                | Detect missing values.                                         |
| <code>DataFrame.notna()</code>                               | Detect existing (non-missing) values.                          |
| <code>DataFrame.bool()</code>                                | Return the bool of a single element PandasObject.              |

### 35.4.4 Indexing, iteration

|                                                                |                                                                           |
|----------------------------------------------------------------|---------------------------------------------------------------------------|
| <code>DataFrame.head([n])</code>                               | Return the first $n$ rows.                                                |
| <code>DataFrame.at</code>                                      | Access a single value for a row/column label pair.                        |
| <code>DataFrame.iat</code>                                     | Access a single value for a row/column pair by integer position.          |
| <code>DataFrame.loc</code>                                     | Access a group of rows and columns by label(s) or a boolean array.        |
| <code>DataFrame.iloc</code>                                    | Purely integer-location based indexing for selection by position.         |
| <code>DataFrame.insert(loc, column, value[, ...])</code>       | Insert column into DataFrame at specified location.                       |
| <code>DataFrame.__iter__()</code>                              | Iterate over infor axis                                                   |
| <code>DataFrame.items()</code>                                 | Iterator over (column name, Series) pairs.                                |
| <code>DataFrame.keys()</code>                                  | Get the 'info axis' (see Indexing for more)                               |
| <code>DataFrame.iteritems()</code>                             | Iterator over (column name, Series) pairs.                                |
| <code>DataFrame.iterrows()</code>                              | Iterate over DataFrame rows as (index, Series) pairs.                     |
| <code>DataFrame.itertuples([index, name])</code>               | Iterate over DataFrame rows as namedtuples.                               |
| <code>DataFrame.lookup(row_labels, col_labels)</code>          | Label-based "fancy indexing" function for DataFrame.                      |
| <code>DataFrame.pop(item)</code>                               | Return item and drop from frame.                                          |
| <code>DataFrame.tail([n])</code>                               | Return the last $n$ rows.                                                 |
| <code>DataFrame.xs(key[, axis, level, drop_level])</code>      | Return cross-section from the Series/DataFrame.                           |
| <code>DataFrame.get(key[, default])</code>                     | Get item from object for given key (DataFrame column, Panel slice, etc.). |
| <code>DataFrame.isin(values)</code>                            | Whether each element in the DataFrame is contained in values.             |
| <code>DataFrame.where(cond[, other, inplace, ...])</code>      | Replace values where the condition is False.                              |
| <code>DataFrame.mask(cond[, other, inplace, axis, ...])</code> | Replace values where the condition is True.                               |
| <code>DataFrame.query(expr[, inplace])</code>                  | Query the columns of a DataFrame with a boolean expression.               |

#### 35.4.4.1 pandas.DataFrame.\_\_iter\_\_

`DataFrame.__iter__()`  
Iterate over infor axis

For more information on `.at`, `.iat`, `.loc`, and `.iloc`, see the *indexing documentation*.

### 35.4.5 Binary operator functions

|                                                                |                                                                                             |
|----------------------------------------------------------------|---------------------------------------------------------------------------------------------|
| <code>DataFrame.add(other[, axis, level, fill_value])</code>   | Addition of dataframe and other, element-wise (binary operator <i>add</i> ).                |
| <code>DataFrame.sub(other[, axis, level, fill_value])</code>   | Subtraction of dataframe and other, element-wise (binary operator <i>sub</i> ).             |
| <code>DataFrame.mul(other[, axis, level, fill_value])</code>   | Multiplication of dataframe and other, element-wise (binary operator <i>mul</i> ).          |
| <code>DataFrame.div(other[, axis, level, fill_value])</code>   | Floating division of dataframe and other, element-wise (binary operator <i>truediv</i> ).   |
| <code>DataFrame.truediv(other[, axis, level, ...])</code>      | Floating division of dataframe and other, element-wise (binary operator <i>truediv</i> ).   |
| <code>DataFrame.floordiv(other[, axis, level, ...])</code>     | Integer division of dataframe and other, element-wise (binary operator <i>floordiv</i> ).   |
| <code>DataFrame.mod(other[, axis, level, fill_value])</code>   | Modulo of dataframe and other, element-wise (binary operator <i>mod</i> ).                  |
| <code>DataFrame.pow(other[, axis, level, fill_value])</code>   | Exponential power of dataframe and other, element-wise (binary operator <i>pow</i> ).       |
| <code>DataFrame.dot(other)</code>                              | Compute the matrix multiplication between the DataFrame and other.                          |
| <code>DataFrame.radd(other[, axis, level, fill_value])</code>  | Addition of dataframe and other, element-wise (binary operator <i>radd</i> ).               |
| <code>DataFrame.rsub(other[, axis, level, fill_value])</code>  | Subtraction of dataframe and other, element-wise (binary operator <i>rsub</i> ).            |
| <code>DataFrame.rmul(other[, axis, level, fill_value])</code>  | Multiplication of dataframe and other, element-wise (binary operator <i>rmul</i> ).         |
| <code>DataFrame.rdiv(other[, axis, level, fill_value])</code>  | Floating division of dataframe and other, element-wise (binary operator <i>rtruediv</i> ).  |
| <code>DataFrame.rtruediv(other[, axis, level, ...])</code>     | Floating division of dataframe and other, element-wise (binary operator <i>rtruediv</i> ).  |
| <code>DataFrame.rfloordiv(other[, axis, level, ...])</code>    | Integer division of dataframe and other, element-wise (binary operator <i>rfloordiv</i> ).  |
| <code>DataFrame.rmod(other[, axis, level, fill_value])</code>  | Modulo of dataframe and other, element-wise (binary operator <i>rmod</i> ).                 |
| <code>DataFrame.rpow(other[, axis, level, fill_value])</code>  | Exponential power of dataframe and other, element-wise (binary operator <i>rpow</i> ).      |
| <code>DataFrame.lt(other[, axis, level])</code>                | Less than of dataframe and other, element-wise (binary operator <i>lt</i> ).                |
| <code>DataFrame.gt(other[, axis, level])</code>                | Greater than of dataframe and other, element-wise (binary operator <i>gt</i> ).             |
| <code>DataFrame.le(other[, axis, level])</code>                | Less than or equal to of dataframe and other, element-wise (binary operator <i>le</i> ).    |
| <code>DataFrame.ge(other[, axis, level])</code>                | Greater than or equal to of dataframe and other, element-wise (binary operator <i>ge</i> ). |
| <code>DataFrame.ne(other[, axis, level])</code>                | Not equal to of dataframe and other, element-wise (binary operator <i>ne</i> ).             |
| <code>DataFrame.eq(other[, axis, level])</code>                | Equal to of dataframe and other, element-wise (binary operator <i>eq</i> ).                 |
| <code>DataFrame.combine(other, func[, fill_value, ...])</code> | Perform column-wise combine with another DataFrame based on a passed function.              |

Table 62 – continued from previous page

|                                             |                                                                        |
|---------------------------------------------|------------------------------------------------------------------------|
| <code>DataFrame.combine_first(other)</code> | Update null elements with value in the same location in <i>other</i> . |
|---------------------------------------------|------------------------------------------------------------------------|

### 35.4.6 Function application, GroupBy & Window

|                                                               |                                                                                                                         |
|---------------------------------------------------------------|-------------------------------------------------------------------------------------------------------------------------|
| <code>DataFrame.apply(func[, axis, broadcast, ...])</code>    | Apply a function along an axis of the DataFrame.                                                                        |
| <code>DataFrame.applymap(func)</code>                         | Apply a function to a Dataframe elementwise.                                                                            |
| <code>DataFrame.pipe(func, *args, **kwargs)</code>            | Apply <code>func(self, *args, **kwargs)</code> .                                                                        |
| <code>DataFrame.agg(func[, axis])</code>                      | Aggregate using one or more operations over the specified axis.                                                         |
| <code>DataFrame.aggregate(func[, axis])</code>                | Aggregate using one or more operations over the specified axis.                                                         |
| <code>DataFrame.transform(func[, axis])</code>                | Call <code>func</code> on self producing a DataFrame with transformed values and that has the same axis length as self. |
| <code>DataFrame.groupby([by, axis, level, ...])</code>        | Group DataFrame or Series using a mapper or by a Series of columns.                                                     |
| <code>DataFrame.rolling(window[, min_periods, ...])</code>    | Provides rolling window calculations.                                                                                   |
| <code>DataFrame.expanding([min_periods, center, axis])</code> | Provides expanding transformations.                                                                                     |
| <code>DataFrame.ewm([com, span, halflife, alpha, ...])</code> | Provides exponential weighted functions.                                                                                |

### 35.4.7 Computations / Descriptive Stats

|                                                               |                                                                                                                |
|---------------------------------------------------------------|----------------------------------------------------------------------------------------------------------------|
| <code>DataFrame.abs()</code>                                  | Return a Series/DataFrame with absolute numeric value of each element.                                         |
| <code>DataFrame.all([axis, bool_only, skipna, level])</code>  | Return whether all elements are True, potentially over an axis.                                                |
| <code>DataFrame.any([axis, bool_only, skipna, level])</code>  | Return whether any element is True, potentially over an axis.                                                  |
| <code>DataFrame.clip([lower, upper, axis, inplace])</code>    | Trim values at input threshold(s).                                                                             |
| <code>DataFrame.clip_lower(threshold[, axis, inplace])</code> | (DEPRECATED) Trim values below a given threshold.                                                              |
| <code>DataFrame.clip_upper(threshold[, axis, inplace])</code> | (DEPRECATED) Trim values above a given threshold.                                                              |
| <code>DataFrame.compound([axis, skipna, level])</code>        | Return the compound percentage of the values for the requested axis.                                           |
| <code>DataFrame.corr([method, min_periods])</code>            | Compute pairwise correlation of columns, excluding NA/null values.                                             |
| <code>DataFrame.corrwith(other[, axis, drop, method])</code>  | Compute pairwise correlation between rows or columns of DataFrame with rows or columns of Series or DataFrame. |
| <code>DataFrame.count([axis, level, numeric_only])</code>     | Count non-NA cells for each column or row.                                                                     |
| <code>DataFrame.cov([min_periods])</code>                     | Compute pairwise covariance of columns, excluding NA/null values.                                              |
| <code>DataFrame.cummax([axis, skipna])</code>                 | Return cumulative maximum over a DataFrame or Series axis.                                                     |
| <code>DataFrame.cummin([axis, skipna])</code>                 | Return cumulative minimum over a DataFrame or Series axis.                                                     |

|                                                                |                                                                                                                                              |
|----------------------------------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------|
| <code>DataFrame.cumprod([axis, skipna])</code>                 | Return cumulative product over a DataFrame or Series axis.                                                                                   |
| <code>DataFrame.cumsum([axis, skipna])</code>                  | Return cumulative sum over a DataFrame or Series axis.                                                                                       |
| <code>DataFrame.describe([percentiles, include, ...])</code>   | Generate descriptive statistics that summarize the central tendency, dispersion and shape of a dataset's distribution, excluding NaN values. |
| <code>DataFrame.diff([periods, axis])</code>                   | First discrete difference of element.                                                                                                        |
| <code>DataFrame.eval(expr[, inplace])</code>                   | Evaluate a string describing operations on DataFrame columns.                                                                                |
| <code>DataFrame.kurt([axis, skipna, level, ...])</code>        | Return unbiased kurtosis over requested axis using Fisher's definition of kurtosis (kurtosis of normal == 0.0).                              |
| <code>DataFrame.kurtosis([axis, skipna, level, ...])</code>    | Return unbiased kurtosis over requested axis using Fisher's definition of kurtosis (kurtosis of normal == 0.0).                              |
| <code>DataFrame.mad([axis, skipna, level])</code>              | Return the mean absolute deviation of the values for the requested axis.                                                                     |
| <code>DataFrame.max([axis, skipna, level, ...])</code>         | Return the maximum of the values for the requested axis.                                                                                     |
| <code>DataFrame.mean([axis, skipna, level, ...])</code>        | Return the mean of the values for the requested axis.                                                                                        |
| <code>DataFrame.median([axis, skipna, level, ...])</code>      | Return the median of the values for the requested axis.                                                                                      |
| <code>DataFrame.min([axis, skipna, level, ...])</code>         | Return the minimum of the values for the requested axis.                                                                                     |
| <code>DataFrame.mode([axis, numeric_only, dropna])</code>      | Get the mode(s) of each element along the selected axis.                                                                                     |
| <code>DataFrame.pct_change([periods, fill_method, ...])</code> | Percentage change between the current and a prior element.                                                                                   |
| <code>DataFrame.prod([axis, skipna, level, ...])</code>        | Return the product of the values for the requested axis.                                                                                     |
| <code>DataFrame.product([axis, skipna, level, ...])</code>     | Return the product of the values for the requested axis.                                                                                     |
| <code>DataFrame.quantile([q, axis, numeric_only, ...])</code>  | Return values at the given quantile over requested axis.                                                                                     |
| <code>DataFrame.rank([axis, method, numeric_only, ...])</code> | Compute numerical data ranks (1 through n) along axis.                                                                                       |
| <code>DataFrame.round([decimals])</code>                       | Round a DataFrame to a variable number of decimal places.                                                                                    |
| <code>DataFrame.sem([axis, skipna, level, ddof, ...])</code>   | Return unbiased standard error of the mean over requested axis.                                                                              |
| <code>DataFrame.skew([axis, skipna, level, ...])</code>        | Return unbiased skew over requested axis Normalized by N-1.                                                                                  |
| <code>DataFrame.sum([axis, skipna, level, ...])</code>         | Return the sum of the values for the requested axis.                                                                                         |
| <code>DataFrame.std([axis, skipna, level, ddof, ...])</code>   | Return sample standard deviation over requested axis.                                                                                        |
| <code>DataFrame.var([axis, skipna, level, ddof, ...])</code>   | Return unbiased variance over requested axis.                                                                                                |
| <code>DataFrame.nunique([axis, dropna])</code>                 | Count distinct observations over requested axis.                                                                                             |

### 35.4.8 Reindexing / Selection / Label manipulation

|                                                               |                                                                                     |
|---------------------------------------------------------------|-------------------------------------------------------------------------------------|
| <code>DataFrame.add_prefix(prefix)</code>                     | Prefix labels with string <i>prefix</i> .                                           |
| <code>DataFrame.add_suffix(suffix)</code>                     | Suffix labels with string <i>suffix</i> .                                           |
| <code>DataFrame.align(other[, join, axis, level, ...])</code> | Align two objects on their axes with the specified join method for each axis Index. |
| <code>DataFrame.at_time(time[, asof, axis])</code>            | Select values at particular time of day (e.g.                                       |

Table 65 – continued from previous page

|                                                                |                                                                                                                                |
|----------------------------------------------------------------|--------------------------------------------------------------------------------------------------------------------------------|
| <code>DataFrame.between_time(start_time, end_time)</code>      | Select values between particular times of the day (e.g., 9:00-9:30 AM).                                                        |
| <code>DataFrame.drop([labels, axis, index, ...])</code>        | Drop specified labels from rows or columns.                                                                                    |
| <code>DataFrame.drop_duplicates([subset, keep, ...])</code>    | Return DataFrame with duplicate rows removed, optionally only considering certain columns.                                     |
| <code>DataFrame.duplicated([subset, keep])</code>              | Return boolean Series denoting duplicate rows, optionally only considering certain columns.                                    |
| <code>DataFrame.equals(other)</code>                           | Test whether two objects contain the same elements.                                                                            |
| <code>DataFrame.filter([items, like, regex, axis])</code>      | Subset rows or columns of dataframe according to labels in the specified index.                                                |
| <code>DataFrame.first(offset)</code>                           | Convenience method for subsetting initial periods of time series data based on a date offset.                                  |
| <code>DataFrame.head([n])</code>                               | Return the first <i>n</i> rows.                                                                                                |
| <code>DataFrame.idxmax([axis, skipna])</code>                  | Return index of first occurrence of maximum over requested axis.                                                               |
| <code>DataFrame.idxmin([axis, skipna])</code>                  | Return index of first occurrence of minimum over requested axis.                                                               |
| <code>DataFrame.last(offset)</code>                            | Convenience method for subsetting final periods of time series data based on a date offset.                                    |
| <code>DataFrame.reindex([labels, index, columns, ...])</code>  | Conform DataFrame to new index with optional filling logic, placing NA/NaN in locations having no value in the previous index. |
| <code>DataFrame.reindex_axis(labels[, axis, ...])</code>       | (DEPRECATED) Conform input object to new index.                                                                                |
| <code>DataFrame.reindex_like(other[, method, ...])</code>      | Return an object with matching indices as other object.                                                                        |
| <code>DataFrame.rename([mapper, index, columns, ...])</code>   | Alter axes labels.                                                                                                             |
| <code>DataFrame.rename_axis([mapper, index, ...])</code>       | Set the name of the axis for the index or columns.                                                                             |
| <code>DataFrame.reset_index([level, drop, ...])</code>         | Reset the index, or a level of it.                                                                                             |
| <code>DataFrame.sample([n, frac, replace, ...])</code>         | Return a random sample of items from an axis of object.                                                                        |
| <code>DataFrame.select(crit[, axis])</code>                    | (DEPRECATED) Return data corresponding to axis labels matching criteria.                                                       |
| <code>DataFrame.set_axis(labels[, axis, inplace])</code>       | Assign desired index to given axis.                                                                                            |
| <code>DataFrame.set_index(keys[, drop, append, ...])</code>    | Set the DataFrame index using existing columns.                                                                                |
| <code>DataFrame.tail([n])</code>                               | Return the last <i>n</i> rows.                                                                                                 |
| <code>DataFrame.take(indices[, axis, convert, is_copy])</code> | Return the elements in the given <i>positional</i> indices along an axis.                                                      |
| <code>DataFrame.truncate([before, after, axis, copy])</code>   | Truncate a Series or DataFrame before and after some index value.                                                              |

### 35.4.9 Missing data handling

|                                                                |                                                               |
|----------------------------------------------------------------|---------------------------------------------------------------|
| <code>DataFrame.dropna([axis, how, thresh, ...])</code>        | Remove missing values.                                        |
| <code>DataFrame.fillna([value, method, axis, ...])</code>      | Fill NA/NaN values using the specified method.                |
| <code>DataFrame.replace([to_replace, value, ...])</code>       | Replace values given in <i>to_replace</i> with <i>value</i> . |
| <code>DataFrame.interpolate([method, axis, limit, ...])</code> | Interpolate values according to different methods.            |

### 35.4.10 Reshaping, sorting, transposing

|                                                                |                                                                                                                                                                                      |
|----------------------------------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>DataFrame.droplevel(level[, axis])</code>                | Return DataFrame with requested index / column level(s) removed.                                                                                                                     |
| <code>DataFrame.pivot([index, columns, values])</code>         | Return reshaped DataFrame organized by given index / column values.                                                                                                                  |
| <code>DataFrame.pivot_table([values, index, ...])</code>       | Create a spreadsheet-style pivot table as a DataFrame.                                                                                                                               |
| <code>DataFrame.reorder_levels(order[, axis])</code>           | Rearrange index levels using input order.                                                                                                                                            |
| <code>DataFrame.sort_values(by[, axis, ascending, ...])</code> | Sort by the values along either axis                                                                                                                                                 |
| <code>DataFrame.sort_index([axis, level, ...])</code>          | Sort object by labels (along an axis)                                                                                                                                                |
| <code>DataFrame.nlargest(n, columns[, keep])</code>            | Return the first <i>n</i> rows ordered by <i>columns</i> in descending order.                                                                                                        |
| <code>DataFrame.nsmallest(n, columns[, keep])</code>           | Return the first <i>n</i> rows ordered by <i>columns</i> in ascending order.                                                                                                         |
| <code>DataFrame.swaplevel([i, j, axis])</code>                 | Swap levels <i>i</i> and <i>j</i> in a MultiIndex on a particular axis.                                                                                                              |
| <code>DataFrame.stack([level, dropna])</code>                  | Stack the prescribed level(s) from columns to index.                                                                                                                                 |
| <code>DataFrame.unstack([level, fill_value])</code>            | Pivot a level of the (necessarily hierarchical) index labels, returning a DataFrame having a new level of column labels whose inner-most level consists of the pivoted index labels. |
| <code>DataFrame.swapaxes(axis1, axis2[, copy])</code>          | Interchange axes and swap values axes appropriately.                                                                                                                                 |
| <code>DataFrame.melt([id_vars, value_vars, ...])</code>        | Unpivots a DataFrame from wide format to long format, optionally leaving identifier variables set.                                                                                   |
| <code>DataFrame.squeeze([axis])</code>                         | Squeeze 1 dimensional axis objects into scalars.                                                                                                                                     |
| <code>DataFrame.to_panel()</code>                              | (DEPRECATED) Transform long (stacked) format (DataFrame) into wide (3D, Panel) format.                                                                                               |
| <code>DataFrame.to_xarray()</code>                             | Return an xarray object from the pandas object.                                                                                                                                      |
| <code>DataFrame.T</code>                                       | Transpose index and columns.                                                                                                                                                         |
| <code>DataFrame.transpose(*args, **kwargs)</code>              | Transpose index and columns.                                                                                                                                                         |

### 35.4.11 Combining / joining / merging

|                                                              |                                                                           |
|--------------------------------------------------------------|---------------------------------------------------------------------------|
| <code>DataFrame.append(other[, ignore_index, ...])</code>    | Append rows of <i>other</i> to the end of caller, returning a new object. |
| <code>DataFrame.assign(**kwargs)</code>                      | Assign new columns to a DataFrame.                                        |
| <code>DataFrame.join(other[, on, how, lsuffix, ...])</code>  | Join columns of another DataFrame.                                        |
| <code>DataFrame.merge(right[, how, on, left_on, ...])</code> | Merge DataFrame or named Series objects with a database-style join.       |
| <code>DataFrame.update(other[, join, overwrite, ...])</code> | Modify in place using non-NA values from another DataFrame.               |

### 35.4.12 Time series-related

|                                                          |                                                                              |
|----------------------------------------------------------|------------------------------------------------------------------------------|
| <code>DataFrame.asfreq(freq[, method, how, ...])</code>  | Convert TimeSeries to specified frequency.                                   |
| <code>DataFrame.asof(when[, subset])</code>              | Return the last row(s) without any NaNs before <i>when</i> .                 |
| <code>DataFrame.shift([periods, freq, axis, ...])</code> | Shift index by desired number of periods with an optional time <i>freq</i> . |
| <code>DataFrame.slice_shift([periods, axis])</code>      | Equivalent to <i>shift</i> without copying data.                             |
| <code>DataFrame.tshift([periods, freq, axis])</code>     | Shift the time index, using the index's frequency if available.              |

Table 69 – continued from previous page

|                                                              |                                                                                                                 |
|--------------------------------------------------------------|-----------------------------------------------------------------------------------------------------------------|
| <code>DataFrame.first_valid_index()</code>                   | Return index for first non-NA/null value.                                                                       |
| <code>DataFrame.last_valid_index()</code>                    | Return index for last non-NA/null value.                                                                        |
| <code>DataFrame.resample(rule[, how, axis, ...])</code>      | Resample time-series data.                                                                                      |
| <code>DataFrame.to_period([freq, axis, copy])</code>         | Convert DataFrame from DatetimeIndex to PeriodIndex with desired frequency (inferred from index if not passed). |
| <code>DataFrame.to_timestamp([freq, how, axis, copy])</code> | Cast to DatetimeIndex of timestamps, at <i>beginning</i> of period.                                             |
| <code>DataFrame.tz_convert(tz[, axis, level, copy])</code>   | Convert tz-aware axis to target time zone.                                                                      |
| <code>DataFrame.tz_localize(tz[, axis, level, ...])</code>   | Localize tz-naive index of a Series or DataFrame to target time zone.                                           |

### 35.4.13 Plotting

`DataFrame.plot` is both a callable method and a namespace attribute for specific plotting methods of the form `DataFrame.plot.<kind>`.

|                                                       |                                                                 |
|-------------------------------------------------------|-----------------------------------------------------------------|
| <code>DataFrame.plot([x, y, kind, ax, ...])</code>    | DataFrame plotting accessor and method                          |
| <code>DataFrame.plot.area([x, y])</code>              | Draw a stacked area plot.                                       |
| <code>DataFrame.plot.bar([x, y])</code>               | Vertical bar plot.                                              |
| <code>DataFrame.plot.barh([x, y])</code>              | Make a horizontal bar plot.                                     |
| <code>DataFrame.plot.box([by])</code>                 | Make a box plot of the DataFrame columns.                       |
| <code>DataFrame.plot.density([bw_method, ind])</code> | Generate Kernel Density Estimate plot using Gaussian kernels.   |
| <code>DataFrame.plot.hexbin(x, y[, C, ...])</code>    | Generate a hexagonal binning plot.                              |
| <code>DataFrame.plot.hist([by, bins])</code>          | Draw one histogram of the DataFrame's columns.                  |
| <code>DataFrame.plot.kde([bw_method, ind])</code>     | Generate Kernel Density Estimate plot using Gaussian kernels.   |
| <code>DataFrame.plot.line([x, y])</code>              | Plot DataFrame columns as lines.                                |
| <code>DataFrame.plot.pie([y])</code>                  | Generate a pie plot.                                            |
| <code>DataFrame.plot.scatter(x, y[, s, c])</code>     | Create a scatter plot with varying marker point size and color. |

#### 35.4.13.1 `pandas.DataFrame.plot.area`

`DataFrame.plot.area` (*x=None, y=None, \*\*kwargs*)

Draw a stacked area plot.

An area plot displays quantitative data visually. This function wraps the matplotlib area function.

##### Parameters

**x** [label or position, optional] Coordinates for the X axis. By default uses the index.

**y** [label or position, optional] Column to plot. By default uses all columns.

**stacked** [bool, default True] Area plots are stacked by default. Set to False to create a unstacked plot.

**\*\*kwargs** [optional] Additional keyword arguments are documented in `pandas.DataFrame.plot()`.

**Returns**

**matplotlib.axes.Axes or numpy.ndarray** Area plot, or array of area plots if subplots is True

See also:

**DataFrame.plot** Make plots of DataFrame using matplotlib / pylab.

**Examples**

Draw an area plot based on basic business metrics:

```
>>> df = pd.DataFrame({
...     'sales': [3, 2, 3, 9, 10, 6],
...     'signups': [5, 5, 6, 12, 14, 13],
...     'visits': [20, 42, 28, 62, 81, 50],
... }, index=pd.date_range(start='2018/01/01', end='2018/07/01',
...                          freq='M'))
>>> ax = df.plot.area()
```

Area plots are stacked by default. To produce an unstacked plot, pass `stacked=False`:

```
>>> ax = df.plot.area(stacked=False)
```

Draw an area plot for a single column:

```
>>> ax = df.plot.area(y='sales')
```

Draw with a different x:

```
>>> df = pd.DataFrame({
...     'sales': [3, 2, 3],
...     'visits': [20, 42, 28],
...     'day': [1, 2, 3],
... })
>>> ax = df.plot.area(x='day')
```

**35.4.13.2 pandas.DataFrame.plot.bar**

**DataFrame.plot.bar** (*x=None, y=None, \*\*kwargs*)

Vertical bar plot.

A bar plot is a plot that presents categorical data with rectangular bars with lengths proportional to the values that they represent. A bar plot shows comparisons among discrete categories. One axis of the plot shows the specific categories being compared, and the other axis represents a measured value.

**Parameters**

**x** [label or position, optional] Allows plotting of one column versus another. If not specified, the index of the DataFrame is used.

**y** [label or position, optional] Allows plotting of one column versus another. If not specified, all numerical columns are used.

**\*\*kwargs** Additional keyword arguments are documented in *pandas.DataFrame.plot()*.

**Returns**

**axes** [matplotlib.axes.Axes or np.ndarray of them] An ndarray is returned with one `matplotlib.axes.Axes` per column when `subplots=True`.

See also:

**`pandas.DataFrame.plot.barh`** Horizontal bar plot.

**`pandas.DataFrame.plot`** Make plots of a DataFrame.

**`matplotlib.pyplot.bar`** Make a bar plot with matplotlib.

## Examples

Basic plot.

```
>>> df = pd.DataFrame({'lab': ['A', 'B', 'C'], 'val': [10, 30, 20]})
>>> ax = df.plot.bar(x='lab', y='val', rot=0)
```

Plot a whole dataframe to a bar plot. Each column is assigned a distinct color, and each row is nested in a group along the horizontal axis.

```
>>> speed = [0.1, 17.5, 40, 48, 52, 69, 88]
>>> lifespan = [2, 8, 70, 1.5, 25, 12, 28]
>>> index = ['snail', 'pig', 'elephant',
...         'rabbit', 'giraffe', 'coyote', 'horse']
>>> df = pd.DataFrame({'speed': speed,
...                   'lifespan': lifespan}, index=index)
>>> ax = df.plot.bar(rot=0)
```

Instead of nesting, the figure can be split by column with `subplots=True`. In this case, a `numpy.ndarray` of `matplotlib.axes.Axes` are returned.

```
>>> axes = df.plot.bar(rot=0, subplots=True)
>>> axes[1].legend(loc=2) # doctest: +SKIP
```

Plot a single column.

```
>>> ax = df.plot.bar(y='speed', rot=0)
```

Plot only selected categories for the DataFrame.

```
>>> ax = df.plot.bar(x='lifespan', rot=0)
```

### 35.4.13.3 `pandas.DataFrame.plot.barh`

`DataFrame.plot.barh` (*x=None, y=None, \*\*kws*)

Make a horizontal bar plot.

A horizontal bar plot is a plot that presents quantitative data with rectangular bars with lengths proportional to the values that they represent. A bar plot shows comparisons among discrete categories. One axis of the plot shows the specific categories being compared, and the other axis represents a measured value.

#### Parameters

**x** [label or position, default `DataFrame.index`] Column to be used for categories.

**y** [label or position, default All numeric columns in dataframe] Columns to be plotted from the DataFrame.

**\*\*kwargs** Keyword arguments to pass on to `pandas.DataFrame.plot()`.

#### Returns

**axes** [`matplotlib.axes.Axes` or `numpy.ndarray` of them.]

See also:

**`pandas.DataFrame.plot.bar`** Vertical bar plot.

**`pandas.DataFrame.plot`** Make plots of DataFrame using matplotlib.

**`matplotlib.axes.Axes.bar`** Plot a vertical bar plot using matplotlib.

## Examples

Basic example

```
>>> df = pd.DataFrame({'lab': ['A', 'B', 'C'], 'val': [10, 30, 20]})
>>> ax = df.plot.barh(x='lab', y='val')
```

Plot a whole DataFrame to a horizontal bar plot

```
>>> speed = [0.1, 17.5, 40, 48, 52, 69, 88]
>>> lifespan = [2, 8, 70, 1.5, 25, 12, 28]
>>> index = ['snail', 'pig', 'elephant',
...         'rabbit', 'giraffe', 'coyote', 'horse']
>>> df = pd.DataFrame({'speed': speed,
...                   'lifespan': lifespan}, index=index)
>>> ax = df.plot.barh()
```

Plot a column of the DataFrame to a horizontal bar plot

```
>>> speed = [0.1, 17.5, 40, 48, 52, 69, 88]
>>> lifespan = [2, 8, 70, 1.5, 25, 12, 28]
>>> index = ['snail', 'pig', 'elephant',
...         'rabbit', 'giraffe', 'coyote', 'horse']
>>> df = pd.DataFrame({'speed': speed,
...                   'lifespan': lifespan}, index=index)
>>> ax = df.plot.barh(y='speed')
```

Plot DataFrame versus the desired column

```
>>> speed = [0.1, 17.5, 40, 48, 52, 69, 88]
>>> lifespan = [2, 8, 70, 1.5, 25, 12, 28]
>>> index = ['snail', 'pig', 'elephant',
...         'rabbit', 'giraffe', 'coyote', 'horse']
>>> df = pd.DataFrame({'speed': speed,
...                   'lifespan': lifespan}, index=index)
>>> ax = df.plot.barh(x='lifespan')
```

### 35.4.13.4 pandas.DataFrame.plot.box

`DataFrame.plot.box` (*by=None*, *\*\*kwargs*)

Make a box plot of the DataFrame columns.

A box plot is a method for graphically depicting groups of numerical data through their quartiles. The box extends from the Q1 to Q3 quartile values of the data, with a line at the median (Q2). The whiskers extend from

the edges of box to show the range of the data. The position of the whiskers is set by default to  $1.5 \times \text{IQR}$  ( $\text{IQR} = Q3 - Q1$ ) from the edges of the box. Outlier points are those past the end of the whiskers.

For further details see Wikipedia's entry for [boxplot](#).

A consideration when using this chart is that the box and the whiskers can overlap, which is very common when plotting small sets of data.

#### Parameters

**by** [string or sequence] Column in the DataFrame to group by.

**\*\*kwds** [optional] Additional keywords are documented in `pandas.DataFrame.plot()`.

#### Returns

**axes** [`matplotlib.axes.Axes` or `numpy.ndarray` of them]

See also:

**`pandas.DataFrame.boxplot`** Another method to draw a box plot.

**`pandas.Series.plot.box`** Draw a box plot from a Series object.

**`matplotlib.pyplot.boxplot`** Draw a box plot in matplotlib.

#### Examples

Draw a box plot from a DataFrame with four columns of randomly generated data.

```
>>> data = np.random.randn(25, 4)
>>> df = pd.DataFrame(data, columns=list('ABCD'))
>>> ax = df.plot.box()
```

### 35.4.13.5 pandas.DataFrame.plot.density

`DataFrame.plot.density` (*bw\_method=None, ind=None, \*\*kwds*)

Generate Kernel Density Estimate plot using Gaussian kernels.

In statistics, [kernel density estimation](#) (KDE) is a non-parametric way to estimate the probability density function (PDF) of a random variable. This function uses Gaussian kernels and includes automatic bandwidth determination.

#### Parameters

**bw\_method** [str, scalar or callable, optional] The method used to calculate the estimator bandwidth. This can be 'scott', 'silverman', a scalar constant or a callable. If None (default), 'scott' is used. See `scipy.stats.gaussian_kde` for more information.

**ind** [NumPy array or integer, optional] Evaluation points for the estimated PDF. If None (default), 1000 equally spaced points are used. If *ind* is a NumPy array, the KDE is evaluated at the points passed. If *ind* is an integer, *ind* number of equally spaced points are used.

**\*\*kwds** [optional] Additional keyword arguments are documented in `pandas.DataFrame.plot()`.

#### Returns

**axes** [`matplotlib.axes.Axes` or `numpy.ndarray` of them]

See also:

**scipy.stats.gaussian\_kde** Representation of a kernel-density estimate using Gaussian kernels. This is the function used internally to estimate the PDF.

**Series.plot.kde** Generate a KDE plot for a Series.

## Examples

Given several Series of points randomly sampled from unknown distributions, estimate their PDFs using KDE with automatic bandwidth determination and plot the results, evaluating them at 1000 equally spaced points (default):

```
>>> df = pd.DataFrame({
...     'x': [1, 2, 2.5, 3, 3.5, 4, 5],
...     'y': [4, 4, 4.5, 5, 5.5, 6, 6],
... })
>>> ax = df.plot.kde()
```

A scalar bandwidth can be specified. Using a small bandwidth value can lead to over-fitting, while using a large bandwidth value may result in under-fitting:

```
>>> ax = df.plot.kde(bw_method=0.3)
```

```
>>> ax = df.plot.kde(bw_method=3)
```

Finally, the *ind* parameter determines the evaluation points for the plot of the estimated PDF:

```
>>> ax = df.plot.kde(ind=[1, 2, 3, 4, 5, 6])
```

### 35.4.13.6 pandas.DataFrame.plot.hexbin

**DataFrame.plot.hexbin** (*x*, *y*, *C=None*, *reduce\_C\_function=None*, *gridsize=None*, *\*\*kws*)

Generate a hexagonal binning plot.

Generate a hexagonal binning plot of *x* versus *y*. If *C* is *None* (the default), this is a histogram of the number of occurrences of the observations at (*x*[*i*], *y*[*i*]).

If *C* is specified, specifies values at given coordinates (*x*[*i*], *y*[*i*]). These values are accumulated for each hexagonal bin and then reduced according to *reduce\_C\_function*, having as default the NumPy's mean function (`numpy.mean()`). (If *C* is specified, it must also be a 1-D sequence of the same length as *x* and *y*, or a column label.)

#### Parameters

**x** [int or str] The column label or position for *x* points.

**y** [int or str] The column label or position for *y* points.

**C** [int or str, optional] The column label or position for the value of (*x*, *y*) point.

**reduce\_C\_function** [callable, default *np.mean*] Function of one argument that reduces all the values in a bin to a single number (e.g. *np.mean*, *np.max*, *np.sum*, *np.std*).

**gridsize** [int or tuple of (int, int), default 100] The number of hexagons in the *x*-direction. The corresponding number of hexagons in the *y*-direction is chosen in a way that the hexagons are approximately regular. Alternatively, *gridsize* can be a tuple with two elements specifying the number of hexagons in the *x*-direction and the *y*-direction.

**\*\*kwargs** Additional keyword arguments are documented in `pandas.DataFrame.plot()`.

#### Returns

**matplotlib.AxesSubplot** The matplotlib `Axes` on which the hexbin is plotted.

See also:

**DataFrame.plot** Make plots of a DataFrame.

**matplotlib.pyplot.hexbin** Hexagonal binning plot using matplotlib, the matplotlib function that is used under the hood.

### Examples

The following examples are generated with random data from a normal distribution.

```
>>> n = 10000
>>> df = pd.DataFrame({'x': np.random.randn(n),
...                    'y': np.random.randn(n)})
>>> ax = df.plot.hexbin(x='x', y='y', gridsize=20)
```

The next example uses `C` and `np.sum` as `reduce_C_function`. Note that `'observations'` values ranges from 1 to 5 but the result plot shows values up to more than 25. This is because of the `reduce_C_function`.

```
>>> n = 500
>>> df = pd.DataFrame({
...     'coord_x': np.random.uniform(-3, 3, size=n),
...     'coord_y': np.random.uniform(30, 50, size=n),
...     'observations': np.random.randint(1, 5, size=n)
... })
>>> ax = df.plot.hexbin(x='coord_x',
...                     y='coord_y',
...                     C='observations',
...                     reduce_C_function=np.sum,
...                     gridsize=10,
...                     cmap="viridis")
```

#### 35.4.13.7 pandas.DataFrame.plot.hist

`DataFrame.plot.hist` (*by=None, bins=10, \*\*kwargs*)

Draw one histogram of the DataFrame's columns.

A histogram is a representation of the distribution of data. This function groups the values of all given Series in the DataFrame into bins and draws all bins in one `matplotlib.axes.Axes`. This is useful when the DataFrame's Series are in a similar scale.

#### Parameters

**by** [str or sequence, optional] Column in the DataFrame to group by.

**bins** [int, default 10] Number of histogram bins to be used.

**\*\*kwargs** Additional keyword arguments are documented in `pandas.DataFrame.plot()`.

#### Returns

**axes** [matplotlib.AxesSubplot histogram.]

See also:

**DataFrame.hist** Draw histograms per DataFrame's Series.

**Series.hist** Draw a histogram with Series' data.

## Examples

When we draw a dice 6000 times, we expect to get each value around 1000 times. But when we draw two dices and sum the result, the distribution is going to be quite different. A histogram illustrates those distributions.

```
>>> df = pd.DataFrame(
...     np.random.randint(1, 7, 6000),
...     columns = ['one'])
>>> df['two'] = df['one'] + np.random.randint(1, 7, 6000)
>>> ax = df.plot.hist(bins=12, alpha=0.5)
```

### 35.4.13.8 pandas.DataFrame.plot.kde

DataFrame.plot.kde (bw\_method=None, ind=None, \*\*kws)

Generate Kernel Density Estimate plot using Gaussian kernels.

In statistics, [kernel density estimation](#) (KDE) is a non-parametric way to estimate the probability density function (PDF) of a random variable. This function uses Gaussian kernels and includes automatic bandwidth determination.

#### Parameters

**bw\_method** [str, scalar or callable, optional] The method used to calculate the estimator bandwidth. This can be 'scott', 'silverman', a scalar constant or a callable. If None (default), 'scott' is used. See [scipy.stats.gaussian\\_kde](#) for more information.

**ind** [NumPy array or integer, optional] Evaluation points for the estimated PDF. If None (default), 1000 equally spaced points are used. If ind is a NumPy array, the KDE is evaluated at the points passed. If ind is an integer, ind number of equally spaced points are used.

**\*\*kws** [optional] Additional keyword arguments are documented in [pandas.DataFrame.plot\(\)](#).

#### Returns

**axes** [matplotlib.axes.Axes or numpy.ndarray of them]

See also:

**scipy.stats.gaussian\_kde** Representation of a kernel-density estimate using Gaussian kernels. This is the function used internally to estimate the PDF.

**Series.plot.kde** Generate a KDE plot for a Series.

## Examples

Given several Series of points randomly sampled from unknown distributions, estimate their PDFs using KDE with automatic bandwidth determination and plot the results, evaluating them at 1000 equally spaced points (default):

```
>>> df = pd.DataFrame({
...     'x': [1, 2, 2.5, 3, 3.5, 4, 5],
...     'y': [4, 4, 4.5, 5, 5.5, 6, 6],
... })
>>> ax = df.plot.kde()
```

A scalar bandwidth can be specified. Using a small bandwidth value can lead to over-fitting, while using a large bandwidth value may result in under-fitting:

```
>>> ax = df.plot.kde(bw_method=0.3)
```

```
>>> ax = df.plot.kde(bw_method=3)
```

Finally, the *ind* parameter determines the evaluation points for the plot of the estimated PDF:

```
>>> ax = df.plot.kde(ind=[1, 2, 3, 4, 5, 6])
```

### 35.4.13.9 pandas.DataFrame.plot.line

`DataFrame.plot.line` (*x=None, y=None, \*\*kwds*)

Plot DataFrame columns as lines.

This function is useful to plot lines using DataFrame's values as coordinates.

#### Parameters

**x** [int or str, optional] Columns to use for the horizontal axis. Either the location or the label of the columns to be used. By default, it will use the DataFrame indices.

**y** [int, str, or list of them, optional] The values to be plotted. Either the location or the label of the columns to be used. By default, it will use the remaining DataFrame numeric columns.

**\*\*kwds** Keyword arguments to pass on to `pandas.DataFrame.plot()`.

#### Returns

**axes** [`matplotlib.axes.Axes` or `numpy.ndarray`] Returns an ndarray when `subplots=True`.

See also:

`matplotlib.pyplot.plot` Plot y versus x as lines and/or markers.

#### Examples

The following example shows the populations for some animals over the years.

```
>>> df = pd.DataFrame({
...     'pig': [20, 18, 489, 675, 1776],
...     'horse': [4, 25, 281, 600, 1900]
... }, index=[1990, 1997, 2003, 2009, 2014])
>>> lines = df.plot.line()
```

An example with subplots, so an array of axes is returned.

```
>>> axes = df.plot.line(subplots=True)
>>> type(axes)
<class 'numpy.ndarray'>
```

The following example shows the relationship between both populations.

```
>>> lines = df.plot.line(x='pig', y='horse')
```

### 35.4.13.10 pandas.DataFrame.plot.pie

`DataFrame.plot.pie` (*y=None, \*\*kws*)

Generate a pie plot.

A pie plot is a proportional representation of the numerical data in a column. This function wraps `matplotlib.pyplot.pie()` for the specified column. If no column reference is passed and `subplots=True` a pie plot is drawn for each numerical column independently.

#### Parameters

**y** [int or label, optional] Label or position of the column to plot. If not provided, `subplots=True` argument must be passed.

**\*\*kws** Keyword arguments to pass on to `pandas.DataFrame.plot()`.

#### Returns

**axes** [matplotlib.axes.Axes or np.ndarray of them.] A NumPy array is returned when `subplots` is True.

See also:

**Series.plot.pie** Generate a pie plot for a Series.

**DataFrame.plot** Make plots of a DataFrame.

### Examples

In the example below we have a DataFrame with the information about planet's mass and radius. We pass the 'mass' column to the pie function to get a pie plot.

```
>>> df = pd.DataFrame({'mass': [0.330, 4.87, 5.97],
...                    'radius': [2439.7, 6051.8, 6378.1]},
...                    index=['Mercury', 'Venus', 'Earth'])
>>> plot = df.plot.pie(y='mass', figsize=(5, 5))
```

```
>>> plot = df.plot.pie(subplots=True, figsize=(6, 3))
```

### 35.4.13.11 pandas.DataFrame.plot.scatter

`DataFrame.plot.scatter` (*x, y, s=None, c=None, \*\*kws*)

Create a scatter plot with varying marker point size and color.

The coordinates of each point are defined by two dataframe columns and filled circles are used to represent each point. This kind of plot is useful to see complex correlations between two variables. Points could be for instance natural 2D coordinates like longitude and latitude in a map or, in general, any pair of metrics that can be plotted against each other.

### Parameters

- x** [int or str] The column name or column position to be used as horizontal coordinates for each point.
- y** [int or str] The column name or column position to be used as vertical coordinates for each point.
- s** [scalar or array\_like, optional] The size of each point. Possible values are:
- A single scalar so all points have the same size.
  - A sequence of scalars, which will be used for each point's size recursively. For instance, when passing [2,14] all points size will be either 2 or 14, alternatively.
- c** [str, int or array\_like, optional] The color of each point. Possible values are:
- A single color string referred to by name, RGB or RGBA code, for instance 'red' or '#a98d19'.
  - A sequence of color strings referred to by name, RGB or RGBA code, which will be used for each point's color recursively. For instance ['green','yellow'] all points will be filled in green or yellow, alternatively.
  - A column name or position whose values will be used to color the marker points according to a colormap.

**\*\*kwargs** Keyword arguments to pass on to `pandas.DataFrame.plot()`.

### Returns

**axes** [`matplotlib.axes.Axes` or `numpy.ndarray` of them]

See also:

`matplotlib.pyplot.scatter` Scatter plot using multiple input data formats.

### Examples

Let's see how to draw a scatter plot using coordinates from the values in a `DataFrame`'s columns.

```
>>> df = pd.DataFrame([[5.1, 3.5, 0], [4.9, 3.0, 0], [7.0, 3.2, 1],
...                    [6.4, 3.2, 1], [5.9, 3.0, 2]],
...                    columns=['length', 'width', 'species'])
>>> ax1 = df.plot.scatter(x='length',
...                       y='width',
...                       c='DarkBlue')
```

And now with the color determined by a column as well.

```
>>> ax2 = df.plot.scatter(x='length',
...                       y='width',
...                       c='species',
...                       colormap='viridis')
```

---

`DataFrame.boxplot([column, by, ax, ...])`

Make a box plot from `DataFrame` columns.

---

`DataFrame.hist([column, by, grid, ...])`

Make a histogram of the `DataFrame`'s.

---

### 35.4.14 Serialization / IO / Conversion

|                                                                |                                                                                                                    |
|----------------------------------------------------------------|--------------------------------------------------------------------------------------------------------------------|
| <code>DataFrame.from_csv(path[, header, sep, ...])</code>      | (DEPRECATED) Read CSV file.                                                                                        |
| <code>DataFrame.from_dict(data[, orient, dtype, ...])</code>   | Construct DataFrame from dict of array-like or dicts.                                                              |
| <code>DataFrame.from_items(items[, columns, orient])</code>    | (DEPRECATED) Construct a DataFrame from a list of tuples.                                                          |
| <code>DataFrame.from_records(data[, index, ...])</code>        | Convert structured or record ndarray to DataFrame.                                                                 |
| <code>DataFrame.info([verbose, buf, max_cols, ...])</code>     | Print a concise summary of a DataFrame.                                                                            |
| <code>DataFrame.to_parquet(fname[, engine, ...])</code>        | Write a DataFrame to the binary parquet format.                                                                    |
| <code>DataFrame.to_pickle(path[, compression, ...])</code>     | Pickle (serialize) object to file.                                                                                 |
| <code>DataFrame.to_csv([path_or_buf, sep, na_rep, ...])</code> | Write object to a comma-separated values (csv) file.                                                               |
| <code>DataFrame.to_hdf(path_or_buf, key, **kwargs)</code>      | Write the contained data to an HDF5 file using HDFStore.                                                           |
| <code>DataFrame.to_sql(name, con[, schema, ...])</code>        | Write records stored in a DataFrame to a SQL database.                                                             |
| <code>DataFrame.to_dict([orient, into])</code>                 | Convert the DataFrame to a dictionary.                                                                             |
| <code>DataFrame.to_excel(excel_writer[, ...])</code>           | Write object to an Excel sheet.                                                                                    |
| <code>DataFrame.to_json([path_or_buf, orient, ...])</code>     | Convert the object to a JSON string.                                                                               |
| <code>DataFrame.to_html([buf, columns, col_space, ...])</code> | Render a DataFrame as an HTML table.                                                                               |
| <code>DataFrame.to_feather(fname)</code>                       | Write out the binary feather-format for DataFrames.                                                                |
| <code>DataFrame.to_latex([buf, columns, ...])</code>           | Render an object to a LaTeX tabular environment table.                                                             |
| <code>DataFrame.to_stata(fname[, convert_dates, ...])</code>   | Export DataFrame object to Stata dta format.                                                                       |
| <code>DataFrame.to_msgpack([path_or_buf, encoding])</code>     | Serialize object to input file path using msgpack format.                                                          |
| <code>DataFrame.to_gbq(destination_table[, ...])</code>        | Write a DataFrame to a Google BigQuery table.                                                                      |
| <code>DataFrame.to_records([index, ...])</code>                | Convert DataFrame to a NumPy record array.                                                                         |
| <code>DataFrame.to_sparse([fill_value, kind])</code>           | Convert to SparseDataFrame.                                                                                        |
| <code>DataFrame.to_dense()</code>                              | Return dense representation of NDFrame (as opposed to sparse).                                                     |
| <code>DataFrame.to_string([buf, columns, ...])</code>          | Render a DataFrame to a console-friendly tabular output.                                                           |
| <code>DataFrame.to_clipboard([excel, sep])</code>              | Copy object to the system clipboard.                                                                               |
| <code>DataFrame.style</code>                                   | Property returning a Styler object containing methods for building a styled HTML representation for the DataFrame. |

### 35.4.15 Sparse

|                                       |                                                                |
|---------------------------------------|----------------------------------------------------------------|
| <code>SparseDataFrame.to_coo()</code> | Return the contents of the frame as a sparse SciPy COO matrix. |
|---------------------------------------|----------------------------------------------------------------|

#### 35.4.15.1 pandas.SparseDataFrame.to\_coo

`SparseDataFrame.to_coo()`

Return the contents of the frame as a sparse SciPy COO matrix.

New in version 0.20.0.

#### Returns

**coo\_matrix** [scipy.sparse.spmatrix] If the caller is heterogeneous and contains booleans or objects, the result will be of dtype=object. See Notes.

### Notes

The dtype will be the lowest-common-denominator type (implicit upcasting); that is to say if the dtypes (even of numeric types) are mixed, the one that accommodates all will be chosen.

e.g. If the dtypes are float16 and float32, dtype will be upcast to float32. By numpy.find\_common\_type convention, mixing int64 and and uint64 will result in a float64 dtype.

```

```

## 35.5 Pandas Arrays

For most data types, pandas uses NumPy arrays as the concrete objects contained with a *Index*, *Series*, or *DataFrame*.

For some data types, pandas extends NumPy's type system.

| Kind of Data        | Pandas Data Type        | Scalar           | Array                   |
|---------------------|-------------------------|------------------|-------------------------|
| TZ-aware datetime   | <i>DatetimeTZDtype</i>  | <i>Timestamp</i> | <i>Datetime Data</i>    |
| Timedeltas          | (none)                  | <i>Timedelta</i> | <i>Timedelta Data</i>   |
| Period (time spans) | <i>PeriodDtype</i>      | <i>Period</i>    | <i>Timespan Data</i>    |
| Intervals           | <i>IntervalDtype</i>    | <i>Interval</i>  | <i>Interval Data</i>    |
| Nullable Integer    | <i>Int64Dtype</i> , ... | (none)           | <i>Nullable Integer</i> |
| Categorical         | <i>CategoricalDtype</i> | (none)           | <i>Categorical Data</i> |
| Sparse              | <i>SparseDtype</i>      | (none)           | <i>Sparse Data</i>      |

Pandas and third-party libraries can extend NumPy's type system (see *Extension Types*). The top-level *array()* method can be used to create a new array, which may be stored in a *Series*, *Index*, or as a column in a *DataFrame*.

---

```
array(data[, dtype, copy])
```

Create an array.

---

### 35.5.1 pandas.array

`pandas.array(data, dtype=None, copy=True)`

Create an array.

New in version 0.24.0.

#### Parameters

**data** [Sequence of objects] The scalars inside *data* should be instances of the scalar type for *dtype*. It's expected that *data* represents a 1-dimensional array of data.

When *data* is an Index or Series, the underlying array will be extracted from *data*.

**dtype** [str, np.dtype, or ExtensionDtype, optional] The dtype to use for the array. This may be a NumPy dtype or an extension type registered with pandas using `pandas.api.extensions.register_extension_dtype()`.

If not specified, there are two possibilities:

1. When *data* is a *Series*, *Index*, or *ExtensionArray*, the *dtype* will be taken from the data.
2. Otherwise, pandas will attempt to infer the *dtype* from the data.

Note that when *data* is a NumPy array, `data.dtype` is *not* used for inferring the array type. This is because NumPy cannot represent all the types of data that can be held in extension arrays.

Currently, pandas will infer an extension dtype for sequences of

| Scalar Type                     | Array Type                                |
|---------------------------------|-------------------------------------------|
| <code>pandas.Interval</code>    | <code>pandas.IntervalArray</code>         |
| <code>pandas.Period</code>      | <code>pandas.arrays.PeriodArray</code>    |
| <code>datetime.datetime</code>  | <code>pandas.arrays.DatetimeArray</code>  |
| <code>datetime.timedelta</code> | <code>pandas.arrays.TimedeltaArray</code> |

For all other cases, NumPy’s usual inference rules will be used.

**copy** [bool, default True] Whether to copy the data, even if not necessary. Depending on the type of *data*, creating the new array may require copying data, even if `copy=False`.

#### Returns

**ExtensionArray** The newly created array.

#### Raises

**ValueError** When *data* is not 1-dimensional.

See also:

**numpy.array** Construct a NumPy array.

**Series** Construct a pandas Series.

**Index** Construct a pandas Index.

**arrays.PandasArray** ExtensionArray wrapping a NumPy array.

**Series.array** Extract the array stored within a Series.

#### Notes

Omitting the *dtype* argument means pandas will attempt to infer the best array type from the values in the data. As new array types are added by pandas and 3rd party libraries, the “best” array type may change. We recommend specifying *dtype* to ensure that

1. the correct array type for the data is returned
2. the returned array type doesn’t change as new extension types are added by pandas and third-party libraries

Additionally, if the underlying memory representation of the returned array matters, we recommend specifying the *dtype* as a concrete object rather than a string alias or allowing it to be inferred. For example, a future version of pandas or a 3rd-party library may include a dedicated ExtensionArray for string data. In this event, the following would no longer return a `arrays.PandasArray` backed by a NumPy array.

```
>>> pd.array(['a', 'b'], dtype=str)
<PandasArray>
['a', 'b']
Length: 2, dtype: str32
```

This would instead return the new `ExtensionArray` dedicated for string data. If you really need the new array to be backed by a NumPy array, specify that in the `dtype`.

```
>>> pd.array(['a', 'b'], dtype=np.dtype("<U1"))
<PandasArray>
['a', 'b']
Length: 2, dtype: str32
```

Or use the dedicated constructor for the array you're expecting, and wrap that in a `PandasArray`

```
>>> pd.array(np.array(['a', 'b'], dtype='<U1'))
<PandasArray>
['a', 'b']
Length: 2, dtype: str32
```

Finally, Pandas has arrays that mostly overlap with NumPy

- `arrays.DatetimeArray`
- `arrays.TimedeltaArray`

When data with a `datetime64[ns]` or `timedelta64[ns]` dtype is passed, pandas will always return a `DatetimeArray` or `TimedeltaArray` rather than a `PandasArray`. This is for symmetry with the case of timezone-aware data, which NumPy does not natively support.

```
>>> pd.array(['2015', '2016'], dtype='datetime64[ns]')
<DatetimeArray>
['2015-01-01 00:00:00', '2016-01-01 00:00:00']
Length: 2, dtype: datetime64[ns]
```

```
>>> pd.array(["1H", "2H"], dtype='timedelta64[ns]')
<TimedeltaArray>
['01:00:00', '02:00:00']
Length: 2, dtype: timedelta64[ns]
```

## Examples

If a `dtype` is not specified, `data` is passed through to `numpy.array()`, and a `arrays.PandasArray` is returned.

```
>>> pd.array([1, 2])
<PandasArray>
[1, 2]
Length: 2, dtype: int64
```

Or the NumPy dtype can be specified

```
>>> pd.array([1, 2], dtype=np.dtype("int32"))
<PandasArray>
[1, 2]
Length: 2, dtype: int32
```

You can use the string alias for `dtype`

```
>>> pd.array(['a', 'b', 'a'], dtype='category')
[a, b, a]
Categories (2, object): [a, b]
```

Or specify the actual dtype

```
>>> pd.array(['a', 'b', 'a'],
...          dtype=pd.CategoricalDtype(['a', 'b', 'c'], ordered=True))
[a, b, a]
Categories (3, object): [a < b < c]
```

Because omitting the *dtype* passes the data through to NumPy, a mixture of valid integers and NA will return a floating-point NumPy array.

```
>>> pd.array([1, 2, np.nan])
<PandasArray>
[1.0, 2.0, nan]
Length: 3, dtype: float64
```

To use pandas' nullable *pandas.arrays.IntegerArray*, specify the dtype:

```
>>> pd.array([1, 2, np.nan], dtype='Int64')
<IntegerArray>
[1, 2, NaN]
Length: 3, dtype: Int64
```

Pandas will infer an *ExtensionArray* for some types of data:

```
>>> pd.array([pd.Period('2000', freq="D"), pd.Period("2000", freq="D")])
<PeriodArray>
['2000-01-01', '2000-01-01']
Length: 2, dtype: period[D]
```

*data* must be 1-dimensional. A *ValueError* is raised when the input has the wrong dimensionality.

```
>>> pd.array(1)
Traceback (most recent call last):
...
ValueError: Cannot pass scalar '1' to 'pandas.array'.
```

## 35.5.2 Datetime Data

NumPy cannot natively represent timezone-aware datetimes. Pandas supports this with the *arrays.DatetimeArray* extension array, which can hold timezone-naive or timezone-aware values.

*Timestamp*, a subclass of *datetime.datetime*, is pandas' scalar type for timezone-naive or timezone-aware datetime data.

---

*Timestamp*

---

Pandas replacement for *datetime.datetime*

---

### 35.5.2.1 pandas.Timestamp

**class** *pandas.Timestamp*

Pandas replacement for *datetime.datetime*

*Timestamp* is the pandas equivalent of python's *Datetime* and is interchangeable with it in most cases. It's the type used for the entries that make up a *DatetimeIndex*, and other timeseries oriented data structures in pandas.

#### Parameters

**ts\_input** [datetime-like, str, int, float] Value to be converted to Timestamp

**freq** [str, DateOffset] Offset which Timestamp will have

**tz** [str, pytz.timezone, dateutil.tz.tzfile or None] Time zone for time which Timestamp will have.

**unit** [str] Unit used for conversion if ts\_input is of type int or float. The valid values are 'D', 'h', 'm', 's', 'ms', 'us', and 'ns'. For example, 's' means seconds and 'ms' means milliseconds.

**year, month, day** [int] New in version 0.19.0.

**hour, minute, second, microsecond** [int, optional, default 0] New in version 0.19.0.

**nanosecond** [int, optional, default 0] New in version 0.23.0.

**tzinfo** [datetime.tzinfo, optional, default None] New in version 0.19.0.

## Notes

There are essentially three calling conventions for the constructor. The primary form accepts four parameters. They can be passed by position or keyword.

The other two forms mimic the parameters from `datetime.datetime`. They can be passed by either position or keyword, but not both mixed together.

## Examples

Using the primary calling convention:

This converts a datetime-like string `>>> pd.Timestamp('2017-01-01T12')` `Timestamp('2017-01-01 12:00:00')`

This converts a float representing a Unix epoch in units of seconds `>>> pd.Timestamp(1513393355.5, unit='s')` `Timestamp('2017-12-16 03:02:35.500000')`

This converts an int representing a Unix-epoch in units of seconds and for a particular time-zone `>>> pd.Timestamp(1513393355, unit='s', tz='US/Pacific')` `Timestamp('2017-12-15 19:02:35-0800', tz='US/Pacific')`

Using the other two forms that mimic the API for `datetime.datetime`:

```
>>> pd.Timestamp(2017, 1, 1, 12)
Timestamp('2017-01-01 12:00:00')
```

```
>>> pd.Timestamp(year=2017, month=1, day=1, hour=12)
Timestamp('2017-01-01 12:00:00')
```

## Attributes

|                     |                                                                                                                                        |
|---------------------|----------------------------------------------------------------------------------------------------------------------------------------|
| <i>resolution</i>   | Return resolution describing the smallest difference between two times that can be represented by Timestamp object <code>_state</code> |
| <i>tz</i>           | Alias for <code>tzinfo</code>                                                                                                          |
| <i>weekday_name</i> | (DEPRECATED) .. deprecated:: 0.23.0                                                                                                    |

**pandas.Timestamp.resolution**

`Timestamp.resolution`  
Return resolution describing the smallest difference between two times that can be represented by `Timestamp` object `state`

**pandas.Timestamp.tz**

`Timestamp.tz`  
Alias for `tzinfo`

**pandas.Timestamp.weekday\_name**

`Timestamp.weekday_name`  
Deprecated since version 0.23.0: Use `Timestamp.day_name()` instead

|------------------------------------------|------------------------------------------------------------------------------------------------------------------------|
| <i>astimezone</i>                        | Convert tz-aware Timestamp to another time zone.                                                                       |
| <i>ceil</i>                              | return a new Timestamp ceiled to this resolution                                                                       |
| <i>combine</i> (date, time)              | date, time -> datetime with same date and time fields                                                                  |
| <i>ctime</i>                             | Return ctime() style string.                                                                                           |
| <i>date</i>                              | Return date object with same year, month and day.                                                                      |
| <i>day_name</i>                          | Return the day name of the Timestamp with specified locale.                                                            |
| <i>dst</i>                               | Return self.tzinfo.dst(self).                                                                                          |
| <i>floor</i>                             | return a new Timestamp floored to this resolution                                                                      |
| <i>fromordinal</i> (ordinal[, freq, tz]) | passed an ordinal, translate and convert to a ts note: by definition there cannot be any tz info on the ordinal itself |
| <i>fromtimestamp</i> (ts)                | timestamp[, tz] -> tz's local time from POSIX timestamp.                                                               |
| <i>isocalendar</i>                       | Return a 3-tuple containing ISO year, week number, and weekday.                                                        |
| <i>isoweekday</i>                        | Return the day of the week represented by the date.                                                                    |
| <i>month_name</i>                        | Return the month name of the Timestamp with specified locale.                                                          |
| <i>normalize</i>                         | Normalize Timestamp to midnight, preserving tz information.                                                            |
| <i>now</i> ([tz])                        | Returns new Timestamp object representing current time local to tz.                                                    |
| <i>replace</i>                           | implements datetime.replace, handles nanoseconds                                                                       |
| <i>round</i>                             | Round the Timestamp to the specified resolution                                                                        |
| <i>strftime</i>                          | format -> strftime() style string.                                                                                     |
| <i>strptime</i>                          | string, format -> new datetime parsed from a string (like time.strptime()).                                            |
| <i>time</i>                              | Return time object with same time but with tzinfo=None.                                                                |
| <i>timestamp</i>                         | Return POSIX timestamp as float.                                                                                       |
| <i>timetuple</i>                         | Return time tuple, compatible with time.localtime().                                                                   |
| <i>timetz</i>                            | Return time object with same time and tzinfo.                                                                          |
| <i>to_datetime64</i>                     | Returns a numpy.datetime64 object with 'ns' precision                                                                  |
| <i>to_julian_date</i>                    | Convert TimeStamp to a Julian Date.                                                                                    |
| <i>to_period</i>                         | Return an period of which this timestamp is an observation.                                                            |
| <i>to_pydatetime</i>                     | Convert a Timestamp object to a native Python datetime object.                                                         |
| <i>today</i> (cls[, tz])                 | Return the current time in the local timezone.                                                                         |
| <i>toordinal</i>                         | Return proleptic Gregorian ordinal.                                                                                    |
| <i>tz_convert</i>                        | Convert tz-aware Timestamp to another time zone.                                                                       |
| <i>tz_localize</i>                       | Convert naive Timestamp to local time zone, or remove timezone from tz-aware Timestamp.                                |
| <i>tzname</i>                            | Return self.tzinfo.tzname(self).                                                                                       |
| <i>utcfromtimestamp</i> (ts)             | Construct a naive UTC datetime from a POSIX timestamp.                                                                 |
| <i>utcnow</i> ()                         | Return a new Timestamp representing UTC day and time.                                                                  |
| <i>utcoffset</i>                         | Return self.tzinfo.utcoffset(self).                                                                                    |

Table 78 – continued from previous page

|                     |                                                                        |
|---------------------|------------------------------------------------------------------------|
| <i>utctimetuple</i> | Return UTC time tuple, compatible with <code>time.localtime()</code> . |
| <i>weekday</i>      | Return the day of the week represented by the date.                    |

**pandas.Timestamp.astimezone**`Timestamp.astimezone`

Convert tz-aware Timestamp to another time zone.

**Parameters**

**tz** [str, pytz.timezone, dateutil.tz.tzfile or None] Time zone for time which Timestamp will be converted to. None will remove timezone holding UTC time.

**Returns**

**converted** [Timestamp]

**Raises**

**TypeError** If Timestamp is tz-naive.

**pandas.Timestamp.ceil**`Timestamp.ceil`

return a new Timestamp ceiled to this resolution

**Parameters**

**freq** [a freq string indicating the ceiling resolution]

**ambiguous** [bool, 'NaT', default 'raise']

- bool contains flags to determine if time is dst or not (note that this flag is only applicable for ambiguous fall dst dates)
- 'NaT' will return NaT for an ambiguous time
- 'raise' will raise an `AmbiguousTimeError` for an ambiguous time

New in version 0.24.0.

**nonexistent** ['shift\_forward', 'shift\_backward', 'NaT', timedelta,]

default 'raise'

A nonexistent time does not exist in a particular timezone where clocks moved forward due to DST.

- 'shift\_forward' will shift the nonexistent time forward to the closest existing time
- 'shift\_backward' will shift the nonexistent time backward to the closest existing time
- 'NaT' will return NaT where there are nonexistent times
- timedelta objects will shift nonexistent times by the timedelta
- 'raise' will raise an `NonExistentTimeError` if there are nonexistent times

New in version 0.24.0.

**Raises**

**ValueError if the freq cannot be converted**

### **pandas.Timestamp.combine**

**classmethod** `Timestamp.combine(date, time)`  
date, time -> datetime with same date and time fields

### **pandas.Timestamp.ctime**

`Timestamp.ctime()`  
Return ctime() style string.

### **pandas.Timestamp.date**

`Timestamp.date()`  
Return date object with same year, month and day.

### **pandas.Timestamp.day\_name**

`Timestamp.day_name`  
Return the day name of the Timestamp with specified locale.

#### **Parameters**

**locale** [string, default None (English locale)] locale determining the language in which to return the day name

#### **Returns**

**day\_name** [string]

.. versionadded:: 0.23.0

### **pandas.Timestamp.dst**

`Timestamp.dst()`  
Return self.tzinfo.dst(self).

### **pandas.Timestamp.floor**

`Timestamp.floor`  
return a new Timestamp floored to this resolution

#### **Parameters**

**freq** [a freq string indicating the flooring resolution]

**ambiguous** [bool, 'NaT', default 'raise']

- bool contains flags to determine if time is dst or not (note that this flag is only applicable for ambiguous fall dst dates)
- 'NaT' will return NaT for an ambiguous time

- ‘raise’ will raise an `AmbiguousTimeError` for an ambiguous time

New in version 0.24.0.

**nonexistent** [`‘shift_forward’`, `‘shift_backward’`, `‘NaT’`, `timedelta`,]

default ‘raise’

A nonexistent time does not exist in a particular timezone where clocks moved forward due to DST.

- ‘shift\_forward’ will shift the nonexistent time forward to the closest existing time
- ‘shift\_backward’ will shift the nonexistent time backward to the closest existing time
- ‘NaT’ will return `NaT` where there are nonexistent times
- `timedelta` objects will shift nonexistent times by the `timedelta`
- ‘raise’ will raise an `NonExistentTimeError` if there are nonexistent times

New in version 0.24.0.

#### Raises

**ValueError if the freq cannot be converted**

### **pandas.Timestamp.fromordinal**

**classmethod** `Timestamp.fromordinal` (*ordinal*, *freq=None*, *tz=None*)

passed an ordinal, translate and convert to a ts note: by definition there cannot be any tz info on the ordinal itself

#### Parameters

**ordinal** [int] date corresponding to a proleptic Gregorian ordinal

**freq** [str, `DateOffset`] Offset which `Timestamp` will have

**tz** [str, `pytz.timezone`, `dateutil.tz.tzfile` or `None`] Time zone for time which `Timestamp` will have.

### **pandas.Timestamp.fromtimestamp**

**classmethod** `Timestamp.fromtimestamp` (*ts*)

`timestamp[, tz]` -> `tz`’s local time from POSIX timestamp.

### **pandas.Timestamp.isocalendar**

`Timestamp.isocalendar()`

Return a 3-tuple containing ISO year, week number, and weekday.

### **pandas.Timestamp.isoweekday**

`Timestamp.isoweekday()`

Return the day of the week represented by the date. Monday == 1 ... Sunday == 7

## **pandas.Timestamp.month\_name**

`Timestamp.month_name`

Return the month name of the Timestamp with specified locale.

### **Parameters**

**locale** [string, default None (English locale)] locale determining the language in which to return the month name

### **Returns**

**month\_name** [string]

.. versionadded:: 0.23.0

## **pandas.Timestamp.normalize**

`Timestamp.normalize`

Normalize Timestamp to midnight, preserving tz information.

## **pandas.Timestamp.now**

**classmethod** `Timestamp.now` (*tz=None*)

Returns new Timestamp object representing current time local to tz.

### **Parameters**

**tz** [str or timezone object, default None] Timezone to localize to

## **pandas.Timestamp.replace**

`Timestamp.replace`

implements datetime.replace, handles nanoseconds

### **Parameters**

**year** [int, optional]

**month** [int, optional]

**day** [int, optional]

**hour** [int, optional]

**minute** [int, optional]

**second** [int, optional]

**microsecond** [int, optional]

**nanosecond** [int, optional]

**tzinfo** [tz-convertible, optional]

**fold** [int, optional, default is 0] added in 3.6, NotImplemented

### **Returns**

**Timestamp with fields replaced**

## pandas.Timestamp.round

`Timestamp.round`

Round the Timestamp to the specified resolution

### Parameters

**freq** [a freq string indicating the rounding resolution]

**ambiguous** [bool, 'NaT', default 'raise']

- bool contains flags to determine if time is dst or not (note that this flag is only applicable for ambiguous fall dst dates)
- 'NaT' will return NaT for an ambiguous time
- 'raise' will raise an AmbiguousTimeError for an ambiguous time

New in version 0.24.0.

**nonexistent** ['shift\_forward', 'shift\_backward', 'NaT', timedelta,]  
default 'raise'

A nonexistent time does not exist in a particular timezone where clocks moved forward due to DST.

- 'shift\_forward' will shift the nonexistent time forward to the closest existing time
- 'shift\_backward' will shift the nonexistent time backward to the closest existing time
- 'NaT' will return NaT where there are nonexistent times
- timedelta objects will shift nonexistent times by the timedelta
- 'raise' will raise an NonExistentTimeError if there are nonexistent times

New in version 0.24.0.

### Returns

a new **Timestamp** rounded to the given resolution of 'freq'

### Raises

**ValueError** if the freq cannot be converted

## pandas.Timestamp.strftime

`Timestamp.strftime()`

format -> strftime() style string.

## pandas.Timestamp.strptime

`Timestamp.strptime()`

string, format -> new datetime parsed from a string (like time.strptime()).

### **pandas.Timestamp.time**

`Timestamp.time()`  
Return time object with same time but with tzinfo=None.

### **pandas.Timestamp.timestamp**

`Timestamp.timestamp()`  
Return POSIX timestamp as float.

### **pandas.Timestamp.timetuple**

`Timestamp.timetuple()`  
Return time tuple, compatible with `time.localtime()`.

### **pandas.Timestamp.timetz**

`Timestamp.timetz()`  
Return time object with same time and tzinfo.

### **pandas.Timestamp.to\_datetime64**

`Timestamp.to_datetime64()`  
Returns a `numpy.datetime64` object with 'ns' precision

### **pandas.Timestamp.to\_julian\_date**

`Timestamp.to_julian_date`  
Convert TimeStamp to a Julian Date. 0 Julian date is noon January 1, 4713 BC.

### **pandas.Timestamp.to\_period**

`Timestamp.to_period`  
Return an period of which this timestamp is an observation.

### **pandas.Timestamp.to\_pydatetime**

`Timestamp.to_pydatetime()`  
Convert a Timestamp object to a native Python datetime object.  
  
If `warn=True`, issue a warning if nanoseconds is nonzero.

### pandas.Timestamp.today

**classmethod** `Timestamp.today(cls, tz=None)`

Return the current time in the local timezone. This differs from `datetime.today()` in that it can be localized to a passed timezone.

#### Parameters

**tz** [str or timezone object, default None] Timezone to localize to

### pandas.Timestamp.toordinal

`Timestamp.toordinal()`

Return proleptic Gregorian ordinal. January 1 of year 1 is day 1.

### pandas.Timestamp.tz\_convert

`Timestamp.tz_convert`

Convert tz-aware Timestamp to another time zone.

#### Parameters

**tz** [str, pytz.timezone, dateutil.tz.tzfile or None] Time zone for time which Timestamp will be converted to. None will remove timezone holding UTC time.

#### Returns

**converted** [Timestamp]

#### Raises

**TypeError** If Timestamp is tz-naive.

### pandas.Timestamp.tz\_localize

`Timestamp.tz_localize`

Convert naive Timestamp to local time zone, or remove timezone from tz-aware Timestamp.

#### Parameters

**tz** [str, pytz.timezone, dateutil.tz.tzfile or None] Time zone for time which Timestamp will be converted to. None will remove timezone holding local time.

**ambiguous** [bool, 'NaT', default 'raise'] When clocks moved backward due to DST, ambiguous times may arise. For example in Central European Time (UTC+01), when going from 03:00 DST to 02:00 non-DST, 02:30:00 local time occurs both at 00:30:00 UTC and at 01:30:00 UTC. In such a situation, the *ambiguous* parameter dictates how ambiguous times should be handled.

- bool contains flags to determine if time is dst or not (note that this flag is only applicable for ambiguous fall dst dates)
- 'NaT' will return NaT for an ambiguous time
- 'raise' will raise an `AmbiguousTimeError` for an ambiguous time

**nonexistent** ['shift\_forward', 'shift\_backward', 'NaT', timedelta,]  
default 'raise'

A nonexistent time does not exist in a particular timezone where clocks moved forward due to DST.

- 'shift\_forward' will shift the nonexistent time forward to the closest existing time
- 'shift\_backward' will shift the nonexistent time backward to the closest existing time
- 'NaT' will return NaT where there are nonexistent times
- timedelta objects will shift nonexistent times by the timedelta
- 'raise' will raise an `NonExistentTimeError` if there are nonexistent times

New in version 0.24.0.

**errors** ['raise', 'coerce', default None]

- **'raise' will raise a `NonExistentTimeError` if a timestamp is not** valid in the specified timezone (e.g. due to a transition from or to DST time). Use `nonexistent='raise'` instead.
- 'coerce' will return NaT if the timestamp can not be converted into the specified timezone. Use `nonexistent='NaT'` instead.

Deprecated since version 0.24.0.

#### Returns

**localized** [Timestamp]

#### Raises

**TypeError** If the Timestamp is tz-aware and tz is not None.

### **pandas.Timestamp.tzname**

`Timestamp.tzname()`  
Return self.tzinfo.tzname(self).

### **pandas.Timestamp.utctimestamp**

**classmethod** `Timestamp.utctimestamp(ts)`  
Construct a naive UTC datetime from a POSIX timestamp.

### **pandas.Timestamp.utcnow**

**classmethod** `Timestamp.utcnow()`  
Return a new Timestamp representing UTC day and time.

### **pandas.Timestamp.utcoffset**

`Timestamp.utcoffset()`  
Return self.tzinfo.utcoffset(self).

**pandas.Timestamp.utctimetuple**`Timestamp.utctimetuple()`Return UTC time tuple, compatible with `time.localtime()`.**pandas.Timestamp.weekday**`Timestamp.weekday()`

Return the day of the week represented by the date. Monday == 0 ... Sunday == 6

|                                                   |                                                                                                                        |
|---------------------------------------------------|------------------------------------------------------------------------------------------------------------------------|
| <i>Timestamp.astimezone</i>                       | Convert tz-aware Timestamp to another time zone.                                                                       |
| <i>Timestamp.ceil</i>                             | return a new Timestamp ceiled to this resolution                                                                       |
| <i>Timestamp.combine(date, time)</i>              | date, time -> datetime with same date and time fields                                                                  |
| <i>Timestamp.ctime</i>                            | Return ctime() style string.                                                                                           |
| <i>Timestamp.date</i>                             | Return date object with same year, month and day.                                                                      |
| <i>Timestamp.day_name</i>                         | Return the day name of the Timestamp with specified locale.                                                            |
| <i>Timestamp.dst</i>                              | Return self.tzinfo.dst(self).                                                                                          |
| <i>Timestamp.floor</i>                            | return a new Timestamp floored to this resolution                                                                      |
| <i>Timestamp.freq</i>                             |                                                                                                                        |
| <i>Timestamp.freqstr</i>                          |                                                                                                                        |
| <i>Timestamp.fromordinal(ordinal[, freq, tz])</i> | passed an ordinal, translate and convert to a ts note: by definition there cannot be any tz info on the ordinal itself |
| <i>Timestamp.fromtimestamp(ts)</i>                | timestamp[, tz] -> tz's local time from POSIX timestamp.                                                               |
| <i>Timestamp.isocalendar</i>                      | Return a 3-tuple containing ISO year, week number, and weekday.                                                        |
| <i>Timestamp.isoformat</i>                        |                                                                                                                        |
| <i>Timestamp.isoweekday</i>                       | Return the day of the week represented by the date.                                                                    |

Table 80 – continued from previous page

|                                         |                                                                                           |
|-----------------------------------------|-------------------------------------------------------------------------------------------|
| <code>Timestamp.month_name</code>       | Return the month name of the Timestamp with specified locale.                             |
| <code>Timestamp.normalize</code>        | Normalize Timestamp to midnight, preserving tz information.                               |
| <code>Timestamp.now([tz])</code>        | Returns new Timestamp object representing current time local to tz.                       |
| <code>Timestamp.replace</code>          | implements <code>datetime.replace</code> , handles nanoseconds                            |
| <code>Timestamp.round</code>            | Round the Timestamp to the specified resolution                                           |
| <code>Timestamp.strftime</code>         | format -> <code>strftime()</code> style string.                                           |
| <code>Timestamp.strptime</code>         | string, format -> new datetime parsed from a string (like <code>time.strptime()</code> ). |
| <code>Timestamp.time</code>             | Return time object with same time but with <code>tzinfo=None</code> .                     |
| <code>Timestamp.timestamp</code>        | Return POSIX timestamp as float.                                                          |
| <code>Timestamp.timetuple</code>        | Return time tuple, compatible with <code>time.localtime()</code> .                        |
| <code>Timestamp.timetz</code>           | Return time object with same time and <code>tzinfo</code> .                               |
| <code>Timestamp.to_datetime64</code>    | Returns a <code>numpy.datetime64</code> object with 'ns' precision                        |
| <code>Timestamp.to_julian_date</code>   | Convert Timestamp to a Julian Date.                                                       |
| <code>Timestamp.to_period</code>        | Return an period of which this timestamp is an observation.                               |
| <code>Timestamp.to_pydatetime</code>    | Convert a Timestamp object to a native Python datetime object.                            |
| <code>Timestamp.today(cls[, tz])</code> | Return the current time in the local timezone.                                            |
| <code>Timestamp.toordinal</code>        | Return proleptic Gregorian ordinal.                                                       |
| <code>Timestamp.tz_convert</code>       | Convert tz-aware Timestamp to another time zone.                                          |
| <code>Timestamp.tz_localize</code>      | Convert naive Timestamp to local time zone, or remove timezone from tz-aware Timestamp.   |
| <code>Timestamp.tzname</code>           | Return <code>self.tzinfo.tzname(self)</code> .                                            |
| <code>Timestamp.utctimestamp(ts)</code> | Construct a naive UTC datetime from a POSIX timestamp.                                    |
| <code>Timestamp.utcnow()</code>         | Return a new Timestamp representing UTC day and time.                                     |
| <code>Timestamp.utcoffset</code>        | Return <code>self.tzinfo.utcoffset(self)</code> .                                         |
| <code>Timestamp.utctimetuple</code>     | Return UTC time tuple, compatible with <code>time.localtime()</code> .                    |
| <code>Timestamp.weekday</code>          | Return the day of the week represented by the date.                                       |

**pandas.Timestamp.freq**`Timestamp.freq`**pandas.Timestamp.freqstr**`Timestamp.freqstr`**pandas.Timestamp.isoformat**`Timestamp.isoformat`

A collection of timestamps may be stored in a `arrays.DatetimeArray`. For timezone-aware data, the `.dtype` of a `DatetimeArray` is a `DatetimeTZDtype`. For timezone-naive data, `np.dtype("datetime64[ns]")` is used.

If the data are tz-aware, then every value in the array must have the same timezone.

|                                                                                                                                |                                                                                                 |
|--------------------------------------------------------------------------------------------------------------------------------|-------------------------------------------------------------------------------------------------|
| <code>arrays.DatetimeArray(values[, dtype, freq, Pandas ExtensionArray for tz-naive or tz-aware date-time data].copy())</code> |                                                                                                 |
| <code>DatetimeTZDtype([unit, tz])</code>                                                                                       | A <code>np.dtype</code> duck-typed class, suitable for holding a custom datetime with tz dtype. |

## pandas.arrays.DatetimeArray

**class** `pandas.arrays.DatetimeArray` (*values*, *dtype*=*dtype('<M8[ns]')*, *freq*=*None*, *copy*=*False*)  
Pandas ExtensionArray for tz-naive or tz-aware datetime data.

New in version 0.24.0.

### Parameters

**values** [Series, Index, DatetimeArray, ndarray] The datetime data.

For `DatetimeArray` *values* (or a Series or Index boxing one), *dtype* and *freq* will be extracted from *values*, with precedence given to

**dtype** [numpy.dtype or DatetimeTZDtype] Note that the only NumPy dtype allowed is 'datetime64[ns]'.

**freq** [str or Offset, optional]

**copy** [bool, default False] Whether to copy the underlying array of values.

### Attributes

|                            |                                                                                                                          |
|----------------------------|--------------------------------------------------------------------------------------------------------------------------|
| <code>asi8</code>          | Integer representation of the values.                                                                                    |
| <code>date</code>          | Returns numpy array of python datetime.date objects (namely, the date part of Timestamps without time-zone information). |
| <code>day</code>           | The days of the datetime.                                                                                                |
| <code>dayofweek</code>     | The day of the week with Monday=0, Sunday=6.                                                                             |
| <code>dayofyear</code>     | The ordinal day of the year.                                                                                             |
| <code>days_in_month</code> | The number of days in the month.                                                                                         |
| <code>daysinmonth</code>   | The number of days in the month.                                                                                         |
| <code>dtype</code>         | The dtype for the DatetimeArray.                                                                                         |
| <code>freq</code>          | Return the frequency object if it is set, otherwise None.                                                                |
| <code>freqstr</code>       | Return the frequency object as a string if its set, otherwise None                                                       |
| <code>hour</code>          | The hours of the datetime.                                                                                               |
| <code>inferred_freq</code> | Tryies to return a string representing a frequency guess, generated by <code>infer_freq</code> .                         |
| <code>is_leap_year</code>  | Boolean indicator if the date belongs to a leap year.                                                                    |

Table 82 – continued from previous page

|                         |                                                                            |
|-------------------------|----------------------------------------------------------------------------|
| <i>is_month_end</i>     | Indicates whether the date is the last day of the month.                   |
| <i>is_month_start</i>   | Indicates whether the date is the first day of the month.                  |
| <i>is_normalized</i>    | Returns True if all of the dates are at midnight (“no time”)               |
| <i>is_quarter_end</i>   | Indicator for whether the date is the last day of a quarter.               |
| <i>is_quarter_start</i> | Indicator for whether the date is the first day of a quarter.              |
| <i>is_year_end</i>      | Indicate whether the date is the last day of the year.                     |
| <i>is_year_start</i>    | Indicate whether the date is the first day of a year.                      |
| <i>microsecond</i>      | The microseconds of the datetime.                                          |
| <i>minute</i>           | The minutes of the datetime.                                               |
| <i>month</i>            | The month as January=1, December=12.                                       |
| <i>nanosecond</i>       | The nanoseconds of the datetime.                                           |
| <i>nbytes</i>           | The number of bytes needed to store this object in memory.                 |
| <i>quarter</i>          | The quarter of the date.                                                   |
| <i>resolution</i>       | Returns day, hour, minute, second, millisecond or microsecond              |
| <i>second</i>           | The seconds of the datetime.                                               |
| <i>shape</i>            | Return a tuple of the array dimensions.                                    |
| <i>size</i>             | The number of elements in this array.                                      |
| <i>time</i>             | Returns numpy array of datetime.time.                                      |
| <i>timetz</i>           | Returns numpy array of datetime.time also containing timezone information. |
| <i>tz</i>               | Return timezone, if any.                                                   |
| <i>tzinfo</i>           | Alias for tz attribute                                                     |
| <i>week</i>             | The week ordinal of the year.                                              |
| <i>weekday</i>          | The day of the week with Monday=0, Sunday=6.                               |
| <i>weekday_name</i>     | (DEPRECATED) The name of day in a week (ex: Friday)                        |
| <i>weekofyear</i>       | The week ordinal of the year.                                              |
| <i>year</i>             | The year of the datetime.                                                  |

**pandas.arrays.DatetimeArray.asi8**`DatetimeArray.asi8`

Integer representation of the values.

**Returns****ndarray** An ndarray with int64 dtype.**pandas.arrays.DatetimeArray.date**`DatetimeArray.date`

Returns numpy array of python datetime.date objects (namely, the date part of Timestamps without time-zone information).

### **pandas.arrays.DatetimeArray.day**

`DatetimeArray.day`  
The days of the datetime.

### **pandas.arrays.DatetimeArray.dayofweek**

`DatetimeArray.dayofweek`  
The day of the week with Monday=0, Sunday=6.

Return the day of the week. It is assumed the week starts on Monday, which is denoted by 0 and ends on Sunday which is denoted by 6. This method is available on both Series with datetime values (using the *dt* accessor) or DatetimeIndex.

#### **Returns**

**Series or Index** Containing integers indicating the day number.

**See also:**

**Series.dt.dayofweek** Alias.

**Series.dt.weekday** Alias.

**Series.dt.day\_name** Returns the name of the day of the week.

### **Examples**

```
>>> s = pd.date_range('2016-12-31', '2017-01-08', freq='D').to_series()
>>> s.dt.dayofweek
2016-12-31    5
2017-01-01    6
2017-01-02    0
2017-01-03    1
2017-01-04    2
2017-01-05    3
2017-01-06    4
2017-01-07    5
2017-01-08    6
Freq: D, dtype: int64
```

### **pandas.arrays.DatetimeArray.dayofyear**

`DatetimeArray.dayofyear`  
The ordinal day of the year.

### **pandas.arrays.DatetimeArray.days\_in\_month**

`DatetimeArray.days_in_month`  
The number of days in the month.

### **pandas.arrays.DatetimeArray.daysinmonth**

`DatetimeArray.daysinmonth`  
The number of days in the month.

### **pandas.arrays.DatetimeArray.dtype**

`DatetimeArray.dtype`  
The dtype for the DatetimeArray.

#### **Returns**

**numpy.dtype or DatetimeTZDtype** If the values are tz-naive, then `np.dtype('datetime64[ns]')` is returned.

If the values are tz-aware, then the `DatetimeTZDtype` is returned.

### **pandas.arrays.DatetimeArray.freq**

`DatetimeArray.freq`  
Return the frequency object if it is set, otherwise None.

### **pandas.arrays.DatetimeArray.freqstr**

`DatetimeArray.freqstr`  
Return the frequency object as a string if its set, otherwise None

### **pandas.arrays.DatetimeArray.hour**

`DatetimeArray.hour`  
The hours of the datetime.

### **pandas.arrays.DatetimeArray.inferred\_freq**

`DatetimeArray.inferred_freq`  
Tries to return a string representing a frequency guess, generated by `infer_freq`. Returns None if it can't autodetect the frequency.

### **pandas.arrays.DatetimeArray.is\_leap\_year**

`DatetimeArray.is_leap_year`  
Boolean indicator if the date belongs to a leap year.

A leap year is a year, which has 366 days (instead of 365) including 29th of February as an intercalary day. Leap years are years which are multiples of four with the exception of years divisible by 100 but not by 400.

#### **Returns**

**Series or ndarray** Booleans indicating if dates belong to a leap year.

## Examples

This method is available on Series with datetime values under the `.dt` accessor, and directly on `DatetimeIndex`.

```
>>> idx = pd.date_range("2012-01-01", "2015-01-01", freq="Y")
>>> idx
DatetimeIndex(['2012-12-31', '2013-12-31', '2014-12-31'],
              dtype='datetime64[ns]', freq='A-DEC')
>>> idx.is_leap_year
array([ True, False, False], dtype=bool)
```

```
>>> dates = pd.Series(idx)
>>> dates_series
0    2012-12-31
1    2013-12-31
2    2014-12-31
dtype: datetime64[ns]
>>> dates_series.dt.is_leap_year
0      True
1     False
2     False
dtype: bool
```

## pandas.arrays.DatetimeArray.is\_month\_end

`DatetimeArray.is_month_end`

Indicates whether the date is the last day of the month.

### Returns

**Series or array** For Series, returns a Series with boolean values. For `DatetimeIndex`, returns a boolean array.

**See also:**

**`is_month_start`** Return a boolean indicating whether the date is the first day of the month.

**`is_month_end`** Return a boolean indicating whether the date is the last day of the month.

## Examples

This method is available on Series with datetime values under the `.dt` accessor, and directly on `DatetimeIndex`.

```
>>> s = pd.Series(pd.date_range("2018-02-27", periods=3))
>>> s
0    2018-02-27
1    2018-02-28
2    2018-03-01
dtype: datetime64[ns]
>>> s.dt.is_month_start
0     False
1     False
2      True
```

(continues on next page)

(continued from previous page)

```
dtype: bool
>>> s.dt.is_month_end
0    False
1     True
2    False
dtype: bool
```

```
>>> idx = pd.date_range("2018-02-27", periods=3)
>>> idx.is_month_start
array([False, False,  True])
>>> idx.is_month_end
array([False,  True, False])
```

## pandas.arrays.DatetimeArray.is\_month\_start

### DatetimeArray.is\_month\_start

Indicates whether the date is the first day of the month.

#### Returns

**Series or array** For Series, returns a Series with boolean values. For DatetimeIndex, returns a boolean array.

#### See also:

**is\_month\_start** Return a boolean indicating whether the date is the first day of the month.

**is\_month\_end** Return a boolean indicating whether the date is the last day of the month.

## Examples

This method is available on Series with datetime values under the `.dt` accessor, and directly on DatetimeIndex.

```
>>> s = pd.Series(pd.date_range("2018-02-27", periods=3))
>>> s
0    2018-02-27
1    2018-02-28
2    2018-03-01
dtype: datetime64[ns]
>>> s.dt.is_month_start
0    False
1    False
2     True
dtype: bool
>>> s.dt.is_month_end
0    False
1     True
2    False
dtype: bool
```

```
>>> idx = pd.date_range("2018-02-27", periods=3)
>>> idx.is_month_start
array([False, False,  True])
```

(continues on next page)

(continued from previous page)

```
>>> idx.is_month_end
array([False,  True,  False])
```

### pandas.arrays.DatetimeArray.is\_normalized

DatetimeArray.**is\_normalized**

Returns True if all of the dates are at midnight (“no time”)

### pandas.arrays.DatetimeArray.is\_quarter\_end

DatetimeArray.**is\_quarter\_end**

Indicator for whether the date is the last day of a quarter.

#### Returns

**is\_quarter\_end** [Series or DatetimeIndex] The same type as the original data with boolean values. Series will have the same name and index. DatetimeIndex will have the same name.

#### See also:

**quarter** Return the quarter of the date.

**is\_quarter\_start** Similar property indicating the quarter start.

### Examples

This method is available on Series with datetime values under the `.dt` accessor, and directly on DatetimeIndex.

```
>>> df = pd.DataFrame({'dates': pd.date_range("2017-03-30",
...                                           periods=4)})
>>> df.assign(quarter=df.dates.dt.quarter,
...           is_quarter_end=df.dates.dt.is_quarter_end)
   dates      quarter  is_quarter_end
0 2017-03-30         1             False
1 2017-03-31         1              True
2 2017-04-01         2             False
3 2017-04-02         2             False
```

```
>>> idx = pd.date_range('2017-03-30', periods=4)
>>> idx
DatetimeIndex(['2017-03-30', '2017-03-31', '2017-04-01', '2017-04-02'],
              dtype='datetime64[ns]', freq='D')
```

```
>>> idx.is_quarter_end
array([False,  True,  False,  False])
```

**pandas.arrays.DatetimeArray.is\_quarter\_start****DatetimeArray.is\_quarter\_start**

Indicator for whether the date is the first day of a quarter.

**Returns****is\_quarter\_start** [Series or DatetimeIndex] The same type as the original data with boolean values. Series will have the same name and index. DatetimeIndex will have the same name.**See also:****quarter** Return the quarter of the date.**is\_quarter\_end** Similar property for indicating the quarter start.**Examples**

This method is available on Series with datetime values under the `.dt` accessor, and directly on `DatetimeIndex`.

```
>>> df = pd.DataFrame({'dates': pd.date_range("2017-03-30",
...                                           periods=4)})
>>> df.assign(quarter=df.dates.dt.quarter,
...           is_quarter_start=df.dates.dt.is_quarter_start)
   dates      quarter  is_quarter_start
0 2017-03-30         1             False
1 2017-03-31         1             False
2 2017-04-01         2              True
3 2017-04-02         2             False
```

```
>>> idx = pd.date_range('2017-03-30', periods=4)
>>> idx
DatetimeIndex(['2017-03-30', '2017-03-31', '2017-04-01', '2017-04-02'],
              dtype='datetime64[ns]', freq='D')
```

```
>>> idx.is_quarter_start
array([False, False,  True, False])
```

**pandas.arrays.DatetimeArray.is\_year\_end****DatetimeArray.is\_year\_end**

Indicate whether the date is the last day of the year.

**Returns****Series or DatetimeIndex** The same type as the original data with boolean values. Series will have the same name and index. DatetimeIndex will have the same name.**See also:****is\_year\_start** Similar property indicating the start of the year.

## Examples

This method is available on Series with datetime values under the `.dt` accessor, and directly on `DatetimeIndex`.

```
>>> dates = pd.Series(pd.date_range("2017-12-30", periods=3))
>>> dates
0    2017-12-30
1    2017-12-31
2    2018-01-01
dtype: datetime64[ns]
```

```
>>> dates.dt.is_year_end
0    False
1     True
2    False
dtype: bool
```

```
>>> idx = pd.date_range("2017-12-30", periods=3)
>>> idx
DatetimeIndex(['2017-12-30', '2017-12-31', '2018-01-01'],
              dtype='datetime64[ns]', freq='D')
```

```
>>> idx.is_year_end
array([False,  True, False])
```

## pandas.arrays.DatetimeArray.is\_year\_start

### `DatetimeArray.is_year_start`

Indicate whether the date is the first day of a year.

#### Returns

**Series or DatetimeIndex** The same type as the original data with boolean values. Series will have the same name and index. `DatetimeIndex` will have the same name.

#### See also:

**`is_year_end`** Similar property indicating the last day of the year.

## Examples

This method is available on Series with datetime values under the `.dt` accessor, and directly on `DatetimeIndex`.

```
>>> dates = pd.Series(pd.date_range("2017-12-30", periods=3))
>>> dates
0    2017-12-30
1    2017-12-31
2    2018-01-01
dtype: datetime64[ns]
```

```
>>> dates.dt.is_year_start
0    False
1    False
2     True
dtype: bool
```

```
>>> idx = pd.date_range("2017-12-30", periods=3)
>>> idx
DatetimeIndex(['2017-12-30', '2017-12-31', '2018-01-01'],
              dtype='datetime64[ns]', freq='D')
```

```
>>> idx.is_year_start
array([False, False,  True])
```

### **pandas.arrays.DatetimeArray.microsecond**

DatetimeArray.**microsecond**  
The microseconds of the datetime.

### **pandas.arrays.DatetimeArray.minute**

DatetimeArray.**minute**  
The minutes of the datetime.

### **pandas.arrays.DatetimeArray.month**

DatetimeArray.**month**  
The month as January=1, December=12.

### **pandas.arrays.DatetimeArray.nanosecond**

DatetimeArray.**nanosecond**  
The nanoseconds of the datetime.

### **pandas.arrays.DatetimeArray.nbytes**

DatetimeArray.**nbytes**  
The number of bytes needed to store this object in memory.

### **pandas.arrays.DatetimeArray.quarter**

DatetimeArray.**quarter**  
The quarter of the date.

### **pandas.arrays.DatetimeArray.resolution**

`DatetimeArray.resolution`

Returns day, hour, minute, second, millisecond or microsecond

### **pandas.arrays.DatetimeArray.second**

`DatetimeArray.second`

The seconds of the datetime.

### **pandas.arrays.DatetimeArray.shape**

`DatetimeArray.shape`

Return a tuple of the array dimensions.

### **pandas.arrays.DatetimeArray.size**

`DatetimeArray.size`

The number of elements in this array.

### **pandas.arrays.DatetimeArray.time**

`DatetimeArray.time`

Returns numpy array of datetime.time. The time part of the Timestamps.

### **pandas.arrays.DatetimeArray.timetz**

`DatetimeArray.timetz`

Returns numpy array of datetime.time also containing timezone information. The time part of the Timestamps.

### **pandas.arrays.DatetimeArray.tz**

`DatetimeArray.tz`

Return timezone, if any.

#### **Returns**

`datetime.tzinfo`, `pytz.tzinfo.BaseTZInfo`, `dateutil.tz.tz.tzfile`, or `None` Returns `None` when the array is tz-naive.

### **pandas.arrays.DatetimeArray.tzinfo**

`DatetimeArray.tzinfo`

Alias for tz attribute

**pandas.arrays.DatetimeArray.week**`DatetimeArray.week`

The week ordinal of the year.

**pandas.arrays.DatetimeArray.weekday**`DatetimeArray.weekday`

The day of the week with Monday=0, Sunday=6.

Return the day of the week. It is assumed the week starts on Monday, which is denoted by 0 and ends on Sunday which is denoted by 6. This method is available on both Series with datetime values (using the *dt* accessor) or DatetimeIndex.

**Returns****Series or Index** Containing integers indicating the day number.**See also:****Series.dt.dayofweek** Alias.**Series.dt.weekday** Alias.**Series.dt.day\_name** Returns the name of the day of the week.**Examples**

```
>>> s = pd.date_range('2016-12-31', '2017-01-08', freq='D').to_series()
>>> s.dt.dayofweek
2016-12-31    5
2017-01-01    6
2017-01-02    0
2017-01-03    1
2017-01-04    2
2017-01-05    3
2017-01-06    4
2017-01-07    5
2017-01-08    6
Freq: D, dtype: int64
```

**pandas.arrays.DatetimeArray.weekday\_name**`DatetimeArray.weekday_name`

The name of day in a week (ex: Friday)

Deprecated since version 0.23.0.

**pandas.arrays.DatetimeArray.weekofyear**`DatetimeArray.weekofyear`

The week ordinal of the year.

**pandas.arrays.DatetimeArray.year**

`DatetimeArray.year`  
The year of the datetime.

**Methods**

|                                                           |                                                                                                                   |
|-----------------------------------------------------------|-------------------------------------------------------------------------------------------------------------------|
| <i>argsort</i> ([ascending, kind])                        | Return the indices that would sort this array.                                                                    |
| <i>astype</i> (dtype[, copy])                             | Cast to a NumPy array with 'dtype'.                                                                               |
| <i>ceil</i> (freq[, ambiguous, nonexistent])              | Perform ceil operation on the data to the specified <i>freq</i> .                                                 |
| <i>copy</i> ([deep])                                      | Return a copy of the array.                                                                                       |
| <i>day_name</i> ([locale])                                | Return the day names of the DateTimeIndex with specified locale.                                                  |
| <i>dropna</i> ()                                          | Return ExtensionArray without NA values                                                                           |
| <i>factorize</i> ([na_sentinel])                          | Encode the extension array as an enumerated type.                                                                 |
| <i>fillna</i> ([value, method, limit])                    | Fill NA/NaN values using the specified method.                                                                    |
| <i>floor</i> (freq[, ambiguous, nonexistent])             | Perform floor operation on the data to the specified <i>freq</i> .                                                |
| <i>isna</i> ()                                            | A 1-D array indicating if each value is missing.                                                                  |
| <i>max</i> ([axis, skipna])                               | Return the maximum value of the Array or maximum along an axis.                                                   |
| <i>min</i> ([axis, skipna])                               | Return the minimum value of the Array or minimum along an axis.                                                   |
| <i>month_name</i> ([locale])                              | Return the month names of the DateTimeIndex with specified locale.                                                |
| <i>normalize</i> ()                                       | Convert times to midnight.                                                                                        |
| <i>repeat</i> (repeats, *args, **kwargs)                  | Repeat elements of an array.                                                                                      |
| <i>round</i> (freq[, ambiguous, nonexistent])             | Perform round operation on the data to the specified <i>freq</i> .                                                |
| <i>searchsorted</i> (value[, side, sorter])               | Find indices where elements should be inserted to maintain order.                                                 |
| <i>shift</i> ([periods, fill_value])                      | Shift values by desired number.                                                                                   |
| <i>strftime</i> (date_format)                             | Convert to Index using specified date_format.                                                                     |
| <i>take</i> (indices[, allow_fill, fill_value])           | Take elements from an array.                                                                                      |
| <i>to_julian_date</i> ()                                  | Convert Datetime Array to float64 ndarray of Julian Dates.                                                        |
| <i>to_period</i> ([freq])                                 | Cast to PeriodArray/Index at a particular frequency.                                                              |
| <i>to_perioddelta</i> (freq)                              | Calculate TimedeltaArray of difference between index values and index converted to PeriodArray at specified freq. |
| <i>to_pydatetime</i> ()                                   | Return Datetime Array/Index as object ndarray of datetime.datetime objects                                        |
| <i>tz_convert</i> (tz)                                    | Convert tz-aware Datetime Array/Index from one time zone to another.                                              |
| <i>tz_localize</i> (tz[, ambiguous, nonexistent, errors]) | Localize tz-naive Datetime Array/Index to tz-aware Datetime Array/Index.                                          |
| <i>unique</i> ()                                          | Compute the ExtensionArray of unique values.                                                                      |

Continued on next page

Table 83 – continued from previous page

|                                     |                                                     |
|-------------------------------------|-----------------------------------------------------|
| <code>value_counts([dropna])</code> | Return a Series containing counts of unique values. |
| <code>view([dtype])</code>          | New view on this array with the same data.          |

**pandas.arrays.DatetimeArray.argsort**

`DatetimeArray.argsort` (*ascending=True*, *kind='quicksort'*, *\*args*, *\*\*kwargs*)

Return the indices that would sort this array.

**Parameters**

**ascending** [bool, default True] Whether the indices should result in an ascending or descending sort.

**kind** [{ 'quicksort', 'mergesort', 'heapsort' }, optional] Sorting algorithm.

**\*args, \*\*kwargs:** passed through to `numpy.argsort()`.

**Returns**

**index\_array** [ndarray] Array of indices that sort `self`.

See also:

`numpy.argsort` Sorting implementation used internally.

**pandas.arrays.DatetimeArray.astype**

`DatetimeArray.astype` (*dtype*, *copy=True*)

Cast to a NumPy array with 'dtype'.

**Parameters**

**dtype** [str or dtype] Typecode or data-type to which the array is cast.

**copy** [bool, default True] Whether to copy the data, even if not necessary. If False, a copy is made only if the old dtype does not match the new dtype.

**Returns**

**array** [ndarray] NumPy ndarray with 'dtype' for its dtype.

**pandas.arrays.DatetimeArray.ceil**

`DatetimeArray.ceil` (*freq*, *ambiguous='raise'*, *nonexistent='raise'*)

Perform ceil operation on the data to the specified *freq*.

**Parameters**

**freq** [str or Offset] The frequency level to ceil the index to. Must be a fixed frequency like 'S' (second) not 'ME' (month end). See *frequency aliases* for a list of possible *freq* values.

**ambiguous** ['infer', bool-ndarray, 'NaT', default 'raise'] Only relevant for `DatetimeIndex`:

- 'infer' will attempt to infer fall dst-transition hours based on order
- bool-ndarray where True signifies a DST time, False designates a non-DST time (note that this flag is only applicable for ambiguous times)

- 'NaT' will return NaT where there are ambiguous times
- 'raise' will raise an AmbiguousTimeError if there are ambiguous times

New in version 0.24.0.

**nonexistent** ['shift\_forward', 'shift\_backward', 'NaT', timedelta,]

default 'raise'

A nonexistent time does not exist in a particular timezone where clocks moved forward due to DST.

- 'shift\_forward' will shift the nonexistent time forward to the closest existing time
- 'shift\_backward' will shift the nonexistent time backward to the closest existing time
- 'NaT' will return NaT where there are nonexistent times
- timedelta objects will shift nonexistent times by the timedelta
- 'raise' will raise an NonExistentTimeError if there are nonexistent times

New in version 0.24.0.

### Returns

**DatetimeIndex, TimedeltaIndex, or Series** Index of the same type for a DatetimeIndex or TimedeltaIndex, or a Series with the same index for a Series.

### Raises

**ValueError** if the 'freq' cannot be converted.

## Examples

### DatetimeIndex

```
>>> rng = pd.date_range('1/1/2018 11:59:00', periods=3, freq='min')
>>> rng
DatetimeIndex(['2018-01-01 11:59:00', '2018-01-01 12:00:00',
               '2018-01-01 12:01:00'],
              dtype='datetime64[ns]', freq='T')
>>> rng.ceil("H")
DatetimeIndex(['2018-01-01 12:00:00', '2018-01-01 12:00:00',
               '2018-01-01 13:00:00'],
              dtype='datetime64[ns]', freq=None)
```

### Series

```
>>> pd.Series(rng).dt.ceil("H")
0    2018-01-01 12:00:00
1    2018-01-01 12:00:00
2    2018-01-01 13:00:00
dtype: datetime64[ns]
```

## pandas.arrays.DatetimeArray.copy

DatetimeArray.**copy** (deep=False)

Return a copy of the array.

**Parameters**

**deep** [bool, default False] Also copy the underlying data backing this array.

**Returns**

**ExtensionArray**

**pandas.arrays.DatetimeArray.day\_name**

DatetimeArray.**day\_name** (*locale=None*)

Return the day names of the DateTimeIndex with specified locale.

New in version 0.23.0.

**Parameters**

**locale** [str, optional] Locale determining the language in which to return the day name.  
Default is English locale.

**Returns**

**Index** Index of day names.

**Examples**

```
>>> idx = pd.date_range(start='2018-01-01', freq='D', periods=3)
>>> idx
DatetimeIndex(['2018-01-01', '2018-01-02', '2018-01-03'],
              dtype='datetime64[ns]', freq='D')
>>> idx.day_name()
Index(['Monday', 'Tuesday', 'Wednesday'], dtype='object')
```

**pandas.arrays.DatetimeArray.dropna**

DatetimeArray.**dropna**()

Return ExtensionArray without NA values

**Returns**

**valid** [ExtensionArray]

**pandas.arrays.DatetimeArray.factorize**

DatetimeArray.**factorize** (*na\_sentinel=-1*)

Encode the extension array as an enumerated type.

**Parameters**

**na\_sentinel** [int, default -1] Value to use in the *labels* array to indicate missing values.

**Returns**

**labels** [ndarray] An integer NumPy array that's an indexer into the original ExtensionArray.

**uniques** [ExtensionArray] An ExtensionArray containing the unique values of *self*.

---

**Note:** *uniques* will *not* contain an entry for the NA value of the ExtensionArray if there are any missing values present in *self*.

---

See also:

***pandas.factorize*** Top-level factorize method that dispatches here.

## Notes

*pandas.factorize()* offers a *sort* keyword as well.

## pandas.arrays.DatetimeArray.fillna

DatetimeArray.**fillna**(*value=None, method=None, limit=None*)

Fill NA/NaN values using the specified method.

### Parameters

**value** [scalar, array-like] If a scalar value is passed it is used to fill all missing values. Alternatively, an array-like ‘value’ can be given. It’s expected that the array-like have the same length as ‘self’.

**method** [{‘backfill’, ‘bfill’, ‘pad’, ‘ffill’, None}, default None] Method to use for filling holes in reindexed Series pad / ffill: propagate last valid observation forward to next valid backfill / bfill: use NEXT valid observation to fill gap

**limit** [int, default None] If method is specified, this is the maximum number of consecutive NaN values to forward/backward fill. In other words, if there is a gap with more than this number of consecutive NaNs, it will only be partially filled. If method is not specified, this is the maximum number of entries along the entire axis where NaNs will be filled.

### Returns

**filled** [ExtensionArray with NA/NaN filled]

## pandas.arrays.DatetimeArray.floor

DatetimeArray.**floor**(*freq, ambiguous=‘raise’, nonexistent=‘raise’*)

Perform floor operation on the data to the specified *freq*.

### Parameters

**freq** [str or Offset] The frequency level to floor the index to. Must be a fixed frequency like ‘S’ (second) not ‘ME’ (month end). See *frequency aliases* for a list of possible *freq* values.

**ambiguous** [‘infer’, bool-ndarray, ‘NaT’, default ‘raise’] Only relevant for DatetimeIndex:

- ‘infer’ will attempt to infer fall dst-transition hours based on order
- bool-ndarray where True signifies a DST time, False designates a non-DST time (note that this flag is only applicable for ambiguous times)

- 'NaT' will return NaT where there are ambiguous times
- 'raise' will raise an AmbiguousTimeError if there are ambiguous times

New in version 0.24.0.

**nonexistent** ['shift\_forward', 'shift\_backward', 'NaT', timedelta,]

default 'raise'

A nonexistent time does not exist in a particular timezone where clocks moved forward due to DST.

- 'shift\_forward' will shift the nonexistent time forward to the closest existing time
- 'shift\_backward' will shift the nonexistent time backward to the closest existing time
- 'NaT' will return NaT where there are nonexistent times
- timedelta objects will shift nonexistent times by the timedelta
- 'raise' will raise an NonExistentTimeError if there are nonexistent times

New in version 0.24.0.

### Returns

**DatetimeIndex, TimedeltaIndex, or Series** Index of the same type for a DatetimeIndex or TimedeltaIndex, or a Series with the same index for a Series.

### Raises

**ValueError** if the 'freq' cannot be converted.

## Examples

### DatetimeIndex

```
>>> rng = pd.date_range('1/1/2018 11:59:00', periods=3, freq='min')
>>> rng
DatetimeIndex(['2018-01-01 11:59:00', '2018-01-01 12:00:00',
               '2018-01-01 12:01:00'],
              dtype='datetime64[ns]', freq='T')
>>> rng.floor('H')
DatetimeIndex(['2018-01-01 11:00:00', '2018-01-01 12:00:00',
               '2018-01-01 12:00:00'],
              dtype='datetime64[ns]', freq=None)
```

### Series

```
>>> pd.Series(rng).dt.floor("H")
0    2018-01-01 11:00:00
1    2018-01-01 12:00:00
2    2018-01-01 12:00:00
dtype: datetime64[ns]
```

## pandas.arrays.DatetimeArray.isna

DatetimeArray.**isna**()

A 1-D array indicating if each value is missing.

**Returns**

**na\_values** [Union[np.ndarray, ExtensionArray]] In most cases, this should return a NumPy ndarray. For exceptional cases like `SparseArray`, where returning an ndarray would be expensive, an `ExtensionArray` may be returned.

**Notes**

If returning an `ExtensionArray`, then

- `na_values._is_boolean` should be `True`
- `na_values` should implement `ExtensionArray._reduce()`
- `na_values.any` and `na_values.all` should be implemented

**pandas.arrays.DatetimeArray.max**

`DatetimeArray.max` (*axis=None, skipna=True, \*args, \*\*kwargs*)  
Return the maximum value of the Array or maximum along an axis.

**See also:**

`numpy.ndarray.max`

**Index.max** Return the maximum value in an Index.

**Series.max** Return the maximum value in a Series.

**pandas.arrays.DatetimeArray.min**

`DatetimeArray.min` (*axis=None, skipna=True, \*args, \*\*kwargs*)  
Return the minimum value of the Array or minimum along an axis.

**See also:**

`numpy.ndarray.min`

**Index.min** Return the minimum value in an Index.

**Series.min** Return the minimum value in a Series.

**pandas.arrays.DatetimeArray.month\_name**

`DatetimeArray.month_name` (*locale=None*)  
Return the month names of the `DateTimeIndex` with specified locale.  
New in version 0.23.0.

**Parameters**

**locale** [str, optional] Locale determining the language in which to return the month name.  
Default is English locale.

**Returns**

**Index** Index of month names.

## Examples

```
>>> idx = pd.date_range(start='2018-01', freq='M', periods=3)
>>> idx
DatetimeIndex(['2018-01-31', '2018-02-28', '2018-03-31'],
              dtype='datetime64[ns]', freq='M')
>>> idx.month_name()
Index(['January', 'February', 'March'], dtype='object')
```

## pandas.arrays.DatetimeArray.normalize

DatetimeArray.**normalize**()

Convert times to midnight.

The time component of the date-time is converted to midnight i.e. 00:00:00. This is useful in cases, when the time does not matter. Length is unaltered. The timezones are unaffected.

This method is available on Series with datetime values under the `.dt` accessor, and directly on Datetime Array/Index.

### Returns

**DatetimeArray, DatetimeIndex or Series** The same type as the original data. Series will have the same name and index. DatetimeIndex will have the same name.

### See also:

**floor** Floor the datetimes to the specified freq.

**ceil** Ceil the datetimes to the specified freq.

**round** Round the datetimes to the specified freq.

## Examples

```
>>> idx = pd.date_range(start='2014-08-01 10:00', freq='H',
...                     periods=3, tz='Asia/Calcutta')
>>> idx
DatetimeIndex(['2014-08-01 10:00:00+05:30',
              '2014-08-01 11:00:00+05:30',
              '2014-08-01 12:00:00+05:30'],
              dtype='datetime64[ns, Asia/Calcutta]', freq='H')
>>> idx.normalize()
DatetimeIndex(['2014-08-01 00:00:00+05:30',
              '2014-08-01 00:00:00+05:30',
              '2014-08-01 00:00:00+05:30'],
              dtype='datetime64[ns, Asia/Calcutta]', freq=None)
```

## pandas.arrays.DatetimeArray.repeat

DatetimeArray.**repeat**(*repeats*, \*args, \*\*kwargs)

Repeat elements of an array.

### See also:

`numpy.ndarray.repeat`

## pandas.arrays.DatetimeArray.round

`DatetimeArray.round(freq, ambiguous='raise', nonexistent='raise')`

Perform round operation on the data to the specified *freq*.

### Parameters

**freq** [str or Offset] The frequency level to round the index to. Must be a fixed frequency like 'S' (second) not 'ME' (month end). See *frequency aliases* for a list of possible *freq* values.

**ambiguous** ['infer', bool-ndarray, 'NaT', default 'raise'] Only relevant for DatetimeIndex:

- 'infer' will attempt to infer fall dst-transition hours based on order
- bool-ndarray where True signifies a DST time, False designates a non-DST time (note that this flag is only applicable for ambiguous times)
- 'NaT' will return NaT where there are ambiguous times
- 'raise' will raise an AmbiguousTimeError if there are ambiguous times

New in version 0.24.0.

**nonexistent** ['shift\_forward', 'shift\_backward', 'NaT', timedelta,]  
default 'raise'

A nonexistent time does not exist in a particular timezone where clocks moved forward due to DST.

- 'shift\_forward' will shift the nonexistent time forward to the closest existing time
- 'shift\_backward' will shift the nonexistent time backward to the closest existing time
- 'NaT' will return NaT where there are nonexistent times
- timedelta objects will shift nonexistent times by the timedelta
- 'raise' will raise a NonExistentTimeError if there are nonexistent times

New in version 0.24.0.

### Returns

**DatetimeIndex, TimedeltaIndex, or Series** Index of the same type for a DatetimeIndex or TimedeltaIndex, or a Series with the same index for a Series.

### Raises

**ValueError** if the 'freq' cannot be converted.

## Examples

### DatetimeIndex

```
>>> rng = pd.date_range('1/1/2018 11:59:00', periods=3, freq='min')
>>> rng
DatetimeIndex(['2018-01-01 11:59:00', '2018-01-01 12:00:00',
               '2018-01-01 12:01:00'],
              dtype='datetime64[ns]', freq='T')
```

(continues on next page)

(continued from previous page)

```
>>> rng.round('H')
DatetimeIndex(['2018-01-01 12:00:00', '2018-01-01 12:00:00',
              '2018-01-01 12:00:00'],
              dtype='datetime64[ns]', freq=None)
```

**Series**

```
>>> pd.Series(rng).dt.round("H")
0    2018-01-01 12:00:00
1    2018-01-01 12:00:00
2    2018-01-01 12:00:00
dtype: datetime64[ns]
```

**pandas.arrays.DatetimeArray.searchsorted**

`DatetimeArray.searchsorted` (*value*, *side*='left', *sorter*=None)

Find indices where elements should be inserted to maintain order.

Find the indices into a sorted array *self* such that, if the corresponding elements in *value* were inserted before the indices, the order of *self* would be preserved.

**Parameters**

**value** [array\_like] Values to insert into *self*.

**side** [{ 'left', 'right' }, optional] If 'left', the index of the first suitable location found is given. If 'right', return the last such index. If there is no suitable index, return either 0 or N (where N is the length of *self*).

**sorter** [1-D array\_like, optional] Optional array of integer indices that sort *self* into ascending order. They are typically the result of `np.argsort`.

**Returns**

**indices** [array of ints] Array of insertion points with the same shape as *value*.

**pandas.arrays.DatetimeArray.shift**

`DatetimeArray.shift` (*periods*=1, *fill\_value*=None)

Shift values by desired number.

Newly introduced missing values are filled with `self.dtype.na_value`.

New in version 0.24.0.

**Parameters**

**periods** [int, default 1] The number of periods to shift. Negative values are allowed for shifting backwards.

**fill\_value** [object, optional] The scalar value to use for newly introduced missing values. The default is `self.dtype.na_value`

New in version 0.24.0.

**Returns**

**shifted** [ExtensionArray]

## Notes

If `self` is empty or `periods` is 0, a copy of `self` is returned.

If `periods > len(self)`, then an array of size `len(self)` is returned, with all values filled with `self.dtype.na_value`.

## pandas.arrays.DatetimeArray.strftime

`DatetimeArray.strftime(date_format)`

Convert to Index using specified `date_format`.

Return an Index of formatted strings specified by `date_format`, which supports the same string format as the python standard library. Details of the string format can be found in [python string format doc](#)

### Parameters

**date\_format** [str] Date format string (e.g. “%Y-%m-%d”).

### Returns

**Index** Index of formatted strings

See also:

**to\_datetime** Convert the given argument to datetime.

**DatetimeIndex.normalize** Return `DatetimeIndex` with times to midnight.

**DatetimeIndex.round** Round the `DatetimeIndex` to the specified freq.

**DatetimeIndex.floor** Floor the `DatetimeIndex` to the specified freq.

## Examples

```
>>> rng = pd.date_range(pd.Timestamp("2018-03-10 09:00"),
...                     periods=3, freq='s')
>>> rng.strftime('%B %d, %Y, %r')
Index(['March 10, 2018, 09:00:00 AM', 'March 10, 2018, 09:00:01 AM',
       'March 10, 2018, 09:00:02 AM'],
      dtype='object')
```

## pandas.arrays.DatetimeArray.take

`DatetimeArray.take(indices, allow_fill=False, fill_value=None)`

Take elements from an array.

### Parameters

**indices** [sequence of integers] Indices to be taken.

**allow\_fill** [bool, default False] How to handle negative values in *indices*.

- False: negative values in *indices* indicate positional indices from the right (the default). This is similar to `numpy.take()`.
- True: negative values in *indices* indicate missing values. These values are set to *fill\_value*. Any other other negative values raise a `ValueError`.

**fill\_value** [any, optional] Fill value to use for NA-indices when *allow\_fill* is True. This may be None, in which case the default NA value for the type, `self.dtype.na_value`, is used.

For many ExtensionArrays, there will be two representations of *fill\_value*: a user-facing “boxed” scalar, and a low-level physical NA value. *fill\_value* should be the user-facing version, and the implementation should handle translating that to the physical version for processing the take if necessary.

### Returns

**ExtensionArray**

### Raises

**IndexError** When the indices are out of bounds for the array.

**ValueError** When *indices* contains negative values other than `-1` and *allow\_fill* is True.

### See also:

`numpy.take`, `pandas.api.extensions.take`

### Notes

`ExtensionArray.take` is called by `Series.__getitem__`, `.loc`, `iloc`, when *indices* is a sequence of values. Additionally, it’s called by `Series.reindex()`, or any other method that causes realignment, with a *fill\_value*.

### Examples

Here’s an example implementation, which relies on casting the extension array to object dtype. This uses the helper method `pandas.api.extensions.take()`.

```
def take(self, indices, allow_fill=False, fill_value=None):
    from pandas.core.algorithms import take

    # If the ExtensionArray is backed by an ndarray, then
    # just pass that here instead of coercing to object.
    data = self.astype(object)

    if allow_fill and fill_value is None:
        fill_value = self.dtype.na_value

    # fill value should always be translated from the scalar
    # type for the array, to the physical storage type for
    # the data, before passing to take.

    result = take(data, indices, fill_value=fill_value,
                  allow_fill=allow_fill)
    return self._from_sequence(result, dtype=self.dtype)
```

### pandas.arrays.DatetimeArray.to\_julian\_date

`DatetimeArray.to_julian_date()`

Convert Datetime Array to float64 ndarray of Julian Dates. 0 Julian date is noon January 1, 4713 BC.

[http://en.wikipedia.org/wiki/Julian\\_day](http://en.wikipedia.org/wiki/Julian_day)

## pandas.arrays.DatetimeArray.to\_period

DatetimeArray.**to\_period** (*freq=None*)

Cast to PeriodArray/Index at a particular frequency.

Converts DatetimeArray/Index to PeriodArray/Index.

### Parameters

**freq** [string or Offset, optional] One of pandas' *offset strings* or an Offset object. Will be inferred by default.

### Returns

**PeriodArray/Index**

### Raises

**ValueError** When converting a DatetimeArray/Index with non-regular values, so that a frequency cannot be inferred.

**See also:**

**PeriodIndex** Immutable ndarray holding ordinal values.

**DatetimeIndex.to\_pydatetime** Return DatetimeIndex as object.

## Examples

```
>>> df = pd.DataFrame({"y": [1,2,3]},
...                     index=pd.to_datetime(["2000-03-31 00:00:00",
...                                           "2000-05-31 00:00:00",
...                                           "2000-08-31 00:00:00"]))
>>> df.index.to_period("M")
PeriodIndex(['2000-03', '2000-05', '2000-08'],
            dtype='period[M]', freq='M')
```

Infer the daily frequency

```
>>> idx = pd.date_range("2017-01-01", periods=2)
>>> idx.to_period()
PeriodIndex(['2017-01-01', '2017-01-02'],
            dtype='period[D]', freq='D')
```

## pandas.arrays.DatetimeArray.to\_perioddelta

DatetimeArray.**to\_perioddelta** (*freq*)

Calculate TimedeltaArray of difference between index values and index converted to PeriodArray at specified freq. Used for vectorized offsets

### Parameters

**freq** [Period frequency]

### Returns

**TimedeltaArray/Index**

**pandas.arrays.DatetimeArray.to\_pydatetime**`DatetimeArray.to_pydatetime()`

Return Datetime Array/Index as object ndarray of datetime.datetime objects

**Returns****datetimes** [ndarray]**pandas.arrays.DatetimeArray.tz\_convert**`DatetimeArray.tz_convert(tz)`

Convert tz-aware Datetime Array/Index from one time zone to another.

**Parameters****tz** [string, pytz.timezone, dateutil.tz.tzfile or None] Time zone for time. Corresponding timestamps would be converted to this time zone of the Datetime Array/Index. A *tz* of None will convert to UTC and remove the timezone information.**Returns****normalized** [same type as self]**Raises****TypeError** If Datetime Array/Index is tz-naive.**See also:****DatetimeIndex.tz** A timezone that has a variable offset from UTC.**DatetimeIndex.tz\_localize** Localize tz-naive DatetimeIndex to a given time zone, or remove timezone from a tz-aware DatetimeIndex.**Examples**With the *tz* parameter, we can change the DatetimeIndex to other time zones:

```
>>> dti = pd.date_range(start='2014-08-01 09:00',
...                      freq='H', periods=3, tz='Europe/Berlin')
```

```
>>> dti
DatetimeIndex(['2014-08-01 09:00:00+02:00',
               '2014-08-01 10:00:00+02:00',
               '2014-08-01 11:00:00+02:00'],
              dtype='datetime64[ns, Europe/Berlin]', freq='H')
```

```
>>> dti.tz_convert('US/Central')
DatetimeIndex(['2014-08-01 02:00:00-05:00',
               '2014-08-01 03:00:00-05:00',
               '2014-08-01 04:00:00-05:00'],
              dtype='datetime64[ns, US/Central]', freq='H')
```

With the *tz=None*, we can remove the timezone (after converting to UTC if necessary):

```
>>> dti = pd.date_range(start='2014-08-01 09:00', freq='H',
...                      periods=3, tz='Europe/Berlin')
```

```
>>> dti
DatetimeIndex(['2014-08-01 09:00:00+02:00',
               '2014-08-01 10:00:00+02:00',
               '2014-08-01 11:00:00+02:00'],
              dtype='datetime64[ns, Europe/Berlin]', freq='H')
```

```
>>> dti.tz_convert(None)
DatetimeIndex(['2014-08-01 07:00:00',
               '2014-08-01 08:00:00',
               '2014-08-01 09:00:00'],
              dtype='datetime64[ns]', freq='H')
```

## pandas.arrays.DatetimeArray.tz\_localize

`DatetimeArray.tz_localize(tz, ambiguous='raise', nonexistent='raise', errors=None)`

Localize tz-naive Datetime Array/Index to tz-aware Datetime Array/Index.

This method takes a time zone (tz) naive Datetime Array/Index object and makes this time zone aware. It does not move the time to another time zone. Time zone localization helps to switch from time zone aware to time zone unaware objects.

### Parameters

**tz** [string, pytz.timezone, dateutil.tz.tzfile or None] Time zone to convert timestamps to. Passing None will remove the time zone information preserving local time.

**ambiguous** ['infer', 'NaT', bool array, default 'raise'] When clocks moved backward due to DST, ambiguous times may arise. For example in Central European Time (UTC+01), when going from 03:00 DST to 02:00 non-DST, 02:30:00 local time occurs both at 00:30:00 UTC and at 01:30:00 UTC. In such a situation, the *ambiguous* parameter dictates how ambiguous times should be handled.

- 'infer' will attempt to infer fall dst-transition hours based on order
- bool-ndarray where True signifies a DST time, False signifies a non-DST time (note that this flag is only applicable for ambiguous times)
- 'NaT' will return NaT where there are ambiguous times
- 'raise' will raise an AmbiguousTimeError if there are ambiguous times

**nonexistent** ['shift\_forward', 'shift\_backward', 'NaT', timedelta,]  
default 'raise'

A nonexistent time does not exist in a particular timezone where clocks moved forward due to DST.

- 'shift\_forward' will shift the nonexistent time forward to the closest existing time
- 'shift\_backward' will shift the nonexistent time backward to the closest existing time
- 'NaT' will return NaT where there are nonexistent times
- timedelta objects will shift nonexistent times by the timedelta
- 'raise' will raise an NonExistentTimeError if there are nonexistent times

New in version 0.24.0.

**errors** [{ 'raise', 'coerce' }, default None]

- 'raise' will raise a `NonExistentTimeError` if a timestamp is not valid in the specified time zone (e.g. due to a transition from or to DST time). Use `nonexistent='raise'` instead.
- 'coerce' will return `NaT` if the timestamp can not be converted to the specified time zone. Use `nonexistent='NaT'` instead.

Deprecated since version 0.24.0.

### Returns

**result** [same type as self] Array/Index converted to the specified time zone.

### Raises

**TypeError** If the Datetime Array/Index is tz-aware and tz is not None.

See also:

**DatetimeIndex.tz\_convert** Convert tz-aware DatetimeIndex from one time zone to another.

### Examples

```
>>> tz_naive = pd.date_range('2018-03-01 09:00', periods=3)
>>> tz_naive
DatetimeIndex(['2018-03-01 09:00:00', '2018-03-02 09:00:00',
              '2018-03-03 09:00:00'],
              dtype='datetime64[ns]', freq='D')
```

Localize DatetimeIndex in US/Eastern time zone:

```
>>> tz_aware = tz_naive.tz_localize(tz='US/Eastern')
>>> tz_aware
DatetimeIndex(['2018-03-01 09:00:00-05:00',
              '2018-03-02 09:00:00-05:00',
              '2018-03-03 09:00:00-05:00'],
              dtype='datetime64[ns, US/Eastern]', freq='D')
```

With the `tz=None`, we can remove the time zone information while keeping the local time (not converted to UTC):

```
>>> tz_aware.tz_localize(None)
DatetimeIndex(['2018-03-01 09:00:00', '2018-03-02 09:00:00',
              '2018-03-03 09:00:00'],
              dtype='datetime64[ns]', freq='D')
```

Be careful with DST changes. When there is sequential data, pandas can infer the DST time: `>>> s = pd.to_datetime(pd.Series([ ... '2018-10-28 01:30:00', ... '2018-10-28 02:00:00', ... '2018-10-28 02:30:00', ... '2018-10-28 02:00:00', ... '2018-10-28 02:30:00', ... '2018-10-28 03:00:00', ... '2018-10-28 03:30:00'])) >>> s.dt.tz_localize('CET', ambiguous='infer')` 2018-10-28 01:30:00+02:00 0 2018-10-28 02:00:00+02:00 1 2018-10-28 02:30:00+02:00 2 2018-10-28 02:00:00+01:00 3 2018-10-28 02:30:00+01:00 4 2018-10-28 03:00:00+01:00 5 2018-10-28 03:30:00+01:00 6 dtype: int64

In some cases, inferring the DST is impossible. In such cases, you can pass an ndarray to the `ambiguous` parameter to set the DST explicitly

```
>>> s = pd.to_datetime(pd.Series([
...     '2018-10-28 01:20:00',
...     '2018-10-28 02:36:00',
...     '2018-10-28 03:46:00']))
>>> s.dt.tz_localize('CET', ambiguous=np.array([True, True, False]))
0    2018-10-28 01:20:00+02:00
1    2018-10-28 02:36:00+02:00
2    2018-10-28 03:46:00+01:00
dtype: datetime64[ns, CET]
```

If the DST transition causes nonexistent times, you can shift these dates forward or backwards with a `timedelta` object or `'shift_forward'` or `'shift_backwards'`. `>>> s = pd.to_datetime(pd.Series([ ... '2015-03-29 02:30:00', ... '2015-03-29 03:30:00']))` `>>> s.dt.tz_localize('Europe/Warsaw', nonexistent='shift_forward')` `0 2015-03-29 03:00:00+02:00 1 2015-03-29 03:30:00+02:00 dtype: datetime64[ns, 'Europe/Warsaw']` `>>> s.dt.tz_localize('Europe/Warsaw', nonexistent='shift_backward')` `0 2015-03-29 01:59:59.999999999+01:00 1 2015-03-29 03:30:00+02:00 dtype: datetime64[ns, 'Europe/Warsaw']` `>>> s.dt.tz_localize('Europe/Warsaw', nonexistent=pd.Timedelta('1H'))` `0 2015-03-29 03:30:00+02:00 1 2015-03-29 03:30:00+02:00 dtype: datetime64[ns, 'Europe/Warsaw']`

### pandas.arrays.DatetimeArray.unique

`DatetimeArray.unique()`

Compute the ExtensionArray of unique values.

#### Returns

**uniques** [ExtensionArray]

### pandas.arrays.DatetimeArray.value\_counts

`DatetimeArray.value_counts(dropna=False)`

Return a Series containing counts of unique values.

#### Parameters

**dropna** [boolean, default True] Don't include counts of NaT values.

#### Returns

**Series**

### pandas.arrays.DatetimeArray.view

`DatetimeArray.view(dtype=None)`

New view on this array with the same data.

#### Parameters

**dtype** [numpy dtype, optional]

#### Returns

**ndarray** With the specified *dtype*.

|     |  |
|-----|--|
| map |  |
|-----|--|

pandas.DatetimeTZDtype

**class** pandas.DatetimeTZDtype (unit='ns', tz=None)  
A np.dtype duck-typed class, suitable for holding a custom datetime with tz dtype.  
THIS IS NOT A REAL NUMPY DTYPE, but essentially a sub-class of np.datetime64[ns]

Attributes

|              |                                                              |
|--------------|--------------------------------------------------------------|
| <i>name</i>  | A string representation of the dtype.                        |
| <i>names</i> | Ordered list of field names, or None if there are no fields. |
| <i>tz</i>    | The timezone.                                                |
| <i>unit</i>  | The precision of the datetime data.                          |

pandas.DatetimeTZDtype.name

DatetimeTZDtype.name  
A string representation of the dtype.

pandas.DatetimeTZDtype.names

DatetimeTZDtype.names  
Ordered list of field names, or None if there are no fields.  
This is for compatibility with NumPy arrays, and may be removed in the future.

pandas.DatetimeTZDtype.tz

DatetimeTZDtype.tz  
The timezone.

pandas.DatetimeTZDtype.unit

DatetimeTZDtype.unit  
The precision of the datetime data.

|         |  |
|---------|--|
| subtype |  |
|---------|--|

Methods

|                                       |                                                   |
|---------------------------------------|---------------------------------------------------|
| <i>construct_array_type()</i>         | Return the array type associated with this dtype  |
| <i>construct_from_string</i> (string) | Construct a DatetimeTZDtype from a string.        |
| <i>is_dtype</i> (dtype)               | Check if we match 'dtype'.                        |
| <i>reset_cache</i> ()                 | clear the cache                                   |
| <i>type</i>                           | alias of pandas._libs.tslibs.timestamps.Timestamp |

### `pandas.DatetimeTZDtype.construct_array_type`

**classmethod** `DatetimeTZDtype.construct_array_type()`

Return the array type associated with this dtype

**Returns**

**type**

### `pandas.DatetimeTZDtype.construct_from_string`

**classmethod** `DatetimeTZDtype.construct_from_string(string)`

Construct a `DatetimeTZDtype` from a string.

**Parameters**

**string** [str] The string alias for this `DatetimeTZDtype`. Should be formatted like `datetime64[ns, <tz>]`, where `<tz>` is the timezone name.

### Examples

```
>>> DatetimeTZDtype.construct_from_string('datetime64[ns, UTC]')
datetime64[ns, UTC]
```

### `pandas.DatetimeTZDtype.is_dtype`

**classmethod** `DatetimeTZDtype.is_dtype(dtype)`

Check if we match 'dtype'.

**Parameters**

**dtype** [object] The object to check.

**Returns**

**is\_dtype** [bool]

### Notes

The default implementation is True if

1. `cls.construct_from_string(dtype)` is an instance of `cls`.
2. `dtype` is an object and is an instance of `cls`
3. `dtype` has a `dtype` attribute, and any of the above conditions is true for `dtype.dtype`.

### `pandas.DatetimeTZDtype.reset_cache`

**classmethod** `DatetimeTZDtype.reset_cache()`

clear the cache

### 35.5.3 Timedelta Data

NumPy can natively represent timedeltas. Pandas provides *Timedelta* for symmetry with *Timestamp*.

|                  |                                                                   |
|------------------|-------------------------------------------------------------------|
| <i>Timedelta</i> | Represents a duration, the difference between two dates or times. |
|------------------|-------------------------------------------------------------------|

#### 35.5.3.1 pandas.Timedelta

**class** pandas.**Timedelta**  
Represents a duration, the difference between two dates or times.  
Timedelta is the pandas equivalent of python's `datetime.timedelta` and is interchangeable with it in most cases.

**Parameters**

- value** [Timedelta, timedelta, np.timedelta64, string, or integer]
- unit** [str, optional] Denote the unit of the input, if input is an integer. Default 'ns'. Possible values: {'Y', 'M', 'W', 'D', 'days', 'day', 'hours', 'hour', 'hr', 'h', 'm', 'minute', 'min', 'minutes', 'T', 'S', 'seconds', 'sec', 'second', 'ms', 'milliseconds', 'millisecond', 'milli', 'millis', 'L', 'us', 'microseconds', 'microsecond', 'micro', 'micros', 'U', 'ns', 'nanoseconds', 'nano', 'nanos', 'nanosecond', 'N'}
- days, seconds, microseconds,**
- milliseconds, minutes, hours, weeks** [numeric, optional] Values for construction in compat with `datetime.timedelta`. np ints and floats will be coerced to python ints and floats.

**Notes**

The `.value` attribute is always in ns.

**Attributes**

|                     |                                                                         |
|---------------------|-------------------------------------------------------------------------|
| <i>asm8</i>         | Return a numpy timedelta64 array scalar view.                           |
| <i>components</i>   | Return a Components NamedTuple-like                                     |
| <i>days</i>         | Number of days.                                                         |
| <i>delta</i>        | Return the timedelta in nanoseconds (ns), for internal compatibility.   |
| <i>microseconds</i> | Number of microseconds ( $\geq 0$ and less than 1 second).              |
| <i>nanoseconds</i>  | Return the number of nanoseconds (n), where $0 \leq n < 1$ microsecond. |
| <i>resolution</i>   | Return a string representing the lowest timedelta resolution.           |
| <i>seconds</i>      | Number of seconds ( $\geq 0$ and less than 1 day).                      |

**pandas.Timedelta.asm8**

`Timedelta.asm8`  
Return a numpy timedelta64 array scalar view.

Provides access to the array scalar view (i.e. a combination of the value and the units) associated with the `numpy.timedelta64().view()`, including a 64-bit integer representation of the timedelta in nanoseconds (Python int compatible).

#### Returns

**numpy.timedelta64 array scalar view** Array scalar view of the timedelta in nanoseconds.

#### Examples

```
>>> td = pd.Timedelta('1 days 2 min 3 us 42 ns')
>>> td.asm8
numpy.timedelta64(86520000003042, 'ns')
```

```
>>> td = pd.Timedelta('2 min 3 s')
>>> td.asm8
numpy.timedelta64(123000000000, 'ns')
```

```
>>> td = pd.Timedelta('3 ms 5 us')
>>> td.asm8
numpy.timedelta64(3005000, 'ns')
```

```
>>> td = pd.Timedelta(42, unit='ns')
>>> td.asm8
numpy.timedelta64(42, 'ns')
```

### pandas.Timedelta.components

`Timedelta.components`

Return a Components NamedTuple-like

### pandas.Timedelta.days

`Timedelta.days`

Number of days.

### pandas.Timedelta.delta

`Timedelta.delta`

Return the timedelta in nanoseconds (ns), for internal compatibility.

#### Returns

**int** Timedelta in nanoseconds.

#### Examples

```
>>> td = pd.Timedelta('1 days 42 ns')
>>> td.delta
86400000000042
```

```
>>> td = pd.Timedelta('3 s')
>>> td.delta
3000000000
```

```
>>> td = pd.Timedelta('3 ms 5 us')
>>> td.delta
3005000
```

```
>>> td = pd.Timedelta(42, unit='ns')
>>> td.delta
42
```

### pandas.Timedelta.microseconds

`Timedelta.microseconds`

Number of microseconds ( $\geq 0$  and less than 1 second).

### pandas.Timedelta.nanoseconds

`Timedelta.nanoseconds`

Return the number of nanoseconds (n), where  $0 \leq n < 1$  microsecond.

#### Returns

**int** Number of nanoseconds.

#### See also:

***Timedelta.components*** Return all attributes with assigned values (i.e. days, hours, minutes, seconds, milliseconds, microseconds, nanoseconds).

### Examples

#### Using string input

```
>>> td = pd.Timedelta('1 days 2 min 3 us 42 ns')
>>> td.nanoseconds
42
```

#### Using integer input

```
>>> td = pd.Timedelta(42, unit='ns')
>>> td.nanoseconds
42
```

### pandas.Timedelta.resolution

`Timedelta.resolution`

Return a string representing the lowest timedelta resolution.

Each timedelta has a defined resolution that represents the lowest OR most granular level of precision. Each level of resolution is represented by a short string as defined below:

Resolution: Return value

- Days: 'D'
- Hours: 'H'
- Minutes: 'T'
- Seconds: 'S'
- Milliseconds: 'L'
- Microseconds: 'U'
- Nanoseconds: 'N'

### Returns

**str** Timedelta resolution.

### Examples

```
>>> td = pd.Timedelta('1 days 2 min 3 us 42 ns')
>>> td.resolution
'N'
```

```
>>> td = pd.Timedelta('1 days 2 min 3 us')
>>> td.resolution
'U'
```

```
>>> td = pd.Timedelta('2 min 3 s')
>>> td.resolution
'S'
```

```
>>> td = pd.Timedelta(36, unit='us')
>>> td.resolution
'U'
```

### pandas.Timedelta.seconds

Timedelta.**seconds**

Number of seconds ( $\geq 0$  and less than 1 day).

| freq         |  |
|--------------|--|
| is_populated |  |
| value        |  |

### Methods

|              |                                                   |
|--------------|---------------------------------------------------|
| <i>ceil</i>  | return a new Timedelta ceiled to this resolution  |
| <i>floor</i> | return a new Timedelta floored to this resolution |

Continued on next page

Table 88 – continued from previous page

|                       |                                                                                                                    |
|-----------------------|--------------------------------------------------------------------------------------------------------------------|
| <i>isoformat</i>      | Format Timedelta as ISO 8601 Duration like P[n]Y[n]M[n]DT[n]H[n]M[n]S, where the [n] s are replaced by the values. |
| <i>round</i>          | Round the Timedelta to the specified resolution                                                                    |
| <i>to_pytimedelta</i> | return an actual datetime.timedelta object note: we lose nanosecond resolution if any                              |
| <i>to_timedelta64</i> | Returns a numpy.timedelta64 object with ‘ns’ precision                                                             |
| <i>total_seconds</i>  | Total duration of timedelta in seconds (to ns precision)                                                           |
| <i>view</i>           | array view compat                                                                                                  |

**pandas.Timedelta.ceil**`Timedelta.ceil`

return a new Timedelta ceiled to this resolution

**Parameters****freq** [a freq string indicating the ceiling resolution]**pandas.Timedelta.floor**`Timedelta.floor`

return a new Timedelta floored to this resolution

**Parameters****freq** [a freq string indicating the flooring resolution]**pandas.Timedelta.isoformat**`Timedelta.isoformat()`Format Timedelta as ISO 8601 Duration like P[n]Y[n]M[n]DT[n]H[n]M[n]S, where the [n] s are replaced by the values. See [https://en.wikipedia.org/wiki/ISO\\_8601#Durations](https://en.wikipedia.org/wiki/ISO_8601#Durations)

New in version 0.20.0.

**Returns****formatted** [str]**See also:***Timestamp.isoformat***Notes**

The longest component is days, whose value may be larger than 365. Every component is always included, even if its value is 0. Pandas uses nanosecond precision, so up to 9 decimal places may be included in the seconds component. Trailing 0's are removed from the seconds component after the decimal. We do not 0 pad components, so it's ...*T5H*..., not ...*T05H*...

## Examples

```
>>> td = pd.Timedelta(days=6, minutes=50, seconds=3,
...                     milliseconds=10, microseconds=10, nanoseconds=12)
>>> td.isoformat()
'P6DT0H50M3.010010012S'
>>> pd.Timedelta(hours=1, seconds=10).isoformat()
'P0DT0H0M10S'
>>> pd.Timedelta(hours=1, seconds=10).isoformat()
'P0DT0H0M10S'
>>> pd.Timedelta(days=500.5).isoformat()
'P500DT12H0MS'
```

## pandas.Timedelta.round

### Timedelta.round

Round the Timedelta to the specified resolution

#### Parameters

**freq** [a freq string indicating the rounding resolution]

#### Returns

a new Timedelta rounded to the given resolution of ‘freq’

#### Raises

ValueError if the freq cannot be converted

## pandas.Timedelta.to\_pytimedelta

### Timedelta.to\_pytimedelta()

return an actual datetime.timedelta object note: we lose nanosecond resolution if any

## pandas.Timedelta.to\_timedelta64

### Timedelta.to\_timedelta64()

Returns a numpy.timedelta64 object with ‘ns’ precision

## pandas.Timedelta.total\_seconds

### Timedelta.total\_seconds()

Total duration of timedelta in seconds (to ns precision)

## pandas.Timedelta.view

### Timedelta.view()

array view compat

### 35.5.3.2 Properties

|                                     |                                                                         |
|-------------------------------------|-------------------------------------------------------------------------|
| <code>Timedelta.asm8</code>         | Return a numpy timedelta64 array scalar view.                           |
| <code>Timedelta.components</code>   | Return a Components NamedTuple-like                                     |
| <code>Timedelta.days</code>         | Number of days.                                                         |
| <code>Timedelta.delta</code>        | Return the timedelta in nanoseconds (ns), for internal compatibility.   |
| <code>Timedelta.freq</code>         |                                                                         |
| <code>Timedelta.is_populated</code> |                                                                         |
| <code>Timedelta.max</code>          |                                                                         |
| <code>Timedelta.microseconds</code> | Number of microseconds ( $\geq 0$ and less than 1 second).              |
| <code>Timedelta.min</code>          |                                                                         |
| <code>Timedelta.nanoseconds</code>  | Return the number of nanoseconds (n), where $0 \leq n < 1$ microsecond. |
| <code>Timedelta.resolution</code>   | Return a string representing the lowest timedelta resolution.           |
| <code>Timedelta.seconds</code>      | Number of seconds ( $\geq 0$ and less than 1 day).                      |
| <code>Timedelta.value</code>        |                                                                         |
| <code>Timedelta.view</code>         | array view compat                                                       |

#### pandas.Timedelta.freq

`Timedelta.freq`

#### pandas.Timedelta.is\_populated

`Timedelta.is_populated`

#### pandas.Timedelta.max

`Timedelta.max = Timedelta('106751 days 23:47:16.854775')`

#### pandas.Timedelta.min

`Timedelta.min = Timedelta('-106752 days +00:12:43.145224')`

#### pandas.Timedelta.value

`Timedelta.value`

### 35.5.3.3 Methods

|                              |                                                   |
|------------------------------|---------------------------------------------------|
| <code>Timedelta.ceil</code>  | return a new Timedelta ceiled to this resolution  |
| <code>Timedelta.floor</code> | return a new Timedelta floored to this resolution |

Table 90 – continued from previous page

|                                 |                                                                                                                    |
|---------------------------------|--------------------------------------------------------------------------------------------------------------------|
| <i>Timedelta.isoformat</i>      | Format Timedelta as ISO 8601 Duration like P[n]Y[n]M[n]DT[n]H[n]M[n]S, where the [n] s are replaced by the values. |
| <i>Timedelta.round</i>          | Round the Timedelta to the specified resolution                                                                    |
| <i>Timedelta.to_pytimedelta</i> | return an actual datetime.timedelta object note: we lose nanosecond resolution if any                              |
| <i>Timedelta.to_timedelta64</i> | Returns a numpy.timedelta64 object with 'ns' precision                                                             |
| <i>Timedelta.total_seconds</i>  | Total duration of timedelta in seconds (to ns precision)                                                           |

A collection of timedeltas may be stored in a `TimedeltaArray`.

```
arrays.TimedeltaArray(values[, dtype, freq,
...])
```

### Attributes

## pandas.arrays.TimedeltaArray

```
class pandas.arrays.TimedeltaArray (values, dtype=dtype('<m8[ns]'), freq=None,
copy=False)
```

### Attributes

|                      |                                                                                                                                  |
|----------------------|----------------------------------------------------------------------------------------------------------------------------------|
| <i>asi8</i>          | Integer representation of the values.                                                                                            |
| <i>components</i>    | Return a dataframe of the components (days, hours, minutes, seconds, milliseconds, microseconds, nanoseconds) of the Timedeltas. |
| <i>days</i>          | Number of days for each element.                                                                                                 |
| <i>dtype</i>         | An instance of 'ExtensionDtype'.                                                                                                 |
| <i>freq</i>          | Return the frequency object if it is set, otherwise None.                                                                        |
| <i>freqstr</i>       | Return the frequency object as a string if its set, otherwise None                                                               |
| <i>inferred_freq</i> | Tryies to return a string representing a frequency guess, generated by infer_freq.                                               |
| <i>microseconds</i>  | Number of microseconds ( $\geq 0$ and less than 1 second) for each element.                                                      |
| <i>nanoseconds</i>   | Number of nanoseconds ( $\geq 0$ and less than 1 microsecond) for each element.                                                  |
| <i>nbytes</i>        | The number of bytes needed to store this object in memory.                                                                       |
| <i>resolution</i>    | Returns day, hour, minute, second, millisecond or microsecond                                                                    |
| <i>seconds</i>       | Number of seconds ( $\geq 0$ and less than 1 day) for each element.                                                              |
| <i>shape</i>         | Return a tuple of the array dimensions.                                                                                          |
| <i>size</i>          | The number of elements in this array.                                                                                            |

**pandas.arrays.TimedeltaArray.asi8**

`TimedeltaArray.asi8`

Integer representation of the values.

**Returns**

**ndarray** An ndarray with int64 dtype.

**pandas.arrays.TimedeltaArray.components**

`TimedeltaArray.components`

Return a dataframe of the components (days, hours, minutes, seconds, milliseconds, microseconds, nanoseconds) of the Timedeltas.

**Returns**

**a DataFrame**

**pandas.arrays.TimedeltaArray.days**

`TimedeltaArray.days`

Number of days for each element.

**pandas.arrays.TimedeltaArray.dtype**

`TimedeltaArray.dtype`

An instance of 'ExtensionDtype'.

**pandas.arrays.TimedeltaArray.freq**

`TimedeltaArray.freq`

Return the frequency object if it is set, otherwise None.

**pandas.arrays.TimedeltaArray.freqstr**

`TimedeltaArray.freqstr`

Return the frequency object as a string if its set, otherwise None

**pandas.arrays.TimedeltaArray.inferred\_freq**

`TimedeltaArray.inferred_freq`

Tries to return a string representing a frequency guess, generated by `infer_freq`. Returns None if it can't autodetect the frequency.

**pandas.arrays.TimedeltaArray.microseconds**

`TimedeltaArray.microseconds`

Number of microseconds ( $\geq 0$  and less than 1 second) for each element.

**pandas.arrays.TimedeltaArray.nanoseconds**`TimedeltaArray.nanoseconds`Number of nanoseconds ( $\geq 0$  and less than 1 microsecond) for each element.**pandas.arrays.TimedeltaArray.nbytes**`TimedeltaArray.nbytes`

The number of bytes needed to store this object in memory.

**pandas.arrays.TimedeltaArray.resolution**`TimedeltaArray.resolution`

Returns day, hour, minute, second, millisecond or microsecond

**pandas.arrays.TimedeltaArray.seconds**`TimedeltaArray.seconds`Number of seconds ( $\geq 0$  and less than 1 day) for each element.**pandas.arrays.TimedeltaArray.shape**`TimedeltaArray.shape`

Return a tuple of the array dimensions.

**pandas.arrays.TimedeltaArray.size**`TimedeltaArray.size`

The number of elements in this array.

**Methods**

|                                                    |                                                                    |
|----------------------------------------------------|--------------------------------------------------------------------|
| <code>argsort([ascending, kind])</code>            | Return the indices that would sort this array.                     |
| <code>astype(dtype[, copy])</code>                 | Cast to a NumPy array with 'dtype'.                                |
| <code>ceil(freq[, ambiguous, nonexistent])</code>  | Perform ceil operation on the data to the specified <i>freq</i> .  |
| <code>copy([deep])</code>                          | Return a copy of the array.                                        |
| <code>dropna()</code>                              | Return ExtensionArray without NA values                            |
| <code>factorize([na_sentinel])</code>              | Encode the extension array as an enumerated type.                  |
| <code>fillna([value, method, limit])</code>        | Fill NA/NaN values using the specified method.                     |
| <code>floor(freq[, ambiguous, nonexistent])</code> | Perform floor operation on the data to the specified <i>freq</i> . |
| <code>isna()</code>                                | A 1-D array indicating if each value is missing.                   |
| <code>max([axis, skipna])</code>                   | Return the maximum value of the Array or maximum along an axis.    |

Table 93 – continued from previous page

|                                                      |                                                                               |
|------------------------------------------------------|-------------------------------------------------------------------------------|
| <code>min([axis, skipna])</code>                     | Return the minimum value of the Array or minimum along an axis.               |
| <code>repeat(repeats, *args, **kwargs)</code>        | Repeat elements of an array.                                                  |
| <code>round(freq[, ambiguous, nonexistent])</code>   | Perform round operation on the data to the specified <i>freq</i> .            |
| <code>searchsorted(value[, side, sorter])</code>     | Find indices where elements should be inserted to maintain order.             |
| <code>shift([periods, fill_value])</code>            | Shift values by desired number.                                               |
| <code>take(indices[, allow_fill, fill_value])</code> | Take elements from an array.                                                  |
| <code>to_pytimedelta()</code>                        | Return Timedelta Array/Index as object ndarray of datetime.timedelta objects. |
| <code>total_seconds()</code>                         | Return total duration of each element expressed in seconds.                   |
| <code>unique()</code>                                | Compute the ExtensionArray of unique values.                                  |
| <code>value_counts([dropna])</code>                  | Return a Series containing counts of unique values.                           |
| <code>view([dtype])</code>                           | New view on this array with the same data.                                    |

**pandas.arrays.TimedeltaArray.argsort**

`TimedeltaArray.argsort` (*ascending=True, kind='quicksort', \*args, \*\*kwargs*)

Return the indices that would sort this array.

**Parameters**

**ascending** [bool, default True] Whether the indices should result in an ascending or descending sort.

**kind** [{ 'quicksort', 'mergesort', 'heapsort' }, optional] Sorting algorithm.

**\*args, \*\*kwargs:** passed through to `numpy.argsort()`.

**Returns**

**index\_array** [ndarray] Array of indices that sort `self`.

See also:

`numpy.argsort` Sorting implementation used internally.

**pandas.arrays.TimedeltaArray.astype**

`TimedeltaArray.astype` (*dtype, copy=True*)

Cast to a NumPy array with 'dtype'.

**Parameters**

**dtype** [str or dtype] Typecode or data-type to which the array is cast.

**copy** [bool, default True] Whether to copy the data, even if not necessary. If False, a copy is made only if the old dtype does not match the new dtype.

**Returns**

**array** [ndarray] NumPy ndarray with 'dtype' for its dtype.

## pandas.arrays.TimedeltaArray.ceil

`TimedeltaArray.ceil(freq, ambiguous='raise', nonexistent='raise')`

Perform ceil operation on the data to the specified *freq*.

### Parameters

**freq** [str or Offset] The frequency level to ceil the index to. Must be a fixed frequency like 'S' (second) not 'ME' (month end). See *frequency aliases* for a list of possible *freq* values.

**ambiguous** ['infer', bool-ndarray, 'NaT', default 'raise'] Only relevant for DatetimeIndex:

- 'infer' will attempt to infer fall dst-transition hours based on order
- bool-ndarray where True signifies a DST time, False designates a non-DST time (note that this flag is only applicable for ambiguous times)
- 'NaT' will return NaT where there are ambiguous times
- 'raise' will raise an AmbiguousTimeError if there are ambiguous times

New in version 0.24.0.

**nonexistent** ['shift\_forward', 'shift\_backward', 'NaT', timedelta,]  
default 'raise'

A nonexistent time does not exist in a particular timezone where clocks moved forward due to DST.

- 'shift\_forward' will shift the nonexistent time forward to the closest existing time
- 'shift\_backward' will shift the nonexistent time backward to the closest existing time
- 'NaT' will return NaT where there are nonexistent times
- timedelta objects will shift nonexistent times by the timedelta
- 'raise' will raise a NonExistentTimeError if there are nonexistent times

New in version 0.24.0.

### Returns

**DatetimeIndex, TimedeltaIndex, or Series** Index of the same type for a DatetimeIndex or TimedeltaIndex, or a Series with the same index for a Series.

### Raises

**ValueError** if the 'freq' cannot be converted.

## Examples

### DatetimeIndex

```
>>> rng = pd.date_range('1/1/2018 11:59:00', periods=3, freq='min')
>>> rng
DatetimeIndex(['2018-01-01 11:59:00', '2018-01-01 12:00:00',
               '2018-01-01 12:01:00'],
              dtype='datetime64[ns]', freq='T')
```

(continues on next page)

(continued from previous page)

```
>>> rng.ceil('H')
DatetimeIndex(['2018-01-01 12:00:00', '2018-01-01 12:00:00',
              '2018-01-01 13:00:00'],
              dtype='datetime64[ns]', freq=None)
```

**Series**

```
>>> pd.Series(rng).dt.ceil("H")
0    2018-01-01 12:00:00
1    2018-01-01 12:00:00
2    2018-01-01 13:00:00
dtype: datetime64[ns]
```

**pandas.arrays.TimedeltaArray.copy****TimedeltaArray.copy** (*deep=False*)

Return a copy of the array.

**Parameters****deep** [bool, default False] Also copy the underlying data backing this array.**Returns****ExtensionArray****pandas.arrays.TimedeltaArray.dropna****TimedeltaArray.dropna** ()

Return ExtensionArray without NA values

**Returns****valid** [ExtensionArray]**pandas.arrays.TimedeltaArray.factorize****TimedeltaArray.factorize** (*na\_sentinel=-1*)

Encode the extension array as an enumerated type.

**Parameters****na\_sentinel** [int, default -1] Value to use in the *labels* array to indicate missing values.**Returns****labels** [ndarray] An integer NumPy array that's an indexer into the original ExtensionArray.**uniques** [ExtensionArray] An ExtensionArray containing the unique values of *self*.

---

**Note:** *uniques* will *not* contain an entry for the NA value of the ExtensionArray if there are any missing values present in *self*.

---

See also:

**pandas.factorize** Top-level factorize method that dispatches here.

## Notes

`pandas.factorize()` offers a *sort* keyword as well.

## pandas.arrays.TimedeltaArray.fillna

`TimedeltaArray.fillna` (*value=None, method=None, limit=None*)

Fill NA/NaN values using the specified method.

### Parameters

**value** [scalar, array-like] If a scalar value is passed it is used to fill all missing values. Alternatively, an array-like ‘value’ can be given. It’s expected that the array-like have the same length as ‘self’.

**method** [{‘backfill’, ‘bfill’, ‘pad’, ‘ffill’, None}, default None] Method to use for filling holes in reindexed Series pad / ffill: propagate last valid observation forward to next valid backfill / bfill: use NEXT valid observation to fill gap

**limit** [int, default None] If method is specified, this is the maximum number of consecutive NaN values to forward/backward fill. In other words, if there is a gap with more than this number of consecutive NaNs, it will only be partially filled. If method is not specified, this is the maximum number of entries along the entire axis where NaNs will be filled.

### Returns

**filled** [ExtensionArray with NA/NaN filled]

## pandas.arrays.TimedeltaArray.floor

`TimedeltaArray.floor` (*freq, ambiguous=‘raise’, nonexistent=‘raise’*)

Perform floor operation on the data to the specified *freq*.

### Parameters

**freq** [str or Offset] The frequency level to floor the index to. Must be a fixed frequency like ‘S’ (second) not ‘ME’ (month end). See *frequency aliases* for a list of possible *freq* values.

**ambiguous** [‘infer’, bool-ndarray, ‘NaT’, default ‘raise’] Only relevant for DatetimeIndex:

- ‘infer’ will attempt to infer fall dst-transition hours based on order
- bool-ndarray where True signifies a DST time, False designates a non-DST time (note that this flag is only applicable for ambiguous times)
- ‘NaT’ will return NaT where there are ambiguous times
- ‘raise’ will raise an AmbiguousTimeError if there are ambiguous times

New in version 0.24.0.

**nonexistent** [‘shift\_forward’, ‘shift\_backward’, ‘NaT’, timedelta,]  
default ‘raise’

A nonexistent time does not exist in a particular timezone where clocks moved forward due to DST.

- ‘shift\_forward’ will shift the nonexistent time forward to the closest existing time
- ‘shift\_backward’ will shift the nonexistent time backward to the closest existing time
- ‘NaT’ will return NaT where there are nonexistent times
- timedelta objects will shift nonexistent times by the timedelta
- ‘raise’ will raise an `NonExistentTimeError` if there are nonexistent times

New in version 0.24.0.

### Returns

**DatetimeIndex, TimedeltaIndex, or Series** Index of the same type for a `DatetimeIndex` or `TimedeltaIndex`, or a `Series` with the same index for a `Series`.

### Raises

**ValueError** if the ‘freq’ cannot be converted.

## Examples

### DatetimeIndex

```
>>> rng = pd.date_range('1/1/2018 11:59:00', periods=3, freq='min')
>>> rng
DatetimeIndex(['2018-01-01 11:59:00', '2018-01-01 12:00:00',
              '2018-01-01 12:01:00'],
              dtype='datetime64[ns]', freq='T')
>>> rng.floor('H')
DatetimeIndex(['2018-01-01 11:00:00', '2018-01-01 12:00:00',
              '2018-01-01 12:00:00'],
              dtype='datetime64[ns]', freq=None)
```

### Series

```
>>> pd.Series(rng).dt.floor("H")
0    2018-01-01 11:00:00
1    2018-01-01 12:00:00
2    2018-01-01 12:00:00
dtype: datetime64[ns]
```

## pandas.arrays.TimedeltaArray.isna

`TimedeltaArray.isna()`

A 1-D array indicating if each value is missing.

### Returns

**na\_values** [Union[np.ndarray, ExtensionArray]] In most cases, this should return a NumPy ndarray. For exceptional cases like `SparseArray`, where returning an ndarray would be expensive, an `ExtensionArray` may be returned.

## Notes

If returning an ExtensionArray, then

- `na_values._is_boolean` should be `True`
- `na_values` should implement `ExtensionArray._reduce()`
- `na_values.any` and `na_values.all` should be implemented

## pandas.arrays.TimedeltaArray.max

`TimedeltaArray.max` (*axis=None, skipna=True, \*args, \*\*kwargs*)  
Return the maximum value of the Array or maximum along an axis.

**See also:**

`numpy.ndarray.max`

**Index.max** Return the maximum value in an Index.

**Series.max** Return the maximum value in a Series.

## pandas.arrays.TimedeltaArray.min

`TimedeltaArray.min` (*axis=None, skipna=True, \*args, \*\*kwargs*)  
Return the minimum value of the Array or minimum along an axis.

**See also:**

`numpy.ndarray.min`

**Index.min** Return the minimum value in an Index.

**Series.min** Return the minimum value in a Series.

## pandas.arrays.TimedeltaArray.repeat

`TimedeltaArray.repeat` (*repeats, \*args, \*\*kwargs*)  
Repeat elements of an array.

**See also:**

`numpy.ndarray.repeat`

## pandas.arrays.TimedeltaArray.round

`TimedeltaArray.round` (*freq, ambiguous='raise', nonexistent='raise'*)  
Perform round operation on the data to the specified *freq*.

### Parameters

**freq** [str or Offset] The frequency level to round the index to. Must be a fixed frequency like 'S' (second) not 'ME' (month end). See *frequency aliases* for a list of possible *freq* values.

**ambiguous** ['infer', bool-ndarray, 'NaT', default 'raise'] Only relevant for DatetimeIndex:

- ‘infer’ will attempt to infer fall dst-transition hours based on order
- bool-ndarray where True signifies a DST time, False designates a non-DST time (note that this flag is only applicable for ambiguous times)
- ‘NaT’ will return NaT where there are ambiguous times
- ‘raise’ will raise an AmbiguousTimeError if there are ambiguous times

New in version 0.24.0.

**nonexistent** [‘shift\_forward’, ‘shift\_backward’, ‘NaT’, timedelta,]

default ‘raise’

A nonexistent time does not exist in a particular timezone where clocks moved forward due to DST.

- ‘shift\_forward’ will shift the nonexistent time forward to the closest existing time
- ‘shift\_backward’ will shift the nonexistent time backward to the closest existing time
- ‘NaT’ will return NaT where there are nonexistent times
- timedelta objects will shift nonexistent times by the timedelta
- ‘raise’ will raise an NonExistentTimeError if there are nonexistent times

New in version 0.24.0.

### Returns

**DatetimeIndex, TimedeltaIndex, or Series** Index of the same type for a DatetimeIndex or TimedeltaIndex, or a Series with the same index for a Series.

### Raises

**ValueError** if the ‘freq’ cannot be converted.

## Examples

### DatetimeIndex

```
>>> rng = pd.date_range('1/1/2018 11:59:00', periods=3, freq='min')
>>> rng
DatetimeIndex(['2018-01-01 11:59:00', '2018-01-01 12:00:00',
              '2018-01-01 12:01:00'],
              dtype='datetime64[ns]', freq='T')
>>> rng.round("H")
DatetimeIndex(['2018-01-01 12:00:00', '2018-01-01 12:00:00',
              '2018-01-01 12:00:00'],
              dtype='datetime64[ns]', freq=None)
```

### Series

```
>>> pd.Series(rng).dt.round("H")
0    2018-01-01 12:00:00
1    2018-01-01 12:00:00
2    2018-01-01 12:00:00
dtype: datetime64[ns]
```

### pandas.arrays.TimedeltaArray.searchsorted

`TimedeltaArray.searchsorted` (*value*, *side*='left', *sorter*=None)

Find indices where elements should be inserted to maintain order.

Find the indices into a sorted array *self* such that, if the corresponding elements in *value* were inserted before the indices, the order of *self* would be preserved.

#### Parameters

**value** [array\_like] Values to insert into *self*.

**side** [{ 'left', 'right' }, optional] If 'left', the index of the first suitable location found is given. If 'right', return the last such index. If there is no suitable index, return either 0 or N (where N is the length of *self*).

**sorter** [1-D array\_like, optional] Optional array of integer indices that sort *self* into ascending order. They are typically the result of `np.argsort`.

#### Returns

**indices** [array of ints] Array of insertion points with the same shape as *value*.

### pandas.arrays.TimedeltaArray.shift

`TimedeltaArray.shift` (*periods*=1, *fill\_value*=None)

Shift values by desired number.

Newly introduced missing values are filled with `self.dtype.na_value`.

New in version 0.24.0.

#### Parameters

**periods** [int, default 1] The number of periods to shift. Negative values are allowed for shifting backwards.

**fill\_value** [object, optional] The scalar value to use for newly introduced missing values. The default is `self.dtype.na_value`

New in version 0.24.0.

#### Returns

**shifted** [ExtensionArray]

#### Notes

If *self* is empty or *periods* is 0, a copy of *self* is returned.

If `periods > len(self)`, then an array of size `len(self)` is returned, with all values filled with `self.dtype.na_value`.

### pandas.arrays.TimedeltaArray.take

`TimedeltaArray.take` (*indices*, *allow\_fill*=False, *fill\_value*=None)

Take elements from an array.

#### Parameters

**indices** [sequence of integers] Indices to be taken.

**allow\_fill** [bool, default False] How to handle negative values in *indices*.

- False: negative values in *indices* indicate positional indices from the right (the default). This is similar to `numpy.take()`.
- True: negative values in *indices* indicate missing values. These values are set to *fill\_value*. Any other other negative values raise a `ValueError`.

**fill\_value** [any, optional] Fill value to use for NA-indices when *allow\_fill* is True. This may be `None`, in which case the default NA value for the type, `self.dtype.na_value`, is used.

For many `ExtensionArrays`, there will be two representations of *fill\_value*: a user-facing “boxed” scalar, and a low-level physical NA value. *fill\_value* should be the user-facing version, and the implementation should handle translating that to the physical version for processing the take if necessary.

### Returns

**ExtensionArray**

### Raises

**IndexError** When the indices are out of bounds for the array.

**ValueError** When *indices* contains negative values other than `-1` and *allow\_fill* is True.

### See also:

`numpy.take`, `pandas.api.extensions.take`

### Notes

`ExtensionArray.take` is called by `Series.__getitem__`, `.loc`, `iloc`, when *indices* is a sequence of values. Additionally, it's called by `Series.reindex()`, or any other method that causes realignment, with a *fill\_value*.

### Examples

Here's an example implementation, which relies on casting the extension array to object dtype. This uses the helper method `pandas.api.extensions.take()`.

```
def take(self, indices, allow_fill=False, fill_value=None):
    from pandas.core.algorithms import take

    # If the ExtensionArray is backed by an ndarray, then
    # just pass that here instead of coercing to object.
    data = self.astype(object)

    if allow_fill and fill_value is None:
        fill_value = self.dtype.na_value

    # fill value should always be translated from the scalar
    # type for the array, to the physical storage type for
    # the data, before passing to take.

    result = take(data, indices, fill_value=fill_value,
```

(continues on next page)

(continued from previous page)

```

        allow_fill=allow_fill)
    return self._from_sequence(result, dtype=self.dtype)

```

## pandas.arrays.TimedeltaArray.to\_pytimedelta

`TimedeltaArray.to_pytimedelta()`

Return Timedelta Array/Index as object ndarray of datetime.timedelta objects.

### Returns

**datetimes** [ndarray]

## pandas.arrays.TimedeltaArray.total\_seconds

`TimedeltaArray.total_seconds()`

Return total duration of each element expressed in seconds.

This method is available directly on TimedeltaArray, TimedeltaIndex and on Series containing timedelta values under the `.dt` namespace.

### Returns

**seconds** [[ndarray, Float64Index, Series]] When the calling object is a TimedeltaArray, the return type is ndarray. When the calling object is a TimedeltaIndex, the return type is a Float64Index. When the calling object is a Series, the return type is Series of type *float64* whose index is the same as the original.

### See also:

**`datetime.timedelta.total_seconds`** Standard library version of this method.

**`TimedeltaIndex.components`** Return a DataFrame with components of each Timedelta.

## Examples

### Series

```

>>> s = pd.Series(pd.to_timedelta(np.arange(5), unit='d'))
>>> s
0    0 days
1    1 days
2    2 days
3    3 days
4    4 days
dtype: timedelta64[ns]

```

```

>>> s.dt.total_seconds()
0         0.0
1    86400.0
2   172800.0
3   259200.0
4   345600.0
dtype: float64

```

**TimedeltaIndex**

```
>>> idx = pd.to_timedelta(np.arange(5), unit='d')
>>> idx
TimedeltaIndex(['0 days', '1 days', '2 days', '3 days', '4 days'],
                dtype='timedelta64[ns]', freq=None)
```

```
>>> idx.total_seconds()
Float64Index([0.0, 86400.0, 172800.0, 259200.000000000003, 345600.0],
              dtype='float64')
```

**pandas.arrays.TimedeltaArray.unique**

`TimedeltaArray.unique()`

Compute the ExtensionArray of unique values.

**Returns**

**uniques** [ExtensionArray]

**pandas.arrays.TimedeltaArray.value\_counts**

`TimedeltaArray.value_counts(dropna=False)`

Return a Series containing counts of unique values.

**Parameters**

**dropna** [boolean, default True] Don't include counts of NaT values.

**Returns**

**Series**

**pandas.arrays.TimedeltaArray.view**

`TimedeltaArray.view(dtype=None)`

New view on this array with the same data.

**Parameters**

**dtype** [numpy dtype, optional]

**Returns**

**ndarray** With the specified *dtype*.

**35.5.4 Timespan Data**

Pandas represents spans of times as *Period* objects.

## 35.5.5 Period

*Period*

Represents a period of time

---

### 35.5.5.1 pandas.Period

**class** pandas.**Period**

Represents a period of time

#### Parameters

- value** [Period or compat.string\_types, default None] The time period represented (e.g., '4Q2005')
- freq** [str, default None] One of pandas period strings or corresponding objects
- year** [int, default None]
- month** [int, default 1]
- quarter** [int, default None]
- day** [int, default 1]
- hour** [int, default 0]
- minute** [int, default 0]
- second** [int, default 0]

#### Attributes

|                      |                                                                      |
|----------------------|----------------------------------------------------------------------|
| <i>day</i>           | Get day of the month that a Period falls on.                         |
| <i>dayofweek</i>     | Day of the week the period lies in, with Monday=0 and Sunday=6.      |
| <i>dayofyear</i>     | Return the day of the year.                                          |
| <i>days_in_month</i> | Get the total number of days in the month that this period falls on. |
| <i>daysinmonth</i>   | Get the total number of days of the month that the Period falls in.  |
| <i>hour</i>          | Get the hour of the day component of the Period.                     |
| <i>minute</i>        | Get minute of the hour component of the Period.                      |
| <i>qyear</i>         | Fiscal year the Period lies in according to its starting-quarter.    |
| <i>second</i>        | Get the second component of the Period.                              |
| <i>start_time</i>    | Get the Timestamp for the start of the period.                       |
| <i>week</i>          | Get the week of the year on the given Period.                        |
| <i>weekday</i>       | Day of the week the period lies in, with Monday=0 and Sunday=6.      |

#### pandas.Period.day

Period.**day**

Get day of the month that a Period falls on.

#### Returns

**int****See also:*****Period.dayofweek*** Get the day of the week.***Period.dayofyear*** Get the day of the year.

### Examples

```
>>> p = pd.Period("2018-03-11", freq='H')
>>> p.day
11
```

### pandas.Period.dayofweek

#### **Period.dayofweek**

Day of the week the period lies in, with Monday=0 and Sunday=6.

If the period frequency is lower than daily (e.g. hourly), and the period spans over multiple days, the day at the start of the period is used.

If the frequency is higher than daily (e.g. monthly), the last day of the period is used.

#### **Returns**

**int** Day of the week.**See also:*****Period.dayofweek*** Day of the week the period lies in.***Period.weekday*** Alias of Period.dayofweek.***Period.day*** Day of the month.***Period.dayofyear*** Day of the year.

### Examples

```
>>> per = pd.Period('2017-12-31 22:00', 'H')
>>> per.dayofweek
6
```

For periods that span over multiple days, the day at the beginning of the period is returned.

```
>>> per = pd.Period('2017-12-31 22:00', '4H')
>>> per.dayofweek
6
>>> per.start_time.dayofweek
6
```

For periods with a frequency higher than days, the last day of the period is returned.

```
>>> per = pd.Period('2018-01', 'M')
>>> per.dayofweek
2
>>> per.end_time.dayofweek
2
```

## pandas.Period.dayofyear

### Period.dayofyear

Return the day of the year.

This attribute returns the day of the year on which the particular date occurs. The return value ranges between 1 to 365 for regular years and 1 to 366 for leap years.

#### Returns

**int** The day of year.

#### See also:

**Period.day** Return the day of the month.

**Period.dayofweek** Return the day of week.

**PeriodIndex.dayofyear** Return the day of year of all indexes.

## Examples

```
>>> period = pd.Period("2015-10-23", freq='H')
>>> period.dayofyear
296
>>> period = pd.Period("2012-12-31", freq='D')
>>> period.dayofyear
366
>>> period = pd.Period("2013-01-01", freq='D')
>>> period.dayofyear
1
```

## pandas.Period.days\_in\_month

### Period.days\_in\_month

Get the total number of days in the month that this period falls on.

#### Returns

**int**

#### See also:

**Period.daysinmonth** Gets the number of days in the month.

**DatetimeIndex.daysinmonth** Gets the number of days in the month.

**calendar.monthrange** Returns a tuple containing weekday (0-6 ~ Mon-Sun) and number of days (28-31).

## Examples

```
>>> p = pd.Period('2018-2-17')
>>> p.days_in_month
28
```

```
>>> pd.Period('2018-03-01').days_in_month
31
```

Handles the leap year case as well:

```
>>> p = pd.Period('2016-2-17')
>>> p.days_in_month
29
```

## pandas.Period.daysinmonth

### Period.**daysinmonth**

Get the total number of days of the month that the Period falls in.

#### Returns

**int**

#### See also:

**Period.days\_in\_month** Return the days of the month.

**Period.dayofyear** Return the day of the year.

## Examples

```
>>> p = pd.Period("2018-03-11", freq='H')
>>> p.daysinmonth
31
```

## pandas.Period.hour

### Period.**hour**

Get the hour of the day component of the Period.

#### Returns

**int** The hour as an integer, between 0 and 23.

#### See also:

**Period.second** Get the second component of the Period.

**Period.minute** Get the minute component of the Period.

## Examples

```
>>> p = pd.Period("2018-03-11 13:03:12.050000")
>>> p.hour
13
```

Period longer than a day

```
>>> p = pd.Period("2018-03-11", freq="M")
>>> p.hour
0
```

## pandas.Period.minute

### Period.minute

Get minute of the hour component of the Period.

#### Returns

**int** The minute as an integer, between 0 and 59.

**See also:**

**Period.hour** Get the hour component of the Period.

**Period.second** Get the second component of the Period.

## Examples

```
>>> p = pd.Period("2018-03-11 13:03:12.050000")
>>> p.minute
3
```

## pandas.Period.qyear

### Period.qyear

Fiscal year the Period lies in according to its starting-quarter.

The *year* and the *qyear* of the period will be the same if the fiscal and calendar years are the same. When they are not, the fiscal year can be different from the calendar year of the period.

#### Returns

**int** The fiscal year of the period.

**See also:**

**Period.year** Return the calendar year of the period.

## Examples

If the natural and fiscal year are the same, *qyear* and *year* will be the same.

```
>>> per = pd.Period('2018Q1', freq='Q')
>>> per.qyear
2018
>>> per.year
2018
```

If the fiscal year starts in April (*Q-MAR*), the first quarter of 2018 will start in April 2017. *year* will then be 2018, but *qyear* will be the fiscal year, 2018.

```
>>> per = pd.Period('2018Q1', freq='Q-MAR')
>>> per.start_time
Timestamp('2017-04-01 00:00:00')
>>> per.qyear
2018
>>> per.year
2017
```

## pandas.Period.second

### Period.**second**

Get the second component of the Period.

#### Returns

**int** The second of the Period (ranges from 0 to 59).

#### See also:

**Period.hour** Get the hour component of the Period.

**Period.minute** Get the minute component of the Period.

## Examples

```
>>> p = pd.Period("2018-03-11 13:03:12.050000")
>>> p.second
12
```

## pandas.Period.start\_time

### Period.**start\_time**

Get the Timestamp for the start of the period.

#### Returns

**Timestamp**

#### See also:

**Period.end\_time** Return the end Timestamp.

**Period.dayofyear** Return the day of year.

**Period.daysinmonth** Return the days in that month.

**Period.dayofweek** Return the day of the week.

## Examples

```
>>> period = pd.Period('2012-1-1', freq='D')
>>> period
Period('2012-01-01', 'D')
```

```
>>> period.start_time
Timestamp('2012-01-01 00:00:00')
```

```
>>> period.end_time
Timestamp('2012-01-01 23:59:59.999999999')
```

## pandas.Period.week

### Period.week

Get the week of the year on the given Period.

#### Returns

**int**

#### See also:

**Period.dayofweek** Get the day component of the Period.

**Period.weekday** Get the day component of the Period.

## Examples

```
>>> p = pd.Period("2018-03-11", "H")
>>> p.week
10
```

```
>>> p = pd.Period("2018-02-01", "D")
>>> p.week
5
```

```
>>> p = pd.Period("2018-01-06", "D")
>>> p.week
1
```

## pandas.Period.weekday

### Period.weekday

Day of the week the period lies in, with Monday=0 and Sunday=6.

If the period frequency is lower than daily (e.g. hourly), and the period spans over multiple days, the day at the start of the period is used.

If the frequency is higher than daily (e.g. monthly), the last day of the period is used.

#### Returns

**int** Day of the week.

See also:

***Period.dayofweek*** Day of the week the period lies in.

***Period.weekday*** Alias of *Period.dayofweek*.

***Period.day*** Day of the month.

***Period.dayofyear*** Day of the year.

## Examples

```
>>> per = pd.Period('2017-12-31 22:00', 'H')
>>> per.dayofweek
6
```

For periods that span over multiple days, the day at the beginning of the period is returned.

```
>>> per = pd.Period('2017-12-31 22:00', '4H')
>>> per.dayofweek
6
>>> per.start_time.dayofweek
6
```

For periods with a frequency higher than days, the last day of the period is returned.

```
>>> per = pd.Period('2018-01', 'M')
>>> per.dayofweek
2
>>> per.end_time.dayofweek
2
```

## Methods

|                     |                                                                                                                    |
|---------------------|--------------------------------------------------------------------------------------------------------------------|
| <i>asfreq</i>       | Convert Period to desired frequency, either at the start or end of the interval                                    |
| <i>strftime</i>     | Returns the string representation of the <i>Period</i> , depending on the selected <i>fmt</i> .                    |
| <i>to_timestamp</i> | Return the Timestamp representation of the Period at the target frequency at the specified end (how) of the Period |

### **pandas.Period.asfreq**

`Period.asfreq()`

Convert Period to desired frequency, either at the start or end of the interval

#### **Parameters**

**freq** [string]

**how** [{ 'E', 'S', 'end', 'start' }, default 'end'] Start or end of the timespan

#### **Returns**

**resampled** [Period]

### **pandas.Period.strftime**

`Period.strftime()`

Returns the string representation of the *Period*, depending on the selected *fmt*. *fmt* must be a string containing one or several directives. The method recognizes the same directives as the `time.strftime()` function of the standard Python distribution, as well as the specific additional directives `%f`, `%F`, `%q`. (formatting & docs originally from `scikits.timeries`)

| Di-<br>rec-<br>tive | Meaning                                                                                                                                                                      | Notes |
|---------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-------|
| %a                  | Locale's abbreviated weekday name.                                                                                                                                           |       |
| %A                  | Locale's full weekday name.                                                                                                                                                  |       |
| %b                  | Locale's abbreviated month name.                                                                                                                                             |       |
| %B                  | Locale's full month name.                                                                                                                                                    |       |
| %c                  | Locale's appropriate date and time representation.                                                                                                                           |       |
| %d                  | Day of the month as a decimal number [01,31].                                                                                                                                |       |
| %f                  | 'Fiscal' year without a century as a decimal number [00,99]                                                                                                                  | (1)   |
| %F                  | 'Fiscal' year with a century as a decimal number                                                                                                                             | (2)   |
| %H                  | Hour (24-hour clock) as a decimal number [00,23].                                                                                                                            |       |
| %I                  | Hour (12-hour clock) as a decimal number [01,12].                                                                                                                            |       |
| %j                  | Day of the year as a decimal number [001,366].                                                                                                                               |       |
| %m                  | Month as a decimal number [01,12].                                                                                                                                           |       |
| %M                  | Minute as a decimal number [00,59].                                                                                                                                          |       |
| %p                  | Locale's equivalent of either AM or PM.                                                                                                                                      | (3)   |
| %q                  | Quarter as a decimal number [01,04]                                                                                                                                          |       |
| %S                  | Second as a decimal number [00,61].                                                                                                                                          | (4)   |
| %U                  | Week number of the year (Sunday as the first day of the week) as a decimal number [00,53]. All days in a new year preceding the first Sunday are considered to be in week 0. | (5)   |
| %w                  | Weekday as a decimal number [0(Sunday),6].                                                                                                                                   |       |
| %W                  | Week number of the year (Monday as the first day of the week) as a decimal number [00,53]. All days in a new year preceding the first Monday are considered to be in week 0. | (5)   |
| %x                  | Locale's appropriate date representation.                                                                                                                                    |       |
| %X                  | Locale's appropriate time representation.                                                                                                                                    |       |
| %y                  | Year without century as a decimal number [00,99].                                                                                                                            |       |
| %Y                  | Year with century as a decimal number.                                                                                                                                       |       |
| %Z                  | Time zone name (no characters if no time zone exists).                                                                                                                       |       |
| %%                  | A literal '%' character.                                                                                                                                                     |       |

## Notes

- (1) The %f directive is the same as %Y if the frequency is not quarterly. Otherwise, it corresponds to the 'fiscal' year, as defined by the *qyear* attribute.
- (2) The %F directive is the same as %Y if the frequency is not quarterly. Otherwise, it corresponds to the 'fiscal' year, as defined by the *qyear* attribute.
- (3) The %p directive only affects the output hour field if the %I directive is used to parse the hour.
- (4) The range really is 0 to 61; this accounts for leap seconds and the (very rare) double leap seconds.
- (5) The %U and %W directives are only used in calculations when the day of the week and the year are specified.

## Examples

```
>>> a = Period(freq='Q-JUL', year=2006, quarter=1)
>>> a.strftime('%F-Q%q')
```

(continues on next page)

(continued from previous page)

```
'2006-Q1'
>>> # Output the last month in the quarter of this date
>>> a.strftime('%b-%Y')
'Oct-2005'
>>>
>>> a = Period(freq='D', year=2001, month=1, day=1)
>>> a.strftime('%d-%b-%Y')
'01-Jan-2006'
>>> a.strftime('%b. %d, %Y was a %A')
'Jan. 01, 2001 was a Monday'
```

pandas.Period.to\_timestamp

Period.to\_timestamp()  
Return the Timestamp representation of the Period at the target frequency at the specified end (how) of the Period

- Parameters**
- freq** [string or DateOffset] Target frequency. Default is 'D' if self.freq is week or longer and 'S' otherwise
  - how** [str, default 'S' (start)] 'S', 'E'. Can be aliased as case insensitive 'Start', 'Finish', 'Begin', 'End'

**Returns**  
**Timestamp**

| <i>Period.daysinmonth</i>   | Get the total number of days of the month that the Period falls in.  |
| <i>Period.end_time</i>      |                                                                      |
| <i>Period.freq</i>          |                                                                      |
| <i>Period.freqstr</i>       |                                                                      |
| <i>Period.hour</i>          | Get the hour of the day component of the Period.                     |
| <i>Period.is_leap_year</i>  |                                                                      |
| <i>Period.minute</i>        | Get minute of the hour component of the Period.                      |
| <i>Period.month</i>         |                                                                      |
| <i>Period.ordinal</i>       |                                                                      |
| <i>Period.quarter</i>       |                                                                      |

### 35.5.5.3 Methods

|                                  |                                                                                                                    |
|----------------------------------|--------------------------------------------------------------------------------------------------------------------|
| <code>Period.asfreq</code>       | Convert Period to desired frequency, either at the start or end of the interval                                    |
| <code>Period.now</code>          |                                                                                                                    |
| <code>Period.strftime</code>     | Returns the string representation of the <i>Period</i> , depending on the selected <i>fmt</i> .                    |
| <code>Period.to_timestamp</code> | Return the Timestamp representation of the Period at the target frequency at the specified end (how) of the Period |

#### pandas.Period.now

`Period.now()`

A collection of timedeltas may be stored in a `arrays.PeriodArray`. Every period in a `PeriodArray` must have the same `freq`.

|                                                                |                                                                                        |
|----------------------------------------------------------------|----------------------------------------------------------------------------------------|
| <code>arrays.DatetimeArray(values[, dtype, freq, copy])</code> | Pandas ExtensionArray for tz-naive or tz-aware date-time data.                         |
| <code>PeriodDtype</code>                                       | A Period duck-typed class, suitable for holding a period with <code>freq</code> dtype. |

#### pandas.PeriodDtype

**class** `pandas.PeriodDtype`

A Period duck-typed class, suitable for holding a period with `freq` dtype.

THIS IS NOT A REAL NUMPY DTYPE, but essentially a sub-class of `np.int64`.

##### Attributes

|                       |                                                              |
|-----------------------|--------------------------------------------------------------|
| <code>na_value</code> | <code>float(x)</code> -> floating point number               |
| <code>name</code>     | A string identifying the data type.                          |
| <code>names</code>    | Ordered list of field names, or None if there are no fields. |

#### pandas.PeriodDtype.na\_value

`PeriodDtype.na_value`

`float(x)` -> floating point number

Convert a string or number to a floating point number, if possible.

#### pandas.PeriodDtype.name

`PeriodDtype.name`

A string identifying the data type.

Will be used for display in, e.g. `Series.dtype`

**pandas.PeriodDtype.names**`PeriodDtype.names`

Ordered list of field names, or None if there are no fields.

This is for compatibility with NumPy arrays, and may be removed in the future.

| subtype |  |
|---------|--|

**Methods**

|                                            |                                                                                                     |
|--------------------------------------------|-----------------------------------------------------------------------------------------------------|
| <code>construct_array_type()</code>        | Return the array type associated with this dtype                                                    |
| <code>construct_from_string(string)</code> | Strict construction from a string, raise a <code>TypeError</code> if not possible                   |
| <code>is_dtype(dtype)</code>               | Return a boolean if we if the passed type is an actual dtype that we can match (via string or type) |
| <code>reset_cache()</code>                 | clear the cache                                                                                     |
| <code>type</code>                          | alias of <code>pandas._libs.tslibs.period.Period</code>                                             |

**pandas.PeriodDtype.construct\_array\_type****classmethod** `PeriodDtype.construct_array_type()`

Return the array type associated with this dtype

**Returns****type****pandas.PeriodDtype.construct\_from\_string****classmethod** `PeriodDtype.construct_from_string(string)`Strict construction from a string, raise a `TypeError` if not possible**pandas.PeriodDtype.is\_dtype****classmethod** `PeriodDtype.is_dtype(dtype)`

Return a boolean if we if the passed type is an actual dtype that we can match (via string or type)

**pandas.PeriodDtype.reset\_cache****classmethod** `PeriodDtype.reset_cache()`

clear the cache

**35.5.6 Interval Data**Arbitrary intervals can be represented as *Interval* objects.

*Interval*Immutable object implementing an Interval, a bounded slice-like interval.

---

### 35.5.6.1 pandas.Interval

**class** pandas.Interval

Immutable object implementing an Interval, a bounded slice-like interval.

New in version 0.20.0.

**Parameters****left** [orderable scalar] Left bound for the interval.**right** [orderable scalar] Right bound for the interval.**closed** [{‘left’, ‘right’, ‘both’, ‘neither’}, default ‘right’] Whether the interval is closed on the left-side, right-side, both or neither.**closed** [{‘right’, ‘left’, ‘both’, ‘neither’}, default ‘right’] Whether the interval is closed on the left-side, right-side, both or neither. See the Notes for more detailed explanation.**See also:****IntervalIndex** An Index of Interval objects that are all closed on the same side.**cut** Convert continuous data into discrete bins (Categorical of Interval objects).**qcut** Convert continuous data into bins (Categorical of Interval objects) based on quantiles.**Period** Represents a period of time.**Notes**

The parameters *left* and *right* must be from the same type, you must be able to compare them and they must satisfy `left <= right`.

A closed interval (in mathematics denoted by square brackets) contains its endpoints, i.e. the closed interval  $[0, 5]$  is characterized by the conditions  $0 \leq x \leq 5$ . This is what `closed='both'` stands for. An open interval (in mathematics denoted by parentheses) does not contain its endpoints, i.e. the open interval  $(0, 5)$  is characterized by the conditions  $0 < x < 5$ . This is what `closed='neither'` stands for. Intervals can also be half-open or half-closed, i.e.  $[0, 5)$  is described by  $0 \leq x < 5$  (`closed='left'`) and  $(0, 5]$  is described by  $0 < x \leq 5$  (`closed='right'`).

**Examples**

It is possible to build Intervals of different types, like numeric ones:

```
>>> iv = pd.Interval(left=0, right=5)
>>> iv
Interval(0, 5, closed='right')
```

You can check if an element belongs to it

```
>>> 2.5 in iv
True
```

You can test the bounds (closed='right', so  $0 < x \leq 5$ ):

```
>>> 0 in iv
False
>>> 5 in iv
True
>>> 0.0001 in iv
True
```

Calculate its length

```
>>> iv.length
5
```

You can operate with + and \* over an Interval and the operation is applied to each of its bounds, so the result depends on the type of the bound elements

```
>>> shifted_iv = iv + 3
>>> shifted_iv
Interval(3, 8, closed='right')
>>> extended_iv = iv * 10.0
>>> extended_iv
Interval(0.0, 50.0, closed='right')
```

To create a time interval you can use Timestamps as the bounds

```
>>> year_2017 = pd.Interval(pd.Timestamp('2017-01-01 00:00:00'),
...                          pd.Timestamp('2018-01-01 00:00:00'),
...                          closed='left')
>>> pd.Timestamp('2017-01-01 00:00:00') in year_2017
True
>>> year_2017.length
Timedelta('365 days 00:00:00')
```

And also you can create string intervals

```
>>> volume_1 = pd.Interval('Ant', 'Dog', closed='both')
>>> 'Bee' in volume_1
True
```

## Attributes

|                     |                                                                              |
|---------------------|------------------------------------------------------------------------------|
| <i>closed</i>       | Whether the interval is closed on the left-side, right-side, both or neither |
| <i>closed_left</i>  | Check if the interval is closed on the left side.                            |
| <i>closed_right</i> | Check if the interval is closed on the right side.                           |
| <i>left</i>         | Left bound for the interval                                                  |
| <i>length</i>       | Return the length of the Interval                                            |
| <i>mid</i>          | Return the midpoint of the Interval                                          |
| <i>open_left</i>    | Check if the interval is open on the left side.                              |
| <i>open_right</i>   | Check if the interval is open on the right side.                             |
| <i>right</i>        | Right bound for the interval                                                 |

### **pandas.Interval.closed**

`Interval.closed`

Whether the interval is closed on the left-side, right-side, both or neither

### **pandas.Interval.closed\_left**

`Interval.closed_left`

Check if the interval is closed on the left side.

For the meaning of *closed* and *open* see *Interval*.

#### **Returns**

**bool** True if the Interval is closed on the left-side, else False.

### **pandas.Interval.closed\_right**

`Interval.closed_right`

Check if the interval is closed on the right side.

For the meaning of *closed* and *open* see *Interval*.

#### **Returns**

**bool** True if the Interval is closed on the left-side, else False.

### **pandas.Interval.left**

`Interval.left`

Left bound for the interval

### **pandas.Interval.length**

`Interval.length`

Return the length of the Interval

### **pandas.Interval.mid**

`Interval.mid`

Return the midpoint of the Interval

### **pandas.Interval.open\_left**

`Interval.open_left`

Check if the interval is open on the left side.

For the meaning of *closed* and *open* see *Interval*.

#### **Returns**

**bool** True if the Interval is closed on the left-side, else False.

### pandas.Interval.open\_right

#### Interval.open\_right

Check if the interval is open on the right side.

For the meaning of *closed* and *open* see *Interval*.

#### Returns

**bool** True if the Interval is closed on the left-side, else False.

### pandas.Interval.right

#### Interval.right

Right bound for the interval

### Methods

---

*overlaps*

Check whether two Interval objects overlap.

---

### pandas.Interval.overlaps

#### Interval.overlaps()

Check whether two Interval objects overlap.

Two intervals overlap if they share a common point, including closed endpoints. Intervals that only have an open endpoint in common do not overlap.

New in version 0.24.0.

#### Parameters

**other** [Interval] The interval to check against for an overlap.

#### Returns

**bool** True if the two intervals overlap, else False.

See also:

**IntervalArray.overlaps** The corresponding method for IntervalArray.

**IntervalIndex.overlaps** The corresponding method for IntervalIndex.

### Examples

```
>>> i1 = pd.Interval(0, 2)
>>> i2 = pd.Interval(1, 3)
>>> i1.overlaps(i2)
True
>>> i3 = pd.Interval(4, 5)
>>> i1.overlaps(i3)
False
```

Intervals that share closed endpoints overlap:

```
>>> i4 = pd.Interval(0, 1, closed='both')
>>> i5 = pd.Interval(1, 2, closed='both')
>>> i4.overlaps(i5)
True
```

Intervals that only have an open endpoint in common do not overlap:

```
>>> i6 = pd.Interval(1, 2, closed='neither')
>>> i4.overlaps(i6)
False
```

### 35.5.6.2 Properties

|                              |                                                                              |
|------------------------------|------------------------------------------------------------------------------|
| <i>Interval.closed</i>       | Whether the interval is closed on the left-side, right-side, both or neither |
| <i>Interval.closed_left</i>  | Check if the interval is closed on the left side.                            |
| <i>Interval.closed_right</i> | Check if the interval is closed on the right side.                           |
| <i>Interval.left</i>         | Left bound for the interval                                                  |
| <i>Interval.length</i>       | Return the length of the Interval                                            |
| <i>Interval.mid</i>          | Return the midpoint of the Interval                                          |
| <i>Interval.open_left</i>    | Check if the interval is open on the left side.                              |
| <i>Interval.open_right</i>   | Check if the interval is open on the right side.                             |
| <i>Interval.overlaps</i>     | Check whether two Interval objects overlap.                                  |
| <i>Interval.right</i>        | Right bound for the interval                                                 |

A collection of intervals may be stored in an *IntervalArray*.

|                      |                                                                  |
|----------------------|------------------------------------------------------------------|
| <i>IntervalArray</i> | Pandas array for interval data that are closed on the same side. |
| <i>IntervalDtype</i> | A Interval duck-typed class, suitable for holding an interval    |

### pandas.IntervalArray

**class** pandas.**IntervalArray**

Pandas array for interval data that are closed on the same side.

New in version 0.24.0.

**Warning:** The indexing behaviors are provisional and may change in a future version of pandas.

#### Parameters

**data** [array-like (1-dimensional)] Array-like containing Interval objects from which to build the IntervalArray.

**closed** [{‘left’, ‘right’, ‘both’, ‘neither’}, default ‘right’] Whether the intervals are closed on the left-side, right-side, both or neither.

**dtype** [dtype or None, default None] If None, dtype will be inferred.

New in version 0.23.0.

**copy** [bool, default False] Copy the input data.

**verify\_integrity** [bool, default True] Verify that the IntervalArray is valid.

See also:

**Index** The base pandas Index type.

**Interval** A bounded slice-like interval; the elements of an IntervalArray.

**interval\_range** Function to create a fixed frequency IntervalIndex.

**cut** Bin values into discrete Intervals.

**qcut** Bin values into equal-sized Intervals based on rank or sample quantiles.

## Notes

See the [user guide](#) for more.

## Examples

A new IntervalArray can be constructed directly from an array-like of Interval objects:

```
>>> pd.IntervalArray([pd.Interval(0, 1), pd.Interval(1, 5)])
IntervalArray([(0, 1], (1, 5]],
              closed='right',
              dtype='interval[int64]')
```

It may also be constructed using one of the constructor methods: `IntervalArray.from_arrays()`, `IntervalArray.from_breaks()`, and `IntervalArray.from_tuples()`.

## Attributes

|                                           |                                                                                                                                                        |
|-------------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>left</code>                         | Return the left endpoints of each Interval in the IntervalArray as an Index                                                                            |
| <code>right</code>                        | Return the right endpoints of each Interval in the IntervalArray as an Index                                                                           |
| <code>closed</code>                       | Whether the intervals are closed on the left-side, right-side, both or neither                                                                         |
| <code>mid</code>                          | Return the midpoint of each Interval in the IntervalArray as an Index                                                                                  |
| <code>length</code>                       | Return an Index with entries denoting the length of each Interval in the IntervalArray                                                                 |
| <code>is_non_overlapping_monotonic</code> | Return True if the IntervalArray is non-overlapping (no Intervals share points) and is either monotonic increasing or monotonic decreasing, else False |

## pandas.IntervalArray.left

`IntervalArray.left`

Return the left endpoints of each Interval in the IntervalArray as an Index

**pandas.IntervalArray.right**`IntervalArray.right`

Return the right endpoints of each Interval in the IntervalArray as an Index

**pandas.IntervalArray.closed**`IntervalArray.closed`

Whether the intervals are closed on the left-side, right-side, both or neither

**pandas.IntervalArray.mid**`IntervalArray.mid`

Return the midpoint of each Interval in the IntervalArray as an Index

**pandas.IntervalArray.length**`IntervalArray.length`

Return an Index with entries denoting the length of each Interval in the IntervalArray

**pandas.IntervalArray.is\_non\_overlapping\_monotonic**`IntervalArray.is_non_overlapping_monotonic`

Return True if the IntervalArray is non-overlapping (no Intervals share points) and is either monotonic increasing or monotonic decreasing, else False

**Methods**

|                                                         |                                                                                        |
|---------------------------------------------------------|----------------------------------------------------------------------------------------|
| <i>from_arrays</i> (left, right[, closed, copy, dtype]) | Construct from two arrays defining the left and right bounds.                          |
| <i>from_tuples</i> (data[, closed, copy, dtype])        | Construct an IntervalArray from an array-like of tuples                                |
| <i>from_breaks</i> (breaks[, closed, copy, dtype])      | Construct an IntervalArray from an array of splits.                                    |
| <i>overlaps</i> (other)                                 | Check elementwise if an Interval overlaps the values in the IntervalArray.             |
| <i>set_closed</i> (closed)                              | Return an IntervalArray identical to the current one, but closed on the specified side |
| <i>to_tuples</i> ([na_tuple])                           | Return an ndarray of tuples of the form (left, right)                                  |

**pandas.IntervalArray.from\_arrays**

**classmethod** `IntervalArray.from_arrays` (*left*, *right*, *closed*='right', *copy*=False, *dtype*=None)

Construct from two arrays defining the left and right bounds.

**Parameters**

**left** [array-like (1-dimensional)] Left bounds for each interval.

**right** [array-like (1-dimensional)] Right bounds for each interval.

**closed** [{‘left’, ‘right’, ‘both’, ‘neither’}, default ‘right’] Whether the intervals are closed on the left-side, right-side, both or neither.

**copy** [boolean, default False] Copy the data.

**dtype** [dtype, optional] If None, dtype will be inferred.

New in version 0.23.0.

## Returns

**IntervalArray**

## Raises

**ValueError** When a value is missing in only one of *left* or *right*. When a value in *left* is greater than the corresponding value in *right*.

## See also:

***interval\_range*** Function to create a fixed frequency IntervalIndex.

***IntervalArray.from\_breaks*** Construct an IntervalArray from an array of splits.

***IntervalArray.from\_tuples*** Construct an IntervalArray from an array-like of tuples.

## Notes

Each element of *left* must be less than or equal to the *right* element at the same position. If an element is missing, it must be missing in both *left* and *right*. A `TypeError` is raised when using an unsupported type for *left* or *right*. At the moment, ‘category’, ‘object’, and ‘string’ subtypes are not supported.

## Examples

```
>>> IntervalArray.from_arrays([0, 1, 2], [1, 2, 3])
IntervalArray([(0, 1], (1, 2], (2, 3])
              closed='right',
              dtype='interval[int64]')
```

## pandas.IntervalArray.from\_tuples

**classmethod** `IntervalArray.from_tuples` (*data*, *closed*=‘right’, *copy*=False, *dtype*=None)

Construct an IntervalArray from an array-like of tuples

### Parameters

**data** [array-like (1-dimensional)] Array of tuples

**closed** [{‘left’, ‘right’, ‘both’, ‘neither’}, default ‘right’] Whether the intervals are closed on the left-side, right-side, both or neither.

**copy** [boolean, default False] by-default copy the data, this is compat only and ignored

**dtype** [dtype or None, default None] If None, dtype will be inferred  
..versionadded:: 0.23.0

See also:

***interval\_range*** Function to create a fixed frequency IntervalIndex.

***IntervalArray.from\_arrays*** Construct an IntervalArray from a left and right array.

***IntervalArray.from\_breaks*** Construct an IntervalArray from an array of splits.

## Examples

```
>>> pd.IntervalArray.from_tuples([(0, 1), (1, 2)])
IntervalArray([(0, 1], (1, 2]],
              closed='right', dtype='interval[int64]')
```

## pandas.IntervalArray.from\_breaks

**classmethod** `IntervalArray.from_breaks` (*breaks*, *closed='right'*, *copy=False*,  
*dtype=None*)

Construct an IntervalArray from an array of splits.

### Parameters

**breaks** [array-like (1-dimensional)] Left and right bounds for each interval.

**closed** [{‘left’, ‘right’, ‘both’, ‘neither’}, default ‘right’] Whether the intervals are closed on the left-side, right-side, both or neither.

**copy** [boolean, default False] copy the data

**dtype** [dtype or None, default None] If None, dtype will be inferred

New in version 0.23.0.

See also:

***interval\_range*** Function to create a fixed frequency IntervalIndex.

***IntervalArray.from\_arrays*** Construct from a left and right array.

***IntervalArray.from\_tuples*** Construct from a sequence of tuples.

## Examples

```
>>> pd.IntervalArray.from_breaks([0, 1, 2, 3])
IntervalArray([(0, 1], (1, 2], (2, 3]]
              closed='right',
              dtype='interval[int64]')
```

## pandas.IntervalArray.overlaps

`IntervalArray.overlaps` (*other*)

Check elementwise if an Interval overlaps the values in the IntervalArray.

Two intervals overlap if they share a common point, including closed endpoints. Intervals that only have an open endpoint in common do not overlap.

New in version 0.24.0.

### Parameters

**other** [Interval] Interval to check against for an overlap.

### Returns

**ndarray** Boolean array positionally indicating where an overlap occurs.

See also:

**Interval.overlaps** Check whether two Interval objects overlap.

## Examples

```
>>> intervals = pd.IntervalArray.from_tuples([(0, 1), (1, 3), (2, 4)])
>>> intervals
IntervalArray([(0, 1], (1, 3], (2, 4]],
              closed='right',
              dtype='interval[int64]')
>>> intervals.overlaps(pd.Interval(0.5, 1.5))
array([ True,  True, False])
```

Intervals that share closed endpoints overlap:

```
>>> intervals.overlaps(pd.Interval(1, 3, closed='left'))
array([ True,  True,  True])
```

Intervals that only have an open endpoint in common do not overlap:

```
>>> intervals.overlaps(pd.Interval(1, 2, closed='right'))
array([False,  True, False])
```

## pandas.IntervalArray.set\_closed

`IntervalArray.set_closed` (*closed*)

Return an IntervalArray identical to the current one, but closed on the specified side

New in version 0.24.0.

### Parameters

**closed** [{‘left’, ‘right’, ‘both’, ‘neither’}] Whether the intervals are closed on the left-side, right-side, both or neither.

### Returns

**new\_index** [IntervalArray]

## Examples

```
>>> index = pd.interval_range(0, 3)
>>> index
IntervalArray([(0, 1], (1, 2], (2, 3]]
             closed='right',
             dtype='interval[int64]')
>>> index.set_closed('both')
IntervalArray([[0, 1], [1, 2], [2, 3]]
             closed='both',
             dtype='interval[int64]')
```

## pandas.IntervalArray.to\_tuples

`IntervalArray.to_tuples` (*na\_tuple=True*)  
Return an ndarray of tuples of the form (left, right)

### Parameters

**na\_tuple** [boolean, default True] Returns NA as a tuple if True, (nan, nan), or just as the NA value itself if False, nan.  
..versionadded:: 0.23.0

### Returns

**tuples:** ndarray

## pandas.IntervalDtype

**class** `pandas.IntervalDtype`  
A Interval duck-typed class, suitable for holding an interval  
THIS IS NOT A REAL NUMPY DTYPE

### Attributes

|              |                                                              |
|--------------|--------------------------------------------------------------|
| <i>names</i> | Ordered list of field names, or None if there are no fields. |
| <i>type</i>  | The scalar type for the array, e.g.                          |

## pandas.IntervalDtype.names

`IntervalDtype.names`  
Ordered list of field names, or None if there are no fields.  
This is for compatibility with NumPy arrays, and may be removed in the future.

## pandas.IntervalDtype.type

`IntervalDtype.type`  
The scalar type for the array, e.g. `int`

It's expected `ExtensionArray[item]` returns an instance of `ExtensionDtype.type` for scalar `item`, assuming that value is valid (not NA). NA values do not need to be instances of `type`.

|          |  |

Methods

|                                            |                                                                                                     |
|--------------------------------------------|-----------------------------------------------------------------------------------------------------|
| <code>construct_array_type()</code>        | Return the array type associated with this dtype                                                    |
| <code>construct_from_string(string)</code> | attempt to construct this type from a string, raise a <code>TypeError</code> if its not possible    |
| <code>is_dtype(dtype)</code>               | Return a boolean if we if the passed type is an actual dtype that we can match (via string or type) |
| <code>reset_cache()</code>                 | clear the cache                                                                                     |

`pandas.IntervalDtype.construct_array_type`

**classmethod** `IntervalDtype.construct_array_type()`  
Return the array type associated with this dtype

Returns  
`type`

`pandas.IntervalDtype.construct_from_string`

**classmethod** `IntervalDtype.construct_from_string(string)`  
attempt to construct this type from a string, raise a `TypeError` if its not possible

`pandas.IntervalDtype.is_dtype`

**classmethod** `IntervalDtype.is_dtype(dtype)`  
Return a boolean if we if the passed type is an actual dtype that we can match (via string or type)

`pandas.IntervalDtype.reset_cache`

**classmethod** `IntervalDtype.reset_cache()`  
clear the cache

35.5.7 Nullable Integer

`numpy.ndarray` cannot natively represent integer-data with missing values. Pandas provides this through `arrays.IntegerArray`.

|                                                        |                                             |
|--------------------------------------------------------|---------------------------------------------|
| <code>arrays.IntegerArray(values, mask[, copy])</code> | Array of integer (optional missing) values. |
|--------------------------------------------------------|---------------------------------------------|

### 35.5.7.1 pandas.arrays.IntegerArray

**class** pandas.arrays.IntegerArray (values, mask, copy=False)

Array of integer (optional missing) values.

We represent an IntegerArray with 2 numpy arrays:

- data: contains a numpy integer array of the appropriate dtype
- mask: a boolean array holding a mask on the data, True is missing

To construct an IntegerArray from generic array-like input, use `integer_array` function instead.

#### Parameters

**values** [integer 1D numpy array]

**mask** [boolean 1D numpy array]

**copy** [bool, default False]

#### Returns

## IntegerArray

### Attributes

|               |                                                            |
|---------------|------------------------------------------------------------|
| <i>nbytes</i> | The number of bytes needed to store this object in memory. |
| <i>ndim</i>   | Extension Arrays are only allowed to be 1-dimensional.     |
| <i>shape</i>  | Return a tuple of the array dimensions.                    |

### pandas.arrays.IntegerArray.nbytes

#### IntegerArray.nbytes

The number of bytes needed to store this object in memory.

### pandas.arrays.IntegerArray.ndim

#### IntegerArray.ndim

Extension Arrays are only allowed to be 1-dimensional.

### pandas.arrays.IntegerArray.shape

#### IntegerArray.shape

Return a tuple of the array dimensions.

|       |  |
|-------|--|
| dtype |  |
|-------|--|

### Methods

|                                                 |                                                                   |
|-------------------------------------------------|-------------------------------------------------------------------|
| <i>argsort</i> ([ascending, kind])              | Return the indices that would sort this array.                    |
| <i>astype</i> (dtype[, copy])                   | Cast to a NumPy array or IntegerArray with 'dtype'.               |
| <i>copy</i> ([deep])                            | Return a copy of the array.                                       |
| <i>dropna</i> ()                                | Return ExtensionArray without NA values                           |
| <i>factorize</i> ([na_sentinel])                | Encode the extension array as an enumerated type.                 |
| <i>fillna</i> ([value, method, limit])          | Fill NA/NaN values using the specified method.                    |
| <i>isna</i> ()                                  | A 1-D array indicating if each value is missing.                  |
| <i>repeat</i> (repeats[, axis])                 | Repeat elements of a ExtensionArray.                              |
| <i>searchsorted</i> (value[, side, sorter])     | Find indices where elements should be inserted to maintain order. |
| <i>shift</i> ([periods, fill_value])            | Shift values by desired number.                                   |
| <i>take</i> (indexer[, allow_fill, fill_value]) | Take elements from an array.                                      |
| <i>unique</i> ()                                | Compute the ExtensionArray of unique values.                      |
| <i>value_counts</i> ([dropna])                  | Returns a Series containing counts of each category.              |

### pandas.arrays.IntegerArray.argsort

`IntegerArray.argsort` (*ascending=True*, *kind='quicksort'*, *\*args*, *\*\*kwargs*)

Return the indices that would sort this array.

#### Parameters

**ascending** [bool, default True] Whether the indices should result in an ascending or descending sort.

**kind** [{ 'quicksort', 'mergesort', 'heapsort' }, optional] Sorting algorithm.

**\*args, \*\*kwargs:** passed through to `numpy.argsort()`.

#### Returns

**index\_array** [ndarray] Array of indices that sort `self`.

See also:

`numpy.argsort` Sorting implementation used internally.

### pandas.arrays.IntegerArray.astype

`IntegerArray.astype` (*dtype*, *copy=True*)

Cast to a NumPy array or IntegerArray with 'dtype'.

#### Parameters

**dtype** [str or dtype] Typecode or data-type to which the array is cast.

**copy** [bool, default True] Whether to copy the data, even if not necessary. If False, a copy is made only if the old dtype does not match the new dtype.

#### Returns

**array** [ndarray or IntegerArray] NumPy ndarray or IntegerArray with 'dtype' for its dtype.

#### Raises

**TypeError** if incompatible type with an IntegerDtype, equivalent of same\_kind casting

### pandas.arrays.IntegerArray.copy

`IntegerArray.copy` (*deep=False*)

Return a copy of the array.

#### Parameters

**deep** [bool, default False] Also copy the underlying data backing this array.

#### Returns

**ExtensionArray**

### pandas.arrays.IntegerArray.dropna

`IntegerArray.dropna()`  
Return ExtensionArray without NA values

#### Returns

**valid** [ExtensionArray]

### pandas.arrays.IntegerArray.factorize

`IntegerArray.factorize (na_sentinel=-1)`  
Encode the extension array as an enumerated type.

#### Parameters

**na\_sentinel** [int, default -1] Value to use in the *labels* array to indicate missing values.

#### Returns

**labels** [ndarray] An integer NumPy array that's an indexer into the original ExtensionArray.

**uniques** [ExtensionArray] An ExtensionArray containing the unique values of *self*.

---

**Note:** *uniques* will *not* contain an entry for the NA value of the ExtensionArray if there are any missing values present in *self*.

---

#### See also:

**pandas.factorize** Top-level factorize method that dispatches here.

#### Notes

`pandas.factorize()` offers a *sort* keyword as well.

### pandas.arrays.IntegerArray.fillna

`IntegerArray.fillna (value=None, method=None, limit=None)`  
Fill NA/NaN values using the specified method.

#### Parameters

**value** [scalar, array-like] If a scalar value is passed it is used to fill all missing values. Alternatively, an array-like 'value' can be given. It's expected that the array-like have the same length as 'self'.

**method** [{ 'backfill', 'bfill', 'pad', 'ffill', None }, default None] Method to use for filling holes in reindexed Series pad / ffill: propagate last valid observation forward to next valid backfill / bfill: use NEXT valid observation to fill gap

**limit** [int, default None] If method is specified, this is the maximum number of consecutive NaN values to forward/backward fill. In other words, if there is a gap with more than this number of consecutive NaNs, it will only be partially filled. If method is not specified, this is the maximum number of entries along the entire axis where NaNs will be filled.

**Returns**

**filled** [ExtensionArray with NA/NaN filled]

**pandas.arrays.IntegerArray.isna**

`IntegerArray.isna()`

A 1-D array indicating if each value is missing.

**Returns**

**na\_values** [Union[np.ndarray, ExtensionArray]] In most cases, this should return a NumPy ndarray. For exceptional cases like `SparseArray`, where returning an ndarray would be expensive, an `ExtensionArray` may be returned.

**Notes**

If returning an `ExtensionArray`, then

- `na_values._is_boolean` should be `True`
- `na_values` should implement `ExtensionArray._reduce()`
- `na_values.any` and `na_values.all` should be implemented

**pandas.arrays.IntegerArray.repeat**

`IntegerArray.repeat(repeats, axis=None)`

Repeat elements of a `ExtensionArray`.

Returns a new `ExtensionArray` where each element of the current `ExtensionArray` is repeated consecutively a given number of times.

**Parameters**

**repeats** [int or array of ints] The number of repetitions for each element. This should be a non-negative integer. Repeating 0 times will return an empty `ExtensionArray`.

**axis** [None] Must be `None`. Has no effect but is accepted for compatibility with `numpy`.

**Returns**

**repeated\_array** [ExtensionArray] Newly created `ExtensionArray` with repeated elements.

**See also:**

**Series.repeat** Equivalent function for `Series`.

**Index.repeat** Equivalent function for `Index`.

**numpy.repeat** Similar method for `numpy.ndarray`.

**ExtensionArray.take** Take arbitrary positions.

## Examples

```
>>> cat = pd.Categorical(['a', 'b', 'c'])
>>> cat
[a, b, c]
Categories (3, object): [a, b, c]
>>> cat.repeat(2)
[a, a, b, b, c, c]
Categories (3, object): [a, b, c]
>>> cat.repeat([1, 2, 3])
[a, b, b, c, c, c]
Categories (3, object): [a, b, c]
```

## pandas.arrays.IntegerArray.searchsorted

`IntegerArray.searchsorted(value, side='left', sorter=None)`

Find indices where elements should be inserted to maintain order.

New in version 0.24.0.

Find the indices into a sorted array *self* (*a*) such that, if the corresponding elements in *v* were inserted before the indices, the order of *self* would be preserved.

Assuming that *a* is sorted:

| <i>side</i> | returned index <i>i</i> satisfies          |
|-------------|--------------------------------------------|
| left        | $\text{self}[i-1] < v \leq \text{self}[i]$ |
| right       | $\text{self}[i-1] \leq v < \text{self}[i]$ |

### Parameters

**value** [array\_like] Values to insert into *self*.

**side** [{‘left’, ‘right’}, optional] If ‘left’, the index of the first suitable location found is given. If ‘right’, return the last such index. If there is no suitable index, return either 0 or N (where N is the length of *self*).

**sorter** [1-D array\_like, optional] Optional array of integer indices that sort array *a* into ascending order. They are typically the result of `argsort`.

### Returns

**indices** [array of ints] Array of insertion points with the same shape as *value*.

See also:

`numpy.searchsorted` Similar method from NumPy.

## pandas.arrays.IntegerArray.shift

`IntegerArray.shift(periods=1, fill_value=None)`

Shift values by desired number.

Newly introduced missing values are filled with `self.dtype.na_value`.

New in version 0.24.0.

**Parameters**

**periods** [int, default 1] The number of periods to shift. Negative values are allowed for shifting backwards.

**fill\_value** [object, optional] The scalar value to use for newly introduced missing values. The default is `self.dtype.na_value`

New in version 0.24.0.

**Returns**

**shifted** [ExtensionArray]

**Notes**

If `self` is empty or `periods` is 0, a copy of `self` is returned.

If `periods > len(self)`, then an array of size `len(self)` is returned, with all values filled with `self.dtype.na_value`.

**pandas.arrays.IntegerArray.take**

`IntegerArray.take(indexer, allow_fill=False, fill_value=None)`

Take elements from an array.

**Parameters**

**indices** [sequence of integers] Indices to be taken.

**allow\_fill** [bool, default False] How to handle negative values in *indices*.

- False: negative values in *indices* indicate positional indices from the right (the default). This is similar to `numpy.take()`.
- True: negative values in *indices* indicate missing values. These values are set to *fill\_value*. Any other other negative values raise a `ValueError`.

**fill\_value** [any, optional] Fill value to use for NA-indices when *allow\_fill* is True. This may be `None`, in which case the default NA value for the type, `self.dtype.na_value`, is used.

For many `ExtensionArrays`, there will be two representations of *fill\_value*: a user-facing “boxed” scalar, and a low-level physical NA value. *fill\_value* should be the user-facing version, and the implementation should handle translating that to the physical version for processing the take if necessary.

**Returns**

**ExtensionArray**

**Raises**

**IndexError** When the indices are out of bounds for the array.

**ValueError** When *indices* contains negative values other than `-1` and *allow\_fill* is True.

**See also:**

`numpy.take`, `pandas.api.extensions.take`

## Notes

`ExtensionArray.take` is called by `Series.__getitem__`, `.loc`, `iloc`, when *indices* is a sequence of values. Additionally, it's called by `Series.reindex()`, or any other method that causes realignment, with a *fill\_value*.

## Examples

Here's an example implementation, which relies on casting the extension array to object dtype. This uses the helper method `pandas.api.extensions.take()`.

```
def take(self, indices, allow_fill=False, fill_value=None):
    from pandas.core.algorithms import take

    # If the ExtensionArray is backed by an ndarray, then
    # just pass that here instead of coercing to object.
    data = self.astype(object)

    if allow_fill and fill_value is None:
        fill_value = self.dtype.na_value

    # fill value should always be translated from the scalar
    # type for the array, to the physical storage type for
    # the data, before passing to take.

    result = take(data, indices, fill_value=fill_value,
                  allow_fill=allow_fill)
    return self._from_sequence(result, dtype=self.dtype)
```

## pandas.arrays.IntegerArray.unique

`IntegerArray.unique()`

Compute the `ExtensionArray` of unique values.

### Returns

**uniques** [`ExtensionArray`]

## pandas.arrays.IntegerArray.value\_counts

`IntegerArray.value_counts(dropna=True)`

Returns a `Series` containing counts of each category.

Every category will have an entry, even those with a count of 0.

### Parameters

**dropna** [boolean, default True] Don't include counts of NaN.

### Returns

**counts** [`Series`]

See also:

`Series.value_counts`

### 35.5.7.2 pandas.Int8Dtype

**class** pandas.Int8Dtype

#### Attributes

|                    |                                                              |
|--------------------|--------------------------------------------------------------|
| <i>itemsizes</i>   | Return the number of bytes in this dtype                     |
| <i>names</i>       | Ordered list of field names, or None if there are no fields. |
| <i>numpy_dtype</i> | Return an instance of our numpy dtype                        |

#### pandas.Int8Dtype.itemsizes

Int8Dtype.**itemsizes**  
Return the number of bytes in this dtype

#### pandas.Int8Dtype.names

Int8Dtype.**names**  
Ordered list of field names, or None if there are no fields.  
  
This is for compatibility with NumPy arrays, and may be removed in the future.

#### pandas.Int8Dtype.numpy\_dtype

Int8Dtype.**numpy\_dtype**  
Return an instance of our numpy dtype

|                            |  |
|----------------------------|--|
| <b>base</b>                |  |
| <b>is_signed_integer</b>   |  |
| <b>is_unsigned_integer</b> |  |
| <b>kind</b>                |  |

#### Methods

|                                       |                                                               |
|---------------------------------------|---------------------------------------------------------------|
| <i>construct_array_type()</i>         | Return the array type associated with this dtype              |
| <i>construct_from_string</i> (string) | Construction from a string, raise a TypeError if not possible |
| <i>is_dtype</i> (dtype)               | Check if we match 'dtype'.                                    |
| <i>type</i>                           | alias of numpy.int8                                           |

#### pandas.Int8Dtype.construct\_array\_type

**classmethod** Int8Dtype.**construct\_array\_type**()  
Return the array type associated with this dtype

#### Returns

type

### pandas.Int8Dtype.construct\_from\_string

**classmethod** `Int8Dtype.construct_from_string(string)`

Construction from a string, raise a TypeError if not possible

### pandas.Int8Dtype.is\_dtype

**classmethod** `Int8Dtype.is_dtype(dtype)`

Check if we match 'dtype'.

#### Parameters

**dtype** [object] The object to check.

#### Returns

**is\_dtype** [bool]

#### Notes

The default implementation is True if

1. `cls.construct_from_string(dtype)` is an instance of `cls`.
2. `dtype` is an object and is an instance of `cls`
3. `dtype` has a `dtype` attribute, and any of the above conditions is true for `dtype.dtype`.

### 35.5.7.3 pandas.Int16Dtype

**class** `pandas.Int16Dtype`

#### Attributes

|                    |                                                              |
|--------------------|--------------------------------------------------------------|
| <i>itemsize</i>    | Return the number of bytes in this dtype                     |
| <i>names</i>       | Ordered list of field names, or None if there are no fields. |
| <i>numpy_dtype</i> | Return an instance of our numpy dtype                        |

### pandas.Int16Dtype.itemsize

`Int16Dtype.itemsize`

Return the number of bytes in this dtype

### pandas.Int16Dtype.names

`Int16Dtype.names`

Ordered list of field names, or None if there are no fields.

This is for compatibility with NumPy arrays, and may be removed in the future.

### `pandas.Int16Dtype.numpy_dtype`

#### `Int16Dtype.numpy_dtype`

Return an instance of our numpy dtype

|                            |  |
|----------------------------|--|
| <b>base</b>                |  |
| <b>is_signed_integer</b>   |  |
| <b>is_unsigned_integer</b> |  |
| <b>kind</b>                |  |

### Methods

|                                            |                                                               |
|--------------------------------------------|---------------------------------------------------------------|
| <code>construct_array_type()</code>        | Return the array type associated with this dtype              |
| <code>construct_from_string(string)</code> | Construction from a string, raise a TypeError if not possible |
| <code>is_dtype(dtype)</code>               | Check if we match 'dtype'.                                    |
| <code>type</code>                          | alias of <code>numpy.int16</code>                             |

### `pandas.Int16Dtype.construct_array_type`

#### **classmethod** `Int16Dtype.construct_array_type()`

Return the array type associated with this dtype

##### Returns

**type**

### `pandas.Int16Dtype.construct_from_string`

#### **classmethod** `Int16Dtype.construct_from_string(string)`

Construction from a string, raise a TypeError if not possible

### `pandas.Int16Dtype.is_dtype`

#### **classmethod** `Int16Dtype.is_dtype(dtype)`

Check if we match 'dtype'.

##### Parameters

**dtype** [object] The object to check.

##### Returns

**is\_dtype** [bool]

### Notes

The default implementation is True if

1. `cls.construct_from_string(dtype)` is an instance of `cls`.
2. `dtype` is an object and is an instance of `cls`
3. `dtype` has a `dtype` attribute, and any of the above conditions is true for `dtype.dtype`.

### 35.5.7.4 pandas.Int32Dtype

**class** `pandas.Int32Dtype`

#### Attributes

|                    |                                                              |
|--------------------|--------------------------------------------------------------|
| <i>itemsize</i>    | Return the number of bytes in this dtype                     |
| <i>names</i>       | Ordered list of field names, or None if there are no fields. |
| <i>numpy_dtype</i> | Return an instance of our numpy dtype                        |

#### `pandas.Int32Dtype.itemsize`

`Int32Dtype.itemsize`

Return the number of bytes in this dtype

#### `pandas.Int32Dtype.names`

`Int32Dtype.names`

Ordered list of field names, or None if there are no fields.

This is for compatibility with NumPy arrays, and may be removed in the future.

#### `pandas.Int32Dtype.numpy_dtype`

`Int32Dtype.numpy_dtype`

Return an instance of our numpy dtype

|                            |  |
|----------------------------|--|
| <b>base</b>                |  |
| <b>is_signed_integer</b>   |  |
| <b>is_unsigned_integer</b> |  |
| <b>kind</b>                |  |

#### Methods

|                                      |                                                                            |
|--------------------------------------|----------------------------------------------------------------------------|
| <i>construct_array_type()</i>        | Return the array type associated with this dtype                           |
| <i>construct_from_string(string)</i> | Construction from a string, raise a <code>TypeError</code> if not possible |
| <i>is_dtype(dtype)</i>               | Check if we match 'dtype'.                                                 |
| <i>type</i>                          | alias of <code>numpy.int32</code>                                          |

**pandas.Int32Dtype.construct\_array\_type****classmethod** `Int32Dtype.construct_array_type()`

Return the array type associated with this dtype

**Returns****type****pandas.Int32Dtype.construct\_from\_string****classmethod** `Int32Dtype.construct_from_string(string)`Construction from a string, raise a `TypeError` if not possible**pandas.Int32Dtype.is\_dtype****classmethod** `Int32Dtype.is_dtype(dtype)`

Check if we match 'dtype'.

**Parameters****dtype** [object] The object to check.**Returns****is\_dtype** [bool]**Notes**

The default implementation is True if

1. `cls.construct_from_string(dtype)` is an instance of `cls`.
2. `dtype` is an object and is an instance of `cls`
3. `dtype` has a `dtype` attribute, and any of the above conditions is true for `dtype.dtype`.

**35.5.7.5 pandas.Int64Dtype****class** `pandas.Int64Dtype`**Attributes**

|                    |                                                              |
|--------------------|--------------------------------------------------------------|
| <i>itemsize</i>    | Return the number of bytes in this dtype                     |
| <i>names</i>       | Ordered list of field names, or None if there are no fields. |
| <i>numpy_dtype</i> | Return an instance of our numpy dtype                        |

**pandas.Int64Dtype.itemsize**`Int64Dtype.itemsize`

Return the number of bytes in this dtype

## pandas.Int64Dtype.names

`Int64Dtype.names`

Ordered list of field names, or None if there are no fields.

This is for compatibility with NumPy arrays, and may be removed in the future.

## pandas.Int64Dtype.numpy\_dtype

`Int64Dtype.numpy_dtype`

Return an instance of our numpy dtype

|                            |  |
|----------------------------|--|
| <b>base</b>                |  |
| <b>is_signed_integer</b>   |  |
| <b>is_unsigned_integer</b> |  |
| <b>kind</b>                |  |

## Methods

|                                            |                                                               |
|--------------------------------------------|---------------------------------------------------------------|
| <code>construct_array_type()</code>        | Return the array type associated with this dtype              |
| <code>construct_from_string(string)</code> | Construction from a string, raise a TypeError if not possible |
| <code>is_dtype(dtype)</code>               | Check if we match 'dtype'.                                    |
| <code>type</code>                          | alias of <code>numpy.int64</code>                             |

## pandas.Int64Dtype.construct\_array\_type

**classmethod** `Int64Dtype.construct_array_type()`

Return the array type associated with this dtype

**Returns**

`type`

## pandas.Int64Dtype.construct\_from\_string

**classmethod** `Int64Dtype.construct_from_string(string)`

Construction from a string, raise a TypeError if not possible

## pandas.Int64Dtype.is\_dtype

**classmethod** `Int64Dtype.is_dtype(dtype)`

Check if we match 'dtype'.

**Parameters**

**dtype** [object] The object to check.

**Returns**

`is_dtype` [bool]

## Notes

The default implementation is True if

1. `cls.construct_from_string(dtype)` is an instance of `cls`.
2. `dtype` is an object and is an instance of `cls`
3. `dtype` has a `dtype` attribute, and any of the above conditions is true for `dtype.dtype`.

### 35.5.7.6 pandas.UInt8Dtype

**class** pandas.UInt8Dtype

#### Attributes

|                    |                                                              |
|--------------------|--------------------------------------------------------------|
| <i>itemsize</i>    | Return the number of bytes in this dtype                     |
| <i>names</i>       | Ordered list of field names, or None if there are no fields. |
| <i>numpy_dtype</i> | Return an instance of our numpy dtype                        |

#### pandas.UInt8Dtype.itemsize

UInt8Dtype.**itemsize**

Return the number of bytes in this dtype

#### pandas.UInt8Dtype.names

UInt8Dtype.**names**

Ordered list of field names, or None if there are no fields.

This is for compatibility with NumPy arrays, and may be removed in the future.

#### pandas.UInt8Dtype.numpy\_dtype

UInt8Dtype.**numpy\_dtype**

Return an instance of our numpy dtype

|                            |  |
|----------------------------|--|
| <b>base</b>                |  |
| <b>is_signed_integer</b>   |  |
| <b>is_unsigned_integer</b> |  |
| <b>kind</b>                |  |

#### Methods

|                                      |                                                               |
|--------------------------------------|---------------------------------------------------------------|
| <i>construct_array_type()</i>        | Return the array type associated with this dtype              |
| <i>construct_from_string(string)</i> | Construction from a string, raise a TypeError if not possible |

|------------------------------|-----------------------------------|
| <code>is_dtype(dtype)</code> | Check if we match 'dtype'.        |
| <code>type</code>            | alias of <code>numpy.uint8</code> |

**pandas.UInt8Dtype.construct\_array\_type**

**classmethod** `UInt8Dtype.construct_array_type()`

Return the array type associated with this dtype

**Returns**

**type**

**pandas.UInt8Dtype.construct\_from\_string**

**classmethod** `UInt8Dtype.construct_from_string(string)`

Construction from a string, raise a `TypeError` if not possible

**pandas.UInt8Dtype.is\_dtype**

**classmethod** `UInt8Dtype.is_dtype(dtype)`

Check if we match 'dtype'.

**Parameters**

**dtype** [object] The object to check.

**Returns**

**is\_dtype** [bool]

**Notes**

The default implementation is True if

1. `cls.construct_from_string(dtype)` is an instance of `cls`.
2. `dtype` is an object and is an instance of `cls`
3. `dtype` has a `dtype` attribute, and any of the above conditions is true for `dtype.dtype`.

**35.5.7.7 pandas.UInt16Dtype**

**class** `pandas.UInt16Dtype`

**Attributes**

|                          |                                                              |
|--------------------------|--------------------------------------------------------------|
| <code>itemsize</code>    | Return the number of bytes in this dtype                     |
| <code>names</code>       | Ordered list of field names, or None if there are no fields. |
| <code>numpy_dtype</code> | Return an instance of our numpy dtype                        |

**pandas.UInt16Dtype.itemsize**`UInt16Dtype.itemsize`

Return the number of bytes in this dtype

**pandas.UInt16Dtype.names**`UInt16Dtype.names`

Ordered list of field names, or None if there are no fields.

This is for compatibility with NumPy arrays, and may be removed in the future.

**pandas.UInt16Dtype.numpy\_dtype**`UInt16Dtype.numpy_dtype`

Return an instance of our numpy dtype

|                            |  |
|----------------------------|--|
| <b>base</b>                |  |

| <code>is_dtype(dtype)</code>               | Check if we match 'dtype'.                                    |
| <code>type</code>                          | alias of <code>numpy.uint16</code>                            |

**pandas.UInt16Dtype.construct\_array\_type****classmethod** `UInt16Dtype.construct_array_type()`

Return the array type associated with this dtype

**Returns****type****pandas.UInt16Dtype.construct\_from\_string****classmethod** `UInt16Dtype.construct_from_string(string)`

Construction from a string, raise a TypeError if not possible

**pandas.UInt16Dtype.is\_dtype****classmethod** `UInt16Dtype.is_dtype(dtype)`

Check if we match 'dtype'.

**Parameters**

**dtype** [object] The object to check.

**Returns**

**is\_dtype** [bool]

**Notes**

The default implementation is True if

1. `cls.construct_from_string(dtype)` is an instance of `cls`.
2. `dtype` is an object and is an instance of `cls`
3. `dtype` has a `dtype` attribute, and any of the above conditions is true for `dtype.dtype`.

**35.5.7.8 pandas.UInt32Dtype**

**class** `pandas.UInt32Dtype`

**Attributes**

|                    |                                                              |
|--------------------|--------------------------------------------------------------|
| <i>itemsize</i>    | Return the number of bytes in this dtype                     |
| <i>names</i>       | Ordered list of field names, or None if there are no fields. |
| <i>numpy_dtype</i> | Return an instance of our numpy dtype                        |

**pandas.UInt32Dtype.itemsize**

`UInt32Dtype.itemsize`

Return the number of bytes in this dtype

**pandas.UInt32Dtype.names**

`UInt32Dtype.names`

Ordered list of field names, or None if there are no fields.

This is for compatibility with NumPy arrays, and may be removed in the future.

**pandas.UInt32Dtype.numpy\_dtype**

`UInt32Dtype.numpy_dtype`

Return an instance of our numpy dtype

|                            |  |
|----------------------------|--|
| <b>base</b>                |  |
| <b>is_signed_integer</b>   |  |
| <b>is_unsigned_integer</b> |  |
| <b>kind</b>                |  |

## Methods

|                                            |                                                               |
|--------------------------------------------|---------------------------------------------------------------|
| <code>construct_array_type()</code>        | Return the array type associated with this dtype              |
| <code>construct_from_string(string)</code> | Construction from a string, raise a TypeError if not possible |
| <code>is_dtype(dtype)</code>               | Check if we match 'dtype'.                                    |
| <code>type</code>                          | alias of <code>numpy.uint32</code>                            |

### `pandas.UInt32Dtype.construct_array_type`

**classmethod** `UInt32Dtype.construct_array_type()`

Return the array type associated with this dtype

#### Returns

`type`

### `pandas.UInt32Dtype.construct_from_string`

**classmethod** `UInt32Dtype.construct_from_string(string)`

Construction from a string, raise a TypeError if not possible

### `pandas.UInt32Dtype.is_dtype`

**classmethod** `UInt32Dtype.is_dtype(dtype)`

Check if we match 'dtype'.

#### Parameters

**dtype** [object] The object to check.

#### Returns

`is_dtype` [bool]

## Notes

The default implementation is True if

1. `cls.construct_from_string(dtype)` is an instance of `cls`.
2. `dtype` is an object and is an instance of `cls`
3. `dtype` has a `dtype` attribute, and any of the above conditions is true for `dtype.dtype`.

### 35.5.7.9 `pandas.UInt64Dtype`

**class** `pandas.UInt64Dtype`

## Attributes

|                    |                                                              |
|--------------------|--------------------------------------------------------------|
| <i>itemsize</i>    | Return the number of bytes in this dtype                     |
| <i>names</i>       | Ordered list of field names, or None if there are no fields. |
| <i>numpy_dtype</i> | Return an instance of our numpy dtype                        |

**pandas.UInt64Dtype.itemsize****UInt64Dtype.itemsize**

Return the number of bytes in this dtype

**pandas.UInt64Dtype.names****UInt64Dtype.names**

Ordered list of field names, or None if there are no fields.

This is for compatibility with NumPy arrays, and may be removed in the future.

**pandas.UInt64Dtype.numpy\_dtype****UInt64Dtype.numpy\_dtype**

Return an instance of our numpy dtype

|                            |  |
|----------------------------|--|
| <b>base</b>                |  |

**Methods**

|                                       |                                                               |
|---------------------------------------|---------------------------------------------------------------|
| <i>construct_array_type()</i>         | Return the array type associated with this dtype              |
| <i>construct_from_string</i> (string) | Construction from a string, raise a TypeError if not possible |
| <i>is_dtype</i> (dtype)               | Check if we match 'dtype'.                                    |
| <i>type</i>                           | alias of <code>numpy.uint64</code>                            |

**pandas.UInt64Dtype.construct\_array\_type****classmethod** **UInt64Dtype.construct\_array\_type()**

Return the array type associated with this dtype

**Returns****type****pandas.UInt64Dtype.construct\_from\_string****classmethod** **UInt64Dtype.construct\_from\_string**(string)

Construction from a string, raise a TypeError if not possible

### pandas.UInt64Dtype.is\_dtype

**classmethod** `UInt64Dtype.is_dtype(dtype)`  
Check if we match 'dtype'.

#### Parameters

**dtype** [object] The object to check.

#### Returns

**is\_dtype** [bool]

#### Notes

The default implementation is True if

1. `cls.construct_from_string(dtype)` is an instance of `cls`.
2. `dtype` is an object and is an instance of `cls`
3. `dtype` has a `dtype` attribute, and any of the above conditions is true for `dtype.dtype`.

## 35.5.8 Categorical Data

Pandas defines a custom data type for representing data that can take only a limited, fixed set of values. The dtype of a `Categorical` can be described by a `pandas.api.types.CategoricalDtype`.

|                                                      |                                                               |
|------------------------------------------------------|---------------------------------------------------------------|
| <code>CategoricalDtype([categories, ordered])</code> | Type for categorical data with the categories and orderedness |
|------------------------------------------------------|---------------------------------------------------------------|

---

### 35.5.8.1 pandas.CategoricalDtype

**class** `pandas.CategoricalDtype(categories=None, ordered=None)`  
Type for categorical data with the categories and orderedness

Changed in version 0.21.0.

#### Parameters

**categories** [sequence, optional] Must be unique, and must not contain any nulls.

**ordered** [bool, default False]

#### See also:

`pandas.Categorical`

#### Notes

This class is useful for specifying the type of a `Categorical` independent of the values. See `CategoricalDtype` for more.

Examples

```
>>> t = pd.CategoricalDtype(categories=['b', 'a'], ordered=True)
>>> pd.Series(['a', 'b', 'a', 'c'], dtype=t)
0      a
1      b
2      a
3    NaN
dtype: category
Categories (2, object): [b < a]
```

Attributes

|                   |                                                      |
|-------------------|------------------------------------------------------|
| <i>categories</i> | An Index containing the unique categories allowed.   |
| <i>ordered</i>    | Whether the categories have an ordered relationship. |

pandas.CategoricalDtype.categories

CategoricalDtype.**categories**  
An Index containing the unique categories allowed.

pandas.CategoricalDtype.ordered

CategoricalDtype.**ordered**  
Whether the categories have an ordered relationship.

Methods

|      |  |
|------|--|
| None |  |
|------|--|

|                                    |                                                      |
|------------------------------------|------------------------------------------------------|
| <i>CategoricalDtype.categories</i> | An Index containing the unique categories allowed.   |
| <i>CategoricalDtype.ordered</i>    | Whether the categories have an ordered relationship. |

Categorical data can be stored in a *pandas.Categorical*

|                                                         |                                                                 |
|---------------------------------------------------------|-----------------------------------------------------------------|
| <i>Categorical</i> (values[, categories, ordered, ...]) | Represents a categorical variable in classic R / S-plus fashion |
|---------------------------------------------------------|-----------------------------------------------------------------|

35.5.8.2 pandas.Categorical

**class** pandas.**Categorical** (*values, categories=None, ordered=None, dtype=None, fastpath=False*)  
Represents a categorical variable in classic R / S-plus fashion

*Categoricals* can only take on only a limited, and usually fixed, number of possible values (*categories*). In contrast to statistical categorical variables, a *Categorical* might have an order, but numerical operations (additions, divisions, ...) are not possible.

All values of the *Categorical* are either in *categories* or *np.nan*. Assigning values outside of *categories* will raise a *ValueError*. Order is defined by the order of the *categories*, not lexical order of the values.

### Parameters

**values** [list-like] The values of the categorical. If categories are given, values not in categories will be replaced with NaN.

**categories** [Index-like (unique), optional] The unique categories for this categorical. If not given, the categories are assumed to be the unique values of *values* (sorted, if possible, otherwise in the order in which they appear).

**ordered** [boolean, (default False)] Whether or not this categorical is treated as a ordered categorical. If True, the resulting categorical will be ordered. An ordered categorical respects, when sorted, the order of its *categories* attribute (which in turn is the *categories* argument, if provided).

**dtype** [CategoricalDtype] An instance of *CategoricalDtype* to use for this categorical  
New in version 0.21.0.

### Raises

**ValueError** If the categories do not validate.

**TypeError** If an explicit *ordered=True* is given but no *categories* and the *values* are not sortable.

See also:

**pandas.api.types.CategoricalDtype** Type for categorical data.

**CategoricalIndex** An Index with an underlying *Categorical*.

### Notes

See the [user guide](#) for more.

### Examples

```
>>> pd.Categorical([1, 2, 3, 1, 2, 3])
[1, 2, 3, 1, 2, 3]
Categories (3, int64): [1, 2, 3]
```

```
>>> pd.Categorical(['a', 'b', 'c', 'a', 'b', 'c'])
[a, b, c, a, b, c]
Categories (3, object): [a, b, c]
```

Ordered *Categoricals* can be sorted according to the custom order of the categories and can have a min and max value.

```
>>> c = pd.Categorical(['a', 'b', 'c', 'a', 'b', 'c'], ordered=True,
...                    categories=['c', 'b', 'a'])
>>> c
[a, b, c, a, b, c]
Categories (3, object): [c < b < a]
>>> c.min()
'c'
```

## Attributes

|                         |                                                      |
|-------------------------|------------------------------------------------------|
| <code>categories</code> | The categories of this categorical.                  |
| <code>codes</code>      | The category codes of this categorical.              |
| <code>ordered</code>    | Whether the categories have an ordered relationship. |
| <code>dtype</code>      | The CategoricalDtype for this instance               |

## `pandas.Categorical.categories`

### `Categorical.categories`

The categories of this categorical.

Setting assigns new values to each category (effectively a rename of each individual category).

The assigned value has to be a list-like object. All items must be unique and the number of items in the new categories must be the same as the number of items in the old categories.

Assigning to *categories* is a inplace operation!

### Raises

**ValueError** If the new categories do not validate as categories or if the number of new categories is unequal the number of old categories

### See also:

`rename_categories`, `reorder_categories`, `add_categories`, `remove_categories`, `remove_unused_categories`, `set_categories`

## `pandas.Categorical.codes`

### `Categorical.codes`

The category codes of this categorical.

Level codes are an array of integer which are the positions of the real values in the categories array.

There is not setter, use the other categorical methods and the normal item setter to change values in the categorical.

## `pandas.Categorical.ordered`

### `Categorical.ordered`

Whether the categories have an ordered relationship.

## `pandas.Categorical.dtype`

### `Categorical.dtype`

The CategoricalDtype for this instance

## Methods

|                                                              |                                                             |
|--------------------------------------------------------------|-------------------------------------------------------------|
| <code>from_codes(codes[, categories, ordered, dtype])</code> | Make a Categorical type from codes and categories or dtype. |
| <code>__array__([dtype])</code>                              | The numpy array interface.                                  |

---

### **pandas.Categorical.from\_codes**

**classmethod** `Categorical.from_codes` (*codes*, *categories=None*, *ordered=None*, *dtype=None*)

Make a Categorical type from codes and categories or dtype.

This constructor is useful if you already have codes and categories/dtype and so do not need the (computation intensive) factorization step, which is usually done on the constructor.

If your data does not follow this convention, please use the normal constructor.

#### **Parameters**

**codes** [array-like, integers] An integer array, where each integer points to a category in categories or dtype.categories, or else is -1 for NaN

**categories** [index-like, optional] The categories for the categorical. Items need to be unique. If the categories are not given here, then they must be provided in *dtype*.

**ordered** [bool, optional] Whether or not this categorical is treated as an ordered categorical. If not given here or in *dtype*, the resulting categorical will be unordered.

**dtype** [CategoricalDtype or the string “category”, optional] If *CategoricalDtype*, cannot be used together with *categories* or *ordered*.

New in version 0.24.0: When *dtype* is provided, neither *categories* nor *ordered* should be provided.

#### **Examples**

```
>>> dtype = pd.CategoricalDtype(['a', 'b'], ordered=True)
>>> pd.Categorical.from_codes(codes=[0, 1, 0, 1], dtype=dtype)
[a, b, a, b]
Categories (2, object): [a < b]
```

### **pandas.Categorical.\_\_array\_\_**

`Categorical.__array__` (*dtype=None*)

The numpy array interface.

#### **Returns**

**values** [numpy array] A numpy array of either the specified dtype or, if dtype==None (default), the same dtype as categorical.categories.dtype

The alternative `Categorical.from_codes()` constructor can be used when you have the categories and integer codes already:

|                                                               |                                                             |
|---------------------------------------------------------------|-------------------------------------------------------------|
| <code>Categorical.from_codes(codes[, categories, ...])</code> | Make a Categorical type from codes and categories or dtype. |
|---------------------------------------------------------------|-------------------------------------------------------------|

---

The dtype information is available on the `Categorical`

|                                     |                                                      |
|-------------------------------------|------------------------------------------------------|
| <code>Categorical.dtype</code>      | The <code>CategoricalDtype</code> for this instance  |
| <code>Categorical.categories</code> | The categories of this categorical.                  |
| <code>Categorical.ordered</code>    | Whether the categories have an ordered relationship. |
| <code>Categorical.codes</code>      | The category codes of this categorical.              |

`np.asarray(categorical)` works by implementing the array interface. Be aware, that this converts the `Categorical` back to a NumPy array, so categories and order information is not preserved!

|                                             |                            |
|---------------------------------------------|----------------------------|
| <code>Categorical.__array__([dtype])</code> | The numpy array interface. |
|---------------------------------------------|----------------------------|

A `Categorical` can be stored in a `Series` or `DataFrame`. To create a `Series` of dtype `category`, use `cat = s.astype(dtype)` or `Series(..., dtype=dtype)` where `dtype` is either

- the string `'category'`
- an instance of `CategoricalDtype`.

If the `Series` is of dtype `CategoricalDtype`, `Series.cat` can be used to change the categorical data. See *Categorical Accessor* for more.

### 35.5.9 Sparse Data

Data where a single value is repeated many times (e.g. 0 or NaN) may be stored efficiently as a *SparseArray*.

|                                                            |                                                         |
|------------------------------------------------------------|---------------------------------------------------------|
| <code>SparseArray(data[, sparse_index, index, ...])</code> | An <code>ExtensionArray</code> for storing sparse data. |
| <code>SparseDtype([dtype, fill_value])</code>              | Dtype for data stored in <i>SparseArray</i> .           |

#### 35.5.9.1 pandas.SparseArray

**class** `pandas.SparseArray` (*data*, *sparse\_index=None*, *index=None*, *fill\_value=None*, *kind='integer'*, *dtype=None*, *copy=False*)

An `ExtensionArray` for storing sparse data.

Changed in version 0.24.0: Implements the `ExtensionArray` interface.

##### Parameters

**data** [array-like] A dense array of values to store in the `SparseArray`. This may contain *fill\_value*.

**sparse\_index** [`SparseIndex`, optional]

**index** [`Index`]

**fill\_value** [scalar, optional] Elements in *data* that are *fill\_value* are not stored in the `SparseArray`. For memory savings, this should be the most common value in *data*. By default, *fill\_value* depends on the dtype of *data*:

| data.dtype  | na_value |
|-------------|----------|
| float       | np.nan   |
| int         | 0        |
| bool        | False    |
| datetime64  | pd.NaT   |
| timedelta64 | pd.NaT   |

The fill value is potentially specified in three ways. In order of precedence, these are

1. The *fill\_value* argument
2. `dtype.fill_value` if *fill\_value* is None and *dtype* is a `SparseDtype`
3. `data.dtype.fill_value` if *fill\_value* is None and *dtype* is not a `SparseDtype` and *data* is a `SparseArray`.

**kind** [{‘integer’, ‘block’}], default ‘integer’] The type of storage for sparse locations.

- ‘block’: Stores a *block* and *block\_length* for each contiguous *span* of sparse values. This is best when sparse data tends to be clumped together, with large regions of fill-value values between sparse values.
- ‘integer’: uses an integer to store the location of each sparse value.

**dtype** [np.dtype or `SparseDtype`, optional] The dtype to use for the `SparseArray`. For numpy dtypes, this determines the dtype of `self.sp_values`. For `SparseDtype`, this determines `self.sp_values` and `self.fill_value`.

**copy** [bool, default False] Whether to explicitly copy the incoming *data* array.

## Attributes

|                   |                                                                                        |
|-------------------|----------------------------------------------------------------------------------------|
| <i>T</i>          | Returns the <code>SparseArray</code> .                                                 |
| <i>density</i>    | The percent of non- <i>fill_value</i> points, as decimal.                              |
| <i>dtype</i>      | An instance of ‘ <code>ExtensionDtype</code> ’.                                        |
| <i>fill_value</i> | Elements in <i>data</i> that are <i>fill_value</i> are not stored.                     |
| <i>kind</i>       | The kind of sparse index for this array.                                               |
| <i>nbytes</i>     | The number of bytes needed to store this object in memory.                             |
| <i>ndim</i>       | Extension Arrays are only allowed to be 1-dimensional.                                 |
| <i>npoints</i>    | The number of non- <i>fill_value</i> points.                                           |
| <i>shape</i>      | Return a tuple of the array dimensions.                                                |
| <i>sp_index</i>   | The <code>SparseIndex</code> containing the location of non- <i>fill_value</i> points. |
| <i>sp_values</i>  | An ndarray containing the non- <i>fill_value</i> values.                               |
| <i>values</i>     | Dense values                                                                           |

## pandas.SparseArray.T

`SparseArray.T`  
Returns the `SparseArray`.

### **pandas.SparseArray.density**

#### **SparseArray.density**

The percent of non- *fill\_value* points, as decimal.

#### **Examples**

```
>>> s = SparseArray([0, 0, 1, 1, 1], fill_value=0)
>>> s.density
0.6
```

### **pandas.SparseArray.dtype**

#### **SparseArray.dtype**

An instance of 'ExtensionDtype'.

### **pandas.SparseArray.fill\_value**

#### **SparseArray.fill\_value**

Elements in *data* that are *fill\_value* are not stored.

For memory savings, this should be the most common value in the array.

### **pandas.SparseArray.kind**

#### **SparseArray.kind**

The kind of sparse index for this array. One of {'integer', 'block'}.

### **pandas.SparseArray.nbytes**

#### **SparseArray.nbytes**

The number of bytes needed to store this object in memory.

### **pandas.SparseArray.ndim**

#### **SparseArray.ndim**

Extension Arrays are only allowed to be 1-dimensional.

### **pandas.SparseArray.npoints**

#### **SparseArray.npoints**

The number of non- *fill\_value* points.

## Examples

```
>>> s = SparseArray([0, 0, 1, 1, 1], fill_value=0)
>>> s.npoints
3
```

### pandas.SparseArray.shape

`SparseArray.shape`

Return a tuple of the array dimensions.

### pandas.SparseArray.sp\_index

`SparseArray.sp_index`

The SparseIndex containing the location of non- `fill_value` points.

### pandas.SparseArray.sp\_values

`SparseArray.sp_values`

An ndarray containing the non- `fill_value` values.

## Examples

```
>>> s = SparseArray([0, 0, 1, 0, 2], fill_value=0)
>>> s.sp_values
array([1, 2])
```

### pandas.SparseArray.values

`SparseArray.values`

Dense values

## Methods

|                                        |                                                      |
|----------------------------------------|------------------------------------------------------|
| <i>all</i> ([axis])                    | Tests whether all elements evaluate True             |
| <i>any</i> ([axis])                    | Tests whether at least one of elements evaluate True |
| <i>argsort</i> ([ascending, kind])     | Return the indices that would sort this array.       |
| <i>astype</i> (dtype, copy)            | Change the dtype of a SparseArray.                   |
| <i>copy</i> ([deep])                   | Return a copy of the array.                          |
| <i>cumsum</i> ([axis])                 | Cumulative sum of non-NA/null values.                |
| <i>dropna</i> ()                       | Return ExtensionArray without NA values              |
| <i>factorize</i> ([na_sentinel])       | Encode the extension array as an enumerated type.    |
| <i>fillna</i> ([value, method, limit]) | Fill missing values with <i>value</i> .              |
| <i>get_values</i> ()                   | Convert SparseArray to a NumPy array.                |
| <i>isna</i> ()                         | A 1-D array indicating if each value is missing.     |

Continued on next page

Table 141 – continued from previous page

|                                                      |                                                                        |
|------------------------------------------------------|------------------------------------------------------------------------|
| <code>map(mapper)</code>                             | Map categories using input correspondence (dict, Series, or function). |
| <code>mean([axis])</code>                            | Mean of non-NA/null values                                             |
| <code>repeat(repeats[, axis])</code>                 | Repeat elements of a ExtensionArray.                                   |
| <code>searchsorted(v[, side, sorter])</code>         | Find indices where elements should be inserted to maintain order.      |
| <code>shift([periods, fill_value])</code>            | Shift values by desired number.                                        |
| <code>sum([axis])</code>                             | Sum of non-NA/null values                                              |
| <code>take(indices[, allow_fill, fill_value])</code> | Take elements from an array.                                           |
| <code>to_dense()</code>                              | Convert SparseArray to a NumPy array.                                  |
| <code>transpose(*axes)</code>                        | Returns the SparseArray.                                               |
| <code>unique()</code>                                | Compute the ExtensionArray of unique values.                           |
| <code>value_counts([dropna])</code>                  | Returns a Series containing counts of unique values.                   |

**pandas.SparseArray.all**

`SparseArray.all` (*axis=None, \*args, \*\*kwargs*)

Tests whether all elements evaluate True

**Returns**

**all** [bool]

**See also:**

`numpy.all`

**pandas.SparseArray.any**

`SparseArray.any` (*axis=0, \*args, \*\*kwargs*)

Tests whether at least one of elements evaluate True

**Returns**

**any** [bool]

**See also:**

`numpy.any`

**pandas.SparseArray.argsort**

`SparseArray.argsort` (*ascending=True, kind='quicksort', \*args, \*\*kwargs*)

Return the indices that would sort this array.

**Parameters**

**ascending** [bool, default True] Whether the indices should result in an ascending or descending sort.

**kind** [{ 'quicksort', 'mergesort', 'heapsort' }, optional] Sorting algorithm.

**\*args, \*\*kwargs:** passed through to `numpy.argsort()`.

**Returns**

**index\_array** [ndarray] Array of indices that sort `self`.

See also:

`numpy.argsort` Sorting implementation used internally.

## **pandas.SparseArray.astype**

`SparseArray.astype(dtype=None, copy=True)`

Change the dtype of a `SparseArray`.

The output will always be a `SparseArray`. To convert to a dense ndarray with a certain dtype, use `numpy.asarray()`.

### **Parameters**

**dtype** [np.dtype or ExtensionDtype] For `SparseDtype`, this changes the dtype of `self.sp_values` and the `self.fill_value`.

For other dtypes, this only changes the dtype of `self.sp_values`.

**copy** [bool, default True] Whether to ensure a copy is made, even if not necessary.

### **Returns**

**SparseArray**

## **Examples**

```
>>> arr = SparseArray([0, 0, 1, 2])
>>> arr
[0, 0, 1, 2]
Fill: 0
IntIndex
Indices: array([2, 3], dtype=int32)
```

```
>>> arr.astype(np.dtype('int32'))
[0, 0, 1, 2]
Fill: 0
IntIndex
Indices: array([2, 3], dtype=int32)
```

Using a NumPy dtype with a different kind (e.g. float) will coerce just `self.sp_values`.

```
>>> arr.astype(np.dtype('float64'))
... # doctest: +NORMALIZE_WHITESPACE
[0, 0, 1.0, 2.0]
Fill: 0
IntIndex
Indices: array([2, 3], dtype=int32)
```

Use a `SparseDtype` if you wish to be change the fill value as well.

```
>>> arr.astype(SparseDtype("float64", fill_value=np.nan))
... # doctest: +NORMALIZE_WHITESPACE
[nan, nan, 1.0, 2.0]
Fill: nan
IntIndex
Indices: array([2, 3], dtype=int32)
```

### pandas.SparseArray.copy

`SparseArray.copy (deep=False)`

Return a copy of the array.

#### Parameters

**deep** [bool, default False] Also copy the underlying data backing this array.

#### Returns

**ExtensionArray**

### pandas.SparseArray.cumsum

`SparseArray.cumsum (axis=0, *args, **kwargs)`

Cumulative sum of non-NA/null values.

When performing the cumulative summation, any non-NA/null values will be skipped. The resulting `SparseArray` will preserve the locations of NaN values, but the fill value will be `np.nan` regardless.

#### Parameters

**axis** [int or None] Axis over which to perform the cumulative summation. If None, perform cumulative summation over flattened array.

#### Returns

**cumsum** [SparseArray]

### pandas.SparseArray.dropna

`SparseArray.dropna ()`

Return `ExtensionArray` without NA values

#### Returns

**valid** [ExtensionArray]

### pandas.SparseArray.factorize

`SparseArray.factorize (na_sentinel=-1)`

Encode the extension array as an enumerated type.

#### Parameters

**na\_sentinel** [int, default -1] Value to use in the *labels* array to indicate missing values.

#### Returns

**labels** [ndarray] An integer NumPy array that's an indexer into the original `ExtensionArray`.

**uniques** [ExtensionArray] An `ExtensionArray` containing the unique values of *self*.

---

**Note:** *uniques* will *not* contain an entry for the NA value of the `ExtensionArray` if there are any missing values present in *self*.

---

See also:

**pandas.factorize** Top-level factorize method that dispatches here.

## Notes

`pandas.factorize()` offers a *sort* keyword as well.

## pandas.SparseArray.fillna

`SparseArray.fillna(value=None, method=None, limit=None)`

Fill missing values with *value*.

### Parameters

**value** [scalar, optional]

**method** [str, optional]

**Warning:** Using ‘method’ will result in high memory use, as all *fill\_value* methods will be converted to an in-memory ndarray

**limit** [int, optional]

### Returns

**SparseArray**

## Notes

When *value* is specified, the result’s *fill\_value* depends on *self.fill\_value*. The goal is to maintain low-memory use.

If *self.fill\_value* is NA, the result dtype will be `SparseDtype(self.dtype, fill_value=value)`. This will preserve amount of memory used before and after filling.

When *self.fill\_value* is not NA, the result dtype will be *self.dtype*. Again, this preserves the amount of memory used.

## pandas.SparseArray.get\_values

`SparseArray.get_values()`

Convert `SparseArray` to a NumPy array.

### Returns

**arr** [NumPy array]

## pandas.SparseArray.isna

`SparseArray.isna()`

A 1-D array indicating if each value is missing.

**Returns**

**na\_values** [Union[np.ndarray, ExtensionArray]] In most cases, this should return a NumPy ndarray. For exceptional cases like `SparseArray`, where returning an ndarray would be expensive, an `ExtensionArray` may be returned.

**Notes**

If returning an `ExtensionArray`, then

- `na_values._is_boolean` should be `True`
- `na_values` should implement `ExtensionArray._reduce()`
- `na_values.any` and `na_values.all` should be implemented

**pandas.SparseArray.map**

`SparseArray.map` (*mapper*)

Map categories using input correspondence (dict, Series, or function).

**Parameters**

**mapper** [dict, Series, callable] The correspondence from old values to new.

**Returns**

**SparseArray** The output array will have the same density as the input. The output fill value will be the result of applying the mapping to `self.fill_value`

**Examples**

```
>>> arr = pd.SparseArray([0, 1, 2])
>>> arr.apply(lambda x: x + 10)
[10, 11, 12]
Fill: 10
IntIndex
Indices: array([1, 2], dtype=int32)
```

```
>>> arr.apply({0: 10, 1: 11, 2: 12})
[10, 11, 12]
Fill: 10
IntIndex
Indices: array([1, 2], dtype=int32)
```

```
>>> arr.apply(pd.Series([10, 11, 12], index=[0, 1, 2]))
[10, 11, 12]
Fill: 10
IntIndex
Indices: array([1, 2], dtype=int32)
```

**pandas.SparseArray.mean**

`SparseArray.mean` (*axis=0, \*args, \*\*kwargs*)

Mean of non-NA/null values

**Returns**

**mean** [float]

**pandas.SparseArray.repeat**

`SparseArray.repeat` (*repeats*, *axis=None*)

Repeat elements of a ExtensionArray.

Returns a new ExtensionArray where each element of the current ExtensionArray is repeated consecutively a given number of times.

**Parameters**

**repeats** [int or array of ints] The number of repetitions for each element. This should be a non-negative integer. Repeating 0 times will return an empty ExtensionArray.

**axis** [None] Must be None. Has no effect but is accepted for compatibility with numpy.

**Returns**

**repeated\_array** [ExtensionArray] Newly created ExtensionArray with repeated elements.

**See also:**

**Series.repeat** Equivalent function for Series.

**Index.repeat** Equivalent function for Index.

**numpy.repeat** Similar method for `numpy.ndarray`.

**ExtensionArray.take** Take arbitrary positions.

**Examples**

```
>>> cat = pd.Categorical(['a', 'b', 'c'])
>>> cat
[a, b, c]
Categories (3, object): [a, b, c]
>>> cat.repeat(2)
[a, a, b, b, c, c]
Categories (3, object): [a, b, c]
>>> cat.repeat([1, 2, 3])
[a, b, b, c, c, c]
Categories (3, object): [a, b, c]
```

**pandas.SparseArray.searchsorted**

`SparseArray.searchsorted` (*v*, *side='left'*, *sorter=None*)

Find indices where elements should be inserted to maintain order.

New in version 0.24.0.

Find the indices into a sorted array *self* (*a*) such that, if the corresponding elements in *v* were inserted before the indices, the order of *self* would be preserved.

Assuming that *a* is sorted:

| <i>side</i> | returned index <i>i</i> satisfies           |
|-------------|---------------------------------------------|
| left        | <code>self[i-1] &lt; v &lt;= self[i]</code> |
| right       | <code>self[i-1] &lt;= v &lt; self[i]</code> |

#### Parameters

**value** [array\_like] Values to insert into *self*.

**side** [{‘left’, ‘right’}, optional] If ‘left’, the index of the first suitable location found is given. If ‘right’, return the last such index. If there is no suitable index, return either 0 or N (where N is the length of *self*).

**sorter** [1-D array\_like, optional] Optional array of integer indices that sort array *a* into ascending order. They are typically the result of `argsort`.

#### Returns

**indices** [array of ints] Array of insertion points with the same shape as *value*.

#### See also:

`numpy.searchsorted` Similar method from NumPy.

### pandas.SparseArray.shift

`SparseArray.shift` (*periods=1, fill\_value=None*)

Shift values by desired number.

Newly introduced missing values are filled with `self.dtype.na_value`.

New in version 0.24.0.

#### Parameters

**periods** [int, default 1] The number of periods to shift. Negative values are allowed for shifting backwards.

**fill\_value** [object, optional] The scalar value to use for newly introduced missing values. The default is `self.dtype.na_value`

New in version 0.24.0.

#### Returns

**shifted** [ExtensionArray]

#### Notes

If *self* is empty or *periods* is 0, a copy of *self* is returned.

If *periods* > `len(self)`, then an array of size `len(self)` is returned, with all values filled with `self.dtype.na_value`.

### pandas.SparseArray.sum

`SparseArray.sum(axis=0, *args, **kwargs)`  
Sum of non-NA/null values

#### Returns

**sum** [float]

### pandas.SparseArray.take

`SparseArray.take(indices, allow_fill=False, fill_value=None)`  
Take elements from an array.

#### Parameters

**indices** [sequence of integers] Indices to be taken.

**allow\_fill** [bool, default False] How to handle negative values in *indices*.

- False: negative values in *indices* indicate positional indices from the right (the default). This is similar to `numpy.take()`.
- True: negative values in *indices* indicate missing values. These values are set to *fill\_value*. Any other other negative values raise a `ValueError`.

**fill\_value** [any, optional] Fill value to use for NA-indices when *allow\_fill* is True. This may be None, in which case the default NA value for the type, `self.dtype.na_value`, is used.

For many ExtensionArrays, there will be two representations of *fill\_value*: a user-facing “boxed” scalar, and a low-level physical NA value. *fill\_value* should be the user-facing version, and the implementation should handle translating that to the physical version for processing the take if necessary.

#### Returns

**ExtensionArray**

#### Raises

**IndexError** When the indices are out of bounds for the array.

**ValueError** When *indices* contains negative values other than `-1` and *allow\_fill* is True.

#### See also:

`numpy.take`, `pandas.api.extensions.take`

### Notes

`ExtensionArray.take` is called by `Series.__getitem__`, `.loc`, `iloc`, when *indices* is a sequence of values. Additionally, it's called by `Series.reindex()`, or any other method that causes realignment, with a *fill\_value*.

### Examples

Here's an example implementation, which relies on casting the extension array to object dtype. This uses the helper method `pandas.api.extensions.take()`.

```
def take(self, indices, allow_fill=False, fill_value=None):
    from pandas.core.algorithms import take

    # If the ExtensionArray is backed by an ndarray, then
    # just pass that here instead of coercing to object.
    data = self.astype(object)

    if allow_fill and fill_value is None:
        fill_value = self.dtype.na_value

    # fill value should always be translated from the scalar
    # type for the array, to the physical storage type for
    # the data, before passing to take.

    result = take(data, indices, fill_value=fill_value,
                  allow_fill=allow_fill)
    return self._from_sequence(result, dtype=self.dtype)
```

### **pandas.SparseArray.to\_dense**

`SparseArray.to_dense()`

Convert SparseArray to a NumPy array.

#### **Returns**

**arr** [NumPy array]

### **pandas.SparseArray.transpose**

`SparseArray.transpose(*axes)`

Returns the SparseArray.

### **pandas.SparseArray.unique**

`SparseArray.unique()`

Compute the ExtensionArray of unique values.

#### **Returns**

**uniques** [ExtensionArray]

### **pandas.SparseArray.value\_counts**

`SparseArray.value_counts(dropna=True)`

Returns a Series containing counts of unique values.

#### **Parameters**

**dropna** [boolean, default True] Don't include counts of NaN, even if NaN is in sp\_values.

#### **Returns**

**counts** [Series]

|         |  |
|---------|--|
| nonzero |  |
|---------|--|

35.5.9.2 pandas.SparseDtype

**class** pandas.**SparseDtype** (*dtype=<class 'numpy.float64'>, fill\_value=None*)  
Dtype for data stored in *SparseArray*.

This dtype implements the pandas ExtensionDtype interface.  
New in version 0.24.0.

Parameters

- dtype** [str, ExtensionDtype, numpy.dtype, type, default numpy.float64] The dtype of the underlying array storing the non-fill value values.
- fill\_value** [scalar, optional] The scalar value not stored in the SparseArray. By default, this depends on *dtype*.

| dtype       | na_value |
|-------------|----------|
| float       | np.nan   |
| int         | 0        |
| bool        | False    |
| datetime64  | pd.NaT   |
| timedelta64 | pd.NaT   |

The default value may be overridden by specifying a *fill\_value*.

Attributes

|                   |                                                              |
|-------------------|--------------------------------------------------------------|
| <i>fill_value</i> | The fill value of the array.                                 |
| <i>kind</i>       | The sparse kind.                                             |
| <i>name</i>       | A string identifying the data type.                          |
| <i>names</i>      | Ordered list of field names, or None if there are no fields. |
| <i>type</i>       | The scalar type for the array, e.g.                          |

pandas.SparseDtype.fill\_value

**SparseDtype.fill\_value**  
The fill value of the array.  
Converting the SparseArray to a dense ndarray will fill the array with this value.

**Warning:** It's possible to end up with a SparseArray that has *fill\_value* values in *sp\_values*. This can occur, for example, when setting *SparseArray.fill\_value* directly.

**pandas.SparseDtype.kind**`SparseDtype.kind`

The sparse kind. Either 'integer', or 'block'.

**pandas.SparseDtype.name**`SparseDtype.name`

A string identifying the data type.

Will be used for display in, e.g. `Series.dtype`**pandas.SparseDtype.names**`SparseDtype.names`

Ordered list of field names, or None if there are no fields.

This is for compatibility with NumPy arrays, and may be removed in the future.

**pandas.SparseDtype.type**`SparseDtype.type`The scalar type for the array, e.g. `int`It's expected `ExtensionArray[item]` returns an instance of `ExtensionDtype.type` for scalar `item`, assuming that value is valid (not NA). NA values do not need to be instances of `type`.

|         |  |
|---------|--|
| subtype |  |
|---------|--|

**Methods**

|                                            |                                                  |
|--------------------------------------------|--------------------------------------------------|
| <code>construct_array_type()</code>        | Return the array type associated with this dtype |
| <code>construct_from_string(string)</code> | Construct a SparseDtype from a string form.      |
| <code>is_dtype(dtype)</code>               | Check if we match 'dtype'.                       |
| <code>update_dtype(dtype)</code>           | Convert the SparseDtype to a new dtype.          |

**pandas.SparseDtype.construct\_array\_type****classmethod** `SparseDtype.construct_array_type()`

Return the array type associated with this dtype

**Returns**`type`**pandas.SparseDtype.construct\_from\_string****classmethod** `SparseDtype.construct_from_string(string)`

Construct a SparseDtype from a string form.

**Parameters**

**string** [str] Can take the following forms.

```
string    dtype    =====    =====  
'int'    SparseDtype[np.int64, 0]  'Sparse'  SparseDtype[np.float64, nan]  
'Sparse[int]' SparseDtype[np.int64, 0] 'Sparse[int, 0]' SparseDtype[np.int64,  
0] =====
```

It is not possible to specify non-default fill values with a string. An argument like 'Sparse[int, 1]' will raise a `TypeError` because the default fill value for integers is 0.

**Returns**

**SparseDtype**

**pandas.SparseDtype.is\_dtype**

**classmethod** `SparseDtype.is_dtype(dtype)`

Check if we match 'dtype'.

**Parameters**

**dtype** [object] The object to check.

**Returns**

**is\_dtype** [bool]

**Notes**

The default implementation is True if

1. `cls.construct_from_string(dtype)` is an instance of `cls`.
2. `dtype` is an object and is an instance of `cls`
3. `dtype` has a `dtype` attribute, and any of the above conditions is true for `dtype.dtype`.

**pandas.SparseDtype.update\_dtype**

**SparseDtype.update\_dtype(dtype)**

Convert the `SparseDtype` to a new `dtype`.

This takes care of converting the `fill_value`.

**Parameters**

**dtype** [Union[str, numpy.dtype, SparseDtype]] The new `dtype` to use.

- For a `SparseDtype`, it is simply returned
- For a NumPy `dtype` (or `str`), the current fill value is converted to the new `dtype`, and a `SparseDtype` with `dtype` and the new fill value is returned.

**Returns**

**SparseDtype** A new `SparseDtype` with the correct `dtype` and fill value for that `dtype`.

**Raises**

**ValueError** When the current fill value cannot be converted to the new *dtype* (e.g. trying to convert `np.nan` to an integer dtype).

Examples

```
>>> SparseDtype(int, 0).update_dtype(float)
Sparse[float64, 0.0]

>>> SparseDtype(int, 1).update_dtype(SparseDtype(float, np.nan))
Sparse[float64, nan]
```

The `Series.sparse` accessor may be used to access sparse-specific attributes and methods if the *Series* contains sparse values. See *Sparse Accessor* for more.

{{ header }}

35.6 Panel

35.6.1 Constructor

*Panel*([data, items, major\_axis, minor\_axis, ...]) (DEPRECATED) Represents wide format panel data, stored as 3-dimensional array.

35.6.1.1 pandas.Panel

**class** `pandas.Panel` (*data=None, items=None, major\_axis=None, minor\_axis=None, copy=False, dtype=None*)  
Represents wide format panel data, stored as 3-dimensional array.  
Deprecated since version 0.20.0: The recommended way to represent 3-D data are with a `MultiIndex` on a `DataFrame` via the `to_frame()` method or with the `xarray` package. Pandas provides a `to_xarray()` method to automate this conversion.

Parameters

- data** [ndarray (items x major x minor), or dict of DataFrames]
- items** [Index or array-like] axis=0
- major\_axis** [Index or array-like] axis=1
- minor\_axis** [Index or array-like] axis=2
- copy** [boolean, default False] Copy data from inputs. Only affects DataFrame / 2d ndarray input
- dtype** [dtype, default None] Data type to force, otherwise infer

Attributes

|             |                                                    |
|-------------|----------------------------------------------------|
| <i>at</i>   | Access a single value for a row/column label pair. |
| <i>axes</i> | Return index label(s) of the internal NDFrame      |

Continued on next page

Table 145 – continued from previous page

|                   |                                                                                 |
|-------------------|---------------------------------------------------------------------------------|
| <i>blocks</i>     | (DEPRECATED) Internal property, property synonym for <code>as_blocks()</code> . |
| <i>dtypes</i>     | Return the dtypes in the DataFrame.                                             |
| <i>empty</i>      | Indicator whether DataFrame is empty.                                           |
| <i>ftypes</i>     | Return the ftypes (indication of sparse/dense and dtype) in DataFrame.          |
| <i>iat</i>        | Access a single value for a row/column pair by integer position.                |
| <i>iloc</i>       | Purely integer-location based indexing for selection by position.               |
| <i>is_copy</i>    | Return the copy.                                                                |
| <i>items</i>      |                                                                                 |
| <i>ix</i>         | A primarily label-location based indexer, with integer position fallback.       |
| <i>loc</i>        | Access a group of rows and columns by label(s) or a boolean array.              |
| <i>major_axis</i> |                                                                                 |
| <i>minor_axis</i> |                                                                                 |
| <i>ndim</i>       | Return an int representing the number of axes / array dimensions.               |
| <i>shape</i>      | Return a tuple of axis dimensions                                               |
| <i>size</i>       | Return an int representing the number of elements in this object.               |
| <i>values</i>     | Return a Numpy representation of the DataFrame.                                 |

**pandas.Panel.at****Panel.at**

Access a single value for a row/column label pair.

Similar to `loc`, in that both provide label-based lookups. Use `at` if you only need to get or set a single value in a DataFrame or Series.

**Raises**

**KeyError** When label does not exist in DataFrame

**See also:**

**DataFrame.iat** Access a single value for a row/column pair by integer position.

**DataFrame.loc** Access a group of rows and columns by label(s).

**Series.at** Access a single value using a label.

**Examples**

```
>>> df = pd.DataFrame([[0, 2, 3], [0, 4, 1], [10, 20, 30]],
...                    index=[4, 5, 6], columns=['A', 'B', 'C'])
>>> df
   A  B  C
4  0  2  3
5  0  4  1
6 10 20 30
```

Get value at specified row/column pair

```
>>> df.at[4, 'B']
2
```

Set value at specified row/column pair

```
>>> df.at[4, 'B'] = 10
>>> df.at[4, 'B']
10
```

Get value within a Series

```
>>> df.loc[5].at['B']
4
```

## pandas.Panel.axes

**Panel.axes**

Return index label(s) of the internal NDFrame

## pandas.Panel.blocks

**Panel.blocks**

Internal property, property synonym for `as_blocks()`.

Deprecated since version 0.21.0.

## pandas.Panel.dtypes

**Panel.dtypes**

Return the dtypes in the DataFrame.

This returns a Series with the data type of each column. The result's index is the original DataFrame's columns. Columns with mixed types are stored with the `object` dtype. See *the User Guide* for more.

### Returns

**pandas.Series** The data type of each column.

See also:

**pandas.DataFrame.ftypes** Dtype and sparsity information.

## Examples

```
>>> df = pd.DataFrame({'float': [1.0],
...                     'int': [1],
...                     'datetime': [pd.Timestamp('20180310')],
...                     'string': ['foo']})
>>> df.dtypes
float          float64
int            int64
```

(continues on next page)

(continued from previous page)

```
datetime    datetime64[ns]
string      object
dtype: object
```

## pandas.Panel.empty

### Panel.empty

Indicator whether DataFrame is empty.

True if DataFrame is entirely empty (no items), meaning any of the axes are of length 0.

#### Returns

**bool** If DataFrame is empty, return True, if not return False.

#### See also:

*pandas.Series.dropna, pandas.DataFrame.dropna*

### Notes

If DataFrame contains only NaNs, it is still not considered empty. See the example below.

### Examples

An example of an actual empty DataFrame. Notice the index is empty:

```
>>> df_empty = pd.DataFrame({'A' : []})
>>> df_empty
Empty DataFrame
Columns: [A]
Index: []
>>> df_empty.empty
True
```

If we only have NaNs in our DataFrame, it is not considered empty! We will need to drop the NaNs to make the DataFrame empty:

```
>>> df = pd.DataFrame({'A' : [np.nan]})
>>> df
   A
0 NaN
>>> df.empty
False
>>> df.dropna().empty
True
```

## pandas.Panel.ftypes

### Panel.ftypes

Return the ftypes (indication of sparse/dense and dtype) in DataFrame.

This returns a Series with the data type of each column. The result's index is the original DataFrame's columns. Columns with mixed types are stored with the `object` dtype. See *the User Guide* for more.

#### Returns

**pandas.Series** The data type and indication of sparse/dense of each column.

#### See also:

**pandas.DataFrame.dtypes** Series with just dtype information.

**pandas.SparseDataFrame** Container for sparse tabular data.

#### Notes

Sparse data should have the same dtypes as its dense representation.

#### Examples

```
>>> arr = np.random.RandomState(0).randn(100, 4)
>>> arr[arr < .8] = np.nan
>>> pd.DataFrame(arr).dtypes
0    float64:dense
1    float64:dense
2    float64:dense
3    float64:dense
dtype: object
```

```
>>> pd.SparseDataFrame(arr).dtypes
0    float64:sparse
1    float64:sparse
2    float64:sparse
3    float64:sparse
dtype: object
```

### pandas.Panel.iat

#### Panel.iat

Access a single value for a row/column pair by integer position.

Similar to `iloc`, in that both provide integer-based lookups. Use `iat` if you only need to get or set a single value in a DataFrame or Series.

#### Raises

**IndexError** When integer position is out of bounds

#### See also:

**DataFrame.at** Access a single value for a row/column label pair.

**DataFrame.loc** Access a group of rows and columns by label(s).

**DataFrame.iloc** Access a group of rows and columns by integer position(s).

## Examples

```
>>> df = pd.DataFrame([[0, 2, 3], [0, 4, 1], [10, 20, 30]],
...                     columns=['A', 'B', 'C'])
>>> df
   A  B  C
0  0  2  3
1  0  4  1
2 10 20 30
```

Get value at specified row/column pair

```
>>> df.iat[1, 2]
1
```

Set value at specified row/column pair

```
>>> df.iat[1, 2] = 10
>>> df.iat[1, 2]
10
```

Get value within a series

```
>>> df.loc[0].iat[1]
2
```

## pandas.Panel.iloc

### Panel.iloc

Purely integer-location based indexing for selection by position.

`.iloc[]` is primarily integer position based (from 0 to `length-1` of the axis), but may also be used with a boolean array.

Allowed inputs are:

- An integer, e.g. 5.
- A list or array of integers, e.g. `[4, 3, 0]`.
- A slice object with ints, e.g. `1:7`.
- A boolean array.
- A callable function with one argument (the calling Series, DataFrame or Panel) and that returns valid output for indexing (one of the above). This is useful in method chains, when you don't have a reference to the calling object, but would like to base your selection on some value.

`.iloc` will raise `IndexError` if a requested indexer is out-of-bounds, except *slice* indexers which allow out-of-bounds indexing (this conforms with python/numpy *slice* semantics).

See more at [ref:Selection by Position <indexing.integer>](#).

See also:

**DataFrame.iat** Fast integer location scalar accessor.

**DataFrame.loc** Purely label-location based indexer for selection by label.

**Series.iloc** Purely integer-location based indexing for selection by position.

## Examples

```
>>> mydict = [{'a': 1, 'b': 2, 'c': 3, 'd': 4},
...           {'a': 100, 'b': 200, 'c': 300, 'd': 400},
...           {'a': 1000, 'b': 2000, 'c': 3000, 'd': 4000}]
>>> df = pd.DataFrame(mydict)
>>> df
```

|   | a    | b    | c    | d    |
|---|------|------|------|------|
| 0 | 1    | 2    | 3    | 4    |
| 1 | 100  | 200  | 300  | 400  |
| 2 | 1000 | 2000 | 3000 | 4000 |

### Indexing just the rows

With a scalar integer.

```
>>> type(df.iloc[0])
<class 'pandas.core.series.Series'>
>>> df.iloc[0]
```

|   | a | b | c | d |
|---|---|---|---|---|
| 0 | 1 | 2 | 3 | 4 |

Name: 0, dtype: int64

With a list of integers.

```
>>> df.iloc[[0]]
```

|   | a | b | c | d |
|---|---|---|---|---|
| 0 | 1 | 2 | 3 | 4 |

```
>>> type(df.iloc[[0]])
<class 'pandas.core.frame.DataFrame'>
```

```
>>> df.iloc[[0, 1]]
```

|   | a   | b   | c   | d   |
|---|-----|-----|-----|-----|
| 0 | 1   | 2   | 3   | 4   |
| 1 | 100 | 200 | 300 | 400 |

With a *slice* object.

```
>>> df.iloc[:3]
```

|   | a    | b    | c    | d    |
|---|------|------|------|------|
| 0 | 1    | 2    | 3    | 4    |
| 1 | 100  | 200  | 300  | 400  |
| 2 | 1000 | 2000 | 3000 | 4000 |

With a boolean mask the same length as the index.

```
>>> df.iloc[[True, False, True]]
```

|   | a    | b    | c    | d    |
|---|------|------|------|------|
| 0 | 1    | 2    | 3    | 4    |
| 2 | 1000 | 2000 | 3000 | 4000 |

With a callable, useful in method chains. The `x` passed to the `lambda` is the `DataFrame` being sliced. This selects the rows whose index label even.

```
>>> df.iloc[lambda x: x.index % 2 == 0]
   a    b    c    d
0   1    2    3    4
2 1000 2000 3000 4000
```

### Indexing both axes

You can mix the indexer types for the index and columns. Use `:` to select the entire axis.

With scalar integers.

```
>>> df.iloc[0, 1]
2
```

With lists of integers.

```
>>> df.iloc[[0, 2], [1, 3]]
   b    d
0   2    4
2 2000 4000
```

With *slice* objects.

```
>>> df.iloc[1:3, 0:3]
   a    b    c
1  100  200  300
2 1000 2000 3000
```

With a boolean array whose length matches the columns.

```
>>> df.iloc[:, [True, False, True, False]]
   a    c
0   1    3
1  100  300
2 1000 3000
```

With a callable function that expects the Series or DataFrame.

```
>>> df.iloc[:, lambda df: [0, 2]]
   a    c
0   1    3
1  100  300
2 1000 3000
```

## pandas.Panel.is\_copy

`Panel.is_copy`

Return the copy.

## pandas.Panel.items

`Panel.items`

## pandas.Panel.ix

### Panel.ix

A primarily label-location based indexer, with integer position fallback.

Warning: Starting in 0.20.0, the .ix indexer is deprecated, in favor of the more strict .iloc and .loc indexers.

.ix[] supports mixed integer and label based access. It is primarily label based, but will fall back to integer positional access unless the corresponding axis is of integer type.

.ix is the most general indexer and will support any of the inputs in .loc and .iloc. .ix also supports floating point label schemes. .ix is exceptionally useful when dealing with mixed positional and label based hierarchical indexes.

However, when an axis is integer based, ONLY label based access and not positional access is supported. Thus, in such cases, it's usually better to be explicit and use .iloc or .loc.

See more at *Advanced Indexing*.

## pandas.Panel.loc

### Panel.loc

Access a group of rows and columns by label(s) or a boolean array.

.loc[] is primarily label based, but may also be used with a boolean array.

Allowed inputs are:

- A single label, e.g. 5 or 'a', (note that 5 is interpreted as a *label* of the index, and **never** as an integer position along the index).
- A list or array of labels, e.g. ['a', 'b', 'c'].
- A slice object with labels, e.g. 'a': 'f'.

**Warning:** Note that contrary to usual python slices, **both** the start and the stop are included

- A boolean array of the same length as the axis being sliced, e.g. [True, False, True].
- A callable function with one argument (the calling Series, DataFrame or Panel) and that returns valid output for indexing (one of the above)

See more at *Selection by Label*

#### Raises

**KeyError:** when any items are not found

See also:

**DataFrame.at** Access a single value for a row/column label pair.

**DataFrame.iloc** Access group of rows and columns by integer position(s).

**DataFrame.xs** Returns a cross-section (row(s) or column(s)) from the Series/DataFrame.

**Series.loc** Access group of values using labels.

## Examples

### Getting values

```
>>> df = pd.DataFrame([[1, 2], [4, 5], [7, 8]],
...                     index=['cobra', 'viper', 'sidewinder'],
...                     columns=['max_speed', 'shield'])
>>> df
```

|            | max_speed | shield |
|------------|-----------|--------|
| cobra      | 1         | 2      |
| viper      | 4         | 5      |
| sidewinder | 7         | 8      |

Single label. Note this returns the row as a Series.

```
>>> df.loc['viper']
max_speed    4
shield       5
Name: viper, dtype: int64
```

List of labels. Note using `[[ ]]` returns a DataFrame.

```
>>> df.loc[['viper', 'sidewinder']]
```

|            | max_speed | shield |
|------------|-----------|--------|
| viper      | 4         | 5      |
| sidewinder | 7         | 8      |

Single label for row and column

```
>>> df.loc['cobra', 'shield']
2
```

Slice with labels for row and single label for column. As mentioned above, note that both the start and stop of the slice are included.

```
>>> df.loc['cobra':'viper', 'max_speed']
cobra    1
viper    4
Name: max_speed, dtype: int64
```

Boolean list with the same length as the row axis

```
>>> df.loc[[False, False, True]]
```

|            | max_speed | shield |
|------------|-----------|--------|
| sidewinder | 7         | 8      |

Conditional that returns a boolean Series

```
>>> df.loc[df['shield'] > 6]
```

|            | max_speed | shield |
|------------|-----------|--------|
| sidewinder | 7         | 8      |

Conditional that returns a boolean Series with column labels specified

```
>>> df.loc[df['shield'] > 6, ['max_speed']]
```

|            | max_speed |
|------------|-----------|
| sidewinder | 7         |

Callable that returns a boolean Series

```
>>> df.loc[lambda df: df['shield'] == 8]
           max_speed  shield
sidewinder         7       8
```

### Setting values

Set value for all items matching the list of labels

```
>>> df.loc[['viper', 'sidewinder'], ['shield']] = 50
>>> df
           max_speed  shield
cobra                1       2
viper                4      50
sidewinder           7      50
```

Set value for an entire row

```
>>> df.loc['cobra'] = 10
>>> df
           max_speed  shield
cobra             10      10
viper             4       50
sidewinder        7       50
```

Set value for an entire column

```
>>> df.loc[:, 'max_speed'] = 30
>>> df
           max_speed  shield
cobra             30      10
viper             30      50
sidewinder        30      50
```

Set value for rows matching callable condition

```
>>> df.loc[df['shield'] > 35] = 0
>>> df
           max_speed  shield
cobra             30      10
viper              0       0
sidewinder         0       0
```

### Getting values on a DataFrame with an index that has integer labels

Another example using integers for the index

```
>>> df = pd.DataFrame([[1, 2], [4, 5], [7, 8]],
...                    index=[7, 8, 9], columns=['max_speed', 'shield'])
>>> df
           max_speed  shield
7                1       2
8                4       5
9                7       8
```

Slice with integer labels for rows. As mentioned above, note that both the start and stop of the slice are included.

```
>>> df.loc[7:9]
      max_speed  shield
7             1       2
8             4       5
9             7       8
```

### Getting values with a MultiIndex

A number of examples using a DataFrame with a MultiIndex

```
>>> tuples = [
...     ('cobra', 'mark i'), ('cobra', 'mark ii'),
...     ('sidewinder', 'mark i'), ('sidewinder', 'mark ii'),
...     ('viper', 'mark ii'), ('viper', 'mark iii')
... ]
>>> index = pd.MultiIndex.from_tuples(tuples)
>>> values = [[12, 2], [0, 4], [10, 20],
...           [1, 4], [7, 1], [16, 36]]
>>> df = pd.DataFrame(values, columns=['max_speed', 'shield'], index=index)
>>> df
```

|            |          | max_speed | shield |
|------------|----------|-----------|--------|
| cobra      | mark i   | 12        | 2      |
|            | mark ii  | 0         | 4      |
| sidewinder | mark i   | 10        | 20     |
|            | mark ii  | 1         | 4      |
| viper      | mark ii  | 7         | 1      |
|            | mark iii | 16        | 36     |

Single label. Note this returns a DataFrame with a single index.

```
>>> df.loc['cobra']
      max_speed  shield
mark i         12       2
mark ii         0       4
```

Single index tuple. Note this returns a Series.

```
>>> df.loc[('cobra', 'mark ii')]
max_speed    0
shield        4
Name: (cobra, mark ii), dtype: int64
```

Single label for row and column. Similar to passing in a tuple, this returns a Series.

```
>>> df.loc['cobra', 'mark i']
max_speed    12
shield        2
Name: (cobra, mark i), dtype: int64
```

Single tuple. Note using [ [ ] ] returns a DataFrame.

```
>>> df.loc[['cobra', 'mark ii']]
      max_speed  shield
cobra mark ii         0       4
```

Single tuple for the index with a single label for the column

```
>>> df.loc[('cobra', 'mark i'), 'shield']
2
```

Slice from index tuple to single label

```
>>> df.loc[('cobra', 'mark i'):('viper', 'mark iii')]
      max_speed  shield
cobra      mark i      12      2
           mark ii      0      4
sidewinder mark i      10     20
           mark ii      1      4
viper      mark ii      7      1
           mark iii     16     36
```

Slice from index tuple to index tuple

```
>>> df.loc[('cobra', 'mark i'):('viper', 'mark ii')]
      max_speed  shield
cobra      mark i      12      2
           mark ii      0      4
sidewinder mark i      10     20
           mark ii      1      4
viper      mark ii      7      1
```

## pandas.Panel.major\_axis

Panel.**major\_axis**

## pandas.Panel.minor\_axis

Panel.**minor\_axis**

## pandas.Panel.ndim

Panel.**ndim**

Return an int representing the number of axes / array dimensions.

Return 1 if Series. Otherwise return 2 if DataFrame.

**See also:**

**ndarray.ndim** Number of array dimensions.

## Examples

```
>>> s = pd.Series({'a': 1, 'b': 2, 'c': 3})
>>> s.ndim
1
```

```
>>> df = pd.DataFrame({'col1': [1, 2], 'col2': [3, 4]})
>>> df.ndim
2
```

## pandas.Panel.shape

### Panel.shape

Return a tuple of axis dimensions

## pandas.Panel.size

### Panel.size

Return an int representing the number of elements in this object.

Return the number of rows if Series. Otherwise return the number of rows times number of columns if DataFrame.

**See also:**

**ndarray.size** Number of elements in the array.

## Examples

```
>>> s = pd.Series({'a': 1, 'b': 2, 'c': 3})
>>> s.size
3
```

```
>>> df = pd.DataFrame({'col1': [1, 2], 'col2': [3, 4]})
>>> df.size
4
```

## pandas.Panel.values

### Panel.values

Return a Numpy representation of the DataFrame.

**Warning:** We recommend using `DataFrame.to_numpy()` instead.

Only the values in the DataFrame will be returned, the axes labels will be removed.

### Returns

**numpy.ndarray** The values of the DataFrame.

**See also:**

**DataFrame.to\_numpy** Recommended alternative to this method.

**pandas.DataFrame.index** Retrieve the index labels.

**pandas.DataFrame.columns** Retrieving the column names.

## Notes

The dtype will be a lower-common-denominator dtype (implicit upcasting); that is to say if the dtypes (even of numeric types) are mixed, the one that accommodates all will be chosen. Use this with care if you are not dealing with the blocks.

e.g. If the dtypes are float16 and float32, dtype will be upcast to float32. If dtypes are int32 and uint8, dtype will be upcast to int32. By `numpy.find_common_type()` convention, mixing int64 and uint64 will result in a float64 dtype.

## Examples

A DataFrame where all columns are the same type (e.g., int64) results in an array of the same type.

```
>>> df = pd.DataFrame({'age':    [ 3,   29],
...                    'height': [94, 170],
...                    'weight': [31, 115]})
>>> df
   age  height  weight
0    3     94     31
1   29    170    115
>>> df.dtypes
age          int64
height       int64
weight       int64
dtype: object
>>> df.values
array([[ 3,  94,  31],
       [29, 170, 115]], dtype=int64)
```

A DataFrame with mixed type columns(e.g., str/object, int64, float32) results in an ndarray of the broadest type that accommodates these mixed types (e.g., object).

```
>>> df2 = pd.DataFrame([('parrot',    24.0, 'second'),
...                     ('lion',     80.5, 1),
...                     ('monkey', np.nan, None)],
...                     columns=('name', 'max_speed', 'rank'))
>>> df2.dtypes
name          object
max_speed     float64
rank          object
dtype: object
>>> df2.values
array([('parrot', 24.0, 'second'],
      ['lion', 80.5, 1],
      ['monkey', nan, None]], dtype=object)
```

|           |  |
|-----------|--|
| timetuple |  |

## Methods

|                                                     |                                                                                                                                              |
|-----------------------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------|
| <i>abs()</i>                                        | Return a Series/DataFrame with absolute numeric value of each element.                                                                       |
| <i>add</i> (other[, axis])                          | Addition of series and other, element-wise (binary operator <i>add</i> ).                                                                    |
| <i>add_prefix</i> (prefix)                          | Prefix labels with string <i>prefix</i> .                                                                                                    |
| <i>add_suffix</i> (suffix)                          | Suffix labels with string <i>suffix</i> .                                                                                                    |
| <i>align</i> (other, **kwargs)                      | Align two objects on their axes with the specified join method for each axis Index.                                                          |
| <i>all</i> ([axis, bool_only, skipna, level])       | Return whether all elements are True, potentially over an axis.                                                                              |
| <i>any</i> ([axis, bool_only, skipna, level])       | Return whether any element is True, potentially over an axis.                                                                                |
| <i>apply</i> (func[, axis])                         | Applies function along axis (or axes) of the Panel.                                                                                          |
| <i>as_blocks</i> ([copy])                           | (DEPRECATED) Convert the frame to a dict of dtype -> Constructor Types that each has a homogeneous dtype.                                    |
| <i>as_matrix</i> ()                                 | Convert the frame to its Numpy-array representation.                                                                                         |
| <i>asfreq</i> (freq[, method, how, normalize, ...]) | Convert TimeSeries to specified frequency.                                                                                                   |
| <i>asof</i> (where[, subset])                       | Return the last row(s) without any NaNs before <i>where</i> .                                                                                |
| <i>astype</i> (dtype[, copy, errors])               | Cast a pandas object to a specified dtype <i>dtype</i> .                                                                                     |
| <i>at_time</i> (time[, asof, axis])                 | Select values at particular time of day (e.g.                                                                                                |
| <i>between_time</i> (start_time, end_time[, ...])   | Select values between particular times of the day (e.g., 9:00-9:30 AM).                                                                      |
| <i>bfill</i> ([axis, inplace, limit, downcast])     | Synonym for <i>DataFrame.fillna()</i> with method='bfill'.                                                                                   |
| <i>bool</i> ()                                      | Return the bool of a single element PandasObject.                                                                                            |
| <i>clip</i> ([lower, upper, axis, inplace])         | Trim values at input threshold(s).                                                                                                           |
| <i>clip_lower</i> (threshold[, axis, inplace])      | (DEPRECATED) Trim values below a given threshold.                                                                                            |
| <i>clip_upper</i> (threshold[, axis, inplace])      | (DEPRECATED) Trim values above a given threshold.                                                                                            |
| <i>compound</i> ([axis, skipna, level])             | Return the compound percentage of the values for the requested axis.                                                                         |
| <i>conform</i> (frame[, axis])                      | Conform input DataFrame to align with chosen axis pair.                                                                                      |
| <i>convert_objects</i> ([convert_dates, ...])       | (DEPRECATED) Attempt to infer better dtype for object columns.                                                                               |
| <i>copy</i> ([deep])                                | Make a copy of this object's indices and data.                                                                                               |
| <i>count</i> ([axis])                               | Return number of observations over requested axis.                                                                                           |
| <i>cummax</i> ([axis, skipna])                      | Return cumulative maximum over a DataFrame or Series axis.                                                                                   |
| <i>cummin</i> ([axis, skipna])                      | Return cumulative minimum over a DataFrame or Series axis.                                                                                   |
| <i>cumprod</i> ([axis, skipna])                     | Return cumulative product over a DataFrame or Series axis.                                                                                   |
| <i>cumsum</i> ([axis, skipna])                      | Return cumulative sum over a DataFrame or Series axis.                                                                                       |
| <i>describe</i> ([percentiles, include, exclude])   | Generate descriptive statistics that summarize the central tendency, dispersion and shape of a dataset's distribution, excluding NaN values. |

|                                                               |                                                                                                                 |
|---------------------------------------------------------------|-----------------------------------------------------------------------------------------------------------------|
| <code>div(other[, axis])</code>                               | Floating division of series and other, element-wise (binary operator <i>truediv</i> ).                          |
| <code>divide(other[, axis])</code>                            | Floating division of series and other, element-wise (binary operator <i>truediv</i> ).                          |
| <code>droplevel(level[, axis])</code>                         | Return DataFrame with requested index / column level(s) removed.                                                |
| <code>dropna([axis, how, inplace])</code>                     | Drop 2D from panel, holding passed axis constant.                                                               |
| <code>eq(other[, axis])</code>                                | Wrapper for comparison method <code>eq</code>                                                                   |
| <code>equals(other)</code>                                    | Test whether two objects contain the same elements.                                                             |
| <code>ffill([axis, inplace, limit, downcast])</code>          | Synonym for <code>DataFrame.fillna()</code> with <code>method='ffill'</code> .                                  |
| <code>fillna([value, method, axis, inplace, ...])</code>      | Fill NA/NaN values using the specified method.                                                                  |
| <code>filter([items, like, regex, axis])</code>               | Subset rows or columns of dataframe according to labels in the specified index.                                 |
| <code>first(offset)</code>                                    | Convenience method for subsetting initial periods of time series data based on a date offset.                   |
| <code>first_valid_index()</code>                              | Return index for first non-NA/null value.                                                                       |
| <code>floordiv(other[, axis])</code>                          | Integer division of series and other, element-wise (binary operator <i>floordiv</i> ).                          |
| <code>fromDict(data[, intersect, orient, dtype])</code>       | Construct Panel from dict of DataFrame objects.                                                                 |
| <code>from_dict(data[, intersect, orient, dtype])</code>      | Construct Panel from dict of DataFrame objects.                                                                 |
| <code>ge(other[, axis])</code>                                | Wrapper for comparison method <code>ge</code>                                                                   |
| <code>get(key[, default])</code>                              | Get item from object for given key (DataFrame column, Panel slice, etc.).                                       |
| <code>get_dtype_counts()</code>                               | Return counts of unique dtypes in this object.                                                                  |
| <code>get_ftype_counts()</code>                               | (DEPRECATED) Return counts of unique ftypes in this object.                                                     |
| <code>get_value(*args, **kwargs)</code>                       | (DEPRECATED) Quickly retrieve single value at (item, major, minor) location.                                    |
| <code>get_values()</code>                                     | Return an ndarray after converting sparse values to dense.                                                      |
| <code>groupby(function[, axis])</code>                        | Group data on given axis, returning GroupBy object.                                                             |
| <code>gt(other[, axis])</code>                                | Wrapper for comparison method <code>gt</code>                                                                   |
| <code>head([n])</code>                                        | Return the first <i>n</i> rows.                                                                                 |
| <code>infer_objects()</code>                                  | Attempt to infer better dtypes for object columns.                                                              |
| <code>interpolate([method, axis, limit, inplace, ...])</code> | Interpolate values according to different methods.                                                              |
| <code>isna()</code>                                           | Detect missing values.                                                                                          |
| <code>isnull()</code>                                         | Detect missing values.                                                                                          |
| <code>iteritems()</code>                                      | Iterate over (label, values) on info axis                                                                       |
| <code>join(other[, how, lsuffix, rsuffix])</code>             | Join items with other Panel either on major and minor axes column.                                              |
| <code>keys()</code>                                           | Get the ‘info axis’ (see Indexing for more)                                                                     |
| <code>kurt([axis, skipna, level, numeric_only])</code>        | Return unbiased kurtosis over requested axis using Fisher’s definition of kurtosis (kurtosis of normal == 0.0). |
| <code>kurtosis([axis, skipna, level, numeric_only])</code>    | Return unbiased kurtosis over requested axis using Fisher’s definition of kurtosis (kurtosis of normal == 0.0). |
| <code>last(offset)</code>                                     | Convenience method for subsetting final periods of time series data based on a date offset.                     |
| <code>last_valid_index()</code>                               | Return index for last non-NA/null value.                                                                        |

|                                                                |                                                                                                                            |
|----------------------------------------------------------------|----------------------------------------------------------------------------------------------------------------------------|
| <code>le(other[, axis])</code>                                 | Wrapper for comparison method <code>le</code>                                                                              |
| <code>lt(other[, axis])</code>                                 | Wrapper for comparison method <code>lt</code>                                                                              |
| <code>mad([axis, skipna, level])</code>                        | Return the mean absolute deviation of the values for the requested axis.                                                   |
| <code>major_xs(key)</code>                                     | Return slice of panel along major axis.                                                                                    |
| <code>mask(cond[, other, inplace, axis, level, ...])</code>    | Replace values where the condition is True.                                                                                |
| <code>max([axis, skipna, level, numeric_only])</code>          | Return the maximum of the values for the requested axis.                                                                   |
| <code>mean([axis, skipna, level, numeric_only])</code>         | Return the mean of the values for the requested axis.                                                                      |
| <code>median([axis, skipna, level, numeric_only])</code>       | Return the median of the values for the requested axis.                                                                    |
| <code>min([axis, skipna, level, numeric_only])</code>          | Return the minimum of the values for the requested axis.                                                                   |
| <code>minor_xs(key)</code>                                     | Return slice of panel along minor axis.                                                                                    |
| <code>mod(other[, axis])</code>                                | Modulo of series and other, element-wise (binary operator <code>mod</code> ).                                              |
| <code>mul(other[, axis])</code>                                | Multiplication of series and other, element-wise (binary operator <code>mul</code> ).                                      |
| <code>multiply(other[, axis])</code>                           | Multiplication of series and other, element-wise (binary operator <code>mul</code> ).                                      |
| <code>ne(other[, axis])</code>                                 | Wrapper for comparison method <code>ne</code>                                                                              |
| <code>notna()</code>                                           | Detect existing (non-missing) values.                                                                                      |
| <code>notnull()</code>                                         | Detect existing (non-missing) values.                                                                                      |
| <code>pct_change([periods, fill_method, limit, freq])</code>   | Percentage change between the current and a prior element.                                                                 |
| <code>pipe(func, *args, **kwargs)</code>                       | Apply <code>func(self, *args, **kwargs)</code> .                                                                           |
| <code>pop(item)</code>                                         | Return item and drop from frame.                                                                                           |
| <code>pow(other[, axis])</code>                                | Exponential power of series and other, element-wise (binary operator <code>pow</code> ).                                   |
| <code>prod([axis, skipna, level, numeric_only, ...])</code>    | Return the product of the values for the requested axis.                                                                   |
| <code>product([axis, skipna, level, numeric_only, ...])</code> | Return the product of the values for the requested axis.                                                                   |
| <code>radd(other[, axis])</code>                               | Addition of series and other, element-wise (binary operator <code>radd</code> ).                                           |
| <code>rank([axis, method, numeric_only, ...])</code>           | Compute numerical data ranks (1 through n) along axis.                                                                     |
| <code>rdiv(other[, axis])</code>                               | Floating division of series and other, element-wise (binary operator <code>rtruediv</code> ).                              |
| <code>reindex(*args, **kwargs)</code>                          | Conform Panel to new index with optional filling logic, placing NA/NaN in locations having no value in the previous index. |
| <code>reindex_axis(labels[, axis, method, level, ...])</code>  | (DEPRECATED) Conform input object to new index.                                                                            |
| <code>reindex_like(other[, method, copy, limit, ...])</code>   | Return an object with matching indices as other object.                                                                    |
| <code>rename([items, major_axis, minor_axis])</code>           | Alter axes input function or functions.                                                                                    |
| <code>rename_axis([mapper, index, columns, axis, ...])</code>  | Set the name of the axis for the index or columns.                                                                         |
| <code>replace([to_replace, value, inplace, limit, ...])</code> | Replace values given in <code>to_replace</code> with <code>value</code> .                                                  |
| <code>resample(rule[, how, axis, fill_method, ...])</code>     | Resample time-series data.                                                                                                 |

Table 146 – continued from previous page

|                                                             |                                                                                                                         |
|-------------------------------------------------------------|-------------------------------------------------------------------------------------------------------------------------|
| <code>rfloordiv(other[, axis])</code>                       | Integer division of series and other, element-wise (binary operator <i>rfloordiv</i> ).                                 |
| <code>rmod(other[, axis])</code>                            | Modulo of series and other, element-wise (binary operator <i>rmod</i> ).                                                |
| <code>rmul(other[, axis])</code>                            | Multiplication of series and other, element-wise (binary operator <i>rmul</i> ).                                        |
| <code>round([decimals])</code>                              | Round each value in Panel to a specified number of decimal places.                                                      |
| <code>rpow(other[, axis])</code>                            | Exponential power of series and other, element-wise (binary operator <i>rpow</i> ).                                     |
| <code>rsub(other[, axis])</code>                            | Subtraction of series and other, element-wise (binary operator <i>rsub</i> ).                                           |
| <code>rtruediv(other[, axis])</code>                        | Floating division of series and other, element-wise (binary operator <i>rtruediv</i> ).                                 |
| <code>sample([n, frac, replace, weights, ...])</code>       | Return a random sample of items from an axis of object.                                                                 |
| <code>select(crit[, axis])</code>                           | (DEPRECATED) Return data corresponding to axis labels matching criteria.                                                |
| <code>sem([axis, skipna, level, ddof, numeric_only])</code> | Return unbiased standard error of the mean over requested axis.                                                         |
| <code>set_axis(labels[, axis, inplace])</code>              | Assign desired index to given axis.                                                                                     |
| <code>set_value(*args, **kwargs)</code>                     | (DEPRECATED) Quickly set single value at (item, major, minor) location.                                                 |
| <code>shift([periods, freq, axis])</code>                   | Shift index by desired number of periods with an optional time freq.                                                    |
| <code>skew([axis, skipna, level, numeric_only])</code>      | Return unbiased skew over requested axis Normalized by N-1.                                                             |
| <code>slice_shift([periods, axis])</code>                   | Equivalent to <i>shift</i> without copying data.                                                                        |
| <code>sort_index([axis, level, ascending, ...])</code>      | Sort object by labels (along an axis)                                                                                   |
| <code>sort_values(*args, **kwargs)</code>                   | NOT IMPLEMENTED: do not call this method, as sorting values is not supported for Panel objects and will raise an error. |
| <code>squeeze([axis])</code>                                | Squeeze 1 dimensional axis objects into scalars.                                                                        |
| <code>std([axis, skipna, level, ddof, numeric_only])</code> | Return sample standard deviation over requested axis.                                                                   |
| <code>sub(other[, axis])</code>                             | Subtraction of series and other, element-wise (binary operator <i>sub</i> ).                                            |
| <code>subtract(other[, axis])</code>                        | Subtraction of series and other, element-wise (binary operator <i>sub</i> ).                                            |
| <code>sum([axis, skipna, level, numeric_only, ...])</code>  | Return the sum of the values for the requested axis.                                                                    |
| <code>swapaxes(axis1, axis2[, copy])</code>                 | Interchange axes and swap values axes appropriately.                                                                    |
| <code>swaplevel([i, j, axis])</code>                        | Swap levels i and j in a MultiIndex on a particular axis                                                                |
| <code>tail([n])</code>                                      | Return the last <i>n</i> rows.                                                                                          |
| <code>take(indices[, axis, convert, is_copy])</code>        | Return the elements in the given <i>positional</i> indices along an axis.                                               |
| <code>to_clipboard([excel, sep])</code>                     | Copy object to the system clipboard.                                                                                    |
| <code>to_csv([path_or_buf, sep, na_rep, ...])</code>        | Write object to a comma-separated values (csv) file.                                                                    |
| <code>to_dense()</code>                                     | Return dense representation of NDFrame (as opposed to sparse).                                                          |

Table 146 – continued from previous page

|                                                               |                                                                                                                                                                               |
|---------------------------------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>to_excel(path[, na_rep, engine])</code>                 | Write each DataFrame in Panel to a separate excel sheet.                                                                                                                      |
| <code>to_frame([filter_observations])</code>                  | Transform wide format into long (stacked) format as DataFrame whose columns are the Panel's items and whose index is a MultiIndex formed of the Panel's major and minor axes. |
| <code>to_hdf(path_or_buf, key, **kwargs)</code>               | Write the contained data to an HDF5 file using HDF-Store.                                                                                                                     |
| <code>to_json([path_or_buf, orient, date_format, ...])</code> | Convert the object to a JSON string.                                                                                                                                          |
| <code>to_latex([buf, columns, col_space, header, ...])</code> | Render an object to a LaTeX tabular environment table.                                                                                                                        |
| <code>to_msgpack([path_or_buf, encoding])</code>              | Serialize object to input file path using msgpack format.                                                                                                                     |
| <code>to_pickle(path[, compression, protocol])</code>         | Pickle (serialize) object to file.                                                                                                                                            |
| <code>to_sparse(*args, **kwargs)</code>                       | NOT IMPLEMENTED: do not call this method, as sparsifying is not supported for Panel objects and will raise an error.                                                          |
| <code>to_sql(name, con[, schema, if_exists, ...])</code>      | Write records stored in a DataFrame to a SQL database.                                                                                                                        |
| <code>to_xarray()</code>                                      | Return an xarray object from the pandas object.                                                                                                                               |
| <code>transform(func, *args, **kwargs)</code>                 | Call <code>func</code> on self producing a NDFrame with transformed values and that has the same axis length as self.                                                         |
| <code>transpose(*args, **kwargs)</code>                       | Permute the dimensions of the Panel                                                                                                                                           |
| <code>truediv(other[, axis])</code>                           | Floating division of series and other, element-wise (binary operator <i>truediv</i> ).                                                                                        |
| <code>truncate([before, after, axis, copy])</code>            | Truncate a Series or DataFrame before and after some index value.                                                                                                             |
| <code>tshift([periods, freq, axis])</code>                    | Shift the time index, using the index's frequency if available.                                                                                                               |
| <code>tz_convert(tz[, axis, level, copy])</code>              | Convert tz-aware axis to target time zone.                                                                                                                                    |
| <code>tz_localize(tz[, axis, level, copy, ...])</code>        | Localize tz-naive index of a Series or DataFrame to target time zone.                                                                                                         |
| <code>update(other[, join, overwrite, ...])</code>            | Modify Panel in place using non-NA values from other Panel.                                                                                                                   |
| <code>var([axis, skipna, level, ddof, numeric_only])</code>   | Return unbiased variance over requested axis.                                                                                                                                 |
| <code>where(cond[, other, inplace, axis, level, ...])</code>  | Replace values where the condition is False.                                                                                                                                  |
| <code>xs(key[, axis])</code>                                  | Return slice of panel along selected axis.                                                                                                                                    |

**pandas.Panel.abs****Panel.abs()**

Return a Series/DataFrame with absolute numeric value of each element.

This function only applies to elements that are all numeric.

**Returns****abs** Series/DataFrame containing the absolute value of each element.**See also:****numpy.absolute** Calculate the absolute value element-wise.

## Notes

For complex inputs,  $1.2 + 1j$ , the absolute value is  $\sqrt{a^2 + b^2}$ .

## Examples

Absolute numeric values in a Series.

```
>>> s = pd.Series([-1.10, 2, -3.33, 4])
>>> s.abs()
0    1.10
1    2.00
2    3.33
3    4.00
dtype: float64
```

Absolute numeric values in a Series with complex numbers.

```
>>> s = pd.Series([1.2 + 1j])
>>> s.abs()
0    1.56205
dtype: float64
```

Absolute numeric values in a Series with a Timedelta element.

```
>>> s = pd.Series([pd.Timedelta('1 days')])
>>> s.abs()
0    1 days
dtype: timedelta64[ns]
```

Select rows with data closest to certain value using argsort (from [StackOverflow](#)).

```
>>> df = pd.DataFrame({
...     'a': [4, 5, 6, 7],
...     'b': [10, 20, 30, 40],
...     'c': [100, 50, -30, -50]
... })
>>> df
   a  b  c
0  4 10 100
1  5 20  50
2  6 30 -30
3  7 40 -50
>>> df.loc[(df.c - 43).abs().argsort()]
   a  b  c
1  5 20  50
0  4 10 100
2  6 30 -30
3  7 40 -50
```

## pandas.Panel.add

`Panel.add(other, axis=0)`

Addition of series and other, element-wise (binary operator *add*). Equivalent to `panel + other`.

### Parameters

**other** [DataFrame or Panel]

**axis** [{items, major\_axis, minor\_axis}] Axis to broadcast over

**Returns**

**Panel**

**See also:**

*Panel.radd*

## pandas.Panel.add\_prefix

`Panel.add_prefix` (*prefix*)

Prefix labels with string *prefix*.

For Series, the row labels are prefixed. For DataFrame, the column labels are prefixed.

**Parameters**

**prefix** [str] The string to add before each label.

**Returns**

**Series or DataFrame** New Series or DataFrame with updated labels.

**See also:**

**Series.add\_suffix** Suffix row labels with string *suffix*.

**DataFrame.add\_suffix** Suffix column labels with string *suffix*.

## Examples

```
>>> s = pd.Series([1, 2, 3, 4])
>>> s
0    1
1    2
2    3
3    4
dtype: int64
```

```
>>> s.add_prefix('item_')
item_0    1
item_1    2
item_2    3
item_3    4
dtype: int64
```

```
>>> df = pd.DataFrame({'A': [1, 2, 3, 4], 'B': [3, 4, 5, 6]})
>>> df
   A  B
0  1  3
1  2  4
2  3  5
3  4  6
```

```
>>> df.add_prefix('col_')
      col_A  col_B
0         1     3
1         2     4
2         3     5
3         4     6
```

## pandas.Panel.add\_suffix

`Panel.add_suffix(suffix)`

Suffix labels with string *suffix*.

For Series, the row labels are suffixed. For DataFrame, the column labels are suffixed.

### Parameters

**suffix** [str] The string to add after each label.

### Returns

**Series or DataFrame** New Series or DataFrame with updated labels.

**See also:**

**Series.add\_prefix** Prefix row labels with string *prefix*.

**DataFrame.add\_prefix** Prefix column labels with string *prefix*.

## Examples

```
>>> s = pd.Series([1, 2, 3, 4])
>>> s
0    1
1    2
2    3
3    4
dtype: int64
```

```
>>> s.add_suffix('_item')
0_item    1
1_item    2
2_item    3
3_item    4
dtype: int64
```

```
>>> df = pd.DataFrame({'A': [1, 2, 3, 4], 'B': [3, 4, 5, 6]})
>>> df
   A  B
0  1  3
1  2  4
2  3  5
3  4  6
```

```
>>> df.add_suffix('_col')
   A_col  B_col
0       1      3
1       2      4
2       3      5
3       4      6
```

## pandas.Panel.align

`Panel.align` (*other*, *\*\*kwargs*)

Align two objects on their axes with the specified join method for each axis Index.

### Parameters

**other** [DataFrame or Series]

**join** [{‘outer’, ‘inner’, ‘left’, ‘right’}, default ‘outer’]

**axis** [allowed axis of the other object, default None] Align on index (0), columns (1), or both (None)

**level** [int or level name, default None] Broadcast across a level, matching Index values on the passed MultiIndex level

**copy** [boolean, default True] Always returns new objects. If copy=False and no reindexing is required then original objects are returned.

**fill\_value** [scalar, default np.NaN] Value to use for missing values. Defaults to NaN, but can be any “compatible” value

**method** [{‘backfill’, ‘bfill’, ‘pad’, ‘ffill’, None}, default None] Method to use for filling holes in reindexed Series pad / ffill: propagate last valid observation forward to next valid backfill / bfill: use NEXT valid observation to fill gap

**limit** [int, default None] If method is specified, this is the maximum number of consecutive NaN values to forward/backward fill. In other words, if there is a gap with more than this number of consecutive NaNs, it will only be partially filled. If method is not specified, this is the maximum number of entries along the entire axis where NaNs will be filled. Must be greater than 0 if not None.

**fill\_axis** [int or labels for object, default 0] Filling axis, method and limit

**broadcast\_axis** [int or labels for object, default None] Broadcast values along this axis, if aligning two objects of different dimensions

### Returns

(**left**, **right**) [(NDFrame, type of other)] Aligned objects

## pandas.Panel.all

`Panel.all` (*axis=0*, *bool\_only=None*, *skipna=True*, *level=None*, *\*\*kwargs*)

Return whether all elements are True, potentially over an axis.

Returns True unless there at least one element within a series or along a Dataframe axis that is False or equivalent (e.g. zero or empty).

### Parameters

**axis** [{0 or 'index', 1 or 'columns', None}, default 0] Indicate which axis or axes should be reduced.

- 0 / 'index' : reduce the index, return a Series whose index is the original column labels.
- 1 / 'columns' : reduce the columns, return a Series whose index is the original index.
- None : reduce all axes, return a scalar.

**bool\_only** [bool, default None] Include only boolean columns. If None, will attempt to use everything, then use only boolean data. Not implemented for Series.

**skipna** [bool, default True] Exclude NA/null values. If the entire row/column is NA and skipna is True, then the result will be True, as for an empty row/column. If skipna is False, then NA are treated as True, because these are not equal to zero.

**level** [int or level name, default None] If the axis is a MultiIndex (hierarchical), count along a particular level, collapsing into a DataFrame.

**\*\*kwargs** [any, default None] Additional keywords have no effect but might be accepted for compatibility with NumPy.

### Returns

**DataFrame or Panel** If level is specified, then, Panel is returned; otherwise, DataFrame is returned.

### See also:

**Series.all** Return True if all elements are True.

**DataFrame.any** Return True if one (or more) elements are True.

## Examples

### Series

```
>>> pd.Series([True, True]).all()
True
>>> pd.Series([True, False]).all()
False
>>> pd.Series([]).all()
True
>>> pd.Series([np.nan]).all()
True
>>> pd.Series([np.nan]).all(skipna=False)
True
```

### DataFrames

Create a dataframe from a dictionary.

```
>>> df = pd.DataFrame({'col1': [True, True], 'col2': [True, False]})
>>> df
   col1  col2
0  True   True
1  True  False
```

Default behaviour checks if column-wise values all return True.

```
>>> df.all()
col1      True
col2     False
dtype: bool
```

Specify `axis='columns'` to check if row-wise values all return True.

```
>>> df.all(axis='columns')
0      True
1     False
dtype: bool
```

Or `axis=None` for whether every value is True.

```
>>> df.all(axis=None)
False
```

## pandas.Panel.any

`Panel.any` (*axis=0*, *bool\_only=None*, *skipna=True*, *level=None*, *\*\*kwargs*)

Return whether any element is True, potentially over an axis.

Returns False unless there at least one element within a series or along a Dataframe axis that is True or equivalent (e.g. non-zero or non-empty).

### Parameters

**axis** [{0 or 'index', 1 or 'columns', None}, default 0] Indicate which axis or axes should be reduced.

- 0 / 'index' : reduce the index, return a Series whose index is the original column labels.
- 1 / 'columns' : reduce the columns, return a Series whose index is the original index.
- None : reduce all axes, return a scalar.

**bool\_only** [bool, default None] Include only boolean columns. If None, will attempt to use everything, then use only boolean data. Not implemented for Series.

**skipna** [bool, default True] Exclude NA/null values. If the entire row/column is NA and skipna is True, then the result will be False, as for an empty row/column. If skipna is False, then NA are treated as True, because these are not equal to zero.

**level** [int or level name, default None] If the axis is a MultiIndex (hierarchical), count along a particular level, collapsing into a DataFrame.

**\*\*kwargs** [any, default None] Additional keywords have no effect but might be accepted for compatibility with NumPy.

### Returns

**DataFrame or Panel** If level is specified, then, Panel is returned; otherwise, DataFrame is returned.

**See also:**

`numpy.any` Numpy version of this method.

**Series.any** Return whether any element is True.

**Series.all** Return whether all elements are True.

**DataFrame.any** Return whether any element is True over requested axis.

**DataFrame.all** Return whether all elements are True over requested axis.

## Examples

### Series

For Series input, the output is a scalar indicating whether any element is True.

```
>>> pd.Series([False, False]).any()
False
>>> pd.Series([True, False]).any()
True
>>> pd.Series([]).any()
False
>>> pd.Series([np.nan]).any()
False
>>> pd.Series([np.nan]).any(skipna=False)
True
```

### DataFrame

Whether each column contains at least one True element (the default).

```
>>> df = pd.DataFrame({"A": [1, 2], "B": [0, 2], "C": [0, 0]})
>>> df
   A  B  C
0  1  0  0
1  2  2  0
```

```
>>> df.any()
A      True
B      True
C     False
dtype: bool
```

Aggregating over the columns.

```
>>> df = pd.DataFrame({"A": [True, False], "B": [1, 2]})
>>> df
   A  B
0  True  1
1 False  2
```

```
>>> df.any(axis='columns')
0      True
1      True
dtype: bool
```

```
>>> df = pd.DataFrame({"A": [True, False], "B": [1, 0]})
>>> df
   A  B
```

(continues on next page)

(continued from previous page)

```
0    True    1
1   False    0
```

```
>>> df.any(axis='columns')
0     True
1    False
dtype: bool
```

Aggregating over the entire DataFrame with `axis=None`.

```
>>> df.any(axis=None)
True
```

`any` for an empty DataFrame is an empty Series.

```
>>> pd.DataFrame([]).any()
Series([], dtype: bool)
```

## pandas.Panel.apply

`Panel.apply(func, axis='major', **kwargs)`

Applies function along axis (or axes) of the Panel.

### Parameters

**func** [function] Function to apply to each combination of ‘other’ axes e.g. if `axis = ‘items’`, the combination of `major_axis/minor_axis` will each be passed as a Series; if `axis = (‘items’, ‘major’)`, DataFrames of items & major axis will be passed

**axis** [{‘items’, ‘minor’, ‘major’}, or {0, 1, 2}, or a tuple with two] axes

**Additional keyword arguments will be passed as keywords to the function**

### Returns

**result** [Panel, DataFrame, or Series]

## Examples

Returns a Panel with the square root of each element

```
>>> p = pd.Panel(np.random.rand(4, 3, 2)) # doctest: +SKIP
>>> p.apply(np.sqrt)
```

Equivalent to `p.sum(1)`, returning a DataFrame

```
>>> p.apply(lambda x: x.sum(), axis=1) # doctest: +SKIP
```

Equivalent to previous:

```
>>> p.apply(lambda x: x.sum(), axis='major') # doctest: +SKIP
```

Return the shapes of each DataFrame over axis 2 (i.e the shapes of items x major), as a Series

```
>>> p.apply(lambda x: x.shape, axis=(0,1)) # doctest: +SKIP
```

## pandas.Panel.as\_blocks

`Panel.as_blocks(copy=True)`

Convert the frame to a dict of dtype -> Constructor Types that each has a homogeneous dtype.

Deprecated since version 0.21.0.

**NOTE: the dtypes of the blocks WILL BE PRESERVED HERE (unlike in `as_matrix`)**

### Parameters

**copy** [boolean, default True]

### Returns

**values** [a dict of dtype -> Constructor Types]

## pandas.Panel.as\_matrix

`Panel.as_matrix()`

Convert the frame to its Numpy-array representation.

Deprecated since version 0.23.0: Use `DataFrame.values()` instead.

### Parameters

**columns** [list, optional, default:None] If None, return all columns, otherwise, returns specified columns.

### Returns

**values** [ndarray] If the caller is heterogeneous and contains booleans or objects, the result will be of dtype=object. See Notes.

### See also:

`DataFrame.values`

## Notes

Return is NOT a Numpy-matrix, rather, a Numpy-array.

The dtype will be a lower-common-denominator dtype (implicit upcasting); that is to say if the dtypes (even of numeric types) are mixed, the one that accommodates all will be chosen. Use this with care if you are not dealing with the blocks.

e.g. If the dtypes are float16 and float32, dtype will be upcast to float32. If dtypes are int32 and uint8, dtype will be upcase to int32. By `numpy.find_common_type` convention, mixing int64 and uint64 will result in a float64 dtype.

This method is provided for backwards compatibility. Generally, it is recommended to use `‘.values’`.

## pandas.Panel.asfreq

`Panel.asfreq(freq, method=None, how=None, normalize=False, fill_value=None)`

Convert TimeSeries to specified frequency.

Optionally provide filling method to pad/backfill missing values.

Returns the original data conformed to a new index with the specified frequency. `resample` is more appropriate if an operation, such as summarization, is necessary to represent the data at the new frequency.

### Parameters

**freq** [DateOffset object, or string]

**method** [{ 'backfill'/'bfill', 'pad'/'ffill' }, default None] Method to use for filling holes in reindexed Series (note this does not fill NaNs that already were present):

- 'pad' / 'ffill': propagate last valid observation forward to next valid
- 'backfill' / 'bfill': use NEXT valid observation to fill

**how** [{ 'start', 'end' }, default end] For PeriodIndex only, see PeriodIndex.asfreq

**normalize** [bool, default False] Whether to reset output index to midnight

**fill\_value** [scalar, optional] Value to use for missing values, applied during upsampling (note this does not fill NaNs that already were present).

New in version 0.20.0.

### Returns

**converted** [same type as caller]

See also:

*reindex*

## Notes

To learn more about the frequency strings, please see [this link](#).

## Examples

Start by creating a series with 4 one minute timestamps.

```
>>> index = pd.date_range('1/1/2000', periods=4, freq='T')
>>> series = pd.Series([0.0, None, 2.0, 3.0], index=index)
>>> df = pd.DataFrame({'s':series})
>>> df
```

|                     | s   |
|---------------------|-----|
| 2000-01-01 00:00:00 | 0.0 |
| 2000-01-01 00:01:00 | NaN |
| 2000-01-01 00:02:00 | 2.0 |
| 2000-01-01 00:03:00 | 3.0 |

Upsample the series into 30 second bins.

```
>>> df.asfreq(freq='30S')
s
2000-01-01 00:00:00    0.0
2000-01-01 00:00:30   NaN
2000-01-01 00:01:00   NaN
2000-01-01 00:01:30   NaN
2000-01-01 00:02:00    2.0
2000-01-01 00:02:30   NaN
2000-01-01 00:03:00    3.0
```

Upsample again, providing a fill value.

```
>>> df.asfreq(freq='30S', fill_value=9.0)
s
2000-01-01 00:00:00    0.0
2000-01-01 00:00:30    9.0
2000-01-01 00:01:00   NaN
2000-01-01 00:01:30    9.0
2000-01-01 00:02:00    2.0
2000-01-01 00:02:30    9.0
2000-01-01 00:03:00    3.0
```

Upsample again, providing a method.

```
>>> df.asfreq(freq='30S', method='bfill')
s
2000-01-01 00:00:00    0.0
2000-01-01 00:00:30   NaN
2000-01-01 00:01:00   NaN
2000-01-01 00:01:30    2.0
2000-01-01 00:02:00    2.0
2000-01-01 00:02:30    3.0
2000-01-01 00:03:00    3.0
```

## pandas.Panel.asof

`Panel.asof (where, subset=None)`

Return the last row(s) without any NaNs before *where*.

The last row (for each element in *where*, if list) without any NaN is taken. In case of a *DataFrame*, the last row without NaN considering only the subset of columns (if not *None*)

New in version 0.19.0: For *DataFrame*

If there is no good value, NaN is returned for a *Series* or a *Series* of NaN values for a *DataFrame*

### Parameters

**where** [date or array-like of dates] Date(s) before which the last row(s) are returned.

**subset** [str or array-like of str, default *None*] For *DataFrame*, if not *None*, only use these columns to check for NaNs.

### Returns

**scalar, Series, or DataFrame**

- scalar : when *self* is a *Series* and *where* is a scalar

- Series: when *self* is a Series and *where* is an array-like, or when *self* is a DataFrame and *where* is a scalar
- DataFrame : when *self* is a DataFrame and *where* is an array-like

See also:

**`merge_asof`** Perform an asof merge. Similar to left join.

## Notes

Dates are assumed to be sorted. Raises if this is not the case.

## Examples

A Series and a scalar *where*.

```
>>> s = pd.Series([1, 2, np.nan, 4], index=[10, 20, 30, 40])
>>> s
10    1.0
20    2.0
30    NaN
40    4.0
dtype: float64
```

```
>>> s.asof(20)
2.0
```

For a sequence *where*, a Series is returned. The first value is NaN, because the first element of *where* is before the first index value.

```
>>> s.asof([5, 20])
5      NaN
20     2.0
dtype: float64
```

Missing values are not considered. The following is 2.0, not NaN, even though NaN is at the index location for 30.

```
>>> s.asof(30)
2.0
```

Take all columns into consideration

```
>>> df = pd.DataFrame({'a': [10, 20, 30, 40, 50],
...                     'b': [None, None, None, None, 500]},
...                     index=pd.DatetimeIndex(['2018-02-27 09:01:00',
...                                              '2018-02-27 09:02:00',
...                                              '2018-02-27 09:03:00',
...                                              '2018-02-27 09:04:00',
...                                              '2018-02-27 09:05:00']))
>>> df.asof(pd.DatetimeIndex(['2018-02-27 09:03:30',
...                           '2018-02-27 09:04:30']))
...
           a    b
2018-02-27 09:03:30  NaN  NaN
2018-02-27 09:04:30  NaN  NaN
```

Take a single column into consideration

```
>>> df.asof(pd.DatetimeIndex(['2018-02-27 09:03:30',
...                           '2018-02-27 09:04:30']),
...         subset=['a'])
              a      b
2018-02-27 09:03:30  30.0 NaN
2018-02-27 09:04:30  40.0 NaN
```

## pandas.Panel.astype

`Panel.astype(dtype, copy=True, errors='raise', **kwargs)`

Cast a pandas object to a specified dtype dtype.

### Parameters

**dtype** [data type, or dict of column name -> data type] Use a numpy.dtype or Python type to cast entire pandas object to the same type. Alternatively, use {col: dtype, ...}, where col is a column label and dtype is a numpy.dtype or Python type to cast one or more of the DataFrame's columns to column-specific types.

**copy** [bool, default True] Return a copy when copy=True (be very careful setting copy=False as changes to values then may propagate to other pandas objects).

**errors** [{ 'raise', 'ignore' }, default 'raise'] Control raising of exceptions on invalid data for provided dtype.

- `raise` : allow exceptions to be raised
- `ignore` : suppress exceptions. On error return original object

New in version 0.20.0.

**kwargs** [keyword arguments to pass on to the constructor]

### Returns

**casted** [same type as caller]

See also:

**to\_datetime** Convert argument to datetime.

**to\_timedelta** Convert argument to timedelta.

**to\_numeric** Convert argument to a numeric type.

**numpy.ndarray.astype** Cast a numpy array to a specified type.

## Examples

```
>>> ser = pd.Series([1, 2], dtype='int32')
>>> ser
0    1
1    2
dtype: int32
>>> ser.astype('int64')
0    1
1    2
dtype: int64
```

Convert to categorical type:

```
>>> ser.astype('category')
0    1
1    2
dtype: category
Categories (2, int64): [1, 2]
```

Convert to ordered categorical type with custom ordering:

```
>>> cat_dtype = pd.api.types.CategoricalDtype(
...             categories=[2, 1], ordered=True)
>>> ser.astype(cat_dtype)
0    1
1    2
dtype: category
Categories (2, int64): [2 < 1]
```

Note that using `copy=False` and changing data on a new pandas object may propagate changes:

```
>>> s1 = pd.Series([1,2])
>>> s2 = s1.astype('int64', copy=False)
>>> s2[0] = 10
>>> s1 # note that s1[0] has changed too
0    10
1     2
dtype: int64
```

## pandas.Panel.at\_time

`Panel.at_time` (*time*, *asof=False*, *axis=None*)

Select values at particular time of day (e.g. 9:30AM).

### Parameters

**time** [datetime.time or string]

**axis** [{0 or 'index', 1 or 'columns'}], default 0] New in version 0.24.0.

### Returns

**values\_at\_time** [same type as caller]

### Raises

**TypeError** If the index is not a *DatetimeIndex*

See also:

**between\_time** Select values between particular times of the day.

**first** Select initial periods of time series based on a date offset.

**last** Select final periods of time series based on a date offset.

**DatetimeIndex.indexer\_at\_time** Get just the index locations for values at particular time of the day.

## Examples

```
>>> i = pd.date_range('2018-04-09', periods=4, freq='12H')
>>> ts = pd.DataFrame({'A': [1,2,3,4]}, index=i)
>>> ts
```

|                     | A |
|---------------------|---|
| 2018-04-09 00:00:00 | 1 |
| 2018-04-09 12:00:00 | 2 |
| 2018-04-10 00:00:00 | 3 |
| 2018-04-10 12:00:00 | 4 |

```
>>> ts.at_time('12:00')
```

|                     | A |
|---------------------|---|
| 2018-04-09 12:00:00 | 2 |
| 2018-04-10 12:00:00 | 4 |

## pandas.Panel.between\_time

`Panel.between_time(start_time, end_time, include_start=True, include_end=True, axis=None)`

Select values between particular times of the day (e.g., 9:00-9:30 AM).

By setting `start_time` to be later than `end_time`, you can get the times that are *not* between the two times.

### Parameters

**start\_time** [datetime.time or string]  
**end\_time** [datetime.time or string]  
**include\_start** [boolean, default True]  
**include\_end** [boolean, default True]  
**axis** [{0 or 'index', 1 or 'columns'}, default 0] New in version 0.24.0.

### Returns

**values\_between\_time** [same type as caller]

### Raises

**TypeError** If the index is not a *DatetimeIndex*

### See also:

**at\_time** Select values at a particular time of the day.

**first** Select initial periods of time series based on a date offset.

**last** Select final periods of time series based on a date offset.

**DatetimeIndex.indexer\_between\_time** Get just the index locations for values between particular times of the day.

## Examples

```
>>> i = pd.date_range('2018-04-09', periods=4, freq='1D20min')
>>> ts = pd.DataFrame({'A': [1,2,3,4]}, index=i)
>>> ts
```

|                     | A |
|---------------------|---|
| 2018-04-09 00:00:00 | 1 |
| 2018-04-10 00:20:00 | 2 |
| 2018-04-11 00:40:00 | 3 |
| 2018-04-12 01:00:00 | 4 |

```
>>> ts.between_time('0:15', '0:45')
```

|                     | A |
|---------------------|---|
| 2018-04-10 00:20:00 | 2 |
| 2018-04-11 00:40:00 | 3 |

You get the times that are *not* between two times by setting `start_time` later than `end_time`:

```
>>> ts.between_time('0:45', '0:15')
```

|                     | A |
|---------------------|---|
| 2018-04-09 00:00:00 | 1 |
| 2018-04-12 01:00:00 | 4 |

## pandas.Panel.bfill

`Panel.bfill` (*axis=None, inplace=False, limit=None, downcast=None*)

Synonym for `DataFrame.fillna()` with `method='bfill'`.

## pandas.Panel.bool

`Panel.bool()`

Return the bool of a single element `PandasObject`.

This must be a boolean scalar value, either `True` or `False`. Raise a `ValueError` if the `PandasObject` does not have exactly 1 element, or that element is not boolean

## pandas.Panel.clip

`Panel.clip` (*lower=None, upper=None, axis=None, inplace=False, \*args, \*\*kwargs*)

Trim values at input threshold(s).

Assigns values outside boundary to boundary values. Thresholds can be singular values or array like, and in the latter case the clipping is performed element-wise in the specified axis.

### Parameters

**lower** [float or array\_like, default None] Minimum threshold value. All values below this threshold will be set to it.

**upper** [float or array\_like, default None] Maximum threshold value. All values above this threshold will be set to it.

**axis** [int or string axis name, optional] Align object with lower and upper along the given axis.

**inplace** [boolean, default False] Whether to perform the operation in place on the data.

New in version 0.21.0.

**\*args, \*\*kwargs** Additional keywords have no effect but might be accepted for compatibility with numpy.

### Returns

**Series or DataFrame** Same type as calling object with the values outside the clip boundaries replaced

### Examples

```
>>> data = {'col_0': [9, -3, 0, -1, 5], 'col_1': [-2, -7, 6, 8, -5]}
>>> df = pd.DataFrame(data)
>>> df
   col_0  col_1
0      9    -2
1     -3    -7
2      0     6
3     -1     8
4      5    -5
```

Clips per column using lower and upper thresholds:

```
>>> df.clip(-4, 6)
   col_0  col_1
0      6    -2
1     -3    -4
2      0     6
3     -1     6
4      5    -4
```

Clips using specific lower and upper thresholds per column element:

```
>>> t = pd.Series([2, -4, -1, 6, 3])
>>> t
0     2
1    -4
2    -1
3     6
4     3
dtype: int64
```

```
>>> df.clip(t, t + 4, axis=0)
   col_0  col_1
0      6     2
1     -3    -4
2      0     3
3      6     8
4      5     3
```

## pandas.Panel.clip\_lower

`Panel.clip_lower(threshold, axis=None, inplace=False)`

Trim values below a given threshold.

Deprecated since version 0.24.0: Use `clip(lower=threshold)` instead.

Elements below the *threshold* will be changed to match the *threshold* value(s). Threshold can be a single value or an array, in the latter case it performs the truncation element-wise.

### Parameters

**threshold** [numeric or array-like] Minimum value allowed. All values below threshold will be set to this value.

- float : every value is compared to *threshold*.
- array-like : The shape of *threshold* should match the object it's compared to. When *self* is a Series, *threshold* should be the length. When *self* is a DataFrame, *threshold* should 2-D and the same shape as *self* for `axis=None`, or 1-D and the same length as the axis being compared.

**axis** [{0 or 'index', 1 or 'columns'}, default 0] Align *self* with *threshold* along the given axis.

**inplace** [boolean, default False] Whether to perform the operation in place on the data.

New in version 0.21.0.

### Returns

**Series or DataFrame** Original data with values trimmed.

See also:

**Series.clip** General purpose method to trim Series values to given threshold(s).

**DataFrame.clip** General purpose method to trim DataFrame values to given threshold(s).

## Examples

Series single threshold clipping:

```
>>> s = pd.Series([5, 6, 7, 8, 9])
>>> s.clip(lower=8)
0      8
1      8
2      8
3      8
4      9
dtype: int64
```

Series clipping element-wise using an array of thresholds. *threshold* should be the same length as the Series.

```
>>> elemwise_thresholds = [4, 8, 7, 2, 5]
>>> s.clip(lower=elemwise_thresholds)
0      5
1      8
2      7
```

(continues on next page)

(continued from previous page)

```
3      8
4      9
dtype: int64
```

DataFrames can be compared to a scalar.

```
>>> df = pd.DataFrame({"A": [1, 3, 5], "B": [2, 4, 6]})
>>> df
   A  B
0  1  2
1  3  4
2  5  6
```

```
>>> df.clip(lower=3)
   A  B
0  3  3
1  3  4
2  5  6
```

Or to an array of values. By default, *threshold* should be the same shape as the DataFrame.

```
>>> df.clip(lower=np.array([[3, 4], [2, 2], [6, 2]]))
   A  B
0  3  4
1  3  4
2  6  6
```

Control how *threshold* is broadcast with *axis*. In this case *threshold* should be the same length as the axis specified by *axis*.

```
>>> df.clip(lower=[3, 3, 5], axis='index')
   A  B
0  3  3
1  3  4
2  5  6
```

```
>>> df.clip(lower=[4, 5], axis='columns')
   A  B
0  4  5
1  4  5
2  5  6
```

### pandas.Panel.clip\_upper

`Panel.clip_upper(threshold, axis=None, inplace=False)`

Trim values above a given threshold.

Deprecated since version 0.24.0: Use `clip(upper=threshold)` instead.

Elements above the *threshold* will be changed to match the *threshold* value(s). Threshold can be a single value or an array, in the latter case it performs the truncation element-wise.

#### Parameters

**threshold** [numeric or array-like] Maximum value allowed. All values above threshold will be set to this value.

- float : every value is compared to *threshold*.
- array-like : The shape of *threshold* should match the object it's compared to. When *self* is a Series, *threshold* should be the length. When *self* is a DataFrame, *threshold* should 2-D and the same shape as *self* for `axis=None`, or 1-D and the same length as the axis being compared.

**axis** [{0 or 'index', 1 or 'columns'}, default 0] Align object with *threshold* along the given axis.

**inplace** [boolean, default False] Whether to perform the operation in place on the data.

New in version 0.21.0.

### Returns

**Series or DataFrame** Original data with values trimmed.

See also:

***Series.clip*** General purpose method to trim Series values to given threshold(s).

***DataFrame.clip*** General purpose method to trim DataFrame values to given threshold(s).

### Examples

```
>>> s = pd.Series([1, 2, 3, 4, 5])
>>> s
0    1
1    2
2    3
3    4
4    5
dtype: int64
```

```
>>> s.clip(upper=3)
0    1
1    2
2    3
3    3
4    3
dtype: int64
```

```
>>> elemwise_thresholds = [5, 4, 3, 2, 1]
>>> elemwise_thresholds
[5, 4, 3, 2, 1]
```

```
>>> s.clip(upper=elemwise_thresholds)
0    1
1    2
2    3
3    2
4    1
dtype: int64
```

**pandas.Panel.compound**

`Panel.compound` (*axis=None, skipna=None, level=None*)

Return the compound percentage of the values for the requested axis.

**Parameters**

**axis** [{items (0), major\_axis (1), minor\_axis (2)}] Axis for the function to be applied on.

**skipna** [bool, default True] Exclude NA/null values when computing the result.

**level** [int or level name, default None] If the axis is a MultiIndex (hierarchical), count along a particular level, collapsing into a DataFrame.

**numeric\_only** [bool, default None] Include only float, int, boolean columns. If None, will attempt to use everything, then use only numeric data. Not implemented for Series.

**\*\*kwargs** Additional keyword arguments to be passed to the function.

**Returns**

**compounded** [DataFrame or Panel (if level specified)]

**pandas.Panel.conform**

`Panel.conform` (*frame, axis='items'*)

Conform input DataFrame to align with chosen axis pair.

**Parameters**

**frame** [DataFrame]

**axis** [{‘items’, ‘major’, ‘minor’}] Axis the input corresponds to. E.g., if axis=‘major’, then the frame’s columns would be items, and the index would be values of the minor axis

**Returns**

**DataFrame**

**pandas.Panel.convert\_objects**

`Panel.convert_objects` (*convert\_dates=True, convert\_numeric=False, convert\_timedeltas=True, copy=True*)

Attempt to infer better dtype for object columns.

Deprecated since version 0.21.0.

**Parameters**

**convert\_dates** [boolean, default True] If True, convert to date where possible. If ‘coerce’, force conversion, with unconvertible values becoming NaT.

**convert\_numeric** [boolean, default False] If True, attempt to coerce to numbers (including strings), with unconvertible values becoming NaN.

**convert\_timedeltas** [boolean, default True] If True, convert to timedelta where possible. If ‘coerce’, force conversion, with unconvertible values becoming NaT.

**copy** [boolean, default True] If True, return a copy even if no copy is necessary (e.g. no conversion was done). Note: This is meant for internal use, and should not be confused with inplace.

#### Returns

**converted** [same as input object]

See also:

**to\_datetime** Convert argument to datetime.

**to\_timedelta** Convert argument to timedelta.

**to\_numeric** Convert argument to numeric type.

### pandas.Panel.copy

`Panel.copy(deep=True)`

Make a copy of this object's indices and data.

When `deep=True` (default), a new object will be created with a copy of the calling object's data and indices. Modifications to the data or indices of the copy will not be reflected in the original object (see notes below).

When `deep=False`, a new object will be created without copying the calling object's data or index (only references to the data and index are copied). Any changes to the data of the original will be reflected in the shallow copy (and vice versa).

#### Parameters

**deep** [bool, default True] Make a deep copy, including a copy of the data and the indices. With `deep=False` neither the indices nor the data are copied.

#### Returns

**copy** [Series, DataFrame or Panel] Object type matches caller.

### Notes

When `deep=True`, data is copied but actual Python objects will not be copied recursively, only the reference to the object. This is in contrast to `copy.deepcopy` in the Standard Library, which recursively copies object data (see examples below).

While `Index` objects are copied when `deep=True`, the underlying numpy array is not copied for performance reasons. Since `Index` is immutable, the underlying data can be safely shared and a copy is not needed.

### Examples

```
>>> s = pd.Series([1, 2], index=["a", "b"])
>>> s
a    1
b    2
dtype: int64
```

```
>>> s_copy = s.copy()
>>> s_copy
a    1
b    2
dtype: int64
```

#### Shallow copy versus default (deep) copy:

```
>>> s = pd.Series([1, 2], index=["a", "b"])
>>> deep = s.copy()
>>> shallow = s.copy(deep=False)
```

Shallow copy shares data and index with original.

```
>>> s is shallow
False
>>> s.values is shallow.values and s.index is shallow.index
True
```

Deep copy has own copy of data and index.

```
>>> s is deep
False
>>> s.values is deep.values or s.index is deep.index
False
```

Updates to the data shared by shallow copy and original is reflected in both; deep copy remains unchanged.

```
>>> s[0] = 3
>>> shallow[1] = 4
>>> s
a    3
b    4
dtype: int64
>>> shallow
a    3
b    4
dtype: int64
>>> deep
a    1
b    2
dtype: int64
```

Note that when copying an object containing Python objects, a deep copy will copy the data, but will not do so recursively. Updating a nested data object will be reflected in the deep copy.

```
>>> s = pd.Series([[1, 2], [3, 4]])
>>> deep = s.copy()
>>> s[0][0] = 10
>>> s
0    [10, 2]
1     [3, 4]
dtype: object
>>> deep
0    [10, 2]
1     [3, 4]
dtype: object
```

## pandas.Panel.count

`Panel.count` (*axis*='major')

Return number of observations over requested axis.

### Parameters

**axis** [{ 'items', 'major', 'minor' } or {0, 1, 2}]

### Returns

**count** [DataFrame]

## pandas.Panel.cummax

`Panel.cummax` (*axis*=None, *skipna*=True, \*args, \*\*kwargs)

Return cumulative maximum over a DataFrame or Series axis.

Returns a DataFrame or Series of the same size containing the cumulative maximum.

### Parameters

**axis** [{0 or 'index', 1 or 'columns'}, default 0] The index or the name of the axis. 0 is equivalent to None or 'index'.

**skipna** [boolean, default True] Exclude NA/null values. If an entire row/column is NA, the result will be NA.

**\*args, \*\*kwargs** : Additional keywords have no effect but might be accepted for compatibility with NumPy.

### Returns

**cummax** [DataFrame or Panel]

See also:

**core.window.Expanding.max** Similar functionality but ignores NaN values.

**Panel.max** Return the maximum over Panel axis.

**Panel.cummax** Return cumulative maximum over Panel axis.

**Panel.cummin** Return cumulative minimum over Panel axis.

**Panel.cumsum** Return cumulative sum over Panel axis.

**Panel.cumprod** Return cumulative product over Panel axis.

## Examples

### Series

```
>>> s = pd.Series([2, np.nan, 5, -1, 0])
>>> s
0    2.0
1    NaN
2    5.0
3   -1.0
4    0.0
dtype: float64
```

By default, NA values are ignored.

```
>>> s.cummax()
0    2.0
1    NaN
2    5.0
3    5.0
4    5.0
dtype: float64
```

To include NA values in the operation, use `skipna=False`

```
>>> s.cummax(skipna=False)
0    2.0
1    NaN
2    NaN
3    NaN
4    NaN
dtype: float64
```

### DataFrame

```
>>> df = pd.DataFrame([[2.0, 1.0],
...                    [3.0, np.nan],
...                    [1.0, 0.0]],
...                    columns=list('AB'))
>>> df
   A    B
0  2.0  1.0
1  3.0  NaN
2  1.0  0.0
```

By default, iterates over rows and finds the maximum in each column. This is equivalent to `axis=None` or `axis='index'`.

```
>>> df.cummax()
   A    B
0  2.0  1.0
1  3.0  NaN
2  3.0  1.0
```

To iterate over columns and find the maximum in each row, use `axis=1`

```
>>> df.cummax(axis=1)
   A    B
0  2.0  2.0
1  3.0  NaN
2  1.0  1.0
```

### pandas.Panel.cummin

`Panel.cummin` (*axis=None, skipna=True, \*args, \*\*kwargs*)

Return cumulative minimum over a DataFrame or Series axis.

Returns a DataFrame or Series of the same size containing the cumulative minimum.

#### Parameters

**axis** [{0 or 'index', 1 or 'columns'}, default 0] The index or the name of the axis. 0 is equivalent to None or 'index'.

**skipna** [boolean, default True] Exclude NA/null values. If an entire row/column is NA, the result will be NA.

**\*args, \*\*kwargs** : Additional keywords have no effect but might be accepted for compatibility with NumPy.

### Returns

**cummin** [DataFrame or Panel]

See also:

**core.window.Expanding.min** Similar functionality but ignores NaN values.

**Panel.min** Return the minimum over Panel axis.

**Panel.cummax** Return cumulative maximum over Panel axis.

**Panel.cummin** Return cumulative minimum over Panel axis.

**Panel.cumsum** Return cumulative sum over Panel axis.

**Panel.cumprod** Return cumulative product over Panel axis.

## Examples

### Series

```
>>> s = pd.Series([2, np.nan, 5, -1, 0])
>>> s
0      2.0
1      NaN
2      5.0
3     -1.0
4      0.0
dtype: float64
```

By default, NA values are ignored.

```
>>> s.cummin()
0      2.0
1      NaN
2      2.0
3     -1.0
4     -1.0
dtype: float64
```

To include NA values in the operation, use `skipna=False`

```
>>> s.cummin(skipna=False)
0      2.0
1      NaN
2      NaN
3      NaN
4      NaN
dtype: float64
```

### DataFrame

```
>>> df = pd.DataFrame([[2.0, 1.0],
...                    [3.0, np.nan],
...                    [1.0, 0.0]],
...                    columns=list('AB'))
>>> df
   A    B
0  2.0  1.0
1  3.0  NaN
2  1.0  0.0
```

By default, iterates over rows and finds the minimum in each column. This is equivalent to `axis=None` or `axis='index'`.

```
>>> df.cummin()
   A    B
0  2.0  1.0
1  2.0  NaN
2  1.0  0.0
```

To iterate over columns and find the minimum in each row, use `axis=1`

```
>>> df.cummin(axis=1)
   A    B
0  2.0  1.0
1  3.0  NaN
2  1.0  0.0
```

## pandas.Panel.cumprod

`Panel.cumprod(axis=None, skipna=True, *args, **kwargs)`

Return cumulative product over a DataFrame or Series axis.

Returns a DataFrame or Series of the same size containing the cumulative product.

### Parameters

**axis** [{0 or 'index', 1 or 'columns'}, default 0] The index or the name of the axis. 0 is equivalent to None or 'index'.

**skipna** [boolean, default True] Exclude NA/null values. If an entire row/column is NA, the result will be NA.

**\*args, \*\*kwargs**: Additional keywords have no effect but might be accepted for compatibility with NumPy.

### Returns

**cumprod** [DataFrame or Panel]

See also:

**core.window.Expanding.prod** Similar functionality but ignores NaN values.

**Panel.prod** Return the product over Panel axis.

**Panel.cummax** Return cumulative maximum over Panel axis.

**Panel.cummin** Return cumulative minimum over Panel axis.

**Panel.cumsum** Return cumulative sum over Panel axis.

**Panel.cumprod** Return cumulative product over Panel axis.

## Examples

### Series

```
>>> s = pd.Series([2, np.nan, 5, -1, 0])
>>> s
0    2.0
1    NaN
2    5.0
3   -1.0
4    0.0
dtype: float64
```

By default, NA values are ignored.

```
>>> s.cumprod()
0    2.0
1    NaN
2   10.0
3  -10.0
4   -0.0
dtype: float64
```

To include NA values in the operation, use `skipna=False`

```
>>> s.cumprod(skipna=False)
0    2.0
1    NaN
2    NaN
3    NaN
4    NaN
dtype: float64
```

### DataFrame

```
>>> df = pd.DataFrame([[2.0, 1.0],
...                    [3.0, np.nan],
...                    [1.0, 0.0]],
...                    columns=list('AB'))
>>> df
   A  B
0  2.0  1.0
1  3.0  NaN
2  1.0  0.0
```

By default, iterates over rows and finds the product in each column. This is equivalent to `axis=None` or `axis='index'`.

```
>>> df.cumprod()
   A  B
0  2.0  1.0
1  6.0  NaN
2  6.0  0.0
```

To iterate over columns and find the product in each row, use `axis=1`

```
>>> df.cumprod(axis=1)
   A      B
0  2.0  2.0
1  3.0  NaN
2  1.0  0.0
```

## pandas.Panel.cumsum

`Panel.cumsum` (*axis=None*, *skipna=True*, *\*args*, *\*\*kwargs*)

Return cumulative sum over a DataFrame or Series axis.

Returns a DataFrame or Series of the same size containing the cumulative sum.

### Parameters

**axis** [{0 or 'index', 1 or 'columns'}, default 0] The index or the name of the axis. 0 is equivalent to None or 'index'.

**skipna** [boolean, default True] Exclude NA/null values. If an entire row/column is NA, the result will be NA.

**\*args, \*\*kwargs** : Additional keywords have no effect but might be accepted for compatibility with NumPy.

### Returns

**cumsum** [DataFrame or Panel]

See also:

**core.window.Expanding.sum** Similar functionality but ignores NaN values.

**Panel.sum** Return the sum over Panel axis.

**Panel.cummax** Return cumulative maximum over Panel axis.

**Panel.cummin** Return cumulative minimum over Panel axis.

**Panel.cumsum** Return cumulative sum over Panel axis.

**Panel.cumprod** Return cumulative product over Panel axis.

## Examples

### Series

```
>>> s = pd.Series([2, np.nan, 5, -1, 0])
>>> s
0      2.0
1      NaN
2      5.0
3     -1.0
4      0.0
dtype: float64
```

By default, NA values are ignored.

```
>>> s.cumsum()
0    2.0
1    NaN
2    7.0
3    6.0
4    6.0
dtype: float64
```

To include NA values in the operation, use `skipna=False`

```
>>> s.cumsum(skipna=False)
0    2.0
1    NaN
2    NaN
3    NaN
4    NaN
dtype: float64
```

### DataFrame

```
>>> df = pd.DataFrame([[2.0, 1.0],
...                    [3.0, np.nan],
...                    [1.0, 0.0]],
...                    columns=list('AB'))
>>> df
   A  B
0  2.0  1.0
1  3.0  NaN
2  1.0  0.0
```

By default, iterates over rows and finds the sum in each column. This is equivalent to `axis=None` or `axis='index'`.

```
>>> df.cumsum()
   A  B
0  2.0  1.0
1  5.0  NaN
2  6.0  1.0
```

To iterate over columns and find the sum in each row, use `axis=1`

```
>>> df.cumsum(axis=1)
   A  B
0  2.0  3.0
1  3.0  NaN
2  1.0  1.0
```

## pandas.Panel.describe

`Panel.describe` (*percentiles=None, include=None, exclude=None*)

Generate descriptive statistics that summarize the central tendency, dispersion and shape of a dataset's distribution, excluding NaN values.

Analyzes both numeric and object series, as well as `DataFrame` column sets of mixed data types. The output will vary depending on what is provided. Refer to the notes below for more detail.

### Parameters

**percentiles** [list-like of numbers, optional] The percentiles to include in the output. All should fall between 0 and 1. The default is `[.25, .5, .75]`, which returns the 25th, 50th, and 75th percentiles.

**include** ['all', list-like of dtypes or None (default), optional] A white list of data types to include in the result. Ignored for `Series`. Here are the options:

- 'all' : All columns of the input will be included in the output.
- A list-like of dtypes : Limits the results to the provided data types. To limit the result to numeric types submit `numpy.number`. To limit it instead to object columns submit the `numpy.object` data type. Strings can also be used in the style of `select_dtypes` (e.g. `df.describe(include=['O'])`). To select pandas categorical columns, use `'category'`
- None (default) : The result will include all numeric columns.

**exclude** [list-like of dtypes or None (default), optional,] A black list of data types to omit from the result. Ignored for `Series`. Here are the options:

- A list-like of dtypes : Excludes the provided data types from the result. To exclude numeric types submit `numpy.number`. To exclude object columns submit the data type `numpy.object`. Strings can also be used in the style of `select_dtypes` (e.g. `df.describe(include=['O'])`). To exclude pandas categorical columns, use `'category'`
- None (default) : The result will exclude nothing.

### Returns

**Series or DataFrame** Summary statistics of the Series or Dataframe provided.

See also:

**DataFrame.count** Count number of non-NA/null observations.

**DataFrame.max** Maximum of the values in the object.

**DataFrame.min** Minimum of the values in the object.

**DataFrame.mean** Mean of the values.

**DataFrame.std** Standard deviation of the observations.

**DataFrame.select\_dtypes** Subset of a DataFrame including/excluding columns based on their dtype.

### Notes

For numeric data, the result's index will include `count`, `mean`, `std`, `min`, `max` as well as `lower`, 50 and upper percentiles. By default the lower percentile is 25 and the upper percentile is 75. The 50 percentile is the same as the median.

For object data (e.g. strings or timestamps), the result's index will include `count`, `unique`, `top`, and `freq`. The `top` is the most common value. The `freq` is the most common value's frequency. Timestamps also include the `first` and `last` items.

If multiple object values have the highest count, then the `count` and `top` results will be arbitrarily chosen from among those with the highest count.

For mixed data types provided via a `DataFrame`, the default is to return only an analysis of numeric columns. If the dataframe consists only of object and categorical data without any numeric columns,

the default is to return an analysis of both the object and categorical columns. If `include='all'` is provided as an option, the result will include a union of attributes of each type.

The *include* and *exclude* parameters can be used to limit which columns in a `DataFrame` are analyzed for the output. The parameters are ignored when analyzing a `Series`.

## Examples

Describing a numeric `Series`.

```
>>> s = pd.Series([1, 2, 3])
>>> s.describe()
count      3.0
mean       2.0
std        1.0
min        1.0
25%        1.5
50%        2.0
75%        2.5
max        3.0
dtype: float64
```

Describing a categorical `Series`.

```
>>> s = pd.Series(['a', 'a', 'b', 'c'])
>>> s.describe()
count      4
unique     3
top        a
freq       2
dtype: object
```

Describing a timestamp `Series`.

```
>>> s = pd.Series([
...     np.datetime64("2000-01-01"),
...     np.datetime64("2010-01-01"),
...     np.datetime64("2010-01-01")
... ])
>>> s.describe()
count      3
unique     2
top      2010-01-01 00:00:00
freq       2
first      2000-01-01 00:00:00
last       2010-01-01 00:00:00
dtype: object
```

Describing a `DataFrame`. By default only numeric fields are returned.

```
>>> df = pd.DataFrame({'categorical': pd.Categorical(['d', 'e', 'f']),
...                    'numeric': [1, 2, 3],
...                    'object': ['a', 'b', 'c']
...                    })
>>> df.describe()
           numeric
count      3.0
```

(continues on next page)

(continued from previous page)

|      |     |
|------|-----|
| mean | 2.0 |
| std  | 1.0 |
| min  | 1.0 |
| 25%  | 1.5 |
| 50%  | 2.0 |
| 75%  | 2.5 |
| max  | 3.0 |

Describing all columns of a DataFrame regardless of data type.

```
>>> df.describe(include='all')
      categorical  numeric  object
count           3        3.0      3
unique           3        NaN      3
top              f        NaN      c
freq            1        NaN      1
mean            NaN        2.0     NaN
std             NaN        1.0     NaN
min             NaN        1.0     NaN
25%            NaN        1.5     NaN
50%            NaN        2.0     NaN
75%            NaN        2.5     NaN
max            NaN        3.0     NaN
```

Describing a column from a DataFrame by accessing it as an attribute.

```
>>> df.numeric.describe()
count    3.0
mean     2.0
std      1.0
min      1.0
25%     1.5
50%     2.0
75%     2.5
max      3.0
Name: numeric, dtype: float64
```

Including only numeric columns in a DataFrame description.

```
>>> df.describe(include=[np.number])
      numeric
count       3.0
mean        2.0
std         1.0
min         1.0
25%         1.5
50%         2.0
75%         2.5
max         3.0
```

Including only string columns in a DataFrame description.

```
>>> df.describe(include=[np.object])
      object
count       3
unique       3
```

(continues on next page)

(continued from previous page)

|      |   |
|------|---|
| top  | c |
| freq | 1 |

Including only categorical columns from a DataFrame description.

```
>>> df.describe(include=['category'])
      categorical
count          3
unique         3
top            f
freq           1
```

Excluding numeric columns from a DataFrame description.

```
>>> df.describe(exclude=[np.number])
      categorical  object
count          3      3
unique         3      3
top            f      c
freq           1      1
```

Excluding object columns from a DataFrame description.

```
>>> df.describe(exclude=[np.object])
      categorical  numeric
count          3      3.0
unique         3      NaN
top            f      NaN
freq           1      NaN
mean          NaN      2.0
std           NaN      1.0
min           NaN      1.0
25%           NaN      1.5
50%           NaN      2.0
75%           NaN      2.5
max           NaN      3.0
```

## pandas.Panel.div

`Panel.div(other, axis=0)`

Floating division of series and other, element-wise (binary operator *truediv*). Equivalent to `panel / other`.

### Parameters

**other** [DataFrame or Panel]

**axis** [{items, major\_axis, minor\_axis}] Axis to broadcast over

### Returns

**Panel**

**See also:**

`Panel.rtruediv`

**pandas.Panel.divide****Panel.divide** (*other*, *axis=0*)Floating division of series and other, element-wise (binary operator *truediv*). Equivalent to `panel / other`.**Parameters****other** [DataFrame or Panel]**axis** [{items, major\_axis, minor\_axis}] Axis to broadcast over**Returns****Panel****See also:***Panel.rtruediv***pandas.Panel.droplevel****Panel.droplevel** (*level*, *axis=0*)

Return DataFrame with requested index / column level(s) removed.

New in version 0.24.0.

**Parameters****level** [int, str, or list-like] If a string is given, must be the name of a level. If list-like, elements must be names or positional indexes of levels.**axis** [{0 or 'index', 1 or 'columns'}, default 0]**Returns****DataFrame.droplevel()****Examples**

```
>>> df = pd.DataFrame([
...     [1, 2, 3, 4],
...     [5, 6, 7, 8],
...     [9, 10, 11, 12]
... ]).set_index([0, 1]).rename_axis(['a', 'b'])
```

```
>>> df.columns = pd.MultiIndex.from_tuples([
...     ('c', 'e'), ('d', 'f')
... ], names=['level_1', 'level_2'])
```

```
>>> df
level_1  c  d
level_2  e  f
a b
1 2      3  4
5 6      7  8
9 10     11 12
```

```
>>> df.droplevel('a')
level_1  c    d
level_2  e    f
b
2         3    4
6         7    8
10        11   12
```

```
>>> df.droplevel('level2', axis=1)
level_1  c    d
a b
1 2         3    4
5 6         7    8
9 10        11   12
```

### pandas.Panel.dropna

`Panel.dropna` (*axis=0*, *how='any'*, *inplace=False*)

Drop 2D from panel, holding passed axis constant.

#### Parameters

**axis** [int, default 0] Axis to hold constant. E.g. `axis=1` will drop `major_axis` entries having a certain amount of NA data

**how** [{`'all'`, `'any'`}, default `'any'`] `'any'`: one or more values are NA in the DataFrame along the axis. For `'all'` they all must be.

**inplace** [bool, default False] If True, do operation inplace and return None.

#### Returns

**dropped** [Panel]

### pandas.Panel.eq

`Panel.eq` (*other*, *axis=None*)

Wrapper for comparison method `eq`

### pandas.Panel.equals

`Panel.equals` (*other*)

Test whether two objects contain the same elements.

This function allows two Series or DataFrames to be compared against each other to see if they have the same shape and elements. NaNs in the same location are considered equal. The column headers do not need to have the same type, but the elements within the columns must be the same dtype.

#### Parameters

**other** [Series or DataFrame] The other Series or DataFrame to be compared with the first.

#### Returns

**bool** True if all elements are the same in both objects, False otherwise.

See also:

**Series.eq** Compare two Series objects of the same length and return a Series where each element is True if the element in each Series is equal, False otherwise.

**DataFrame.eq** Compare two DataFrame objects of the same shape and return a DataFrame where each element is True if the respective element in each DataFrame is equal, False otherwise.

**assert\_series\_equal** Return True if left and right Series are equal, False otherwise.

**assert\_frame\_equal** Return True if left and right DataFrames are equal, False otherwise.

**numpy.array\_equal** Return True if two arrays have the same shape and elements, False otherwise.

## Notes

This function requires that the elements have the same dtype as their respective elements in the other Series or DataFrame. However, the column labels do not need to have the same type, as long as they are still considered equal.

## Examples

```
>>> df = pd.DataFrame({1: [10], 2: [20]})
>>> df
   1  2
0 10 20
```

DataFrames `df` and `exactly_equal` have the same types and values for their elements and column labels, which will return True.

```
>>> exactly_equal = pd.DataFrame({1: [10], 2: [20]})
>>> exactly_equal
   1  2
0 10 20
>>> df.equals(exactly_equal)
True
```

DataFrames `df` and `different_column_type` have the same element types and values, but have different types for the column labels, which will still return True.

```
>>> different_column_type = pd.DataFrame({1.0: [10], 2.0: [20]})
>>> different_column_type
   1.0  2.0
0   10   20
>>> df.equals(different_column_type)
True
```

DataFrames `df` and `different_data_type` have different types for the same values for their elements, and will return False even though their column labels are the same values and types.

```
>>> different_data_type = pd.DataFrame({1: [10.0], 2: [20.0]})
>>> different_data_type
   1  2
0 10.0 20.0
>>> df.equals(different_data_type)
False
```

**pandas.Panel.fffll**

`Panel.fffll` (*axis=None, inplace=False, limit=None, downcast=None*)  
 Synonym for `DataFrame.fillna()` with `method='fffll'`.

**pandas.Panel.fillna**

`Panel.fillna` (*value=None, method=None, axis=None, inplace=False, limit=None, downcast=None, \*\*kwargs*)  
 Fill NA/NaN values using the specified method.

**Parameters**

**value** [scalar, dict, Series, or DataFrame] Value to use to fill holes (e.g. 0), alternately a dict/Series/DataFrame of values specifying which value to use for each index (for a Series) or column (for a DataFrame). (values not in the dict/Series/DataFrame will not be filled). This value cannot be a list.

**method** [{‘backfill’, ‘bfill’, ‘pad’, ‘fffll’, None}, default None] Method to use for filling holes in reindexed Series `pad / ffffll`: propagate last valid observation forward to next valid `backfill / bfffll`: use NEXT valid observation to fill gap

**axis** [{0, 1, 2, ‘items’, ‘major\_axis’, ‘minor\_axis’}]

**inplace** [boolean, default False] If True, fill in place. Note: this will modify any other views on this object, (e.g. a no-copy slice for a column in a DataFrame).

**limit** [int, default None] If method is specified, this is the maximum number of consecutive NaN values to forward/backward fill. In other words, if there is a gap with more than this number of consecutive NaNs, it will only be partially filled. If method is not specified, this is the maximum number of entries along the entire axis where NaNs will be filled. Must be greater than 0 if not None.

**downcast** [dict, default is None] a dict of item->dtype of what to downcast if possible, or the string ‘infer’ which will try to downcast to an appropriate equal type (e.g. float64 to int64 if possible)

**Returns**

**filled** [Panel]

See also:

**interpolate** Fill NaN values using interpolation.

*reindex, asfreq*

**Examples**

```
>>> df = pd.DataFrame([[np.nan, 2, np.nan, 0],
...                    [3, 4, np.nan, 1],
...                    [np.nan, np.nan, np.nan, 5],
...                    [np.nan, 3, np.nan, 4]],
...                    columns=list('ABCD'))
>>> df
   A    B    C    D
0 NaN  2.0 NaN    0
```

(continues on next page)

(continued from previous page)

|   |     |     |     |   |
|---|-----|-----|-----|---|
| 1 | 3.0 | 4.0 | NaN | 1 |
| 2 | NaN | NaN | NaN | 5 |
| 3 | NaN | 3.0 | NaN | 4 |

Replace all NaN elements with 0s.

```
>>> df.fillna(0)
   A    B    C    D
0  0.0  2.0  0.0  0
1  3.0  4.0  0.0  1
2  0.0  0.0  0.0  5
3  0.0  3.0  0.0  4
```

We can also propagate non-null values forward or backward.

```
>>> df.fillna(method='ffill')
   A    B    C    D
0  NaN  2.0  NaN  0
1  3.0  4.0  NaN  1
2  3.0  4.0  NaN  5
3  3.0  3.0  NaN  4
```

Replace all NaN elements in column 'A', 'B', 'C', and 'D', with 0, 1, 2, and 3 respectively.

```
>>> values = {'A': 0, 'B': 1, 'C': 2, 'D': 3}
>>> df.fillna(value=values)
   A    B    C    D
0  0.0  2.0  2.0  0
1  3.0  4.0  2.0  1
2  0.0  1.0  2.0  5
3  0.0  3.0  2.0  4
```

Only replace the first NaN element.

```
>>> df.fillna(value=values, limit=1)
   A    B    C    D
0  0.0  2.0  2.0  0
1  3.0  4.0  NaN  1
2  NaN  1.0  NaN  5
3  NaN  3.0  NaN  4
```

## pandas.Panel.filter

`Panel.filter` (*items=None, like=None, regex=None, axis=None*)

Subset rows or columns of dataframe according to labels in the specified index.

Note that this routine does not filter a dataframe on its contents. The filter is applied to the labels of the index.

### Parameters

**items** [list-like] List of axis to restrict to (must not all be present).

**like** [string] Keep axis where “arg in col == True”.

**regex** [string (regular expression)] Keep axis with `re.search(regex, col) == True`.

**axis** [int or string axis name] The axis to filter on. By default this is the info axis, ‘index’ for Series, ‘columns’ for DataFrame.

### Returns

same type as input object

### See also:

`DataFrame.loc`

### Notes

The `items`, `like`, and `regex` parameters are enforced to be mutually exclusive.

`axis` defaults to the info axis that is used when indexing with `[]`.

### Examples

```
>>> df = pd.DataFrame(np.array([[1,2,3], [4,5,6]]),
...                    index=['mouse', 'rabbit'],
...                    columns=['one', 'two', 'three'])
```

```
>>> # select columns by name
>>> df.filter(items=['one', 'three'])
      one  three
mouse    1     3
rabbit    4     6
```

```
>>> # select columns by regular expression
>>> df.filter(regex='e$', axis=1)
      one  three
mouse    1     3
rabbit    4     6
```

```
>>> # select rows containing 'bbi'
>>> df.filter(like='bbi', axis=0)
      one  two  three
rabbit    4    5     6
```

## pandas.Panel.first

`Panel.first` (*offset*)

Convenience method for subsetting initial periods of time series data based on a date offset.

### Parameters

**offset** [string, `DateOffset`, `dateutil.relativedelta`]

### Returns

**subset** [same type as caller]

### Raises

**TypeError** If the index is not a `DatetimeIndex`

See also:

**last** Select final periods of time series based on a date offset.

**at\_time** Select values at a particular time of the day.

**between\_time** Select values between particular times of the day.

## Examples

```
>>> i = pd.date_range('2018-04-09', periods=4, freq='2D')
>>> ts = pd.DataFrame({'A': [1,2,3,4]}, index=i)
>>> ts
```

|            | A |
|------------|---|
| 2018-04-09 | 1 |
| 2018-04-11 | 2 |
| 2018-04-13 | 3 |
| 2018-04-15 | 4 |

Get the rows for the first 3 days:

```
>>> ts.first('3D')
```

|            | A |
|------------|---|
| 2018-04-09 | 1 |
| 2018-04-11 | 2 |

Notice the data for 3 first calendar days were returned, not the first 3 days observed in the dataset, and therefore data for 2018-04-13 was not returned.

## pandas.Panel.first\_valid\_index

`Panel.first_valid_index()`  
Return index for first non-NA/null value.

### Returns

**scalar** [type of index]

## Notes

If all elements are non-NA/null, returns None. Also returns None for empty NDFrame.

## pandas.Panel.floordiv

`Panel.floordiv(other, axis=0)`  
Integer division of series and other, element-wise (binary operator *floordiv*). Equivalent to `panel // other`.

### Parameters

**other** [DataFrame or Panel]

**axis** [{items, major\_axis, minor\_axis}] Axis to broadcast over

### Returns

## Panel

See also:

`Panel.rfloordiv`

### pandas.Panel.fromDict

**classmethod** `Panel.fromDict` (*data*, *intersect=False*, *orient='items'*, *dtype=None*)

Construct Panel from dict of DataFrame objects.

#### Parameters

**data** [dict] {field : DataFrame}

**intersect** [boolean] Intersect indexes of input DataFrames

**orient** [{ 'items', 'minor' }, default 'items'] The “orientation” of the data. If the keys of the passed dict should be the items of the result panel, pass 'items' (default). Otherwise if the columns of the values of the passed DataFrame objects should be the items (which in the case of mixed-dtype data you should do), instead pass 'minor'

**dtype** [dtype, default None] Data type to force, otherwise infer

#### Returns

**Panel**

### pandas.Panel.from\_dict

**classmethod** `Panel.from_dict` (*data*, *intersect=False*, *orient='items'*, *dtype=None*)

Construct Panel from dict of DataFrame objects.

#### Parameters

**data** [dict] {field : DataFrame}

**intersect** [boolean] Intersect indexes of input DataFrames

**orient** [{ 'items', 'minor' }, default 'items'] The “orientation” of the data. If the keys of the passed dict should be the items of the result panel, pass 'items' (default). Otherwise if the columns of the values of the passed DataFrame objects should be the items (which in the case of mixed-dtype data you should do), instead pass 'minor'

**dtype** [dtype, default None] Data type to force, otherwise infer

#### Returns

**Panel**

### pandas.Panel.ge

`Panel.ge` (*other*, *axis=None*)

Wrapper for comparison method ge

**pandas.Panel.get****Panel.get** (*key*, *default=None*)

Get item from object for given key (DataFrame column, Panel slice, etc.). Returns default value if not found.

**Parameters****key** [object]**Returns****value** [same type as items contained in object]**pandas.Panel.get\_dtype\_counts****Panel.get\_dtype\_counts** ()

Return counts of unique dtypes in this object.

**Returns****dtype** [Series] Series with the count of columns with each dtype.**See also:****dtypes** Return the dtypes in this object.**Examples**

```
>>> a = [['a', 1, 1.0], ['b', 2, 2.0], ['c', 3, 3.0]]
>>> df = pd.DataFrame(a, columns=['str', 'int', 'float'])
>>> df
   str  int  float
0   a    1    1.0
1   b    2    2.0
2   c    3    3.0
```

```
>>> df.get_dtype_counts()
float64    1
int64      1
object     1
dtype: int64
```

**pandas.Panel.get\_ftype\_counts****Panel.get\_ftype\_counts** ()

Return counts of unique ftypes in this object.

Deprecated since version 0.23.0.

This is useful for SparseDataFrame or for DataFrames containing sparse arrays.

**Returns****dtype** [Series] Series with the count of columns with each type and sparsity (dense/sparse)

See also:

**ftypes** Return ftypes (indication of sparse/dense and dtype) in this object.

### Examples

```
>>> a = [['a', 1, 1.0], ['b', 2, 2.0], ['c', 3, 3.0]]
>>> df = pd.DataFrame(a, columns=['str', 'int', 'float'])
>>> df
   str  int  float
0   a    1   1.0
1   b    2   2.0
2   c    3   3.0
```

```
>>> df.get_ftype_counts() # doctest: +SKIP
float64:dense    1
int64:dense      1
object:dense     1
dtype: int64
```

### pandas.Panel.get\_value

`Panel.get_value(*args, **kwargs)`

Quickly retrieve single value at (item, major, minor) location.

Deprecated since version 0.21.0.

Please use `.at[]` or `.iat[]` accessors.

#### Parameters

**item** [item label (panel item)]

**major** [major axis label (panel item row)]

**minor** [minor axis label (panel item column)]

**takeable** [interpret the passed labels as indexers, default False]

#### Returns

**value** [scalar value]

### pandas.Panel.get\_values

`Panel.get_values()`

Return an ndarray after converting sparse values to dense.

This is the same as `.values` for non-sparse data. For sparse data contained in a *pandas.SparseArray*, the data are first converted to a dense representation.

#### Returns

**numpy.ndarray** Numpy representation of DataFrame

See also:

**values** Numpy representation of DataFrame.

**pandas.SparseArray** Container for sparse data.

## Examples

```
>>> df = pd.DataFrame({'a': [1, 2], 'b': [True, False],
...                     'c': [1.0, 2.0]})
>>> df
   a    b    c
0  1  True  1.0
1  2 False  2.0
```

```
>>> df.get_values()
array([[1, True, 1.0], [2, False, 2.0]], dtype=object)
```

```
>>> df = pd.DataFrame({"a": pd.SparseArray([1, None, None]),
...                     "c": [1.0, 2.0, 3.0]})
>>> df
   a    c
0  1.0  1.0
1  NaN  2.0
2  NaN  3.0
```

```
>>> df.get_values()
array([[ 1.,  1.],
       [nan,  2.],
       [nan,  3.]])
```

## pandas.Panel.groupby

**Panel.groupby** (*function*, *axis*=*'major'*)  
Group data on given axis, returning GroupBy object.

### Parameters

**function** [callable] Mapping function for chosen access  
**axis** [{*'major'*, *'minor'*, *'items'*}, default *'major'*]

### Returns

**grouped** [PanelGroupBy]

## pandas.Panel.gt

**Panel.gt** (*other*, *axis*=*None*)  
Wrapper for comparison method gt

## pandas.Panel.head

**Panel.head** (*n*=5)  
Return the first *n* rows.

This function returns the first *n* rows for the object based on position. It is useful for quickly testing if your object has the right type of data in it.

**Parameters**

**n** [int, default 5] Number of rows to select.

**Returns**

**obj\_head** [same type as caller] The first *n* rows of the caller object.

**See also:**

**DataFrame.tail** Returns the last *n* rows.

**Examples**

```
>>> df = pd.DataFrame({'animal': ['alligator', 'bee', 'falcon', 'lion',  
...                               'monkey', 'parrot', 'shark', 'whale', 'zebra']})  
>>> df  
   animal  
0  alligator  
1     bee  
2   falcon  
3    lion  
4   monkey  
5   parrot  
6    shark  
7   whale  
8    zebra
```

**Viewing the first 5 lines**

```
>>> df.head()  
   animal  
0  alligator  
1     bee  
2   falcon  
3    lion  
4   monkey
```

**Viewing the first *n* lines (three in this case)**

```
>>> df.head(3)  
   animal  
0  alligator  
1     bee  
2   falcon
```

**pandas.Panel.infer\_objects****Panel.infer\_objects()**

Attempt to infer better dtypes for object columns.

Attempts soft conversion of object-dtyped columns, leaving non-object and unconvertible columns unchanged. The inference rules are the same as during normal Series/DataFrame construction.

New in version 0.21.0.

**Returns**

**converted** [same type as input object]

See also:

**to\_datetime** Convert argument to datetime.

**to\_timedelta** Convert argument to timedelta.

**to\_numeric** Convert argument to numeric type.

## Examples

```
>>> df = pd.DataFrame({"A": ["a", 1, 2, 3]})
>>> df = df.iloc[1:]
>>> df
   A
1  1
2  2
3  3
```

```
>>> df.dtypes
A    object
dtype: object
```

```
>>> df.infer_objects().dtypes
A    int64
dtype: object
```

## pandas.Panel.interpolate

`Panel.interpolate` (*method='linear', axis=0, limit=None, inplace=False, limit\_direction='forward', limit\_area=None, downcast=None, \*\*kwargs*)  
Interpolate values according to different methods.

Please note that only `method='linear'` is supported for DataFrame/Series with a MultiIndex.

### Parameters

**method** [str, default 'linear'] Interpolation technique to use. One of:

- 'linear': Ignore the index and treat the values as equally spaced. This is the only method supported on MultiIndexes.
- 'time': Works on daily and higher resolution data to interpolate given length of interval.
- 'index', 'values': use the actual numerical values of the index.
- 'pad': Fill in NaNs using existing values.
- 'nearest', 'zero', 'slinear', 'quadratic', 'cubic', 'spline', 'barycentric', 'polynomial': Passed to `scipy.interpolate.interpld`. Both 'polynomial' and 'spline' require that you also specify an *order* (int), e.g. `df.interpolate(method='polynomial', order=4)`. These use the numerical values of the index.
- 'krogh', 'piecewise\_polynomial', 'spline', 'pchip', 'akima': Wrappers around the SciPy interpolation methods of similar names. See *Notes*.

- ‘from\_derivatives’: Refers to `scipy.interpolate.BPoly.from_derivatives` which replaces ‘piecewise\_polynomial’ interpolation method in scipy 0.18.

New in version 0.18.1: Added support for the ‘akima’ method. Added interpolate method ‘from\_derivatives’ which replaces ‘piecewise\_polynomial’ in SciPy 0.18; backwards-compatible with SciPy < 0.18

**axis** [{0 or ‘index’, 1 or ‘columns’, None}, default None] Axis to interpolate along.

**limit** [int, optional] Maximum number of consecutive NaNs to fill. Must be greater than 0.

**inplace** [bool, default False] Update the data in place if possible.

**limit\_direction** [{‘forward’, ‘backward’, ‘both’}, default ‘forward’] If limit is specified, consecutive NaNs will be filled in this direction.

**limit\_area** [{None, ‘inside’, ‘outside’}, default None] If limit is specified, consecutive NaNs will be filled with this restriction.

- None: No fill restriction.
- ‘inside’: Only fill NaNs surrounded by valid values (interpolate).
- ‘outside’: Only fill NaNs outside valid values (extrapolate).

New in version 0.21.0.

**downcast** [optional, ‘infer’ or None, defaults to None] Downcast dtypes if possible.

**\*\*kwargs** Keyword arguments to pass on to the interpolating function.

### Returns

**Series or DataFrame** Returns the same object type as the caller, interpolated at some or all NaN values

### See also:

**fillna** Fill missing values using different methods.

**scipy.interpolate.Akima1DInterpolator** Piecewise cubic polynomials (Akima interpolator).

**scipy.interpolate.BPoly.from\_derivatives** Piecewise polynomial in the Bernstein basis.

**scipy.interpolate.interpld** Interpolate a 1-D function.

**scipy.interpolate.KroghInterpolator** Interpolate polynomial (Krogh interpolator).

**scipy.interpolate.PchipInterpolator** PCHIP 1-d monotonic cubic interpolation.

**scipy.interpolate.CubicSpline** Cubic spline data interpolator.

### Notes

The ‘krogh’, ‘piecewise\_polynomial’, ‘spline’, ‘pchip’ and ‘akima’ methods are wrappers around the respective SciPy implementations of similar names. These use the actual numerical values of the index. For more information on their behavior, see the [SciPy documentation](#) and [SciPy tutorial](#).

## Examples

Filling in NaN in a *Series* via linear interpolation.

```
>>> s = pd.Series([0, 1, np.nan, 3])
>>> s
0    0.0
1    1.0
2    NaN
3    3.0
dtype: float64
>>> s.interpolate()
0    0.0
1    1.0
2    2.0
3    3.0
dtype: float64
```

Filling in NaN in a *Series* by padding, but filling at most two consecutive NaN at a time.

```
>>> s = pd.Series([np.nan, "single_one", np.nan,
...                "fill_two_more", np.nan, np.nan, np.nan,
...                4.71, np.nan])
>>> s
0          NaN
1    single_one
2          NaN
3    fill_two_more
4          NaN
5          NaN
6          NaN
7          4.71
8          NaN
dtype: object
>>> s.interpolate(method='pad', limit=2)
0          NaN
1    single_one
2    single_one
3    fill_two_more
4    fill_two_more
5    fill_two_more
6          NaN
7          4.71
8          4.71
dtype: object
```

Filling in NaN in a *Series* via polynomial interpolation or splines: Both ‘polynomial’ and ‘spline’ methods require that you also specify an `order` (int).

```
>>> s = pd.Series([0, 2, np.nan, 8])
>>> s.interpolate(method='polynomial', order=2)
0    0.000000
1    2.000000
2    4.666667
3    8.000000
dtype: float64
```

Fill the *DataFrame* forward (that is, going down) along each column using linear interpolation.

Note how the last entry in column ‘a’ is interpolated differently, because there is no entry after it to use for interpolation. Note how the first entry in column ‘b’ remains NaN, because there is no entry before it to use for interpolation.

```
>>> df = pd.DataFrame([(0.0, np.nan, -1.0, 1.0),
...                    (np.nan, 2.0, np.nan, np.nan),
...                    (2.0, 3.0, np.nan, 9.0),
...                    (np.nan, 4.0, -4.0, 16.0)],
...                    columns=list('abcd'))
>>> df
   a    b    c    d
0  0.0 NaN -1.0  1.0
1  NaN  2.0 NaN  NaN
2  2.0  3.0 NaN  9.0
3  NaN  4.0 -4.0 16.0
>>> df.interpolate(method='linear', limit_direction='forward', axis=0)
   a    b    c    d
0  0.0 NaN -1.0  1.0
1  1.0  2.0 -2.0  5.0
2  2.0  3.0 -3.0  9.0
3  2.0  4.0 -4.0 16.0
```

Using polynomial interpolation.

```
>>> df['d'].interpolate(method='polynomial', order=2)
0    1.0
1    4.0
2    9.0
3   16.0
Name: d, dtype: float64
```

## pandas.Panel.isna

`Panel.isna()`

Detect missing values.

Return a boolean same-sized object indicating if the values are NA. NA values, such as `None` or `numpy.NaN`, gets mapped to `True` values. Everything else gets mapped to `False` values. Characters such as empty strings `''` or `numpy.inf` are not considered NA values (unless you set `pandas.options.mode.use_inf_as_na = True`).

### Returns

**NDFrame** Mask of bool values for each element in NDFrame that indicates whether an element is not an NA value.

See also:

**NDFrame.isnull** Alias of `isna`.

**NDFrame.notna** Boolean inverse of `isna`.

**NDFrame.dropna** Omit axes labels with missing values.

**isna** Top-level `isna`.

## Examples

Show which entries in a DataFrame are NA.

```
>>> df = pd.DataFrame({'age': [5, 6, np.NaN],
...                     'born': [pd.NaT, pd.Timestamp('1939-05-27'),
...                               pd.Timestamp('1940-04-25')],
...                     'name': ['Alfred', 'Batman', ''],
...                     'toy': [None, 'Batmobile', 'Joker']})
>>> df
   age      born   name    toy
0  5.0      NaT  Alfred  None
1  6.0 1939-05-27  Batman Batmobile
2  NaN 1940-04-25      Joker
```

```
>>> df.isna()
   age  born  name  toy
0 False  True False  True
1 False False False False
2  True False False False
```

Show which entries in a Series are NA.

```
>>> ser = pd.Series([5, 6, np.NaN])
>>> ser
0    5.0
1    6.0
2    NaN
dtype: float64
```

```
>>> ser.isna()
0    False
1    False
2     True
dtype: bool
```

## pandas.Panel.isnull

`Panel.isnull()`

Detect missing values.

Return a boolean same-sized object indicating if the values are NA. NA values, such as `None` or `numpy.NaN`, gets mapped to `True` values. Everything else gets mapped to `False` values. Characters such as empty strings `' '` or `numpy.inf` are not considered NA values (unless you set `pandas.options.mode.use_inf_as_na = True`).

### Returns

**NDFrame** Mask of bool values for each element in NDFrame that indicates whether an element is not an NA value.

See also:

**NDFrame.isnull** Alias of `isna`.

**NDFrame.notna** Boolean inverse of `isna`.

**NDFrame.dropna** Omit axes labels with missing values.

**isna** Top-level isna.

## Examples

Show which entries in a DataFrame are NA.

```
>>> df = pd.DataFrame({'age': [5, 6, np.NaN],
...                    'born': [pd.NaT, pd.Timestamp('1939-05-27'),
...                             pd.Timestamp('1940-04-25')],
...                    'name': ['Alfred', 'Batman', ''],
...                    'toy': [None, 'Batmobile', 'Joker']})
>>> df
   age      born    name    toy
0  5.0      NaT  Alfred    None
1  6.0 1939-05-27  Batman  Batmobile
2  NaN 1940-04-25     Joker    Joker
```

```
>>> df.isna()
   age  born  name  toy
0 False  True False  True
1 False False False False
2  True False False False
```

Show which entries in a Series are NA.

```
>>> ser = pd.Series([5, 6, np.NaN])
>>> ser
0    5.0
1    6.0
2    NaN
dtype: float64
```

```
>>> ser.isna()
0    False
1    False
2     True
dtype: bool
```

## pandas.Panel.iteritems

**Panel.iteritems()**

Iterate over (label, values) on info axis

This is index for Series, columns for DataFrame, major\_axis for Panel, and so on.

## pandas.Panel.join

**Panel.join**(other, how='left', lsuffix="", rsuffix="")

Join items with other Panel either on major and minor axes column.

### Parameters

**other** [Panel or list of Panels] Index should be similar to one of the columns in this one

**how** [{ 'left', 'right', 'outer', 'inner' }] How to handle indexes of the two objects. Default: 'left' for joining on index, None otherwise \* left: use calling frame's index \* right: use input frame's index \* outer: form union of indexes \* inner: use intersection of indexes

**lsuffix** [string] Suffix to use from left frame's overlapping columns

**rsuffix** [string] Suffix to use from right frame's overlapping columns

### Returns

**joined** [Panel]

## pandas.Panel.keys

`Panel.keys()`

Get the 'info axis' (see Indexing for more)

This is index for Series, columns for DataFrame and major\_axis for Panel.

## pandas.Panel.kurt

`Panel.kurt(axis=None, skipna=None, level=None, numeric_only=None, **kwargs)`

Return unbiased kurtosis over requested axis using Fisher's definition of kurtosis (kurtosis of normal == 0.0). Normalized by N-1.

### Parameters

**axis** [{items (0), major\_axis (1), minor\_axis (2)}] Axis for the function to be applied on.

**skipna** [bool, default True] Exclude NA/null values when computing the result.

**level** [int or level name, default None] If the axis is a MultiIndex (hierarchical), count along a particular level, collapsing into a DataFrame.

**numeric\_only** [bool, default None] Include only float, int, boolean columns. If None, will attempt to use everything, then use only numeric data. Not implemented for Series.

**\*\*kwargs** Additional keyword arguments to be passed to the function.

### Returns

**kurt** [DataFrame or Panel (if level specified)]

## pandas.Panel.kurtosis

`Panel.kurtosis(axis=None, skipna=None, level=None, numeric_only=None, **kwargs)`

Return unbiased kurtosis over requested axis using Fisher's definition of kurtosis (kurtosis of normal == 0.0). Normalized by N-1.

### Parameters

**axis** [{items (0), major\_axis (1), minor\_axis (2)}] Axis for the function to be applied on.

**skipna** [bool, default True] Exclude NA/null values when computing the result.

**level** [int or level name, default None] If the axis is a MultiIndex (hierarchical), count along a particular level, collapsing into a DataFrame.

**numeric\_only** [bool, default None] Include only float, int, boolean columns. If None, will attempt to use everything, then use only numeric data. Not implemented for Series.

**\*\*kwargs** Additional keyword arguments to be passed to the function.

### Returns

**kurt** [DataFrame or Panel (if level specified)]

## pandas.Panel.last

`Panel.last` (*offset*)

Convenience method for subsetting final periods of time series data based on a date offset.

### Parameters

**offset** [string, DateOffset, dateutil.relativedelta]

### Returns

**subset** [same type as caller]

### Raises

**TypeError** If the index is not a *DatetimeIndex*

### See also:

**first** Select initial periods of time series based on a date offset.

**at\_time** Select values at a particular time of the day.

**between\_time** Select values between particular times of the day.

## Examples

```
>>> i = pd.date_range('2018-04-09', periods=4, freq='2D')
>>> ts = pd.DataFrame({'A': [1,2,3,4]}, index=i)
>>> ts
              A
2018-04-09    1
2018-04-11    2
2018-04-13    3
2018-04-15    4
```

Get the rows for the last 3 days:

```
>>> ts.last('3D')
              A
2018-04-13    3
2018-04-15    4
```

Notice the data for 3 last calendar days were returned, not the last 3 observed days in the dataset, and therefore data for 2018-04-11 was not returned.

### pandas.Panel.last\_valid\_index

`Panel.last_valid_index()`  
Return index for last non-NA/null value.

#### Returns

**scalar** [type of index]

#### Notes

If all elements are non-NA/null, returns None. Also returns None for empty NDFrame.

### pandas.Panel.le

`Panel.le(other, axis=None)`  
Wrapper for comparison method le

### pandas.Panel.lt

`Panel.lt(other, axis=None)`  
Wrapper for comparison method lt

### pandas.Panel.mad

`Panel.mad(axis=None, skipna=None, level=None)`  
Return the mean absolute deviation of the values for the requested axis.

#### Parameters

**axis** [{items (0), major\_axis (1), minor\_axis (2)}] Axis for the function to be applied on.

**skipna** [bool, default True] Exclude NA/null values when computing the result.

**level** [int or level name, default None] If the axis is a MultiIndex (hierarchical), count along a particular level, collapsing into a DataFrame.

**numeric\_only** [bool, default None] Include only float, int, boolean columns. If None, will attempt to use everything, then use only numeric data. Not implemented for Series.

**\*\*kwargs** Additional keyword arguments to be passed to the function.

#### Returns

**mad** [DataFrame or Panel (if level specified)]

### pandas.Panel.major\_xs

`Panel.major_xs(key)`  
Return slice of panel along major axis.

#### Parameters

**key** [object] Major axis label

**Returns**

**y** [DataFrame] index -> minor axis, columns -> items

**Notes**

major\_xs is only for getting, not setting values.

MultiIndex Slicers is a generic way to get/set values on any level or levels and is a superset of major\_xs functionality, see *MultiIndex Slicers*

**pandas.Panel.mask**

`Panel.mask(cond, other=nan, inplace=False, axis=None, level=None, errors='raise', try_cast=False, raise_on_error=None)`

Replace values where the condition is True.

**Parameters**

**cond** [boolean NDFrame, array-like, or callable] Where *cond* is False, keep the original value. Where True, replace with corresponding value from *other*. If *cond* is callable, it is computed on the NDFrame and should return boolean NDFrame or array. The callable must not change input NDFrame (though pandas doesn't check it).

New in version 0.18.1: A callable can be used as cond.

**other** [scalar, NDFrame, or callable] Entries where *cond* is True are replaced with corresponding value from *other*. If *other* is callable, it is computed on the NDFrame and should return scalar or NDFrame. The callable must not change input NDFrame (though pandas doesn't check it).

New in version 0.18.1: A callable can be used as other.

**inplace** [boolean, default False] Whether to perform the operation in place on the data.

**axis** [int, default None] Alignment axis if needed.

**level** [int, default None] Alignment level if needed.

**errors** [str, {'raise', 'ignore'}, default *raise*] Note that currently this parameter won't affect the results and will always coerce to a suitable dtype.

- *raise* : allow exceptions to be raised.
- *ignore* : suppress exceptions. On error return original object.

**try\_cast** [boolean, default False] Try to cast the result back to the input type (if possible).

**raise\_on\_error** [boolean, default True] Whether to raise on invalid data types (e.g. trying to where on strings).

Deprecated since version 0.21.0: Use *errors*.

**Returns**

**wh** [same type as caller]

See also:

**DataFrame.where()** Return an object of same shape as self.

## Notes

The mask method is an application of the if-then idiom. For each element in the calling DataFrame, if `cond` is `False` the element is used; otherwise the corresponding element from the DataFrame `other` is used.

The signature for `DataFrame.where()` differs from `numpy.where()`. Roughly `df1.where(m, df2)` is equivalent to `np.where(m, df1, df2)`.

For further details and examples see the mask documentation in *indexing*.

## Examples

```
>>> s = pd.Series(range(5))
>>> s.where(s > 0)
0    NaN
1    1.0
2    2.0
3    3.0
4    4.0
dtype: float64
```

```
>>> s.mask(s > 0)
0    0.0
1    NaN
2    NaN
3    NaN
4    NaN
dtype: float64
```

```
>>> s.where(s > 1, 10)
0    10
1    10
2     2
3     3
4     4
dtype: int64
```

```
>>> df = pd.DataFrame(np.arange(10).reshape(-1, 2), columns=['A', 'B'])
>>> m = df % 3 == 0
>>> df.where(m, -df)
   A  B
0  0 -1
1 -2  3
2 -4 -5
3  6 -7
4 -8  9
>>> df.where(m, -df) == np.where(m, df, -df)
   A    B
0  True  True
1  True  True
2  True  True
3  True  True
4  True  True
>>> df.where(m, -df) == df.mask(~m, -df)
   A    B
```

(continues on next page)

(continued from previous page)

```
0  True  True
1  True  True
2  True  True
3  True  True
4  True  True
```

## pandas.Panel.max

Panel.**max** (*axis=None, skipna=None, level=None, numeric\_only=None, \*\*kwargs*)

Return the maximum of the values for the requested axis.

If you want the *index* of the maximum, use `idxmax`. This is the equivalent of the `numpy.ndarray` method `argmax`.

### Parameters

**axis** [{items (0), major\_axis (1), minor\_axis (2)}] Axis for the function to be applied on.

**skipna** [bool, default True] Exclude NA/null values when computing the result.

**level** [int or level name, default None] If the axis is a MultiIndex (hierarchical), count along a particular level, collapsing into a DataFrame.

**numeric\_only** [bool, default None] Include only float, int, boolean columns. If None, will attempt to use everything, then use only numeric data. Not implemented for Series.

**\*\*kwargs** Additional keyword arguments to be passed to the function.

### Returns

**max** [DataFrame or Panel (if level specified)]

### See also:

**Series.sum** Return the sum.

**Series.min** Return the minimum.

**Series.max** Return the maximum.

**Series.idxmin** Return the index of the minimum.

**Series.idxmax** Return the index of the maximum.

**DataFrame.min** Return the sum over the requested axis.

**DataFrame.min** Return the minimum over the requested axis.

**DataFrame.max** Return the maximum over the requested axis.

**DataFrame.idxmin** Return the index of the minimum over the requested axis.

**DataFrame.idxmax** Return the index of the maximum over the requested axis.

## Examples

```
>>> idx = pd.MultiIndex.from_arrays([
...     ['warm', 'warm', 'cold', 'cold'],
...     ['dog', 'falcon', 'fish', 'spider']],
...     names=['blooded', 'animal'])
>>> s = pd.Series([4, 2, 0, 8], name='legs', index=idx)
>>> s
blooded  animal
warm     dog      4
         falcon   2
cold     fish     0
         spider   8
Name: legs, dtype: int64
```

```
>>> s.max()
8
```

Max using level names, as well as indices.

```
>>> s.max(level='blooded')
blooded
warm     4
cold     8
Name: legs, dtype: int64
```

```
>>> s.max(level=0)
blooded
warm     4
cold     8
Name: legs, dtype: int64
```

## pandas.Panel.mean

`Panel.mean` (*axis=None, skipna=None, level=None, numeric\_only=None, \*\*kwargs*)

Return the mean of the values for the requested axis.

### Parameters

**axis** [{items (0), major\_axis (1), minor\_axis (2)}] Axis for the function to be applied on.

**skipna** [bool, default True] Exclude NA/null values when computing the result.

**level** [int or level name, default None] If the axis is a MultiIndex (hierarchical), count along a particular level, collapsing into a DataFrame.

**numeric\_only** [bool, default None] Include only float, int, boolean columns. If None, will attempt to use everything, then use only numeric data. Not implemented for Series.

**\*\*kwargs** Additional keyword arguments to be passed to the function.

### Returns

**mean** [DataFrame or Panel (if level specified)]

### pandas.Panel.median

`Panel.median` (*axis=None, skipna=None, level=None, numeric\_only=None, \*\*kwargs*)

Return the median of the values for the requested axis.

#### Parameters

**axis** [{items (0), major\_axis (1), minor\_axis (2)}] Axis for the function to be applied on.

**skipna** [bool, default True] Exclude NA/null values when computing the result.

**level** [int or level name, default None] If the axis is a MultiIndex (hierarchical), count along a particular level, collapsing into a DataFrame.

**numeric\_only** [bool, default None] Include only float, int, boolean columns. If None, will attempt to use everything, then use only numeric data. Not implemented for Series.

**\*\*kwargs** Additional keyword arguments to be passed to the function.

#### Returns

**median** [DataFrame or Panel (if level specified)]

### pandas.Panel.min

`Panel.min` (*axis=None, skipna=None, level=None, numeric\_only=None, \*\*kwargs*)

Return the minimum of the values for the requested axis.

If you want the *index* of the minimum, use `idxmin`. This is the equivalent of the `numpy.ndarray` method `argmin`.

#### Parameters

**axis** [{items (0), major\_axis (1), minor\_axis (2)}] Axis for the function to be applied on.

**skipna** [bool, default True] Exclude NA/null values when computing the result.

**level** [int or level name, default None] If the axis is a MultiIndex (hierarchical), count along a particular level, collapsing into a DataFrame.

**numeric\_only** [bool, default None] Include only float, int, boolean columns. If None, will attempt to use everything, then use only numeric data. Not implemented for Series.

**\*\*kwargs** Additional keyword arguments to be passed to the function.

#### Returns

**min** [DataFrame or Panel (if level specified)]

#### See also:

**Series.sum** Return the sum.

**Series.min** Return the minimum.

**Series.max** Return the maximum.

**Series.idxmin** Return the index of the minimum.

**Series.idxmax** Return the index of the maximum.

**DataFrame.min** Return the sum over the requested axis.

**DataFrame.min** Return the minimum over the requested axis.

**DataFrame.max** Return the maximum over the requested axis.

**DataFrame.idxmin** Return the index of the minimum over the requested axis.

**DataFrame.idxmax** Return the index of the maximum over the requested axis.

## Examples

```
>>> idx = pd.MultiIndex.from_arrays([
...     ['warm', 'warm', 'cold', 'cold'],
...     ['dog', 'falcon', 'fish', 'spider']],
...     names=['blooded', 'animal'])
>>> s = pd.Series([4, 2, 0, 8], name='legs', index=idx)
>>> s
blooded  animal
warm     dog      4
         falcon   2
cold     fish     0
         spider   8
Name: legs, dtype: int64
```

```
>>> s.min()
0
```

Min using level names, as well as indices.

```
>>> s.min(level='blooded')
blooded
warm     2
cold     0
Name: legs, dtype: int64
```

```
>>> s.min(level=0)
blooded
warm     2
cold     0
Name: legs, dtype: int64
```

## pandas.Panel.minor\_xs

**Panel.minor\_xs** (*key*)

Return slice of panel along minor axis.

### Parameters

**key** [object] Minor axis label

### Returns

**y** [DataFrame] index -> major axis, columns -> items

## Notes

`minor_xs` is only for getting, not setting values.

`MultiIndex Slicers` is a generic way to get/set values on any level or levels and is a superset of `minor_xs` functionality, see *MultiIndex Slicers*

## pandas.Panel.mod

`Panel.mod(other, axis=0)`

Modulo of series and other, element-wise (binary operator *mod*). Equivalent to `panel % other`.

### Parameters

**other** [DataFrame or Panel]

**axis** [{items, major\_axis, minor\_axis}] Axis to broadcast over

### Returns

**Panel**

### See also:

`Panel.rmod`

## pandas.Panel.mul

`Panel.mul(other, axis=0)`

Multiplication of series and other, element-wise (binary operator *mul*). Equivalent to `panel * other`.

### Parameters

**other** [DataFrame or Panel]

**axis** [{items, major\_axis, minor\_axis}] Axis to broadcast over

### Returns

**Panel**

### See also:

`Panel.rmul`

## pandas.Panel.multiply

`Panel.multiply(other, axis=0)`

Multiplication of series and other, element-wise (binary operator *mul*). Equivalent to `panel * other`.

### Parameters

**other** [DataFrame or Panel]

**axis** [{items, major\_axis, minor\_axis}] Axis to broadcast over

### Returns

**Panel**

See also:

`Panel.rmul`

## `pandas.Panel.ne`

`Panel.ne` (*other*, *axis=None*)

Wrapper for comparison method `ne`

## `pandas.Panel.notna`

`Panel.notna` ()

Detect existing (non-missing) values.

Return a boolean same-sized object indicating if the values are not NA. Non-missing values get mapped to True. Characters such as empty strings '' or `numpy.inf` are not considered NA values (unless you set `pandas.options.mode.use_inf_as_na = True`). NA values, such as `None` or `numpy.NaN`, get mapped to False values.

### Returns

**NDFrame** Mask of bool values for each element in NDFrame that indicates whether an element is not an NA value.

See also:

**NDFrame.notnull** Alias of `notna`.

**NDFrame.isna** Boolean inverse of `notna`.

**NDFrame.dropna** Omit axes labels with missing values.

**notna** Top-level `notna`.

## Examples

Show which entries in a DataFrame are not NA.

```
>>> df = pd.DataFrame({'age': [5, 6, np.NaN],
...                     'born': [pd.NaT, pd.Timestamp('1939-05-27'),
...                               pd.Timestamp('1940-04-25')],
...                     'name': ['Alfred', 'Batman', ''],
...                     'toy': [None, 'Batmobile', 'Joker']})
>>> df
   age      born  name      toy
0  5.0      NaT  Alfred    None
1  6.0  1939-05-27  Batman  Batmobile
2  NaN  1940-04-25      Joker
```

```
>>> df.notna()
   age  born  name  toy
0  True  False  True  False
1  True   True  True   True
2  False   True  True   True
```

Show which entries in a Series are not NA.

```
>>> ser = pd.Series([5, 6, np.NaN])
>>> ser
0    5.0
1    6.0
2    NaN
dtype: float64
```

```
>>> ser.notna()
0    True
1    True
2   False
dtype: bool
```

## pandas.Panel.notnull

`Panel.notnull()`

Detect existing (non-missing) values.

Return a boolean same-sized object indicating if the values are not NA. Non-missing values get mapped to True. Characters such as empty strings '' or `numpy.inf` are not considered NA values (unless you set `pandas.options.mode.use_inf_as_na = True`). NA values, such as `None` or `numpy.NaN`, get mapped to False values.

### Returns

**NDFrame** Mask of bool values for each element in NDFrame that indicates whether an element is not an NA value.

### See also:

**NDFrame.notnull** Alias of `notna`.

**NDFrame.isna** Boolean inverse of `notna`.

**NDFrame.dropna** Omit axes labels with missing values.

**notna** Top-level `notna`.

## Examples

Show which entries in a DataFrame are not NA.

```
>>> df = pd.DataFrame({'age': [5, 6, np.NaN],
...                    'born': [pd.NaT, pd.Timestamp('1939-05-27'),
...                             pd.Timestamp('1940-04-25')],
...                    'name': ['Alfred', 'Batman', ''],
...                    'toy': [None, 'Batmobile', 'Joker']})
>>> df
   age      born   name      toy
0  5.0      NaT  Alfred    None
1  6.0  1939-05-27  Batman  Batmobile
2  NaN  1940-04-25      Joker
```

```
>>> df.notna()
   age      born   name      toy
```

(continues on next page)

(continued from previous page)

```

0    True  False  True  False
1    True   True  True   True
2   False   True  True   True

```

Show which entries in a Series are not NA.

```

>>> ser = pd.Series([5, 6, np.NaN])
>>> ser
0     5.0
1     6.0
2     NaN
dtype: float64

```

```

>>> ser.notna()
0     True
1     True
2    False
dtype: bool

```

## pandas.Panel.pct\_change

`Panel.pct_change` (*periods=1, fill\_method='pad', limit=None, freq=None, \*\*kwargs*)

Percentage change between the current and a prior element.

Computes the percentage change from the immediately previous row by default. This is useful in comparing the percentage of change in a time series of elements.

### Parameters

**periods** [int, default 1] Periods to shift for forming percent change.

**fill\_method** [str, default 'pad'] How to handle NAs before computing percent changes.

**limit** [int, default None] The number of consecutive NAs to fill before stopping.

**freq** [DateOffset, timedelta, or offset alias string, optional] Increment to use from time series API (e.g. 'M' or BDay()).

**\*\*kwargs** Additional keyword arguments are passed into *DataFrame.shift* or *Series.shift*.

### Returns

**chg** [Series or DataFrame] The same type as the calling object.

See also:

**Series.diff** Compute the difference of two elements in a Series.

**DataFrame.diff** Compute the difference of two elements in a DataFrame.

**Series.shift** Shift the index by some number of periods.

**DataFrame.shift** Shift the index by some number of periods.

## Examples

### Series

```
>>> s = pd.Series([90, 91, 85])
>>> s
0    90
1    91
2    85
dtype: int64
```

```
>>> s.pct_change()
0      NaN
1    0.011111
2   -0.065934
dtype: float64
```

```
>>> s.pct_change(periods=2)
0      NaN
1      NaN
2   -0.055556
dtype: float64
```

See the percentage change in a Series where filling NAs with last valid observation forward to next valid.

```
>>> s = pd.Series([90, 91, None, 85])
>>> s
0    90.0
1    91.0
2     NaN
3    85.0
dtype: float64
```

```
>>> s.pct_change(fill_method='ffill')
0      NaN
1    0.011111
2    0.000000
3   -0.065934
dtype: float64
```

## DataFrame

Percentage change in French franc, Deutsche Mark, and Italian lira from 1980-01-01 to 1980-03-01.

```
>>> df = pd.DataFrame({
...     'FR': [4.0405, 4.0963, 4.3149],
...     'GR': [1.7246, 1.7482, 1.8519],
...     'IT': [804.74, 810.01, 860.13]},
...     index=['1980-01-01', '1980-02-01', '1980-03-01'])
>>> df
```

|            | FR     | GR     | IT     |

| APPL | 30586265 | 40912316 | 41403351 |

```
>>> df.pct_change(axis='columns')
      2016      2015      2014
GOOG   NaN -0.151997 -0.086016
APPL   NaN  0.337604  0.012002
```

## pandas.Panel.pipe

`Panel.pipe(func, *args, **kwargs)`  
 Apply func(self, \*args, \*\*kwargs).

### Parameters

**func** [function] function to apply to the NDFrame. `args`, and `kwargs` are passed into `func`. Alternatively a (callable, `data_keyword`) tuple where `data_keyword` is a string indicating the keyword of callable that expects the NDFrame.

**args** [iterable, optional] positional arguments passed into `func`.

**kwargs** [mapping, optional] a dictionary of keyword arguments passed into `func`.

### Returns

**object** [the return type of `func`.]

### See also:

`DataFrame.apply`, `DataFrame.applymap`, `Series.map`

## Notes

Use `.pipe` when chaining together functions that expect Series, DataFrames or GroupBy objects. Instead of writing

```
>>> f(g(h(df), arg1=a), arg2=b, arg3=c)
```

You can write

```
>>> (df.pipe(h)
...   .pipe(g, arg1=a)
...   .pipe(f, arg2=b, arg3=c)
... )
```

If you have a function that takes the data as (say) the second argument, pass a tuple indicating which keyword expects the data. For example, suppose `f` takes its data as `arg2`:

```
>>> (df.pipe(h)
...   .pipe(g, arg1=a)
...   .pipe((f, 'arg2'), arg1=a, arg3=c)
...   )
```

## pandas.Panel.pop

`Panel.pop(item)`

Return item and drop from frame. Raise `KeyError` if not found.

### Parameters

**item** [str] Column label to be popped

### Returns

**popped** [Series]

## Examples

```
>>> df = pd.DataFrame([('falcon', 'bird', 389.0),
...                     ('parrot', 'bird', 24.0),
...                     ('lion', 'mammal', 80.5),
...                     ('monkey', 'mammal', np.nan)],
...                     columns=('name', 'class', 'max_speed'))
>>> df
   name  class  max_speed
0  falcon   bird    389.0
1  parrot   bird     24.0
2   lion  mammal     80.5
3  monkey  mammal      NaN
```

```
>>> df.pop('class')
0    bird
1    bird
2  mammal
3  mammal
Name: class, dtype: object
```

```
>>> df
   name  max_speed
0  falcon    389.0
1  parrot     24.0
2   lion     80.5
3  monkey      NaN
```

## pandas.Panel.pow

`Panel.pow(other, axis=0)`

Exponential power of series and other, element-wise (binary operator *pow*). Equivalent to `panel ** other`.

### Parameters

**other** [DataFrame or Panel]

**axis** [{items, major\_axis, minor\_axis}] Axis to broadcast over

### Returns

**Panel**

**See also:**

`Panel.rpow`

## pandas.Panel.prod

`Panel.prod(axis=None, skipna=None, level=None, numeric_only=None, min_count=0, **kwargs)`

Return the product of the values for the requested axis.

### Parameters

**axis** [{items (0), major\_axis (1), minor\_axis (2)}] Axis for the function to be applied on.

**skipna** [bool, default True] Exclude NA/null values when computing the result.

**level** [int or level name, default None] If the axis is a MultiIndex (hierarchical), count along a particular level, collapsing into a DataFrame.

**numeric\_only** [bool, default None] Include only float, int, boolean columns. If None, will attempt to use everything, then use only numeric data. Not implemented for Series.

**min\_count** [int, default 0] The required number of valid values to perform the operation. If fewer than `min_count` non-NA values are present the result will be NA.

New in version 0.22.0: Added with the default being 0. This means the sum of an all-NA or empty Series is 0, and the product of an all-NA or empty Series is 1.

**\*\*kwargs** Additional keyword arguments to be passed to the function.

### Returns

**prod** [DataFrame or Panel (if level specified)]

## Examples

By default, the product of an empty or all-NA Series is 1

```
>>> pd.Series([]).prod()
1.0
```

This can be controlled with the `min_count` parameter

```
>>> pd.Series([]).prod(min_count=1)
nan
```

Thanks to the `skipna` parameter, `min_count` handles all-NA and empty series identically.

```
>>> pd.Series([np.nan]).prod()
1.0
```

```
>>> pd.Series([np.nan]).prod(min_count=1)
nan
```

## pandas.Panel.product

`Panel.product` (*axis=None*, *skipna=None*, *level=None*, *numeric\_only=None*, *min\_count=0*, *\*\*kwargs*)

Return the product of the values for the requested axis.

### Parameters

**axis** [{items (0), major\_axis (1), minor\_axis (2)}] Axis for the function to be applied on.

**skipna** [bool, default True] Exclude NA/null values when computing the result.

**level** [int or level name, default None] If the axis is a MultiIndex (hierarchical), count along a particular level, collapsing into a DataFrame.

**numeric\_only** [bool, default None] Include only float, int, boolean columns. If None, will attempt to use everything, then use only numeric data. Not implemented for Series.

**min\_count** [int, default 0] The required number of valid values to perform the operation. If fewer than `min_count` non-NA values are present the result will be NA.

New in version 0.22.0: Added with the default being 0. This means the sum of an all-NA or empty Series is 0, and the product of an all-NA or empty Series is 1.

**\*\*kwargs** Additional keyword arguments to be passed to the function.

### Returns

**prod** [DataFrame or Panel (if level specified)]

## Examples

By default, the product of an empty or all-NA Series is 1

```
>>> pd.Series([]).prod()
1.0
```

This can be controlled with the `min_count` parameter

```
>>> pd.Series([]).prod(min_count=1)
nan
```

Thanks to the `skipna` parameter, `min_count` handles all-NA and empty series identically.

```
>>> pd.Series([np.nan]).prod()
1.0
```

```
>>> pd.Series([np.nan]).prod(min_count=1)
nan
```

## pandas.Panel.radd

`Panel.radd(other, axis=0)`

Addition of series and other, element-wise (binary operator *radd*). Equivalent to `other + panel`.

### Parameters

**other** [DataFrame or Panel]

**axis** [{items, major\_axis, minor\_axis}] Axis to broadcast over

### Returns

**Panel**

### See also:

`Panel.add`

## pandas.Panel.rank

`Panel.rank(axis=0, method='average', numeric_only=None, na_option='keep', ascending=True, pct=False)`

Compute numerical data ranks (1 through n) along axis. Equal values are assigned a rank that is the average of the ranks of those values.

### Parameters

**axis** [{0 or 'index', 1 or 'columns'}, default 0] index to direct ranking

**method** [{ 'average', 'min', 'max', 'first', 'dense' }]

- average: average rank of group
- min: lowest rank in group
- max: highest rank in group
- first: ranks assigned in order they appear in the array
- dense: like 'min', but rank always increases by 1 between groups

**numeric\_only** [boolean, default None] Include only float, int, boolean data. Valid only for DataFrame or Panel objects

**na\_option** [{ 'keep', 'top', 'bottom' }]

- keep: leave NA values where they are
- top: smallest rank if ascending
- bottom: smallest rank if descending

**ascending** [boolean, default True] False for ranks by high (1) to low (N)

**pct** [boolean, default False] Computes percentage rank of data

### Returns

**ranks** [same type as caller]

## pandas.Panel.rdiv

`Panel.rdiv(other, axis=0)`

Floating division of series and other, element-wise (binary operator *rtruediv*). Equivalent to `other / panel`.

### Parameters

**other** [DataFrame or Panel]

**axis** [{items, major\_axis, minor\_axis}] Axis to broadcast over

### Returns

**Panel**

See also:

`Panel.truediv`

## pandas.Panel.reindex

`Panel.reindex(*args, **kwargs)`

Conform Panel to new index with optional filling logic, placing NA/NaN in locations having no value in the previous index. A new object is produced unless the new index is equivalent to the current one and `copy=False`.

### Parameters

**items, major\_axis, minor\_axis** [array-like, optional] New labels / index to conform to, should be specified using keywords. Preferably an Index object to avoid duplicating data

**method** [{None, 'backfill'/'bfill', 'pad'/'ffill', 'nearest'}] Method to use for filling holes in reindexed DataFrame. Please note: this is only applicable to DataFrames/Series with a monotonically increasing/decreasing index.

- None (default): don't fill gaps
- pad / ffill: propagate last valid observation forward to next valid
- backfill / bfill: use next valid observation to fill gap
- nearest: use nearest valid observations to fill gap

**copy** [bool, default True] Return a new object, even if the passed indexes are the same.

**level** [int or name] Broadcast across a level, matching Index values on the passed Multi-Index level.

**fill\_value** [scalar, default np.NaN] Value to use for missing values. Defaults to NaN, but can be any "compatible" value.

**limit** [int, default None] Maximum number of consecutive elements to forward or backward fill.

**tolerance** [optional] Maximum distance between original and new labels for inexact matches. The values of the index at the matching locations must satisfy the equation `abs(index[indexer] - target) <= tolerance`.

Tolerance may be a scalar value, which applies the same tolerance to all values, or list-like, which applies variable tolerance per element. List-like includes list, tuple,

array, Series, and must be the same size as the index and its dtype must exactly match the index's type.

New in version 0.21.0: (list-like tolerance)

### Returns

**Panel with changed index.**

See also:

**DataFrame.set\_index** Set row labels.

**DataFrame.reset\_index** Remove row labels or move them to new columns.

**DataFrame.reindex\_like** Change to same indices as other DataFrame.

### Examples

DataFrame.reindex supports two calling conventions

- (index=index\_labels, columns=column\_labels, ...)
- (labels, axis={'index', 'columns'}, ...)

We *highly* recommend using keyword arguments to clarify your intent.

Create a dataframe with some fictional data.

```
>>> index = ['Firefox', 'Chrome', 'Safari', 'IE10', 'Konqueror']
>>> df = pd.DataFrame({
...     'http_status': [200, 200, 404, 404, 301],
...     'response_time': [0.04, 0.02, 0.07, 0.08, 1.0]},
...     index=index)
>>> df
```

|           | http_status | response_time |
|-----------|-------------|---------------|
| Firefox   | 200         | 0.04          |
| Chrome    | 200         | 0.02          |
| Safari    | 404         | 0.07          |
| IE10      | 404         | 0.08          |
| Konqueror | 301         | 1.00          |

Create a new index and reindex the dataframe. By default values in the new index that do not have corresponding records in the dataframe are assigned NaN.

```
>>> new_index= ['Safari', 'Iceweasel', 'Comodo Dragon', 'IE10',
...             'Chrome']
>>> df.reindex(new_index)
```

|               | http_status | response_time |
|---------------|-------------|---------------|
| Safari        | 404.0       | 0.07          |
| Iceweasel     | NaN         | NaN           |
| Comodo Dragon | NaN         | NaN           |
| IE10          | 404.0       | 0.08          |
| Chrome        | 200.0       | 0.02          |

We can fill in the missing values by passing a value to the keyword `fill_value`. Because the index is not monotonically increasing or decreasing, we cannot use arguments to the keyword `method` to fill the NaN values.

```
>>> df.reindex(new_index, fill_value=0)
           http_status  response_time
Safari                404             0.07
Iceweasel              0             0.00
Comodo Dragon          0             0.00
IE10                  404             0.08
Chrome                200             0.02
```

```
>>> df.reindex(new_index, fill_value='missing')
           http_status  response_time
Safari                404             0.07
Iceweasel            missing          missing
Comodo Dragon        missing          missing
IE10                  404             0.08
Chrome                200             0.02
```

We can also reindex the columns.

```
>>> df.reindex(columns=['http_status', 'user_agent'])
           http_status  user_agent
Firefox              200         NaN
Chrome               200         NaN
Safari               404         NaN
IE10                 404         NaN
Konqueror            301         NaN
```

Or we can use “axis-style” keyword arguments

```
>>> df.reindex(['http_status', 'user_agent'], axis="columns")
           http_status  user_agent
Firefox              200         NaN
Chrome               200         NaN
Safari               404         NaN
IE10                 404         NaN
Konqueror            301         NaN
```

To further illustrate the filling functionality in `reindex`, we will create a dataframe with a monotonically increasing index (for example, a sequence of dates).

```
>>> date_index = pd.date_range('1/1/2010', periods=6, freq='D')
>>> df2 = pd.DataFrame({"prices": [100, 101, np.nan, 100, 89, 88]},
...                     index=date_index)
>>> df2
           prices
2010-01-01    100.0
2010-01-02    101.0
2010-01-03      NaN
2010-01-04    100.0
2010-01-05     89.0
2010-01-06     88.0
```

Suppose we decide to expand the dataframe to cover a wider date range.

```
>>> date_index2 = pd.date_range('12/29/2009', periods=10, freq='D')
>>> df2.reindex(date_index2)
           prices
2009-12-29      NaN
```

(continues on next page)

(continued from previous page)

|            |       |
|------------|-------|
| 2009-12-30 | NaN   |
| 2009-12-31 | NaN   |
| 2010-01-01 | 100.0 |
| 2010-01-02 | 101.0 |
| 2010-01-03 | NaN   |
| 2010-01-04 | 100.0 |
| 2010-01-05 | 89.0  |
| 2010-01-06 | 88.0  |
| 2010-01-07 | NaN   |

The index entries that did not have a value in the original data frame (for example, '2009-12-29') are by default filled with NaN. If desired, we can fill in the missing values using one of several options.

For example, to back-propagate the last valid value to fill the NaN values, pass `bfill` as an argument to the `method` keyword.

```
>>> df2.reindex(date_index2, method='bfill')
prices
2009-12-29    100.0
2009-12-30    100.0
2009-12-31    100.0
2010-01-01    100.0
2010-01-02    101.0
2010-01-03     NaN
2010-01-04    100.0
2010-01-05     89.0
2010-01-06     88.0
2010-01-07     NaN
```

Please note that the NaN value present in the original dataframe (at index value 2010-01-03) will not be filled by any of the value propagation schemes. This is because filling while reindexing does not look at dataframe values, but only compares the original and desired indexes. If you do want to fill in the NaN values present in the original dataframe, use the `fillna()` method.

See the *user guide* for more.

### pandas.Panel.reindex\_axis

`Panel.reindex_axis(labels, axis=0, method=None, level=None, copy=True, limit=None, fill_value=nan)`

Conform input object to new index.

Deprecated since version 0.21.0: Use `reindex` instead.

By default, places NaN in locations having no value in the previous index. A new object is produced unless the new index is equivalent to the current one and `copy=False`.

#### Parameters

**labels** [array-like] New labels / index to conform to. Preferably an Index object to avoid duplicating data.

**axis** [{0, 1, 2, 'items', 'major\_axis', 'minor\_axis'}] Indicate whether to use rows or columns.

**method** [{None, 'backfill'/'bfill', 'pad'/'ffill', 'nearest'}, optional] Method to use for filling holes in reindexed DataFrame:

- default: don't fill gaps.
- pad / ffill: propagate last valid observation forward to next valid.
- backfill / bfill: use next valid observation to fill gap.
- nearest: use nearest valid observations to fill gap.

**level** [int or str] Broadcast across a level, matching Index values on the passed MultiIndex level.

**copy** [bool, default True] Return a new object, even if the passed indexes are the same.

**limit** [int, optional] Maximum number of consecutive elements to forward or backward fill.

**fill\_value** [float, default NaN] Value used to fill in locations having no value in the previous index.

New in version 0.21.0: (list-like tolerance)

### Returns

**Panel** Returns a new DataFrame object with new indices, unless the new index is equivalent to the current one and copy=False.

See also:

**DataFrame.set\_index** Set row labels.

**DataFrame.reset\_index** Remove row labels or move them to new columns.

**DataFrame.reindex** Change to new indices or expand indices.

**DataFrame.reindex\_like** Change to same indices as other DataFrame.

### Examples

```
>>> df = pd.DataFrame({'num_legs': [4, 2], 'num_wings': [0, 2]},
...                    index=['dog', 'hawk'])
>>> df
   num_legs  num_wings
dog         4         0
hawk        2         2
>>> df.reindex(['num_wings', 'num_legs', 'num_heads'],
...            axis='columns')
   num_wings  num_legs  num_heads
dog         0         4        NaN
hawk        2         2        NaN
```

### pandas.Panel.reindex\_like

**Panel.reindex\_like** (*other, method=None, copy=True, limit=None, tolerance=None*)

Return an object with matching indices as other object.

Conform the object to the same index on all axes. Optional filling logic, placing NaN in locations having no value in the previous index. A new object is produced unless the new index is equivalent to the current one and copy=False.

### Parameters

**other** [Object of the same data type] Its row and column indices are used to define the new indices of this object.

**method** [{None, 'backfill'/'bfill', 'pad'/'ffill', 'nearest'}] Method to use for filling holes in reindexed DataFrame. Please note: this is only applicable to DataFrames/Series with a monotonically increasing/decreasing index.

- None (default): don't fill gaps
- pad / ffill: propagate last valid observation forward to next valid
- backfill / bfill: use next valid observation to fill gap
- nearest: use nearest valid observations to fill gap

**copy** [bool, default True] Return a new object, even if the passed indexes are the same.

**limit** [int, default None] Maximum number of consecutive labels to fill for inexact matches.

**tolerance** [optional] Maximum distance between original and new labels for inexact matches. The values of the index at the matching locations must satisfy the equation  $\text{abs}(\text{index}[\text{indexer}] - \text{target}) \leq \text{tolerance}$ .

Tolerance may be a scalar value, which applies the same tolerance to all values, or list-like, which applies variable tolerance per element. List-like includes list, tuple, array, Series, and must be the same size as the index and its dtype must exactly match the index's type.

New in version 0.21.0: (list-like tolerance)

### Returns

**Series or DataFrame** Same type as caller, but with changed indices on each axis.

See also:

**DataFrame.set\_index** Set row labels.

**DataFrame.reset\_index** Remove row labels or move them to new columns.

**DataFrame.reindex** Change to new indices or expand indices.

### Notes

Same as calling `.reindex(index=other.index, columns=other.columns, ...)`.

### Examples

```
>>> df1 = pd.DataFrame([[24.3, 75.7, 'high'],
...                     [31, 87.8, 'high'],
...                     [22, 71.6, 'medium'],
...                     [35, 95, 'medium']],
...                     columns=['temp_celsius', 'temp_fahrenheit', 'windspeed'],
...                     index=pd.date_range(start='2014-02-12',
...                                         end='2014-02-15', freq='D'))
```

```
>>> df1
      temp_celsius  temp_fahrenheit  windspeed
2014-02-12         24.3             75.7      high
2014-02-13         31.0             87.8      high
2014-02-14         22.0             71.6    medium
2014-02-15         35.0             95.0    medium
```

```
>>> df2 = pd.DataFrame([[28, 'low'],
...                      [30, 'low'],
...                      [35.1, 'medium']],
...                     columns=['temp_celsius', 'windspeed'],
...                     index=pd.DatetimeIndex(['2014-02-12', '2014-02-13',
...                                             '2014-02-15']))
```

```
>>> df2
      temp_celsius  windspeed
2014-02-12         28.0      low
2014-02-13         30.0      low
2014-02-15         35.1    medium
```

```
>>> df2.reindex_like(df1)
      temp_celsius  temp_fahrenheit  windspeed
2014-02-12         28.0             NaN      low
2014-02-13         30.0             NaN      low
2014-02-14         NaN             NaN      NaN
2014-02-15         35.1             NaN    medium
```

## pandas.Panel.rename

`Panel.rename` (*items=None, major\_axis=None, minor\_axis=None, \*\*kwargs*)

Alter axes input function or functions. Function / dict values must be unique (1-to-1). Labels not contained in a dict / Series will be left as-is. Extra labels listed don't throw an error. Alternatively, change `Series.name` with a scalar value (Series only).

### Parameters

**items, major\_axis, minor\_axis** [scalar, list-like, dict-like or function, optional] Scalar or list-like will alter the `Series.name` attribute, and raise on `DataFrame` or `Panel`. dict-like or functions are transformations to apply to that axis' values

**copy** [boolean, default True] Also copy underlying data

**inplace** [boolean, default False] Whether to return a new `Panel`. If True then value of `copy` is ignored.

**level** [int or level name, default None] In case of a `MultiIndex`, only rename labels in the specified level.

### Returns

**renamed** [`Panel` (new object)]

### See also:

`pandas.NDFrame.rename_axis`

## Examples

```
>>> s = pd.Series([1, 2, 3])
>>> s
0    1
1    2
2    3
dtype: int64
>>> s.rename("my_name") # scalar, changes Series.name
0    1
1    2
2    3
Name: my_name, dtype: int64
>>> s.rename(lambda x: x ** 2) # function, changes labels
0    1
1    2
4    3
dtype: int64
>>> s.rename({1: 3, 2: 5}) # mapping, changes labels
0    1
3    2
5    3
dtype: int64
```

Since DataFrame doesn't have a `.name` attribute, only mapping-type arguments are allowed.

```
>>> df = pd.DataFrame({"A": [1, 2, 3], "B": [4, 5, 6]})
>>> df.rename(2)
Traceback (most recent call last):
...
TypeError: 'int' object is not callable
```

`DataFrame.rename` supports two calling conventions

- `(index=index_mapper, columns=columns_mapper, ...)`
- `(mapper, axis={'index', 'columns'}, ...)`

We *highly* recommend using keyword arguments to clarify your intent.

```
>>> df.rename(index=str, columns={"A": "a", "B": "c"})
   a  c
0  1  4
1  2  5
2  3  6
```

```
>>> df.rename(index=str, columns={"A": "a", "C": "c"})
   a  B
0  1  4
1  2  5
2  3  6
```

Using axis-style parameters

```
>>> df.rename(str.lower, axis='columns')
   a  b
0  1  4
```

(continues on next page)

(continued from previous page)

```
1  2  5
2  3  6
```

```
>>> df.rename({1: 2, 2: 4}, axis='index')
   A  B
0  1  4
2  2  5
4  3  6
```

See the *user guide* for more.

## pandas.Panel.rename\_axis

`Panel.rename_axis` (*mapper=None, index=None, columns=None, axis=None, copy=True, inplace=False*)

Set the name of the axis for the index or columns.

### Parameters

**mapper** [scalar, list-like, optional] Value to set the axis name attribute.

**index, columns** [scalar, list-like, dict-like or function, optional] A scalar, list-like, dict-like or functions transformations to apply to that axis' values.

Use either `mapper` and `axis` to specify the axis to target with `mapper`, or `index` and/or `columns`.

Changed in version 0.24.0.

**axis** [{0 or 'index', 1 or 'columns'}], default 0] The axis to rename.

**copy** [bool, default True] Also copy underlying data.

**inplace** [bool, default False] Modifies the object directly, instead of creating a new Series or DataFrame.

### Returns

**Series, DataFrame, or None** The same type as the caller or None if *inplace* is True.

See also:

**Series.rename** Alter Series index labels or name.

**DataFrame.rename** Alter DataFrame index labels or name.

**Index.rename** Set new names on index.

## Notes

Prior to version 0.21.0, `rename_axis` could also be used to change the axis *labels* by passing a mapping or scalar. This behavior is deprecated and will be removed in a future version. Use `rename` instead.

`DataFrame.rename_axis` supports two calling conventions

- (`index=index_mapper, columns=columns_mapper, ...`)
- (`mapper, axis={'index', 'columns'}, ...`)

The first calling convention will only modify the names of the index and/or the names of the Index object that is the columns. In this case, the parameter `copy` is ignored.

The second calling convention will modify the names of the the corresponding index if `mapper` is a list or a scalar. However, if `mapper` is dict-like or a function, it will use the deprecated behavior of modifying the axis *labels*.

We *highly* recommend using keyword arguments to clarify your intent.

## Examples

### Series

```
>>> s = pd.Series(["dog", "cat", "monkey"])
>>> s
0      dog
1      cat
2    monkey
dtype: object
>>> s.rename_axis("animal")
animal
0      dog
1      cat
2    monkey
dtype: object
```

### DataFrame

```
>>> df = pd.DataFrame({"num_legs": [4, 4, 2],
...                    "num_arms": [0, 0, 2]},
...                    ["dog", "cat", "monkey"])
>>> df
   num_legs  num_arms
dog         4         0
cat         4         0
monkey      2         2
>>> df = df.rename_axis("animal")
>>> df
   num_legs  num_arms
animal
dog         4         0
cat         4         0
monkey      2         2
>>> df = df.rename_axis("limbs", axis="columns")
>>> df
limbs  num_legs  num_arms
animal
dog         4         0
cat         4         0
monkey      2         2
```

### MultiIndex

```
>>> df.index = pd.MultiIndex.from_product(['mammal'],
...                                       ['dog', 'cat', 'monkey']],
...                               names=['type', 'name'])
>>> df
```

(continues on next page)

(continued from previous page)

| limbs  |        | num_legs | num_arms |
|--------|--------|----------|----------|
| type   | name   |          |          |
| mammal | dog    | 4        | 0        |
|        | cat    | 4        | 0        |
|        | monkey | 2        | 2        |

```
>>> df.rename_axis(index={'type': 'class'})
```

| limbs  |        | num_legs | num_arms |
|--------|--------|----------|----------|
| class  | name   |          |          |
| mammal | dog    | 4        | 0        |
|        | cat    | 4        | 0        |
|        | monkey | 2        | 2        |

```
>>> df.rename_axis(columns=str.upper)
```

| LIMBS  |        | num_legs | num_arms |
|--------|--------|----------|----------|
| type   | name   |          |          |
| mammal | dog    | 4        | 0        |
|        | cat    | 4        | 0        |
|        | monkey | 2        | 2        |

## pandas.Panel.replace

`Panel.replace(to_replace=None, value=None, inplace=False, limit=None, regex=False, method='pad')`

Replace values given in *to\_replace* with *value*.

Values of the NDFrame are replaced with other values dynamically. This differs from updating with `.loc` or `.iloc`, which require you to specify a location to update with some value.

### Parameters

**to\_replace** [str, regex, list, dict, Series, int, float, or None] How to find the values that will be replaced.

- numeric, str or regex:
  - numeric: numeric values equal to *to\_replace* will be replaced with *value*
  - str: string exactly matching *to\_replace* will be replaced with *value*
  - regex: regexs matching *to\_replace* will be replaced with *value*
- list of str, regex, or numeric:
  - First, if *to\_replace* and *value* are both lists, they **must** be the same length.
  - Second, if `regex=True` then all of the strings in **both** lists will be interpreted as regexs otherwise they will match directly. This doesn't matter much for *value* since there are only a few possible substitution regexes you can use.
  - str, regex and numeric rules apply as above.
- dict:
  - Dicts can be used to specify different replacement values for different existing values. For example, `{ 'a': 'b', 'y': 'z' }` replaces the value 'a' with 'b' and 'y' with 'z'. To use a dict in this way the *value* parameter should be *None*.

- For a DataFrame a dict can specify that different values should be replaced in different columns. For example, `{ 'a': 1, 'b': 'z' }` looks for the value 1 in column 'a' and the value 'z' in column 'b' and replaces these values with whatever is specified in *value*. The *value* parameter should not be `None` in this case. You can treat this as a special case of passing two lists except that you are specifying the column to search in.
- For a DataFrame nested dictionaries, e.g., `{ 'a': { 'b': np.nan } }`, are read as follows: look in column 'a' for the value 'b' and replace it with NaN. The *value* parameter should be `None` to use a nested dict in this way. You can nest regular expressions as well. Note that column names (the top-level dictionary keys in a nested dictionary) **cannot** be regular expressions.
- `None`:
  - This means that the *regex* argument must be a string, compiled regular expression, or list, dict, ndarray or Series of such elements. If *value* is also `None` then this **must** be a nested dictionary or Series.

See the examples section for examples of each of these.

**value** [scalar, dict, list, str, regex, default `None`] Value to replace any values matching *to\_replace* with. For a DataFrame a dict of values can be used to specify which value to use for each column (columns not in the dict will not be filled). Regular expressions, strings and lists or dicts of such objects are also allowed.

**inplace** [bool, default `False`] If `True`, in place. Note: this will modify any other views on this object (e.g. a column from a DataFrame). Returns the caller if this is `True`.

**limit** [int, default `None`] Maximum size gap to forward or backward fill.

**regex** [bool or same types as *to\_replace*, default `False`] Whether to interpret *to\_replace* and/or *value* as regular expressions. If this is `True` then *to\_replace* must be a string. Alternatively, this could be a regular expression or a list, dict, or array of regular expressions in which case *to\_replace* must be `None`.

**method** [{ 'pad', 'ffill', 'bfill', `None` }] The method to use when for replacement, when *to\_replace* is a scalar, list or tuple and *value* is `None`.

Changed in version 0.23.0: Added to DataFrame.

## Returns

**NDFrame** Object after replacement.

## Raises

### AssertionError

- If *regex* is not a `bool` and *to\_replace* is not `None`.

### TypeError

- If *to\_replace* is a dict and *value* is not a list, dict, ndarray, or Series
- If *to\_replace* is `None` and *regex* is not compilable into a regular expression or is a list, dict, ndarray, or Series.
- When replacing multiple `bool` or `datetime64` objects and the arguments to *to\_replace* does not match the type of the value being replaced

### ValueError

- If a `list` or an `ndarray` is passed to `to_replace` and `value` but they are not the same length.

See also:

**`NDFrame.fillna`** Fill NA values.

**`NDFrame.where`** Replace values based on boolean condition.

**`Series.str.replace`** Simple string replacement.

## Notes

- Regex substitution is performed under the hood with `re.sub`. The rules for substitution for `re.sub` are the same.
- Regular expressions will only substitute on strings, meaning you cannot provide, for example, a regular expression matching floating point numbers and expect the columns in your frame that have a numeric dtype to be matched. However, if those floating point numbers *are* strings, then you can do this.
- This method has *a lot* of options. You are encouraged to experiment and play with this method to gain intuition about how it works.
- When dict is used as the `to_replace` value, it is like key(s) in the dict are the `to_replace` part and value(s) in the dict are the `value` parameter.

## Examples

### Scalar ‘to\_replace’ and ‘value’

```
>>> s = pd.Series([0, 1, 2, 3, 4])
>>> s.replace(0, 5)
0    5
1    1
2    2
3    3
4    4
dtype: int64
```

```
>>> df = pd.DataFrame({'A': [0, 1, 2, 3, 4],
...                    'B': [5, 6, 7, 8, 9],
...                    'C': ['a', 'b', 'c', 'd', 'e']})
>>> df.replace(0, 5)
   A  B  C
0  5  5  a
1  1  6  b
2  2  7  c
3  3  8  d
4  4  9  e
```

### List-like ‘to\_replace’

```
>>> df.replace([0, 1, 2, 3], 4)
   A  B  C
0  4  5  a
1  4  6  b
```

(continues on next page)

(continued from previous page)

```

2  4  7  c
3  4  8  d
4  4  9  e

```

```

>>> df.replace([0, 1, 2, 3], [4, 3, 2, 1])
   A  B  C
0  4  5  a
1  3  6  b
2  2  7  c
3  1  8  d
4  4  9  e

```

```

>>> s.replace([1, 2], method='bfill')
0    0
1    3
2    3
3    3
4    4
dtype: int64

```

**dict-like ‘to\_replace’**

```

>>> df.replace({0: 10, 1: 100})
   A  B  C
0  10  5  a
1 100  6  b
2   2  7  c
3   3  8  d
4   4  9  e

```

```

>>> df.replace({'A': 0, 'B': 5}, 100)
   A   B  C
0 100 100  a
1   1   6  b
2   2   7  c
3   3   8  d
4   4   9  e

```

```

>>> df.replace({'A': {0: 100, 4: 400}})
   A  B  C
0 100  5  a
1   1  6  b
2   2  7  c
3   3  8  d
4 400  9  e

```

**Regular expression ‘to\_replace’**

```

>>> df = pd.DataFrame({'A': ['bat', 'foo', 'bait'],
...                     'B': ['abc', 'bar', 'xyz']})
>>> df.replace(to_replace=r'^ba.$', value='new', regex=True)
   A  B
0  new abc
1  foo new
2  bait xyz

```

```
>>> df.replace({'A': r'^ba.$'}, {'A': 'new'}, regex=True)
   A  B
0  new abc
1  foo bar
2  bait xyz
```

```
>>> df.replace(regex=r'^ba.$', value='new')
   A  B
0  new abc
1  foo new
2  bait xyz
```

```
>>> df.replace(regex={'r'^ba.$': 'new', 'foo': 'xyz'})
   A  B
0  new abc
1  xyz new
2  bait xyz
```

```
>>> df.replace(regex=[r'^ba.$', 'foo'], value='new')
   A  B
0  new abc
1  new new
2  bait xyz
```

Note that when replacing multiple bool or datetime64 objects, the data types in the *to\_replace* parameter must match the data type of the value being replaced:

```
>>> df = pd.DataFrame({'A': [True, False, True],
...                    'B': [False, True, False]})
>>> df.replace({'a string': 'new value', True: False}) # raises
Traceback (most recent call last):
...
TypeError: Cannot compare types 'ndarray(dtype=bool)' and 'str'
```

This raises a `TypeError` because one of the dict keys is not of the correct type for replacement.

Compare the behavior of `s.replace({'a': None})` and `s.replace('a', None)` to understand the peculiarities of the *to\_replace* parameter:

```
>>> s = pd.Series([10, 'a', 'a', 'b', 'a'])
```

When one uses a dict as the *to\_replace* value, it is like the value(s) in the dict are equal to the *value* parameter. `s.replace({'a': None})` is equivalent to `s.replace(to_replace={'a': None}, value=None, method=None)`:

```
>>> s.replace({'a': None})
0    10
1    None
2    None
3     b
4    None
dtype: object
```

When `value=None` and *to\_replace* is a scalar, list or tuple, *replace* uses the method parameter (default 'pad') to do the replacement. So this is why the 'a' values are being replaced by 10 in rows 1 and 2 and 'b' in row 4 in this case. The command `s.replace('a', None)` is actually equivalent to `s.replace(to_replace='a', value=None, method='pad')`:

```
>>> s.replace('a', None)
0      10
1      10
2      10
3       b
4       b
dtype: object
```

## pandas.Panel.resample

`Panel.resample(rule, how=None, axis=0, fill_method=None, closed=None, label=None, convention='start', kind=None, loffset=None, limit=None, base=0, on=None, level=None)`

Resample time-series data.

Convenience method for frequency conversion and resampling of time series. Object must have a datetime-like index (*DatetimeIndex*, *PeriodIndex*, or *TimedeltaIndex*), or pass datetime-like values to the *on* or *level* keyword.

### Parameters

**rule** [str] The offset string or object representing target conversion.

**how** [str] Method for down/re-sampling, default to 'mean' for downsampling.

Deprecated since version 0.18.0: The new syntax is `.resample(...).mean()`, or `.resample(...).apply(<func>)`

**axis** [{0 or 'index', 1 or 'columns'}, default 0] Which axis to use for up- or down-sampling. For *Series* this will default to 0, i.e. along the rows. Must be *DatetimeIndex*, *TimedeltaIndex* or *PeriodIndex*.

**fill\_method** [str, default None] Filling method for upsampling.

Deprecated since version 0.18.0: The new syntax is `.resample(...).<func>()`, e.g. `.resample(...).pad()`

**closed** [{ 'right', 'left' }, default None] Which side of bin interval is closed. The default is 'left' for all frequency offsets except for 'M', 'A', 'Q', 'BM', 'BA', 'BQ', and 'W' which all have a default of 'right'.

**label** [{ 'right', 'left' }, default None] Which bin edge label to label bucket with. The default is 'left' for all frequency offsets except for 'M', 'A', 'Q', 'BM', 'BA', 'BQ', and 'W' which all have a default of 'right'.

**convention** [{ 'start', 'end', 's', 'e' }, default 'start'] For *PeriodIndex* only, controls whether to use the start or end of *rule*.

**kind** [{ 'timestamp', 'period' }, optional, default None] Pass 'timestamp' to convert the resulting index to a *DatetimeIndex* or 'period' to convert it to a *PeriodIndex*. By default the input representation is retained.

**loffset** [timedelta, default None] Adjust the resampled time labels.

**limit** [int, default None] Maximum size gap when reindexing with *fill\_method*.

Deprecated since version 0.18.0.

**base** [int, default 0] For frequencies that evenly subdivide 1 day, the "origin" of the aggregated intervals. For example, for '5min' frequency, base could range from 0 through 4. Defaults to 0.

**on** [str, optional] For a DataFrame, column to use instead of index for resampling. Column must be datetime-like.

New in version 0.19.0.

**level** [str or int, optional] For a MultiIndex, level (name or number) to use for resampling. *level* must be datetime-like.

New in version 0.19.0.

### Returns

**Resampler object**

**See also:**

***groupby*** Group by mapping, function, label, or list of labels.

***Series.resample*** Resample a Series.

***DataFrame.resample*** Resample a DataFrame.

### Notes

See the [user guide](#) for more.

To learn more about the offset strings, please see [this link](#).

### Examples

Start by creating a series with 9 one minute timestamps.

```
>>> index = pd.date_range('1/1/2000', periods=9, freq='T')
>>> series = pd.Series(range(9), index=index)
>>> series
2000-01-01 00:00:00    0
2000-01-01 00:01:00    1
2000-01-01 00:02:00    2
2000-01-01 00:03:00    3
2000-01-01 00:04:00    4
2000-01-01 00:05:00    5
2000-01-01 00:06:00    6
2000-01-01 00:07:00    7
2000-01-01 00:08:00    8
Freq: T, dtype: int64
```

Downsample the series into 3 minute bins and sum the values of the timestamps falling into a bin.

```
>>> series.resample('3T').sum()
2000-01-01 00:00:00    3
2000-01-01 00:03:00   12
2000-01-01 00:06:00   21
Freq: 3T, dtype: int64
```

Downsample the series into 3 minute bins as above, but label each bin using the right edge instead of the left. Please note that the value in the bucket used as the label is not included in the bucket, which it labels. For example, in the original series the bucket 2000-01-01 00:03:00 contains the value 3, but the summed value in the resampled bucket with the label 2000-01-01 00:03:00 does not include 3 (if

it did, the summed value would be 6, not 3). To include this value close the right side of the bin interval as illustrated in the example below this one.

```
>>> series.resample('3T', label='right').sum()
2000-01-01 00:03:00    3
2000-01-01 00:06:00   12
2000-01-01 00:09:00   21
Freq: 3T, dtype: int64
```

Downsample the series into 3 minute bins as above, but close the right side of the bin interval.

```
>>> series.resample('3T', label='right', closed='right').sum()
2000-01-01 00:00:00    0
2000-01-01 00:03:00    6
2000-01-01 00:06:00   15
2000-01-01 00:09:00   15
Freq: 3T, dtype: int64
```

Upsample the series into 30 second bins.

```
>>> series.resample('30S').asfreq()[0:5]    # Select first 5 rows
2000-01-01 00:00:00    0.0
2000-01-01 00:00:30   NaN
2000-01-01 00:01:00    1.0
2000-01-01 00:01:30   NaN
2000-01-01 00:02:00    2.0
Freq: 30S, dtype: float64
```

Upsample the series into 30 second bins and fill the NaN values using the pad method.

```
>>> series.resample('30S').pad()[0:5]
2000-01-01 00:00:00    0
2000-01-01 00:00:30    0
2000-01-01 00:01:00    1
2000-01-01 00:01:30    1
2000-01-01 00:02:00    2
Freq: 30S, dtype: int64
```

Upsample the series into 30 second bins and fill the NaN values using the bfill method.

```
>>> series.resample('30S').bfill()[0:5]
2000-01-01 00:00:00    0
2000-01-01 00:00:30    1
2000-01-01 00:01:00    1
2000-01-01 00:01:30    2
2000-01-01 00:02:00    2
Freq: 30S, dtype: int64
```

Pass a custom function via apply

```
>>> def custom_resampler(array_like):
...     return np.sum(array_like) + 5
...
>>> series.resample('3T').apply(custom_resampler)
2000-01-01 00:00:00    8
2000-01-01 00:03:00   17
2000-01-01 00:06:00   26
Freq: 3T, dtype: int64
```

For a Series with a PeriodIndex, the keyword *convention* can be used to control whether to use the start or end of *rule*.

Resample a year by quarter using 'start' *convention*. Values are assigned to the first quarter of the period.

```
>>> s = pd.Series([1, 2], index=pd.period_range('2012-01-01',
...                                           freq='A',
...                                           periods=2))
>>> s
2012    1
2013    2
Freq: A-DEC, dtype: int64
>>> s.resample('Q', convention='start').asfreq()
2012Q1    1.0
2012Q2     NaN
2012Q3     NaN
2012Q4     NaN
2013Q1    2.0
2013Q2     NaN
2013Q3     NaN
2013Q4     NaN
Freq: Q-DEC, dtype: float64
```

Resample quarters by month using 'end' *convention*. Values are assigned to the last month of the period.

```
>>> q = pd.Series([1, 2, 3, 4], index=pd.period_range('2018-01-01',
...                                           freq='Q',
...                                           periods=4))
>>> q
2018Q1    1
2018Q2    2
2018Q3    3
2018Q4    4
Freq: Q-DEC, dtype: int64
>>> q.resample('M', convention='end').asfreq()
2018-03    1.0
2018-04     NaN
2018-05     NaN
2018-06    2.0
2018-07     NaN
2018-08     NaN
2018-09    3.0
2018-10     NaN
2018-11     NaN
2018-12    4.0
Freq: M, dtype: float64
```

For DataFrame objects, the keyword *on* can be used to specify the column instead of the index for resampling.

```
>>> d = dict({'price': [10, 11, 9, 13, 14, 18, 17, 19],
...          'volume': [50, 60, 40, 100, 50, 100, 40, 50]})
>>> df = pd.DataFrame(d)
>>> df['week_starting'] = pd.date_range('01/01/2018',
...                                     periods=8,
...                                     freq='W')
>>> df
   price  volume week_starting
```

(continues on next page)

(continued from previous page)

```

0      10      50   2018-01-07
1      11      60   2018-01-14
2       9      40   2018-01-21
3      13     100   2018-01-28
4      14      50   2018-02-04
5      18     100   2018-02-11
6      17      40   2018-02-18
7      19      50   2018-02-25
>>> df.resample('M', on='week_starting').mean()
           price  volume
week_starting
2018-01-31    10.75    62.5
2018-02-28    17.00    60.0

```

For a `DataFrame` with `MultiIndex`, the keyword *level* can be used to specify on which level the resampling needs to take place.

```

>>> days = pd.date_range('1/1/2000', periods=4, freq='D')
>>> d2 = dict({'price': [10, 11, 9, 13, 14, 18, 17, 19],
...           'volume': [50, 60, 40, 100, 50, 100, 40, 50]})
>>> df2 = pd.DataFrame(d2,
...                     index=pd.MultiIndex.from_product([days,
...                                                         ['morning',
...                                                         'afternoon']])
>>> df2
           price  volume
2000-01-01 morning    10     50
           afternoon    11     60
2000-01-02 morning     9     40
           afternoon    13    100
2000-01-03 morning    14     50
           afternoon    18    100
2000-01-04 morning    17     40
           afternoon    19     50
>>> df2.resample('D', level=0).sum()
           price  volume
2000-01-01     21    110
2000-01-02     22    140
2000-01-03     32    150
2000-01-04     36     90

```

### pandas.Panel.rfloordiv

`Panel.rfloordiv` (*other*, *axis=0*)

Integer division of series and other, element-wise (binary operator *rfloordiv*). Equivalent to `other // panel`.

#### Parameters

**other** [DataFrame or Panel]

**axis** [{items, major\_axis, minor\_axis}] Axis to broadcast over

#### Returns

**Panel**

See also:

`Panel.floordiv`

### **pandas.Panel.rmod**

`Panel.rmod(other, axis=0)`

Modulo of series and other, element-wise (binary operator *rmod*). Equivalent to `other % panel`.

#### **Parameters**

**other** [DataFrame or Panel]

**axis** [{items, major\_axis, minor\_axis}] Axis to broadcast over

#### **Returns**

**Panel**

See also:

`Panel.mod`

### **pandas.Panel.rmul**

`Panel.rmul(other, axis=0)`

Multiplication of series and other, element-wise (binary operator *rmul*). Equivalent to `other * panel`.

#### **Parameters**

**other** [DataFrame or Panel]

**axis** [{items, major\_axis, minor\_axis}] Axis to broadcast over

#### **Returns**

**Panel**

See also:

`Panel.mul`

### **pandas.Panel.round**

`Panel.round(decimals=0, *args, **kwargs)`

Round each value in Panel to a specified number of decimal places.

New in version 0.18.0.

#### **Parameters**

**decimals** [int] Number of decimal places to round to (default: 0). If decimals is negative, it specifies the number of positions to the left of the decimal point.

#### **Returns**

**Panel object**

See also:

`numpy.around`

### pandas.Panel.rpow

`Panel.rpow(other, axis=0)`

Exponential power of series and other, element-wise (binary operator *rpow*). Equivalent to `other ** panel`.

#### Parameters

**other** [DataFrame or Panel]

**axis** [{items, major\_axis, minor\_axis}] Axis to broadcast over

#### Returns

**Panel**

#### See also:

*Panel.pow*

### pandas.Panel.rsub

`Panel.rsub(other, axis=0)`

Subtraction of series and other, element-wise (binary operator *rsub*). Equivalent to `other - panel`.

#### Parameters

**other** [DataFrame or Panel]

**axis** [{items, major\_axis, minor\_axis}] Axis to broadcast over

#### Returns

**Panel**

#### See also:

*Panel.sub*

### pandas.Panel.rtruediv

`Panel.rtruediv(other, axis=0)`

Floating division of series and other, element-wise (binary operator *rtruediv*). Equivalent to `other / panel`.

#### Parameters

**other** [DataFrame or Panel]

**axis** [{items, major\_axis, minor\_axis}] Axis to broadcast over

#### Returns

**Panel**

#### See also:

*Panel.truediv*

**pandas.Panel.sample**

`Panel.sample` (*n=None*, *frac=None*, *replace=False*, *weights=None*, *random\_state=None*, *axis=None*)

Return a random sample of items from an axis of object.

You can use *random\_state* for reproducibility.

**Parameters**

**n** [int, optional] Number of items from axis to return. Cannot be used with *frac*. Default = 1 if *frac* = None.

**frac** [float, optional] Fraction of axis items to return. Cannot be used with *n*.

**replace** [bool, default False] Sample with or without replacement.

**weights** [str or ndarray-like, optional] Default 'None' results in equal probability weighting. If passed a Series, will align with target object on index. Index values in weights not found in sampled object will be ignored and index values in sampled object not in weights will be assigned weights of zero. If called on a DataFrame, will accept the name of a column when *axis* = 0. Unless weights are a Series, weights must be same length as axis being sampled. If weights do not sum to 1, they will be normalized to sum to 1. Missing values in the weights column will be treated as zero. Infinite values not allowed.

**random\_state** [int or numpy.random.RandomState, optional] Seed for the random number generator (if int), or numpy RandomState object.

**axis** [int or string, optional] Axis to sample. Accepts axis number or name. Default is stat axis for given data type (0 for Series and DataFrames, 1 for Panels).

**Returns**

**Series or DataFrame** A new object of same type as caller containing *n* items randomly sampled from the caller object.

See also:

[`numpy.random.choice`](#) Generates a random sample from a given 1-D numpy array.

**Examples**

```
>>> df = pd.DataFrame({'num_legs': [2, 4, 8, 0],
...                    'num_wings': [2, 0, 0, 0],
...                    'num_specimen_seen': [10, 2, 1, 8]},
...                    index=['falcon', 'dog', 'spider', 'fish'])
>>> df
```

|        | num_legs | num_wings | num_specimen_seen |
|--------|----------|-----------|-------------------|
| falcon | 2        | 2         | 10                |
| dog    | 4        | 0         | 2                 |
| spider | 8        | 0         | 1                 |
| fish   | 0        | 0         | 8                 |

Extract 3 random elements from the Series `df['num_legs']`: Note that we use *random\_state* to ensure the reproducibility of the examples.

```
>>> df['num_legs'].sample(n=3, random_state=1)
fish      0
spider    8
falcon    2
Name: num_legs, dtype: int64
```

A random 50% sample of the DataFrame with replacement:

```
>>> df.sample(frac=0.5, replace=True, random_state=1)
   num_legs  num_wings  num_specimen_seen
dog         4         0                 2
fish        0         0                 8
```

Using a DataFrame column as weights. Rows with larger value in the `num_specimen_seen` column are more likely to be sampled.

```
>>> df.sample(n=2, weights='num_specimen_seen', random_state=1)
   num_legs  num_wings  num_specimen_seen
falcon     2         2                 10
fish       0         0                 8
```

## pandas.Panel.select

`Panel.select(crit, axis=0)`

Return data corresponding to axis labels matching criteria.

Deprecated since version 0.21.0: Use `df.loc[df.index.map(crit)]` to select via labels

### Parameters

**crit** [function] To be called on each index (label). Should return True or False

**axis** [int]

### Returns

**selection** [same type as caller]

## pandas.Panel.sem

`Panel.sem(axis=None, skipna=None, level=None, ddof=1, numeric_only=None, **kwargs)`

Return unbiased standard error of the mean over requested axis.

Normalized by N-1 by default. This can be changed using the `ddof` argument

### Parameters

**axis** [{items (0), major\_axis (1), minor\_axis (2)}]

**skipna** [boolean, default True] Exclude NA/null values. If an entire row/column is NA, the result will be NA

**level** [int or level name, default None] If the axis is a MultiIndex (hierarchical), count along a particular level, collapsing into a DataFrame

**ddof** [int, default 1] Delta Degrees of Freedom. The divisor used in calculations is N - ddof, where N represents the number of elements.

**numeric\_only** [boolean, default None] Include only float, int, boolean columns. If None, will attempt to use everything, then use only numeric data. Not implemented for Series.

#### Returns

**sem** [DataFrame or Panel (if level specified)]

### pandas.Panel.set\_axis

`Panel.set_axis(labels, axis=0, inplace=None)`

Assign desired index to given axis.

Indexes for column or row labels can be changed by assigning a list-like or Index.

Changed in version 0.21.0: The signature is now *labels* and *axis*, consistent with the rest of pandas API. Previously, the *axis* and *labels* arguments were respectively the first and second positional arguments.

#### Parameters

**labels** [list-like, Index] The values for the new index.

**axis** [{0 or 'index', 1 or 'columns'}, default 0] The axis to update. The value 0 identifies the rows, and 1 identifies the columns.

**inplace** [boolean, default None] Whether to return a new %(klass)s instance.

**Warning:** `inplace=None` currently falls back to `True`, but in a future version, will default to `False`. Use `inplace=True` explicitly rather than relying on the default.

#### Returns

**renamed** [%(klass)s or None] An object of same type as caller if `inplace=False`, None otherwise.

#### See also:

**DataFrame.rename\_axis** Alter the name of the index or columns.

### Examples

#### Series

```
>>> s = pd.Series([1, 2, 3])
>>> s
0    1
1    2
2    3
dtype: int64
```

```
>>> s.set_axis(['a', 'b', 'c'], axis=0, inplace=False)
a    1
b    2
c    3
dtype: int64
```

The original object is not modified.

```
>>> s
0    1
1    2
2    3
dtype: int64
```

### DataFrame

```
>>> df = pd.DataFrame({"A": [1, 2, 3], "B": [4, 5, 6]})
```

Change the row labels.

```
>>> df.set_axis(['a', 'b', 'c'], axis='index', inplace=False)
   A  B
a  1  4
b  2  5
c  3  6
```

Change the column labels.

```
>>> df.set_axis(['I', 'II'], axis='columns', inplace=False)
   I  II
0  1   4
1  2   5
2  3   6
```

Now, update the labels inplace.

```
>>> df.set_axis(['i', 'ii'], axis='columns', inplace=True)
>>> df
   i  ii
0  1   4
1  2   5
2  3   6
```

## pandas.Panel.set\_value

`Panel.set_value(*args, **kwargs)`

Quickly set single value at (item, major, minor) location.

Deprecated since version 0.21.0.

Please use `.at[]` or `.iat[]` accessors.

### Parameters

**item** [item label (panel item)]

**major** [major axis label (panel item row)]

**minor** [minor axis label (panel item column)]

**value** [scalar]

**takeable** [interpret the passed labels as indexers, default False]

### Returns

**panel** [Panel] If label combo is contained, will be reference to calling Panel, otherwise a new object

### pandas.Panel.shift

`Panel.shift` (*periods=1, freq=None, axis='major'*)

Shift index by desired number of periods with an optional time freq.

The shifted data will not include the dropped periods and the shifted axis will be smaller than the original. This is different from the behavior of `DataFrame.shift()`

#### Parameters

**periods** [int] Number of periods to move, can be positive or negative

**freq** [DateOffset, timedelta, or time rule string, optional]

**axis** [{ 'items', 'major', 'minor' } or {0, 1, 2}]

#### Returns

**shifted** [Panel]

### pandas.Panel.skew

`Panel.skew` (*axis=None, skipna=None, level=None, numeric\_only=None, \*\*kwargs*)

Return unbiased skew over requested axis Normalized by N-1.

#### Parameters

**axis** [{items (0), major\_axis (1), minor\_axis (2)}] Axis for the function to be applied on.

**skipna** [bool, default True] Exclude NA/null values when computing the result.

**level** [int or level name, default None] If the axis is a MultiIndex (hierarchical), count along a particular level, collapsing into a DataFrame.

**numeric\_only** [bool, default None] Include only float, int, boolean columns. If None, will attempt to use everything, then use only numeric data. Not implemented for Series.

**\*\*kwargs** Additional keyword arguments to be passed to the function.

#### Returns

**skew** [DataFrame or Panel (if level specified)]

### pandas.Panel.slice\_shift

`Panel.slice_shift` (*periods=1, axis=0*)

Equivalent to *shift* without copying data. The shifted data will not include the dropped periods and the shifted axis will be smaller than the original.

#### Parameters

**periods** [int] Number of periods to move, can be positive or negative

#### Returns

**shifted** [same type as caller]

## Notes

While the *slice\_shift* is faster than *shift*, you may pay for it later during alignment.

### pandas.Panel.sort\_index

`Panel.sort_index(axis=0, level=None, ascending=True, inplace=False, kind='quicksort', na_position='last', sort_remaining=True)`  
Sort object by labels (along an axis)

#### Parameters

**axis** [% (axes)s to direct sorting]

**level** [int or level name or list of ints or list of level names] if not None, sort on values in specified index level(s)

**ascending** [boolean, default True] Sort ascending vs. descending

**inplace** [bool, default False] if True, perform operation in-place

**kind** [{ 'quicksort', 'mergesort', 'heapsort' }, default 'quicksort'] Choice of sorting algorithm. See also `ndarray.sort` for more information. *mergesort* is the only stable algorithm. For DataFrames, this option is only applied when sorting on a single column or label.

**na\_position** [{ 'first', 'last' }, default 'last'] *first* puts NaNs at the beginning, *last* puts NaNs at the end. Not implemented for MultiIndex.

**sort\_remaining** [bool, default True] if true and sorting by level and index is multilevel, sort by other levels too (in order) after sorting by specified level

#### Returns

**sorted\_obj** [% (klass)s]

### pandas.Panel.sort\_values

`Panel.sort_values(*args, **kwargs)`

NOT IMPLEMENTED: do not call this method, as sorting values is not supported for Panel objects and will raise an error.

### pandas.Panel.squeeze

`Panel.squeeze(axis=None)`

Squeeze 1 dimensional axis objects into scalars.

Series or DataFrames with a single element are squeezed to a scalar. DataFrames with a single column or a single row are squeezed to a Series. Otherwise the object is unchanged.

This method is most useful when you don't know if your object is a Series or DataFrame, but you do know it has just a single column. In that case you can safely call *squeeze* to ensure you have a Series.

#### Parameters

**axis** [{0 or 'index', 1 or 'columns', None}, default None] A specific axis to squeeze. By default, all length-1 axes are squeezed.

New in version 0.20.0.

### Returns

**DataFrame, Series, or scalar** The projection after squeezing *axis* or all the axes.

See also:

**Series.iloc** Integer-location based indexing for selecting scalars.

**DataFrame.iloc** Integer-location based indexing for selecting Series.

**Series.to\_frame** Inverse of DataFrame.squeeze for a single-column DataFrame.

### Examples

```
>>> primes = pd.Series([2, 3, 5, 7])
```

Slicing might produce a Series with a single value:

```
>>> even_primes = primes[primes % 2 == 0]
>>> even_primes
0    2
dtype: int64
```

```
>>> even_primes.squeeze()
2
```

Squeezing objects with more than one value in every axis does nothing:

```
>>> odd_primes = primes[primes % 2 == 1]
>>> odd_primes
1    3
2    5
3    7
dtype: int64
```

```
>>> odd_primes.squeeze()
1    3
2    5
3    7
dtype: int64
```

Squeezing is even more effective when used with DataFrames.

```
>>> df = pd.DataFrame([[1, 2], [3, 4]], columns=['a', 'b'])
>>> df
   a  b
0  1  2
1  3  4
```

Slicing a single column will produce a DataFrame with the columns having only one value:

```
>>> df_a = df[['a']]
>>> df_a
   a
0  1
1  3
```

So the columns can be squeezed down, resulting in a Series:

```
>>> df_a.squeeze('columns')
0    1
1    3
Name: a, dtype: int64
```

Slicing a single row from a single column will produce a single scalar DataFrame:

```
>>> df_0a = df.loc[df.index < 1, ['a']]
>>> df_0a
   a
0  1
```

Squeezing the rows produces a single scalar Series:

```
>>> df_0a.squeeze('rows')
a    1
Name: 0, dtype: int64
```

Squeezing all axes will project directly into a scalar:

```
>>> df_0a.squeeze()
1
```

## pandas.Panel.std

`Panel.std` (*axis=None*, *skipna=None*, *level=None*, *ddof=1*, *numeric\_only=None*, *\*\*kwargs*)

Return sample standard deviation over requested axis.

Normalized by N-1 by default. This can be changed using the *ddof* argument

### Parameters

**axis** [{items (0), major\_axis (1), minor\_axis (2)}]

**skipna** [boolean, default True] Exclude NA/null values. If an entire row/column is NA, the result will be NA

**level** [int or level name, default None] If the axis is a MultiIndex (hierarchical), count along a particular level, collapsing into a DataFrame

**ddof** [int, default 1] Delta Degrees of Freedom. The divisor used in calculations is N - ddof, where N represents the number of elements.

**numeric\_only** [boolean, default None] Include only float, int, boolean columns. If None, will attempt to use everything, then use only numeric data. Not implemented for Series.

### Returns

**std** [DataFrame or Panel (if level specified)]

## pandas.Panel.sub

`Panel.sub` (*other*, *axis=0*)

Subtraction of series and other, element-wise (binary operator *sub*). Equivalent to `panel - other`.

### Parameters

**other** [DataFrame or Panel]

**axis** [{items, major\_axis, minor\_axis}] Axis to broadcast over

#### Returns

**Panel**

**See also:**

*Panel.rsub*

### pandas.Panel.subtract

`Panel.subtract(other, axis=0)`

Subtraction of series and other, element-wise (binary operator *sub*). Equivalent to `panel - other`.

#### Parameters

**other** [DataFrame or Panel]

**axis** [{items, major\_axis, minor\_axis}] Axis to broadcast over

#### Returns

**Panel**

**See also:**

*Panel.rsub*

### pandas.Panel.sum

`Panel.sum(axis=None, skipna=None, level=None, numeric_only=None, min_count=0, **kwargs)`

Return the sum of the values for the requested axis.

This is equivalent to the method `numpy.sum`.

#### Parameters

**axis** [{items (0), major\_axis (1), minor\_axis (2)}] Axis for the function to be applied on.

**skipna** [bool, default True] Exclude NA/null values when computing the result.

**level** [int or level name, default None] If the axis is a MultiIndex (hierarchical), count along a particular level, collapsing into a DataFrame.

**numeric\_only** [bool, default None] Include only float, int, boolean columns. If None, will attempt to use everything, then use only numeric data. Not implemented for Series.

**min\_count** [int, default 0] The required number of valid values to perform the operation. If fewer than `min_count` non-NA values are present the result will be NA.

New in version 0.22.0: Added with the default being 0. This means the sum of an all-NA or empty Series is 0, and the product of an all-NA or empty Series is 1.

**\*\*kwargs** Additional keyword arguments to be passed to the function.

#### Returns

**sum** [DataFrame or Panel (if level specified)]

See also:

**Series.sum** Return the sum.

**Series.min** Return the minimum.

**Series.max** Return the maximum.

**Series.idxmin** Return the index of the minimum.

**Series.idxmax** Return the index of the maximum.

**DataFrame.min** Return the sum over the requested axis.

**DataFrame.min** Return the minimum over the requested axis.

**DataFrame.max** Return the maximum over the requested axis.

**DataFrame.idxmin** Return the index of the minimum over the requested axis.

**DataFrame.idxmax** Return the index of the maximum over the requested axis.

## Examples

```
>>> idx = pd.MultiIndex.from_arrays([
...     ['warm', 'warm', 'cold', 'cold'],
...     ['dog', 'falcon', 'fish', 'spider']],
...     names=['blooded', 'animal'])
>>> s = pd.Series([4, 2, 0, 8], name='legs', index=idx)
>>> s
blooded  animal
warm     dog      4
         falcon   2
cold     fish     0
         spider   8
Name: legs, dtype: int64
```

```
>>> s.sum()
14
```

Sum using level names, as well as indices.

```
>>> s.sum(level='blooded')
blooded
warm     6
cold     8
Name: legs, dtype: int64
```

```
>>> s.sum(level=0)
blooded
warm     6
cold     8
Name: legs, dtype: int64
```

By default, the sum of an empty or all-NA Series is 0.

```
>>> pd.Series([]).sum() # min_count=0 is the default
0.0
```

This can be controlled with the `min_count` parameter. For example, if you'd like the sum of an empty series to be NaN, pass `min_count=1`.

```
>>> pd.Series([]).sum(min_count=1)
nan
```

Thanks to the `skipna` parameter, `min_count` handles all-NA and empty series identically.

```
>>> pd.Series([np.nan]).sum()
0.0
```

```
>>> pd.Series([np.nan]).sum(min_count=1)
nan
```

## pandas.Panel.swapaxes

`Panel.swapaxes` (*axis1*, *axis2*, *copy=True*)

Interchange axes and swap values axes appropriately.

### Returns

**y** [same as input]

## pandas.Panel.swaplevel

`Panel.swaplevel` (*i=-2*, *j=-1*, *axis=0*)

Swap levels *i* and *j* in a MultiIndex on a particular axis

### Parameters

**i, j** [int, string (can be mixed)] Level of index to be swapped. Can pass level name as string.

### Returns

**swapped** [same type as caller (new object)]

**.. versionchanged:: 0.18.1** The indexes *i* and *j* are now optional, and default to the two innermost levels of the index.

## pandas.Panel.tail

`Panel.tail` (*n=5*)

Return the last *n* rows.

This function returns last *n* rows from the object based on position. It is useful for quickly verifying data, for example, after sorting or appending rows.

### Parameters

**n** [int, default 5] Number of rows to select.

### Returns

**type of caller** The last *n* rows of the caller object.

See also:

**DataFrame.head** The first  $n$  rows of the caller object.

### Examples

```
>>> df = pd.DataFrame({'animal': ['alligator', 'bee', 'falcon', 'lion',
...                               'monkey', 'parrot', 'shark', 'whale', 'zebra']})
>>> df
   animal
0  alligator
1      bee
2   falcon
3     lion
4   monkey
5   parrot
6   shark
7   whale
8   zebra
```

Viewing the last 5 lines

```
>>> df.tail()
   animal
4  monkey
5  parrot
6   shark
7   whale
8   zebra
```

Viewing the last  $n$  lines (three in this case)

```
>>> df.tail(3)
   animal
6  shark
7  whale
8  zebra
```

### pandas.Panel.take

**Panel.take** (*indices*, *axis=0*, *convert=None*, *is\_copy=True*, *\*\*kwargs*)

Return the elements in the given *positional* indices along an axis.

This means that we are not indexing according to actual values in the index attribute of the object. We are indexing according to the actual position of the element in the object.

#### Parameters

**indices** [array-like] An array of ints indicating which positions to take.

**axis** [{0 or 'index', 1 or 'columns', None}, default 0] The axis on which to select elements. 0 means that we are selecting rows, 1 means that we are selecting columns.

**convert** [bool, default True] Whether to convert negative indices into positive ones. For example, -1 would map to the `len(axis) - 1`. The conversions are similar to the behavior of indexing a regular Python list.

Deprecated since version 0.21.0: In the future, negative indices will always be converted.

**is\_copy** [bool, default True] Whether to return a copy of the original object or not.

**\*\*kwargs** For compatibility with `numpy.take()`. Has no effect on the output.

### Returns

**taken** [same type as caller] An array-like containing the elements taken from the object.

See also:

**DataFrame.loc** Select a subset of a DataFrame by labels.

**DataFrame.iloc** Select a subset of a DataFrame by positions.

**numpy.take** Take elements from an array along an axis.

### Examples

```
>>> df = pd.DataFrame([('falcon', 'bird', 389.0),
...                     ('parrot', 'bird', 24.0),
...                     ('lion', 'mammal', 80.5),
...                     ('monkey', 'mammal', np.nan)],
...                     columns=['name', 'class', 'max_speed'],
...                     index=[0, 2, 3, 1])
>>> df
```

|   | name   | class  | max_speed |
|---|--------|--------|-----------|
| 0 | falcon | bird   | 389.0     |
| 2 | parrot | bird   | 24.0      |
| 3 | lion   | mammal | 80.5      |
| 1 | monkey | mammal | NaN       |

Take elements at positions 0 and 3 along the axis 0 (default).

Note how the actual indices selected (0 and 1) do not correspond to our selected indices 0 and 3. That's because we are selecting the 0th and 3rd rows, not rows whose indices equal 0 and 3.

```
>>> df.take([0, 3])
```

|   | name   | class  | max_speed |
|---|--------|--------|-----------|
| 0 | falcon | bird   | 389.0     |
| 1 | monkey | mammal | NaN       |

Take elements at indices 1 and 2 along the axis 1 (column selection).

```
>>> df.take([1, 2], axis=1)
```

|   | class  | max_speed |
|---|--------|-----------|
| 0 | bird   | 389.0     |
| 2 | bird   | 24.0      |
| 3 | mammal | 80.5      |
| 1 | mammal | NaN       |

We may take elements using negative integers for positive indices, starting from the end of the object, just like with Python lists.

```
>>> df.take([-1, -2])
```

|   | name   | class  | max_speed |
|---|--------|--------|-----------|
| 1 | monkey | mammal | NaN       |
| 3 | lion   | mammal | 80.5      |

## pandas.Panel.to\_clipboard

`Panel.to_clipboard(excel=True, sep=None, **kwargs)`

Copy object to the system clipboard.

Write a text representation of object to the system clipboard. This can be pasted into Excel, for example.

### Parameters

**excel** [bool, default True]

- True, use the provided separator, writing in a csv format for allowing easy pasting into excel.
- False, write a string representation of the object to the clipboard.

**sep** [str, default '\t'] Field delimiter.

**\*\*kwargs** These parameters will be passed to `DataFrame.to_csv`.

See also:

**DataFrame.to\_csv** Write a DataFrame to a comma-separated values (csv) file.

**read\_clipboard** Read text from clipboard and pass to `read_table`.

### Notes

Requirements for your platform.

- Linux : `xclip`, or `xsel` (with `gtk` or `PyQt4` modules)
- Windows : none
- OS X : none

### Examples

Copy the contents of a DataFrame to the clipboard.

```
>>> df = pd.DataFrame([[1, 2, 3], [4, 5, 6]], columns=['A', 'B', 'C'])
>>> df.to_clipboard(sep=',')
... # Wrote the following to the system clipboard:
... # ,A,B,C
... # 0,1,2,3
... # 1,4,5,6
```

We can omit the the index by passing the keyword `index` and setting it to false.

```
>>> df.to_clipboard(sep=',', index=False)
... # Wrote the following to the system clipboard:
... # A,B,C
... # 1,2,3
... # 4,5,6
```

**pandas.Panel.to\_csv**

```
Panel.to_csv(path_or_buf=None, sep=', ', na_rep="", float_format=None, columns=None,
             header=True, index=True, index_label=None, mode='w', encoding=None,
             compression='infer', quoting=None, quotechar='"', line_terminator=None,
             chunksize=None, tupleize_cols=None, date_format=None, doublequote=True,
             escapechar=None, decimal='.')
```

Write object to a comma-separated values (csv) file.

Changed in version 0.24.0: The order of arguments for Series was changed.

**Parameters**

**path\_or\_buf** [str or file handle, default None] File path or object, if None is provided the result is returned as a string.

Changed in version 0.24.0: Was previously named “path” for Series.

**sep** [str, default ‘,’] String of length 1. Field delimiter for the output file.

**na\_rep** [str, default ‘’] Missing data representation.

**float\_format** [str, default None] Format string for floating point numbers.

**columns** [sequence, optional] Columns to write.

**header** [bool or list of str, default True] Write out the column names. If a list of strings is given it is assumed to be aliases for the column names.

Changed in version 0.24.0: Previously defaulted to False for Series.

**index** [bool, default True] Write row names (index).

**index\_label** [str or sequence, or False, default None] Column label for index column(s) if desired. If None is given, and *header* and *index* are True, then the index names are used. A sequence should be given if the object uses MultiIndex. If False do not print fields for index names. Use *index\_label=False* for easier importing in R.

**mode** [str] Python write mode, default ‘w’.

**encoding** [str, optional] A string representing the encoding to use in the output file, defaults to ‘ascii’ on Python 2 and ‘utf-8’ on Python 3.

**compression** [str, default ‘infer’] Compression mode among the following possible values: {‘infer’, ‘gzip’, ‘bz2’, ‘zip’, ‘xz’, None}. If ‘infer’ and *path\_or\_buf* is path-like, then detect compression from the following extensions: ‘.gz’, ‘.bz2’, ‘.zip’ or ‘.xz’. (otherwise no compression).

Changed in version 0.24.0: ‘infer’ option added and set to default.

**quoting** [optional constant from csv module] Defaults to csv.QUOTE\_MINIMAL. If you have set a *float\_format* then floats are converted to strings and thus csv.QUOTE\_NONNUMERIC will treat them as non-numeric.

**quotechar** [str, default ‘”’] String of length 1. Character used to quote fields.

**line\_terminator** [string, optional] The newline character or character sequence to use in the output file. Defaults to *os.linesep*, which depends on the OS in which this method is called (‘\n’ for linux, ‘\r\n’ for Windows, i.e.).

Changed in version 0.24.0.

**chunksize** [int or None] Rows to write at a time.

**tupleize\_cols** [bool, default False] Write MultiIndex columns as a list of tuples (if True) or in the new, expanded format, where each MultiIndex column is a row in the CSV (if False).

Deprecated since version 0.21.0: This argument will be removed and will always write each row of the multi-index as a separate row in the CSV file.

**date\_format** [str, default None] Format string for datetime objects.

**doublequote** [bool, default True] Control quoting of *quotechar* inside a field.

**escapechar** [str, default None] String of length 1. Character used to escape *sep* and *quotechar* when appropriate.

**decimal** [str, default '.'] Character recognized as decimal separator. E.g. use ',' for European data.

### Returns

**None or str** If *path\_or\_buf* is None, returns the resulting csv format as a string. Otherwise returns None.

See also:

**read\_csv** Load a CSV file into a DataFrame.

**to\_excel** Load an Excel file into a DataFrame.

### Examples

```
>>> df = pd.DataFrame({'name': ['Raphael', 'Donatello'],
...                    'mask': ['red', 'purple'],
...                    'weapon': ['sai', 'bo staff']})
>>> df.to_csv(index=False)
'name,mask,weapon\nRaphael,red,sai\nDonatello,purple,bo staff\n'
```

## pandas.Panel.to\_dense

`Panel.to_dense()`

Return dense representation of NDFrame (as opposed to sparse).

## pandas.Panel.to\_excel

`Panel.to_excel(path, na_rep="", engine=None, **kwargs)`

Write each DataFrame in Panel to a separate excel sheet.

### Parameters

**path** [string or ExcelWriter object] File path or existing ExcelWriter

**na\_rep** [string, default ''] Missing data representation

**engine** [string, default None] write engine to use - you can also set this via the options `io.excel.xlsx.writer`, `io.excel.xls.writer`, and `io.excel.xlsm.writer`.

### Other Parameters

**float\_format** [string, default None] Format string for floating point numbers

**cols** [sequence, optional] Columns to write

**header** [boolean or list of string, default True] Write out column names. If a list of string is given it is assumed to be aliases for the column names

**index** [boolean, default True] Write row names (index)

**index\_label** [string or sequence, default None] Column label for index column(s) if desired. If None is given, and *header* and *index* are True, then the index names are used. A sequence should be given if the DataFrame uses MultiIndex.

**startrow** [upper left cell row to dump data frame]

**startcol** [upper left cell column to dump data frame]

## Notes

Keyword arguments (and `na_rep`) are passed to the `to_excel` method for each DataFrame written.

## pandas.Panel.to\_frame

`Panel.to_frame (filter_observations=True)`

Transform wide format into long (stacked) format as DataFrame whose columns are the Panel's items and whose index is a MultiIndex formed of the Panel's major and minor axes.

### Parameters

**filter\_observations** [boolean, default True] Drop (major, minor) pairs without a complete set of observations across all the items

### Returns

**y** [DataFrame]

## pandas.Panel.to\_hdf

`Panel.to_hdf (path_or_buf, key, **kwargs)`

Write the contained data to an HDF5 file using HDFStore.

Hierarchical Data Format (HDF) is self-describing, allowing an application to interpret the structure and contents of a file with no outside information. One HDF file can hold a mix of related objects which can be accessed as a group or as individual objects.

In order to add another DataFrame or Series to an existing HDF file please use append mode and a different a key.

For more information see the *user guide*.

### Parameters

**path\_or\_buf** [str or pandas.HDFStore] File path or HDFStore object.

**key** [str] Identifier for the group in the store.

**mode** [{ 'a', 'w', 'r+' }, default 'a'] Mode to open file:

- 'w': write, a new file is created (an existing file with the same name would be deleted).

- 'a': append, an existing file is opened for reading and writing, and if the file does not exist it is created.
- 'r+': similar to 'a', but the file must already exist.

**format** [{ 'fixed', 'table' }, default 'fixed'] Possible values:

- 'fixed': Fixed format. Fast writing/reading. Not-appendable, nor searchable.
- 'table': Table format. Write as a PyTables Table structure which may perform worse but allow more flexible operations like searching / selecting subsets of the data.

**append** [bool, default False] For Table formats, append the input data to the existing.

**data\_columns** [list of columns or True, optional] List of columns to create as indexed data columns for on-disk queries, or True to use all columns. By default only the axes of the object are indexed. See *Query via Data Columns*. Applicable only to format='table'.

**complevel** [{0-9}, optional] Specifies a compression level for data. A value of 0 disables compression.

**complib** [{ 'zlib', 'lzo', 'bzip2', 'blosc' }, default 'zlib'] Specifies the compression library to be used. As of v0.20.2 these additional compressors for Blosc are supported (default if no compressor specified: 'blosc:blosclz'): { 'blosc:blosclz', 'blosc:lz4', 'blosc:lz4hc', 'blosc:snappy', 'blosc:zlib', 'blosc:zstd' }. Specifying a compression library which is not available issues a ValueError.

**fletcher32** [bool, default False] If applying compression use the fletcher32 checksum.

**dropna** [bool, default False] If true, ALL nan rows will not be written to store.

**errors** [str, default 'strict'] Specifies how encoding and decoding errors are to be handled. See the errors argument for `open()` for a full list of options.

See also:

**DataFrame.read\_hdf** Read from HDF file.

**DataFrame.to\_parquet** Write a DataFrame to the binary parquet format.

**DataFrame.to\_sql** Write to a sql table.

**DataFrame.to\_feather** Write out feather-format for DataFrames.

**DataFrame.to\_csv** Write out to a csv file.

## Examples

```
>>> df = pd.DataFrame({'A': [1, 2, 3], 'B': [4, 5, 6]},
...                   index=['a', 'b', 'c'])
>>> df.to_hdf('data.h5', key='df', mode='w')
```

We can add another object to the same file:

```
>>> s = pd.Series([1, 2, 3, 4])
>>> s.to_hdf('data.h5', key='s')
```

Reading from HDF file:

```
>>> pd.read_hdf('data.h5', 'df')
A  B
a  1  4
b  2  5
c  3  6
>>> pd.read_hdf('data.h5', 's')
0    1
1    2
2    3
3    4
dtype: int64
```

Deleting file with data:

```
>>> import os
>>> os.remove('data.h5')
```

## pandas.Panel.to\_json

`Panel.to_json`(*path\_or\_buf=None*, *orient=None*, *date\_format=None*, *double\_precision=10*, *force\_ascii=True*, *date\_unit='ms'*, *default\_handler=None*, *lines=False*, *compression='infer'*, *index=True*)

Convert the object to a JSON string.

Note NaN's and None will be converted to null and datetime objects will be converted to UNIX timestamps.

### Parameters

**path\_or\_buf** [string or file handle, optional] File path or object. If not specified, the result is returned as a string.

**orient** [string] Indication of expected JSON string format.

- Series
  - default is 'index'
  - allowed values are: {'split','records','index','table'}
- DataFrame
  - default is 'columns'
  - allowed values are: {'split','records','index','columns','values','table'}
- The format of the JSON string
  - 'split' : dict like {'index' -> [index], 'columns' -> [columns], 'data' -> [values]}
  - 'records' : list like [{column -> value}, ... , {column -> value}]
  - 'index' : dict like {index -> {column -> value}}
  - 'columns' : dict like {column -> {index -> value}}
  - 'values' : just the values array
  - 'table' : dict like {'schema': {schema}, 'data': {data}} describing the data, and the data component is like `orient='records'`.

Changed in version 0.20.0.

**date\_format** [{None, 'epoch', 'iso'}] Type of date conversion. 'epoch' = epoch milliseconds, 'iso' = ISO8601. The default depends on the *orient*. For *orient*='table', the default is 'iso'. For all other orients, the default is 'epoch'.

**double\_precision** [int, default 10] The number of decimal places to use when encoding floating point values.

**force\_ascii** [bool, default True] Force encoded string to be ASCII.

**date\_unit** [string, default 'ms' (milliseconds)] The time unit to encode to, governs timestamp and ISO8601 precision. One of 's', 'ms', 'us', 'ns' for second, millisecond, microsecond, and nanosecond respectively.

**default\_handler** [callable, default None] Handler to call if object cannot otherwise be converted to a suitable format for JSON. Should receive a single argument which is the object to convert and return a serialisable object.

**lines** [bool, default False] If 'orient' is 'records' write out line delimited json format. Will throw ValueError if incorrect 'orient' since others are not list like.

New in version 0.19.0.

**compression** [{ 'infer', 'gzip', 'bz2', 'zip', 'xz', None}] A string representing the compression to use in the output file, only used when the first argument is a filename. By default, the compression is inferred from the filename.

New in version 0.21.0.

Changed in version 0.24.0: 'infer' option added and set to default

**index** [bool, default True] Whether to include the index values in the JSON string. Not including the index (*index=False*) is only supported when *orient* is 'split' or 'table'.

New in version 0.23.0.

See also:

*read\_json*

## Examples

```
>>> df = pd.DataFrame([[ 'a', 'b'], [ 'c', 'd']],
...                    index=['row 1', 'row 2'],
...                    columns=['col 1', 'col 2'])
>>> df.to_json(orient='split')
'{"columns":["col 1","col 2"],
  "index":["row 1","row 2"],
  "data":[["a","b"],["c","d"]}]'
```

Encoding/decoding a Dataframe using 'records' formatted JSON. Note that index labels are not preserved with this encoding.

```
>>> df.to_json(orient='records')
'[{"col 1":"a","col 2":"b"}, {"col 1":"c","col 2":"d"}]'
```

Encoding/decoding a Dataframe using 'index' formatted JSON:

```
>>> df.to_json(orient='index')
'{"row 1":{"col 1":"a","col 2":"b"},"row 2":{"col 1":"c","col 2":"d"}}'
```

Encoding/decoding a Dataframe using 'columns' formatted JSON:

```
>>> df.to_json(orient='columns')
'{"col 1":{"row 1":"a","row 2":"c"},"col 2":{"row 1":"b","row 2":"d"}}'
```

Encoding/decoding a Dataframe using 'values' formatted JSON:

```
>>> df.to_json(orient='values')
'[[{"a","b"}, {"c","d"}]'
```

Encoding with Table Schema

```
>>> df.to_json(orient='table')
'{"schema": {"fields": [{"name": "index", "type": "string"},
                        {"name": "col 1", "type": "string"},
                        {"name": "col 2", "type": "string"}],
  "primaryKey": "index",
  "pandas_version": "0.20.0"},
 "data": [{"index": "row 1", "col 1": "a", "col 2": "b"},
           {"index": "row 2", "col 1": "c", "col 2": "d"}]}'
```

## pandas.Panel.to\_latex

`Panel.to_latex` (*buf=None*, *columns=None*, *col\_space=None*, *header=True*, *index=True*, *na\_rep='NaN'*, *formatters=None*, *float\_format=None*, *sparsify=None*, *index\_names=True*, *bold\_rows=False*, *column\_format=None*, *longtable=None*, *escape=None*, *encoding=None*, *decimal='.'*, *multicolumn=None*, *multicolumn\_format=None*, *multirow=None*)

Render an object to a LaTeX tabular environment table.

Render an object to a tabular environment table. You can splice this into a LaTeX document. Requires `usepackage{booktabs}`.

Changed in version 0.20.2: Added to Series

### Parameters

**buf** [file descriptor or None] Buffer to write to. If None, the output is returned as a string.

**columns** [list of label, optional] The subset of columns to write. Writes all columns by default.

**col\_space** [int, optional] The minimum width of each column.

**header** [bool or list of str, default True] Write out the column names. If a list of strings is given, it is assumed to be aliases for the column names.

**index** [bool, default True] Write row names (index).

**na\_rep** [str, default 'NaN'] Missing data representation.

**formatters** [list of functions or dict of {str: function}, optional] Formatter functions to apply to columns' elements by position or name. The result of each function must be a unicode string. List must be of length equal to the number of columns.

**float\_format** [str, optional] Format string for floating point numbers.

**sparsify** [bool, optional] Set to False for a DataFrame with a hierarchical index to print every multiindex key at each row. By default, the value will be read from the config module.

**index\_names** [bool, default True] Prints the names of the indexes.

**bold\_rows** [bool, default False] Make the row labels bold in the output.

**column\_format** [str, optional] The columns format as specified in [LaTeX table format](#) e.g. 'rcl' for 3 columns. By default, 'l' will be used for all columns except columns of numbers, which default to 'r'.

**longtable** [bool, optional] By default, the value will be read from the pandas config module. Use a longtable environment instead of tabular. Requires adding a usepackage{longtable} to your LaTeX preamble.

**escape** [bool, optional] By default, the value will be read from the pandas config module. When set to False prevents from escaping latex special characters in column names.

**encoding** [str, optional] A string representing the encoding to use in the output file, defaults to 'ascii' on Python 2 and 'utf-8' on Python 3.

**decimal** [str, default '.'] Character recognized as decimal separator, e.g. ',' in Europe. .. versionadded:: 0.18.0

**multicolumn** [bool, default True] Use multicolumn to enhance MultiIndex columns. The default will be read from the config module. .. versionadded:: 0.20.0

**multicolumn\_format** [str, default 'l'] The alignment for multicolumns, similar to *column\_format* The default will be read from the config module. .. versionadded:: 0.20.0

**multirow** [bool, default False] Use multirow to enhance MultiIndex rows. Requires adding a usepackage{multirow} to your LaTeX preamble. Will print centered labels (instead of top-aligned) across the contained rows, separating groups via clines. The default will be read from the pandas config module. .. versionadded:: 0.20.0

### Returns

**str or None** If buf is None, returns the resulting LaTeX format as a string. Otherwise returns None.

### See also:

**DataFrame.to\_string** Render a DataFrame to a console-friendly tabular output.

**DataFrame.to\_html** Render a DataFrame as an HTML table.

### Examples

```
>>> df = pd.DataFrame({'name': ['Raphael', 'Donatello'],
...                    'mask': ['red', 'purple'],
...                    'weapon': ['sai', 'bo staff']})
>>> df.to_latex(index=False) # doctest: +NORMALIZE_WHITESPACE
'\begin{tabular}{lll}\n\\toprule\n      name &      mask &      weapon\n\\\\\n\\midrule\n  Raphael &      red &      sai \\\n\\bottomrule\n\\end{tabular}\n'
```

### pandas.Panel.to\_msgpack

**Panel.to\_msgpack** (*path\_or\_buf=None, encoding='utf-8', \*\*kwargs*)  
Serialize object to input file path using msgpack format.

THIS IS AN EXPERIMENTAL LIBRARY and the storage format may not be stable until a future release.

**Parameters**

- path** [string File path, buffer-like, or None] if None, return generated string
- append** [bool whether to append to an existing msgpack] (default is False)
- compress** [type of compressor (zlib or blosc), default to None (no) compression]

**pandas.Panel.to\_pickle**

`Panel.to_pickle(path, compression='infer', protocol=4)`

Pickle (serialize) object to file.

**Parameters**

- path** [str] File path where the pickled object will be stored.
- compression** [{ 'infer', 'gzip', 'bz2', 'zip', 'xz', None }, default 'infer'] A string representing the compression to use in the output file. By default, infers from the file extension in specified path.

New in version 0.20.0.

- protocol** [int] Int which indicates which protocol should be used by the pickler, default HIGHEST\_PROTOCOL (see [?] paragraph 12.1.2). The possible values for this parameter depend on the version of Python. For Python 2.x, possible values are 0, 1, 2. For Python >= 3.0, 3 is a valid value. For Python >= 3.4, 4 is a valid value. A negative value for the protocol parameter is equivalent to setting its value to HIGHEST\_PROTOCOL.

New in version 0.21.0.

See also:

**read\_pickle** Load pickled pandas object (or any object) from file.

**DataFrame.to\_hdf** Write DataFrame to an HDF5 file.

**DataFrame.to\_sql** Write DataFrame to a SQL database.

**DataFrame.to\_parquet** Write a DataFrame to the binary parquet format.

**Examples**

```
>>> original_df = pd.DataFrame({"foo": range(5), "bar": range(5, 10)})
>>> original_df
   foo  bar
0    0    5
1    1    6
2    2    7
3    3    8
4    4    9
>>> original_df.to_pickle("./dummy.pkl")
```

```
>>> unpickled_df = pd.read_pickle("./dummy.pkl")
>>> unpickled_df
   foo  bar
0    0    5
```

(continues on next page)

(continued from previous page)

|   |   |   |
|---|---|---|
| 1 | 1 | 6 |
| 2 | 2 | 7 |
| 3 | 3 | 8 |
| 4 | 4 | 9 |

```
>>> import os
>>> os.remove("./dummy.pkl")
```

### pandas.Panel.to\_sparse

`Panel.to_sparse(*args, **kwargs)`

NOT IMPLEMENTED: do not call this method, as sparsifying is not supported for Panel objects and will raise an error.

Convert to SparsePanel.

### pandas.Panel.to\_sql

`Panel.to_sql(name, con, schema=None, if_exists='fail', index=True, index_label=None, chunk-size=None, dtype=None, method=None)`

Write records stored in a DataFrame to a SQL database.

Databases supported by SQLAlchemy [?] are supported. Tables can be newly created, appended to, or overwritten.

#### Parameters

**name** [string] Name of SQL table.

**con** [sqlalchemy.engine.Engine or sqlite3.Connection] Using SQLAlchemy makes it possible to use any DB supported by that library. Legacy support is provided for sqlite3.Connection objects.

**schema** [string, optional] Specify the schema (if database flavor supports this). If None, use default schema.

**if\_exists** [{ 'fail', 'replace', 'append' }, default 'fail'] How to behave if the table already exists.

- fail: Raise a ValueError.
- replace: Drop the table before inserting new values.
- append: Insert new values to the existing table.

**index** [bool, default True] Write DataFrame index as a column. Uses *index\_label* as the column name in the table.

**index\_label** [string or sequence, default None] Column label for index column(s). If None is given (default) and *index* is True, then the index names are used. A sequence should be given if the DataFrame uses MultiIndex.

**chunksize** [int, optional] Rows will be written in batches of this size at a time. By default, all rows will be written at once.

**dtype** [dict, optional] Specifying the datatype for columns. The keys should be the column names and the values should be the SQLAlchemy types or strings for the sqlite3 legacy mode.

**method** [{None, 'multi', callable}, default None] Controls the SQL insertion clause used:

- None : Uses standard SQL INSERT clause (one per row).
- 'multi': Pass multiple values in a single INSERT clause.
- callable with signature (pd\_table, conn, keys, data\_iter).

Details and a sample callable implementation can be found in the section *insert method*.

New in version 0.24.0.

### Raises

**ValueError** When the table already exists and *if\_exists* is 'fail' (the default).

**See also:**

**read\_sql** Read a DataFrame from a table.

### Notes

Timezone aware datetime columns will be written as Timestamp with timezone type with SQLAlchemy if supported by the database. Otherwise, the datetimes will be stored as timezone unaware timestamps local to the original timezone.

New in version 0.24.0.

### References

[?], [?]

### Examples

Create an in-memory SQLite database.

```
>>> from sqlalchemy import create_engine
>>> engine = create_engine('sqlite://', echo=False)
```

Create a table from scratch with 3 rows.

```
>>> df = pd.DataFrame({'name' : ['User 1', 'User 2', 'User 3']})
>>> df
   name
0  User 1
1  User 2
2  User 3
```

```
>>> df.to_sql('users', con=engine)
>>> engine.execute("SELECT * FROM users").fetchall()
[(0, 'User 1'), (1, 'User 2'), (2, 'User 3')]
```

```
>>> df1 = pd.DataFrame({'name' : ['User 4', 'User 5']})
>>> df1.to_sql('users', con=engine, if_exists='append')
>>> engine.execute("SELECT * FROM users").fetchall()
```

(continues on next page)

(continued from previous page)

```
[(0, 'User 1'), (1, 'User 2'), (2, 'User 3'),
 (0, 'User 4'), (1, 'User 5')]
```

Overwrite the table with just df1.

```
>>> df1.to_sql('users', con=engine, if_exists='replace',
...           index_label='id')
>>> engine.execute("SELECT * FROM users").fetchall()
[(0, 'User 4'), (1, 'User 5')]
```

Specify the dtype (especially useful for integers with missing values). Notice that while pandas is forced to store the data as floating point, the database supports nullable integers. When fetching the data with Python, we get back integer scalars.

```
>>> df = pd.DataFrame({"A": [1, None, 2]})
>>> df
   A
0  1.0
1  NaN
2  2.0
```

```
>>> from sqlalchemy.types import Integer
>>> df.to_sql('integers', con=engine, index=False,
...         dtype={"A": Integer()})
```

```
>>> engine.execute("SELECT * FROM integers").fetchall()
[(1,), (None,), (2,)]
```

## pandas.Panel.to\_xarray

`Panel.to_xarray()`

Return an xarray object from the pandas object.

### Returns

**xarray.DataArray or xarray.Dataset** Data in the pandas structure converted to Dataset if the object is a DataFrame, or a DataArray if the object is a Series.

See also:

**DataFrame.to\_hdf** Write DataFrame to an HDF5 file.

**DataFrame.to\_parquet** Write a DataFrame to the binary parquet format.

## Notes

See the [xarray docs](#)

## Examples

```
>>> df = pd.DataFrame([('falcon', 'bird', 389.0, 2),
...                     ('parrot', 'bird', 24.0, 2),
...                     ('lion', 'mammal', 80.5, 4),
...                     ('monkey', 'mammal', np.nan, 4)],
...                     columns=['name', 'class', 'max_speed',
...                               'num_legs'])
>>> df
```

|   | name   | class  | max_speed | num_legs |
|---|--------|--------|-----------|----------|
| 0 | falcon | bird   | 389.0     | 2        |
| 1 | parrot | bird   | 24.0      | 2        |
| 2 | lion   | mammal | 80.5      | 4        |
| 3 | monkey | mammal | NaN       | 4        |

```
>>> df.to_xarray()
<xarray.Dataset>
Dimensions:      (index: 4)
Coordinates:
  * index        (index) int64 0 1 2 3
Data variables:
  name           (index) object 'falcon' 'parrot' 'lion' 'monkey'
  class          (index) object 'bird' 'bird' 'mammal' 'mammal'
  max_speed      (index) float64 389.0 24.0 80.5 nan
  num_legs       (index) int64 2 2 4 4
```

```
>>> df['max_speed'].to_xarray()
<xarray.DataArray 'max_speed' (index: 4)>
array([389. , 24. , 80.5, nan])
Coordinates:
  * index      (index) int64 0 1 2 3
```

```
>>> dates = pd.to_datetime(['2018-01-01', '2018-01-01',
...                          '2018-01-02', '2018-01-02'])
>>> df_multiindex = pd.DataFrame({'date': dates,
...                               'animal': ['falcon', 'parrot', 'falcon',
...                                         'parrot'],
...                               'speed': [350, 18, 361, 15]}).set_index(['date',
...                               'animal'])
>>> df_multiindex
```

|  | date       | animal | speed |
|--|------------|--------|-------|
|  | 2018-01-01 | falcon | 350   |
|  |            | parrot | 18    |
|  | 2018-01-02 | falcon | 361   |
|  |            | parrot | 15    |

```
>>> df_multiindex.to_xarray()
<xarray.Dataset>
Dimensions:      (animal: 2, date: 2)
Coordinates:
  * date         (date) datetime64[ns] 2018-01-01 2018-01-02
  * animal       (animal) object 'falcon' 'parrot'
Data variables:
  speed         (date, animal) int64 350 18 361 15
```

## pandas.Panel.transform

`Panel.transform(func, *args, **kwargs)`

Call `func` on self producing a NDFrame with transformed values and that has the same axis length as self.

New in version 0.20.0.

### Parameters

**func** [function, str, list or dict] Function to use for transforming the data. If a function, must either work when passed a NDFrame or when passed to NDFrame.apply.

Accepted combinations are:

- function
- string function name
- list of functions and/or function names, e.g. `[np.exp, 'sqrt']`
- dict of axis labels -> functions, function names or list of such.

**\*args** Positional arguments to pass to `func`.

**\*\*kwargs** Keyword arguments to pass to `func`.

### Returns

**NDFrame** A NDFrame that must have the same length as self.

### Raises

**ValueError** [If the returned NDFrame has a different length than self.]

See also:

**NDFrame.agg** Only perform aggregating type operations.

**NDFrame.apply** Invoke function on a NDFrame.

## Examples

```

>>> df = pd.DataFrame({'A': range(3), 'B': range(1, 4)})
>>> df
   A  B
0  0  1
1  1  2
2  2  3
>>> df.transform(lambda x: x + 1)
   A  B
0  1  2
1  2  3
2  3  4

```

Even though the resulting NDFrame must have the same length as the input NDFrame, it is possible to provide several input functions:

```

>>> s = pd.Series(range(3))
>>> s
0    0

```

(continues on next page)

(continued from previous page)

```

1      1
2      2
dtype: int64
>>> s.transform([np.sqrt, np.exp])
      sqrt      exp
0  0.000000  1.000000
1  1.000000  2.718282
2  1.414214  7.389056

```

## pandas.Panel.transpose

`Panel.transpose(*args, **kwargs)`

Permute the dimensions of the Panel

### Parameters

**args** [three positional arguments: each one of]

**{0, 1, 2, 'items', 'major\_axis', 'minor\_axis'}**

**copy** [boolean, default False] Make a copy of the underlying data. Mixed-dtype data will always result in a copy

### Returns

**y** [same as input]

## Examples

```

>>> p.transpose(2, 0, 1)
>>> p.transpose(2, 0, 1, copy=True)

```

## pandas.Panel.truediv

`Panel.truediv(other, axis=0)`

Floating division of series and other, element-wise (binary operator *truediv*). Equivalent to `panel / other`.

### Parameters

**other** [DataFrame or Panel]

**axis** [{items, major\_axis, minor\_axis}] Axis to broadcast over

### Returns

**Panel**

**See also:**

`Panel.rtruediv`

**pandas.Panel.truncate**

`Panel.truncate` (*before=None, after=None, axis=None, copy=True*)

Truncate a Series or DataFrame before and after some index value.

This is a useful shorthand for boolean indexing based on index values above or below certain thresholds.

**Parameters**

**before** [date, string, int] Truncate all rows before this index value.

**after** [date, string, int] Truncate all rows after this index value.

**axis** [{0 or 'index', 1 or 'columns'}, optional] Axis to truncate. Truncates the index (rows) by default.

**copy** [boolean, default is True,] Return a copy of the truncated section.

**Returns**

**type of caller** The truncated Series or DataFrame.

**See also:**

**DataFrame.loc** Select a subset of a DataFrame by label.

**DataFrame.iloc** Select a subset of a DataFrame by position.

**Notes**

If the index being truncated contains only datetime values, *before* and *after* may be specified as strings instead of Timestamps.

**Examples**

```
>>> df = pd.DataFrame({'A': ['a', 'b', 'c', 'd', 'e'],
...                    'B': ['f', 'g', 'h', 'i', 'j'],
...                    'C': ['k', 'l', 'm', 'n', 'o']},
...                    index=[1, 2, 3, 4, 5])
>>> df
   A B C
1  a f k
2  b g l
3  c h m
4  d i n
5  e j o
```

```
>>> df.truncate(before=2, after=4)
   A B C
2  b g l
3  c h m
4  d i n
```

The columns of a DataFrame can be truncated.

```
>>> df.truncate(before="A", after="B", axis="columns")
   A  B
1  a  f
2  b  g
3  c  h
4  d  i
5  e  j
```

For Series, only rows can be truncated.

```
>>> df['A'].truncate(before=2, after=4)
2    b
3    c
4    d
Name: A, dtype: object
```

The index values in `truncate` can be datetimes or string dates.

```
>>> dates = pd.date_range('2016-01-01', '2016-02-01', freq='s')
>>> df = pd.DataFrame(index=dates, data={'A': 1})
>>> df.tail()
                A
2016-01-31 23:59:56  1
2016-01-31 23:59:57  1
2016-01-31 23:59:58  1
2016-01-31 23:59:59  1
2016-02-01 00:00:00  1
```

```
>>> df.truncate(before=pd.Timestamp('2016-01-05'),
...             after=pd.Timestamp('2016-01-10')).tail()
                A
2016-01-09 23:59:56  1
2016-01-09 23:59:57  1
2016-01-09 23:59:58  1
2016-01-09 23:59:59  1
2016-01-10 00:00:00  1
```

Because the index is a `DatetimeIndex` containing only dates, we can specify *before* and *after* as strings. They will be coerced to `Timestamps` before truncation.

```
>>> df.truncate('2016-01-05', '2016-01-10').tail()
                A
2016-01-09 23:59:56  1
2016-01-09 23:59:57  1
2016-01-09 23:59:58  1
2016-01-09 23:59:59  1
2016-01-10 00:00:00  1
```

Note that `truncate` assumes a 0 value for any unspecified time component (midnight). This differs from partial string slicing, which returns any partially matching dates.

```
>>> df.loc['2016-01-05':'2016-01-10', :].tail()
                A
2016-01-10 23:59:55  1
2016-01-10 23:59:56  1
2016-01-10 23:59:57  1
```

(continues on next page)

(continued from previous page)

```
2016-01-10 23:59:58 1
2016-01-10 23:59:59 1
```

**pandas.Panel.tshift****Panel.tshift** (*periods=1, freq=None, axis='major'*)

Shift the time index, using the index's frequency if available.

**Parameters****periods** [int] Number of periods to move, can be positive or negative**freq** [DateOffset, timedelta, or time rule string, default None] Increment to use from the tseries module or time rule (e.g. 'EOM')**axis** [int or basestring] Corresponds to the axis that contains the Index**Returns****shifted** [NDFrame]**Notes**

If freq is not specified then tries to use the freq or inferred\_freq attributes of the index. If neither of those attributes exist, a ValueError is thrown

**pandas.Panel.tz\_convert****Panel.tz\_convert** (*tz, axis=0, level=None, copy=True*)

Convert tz-aware axis to target time zone.

**Parameters****tz** [string or pytz.timezone object]**axis** [the axis to convert]**level** [int, str, default None] If axis is a MultiIndex, convert a specific level. Otherwise must be None**copy** [boolean, default True] Also make a copy of the underlying data**Raises****TypeError** If the axis is tz-naive.**pandas.Panel.tz\_localize****Panel.tz\_localize** (*tz, axis=0, level=None, copy=True, ambiguous='raise', nonexistent='raise'*)

Localize tz-naive index of a Series or DataFrame to target time zone.

This operation localizes the Index. To localize the values in a timezone-naive Series, use *Series.dt.tz\_localize()*.

**Parameters****tz** [string or pytz.timezone object]

**axis** [the axis to localize]

**level** [int, str, default None] If axis is a MultiIndex, localize a specific level. Otherwise must be None

**copy** [boolean, default True] Also make a copy of the underlying data

**ambiguous** ['infer', bool-ndarray, 'NaT', default 'raise'] When clocks moved backward due to DST, ambiguous times may arise. For example in Central European Time (UTC+01), when going from 03:00 DST to 02:00 non-DST, 02:30:00 local time occurs both at 00:30:00 UTC and at 01:30:00 UTC. In such a situation, the *ambiguous* parameter dictates how ambiguous times should be handled.

- 'infer' will attempt to infer fall dst-transition hours based on order
- bool-ndarray where True signifies a DST time, False designates a non-DST time (note that this flag is only applicable for ambiguous times)
- 'NaT' will return NaT where there are ambiguous times
- 'raise' will raise an AmbiguousTimeError if there are ambiguous times

**nonexistent** [str, default 'raise'] A nonexistent time does not exist in a particular timezone where clocks moved forward due to DST. Valid values are:

- 'shift\_forward' will shift the nonexistent time forward to the closest existing time
- 'shift\_backward' will shift the nonexistent time backward to the closest existing time
- 'NaT' will return NaT where there are nonexistent times
- timedelta objects will shift nonexistent times by the timedelta
- 'raise' will raise a NonExistentTimeError if there are nonexistent times

New in version 0.24.0.

### Returns

**Series or DataFrame** Same type as the input.

### Raises

**TypeError** If the TimeSeries is tz-aware and tz is not None.

## Examples

Localize local times:

```
>>> s = pd.Series([1],
... index=pd.DatetimeIndex(['2018-09-15 01:30:00']))
>>> s.tz_localize('CET')
2018-09-15 01:30:00+02:00    1
dtype: int64
```

Be careful with DST changes. When there is sequential data, pandas can infer the DST time:

```
>>> s = pd.Series(range(7), index=pd.DatetimeIndex([
... '2018-10-28 01:30:00',
... '2018-10-28 02:00:00',
... '2018-10-28 02:30:00',
... '2018-10-28 02:00:00',
```

(continues on next page)

(continued from previous page)

```

... '2018-10-28 02:30:00',
... '2018-10-28 03:00:00',
... '2018-10-28 03:30:00']))
>>> s.tz_localize('CET', ambiguous='infer')
2018-10-28 01:30:00+02:00    0
2018-10-28 02:00:00+02:00    1
2018-10-28 02:30:00+02:00    2
2018-10-28 02:00:00+01:00    3
2018-10-28 02:30:00+01:00    4
2018-10-28 03:00:00+01:00    5
2018-10-28 03:30:00+01:00    6
dtype: int64

```

In some cases, inferring the DST is impossible. In such cases, you can pass an ndarray to the `ambiguous` parameter to set the DST explicitly

```

>>> s = pd.Series(range(3), index=pd.DatetimeIndex([
... '2018-10-28 01:20:00',
... '2018-10-28 02:36:00',
... '2018-10-28 03:46:00']))
>>> s.tz_localize('CET', ambiguous=np.array([True, True, False]))
2018-10-28 01:20:00+02:00    0
2018-10-28 02:36:00+02:00    1
2018-10-28 03:46:00+01:00    2
dtype: int64

```

If the DST transition causes nonexistent times, you can shift these dates forward or backwards with a `timedelta` object or `'shift_forward'` or `'shift_backwards'`. `>>> s = pd.Series(range(2), index=pd.DatetimeIndex(['2015-03-29 02:30:00', '2015-03-29 03:30:00'])) >>> s.tz_localize('Europe/Warsaw', nonexistent='shift_forward')` 2015-03-29 03:00:00+02:00 0 2015-03-29 03:30:00+02:00 1 dtype: int64 `>>> s.tz_localize('Europe/Warsaw', nonexistent='shift_backward')` 2015-03-29 01:59:59.999999999+01:00 0 2015-03-29 03:30:00+02:00 1 dtype: int64 `>>> s.tz_localize('Europe/Warsaw', nonexistent=pd.Timedelta('1H'))` 2015-03-29 03:30:00+02:00 0 2015-03-29 03:30:00+02:00 1 dtype: int64

## pandas.Panel.update

`Panel.update(other, join='left', overwrite=True, filter_func=None, errors='ignore')`

Modify Panel in place using non-NA values from other Panel.

May also use object coercible to Panel. Will align on items.

### Parameters

**other** [Panel, or object coercible to Panel] The object from which the caller will be updated.

**join** [{ 'left', 'right', 'outer', 'inner' }, default 'left'] How individual DataFrames are joined.

**overwrite** [bool, default True] If True then overwrite values for common keys in the calling Panel.

**filter\_func** [callable(1d-array) -> 1d-array<bool>, default None] Can choose to replace values other than NA. Return True for values that should be updated.

**errors** [{‘raise’, ‘ignore’}, default ‘ignore’] If ‘raise’, will raise an error if a DataFrame and other both.

Changed in version 0.24.0: Changed from *raise\_conflict=False|True* to *errors=‘ignore’|‘raise’*.

See also:

**DataFrame.update** Similar method for DataFrames.

**dict.update** Similar method for dictionaries.

## pandas.Panel.var

**Panel.var** (*axis=None, skipna=None, level=None, ddof=1, numeric\_only=None, \*\*kwargs*)

Return unbiased variance over requested axis.

Normalized by N-1 by default. This can be changed using the *ddof* argument

### Parameters

**axis** [{items (0), major\_axis (1), minor\_axis (2)}]

**skipna** [boolean, default True] Exclude NA/null values. If an entire row/column is NA, the result will be NA

**level** [int or level name, default None] If the axis is a MultiIndex (hierarchical), count along a particular level, collapsing into a DataFrame

**ddof** [int, default 1] Delta Degrees of Freedom. The divisor used in calculations is N - ddof, where N represents the number of elements.

**numeric\_only** [boolean, default None] Include only float, int, boolean columns. If None, will attempt to use everything, then use only numeric data. Not implemented for Series.

### Returns

**var** [DataFrame or Panel (if level specified)]

## pandas.Panel.where

**Panel.where** (*cond, other=nan, inplace=False, axis=None, level=None, errors=‘raise’, try\_cast=False, raise\_on\_error=None*)

Replace values where the condition is False.

### Parameters

**cond** [boolean NDFrame, array-like, or callable] Where *cond* is True, keep the original value. Where False, replace with corresponding value from *other*. If *cond* is callable, it is computed on the NDFrame and should return boolean NDFrame or array. The callable must not change input NDFrame (though pandas doesn’t check it).

New in version 0.18.1: A callable can be used as *cond*.

**other** [scalar, NDFrame, or callable] Entries where *cond* is False are replaced with corresponding value from *other*. If *other* is callable, it is computed on the NDFrame and should return scalar or NDFrame. The callable must not change input NDFrame (though pandas doesn’t check it).

New in version 0.18.1: A callable can be used as *other*.

**inplace** [boolean, default False] Whether to perform the operation in place on the data.

**axis** [int, default None] Alignment axis if needed.

**level** [int, default None] Alignment level if needed.

**errors** [str, {'raise', 'ignore'}, default *raise*] Note that currently this parameter won't affect the results and will always coerce to a suitable dtype.

- *raise* : allow exceptions to be raised.
- *ignore* : suppress exceptions. On error return original object.

**try\_cast** [boolean, default False] Try to cast the result back to the input type (if possible).

**raise\_on\_error** [boolean, default True] Whether to raise on invalid data types (e.g. trying to where on strings).

Deprecated since version 0.21.0: Use *errors*.

### Returns

**wh** [same type as caller]

### See also:

***DataFrame.mask()*** Return an object of same shape as self.

### Notes

The where method is an application of the if-then idiom. For each element in the calling DataFrame, if *cond* is *True* the element is used; otherwise the corresponding element from the DataFrame *other* is used.

The signature for *DataFrame.where()* differs from *numpy.where()*. Roughly *df1.where(m, df2)* is equivalent to *np.where(m, df1, df2)*.

For further details and examples see the *where* documentation in *indexing*.

### Examples

```
>>> s = pd.Series(range(5))
>>> s.where(s > 0)
0    NaN
1    1.0
2    2.0
3    3.0
4    4.0
dtype: float64
```

```
>>> s.mask(s > 0)
0    0.0
1    NaN
2    NaN
3    NaN
4    NaN
dtype: float64
```

```
>>> s.where(s > 1, 10)
0    10
1    10
2     2
3     3
4     4
dtype: int64
```

```
>>> df = pd.DataFrame(np.arange(10).reshape(-1, 2), columns=['A', 'B'])
>>> m = df % 3 == 0
>>> df.where(m, -df)
   A  B
0  0 -1
1 -2  3
2 -4 -5
3  6 -7
4 -8  9
>>> df.where(m, -df) == np.where(m, df, -df)
   A      B
0  True  True
1  True  True
2  True  True
3  True  True
4  True  True
>>> df.where(m, -df) == df.mask(~m, -df)
   A      B
0  True  True
1  True  True
2  True  True
3  True  True
4  True  True
```

## pandas.Panel.xs

`Panel.xs` (*key*, *axis=1*)

Return slice of panel along selected axis.

### Parameters

**key** [object] Label

**axis** [{ 'items', 'major', 'minor'}, default 1/'major']

### Returns

**y** [ndim(self)-1]

## Notes

`xs` is only for getting, not setting values.

`MultiIndex Slicers` is a generic way to get/set values on any level or levels and is a superset of `xs` functionality, see *MultiIndex Slicers*

### 35.6.2 Properties and underlying data

#### Axes

- **items**: axis 0; each item corresponds to a DataFrame contained inside
- **major\_axis**: axis 1; the index (rows) of each of the DataFrames
- **minor\_axis**: axis 2; the columns of each of the DataFrames

|                                 |                                                                        |
|---------------------------------|------------------------------------------------------------------------|
| <i>Panel.values</i>             | Return a Numpy representation of the DataFrame.                        |
| <i>Panel.axes</i>               | Return index label(s) of the internal NDFrame                          |
| <i>Panel.ndim</i>               | Return an int representing the number of axes / array dimensions.      |
| <i>Panel.size</i>               | Return an int representing the number of elements in this object.      |
| <i>Panel.shape</i>              | Return a tuple of axis dimensions                                      |
| <i>Panel.dtypes</i>             | Return the dtypes in the DataFrame.                                    |
| <i>Panel.ftypes</i>             | Return the ftypes (indication of sparse/dense and dtype) in DataFrame. |
| <i>Panel.get_dtype_counts()</i> | Return counts of unique dtypes in this object.                         |
| <i>Panel.get_ftype_counts()</i> | (DEPRECATED) Return counts of unique ftypes in this object.            |

### 35.6.3 Conversion

|                                            |                                                  |
|--------------------------------------------|--------------------------------------------------|
| <i>Panel.astype(dtype[, copy, errors])</i> | Cast a pandas object to a specified dtype dtype. |
| <i>Panel.copy([deep])</i>                  | Make a copy of this object's indices and data.   |
| <i>Panel.isna()</i>                        | Detect missing values.                           |
| <i>Panel.notna()</i>                       | Detect existing (non-missing) values.            |

### 35.6.4 Getting and setting

|                                         |                                                                              |
|-----------------------------------------|------------------------------------------------------------------------------|
| <i>Panel.get_value(*args, **kwargs)</i> | (DEPRECATED) Quickly retrieve single value at (item, major, minor) location. |
| <i>Panel.set_value(*args, **kwargs)</i> | (DEPRECATED) Quickly set single value at (item, major, minor) location.      |

### 35.6.5 Indexing, iteration, slicing

|                  |                                                                  |
|------------------|------------------------------------------------------------------|
| <i>Panel.at</i>  | Access a single value for a row/column label pair.               |
| <i>Panel.iat</i> | Access a single value for a row/column pair by integer position. |

Table 150 – continued from previous page

|                                    |                                                                    |
|------------------------------------|--------------------------------------------------------------------|
| <code>Panel.loc</code>             | Access a group of rows and columns by label(s) or a boolean array. |
| <code>Panel.iloc</code>            | Purely integer-location based indexing for selection by position.  |
| <code>Panel.__iter__()</code>      | Iterate over infor axis                                            |
| <code>Panel.iteritems()</code>     | Iterate over (label, values) on info axis                          |
| <code>Panel.pop(item)</code>       | Return item and drop from frame.                                   |
| <code>Panel.xs(key[, axis])</code> | Return slice of panel along selected axis.                         |
| <code>Panel.major_xs(key)</code>   | Return slice of panel along major axis.                            |
| <code>Panel.minor_xs(key)</code>   | Return slice of panel along minor axis.                            |

### 35.6.5.1 pandas.Panel.\_\_iter\_\_

`Panel.__iter__()`  
Iterate over infor axis

For more information on `.at`, `.iat`, `.loc`, and `.iloc`, see the *indexing documentation*.

## 35.6.6 Binary operator functions

|                                             |                                                                                         |
|---------------------------------------------|-----------------------------------------------------------------------------------------|
| <code>Panel.add(other[, axis])</code>       | Addition of series and other, element-wise (binary operator <i>add</i> ).               |
| <code>Panel.sub(other[, axis])</code>       | Subtraction of series and other, element-wise (binary operator <i>sub</i> ).            |
| <code>Panel.mul(other[, axis])</code>       | Multiplication of series and other, element-wise (binary operator <i>mul</i> ).         |
| <code>Panel.div(other[, axis])</code>       | Floating division of series and other, element-wise (binary operator <i>truediv</i> ).  |
| <code>Panel.truediv(other[, axis])</code>   | Floating division of series and other, element-wise (binary operator <i>truediv</i> ).  |
| <code>Panel.floordiv(other[, axis])</code>  | Integer division of series and other, element-wise (binary operator <i>floordiv</i> ).  |
| <code>Panel.mod(other[, axis])</code>       | Modulo of series and other, element-wise (binary operator <i>mod</i> ).                 |
| <code>Panel.pow(other[, axis])</code>       | Exponential power of series and other, element-wise (binary operator <i>pow</i> ).      |
| <code>Panel.radd(other[, axis])</code>      | Addition of series and other, element-wise (binary operator <i>radd</i> ).              |
| <code>Panel.rsub(other[, axis])</code>      | Subtraction of series and other, element-wise (binary operator <i>rsub</i> ).           |
| <code>Panel.rmul(other[, axis])</code>      | Multiplication of series and other, element-wise (binary operator <i>rmul</i> ).        |
| <code>Panel.rdiv(other[, axis])</code>      | Floating division of series and other, element-wise (binary operator <i>rtruediv</i> ). |
| <code>Panel.rtruediv(other[, axis])</code>  | Floating division of series and other, element-wise (binary operator <i>rtruediv</i> ). |
| <code>Panel.rfloordiv(other[, axis])</code> | Integer division of series and other, element-wise (binary operator <i>rfloordiv</i> ). |
| <code>Panel.rmod(other[, axis])</code>      | Modulo of series and other, element-wise (binary operator <i>rmod</i> ).                |

Table 151 – continued from previous page

|                                   |                                                                                     |
|-----------------------------------|-------------------------------------------------------------------------------------|
| <i>Panel.rpow</i> (other[, axis]) | Exponential power of series and other, element-wise (binary operator <i>rpow</i> ). |
| <i>Panel.lt</i> (other[, axis])   | Wrapper for comparison method lt                                                    |
| <i>Panel.gt</i> (other[, axis])   | Wrapper for comparison method gt                                                    |
| <i>Panel.le</i> (other[, axis])   | Wrapper for comparison method le                                                    |
| <i>Panel.ge</i> (other[, axis])   | Wrapper for comparison method ge                                                    |
| <i>Panel.ne</i> (other[, axis])   | Wrapper for comparison method ne                                                    |
| <i>Panel.eq</i> (other[, axis])   | Wrapper for comparison method eq                                                    |

### 35.6.7 Function application, GroupBy

|                                         |                                                     |
|-----------------------------------------|-----------------------------------------------------|
| <i>Panel.apply</i> (func[, axis])       | Applies function along axis (or axes) of the Panel. |
| <i>Panel.groupby</i> (function[, axis]) | Group data on given axis, returning GroupBy object. |

### 35.6.8 Computations / Descriptive Stats

|                                                           |                                                                        |
|-----------------------------------------------------------|------------------------------------------------------------------------|
| <i>Panel.abs</i> ()                                       | Return a Series/DataFrame with absolute numeric value of each element. |
| <i>Panel.clip</i> ([lower, upper, axis, inplace])         | Trim values at input threshold(s).                                     |
| <i>Panel.clip_lower</i> (threshold[, axis, inplace])      | (DEPRECATED) Trim values below a given threshold.                      |
| <i>Panel.clip_upper</i> (threshold[, axis, inplace])      | (DEPRECATED) Trim values above a given threshold.                      |
| <i>Panel.count</i> ([axis])                               | Return number of observations over requested axis.                     |
| <i>Panel.cummax</i> ([axis, skipna])                      | Return cumulative maximum over a DataFrame or Series axis.             |
| <i>Panel.cummin</i> ([axis, skipna])                      | Return cumulative minimum over a DataFrame or Series axis.             |
| <i>Panel.cumprod</i> ([axis, skipna])                     | Return cumulative product over a DataFrame or Series axis.             |
| <i>Panel.cumsum</i> ([axis, skipna])                      | Return cumulative sum over a DataFrame or Series axis.                 |
| <i>Panel.max</i> ([axis, skipna, level, numeric_only])    | Return the maximum of the values for the requested axis.               |
| <i>Panel.mean</i> ([axis, skipna, level, numeric_only])   | Return the mean of the values for the requested axis.                  |
| <i>Panel.median</i> ([axis, skipna, level, numeric_only]) | Return the median of the values for the requested axis.                |
| <i>Panel.min</i> ([axis, skipna, level, numeric_only])    | Return the minimum of the values for the requested axis.               |
| <i>Panel.pct_change</i> ([periods, fill_method, ...])     | Percentage change between the current and a prior element.             |
| <i>Panel.prod</i> ([axis, skipna, level, ...])            | Return the product of the values for the requested axis.               |
| <i>Panel.sem</i> ([axis, skipna, level, ddof, ...])       | Return unbiased standard error of the mean over requested axis.        |
| <i>Panel.skew</i> ([axis, skipna, level, numeric_only])   | Return unbiased skew over requested axis Normalized by N-1.            |
| <i>Panel.sum</i> ([axis, skipna, level, ...])             | Return the sum of the values for the requested axis.                   |
| <i>Panel.std</i> ([axis, skipna, level, ddof, ...])       | Return sample standard deviation over requested axis.                  |
| <i>Panel.var</i> ([axis, skipna, level, ddof, ...])       | Return unbiased variance over requested axis.                          |

### 35.6.9 Reindexing / Selection / Label manipulation

|                                                              |                                                                                                                            |
|--------------------------------------------------------------|----------------------------------------------------------------------------------------------------------------------------|
| <code>Panel.add_prefix(prefix)</code>                        | Prefix labels with string <i>prefix</i> .                                                                                  |
| <code>Panel.add_suffix(suffix)</code>                        | Suffix labels with string <i>suffix</i> .                                                                                  |
| <code>Panel.drop([labels, axis, index, columns, ...])</code> |                                                                                                                            |
| <code>Panel.equals(other)</code>                             | Test whether two objects contain the same elements.                                                                        |
| <code>Panel.filter([items, like, regex, axis])</code>        | Subset rows or columns of dataframe according to labels in the specified index.                                            |
| <code>Panel.first(offset)</code>                             | Convenience method for subsetting initial periods of time series data based on a date offset.                              |
| <code>Panel.last(offset)</code>                              | Convenience method for subsetting final periods of time series data based on a date offset.                                |
| <code>Panel.reindex(*args, **kwargs)</code>                  | Conform Panel to new index with optional filling logic, placing NA/NaN in locations having no value in the previous index. |
| <code>Panel.reindex_axis(labels[, axis, method, ...])</code> | (DEPRECATED) Conform input object to new index.                                                                            |
| <code>Panel.reindex_like(other[, method, copy, ...])</code>  | Return an object with matching indices as other object.                                                                    |
| <code>Panel.rename([items, major_axis, minor_axis])</code>   | Alter axes input function or functions.                                                                                    |
| <code>Panel.sample([n, frac, replace, weights, ...])</code>  | Return a random sample of items from an axis of object.                                                                    |
| <code>Panel.select(crit[, axis])</code>                      | (DEPRECATED) Return data corresponding to axis labels matching criteria.                                                   |
| <code>Panel.take(indices[, axis, convert, is_copy])</code>   | Return the elements in the given <i>positional</i> indices along an axis.                                                  |
| <code>Panel.truncate([before, after, axis, copy])</code>     | Truncate a Series or DataFrame before and after some index value.                                                          |

### 35.6.9.1 pandas.Panel.drop

`Panel.drop(labels=None, axis=0, index=None, columns=None, level=None, inplace=False, errors='raise')`

## 35.6.10 Missing data handling

|                                                 |                                                   |
|-------------------------------------------------|---------------------------------------------------|
| <code>Panel.dropna([axis, how, inplace])</code> | Drop 2D from panel, holding passed axis constant. |
|-------------------------------------------------|---------------------------------------------------|

## 35.6.11 Reshaping, sorting, transposing

|                                                              |                                                          |
|--------------------------------------------------------------|----------------------------------------------------------|
| <code>Panel.sort_index([axis, level, ascending, ...])</code> | Sort object by labels (along an axis)                    |
| <code>Panel.swaplevel([i, j, axis])</code>                   | Swap levels i and j in a MultiIndex on a particular axis |
| <code>Panel.transpose(*args, **kwargs)</code>                | Permute the dimensions of the Panel                      |
| <code>Panel.swapaxes(axis1, axis2[, copy])</code>            | Interchange axes and swap values axes appropriately.     |
| <code>Panel.conform(frame[, axis])</code>                    | Conform input DataFrame to align with chosen axis pair.  |

## 35.6.12 Combining / joining / merging

|                                                         |                                                                    |
|---------------------------------------------------------|--------------------------------------------------------------------|
| <code>Panel.join(other[, how, lsuffix, rsuffix])</code> | Join items with other Panel either on major and minor axes column. |
|---------------------------------------------------------|--------------------------------------------------------------------|

Continued on next page

Table 157 – continued from previous page

|                                                     |                                                             |
|-----------------------------------------------------|-------------------------------------------------------------|
| <i>Panel.update</i> (other[, join, overwrite, ...]) | Modify Panel in place using non-NA values from other Panel. |
|-----------------------------------------------------|-------------------------------------------------------------|

### 35.6.13 Time series-related

|                                                           |                                                                       |
|-----------------------------------------------------------|-----------------------------------------------------------------------|
| <i>Panel.asfreq</i> (freq[, method, how, normalize, ...]) | Convert TimeSeries to specified frequency.                            |
| <i>Panel.shift</i> ([periods, freq, axis])                | Shift index by desired number of periods with an optional time freq.  |
| <i>Panel.resample</i> (rule[, how, axis, ...])            | Resample time-series data.                                            |
| <i>Panel.tz_convert</i> (tz[, axis, level, copy])         | Convert tz-aware axis to target time zone.                            |
| <i>Panel.tz_localize</i> (tz[, axis, level, copy, ...])   | Localize tz-naive index of a Series or DataFrame to target time zone. |

### 35.6.14 Serialization / IO / Conversion

|                                                           |                                                                                                                                                                               |
|-----------------------------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <i>Panel.from_dict</i> (data[, intersect, orient, dtype]) | Construct Panel from dict of DataFrame objects.                                                                                                                               |
| <i>Panel.to_pickle</i> (path[, compression, protocol])    | Pickle (serialize) object to file.                                                                                                                                            |
| <i>Panel.to_excel</i> (path[, na_rep, engine])            | Write each DataFrame in Panel to a separate excel sheet.                                                                                                                      |
| <i>Panel.to_hdf</i> (path_or_buf, key, **kwargs)          | Write the contained data to an HDF5 file using HDFStore.                                                                                                                      |
| <i>Panel.to_sparse</i> (*args, **kwargs)                  | NOT IMPLEMENTED: do not call this method, as sparsifying is not supported for Panel objects and will raise an error.                                                          |
| <i>Panel.to_frame</i> ([filter_observations])             | Transform wide format into long (stacked) format as DataFrame whose columns are the Panel's items and whose index is a MultiIndex formed of the Panel's major and minor axes. |
| <i>Panel.to_clipboard</i> ([excel, sep])                  | Copy object to the system clipboard.                                                                                                                                          |

{{ header }}

## 35.7 Indexing

### 35.7.1 Index

Many of these methods or variants thereof are available on the objects that contain an index (Series/DataFrame) and those should most likely be used before calling these methods directly.

|              |                                                           |
|--------------|-----------------------------------------------------------|
| <i>Index</i> | Immutable ndarray implementing an ordered, sliceable set. |
|--------------|-----------------------------------------------------------|

#### 35.7.1.1 pandas.Index

**class** pandas.Index

Immutable ndarray implementing an ordered, sliceable set. The basic object storing axis labels for all pandas objects.

### Parameters

**data** [array-like (1-dimensional)]

**dtype** [NumPy dtype (default: object)] If dtype is None, we find the dtype that best fits the data. If an actual dtype is provided, we coerce to that dtype if it's safe. Otherwise, an error will be raised.

**copy** [bool] Make a copy of input ndarray

**name** [object] Name to be stored in the index

**tupleize\_cols** [bool (default: True)] When True, attempt to create a MultiIndex if possible

See also:

**RangeIndex** Index implementing a monotonic integer range.

**CategoricalIndex** Index of *Categorical*s.

**MultiIndex** A multi-level, or hierarchical, Index.

**IntervalIndex** An Index of *Interval*s.

*DatetimeIndex*, *TimedeltaIndex*, *PeriodIndex*, *Int64Index*, *UInt64Index*,  
*Float64Index*

### Notes

An Index instance can **only** contain hashable objects

### Examples

```
>>> pd.Index([1, 2, 3])
Int64Index([1, 2, 3], dtype='int64')
```

```
>>> pd.Index(list('abc'))
Index(['a', 'b', 'c'], dtype='object')
```

### Attributes

|                      |                                                                        |
|----------------------|------------------------------------------------------------------------|
| <i>T</i>             | Return the transpose, which is by definition self.                     |
| <i>array</i>         | The ExtensionArray of the data backing this Series or Index.           |
| <i>base</i>          | Return the base object if the memory of the underlying data is shared. |
| <i>data</i>          | Return the data pointer of the underlying data.                        |
| <i>dtype</i>         | Return the dtype object of the underlying data.                        |
| <i>dtype_str</i>     | Return the dtype str of the underlying data.                           |
| <i>flags</i>         |                                                                        |
| <i>hasnans</i>       | Return if I have any nans; enables various perf speedups.              |
| <i>inferred_type</i> | Return a string of the type inferred from the values.                  |

Table 161 – continued from previous page

|                                |                                                                                |
|--------------------------------|--------------------------------------------------------------------------------|
| <i>is_monotonic</i>            | Alias for <code>is_monotonic_increasing</code> .                               |
| <i>is_monotonic_decreasing</i> | Return if the index is monotonic decreasing (only equal or decreasing) values. |
| <i>is_monotonic_increasing</i> | Return if the index is monotonic increasing (only equal or increasing) values. |
| <i>is_unique</i>               | Return if the index has unique values.                                         |
| <i>itemsize</i>                | Return the size of the dtype of the item of the underlying data.               |
| <i>nbytes</i>                  | Return the number of bytes in the underlying data.                             |
| <i>ndim</i>                    | Number of dimensions of the underlying data, by definition 1.                  |
| <i>shape</i>                   | Return a tuple of the shape of the underlying data.                            |
| <i>size</i>                    | Return the number of elements in the underlying data.                          |
| <i>strides</i>                 | Return the strides of the underlying data.                                     |
| <i>values</i>                  | Return an array representing the data in the Index.                            |

**pandas.Index.T****Index.T**

Return the transpose, which is by definition self.

**pandas.Index.array****Index.array**

The ExtensionArray of the data backing this Series or Index.

New in version 0.24.0.

**Returns**

**array** [ExtensionArray] An ExtensionArray of the values stored within. For extension types, this is the actual array. For NumPy native types, this is a thin (no copy) wrapper around `numpy.ndarray`.

`.array` differs `.values` which may require converting the data to a different form.

**See also:**

**Index.to\_numpy** Similar method that always returns a NumPy array.

**Series.to\_numpy** Similar method that always returns a NumPy array.

**Notes**

This table lays out the different array types for each extension dtype within pandas.

| dtype              | array type    |
|--------------------|---------------|
| category           | Categorical   |
| period             | PeriodArray   |
| interval           | IntervalArray |
| IntegerNA          | IntegerArray  |
| datetime64[ns, tz] | DatetimeArray |

For any 3rd-party extension types, the array type will be an ExtensionArray.

For all remaining dtypes `.array` will be a `arrays.NumpyExtensionArray` wrapping the actual ndarray stored within. If you absolutely need a NumPy array (possibly with copying / coercing data), then use `Series.to_numpy()` instead.

## Examples

For regular NumPy types like int, and float, a PandasArray is returned.

```
>>> pd.Series([1, 2, 3]).array
<PandasArray>
[1, 2, 3]
Length: 3, dtype: int64
```

For extension types, like Categorical, the actual ExtensionArray is returned

```
>>> ser = pd.Series(pd.Categorical(['a', 'b', 'a']))
>>> ser.array
[a, b, a]
Categories (2, object): [a, b]
```

## pandas.Index.base

`Index.base`

Return the base object if the memory of the underlying data is shared.

## pandas.Index.data

`Index.data`

Return the data pointer of the underlying data.

## pandas.Index.dtype

`Index.dtype`

Return the dtype object of the underlying data.

## pandas.Index.dtype\_str

`Index.dtype_str`

Return the dtype str of the underlying data.

## pandas.Index.flags

`Index.flags`

**pandas.Index.hasnans****Index.hasnans**

Return if I have any nans; enables various perf speedups.

**pandas.Index.inferred\_type****Index.inferred\_type**

Return a string of the type inferred from the values.

**pandas.Index.is\_monotonic****Index.is\_monotonic**

Alias for is\_monotonic\_increasing.

**pandas.Index.is\_monotonic\_decreasing****Index.is\_monotonic\_decreasing**

Return if the index is monotonic decreasing (only equal or decreasing) values.

**Examples**

```
>>> Index([3, 2, 1]).is_monotonic_decreasing
True
>>> Index([3, 2, 2]).is_monotonic_decreasing
True
>>> Index([3, 1, 2]).is_monotonic_decreasing
False
```

**pandas.Index.is\_monotonic\_increasing****Index.is\_monotonic\_increasing**

Return if the index is monotonic increasing (only equal or increasing) values.

**Examples**

```
>>> Index([1, 2, 3]).is_monotonic_increasing
True
>>> Index([1, 2, 2]).is_monotonic_increasing
True
>>> Index([1, 3, 2]).is_monotonic_increasing
False
```

**pandas.Index.is\_unique****Index.is\_unique**

Return if the index has unique values.

### **pandas.Index.itemsize**

#### **Index.itemsize**

Return the size of the dtype of the item of the underlying data.

### **pandas.Index.nbytes**

#### **Index.nbytes**

Return the number of bytes in the underlying data.

### **pandas.Index.ndim**

#### **Index.ndim**

Number of dimensions of the underlying data, by definition 1.

### **pandas.Index.shape**

#### **Index.shape**

Return a tuple of the shape of the underlying data.

### **pandas.Index.size**

#### **Index.size**

Return the number of elements in the underlying data.

### **pandas.Index.strides**

#### **Index.strides**

Return the strides of the underlying data.

### **pandas.Index.values**

#### **Index.values**

Return an array representing the data in the Index.

**Warning:** We recommend using *Index.array* or *Index.to\_numpy()*, depending on whether you need a reference to the underlying data or a NumPy array.

#### **Returns**

**array:** `numpy.ndarray` or `ExtensionArray`

#### **See also:**

***Index.array*** Reference to the underlying data.

***Index.to\_numpy*** A NumPy array representing the underlying data.

Return

|                       |  |
|-----------------------|--|
| <b>asi8</b>           |  |
| <b>empty</b>          |  |
| <b>has_duplicates</b> |  |
| <b>is_all_dates</b>   |  |
| <b>name</b>           |  |
| <b>names</b>          |  |
| <b>nlevels</b>        |  |

## Methods

|                                                         |                                                                                                          |
|---------------------------------------------------------|----------------------------------------------------------------------------------------------------------|
| <i>all</i> (*args, **kwargs)                            | Return whether all elements are True.                                                                    |
| <i>any</i> (*args, **kwargs)                            | Return whether any element is True.                                                                      |
| <i>append</i> (other)                                   | Append a collection of Index options together.                                                           |
| <i>argmax</i> ([axis, skipna])                          | Return a ndarray of the maximum argument indexer.                                                        |
| <i>argmin</i> ([axis, skipna])                          | Return a ndarray of the minimum argument indexer.                                                        |
| <i>argsort</i> (*args, **kwargs)                        | Return the integer indices that would sort the index.                                                    |
| <i>asof</i> (label)                                     | Return the label from the index, or, if not present, the previous one.                                   |
| <i>asof_locs</i> (where, mask)                          | Finds the locations (indices) of the labels from the index for every entry in the <i>where</i> argument. |
| <i>astype</i> (dtype[, copy])                           | Create an Index with values cast to dtypes.                                                              |
| <i>contains</i> (key)                                   | Return a boolean indicating whether the provided key is in the index.                                    |
| <i>copy</i> ([name, deep, dtype])                       | Make a copy of this object.                                                                              |
| <i>delete</i> (loc)                                     | Make new Index with passed location(-s) deleted.                                                         |
| <i>difference</i> (other[, sort])                       | Return a new Index with elements from the index that are not in <i>other</i> .                           |
| <i>drop</i> (labels[, errors])                          | Make new Index with passed list of labels deleted.                                                       |
| <i>drop_duplicates</i> ([keep])                         | Return Index with duplicate values removed.                                                              |
| <i>droplevel</i> ([level])                              | Return index with requested level(s) removed.                                                            |
| <i>dropna</i> ([how])                                   | Return Index without NA/NaN values                                                                       |
| <i>duplicated</i> ([keep])                              | Indicate duplicate index values.                                                                         |
| <i>equals</i> (other)                                   | Determines if two Index objects contain the same elements.                                               |
| <i>factorize</i> ([sort, na_sentinel])                  | Encode the object as an enumerated type or categorical variable.                                         |
| <i>fillna</i> ([value, downcast])                       | Fill NA/NaN values with the specified value                                                              |
| <i>format</i> ([name, formatter])                       | Render a string representation of the Index.                                                             |
| <i>get_duplicates</i> ()                                | (DEPRECATED) Extract duplicated index elements.                                                          |
| <i>get_indexer</i> (target[, method, limit, tolerance]) | Compute indexer and mask for new index given the current index.                                          |
| <i>get_indexer_for</i> (target, **kwargs)               | Guaranteed return of an indexer even when non-unique.                                                    |
| <i>get_indexer_non_unique</i> (target)                  | Compute indexer and mask for new index given the current index.                                          |
| <i>get_level_values</i> (level)                         | Return an Index of values for requested level.                                                           |
| <i>get_loc</i> (key[, method, tolerance])               | Get integer location, slice or boolean mask for requested label.                                         |

Table 162 – continued from previous page

|                                                               |                                                                                                        |
|---------------------------------------------------------------|--------------------------------------------------------------------------------------------------------|
| <code>get_slice_bound(label, side, kind)</code>               | Calculate slice bound that corresponds to given label.                                                 |
| <code>get_value(series, key)</code>                           | Fast lookup of value from 1-dimensional ndarray.                                                       |
| <code>get_values()</code>                                     | Return <i>Index</i> data as an <i>numpy.ndarray</i> .                                                  |
| <code>groupby(values)</code>                                  | Group the index labels by a given array of values.                                                     |
| <code>identical(other)</code>                                 | Similar to <code>equals</code> , but check that other comparable attributes are also equal.            |
| <code>insert(loc, item)</code>                                | Make new <i>Index</i> inserting new item at location.                                                  |
| <code>intersection(other)</code>                              | Form the intersection of two <i>Index</i> objects.                                                     |
| <code>is_(other)</code>                                       | More flexible, faster check like <code>is</code> but that works through views.                         |
| <code>is_categorical()</code>                                 | Check if the <i>Index</i> holds categorical data.                                                      |
| <code>isin(values[, level])</code>                            | Return a boolean array where the index values are in <i>values</i> .                                   |
| <code>isna()</code>                                           | Detect missing values.                                                                                 |
| <code>isnull()</code>                                         | Detect missing values.                                                                                 |
| <code>item()</code>                                           | Return the first element of the underlying data as a python scalar.                                    |
| <code>join(other[, how, level, return_indexers, sort])</code> | Compute <code>join_index</code> and <code>indexers</code> to conform data structures to the new index. |
| <code>map(mapper[, na_action])</code>                         | Map values using input correspondence (a dict, <i>Series</i> , or function).                           |
| <code>max([axis, skipna])</code>                              | Return the maximum value of the <i>Index</i> .                                                         |
| <code>memory_usage([deep])</code>                             | Memory usage of the values                                                                             |
| <code>min([axis, skipna])</code>                              | Return the minimum value of the <i>Index</i> .                                                         |
| <code>notna()</code>                                          | Detect existing (non-missing) values.                                                                  |
| <code>notnull()</code>                                        | Detect existing (non-missing) values.                                                                  |
| <code>nunique([dropna])</code>                                | Return number of unique elements in the object.                                                        |
| <code>putmask(mask, value)</code>                             | Return a new <i>Index</i> of the values set with the mask.                                             |
| <code>ravel([order])</code>                                   | Return an ndarray of the flattened values of the underlying data.                                      |
| <code>reindex(target[, method, level, limit, ...])</code>     | Create index with target's values (move/add/delete values as necessary).                               |
| <code>rename(name[, inplace])</code>                          | Alter <i>Index</i> or <i>MultiIndex</i> name.                                                          |
| <code>repeat(repeats[, axis])</code>                          | Repeat elements of a <i>Index</i> .                                                                    |
| <code>searchsorted(value[, side, sorter])</code>              | Find indices where elements should be inserted to maintain order.                                      |
| <code>set_names(names[, level, inplace])</code>               | Set <i>Index</i> or <i>MultiIndex</i> name.                                                            |
| <code>set_value(arr, key, value)</code>                       | Fast lookup of value from 1-dimensional ndarray.                                                       |
| <code>shift([periods, freq])</code>                           | Shift index by desired number of time frequency increments.                                            |
| <code>slice_indexer([start, end, step, kind])</code>          | For an ordered or unique index, compute the slice indexer for input labels and step.                   |
| <code>slice_locs([start, end, step, kind])</code>             | Compute slice locations for input labels.                                                              |
| <code>sort_values([return_indexer, ascending])</code>         | Return a sorted copy of the index.                                                                     |
| <code>sortlevel([level, ascending, sort_remaining])</code>    | For internal compatibility with with the <i>Index</i> API.                                             |
| <code>str</code>                                              | alias of <code>pandas.core.strings.StringMethods</code>                                                |
| <code>summary([name])</code>                                  | (DEPRECATED) Return a summarized representation.                                                       |
| <code>symmetric_difference(other[, result_name])</code>       | Compute the symmetric difference of two <i>Index</i> objects.                                          |

Table 162 – continued from previous page

|                                                              |                                                                                                                                      |
|--------------------------------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------|
| <code>take(indices[, axis, allow_fill, fill_value])</code>   | Return a new Index of the values selected by the indices.                                                                            |
| <code>to_flat_index()</code>                                 | Identity method.                                                                                                                     |
| <code>to_frame([index, name])</code>                         | Create a DataFrame with a column containing the Index.                                                                               |
| <code>to_list()</code>                                       | Return a list of the values.                                                                                                         |
| <code>to_native_types([slicer])</code>                       | Format specified values of <i>self</i> and return them.                                                                              |
| <code>to_numpy([dtype, copy])</code>                         | A NumPy ndarray representing the values in this Series or Index.                                                                     |
| <code>to_series([index, name])</code>                        | Create a Series with both index and values equal to the index keys useful with map for returning an indexer based on an index.       |
| <code>tolist()</code>                                        | Return a list of the values.                                                                                                         |
| <code>transpose(*args, **kwargs)</code>                      | Return the transpose, which is by definition self.                                                                                   |
| <code>union(other)</code>                                    | Form the union of two Index objects and sorts if possible.                                                                           |
| <code>unique([level])</code>                                 | Return unique values in the index.                                                                                                   |
| <code>value_counts([normalize, sort, ascending, ...])</code> | Return a Series containing counts of unique values.                                                                                  |
| <code>where(cond[, other])</code>                            | Return an Index of same shape as self and whose corresponding entries are from self where cond is True and otherwise are from other. |

**pandas.Index.all**`Index.all (*args, **kwargs)`

Return whether all elements are True.

**Parameters****\*args** These parameters will be passed to `numpy.all`.**\*\*kwargs** These parameters will be passed to `numpy.all`.**Returns****all** [bool or array\_like (if axis is specified)] A single element array\_like may be converted to bool.**See also:****pandas.Index.any** Return whether any element in an Index is True.**pandas.Series.any** Return whether any element in a Series is True.**pandas.Series.all** Return whether all elements in a Series are True.**Notes**

Not a Number (NaN), positive infinity and negative infinity evaluate to True because these are not equal to zero.

**Examples****all**

True, because nonzero integers are considered True.

```
>>> pd.Index([1, 2, 3]).all()
True
```

False, because 0 is considered False.

```
>>> pd.Index([0, 1, 2]).all()
False
```

### any

True, because 1 is considered True.

```
>>> pd.Index([0, 0, 1]).any()
True
```

False, because 0 is considered False.

```
>>> pd.Index([0, 0, 0]).any()
False
```

## pandas.Index.any

`Index.any(*args, **kwargs)`

Return whether any element is True.

### Parameters

**\*args** These parameters will be passed to `numpy.any`.

**\*\*kwargs** These parameters will be passed to `numpy.any`.

### Returns

**any** [bool or array\_like (if axis is specified)] A single element array\_like may be converted to bool.

### See also:

**pandas.Index.all** Return whether all elements are True.

**pandas.Series.all** Return whether all elements are True.

## Notes

Not a Number (NaN), positive infinity and negative infinity evaluate to True because these are not equal to zero.

## Examples

```
>>> index = pd.Index([0, 1, 2])
>>> index.any()
True
```

```
>>> index = pd.Index([0, 0, 0])
>>> index.any()
False
```

## pandas.Index.append

`Index.append` (*other*)

Append a collection of Index options together.

### Parameters

**other** [Index or list/tuple of indices]

### Returns

**appended** [Index]

## pandas.Index.argmax

`Index.argmax` (*axis=None, skipna=True*)

Return a ndarray of the maximum argument indexer.

### Parameters

**axis** [{None}] Dummy argument for consistency with Series

**skipna** [bool, default True]

### See also:

`numpy.ndarray.argmax`

## pandas.Index.argmin

`Index.argmin` (*axis=None, skipna=True*)

Return a ndarray of the minimum argument indexer.

### Parameters

**axis** [{None}] Dummy argument for consistency with Series

**skipna** [bool, default True]

### See also:

`numpy.ndarray.argmin`

## pandas.Index.argsort

`Index.argsort` (*\*args, \*\*kwargs*)

Return the integer indices that would sort the index.

### Parameters

**\*args** Passed to `numpy.ndarray.argsort`.

**\*\*kwargs** Passed to `numpy.ndarray.argsort`.

**Returns**

**numpy.ndarray** Integer indices that would sort the index if used as an indexer.

**See also:**

**numpy.argsort** Similar method for NumPy arrays.

**Index.sort\_values** Return sorted copy of Index.

**Examples**

```
>>> idx = pd.Index(['b', 'a', 'd', 'c'])
>>> idx
Index(['b', 'a', 'd', 'c'], dtype='object')
```

```
>>> order = idx.argsort()
>>> order
array([1, 0, 3, 2])
```

```
>>> idx[order]
Index(['a', 'b', 'c', 'd'], dtype='object')
```

**pandas.Index.asof**

**Index.asof** (*label*)

Return the label from the index, or, if not present, the previous one.

Assuming that the index is sorted, return the passed index label if it is in the index, or return the previous index label if the passed one is not in the index.

**Parameters**

**label** [object] The label up to which the method returns the latest index label.

**Returns**

**object** The passed label if it is in the index. The previous label if the passed label is not in the sorted index or *NaN* if there is no such label.

**See also:**

**Series.asof** Return the latest value in a Series up to the passed index.

**merge\_asof** Perform an asof merge (similar to left join but it matches on nearest key rather than equal key).

**Index.get\_loc** An *asof* is a thin wrapper around *get\_loc* with *method='pad'*.

**Examples**

*Index.asof* returns the latest index label up to the passed label.

```
>>> idx = pd.Index(['2013-12-31', '2014-01-02', '2014-01-03'])
>>> idx.asof('2014-01-01')
'2013-12-31'
```

If the label is in the index, the method returns the passed label.

```
>>> idx.asof('2014-01-02')
'2014-01-02'
```

If all of the labels in the index are later than the passed label, NaN is returned.

```
>>> idx.asof('1999-01-02')
nan
```

If the index is not sorted, an error is raised.

```
>>> idx_not_sorted = pd.Index(['2013-12-31', '2015-01-02',
...                             '2014-01-03'])
>>> idx_not_sorted.asof('2013-12-31')
Traceback (most recent call last):
ValueError: index must be monotonic increasing or decreasing
```

## pandas.Index.asof\_locs

`Index.asof_locs` (*where, mask*)

Finds the locations (indices) of the labels from the index for every entry in the *where* argument.

As in the *asof* function, if the label (a particular entry in *where*) is not in the index, the latest index label upto the passed label is chosen and its index returned.

If all of the labels in the index are later than a label in *where*, -1 is returned.

*mask* is used to ignore NA values in the index during calculation.

### Parameters

**where** [Index] An Index consisting of an array of timestamps.

**mask** [array-like] Array of booleans denoting where values in the original data are not NA.

### Returns

**numpy.ndarray** An array of locations (indices) of the labels from the Index which correspond to the return values of the *asof* function for every element in *where*.

## pandas.Index.astype

`Index.astype` (*dtype, copy=True*)

Create an Index with values cast to dtypes. The class of a new Index is determined by *dtype*. When conversion is impossible, a `ValueError` exception is raised.

### Parameters

**dtype** [numpy dtype or pandas type] Note that any signed integer *dtype* is treated as `'int64'`, and any unsigned integer *dtype* is treated as `'uint64'`, regardless of the size.

**copy** [bool, default True] By default, *astype* always returns a newly allocated object. If *copy* is set to False and internal requirements on *dtype* are satisfied, the original data is used to create a new Index or the original Index is returned.

New in version 0.19.0.

## pandas.Index.contains

`Index.contains` (*key*)

Return a boolean indicating whether the provided key is in the index.

### Parameters

**key** [label] The key to check if it is present in the index.

### Returns

**bool** Whether the key search is in the index.

**See also:**

**`Index.isin`** Returns an ndarray of boolean dtype indicating whether the list-like key is in the index.

## Examples

```
>>> idx = pd.Index([1, 2, 3, 4])
>>> idx
Int64Index([1, 2, 3, 4], dtype='int64')
```

```
>>> idx.contains(2)
True
>>> idx.contains(6)
False
```

This is equivalent to:

```
>>> 2 in idx
True
>>> 6 in idx
False
```

## pandas.Index.copy

`Index.copy` (*name=None, deep=False, dtype=None, \*\*kwargs*)

Make a copy of this object. Name and dtype sets those attributes on the new object.

### Parameters

**name** [string, optional]

**deep** [boolean, default False]

**dtype** [numpy dtype or pandas type]

### Returns

**copy** [Index]

## Notes

In most cases, there should be no functional difference from using `deep`, but if `deep` is passed it will attempt to deepcopy.

**pandas.Index.delete**`Index.delete` (*loc*)

Make new Index with passed location(-s) deleted.

**Returns****new\_index** [Index]**pandas.Index.difference**`Index.difference` (*other, sort=True*)Return a new Index with elements from the index that are not in *other*.

This is the set difference of two Index objects.

**Parameters****other** [Index or array-like]**sort** [bool, default True] Sort the resulting index if possible

New in version 0.24.0.

**Returns****difference** [Index]**Examples**

```

>>> idx1 = pd.Index([2, 1, 3, 4])
>>> idx2 = pd.Index([3, 4, 5, 6])
>>> idx1.difference(idx2)
Int64Index([1, 2], dtype='int64')
>>> idx1.difference(idx2, sort=False)
Int64Index([2, 1], dtype='int64')

```

**pandas.Index.drop**`Index.drop` (*labels, errors='raise'*)

Make new Index with passed list of labels deleted.

**Parameters****labels** [array-like]**errors** [{‘ignore’, ‘raise’}, default ‘raise’] If ‘ignore’, suppress error and existing labels are dropped.**Returns****dropped** [Index]**Raises****KeyError** If not all of the labels are found in the selected axis

## pandas.Index.drop\_duplicates

`Index.drop_duplicates` (*keep='first'*)

Return Index with duplicate values removed.

### Parameters

**keep** [{ 'first', 'last', False }, default 'first']

- 'first' : Drop duplicates except for the first occurrence.
- 'last' : Drop duplicates except for the last occurrence.
- False : Drop all duplicates.

### Returns

**deduplicated** [Index]

See also:

**Series.drop\_duplicates** Equivalent method on Series.

**DataFrame.drop\_duplicates** Equivalent method on DataFrame.

**Index.duplicated** Related method on Index, indicating duplicate Index values.

## Examples

Generate an pandas.Index with duplicate values.

```
>>> idx = pd.Index(['lama', 'cow', 'lama', 'beetle', 'lama', 'hippo'])
```

The *keep* parameter controls which duplicate values are removed. The value 'first' keeps the first occurrence for each set of duplicated entries. The default value of *keep* is 'first'.

```
>>> idx.drop_duplicates(keep='first')
Index(['lama', 'cow', 'beetle', 'hippo'], dtype='object')
```

The value 'last' keeps the last occurrence for each set of duplicated entries.

```
>>> idx.drop_duplicates(keep='last')
Index(['cow', 'beetle', 'lama', 'hippo'], dtype='object')
```

The value False discards all sets of duplicated entries.

```
>>> idx.drop_duplicates(keep=False)
Index(['cow', 'beetle', 'hippo'], dtype='object')
```

## pandas.Index.droplevel

`Index.droplevel` (*level=0*)

Return index with requested level(s) removed.

If resulting index has only 1 level left, the result will be of Index type, not MultiIndex.

New in version 0.23.1: (support for non-MultiIndex)

### Parameters

**level** [int, str, or list-like, default 0] If a string is given, must be the name of a level. If list-like, elements must be names or indexes of levels.

#### Returns

**index** [Index or MultiIndex]

### pandas.Index.dropna

`Index.dropna (how='any')`

Return Index without NA/NaN values

#### Parameters

**how** [{ 'any', 'all' }, default 'any'] If the Index is a MultiIndex, drop the value when any or all levels are NaN.

#### Returns

**valid** [Index]

### pandas.Index.duplicated

`Index.duplicated (keep='first')`

Indicate duplicate index values.

Duplicated values are indicated as `True` values in the resulting array. Either all duplicates, all except the first, or all except the last occurrence of duplicates can be indicated.

#### Parameters

**keep** [{ 'first', 'last', False }, default 'first'] The value or values in a set of duplicates to mark as missing.

- 'first' : Mark duplicates as `True` except for the first occurrence.
- 'last' : Mark duplicates as `True` except for the last occurrence.
- False : Mark all duplicates as `True`.

#### Returns

`numpy.ndarray`

See also:

**pandas.Series.duplicated** Equivalent method on `pandas.Series`.

**pandas.DataFrame.duplicated** Equivalent method on `pandas.DataFrame`.

**pandas.Index.drop\_duplicates** Remove duplicate values from Index.

### Examples

By default, for each set of duplicated values, the first occurrence is set to `False` and all others to `True`:

```
>>> idx = pd.Index(['lama', 'cow', 'lama', 'beetle', 'lama'])
>>> idx.duplicated()
array([False, False,  True, False,  True])
```

which is equivalent to

```
>>> idx.duplicated(keep='first')
array([False, False,  True, False,  True])
```

By using 'last', the last occurrence of each set of duplicated values is set on False and all others on True:

```
>>> idx.duplicated(keep='last')
array([ True, False,  True, False, False])
```

By setting keep on False, all duplicates are True:

```
>>> idx.duplicated(keep=False)
array([ True, False,  True, False,  True])
```

## pandas.Index.equals

`Index.equals` (*other*)

Determines if two Index objects contain the same elements.

## pandas.Index.factorize

`Index.factorize` (*sort=False*, *na\_sentinel=-1*)

Encode the object as an enumerated type or categorical variable.

This method is useful for obtaining a numeric representation of an array when all that matters is identifying distinct values. *factorize* is available as both a top-level function `pandas.factorize()`, and as a method `Series.factorize()` and `Index.factorize()`.

### Parameters

**sort** [boolean, default False] Sort *uniques* and shuffle *labels* to maintain the relationship.

**na\_sentinel** [int, default -1] Value to mark “not found”.

### Returns

**labels** [ndarray] An integer ndarray that’s an indexer into *uniques*. `uniques.take(labels)` will have the same values as *values*.

**uniques** [ndarray, Index, or Categorical] The unique valid values. When *values* is Categorical, *uniques* is a Categorical. When *values* is some other pandas object, an *Index* is returned. Otherwise, a 1-D ndarray is returned.

---

**Note:** Even if there’s a missing value in *values*, *uniques* will *not* contain an entry for it.

---

### See also:

**cut** Discretize continuous-valued array.

**unique** Find the unique value in an array.

## Examples

These examples all show `factorize` as a top-level method like `pd.factorize(values)`. The results are identical for methods like `Series.factorize()`.

```
>>> labels, uniques = pd.factorize(['b', 'b', 'a', 'c', 'b'])
>>> labels
array([0, 0, 1, 2, 0])
>>> uniques
array(['b', 'a', 'c'], dtype=object)
```

With `sort=True`, the *uniques* will be sorted, and *labels* will be shuffled so that the relationship is the maintained.

```
>>> labels, uniques = pd.factorize(['b', 'b', 'a', 'c', 'b'], sort=True)
>>> labels
array([1, 1, 0, 2, 1])
>>> uniques
array(['a', 'b', 'c'], dtype=object)
```

Missing values are indicated in *labels* with *na\_sentinel* (-1 by default). Note that missing values are never included in *uniques*.

```
>>> labels, uniques = pd.factorize(['b', None, 'a', 'c', 'b'])
>>> labels
array([ 0, -1,  1,  2,  0])
>>> uniques
array(['b', 'a', 'c'], dtype=object)
```

Thus far, we've only factorized lists (which are internally coerced to NumPy arrays). When factorizing pandas objects, the type of *uniques* will differ. For Categoricals, a *Categorical* is returned.

```
>>> cat = pd.Categorical(['a', 'a', 'c'], categories=['a', 'b', 'c'])
>>> labels, uniques = pd.factorize(cat)
>>> labels
array([0, 0, 1])
>>> uniques
[a, c]
Categories (3, object): [a, b, c]
```

Notice that 'b' is in `uniques.categories`, despite not being present in `cat.values`.

For all other pandas objects, an Index of the appropriate type is returned.

```
>>> cat = pd.Series(['a', 'a', 'c'])
>>> labels, uniques = pd.factorize(cat)
>>> labels
array([0, 0, 1])
>>> uniques
Index(['a', 'c'], dtype='object')
```

## pandas.Index.fillna

`Index.fillna` (*value=None, downcast=None*)

Fill NA/NaN values with the specified value

### Parameters

**value** [scalar] Scalar value to use to fill holes (e.g. 0). This value cannot be a list-likes.

**downcast** [dict, default is None] a dict of item->dtype of what to downcast if possible, or the string 'infer' which will try to downcast to an appropriate equal type (e.g. float64 to int64 if possible)

#### Returns

**filled** [Index]

### pandas.Index.format

`Index.format` (*name=False, formatter=None, \*\*kwargs*)

Render a string representation of the Index.

### pandas.Index.get\_duplicates

`Index.get_duplicates()`

Extract duplicated index elements.

Deprecated since version 0.23.0: Use `idx[idx.duplicated()].unique()` instead

Returns a sorted list of index elements which appear more than once in the index.

#### Returns

**array-like** List of duplicated indexes.

See also:

**`Index.duplicated`** Return boolean array denoting duplicates.

**`Index.drop_duplicates`** Return Index with duplicates removed.

### Examples

Works on different Index of types.

```
>>> pd.Index([1, 2, 2, 3, 3, 3, 4]).get_duplicates() # doctest: +SKIP
[2, 3]
```

Note that for a `DatetimeIndex`, it does not return a list but a new `DatetimeIndex`:

```
>>> dates = pd.to_datetime(['2018-01-01', '2018-01-02', '2018-01-03',
...                          '2018-01-03', '2018-01-04', '2018-01-04'],
...                          format='%Y-%m-%d')
>>> pd.Index(dates).get_duplicates() # doctest: +SKIP
DatetimeIndex(['2018-01-03', '2018-01-04'],
              dtype='datetime64[ns]', freq=None)
```

Sorts duplicated elements even when indexes are unordered.

```
>>> pd.Index([1, 2, 3, 2, 3, 4, 3]).get_duplicates() # doctest: +SKIP
[2, 3]
```

Return empty array-like structure when all elements are unique.

```
>>> pd.Index([1, 2, 3, 4]).get_duplicates() # doctest: +SKIP
[]
>>> dates = pd.to_datetime(['2018-01-01', '2018-01-02', '2018-01-03'],
...                          format='%Y-%m-%d')
>>> pd.Index(dates).get_duplicates() # doctest: +SKIP
DatetimeIndex([], dtype='datetime64[ns]', freq=None)
```

## pandas.Index.get\_indexer

`Index.get_indexer` (*target*, *method=None*, *limit=None*, *tolerance=None*)

Compute indexer and mask for new index given the current index. The indexer should be then used as an input to `ndarray.take` to align the current data to the new index.

### Parameters

**target** [Index]

**method** [{None, 'pad'/'ffill', 'backfill'/'bfill', 'nearest'}, optional]

- default: exact matches only.
- pad / ffill: find the PREVIOUS index value if no exact match.
- backfill / bfill: use NEXT index value if no exact match
- nearest: use the NEAREST index value if no exact match. Tied distances are broken by preferring the larger index value.

**limit** [int, optional] Maximum number of consecutive labels in *target* to match for inexact matches.

**tolerance** [optional] Maximum distance between original and new labels for inexact matches. The values of the index at the matching locations must satisfy the equation `abs(index[indexer] - target) <= tolerance`.

Tolerance may be a scalar value, which applies the same tolerance to all values, or list-like, which applies variable tolerance per element. List-like includes list, tuple, array, Series, and must be the same size as the index and its dtype must exactly match the index's type.

New in version 0.21.0: (list-like tolerance)

### Returns

**indexer** [ndarray of int] Integers from 0 to *n* - 1 indicating that the index at these positions matches the corresponding target values. Missing values in the target are marked by -1.

## Examples

```
>>> index = pd.Index(['c', 'a', 'b'])
>>> index.get_indexer(['a', 'b', 'x'])
array([ 1,  2, -1])
```

Notice that the return value is an array of locations in *index* and *x* is marked by -1, as it is not in *index*.

### pandas.Index.get\_indexer\_for

`Index.get_indexer_for(target, **kwargs)`

Guaranteed return of an indexer even when non-unique.

This dispatches to `get_indexer` or `get_indexer_nonunique` as appropriate.

### pandas.Index.get\_indexer\_non\_unique

`Index.get_indexer_non_unique(target)`

Compute indexer and mask for new index given the current index. The indexer should be then used as an input to `ndarray.take` to align the current data to the new index.

#### Parameters

**target** [Index]

#### Returns

**indexer** [ndarray of int] Integers from 0 to `n - 1` indicating that the index at these positions matches the corresponding target values. Missing values in the target are marked by `-1`.

**missing** [ndarray of int] An indexer into the target of the values not found. These correspond to the `-1` in the indexer array

### pandas.Index.get\_level\_values

`Index.get_level_values(level)`

Return an Index of values for requested level.

This is primarily useful to get an individual level of values from a `MultiIndex`, but is provided on `Index` as well for compatability.

#### Parameters

**level** [int or str] It is either the integer position or the name of the level.

#### Returns

**values** [Index] Calling object, as there is only one level in the `Index`.

See also:

**MultiIndex.get\_level\_values** Get values for a level of a `MultiIndex`.

### Notes

For `Index`, level should be 0, since there are no multiple levels.

### Examples

```
>>> idx = pd.Index(list('abc'))
>>> idx
Index(['a', 'b', 'c'], dtype='object')
```

Get level values by supplying *level* as integer:

```
>>> idx.get_level_values(0)
Index(['a', 'b', 'c'], dtype='object')
```

## pandas.Index.get\_loc

`Index.get_loc(key, method=None, tolerance=None)`

Get integer location, slice or boolean mask for requested label.

### Parameters

**key** [label]

**method** [{None, 'pad'/'ffill', 'backfill'/'bfill', 'nearest'}, optional]

- default: exact matches only.
- pad / ffill: find the PREVIOUS index value if no exact match.
- backfill / bfill: use NEXT index value if no exact match
- nearest: use the NEAREST index value if no exact match. Tied distances are broken by preferring the larger index value.

**tolerance** [optional] Maximum distance from index value for inexact matches. The value of the index at the matching location must satisfy the equation  $\text{abs}(\text{index}[\text{loc}] - \text{key}) \leq \text{tolerance}$ .

Tolerance may be a scalar value, which applies the same tolerance to all values, or list-like, which applies variable tolerance per element. List-like includes list, tuple, array, Series, and must be the same size as the index and its dtype must exactly match the index's type.

New in version 0.21.0: (list-like tolerance)

### Returns

**loc** [int if unique index, slice if monotonic index, else mask]

## Examples

```
>>> unique_index = pd.Index(list('abc'))
>>> unique_index.get_loc('b')
1
```

```
>>> monotonic_index = pd.Index(list('abbc'))
>>> monotonic_index.get_loc('b')
slice(1, 3, None)
```

```
>>> non_monotonic_index = pd.Index(list('abcb'))
>>> non_monotonic_index.get_loc('b')
array([False,  True, False,  True], dtype=bool)
```

### pandas.Index.get\_slice\_bound

`Index.get_slice_bound` (*label, side, kind*)

Calculate slice bound that corresponds to given label.

Returns leftmost (one-past-the-rightmost if `side=='right'`) position of given label.

#### Parameters

**label** [object]

**side** [{ 'left', 'right' }]

**kind** [{ 'ix', 'loc', 'getitem' }]

### pandas.Index.get\_value

`Index.get_value` (*series, key*)

Fast lookup of value from 1-dimensional ndarray. Only use this if you know what you're doing.

### pandas.Index.get\_values

`Index.get_values` ()

Return *Index* data as an *numpy.ndarray*.

#### Returns

**numpy.ndarray** A one-dimensional numpy array of the *Index* values.

**See also:**

***Index.values*** The attribute that `get_values` wraps.

### Examples

Getting the *Index* values of a *DataFrame*:

```
>>> df = pd.DataFrame([[1, 2, 3], [4, 5, 6], [7, 8, 9]],
...                    index=['a', 'b', 'c'], columns=['A', 'B', 'C'])
>>> df
   A  B  C
a  1  2  3
b  4  5  6
c  7  8  9
>>> df.index.get_values()
array(['a', 'b', 'c'], dtype=object)
```

Standalone *Index* values:

```
>>> idx = pd.Index(['1', '2', '3'])
>>> idx.get_values()
array(['1', '2', '3'], dtype=object)
```

*MultiIndex* arrays also have only one dimension:

```

>>> midx = pd.MultiIndex.from_arrays([[1, 2, 3], ['a', 'b', 'c']],
...                                 names=('number', 'letter'))
>>> midx.get_values()
array([(1, 'a'), (2, 'b'), (3, 'c')], dtype=object)
>>> midx.get_values().ndim
1

```

## pandas.Index.groupby

`Index.groupby` (*values*)

Group the index labels by a given array of values.

### Parameters

**values** [array] Values used to determine the groups.

### Returns

**groups** [dict] {group name -> group labels}

## pandas.Index.identical

`Index.identical` (*other*)

Similar to equals, but check that other comparable attributes are also equal.

## pandas.Index.insert

`Index.insert` (*loc*, *item*)

Make new Index inserting new item at location.

Follows Python list.append semantics for negative values.

### Parameters

**loc** [int]

**item** [object]

### Returns

**new\_index** [Index]

## pandas.Index.intersection

`Index.intersection` (*other*)

Form the intersection of two Index objects.

This returns a new Index with elements common to the index and *other*, preserving the order of the calling index.

### Parameters

**other** [Index or array-like]

### Returns

**intersection** [Index]

## Examples

```
>>> idx1 = pd.Index([1, 2, 3, 4])
>>> idx2 = pd.Index([3, 4, 5, 6])
>>> idx1.intersection(idx2)
Int64Index([3, 4], dtype='int64')
```

## pandas.Index.is\_

`Index.is_()` (*other*)

More flexible, faster check like `is` but that works through views.

Note: this is *not* the same as `Index.identical()`, which checks that metadata is also the same.

### Parameters

**other** [object] other object to compare against.

### Returns

**True if both have same underlying data, False otherwise** [bool]

## pandas.Index.is\_categorical

`Index.is_categorical()`

Check if the Index holds categorical data.

### Returns

**boolean** True if the Index is categorical.

**See also:**

**CategoricalIndex** Index for categorical data.

## Examples

```
>>> idx = pd.Index(["Watermelon", "Orange", "Apple",
...                 "Watermelon"]).astype("category")
>>> idx.is_categorical()
True
```

```
>>> idx = pd.Index([1, 3, 5, 7])
>>> idx.is_categorical()
False
```

```
>>> s = pd.Series(["Peter", "Victor", "Elisabeth", "Mar"])
>>> s
0      Peter
1      Victor
2  Elisabeth
3         Mar
dtype: object
>>> s.index.is_categorical()
False
```

## pandas.Index.isin

`Index.isin(values, level=None)`

Return a boolean array where the index values are in *values*.

Compute boolean array of whether each index value is found in the passed set of values. The length of the returned boolean array matches the length of the index.

### Parameters

**values** [set or list-like] Sought values.

New in version 0.18.1: Support for values as a set.

**level** [str or int, optional] Name or position of the index level to use (if the index is a *MultiIndex*).

### Returns

**is\_contained** [ndarray] NumPy array of boolean values.

See also:

**Series.isin** Same for Series.

**DataFrame.isin** Same method for DataFrames.

## Notes

In the case of *MultiIndex* you must either specify *values* as a list-like object containing tuples that are the same length as the number of levels, or specify *level*. Otherwise it will raise a `ValueError`.

If *level* is specified:

- if it is the name of one *and only one* index level, use that level;
- otherwise it should be a number indicating level position.

## Examples

```
>>> idx = pd.Index([1,2,3])
>>> idx
Int64Index([1, 2, 3], dtype='int64')
```

Check whether each index value in a list of values. `>>> idx.isin([1, 4])` `array([ True, False, False])`

```
>>> midx = pd.MultiIndex.from_arrays([[1,2,3],
...                                  ['red', 'blue', 'green']],
...                                  names=('number', 'color'))
>>> midx
MultiIndex(levels=[[1, 2, 3], ['blue', 'green', 'red']],
            labels=[[0, 1, 2], [2, 0, 1]],
            names=['number', 'color'])
```

Check whether the strings in the ‘color’ level of the *MultiIndex* are in a list of colors.

```
>>> midx.isin(['red', 'orange', 'yellow'], level='color')
array([ True, False, False])
```

To check across the levels of a MultiIndex, pass a list of tuples:

```
>>> midx.isin([(1, 'red'), (3, 'red')])
array([ True, False, False])
```

For a DatetimeIndex, string values in *values* are converted to Timestamps.

```
>>> dates = ['2000-03-11', '2000-03-12', '2000-03-13']
>>> dti = pd.to_datetime(dates)
>>> dti
DatetimeIndex(['2000-03-11', '2000-03-12', '2000-03-13'],
              dtype='datetime64[ns]', freq=None)
```

```
>>> dti.isin(['2000-03-11'])
array([ True, False, False])
```

## pandas.Index.isna

`Index.isna()`

Detect missing values.

Return a boolean same-sized object indicating if the values are NA. NA values, such as `None`, `numpy.NaN` or `pd.NaT`, get mapped to `True` values. Everything else get mapped to `False` values. Characters such as empty strings `''` or `numpy.inf` are not considered NA values (unless you set `pandas.options.mode.use_inf_as_na = True`).

New in version 0.20.0.

### Returns

**numpy.ndarray** A boolean array of whether my values are NA

See also:

**pandas.Index.notna** Boolean inverse of `isna`.

**pandas.Index.dropna** Omit entries with missing values.

**pandas.isna** Top-level `isna`.

**Series.isna** Detect missing values in Series object.

## Examples

Show which entries in a `pandas.Index` are NA. The result is an array.

```
>>> idx = pd.Index([5.2, 6.0, np.NaN])
>>> idx
Float64Index([5.2, 6.0, nan], dtype='float64')
>>> idx.isna()
array([False, False,  True], dtype=bool)
```

Empty strings are not considered NA values. `None` is considered an NA value.

```
>>> idx = pd.Index(['black', '', 'red', None])
>>> idx
Index(['black', '', 'red', None], dtype='object')
```

(continues on next page)

(continued from previous page)

```
>>> idx.isna()
array([False, False, False,  True], dtype=bool)
```

For datetimes, *NaT* (Not a Time) is considered as an NA value.

```
>>> idx = pd.DatetimeIndex([pd.Timestamp('1940-04-25'),
...                          pd.Timestamp(''), None, pd.NaT])
>>> idx
DatetimeIndex(['1940-04-25', 'NaT', 'NaT', 'NaT'],
              dtype='datetime64[ns]', freq=None)
>>> idx.isna()
array([False,  True,  True,  True], dtype=bool)
```

## pandas.Index.isnull

`Index.isnull()`

Detect missing values.

Return a boolean same-sized object indicating if the values are NA. NA values, such as `None`, `numpy.NaN` or `pd.NaT`, get mapped to `True` values. Everything else get mapped to `False` values. Characters such as empty strings `''` or `numpy.inf` are not considered NA values (unless you set `pandas.options.mode.use_inf_as_na = True`).

New in version 0.20.0.

### Returns

**numpy.ndarray** A boolean array of whether my values are NA

See also:

**pandas.Index.notna** Boolean inverse of `isna`.

**pandas.Index.dropna** Omit entries with missing values.

**pandas.isna** Top-level `isna`.

**Series.isna** Detect missing values in Series object.

## Examples

Show which entries in a `pandas.Index` are NA. The result is an array.

```
>>> idx = pd.Index([5.2, 6.0, np.NaN])
>>> idx
Float64Index([5.2, 6.0, nan], dtype='float64')
>>> idx.isna()
array([False, False,  True], dtype=bool)
```

Empty strings are not considered NA values. `None` is considered an NA value.

```
>>> idx = pd.Index(['black', '', 'red', None])
>>> idx
Index(['black', '', 'red', None], dtype='object')
>>> idx.isna()
array([False, False, False,  True], dtype=bool)
```

For datetimes, *NaT* (Not a Time) is considered as an NA value.

```
>>> idx = pd.DatetimeIndex([pd.Timestamp('1940-04-25'),
...                          pd.Timestamp(''), None, pd.NaT])
>>> idx
DatetimeIndex(['1940-04-25', 'NaT', 'NaT', 'NaT'],
              dtype='datetime64[ns]', freq=None)
>>> idx.isna()
array([False,  True,  True,  True], dtype=bool)
```

## pandas.Index.item

`Index.item()`

Return the first element of the underlying data as a python scalar.

## pandas.Index.join

`Index.join(other, how='left', level=None, return_indexers=False, sort=False)`

Compute `join_index` and `indexers` to conform data structures to the new index.

### Parameters

**other** [Index]

**how** [{ 'left', 'right', 'inner', 'outer' }]

**level** [int or level name, default None]

**return\_indexers** [boolean, default False]

**sort** [boolean, default False] Sort the join keys lexicographically in the result Index. If False, the order of the join keys depends on the join type (how keyword)

New in version 0.20.0.

### Returns

**join\_index, (left\_indexer, right\_indexer)**

## pandas.Index.map

`Index.map(mapper, na_action=None)`

Map values using input correspondence (a dict, Series, or function).

### Parameters

**mapper** [function, dict, or Series] Mapping correspondence.

**na\_action** [{None, 'ignore'}] If 'ignore', propagate NA values, without passing them to the mapping correspondence.

### Returns

**applied** [Union[Index, MultiIndex], inferred] The output of the mapping function applied to the index. If the function returns a tuple with more than one element a MultiIndex will be returned.

**pandas.Index.max**`Index.max` (*axis=None, skipna=True*)

Return the maximum value of the Index.

**Parameters****axis** [int, optional] For compatibility with NumPy. Only 0 or None are allowed.**skipna** [bool, default True]**Returns****scalar** Maximum value.**See also:****`Index.min`** Return the minimum value in an Index.**`Series.max`** Return the maximum value in a Series.**`DataFrame.max`** Return the maximum values in a DataFrame.**Examples**

```
>>> idx = pd.Index([3, 2, 1])
>>> idx.max()
3
```

```
>>> idx = pd.Index(['c', 'b', 'a'])
>>> idx.max()
'c'
```

For a MultiIndex, the maximum is determined lexicographically.

```
>>> idx = pd.MultiIndex.from_product([('a', 'b'), (2, 1)])
>>> idx.max()
('b', 2)
```

**pandas.Index.memory\_usage**`Index.memory_usage` (*deep=False*)

Memory usage of the values

**Parameters****deep** [bool] Introspect the data deeply, interrogate *object* dtypes for system-level memory consumption**Returns****bytes used****See also:**`numpy.ndarray.nbytes`

## Notes

Memory usage does not include memory consumed by elements that are not components of the array if `deep=False` or if used on PyPy

## pandas.Index.min

`Index.min` (*axis=None, skipna=True*)

Return the minimum value of the Index.

### Parameters

**axis** [{None}] Dummy argument for consistency with Series

**skipna** [bool, default True]

### Returns

**scalar** Minimum value.

### See also:

**Index.max** Return the maximum value of the object.

**Series.min** Return the minimum value in a Series.

**DataFrame.min** Return the minimum values in a DataFrame.

## Examples

```
>>> idx = pd.Index([3, 2, 1])
>>> idx.min()
1
```

```
>>> idx = pd.Index(['c', 'b', 'a'])
>>> idx.min()
'a'
```

For a MultiIndex, the minimum is determined lexicographically.

```
>>> idx = pd.MultiIndex.from_product([('a', 'b'), (2, 1)])
>>> idx.min()
('a', 1)
```

## pandas.Index.notna

`Index.notna` ()

Detect existing (non-missing) values.

Return a boolean same-sized object indicating if the values are not NA. Non-missing values get mapped to True. Characters such as empty strings '' or `numpy.inf` are not considered NA values (unless you set `pandas.options.mode.use_inf_as_na = True`). NA values, such as `None` or `numpy.NaN`, get mapped to False values.

New in version 0.20.0.

### Returns

**numpy.ndarray** Boolean array to indicate which entries are not NA.

See also:

**Index.notnull** Alias of notna.

**Index.isna** Inverse of notna.

**pandas.notna** Top-level notna.

## Examples

Show which entries in an Index are not NA. The result is an array.

```
>>> idx = pd.Index([5.2, 6.0, np.NaN])
>>> idx
Float64Index([5.2, 6.0, nan], dtype='float64')
>>> idx.notna()
array([ True,  True, False])
```

Empty strings are not considered NA values. None is considered a NA value.

```
>>> idx = pd.Index(['black', '', 'red', None])
>>> idx
Index(['black', '', 'red', None], dtype='object')
>>> idx.notna()
array([ True,  True,  True, False])
```

## pandas.Index.notnull

**Index.notnull()**

Detect existing (non-missing) values.

Return a boolean same-sized object indicating if the values are not NA. Non-missing values get mapped to True. Characters such as empty strings '' or `numpy.inf` are not considered NA values (unless you set `pandas.options.mode.use_inf_as_na = True`). NA values, such as `None` or `numpy.NaN`, get mapped to False values.

New in version 0.20.0.

### Returns

**numpy.ndarray** Boolean array to indicate which entries are not NA.

See also:

**Index.notnull** Alias of notna.

**Index.isna** Inverse of notna.

**pandas.notna** Top-level notna.

## Examples

Show which entries in an Index are not NA. The result is an array.

```
>>> idx = pd.Index([5.2, 6.0, np.NaN])
>>> idx
Float64Index([5.2, 6.0, nan], dtype='float64')
>>> idx.notna()
array([ True,  True, False])
```

Empty strings are not considered NA values. None is considered a NA value.

```
>>> idx = pd.Index(['black', '', 'red', None])
>>> idx
Index(['black', '', 'red', None], dtype='object')
>>> idx.notna()
array([ True,  True,  True, False])
```

### pandas.Index.nunique

`Index.nunique` (*dropna=True*)

Return number of unique elements in the object.

Excludes NA values by default.

#### Parameters

**dropna** [boolean, default True] Don't include NaN in the count.

#### Returns

**nunique** [int]

### pandas.Index.putmask

`Index.putmask` (*mask, value*)

Return a new Index of the values set with the mask.

#### See also:

`numpy.ndarray.putmask`

### pandas.Index.ravel

`Index.ravel` (*order='C'*)

Return an ndarray of the flattened values of the underlying data.

#### See also:

`numpy.ndarray.ravel`

### pandas.Index.reindex

`Index.reindex` (*target, method=None, level=None, limit=None, tolerance=None*)

Create index with target's values (move/add/delete values as necessary).

#### Parameters

**target** [an iterable]

**Returns****new\_index** [pd.Index] Resulting index**indexer** [np.ndarray or None] Indices of output values in original index**pandas.Index.rename****Index.rename** (*name*, *inplace=False*)

Alter Index or MultiIndex name.

Able to set new names without level. Defaults to returning new index. Length of names must match number of levels in MultiIndex.

**Parameters****name** [label or list of labels] Name(s) to set.**inplace** [boolean, default False] Modifies the object directly, instead of creating a new Index or MultiIndex.**Returns****Index** The same type as the caller or None if inplace is True.**See also:****Index.set\_names** Able to set new names partially and by level.**Examples**

```
>>> idx = pd.Index(['A', 'C', 'A', 'B'], name='score')
>>> idx.rename('grade')
Index(['A', 'C', 'A', 'B'], dtype='object', name='grade')
```

```
>>> idx = pd.MultiIndex.from_product(['python', 'cobra',
...                                  [2018, 2019]],
...                                  names=['kind', 'year'])
>>> idx
MultiIndex(levels=[['cobra', 'python'], [2018, 2019]],
            labels=[[1, 1, 0, 0], [0, 1, 0, 1]],
            names=['kind', 'year'])
>>> idx.rename(['species', 'year'])
MultiIndex(levels=[['cobra', 'python'], [2018, 2019]],
            labels=[[1, 1, 0, 0], [0, 1, 0, 1]],
            names=['species', 'year'])
>>> idx.rename('species')
Traceback (most recent call last):
TypeError: Must pass list-like as `names`.
```

**pandas.Index.repeat****Index.repeat** (*repeats*, *axis=None*)

Repeat elements of a Index.

Returns a new Index where each element of the current Index is repeated consecutively a given number of times.

**Parameters**

**repeats** [int or array of ints] The number of repetitions for each element. This should be a non-negative integer. Repeating 0 times will return an empty Index.

**axis** [None] Must be `None`. Has no effect but is accepted for compatibility with numpy.

**Returns**

**repeated\_index** [Index] Newly created Index with repeated elements.

See also:

**`Series.repeat`** Equivalent function for Series.

**`numpy.repeat`** Similar method for `numpy.ndarray`.

**Examples**

```
>>> idx = pd.Index(['a', 'b', 'c'])
>>> idx
Index(['a', 'b', 'c'], dtype='object')
>>> idx.repeat(2)
Index(['a', 'a', 'b', 'b', 'c', 'c'], dtype='object')
>>> idx.repeat([1, 2, 3])
Index(['a', 'b', 'b', 'c', 'c', 'c'], dtype='object')
```

**pandas.Index.searchsorted**

`Index.searchsorted` (*value*, *side*='left', *sorter*=None)

Find indices where elements should be inserted to maintain order.

Find the indices into a sorted `IndexOpsMixin` *self* such that, if the corresponding elements in *value* were inserted before the indices, the order of *self* would be preserved.

**Parameters**

**value** [array\_like] Values to insert into *self*.

**side** [{ 'left', 'right' }, optional] If 'left', the index of the first suitable location found is given. If 'right', return the last such index. If there is no suitable index, return either 0 or N (where N is the length of *self*).

**sorter** [1-D array\_like, optional] Optional array of integer indices that sort *self* into ascending order. They are typically the result of `np.argsort`.

**Returns**

**int or array of int** A scalar or array of insertion points with the same shape as *value*.

Changed in version 0.24.0: If *value* is a scalar, an int is now always returned. Previously, scalar inputs returned an 1-item array for *Series* and *Categorical*.

See also:

`numpy.searchsorted`

**Notes**

Binary search is used to find the required insertion points.

## Examples

```
>>> x = pd.Series([1, 2, 3])
>>> x
0    1
1    2
2    3
dtype: int64
```

```
>>> x.searchsorted(4)
3
```

```
>>> x.searchsorted([0, 4])
array([0, 3])
```

```
>>> x.searchsorted([1, 3], side='left')
array([0, 2])
```

```
>>> x.searchsorted([1, 3], side='right')
array([1, 3])
```

```
>>> x = pd.Categorical(['apple', 'bread', 'bread',
                        'cheese', 'milk'], ordered=True)
[apple, bread, bread, cheese, milk]
Categories (4, object): [apple < bread < cheese < milk]
```

```
>>> x.searchsorted('bread')
1
```

```
>>> x.searchsorted(['bread'], side='right')
array([3])
```

## pandas.Index.set\_names

`Index.set_names` (*names, level=None, inplace=False*)

Set Index or MultiIndex name.

Able to set new names partially and by level.

### Parameters

**names** [label or list of label] Name(s) to set.

**level** [int, label or list of int or label, optional] If the index is a MultiIndex, level(s) to set (None for all levels). Otherwise level must be None.

**inplace** [bool, default False] Modifies the object directly, instead of creating a new Index or MultiIndex.

### Returns

**Index** The same type as the caller or None if inplace is True.

See also:

**Index.rename** Able to set new names without level.

## Examples

```
>>> idx = pd.Index([1, 2, 3, 4])
>>> idx
Int64Index([1, 2, 3, 4], dtype='int64')
>>> idx.set_names('quarter')
Int64Index([1, 2, 3, 4], dtype='int64', name='quarter')

>>> idx = pd.MultiIndex.from_product(['python', 'cobra'],
...                                  [2018, 2019])
>>> idx
MultiIndex(levels=[['cobra', 'python'], [2018, 2019]],
            labels=[[1, 1, 0, 0], [0, 1, 0, 1]])
>>> idx.set_names(['kind', 'year'], inplace=True)
>>> idx
MultiIndex(levels=[['cobra', 'python'], [2018, 2019]],
            labels=[[1, 1, 0, 0], [0, 1, 0, 1]],
            names=['kind', 'year'])
>>> idx.set_names('species', level=0)
MultiIndex(levels=[['cobra', 'python'], [2018, 2019]],
            labels=[[1, 1, 0, 0], [0, 1, 0, 1]],
            names=['species', 'year'])
```

## pandas.Index.set\_value

`Index.set_value(arr, key, value)`  
Fast lookup of value from 1-dimensional ndarray.

## Notes

Only use this if you know what you're doing.

## pandas.Index.shift

`Index.shift(periods=1, freq=None)`  
Shift index by desired number of time frequency increments.

This method is for shifting the values of datetime-like indexes by a specified time increment a given number of times.

### Parameters

**periods** [int, default 1] Number of periods (or increments) to shift by, can be positive or negative.

**freq** [pandas.DateOffset, pandas.Timedelta or string, optional] Frequency increment to shift by. If None, the index is shifted by its own *freq* attribute. Offset aliases are valid strings, e.g., 'D', 'W', 'M' etc.

### Returns

**pandas.Index** shifted index

See also:

**Series.shift** Shift values of Series.

## Notes

This method is only implemented for datetime-like index classes, i.e., `DatetimeIndex`, `PeriodIndex` and `TimedeltaIndex`.

## Examples

Put the first 5 month starts of 2011 into an index.

```
>>> month_starts = pd.date_range('1/1/2011', periods=5, freq='MS')
>>> month_starts
DatetimeIndex(['2011-01-01', '2011-02-01', '2011-03-01', '2011-04-01',
              '2011-05-01'],
              dtype='datetime64[ns]', freq='MS')
```

Shift the index by 10 days.

```
>>> month_starts.shift(10, freq='D')
DatetimeIndex(['2011-01-11', '2011-02-11', '2011-03-11', '2011-04-11',
              '2011-05-11'],
              dtype='datetime64[ns]', freq=None)
```

The default value of *freq* is the *freq* attribute of the index, which is 'MS' (month start) in this example.

```
>>> month_starts.shift(10)
DatetimeIndex(['2011-11-01', '2011-12-01', '2012-01-01', '2012-02-01',
              '2012-03-01'],
              dtype='datetime64[ns]', freq='MS')
```

## pandas.Index.slice\_indexer

`Index.slice_indexer` (*start=None, end=None, step=None, kind=None*)

For an ordered or unique index, compute the slice indexer for input labels and step.

### Parameters

**start** [label, default None] If None, defaults to the beginning

**end** [label, default None] If None, defaults to the end

**step** [int, default None]

**kind** [string, default None]

### Returns

**indexer** [slice]

### Raises

**KeyError** [If key does not exist, or key is not unique and index is] not ordered.

## Notes

This function assumes that the data is sorted, so use at your own peril

## Examples

This is a method on all index types. For example you can do:

```
>>> idx = pd.Index(list('abcd'))
>>> idx.slice_indexer(start='b', end='c')
slice(1, 3)
```

```
>>> idx = pd.MultiIndex.from_arrays([list('abcd'), list('efgh')])
>>> idx.slice_indexer(start='b', end=('c', 'g'))
slice(1, 3)
```

## pandas.Index.slice\_locs

`Index.slice_locs` (*start=None, end=None, step=None, kind=None*)

Compute slice locations for input labels.

### Parameters

**start** [label, default None] If None, defaults to the beginning

**end** [label, default None] If None, defaults to the end

**step** [int, defaults None] If None, defaults to 1

**kind** [{‘ix’, ‘loc’, ‘getitem’} or None]

### Returns

**start, end** [int]

See also:

**Index.get\_loc** Get location for a single label.

## Notes

This method only works if the index is monotonic or unique.

## Examples

```
>>> idx = pd.Index(list('abcd'))
>>> idx.slice_locs(start='b', end='c')
(1, 3)
```

## pandas.Index.sort\_values

`Index.sort_values` (*return\_indexer=False, ascending=True*)

Return a sorted copy of the index.

Return a sorted copy of the index, and optionally return the indices that sorted the index itself.

### Parameters

**return\_indexer** [bool, default False] Should the indices that would sort the index be returned.

**ascending** [bool, default True] Should the index values be sorted in an ascending order.

#### Returns

**sorted\_index** [pandas.Index] Sorted copy of the index.

**indexer** [numpy.ndarray, optional] The indices that the index itself was sorted by.

See also:

**pandas.Series.sort\_values** Sort values of a Series.

**pandas.DataFrame.sort\_values** Sort values in a DataFrame.

#### Examples

```
>>> idx = pd.Index([10, 100, 1, 1000])
>>> idx
Int64Index([10, 100, 1, 1000], dtype='int64')
```

Sort values in ascending order (default behavior).

```
>>> idx.sort_values()
Int64Index([1, 10, 100, 1000], dtype='int64')
```

Sort values in descending order, and also get the indices *idx* was sorted by.

```
>>> idx.sort_values(ascending=False, return_indexer=True)
(Int64Index([1000, 100, 10, 1], dtype='int64'), array([3, 1, 0, 2]))
```

#### pandas.Index.sortlevel

**Index.sortlevel** (*level=None, ascending=True, sort\_remaining=None*)

For internal compatibility with with the Index API.

Sort the Index. This is for compat with MultiIndex

#### Parameters

**ascending** [boolean, default True] False to sort in descending order

**level, sort\_remaining** are compat parameters

#### Returns

**sorted\_index** [Index]

#### pandas.Index.str

**Index.str** ()

Vectorized string functions for Series and Index. NAs stay NA unless handled otherwise by a particular method. Patterned after Python's string methods, with some inspiration from R's stringr package.

## Examples

```
>>> s.str.split('_')
>>> s.str.replace('_', '')
```

## pandas.Index.summary

`Index.summary` (*name=None*)  
Return a summarized representation.  
Deprecated since version 0.23.0.

## pandas.Index.symmetric\_difference

`Index.symmetric_difference` (*other, result\_name=None*)  
Compute the symmetric difference of two Index objects.

It's sorted if sorting is possible.

### Parameters

**other** [Index or array-like]  
**result\_name** [str]

### Returns

**symmetric\_difference** [Index]

## Notes

`symmetric_difference` contains elements that appear in either `idx1` or `idx2` but not both. Equivalent to the Index created by `idx1.difference(idx2) | idx2.difference(idx1)` with duplicates dropped.

## Examples

```
>>> idx1 = pd.Index([1, 2, 3, 4])
>>> idx2 = pd.Index([2, 3, 4, 5])
>>> idx1.symmetric_difference(idx2)
Int64Index([1, 5], dtype='int64')
```

You can also use the `^` operator:

```
>>> idx1 ^ idx2
Int64Index([1, 5], dtype='int64')
```

## pandas.Index.take

`Index.take` (*indices, axis=0, allow\_fill=True, fill\_value=None, \*\*kwargs*)  
Return a new Index of the values selected by the indices.  
For internal compatibility with numpy arrays.

**Parameters**

**indices** [list] Indices to be taken

**axis** [int, optional] The axis over which to select values, always 0.

**allow\_fill** [bool, default True]

**fill\_value** [bool, default None] If allow\_fill=True and fill\_value is not None, indices specified by -1 is regarded as NA. If Index doesn't hold NA, raise ValueError

**See also:**

`numpy.ndarray.take`

**pandas.Index.to\_flat\_index**

`Index.to_flat_index()`

Identity method.

New in version 0.24.0.

This is implemented for compatability with subclass implementations when chaining.

**Returns**

**pd.Index** Caller.

**See also:**

***MultiIndex.to\_flat\_index*** Subclass implementation.

**pandas.Index.to\_frame**

`Index.to_frame(index=True, name=None)`

Create a DataFrame with a column containing the Index.

New in version 0.24.0.

**Parameters**

**index** [boolean, default True] Set the index of the returned DataFrame as the original Index.

**name** [object, default None] The passed name should substitute for the index name (if it has one).

**Returns**

**DataFrame** DataFrame containing the original Index data.

**See also:**

***Index.to\_series*** Convert an Index to a Series.

***Series.to\_frame*** Convert Series to DataFrame.

## Examples

```
>>> idx = pd.Index(['Ant', 'Bear', 'Cow'], name='animal')
>>> idx.to_frame()
      animal
animal
Ant      Ant
Bear    Bear
Cow     Cow
```

By default, the original Index is reused. To enforce a new Index:

```
>>> idx.to_frame(index=False)
      animal
0      Ant
1     Bear
2      Cow
```

To override the name of the resulting column, specify *name*:

```
>>> idx.to_frame(index=False, name='zoo')
      zoo
0      Ant
1     Bear
2      Cow
```

## pandas.Index.to\_list

`Index.to_list()`

Return a list of the values.

These are each a scalar type, which is a Python scalar (for str, int, float) or a pandas scalar (for Timestamp/Timedelta/Interval/Period)

**See also:**

`numpy.ndarray.tolist`

## pandas.Index.to\_native\_types

`Index.to_native_types(slicer=None, **kwargs)`

Format specified values of *self* and return them.

### Parameters

**slicer** [int, array-like] An indexer into *self* that specifies which values are used in the formatting process.

**kwargs** [dict] Options for specifying how the values should be formatted. These options include the following:

- 1) **na\_rep** [str] The value that serves as a placeholder for NULL values
- 2) **quoting** [bool or None] Whether or not there are quoted values in *self*
- 3) **date\_format** [str] The format used to represent date-like values

## pandas.Index.to\_numpy

`Index.to_numpy(dtype=None, copy=False)`

A NumPy ndarray representing the values in this Series or Index.

New in version 0.24.0.

### Parameters

**dtype** [str or numpy.dtype, optional] The dtype to pass to `numpy.asarray()`

**copy** [bool, default False] Whether to ensure that the returned value is a not a view on another array. Note that `copy=False` does not *ensure* that `to_numpy()` is no-copy. Rather, `copy=True` ensure that a copy is made, even if not strictly necessary.

### Returns

**numpy.ndarray**

See also:

**Series.array** Get the actual data stored within.

**Index.array** Get the actual data stored within.

**DataFrame.to\_numpy** Similar method for DataFrame.

### Notes

The returned array will be the same up to equality (values equal in *self* will be equal in the returned array; likewise for values that are not equal). When *self* contains an ExtensionArray, the dtype may be different. For example, for a category-dtype Series, `to_numpy()` will return a NumPy array and the categorical dtype will be lost.

For NumPy dtypes, this will be a reference to the actual data stored in this Series or Index (assuming `copy=False`). Modifying the result in place will modify the data stored in the Series or Index (not that we recommend doing that).

For extension types, `to_numpy()` *may* require copying data and coercing the result to a NumPy type (possibly object), which may be expensive. When you need a no-copy reference to the underlying data, `Series.array` should be used instead.

This table lays out the different dtypes and default return types of `to_numpy()` for various dtypes within pandas.

| dtype              | array type                       |
|--------------------|----------------------------------|
| category[T]        | ndarray[T] (same dtype as input) |
| period             | ndarray[object] (Periods)        |
| interval           | ndarray[object] (Intervals)      |
| IntegerNA          | ndarray[object]                  |
| datetime64[ns]     | datetime64[ns]                   |
| datetime64[ns, tz] | ndarray[object] (Timestamps)     |

### Examples

```
>>> ser = pd.Series(pd.Categorical(['a', 'b', 'a']))
>>> ser.to_numpy()
array(['a', 'b', 'a'], dtype=object)
```

Specify the *dtype* to control how datetime-aware data is represented. Use `dtype=object` to return an ndarray of pandas *Timestamp* objects, each with the correct `tz`.

```
>>> ser = pd.Series(pd.date_range('2000', periods=2, tz="CET"))
>>> ser.to_numpy(dtype=object)
array([Timestamp('2000-01-01 00:00:00+0100', tz='CET', freq='D'),
       Timestamp('2000-01-02 00:00:00+0100', tz='CET', freq='D')],
      dtype=object)
```

Or `dtype='datetime64[ns]'` to return an ndarray of native `datetime64` values. The values are converted to UTC and the timezone info is dropped.

```
>>> ser.to_numpy(dtype="datetime64[ns]")
... # doctest: +ELLIPSIS
array(['1999-12-31T23:00:00.000000000', '2000-01-01T23:00:00...'],
      dtype='datetime64[ns]')
```

## pandas.Index.to\_series

`Index.to_series (index=None, name=None)`

Create a Series with both index and values equal to the index keys useful with `map` for returning an indexer based on an index.

### Parameters

**index** [Index, optional] index of resulting Series. If None, defaults to original index

**name** [string, optional] name of resulting Series. If None, defaults to name of original index

### Returns

**Series** [dtype will be based on the type of the Index values.]

## pandas.Index.tolist

`Index.tolist ()`

Return a list of the values.

These are each a scalar type, which is a Python scalar (for str, int, float) or a pandas scalar (for `Timestamp`/`Timedelta`/`Interval`/`Period`)

### See also:

`numpy.ndarray.tolist`

## pandas.Index.transpose

`Index.transpose (*args, **kwargs)`

Return the transpose, which is by definition self.

**pandas.Index.union****Index.union** (*other*)

Form the union of two Index objects and sorts if possible.

**Parameters****other** [Index or array-like]**Returns****union** [Index]**Examples**

```
>>> idx1 = pd.Index([1, 2, 3, 4])
>>> idx2 = pd.Index([3, 4, 5, 6])
>>> idx1.union(idx2)
Int64Index([1, 2, 3, 4, 5, 6], dtype='int64')
```

**pandas.Index.unique****Index.unique** (*level=None*)

Return unique values in the index. Uniques are returned in order of appearance, this does NOT sort.

**Parameters****level** [int or str, optional, default None] Only return values from specified level (for MultiIndex)

New in version 0.23.0.

**Returns****Index without duplicates****See also:***unique, Series.unique***pandas.Index.value\_counts****Index.value\_counts** (*normalize=False, sort=True, ascending=False, bins=None, dropna=True*)

Return a Series containing counts of unique values.

The resulting object will be in descending order so that the first element is the most frequently-occurring element. Excludes NA values by default.

**Parameters****normalize** [boolean, default False] If True then the object returned will contain the relative frequencies of the unique values.**sort** [boolean, default True] Sort by values.**ascending** [boolean, default False] Sort in ascending order.**bins** [integer, optional] Rather than count values, group them into half-open bins, a convenience for `pd.cut`, only works with numeric data.

**dropna** [boolean, default True] Don't include counts of NaN.

### Returns

**counts** [Series]

See also:

**Series.count** Number of non-NA elements in a Series.

**DataFrame.count** Number of non-NA elements in a DataFrame.

### Examples

```
>>> index = pd.Index([3, 1, 2, 3, 4, np.nan])
>>> index.value_counts()
3.0    2
4.0    1
2.0    1
1.0    1
dtype: int64
```

With *normalize* set to *True*, returns the relative frequency by dividing all values by the sum of values.

```
>>> s = pd.Series([3, 1, 2, 3, 4, np.nan])
>>> s.value_counts(normalize=True)
3.0    0.4
4.0    0.2
2.0    0.2
1.0    0.2
dtype: float64
```

### bins

Bins can be useful for going from a continuous variable to a categorical variable; instead of counting unique apparitions of values, divide the index in the specified number of half-open bins.

```
>>> s.value_counts(bins=3)
(2.0, 3.0]    2
(0.996, 2.0]   2
(3.0, 4.0]    1
dtype: int64
```

### dropna

With *dropna* set to *False* we can also see NaN index values.

```
>>> s.value_counts(dropna=False)
3.0    2
NaN    1
4.0    1
2.0    1
1.0    1
dtype: int64
```

**pandas.Index.where**`Index.where` (*cond*, *other=None*)

Return an Index of same shape as self and whose corresponding entries are from self where *cond* is True and otherwise are from *other*.

New in version 0.19.0.

**Parameters**

**cond** [boolean array-like with the same length as self]

**other** [scalar, or array-like]

|                                            |                                                                                |
|--------------------------------------------|--------------------------------------------------------------------------------|
| <code>Index.values</code>                  | Return an array representing the data in the Index.                            |
| <code>Index.is_monotonic</code>            | Alias for <code>is_monotonic_increasing</code> .                               |
| <code>Index.is_monotonic_increasing</code> | Return if the index is monotonic increasing (only equal or increasing) values. |
| <code>Index.is_monotonic_decreasing</code> | Return if the index is monotonic decreasing (only equal or decreasing) values. |
| <code>Index.is_unique</code>               | Return if the index has unique values.                                         |
| <code>Index.has_duplicates</code>          |                                                                                |
| <code>Index.hasnans</code>                 | Return if I have any nans; enables various perf speedups.                      |
| <code>Index.dtype</code>                   | Return the dtype object of the underlying data.                                |
| <code>Index.dtype_str</code>               | Return the dtype str of the underlying data.                                   |
| <code>Index.inferred_type</code>           | Return a string of the type inferred from the values.                          |
| <code>Index.is_all_dates</code>            |                                                                                |
| <code>Index.shape</code>                   | Return a tuple of the shape of the underlying data.                            |
| <code>Index.name</code>                    |                                                                                |
| <code>Index.names</code>                   |                                                                                |
| <code>Index.nbytes</code>                  | Return the number of bytes in the underlying data.                             |
| <code>Index.ndim</code>                    | Number of dimensions of the underlying data, by definition 1.                  |
| <code>Index.size</code>                    | Return the number of elements in the underlying data.                          |
| <code>Index.empty</code>                   |                                                                                |
| <code>Index.strides</code>                 | Return the strides of the underlying data.                                     |

|                                             |                                                                               |
|---------------------------------------------|-------------------------------------------------------------------------------|
| <i>Index.all(*args, **kwargs)</i>           | Return whether all elements are True.                                         |
| <i>Index.any(*args, **kwargs)</i>           | Return whether any element is True.                                           |
| <i>Index.argmin([axis, skipna])</i>         | Return a ndarray of the minimum argument indexer.                             |
| <i>Index.argmax([axis, skipna])</i>         | Return a ndarray of the maximum argument indexer.                             |
| <i>Index.copy([name, deep, dtype])</i>      | Make a copy of this object.                                                   |
| <i>Index.delete(loc)</i>                    | Make new Index with passed location(-s) deleted.                              |
| <i>Index.drop(labels[, errors])</i>         | Make new Index with passed list of labels deleted.                            |
| <i>Index.drop_duplicates([keep])</i>        | Return Index with duplicate values removed.                                   |
| <i>Index.duplicated([keep])</i>             | Indicate duplicate index values.                                              |
| <i>Index.equals(other)</i>                  | Determines if two Index objects contain the same elements.                    |
| <i>Index.factorize([sort, na_sentinel])</i> | Encode the object as an enumerated type or categorical variable.              |
| <i>Index.identical(other)</i>               | Similar to equals, but check that other comparable attributes are also equal. |
| <i>Index.insert(loc, item)</i>              | Make new Index inserting new item at location.                                |

Table 164 – continued from previous page

|                                                     |                                                                                                                                      |
|-----------------------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------|
| <i>Index.is_(other)</i>                             | More flexible, faster check like <code>is</code> but that works through views.                                                       |
| <i>Index.is_boolean()</i>                           |                                                                                                                                      |
| <i>Index.is_categorical()</i>                       | Check if the Index holds categorical data.                                                                                           |
| <i>Index.is_floating()</i>                          |                                                                                                                                      |
| <i>Index.is_integer()</i>                           |                                                                                                                                      |
| <i>Index.is_interval()</i>                          |                                                                                                                                      |
| <i>Index.is_mixed()</i>                             |                                                                                                                                      |
| <i>Index.is_numeric()</i>                           |                                                                                                                                      |
| <i>Index.is_object()</i>                            |                                                                                                                                      |
| <i>Index.min([axis, skipna])</i>                    | Return the minimum value of the Index.                                                                                               |
| <i>Index.max([axis, skipna])</i>                    | Return the maximum value of the Index.                                                                                               |
| <i>Index.reindex(target[, method, level, ...])</i>  | Create index with target's values (move/add/delete values as necessary).                                                             |
| <i>Index.rename(name[, inplace])</i>                | Alter Index or MultiIndex name.                                                                                                      |
| <i>Index.repeat(repeats[, axis])</i>                | Repeat elements of a Index.                                                                                                          |
| <i>Index.where(cond[, other])</i>                   | Return an Index of same shape as self and whose corresponding entries are from self where cond is True and otherwise are from other. |
| <i>Index.take(indices[, axis, allow_fill, ...])</i> | Return a new Index of the values selected by the indices.                                                                            |
| <i>Index.putmask(mask, value)</i>                   | Return a new Index of the values set with the mask.                                                                                  |
| <i>Index.unique([level])</i>                        | Return unique values in the index.                                                                                                   |
| <i>Index.nunique([dropna])</i>                      | Return number of unique elements in the object.                                                                                      |
| <i>Index.value_counts([normalize, sort, ...])</i>   | Return a Series containing counts of unique values.                                                                                  |

|-------------------------------------------------------|-----------------------------------------------|
| <code>Index.set_names(names[, level, inplace])</code> | Set Index or MultiIndex name.                 |
| <code>Index.is_lexsorted_for_tuple(tup)</code>        |                                               |
| <code>Index.droplevel([level])</code>                 | Return index with requested level(s) removed. |

**pandas.Index.is\_lexsorted\_for\_tuple**`Index.is_lexsorted_for_tuple(tup)`**35.7.1.5 Missing Values**

|                                              |                                             |
|----------------------------------------------|---------------------------------------------|
| <code>Index.fillna([value, downcast])</code> | Fill NA/NaN values with the specified value |
| <code>Index.dropna([how])</code>             | Return Index without NA/NaN values          |
| <code>Index.isna()</code>                    | Detect missing values.                      |
| <code>Index.notna()</code>                   | Detect existing (non-missing) values.       |

**35.7.1.6 Conversion**

|                                              |                                                                                                                                |
|----------------------------------------------|--------------------------------------------------------------------------------------------------------------------------------|
| <code>Index.astype(dtype[, copy])</code>     | Create an Index with values cast to dtypes.                                                                                    |
| <code>Index.item()</code>                    | Return the first element of the underlying data as a python scalar.                                                            |
| <code>Index.map(mapper[, na_action])</code>  | Map values using input correspondence (a dict, Series, or function).                                                           |
| <code>Index.ravel([order])</code>            | Return an ndarray of the flattened values of the underlying data.                                                              |
| <code>Index.to_list()</code>                 | Return a list of the values.                                                                                                   |
| <code>Index.to_native_types([slicer])</code> | Format specified values of <i>self</i> and return them.                                                                        |
| <code>Index.to_series([index, name])</code>  | Create a Series with both index and values equal to the index keys useful with map for returning an indexer based on an index. |
| <code>Index.to_frame([index, name])</code>   | Create a DataFrame with a column containing the Index.                                                                         |
| <code>Index.view([cls])</code>               |                                                                                                                                |

**pandas.Index.view**`Index.view(cls=None)`

### 35.7.1.7 Sorting

|                                                       |                                                                   |
|-------------------------------------------------------|-------------------------------------------------------------------|
| <i>Index.argsort(*args, **kwargs)</i>                 | Return the integer indices that would sort the index.             |
| <i>Index.searchsorted(value[, side, sorter])</i>      | Find indices where elements should be inserted to maintain order. |
| <i>Index.sort_values([return_indexer, ascending])</i> | Return a sorted copy of the index.                                |

### 35.7.1.8 Time-specific operations

|                                     |                                                             |
|-------------------------------------|-------------------------------------------------------------|
| <i>Index.shift([periods, freq])</i> | Shift index by desired number of time frequency increments. |
|-------------------------------------|-------------------------------------------------------------|

### 35.7.1.9 Combining / joining / set operations

|                                                         |                                                                                |
|---------------------------------------------------------|--------------------------------------------------------------------------------|
| <i>Index.append(other)</i>                              | Append a collection of Index options together.                                 |
| <i>Index.join(other[, how, level, ...])</i>             | Compute join_index and indexers to conform data structures to the new index.   |
| <i>Index.intersection(other)</i>                        | Form the intersection of two Index objects.                                    |
| <i>Index.union(other)</i>                               | Form the union of two Index objects and sorts if possible.                     |
| <i>Index.difference(other[, sort])</i>                  | Return a new Index with elements from the index that are not in <i>other</i> . |
| <i>Index.symmetric_difference(other[, result_name])</i> | re- Compute the symmetric difference of two Index objects.                     |

### 35.7.1.10 Selecting

|                                                        |                                                                                                          |
|--------------------------------------------------------|----------------------------------------------------------------------------------------------------------|
| <i>Index.asof(label)</i>                               | Return the label from the index, or, if not present, the previous one.                                   |
| <i>Index.asof_locs(where, mask)</i>                    | Finds the locations (indices) of the labels from the index for every entry in the <i>where</i> argument. |
| <i>Index.contains(key)</i>                             | Return a boolean indicating whether the provided key is in the index.                                    |
| <i>Index.get_duplicates()</i>                          | (DEPRECATED) Extract duplicated index elements.                                                          |
| <i>Index.get_indexer(target[, method, limit, ...])</i> | Compute indexer and mask for new index given the current index.                                          |
| <i>Index.get_indexer_for(target, **kwargs)</i>         | Guaranteed return of an indexer even when non-unique.                                                    |
| <i>Index.get_indexer_non_unique(target)</i>            | Compute indexer and mask for new index given the current index.                                          |
| <i>Index.get_level_values(level)</i>                   | Return an Index of values for requested level.                                                           |
| <i>Index.get_loc(key[, method, tolerance])</i>         | Get integer location, slice or boolean mask for requested label.                                         |
| <i>Index.get_slice_bound(label, side, kind)</i>        | Calculate slice bound that corresponds to given label.                                                   |
| <i>Index.get_value(series, key)</i>                    | Fast lookup of value from 1-dimensional ndarray.                                                         |
| <i>Index.get_values()</i>                              | Return <i>Index</i> data as a <i>numpy.ndarray</i> .                                                     |
| <i>Index.set_value(arr, key, value)</i>                | Fast lookup of value from 1-dimensional ndarray.                                                         |
| <i>Index.isin(values[, level])</i>                     | Return a boolean array where the index values are in <i>values</i> .                                     |

Table 171 – continued from previous page

|                                                            |                                                                                      |
|------------------------------------------------------------|--------------------------------------------------------------------------------------|
| <code>Index.slice_indexer([start, end, step, kind])</code> | For an ordered or unique index, compute the slice indexer for input labels and step. |
| <code>Index.slice_locs([start, end, step, kind])</code>    | Compute slice locations for input labels.                                            |

### 35.7.2 Numeric Index

|                           |                                                           |
|---------------------------|-----------------------------------------------------------|
| <code>RangeIndex</code>   | Immutable Index implementing a monotonic integer range.   |
| <code>Int64Index</code>   | Immutable ndarray implementing an ordered, sliceable set. |
| <code>UInt64Index</code>  | Immutable ndarray implementing an ordered, sliceable set. |
| <code>Float64Index</code> | Immutable ndarray implementing an ordered, sliceable set. |

#### 35.7.2.1 pandas.RangeIndex

**class** pandas.RangeIndex

Immutable Index implementing a monotonic integer range.

RangeIndex is a memory-saving special case of Int64Index limited to representing monotonic ranges. Using RangeIndex may in some instances improve computing speed.

This is the default index type used by DataFrame and Series when no explicit index is provided by the user.

##### Parameters

- start** [int (default: 0), or other RangeIndex instance] If int and “stop” is not given, interpreted as “stop” instead.
- stop** [int (default: 0)]
- step** [int (default: 1)]
- name** [object, optional] Name to be stored in the index
- copy** [bool, default False] Unused, accepted for homogeneity with other index types.

See also:

**Index** The base pandas Index type.

**Int64Index** Index of int64 data.

##### Attributes

|      |  |
|------|--|
| None |  |
|------|--|

##### Methods

|                                              |                                                               |
|----------------------------------------------|---------------------------------------------------------------|
| <code>from_range(data[, name, dtype])</code> | Create RangeIndex from a range (py3), or xrange (py2) object. |
|----------------------------------------------|---------------------------------------------------------------|

**pandas.RangeIndex.from\_range**

**classmethod** `RangeIndex.from_range` (*data*, *name=None*, *dtype=None*, *\*\*kwargs*)  
 Create RangeIndex from a range (py3), or xrange (py2) object.

**35.7.2.2 pandas.Int64Index**

**class** `pandas.Int64Index`

Immutable ndarray implementing an ordered, sliceable set. The basic object storing axis labels for all pandas objects. Int64Index is a special case of *Index* with purely integer labels.

**Parameters**

**data** [array-like (1-dimensional)]  
**dtype** [NumPy dtype (default: int64)]  
**copy** [bool] Make a copy of input ndarray  
**name** [object] Name to be stored in the index

**See also:**

**Index** The base pandas Index type.

**Notes**

An Index instance can **only** contain hashable objects.

**Attributes**

**35.7.2.3 pandas.UInt64Index**

**class** `pandas.UInt64Index`

Immutable ndarray implementing an ordered, sliceable set. The basic object storing axis labels for all pandas objects. UInt64Index is a special case of *Index* with purely unsigned integer labels.

**Parameters**

**data** [array-like (1-dimensional)]  
**dtype** [NumPy dtype (default: uint64)]  
**copy** [bool] Make a copy of input ndarray  
**name** [object] Name to be stored in the index

**See also:**

**Index** The base pandas Index type.

### Notes

An Index instance can **only** contain hashable objects.

## 35.7.2.4 pandas.Float64Index

**class** pandas.**Float64Index**

Immutable ndarray implementing an ordered, sliceable set. The basic object storing axis labels for all pandas objects. Float64Index is a special case of *Index* with purely float labels.

### Parameters

**data** [array-like (1-dimensional)]  
**dtype** [NumPy dtype (default: float64)]  
**copy** [bool] Make a copy of input ndarray  
**name** [object] Name to be stored in the index

**See also:**

**Index** The base pandas Index type.

### Notes

An Index instance can **only** contain hashable objects.

| <code>CategoricalIndex</code> | Immutable Index implementing an ordered, sliceable set. |
|-------------------------------|---------------------------------------------------------|

---

#### 35.7.3.1 pandas.CategoricalIndex

**class** `pandas.CategoricalIndex`  
Immutable Index implementing an ordered, sliceable set. CategoricalIndex represents a sparsely populated Index with an underlying Categorical.

**Parameters**

- data** [array-like or Categorical, (1-dimensional)]
- categories** [optional, array-like] categories for the CategoricalIndex
- ordered** [boolean,] designating if the categories are ordered
- copy** [bool] Make a copy of input ndarray
- name** [object] Name to be stored in the index

**See also:**

`Categorical`, `Index`

**Attributes**

|                   |  |
|-------------------|--|
| <b>codes</b>      |  |
| <b>categories</b> |  |
| <b>ordered</b>    |  |

**Methods**

|                                                        |                                                                      |
|--------------------------------------------------------|----------------------------------------------------------------------|
| <code>rename_categories(*args, **kwargs)</code>        | Renames categories.                                                  |
| <code>reorder_categories(*args, **kwargs)</code>       | Reorders categories as specified in new_categories.                  |
| <code>add_categories(*args, **kwargs)</code>           | Add new categories.                                                  |
| <code>remove_categories(*args, **kwargs)</code>        | Removes the specified categories.                                    |
| <code>remove_unused_categories(*args, **kwargs)</code> | Removes categories which are not used.                               |
| <code>set_categories(*args, **kwargs)</code>           | Sets the categories to the specified new_categories.                 |
| <code>as_ordered(*args, **kwargs)</code>               | Set the Categorical to be ordered.                                   |
| <code>as_unordered(*args, **kwargs)</code>             | Set the Categorical to be unordered.                                 |
| <code>map(mapper)</code>                               | Map values using input correspondence (a dict, Series, or function). |

---

## pandas.CategoricalIndex.rename\_categories

`CategoricalIndex.rename_categories(*args, **kwargs)`

Renames categories.

### Parameters

**new\_categories** [list-like, dict-like or callable]

- list-like: all items must be unique and the number of items in the new categories must match the existing number of categories.
- dict-like: specifies a mapping from old categories to new. Categories not contained in the mapping are passed through and extra categories in the mapping are ignored.

New in version 0.21.0.

- callable : a callable that is called on all items in the old categories and whose return values comprise the new categories.

New in version 0.23.0.

**Warning:** Currently, Series are considered list like. In a future version of pandas they'll be considered dict-like.

**inplace** [boolean (default: False)] Whether or not to rename the categories inplace or return a copy of this categorical with renamed categories.

### Returns

**cat** [Categorical or None] With `inplace=False`, the new categorical is returned. With `inplace=True`, there is no return value.

### Raises

**ValueError** If new categories are list-like and do not have the same number of items than the current categories or do not validate as categories

### See also:

`reorder_categories`, `add_categories`, `remove_categories`,  
`remove_unused_categories`, `set_categories`

## Examples

```
>>> c = pd.Categorical(['a', 'a', 'b'])
>>> c.rename_categories([0, 1])
[0, 0, 1]
Categories (2, int64): [0, 1]
```

For dict-like `new_categories`, extra keys are ignored and categories not in the dictionary are passed through

```
>>> c.rename_categories({'a': 'A', 'c': 'C'})
[A, A, b]
Categories (2, object): [A, b]
```

You may also provide a callable to create the new categories

```
>>> c.rename_categories(lambda x: x.upper())
[A, A, B]
Categories (2, object): [A, B]
```

## pandas.CategoricalIndex.reorder\_categories

`CategoricalIndex.reorder_categories(*args, **kwargs)`

Reorders categories as specified in `new_categories`.

`new_categories` need to include all old categories and no new category items.

### Parameters

**new\_categories** [Index-like] The categories in new order.

**ordered** [boolean, optional] Whether or not the categorical is treated as a ordered categorical. If not given, do not change the ordered information.

**inplace** [boolean (default: False)] Whether or not to reorder the categories inplace or return a copy of this categorical with reordered categories.

### Returns

**cat** [Categorical with reordered categories or None if inplace.]

### Raises

**ValueError** If the new categories do not contain all old category items or any new ones

### See also:

`rename_categories`, `add_categories`, `remove_categories`,  
`remove_unused_categories`, `set_categories`

## pandas.CategoricalIndex.add\_categories

`CategoricalIndex.add_categories(*args, **kwargs)`

Add new categories.

`new_categories` will be included at the last/highest place in the categories and will be unused directly after this call.

### Parameters

**new\_categories** [category or list-like of category] The new categories to be included.

**inplace** [boolean (default: False)] Whether or not to add the categories inplace or return a copy of this categorical with added categories.

### Returns

**cat** [Categorical with new categories added or None if inplace.]

### Raises

**ValueError** If the new categories include old categories or do not validate as categories

### See also:

`rename_categories`, `reorder_categories`, `remove_categories`,  
`remove_unused_categories`, `set_categories`

### **pandas.CategoricalIndex.remove\_categories**

`CategoricalIndex.remove_categories(*args, **kwargs)`

Removes the specified categories.

*removals* must be included in the old categories. Values which were in the removed categories will be set to NaN

#### **Parameters**

**removals** [category or list of categories] The categories which should be removed.

**inplace** [boolean (default: False)] Whether or not to remove the categories inplace or return a copy of this categorical with removed categories.

#### **Returns**

**cat** [Categorical with removed categories or None if inplace.]

#### **Raises**

**ValueError** If the removals are not contained in the categories

#### **See also:**

*rename\_categories, reorder\_categories, add\_categories,*  
*remove\_unused\_categories, set\_categories*

### **pandas.CategoricalIndex.remove\_unused\_categories**

`CategoricalIndex.remove_unused_categories(*args, **kwargs)`

Removes categories which are not used.

#### **Parameters**

**inplace** [boolean (default: False)] Whether or not to drop unused categories inplace or return a copy of this categorical with unused categories dropped.

#### **Returns**

**cat** [Categorical with unused categories dropped or None if inplace.]

#### **See also:**

*rename\_categories, reorder\_categories, add\_categories, remove\_categories,*  
*set\_categories*

### **pandas.CategoricalIndex.set\_categories**

`CategoricalIndex.set_categories(*args, **kwargs)`

Sets the categories to the specified new\_categories.

*new\_categories* can include new categories (which will result in unused categories) or remove old categories (which results in values set to NaN). If *rename==True*, the categories will simply be renamed (less or more items than in old categories will result in values set to NaN or in unused categories respectively).

This method can be used to perform more than one action of adding, removing, and reordering simultaneously and is therefore faster than performing the individual steps via the more specialised methods.

On the other hand this methods does not do checks (e.g., whether the old categories are included in the new categories on a reorder), which can result in surprising changes, for example when using special string dtypes on python3, which does not considers a S1 string equal to a single char python string.

#### Parameters

**new\_categories** [Index-like] The categories in new order.

**ordered** [boolean, (default: False)] Whether or not the categorical is treated as a ordered categorical. If not given, do not change the ordered information.

**rename** [boolean (default: False)] Whether or not the new\_categories should be considered as a rename of the old categories or as reordered categories.

**inplace** [boolean (default: False)] Whether or not to reorder the categories inplace or return a copy of this categorical with reordered categories.

#### Returns

**cat** [Categorical with reordered categories or None if inplace.]

#### Raises

**ValueError** If new\_categories does not validate as categories

#### See also:

*rename\_categories, reorder\_categories, add\_categories, remove\_categories, remove\_unused\_categories*

### **pandas.CategoricalIndex.as\_ordered**

`CategoricalIndex.as_ordered(*args, **kwargs)`

Set the Categorical to be ordered.

#### Parameters

**inplace** [boolean (default: False)] Whether or not to set the ordered attribute inplace or return a copy of this categorical with ordered set to True

### **pandas.CategoricalIndex.as\_unordered**

`CategoricalIndex.as_unordered(*args, **kwargs)`

Set the Categorical to be unordered.

#### Parameters

**inplace** [boolean (default: False)] Whether or not to set the ordered attribute inplace or return a copy of this categorical with ordered set to False

### **pandas.CategoricalIndex.map**

`CategoricalIndex.map(mapper)`

Map values using input correspondence (a dict, Series, or function).

Maps the values (their categories, not the codes) of the index to new categories. If the mapping correspondence is one-to-one the result is a *CategoricalIndex* which has the same order property as the original, otherwise an *Index* is returned.

If a *dict* or *Series* is used any unmapped category is mapped to *NaN*. Note that if this happens an *Index* will be returned.

#### Parameters

**mapper** [function, dict, or Series] Mapping correspondence.

#### Returns

**pandas.CategoricalIndex or pandas.Index** Mapped index.

See also:

**Index.map** Apply a mapping correspondence on an *Index*.

**Series.map** Apply a mapping correspondence on a *Series*.

**Series.apply** Apply more complex functions on a *Series*.

#### Examples

```
>>> idx = pd.CategoricalIndex(['a', 'b', 'c'])
>>> idx
CategoricalIndex(['a', 'b', 'c'], categories=['a', 'b', 'c'],
                  ordered=False, dtype='category')
>>> idx.map(lambda x: x.upper())
CategoricalIndex(['A', 'B', 'C'], categories=['A', 'B', 'C'],
                  ordered=False, dtype='category')
>>> idx.map({'a': 'first', 'b': 'second', 'c': 'third'})
CategoricalIndex(['first', 'second', 'third'], categories=['first',
                  'second', 'third'], ordered=False, dtype='category')
```

If the mapping is one-to-one the ordering of the categories is preserved:

```
>>> idx = pd.CategoricalIndex(['a', 'b', 'c'], ordered=True)
>>> idx
CategoricalIndex(['a', 'b', 'c'], categories=['a', 'b', 'c'],
                  ordered=True, dtype='category')
>>> idx.map({'a': 3, 'b': 2, 'c': 1})
CategoricalIndex([3, 2, 1], categories=[3, 2, 1], ordered=True,
                  dtype='category')
```

If the mapping is not one-to-one an *Index* is returned:

```
>>> idx.map({'a': 'first', 'b': 'second', 'c': 'first'})
Index(['first', 'second', 'first'], dtype='object')
```

If a *dict* is used, all unmapped categories are mapped to *NaN* and the result is an *Index*:

```
>>> idx.map({'a': 'first', 'b': 'second'})
Index(['first', 'second', nan], dtype='object')
```

### 35.7.3.2 Categorical Components

| <i>CategoricalIndex.set_categories(*args, **kwargs)</i> | Sets the categories to the specified new_categories. |
| <i>CategoricalIndex.as_ordered(*args, **kwargs)</i>     | Set the Categorical to be ordered.                   |
| <i>CategoricalIndex.as_unordered(*args, **kwargs)</i>   | Set the Categorical to be unordered.                 |

**pandas.CategoricalIndex.codes**`CategoricalIndex.codes`**pandas.CategoricalIndex.categories**`CategoricalIndex.categories`**pandas.CategoricalIndex.ordered**`CategoricalIndex.ordered`**35.7.3.3 Modifying and Computations**

|                                       |                                                                       |
|---------------------------------------|-----------------------------------------------------------------------|
| <i>CategoricalIndex.map(mapper)</i>   | Map values using input correspondence (a dict, Series, or function).  |
| <i>CategoricalIndex.equals(other)</i> | Determines if two CategoricalIndex objects contain the same elements. |

**pandas.CategoricalIndex.equals**

`CategoricalIndex.equals(other)`  
 Determines if two CategoricalIndex objects contain the same elements.

**35.7.4 IntervalIndex**

*IntervalIndex*

Immutable index of intervals that are closed on the same side.

### 35.7.4.1 pandas.IntervalIndex

**class** pandas.IntervalIndex

Immutable index of intervals that are closed on the same side.

New in version 0.20.0.

**Warning:** The indexing behaviors are provisional and may change in a future version of pandas.

#### Parameters

**data** [array-like (1-dimensional)] Array-like containing Interval objects from which to build the IntervalIndex.**closed** [{‘left’, ‘right’, ‘both’, ‘neither’}, default ‘right’] Whether the intervals are closed on the left-side, right-side, both or neither.**dtype** [dtype or None, default None] If None, dtype will be inferred.

New in version 0.23.0.

**copy** [bool, default False] Copy the input data.**name** [object, optional] Name to be stored in the index.**verify\_integrity** [bool, default True] Verify that the IntervalIndex is valid.

#### See also:

**Index** The base pandas Index type.**Interval** A bounded slice-like interval; the elements of an IntervalIndex.**interval\_range** Function to create a fixed frequency IntervalIndex.**cut** Bin values into discrete Intervals.**qcut** Bin values into equal-sized Intervals based on rank or sample quantiles.

#### Notes

See the [user guide](#) for more.

#### Examples

A new IntervalIndex is typically constructed using `interval_range()`:

```
>>> pd.interval_range(start=0, end=5)
IntervalIndex([(0, 1], (1, 2], (2, 3], (3, 4], (4, 5]],
              closed='right',
              dtype='interval[int64]')
```

It may also be constructed using one of the constructor methods: `IntervalIndex.from_arrays()`, `IntervalIndex.from_breaks()`, and `IntervalIndex.from_tuples()`.

See further examples in the doc strings of `interval_range` and the mentioned constructor methods.

### Attributes

|                             |                                                                                        |
|-----------------------------|----------------------------------------------------------------------------------------|
| <code>left</code>           | Return the left endpoints of each Interval in the IntervalIndex as an Index            |
| <code>right</code>          | Return the right endpoints of each Interval in the IntervalIndex as an Index           |
| <code>closed</code>         | Whether the intervals are closed on the left-side, right-side, both or neither         |
| <code>mid</code>            | Return the midpoint of each Interval in the IntervalIndex as an Index                  |
| <code>length</code>         | Return an Index with entries denoting the length of each Interval in the IntervalIndex |
| <code>values</code>         | Return the IntervalIndex's data as an IntervalArray.                                   |
| <code>is_overlapping</code> | Return True if the IntervalIndex has overlapping intervals, else False.                |

#### **pandas.IntervalIndex.left**

`IntervalIndex.left`

Return the left endpoints of each Interval in the IntervalIndex as an Index

#### **pandas.IntervalIndex.right**

`IntervalIndex.right`

Return the right endpoints of each Interval in the IntervalIndex as an Index

#### **pandas.IntervalIndex.closed**

`IntervalIndex.closed`

Whether the intervals are closed on the left-side, right-side, both or neither

#### **pandas.IntervalIndex.mid**

`IntervalIndex.mid`

Return the midpoint of each Interval in the IntervalIndex as an Index

#### **pandas.IntervalIndex.length**

`IntervalIndex.length`

Return an Index with entries denoting the length of each Interval in the IntervalIndex

## pandas.IntervalIndex.values

### IntervalIndex.values

Return the IntervalIndex's data as an IntervalArray.

## pandas.IntervalIndex.is\_overlapping

### IntervalIndex.is\_overlapping

Return True if the IntervalIndex has overlapping intervals, else False.

Two intervals overlap if they share a common point, including closed endpoints. Intervals that only have an open endpoint in common do not overlap.

New in version 0.24.0.

#### Returns

**bool** Boolean indicating if the IntervalIndex has overlapping intervals.

See also:

**Interval.overlaps** Check whether two Interval objects overlap.

**IntervalIndex.overlaps** Check an IntervalIndex elementwise for overlaps.

## Examples

```
>>> index = pd.IntervalIndex.from_tuples([(0, 2), (1, 3), (4, 5)])
>>> index
IntervalIndex([(0, 2], (1, 3], (4, 5]],
              closed='right',
              dtype='interval[int64]')
>>> index.is_overlapping
True
```

Intervals that share closed endpoints overlap:

```
>>> index = pd.interval_range(0, 3, closed='both')
>>> index
IntervalIndex([[0, 1], [1, 2], [2, 3]],
              closed='both',
              dtype='interval[int64]')
>>> index.is_overlapping
True
```

Intervals that only have an open endpoint in common do not overlap:

```
>>> index = pd.interval_range(0, 3, closed='left')
>>> index
IntervalIndex([[0, 1), [1, 2), [2, 3]],
              closed='left',
              dtype='interval[int64]')
>>> index.is_overlapping
False
```

|                              |  |
|------------------------------|--|
| is_non_overlapping_monotonic |  |
|------------------------------|--|

## Methods

|                                                               |                                                                                        |
|---------------------------------------------------------------|----------------------------------------------------------------------------------------|
| <code>from_arrays(left, right[, closed, name, ...])</code>    | Construct from two arrays defining the left and right bounds.                          |
| <code>from_tuples(data[, closed, name, copy, dtype])</code>   | Construct an IntervalIndex from an array-like of tuples                                |
| <code>from_breaks(breaks[, closed, name, copy, dtype])</code> | Construct an IntervalIndex from an array of splits.                                    |
| <code>overlaps(other)</code>                                  | Check elementwise if an Interval overlaps the values in the IntervalIndex.             |
| <code>set_closed(closed)</code>                               | Return an IntervalIndex identical to the current one, but closed on the specified side |
| <code>to_tuples([na_tuple])</code>                            | Return an Index of tuples of the form (left, right)                                    |
| <code>contains(key)</code>                                    | Return a boolean indicating if the key is IN the index                                 |

## pandas.IntervalIndex.from\_arrays

**classmethod** `IntervalIndex.from_arrays` (*left*, *right*, *closed*='right', *name*=None, *copy*=False, *dtype*=None)

Construct from two arrays defining the left and right bounds.

### Parameters

**left** [array-like (1-dimensional)] Left bounds for each interval.

**right** [array-like (1-dimensional)] Right bounds for each interval.

**closed** [{ 'left', 'right', 'both', 'neither' }, default 'right'] Whether the intervals are closed on the left-side, right-side, both or neither.

**copy** [boolean, default False] Copy the data.

**dtype** [dtype, optional] If None, dtype will be inferred.

New in version 0.23.0.

### Returns

**IntervalIndex**

### Raises

**ValueError** When a value is missing in only one of *left* or *right*. When a value in *left* is greater than the corresponding value in *right*.

### See also:

**interval\_range** Function to create a fixed frequency IntervalIndex.

**IntervalIndex.from\_breaks** Construct an IntervalIndex from an array of splits.

**IntervalIndex.from\_tuples** Construct an IntervalIndex from an array-like of tuples.

## Notes

Each element of *left* must be less than or equal to the *right* element at the same position. If an element is missing, it must be missing in both *left* and *right*. A `TypeError` is raised when using an unsupported type for *left* or *right*. At the moment, 'category', 'object', and 'string' subtypes are not supported.

## Examples

```
>>> IntervalIndex.from_arrays([0, 1, 2], [1, 2, 3])
IntervalIndex([(0, 1], (1, 2], (2, 3])
              closed='right',
              dtype='interval[int64]')
```

## pandas.IntervalIndex.from\_tuples

**classmethod** `IntervalIndex.from_tuples` (*data*, *closed='right'*, *name=None*, *copy=False*, *dtype=None*)

Construct an IntervalIndex from an array-like of tuples

### Parameters

**data** [array-like (1-dimensional)] Array of tuples

**closed** [{‘left’, ‘right’, ‘both’, ‘neither’}, default ‘right’] Whether the intervals are closed on the left-side, right-side, both or neither.

**copy** [boolean, default False] by-default copy the data, this is compat only and ignored

**dtype** [dtype or None, default None] If None, dtype will be inferred

..versionadded:: 0.23.0

See also:

**interval\_range** Function to create a fixed frequency IntervalIndex.

**IntervalIndex.from\_arrays** Construct an IntervalIndex from a left and right array.

**IntervalIndex.from\_breaks** Construct an IntervalIndex from an array of splits.

## Examples

```
>>> pd.IntervalIndex.from_tuples([(0, 1), (1, 2)])
IntervalIndex([(0, 1], (1, 2]),
              closed='right', dtype='interval[int64]')
```

## pandas.IntervalIndex.from\_breaks

**classmethod** `IntervalIndex.from_breaks` (*breaks*, *closed='right'*, *name=None*, *copy=False*, *dtype=None*)

Construct an IntervalIndex from an array of splits.

### Parameters

**breaks** [array-like (1-dimensional)] Left and right bounds for each interval.

**closed** [{‘left’, ‘right’, ‘both’, ‘neither’}, default ‘right’] Whether the intervals are closed on the left-side, right-side, both or neither.

**copy** [boolean, default False] copy the data

**dtype** [dtype or None, default None] If None, dtype will be inferred

New in version 0.23.0.

See also:

***interval\_range*** Function to create a fixed frequency IntervalIndex.

***IntervalIndex.from\_arrays*** Construct from a left and right array.

***IntervalIndex.from\_tuples*** Construct from a sequence of tuples.

## Examples

```
>>> pd.IntervalIndex.from_breaks([0, 1, 2, 3])
IntervalIndex([(0, 1], (1, 2], (2, 3]),
              closed='right',
              dtype='interval[int64]')
```

## pandas.IntervalIndex.overlaps

**IntervalIndex.overlaps** (*other*)

Check elementwise if an Interval overlaps the values in the IntervalIndex.

Two intervals overlap if they share a common point, including closed endpoints. Intervals that only have an open endpoint in common do not overlap.

New in version 0.24.0.

### Parameters

**other** [Interval] Interval to check against for an overlap.

### Returns

**ndarray** Boolean array positionally indicating where an overlap occurs.

See also:

***Interval.overlaps*** Check whether two Interval objects overlap.

## Examples

```
>>> intervals = pd.IntervalIndex.from_tuples([(0, 1), (1, 3), (2, 4)])
>>> intervals
IntervalIndex([(0, 1], (1, 3], (2, 4]),
              closed='right',
              dtype='interval[int64]')
>>> intervals.overlaps(pd.Interval(0.5, 1.5))
array([ True,  True, False])
```

Intervals that share closed endpoints overlap:

```
>>> intervals.overlaps(pd.Interval(1, 3, closed='left'))
array([ True,  True,  True])
```

Intervals that only have an open endpoint in common do not overlap:

```
>>> intervals.overlaps(pd.Interval(1, 2, closed='right'))
array([False,  True, False])
```

**pandas.IntervalIndex.set\_closed**`IntervalIndex.set_closed(closed)`

Return an IntervalIndex identical to the current one, but closed on the specified side

New in version 0.24.0.

**Parameters**

**closed** [{‘left’, ‘right’, ‘both’, ‘neither’}] Whether the intervals are closed on the left-side, right-side, both or neither.

**Returns**

**new\_index** [IntervalIndex]

**Examples**

```
>>> index = pd.interval_range(0, 3)
>>> index
IntervalIndex([(0, 1], (1, 2], (2, 3])
              closed='right',
              dtype='interval[int64]')
>>> index.set_closed('both')
IntervalIndex([[0, 1], [1, 2], [2, 3])
              closed='both',
              dtype='interval[int64]')
```

**pandas.IntervalIndex.contains**`IntervalIndex.contains(key)`

Return a boolean indicating if the key is IN the index

We accept / allow keys to be not *just* actual objects.

**Parameters**

**key** [int, float, Interval]

**Returns**

**boolean**

**35.7.4.2 IntervalIndex Components**

|                                                               |                                                                             |
|---------------------------------------------------------------|-----------------------------------------------------------------------------|
| <code>IntervalIndex.from_arrays(left, right[, ...])</code>    | Construct from two arrays defining the left and right bounds.               |
| <code>IntervalIndex.from_tuples(data[, closed, ...])</code>   | Construct an IntervalIndex from an array-like of tuples                     |
| <code>IntervalIndex.from_breaks(breaks[, closed, ...])</code> | Construct an IntervalIndex from an array of splits.                         |
| <code>IntervalIndex.contains(key)</code>                      | Return a boolean indicating if the key is IN the index                      |
| <code>IntervalIndex.left</code>                               | Return the left endpoints of each Interval in the IntervalIndex as an Index |

Table 182 – continued from previous page

|                                                          |                                                                                        |
|----------------------------------------------------------|----------------------------------------------------------------------------------------|
| <i>IntervalIndex.right</i>                               | Return the right endpoints of each Interval in the IntervalIndex as an Index           |
| <i>IntervalIndex.mid</i>                                 | Return the midpoint of each Interval in the IntervalIndex as an Index                  |
| <i>IntervalIndex.closed</i>                              | Whether the intervals are closed on the left-side, right-side, both or neither         |
| <i>IntervalIndex.length</i>                              | Return an Index with entries denoting the length of each Interval in the IntervalIndex |
| <i>IntervalIndex.values</i>                              | Return the IntervalIndex's data as an IntervalArray.                                   |
| <i>IntervalIndex.is_non_overlapping_monotonic</i>        |                                                                                        |
| <i>IntervalIndex.is_overlapping</i>                      | Return True if the IntervalIndex has overlapping intervals, else False.                |
| <i>IntervalIndex.get_loc</i> (key[, method])             | Get integer location, slice or boolean mask for requested label.                       |
| <i>IntervalIndex.get_indexer</i> (target[, method, ...]) | Compute indexer and mask for new index given the current index.                        |
| <i>IntervalIndex.set_closed</i> (closed)                 | Return an IntervalIndex identical to the current one, but closed on the specified side |
| <i>IntervalIndex.overlaps</i> (other)                    | Check elementwise if an Interval overlaps the values in the IntervalIndex.             |

**pandas.IntervalIndex.is\_non\_overlapping\_monotonic**IntervalIndex.**is\_non\_overlapping\_monotonic****pandas.IntervalIndex.get\_loc**IntervalIndex.**get\_loc** (*key*, *method=None*)

Get integer location, slice or boolean mask for requested label.

**Parameters****key** [label]**method** [{None}, optional]

- default: matches where the label is within an interval only.

**Returns****loc** [int if unique index, slice if monotonic index, else mask]**Examples**

```
>>> i1, i2 = pd.Interval(0, 1), pd.Interval(1, 2)
>>> index = pd.IntervalIndex([i1, i2])
>>> index.get_loc(1)
0
```

You can also supply an interval or an location for a point inside an interval.

```
>>> index.get_loc(pd.Interval(0, 2))
array([0, 1], dtype=int64)
>>> index.get_loc(1.5)
1
```

If a label is in several intervals, you get the locations of all the relevant intervals.

```
>>> i3 = pd.Interval(0, 2)
>>> overlapping_index = pd.IntervalIndex([i2, i3])
>>> overlapping_index.get_loc(1.5)
array([0, 1], dtype=int64)
```

## pandas.IntervalIndex.get\_indexer

`IntervalIndex.get_indexer` (*target*, *method=None*, *limit=None*, *tolerance=None*)

Compute indexer and mask for new index given the current index. The indexer should be then used as an input to `ndarray.take` to align the current data to the new index.

### Parameters

**target** [IntervalIndex or list of Intervals]

**method** [{None, 'pad'/'ffill', 'backfill'/'bfill', 'nearest'}], optional

- default: exact matches only.
- pad / ffill: find the PREVIOUS index value if no exact match.
- backfill / bfill: use NEXT index value if no exact match
- nearest: use the NEAREST index value if no exact match. Tied distances are broken by preferring the larger index value.

**limit** [int, optional] Maximum number of consecutive labels in *target* to match for inexact matches.

**tolerance** [optional] Maximum distance between original and new labels for inexact matches. The values of the index at the matching locations must satisfy the equation `abs(index[indexer] - target) <= tolerance`.

Tolerance may be a scalar value, which applies the same tolerance to all values, or list-like, which applies variable tolerance per element. List-like includes list, tuple, array, Series, and must be the same size as the index and its dtype must exactly match the index's type.

New in version 0.21.0: (list-like tolerance)

### Returns

**indexer** [ndarray of int] Integers from 0 to *n* - 1 indicating that the index at these positions matches the corresponding target values. Missing values in the target are marked by -1.

## Examples

```
>>> index = pd.Index(['c', 'a', 'b'])
>>> index.get_indexer(['a', 'b', 'x'])
array([ 1,  2, -1])
```

Notice that the return value is an array of locations in *index* and *x* is marked by -1, as it is not in *index*.

## 35.7.5 MultiIndex

*MultiIndex*

A multi-level, or hierarchical, index object for pandas objects.

### 35.7.5.1 pandas.MultiIndex

**class** pandas.**MultiIndex**

A multi-level, or hierarchical, index object for pandas objects.

#### Parameters

**levels** [sequence of arrays] The unique labels for each level.

**codes** [sequence of arrays] Integers for each level designating which label at each location.

New in version 0.24.0.

**labels** [sequence of arrays] Integers for each level designating which label at each location.

Deprecated since version 0.24.0: Use `codes` instead

**sortorder** [optional int] Level of sortedness (must be lexicographically sorted by that level).

**names** [optional sequence of objects] Names for each of the index levels. (name is accepted for compat).

**copy** [bool, default False] Copy the meta-data.

**verify\_integrity** [bool, default True] Check that the levels/codes are consistent and valid.

See also:

***MultiIndex.from\_arrays*** Convert list of arrays to MultiIndex.

***MultiIndex.from\_product*** Create a MultiIndex from the cartesian product of iterables.

***MultiIndex.from\_tuples*** Convert list of tuples to a MultiIndex.

***MultiIndex.from\_frame*** Make a MultiIndex from a DataFrame.

***Index*** The base pandas Index type.

#### Notes

See the [user guide](#) for more.

#### Examples

A new MultiIndex is typically constructed using one of the helper methods *MultiIndex.from\_arrays()*, *MultiIndex.from\_product()* and *MultiIndex.from\_tuples()*. For example (using *.from\_arrays()*):

```
>>> arrays = [[1, 1, 2, 2], ['red', 'blue', 'red', 'blue']]
>>> pd.MultiIndex.from_arrays(arrays, names=('number', 'color'))
MultiIndex(levels=[[1, 2], ['blue', 'red']],
            labels=[[0, 0, 1, 1], [1, 0, 1, 0]],
            names=['number', 'color'])
```

See further examples for how to construct a MultiIndex in the doc strings of the mentioned helper methods.

## Attributes

|                 |                                              |
|-----------------|----------------------------------------------|
| <i>names</i>    | Names of levels in MultiIndex                |
| <i>nlevels</i>  | Integer number of levels in this MultiIndex. |
| <i>levshape</i> | A tuple with the length of each level.       |

### **pandas.MultiIndex.names**

`MultiIndex.names`  
Names of levels in MultiIndex

### **pandas.MultiIndex.nlevels**

`MultiIndex.nlevels`  
Integer number of levels in this MultiIndex.

### **pandas.MultiIndex.levshape**

`MultiIndex.levshape`  
A tuple with the length of each level.

## Methods

|                                                       |                                                                                                                         |
|-------------------------------------------------------|-------------------------------------------------------------------------------------------------------------------------|
| <i>from_arrays</i> (arrays[, sortorder, names])       | Convert arrays to MultiIndex.                                                                                           |
| <i>from_tuples</i> (tuples[, sortorder, names])       | Convert list of tuples to MultiIndex.                                                                                   |
| <i>from_product</i> (iterables[, sortorder, names])   | Make a MultiIndex from the cartesian product of multiple iterables.                                                     |
| <i>from_frame</i> (df[, sortorder, names])            | Make a MultiIndex from a DataFrame.                                                                                     |
| <i>set_levels</i> (levels[, level, inplace, ...])     | Set new levels on MultiIndex.                                                                                           |
| <i>set_codes</i> (codes[, level, inplace, ...])       | Set new codes on MultiIndex.                                                                                            |
| <i>to_frame</i> ([index, name])                       | Create a DataFrame with the levels of the MultiIndex as columns.                                                        |
| <i>to_flat_index</i> ()                               | Convert a MultiIndex to an Index of Tuples containing the level values.                                                 |
| <i>is_lexsorted</i> ()                                | Return True if the codes are lexicographically sorted                                                                   |
| <i>sortlevel</i> ([level, ascending, sort_remaining]) | Sort MultiIndex at the requested level.                                                                                 |
| <i>droplevel</i> ([level])                            | Return index with requested level(s) removed.                                                                           |
| <i>swaplevel</i> ([i, j])                             | Swap level i with level j.                                                                                              |
| <i>reorder_levels</i> (order)                         | Rearrange levels using input order.                                                                                     |
| <i>remove_unused_levels</i> ()                        | Create a new MultiIndex from the current that removes unused levels, meaning that they are not expressed in the labels. |

**pandas.MultiIndex.from\_arrays****classmethod** `MultiIndex.from_arrays` (*arrays, sortorder=None, names=None*)

Convert arrays to MultiIndex.

**Parameters****arrays** [list / sequence of array-likes] Each array-like gives one level's value for each data point. `len(arrays)` is the number of levels.**sortorder** [int or None] Level of sortedness (must be lexicographically sorted by that level).**names** [list / sequence of str, optional] Names for the levels in the index.**Returns****index** [MultiIndex]

See also:

***MultiIndex.from\_tuples*** Convert list of tuples to MultiIndex.***MultiIndex.from\_product*** Make a MultiIndex from cartesian product of iterables.***MultiIndex.from\_frame*** Make a MultiIndex from a DataFrame.**Examples**

```
>>> arrays = [[1, 1, 2, 2], ['red', 'blue', 'red', 'blue']]
>>> pd.MultiIndex.from_arrays(arrays, names=('number', 'color'))
MultiIndex(levels=[[1, 2], ['blue', 'red']],
            labels=[[0, 0, 1, 1], [1, 0, 1, 0]],
            names=['number', 'color'])
```

**pandas.MultiIndex.from\_tuples****classmethod** `MultiIndex.from_tuples` (*tuples, sortorder=None, names=None*)

Convert list of tuples to MultiIndex.

**Parameters****tuples** [list / sequence of tuple-likes] Each tuple is the index of one row/column.**sortorder** [int or None] Level of sortedness (must be lexicographically sorted by that level).**names** [list / sequence of str, optional] Names for the levels in the index.**Returns****index** [MultiIndex]

See also:

***MultiIndex.from\_arrays*** Convert list of arrays to MultiIndex.***MultiIndex.from\_product*** Make a MultiIndex from cartesian product of iterables.***MultiIndex.from\_frame*** Make a MultiIndex from a DataFrame.

## Examples

```
>>> tuples = [(1, u'red'), (1, u'blue'),
...           (2, u'red'), (2, u'blue')]
>>> pd.MultiIndex.from_tuples(tuples, names=('number', 'color'))
MultiIndex(levels=[[1, 2], ['blue', 'red']],
            labels=[[0, 0, 1, 1], [1, 0, 1, 0]],
            names=['number', 'color'])
```

## pandas.MultiIndex.from\_product

**classmethod** `MultiIndex.from_product` (*iterables, sortorder=None, names=None*)

Make a MultiIndex from the cartesian product of multiple iterables.

### Parameters

**iterables** [list / sequence of iterables] Each iterable has unique labels for each level of the index.

**sortorder** [int or None] Level of sortedness (must be lexicographically sorted by that level).

**names** [list / sequence of str, optional] Names for the levels in the index.

### Returns

**index** [MultiIndex]

See also:

**MultiIndex.from\_arrays** Convert list of arrays to MultiIndex.

**MultiIndex.from\_tuples** Convert list of tuples to MultiIndex.

**MultiIndex.from\_frame** Make a MultiIndex from a DataFrame.

## Examples

```
>>> numbers = [0, 1, 2]
>>> colors = ['green', 'purple']
>>> pd.MultiIndex.from_product([numbers, colors],
...                             names=['number', 'color'])
MultiIndex(levels=[[0, 1, 2], ['green', 'purple']],
            labels=[[0, 0, 1, 1, 2, 2], [0, 1, 0, 1, 0, 1]],
            names=['number', 'color'])
```

## pandas.MultiIndex.from\_frame

**classmethod** `MultiIndex.from_frame` (*df, sortorder=None, names=None*)

Make a MultiIndex from a DataFrame.

New in version 0.24.0.

### Parameters

**df** [DataFrame] DataFrame to be converted to MultiIndex.

**sortorder** [int, optional] Level of sortedness (must be lexicographically sorted by that level).

**names** [list-like, optional] If no names are provided, use the column names, or tuple of column names if the columns is a MultiIndex. If a sequence, overwrite names with the given sequence.

### Returns

**MultiIndex** The MultiIndex representation of the given DataFrame.

See also:

**MultiIndex.from\_arrays** Convert list of arrays to MultiIndex.

**MultiIndex.from\_tuples** Convert list of tuples to MultiIndex.

**MultiIndex.from\_product** Make a MultiIndex from cartesian product of iterables.

### Examples

```
>>> df = pd.DataFrame([['HI', 'Temp'], ['HI', 'Precip'],
...                     ['NJ', 'Temp'], ['NJ', 'Precip']],
...                     columns=['a', 'b'])
>>> df
   a      b
0  HI  Temp
1  HI  Precip
2  NJ  Temp
3  NJ  Precip
```

```
>>> pd.MultiIndex.from_frame(df)
MultiIndex(levels=[['HI', 'NJ'], ['Precip', 'Temp']],
            labels=[[0, 0, 1, 1], [1, 0, 1, 0]],
            names=['a', 'b'])
```

Using explicit names, instead of the column names

```
>>> pd.MultiIndex.from_frame(df, names=['state', 'observation'])
MultiIndex(levels=[['HI', 'NJ'], ['Precip', 'Temp']],
            labels=[[0, 0, 1, 1], [1, 0, 1, 0]],
            names=['state', 'observation'])
```

## pandas.MultiIndex.set\_levels

**MultiIndex.set\_levels** (*levels*, *level=None*, *inplace=False*, *verify\_integrity=True*)

Set new levels on MultiIndex. Defaults to returning new index.

### Parameters

**levels** [sequence or list of sequence] new level(s) to apply

**level** [int, level name, or sequence of int/level names (default None)] level(s) to set (None for all levels)

**inplace** [bool] if True, mutates in place

**verify\_integrity** [bool (default True)] if True, checks that levels and codes are compatible

**Returns****new index (of same type and class...etc)****Examples**

```

>>> idx = pd.MultiIndex.from_tuples([(1, u'one'), (1, u'two'),
                                     (2, u'one'), (2, u'two')],
                                     names=['foo', 'bar'])

>>> idx.set_levels(['a', 'b'], [1, 2])
MultiIndex(levels=[[u'a', u'b'], [1, 2]],
            labels=[[0, 0, 1, 1], [0, 1, 0, 1]],
            names=[u'foo', u'bar'])

>>> idx.set_levels(['a', 'b'], level=0)
MultiIndex(levels=[[u'a', u'b'], [u'one', u'two']],
            labels=[[0, 0, 1, 1], [0, 1, 0, 1]],
            names=[u'foo', u'bar'])

>>> idx.set_levels(['a', 'b'], level='bar')
MultiIndex(levels=[[1, 2], [u'a', u'b']],
            labels=[[0, 0, 1, 1], [0, 1, 0, 1]],
            names=[u'foo', u'bar'])

>>> idx.set_levels(['a', 'b'], [1, 2], level=[0, 1])
MultiIndex(levels=[[u'a', u'b'], [1, 2]],
            labels=[[0, 0, 1, 1], [0, 1, 0, 1]],
            names=[u'foo', u'bar'])

```

**pandas.MultiIndex.set\_codes**`MultiIndex.set_codes` (*codes*, *level=None*, *inplace=False*, *verify\_integrity=True*)

Set new codes on MultiIndex. Defaults to returning new index.

New in version 0.24.0: New name for deprecated method `set_labels`.**Parameters****codes** [sequence or list of sequence] new codes to apply**level** [int, level name, or sequence of int/level names (default None)] level(s) to set (None for all levels)**inplace** [bool] if True, mutates in place**verify\_integrity** [bool (default True)] if True, checks that levels and codes are compatible**Returns****new index (of same type and class...etc)****Examples**

```

>>> idx = pd.MultiIndex.from_tuples([(1, u'one'), (1, u'two'),
                                     (2, u'one'), (2, u'two')],
                                     names=['foo', 'bar'])

>>> idx.set_codes([[1, 0, 1, 0], [0, 0, 1, 1]])
MultiIndex(levels=[[1, 2], [u'one', u'two']],
            labels=[[1, 0, 1, 0], [0, 0, 1, 1]],

```

(continues on next page)

(continued from previous page)

```

        names=[u'foo', u'bar'])
>>> idx.set_codes([1,0,1,0], level=0)
MultiIndex(levels=[[1, 2], [u'one', u'two']],
            labels=[[1, 0, 1, 0], [0, 1, 0, 1]],
            names=[u'foo', u'bar'])
>>> idx.set_codes([0,0,1,1], level='bar')
MultiIndex(levels=[[1, 2], [u'one', u'two']],
            labels=[[0, 0, 1, 1], [0, 0, 1, 1]],
            names=[u'foo', u'bar'])
>>> idx.set_codes([[1,0,1,0], [0,0,1,1]], level=[0,1])
MultiIndex(levels=[[1, 2], [u'one', u'two']],
            labels=[[1, 0, 1, 0], [0, 0, 1, 1]],
            names=[u'foo', u'bar'])

```

### pandas.MultiIndex.to\_frame

`MultiIndex.to_frame(index=True, name=None)`

Create a DataFrame with the levels of the MultiIndex as columns.

Column ordering is determined by the DataFrame constructor with data as a dict.

New in version 0.24.0.

#### Parameters

**index** [boolean, default True] Set the index of the returned DataFrame as the original MultiIndex.

**name** [list / sequence of strings, optional] The passed names should substitute index level names.

#### Returns

**DataFrame** [a DataFrame containing the original MultiIndex data.]

#### See also:

*DataFrame*

### pandas.MultiIndex.to\_flat\_index

`MultiIndex.to_flat_index()`

Convert a MultiIndex to an Index of Tuples containing the level values.

New in version 0.24.0.

#### Returns

**pd.Index** Index with the MultiIndex data represented in Tuples.

#### Notes

This method will simply return the caller if called by anything other than a MultiIndex.

## Examples

```
>>> index = pd.MultiIndex.from_product(
...     [['foo', 'bar'], ['baz', 'qux']],
...     names=['a', 'b'])
>>> index.to_flat_index()
Index([('foo', 'baz'), ('foo', 'qux'),
      ('bar', 'baz'), ('bar', 'qux')],
      dtype='object')
```

### pandas.MultiIndex.is\_lexsorted

`MultiIndex.is_lexsorted()`

Return True if the codes are lexicographically sorted

### pandas.MultiIndex.sortlevel

`MultiIndex.sortlevel (level=0, ascending=True, sort_remaining=True)`

Sort MultiIndex at the requested level. The result will respect the original ordering of the associated factor at that level.

#### Parameters

**level** [list-like, int or str, default 0] If a string is given, must be a name of the level If list-like must be names or ints of levels.

**ascending** [boolean, default True] False to sort in descending order Can also be a list to specify a directed ordering

**sort\_remaining** [sort by the remaining levels after level]

#### Returns

**sorted\_index** [pd.MultiIndex] Resulting index

**indexer** [np.ndarray] Indices of output values in original index

### pandas.MultiIndex.droplevel

`MultiIndex.droplevel (level=0)`

Return index with requested level(s) removed.

If resulting index has only 1 level left, the result will be of Index type, not MultiIndex.

New in version 0.23.1: (support for non-MultiIndex)

#### Parameters

**level** [int, str, or list-like, default 0] If a string is given, must be the name of a level If list-like, elements must be names or indexes of levels.

#### Returns

**index** [Index or MultiIndex]

**pandas.MultiIndex.swaplevel**`MultiIndex.swaplevel (i=-2, j=-1)`Swap level *i* with level *j*.

Calling this method does not change the ordering of the values.

**Parameters****i** [int, str, default -2] First level of index to be swapped. Can pass level name as string. Type of parameters can be mixed.**j** [int, str, default -1] Second level of index to be swapped. Can pass level name as string. Type of parameters can be mixed.**Returns****MultiIndex** A new MultiIndex**.. versionchanged:: 0.18.1** The indexes *i* and *j* are now optional, and default to the two innermost levels of the index.**See also:****Series.swaplevel** Swap levels *i* and *j* in a MultiIndex.**Dataframe.swaplevel** Swap levels *i* and *j* in a MultiIndex on a particular axis.**Examples**

```

>>> mi = pd.MultiIndex(levels=[['a', 'b'], ['bb', 'aa']],
...                     codes=[[0, 0, 1, 1], [0, 1, 0, 1]])
>>> mi
MultiIndex(levels=[['a', 'b'], ['bb', 'aa']],
            labels=[[0, 0, 1, 1], [0, 1, 0, 1]])
>>> mi.swaplevel(0, 1)
MultiIndex(levels=[['bb', 'aa'], ['a', 'b']],
            labels=[[0, 1, 0, 1], [0, 0, 1, 1]])

```

**pandas.MultiIndex.reorder\_levels**`MultiIndex.reorder_levels (order)`

Rearrange levels using input order. May not drop or duplicate levels

**pandas.MultiIndex.remove\_unused\_levels**`MultiIndex.remove_unused_levels ()`

Create a new MultiIndex from the current that removes unused levels, meaning that they are not expressed in the labels.

The resulting MultiIndex will have the same outward appearance, meaning the same `.values` and ordering. It will also be `.equals()` to the original.

New in version 0.20.0.

**Returns**

## MultiIndex

### Examples

```
>>> i = pd.MultiIndex.from_product([range(2), list('ab')])
MultiIndex(levels=[[0, 1], ['a', 'b']],
            labels=[[0, 0, 1, 1], [0, 1, 0, 1]])
```

```
>>> i[2:]
MultiIndex(levels=[[0, 1], ['a', 'b']],
            labels=[[1, 1], [0, 1]])
```

The 0 from the first level is not represented and can be removed

```
>>> i[2:].remove_unused_levels()
MultiIndex(levels=[[1], ['a', 'b']],
            labels=[[0, 0], [0, 1]])
```

*IndexSlice*

Create an object to more easily perform multi-index slicing

---

### 35.7.5.2 pandas.IndexSlice

`pandas.IndexSlice = <pandas.core.indexing._IndexSlice object>`

Create an object to more easily perform multi-index slicing

See also:

**`MultiIndex.remove_unused_levels`** New MultiIndex with no unused levels.

### Notes

See *Defined Levels* for further info on slicing a MultiIndex.

### Examples

```
>>> midx = pd.MultiIndex.from_product(['A0', 'A1'], ['B0', 'B1', 'B2', 'B3'])
>>> columns = ['foo', 'bar']
>>> dfmi = pd.DataFrame(np.arange(16).reshape((len(midx), len(columns))),
                        index=midx, columns=columns)
```

Using the default slice command:

```
>>> dfmi.loc[(slice(None), slice('B0', 'B1')), :]
      foo  bar
A0 B0    0    1
   B1    2    3
A1 B0    8    9
   B1   10   11
```

Using the IndexSlice class for a more intuitive command:

```
>>> idx = pd.IndexSlice
>>> dfmi.loc[idx[:, 'B0':'B1'], :]
      foo  bar
A0 B0    0   1
   B1    2   3
A1 B0    8   9
   B1   10  11
```

### 35.7.5.3 MultiIndex Constructors

|                                                          |                                                                     |
|----------------------------------------------------------|---------------------------------------------------------------------|
| <i>MultiIndex.from_arrays</i> (arrays[, sortorder, ...]) | Convert arrays to MultiIndex.                                       |
| <i>MultiIndex.from_tuples</i> (tuples[, sortorder, ...]) | Convert list of tuples to MultiIndex.                               |
| <i>MultiIndex.from_product</i> (iterables[, ...])        | Make a MultiIndex from the cartesian product of multiple iterables. |
| <i>MultiIndex.from_frame</i> (df[, sortorder, names])    | Make a MultiIndex from a DataFrame.                                 |

### 35.7.5.4 MultiIndex Properties

|                            |                                              |
|----------------------------|----------------------------------------------|
| <i>MultiIndex.names</i>    | Names of levels in MultiIndex                |
| <i>MultiIndex.levels</i>   |                                              |
| <i>MultiIndex.codes</i>    |                                              |
| <i>MultiIndex.nlevels</i>  | Integer number of levels in this MultiIndex. |
| <i>MultiIndex.levshape</i> | A tuple with the length of each level.       |

### pandas.MultiIndex.levels

MultiIndex.levels

### pandas.MultiIndex.codes

MultiIndex.codes

### 35.7.5.5 MultiIndex Components

|                                                           |                                                                                                     |
|-----------------------------------------------------------|-----------------------------------------------------------------------------------------------------|
| <i>MultiIndex.set_levels</i> (levels[, level, ...])       | Set new levels on MultiIndex.                                                                       |
| <i>MultiIndex.set_codes</i> (codes[, level, ...])         | Set new codes on MultiIndex.                                                                        |
| <i>MultiIndex.to_hierarchical</i> (n_repeat[, n_shuffle]) | (DEPRECATED) Return a MultiIndex reshaped to conform to the shapes given by n_repeat and n_shuffle. |
| <i>MultiIndex.to_flat_index</i> ()                        | Convert a MultiIndex to an Index of Tuples containing the level values.                             |
| <i>MultiIndex.to_frame</i> ([index, name])                | Create a DataFrame with the levels of the MultiIndex as columns.                                    |
| <i>MultiIndex.is_lexsorted</i> ()                         | Return True if the codes are lexicographically sorted                                               |
| <i>MultiIndex.sortlevel</i> ([level, ascending, ...])     | Sort MultiIndex at the requested level.                                                             |

Continued on next page

Table 189 – continued from previous page

|                                                |                                                                                                                         |
|------------------------------------------------|-------------------------------------------------------------------------------------------------------------------------|
| <code>MultiIndex.droplevel([level])</code>     | Return index with requested level(s) removed.                                                                           |
| <code>MultiIndex.swaplevel([i, j])</code>      | Swap level i with level j.                                                                                              |
| <code>MultiIndex.reorder_levels(order)</code>  | Rearrange levels using input order.                                                                                     |
| <code>MultiIndex.remove_unused_levels()</code> | Create a new MultiIndex from the current that removes unused levels, meaning that they are not expressed in the labels. |

**pandas.MultiIndex.to\_hierarchical**

`MultiIndex.to_hierarchical(n_repeat, n_shuffle=1)`

Return a MultiIndex reshaped to conform to the shapes given by `n_repeat` and `n_shuffle`.

Deprecated since version 0.24.0.

Useful to replicate and rearrange a MultiIndex for combination with another Index with `n_repeat` items.

**Parameters**

**n\_repeat** [int] Number of times to repeat the labels on self

**n\_shuffle** [int] Controls the reordering of the labels. If the result is going to be an inner level in a MultiIndex, `n_shuffle` will need to be greater than one. The size of each label must be divisible by `n_shuffle`.

**Returns**

**MultiIndex**

**Examples**

```
>>> idx = pd.MultiIndex.from_tuples([(1, u'one'), (1, u'two'),
                                     (2, u'one'), (2, u'two')])
>>> idx.to_hierarchical(3)
MultiIndex(levels=[[1, 2], [u'one', u'two']],
            labels=[[0, 0, 0, 0, 0, 0, 1, 1, 1, 1, 1, 1],
                   [0, 0, 0, 1, 1, 1, 0, 0, 0, 1, 1, 1]])
```

**35.7.5.6 MultiIndex Selecting**

|                                                            |                                                                                      |
|------------------------------------------------------------|--------------------------------------------------------------------------------------|
| <code>MultiIndex.get_loc(key[, method])</code>             | Get location for a label or a tuple of labels as an integer, slice or boolean mask.  |
| <code>MultiIndex.get_loc_level(key[, level, ...])</code>   | Get both the location for the requested label(s) and the resulting sliced index.     |
| <code>MultiIndex.get_indexer(target[, method, ...])</code> | Compute indexer and mask for new index given the current index.                      |
| <code>MultiIndex.get_level_values(level)</code>            | Return vector of label values for requested level, equal to the length of the index. |

**pandas.MultiIndex.get\_loc**

`MultiIndex.get_loc(key, method=None)`

Get location for a label or a tuple of labels as an integer, slice or boolean mask.

**Parameters****key** [label or tuple of labels (one for each level)]**method** [None]**Returns****loc** [int, slice object or boolean mask] If the key is past the lexsort depth, the return may be a boolean mask array, otherwise it is always a slice or int.**See also:****Index.get\_loc** The get\_loc method for (single-level) index.**MultiIndex.slice\_locs** Get slice location given start label(s) and end label(s).**MultiIndex.get\_locs** Get location for a label/slice/list/mask or a sequence of such.**Notes**

The key cannot be a slice, list of same-level labels, a boolean mask, or a sequence of such. If you want to use those, use `MultiIndex.get_locs()` instead.

**Examples**

```
>>> mi = pd.MultiIndex.from_arrays([list('abb'), list('def')])
```

```
>>> mi.get_loc('b')
slice(1, 3, None)
```

```
>>> mi.get_loc(('b', 'e'))
1
```

**pandas.MultiIndex.get\_loc\_level****MultiIndex.get\_loc\_level** (*key*, *level=0*, *drop\_level=True*)

Get both the location for the requested label(s) and the resulting sliced index.

**Parameters****key** [label or sequence of labels]**level** [int/level name or list thereof, optional]**drop\_level** [bool, default True] if False, the resulting index will not drop any level.**Returns****loc** [A 2-tuple where the elements are:] Element 0: int, slice object or boolean array Element 1: The resulting sliced multiindex/index. If the key contains all levels, this will be None.**See also:****MultiIndex.get\_loc** Get location for a label or a tuple of labels.**MultiIndex.get\_locs** Get location for a label/slice/list/mask or a sequence of such.

## Examples

```
>>> mi = pd.MultiIndex.from_arrays([list('abb'), list('def')],
...                                names=['A', 'B'])
```

```
>>> mi.get_loc_level('b')
(slice(1, 3, None), Index(['e', 'f'], dtype='object', name='B'))
```

```
>>> mi.get_loc_level('e', level='B')
(array([False,  True, False], dtype=bool),
 Index(['b'], dtype='object', name='A'))
```

```
>>> mi.get_loc_level(['b', 'e'])
(1, None)
```

## pandas.MultiIndex.get\_indexer

`MultiIndex.get_indexer` (*target*, *method=None*, *limit=None*, *tolerance=None*)

Compute indexer and mask for new index given the current index. The indexer should be then used as an input to `ndarray.take` to align the current data to the new index.

### Parameters

**target** [MultiIndex or list of tuples]

**method** [{None, 'pad'/'ffill', 'backfill'/'bfill', 'nearest'}], optional

- default: exact matches only.
- pad / ffill: find the PREVIOUS index value if no exact match.
- backfill / bfill: use NEXT index value if no exact match
- nearest: use the NEAREST index value if no exact match. Tied distances are broken by preferring the larger index value.

**limit** [int, optional] Maximum number of consecutive labels in *target* to match for inexact matches.

**tolerance** [optional] Maximum distance between original and new labels for inexact matches. The values of the index at the matching locations must satisfy the equation `abs(index[indexer] - target) <= tolerance`.

Tolerance may be a scalar value, which applies the same tolerance to all values, or list-like, which applies variable tolerance per element. List-like includes list, tuple, array, Series, and must be the same size as the index and its dtype must exactly match the index's type.

New in version 0.21.0: (list-like tolerance)

### Returns

**indexer** [ndarray of int] Integers from 0 to *n* - 1 indicating that the index at these positions matches the corresponding target values. Missing values in the target are marked by -1.

## Examples

```
>>> index = pd.Index(['c', 'a', 'b'])
>>> index.get_indexer(['a', 'b', 'x'])
array([ 1,  2, -1])
```

Notice that the return value is an array of locations in `index` and `x` is marked by `-1`, as it is not in `index`.

## pandas.MultiIndex.get\_level\_values

`MultiIndex.get_level_values` (*level*)

Return vector of label values for requested level, equal to the length of the index.

### Parameters

**level** [int or str] *level* is either the integer position of the level in the MultiIndex, or the name of the level.

### Returns

**values** [Index] *values* is a level of this MultiIndex converted to a single *Index* (or subclass thereof).

## Examples

Create a MultiIndex:

```
>>> mi = pd.MultiIndex.from_arrays((list('abc'), list('def')))
>>> mi.names = ['level_1', 'level_2']
```

Get level values by supplying level as either integer or name:

```
>>> mi.get_level_values(0)
Index(['a', 'b', 'c'], dtype='object', name='level_1')
>>> mi.get_level_values('level_2')
Index(['d', 'e', 'f'], dtype='object', name='level_2')
```

## 35.7.6 DatetimeIndex

*DatetimeIndex*

Immutable ndarray of datetime64 data, represented internally as int64, and which can be boxed to Timestamp objects that are subclasses of datetime and carry meta-data such as frequency information.

---

### 35.7.6.1 pandas.DatetimeIndex

**class** pandas.DatetimeIndex

Immutable ndarray of datetime64 data, represented internally as int64, and which can be boxed to Timestamp objects that are subclasses of datetime and carry metadata such as frequency information.

### Parameters

**data** [array-like (1-dimensional), optional] Optional datetime-like data to construct index with

**copy** [bool] Make a copy of input ndarray

**freq** [string or pandas offset object, optional] One of pandas date offset strings or corresponding objects. The string 'infer' can be passed in order to set the frequency of the index as the inferred frequency upon creation

**start** [starting value, datetime-like, optional] If data is None, start is used as the start point in generating regular timestamp data.

Deprecated since version 0.24.0.

**periods** [int, optional, > 0] Number of periods to generate, if generating index. Takes precedence over end argument

Deprecated since version 0.24.0.

**end** [end time, datetime-like, optional] If periods is none, generated index will extend to first conforming time on or just past end argument

Deprecated since version 0.24.0.

**closed** [string or None, default None] Make the interval closed with respect to the given frequency to the 'left', 'right', or both sides (None)

Deprecated since version 0.24.: 0

**tz** [pytz.timezone or dateutil.tz.tzfile]

**ambiguous** ['infer', bool-ndarray, 'NaT', default 'raise'] When clocks moved backward due to DST, ambiguous times may arise. For example in Central European Time (UTC+01), when going from 03:00 DST to 02:00 non-DST, 02:30:00 local time occurs both at 00:30:00 UTC and at 01:30:00 UTC. In such a situation, the *ambiguous* parameter dictates how ambiguous times should be handled.

- 'infer' will attempt to infer fall dst-transition hours based on order
- bool-ndarray where True signifies a DST time, False signifies a non-DST time (note that this flag is only applicable for ambiguous times)
- 'NaT' will return NaT where there are ambiguous times
- 'raise' will raise an AmbiguousTimeError if there are ambiguous times

**name** [object] Name to be stored in the index

**dayfirst** [bool, default False] If True, parse dates in *data* with the day first order

**yearfirst** [bool, default False] If True parse dates in *data* with the year first order

See also:

**Index** The base pandas Index type.

**TimedeltaIndex** Index of timedelta64 data.

**PeriodIndex** Index of Period data.

**to\_datetime** Convert argument to datetime.

**date\_range** Create a fixed-frequency DatetimeIndex.

## Notes

To learn more about the frequency strings, please see [this link](#).

Creating a DatetimeIndex based on *start*, *periods*, and *end* has been deprecated in favor of `date_range()`.

## Attributes

|                               |                                                                                                                          |
|-------------------------------|--------------------------------------------------------------------------------------------------------------------------|
| <code>year</code>             | The year of the datetime.                                                                                                |
| <code>month</code>            | The month as January=1, December=12.                                                                                     |
| <code>day</code>              | The days of the datetime.                                                                                                |
| <code>hour</code>             | The hours of the datetime.                                                                                               |
| <code>minute</code>           | The minutes of the datetime.                                                                                             |
| <code>second</code>           | The seconds of the datetime.                                                                                             |
| <code>microsecond</code>      | The microseconds of the datetime.                                                                                        |
| <code>nanosecond</code>       | The nanoseconds of the datetime.                                                                                         |
| <code>date</code>             | Returns numpy array of python datetime.date objects (namely, the date part of Timestamps without time-zone information). |
| <code>time</code>             | Returns numpy array of datetime.time.                                                                                    |
| <code>timetz</code>           | Returns numpy array of datetime.time also containing timezone information.                                               |
| <code>dayofyear</code>        | The ordinal day of the year.                                                                                             |
| <code>weekofyear</code>       | The week ordinal of the year.                                                                                            |
| <code>week</code>             | The week ordinal of the year.                                                                                            |
| <code>dayofweek</code>        | The day of the week with Monday=0, Sunday=6.                                                                             |
| <code>weekday</code>          | The day of the week with Monday=0, Sunday=6.                                                                             |
| <code>quarter</code>          | The quarter of the date.                                                                                                 |
| <code>freq</code>             | Return the frequency object if it is set, otherwise None.                                                                |
| <code>freqstr</code>          | Return the frequency object as a string if it is set, otherwise None.                                                    |
| <code>is_month_start</code>   | Indicates whether the date is the first day of the month.                                                                |
| <code>is_month_end</code>     | Indicates whether the date is the last day of the month.                                                                 |
| <code>is_quarter_start</code> | Indicator for whether the date is the first day of a quarter.                                                            |
| <code>is_quarter_end</code>   | Indicator for whether the date is the last day of a quarter.                                                             |
| <code>is_year_start</code>    | Indicate whether the date is the first day of a year.                                                                    |
| <code>is_year_end</code>      | Indicate whether the date is the last day of the year.                                                                   |
| <code>is_leap_year</code>     | Boolean indicator if the date belongs to a leap year.                                                                    |
| <code>inferred_freq</code>    | Tries to return a string representing a frequency guess, generated by <code>infer_freq</code> .                          |

## pandas.DatetimeIndex.year

`DatetimeIndex.year`

The year of the datetime.

### **pandas.DatetimeIndex.month**

`DatetimeIndex.month`

The month as January=1, December=12.

### **pandas.DatetimeIndex.day**

`DatetimeIndex.day`

The days of the datetime.

### **pandas.DatetimeIndex.hour**

`DatetimeIndex.hour`

The hours of the datetime.

### **pandas.DatetimeIndex.minute**

`DatetimeIndex.minute`

The minutes of the datetime.

### **pandas.DatetimeIndex.second**

`DatetimeIndex.second`

The seconds of the datetime.

### **pandas.DatetimeIndex.microsecond**

`DatetimeIndex.microsecond`

The microseconds of the datetime.

### **pandas.DatetimeIndex.nanosecond**

`DatetimeIndex.nanosecond`

The nanoseconds of the datetime.

### **pandas.DatetimeIndex.date**

`DatetimeIndex.date`

Returns numpy array of python datetime.date objects (namely, the date part of Timestamps without time-zone information).

### **pandas.DatetimeIndex.time**

`DatetimeIndex.time`

Returns numpy array of datetime.time. The time part of the Timestamps.

**pandas.DatetimeIndex.timetz**`DatetimeIndex.timetz`

Returns numpy array of datetime.time also containing timezone information. The time part of the Timestamps.

**pandas.DatetimeIndex.dayofyear**`DatetimeIndex.dayofyear`

The ordinal day of the year.

**pandas.DatetimeIndex.weekofyear**`DatetimeIndex.weekofyear`

The week ordinal of the year.

**pandas.DatetimeIndex.week**`DatetimeIndex.week`

The week ordinal of the year.

**pandas.DatetimeIndex.dayofweek**`DatetimeIndex.dayofweek`

The day of the week with Monday=0, Sunday=6.

Return the day of the week. It is assumed the week starts on Monday, which is denoted by 0 and ends on Sunday which is denoted by 6. This method is available on both Series with datetime values (using the *dt* accessor) or DatetimeIndex.

**Returns**

**Series or Index** Containing integers indicating the day number.

**See also:**

***Series.dt.dayofweek*** Alias.

***Series.dt.weekday*** Alias.

***Series.dt.day\_name*** Returns the name of the day of the week.

**Examples**

```
>>> s = pd.date_range('2016-12-31', '2017-01-08', freq='D').to_series()
>>> s.dt.dayofweek
2016-12-31    5
2017-01-01    6
2017-01-02    0
2017-01-03    1
2017-01-04    2
```

(continues on next page)

(continued from previous page)

```
2017-01-05    3
2017-01-06    4
2017-01-07    5
2017-01-08    6
Freq: D, dtype: int64
```

### pandas.DatetimeIndex.weekday

#### DatetimeIndex.**weekday**

The day of the week with Monday=0, Sunday=6.

Return the day of the week. It is assumed the week starts on Monday, which is denoted by 0 and ends on Sunday which is denoted by 6. This method is available on both Series with datetime values (using the *dt* accessor) or DatetimeIndex.

#### Returns

**Series or Index** Containing integers indicating the day number.

#### See also:

**Series.dt.dayofweek** Alias.

**Series.dt.weekday** Alias.

**Series.dt.day\_name** Returns the name of the day of the week.

### Examples

```
>>> s = pd.date_range('2016-12-31', '2017-01-08', freq='D').to_series()
>>> s.dt.dayofweek
2016-12-31    5
2017-01-01    6
2017-01-02    0
2017-01-03    1
2017-01-04    2
2017-01-05    3
2017-01-06    4
2017-01-07    5
2017-01-08    6
Freq: D, dtype: int64
```

### pandas.DatetimeIndex.quarter

#### DatetimeIndex.**quarter**

The quarter of the date.

### pandas.DatetimeIndex.freq

#### DatetimeIndex.**freq**

Return the frequency object if it is set, otherwise None.

**pandas.DatetimeIndex.freqstr**`DatetimeIndex.freqstr`

Return the frequency object as a string if it is set, otherwise None.

**pandas.DatetimeIndex.is\_month\_start**`DatetimeIndex.is_month_start`

Indicates whether the date is the first day of the month.

**Returns****Series or array** For Series, returns a Series with boolean values. For DatetimeIndex, returns a boolean array.**See also:****`is_month_start`** Return a boolean indicating whether the date is the first day of the month.**`is_month_end`** Return a boolean indicating whether the date is the last day of the month.**Examples**This method is available on Series with datetime values under the `.dt` accessor, and directly on `DatetimeIndex`.

```
>>> s = pd.Series(pd.date_range("2018-02-27", periods=3))
>>> s
0    2018-02-27
1    2018-02-28
2    2018-03-01
dtype: datetime64[ns]
>>> s.dt.is_month_start
0    False
1    False
2     True
dtype: bool
>>> s.dt.is_month_end
0    False
1     True
2    False
dtype: bool
```

```
>>> idx = pd.date_range("2018-02-27", periods=3)
>>> idx.is_month_start
array([False, False,  True])
>>> idx.is_month_end
array([False,  True, False])
```

**pandas.DatetimeIndex.is\_month\_end**`DatetimeIndex.is_month_end`

Indicates whether the date is the last day of the month.

**Returns**

**Series or array** For Series, returns a Series with boolean values. For DatetimeIndex, returns a boolean array.

**See also:**

**`is_month_start`** Return a boolean indicating whether the date is the first day of the month.

**`is_month_end`** Return a boolean indicating whether the date is the last day of the month.

## Examples

This method is available on Series with datetime values under the `.dt` accessor, and directly on DatetimeIndex.

```
>>> s = pd.Series(pd.date_range("2018-02-27", periods=3))
>>> s
0    2018-02-27
1    2018-02-28
2    2018-03-01
dtype: datetime64[ns]
>>> s.dt.is_month_start
0    False
1    False
2     True
dtype: bool
>>> s.dt.is_month_end
0    False
1     True
2    False
dtype: bool
```

```
>>> idx = pd.date_range("2018-02-27", periods=3)
>>> idx.is_month_start
array([False, False,  True])
>>> idx.is_month_end
array([False,  True, False])
```

## pandas.DatetimeIndex.is\_quarter\_start

DatetimeIndex.**`is_quarter_start`**

Indicator for whether the date is the first day of a quarter.

### Returns

**`is_quarter_start`** [Series or DatetimeIndex] The same type as the original data with boolean values. Series will have the same name and index. DatetimeIndex will have the same name.

**See also:**

**`quarter`** Return the quarter of the date.

**`is_quarter_end`** Similar property for indicating the quarter start.

## Examples

This method is available on Series with datetime values under the `.dt` accessor, and directly on `DatetimeIndex`.

```
>>> df = pd.DataFrame({'dates': pd.date_range("2017-03-30",
...                                           periods=4)})
>>> df.assign(quarter=df.dates.dt.quarter,
...           is_quarter_start=df.dates.dt.is_quarter_start)
   dates      quarter  is_quarter_start
0 2017-03-30         1             False
1 2017-03-31         1             False
2 2017-04-01         2              True
3 2017-04-02         2             False
```

```
>>> idx = pd.date_range('2017-03-30', periods=4)
>>> idx
DatetimeIndex(['2017-03-30', '2017-03-31', '2017-04-01', '2017-04-02'],
              dtype='datetime64[ns]', freq='D')
```

```
>>> idx.is_quarter_start
array([False, False,  True, False])
```

## pandas.DatetimeIndex.is\_quarter\_end

### DatetimeIndex.is\_quarter\_end

Indicator for whether the date is the last day of a quarter.

#### Returns

**is\_quarter\_end** [Series or DatetimeIndex] The same type as the original data with boolean values. Series will have the same name and index. DatetimeIndex will have the same name.

See also:

**quarter** Return the quarter of the date.

**is\_quarter\_start** Similar property indicating the quarter start.

## Examples

This method is available on Series with datetime values under the `.dt` accessor, and directly on `DatetimeIndex`.

```
>>> df = pd.DataFrame({'dates': pd.date_range("2017-03-30",
...                                           periods=4)})
>>> df.assign(quarter=df.dates.dt.quarter,
...           is_quarter_end=df.dates.dt.is_quarter_end)
   dates      quarter  is_quarter_end
0 2017-03-30         1             False
1 2017-03-31         1              True
2 2017-04-01         2             False
3 2017-04-02         2             False
```

```
>>> idx = pd.date_range('2017-03-30', periods=4)
>>> idx
DatetimeIndex(['2017-03-30', '2017-03-31', '2017-04-01', '2017-04-02'],
              dtype='datetime64[ns]', freq='D')
```

```
>>> idx.is_quarter_end
array([False,  True, False, False])
```

## pandas.DatetimeIndex.is\_year\_start

### DatetimeIndex.is\_year\_start

Indicate whether the date is the first day of a year.

#### Returns

**Series or DatetimeIndex** The same type as the original data with boolean values. Series will have the same name and index. DatetimeIndex will have the same name.

#### See also:

**is\_year\_end** Similar property indicating the last day of the year.

## Examples

This method is available on Series with datetime values under the `.dt` accessor, and directly on `DatetimeIndex`.

```
>>> dates = pd.Series(pd.date_range("2017-12-30", periods=3))
>>> dates
0    2017-12-30
1    2017-12-31
2    2018-01-01
dtype: datetime64[ns]
```

```
>>> dates.dt.is_year_start
0    False
1    False
2     True
dtype: bool
```

```
>>> idx = pd.date_range("2017-12-30", periods=3)
>>> idx
DatetimeIndex(['2017-12-30', '2017-12-31', '2018-01-01'],
              dtype='datetime64[ns]', freq='D')
```

```
>>> idx.is_year_start
array([False, False,  True])
```

## pandas.DatetimeIndex.is\_year\_end

### DatetimeIndex.is\_year\_end

Indicate whether the date is the last day of the year.

**Returns**

**Series or DatetimeIndex** The same type as the original data with boolean values. Series will have the same name and index. DatetimeIndex will have the same name.

**See also:**

**`is_year_start`** Similar property indicating the start of the year.

**Examples**

This method is available on Series with datetime values under the `.dt` accessor, and directly on `DatetimeIndex`.

```
>>> dates = pd.Series(pd.date_range("2017-12-30", periods=3))
>>> dates
0    2017-12-30
1    2017-12-31
2    2018-01-01
dtype: datetime64[ns]
```

```
>>> dates.dt.is_year_end
0    False
1     True
2    False
dtype: bool
```

```
>>> idx = pd.date_range("2017-12-30", periods=3)
>>> idx
DatetimeIndex(['2017-12-30', '2017-12-31', '2018-01-01'],
              dtype='datetime64[ns]', freq='D')
```

```
>>> idx.is_year_end
array([False,  True, False])
```

**pandas.DatetimeIndex.is\_leap\_year****DatetimeIndex.is\_leap\_year**

Boolean indicator if the date belongs to a leap year.

A leap year is a year, which has 366 days (instead of 365) including 29th of February as an intercalary day. Leap years are years which are multiples of four with the exception of years divisible by 100 but not by 400.

**Returns**

**Series or ndarray** Booleans indicating if dates belong to a leap year.

**Examples**

This method is available on Series with datetime values under the `.dt` accessor, and directly on `DatetimeIndex`.

```
>>> idx = pd.date_range("2012-01-01", "2015-01-01", freq="Y")
>>> idx
DatetimeIndex(['2012-12-31', '2013-12-31', '2014-12-31'],
              dtype='datetime64[ns]', freq='A-DEC')
>>> idx.is_leap_year
array([ True, False, False], dtype=bool)
```

```
>>> dates = pd.Series(idx)
>>> dates_series
0    2012-12-31
1    2013-12-31
2    2014-12-31
dtype: datetime64[ns]
>>> dates_series.dt.is_leap_year
0      True
1     False
2     False
dtype: bool
```

### pandas.DatetimeIndex.inferred\_freq

`DatetimeIndex.inferred_freq`

Tries to return a string representing a frequency guess, generated by `infer_freq`. Returns `None` if it can't autodetect the frequency.

|    |  |
|----|--|
| tz |  |
|----|--|

### Methods

|                                        |                                                                                                                           |
|----------------------------------------|---------------------------------------------------------------------------------------------------------------------------|
| <i>normalize(*args, **kwargs)</i>      | Convert times to midnight.                                                                                                |
| <i>strftime(*args, **kwargs)</i>       | Convert to Index using specified <code>date_format</code> .                                                               |
| <i>snap([freq])</i>                    | Snap time stamps to nearest occurring frequency                                                                           |
| <i>tz_convert(*args, **kwargs)</i>     | Convert tz-aware Datetime Array/Index from one time zone to another.                                                      |
| <i>tz_localize(*args, **kwargs)</i>    | Localize tz-naive Datetime Array/Index to tz-aware Datetime Array/Index.                                                  |
| <i>round(*args, **kwargs)</i>          | Perform round operation on the data to the specified <i>freq</i> .                                                        |
| <i>floor(*args, **kwargs)</i>          | Perform floor operation on the data to the specified <i>freq</i> .                                                        |
| <i>ceil(*args, **kwargs)</i>           | Perform ceil operation on the data to the specified <i>freq</i> .                                                         |
| <i>to_period(*args, **kwargs)</i>      | Cast to PeriodArray/Index at a particular frequency.                                                                      |
| <i>to_perioddelta(*args, **kwargs)</i> | Calculate TimedeltaArray of difference between index values and index converted to PeriodArray at specified <i>freq</i> . |
| <i>to_pydatetime(*args, **kwargs)</i>  | Return Datetime Array/Index as object ndarray of <code>datetime.datetime</code> objects                                   |

Table 193 – continued from previous page

|                                                |                                                                                                                               |
|------------------------------------------------|-------------------------------------------------------------------------------------------------------------------------------|
| <code>to_series([keep_tz, index, name])</code> | Create a Series with both index and values equal to the index keys useful with map for returning an indexer based on an index |
| <code>to_frame([index, name])</code>           | Create a DataFrame with a column containing the Index.                                                                        |
| <code>month_name(*args, **kwargs)</code>       | Return the month names of the DateTimeIndex with specified locale.                                                            |
| <code>day_name(*args, **kwargs)</code>         | Return the day names of the DateTimeIndex with specified locale.                                                              |

**pandas.DatetimeIndex.normalize**

`DatetimeIndex.normalize(*args, **kwargs)`

Convert times to midnight.

The time component of the date-time is converted to midnight i.e. 00:00:00. This is useful in cases, when the time does not matter. Length is unaltered. The timezones are unaffected.

This method is available on Series with datetime values under the `.dt` accessor, and directly on Datetime Array/Index.

**Returns**

**DatetimeArray, DatetimeIndex or Series** The same type as the original data. Series will have the same name and index. DatetimeIndex will have the same name.

**See also:**

**floor** Floor the datetimes to the specified freq.

**ceil** Ceil the datetimes to the specified freq.

**round** Round the datetimes to the specified freq.

**Examples**

```
>>> idx = pd.date_range(start='2014-08-01 10:00', freq='H',
...                      periods=3, tz='Asia/Calcutta')
>>> idx
DatetimeIndex(['2014-08-01 10:00:00+05:30',
               '2014-08-01 11:00:00+05:30',
               '2014-08-01 12:00:00+05:30'],
              dtype='datetime64[ns, Asia/Calcutta]', freq='H')
>>> idx.normalize()
DatetimeIndex(['2014-08-01 00:00:00+05:30',
               '2014-08-01 00:00:00+05:30',
               '2014-08-01 00:00:00+05:30'],
              dtype='datetime64[ns, Asia/Calcutta]', freq=None)
```

**pandas.DatetimeIndex.strftime**

`DatetimeIndex.strftime(*args, **kwargs)`

Convert to Index using specified date\_format.

Return an Index of formatted strings specified by `date_format`, which supports the same string format as the python standard library. Details of the string format can be found in [python string format doc](#)

**Parameters**

**date\_format** [str] Date format string (e.g. “%Y-%m-%d”).

**Returns**

**Index** Index of formatted strings

See also:

**to\_datetime** Convert the given argument to datetime.

**DatetimeIndex.normalize** Return DatetimeIndex with times to midnight.

**DatetimeIndex.round** Round the DatetimeIndex to the specified freq.

**DatetimeIndex.floor** Floor the DatetimeIndex to the specified freq.

**Examples**

```
>>> rng = pd.date_range(pd.Timestamp("2018-03-10 09:00"),
...                      periods=3, freq='s')
>>> rng.strftime('%B %d, %Y, %r')
Index(['March 10, 2018, 09:00:00 AM', 'March 10, 2018, 09:00:01 AM',
       'March 10, 2018, 09:00:02 AM'],
      dtype='object')
```

**pandas.DatetimeIndex.snap**

`DatetimeIndex.snap` (*freq='S'*)

Snap time stamps to nearest occurring frequency

**pandas.DatetimeIndex.tz\_convert**

`DatetimeIndex.tz_convert` (*\*args, \*\*kwargs*)

Convert tz-aware Datetime Array/Index from one time zone to another.

**Parameters**

**tz** [string, pytz.timezone, dateutil.tz.tzfile or None] Time zone for time. Corresponding timestamps would be converted to this time zone of the Datetime Array/Index. A *tz* of None will convert to UTC and remove the timezone information.

**Returns**

**normalized** [same type as self]

**Raises**

**TypeError** If Datetime Array/Index is tz-naive.

See also:

**DatetimeIndex.tz** A timezone that has a variable offset from UTC.

**DatetimeIndex.tz\_localize** Localize tz-naive DatetimeIndex to a given time zone, or remove timezone from a tz-aware DatetimeIndex.

## Examples

With the *tz* parameter, we can change the DatetimeIndex to other time zones:

```
>>> dti = pd.date_range(start='2014-08-01 09:00',
...                       freq='H', periods=3, tz='Europe/Berlin')
```

```
>>> dti
DatetimeIndex(['2014-08-01 09:00:00+02:00',
               '2014-08-01 10:00:00+02:00',
               '2014-08-01 11:00:00+02:00'],
              dtype='datetime64[ns, Europe/Berlin]', freq='H')
```

```
>>> dti.tz_convert('US/Central')
DatetimeIndex(['2014-08-01 02:00:00-05:00',
               '2014-08-01 03:00:00-05:00',
               '2014-08-01 04:00:00-05:00'],
              dtype='datetime64[ns, US/Central]', freq='H')
```

With the *tz=None*, we can remove the timezone (after converting to UTC if necessary):

```
>>> dti = pd.date_range(start='2014-08-01 09:00', freq='H',
...                       periods=3, tz='Europe/Berlin')
```

```
>>> dti
DatetimeIndex(['2014-08-01 09:00:00+02:00',
               '2014-08-01 10:00:00+02:00',
               '2014-08-01 11:00:00+02:00'],
              dtype='datetime64[ns, Europe/Berlin]', freq='H')
```

```
>>> dti.tz_convert(None)
DatetimeIndex(['2014-08-01 07:00:00',
               '2014-08-01 08:00:00',
               '2014-08-01 09:00:00'],
              dtype='datetime64[ns]', freq='H')
```

## pandas.DatetimeIndex.tz\_localize

**DatetimeIndex.tz\_localize** (\*args, \*\*kwargs)

Localize tz-naive Datetime Array/Index to tz-aware Datetime Array/Index.

This method takes a time zone (tz) naive Datetime Array/Index object and makes this time zone aware. It does not move the time to another time zone. Time zone localization helps to switch from time zone aware to time zone unaware objects.

### Parameters

**tz** [string, pytz.timezone, dateutil.tz.tzfile or None] Time zone to convert timestamps to. Passing None will remove the time zone information preserving local time.

**ambiguous** ['infer', 'NaT', bool array, default 'raise'] When clocks moved backward due to DST, ambiguous times may arise. For example in Central European Time

(UTC+01), when going from 03:00 DST to 02:00 non-DST, 02:30:00 local time occurs both at 00:30:00 UTC and at 01:30:00 UTC. In such a situation, the *ambiguous* parameter dictates how ambiguous times should be handled.

- ‘infer’ will attempt to infer fall dst-transition hours based on order
- bool-ndarray where True signifies a DST time, False signifies a non-DST time (note that this flag is only applicable for ambiguous times)
- ‘NaT’ will return NaT where there are ambiguous times
- ‘raise’ will raise an AmbiguousTimeError if there are ambiguous times

**nonexistent** [‘shift\_forward’, ‘shift\_backward’, ‘NaT’, timedelta,]

default ‘raise’

A nonexistent time does not exist in a particular timezone where clocks moved forward due to DST.

- ‘shift\_forward’ will shift the nonexistent time forward to the closest existing time
- ‘shift\_backward’ will shift the nonexistent time backward to the closest existing time
- ‘NaT’ will return NaT where there are nonexistent times
- timedelta objects will shift nonexistent times by the timedelta
- ‘raise’ will raise an NonExistentTimeError if there are nonexistent times

New in version 0.24.0.

**errors** [{‘raise’, ‘coerce’}, default None]

- ‘raise’ will raise a NonExistentTimeError if a timestamp is not valid in the specified time zone (e.g. due to a transition from or to DST time). Use `nonexistent=‘raise’` instead.
- ‘coerce’ will return NaT if the timestamp can not be converted to the specified time zone. Use `nonexistent=‘NaT’` instead.

Deprecated since version 0.24.0.

### Returns

**result** [same type as self] Array/Index converted to the specified time zone.

### Raises

**TypeError** If the Datetime Array/Index is tz-aware and tz is not None.

See also:

**DatetimeIndex.tz\_convert** Convert tz-aware DatetimeIndex from one time zone to another.

### Examples

```
>>> tz_naive = pd.date_range('2018-03-01 09:00', periods=3)
>>> tz_naive
DatetimeIndex(['2018-03-01 09:00:00', '2018-03-02 09:00:00',
               '2018-03-03 09:00:00'],
              dtype='datetime64[ns]', freq='D')
```

Localize DatetimeIndex in US/Eastern time zone:

```
>>> tz_aware = tz_naive.tz_localize(tz='US/Eastern')
>>> tz_aware
DatetimeIndex(['2018-03-01 09:00:00-05:00',
               '2018-03-02 09:00:00-05:00',
               '2018-03-03 09:00:00-05:00'],
              dtype='datetime64[ns, US/Eastern]', freq='D')
```

With the `tz=None`, we can remove the time zone information while keeping the local time (not converted to UTC):

```
>>> tz_aware.tz_localize(None)
DatetimeIndex(['2018-03-01 09:00:00', '2018-03-02 09:00:00',
               '2018-03-03 09:00:00'],
              dtype='datetime64[ns]', freq='D')
```

Be careful with DST changes. When there is sequential data, pandas can infer the DST time: `>>> s = pd.to_datetime(pd.Series([ ... '2018-10-28 01:30:00', ... '2018-10-28 02:00:00', ... '2018-10-28 02:30:00', ... '2018-10-28 02:00:00', ... '2018-10-28 02:30:00', ... '2018-10-28 03:00:00', ... '2018-10-28 03:30:00'])) >>> s.dt.tz_localize('CET', ambiguous='infer')` 2018-10-28 01:30:00+02:00 0 2018-10-28 02:00:00+02:00 1 2018-10-28 02:30:00+02:00 2 2018-10-28 02:00:00+01:00 3 2018-10-28 02:30:00+01:00 4 2018-10-28 03:00:00+01:00 5 2018-10-28 03:30:00+01:00 6 dtype: int64

In some cases, inferring the DST is impossible. In such cases, you can pass an ndarray to the `ambiguous` parameter to set the DST explicitly

```
>>> s = pd.to_datetime(pd.Series([
... '2018-10-28 01:20:00',
... '2018-10-28 02:36:00',
... '2018-10-28 03:46:00']))
>>> s.dt.tz_localize('CET', ambiguous=np.array([True, True, False]))
0    2018-10-28 01:20:00+02:00
1    2018-10-28 02:36:00+02:00
2    2018-10-28 03:46:00+01:00
dtype: datetime64[ns, CET]
```

If the DST transition causes nonexistent times, you can shift these dates forward or backwards with a `timedelta` object or `'shift_forward'` or `'shift_backwards'`. `>>> s = pd.to_datetime(pd.Series([ ... '2015-03-29 02:30:00', ... '2015-03-29 03:30:00'])) >>> s.dt.tz_localize('Europe/Warsaw', nonexistent='shift_forward')` 0 2015-03-29 03:00:00+02:00 1 2015-03-29 03:30:00+02:00 dtype: datetime64[ns, 'Europe/Warsaw'] `>>> s.dt.tz_localize('Europe/Warsaw', nonexistent='shift_backward')` 0 2015-03-29 01:59:59.999999999+01:00 1 2015-03-29 03:30:00+02:00 dtype: datetime64[ns, 'Europe/Warsaw'] `>>> s.dt.tz_localize('Europe/Warsaw', nonexistent=pd.Timedelta('1H'))` 0 2015-03-29 03:30:00+02:00 1 2015-03-29 03:30:00+02:00 dtype: datetime64[ns, 'Europe/Warsaw']

## pandas.DatetimeIndex.round

`DatetimeIndex.round(*args, **kwargs)`

Perform round operation on the data to the specified *freq*.

### Parameters

**freq** [str or Offset] The frequency level to round the index to. Must be a fixed frequency like 'S' (second) not 'ME' (month end). See *frequency aliases* for a list of possible *freq* values.

**ambiguous** ['infer', bool-ndarray, 'NaT', default 'raise'] Only relevant for DatetimeIndex:

- 'infer' will attempt to infer fall dst-transition hours based on order
- bool-ndarray where True signifies a DST time, False designates a non-DST time (note that this flag is only applicable for ambiguous times)
- 'NaT' will return NaT where there are ambiguous times
- 'raise' will raise an AmbiguousTimeError if there are ambiguous times

New in version 0.24.0.

**nonexistent** ['shift\_forward', 'shift\_backward', 'NaT', timedelta,]  
default 'raise'

A nonexistent time does not exist in a particular timezone where clocks moved forward due to DST.

- 'shift\_forward' will shift the nonexistent time forward to the closest existing time
- 'shift\_backward' will shift the nonexistent time backward to the closest existing time
- 'NaT' will return NaT where there are nonexistent times
- timedelta objects will shift nonexistent times by the timedelta
- 'raise' will raise an NonExistentTimeError if there are nonexistent times

New in version 0.24.0.

### Returns

**DatetimeIndex, TimedeltaIndex, or Series** Index of the same type for a DatetimeIndex or TimedeltaIndex, or a Series with the same index for a Series.

### Raises

**ValueError** if the 'freq' cannot be converted.

## Examples

### DatetimeIndex

```
>>> rng = pd.date_range('1/1/2018 11:59:00', periods=3, freq='min')
>>> rng
DatetimeIndex(['2018-01-01 11:59:00', '2018-01-01 12:00:00',
               '2018-01-01 12:01:00'],
              dtype='datetime64[ns]', freq='T')
>>> rng.round('H')
DatetimeIndex(['2018-01-01 12:00:00', '2018-01-01 12:00:00',
               '2018-01-01 12:00:00'],
              dtype='datetime64[ns]', freq=None)
```

### Series

```
>>> pd.Series(rng).dt.round("H")
0    2018-01-01 12:00:00
1    2018-01-01 12:00:00
```

(continues on next page)

(continued from previous page)

```
2    2018-01-01 12:00:00
dtype: datetime64[ns]
```

**pandas.DatetimeIndex.floor****DatetimeIndex.floor** (\*args, \*\*kwargs)Perform floor operation on the data to the specified *freq*.**Parameters**

**freq** [str or Offset] The frequency level to floor the index to. Must be a fixed frequency like 'S' (second) not 'ME' (month end). See *frequency aliases* for a list of possible *freq* values.

**ambiguous** ['infer', bool-ndarray, 'NaT', default 'raise'] Only relevant for DatetimeIndex:

- 'infer' will attempt to infer fall dst-transition hours based on order
- bool-ndarray where True signifies a DST time, False designates a non-DST time (note that this flag is only applicable for ambiguous times)
- 'NaT' will return NaT where there are ambiguous times
- 'raise' will raise an AmbiguousTimeError if there are ambiguous times

New in version 0.24.0.

**nonexistent** ['shift\_forward', 'shift\_backward', 'NaT', timedelta,]  
default 'raise'

A nonexistent time does not exist in a particular timezone where clocks moved forward due to DST.

- 'shift\_forward' will shift the nonexistent time forward to the closest existing time
- 'shift\_backward' will shift the nonexistent time backward to the closest existing time
- 'NaT' will return NaT where there are nonexistent times
- timedelta objects will shift nonexistent times by the timedelta
- 'raise' will raise an NonExistentTimeError if there are nonexistent times

New in version 0.24.0.

**Returns**

**DatetimeIndex, TimedeltaIndex, or Series** Index of the same type for a DatetimeIndex or TimedeltaIndex, or a Series with the same index for a Series.

**Raises**

**ValueError** if the 'freq' cannot be converted.

**Examples****DatetimeIndex**

```
>>> rng = pd.date_range('1/1/2018 11:59:00', periods=3, freq='min')
>>> rng
DatetimeIndex(['2018-01-01 11:59:00', '2018-01-01 12:00:00',
               '2018-01-01 12:01:00'],
              dtype='datetime64[ns]', freq='T')
>>> rng.floor('H')
DatetimeIndex(['2018-01-01 11:00:00', '2018-01-01 12:00:00',
               '2018-01-01 12:00:00'],
              dtype='datetime64[ns]', freq=None)
```

### Series

```
>>> pd.Series(rng).dt.floor("H")
0    2018-01-01 11:00:00
1    2018-01-01 12:00:00
2    2018-01-01 12:00:00
dtype: datetime64[ns]
```

## pandas.DatetimeIndex.ceil

`DatetimeIndex.ceil(*args, **kwargs)`

Perform ceil operation on the data to the specified *freq*.

### Parameters

**freq** [str or Offset] The frequency level to ceil the index to. Must be a fixed frequency like 'S' (second) not 'ME' (month end). See *frequency aliases* for a list of possible *freq* values.

**ambiguous** ['infer', bool-ndarray, 'NaT', default 'raise'] Only relevant for `DatetimeIndex`:

- 'infer' will attempt to infer fall dst-transition hours based on order
- bool-ndarray where True signifies a DST time, False designates a non-DST time (note that this flag is only applicable for ambiguous times)
- 'NaT' will return NaT where there are ambiguous times
- 'raise' will raise an `AmbiguousTimeError` if there are ambiguous times

New in version 0.24.0.

**nonexistent** ['shift\_forward', 'shift\_backward', 'NaT', timedelta,]

default 'raise'

A nonexistent time does not exist in a particular timezone where clocks moved forward due to DST.

- 'shift\_forward' will shift the nonexistent time forward to the closest existing time
- 'shift\_backward' will shift the nonexistent time backward to the closest existing time
- 'NaT' will return NaT where there are nonexistent times
- timedelta objects will shift nonexistent times by the timedelta
- 'raise' will raise an `NonExistentTimeError` if there are nonexistent times

New in version 0.24.0.

**Returns**

**DatetimeIndex, TimedeltaIndex, or Series** Index of the same type for a DatetimeIndex or TimedeltaIndex, or a Series with the same index for a Series.

**Raises**

**ValueError** if the ‘freq’ cannot be converted.

**Examples****DatetimeIndex**

```
>>> rng = pd.date_range('1/1/2018 11:59:00', periods=3, freq='min')
>>> rng
DatetimeIndex(['2018-01-01 11:59:00', '2018-01-01 12:00:00',
              '2018-01-01 12:01:00'],
              dtype='datetime64[ns]', freq='T')
>>> rng.ceil('H')
DatetimeIndex(['2018-01-01 12:00:00', '2018-01-01 12:00:00',
              '2018-01-01 13:00:00'],
              dtype='datetime64[ns]', freq=None)
```

**Series**

```
>>> pd.Series(rng).dt.ceil("H")
0    2018-01-01 12:00:00
1    2018-01-01 12:00:00
2    2018-01-01 13:00:00
dtype: datetime64[ns]
```

**pandas.DatetimeIndex.to\_period**

`DatetimeIndex.to_period(*args, **kwargs)`

Cast to PeriodArray/Index at a particular frequency.

Converts DatetimeArray/Index to PeriodArray/Index.

**Parameters**

**freq** [string or Offset, optional] One of pandas’ *offset strings* or an Offset object. Will be inferred by default.

**Returns**

**PeriodArray/Index**

**Raises**

**ValueError** When converting a DatetimeArray/Index with non-regular values, so that a frequency cannot be inferred.

**See also:**

**PeriodIndex** Immutable ndarray holding ordinal values.

**DatetimeIndex.to\_pydatetime** Return DatetimeIndex as object.

## Examples

```
>>> df = pd.DataFrame({"y": [1,2,3]},
...                    index=pd.to_datetime(["2000-03-31 00:00:00",
...                    "2000-05-31 00:00:00",
...                    "2000-08-31 00:00:00"]))
>>> df.index.to_period("M")
PeriodIndex(['2000-03', '2000-05', '2000-08'],
            dtype='period[M]', freq='M')
```

Infer the daily frequency

```
>>> idx = pd.date_range("2017-01-01", periods=2)
>>> idx.to_period()
PeriodIndex(['2017-01-01', '2017-01-02'],
            dtype='period[D]', freq='D')
```

## pandas.DatetimeIndex.to\_perioddelta

`DatetimeIndex.to_perioddelta(*args, **kwargs)`

Calculate TimedeltaArray of difference between index values and index converted to PeriodArray at specified freq. Used for vectorized offsets

### Parameters

**freq** [Period frequency]

### Returns

TimedeltaArray/Index

## pandas.DatetimeIndex.to\_pydatetime

`DatetimeIndex.to_pydatetime(*args, **kwargs)`

Return Datetime Array/Index as object ndarray of datetime.datetime objects

### Returns

**datetimes** [ndarray]

## pandas.DatetimeIndex.to\_series

`DatetimeIndex.to_series(keep_tz=None, index=None, name=None)`

Create a Series with both index and values equal to the index keys useful with map for returning an indexer based on an index

### Parameters

**keep\_tz** [optional, defaults False] Return the data keeping the timezone.

If keep\_tz is True:

If the timezone is not set, the resulting Series will have a datetime64[ns] dtype.

Otherwise the Series will have an datetime64[ns, tz] dtype; the tz will be preserved.

If `keep_tz` is False:

Series will have a `datetime64[ns]` dtype. TZ aware objects will have the tz removed.

Changed in version 0.24: The default value will change to True in a future release. You can set `keep_tz=True` to already obtain the future behaviour and silence the warning.

**index** [Index, optional] index of resulting Series. If None, defaults to original index

**name** [string, optional] name of resulting Series. If None, defaults to name of original index

### Returns

Series

## pandas.DatetimeIndex.to\_frame

`DatetimeIndex.to_frame(index=True, name=None)`

Create a DataFrame with a column containing the Index.

New in version 0.24.0.

### Parameters

**index** [boolean, default True] Set the index of the returned DataFrame as the original Index.

**name** [object, default None] The passed name should substitute for the index name (if it has one).

### Returns

**DataFrame** DataFrame containing the original Index data.

See also:

**`Index.to_series`** Convert an Index to a Series.

**`Series.to_frame`** Convert Series to DataFrame.

## Examples

```
>>> idx = pd.Index(['Ant', 'Bear', 'Cow'], name='animal')
>>> idx.to_frame()
      animal
animal
Ant      Ant
Bear    Bear
Cow     Cow
```

By default, the original Index is reused. To enforce a new Index:

```
>>> idx.to_frame(index=False)
      animal
0      Ant
1     Bear
2      Cow
```

To override the name of the resulting column, specify *name*:

```
>>> idx.to_frame(index=False, name='zoo')
      zoo
0    Ant
1   Bear
2    Cow
```

## pandas.DatetimeIndex.month\_name

`DatetimeIndex.month_name(*args, **kwargs)`

Return the month names of the `DatetimeIndex` with specified locale.

New in version 0.23.0.

### Parameters

**locale** [str, optional] Locale determining the language in which to return the month name.  
Default is English locale.

### Returns

**Index** Index of month names.

## Examples

```
>>> idx = pd.date_range(start='2018-01', freq='M', periods=3)
>>> idx
DatetimeIndex(['2018-01-31', '2018-02-28', '2018-03-31'],
              dtype='datetime64[ns]', freq='M')
>>> idx.month_name()
Index(['January', 'February', 'March'], dtype='object')
```

## pandas.DatetimeIndex.day\_name

`DatetimeIndex.day_name(*args, **kwargs)`

Return the day names of the `DatetimeIndex` with specified locale.

New in version 0.23.0.

### Parameters

**locale** [str, optional] Locale determining the language in which to return the day name.  
Default is English locale.

### Returns

**Index** Index of day names.

## Examples

```
>>> idx = pd.date_range(start='2018-01-01', freq='D', periods=3)
>>> idx
DatetimeIndex(['2018-01-01', '2018-01-02', '2018-01-03'],
              dtype='datetime64[ns]', freq='D')
```

(continues on next page)

(continued from previous page)

```
>>> idx.day_name()
Index(['Monday', 'Tuesday', 'Wednesday'], dtype='object')
```

### 35.7.6.2 Time/Date Components

|                                       |                                                                                                                         |
|---------------------------------------|-------------------------------------------------------------------------------------------------------------------------|
| <i>DatetimeIndex.year</i>             | The year of the datetime.                                                                                               |
| <i>DatetimeIndex.month</i>            | The month as January=1, December=12.                                                                                    |
| <i>DatetimeIndex.day</i>              | The days of the datetime.                                                                                               |
| <i>DatetimeIndex.hour</i>             | The hours of the datetime.                                                                                              |
| <i>DatetimeIndex.minute</i>           | The minutes of the datetime.                                                                                            |
| <i>DatetimeIndex.second</i>           | The seconds of the datetime.                                                                                            |
| <i>DatetimeIndex.microsecond</i>      | The microseconds of the datetime.                                                                                       |
| <i>DatetimeIndex.nanosecond</i>       | The nanoseconds of the datetime.                                                                                        |
| <i>DatetimeIndex.date</i>             | Returns numpy array of python datetime.date objects (namely, the date part of Timestamps without timezone information). |
| <i>DatetimeIndex.time</i>             | Returns numpy array of datetime.time.                                                                                   |
| <i>DatetimeIndex.timetz</i>           | Returns numpy array of datetime.time also containing timezone information.                                              |
| <i>DatetimeIndex.dayofyear</i>        | The ordinal day of the year.                                                                                            |
| <i>DatetimeIndex.weekofyear</i>       | The week ordinal of the year.                                                                                           |
| <i>DatetimeIndex.week</i>             | The week ordinal of the year.                                                                                           |
| <i>DatetimeIndex.dayofweek</i>        | The day of the week with Monday=0, Sunday=6.                                                                            |
| <i>DatetimeIndex.weekday</i>          | The day of the week with Monday=0, Sunday=6.                                                                            |
| <i>DatetimeIndex.quarter</i>          | The quarter of the date.                                                                                                |
| <i>DatetimeIndex.tz</i>               |                                                                                                                         |
| <i>DatetimeIndex.freq</i>             | Return the frequency object if it is set, otherwise None.                                                               |
| <i>DatetimeIndex.freqstr</i>          | Return the frequency object as a string if it is set, otherwise None.                                                   |
| <i>DatetimeIndex.is_month_start</i>   | Indicates whether the date is the first day of the month.                                                               |
| <i>DatetimeIndex.is_month_end</i>     | Indicates whether the date is the last day of the month.                                                                |
| <i>DatetimeIndex.is_quarter_start</i> | Indicator for whether the date is the first day of a quarter.                                                           |
| <i>DatetimeIndex.is_quarter_end</i>   | Indicator for whether the date is the last day of a quarter.                                                            |
| <i>DatetimeIndex.is_year_start</i>    | Indicate whether the date is the first day of a year.                                                                   |
| <i>DatetimeIndex.is_year_end</i>      | Indicate whether the date is the last day of the year.                                                                  |
| <i>DatetimeIndex.is_leap_year</i>     | Boolean indicator if the date belongs to a leap year.                                                                   |
| <i>DatetimeIndex.inferred_freq</i>    | Tryies to return a string representing a frequency guess, generated by infer_freq.                                      |

### pandas.DatetimeIndex.tz

DatetimeIndex.tz

### 35.7.6.3 Selecting

|                                                             |                                                                                       |
|-------------------------------------------------------------|---------------------------------------------------------------------------------------|
| <code>DatetimeIndex.indexer_at_time(time[, asof])</code>    | Returns index locations of index values at particular time of day (e.g.               |
| <code>DatetimeIndex.indexer_between_time(...[, ...])</code> | Return index locations of values between particular times of day (e.g., 9:00-9:30AM). |

---

### pandas.DatetimeIndex.indexer\_at\_time

`DatetimeIndex.indexer_at_time` (*time*, *asof=False*)

Returns index locations of index values at particular time of day (e.g. 9:30AM).

#### Parameters

**time** [datetime.time or string] datetime.time or string in appropriate format (“%H:%M”, “%H%M”, “%I:%M%p”, “%I%M%p”, “%H:%M:%S”, “%H%M%S”, “%I:%M:%S%p”, “%I%M%S%p”).

#### Returns

**values\_at\_time** [array of integers]

#### See also:

`indexer_between_time`, `DataFrame.at_time`

### pandas.DatetimeIndex.indexer\_between\_time

`DatetimeIndex.indexer_between_time` (*start\_time*, *end\_time*, *include\_start=True*, *include\_end=True*)

Return index locations of values between particular times of day (e.g., 9:00-9:30AM).

#### Parameters

**start\_time, end\_time** [datetime.time, str] datetime.time or string in appropriate format (“%H:%M”, “%H%M”, “%I:%M%p”, “%I%M%p”, “%H:%M:%S”, “%H%M%S”, “%I:%M:%S%p”, “%I%M%S%p”).

**include\_start** [boolean, default True]

**include\_end** [boolean, default True]

#### Returns

**values\_between\_time** [array of integers]

#### See also:

`indexer_at_time`, `DataFrame.between_time`

## 35.7.6.4 Time-specific operations

|                                                        |                                                                      |
|--------------------------------------------------------|----------------------------------------------------------------------|
| <code>DatetimeIndex.normalize(*args, **kwargs)</code>  | Convert times to midnight.                                           |
| <code>DatetimeIndex.strftime(*args, **kwargs)</code>   | Convert to Index using specified date_format.                        |
| <code>DatetimeIndex.snap([freq])</code>                | Snap time stamps to nearest occurring frequency                      |
| <code>DatetimeIndex.tz_convert(*args, **kwargs)</code> | Convert tz-aware Datetime Array/Index from one time zone to another. |

---

Continued on next page

Table 196 – continued from previous page

|                                                         |                                                                          |
|---------------------------------------------------------|--------------------------------------------------------------------------|
| <code>DatetimeIndex.tz_localize(*args, **kwargs)</code> | Localize tz-naive Datetime Array/Index to tz-aware Datetime Array/Index. |
| <code>DatetimeIndex.round(*args, **kwargs)</code>       | Perform round operation on the data to the specified <i>freq</i> .       |
| <code>DatetimeIndex.floor(*args, **kwargs)</code>       | Perform floor operation on the data to the specified <i>freq</i> .       |
| <code>DatetimeIndex.ceil(*args, **kwargs)</code>        | Perform ceil operation on the data to the specified <i>freq</i> .        |
| <code>DatetimeIndex.month_name(*args, **kwargs)</code>  | Return the month names of the DateTimeIndex with specified locale.       |
| <code>DatetimeIndex.day_name(*args, **kwargs)</code>    | Return the day names of the DateTimeIndex with specified locale.         |

### 35.7.6.5 Conversion

|                                                              |                                                                                                                               |
|--------------------------------------------------------------|-------------------------------------------------------------------------------------------------------------------------------|
| <code>DatetimeIndex.to_period(*args, **kwargs)</code>        | Cast to PeriodArray/Index at a particular frequency.                                                                          |
| <code>DatetimeIndex.to_perioddelta(*args, **kwargs)</code>   | Calculate TimedeltaArray of difference between index values and index converted to PeriodArray at specified <i>freq</i> .     |
| <code>DatetimeIndex.to_pydatetime(*args, **kwargs)</code>    | Return Datetime Array/Index as object ndarray of date-time.datetime objects                                                   |
| <code>DatetimeIndex.to_series([keep_tz, index, name])</code> | Create a Series with both index and values equal to the index keys useful with map for returning an indexer based on an index |
| <code>DatetimeIndex.to_frame([index, name])</code>           | Create a DataFrame with a column containing the Index.                                                                        |

## 35.7.7 TimedeltaIndex

|                             |                                                                                                                     |
|-----------------------------|---------------------------------------------------------------------------------------------------------------------|
| <code>TimedeltaIndex</code> | Immutable ndarray of timedelta64 data, represented internally as int64, and which can be boxed to timedelta objects |
|-----------------------------|---------------------------------------------------------------------------------------------------------------------|

### 35.7.7.1 pandas.TimedeltaIndex

**class** `pandas.TimedeltaIndex`

Immutable ndarray of timedelta64 data, represented internally as int64, and which can be boxed to timedelta objects

#### Parameters

**data** [array-like (1-dimensional), optional] Optional timedelta-like data to construct index with

**unit** [unit of the arg (D,h,m,s,ms,us,ns) denote the unit, optional] which is an integer/float number

**freq** [string or pandas offset object, optional] One of pandas date offset strings or corresponding objects. The string ‘infer’ can be passed in order to set the frequency of the index as the inferred frequency upon creation

**copy** [bool] Make a copy of input ndarray

**start** [starting value, timedelta-like, optional] If data is None, start is used as the start point in generating regular timedelta data.

Deprecated since version 0.24.0.

**periods** [int, optional, > 0] Number of periods to generate, if generating index. Takes precedence over end argument

Deprecated since version 0.24.0.

**end** [end time, timedelta-like, optional] If periods is none, generated index will extend to first conforming time on or just past end argument

Deprecated since version 0.24.: 0

**closed** [string or None, default None] Make the interval closed with respect to the given frequency to the 'left', 'right', or both sides (None)

Deprecated since version 0.24.: 0

**name** [object] Name to be stored in the index

See also:

**Index** The base pandas Index type.

**Timedelta** Represents a duration between two dates or times.

**DatetimeIndex** Index of datetime64 data.

**PeriodIndex** Index of Period data.

**timedelta\_range** Create a fixed-frequency TimedeltaIndex.

## Notes

To learn more about the frequency strings, please see [this link](#).

Creating a TimedeltaIndex based on *start*, *periods*, and *end* has been deprecated in favor of *timedelta\_range()*.

## Attributes

|                      |                                                                                                                                  |
|----------------------|----------------------------------------------------------------------------------------------------------------------------------|
| <i>days</i>          | Number of days for each element.                                                                                                 |
| <i>seconds</i>       | Number of seconds ( $\geq 0$ and less than 1 day) for each element.                                                              |
| <i>microseconds</i>  | Number of microseconds ( $\geq 0$ and less than 1 second) for each element.                                                      |
| <i>nanoseconds</i>   | Number of nanoseconds ( $\geq 0$ and less than 1 microsecond) for each element.                                                  |
| <i>components</i>    | Return a dataframe of the components (days, hours, minutes, seconds, milliseconds, microseconds, nanoseconds) of the Timedeltas. |
| <i>inferred_freq</i> | Tryies to return a string representing a frequency guess, generated by <i>infer_freq</i> .                                       |

### pandas.TimedeltaIndex.days

TimedeltaIndex.**days**

Number of days for each element.

**pandas.TimedeltaIndex.seconds**`TimedeltaIndex.seconds`Number of seconds ( $\geq 0$  and less than 1 day) for each element.**pandas.TimedeltaIndex.microseconds**`TimedeltaIndex.microseconds`Number of microseconds ( $\geq 0$  and less than 1 second) for each element.**pandas.TimedeltaIndex.nanoseconds**`TimedeltaIndex.nanoseconds`Number of nanoseconds ( $\geq 0$  and less than 1 microsecond) for each element.**pandas.TimedeltaIndex.components**`TimedeltaIndex.components`

Return a dataframe of the components (days, hours, minutes, seconds, milliseconds, microseconds, nanoseconds) of the Timedeltas.

**Returns****a DataFrame****pandas.TimedeltaIndex.inferred\_freq**`TimedeltaIndex.inferred_freq`Tries to return a string representing a frequency guess, generated by `infer_freq`. Returns None if it can't autodetect the frequency.**Methods**

|                                                    |                                                                                                                                           |
|----------------------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------|
| <code>to_pytimedelta(*args, **kwargs)</code>       | Return Timedelta Array/Index as object ndarray of <code>datetime.timedelta</code> objects.                                                |
| <code>to_series([index, name])</code>              | Create a Series with both index and values equal to the index keys useful with <code>map</code> for returning an index based on an index. |
| <code>round(freq[, ambiguous, nonexistent])</code> | Perform round operation on the data to the specified <i>freq</i> .                                                                        |
| <code>floor(freq[, ambiguous, nonexistent])</code> | Perform floor operation on the data to the specified <i>freq</i> .                                                                        |
| <code>ceil(freq[, ambiguous, nonexistent])</code>  | Perform ceil operation on the data to the specified <i>freq</i> .                                                                         |
| <code>to_frame([index, name])</code>               | Create a DataFrame with a column containing the Index.                                                                                    |

### **pandas.TimedeltaIndex.to\_pytimedelta**

`TimedeltaIndex.to_pytimedelta(*args, **kwargs)`

Return Timedelta Array/Index as object ndarray of datetime.timedelta objects.

#### **Returns**

**datetimes** [ndarray]

### **pandas.TimedeltaIndex.to\_series**

`TimedeltaIndex.to_series(index=None, name=None)`

Create a Series with both index and values equal to the index keys useful with map for returning an indexer based on an index.

#### **Parameters**

**index** [Index, optional] index of resulting Series. If None, defaults to original index

**name** [string, optional] name of resulting Series. If None, defaults to name of original index

#### **Returns**

**Series** [dtype will be based on the type of the Index values.]

### **pandas.TimedeltaIndex.round**

`TimedeltaIndex.round(freq, ambiguous='raise', nonexistent='raise')`

Perform round operation on the data to the specified *freq*.

#### **Parameters**

**freq** [str or Offset] The frequency level to round the index to. Must be a fixed frequency like 'S' (second) not 'ME' (month end). See *frequency aliases* for a list of possible *freq* values.

**ambiguous** ['infer', bool-ndarray, 'NaT', default 'raise'] Only relevant for DatetimeIndex:

- 'infer' will attempt to infer fall dst-transition hours based on order
- bool-ndarray where True signifies a DST time, False designates a non-DST time (note that this flag is only applicable for ambiguous times)
- 'NaT' will return NaT where there are ambiguous times
- 'raise' will raise an AmbiguousTimeError if there are ambiguous times

New in version 0.24.0.

**nonexistent** ['shift\_forward', 'shift\_backward', 'NaT', timedelta,]  
default 'raise'

A nonexistent time does not exist in a particular timezone where clocks moved forward due to DST.

- 'shift\_forward' will shift the nonexistent time forward to the closest existing time
- 'shift\_backward' will shift the nonexistent time backward to the closest existing time

- ‘NaT’ will return NaT where there are nonexistent times
- timedelta objects will shift nonexistent times by the timedelta
- ‘raise’ will raise an `NonExistentTimeError` if there are nonexistent times

New in version 0.24.0.

#### Returns

**DatetimeIndex, TimedeltaIndex, or Series** Index of the same type for a `DatetimeIndex` or `TimedeltaIndex`, or a `Series` with the same index for a `Series`.

#### Raises

**ValueError** if the ‘freq’ cannot be converted.

### Examples

#### DatetimeIndex

```
>>> rng = pd.date_range('1/1/2018 11:59:00', periods=3, freq='min')
>>> rng
DatetimeIndex(['2018-01-01 11:59:00', '2018-01-01 12:00:00',
              '2018-01-01 12:01:00'],
              dtype='datetime64[ns]', freq='T')
>>> rng.round("H")
DatetimeIndex(['2018-01-01 12:00:00', '2018-01-01 12:00:00',
              '2018-01-01 12:00:00'],
              dtype='datetime64[ns]', freq=None)
```

#### Series

```
>>> pd.Series(rng).dt.round("H")
0    2018-01-01 12:00:00
1    2018-01-01 12:00:00
2    2018-01-01 12:00:00
dtype: datetime64[ns]
```

### pandas.TimedeltaIndex.floor

`TimedeltaIndex.floor` (*freq*, *ambiguous*=‘raise’, *nonexistent*=‘raise’)

Perform floor operation on the data to the specified *freq*.

#### Parameters

**freq** [str or Offset] The frequency level to floor the index to. Must be a fixed frequency like ‘S’ (second) not ‘ME’ (month end). See *frequency aliases* for a list of possible *freq* values.

**ambiguous** [‘infer’, bool-ndarray, ‘NaT’, default ‘raise’] Only relevant for `DatetimeIndex`:

- ‘infer’ will attempt to infer fall dst-transition hours based on order
- bool-ndarray where True signifies a DST time, False designates a non-DST time (note that this flag is only applicable for ambiguous times)
- ‘NaT’ will return NaT where there are ambiguous times

- ‘raise’ will raise an `AmbiguousTimeError` if there are ambiguous times

New in version 0.24.0.

**nonexistent** [`‘shift_forward’`, `‘shift_backward’`, `‘NaT’`, `timedelta`,]

default ‘raise’

A nonexistent time does not exist in a particular timezone where clocks moved forward due to DST.

- ‘shift\_forward’ will shift the nonexistent time forward to the closest existing time
- ‘shift\_backward’ will shift the nonexistent time backward to the closest existing time
- ‘NaT’ will return `NaT` where there are nonexistent times
- `timedelta` objects will shift nonexistent times by the `timedelta`
- ‘raise’ will raise an `NonExistentTimeError` if there are nonexistent times

New in version 0.24.0.

### Returns

**DatetimeIndex, TimedeltaIndex, or Series** Index of the same type for a `DatetimeIndex` or `TimedeltaIndex`, or a `Series` with the same index for a `Series`.

### Raises

**ValueError** if the ‘freq’ cannot be converted.

## Examples

### DatetimeIndex

```
>>> rng = pd.date_range('1/1/2018 11:59:00', periods=3, freq='min')
>>> rng
DatetimeIndex(['2018-01-01 11:59:00', '2018-01-01 12:00:00',
              '2018-01-01 12:01:00'],
              dtype='datetime64[ns]', freq='T')
>>> rng.floor('H')
DatetimeIndex(['2018-01-01 11:00:00', '2018-01-01 12:00:00',
              '2018-01-01 12:00:00'],
              dtype='datetime64[ns]', freq=None)
```

### Series

```
>>> pd.Series(rng).dt.floor("H")
0    2018-01-01 11:00:00
1    2018-01-01 12:00:00
2    2018-01-01 12:00:00
dtype: datetime64[ns]
```

## pandas.TimedeltaIndex.ceil

`TimedeltaIndex.ceil(freq, ambiguous='raise', nonexistent='raise')`

Perform ceil operation on the data to the specified *freq*.

### Parameters

**freq** [str or Offset] The frequency level to ceil the index to. Must be a fixed frequency like 'S' (second) not 'ME' (month end). See *frequency aliases* for a list of possible *freq* values.

**ambiguous** ['infer', bool-ndarray, 'NaT', default 'raise'] Only relevant for DatetimeIndex:

- 'infer' will attempt to infer fall dst-transition hours based on order
- bool-ndarray where True signifies a DST time, False designates a non-DST time (note that this flag is only applicable for ambiguous times)
- 'NaT' will return NaT where there are ambiguous times
- 'raise' will raise an AmbiguousTimeError if there are ambiguous times

New in version 0.24.0.

**nonexistent** ['shift\_forward', 'shift\_backward', 'NaT', timedelta,]

default 'raise'

A nonexistent time does not exist in a particular timezone where clocks moved forward due to DST.

- 'shift\_forward' will shift the nonexistent time forward to the closest existing time
- 'shift\_backward' will shift the nonexistent time backward to the closest existing time
- 'NaT' will return NaT where there are nonexistent times
- timedelta objects will shift nonexistent times by the timedelta
- 'raise' will raise an NonExistentTimeError if there are nonexistent times

New in version 0.24.0.

### Returns

**DatetimeIndex, TimedeltaIndex, or Series** Index of the same type for a DatetimeIndex or TimedeltaIndex, or a Series with the same index for a Series.

### Raises

**ValueError** if the 'freq' cannot be converted.

## Examples

### DatetimeIndex

```
>>> rng = pd.date_range('1/1/2018 11:59:00', periods=3, freq='min')
>>> rng
DatetimeIndex(['2018-01-01 11:59:00', '2018-01-01 12:00:00',
               '2018-01-01 12:01:00'],
              dtype='datetime64[ns]', freq='T')
>>> rng.ceil('H')
DatetimeIndex(['2018-01-01 12:00:00', '2018-01-01 12:00:00',
               '2018-01-01 13:00:00'],
              dtype='datetime64[ns]', freq=None)
```

### Series

```
>>> pd.Series(rng).dt.ceil("H")
0    2018-01-01 12:00:00
1    2018-01-01 12:00:00
2    2018-01-01 13:00:00
dtype: datetime64[ns]
```

## pandas.TimedeltaIndex.to\_frame

`TimedeltaIndex.to_frame(index=True, name=None)`

Create a DataFrame with a column containing the Index.

New in version 0.24.0.

### Parameters

**index** [boolean, default True] Set the index of the returned DataFrame as the original Index.

**name** [object, default None] The passed name should substitute for the index name (if it has one).

### Returns

**DataFrame** DataFrame containing the original Index data.

See also:

**Index.to\_series** Convert an Index to a Series.

**Series.to\_frame** Convert Series to DataFrame.

## Examples

```
>>> idx = pd.Index(['Ant', 'Bear', 'Cow'], name='animal')
>>> idx.to_frame()
      animal
animal
Ant      Ant
Bear    Bear
Cow     Cow
```

By default, the original Index is reused. To enforce a new Index:

```
>>> idx.to_frame(index=False)
      animal
0      Ant
1     Bear
2      Cow
```

To override the name of the resulting column, specify *name*:

```
>>> idx.to_frame(index=False, name='zoo')
      zoo
0      Ant
1     Bear
2      Cow
```

### 35.7.7.2 Components

|                                           |                                                                                                                                  |
|-------------------------------------------|----------------------------------------------------------------------------------------------------------------------------------|
| <code>TimedeltaIndex.days</code>          | Number of days for each element.                                                                                                 |
| <code>TimedeltaIndex.seconds</code>       | Number of seconds ( $\geq 0$ and less than 1 day) for each element.                                                              |
| <code>TimedeltaIndex.microseconds</code>  | Number of microseconds ( $\geq 0$ and less than 1 second) for each element.                                                      |
| <code>TimedeltaIndex.nanoseconds</code>   | Number of nanoseconds ( $\geq 0$ and less than 1 microsecond) for each element.                                                  |
| <code>TimedeltaIndex.components</code>    | Return a dataframe of the components (days, hours, minutes, seconds, milliseconds, microseconds, nanoseconds) of the Timedeltas. |
| <code>TimedeltaIndex.inferred_freq</code> | Tryies to return a string representing a frequency guess, generated by <code>infer_freq</code> .                                 |

### 35.7.7.3 Conversion

|                                                             |                                                                                                                                |
|-------------------------------------------------------------|--------------------------------------------------------------------------------------------------------------------------------|
| <code>TimedeltaIndex.to_pytimedelta(*args, **kwargs)</code> | Return Timedelta Array/Index as object ndarray of date-time.timedelta objects.                                                 |
