Zippered HTML

Date: Jan 11, 2019 **Version:** 0.24.0rc1

Binary Installers: <https://pypi.org/project/pandas>

Source Repository: <https://github.com/pandas-dev/pandas>

Issues & Ideas: <https://github.com/pandas-dev/pandas/issues>

Q&A Support: <https://stackoverflow.com/questions/tagged/pandas>

Developer Mailing List: <https://groups.google.com/forum/#!forum/pydata>

pandas is a **Python** package providing fast, flexible, and expressive data structures designed to make working with “relational” or “labeled” data both easy and intuitive. It aims to be the fundamental high-level building block for doing practical, **real world** data analysis in Python. Additionally, it has the broader goal of becoming **the most powerful and flexible open source data analysis / manipulation tool available in any language**. It is already well on its way toward this goal.

pandas is well suited for many different kinds of data:

- Tabular data with heterogeneously-typed columns, as in an SQL table or Excel spreadsheet
- Ordered and unordered (not necessarily fixed-frequency) time series data.
- Arbitrary matrix data (homogeneously typed or heterogeneous) with row and column labels
- Any other form of observational / statistical data sets. The data actually need not be labeled at all to be placed into a pandas data structure

The two primary data structures of pandas, *Series* (1-dimensional) and *DataFrame* (2-dimensional), handle the vast majority of typical use cases in finance, statistics, social science, and many areas of engineering. For R users, *DataFrame* provides everything that R’s *data.frame* provides and much more. pandas is built on top of **NumPy** and is intended to integrate well within a scientific computing environment with many other 3rd party libraries.

Here are just a few of the things that pandas does well:

- Easy handling of **missing data** (represented as NaN) in floating point as well as non-floating point data
- Size mutability: columns can be **inserted and deleted** from *DataFrame* and higher dimensional objects
- Automatic and explicit **data alignment**: objects can be explicitly aligned to a set of labels, or the user can simply ignore the labels and let *Series*, *DataFrame*, etc. automatically align the data for you in computations
- Powerful, flexible **group by** functionality to perform split-apply-combine operations on data sets, for both aggregating and transforming data
- Make it **easy to convert** ragged, differently-indexed data in other Python and NumPy data structures into *DataFrame* objects
- Intelligent label-based **slicing, fancy indexing, and subsetting** of large data sets
- Intuitive **merging** and **joining** data sets
- Flexible **reshaping** and pivoting of data sets
- **Hierarchical** labeling of axes (possible to have multiple labels per tick)
- Robust IO tools for loading data from **flat files** (CSV and delimited), Excel files, databases, and saving / loading data from the ultrafast **HDF5 format**
- **Time series**-specific functionality: date range generation and frequency conversion, moving window statistics, moving window linear regressions, date shifting and lagging, etc.

Many of these principles are here to address the shortcomings frequently experienced using other languages / scientific research environments. For data scientists, working with data is typically divided into multiple stages: munging and cleaning data, analyzing / modeling it, then organizing the results of the analysis into a form suitable for plotting or tabular display. pandas is the ideal tool for all of these tasks.

Some other notes

- pandas is **fast**. Many of the low-level algorithmic bits have been extensively tweaked in [Cython](#) code. However, as with anything else generalization usually sacrifices performance. So if you focus on one feature for your application you may be able to create a faster specialized tool.
- pandas is a dependency of [statsmodels](#), making it an important part of the statistical computing ecosystem in Python.
- pandas has been used extensively in production in financial applications.

Note: This documentation assumes general familiarity with NumPy. If you haven't used NumPy much or at all, do invest some time in [learning about NumPy](#) first.

See the package overview for more detail about what's in the library.

WHAT'S NEW IN 0.24.0 (JANUARY XX, 2019)

Warning: The 0.24.x series of releases will be the last to support Python 2. Future feature releases will support Python 3 only. See *Plan for dropping Python 2.7* for more.

{{ header }}

These are the changes in pandas 0.24.0. See release for a full changelog including other versions of pandas.

1.1 New features

- `merge()` now directly allows merge between objects of type `DataFrame` and named `Series`, without the need to convert the `Series` object into a `DataFrame` beforehand ([GH21220](#))
- `ExcelWriter` now accepts `mode` as a keyword argument, enabling append to existing workbooks when using the `openpyxl` engine ([GH3441](#))
- `FrozenList` has gained the `.union()` and `.difference()` methods. This functionality greatly simplifies groupby's that rely on explicitly excluding certain columns. See *Splitting an object into groups* for more information ([GH15475](#), [GH15506](#)).
- `DataFrame.to_parquet()` now accepts `index` as an argument, allowing the user to override the engine's default behavior to include or omit the dataframe's indexes from the resulting Parquet file. ([GH20768](#))
- `DataFrame.corr()` and `Series.corr()` now accept a callable for generic calculation methods of correlation, e.g. histogram intersection ([GH22684](#))
- `DataFrame.to_string()` now accepts `decimal` as an argument, allowing the user to specify which decimal separator should be used in the output. ([GH23614](#))
- `read_feather()` now accepts `columns` as an argument, allowing the user to specify which columns should be read. ([GH24025](#))
- `DataFrame.to_html()` now accepts `render_links` as an argument, allowing the user to generate HTML with links to any URLs that appear in the `DataFrame`. See the *section on writing HTML* in the IO docs for example usage. ([GH2679](#))
- `pandas.read_csv()` now supports pandas extension types as an argument to `dtype`, allowing the user to use pandas extension types when reading CSVs. ([GH23228](#))
- `DataFrame.shift()`, `Series.shift()`, `ExtensionArray.shift()`, `SparseArray.shift()`, `Period.shift()`, `GroupBy.shift()`, `Categorical.shift()`, `NDFrame.shift()` and `Block.shift()` now accept `fill_value` as an argument, allowing the user to specify a value which will be used instead of NA/NaT in the empty periods. ([GH15486](#))

1.1.1 Accessing the values in a Series or Index

`Series.array` and `Index.array` have been added for extracting the array backing a `Series` or `Index`. ([GH19954](#), [GH23623](#))

```
In [1]: idx = pd.period_range('2000', periods=4)

In [2]: idx.array
Out[2]:
<PeriodArray>
['2000-01-01', '2000-01-02', '2000-01-03', '2000-01-04']
Length: 4, dtype: period[D]

In [3]: pd.Series(idx).array
////////////////////////////////////
↪
<PeriodArray>
['2000-01-01', '2000-01-02', '2000-01-03', '2000-01-04']
Length: 4, dtype: period[D]
```

Historically, this would have been done with `series.values`, but with `.values` it was unclear whether the returned value would be the actual array, some transformation of it, or one of pandas custom arrays (like `Categorical`). For example, with `PeriodIndex`, `.values` generates a new ndarray of period objects each time.

[illegible]

If you need an actual NumPy array, use `Series.to_numpy()` or `Index.to_numpy()`.

[illegible]

For Series and Indexes backed by normal NumPy arrays, `Series.array` will return a new `arrays.PandasArray`, which is a thin (no-copy) wrapper around a `numpy.ndarray`. `arrays.PandasArray` isn't especially useful on its own, but it does provide the same interface as any extension array defined in pandas or by a third-party library.

```
In [8]: ser = pd.Series([1, 2, 3])

In [9]: ser.array
Out[9]:
<PandasArray>
[1, 2, 3]
Length: 3, dtype: int64
```

(continues on next page)

(continued from previous page)

```
In [10]: ser.to_numpy()
Out[10]: array([1, 2, 3])
```

We haven't removed or deprecated `Series.values` or `DataFrame.values`, but we highly recommend and using `.array` or `.to_numpy()` instead.

See *Dtypes* and *Attributes and Underlying Data* for more.

1.1.2 ExtensionArray operator support

A `Series` based on an `ExtensionArray` now supports arithmetic and comparison operators ([GH19577](#)). There are two approaches for providing operator support for an `ExtensionArray`:

1. Define each of the operators on your `ExtensionArray` subclass.
2. Use an operator implementation from pandas that depends on operators that are already defined on the underlying elements (scalars) of the `ExtensionArray`.

See the *ExtensionArray Operator Support* documentation section for details on both ways of adding operator support.

1.1.3 Optional Integer NA Support

Pandas has gained the ability to hold integer dtypes with missing values. This long requested feature is enabled through the use of *extension types*. Here is an example of the usage.

We can construct a `Series` with the specified dtype. The dtype string `Int64` is a pandas `ExtensionDtype`. Specifying a list or array using the traditional missing value marker of `np.nan` will infer to integer dtype. The display of the `Series` will also use the `NaN` to indicate missing values in string outputs. ([GH20700](#), [GH20747](#), [GH22441](#), [GH21789](#), [GH22346](#))

```
In [11]: s = pd.Series([1, 2, np.nan], dtype='Int64')
In [12]: s
Out[12]:
0      1
1      2
2     NaN
Length: 3, dtype: Int64
```

Operations on these dtypes will propagate `NaN` as other pandas operations.

```
# arithmetic
In [13]: s + 1
Out[13]:
0      2
1      3
2     NaN
Length: 3, dtype: Int64

# comparison
In [14]: s == 1
Out[14]:
0      True
1     False
2     False
```

(continues on next page)

(continued from previous page)

```
In [22]: df['A'].astype(float)
Out[22]:
0    1.0
1    2.0
2    NaN
Name: A, Length: 3, dtype: float64
```

Reduction and groupby operations such as ‘sum’ work.

```
In [23]: df.sum()
Out[23]:
A    3
B    5
C    aab
Length: 3, dtype: object

In [24]: df.groupby('B').A.sum()
Out[24]:
B
1    3
3    0
Name: A, Length: 2, dtype: Int64
```

Warning: The Integer NA support currently uses the capitalized dtype version, e.g. `Int8` as compared to the traditional `int8`. This may be changed at a future date.

See *Nullable Integer Data Type* for more.

1.1.4 Array

A new top-level method `array()` has been added for creating 1-dimensional arrays ([GH22860](#)). This can be used to create any *extension array*, including extension arrays registered by *3rd party libraries*. See

See *Dtypes* for more on extension arrays.

```
In [25]: pd.array([1, 2, np.nan], dtype='Int64')
Out[25]:
<IntegerArray>
[1, 2, NaN]
Length: 3, dtype: Int64

In [26]: pd.array(['a', 'b', 'c'], dtype='category')
Out[26]:
[a, b, c]
Categories (3, object): [a, b, c]
```

Passing data for which there isn’t dedicated extension type (e.g. `float`, `integer`, etc.) will return a new `arrays`. `PandasArray`, which is just a thin (no-copy) wrapper around a `numpy.ndarray` that satisfies the extension array interface.

```
In [27]: pd.array([1, 2, 3])
Out[27]:
```

(continues on next page)

(continued from previous page)

```
<PandasArray>
[1, 2, 3]
Length: 3, dtype: int64
```

On their own, a `arrays.PandasArray` isn't a very useful object. But if you need write low-level code that works generically for any `ExtensionArray`, `arrays.PandasArray` satisfies that need.

Notice that by default, if no `dtype` is specified, the `dtype` of the returned array is inferred from the data. In particular, note that the first example of `[1, 2, np.nan]` would have returned a floating-point array, since `NaN` is a float.

```
In [28]: pd.array([1, 2, np.nan])
Out[28]:
<PandasArray>
[1.0, 2.0, nan]
Length: 3, dtype: float64
```

1.1.5 `read_html` Enhancements

`read_html()` previously ignored `colspan` and `rowspan` attributes. Now it understands them, treating them as sequences of cells with the same value. (GH17054)

```
In [29]: result = pd.read_html("""
....:     <table>
....:         <thead>
....:             <tr>
....:                 <th>A</th><th>B</th><th>C</th>
....:             </tr>
....:         </thead>
....:         <tbody>
....:             <tr>
....:                 <td colspan="2">1</td><td>2</td>
....:             </tr>
....:         </tbody>
....:     </table>""")
....:
```

Previous Behavior:

```
In [13]: result
Out [13]:
[   A  B  C
 0  1  2 NaN]
```

New Behavior:

```
In [30]: result
Out[30]:
[   A  B  C
 0  1  1  2

[1 rows x 3 columns]]
```

Warning: For backwards compatibility, `Series.values` continues to return a NumPy array of objects for Interval and Period data. We recommend using `Series.array` when you need the array of data stored in the Series, and `Series.to_numpy()` when you know you need a NumPy array.

See *Dtypes* and *Attributes and Underlying Data* for more.

1.1.7 New `Styler.pipe()` method

The `Styler` class has gained a `pipe()` method. This provides a convenient way to apply users' predefined styling functions, and can help reduce "boilerplate" when using `DataFrame` styling functionality repeatedly within a notebook. (GH23229)

```
In [39]: df = pd.DataFrame({'N': [1250, 1500, 1750], 'X': [0.25, 0.35, 0.50]})

In [40]: def format_and_align(styler):
.....:     return (styler.format({'N': '{:,}', 'X': '{:.1%}'})
.....:             .set_properties(**{'text-align': 'right'}))
.....:

In [41]: df.style.pipe(format_and_align).set_caption('Summary of results.')
Out[41]: <pandas.io.formats.style.Styler at 0x7fd50a048be0>
```

Similar methods already exist for other classes in pandas, including `DataFrame.pipe()`, `pandas.core.groupby.GroupBy.pipe()`, and `pandas.core.resample.Resampler.pipe()`.

1.1.8 Joining with two multi-indexes

`DataFrame.merge()` and `DataFrame.join()` can now be used to join multi-indexed `Dataframe` instances on the overlapping index levels (GH6360)

See the *Merge, join, and concatenate* documentation section.

```
In [42]: index_left = pd.MultiIndex.from_tuples([('K0', 'X0'), ('K0', 'X1'),
.....:                                         ('K1', 'X2')],
.....:                                         names=['key', 'X'])

In [43]: left = pd.DataFrame({'A': ['A0', 'A1', 'A2'],
.....:                       'B': ['B0', 'B1', 'B2']}, index=index_left)
.....:

In [44]: index_right = pd.MultiIndex.from_tuples([('K0', 'Y0'), ('K1', 'Y1'),
.....:                                         ('K2', 'Y2'), ('K2', 'Y3')],
.....:                                         names=['key', 'Y'])

In [45]: right = pd.DataFrame({'C': ['C0', 'C1', 'C2', 'C3'],
.....:                       'D': ['D0', 'D1', 'D2', 'D3']}, index=index_right)
.....:

In [46]: left.join(right)
Out[46]:
      A  B  C  D
key X  Y
```

(continues on next page)

```
K0  X0 Y0  A0  B0  C0  D0
     X1 Y0  A1  B1  C0  D0
K1  X2 Y1  A2  B2  C1  D1

[3 rows x 4 columns]
```

```
In [47]: pd.merge(left.reset_index(), right.reset_index(),
.....:              on=['key'], how='inner').set_index(['key', 'X', 'Y'])
.....:

Out[47]:
```

			A	B	C	D
key	X	Y				
K0	X0	Y0	A0	B0	C0	D0
	X1	Y0	A1	B1	C0	D0
K1	X2	Y1	A2	B2	C1	D1

```
[3 rows x 4 columns]
```

```
In [48]: mi = pd.MultiIndex.from_product([list('AB'), list('CD'), list('EF')],
.....:                                  names=['AB', 'CD', 'EF'])
.....:

In [49]: df = pd.DataFrame([i for i in range(len(mi))], index=mi, columns=['N'])

In [50]: df
Out[50]:
```

			N
AB	CD	EF	
A	C	E	0
		F	1
	D	E	2
		F	3
B	C	E	4
		F	5
	D	E	6
		F	7

```
[8 rows x 1 columns]

In [51]: df.rename_axis(index={'CD': 'New'})
//////////
↪
```

			N
AB	New	EF	

(continued from previous page)

```

A  C    E    0
   F    1
   D    E    2
   F    3
B  C    E    4
   F    5
   D    E    6
   F    7

[8 rows x 1 columns]
```

See the *Advanced documentation on renaming* for more details.

1.1.10 Other Enhancements

- `to_datetime()` now supports the `%Z` and `%z` directive when passed into `format` ([GH13486](#))
- `Series.mode()` and `DataFrame.mode()` now support the `dropna` parameter which can be used to specify whether NaN/NaT values should be considered ([GH17534](#))
- `DataFrame.to_csv()` and `Series.to_csv()` now support the `compression` keyword when a file handle is passed. ([GH21227](#))
- `Index.droplevel()` is now implemented also for flat indexes, for compatibility with `MultiIndex` ([GH21115](#))
- `Series.droplevel()` and `DataFrame.droplevel()` are now implemented ([GH20342](#))
- Added support for reading from/writing to Google Cloud Storage via the `gcsfs` library ([GH19454](#), [GH23094](#))
- `DataFrame.to_gbq()` and `read_gbq()` signature and documentation updated to reflect changes from the [Pandas-GBQ library version 0.8.0](#). Adds a `credentials` argument, which enables the use of any kind of [google-auth credentials](#). ([GH21627](#), [GH22557](#), [GH23662](#))
- New method `HDFStore.walk()` will recursively walk the group hierarchy of an HDF5 file ([GH10932](#))
- `read_html()` copies cell data across `colspan` and `rowspan`, and it treats all-th table rows as headers if `header` kwarg is not given and there is no `thead` ([GH17054](#))
- `Series.nlargest()`, `Series.nsmallest()`, `DataFrame.nlargest()`, and `DataFrame.nsmallest()` now accept the value `"all"` for the `keep` argument. This keeps all ties for the `nth` largest/smallest value ([GH16818](#))
- `IntervalIndex` has gained the `set_closed()` method to change the existing `closed` value ([GH21670](#))
- `to_csv()`, `to_csv()`, `to_json()`, and `to_json()` now support `compression='infer'` to infer compression based on filename extension ([GH15008](#)). The default compression for `to_csv`, `to_json`, and `to_pickle` methods has been updated to `'infer'` ([GH22004](#)).
- `DataFrame.to_sql()` now supports writing `TIMESTAMP WITH TIME ZONE` types for supported databases. For databases that don't support timezones, datetime data will be stored as timezone unaware local timestamps. See the *Datetime data types* for implications ([GH9086](#)).
- `to_timedelta()` now supports iso-formatted timedelta strings ([GH21877](#))
- `Series` and `DataFrame` now support `Iterable` in constructor ([GH2193](#))
- `DatetimeIndex` has gained the `DatetimeIndex.timestz` attribute. This returns the local time with timezone information. ([GH21358](#))

- `Timestamp.round()`, `Timestamp.ceil()`, and `Timestamp.floor()` for `DatetimeIndex` and `Timestamp` now support an ambiguous argument for handling datetimes that are rounded to ambiguous times ([GH18946](#))
- `Timestamp.round()`, `Timestamp.ceil()`, and `Timestamp.floor()` for `DatetimeIndex` and `Timestamp` now support a nonexistent argument for handling datetimes that are rounded to nonexistent times. See *Nonexistent Times when Localizing* ([GH22647](#))
- `pandas.core.resample.Resampler` now is iterable like `pandas.core.groupby.GroupBy` ([GH15314](#)).
- `Series.resample()` and `DataFrame.resample()` have gained the `pandas.core.resample.Resampler.quantile()` ([GH15023](#)).
- `DataFrame.resample()` and `Series.resample()` with a `PeriodIndex` will now respect the base argument in the same fashion as with a `DatetimeIndex`. ([GH23882](#))
- `pandas.api.types.is_list_like()` has gained a keyword `allow_sets` which is `True` by default; if `False`, all instances of `set` will not be considered “list-like” anymore ([GH23061](#))
- `Index.to_frame()` now supports overriding column name(s) ([GH22580](#)).
- `Categorical.from_codes()` now can take a `dtype` parameter as an alternative to passing categories and ordered ([GH24398](#)).
- New attribute `__git_version__` will return git commit sha of current build ([GH21295](#)).
- Compatibility with Matplotlib 3.0 ([GH22790](#)).
- Added `Interval.overlaps()`, `IntervalArray.overlaps()`, and `IntervalIndex.overlaps()` for determining overlaps between interval-like objects ([GH21998](#))
- `read_fwf()` now accepts keyword `infer_nrows` ([GH15138](#)).
- `to_parquet()` now supports writing a `DataFrame` as a directory of parquet files partitioned by a subset of the columns when `engine = 'pyarrow'` ([GH23283](#))
- `Timestamp.tz_localize()`, `DatetimeIndex.tz_localize()`, and `Series.tz_localize()` have gained the nonexistent argument for alternative handling of nonexistent times. See *Nonexistent Times when Localizing* ([GH8917](#), [GH24466](#))
- `Index.difference()` now has an optional `sort` parameter to specify whether the results should be sorted if possible ([GH17839](#))
- `read_excel()` now accepts `usecols` as a list of column names or callable ([GH18273](#))
- `MultiIndex.to_flat_index()` has been added to flatten multiple levels into a single-level `Index` object.
- `DataFrame.to_stata()` and `pandas.io.stata.StataWriter` can write mixed sting columns to Stata `strl` format ([GH23633](#))
- `DataFrame.between_time()` and `DataFrame.at_time()` have gained the `axis` parameter ([GH8839](#))
- The `scatter_matrix`, `andrews_curves`, `parallel_coordinates`, `lag_plot`, `autocorrelation_plot`, `bootstrap_plot`, and `radviz` plots from the `pandas.plotting` module are now accessible from calling `DataFrame.plot()` ([GH11978](#))
- `DataFrame.to_records()` now accepts `index_dtypes` and `column_dtypes` parameters to allow different data types in stored column and index records ([GH18146](#))
- `IntervalIndex` has gained the `is_overlapping` attribute to indicate if the `IntervalIndex` contains any overlapping intervals ([GH23309](#))

- `pandas.DataFrame.to_sql()` has gained the `method` argument to control SQL insertion clause. See the *insertion method* section in the documentation. (GH8953)
- `DataFrame.corrwith()` now supports Spearman's rank correlation, Kendall's tau as well as callable correlation methods. (GH21925)
- `DataFrame.to_json()`, `DataFrame.to_csv()`, `DataFrame.to_pickle()`, and `DataFrame.to_XXX()` etc. now support tilde(~) in path argument. (GH23473)

1.2 Backwards incompatible API changes

- A newly constructed empty `DataFrame` with integer as the dtype will now only be cast to float64 if index is specified (GH22858)
- `Series.str.cat()` will now raise if others is a set (GH23009)
- Passing scalar values to `DatetimeIndex` or `TimedeltaIndex` will now raise `TypeError` instead of `ValueError` (GH23539)
- `max_rows` and `max_cols` parameters removed from `HTMLFormatter` since truncation is handled by `DataFrameFormatter` (GH23818)
- `read_csv()` will now raise a `ValueError` if a column with missing values is declared as having dtype `bool` (GH20591)
- The column order of the resultant `DataFrame` from `MultiIndex.to_frame()` is now guaranteed to match the `MultiIndex.names` order. (GH22420)
- Incorrectly passing a `DatetimeIndex` to `MultiIndex.from_tuples()`, rather than a sequence of tuples, now raises a `TypeError` rather than a `ValueError` (GH24024)
- `pd.offsets.generate_range()` argument `time_rule` has been removed; use `offset` instead (GH24157)
- In 0.23.x, pandas would raise a `ValueError` on a merge of a numeric column (e.g. `int` dtyped column) and an object dtyped column (GH9780). We have re-enabled the ability to merge object and other dtypes; pandas will still raise on a merge between a numeric and an object dtyped column that is composed only of strings (GH21681)

1.2.1 Percentage change on groupby

Fixed a bug where calling `pandas.core.groupby.SeriesGroupBy.pct_change()` or `pandas.core.groupby.DataFrameGroupBy.pct_change()` would previously work across groups when calculating the percent change, where it now correctly works per group (GH21200, GH21235).

```
In [52]: df = pd.DataFrame({'grp': ['a', 'a', 'b'], 'foo': [1.0, 1.1, 2.2]})

In [53]: df
Out[53]:
```

	grp	foo
0	a	1.0
1	a	1.1
2	b	2.2

```
[3 rows x 2 columns]
```

Previous behavior:

```
In [1]: df.groupby('grp').pct_change()
Out[1]:
      foo
0   NaN
1   0.1
2   1.0
```

New behavior:

```
In [54]: df.groupby('grp').pct_change()
Out[54]:
      foo
0   NaN
1   0.1
2   NaN

[3 rows x 1 columns]
```

1.2.2 Dependencies have increased minimum versions

We have updated our minimum supported versions of dependencies ([GH21242](#), [GH18742](#), [GH23774](#)). If installed, we now require:

Package	Minimum Version	Required
numpy	1.12.0	X
bottleneck	1.2.0	
fastparquet	0.2.1	
matplotlib	2.0.0	
numexpr	2.6.1	
pandas-gbq	0.8.0	
pyarrow	0.7.0	
pytables	3.4.2	
scipy	0.18.1	
xlrd	1.0.0	
pytest (dev)	3.6	

Additionally we no longer depend on `feather-format` for feather based storage and replaced it with references to `pyarrow` ([GH21639](#) and [GH23053](#)).

1.2.3 `os.linesep` is used for `line_terminator` of `DataFrame.to_csv`

`DataFrame.to_csv()` now uses `os.linesep()` rather than `'\n'` for the default line terminator ([GH20353](#)). This change only affects when running on Windows, where `'\r\n'` was used for line terminator even when `'\n'` was passed in `line_terminator`.

Previous Behavior on Windows:

```
In [1]: data = pd.DataFrame({"string_with_lf": ["a\nbc"],
...:                        "string_with_crlf": ["a\r\nbc"]})

In [2]: # When passing file PATH to to_csv,
...: # line_terminator does not work, and csv is saved with '\r\n'.
```

(continues on next page)

(continued from previous page)

```

...: # Also, this converts all '\n's in the data to '\r\n'.
...: data.to_csv("test.csv", index=False, line_terminator='\n')

In [3]: with open("test.csv", mode='rb') as f:
...:     print(f.read())
Out[3]: b'string_with_lf,string_with_crlf\r\n"a\r\nbc","a\r\nbc"\r\n'

In [4]: # When passing file OBJECT with newline option to
...: # to_csv, line_terminator works.
...: with open("test2.csv", mode='w', newline='\n') as f:
...:     data.to_csv(f, index=False, line_terminator='\n')

In [5]: with open("test2.csv", mode='rb') as f:
...:     print(f.read())
Out[5]: b'string_with_lf,string_with_crlf\n"a\nbc","a\r\nbc"\n'

```

New Behavior on Windows:

Passing `line_terminator` explicitly, set the line terminator to that character.

```

In [1]: data = pd.DataFrame({"string_with_lf": ["a\nbc"],
...:                        "string_with_crlf": ["a\r\nbc"]})

In [2]: data.to_csv("test.csv", index=False, line_terminator='\n')

In [3]: with open("test.csv", mode='rb') as f:
...:     print(f.read())
Out[3]: b'string_with_lf,string_with_crlf\n"a\nbc","a\r\nbc"\n'

```

On Windows, the value of `os.linesep` is `'\r\n'`, so if `line_terminator` is not set, `'\r\n'` is used for line terminator.

```

In [1]: data = pd.DataFrame({"string_with_lf": ["a\nbc"],
...:                        "string_with_crlf": ["a\r\nbc"]})

In [2]: data.to_csv("test.csv", index=False)

In [3]: with open("test.csv", mode='rb') as f:
...:     print(f.read())
Out[3]: b'string_with_lf,string_with_crlf\r\n"a\nbc","a\r\nbc"\r\n'

```

For file objects, specifying `newline` is not sufficient to set the line terminator. You must pass in the `line_terminator` explicitly, even in this case.

```

In [1]: data = pd.DataFrame({"string_with_lf": ["a\nbc"],
...:                        "string_with_crlf": ["a\r\nbc"]})

In [2]: with open("test2.csv", mode='w', newline='\n') as f:
...:     data.to_csv(f, index=False)

In [3]: with open("test2.csv", mode='rb') as f:
...:     print(f.read())
Out[3]: b'string_with_lf,string_with_crlf\r\n"a\nbc","a\r\nbc"\r\n'

```

1.2.4 Proper handling of *np.NaN* in a string data-typed column with the Python engine

There was bug in `read_excel()` and `read_csv()` with the Python engine, where missing values turned to 'nan' with `dtype=str` and `na_filter=True`. Now, these missing values are converted to the string missing indicator, `np.nan`. (GH20377)

Previous Behavior:

```
In [5]: data = 'a,b,c\n1,,3\n4,5,6'
In [6]: df = pd.read_csv(StringIO(data), engine='python', dtype=str, na_filter=True)
In [7]: df.loc[0, 'b']
Out[7]:
'nan'
```

New Behavior:

```
In [55]: data = 'a,b,c\n1,,3\n4,5,6'

In [56]: df = pd.read_csv(StringIO(data), engine='python', dtype=str, na_filter=True)

In [57]: df.loc[0, 'b']
Out[57]: nan
```

Notice how we now instead output `np.nan` itself instead of a stringified form of it.

1.2.5 Parsing Datetime Strings with Timezone Offsets

Previously, parsing datetime strings with UTC offsets with `to_datetime()` or `DatetimeIndex` would automatically convert the datetime to UTC without timezone localization. This is inconsistent from parsing the same datetime string with `Timestamp` which would preserve the UTC offset in the `tz` attribute. Now, `to_datetime()` preserves the UTC offset in the `tz` attribute when all the datetime strings have the same UTC offset (GH17697, GH11736, GH22457)

Previous Behavior:

```
In [2]: pd.to_datetime("2015-11-18 15:30:00+05:30")
Out[2]: Timestamp('2015-11-18 10:00:00')

In [3]: pd.Timestamp("2015-11-18 15:30:00+05:30")
Out[3]: Timestamp('2015-11-18 15:30:00+0530', tz='pytz.FixedOffset(330)')

# Different UTC offsets would automatically convert the datetimes to UTC (without a_
↳UTC timezone)
In [4]: pd.to_datetime(["2015-11-18 15:30:00+05:30", "2015-11-18 16:30:00+06:30"])
Out[4]: DatetimeIndex(['2015-11-18 10:00:00', '2015-11-18 10:00:00'], dtype=
↳'datetime64[ns]', freq=None)
```

New Behavior:

```
In [58]: pd.to_datetime("2015-11-18 15:30:00+05:30")
Out[58]: Timestamp('2015-11-18 15:30:00+0530', tz='pytz.FixedOffset(330)')

In [59]: pd.Timestamp("2015-11-18 15:30:00+05:30")
Out[59]: Timestamp('2015-11-18 15:30:00+0530', tz='pytz.FixedOffset(330)')
```

Parsing datetime strings with the same UTC offset will preserve the UTC offset in the `tz`

```
In [60]: pd.to_datetime(["2015-11-18 15:30:00+05:30"] * 2)
Out [60]: DatetimeIndex(['2015-11-18 15:30:00+05:30', '2015-11-18 15:30:00+05:30'],
↳dtype='datetime64[ns, pytz.FixedOffset(330)]', freq=None)
```

Parsing datetime strings with different UTC offsets will now create an Index of `datetime.datetime` objects with different UTC offsets

```
In [61]: idx = pd.to_datetime(["2015-11-18 15:30:00+05:30",
.....:                        "2015-11-18 16:30:00+06:30"])
.....:

In [62]: idx
Out [62]: Index([2015-11-18 15:30:00+05:30, 2015-11-18 16:30:00+06:30], dtype='object')

In [63]: idx[0]
Out [63]:
↳datetime.datetime(2015, 11, 18, 15, 30, tzinfo=tzoffset(None, 19800))

In [64]: idx[1]
↳datetime.datetime(2015, 11, 18, 16, 30, tzinfo=tzoffset(None, 23400))
```

Passing `utc=True` will mimic the previous behavior but will correctly indicate that the dates have been converted to UTC

```
In [65]: pd.to_datetime(["2015-11-18 15:30:00+05:30",
.....:                  "2015-11-18 16:30:00+06:30"], utc=True)
.....:
Out [65]: DatetimeIndex(['2015-11-18 10:00:00+00:00', '2015-11-18 10:00:00+00:00'],
↳dtype='datetime64[ns, UTC]', freq=None)
```

1.2.6 Time values in `dt.end_time` and `to_timestamp(how='end')`

The time values in `Period` and `PeriodIndex` objects are now set to `'23:59:59.999999999'` when calling `Series.dt.end_time`, `Period.end_time`, `PeriodIndex.end_time`, `Period.to_timestamp()` with `how='end'`, or `PeriodIndex.to_timestamp()` with `how='end'` ([GH17157](#))

Previous Behavior:

```
In [2]: p = pd.Period('2017-01-01', 'D')
In [3]: pi = pd.PeriodIndex([p])

In [4]: pd.Series(pi).dt.end_time[0]
Out [4]: Timestamp(2017-01-01 00:00:00)

In [5]: p.end_time
Out [5]: Timestamp(2017-01-01 23:59:59.999999999)
```

New Behavior:

Calling `Series.dt.end_time` will now result in a time of `'23:59:59.999999999'` as is the case with `Period.end_time`, for example

```
In [66]: p = pd.Period('2017-01-01', 'D')

In [67]: pi = pd.PeriodIndex([p])

In [68]: pd.Series(pi).dt.end_time[0]
Out[68]: Timestamp('2017-01-01 23:59:59.999999999')

In [69]: p.end_time
Out[69]: Timestamp('2017-01-01 23:59:59.999999999')
```

1.2.7 Datetime w/tz and unique

The return type of `Series.unique()` for datetime with timezone values has changed from an `numpy.ndarray` of `Timestamp` objects to a `arrays.DatetimeArray` ([GH24024](#)).

```
In [70]: ser = pd.Series([pd.Timestamp('2000', tz='UTC'),
.....:                    pd.Timestamp('2000', tz='UTC')])
.....:
```

Previous Behavior:

```
In [3]: ser.unique()
Out[3]: array([Timestamp('2000-01-01 00:00:00+0000', tz='UTC')], dtype=object)
```

New Behavior:

```
In [71]: ser.unique()
Out[71]:
<DatetimeArray>
['2000-01-01 00:00:00+00:00']
Length: 1, dtype: datetime64[ns, UTC]
```

1.2.8 Sparse Data Structure Refactor

`SparseArray`, the array backing `SparseSeries` and the columns in a `SparseDataFrame`, is now an extension array ([GH21978](#), [GH19056](#), [GH22835](#)). To conform to this interface and for consistency with the rest of pandas, some API breaking changes were made:

- `SparseArray` is no longer a subclass of `numpy.ndarray`. To convert a `SparseArray` to a NumPy array, use `numpy.asarray()`.
- `SparseArray.dtype` and `SparseSeries.dtype` are now instances of `SparseDtype`, rather than `np.dtype`. Access the underlying dtype with `SparseDtype.subdtype`.
- `numpy.asarray(sparse_array)` now returns a dense array with all the values, not just the non-fill-value values ([GH14167](#))
- `SparseArray.take` now matches the API of `pandas.api.extensions.ExtensionArray.take()` ([GH19506](#)):
 - The default value of `allow_fill` has changed from `False` to `True`.
 - The `out` and `mode` parameters are now longer accepted (previously, this raised if they were specified).
 - Passing a scalar for `indices` is no longer allowed.

- The result of `concat()` with a mix of sparse and dense Series is a Series with sparse values, rather than a `SparseSeries`.
- `SparseDataFrame.combine` and `DataFrame.combine_first` no longer supports combining a sparse column with a dense column while preserving the sparse subtype. The result will be an object-dtype `SparseArray`.
- Setting `SparseArray.fill_value` to a fill value with a different dtype is now allowed.
- `DataFrame[column]` is now a Series with sparse values, rather than a `SparseSeries`, when slicing a single column with sparse values ([GH23559](#)).
- The result of `Series.where()` is now a Series with sparse values, like with other extension arrays ([GH24077](#)).

Some new warnings are issued for operations that require or are likely to materialize a large dense array:

- A `errors.PerformanceWarning` is issued when using `fillna` with a method, as a dense array is constructed to create the filled array. Filling with a value is the efficient way to fill a sparse array.
- A `errors.PerformanceWarning` is now issued when concatenating sparse Series with differing fill values. The fill value from the first sparse array continues to be used.

In addition to these API breaking changes, many *Performance Improvements and Bug Fixes have been made*.

Finally, a `Series.sparse` accessor was added to provide sparse-specific methods like `Series.sparse.from_coo()`.

```
In [72]: s = pd.Series([0, 0, 1, 1, 1], dtype='Sparse[int]')
In [73]: s.sparse.density
Out[73]: 0.6
```

1.2.9 `get_dummies()` always returns a DataFrame

Previously, when `sparse=True` was passed to `get_dummies()`, the return value could be either a `DataFrame` or a `SparseDataFrame`, depending on whether all or a just a subset of the columns were dummy-encoded. Now, a `DataFrame` is always returned ([GH24284](#)).

Previous Behavior

The first `get_dummies()` returns a `DataFrame` because the column A is not dummy encoded. When just ["B", "C"] are passed to `get_dummies`, then all the columns are dummy-encoded, and a `SparseDataFrame` was returned.

```
In [2]: df = pd.DataFrame({"A": [1, 2], "B": ['a', 'b'], "C": ['a', 'a']})
In [3]: type(pd.get_dummies(df, sparse=True))
Out[3]: pandas.core.frame.DataFrame

In [4]: type(pd.get_dummies(df[['B', 'C']], sparse=True))
Out[4]: pandas.core.sparse.frame.SparseDataFrame
```

New Behavior

Now, the return type is consistently a `DataFrame`.

```
In [74]: type(pd.get_dummies(df, sparse=True))
Out[74]: pandas.core.frame.DataFrame
```

(continues on next page)

(continued from previous page)

```
In [75]: type(pd.get_dummies(df[['B', 'C']], sparse=True))
Out[75]: pandas.core.sparse.frame.SparseDataFrame
```

Note: There's no difference in memory usage between a `SparseDataFrame` and a `DataFrame` with sparse values. The memory usage will be the same as in the previous version of pandas.

1.2.10 Raise `ValueError` in `DataFrame.to_dict(orient='index')`

Bug in `DataFrame.to_dict()` raises `ValueError` when used with `orient='index'` and a non-unique index instead of losing data ([GH22801](#))

```
In [76]: df = pd.DataFrame({'a': [1, 2], 'b': [0.5, 0.75]}, index=['A', 'A'])

In [77]: df
Out[77]:
   a    b
A  1  0.50
A  2  0.75

[2 rows x 2 columns]

In [78]: df.to_dict(orient='index')
ValueError                                Traceback (most recent call last)
<ipython-input-78-f5309a7c6adb> in <module>
----> 1 df.to_dict(orient='index')

/pandas/pandas/core/frame.py in to_dict(self, orient, into)
    1303         if not self.index.is_unique:
    1304             raise ValueError(
-> 1305                 "DataFrame index must be unique for orient='index'."
    1306             )
    1307         return into_c((t[0], dict(zip(self.columns, t[1:]))))

ValueError: DataFrame index must be unique for orient='index'.
```

1.2.11 Tick `DateOffset` Normalize Restrictions

Creating a `Tick` object (`Day`, `Hour`, `Minute`, `Second`, `Milli`, `Micro`, `Nano`) with `normalize=True` is no longer supported. This prevents unexpected behavior where addition could fail to be monotone or associative. ([GH21427](#))

Previous Behavior:

```
In [2]: ts = pd.Timestamp('2018-06-11 18:01:14')

In [3]: ts
Out[3]: Timestamp('2018-06-11 18:01:14')
```

(continues on next page)

(continued from previous page)

```
In [4]: tic = pd.offsets.Hour(n=2, normalize=True)
      ...:

In [5]: tic
Out[5]: <2 * Hours>

In [6]: ts + tic
Out[6]: Timestamp('2018-06-11 00:00:00')

In [7]: ts + tic + tic + tic == ts + (tic + tic + tic)
Out[7]: False
```

New Behavior:

```
In [79]: ts = pd.Timestamp('2018-06-11 18:01:14')

In [80]: tic = pd.offsets.Hour(n=2)

In [81]: ts + tic + tic + tic == ts + (tic + tic + tic)
Out[81]: True
```

1.2.12 Period Subtraction

Subtraction of a Period from another Period will give a DateOffset. instead of an integer ([GH21314](#))

Previous Behavior:

```
In [2]: june = pd.Period('June 2018')

In [3]: april = pd.Period('April 2018')

In [4]: june - april
Out [4]: 2
```

New Behavior:

```
In [82]: june = pd.Period('June 2018')

In [83]: april = pd.Period('April 2018')

In [84]: june - april
Out[84]: <2 * MonthEnds>
```

Similarly, subtraction of a Period from a PeriodIndex will now return an Index of DateOffset objects instead of an Int64Index

Previous Behavior:

```
In [2]: pi = pd.period_range('June 2018', freq='M', periods=3)

In [3]: pi - pi[0]
Out[3]: Int64Index([0, 1, 2], dtype='int64')
```

New Behavior:

```
In [85]: pi = pd.period_range('June 2018', freq='M', periods=3)
In [86]: pi - pi[0]
Out[86]: Index([<0 * MonthEnds>, <MonthEnd>, <2 * MonthEnds>], dtype='object')
```

1.2.13 Addition/Subtraction of NaN from DataFrame

Adding or subtracting NaN from a DataFrame column with `timedelta64[ns]` dtype will now raise a `TypeError` instead of returning all-NaT. This is for compatibility with `TimedeltaIndex` and `Series` behavior (GH22163)

```
In [87]: df = pd.DataFrame([pd.Timedelta(days=1)])
In [88]: df
Out[88]:
      0
0 1 days

[1 rows x 1 columns]
```

Previous Behavior:

```
In [4]: df = pd.DataFrame([pd.Timedelta(days=1)])
In [5]: df - np.nan
Out[5]:
      0
0 NaT
```

New Behavior:

```
In [2]: df - np.nan
...
TypeError: unsupported operand type(s) for -: 'TimedeltaIndex' and 'float'
```

1.2.14 DataFrame Comparison Operations Broadcasting Changes

Previously, the broadcasting behavior of DataFrame comparison operations (`==`, `!=`, ...) was inconsistent with the behavior of arithmetic operations (`+`, `-`, ...). The behavior of the comparison operations has been changed to match the arithmetic operations in these cases. (GH22880)

The affected cases are:

- operating against a 2-dimensional `np.ndarray` with either 1 row or 1 column will now broadcast the same way a `np.ndarray` would (GH23000).
- a list or tuple with length matching the number of rows in the DataFrame will now raise `ValueError` instead of operating column-by-column (GH22880).
- a list or tuple with length matching the number of columns in the DataFrame will now operate row-by-row instead of raising `ValueError` (GH22880).

```
In [89]: arr = np.arange(6).reshape(3, 2)
In [90]: df = pd.DataFrame(arr)
```

(continues on next page)

(continued from previous page)

```
In [91]: df
Out[91]:
   0  1
0  0  1
1  2  3
2  4  5

[3 rows x 2 columns]
```

Previous Behavior:

```
In [5]: df == arr[[0], :]
...: # comparison previously broadcast where arithmetic would raise
Out[5]:
   0  1
0  True  True
1  False False
2  False False
In [6]: df + arr[[0], :]
...
ValueError: Unable to coerce to DataFrame, shape must be (3, 2): given (1, 2)

In [7]: df == (1, 2)
...: # length matches number of columns;
...: # comparison previously raised where arithmetic would broadcast
...
ValueError: Invalid broadcasting comparison [(1, 2)] with block values
In [8]: df + (1, 2)
Out[8]:
   0  1
0  1  3
1  3  5
2  5  7

In [9]: df == (1, 2, 3)
...: # length matches number of rows
...: # comparison previously broadcast where arithmetic would raise
Out[9]:
   0  1
0  False  True
1  True  False
2  False  False
In [10]: df + (1, 2, 3)
...
ValueError: Unable to coerce to Series, length must be 2: given 3
```

New Behavior:

```
# Comparison operations and arithmetic operations both broadcast.
In [92]: df == arr[[0], :]
Out[92]:
   0  1
0  True  True
1  False False
2  False False
```

(continues on next page)

(continued from previous page)

[3 rows x 2 columns]

In [93]: df + arr[[0], :]

Out [93]:

```

→
  0  1
0  0  2
1  2  4
2  4  6

```

[3 rows x 2 columns]

Comparison operations and arithmetic operations both broadcast.

In [94]: df == (1, 2)**Out [94]:**

```

      0      1
0  False False
1  False False
2  False False

```

[3 rows x 2 columns]

In [95]: df + (1, 2)

Out [95]:

```

→
  0  1
0  1  3
1  3  5
2  5  7

```

[3 rows x 2 columns]

Comparison operations and arithmetic operations both raise ValueError.

In [6]: df == (1, 2, 3)

...

ValueError: Unable to coerce to Series, length must be 2: given 3

In [7]: df + (1, 2, 3)

...

ValueError: Unable to coerce to Series, length must be 2: given 3

1.2.15 DataFrame Arithmetic Operations Broadcasting Changes

DataFrame arithmetic operations when operating with 2-dimensional `np.ndarray` objects now broadcast in the same way as `np.ndarray` broadcast. ([GH23000](#))

In [96]: arr = np.arange(6).reshape(3, 2)**In [97]:** df = pd.DataFrame(arr)**In [98]:** df**Out [98]:**

```

  0  1
0  0  1

```

(continues on next page)

(continued from previous page)

```

1  2  3
2  4  5

[3 rows x 2 columns]
```

Previous Behavior:

```

In [5]: df + arr[[0], :]    # 1 row, 2 columns
...
ValueError: Unable to coerce to DataFrame, shape must be (3, 2): given (1, 2)
In [6]: df + arr[:, [1]]    # 1 column, 3 rows
...
ValueError: Unable to coerce to DataFrame, shape must be (3, 2): given (3, 1)
```

New Behavior:

```

In [99]: df + arr[[0], :]    # 1 row, 2 columns
Out[99]:
   0  1
0  0  2
1  2  4
2  4  6

[3 rows x 2 columns]

In [100]: df + arr[:, [1]]    # 1 column, 3 rows
Out[100]:
   0  1
0  1  2
1  5  6
2  9 10

[3 rows x 2 columns]
```

1.2.16 ExtensionType Changes

Equality and Hashability

Pandas now requires that extension dtypes be hashable. The base class implements a default `__eq__` and `__hash__`. If you have a parametrized dtype, you should update the `ExtensionDtype._metadata` tuple to match the signature of your `__init__` method. See `pandas.api.extensions.ExtensionDtype` for more ([GH22476](#)).

Reshaping changes

- `dropna()` has been added ([GH21185](#))
- `repeat()` has been added ([GH24349](#))
- The `ExtensionArray` constructor, `_from_sequence` now take the keyword arg `copy=False` ([GH21185](#))
- `pandas.api.extensions.ExtensionArray.shift()` added as part of the basic `ExtensionArray` interface ([GH22387](#)).
- `searchsorted()` has been added ([GH24350](#))
- Support for reduction operations such as `sum`, `mean` via opt-in base class method override ([GH22762](#))

- `ExtensionArray.isna()` is allowed to return an `ExtensionArray` (GH22325).

Dtype changes

- `ExtensionDtype` has gained the ability to instantiate from string dtypes, e.g. `decimal` would instantiate a registered `DecimalDtype`; furthermore the `ExtensionDtype` has gained the method `construct_array_type` (GH21185)
- Added `ExtensionDtype._is_numeric` for controlling whether an extension dtype is considered numeric (GH22290).
- Added `pandas.api.types.register_extension_dtype()` to register an extension type with pandas (GH22664)
- Updated the `.type` attribute for `PeriodDtype`, `DatetimeTZDtype`, and `IntervalDtype` to be instances of the dtype (`Period`, `Timestamp`, and `Interval` respectively) (GH22938)

Other changes

- A default repr for `pandas.api.extensions.ExtensionArray` is now provided (GH23601).
- An `ExtensionArray` with a boolean dtype now works correctly as a boolean indexer. `pandas.api.types.is_bool_dtype()` now properly considers them boolean (GH22326)

Bug Fixes

- Bug in `Series.get()` for Series using `ExtensionArray` and integer index (GH21257)
- `shift()` now dispatches to `ExtensionArray.shift()` (GH22386)
- `Series.combine()` works correctly with `ExtensionArray` inside of Series (GH20825)
- `Series.combine()` with scalar argument now works for any function type (GH21248)
- `Series.astype()` and `DataFrame.astype()` now dispatch to `ExtensionArray.astype()` (GH21185).
- Slicing a single row of a `DataFrame` with multiple `ExtensionArrays` of the same type now preserves the dtype, rather than coercing to object (GH22784)
- Bug when concatenating multiple Series with different extension dtypes not casting to object dtype (GH22994)
- Series backed by an `ExtensionArray` now work with `util.hash_pandas_object()` (GH23066)
- `DataFrame.stack()` no longer converts to object dtype for DataFrames where each column has the same extension dtype. The output Series will have the same dtype as the columns (GH23077).
- `Series.unstack()` and `DataFrame.unstack()` no longer convert extension arrays to object-dtype ndarrays. Each column in the output `DataFrame` will now have the same dtype as the input (GH23077).
- Bug when grouping `Dataframe.groupby()` and aggregating on `ExtensionArray` it was not returning the actual `ExtensionArray` dtype (GH23227).
- Bug in `pandas.merge()` when merging on an extension array-backed column (GH23020).

1.2.17 Series and Index Data-Dtype Incompatibilities

Series and Index constructors now raise when the data is incompatible with a passed `dtype=` (GH15832)

Previous Behavior:

```
In [4]: pd.Series([-1], dtype="uint64")
Out [4]:
0      18446744073709551615
dtype: uint64
```

New Behavior:

```
In [4]: pd.Series([-1], dtype="uint64")
Out [4]:
...
OverflowError: Trying to coerce negative values to unsigned integers
```

1.2.18 Crosstab Preserves Dtypes

`crosstab()` will preserve now dtypes in some cases that previously would cast from integer dtype to floating dtype (GH22019)

Previous Behavior:

```
In [3]: df = pd.DataFrame({'a': [1, 2, 2, 2, 2], 'b': [3, 3, 4, 4, 4],
...:                      'c': [1, 1, np.nan, 1, 1]})
In [4]: pd.crosstab(df.a, df.b, normalize='columns')
Out[4]:
b      3      4
a
1    0.5    0.0
2    0.5    1.0
```

New Behavior:

```
In [3]: df = pd.DataFrame({'a': [1, 2, 2, 2, 2],
...:                      'b': [3, 3, 4, 4, 4],
...:                      'c': [1, 1, np.nan, 1, 1]})
In [4]: pd.crosstab(df.a, df.b, normalize='columns')
```

1.2.19 Concatenation Changes

Calling `pandas.concat()` on a Categorical of ints with NA values now causes them to be processed as objects when concatenating with anything other than another Categorical of ints (GH19214)

```
In [101]: s = pd.Series([0, 1, np.nan])

In [102]: c = pd.Series([0, 1, np.nan], dtype="category")
```

Previous Behavior

```
In [3]: pd.concat([s, c])
Out[3]:
0      0.0
1      1.0
2      NaN
0      0.0
1      1.0
2      NaN
dtype: float64
```

New Behavior

```
In [103]: pd.concat([s, c])
Out[103]:
0      0
1      1
2     NaN
0      0
1      1
2     NaN
Length: 6, dtype: object
```

1.2.20 Datetimelike API Changes

- For `DatetimeIndex` and `TimedeltaIndex` with non-None `freq` attribute, addition or subtraction of integer-dtyped array or `Index` will return an object of the same class ([GH19959](#))
- `DateOffset` objects are now immutable. Attempting to alter one of these will now raise `AttributeError` ([GH21341](#))
- `PeriodIndex` subtraction of another `PeriodIndex` will now return an object-dtype `Index` of `DateOffset` objects instead of raising a `TypeError` ([GH20049](#))
- `cut()` and `qcut()` now returns a `DatetimeIndex` or `TimedeltaIndex` bins when the input is datetime or timedelta dtype respectively and `retbins=True` ([GH19891](#))
- `DatetimeIndex.to_period()` and `Timestamp.to_period()` will issue a warning when timezone information will be lost ([GH21333](#))
- `PeriodIndex.tz_convert()` and `PeriodIndex.tz_localize()` have been removed ([GH21781](#))

1.2.21 Other API Changes

- Accessing a level of a `MultiIndex` with a duplicate name (e.g. in `get_level_values()`) now raises a `ValueError` instead of a `KeyError` ([GH21678](#)).
- Invalid construction of `IntervalDtype` will now always raise a `TypeError` rather than a `ValueError` if the subtype is invalid ([GH21185](#))
- Trying to reindex a `DataFrame` with a non unique `MultiIndex` now raises a `ValueError` instead of an `Exception` ([GH21770](#))
- `Index` subtraction will attempt to operate element-wise instead of raising `TypeError` ([GH19369](#))
- `pandas.io.formats.style.Styler` supports a `number-format` property when using `to_excel()` ([GH22015](#))
- `DataFrame.corr()` and `Series.corr()` now raise a `ValueError` along with a helpful error message instead of a `KeyError` when supplied with an invalid method ([GH22298](#))
- `shift()` will now always return a copy, instead of the previous behaviour of returning self when shifting by 0 ([GH22397](#))
- `DataFrame.set_index()` now allows all one-dimensional list-likes, raises a `TypeError` for incorrect types, has an improved `KeyError` message, and will not fail on duplicate column names with `drop=True`. ([GH22484](#))
- Slicing a single row of a `DataFrame` with multiple `ExtensionArrays` of the same type now preserves the dtype, rather than coercing to object ([GH22784](#))

- `DateOffset` attribute `_cacheable` and method `_should_cache` have been removed (GH23118)
- `Series.searchsorted()`, when supplied a scalar value to search for, now returns a scalar instead of an array (GH23801).
- `Categorical.searchsorted()`, when supplied a scalar value to search for, now returns a scalar instead of an array (GH23466).
- `Categorical.searchsorted()` now raises a `KeyError` rather than a `ValueError`, if a searched for key is not found in its categories (GH23466).
- `Index.hasnans()` and `Series.hasnans()` now always return a python boolean. Previously, a python or a numpy boolean could be returned, depending on circumstances (GH23294).
- The order of the arguments of `DataFrame.to_html()` and `DataFrame.to_string()` is rearranged to be consistent with each other. (GH23614)
- `CategoricalIndex.reindex()` now raises a `ValueError` if the target index is non-unique and not equal to the current index. It previously only raised if the target index was not of a categorical dtype (GH23963).
- `Series.to_list()` and `Index.to_list()` are now aliases of `Series.tolist` respectively `Index.tolist` (GH8826)
- The result of `SparseSeries.unstack` is now a `DataFrame` with sparse values, rather than a `SparseDataFrame` (issue:24372).

1.3 Deprecations

- `MultiIndex.labels` has been deprecated and replaced by `MultiIndex.codes`. The functionality is unchanged. The new name better reflects the natures of these codes and makes the `MultiIndex` API more similar to the API for `CategoricalIndex` (GH13443). As a consequence, other uses of the name `labels` in `MultiIndex` have also been deprecated and replaced with `codes`:
 - You should initialize a `MultiIndex` instance using a parameter named `codes` rather than `labels`.
 - `MultiIndex.set_labels` has been deprecated in favor of `MultiIndex.set_codes()`.
 - For method `MultiIndex.copy()`, the `labels` parameter has been deprecated and replaced by a `codes` parameter.
- `DataFrame.to_stata()`, `read_stata()`, `StataReader` and `StataWriter` have deprecated the encoding argument. The encoding of a Stata dta file is determined by the file type and cannot be changed (GH21244)
- `MultiIndex.to_hierarchical()` is deprecated and will be removed in a future version (GH21613)
- `Series.ptp()` is deprecated. Use `numpy.ptp` instead (GH21614)
- `Series.compress()` is deprecated. Use `Series[condition]` instead (GH18262)
- The signature of `Series.to_csv()` has been uniformed to that of `DataFrame.to_csv()`: the name of the first argument is now `path_or_buf`, the order of subsequent arguments has changed, the header argument now defaults to `True`. (GH19715)
- `Categorical.from_codes()` has deprecated providing float values for the `codes` argument. (GH21767)
- `pandas.read_table()` is deprecated. Instead, use `read_csv()` passing `sep='\t'` if necessary (GH21948)
- `Series.str.cat()` has deprecated using arbitrary list-likes *within* list-likes. A list-like container may still contain many `Series`, `Index` or 1-dimensional `np.ndarray`, or alternatively, only scalar values. (GH21950)

- `FrozenNDArray.searchsorted()` has deprecated the `v` parameter in favor of `value` (GH14645)
- `DatetimeIndex.shift()` and `PeriodIndex.shift()` now accept `periods` argument instead of `n` for consistency with `Index.shift()` and `Series.shift()`. Using `n` throws a deprecation warning (GH22458, GH22912)
- The `fastpath` keyword of the different `Index` constructors is deprecated (GH23110).
- `Timestamp.tz_localize()`, `DatetimeIndex.tz_localize()`, and `Series.tz_localize()` have deprecated the `errors` argument in favor of the nonexistent argument (GH8917)
- The class `FrozenNDArray` has been deprecated. When unpickling, `FrozenNDArray` will be unpickled to `np.ndarray` once this class is removed (GH9031)
- The methods `DataFrame.update()` and `Panel.update()` have deprecated the `raise_conflict=False|True` keyword in favor of `errors='ignore'|'raise'` (GH23585)
- The methods `Series.str.partition()` and `Series.str.rpartition()` have deprecated the `pat` keyword in favor of `sep` (GH22676)
- Deprecated the `nthreads` keyword of `pandas.read_feather()` in favor of `use_threads` to reflect the changes in `pyarrow>=0.11.0`. (GH23053)
- `ExtensionArray._formatting_values()` is deprecated. Use `ExtensionArray._formatter` instead. (GH23601)
- `pandas.read_excel()` has deprecated accepting `usecols` as an integer. Please pass in a list of ints from 0 to `usecols` inclusive instead (GH23527)
- Constructing a `TimedeltaIndex` from data with `datetime64`-typed data is deprecated, will raise `TypeError` in a future version (GH23539)
- Constructing a `DatetimeIndex` from data with `timedelta64`-typed data is deprecated, will raise `TypeError` in a future version (GH23675)
- The `keep_tz=False` option (the default) of the `keep_tz` keyword of `DatetimeIndex.to_series()` is deprecated (GH17832).
- Timezone converting a `tz-aware datetime.datetime` or `Timestamp` with `Timestamp` and the `tz` argument is now deprecated. Instead, use `Timestamp.tz_convert()` (GH23579)
- `pandas.api.types.is_period()` is deprecated in favor of `pandas.api.types.is_period_dtype` (GH23917)
- `pandas.api.types.is_datetimetz()` is deprecated in favor of `pandas.api.types.is_datetime64tz` (GH23917)
- Creating a `TimedeltaIndex`, `DatetimeIndex`, or `PeriodIndex` by passing range arguments `start`, `end`, and `periods` is deprecated in favor of `timedelta_range()`, `date_range()`, or `period_range()` (GH23919)
- Passing a string alias like `'datetime64[ns, UTC]'` as the `unit` parameter to `DatetimeTZDtype` is deprecated. Use `DatetimeTZDtype.construct_from_string` instead (GH23990).
- The `skipna` parameter of `infer_dtype()` will switch to `True` by default in a future version of pandas (GH17066, GH24050)
- In `Series.where()` with Categorical data, providing an `other` that is not present in the categories is deprecated. Convert the categorical to a different dtype or add the `other` to the categories first (GH24077).
- `Series.clip_lower()`, `Series.clip_upper()`, `DataFrame.clip_lower()` and `DataFrame.clip_upper()` are deprecated and will be removed in a future version. Use `Series`.

`clip(lower=threshold)`, `Series.clip(upper=threshold)` and the equivalent `DataFrame` methods (GH24203)

- `Series.nonzero()` is deprecated and will be removed in a future version (GH18262)
- Passing an integer to `Series.fillna()` and `DataFrame.fillna()` with `timedelta64[ns]` dtypes is deprecated, will raise `TypeError` in a future version. Use `“obj.fillna(pd.Timedelta(...))”` instead (GH24694)

1.3.1 Integer Addition/Subtraction with Datetimes and Timedeltas is Deprecated

In the past, users could—in some cases—add or subtract integers or integer-dtype arrays from `Timestamp`, `DatetimeIndex` and `TimedeltaIndex`.

This usage is now deprecated. Instead add or subtract integer multiples of the object’s `freq` attribute (GH21939, GH23878).

Previous Behavior:

```
In [5]: ts = pd.Timestamp('1994-05-06 12:15:16', freq=pd.offsets.Hour())
In [6]: ts + 2
Out[6]: Timestamp('1994-05-06 14:15:16', freq='H')

In [7]: tdi = pd.timedelta_range('1D', periods=2)
In [8]: tdi - np.array([2, 1])
Out[8]: TimedeltaIndex(['-1 days', '1 days'], dtype='timedelta64[ns]', freq=None)

In [9]: dti = pd.date_range('2001-01-01', periods=2, freq='7D')
In [10]: dti + pd.Index([1, 2])
Out[10]: DatetimeIndex(['2001-01-08', '2001-01-22'], dtype='datetime64[ns]',
↳freq=None)
```

New Behavior:

```
In [104]: ts = pd.Timestamp('1994-05-06 12:15:16', freq=pd.offsets.Hour())
In [105]: ts + 2 * ts.freq
Out[105]: Timestamp('1994-05-06 14:15:16', freq='H')

In [106]: tdi = pd.timedelta_range('1D', periods=2)
In [107]: tdi - np.array([2 * tdi.freq, 1 * tdi.freq])
Out[107]: TimedeltaIndex(['-1 days', '1 days'], dtype='timedelta64[ns]', freq=None)

In [108]: dti = pd.date_range('2001-01-01', periods=2, freq='7D')
In [109]: dti + pd.Index([1 * dti.freq, 2 * dti.freq])
Out[109]: DatetimeIndex(['2001-01-08', '2001-01-22'], dtype='datetime64[ns]',
↳freq=None)
```

1.3.2 Passing Integer data and a timezone to DatetimeIndex

The behavior of `DatetimeIndex` when passed integer data and a timezone is changing in a future version of pandas. Previously, these were interpreted as wall times in the desired timezone. In the future, these will be interpreted as wall times in UTC, which are then converted to the desired timezone (GH24559).

The default behavior remains the same, but issues a warning:

```
In [3]: pd.DatetimeIndex([946684800000000000], tz="US/Central")
/bin/ipython:1: FutureWarning:
    Passing integer-dtype data and a timezone to DatetimeIndex. Integer values
    will be interpreted differently in a future version of pandas. Previously,
    these were viewed as datetime64[ns] values representing the wall time
    *in the specified timezone*. In the future, these will be viewed as
    datetime64[ns] values representing the wall time *in UTC*. This is similar
    to a nanosecond-precision UNIX epoch. To accept the future behavior, use

        pd.to_datetime(integer_data, utc=True).tz_convert(tz)

    To keep the previous behavior, use

        pd.to_datetime(integer_data).tz_localize(tz)

#!/bin/python3
Out[3]: DatetimeIndex(['2000-01-01 00:00:00-06:00'], dtype='datetime64[ns, US/
↪Central]', freq=None)
```

As the warning message explains, opt in to the future behavior by specifying that the integer values are UTC, and then converting to the final timezone:

```
In [110]: pd.to_datetime([946684800000000000], utc=True).tz_convert('US/Central')
Out[110]: DatetimeIndex(['1999-12-31 18:00:00-06:00'], dtype='datetime64[ns, US/
↪Central]', freq=None)
```

The old behavior can be retained with by localizing directly to the final timezone:

```
In [111]: pd.to_datetime([946684800000000000]).tz_localize('US/Central')
Out[111]: DatetimeIndex(['2000-01-01 00:00:00-06:00'], dtype='datetime64[ns, US/
↪Central]', freq=None)
```

1.3.3 Converting Timezone-Aware Series and Index to NumPy Arrays

The conversion from a `Series` or `Index` with timezone-aware datetime data will change to preserve timezones by default (GH23569).

NumPy doesn't have a dedicated dtype for timezone-aware datetimes. In the past, converting a `Series` or `DatetimeIndex` with timezone-aware datetimes would convert to a NumPy array by

1. converting the tz-aware data to UTC
2. dropping the timezone-info
3. returning a `numpy.ndarray` with `datetime64[ns]` dtype

Future versions of pandas will preserve the timezone information by returning an object-dtype NumPy array where each value is a `Timestamp` with the correct timezone attached

```
In [112]: ser = pd.Series(pd.date_range('2000', periods=2, tz="CET"))

In [113]: ser
Out[113]:
0    2000-01-01 00:00:00+01:00
1    2000-01-02 00:00:00+01:00
Length: 2, dtype: datetime64[ns, CET]
```

The default behavior remains the same, but issues a warning

```
In [8]: np.asarray(ser)
/bin/ipython:1: FutureWarning: Converting timezone-aware DatetimeArray to timezone-
naive
    ndarray with 'datetime64[ns]' dtype. In the future, this will return an ndarray
    with 'object' dtype where each element is a 'pandas.Timestamp' with the correct
    tz'.

    To accept the future behavior, pass 'dtype=object'.
    To keep the old behavior, pass 'dtype="datetime64[ns]"'.
    #!/bin/python3
Out[8]:
array(['1999-12-31T23:00:00.000000000', '2000-01-01T23:00:00.000000000'],
      dtype='datetime64[ns]')
```

The previous or future behavior can be obtained, without any warnings, by specifying the dtype

Previous Behavior

```
In [114]: np.asarray(ser, dtype='datetime64[ns]')
Out[114]: array(['1999-12-31T23:00:00.000000000', '2000-01-01T23:00:00.000000000'],
               dtype='datetime64[ns]')
```

Future Behavior

```
# New behavior
In [115]: np.asarray(ser, dtype=object)
Out[115]:
array([Timestamp('2000-01-01 00:00:00+0100', tz='CET', freq='D'),
      Timestamp('2000-01-02 00:00:00+0100', tz='CET', freq='D')], dtype=object)
```

Or by using `Series.to_numpy()`

```
In [116]: ser.to_numpy()
Out[116]:
array([Timestamp('2000-01-01 00:00:00+0100', tz='CET', freq='D'),
      Timestamp('2000-01-02 00:00:00+0100', tz='CET', freq='D')], dtype=object)

In [117]: ser.to_numpy(dtype="datetime64[ns]")
Out[117]:
array(['1999-12-31T23:00:00.000000000', '2000-01-01T23:00:00.000000000'], dtype=
      'datetime64[ns]')
```

All the above applies to a `DatetimeIndex` with tz-aware values as well.

1.4 Removal of prior version deprecations/changes

- The `LongPanel` and `WidePanel` classes have been removed ([GH10892](#))
- `Series.repeat()` has renamed the `reps` argument to `repeats` ([GH14645](#))
- Several private functions were removed from the (non-public) module `pandas.core.common` ([GH22001](#))
- Removal of the previously deprecated module `pandas.core.datetools` ([GH14105](#), [GH14094](#))
- Strings passed into `DataFrame.groupby()` that refer to both column and index levels will raise a `ValueError` ([GH14432](#))
- `Index.repeat()` and `MultiIndex.repeat()` have renamed the `n` argument to `repeats` ([GH14645](#))

- The `Series` constructor and `.astype` method will now raise a `ValueError` if timestamp dtypes are passed in without a unit (e.g. `np.datetime64`) for the `dtype` parameter ([GH15987](#))
- Removal of the previously deprecated `as_indexer` keyword completely from `str.match()` ([GH22356](#), [GH6581](#))
- The modules `pandas.types`, `pandas.computation`, and `pandas.util.decorators` have been removed ([GH16157](#), [GH16250](#))
- Removed the `pandas.formats.style` shim for `pandas.io.formats.style.Styler` ([GH16059](#))
- `pandas.pnow`, `pandas.match`, `pandas.groupby`, `pd.get_store`, `pd.Expr`, and `pd.Term` have been removed ([GH15538](#), [GH15940](#))
- `Categorical.searchsorted()` and `Series.searchsorted()` have renamed the `v` argument to `value` ([GH14645](#))
- `pandas.parser`, `pandas.lib`, and `pandas.tslib` have been removed ([GH15537](#))
- `Index.searchsorted()` have renamed the `key` argument to `value` ([GH14645](#))
- `DataFrame consolidate` and `Series consolidate` have been removed ([GH15501](#))
- Removal of the previously deprecated module `pandas.json` ([GH19944](#))
- The module `pandas.tools` has been removed ([GH15358](#), [GH16005](#))
- `SparseArray.get_values()` and `SparseArray.to_dense()` have dropped the `fill` parameter ([GH14686](#))
- `DataFrame.sortlevel` and `Series.sortlevel` have been removed ([GH15099](#))
- `SparseSeries.to_dense()` has dropped the `sparse_only` parameter ([GH14686](#))
- `DataFrame.astype()` and `Series.astype()` have renamed the `raise_on_error` argument to `errors` ([GH14967](#))
- `is_sequence`, `is_any_int_dtype`, and `is_floating_dtype` have been removed from `pandas.api.types` ([GH16163](#), [GH16189](#))

1.5 Performance Improvements

- Slicing `Series` and `DataFrames` with an monotonically increasing `CategoricalIndex` is now very fast and has speed comparable to slicing with an `Int64Index`. The speed increase is both when indexing by label (using `.loc`) and position (`.iloc`) ([GH20395](#)) Slicing a monotonically increasing `CategoricalIndex` itself (i.e. `ci[1000:2000]`) shows similar speed improvements as above ([GH21659](#))
- Improved performance of `CategoricalIndex.equals()` when comparing to another `CategoricalIndex` ([GH24023](#))
- Improved performance of `Series.describe()` in case of numeric dtypes ([GH21274](#))
- Improved performance of `pandas.core.groupby.GroupBy.rank()` when dealing with tied rankings ([GH21237](#))
- Improved performance of `DataFrame.set_index()` with columns consisting of `Period` objects ([GH21582](#), [GH21606](#))
- Improved performance of `Series.at()` and `Index.get_value()` for Extension Arrays values (e.g. `Categorical`) ([GH24204](#))

- Improved performance of membership checks in `Categorical` and `CategoricalIndex` (i.e. `x in cat`-style checks are much faster). `CategoricalIndex.contains()` is likewise much faster ([GH21369](#), [GH21508](#))
- Improved performance of `HDFStore.groups()` (and dependent functions like `HDFStore.keys()`. (i.e. `x in store` checks are much faster) ([GH21372](#))
- Improved the performance of `pandas.get_dummies()` with `sparse=True` ([GH21997](#))
- Improved performance of `IndexEngine.get_indexer_non_unique()` for sorted, non-unique indexes ([GH9466](#))
- Improved performance of `PeriodIndex.unique()` ([GH23083](#))
- Improved performance of `concat()` for `Series` objects ([GH23404](#))
- Improved performance of `DatetimeIndex.normalize()` and `Timestamp.normalize()` for time-zone naive or UTC datetimes ([GH23634](#))
- Improved performance of `DatetimeIndex.tz_localize()` and various `DatetimeIndex` attributes with `dateutil` UTC timezone ([GH23772](#))
- Fixed a performance regression on Windows with Python 3.7 of `read_csv()` ([GH23516](#))
- Improved performance of `Categorical` constructor for `Series` objects ([GH23814](#))
- Improved performance of `where()` for `Categorical` data ([GH24077](#))
- Improved performance of iterating over a `Series`. Using `DataFrame.itertuples()` now creates iterators without internally allocating lists of all elements ([GH20783](#))
- Improved performance of `Period` constructor, additionally benefiting `PeriodArray` and `PeriodIndex` creation ([GH24084](#) and [GH24118](#))
- Improved performance of tz-aware `DatetimeArray` binary operations ([GH24491](#))

1.6 Bug Fixes

1.6.1 Categorical

- Bug in `Categorical.from_codes()` where `NaN` values in `codes` were silently converted to 0 ([GH21767](#)). In the future this will raise a `ValueError`. Also changes the behavior of `.from_codes([1, 1, 2.0])`.
- Bug in `Categorical.sort_values()` where `NaN` values were always positioned in front regardless of `na_position` value. ([GH22556](#)).
- Bug when indexing with a boolean-valued `Categorical`. Now a boolean-valued `Categorical` is treated as a boolean mask ([GH22665](#))
- Constructing a `CategoricalIndex` with empty values and boolean categories was raising a `ValueError` after a change to `dtype` coercion ([GH22702](#)).
- Bug in `Categorical.take()` with a user-provided `fill_value` not encoding the `fill_value`, which could result in a `ValueError`, incorrect results, or a segmentation fault ([GH23296](#)).
- In `Series.unstack()`, specifying a `fill_value` not present in the categories now raises a `TypeError` rather than ignoring the `fill_value` ([GH23284](#))
- Bug when resampling `DataFrame.resample()` and aggregating on categorical data, the categorical dtype was getting lost. ([GH23227](#))

- Bug in many methods of the `.str`-accessor, which always failed on calling the `CategoricalIndex.str` constructor ([GH23555](#), [GH23556](#))
- Bug in `Series.where()` losing the categorical dtype for categorical data ([GH24077](#))
- Bug in `Categorical.apply()` where NaN values could be handled unpredictably. They now remain unchanged ([GH24241](#))
- Bug in `Categorical` comparison methods incorrectly raising `ValueError` when operating against a `DataFrame` ([GH24630](#))
- Bug in `Categorical.set_categories()` where setting fewer new categories with `rename=True` caused a segmentation fault ([GH24675](#))

1.6.2 Datetimelike

- Fixed bug where two `DateOffset` objects with different `normalize` attributes could evaluate as equal ([GH21404](#))
- Fixed bug where `Timestamp.resolution()` incorrectly returned 1-microsecond `timedelta` instead of 1-nanosecond `Timedelta` ([GH21336](#), [GH21365](#))
- Bug in `to_datetime()` that did not consistently return an `Index` when `box=True` was specified ([GH21864](#))
- Bug in `DatetimeIndex` comparisons where string comparisons incorrectly raises `TypeError` ([GH22074](#))
- Bug in `DatetimeIndex` comparisons when comparing against `timedelta64[ns]` dtyped arrays; in some cases `TypeError` was incorrectly raised, in others it incorrectly failed to raise ([GH22074](#))
- Bug in `DatetimeIndex` comparisons when comparing against object-dtyped arrays ([GH22074](#))
- Bug in `DataFrame` with `datetime64[ns]` dtype addition and subtraction with `Timedelta`-like objects ([GH22005](#), [GH22163](#))
- Bug in `DataFrame` with `datetime64[ns]` dtype addition and subtraction with `DateOffset` objects returning an object dtype instead of `datetime64[ns]` dtype ([GH21610](#), [GH22163](#))
- Bug in `DataFrame` with `datetime64[ns]` dtype comparing against `NaT` incorrectly ([GH22242](#), [GH22163](#))
- Bug in `DataFrame` with `datetime64[ns]` dtype subtracting `Timestamp`-like object incorrectly returned `datetime64[ns]` dtype instead of `timedelta64[ns]` dtype ([GH8554](#), [GH22163](#))
- Bug in `DataFrame` with `datetime64[ns]` dtype subtracting `np.datetime64` object with non-nanosecond unit failing to convert to nanoseconds ([GH18874](#), [GH22163](#))
- Bug in `DataFrame` comparisons against `Timestamp`-like objects failing to raise `TypeError` for inequality checks with mismatched types ([GH8932](#), [GH22163](#))
- Bug in `DataFrame` with mixed dtypes including `datetime64[ns]` incorrectly raising `TypeError` on equality comparisons ([GH13128](#), [GH22163](#))
- Bug in `DataFrame.values` returning a `DatetimeIndex` for a single-column `DataFrame` with tz-aware datetime values. Now a 2-D `numpy.ndarray` of `Timestamp` objects is returned ([GH24024](#))
- Bug in `DataFrame.eq()` comparison against `NaT` incorrectly returning `True` or `NaN` ([GH15697](#), [GH22163](#))
- Bug in `DatetimeIndex` subtraction that incorrectly failed to raise `OverflowError` ([GH22492](#), [GH22508](#))
- Bug in `DatetimeIndex` incorrectly allowing indexing with `Timedelta` object ([GH20464](#))
- Bug in `DatetimeIndex` where frequency was being set if original frequency was `None` ([GH22150](#))

- Bug in rounding methods of `DatetimeIndex` (`round()`, `ceil()`, `floor()`) and `Timestamp` (`round()`, `ceil()`, `floor()`) could give rise to loss of precision ([GH22591](#))
- Bug in `to_datetime()` with an `Index` argument that would drop the name from the result ([GH21697](#))
- Bug in `PeriodIndex` where adding or subtracting a `timedelta` or `Tick` object produced incorrect results ([GH22988](#))
- Bug in the `Series` repr with period-dtype data missing a space before the data ([GH23601](#))
- Bug in `date_range()` when decrementing a start date to a past end date by a negative frequency ([GH23270](#))
- Bug in `Series.min()` which would return `NaN` instead of `NaT` when called on a series of `NaT` ([GH23282](#))
- Bug in `Series.combine_first()` not properly aligning categoricals, so that missing values in `self` where not filled by valid values from `other` ([GH24147](#))
- Bug in `DataFrame.combine()` with datetimelike values raising a `TypeError` ([GH23079](#))
- Bug in `date_range()` with frequency of `Day` or higher where dates sufficiently far in the future could wrap around to the past instead of raising `OutOfBoundsDatetime` ([GH14187](#))
- Bug in `period_range()` ignoring the frequency of start and end when those are provided as `Period` objects ([GH20535](#)).
- Bug in `PeriodIndex` with attribute `freq.n` greater than 1 where adding a `DateOffset` object would return incorrect results ([GH23215](#))
- Bug in `Series` that interpreted string indices as lists of characters when setting datetimelike values ([GH23451](#))
- Bug in `DataFrame` when creating a new column from an `ndarray` of `Timestamp` objects with timezones creating an object-dtype column, rather than datetime with timezone ([GH23932](#))
- Bug in `Timestamp` constructor which would drop the frequency of an input `Timestamp` ([GH22311](#))
- Bug in `DatetimeIndex` where calling `np.array(dtindex, dtype=object)` would incorrectly return an array of long objects ([GH23524](#))
- Bug in `Index` where passing a timezone-aware `DatetimeIndex` and `dtype=object` would incorrectly raise a `ValueError` ([GH23524](#))
- Bug in `Index` where calling `np.array(dtindex, dtype=object)` on a timezone-naive `DatetimeIndex` would return an array of datetime objects instead of `Timestamp` objects, potentially losing nanosecond portions of the timestamps ([GH23524](#))
- Bug in `Categorical.__setitem__` not allowing setting with another `Categorical` when both are unordered and have the same categories, but in a different order ([GH24142](#))
- Bug in `date_range()` where using dates with millisecond resolution or higher could return incorrect values or the wrong number of values in the index ([GH24110](#))
- Bug in `DatetimeIndex` where constructing a `DatetimeIndex` from a `Categorical` or `CategoricalIndex` would incorrectly drop timezone information ([GH18664](#))
- Bug in `DatetimeIndex` and `TimedeltaIndex` where indexing with `Ellipsis` would incorrectly lose the index's `freq` attribute ([GH21282](#))
- Clarified error message produced when passing an incorrect `freq` argument to `DatetimeIndex` with `NaT` as the first entry in the passed data ([GH11587](#))
- Bug in `to_datetime()` where `box` and `utc` arguments were ignored when passing a `DataFrame` or dict of unit mappings ([GH23760](#))
- Bug in `Series.dt` where the cache would not update properly after an in-place operation ([GH24408](#))

- Bug in `PeriodIndex` where comparisons against an array-like object with length 1 failed to raise `ValueError` ([GH23078](#))
- Bug in `DatetimeIndex.astype()`, `PeriodIndex.astype()` and `TimedeltaIndex.astype()` ignoring the sign of the dtype for unsigned integer dtypes ([GH24405](#)).
- Fixed bug in `Series.max()` with `datetime64[ns]`-dtype failing to return `NaT` when nulls are present and `skipna=False` is passed ([GH24265](#))
- Bug in `to_datetime()` where arrays of datetime objects containing both timezone-aware and timezone-naive datetimes would fail to raise `ValueError` ([GH24569](#))

1.6.3 Timedelta

- Bug in `DataFrame` with `timedelta64[ns]` dtype division by `Timedelta`-like scalar incorrectly returning `timedelta64[ns]` dtype instead of `float64` dtype ([GH20088](#), [GH22163](#))
- Bug in adding a `Index` with object dtype to a `Series` with `timedelta64[ns]` dtype incorrectly raising ([GH22390](#))
- Bug in multiplying a `Series` with numeric dtype against a `timedelta` object ([GH22390](#))
- Bug in `Series` with numeric dtype when adding or subtracting an array or `Series` with `timedelta64` dtype ([GH22390](#))
- Bug in `Index` with numeric dtype when multiplying or dividing an array with dtype `timedelta64` ([GH22390](#))
- Bug in `TimedeltaIndex` incorrectly allowing indexing with `Timestamp` object ([GH20464](#))
- Fixed bug where subtracting `Timedelta` from an object-dtyped array would raise `TypeError` ([GH21980](#))
- Fixed bug in adding a `DataFrame` with all-`timedelta64[ns]` dtypes to a `DataFrame` with all-integer dtypes returning incorrect results instead of raising `TypeError` ([GH22696](#))
- Bug in `TimedeltaIndex` where adding a timezone-aware datetime scalar incorrectly returned a timezone-naive `DatetimeIndex` ([GH23215](#))
- Bug in `TimedeltaIndex` where adding `np.timedelta64('NaT')` incorrectly returned an all-`NaT` `DatetimeIndex` instead of an all-`NaT` `TimedeltaIndex` ([GH23215](#))
- Bug in `Timedelta` and `to_timedelta()` have inconsistencies in supported unit string ([GH21762](#))
- Bug in `TimedeltaIndex` division where dividing by another `TimedeltaIndex` raised `TypeError` instead of returning a `Float64Index` ([GH23829](#), [GH22631](#))
- Bug in `TimedeltaIndex` comparison operations where comparing against non-`Timedelta`-like objects would raise `TypeError` instead of returning all-`False` for `__eq__` and all-`True` for `__ne__` ([GH24056](#))

1.6.4 Timezones

- Bug in `Index.shift()` where an `AssertionError` would raise when shifting across DST ([GH8616](#))
- Bug in `Timestamp` constructor where passing an invalid timezone offset designator (Z) would not raise a `ValueError` ([GH8910](#))
- Bug in `Timestamp.replace()` where replacing at a DST boundary would retain an incorrect offset ([GH7825](#))
- Bug in `Series.replace()` with `datetime64[ns, tz]` data when replacing `NaT` ([GH11792](#))

- Bug in `Timestamp` when passing different string date formats with a timezone offset would produce different timezone offsets ([GH12064](#))
- Bug when comparing a tz-naive `Timestamp` to a tz-aware `DatetimeIndex` which would coerce the `DatetimeIndex` to tz-naive ([GH12601](#))
- Bug in `Series.truncate()` with a tz-aware `DatetimeIndex` which would cause a core dump ([GH9243](#))
- Bug in `Series` constructor which would coerce tz-aware and tz-naive `Timestamp` to tz-aware ([GH13051](#))
- Bug in `Index` with `datetime64[ns, tz]` dtype that did not localize integer data correctly ([GH20964](#))
- Bug in `DatetimeIndex` where constructing with an integer and tz would not localize correctly ([GH12619](#))
- Fixed bug where `DataFrame.describe()` and `Series.describe()` on tz-aware datetimes did not show *first* and *last* result ([GH21328](#))
- Bug in `DatetimeIndex` comparisons failing to raise `TypeError` when comparing timezone-aware `DatetimeIndex` against `np.datetime64` ([GH22074](#))
- Bug in `DataFrame` assignment with a timezone-aware scalar ([GH19843](#))
- Bug in `DataFrame.asof()` that raised a `TypeError` when attempting to compare tz-naive and tz-aware timestamps ([GH21194](#))
- Bug when constructing a `DatetimeIndex` with `Timestamp` constructed with the `replace` method across DST ([GH18785](#))
- Bug when setting a new value with `DataFrame.loc()` with a `DatetimeIndex` with a DST transition ([GH18308](#), [GH20724](#))
- Bug in `Index.unique()` that did not re-localize tz-aware dates correctly ([GH21737](#))
- Bug when indexing a `Series` with a DST transition ([GH21846](#))
- Bug in `DataFrame.resample()` and `Series.resample()` where an `AmbiguousTimeError` or `NonExistentTimeError` would raise if a timezone aware timeseries ended on a DST transition ([GH19375](#), [GH10117](#))
- Bug in `DataFrame.drop()` and `Series.drop()` when specifying a tz-aware `Timestamp` key to drop from a `DatetimeIndex` with a DST transition ([GH21761](#))
- Bug in `DatetimeIndex` constructor where `NaT` and `dateutil.tz.tzlocal` would raise an `OutOfBoundsDatetime` error ([GH23807](#))
- Bug in `DatetimeIndex.tz_localize()` and `Timestamp.tz_localize()` with `dateutil.tz.tzlocal` near a DST transition that would return an incorrectly localized datetime ([GH23807](#))
- Bug in `Timestamp` constructor where a `dateutil.tz.tzutc` timezone passed with a `datetime.datetime` argument would be converted to a `pytz.UTC` timezone ([GH23807](#))
- Bug in `to_datetime()` where `utc=True` was not respected when specifying a unit and `errors='ignore'` ([GH23758](#))
- Bug in `to_datetime()` where `utc=True` was not respected when passing a `Timestamp` ([GH24415](#))
- Bug in `DataFrame.any()` returns wrong value when `axis=1` and the data is of datetimelike type ([GH23070](#))
- Bug in `DatetimeIndex.to_period()` where a timezone aware index was converted to UTC first before creating `PeriodIndex` ([GH22905](#))
- Bug in `DataFrame.tz_localize()`, `DataFrame.tz_convert()`, `Series.tz_localize()`, and `Series.tz_convert()` where `copy=False` would mutate the original argument inplace ([GH6326](#))

1.6.5 Offsets

- Bug in `FY5253` where date offsets could incorrectly raise an `AssertionError` in arithmetic operations ([GH14774](#))
- Bug in `DateOffset` where keyword arguments `week` and `milliseconds` were accepted and ignored. Passing these will now raise `ValueError` ([GH19398](#))
- Bug in adding `DateOffset` with `DataFrame` or `PeriodIndex` incorrectly raising `TypeError` ([GH23215](#))
- Bug in comparing `DateOffset` objects with non-`DateOffset` objects, particularly strings, raising `ValueError` instead of returning `False` for equality checks and `True` for not-equal checks ([GH23524](#))

1.6.6 Numeric

- Bug in `Series.__rmatmul__` doesn't support matrix vector multiplication ([GH21530](#))
- Bug in `factorize()` fails with read-only array ([GH12813](#))
- Fixed bug in `unique()` handled signed zeros inconsistently: for some inputs `0.0` and `-0.0` were treated as equal and for some inputs as different. Now they are treated as equal for all inputs ([GH21866](#))
- Bug in `DataFrame.agg()`, `DataFrame.transform()` and `DataFrame.apply()` where, when supplied with a list of functions and `axis=1` (e.g. `df.apply(['sum', 'mean'], axis=1)`), a `TypeError` was wrongly raised. For all three methods such calculation are now done correctly. ([GH16679](#)).
- Bug in `Series` comparison against datetime-like scalars and arrays ([GH22074](#))
- Bug in `DataFrame` multiplication between boolean dtype and integer returning object dtype instead of integer dtype ([GH22047](#), [GH22163](#))
- Bug in `DataFrame.apply()` where, when supplied with a string argument and additional positional or keyword arguments (e.g. `df.apply('sum', min_count=1)`), a `TypeError` was wrongly raised ([GH22376](#))
- Bug in `DataFrame.astype()` to extension dtype may raise `AttributeError` ([GH22578](#))
- Bug in `DataFrame` with `timedelta64[ns]` dtype arithmetic operations with `ndarray` with integer dtype incorrectly treating the `ndarray` as `timedelta64[ns]` dtype ([GH23114](#))
- Bug in `Series.rpow()` with object dtype `NaN` for `1 ** NA` instead of `1` ([GH22922](#)).
- `Series.agg()` can now handle numpy NaN-aware methods like `numpy.nansum()` ([GH19629](#))
- Bug in `Series.rank()` and `DataFrame.rank()` when `pct=True` and more than 2:sup:24 rows are present resulted in percentages greater than 1.0 ([GH18271](#))
- Calls such as `DataFrame.round()` with a non-unique `CategoricalIndex()` now return expected data. Previously, data would be improperly duplicated ([GH21809](#)).
- Added `log10`, `floor` and `ceil` to the list of supported functions in `DataFrame.eval()` ([GH24139](#), [GH24353](#))
- Logical operations `&`, `|`, `^` between `Series` and `Index` will no longer raise `ValueError` ([GH22092](#))
- Checking PEP 3141 numbers in `is_scalar()` function returns `True` ([GH22903](#))
- Reduction methods like `Series.sum()` now accept the default value of `keepdims=False` when called from a NumPy ufunc, rather than raising a `TypeError`. Full support for `keepdims` has not been implemented ([GH24356](#)).

1.6.7 Conversion

- Bug in `DataFrame.combine_first()` in which column types were unexpectedly converted to float (GH20699)
- Bug in `DataFrame.clip()` in which column types are not preserved and casted to float (GH24162)
- Bug in `DataFrame.clip()` when order of columns of dataframes doesn't match, result observed is wrong in numeric values (GH20911)
- Bug in `DataFrame.astype()` where converting to an extension dtype when duplicate column names are present causes a `RecursionError` (GH24704)

1.6.8 Strings

- Bug in `Index.str.partition()` was not nan-safe (GH23558).
- Bug in `Index.str.split()` was not nan-safe (GH23677).
- Bug `Series.str.contains()` not respecting the `na` argument for a Categorical dtype Series (GH22158)
- Bug in `Index.str.cat()` when the result contained only NaN (GH24044)

1.6.9 Interval

- Bug in the `IntervalIndex` constructor where the `closed` parameter did not always override the inferred `closed` (GH19370)
- Bug in the `IntervalIndex` repr where a trailing comma was missing after the list of intervals (GH20611)
- Bug in `Interval` where scalar arithmetic operations did not retain the `closed` value (GH22313)
- Bug in `IntervalIndex` where indexing with datetime-like values raised a `KeyError` (GH20636)
- Bug in `IntervalTree` where data containing NaN triggered a warning and resulted in incorrect indexing queries with `IntervalIndex` (GH23352)

1.6.10 Indexing

- Bug in `DataFrame.ne()` fails if columns contain column name "dtype" (GH22383)
- The traceback from a `KeyError` when asking `.loc` for a single missing label is now shorter and more clear (GH21557)
- `PeriodIndex` now emits a `KeyError` when a malformed string is looked up, which is consistent with the behavior of `DatetimeIndex` (GH22803)
- When `.ix` is asked for a missing integer label in a `MultiIndex` with a first level of integer type, it now raises a `KeyError`, consistently with the case of a flat `Int64Index`, rather than falling back to positional indexing (GH21593)
- Bug in `Index.reindex()` when reindexing a tz-naive and tz-aware `DatetimeIndex` (GH8306)
- Bug in `Series.reindex()` when reindexing an empty series with a `datetime64[ns, tz]` dtype (GH20869)
- Bug in `DataFrame` when setting values with `.loc` and a timezone aware `DatetimeIndex` (GH11365)

- `DataFrame.__getitem__` now accepts dictionaries and dictionary keys as list-likes of labels, consistently with `Series.__getitem__` (GH21294)
- Fixed `DataFrame[np.nan]` when columns are non-unique (GH21428)
- Bug when indexing `DatetimeIndex` with nanosecond resolution dates and timezones (GH11679)
- Bug where indexing with a Numpy array containing negative values would mutate the indexer (GH21867)
- Bug where mixed indexes wouldn't allow integers for `.at` (GH19860)
- `Float64Index.get_loc` now raises `KeyError` when boolean key passed. (GH19087)
- Bug in `DataFrame.loc()` when indexing with an `IntervalIndex` (GH19977)
- `Index` no longer mangles `None`, `NaN` and `NaT`, i.e. they are treated as three different keys. However, for numeric `Index` all three are still coerced to a `NaN` (GH22332)
- Bug in scalar in `Index` if scalar is a float while the `Index` is of integer dtype (GH22085)
- Bug in `MultiIndex.set_levels()` when levels value is not subscriptable (GH23273)
- Bug where setting a `timedelta` column by `Index` causes it to be casted to double, and therefore lose precision (GH23511)
- Bug in `Index.union()` and `Index.intersection()` where name of the `Index` of the result was not computed correctly for certain cases (GH9943, GH9862)
- Bug in `Index` slicing with boolean `Index` may raise `TypeError` (GH22533)
- Bug in `PeriodArray.__setitem__` when accepting slice and list-like value (GH23978)
- Bug in `DatetimeIndex`, `TimedeltaIndex` where indexing with `Ellipsis` would lose their `freq` attribute (GH21282)
- Bug in `iat` where using it to assign an incompatible value would create a new column (GH23236)

1.6.11 Missing

- Bug in `DataFrame.fillna()` where a `ValueError` would raise when one column contained a `datetime64[ns, tz]` dtype (GH15522)
- Bug in `Series.hasnans()` that could be incorrectly cached and return incorrect answers if null elements are introduced after an initial call (GH19700)
- `Series.isin()` now treats all `NaN`-floats as equal also for `np.object-dtype`. This behavior is consistent with the behavior for `float64` (GH22119)
- `unique()` no longer mangles `NaN`-floats and the `NaT`-object for `np.object-dtype`, i.e. `NaT` is no longer coerced to a `NaN`-value and is treated as a different entity. (GH22295)
- `DataFrame()` and `Series()` now properly handle numpy masked arrays with hardened masks. Previously, constructing a `DataFrame` or `Series` from a masked array with a hard mask would create a pandas object containing the underlying value, rather than the expected `NaN`. (GH24574)

1.6.12 MultiIndex

- Bug in `io.formats.style.Styler.applymap()` where `subset=` with `MultiIndex` slice would reduce to `Series` (GH19861)
- Removed compatibility for `MultiIndex` pickles prior to version 0.8.0; compatibility with `MultiIndex` pickles from version 0.13 forward is maintained (GH21654)

- `MultiIndex.get_loc_level()` (and as a consequence, `.loc` on a `Series` or `DataFrame` with a `MultiIndex` index) will now raise a `KeyError`, rather than returning an empty slice, if asked a label which is present in the levels but is unused (GH22221)
- `MultiIndex` has gained the `MultiIndex.from_frame()`, it allows constructing a `MultiIndex` object from a `DataFrame` (GH22420)
- Fix `TypeError` in Python 3 when creating `MultiIndex` in which some levels have mixed types, e.g. when some labels are tuples (GH15457)

1.6.13 I/O

- Bug in `read_csv()` in which a column specified with `CategoricalDtype` of boolean categories was not being correctly coerced from string values to booleans (GH20498)
- Bug in `DataFrame.to_sql()` when writing timezone aware data (`datetime64[ns, tz]` dtype) would raise a `TypeError` (GH9086)
- Bug in `DataFrame.to_sql()` where a naive `DatetimeIndex` would be written as `TIMESTAMP WITH TIMEZONE` type in supported databases, e.g. PostgreSQL (GH23510)
- Bug in `read_excel()` when `parse_cols` is specified with an empty dataset (GH9208)
- `read_html()` no longer ignores all-whitespace `<tr>` within `<thead>` when considering the `skiprows` and `header` arguments. Previously, users had to decrease their `header` and `skiprows` values on such tables to work around the issue. (GH21641)
- `read_excel()` will correctly show the deprecation warning for previously deprecated `sheetname` (GH17994)
- `read_csv()` and `func:read_table()` will throw `UnicodeError` and not `coredump` on badly encoded strings (GH22748)
- `read_csv()` will correctly parse timezone-aware datetimes (GH22256)
- Bug in `read_csv()` in which memory management was prematurely optimized for the C engine when the data was being read in chunks (GH23509)
- Bug in `read_csv()` in unnamed columns were being improperly identified when extracting a multi-index (GH23687)
- `read_sas()` will parse numbers in `sas7bdat`-files that have width less than 8 bytes correctly. (GH21616)
- `read_sas()` will correctly parse `sas7bdat` files with many columns (GH22628)
- `read_sas()` will correctly parse `sas7bdat` files with data page types having also bit 7 set (so page type is $128 + 256 = 384$) (GH16615)
- Bug in `read_sas()` in which an incorrect error was raised on an invalid file format. (GH24548)
- Bug in `detect_client_encoding()` where potential `IOError` goes unhandled when importing in a `mod_wsgi` process due to restricted access to `stdout`. (GH21552)
- Bug in `DataFrame.to_html()` with `index=False` misses truncation indicators (...) on truncated `DataFrame` (GH15019, GH22783)
- Bug in `DataFrame.to_html()` with `index=False` when both columns and row index are `MultiIndex` (GH22579)
- Bug in `DataFrame.to_html()` with `index_names=False` displaying index name (GH22747)
- Bug in `DataFrame.to_html()` with `header=False` not displaying row index names (GH23788)
- Bug in `DataFrame.to_html()` with `sparsify=False` that caused it to raise `TypeError` (GH22887)

- Bug in `DataFrame.to_string()` that broke column alignment when `index=False` and width of first column's values is greater than the width of first column's header ([GH16839](#), [GH13032](#))
- Bug in `DataFrame.to_string()` that caused representations of `DataFrame` to not take up the whole window ([GH22984](#))
- Bug in `DataFrame.to_csv()` where a single level `MultiIndex` incorrectly wrote a tuple. Now just the value of the index is written ([GH19589](#)).
- `HDFStore` will raise `ValueError` when the `format` kwarg is passed to the constructor ([GH13291](#))
- Bug in `HDFStore.append()` when appending a `DataFrame` with an empty string column and `min_itemsize < 8` ([GH12242](#))
- Bug in `read_csv()` in which memory leaks occurred in the C engine when parsing NaN values due to insufficient cleanup on completion or error ([GH21353](#))
- Bug in `read_csv()` in which incorrect error messages were being raised when `skipfooter` was passed in along with `nrows`, `iterator`, or `chunksize` ([GH23711](#))
- Bug in `read_csv()` in which `MultiIndex` index names were being improperly handled in the cases when they were not provided ([GH23484](#))
- Bug in `read_csv()` in which unnecessary warnings were being raised when the dialect's values conflicted with the default arguments ([GH23761](#))
- Bug in `read_html()` in which the error message was not displaying the valid flavors when an invalid one was provided ([GH23549](#))
- Bug in `read_excel()` in which extraneous header names were extracted, even though none were specified ([GH11733](#))
- Bug in `read_excel()` in which column names were not being properly converted to string sometimes in Python 2.x ([GH23874](#))
- Bug in `read_excel()` in which `index_col=None` was not being respected and parsing index columns anyway ([GH18792](#), [GH20480](#))
- Bug in `read_excel()` in which `usecols` was not being validated for proper column names when passed in as a string ([GH20480](#))
- Bug in `DataFrame.to_dict()` when the resulting dict contains non-Python scalars in the case of numeric data ([GH23753](#))
- `DataFrame.to_string()`, `DataFrame.to_html()`, `DataFrame.to_latex()` will correctly format output when a string is passed as the `float_format` argument ([GH21625](#), [GH22270](#))
- Bug in `read_csv()` that caused it to raise `OverflowError` when trying to use 'inf' as `na_value` with integer index column ([GH17128](#))
- Bug in `read_fwf()` in which the compression type of a file was not being properly inferred ([GH22199](#))
- Bug in `pandas.io.json.json_normalize()` that caused it to raise `TypeError` when two consecutive elements of `record_path` are dicts ([GH22706](#))
- Bug in `DataFrame.to_stata()`, `pandas.io.stata.StataWriter` and `pandas.io.stata.StataWriter117` where a exception would leave a partially written and invalid dta file ([GH23573](#))
- Bug in `DataFrame.to_stata()` and `pandas.io.stata.StataWriter117` that produced invalid files when using strLs with non-ASCII characters ([GH23573](#))
- Bug in `HDFStore` that caused it to raise `ValueError` when reading a `Dataframe` in Python 3 from fixed format written in Python 2 ([GH24510](#))

1.6.14 Plotting

- Bug in `DataFrame.plot.scatter()` and `DataFrame.plot.hexbin()` caused x-axis label and tick-labels to disappear when colorbar was on in IPython inline backend ([GH10611](#), [GH10678](#), and [GH20455](#))
- Bug in plotting a Series with datetimes using `matplotlib.axes.Axes.scatter()` ([GH22039](#))
- Bug in `DataFrame.plot.bar()` caused bars to use multiple colors instead of a single one ([GH20585](#))
- Bug in validating color parameter caused extra color to be appended to the given color array. This happened to multiple plotting functions using matplotlib. ([GH20726](#))

1.6.15 Groupby/Resample/Rolling

- Bug in `pandas.core.groupby.GroupBy.first()` and `pandas.core.groupby.GroupBy.last()` with `as_index=False` leading to the loss of timezone information ([GH15884](#))
- Bug in `DataFrame.resample()` when downsampling across a DST boundary ([GH8531](#))
- Bug in date anchoring for `DataFrame.resample()` with offset Day when `n > 1` ([GH24127](#))
- Bug where `ValueError` is wrongly raised when calling `count()` method of a `SeriesGroupBy` when the grouping variable only contains NaNs and numpy version `< 1.13` ([GH21956](#)).
- Multiple bugs in `pandas.core.window.Rolling.min()` with `closed='left'` and a datetime-like index leading to incorrect results and also segfault. ([GH21704](#))
- Bug in `pandas.core.resample.Resampler.apply()` when passing positional arguments to applied func ([GH14615](#)).
- Bug in `Series.resample()` when passing `numpy.timedelta64` to `loffset` kwarg ([GH7687](#)).
- Bug in `pandas.core.resample.Resampler.asfreq()` when frequency of `TimedeltaIndex` is a subperiod of a new frequency ([GH13022](#)).
- Bug in `pandas.core.groupby.SeriesGroupBy.mean()` when values were integral but could not fit inside of `int64`, overflowing instead. ([GH22487](#))
- `pandas.core.groupby.RollingGroupBy.agg()` and `pandas.core.groupby.ExpandingGroupBy.agg()` now support multiple aggregation functions as parameters ([GH15072](#))
- Bug in `DataFrame.resample()` and `Series.resample()` when resampling by a weekly offset ('W') across a DST transition ([GH9119](#), [GH21459](#))
- Bug in `DataFrame.expanding()` in which the `axis` argument was not being respected during aggregations ([GH23372](#))
- Bug in `pandas.core.groupby.GroupBy.transform()` which caused missing values when the input function can accept a `DataFrame` but renames it ([GH23455](#)).
- Bug in `pandas.core.groupby.GroupBy.nth()` where column order was not always preserved ([GH20760](#))
- Bug in `pandas.core.groupby.GroupBy.rank()` with `method='dense'` and `pct=True` when a group has only one member would raise a `ZeroDivisionError` ([GH23666](#)).
- Calling `pandas.core.groupby.GroupBy.rank()` with empty groups and `pct=True` was raising a `ZeroDivisionError` ([GH22519](#))
- Bug in `DataFrame.resample()` when resampling `NaT` in `TimeDeltaIndex` ([GH13223](#)).
- Bug in `DataFrame.groupby()` did not respect the `observed` argument when selecting a column and instead always used `observed=False` ([GH23970](#))

1.6.16 Reshaping

- Bug in `pandas.concat()` when joining resampled DataFrames with timezone aware index ([GH13783](#))
- Bug in `pandas.concat()` when joining only *Series* the *names* argument of *concat* is no longer ignored ([GH23490](#))
- Bug in `Series.combine_first()` with `datetime64[ns, tz]` dtype which would return tz-naive result ([GH21469](#))
- Bug in `Series.where()` and `DataFrame.where()` with `datetime64[ns, tz]` dtype ([GH21546](#))
- Bug in `DataFrame.where()` with an empty `DataFrame` and empty `cond` having non-bool dtype ([GH21947](#))
- Bug in `Series.mask()` and `DataFrame.mask()` with list conditionals ([GH21891](#))
- Bug in `DataFrame.replace()` raises `RecursionError` when converting `OutOfBounds` `datetime64[ns, tz]` ([GH20380](#))
- `pandas.core.groupby.GroupBy.rank()` now raises a `ValueError` when an invalid value is passed for argument `na_option` ([GH22124](#))
- Bug in `get_dummies()` with Unicode attributes in Python 2 ([GH22084](#))
- Bug in `DataFrame.replace()` raises `RecursionError` when replacing empty lists ([GH22083](#))
- Bug in `Series.replace()` and `DataFrame.replace()` when dict is used as the `to_replace` value and one key in the dict is another key's value, the results were inconsistent between using integer key and using string key ([GH20656](#))
- Bug in `DataFrame.drop_duplicates()` for empty `DataFrame` which incorrectly raises an error ([GH20516](#))
- Bug in `pandas.wide_to_long()` when a string is passed to the `stubnames` argument and a column name is a substring of that `stubname` ([GH22468](#))
- Bug in `merge()` when merging `datetime64[ns, tz]` data that contained a DST transition ([GH18885](#))
- Bug in `merge_asof()` when merging on float values within defined tolerance ([GH22981](#))
- Bug in `pandas.concat()` when concatenating a multicolumn `DataFrame` with tz-aware data against a `DataFrame` with a different number of columns ([GH22796](#))
- Bug in `merge_asof()` where confusing error message raised when attempting to merge with missing values ([GH23189](#))
- Bug in `DataFrame.nsmallest()` and `DataFrame.nlargest()` for dataframes that have a `MultiIndex` for columns ([GH23033](#)).
- Bug in `pandas.melt()` when passing column names that are not present in `DataFrame` ([GH23575](#))
- Bug in `DataFrame.append()` with a `Series` with a `dateutil` timezone would raise a `TypeError` ([GH23682](#))
- Bug in `Series` construction when passing no data and `dtype=str` ([GH22477](#))
- Bug in `cut()` with `bins` as an overlapping `IntervalIndex` where multiple bins were returned per item instead of raising a `ValueError` ([GH23980](#))
- Bug in `pandas.concat()` when joining `Series datetime64tz` with `Series category` would lose timezone ([GH23816](#))
- Bug in `DataFrame.join()` when joining on partial `MultiIndex` would drop names ([GH20452](#)).
- `DataFrame.nlargest()` and `DataFrame.nsmallest()` now returns the correct `n` values when `keep != 'all'` also when tied on the first columns ([GH22752](#))

- Constructing a DataFrame with an index argument that wasn't already an instance of Index was broken (GH22227).
- Bug in DataFrame prevented list subclasses to be used to construction (GH21226)
- Bug in DataFrame.unstack() and DataFrame.pivot_table() returning a misleading error message when the resulting DataFrame has more elements than int32 can handle. Now, the error message is improved, pointing towards the actual problem (GH20601)
- Bug in DataFrame.unstack() where a ValueError was raised when unstacking timezone aware values (GH18338)
- Bug in DataFrame.stack() where timezone aware values were converted to timezone naive values (GH19420)
- Bug in merge_asof() where a TypeError was raised when by_col were timezone aware values (GH21184)

1.6.17 Sparse

- Updating a boolean, datetime, or timedelta column to be Sparse now works (GH22367)
- Bug in Series.to_sparse() with Series already holding sparse data not constructing properly (GH22389)
- Providing a sparse_index to the SparseArray constructor no longer defaults the na-value to np.nan for all dtypes. The correct na_value for data.dtype is now used.
- Bug in SparseArray.nbytes under-reporting its memory usage by not including the size of its sparse index.
- Improved performance of Series.shift() for non-NA fill_value, as values are no longer converted to a dense array.
- Bug in DataFrame.groupby not including fill_value in the groups for non-NA fill_value when grouping by a sparse column (GH5078)
- Bug in unary inversion operator (~) on a SparseSeries with boolean values. The performance of this has also been improved (GH22835)
- Bug in SparseArray.unique() not returning the unique values (GH19595)
- Bug in SparseArray.nonzero() and SparseDataFrame.dropna() returning shifted/incorrect results (GH21172)
- Bug in DataFrame.apply() where dtypes would lose sparseness (GH23744)
- Bug in concat() when concatenating a list of Series with all-sparse values changing the fill_value and converting to a dense Series (GH24371)

1.6.18 Style

- background_gradient() now takes a text_color_threshold parameter to automatically lighten the text color based on the luminance of the background color. This improves readability with dark background colors without the need to limit the background colormap range. (GH21258)
- background_gradient() now also supports tablewise application (in addition to rowwise and columnwise) with axis=None (GH15204)
- bar() now also supports tablewise application (in addition to rowwise and columnwise) with axis=None and setting clipping range with vmin and vmax (GH21548 and GH21526). NaN values are also handled properly.

1.6.19 Build Changes

- Building pandas for development now requires `cython >= 0.28.2` ([GH21688](#))
- Testing pandas now requires `hypothesis>=3.58`. You can find [the Hypothesis docs here](#), and a pandas-specific introduction *in the contributing guide*. ([GH22280](#))
- Building pandas on macOS now targets minimum macOS 10.9 if run on macOS 10.9 or above ([GH23424](#))

1.6.20 Other

- Bug where C variables were declared with external linkage causing import errors if certain other C libraries were imported before Pandas. ([GH24113](#))

1.7 Contributors

A total of 334 people contributed patches to this release. People with a “+” by their names contributed a patch for the first time.

INSTALLATION

The easiest way to install pandas is to install it as part of the [Anaconda](#) distribution, a cross platform distribution for data analysis and scientific computing. This is the recommended installation method for most users.

Instructions for installing from source, [PyPI](#), [ActivePython](#), various Linux distributions, or a [development version](#) are also provided.

2.1 Plan for dropping Python 2.7

The Python core team plans to stop supporting Python 2.7 on January 1st, 2020. In line with [NumPy's plans](#), all pandas releases through December 31, 2018 will support Python 2.

The 0.24.x feature release will be the last release to support Python 2. The released package will continue to be available on PyPI and through conda.

Starting **January 1, 2019**, all new feature releases (> 0.24) will be Python 3 only.

If there are people interested in continued support for Python 2.7 past December 31, 2018 (either backporting bug fixes or funding) please reach out to the maintainers on the issue tracker.

For more information, see the [Python 3 statement](#) and the [Porting to Python 3 guide](#).

2.2 Python version support

Officially Python 2.7, 3.5, 3.6, and 3.7.

2.3 Installing pandas

2.3.1 Installing with Anaconda

Installing pandas and the rest of the [NumPy](#) and [SciPy](#) stack can be a little difficult for inexperienced users.

The simplest way to install not only pandas, but Python and the most popular packages that make up the [SciPy](#) stack ([IPython](#), [NumPy](#), [Matplotlib](#), ...) is with [Anaconda](#), a cross-platform (Linux, Mac OS X, Windows) Python distribution for data analytics and scientific computing.

After running the installer, the user will have access to pandas and the rest of the [SciPy](#) stack without needing to install anything else, and without needing to wait for any software to be compiled.

Installation instructions for [Anaconda](#) can be found [here](#).

A full list of the packages available as part of the [Anaconda](#) distribution [can be found here](#).

Another advantage to installing Anaconda is that you don't need admin rights to install it. Anaconda can install in the user's home directory, which makes it trivial to delete Anaconda if you decide (just delete that folder).

2.3.2 Installing with Miniconda

The previous section outlined how to get pandas installed as part of the [Anaconda](#) distribution. However this approach means you will install well over one hundred packages and involves downloading the installer which is a few hundred megabytes in size.

If you want to have more control on which packages, or have a limited internet bandwidth, then installing pandas with [Miniconda](#) may be a better solution.

[Conda](#) is the package manager that the [Anaconda](#) distribution is built upon. It is a package manager that is both cross-platform and language agnostic (it can play a similar role to a pip and virtualenv combination).

[Miniconda](#) allows you to create a minimal self contained Python installation, and then use the [Conda](#) command to install additional packages.

First you will need [Conda](#) to be installed and downloading and running the [Miniconda](#) will do this for you. The installer [can be found here](#)

The next step is to create a new conda environment. A conda environment is like a virtualenv that allows you to specify a specific version of Python and set of libraries. Run the following commands from a terminal window:

```
conda create -n name_of_my_env python
```

This will create a minimal environment with only Python installed in it. To put your self inside this environment run:

```
source activate name_of_my_env
```

On Windows the command is:

```
activate name_of_my_env
```

The final step required is to install pandas. This can be done with the following command:

```
conda install pandas
```

To install a specific pandas version:

```
conda install pandas=0.20.3
```

To install other packages, IPython for example:

```
conda install ipython
```

To install the full [Anaconda](#) distribution:

```
conda install anaconda
```

If you need packages that are available to pip but not conda, then install pip, and then use pip to install those packages:

```
conda install pip
pip install django
```

2.3.3 Installing from PyPI

pandas can be installed via pip from [PyPI](#).

```
pip install pandas
```

2.3.4 Installing with ActivePython

Installation instructions for [ActivePython](#) can be found [here](#). Versions 2.7 and 3.5 include pandas.

2.3.5 Installing using your Linux distribution's package manager.

The commands in this table will install pandas for Python 3 from your distribution. To install pandas for Python 2, you may need to use the `python-pandas` package.

Distribution	Status	Download / Repository Link	Install method
Debian	stable	official Debian repository	<code>sudo apt-get install python3-pandas</code>
Debian & Ubuntu	unstable (latest packages)	NeuroDebian	<code>sudo apt-get install python3-pandas</code>
Ubuntu	stable	official Ubuntu repository	<code>sudo apt-get install python3-pandas</code>
OpenSuse	stable	OpenSuse Repository	<code>zypper in python3-pandas</code>
Fedora	stable	official Fedora repository	<code>dnf install python3-pandas</code>
Centos/RHEL	stable	EPEL repository	<code>yum install python3-pandas</code>

However, the packages in the linux package managers are often a few versions behind, so to get the newest version of pandas, it's recommended to install using the `pip` or `conda` methods described above.

2.3.6 Installing from source

See the *contributing guide* for complete instructions on building from the git source tree. Further, see *creating a development environment* if you wish to create a *pandas* development environment.

2.4 Running the test suite

pandas is equipped with an exhaustive set of unit tests, covering about 97% of the code base as of this writing. To run it on your machine to verify that everything is working (and that you have all of the dependencies, soft and hard, installed), make sure you have `pytest` ≥ 3.6 and `Hypothesis` ≥ 3.58 , then run:

```
>>> pd.test()
running: pytest --skip-slow --skip-network C:\Users\TP\Anaconda3\envs\py36\lib\site-
packages\pandas
===== test session starts =====
```

(continues on next page)

(continued from previous page)

```
platform win32 -- Python 3.6.2, pytest-3.6.0, py-1.4.34, pluggy-0.4.0
rootdir: C:\Users\TP\Documents\Python\pandasdev\pandas, inifile: setup.cfg
collected 12145 items / 3 skipped

```

2.5 Dependencies

- **setuptools**: 24.2.0 or higher
- **NumPy**: 1.12.0 or higher
- **python-dateutil**: 2.5.0 or higher
- **pytz**

2.5.1 Recommended Dependencies

- **numexpr**: for accelerating certain numerical operations. **numexpr** uses multiple cores as well as smart chunking and caching to achieve large speedups. If installed, must be Version 2.6.1 or higher.
- **bottleneck**: for accelerating certain types of nan evaluations. **bottleneck** uses specialized cython routines to achieve large speedups. If installed, must be Version 1.2.0 or higher.

Note: You are highly encouraged to install these libraries, as they provide speed improvements, especially when working with large data sets.

2.5.2 Optional Dependencies

- **Cython**: Only necessary to build development version. Version 0.28.2 or higher.
- **SciPy**: miscellaneous statistical functions, Version 0.18.1 or higher
- **xarray**: pandas like handling for > 2 dims, needed for converting Panels to xarray objects. Version 0.7.0 or higher is recommended.
- **PyTables**: necessary for HDF5-based storage, Version 3.4.2 or higher
- **pyarrow** (>= 0.7.0): necessary for feather-based storage.
- **Apache Parquet**, either **pyarrow** (>= 0.7.0) or **fastparquet** (>= 0.2.1) for parquet-based storage. The **snappy** and **brotli** are available for compression support.
- **SQLAlchemy**: for SQL database support. Version 0.8.1 or higher recommended. Besides SQLAlchemy, you also need a database specific driver. You can find an overview of supported drivers for each SQL dialect in the [SQLAlchemy docs](#). Some common drivers are:
 - **psycopg2**: for PostgreSQL
 - **pymysql**: for MySQL.

- `SQLite`: for SQLite, this is included in Python’s standard library by default.
- `matplotlib`: for plotting, Version 2.0.0 or higher.
- For Excel I/O:
 - `xlrd/xlwt`: Excel reading (`xlrd`), version 1.0.0 or higher required, and writing (`xlwt`)
 - `openpyxl`: `openpyxl` version 2.4.0 for writing .xlsx files (`xlrd` $\geq$ 0.9.0)
 - `XlsxWriter`: Alternative Excel writer
- `Jinja2`: Template engine for conditional HTML formatting.
- `s3fs`: necessary for Amazon S3 access (`s3fs` $\geq$ 0.0.7).
- `blosc`: for msgpack compression using `blosc`
- `gcsfs`: necessary for Google Cloud Storage access (`gcsfs` $\geq$ 0.1.0).
- One of `qtpy` (requires `PyQt` or `PySide`), `PyQt5`, `PyQt4`, `pygtk`, `xsel`, or `xclip`: necessary to use `read_clipboard()`. Most package managers on Linux distributions will have `xclip` and/or `xsel` immediately available for installation.
- `pandas-gbq`: for Google BigQuery I/O. (`pandas-gbq` $\geq$ 0.8.0)
- `Backports.lzma`: Only for Python 2, for writing to and/or reading from an xz compressed DataFrame in CSV; Python 3 support is built into the standard library.
- One of the following combinations of libraries is needed to use the top-level `read_html()` function:
Changed in version 0.23.0.

Note: If using `BeautifulSoup4` a minimum version of 4.2.1 is required

- `BeautifulSoup4` and `html5lib` (Any recent version of `html5lib` is okay.)
- `BeautifulSoup4` and `lxml`
- `BeautifulSoup4` and `html5lib` and `lxml`
- Only `lxml`, although see *HTML Table Parsing* for reasons as to why you should probably **not** take this approach.

Warning:

- if you install `BeautifulSoup4` you must install either `lxml` or `html5lib` or both. `read_html()` will **not** work with *only* `BeautifulSoup4` installed.
- You are highly encouraged to read *HTML Table Parsing gotchas*. It explains issues surrounding the installation and usage of the above three libraries.

Note:

- if you’re on a system with `apt-get` you can do

```
sudo apt-get build-dep python-lxml
```

to get the necessary dependencies for installation of `lxml`. This will prevent further headaches down the line.

Note: Without the optional dependencies, many useful features will not work. Hence, it is highly recommended that you install these. A packaged distribution like [Anaconda](#), [ActivePython](#) (version 2.7 or 3.5), or [Enthought Canopy](#) may be worth considering.

 - *Updating your pull request*
 - *Delete your merged branch (optional)*

3.1 Where to start?

All contributions, bug reports, bug fixes, documentation improvements, enhancements, and ideas are welcome.

If you are brand new to pandas or open-source development, we recommend going through the [GitHub “issues” tab](#) to find issues that interest you. There are a number of issues listed under [Docs](#) and [good first issue](#) where you could start out. Once you’ve found an interesting issue, you can return here to get your development environment setup.

Feel free to ask questions on the [mailing list](#) or on [Gitter](#).

3.2 Bug reports and enhancement requests

Bug reports are an important part of making *pandas* more stable. Having a complete bug report will allow others to reproduce the bug and provide insight into fixing. See [this stackoverflow article](#) and [this blogpost](#) for tips on writing a good bug report.

Trying the bug-producing code out on the *master* branch is often a worthwhile exercise to confirm the bug still exists. It is also worth searching existing bug reports and pull requests to see if the issue has already been reported and/or fixed.

Bug reports must:

1. Include a short, self-contained Python snippet reproducing the problem. You can format the code nicely by using [GitHub Flavored Markdown](#):

```
```python
>>> from pandas import DataFrame
```

(continues on next page)

(continued from previous page)

```
>>> df = DataFrame(...)
...
...
```

2. Include the full version string of *pandas* and its dependencies. You can use the built in function:

```
>>> import pandas as pd
>>> pd.show_versions()
```

3. Explain why the current behavior is wrong/not desired and what you expect instead.

The issue will then show up to the *pandas* community and be open to comments/ideas from others.

## 3.3 Working with the code

Now that you have an issue you want to fix, enhancement to add, or documentation to improve, you need to learn how to work with GitHub and the *pandas* code base.

### 3.3.1 Version control, Git, and GitHub

To the new user, working with Git is one of the more daunting aspects of contributing to *pandas*. It can very quickly become overwhelming, but sticking to the guidelines below will help keep the process straightforward and mostly trouble free. As always, if you are having difficulties please feel free to ask for help.

The code is hosted on [GitHub](#). To contribute you will need to sign up for a [free GitHub account](#). We use [Git](#) for version control to allow many people to work together on the project.

Some great resources for learning Git:

- the [GitHub help pages](#).
- the [NumPy's documentation](#).
- Matthew Brett's [Pydagogue](#).

### 3.3.2 Getting started with Git

[GitHub has instructions](#) for installing git, setting up your SSH key, and configuring git. All these steps need to be completed before you can work seamlessly between your local repository and GitHub.

### 3.3.3 Forking

You will need your own fork to work on the code. Go to the [pandas project page](#) and hit the `Fork` button. You will want to clone your fork to your machine:

```
git clone https://github.com/your-user-name/pandas.git pandas-yourname
cd pandas-yourname
git remote add upstream https://github.com/pandas-dev/pandas.git
```

This creates the directory *pandas-yourname* and connects your repository to the upstream (main project) *pandas* repository.

### 3.3.4 Creating a development environment

To test out code changes, you'll need to build pandas from source, which requires a C compiler and Python environment. If you're making documentation changes, you can skip to *Contributing to the documentation* but you won't be able to build the documentation locally before pushing your changes.

#### 3.3.4.1 Installing a C Compiler

Pandas uses C extensions (mostly written using Cython) to speed up certain operations. To install pandas from source, you need to compile these C extensions, which means you need a C compiler. This process depends on which platform you're using. Follow the [Cython contributing guide](#) for getting a compiler installed. You don't need to do any of the `./configure` or `make` steps; you only need to install the compiler.

For Windows developers, when using Python 3.5 and later, it is sufficient to install [Visual Studio 2017](#) with the **Python development workload** and the **Python native development tools** option. Otherwise, the following links may be helpful.

- <https://blogs.msdn.microsoft.com/pythonengineering/2017/03/07/python-support-in-vs2017/>
- <https://blogs.msdn.microsoft.com/pythonengineering/2016/04/11/unable-to-find-vcvarsall-bat/>
- <https://github.com/conda/conda-recipes/wiki/Building-from-Source-on-Windows-32-bit-and-64-bit>
- <https://cowboyprogrammer.org/building-python-wheels-for-windows/>
- <https://blog.ionelm.ro/2014/12/21/compiling-python-extensions-on-windows/>
- <https://support.enthought.com/hc/en-us/articles/204469260-Building-Python-extensions-with-Canopy>

Let us know if you have any difficulties by opening an issue or reaching out on [Gitter](#).

#### 3.3.4.2 Creating a Python Environment

Now that you have a C compiler, create an isolated pandas development environment:

- Install either [Anaconda](#) or [miniconda](#)
- Make sure your conda is up to date (`conda update conda`)
- Make sure that you have *cloned the repository*
- `cd` to the *pandas* source directory

We'll now kick off a three-step process:

1. Install the build dependencies
2. Build and install pandas
3. Install the optional dependencies

```
Create and activate the build environment
conda env create -f environment.yml
conda activate pandas-dev

or with older versions of Anaconda:
source activate pandas-dev

Build and install pandas
python setup.py build_ext --inplace -j 4
python -m pip install -e .
```

At this point you should be able to import pandas from your locally built version:

```
$ python # start an interpreter
>>> import pandas
>>> print(pandas.__version__)
0.22.0.dev0+29.g4ad6d4d74
```

This will create the new environment, and not touch any of your existing environments, nor any existing Python installation.

To view your environments:

```
conda info -e
```

To return to your root environment:

```
conda deactivate
```

See the full conda docs [here](#).

### 3.3.4.3 Creating a Python Environment (pip)

If you aren't using conda for your development environment, follow these instructions. You'll need to have at least python3.5 installed on your system.

```
Create a virtual environment
Use an ENV_DIR of your choice. We'll use ~/virtualenvs/pandas-dev
Any parent directories should already exist
python3 -m venv ~/virtualenvs/pandas-dev
Activate the virtualenv
. ~/virtualenvs/pandas-dev/bin/activate

Install the build dependencies
python -m pip install -r requirements-dev.txt

Build and install pandas
python setup.py build_ext --inplace -j 4
python -m pip install -e .
```

### 3.3.5 Creating a branch

You want your master branch to reflect only production-ready code, so create a feature branch for making your changes. For example:

```
git branch shiny-new-feature
git checkout shiny-new-feature
```

The above can be simplified to:

```
git checkout -b shiny-new-feature
```

This changes your working directory to the shiny-new-feature branch. Keep any changes in this branch specific to one bug or feature so it is clear what the branch brings to *pandas*. You can have many shiny-new-features and switch in between them using the git checkout command.

When creating this branch, make sure your master branch is up to date with the latest upstream master version. To update your local master branch, you can do:

```
git checkout master
git pull upstream master --ff-only
```

When you want to update the feature branch with changes in master after you created the branch, check the section on *updating a PR*.

## 3.4 Contributing to the documentation

Contributing to the documentation benefits everyone who uses *pandas*. We encourage you to help us improve the documentation, and you don't have to be an expert on *pandas* to do so! In fact, there are sections of the docs that are worse off after being written by experts. If something in the docs doesn't make sense to you, updating the relevant section after you figure it out is a great way to ensure it will help the next person.

### Documentation:

- *About the pandas documentation*
- *Updating a pandas docstring*
- *How to build the pandas documentation*
  - *Requirements*
  - *Building the documentation*
  - *Building master branch documentation*

### 3.4.1 About the *pandas* documentation

The documentation is written in **reStructuredText**, which is almost like writing in plain English, and built using **Sphinx**. The Sphinx Documentation has an excellent [introduction to reST](#). Review the Sphinx docs to perform more complex changes to the documentation as well.

Some other important things to know about the docs:

- The *pandas* documentation consists of two parts: the docstrings in the code itself and the docs in this folder `pandas/doc/`.  
The docstrings provide a clear explanation of the usage of the individual functions, while the documentation in this folder consists of tutorial-like overviews per topic together with some other information (what's new, installation, etc).
- The docstrings follow a pandas convention, based on the **Numpy Docstring Standard**. Follow the *pandas docstring guide* for detailed instructions on how to write a correct docstring. `{{ header }}`

#### 3.4.1.1 pandas docstring guide

##### About docstrings and standards

A Python docstring is a string used to document a Python module, class, function or method, so programmers can understand what it does without having to read the details of the implementation.

Also, it is a common practice to generate online (html) documentation automatically from docstrings. [Sphinx](#) serves this purpose.

Next example gives an idea on how a docstring looks like:

```
def add(num1, num2):
 """
 Add up two integer numbers.

 This function simply wraps the `+` operator, and does not
 do anything interesting, except for illustrating what is
 the docstring of a very simple function.

 Parameters

 num1 : int
 First number to add
 num2 : int
 Second number to add

 Returns

 int
 The sum of `num1` and `num2`

 See Also

 subtract : Subtract one integer from another

 Examples

 >>> add(2, 2)
 4
 >>> add(25, 0)
 25
 >>> add(10, -10)
 0
 """
 return num1 + num2
```

Some standards exist about docstrings, so they are easier to read, and they can be exported to other formats such as html or pdf.

The first conventions every Python docstring should follow are defined in [PEP-257](#).

As PEP-257 is quite open, and some other standards exist on top of it. In the case of pandas, the numpy docstring convention is followed. The conventions is explained in this document:

- [numpydoc docstring guide](#) (which is based in the original [Guide to NumPy/SciPy documentation](#))

numpydoc is a Sphinx extension to support the numpy docstring convention.

The standard uses reStructuredText (reST). reStructuredText is a markup language that allows encoding styles in plain text files. Documentation about reStructuredText can be found in:

- [Sphinx reStructuredText primer](#)
- [Quick reStructuredText reference](#)
- [Full reStructuredText specification](#)

Pandas has some helpers for sharing docstrings between related classes, see *Sharing Docstrings*.

The rest of this document will summarize all the above guides, and will provide additional convention specific to the pandas project.

## Writing a docstring

### General rules

Docstrings must be defined with three double-quotes. No blank lines should be left before or after the docstring. The text starts in the next line after the opening quotes. The closing quotes have their own line (meaning that they are not at the end of the last sentence).

In rare occasions reST styles like bold text or italics will be used in docstrings, but it is common to have inline code, which is presented between backticks. It is considered inline code:

- The name of a parameter
- Python code, a module, function, built-in, type, literal... (e.g. `os`, `list`, `numpy.abs`, `datetime.date`, `True`)
- A pandas class (in the form `:class:`pandas.Series``)
- A pandas method (in the form `:meth:`pandas.Series.sum``)
- A pandas function (in the form `:func:`pandas.to_datetime``)

---

**Note:** To display only the last component of the linked class, method or function, prefix it with `~`. For example, `:class:`~pandas.Series`` will link to `pandas.Series` but only display the last part, `Series` as the link text. See [Sphinx cross-referencing syntax](#) for details.

---

#### Good:

```
def add_values(arr):
 """
 Add the values in `arr`.

 This is equivalent to Python `sum` of :meth:`pandas.Series.sum`.

 Some sections are omitted here for simplicity.
 """
 return sum(arr)
```

#### Bad:

```
def func():

 """Some function.

 With several mistakes in the docstring.

 It has a blank line after the signature `def func():`.

 The text 'Some function' should go in the line after the
 opening quotes of the docstring, not in the same line.

 There is a blank line between the docstring and the first line
 of code `foo = 1`.
```

(continues on next page)

(continued from previous page)

```

The closing quotes should be in the next line, not in this one."""

foo = 1
bar = 2
return foo + bar

```

## Section 1: Short summary

The short summary is a single sentence that expresses what the function does in a concise way.

The short summary must start with a capital letter, end with a dot, and fit in a single line. It needs to express what the object does without providing details. For functions and methods, the short summary must start with an infinitive verb.

### Good:

```

def astype(dtype):
 """
 Cast Series type.

 This section will provide further details.
 """
 pass

```

### Bad:

```

def astype(dtype):
 """
 Casts Series type.

 Verb in third-person of the present simple, should be infinitive.
 """
 pass

```

```

def astype(dtype):
 """
 Method to cast Series type.

 Does not start with verb.
 """
 pass

```

```

def astype(dtype):
 """
 Cast Series type

 Missing dot at the end.
 """
 pass

```

```

def astype(dtype):
 """
 Cast Series type from its current type to the new type defined in

```

(continues on next page)

(continued from previous page)

```
the parameter dtype.

Summary is too verbose and doesn't fit in a single line.
"""
pass
```

## Section 2: Extended summary

The extended summary provides details on what the function does. It should not go into the details of the parameters, or discuss implementation notes, which go in other sections.

A blank line is left between the short summary and the extended summary. And every paragraph in the extended summary is finished by a dot.

The extended summary should provide details on why the function is useful and their use cases, if it is not too generic.

```
def unstack():
 """
 Pivot a row index to columns.

 When using a MultiIndex, a level can be pivoted so each value in
 the index becomes a column. This is especially useful when a subindex
 is repeated for the main index, and data is easier to visualize as a
 pivot table.

 The index level will be automatically removed from the index when added
 as columns.
 """
 pass
```

## Section 3: Parameters

The details of the parameters will be added in this section. This section has the title “Parameters”, followed by a line with a hyphen under each letter of the word “Parameters”. A blank line is left before the section title, but not after, and not between the line with the word “Parameters” and the one with the hyphens.

After the title, each parameter in the signature must be documented, including *\*args* and *\*\*kwargs*, but not *self*.

The parameters are defined by their name, followed by a space, a colon, another space, and the type (or types). Note that the space between the name and the colon is important. Types are not defined for *\*args* and *\*\*kwargs*, but must be defined for all other parameters. After the parameter definition, it is required to have a line with the parameter description, which is indented, and can have multiple lines. The description must start with a capital letter, and finish with a dot.

For keyword arguments with a default value, the default will be listed after a comma at the end of the type. The exact form of the type in this case will be “int, default 0”. In some cases it may be useful to explain what the default argument means, which can be added after a comma “int, default -1, meaning all cpus”.

In cases where the default value is *None*, meaning that the value will not be used. Instead of “str, default None”, it is preferred to write “str, optional”. When *None* is a value being used, we will keep the form “str, default None”. For example, in `df.to_csv(compression=None)`, *None* is not a value being used, but means that compression is optional, and no compression is being used if not provided. In this case we will use *str, optional*.

Only in cases like *func(value=None)* and *None* is being used in the same way as *0* or *foo* would be used, then we will specify “str, int or None, default None”.

**Good:**

```
class Series:
 def plot(self, kind, color='blue', **kwargs):
 """
 Generate a plot.

 Render the data in the Series as a matplotlib plot of the
 specified kind.

 Parameters

 kind : str
 Kind of matplotlib plot.
 color : str, default 'blue'
 Color name or rgb code.
 **kwargs
 These parameters will be passed to the matplotlib plotting
 function.
 """
 pass
```

**Bad:**

```
class Series:
 def plot(self, kind, **kwargs):
 """
 Generate a plot.

 Render the data in the Series as a matplotlib plot of the
 specified kind.

 Note the blank line between the parameters title and the first
 parameter. Also, note that after the name of the parameter `kind`
 and before the colon, a space is missing.

 Also, note that the parameter descriptions do not start with a
 capital letter, and do not finish with a dot.

 Finally, the `**kwargs` parameter is missing.

 Parameters

 kind: str
 kind of matplotlib plot
 """
 pass
```

## Parameter types

When specifying the parameter types, Python built-in data types can be used directly (the Python type is preferred to the more verbose string, integer, boolean, etc):

- int

- float
- str
- bool

For complex types, define the subtypes. For *dict* and *tuple*, as more than one type is present, we use the brackets to help read the type (curly brackets for *dict* and normal brackets for *tuple*):

- list of int
- dict of {str : int}
- tuple of (str, int, int)
- tuple of (str,)
- set of str

In case where there are just a set of values allowed, list them in curly brackets and separated by commas (followed by a space). If the values are ordinal and they have an order, list them in this order. Otherwise, list the default value first, if there is one:

- {0, 10, 25}
- {'simple', 'advanced'}
- {'low', 'medium', 'high'}
- {'cat', 'dog', 'bird'}

If the type is defined in a Python module, the module must be specified:

- datetime.date
- datetime.datetime
- decimal.Decimal

If the type is in a package, the module must be also specified:

- numpy.ndarray
- scipy.sparse.coo\_matrix

If the type is a pandas type, also specify pandas except for Series and DataFrame:

- Series
- DataFrame
- pandas.Index
- pandas.Categorical
- pandas.SparseArray

If the exact type is not relevant, but must be compatible with a numpy array, array-like can be specified. If Any type that can be iterated is accepted, iterable can be used:

- array-like
- iterable

If more than one type is accepted, separate them by commas, except the last two types, that need to be separated by the word 'or':

- int or float
- float, decimal.Decimal or None

- str or list of str

If `None` is one of the accepted values, it always needs to be the last in the list.

For axis, the convention is to use something like:

- axis : {0 or 'index', 1 or 'columns', None}, default None

## Section 4: Returns or Yields

If the method returns a value, it will be documented in this section. Also if the method yields its output.

The title of the section will be defined in the same way as the “Parameters”. With the names “Returns” or “Yields” followed by a line with as many hyphens as the letters in the preceding word.

The documentation of the return is also similar to the parameters. But in this case, no name will be provided, unless the method returns or yields more than one value (a tuple of values).

The types for “Returns” and “Yields” are the same as the ones for the “Parameters”. Also, the description must finish with a dot.

For example, with a single value:

```
def sample():
 """
 Generate and return a random number.

 The value is sampled from a continuous uniform distribution between
 0 and 1.

 Returns

 float
 Random number generated.
 """
 return np.random.random()
```

With more than one value:

```
import string

def random_letters():
 """
 Generate and return a sequence of random letters.

 The length of the returned string is also random, and is also
 returned.

 Returns

 length : int
 Length of the returned string.
 letters : str
 String of random letters.
 """
 length = np.random.randint(1, 10)
 letters = ''.join(np.random.choice(string.ascii_lowercase)
 for i in range(length))
 return length, letters
```

If the method yields its value:

```
def sample_values():
 """
 Generate an infinite sequence of random numbers.

 The values are sampled from a continuous uniform distribution between
 0 and 1.

 Yields

 float
 Random number generated.
 """
 while True:
 yield np.random.random()
```

## Section 5: See Also

This section is used to let users know about pandas functionality related to the one being documented. In rare cases, if no related methods or functions can be found at all, this section can be skipped.

An obvious example would be the *head()* and *tail()* methods. As *tail()* does the equivalent as *head()* but at the end of the *Series* or *DataFrame* instead of at the beginning, it is good to let the users know about it.

To give an intuition on what can be considered related, here there are some examples:

- `loc` and `iloc`, as they do the same, but in one case providing indices and in the other positions
- `max` and `min`, as they do the opposite
- `iterrows`, `itertuples` and `iteritems`, as it is easy that a user looking for the method to iterate over columns ends up in the method to iterate over rows, and vice-versa
- `fillna` and `dropna`, as both methods are used to handle missing values
- `read_csv` and `to_csv`, as they are complementary
- `merge` and `join`, as one is a generalization of the other
- `astype` and `pandas.to_datetime`, as users may be reading the documentation of `astype` to know how to cast as a date, and the way to do it is with `pandas.to_datetime`
- `where` is related to `numpy.where`, as its functionality is based on it

When deciding what is related, you should mainly use your common sense and think about what can be useful for the users reading the documentation, especially the less experienced ones.

When relating to other libraries (mainly `numpy`), use the name of the module first (not an alias like `np`). If the function is in a module which is not the main one, like `scipy.sparse`, list the full module (e.g. `scipy.sparse.coo_matrix`).

This section, as the previous, also has a header, “See Also” (note the capital S and A). Also followed by the line with hyphens, and preceded by a blank line.

After the header, we will add a line for each related method or function, followed by a space, a colon, another space, and a short description that illustrated what this method or function does, why is it relevant in this context, and what are the key differences between the documented function and the one referencing. The description must also finish with a dot.

Note that in “Returns” and “Yields”, the description is located in the following line than the type. But in this section it is located in the same line, with a colon in between. If the description does not fit in the same line, it can continue in the next ones, but it has to be indented in them.

For example:

```
class Series:
 def head(self):
 """
 Return the first 5 elements of the Series.

 This function is mainly useful to preview the values of the
 Series without displaying the whole of it.

 Returns

 Series
 Subset of the original series with the 5 first values.

 See Also

 Series.tail : Return the last 5 elements of the Series.
 Series.iloc : Return a slice of the elements in the Series,
 which can also be used to return the first or last n.
 """
 return self.iloc[:5]
```

## Section 6: Notes

This is an optional section used for notes about the implementation of the algorithm. Or to document technical aspects of the function behavior.

Feel free to skip it, unless you are familiar with the implementation of the algorithm, or you discover some counter-intuitive behavior while writing the examples for the function.

This section follows the same format as the extended summary section.

## Section 7: Examples

This is one of the most important sections of a docstring, even if it is placed in the last position. As often, people understand concepts better with examples, than with accurate explanations.

Examples in docstrings, besides illustrating the usage of the function or method, must be valid Python code, that in a deterministic way returns the presented output, and that can be copied and run by users.

They are presented as a session in the Python terminal. `>>>` is used to present code. `...` is used for code continuing from the previous line. Output is presented immediately after the last line of code generating the output (no blank lines in between). Comments describing the examples can be added with blank lines before and after them.

The way to present examples is as follows:

1. Import required libraries (except `numpy` and `pandas`)
2. Create the data required for the example
3. Show a very basic example that gives an idea of the most common use case

4. Add examples with explanations that illustrate how the parameters can be used for extended functionality

A simple example could be:

```
class Series:

 def head(self, n=5):
 """
 Return the first elements of the Series.

 This function is mainly useful to preview the values of the
 Series without displaying the whole of it.

 Parameters

 n : int
 Number of values to return.

 Return

 pandas.Series
 Subset of the original series with the n first values.

 See Also

 tail : Return the last n elements of the Series.

 Examples

 >>> s = pd.Series(['Ant', 'Bear', 'Cow', 'Dog', 'Falcon',
 ... 'Lion', 'Monkey', 'Rabbit', 'Zebra'])
 >>> s.head()
 0 Ant
 1 Bear
 2 Cow
 3 Dog
 4 Falcon
 dtype: object

 With the `n` parameter, we can change the number of returned rows:

 >>> s.head(n=3)
 0 Ant
 1 Bear
 2 Cow
 dtype: object
 """
 return self.iloc[:n]
```

The examples should be as concise as possible. In cases where the complexity of the function requires long examples, is recommended to use blocks with headers in bold. Use double star **\*\*** to make a text bold, like in ***\*\*this example\*\****.

### Conventions for the examples

Code in examples is assumed to always start with these two lines which are not shown:

```
import numpy as np
import pandas as pd
```

Any other module used in the examples must be explicitly imported, one per line (as recommended in [PEP 8#imports](#)) and avoiding aliases. Avoid excessive imports, but if needed, imports from the standard library go first, followed by third-party libraries (like matplotlib).

When illustrating examples with a single `Series` use the name `s`, and if illustrating with a single `DataFrame` use the name `df`. For indices, `idx` is the preferred name. If a set of homogeneous `Series` or `DataFrame` is used, name them `s1`, `s2`, `s3...` or `df1`, `df2`, `df3...`. If the data is not homogeneous, and more than one structure is needed, name them with something meaningful, for example `df_main` and `df_to_join`.

Data used in the example should be as compact as possible. The number of rows is recommended to be around 4, but make it a number that makes sense for the specific example. For example in the `head` method, it requires to be higher than 5, to show the example with the default values. If doing the `mean`, we could use something like `[1, 2, 3]`, so it is easy to see that the value returned is the mean.

For more complex examples (grouping for example), avoid using data without interpretation, like a matrix of random numbers with columns A, B, C, D... And instead use a meaningful example, which makes it easier to understand the concept. Unless required by the example, use names of animals, to keep examples consistent. And numerical properties of them.

When calling the method, keywords arguments `head(n=3)` are preferred to positional arguments `head(3)`.

**Good:**

```
class Series:

 def mean(self):
 """
 Compute the mean of the input.

 Examples

 >>> s = pd.Series([1, 2, 3])
 >>> s.mean()
 2
 """
 pass

 def fillna(self, value):
 """
 Replace missing values by `value`.

 Examples

 >>> s = pd.Series([1, np.nan, 3])
 >>> s.fillna(0)
 [1, 0, 3]
 """
 pass

 def groupby_mean(self):
 """
 Group by index and return mean.

 Examples
```

(continues on next page)

(continued from previous page)

```

>>> s = pd.Series([380., 370., 24., 26],
... name='max_speed',
... index=['falcon', 'falcon', 'parrot', 'parrot'])
>>> s.groupby_mean()
index
falcon 375.0
parrot 25.0
Name: max_speed, dtype: float64
"""
pass

def contains(self, pattern, case_sensitive=True, na=numpy.nan):
 """
 Return whether each value contains `pattern`.

 In this case, we are illustrating how to use sections, even
 if the example is simple enough and does not require them.

 Examples

 >>> s = pd.Series('Antelope', 'Lion', 'Zebra', np.nan)
 >>> s.contains(pattern='a')
 0 False
 1 False
 2 True
 3 NaN
 dtype: bool

 Case sensitivity

 With `case_sensitive` set to `False` we can match `a` with both
 `a` and `A`:

 >>> s.contains(pattern='a', case_sensitive=False)
 0 True
 1 False
 2 True
 3 NaN
 dtype: bool

 Missing values

 We can fill missing values in the output using the `na` parameter:

 >>> s.contains(pattern='a', na=False)
 0 False
 1 False
 2 True
 3 False
 dtype: bool
 """
 pass

```

**Bad:**

```
def method(foo=None, bar=None):
 """
 A sample DataFrame method.

 Do not import numpy and pandas.

 Try to use meaningful data, when it makes the example easier
 to understand.

 Try to avoid positional arguments like in `df.method(1)`. They
 can be all right if previously defined with a meaningful name,
 like in `present_value(interest_rate)`, but avoid them otherwise.

 When presenting the behavior with different parameters, do not place
 all the calls one next to the other. Instead, add a short sentence
 explaining what the example shows.

 Examples

 >>> import numpy as np
 >>> import pandas as pd
 >>> df = pd.DataFrame(np.random.randn(3, 3),
 ... columns=('a', 'b', 'c'))
 >>> df.method(1)
 21
 >>> df.method(bar=14)
 123
 """
 pass
```

### Tips for getting your examples pass the doctests

Getting the examples pass the doctests in the validation script can sometimes be tricky. Here are some attention points:

- Import all needed libraries (except for pandas and numpy, those are already imported as `import pandas as pd` and `import numpy as np`) and define all variables you use in the example.
- Try to avoid using random data. However random data might be OK in some cases, like if the function you are documenting deals with probability distributions, or if the amount of data needed to make the function result meaningful is too much, such that creating it manually is very cumbersome. In those cases, always use a fixed random seed to make the generated examples predictable. Example:

```
>>> np.random.seed(42)
>>> df = pd.DataFrame({'normal': np.random.normal(100, 5, 20)})
```

- If you have a code snippet that wraps multiple lines, you need to use `'...'` on the continued lines:

```
>>> df = pd.DataFrame([[1, 2, 3], [4, 5, 6]], index=['a', 'b', 'c'],
... columns=['A', 'B'])
```

- If you want to show a case where an exception is raised, you can do:

```
>>> pd.to_datetime(["712-01-01"])
Traceback (most recent call last):
OutOfBoundsDatetime: Out of bounds nanosecond timestamp: 712-01-01 00:00:00
```

It is essential to include the “Traceback (most recent call last):”, but for the actual error only the error name is sufficient.

- If there is a small part of the result that can vary (e.g. a hash in an object representation), you can use `...` to represent this part.

If you want to show that `s.plot()` returns a matplotlib `AxesSubplot` object, this will fail the doctest

```
>>> s.plot()
<matplotlib.axes._subplots.AxesSubplot at 0x7efd0c0b0690>
```

However, you can do (notice the comment that needs to be added)

```
>>> s.plot()
<matplotlib.axes._subplots.AxesSubplot at ...>
```

## Plots in examples

There are some methods in pandas returning plots. To render the plots generated by the examples in the documentation, the `.. plot::` directive exists.

To use it, place the next code after the “Examples” header as shown below. The plot will be generated automatically when building the documentation.

```
class Series:
 def plot(self):
 """
 Generate a plot with the `Series` data.

 Examples

 .. plot::
 :context: close-figs

 >>> s = pd.Series([1, 2, 3])
 >>> s.plot()

 """
 pass
```

## Sharing Docstrings

Pandas has a system for sharing docstrings, with slight variations, between classes. This helps us keep docstrings consistent, while keeping things clear for the user reading. It comes at the cost of some complexity when writing.

Each shared docstring will have a base template with variables, like `%(klass)s`. The variables filled in later on using the `Substitution` decorator. Finally, docstrings can be appended to with the `Appender` decorator.

In this example, we’ll create a parent docstring normally (this is like `pandas.core.generic.NDFrame`). Then we’ll have two children (like `pandas.core.series.Series` and `pandas.core.frame.DataFrame`). We’ll substitute the children’s class names in this docstring.

```
class Parent:
 def my_function(self):
 """Apply my function to %(klass)s."""
```

(continues on next page)

(continued from previous page)

```

...

class ChildA(Parent):
 @Substitution(klass="ChildA")
 @Appender(Parent.my_function.__doc__)
 def my_function(self):
 ...

class ChildB(Parent):
 @Substitution(klass="ChildB")
 @Appender(Parent.my_function.__doc__)
 def my_function(self):
 ...

```

The resulting docstrings are

```

>>> print(Parent.my_function.__doc__)
Apply my function to %(klass)s.
>>> print(ChildA.my_function.__doc__)
Apply my function to ChildA.
>>> print(ChildB.my_function.__doc__)
Apply my function to ChildB.

```

Notice two things:

1. We “append” the parent docstring to the children docstrings, which are initially empty.
2. Python decorators are applied inside out. So the order is Append then Substitution, even though Substitution comes first in the file.

Our files will often contain a module-level `_shared_doc_kwargs` with some common substitution values (things like `klass`, `axes`, etc).

You can substitute and append in one shot with something like

```

@Appender(template % _shared_doc_kwargs)
def my_function(self):
 ...

```

where `template` may come from a module-level `_shared_docs` dictionary mapping function names to docstrings. Wherever possible, we prefer using `Appender` and `Substitution`, since the docstring-writing processes is slightly closer to normal.

See `pandas.core.generic.NDFrame.fillna` for an example `template`, and `pandas.core.series.Series.fillna` and `pandas.core.generic.frame.fillna` for the filled versions.

- The tutorials make heavy use of the [ipython directive](#) sphinx extension. This directive lets you put code in the documentation which will be run during the doc build. For example:

```

.. ipython:: python

 x = 2
 x**3

```

will be rendered as:

```
In [1]: x = 2

In [2]: x**3
Out[2]: 8
```

Almost all code examples in the docs are run (and the output saved) during the doc build. This approach means that code examples will always be up to date, but it does make the doc building a bit more complex.

- Our API documentation in `doc/source/api.rst` houses the auto-generated documentation from the docstrings. For classes, there are a few subtleties around controlling which methods and attributes have pages auto-generated.

We have two autosummary templates for classes.

1. `_templates/autosummary/class.rst`. Use this when you want to automatically generate a page for every public method and attribute on the class. The `Attributes` and `Methods` sections will be automatically added to the class' rendered documentation by `numpydoc`. See `DataFrame` for an example.
2. `_templates/autosummary/class_without_autosummary`. Use this when you want to pick a subset of methods / attributes to auto-generate pages for. When using this template, you should include an `Attributes` and `Methods` section in the class docstring. See `CategoricalIndex` for an example.

Every method should be included in a `toctree` in `api.rst`, else Sphinx will emit a warning.

---

**Note:** The `.rst` files are used to automatically generate Markdown and HTML versions of the docs. For this reason, please do not edit `CONTRIBUTING.md` directly, but instead make any changes to `doc/source/contributing.rst`. Then, to generate `CONTRIBUTING.md`, use `pandoc` with the following command:

```
pandoc doc/source/contributing.rst -t markdown_github > CONTRIBUTING.md
```

---

The utility script `scripts/validate_docstrings.py` can be used to get a csv summary of the API documentation. And also validate common errors in the docstring of a specific class, function or method. The summary also compares the list of methods documented in `doc/source/api.rst` (which is used to generate the [API Reference](#) page) and the actual public methods. This will identify methods documented in `doc/source/api.rst` that are not actually class methods, and existing methods that are not documented in `doc/source/api.rst`.

### 3.4.2 Updating a *pandas* docstring

When improving a single function or method's docstring, it is not necessarily needed to build the full documentation (see next section). However, there is a script that checks a docstring (for example for the `DataFrame.mean` method):

```
python scripts/validate_docstrings.py pandas.DataFrame.mean
```

This script will indicate some formatting errors if present, and will also run and test the examples included in the docstring. Check the *pandas docstring guide* for a detailed guide on how to format the docstring.

The examples in the docstring ('doctests') must be valid Python code, that in a deterministic way returns the presented output, and that can be copied and run by users. This can be checked with the script above, and is also tested on Travis. A failing doctest will be a blocker for merging a PR. Check the *examples* section in the docstring guide for some tips and tricks to get the doctests passing.

When doing a PR with a docstring update, it is good to post the output of the validation script in a comment on github.

### 3.4.3 How to build the *pandas* documentation

#### 3.4.3.1 Requirements

First, you need to have a development environment to be able to build pandas (see the docs on *creating a development environment above*).

#### 3.4.3.2 Building the documentation

So how do you build the docs? Navigate to your local `pandas/doc/` directory in the console and run:

```
python make.py html
```

Then you can find the HTML output in the folder `pandas/doc/build/html/`.

The first time you build the docs, it will take quite a while because it has to run all the code examples and build all the generated docstring pages. In subsequent evocations, sphinx will try to only build the pages that have been modified.

If you want to do a full clean build, do:

```
python make.py clean
python make.py html
```

You can tell `make.py` to compile only a single section of the docs, greatly reducing the turn-around time for checking your changes.

```
omit autosummary and API section
python make.py clean
python make.py --no-api

compile the docs with only a single
section, that which is in indexing.rst
python make.py clean
python make.py --single indexing

compile the reference docs for a single function
python make.py clean
python make.py --single DataFrame.join
```

For comparison, a full documentation build may take 15 minutes, but a single section may take 15 seconds. Subsequent builds, which only process portions you have changed, will be faster.

You can also specify to use multiple cores to speed up the documentation build:

```
python make.py html --num-jobs 4
```

Open the following file in a web browser to see the full documentation you just built:

```
pandas/docs/build/html/index.html
```

And you'll have the satisfaction of seeing your new and improved documentation!

#### 3.4.3.3 Building master branch documentation

When pull requests are merged into the *pandas* `master` branch, the main parts of the documentation are also built by Travis-CI. These docs are then hosted [here](#), see also the *Continuous Integration* section.

## 3.5 Contributing to the code base

### Code Base:

- *Code standards*
  - *C (cpplint)*
  - *Python (PEP8)*
  - *Import Formatting*
  - *Backwards Compatibility*
- *Testing With Continuous Integration*
- *Test-driven development/code writing*
  - *Writing tests*
  - *Transitioning to pytest*
  - *Using pytest*
  - *Using hypothesis*
  - *Testing Warnings*
- *Running the test suite*
- *Running the performance test suite*
- *Documenting your code*

### 3.5.1 Code standards

Writing good code is not just about what you write. It is also about *how* you write it. During *Continuous Integration* testing, several tools will be run to check your code for stylistic errors. Generating any warnings will cause the test to fail. Thus, good style is a requirement for submitting code to *pandas*.

There is a tool in pandas to help contributors verify their changes before contributing them to the project:

```
./ci/code_checks.sh
```

The script verify the linting of code files, it looks for common mistake patterns (like missing spaces around sphinx directives that make the documentation not being rendered properly) and it also validates the doctests. It is possible to run the checks independently by using the parameters `lint`, `patterns` and `doctests` (e.g. `./ci/code_checks.sh lint`).

In addition, because a lot of people use our library, it is important that we do not make sudden changes to the code that could have the potential to break a lot of user code as a result, that is, we need it to be as *backwards compatible* as possible to avoid mass breakages.

Additional standards are outlined on the [code style wiki page](#).

#### 3.5.1.1 C (cpplint)

*pandas* uses the [Google](#) standard. Google provides an open source style checker called `cpplint`, but we use a fork of it that can be found [here](#). Here are *some* of the more common `cpplint` issues:

- we restrict line-length to 80 characters to promote readability
- every header file must include a header guard to avoid name collisions if re-included

*Continuous Integration* will run the `cpplint` tool and report any stylistic errors in your code. Therefore, it is helpful before submitting code to run the check yourself:

```
cpplint --extensions=c,h --headers=h --filter=--readability/casting,-runtime/int,-
↳build/include_subdir modified-c-file
```

You can also run this command on an entire directory if necessary:

```
cpplint --extensions=c,h --headers=h --filter=--readability/casting,-runtime/int,-
↳build/include_subdir --recursive modified-c-directory
```

To make your commits compliant with this standard, you can install the `ClangFormat` tool, which can be downloaded [here](#). To configure, in your home directory, run the following command:

```
clang-format style=google -dump-config > .clang-format
```

Then modify the file to ensure that any indentation width parameters are at least four. Once configured, you can run the tool as follows:

```
clang-format modified-c-file
```

This will output what your file will look like if the changes are made, and to apply them, run the following command:

```
clang-format -i modified-c-file
```

To run the tool on an entire directory, you can run the following analogous commands:

```
clang-format modified-c-directory/*.c modified-c-directory/*.h
clang-format -i modified-c-directory/*.c modified-c-directory/*.h
```

Do note that this tool is best-effort, meaning that it will try to correct as many errors as possible, but it may not correct *all* of them. Thus, it is recommended that you run `cpplint` to double check and make any other style fixes manually.

### 3.5.1.2 Python (PEP8)

*pandas* uses the `PEP8` standard. There are several tools to ensure you abide by this standard. Here are *some* of the more common `PEP8` issues:

- we restrict line-length to 79 characters to promote readability
- passing arguments should have spaces after commas, e.g. `foo(arg1, arg2, kw1='bar')`

*Continuous Integration* will run the `flake8` tool and report any stylistic errors in your code. Therefore, it is helpful before submitting code to run the check yourself on the diff:

```
git diff upstream/master -u -- "*.py" | flake8 --diff
```

This command will catch any stylistic errors in your changes specifically, but be beware it may not catch all of them. For example, if you delete the only usage of an imported function, it is stylistically incorrect to import an unused function. However, style-checking the diff will not catch this because the actual import is not part of the diff. Thus, for completeness, you should run this command, though it will take longer:

```
git diff upstream/master --name-only -- "*.py" | xargs -r flake8
```

Note that on OSX, the `-r` flag is not available, so you have to omit it and run this slightly modified command:

```
git diff upstream/master --name-only -- "*.py" | xargs flake8
```

Windows does not support the `xargs` command (unless installed for example via the [MinGW](#) toolchain), but one can imitate the behaviour as follows:

```
for /f %i in ('git diff upstream/master --name-only -- "*.py"') do flake8 %i
```

This will get all the files being changed by the PR (and ending with `.py`), and run `flake8` on them, one after the other.

### 3.5.1.3 Import Formatting

*pandas* uses `isort` to standardise import formatting across the codebase.

A guide to import layout as per pep8 can be found [here](#).

A summary of our current import sections ( in order ):

- Future
- Python Standard Library
- Third Party
- `pandas._libs`, `pandas.compat`, `pandas.util._*`, `pandas.errors` (largely not dependent on `pandas.core`)
- `pandas.core.dtypes` (largely not dependent on the rest of `pandas.core`)
- Rest of `pandas.core.*`
- Non-core `pandas.io`, `pandas.plotting`, `pandas.tseries`
- Local application/library specific imports

Imports are alphabetically sorted within these sections.

As part of *Continuous Integration* checks we run:

```
isort --recursive --check-only pandas
```

to check that imports are correctly formatted as per the *setup.cfg*.

If you see output like the below in *Continuous Integration* checks:

```
Check import format using isort
ERROR: /home/travis/build/pandas-dev/pandas/pandas/io/pytables.py Imports are
→incorrectly sorted
Check import format using isort DONE
The command "ci/code_checks.sh" exited with 1
```

You should run:

```
isort pandas/io/pytables.py
```

to automatically format imports correctly. This will modify your local copy of the files.

The `-recursive` flag can be passed to sort all files in a directory.

You can then verify the changes look ok, then *git commit* and *push*.

### 3.5.1.4 Backwards Compatibility

Please try to maintain backward compatibility. *pandas* has lots of users with lots of existing code, so don't break it if at all possible. If you think breakage is required, clearly state why as part of the pull request. Also, be careful when changing method signatures and add deprecation warnings where needed. Also, add the deprecated sphinx directive to the deprecated functions or methods.

If a function with the same arguments as the one being deprecated exist, you can use the `pandas.util._decorators.deprecate`:

```
from pandas.util._decorators import deprecate

deprecate('old_func', 'new_func', '0.21.0')
```

Otherwise, you need to do it manually:

```
import warnings

def old_func():
 """Summary of the function.

 .. deprecated:: 0.21.0
 Use new_func instead.
 """
 warnings.warn('Use new_func instead.', FutureWarning, stacklevel=2)
 new_func()

def new_func():
 pass
```

You'll also need to

1. write a new test that asserts a warning is issued when calling with the deprecated argument
2. Update all of pandas existing tests and code to use the new argument

See *Testing Warnings* for more.

## 3.5.2 Testing With Continuous Integration

The *pandas* test suite will run automatically on [Travis-CI](#) and [Azure Pipelines](#) continuous integration services, once your pull request is submitted. However, if you wish to run the test suite on a branch prior to submitting the pull request, then the continuous integration services need to be hooked to your GitHub repository. Instructions are here for [Travis-CI](#) and [Azure Pipelines](#).

A pull-request will be considered for merging when you have an all 'green' build. If any tests are failing, then you will get a red 'X', where you can click through to see the individual failed tests. This is an example of a green build.

**All checks have passed**

2 successful checks

[Hide all checks](#)**continuous-integration/travis-ci/pr** — The Travis CI build passed**pandas-dev.pandas** Successful in 36m — Build #20190109.23 succeeded**This branch has no conflicts with the base branch**

Merging can be performed automatically.

**Squash and merge**or view [command line instructions](#).

---

**Note:** Each time you push to *your* fork, a *new* run of the tests will be triggered on the CI. You can enable the auto-cancel feature, which removes any non-currently-running tests for that same pull-request, for [Travis-CI here](#).

---

### 3.5.3 Test-driven development/code writing

*pandas* is serious about testing and strongly encourages contributors to embrace [test-driven development \(TDD\)](#). This development process “relies on the repetition of a very short development cycle: first the developer writes an (initially failing) automated test case that defines a desired improvement or new function, then produces the minimum amount of code to pass that test.” So, before actually writing any code, you should write your tests. Often the test can be taken from the original GitHub issue. However, it is always worth considering additional use cases and writing corresponding tests.

Adding tests is one of the most common requests after code is pushed to *pandas*. Therefore, it is worth getting in the habit of writing tests ahead of time so this is never an issue.

Like many packages, *pandas* uses [pytest](#) and the convenient extensions in [numpy.testing](#).

---

**Note:** The earliest supported pytest version is 3.6.0.

---

#### 3.5.3.1 Writing tests

All tests should go into the `tests` subdirectory of the specific package. This folder contains many current examples of tests, and we suggest looking to these for inspiration. If your test requires working with files or network connectivity, there is more information on the [testing page](#) of the wiki.

The `pandas.util.testing` module has many special `assert` functions that make it easier to make statements about whether `Series` or `DataFrame` objects are equivalent. The easiest way to verify that your code is correct is to explicitly construct the result you expect, then compare the actual result to the expected correct result:

```
def test_pivot(self):
 data = {
 'index' : ['A', 'B', 'C', 'C', 'B', 'A'],
 'columns' : ['One', 'One', 'One', 'Two', 'Two', 'Two'],
 'values' : [1., 2., 3., 3., 2., 1.]
 }

 frame = DataFrame(data)
 pivoted = frame.pivot(index='index', columns='columns', values='values')

 expected = DataFrame({
 'One' : {'A' : 1., 'B' : 2., 'C' : 3.},
 'Two' : {'A' : 1., 'B' : 2., 'C' : 3.}
 })

 assert_frame_equal(pivoted, expected)
```

### 3.5.3.2 Transitioning to pytest

*pandas* existing test structure is *mostly* classed based, meaning that you will typically find tests wrapped in a class.

```
class TestReallyCoolFeature(object):
 pass
```

Going forward, we are moving to a more *functional* style using the *pytest* framework, which offers a richer testing framework that will facilitate testing and developing. Thus, instead of writing test classes, we will write test functions like this:

```
def test_really_cool_feature():
 pass
```

### 3.5.3.3 Using pytest

Here is an example of a self-contained set of tests that illustrate multiple features that we like to use.

- functional style: tests are like `test_*` and *only* take arguments that are either fixtures or parameters
- `pytest.mark` can be used to set metadata on test functions, e.g. `skip` or `xfail`.
- using `parametrize`: allow testing of multiple cases
- to set a mark on a parameter, `pytest.param(..., marks=...)` syntax should be used
- `fixture`, code for object construction, on a per-test basis
- using bare `assert` for scalars and truth-testing
- `tm.assert_series_equal` (and its counter part `tm.assert_frame_equal`), for *pandas* object comparisons.
- the typical pattern of constructing an `expected` and comparing versus the `result`

We would name this file `test_cool_feature.py` and put in an appropriate place in the *pandas*/tests/ structure.

```
import pytest
import numpy as np
import pandas as pd

@pytest.mark.parametrize('dtype', ['int8', 'int16', 'int32', 'int64'])
def test_dtypes(dtype):
 assert str(np.dtype(dtype)) == dtype

@pytest.mark.parametrize(
 'dtype', ['float32', pytest.param('int16', marks=pytest.mark.skip),
 pytest.param('int32', marks=pytest.mark.xfail(
 reason='to show how it works'))])
def test_mark(dtype):
 assert str(np.dtype(dtype)) == 'float32'

@pytest.fixture
def series():
 return pd.Series([1, 2, 3])

@pytest.fixture(params=['int8', 'int16', 'int32', 'int64'])
def dtype(request):
 return request.param

def test_series(series, dtype):
 result = series.astype(dtype)
 assert result.dtype == dtype

 expected = pd.Series([1, 2, 3], dtype=dtype)
 tm.assert_series_equal(result, expected)
```

A test run of this yields

```
((pandas) bash-3.2$ pytest test_cool_feature.py -v
===== test session starts =====
platform darwin -- Python 3.6.2, pytest-3.6.0, py-1.4.31, pluggy-0.4.0
collected 11 items

tester.py::test_dtypes[int8] PASSED
tester.py::test_dtypes[int16] PASSED
tester.py::test_dtypes[int32] PASSED
tester.py::test_dtypes[int64] PASSED
tester.py::test_mark[float32] PASSED
tester.py::test_mark[int16] SKIPPED
tester.py::test_mark[int32] xfail
tester.py::test_series[int8] PASSED
tester.py::test_series[int16] PASSED
tester.py::test_series[int32] PASSED
tester.py::test_series[int64] PASSED
```

Tests that we have parametrized are now accessible via the test name, for example we could run these with `-k int8` to sub-select *only* those tests which match `int8`.

```
((pandas) bash-3.2$ pytest test_cool_feature.py -v -k int8

test_cool_feature.py::test_dtypes[int8] PASSED
test_cool_feature.py::test_series[int8] PASSED
```

### 3.5.3.4 Using hypothesis

Hypothesis is a library for property-based testing. Instead of explicitly parametrizing a test, you can describe *all* valid inputs and let Hypothesis try to find a failing input. Even better, no matter how many random examples it tries, Hypothesis always reports a single minimal counterexample to your assertions - often an example that you would never have thought to test.

See [Getting Started with Hypothesis](#) for more of an introduction, then refer to the [Hypothesis documentation](#) for details.

```
import json
from hypothesis import given, strategies as st

any_json_value = st.deferred(lambda: st.one_of(
 st.none(), st.booleans(), st.floats(allow_nan=False), st.text(),
 st.lists(any_json_value), st.dictionaries(st.text(), any_json_value)
))

@given(value=any_json_value)
def test_json_roundtrip(value):
 result = json.loads(json.dumps(value))
 assert value == result
```

This test shows off several useful features of Hypothesis, as well as demonstrating a good use-case: checking properties that should hold over a large or complicated domain of inputs.

To keep the Pandas test suite running quickly, parametrized tests are preferred if the inputs or logic are simple, with Hypothesis tests reserved for cases with complex logic or where there are too many combinations of options or subtle interactions to test (or think of!) all of them.

### 3.5.3.5 Testing Warnings

By default, one of pandas CI workers will fail if any unhandled warnings are emitted.

If your change involves checking that a warning is actually emitted, use `tm.assert_produces_warning(ExpectedWarning)`.

```
import pandas.util.testing as tm

df = pd.DataFrame()
with tm.assert_produces_warning(FutureWarning):
 df.some_operation()
```

We prefer this to the `pytest.warns` context manager because ours checks that the warning's `stacklevel` is set correctly. The `stacklevel` is what ensure the *user's* file name and line number is printed in the warning, rather than some-

thing internal to pandas. It represents the number of function calls from user code (e.g. `df.some_operation()`) to the function that actually emits the warning. Our linter will fail the build if you use `pytest.warns` in a test.

If you have a test that would emit a warning, but you aren't actually testing the warning itself (say because it's going to be removed in the future, or because we're matching a 3rd-party library's behavior), then use `pytest.mark.filterwarnings` to ignore the error.

```
@pytest.mark.filterwarnings("ignore:msg:category")
def test_thing(self):
 ...
```

If the test generates a warning of class `category` whose message starts with `msg`, the warning will be ignored and the test will pass.

If you need finer-grained control, you can use Python's usual `warnings` module to control whether a warning is ignored / raised at different places within a single test.

```
with warnings.catch_warnings():
 warnings.simplefilter("ignore", FutureWarning)
 # Or use warnings.filterwarnings(...)
```

Alternatively, consider breaking up the unit test.

### 3.5.4 Running the test suite

The tests can then be run directly inside your Git clone (without having to install *pandas*) by typing:

```
pytest pandas
```

The tests suite is exhaustive and takes around 20 minutes to run. Often it is worth running only a subset of tests first around your changes before running the entire suite.

The easiest way to do this is with:

```
pytest pandas/path/to/test.py -k regex_matching_test_name
```

Or with one of the following constructs:

```
pytest pandas/tests/[test-module].py
pytest pandas/tests/[test-module].py::[TestClass]
pytest pandas/tests/[test-module].py::[TestClass]::[test_method]
```

Using `pytest-xdist`, one can speed up local testing on multicore machines. To use this feature, you will need to install *pytest-xdist* via:

```
pip install pytest-xdist
```

Two scripts are provided to assist with this. These scripts distribute testing across 4 threads.

On Unix variants, one can type:

```
test_fast.sh
```

On Windows, one can type:

```
test_fast.bat
```

This can significantly reduce the time it takes to locally run tests before submitting a pull request.

For more, see the [pytest](#) documentation.

New in version 0.20.0.

Furthermore one can run

```
pd.test()
```

with an imported pandas to run tests similarly.

### 3.5.5 Running the performance test suite

Performance matters and it is worth considering whether your code has introduced performance regressions. *pandas* is in the process of migrating to [asv benchmarks](#) to enable easy monitoring of the performance of critical *pandas* operations. These benchmarks are all found in the `pandas/asv_bench` directory. *asv* supports both python2 and python3.

To use all features of *asv*, you will need either `conda` or `virtualenv`. For more details please check the [asv installation webpage](#).

To install *asv*:

```
pip install git+https://github.com/spacetelescope/asv
```

If you need to run a benchmark, change your directory to `asv_bench/` and run:

```
asv continuous -f 1.1 upstream/master HEAD
```

You can replace `HEAD` with the name of the branch you are working on, and report benchmarks that changed by more than 10%. The command uses `conda` by default for creating the benchmark environments. If you want to use `virtualenv` instead, write:

```
asv continuous -f 1.1 -E virtualenv upstream/master HEAD
```

The `-E virtualenv` option should be added to all *asv* commands that run benchmarks. The default value is defined in `asv.conf.json`.

Running the full test suite can take up to one hour and use up to 3GB of RAM. Usually it is sufficient to paste only a subset of the results into the pull request to show that the committed changes do not cause unexpected performance regressions. You can run specific benchmarks using the `-b` flag, which takes a regular expression. For example, this will only run tests from a `pandas/asv_bench/benchmarks/groupby.py` file:

```
asv continuous -f 1.1 upstream/master HEAD -b ^groupby
```

If you want to only run a specific group of tests from a file, you can do it using `.` as a separator. For example:

```
asv continuous -f 1.1 upstream/master HEAD -b groupby.GroupByMethods
```

will only run the `GroupByMethods` benchmark defined in `groupby.py`.

You can also run the benchmark suite using the version of *pandas* already installed in your current Python environment. This can be useful if you do not have `virtualenv` or `conda`, or are using the `setup.py develop` approach discussed above; for the in-place build you need to set `PYTHONPATH`, e.g. `PYTHONPATH="$PWD/.."` *asv* [remaining arguments]. You can run benchmarks using an existing Python environment by:

```
asv run -e -E existing
```

or, to use a specific Python interpreter,:

```
asv run -e -E existing:python3.5
```

This will display stderr from the benchmarks, and use your local `python` that comes from your `$PATH`.

Information on how to write a benchmark and how to use `asv` can be found in the [asv documentation](#).

### 3.5.6 Documenting your code

Changes should be reflected in the release notes located in `doc/source/whatsnew/vx.y.z.rst`. This file contains an ongoing change log for each release. Add an entry to this file to document your fix, enhancement or (unavoidable) breaking change. Make sure to include the GitHub issue number when adding your entry (using `:issue:`1234`` where 1234 is the issue/pull request number).

If your code is an enhancement, it is most likely necessary to add usage examples to the existing documentation. This can be done following the section regarding documentation *above*. Further, to let users know when this feature was added, the `versionadded` directive is used. The sphinx syntax for that is:

```
.. versionadded:: 0.21.0
```

This will put the text *New in version 0.21.0* wherever you put the sphinx directive. This should also be put in the docstring when adding a new function or method ([example](#)) or a new keyword argument ([example](#)).

## 3.6 Contributing your changes to *pandas*

### 3.6.1 Committing your code

Keep style fixes to a separate commit to make your pull request more readable.

Once you've made changes, you can see them by typing:

```
git status
```

If you have created a new file, it is not being tracked by git. Add it by typing:

```
git add path/to/file-to-be-added.py
```

Doing 'git status' again should give something like:

```
On branch shiny-new-feature
#
modified: /relative/path/to/file-you-added.py
#
```

Finally, commit your changes to your local repository with an explanatory message. *Pandas* uses a convention for commit message prefixes and layout. Here are some common prefixes along with general guidelines for when to use them:

- ENH: Enhancement, new functionality
- BUG: Bug fix

- DOC: Additions/updates to documentation
- TST: Additions/updates to tests
- BLD: Updates to the build process/scripts
- PERF: Performance improvement
- CLN: Code cleanup

The following defines how a commit message should be structured. Please reference the relevant GitHub issues in your commit message using GH1234 or #1234. Either style is fine, but the former is generally preferred:

- a subject line with < 80 chars.
- One blank line.
- Optionally, a commit message body.

Now you can commit your changes in your local repository:

```
git commit -m
```

### 3.6.2 Pushing your changes

When you want your changes to appear publicly on your GitHub page, push your forked feature branch's commits:

```
git push origin shiny-new-feature
```

Here `origin` is the default name given to your remote repository on GitHub. You can see the remote repositories:

```
git remote -v
```

If you added the upstream repository as described above you will see something like:

```
origin git@github.com:yourname/pandas.git (fetch)
origin git@github.com:yourname/pandas.git (push)
upstream git://github.com/pandas-dev/pandas.git (fetch)
upstream git://github.com/pandas-dev/pandas.git (push)
```

Now your code is on GitHub, but it is not yet a part of the *pandas* project. For that to happen, a pull request needs to be submitted on GitHub.

### 3.6.3 Review your code

When you're ready to ask for a code review, file a pull request. Before you do, once again make sure that you have followed all the guidelines outlined in this document regarding code style, tests, performance tests, and documentation. You should also double check your branch changes against the branch it was based on:

1. Navigate to your repository on GitHub – <https://github.com/your-user-name/pandas>
2. Click on `Branches`
3. Click on the `Compare` button for your feature branch
4. Select the `base` and `compare` branches, if necessary. This will be `master` and `shiny-new-feature`, respectively.

### 3.6.4 Finally, make the pull request

If everything looks good, you are ready to make a pull request. A pull request is how code from a local repository becomes available to the GitHub community and can be looked at and eventually merged into the master version. This pull request and its associated changes will eventually be committed to the master branch and available in the next release. To submit a pull request:

1. Navigate to your repository on GitHub
2. Click on the Pull Request button
3. You can then click on Commits and Files Changed to make sure everything looks okay one last time
4. Write a description of your changes in the Preview Discussion tab
5. Click Send Pull Request.

This request then goes to the repository maintainers, and they will review the code.

### 3.6.5 Updating your pull request

Based on the review you get on your pull request, you will probably need to make some changes to the code. In that case, you can make them in your branch, add a new commit to that branch, push it to GitHub, and the pull request will be automatically updated. Pushing them to GitHub again is done by:

```
git push origin shiny-new-feature
```

This will automatically update your pull request with the latest code and restart the *Continuous Integration* tests.

Another reason you might need to update your pull request is to solve conflicts with changes that have been merged into the master branch since you opened your pull request.

To do this, you need to “merge upstream master” in your branch:

```
git checkout shiny-new-feature
git fetch upstream
git merge upstream/master
```

If there are no conflicts (or they could be fixed automatically), a file with a default commit message will open, and you can simply save and quit this file.

If there are merge conflicts, you need to solve those conflicts. See for example at <https://help.github.com/articles/resolving-a-merge-conflict-using-the-command-line/> for an explanation on how to do this. Once the conflicts are merged and the files where the conflicts were solved are added, you can run `git commit` to save those fixes.

If you have uncommitted changes at the moment you want to update the branch with master, you will need to `stash` them prior to updating (see the [stash docs](#)). This will effectively store your changes and they can be reapplied after updating.

After the feature branch has been update locally, you can now update your pull request by pushing to the branch on GitHub:

```
git push origin shiny-new-feature
```

### 3.6.6 Delete your merged branch (optional)

Once your feature branch is accepted into upstream, you’ll probably want to get rid of the branch. First, merge upstream master into your branch so git knows it is safe to delete your branch:

```
git fetch upstream
git checkout master
git merge upstream/master
```

Then you can do:

```
git branch -d shiny-new-feature
```

Make sure you use a lower-case `-d`, or else git won't warn you if your feature branch has not actually been merged.

The branch will still exist on GitHub, so to delete it there do:

```
git push origin --delete shiny-new-feature
```

{{ header }}

## PACKAGE OVERVIEW

*pandas* is an open source, BSD-licensed library providing high-performance, easy-to-use data structures and data analysis tools for the [Python](#) programming language.

*pandas* consists of the following elements:

- A set of labeled array data structures, the primary of which are Series and DataFrame.
- Index objects enabling both simple axis indexing and multi-level / hierarchical axis indexing.
- An integrated group by engine for aggregating and transforming data sets.
- Date range generation (`date_range`) and custom date offsets enabling the implementation of customized frequencies.
- Input/Output tools: loading tabular data from flat files (CSV, delimited, Excel 2003), and saving and loading pandas objects from the fast and efficient PyTables/HDF5 format.
- Memory-efficient “sparse” versions of the standard data structures for storing data that is mostly missing or mostly constant (some fixed value).
- Moving window statistics (rolling mean, rolling standard deviation, etc.).

### 4.1 Data Structures

| Dimensions | Name      | Description                                                                                      |
|------------|-----------|--------------------------------------------------------------------------------------------------|
| 1          | Series    | 1D labeled homogeneously-typed array                                                             |
| 2          | DataFrame | General 2D labeled, size-mutable tabular structure with potentially heterogeneously-typed column |

#### 4.1.1 Why more than one data structure?

The best way to think about the pandas data structures is as flexible containers for lower dimensional data. For example, DataFrame is a container for Series, and Series is a container for scalars. We would like to be able to insert and remove objects from these containers in a dictionary-like fashion.

Also, we would like sensible default behaviors for the common API functions which take into account the typical orientation of time series and cross-sectional data sets. When using ndarrays to store 2- and 3-dimensional data, a burden is placed on the user to consider the orientation of the data set when writing functions; axes are considered more or less equivalent (except when C- or Fortran-contiguity matters for performance). In pandas, the axes are intended to lend more semantic meaning to the data; i.e., for a particular data set there is likely to be a “right” way to orient the data. The goal, then, is to reduce the amount of mental effort required to code up data transformations in downstream functions.

For example, with tabular data (DataFrame) it is more semantically helpful to think of the **index** (the rows) and the **columns** rather than axis 0 and axis 1. Iterating through the columns of the DataFrame thus results in more readable code:

```
for col in df.columns:
 series = df[col]
 # do something with series
```

## 4.2 Mutability and copying of data

All pandas data structures are value-mutable (the values they contain can be altered) but not always size-mutable. The length of a Series cannot be changed, but, for example, columns can be inserted into a DataFrame. However, the vast majority of methods produce new objects and leave the input data untouched. In general we like to **favor immutability** where sensible.

## 4.3 Getting Support

The first stop for pandas issues and ideas is the [Github Issue Tracker](#). If you have a general question, pandas community experts can answer through [Stack Overflow](#).

## 4.4 Community

pandas is actively supported today by a community of like-minded individuals around the world who contribute their valuable time and energy to help make open source pandas possible. Thanks to [all of our contributors](#).

If you're interested in contributing, please visit the *contributing guide*.

pandas is a [NumFOCUS](#) sponsored project. This will help ensure the success of development of pandas as a world-class open-source project, and makes it possible to [donate](#) to the project.

## 4.5 Project Governance

The governance process that pandas project has used informally since its inception in 2008 is formalized in [Project Governance documents](#). The documents clarify how decisions are made and how the various elements of our community interact, including the relationship between open source collaborative development and work that may be funded by for-profit or non-profit entities.

Wes McKinney is the Benevolent Dictator for Life (BDFL).

## 4.6 Development Team

The list of the Core Team members and more detailed information can be found on the [people's page](#) of the governance repo.

## 4.7 Institutional Partners

The information about current institutional partners can be found on [pandas website page](#).

## 4.8 License

BSD 3-Clause License

{{ header }}

## 10 MINUTES TO PANDAS

This is a short introduction to pandas, geared mainly for new users. You can see more complex recipes in the *Cookbook*. Customarily, we import as follows:

```
In [1]: import numpy as np
In [2]: import pandas as pd
```

### 5.1 Object Creation

See the *Data Structure Intro* section.

Creating a *Series* by passing a list of values, letting pandas create a default integer index:

```
In [3]: s = pd.Series([1, 3, 5, np.nan, 6, 8])

In [4]: s
Out[4]:
0 1.0
1 3.0
2 5.0
3 NaN
4 6.0
5 8.0
dtype: float64
```

Creating a *DataFrame* by passing a NumPy array, with a datetime index and labeled columns:

```
In [5]: dates = pd.date_range('20130101', periods=6)

In [6]: dates
Out[6]:
DatetimeIndex(['2013-01-01', '2013-01-02', '2013-01-03', '2013-01-04',
 '2013-01-05', '2013-01-06'],
 dtype='datetime64[ns]', freq='D')

In [7]: df = pd.DataFrame(np.random.randn(6, 4), index=dates, columns=list('ABCD'))

In [8]: df
Out[8]:
 A B C D
2013-01-01 0.872523 -0.074393 1.629377 -1.847811
```

(continues on next page)

(continued from previous page)

```

2013-01-02 0.937344 0.165604 -0.370979 0.481338
2013-01-03 2.534641 1.281051 -0.283892 0.155831
2013-01-04 -0.449553 -0.177382 -1.591217 1.281605
2013-01-05 0.952782 -0.224539 -0.896418 -0.021323
2013-01-06 0.218477 -0.644854 0.433885 1.559704

```

Creating a DataFrame by passing a dict of objects that can be converted to series-like.

```

In [9]: df2 = pd.DataFrame({'A': 1.,
...: 'B': pd.Timestamp('20130102'),
...: 'C': pd.Series(1, index=list(range(4)), dtype='float32'),
...: 'D': np.array([3] * 4, dtype='int32'),
...: 'E': pd.Categorical(["test", "train", "test", "train"]),
...: 'F': 'foo'})

```

```

In [10]: df2

```

```

Out[10]:
 A B C D E F
0 1.0 2013-01-02 1.0 3 test foo
1 1.0 2013-01-02 1.0 3 train foo
2 1.0 2013-01-02 1.0 3 test foo
3 1.0 2013-01-02 1.0 3 train foo

```

The columns of the resulting DataFrame have different *dtypes*.

```

In [11]: df2.dtypes

```

```

Out[11]:
A float64
B datetime64[ns]
C float32
D int32
E category
F object
dtype: object

```

If you're using IPython, tab completion for column names (as well as public attributes) is automatically enabled. Here's a subset of the attributes that will be completed:

```

In [12]: df2.<TAB> # noga: E225, E999
df2.A df2.bool
df2.abs df2.boxplot
df2.add df2.C
df2.add_prefix df2.clip
df2.add_suffix df2.clip_lower
df2.align df2.clip_upper
df2.all df2.columns
df2.any df2.combine
df2.append df2.combine_first
df2.apply df2.compound
df2.applymap df2.consolidate
df2.D

```

As you can see, the columns A, B, C, and D are automatically tab completed. E is there as well; the rest of the attributes have been truncated for brevity.

## 5.2 Viewing Data

See the *Basics section*.

Here is how to view the top and bottom rows of the frame:

```
In [13]: df.head()
Out[13]:
```

|            | A         | B         | C         | D         |
|------------|-----------|-----------|-----------|-----------|
| 2013-01-01 | 0.872523  | -0.074393 | 1.629377  | -1.847811 |
| 2013-01-02 | 0.937344  | 0.165604  | -0.370979 | 0.481338  |
| 2013-01-03 | 2.534641  | 1.281051  | -0.283892 | 0.155831  |
| 2013-01-04 | -0.449553 | -0.177382 | -1.591217 | 1.281605  |
| 2013-01-05 | 0.952782  | -0.224539 | -0.896418 | -0.021323 |

```
In [14]: df.tail(3)
Out[14]:
```

|            | A         | B         | C         | D         |
|------------|-----------|-----------|-----------|-----------|
| 2013-01-04 | -0.449553 | -0.177382 | -1.591217 | 1.281605  |
| 2013-01-05 | 0.952782  | -0.224539 | -0.896418 | -0.021323 |
| 2013-01-06 | 0.218477  | -0.644854 | 0.433885  | 1.559704  |

Display the index, columns:

```
In [15]: df.index
Out[15]:
DatetimeIndex(['2013-01-01', '2013-01-02', '2013-01-03', '2013-01-04',
 '2013-01-05', '2013-01-06'],
 dtype='datetime64[ns]', freq='D')

In [16]: df.columns
Out[16]:
Index(['A', 'B', 'C', 'D'], dtype='object')
```

`DataFrame.to_numpy()` gives a NumPy representation of the underlying data. Note that this can be an expensive operation when your `DataFrame` has columns with different data types, which comes down to a fundamental difference between pandas and NumPy: **NumPy arrays have one dtype for the entire array, while pandas DataFrames have one dtype per column**. When you call `DataFrame.to_numpy()`, pandas will find the NumPy dtype that can hold *all* of the dtypes in the `DataFrame`. This may end up being `object`, which requires casting every value to a Python object.

For `df`, our `DataFrame` of all floating-point values, `DataFrame.to_numpy()` is fast and doesn't require copying data.

```
In [17]: df.to_numpy()
Out[17]:
array([[0.8725227, -0.07439341, 1.6293766, -1.84781086],
 [0.93734365, 0.16560405, -0.37097867, 0.48133844],
 [2.53464145, 1.28105133, -0.28389155, 0.15583057],
 [-0.44955264, -0.17738221, -1.59121673, 1.28160543],
 [0.95278151, -0.22453898, -0.89641804, -0.02132264],
 [0.21847715, -0.64485378, 0.4338851, 1.55970444]])
```

For `df2`, the `DataFrame` with multiple dtypes, `DataFrame.to_numpy()` is relatively expensive.

```
In [18]: df2.to_numpy()
Out[18]:
array([[1.0, Timestamp('2013-01-02 00:00:00'), 1.0, 3, 'test', 'foo'],
 [1.0, Timestamp('2013-01-02 00:00:00'), 1.0, 3, 'train', 'foo'],
 [1.0, Timestamp('2013-01-02 00:00:00'), 1.0, 3, 'test', 'foo'],
 [1.0, Timestamp('2013-01-02 00:00:00'), 1.0, 3, 'train', 'foo']], dtype=object)
```

---

**Note:** `DataFrame.to_numpy()` does *not* include the index or column labels in the output.

---

`describe()` shows a quick statistic summary of your data:

```
In [19]: df.describe()
Out[19]:
```

|       | A         | B         | C         | D         |
|-------|-----------|-----------|-----------|-----------|
| count | 6.000000  | 6.000000  | 6.000000  | 6.000000  |
| mean  | 0.844369  | 0.054248  | -0.179874 | 0.268224  |
| std   | 0.994403  | 0.656371  | 1.113800  | 1.209492  |
| min   | -0.449553 | -0.644854 | -1.591217 | -1.847811 |
| 25%   | 0.381989  | -0.212750 | -0.765058 | 0.022966  |
| 50%   | 0.904933  | -0.125888 | -0.327435 | 0.318585  |
| 75%   | 0.948922  | 0.105605  | 0.254441  | 1.081539  |
| max   | 2.534641  | 1.281051  | 1.629377  | 1.559704  |

Transposing your data:

```
In [20]: df.T
Out[20]:
```

|   | 2013-01-01 | 2013-01-02 | 2013-01-03 | 2013-01-04 | 2013-01-05 | 2013-01-06 |
|---|------------|------------|------------|------------|------------|------------|
| A | 0.872523   | 0.937344   | 2.534641   | -0.449553  | 0.952782   | 0.218477   |
| B | -0.074393  | 0.165604   | 1.281051   | -0.177382  | -0.224539  | -0.644854  |
| C | 1.629377   | -0.370979  | -0.283892  | -1.591217  | -0.896418  | 0.433885   |
| D | -1.847811  | 0.481338   | 0.155831   | 1.281605   | -0.021323  | 1.559704   |

Sorting by an axis:

```
In [21]: df.sort_index(axis=1, ascending=False)
Out[21]:
```

|            | D         | C         | B         | A         |
|------------|-----------|-----------|-----------|-----------|
| 2013-01-01 | -1.847811 | 1.629377  | -0.074393 | 0.872523  |
| 2013-01-02 | 0.481338  | -0.370979 | 0.165604  | 0.937344  |
| 2013-01-03 | 0.155831  | -0.283892 | 1.281051  | 2.534641  |
| 2013-01-04 | 1.281605  | -1.591217 | -0.177382 | -0.449553 |
| 2013-01-05 | -0.021323 | -0.896418 | -0.224539 | 0.952782  |
| 2013-01-06 | 1.559704  | 0.433885  | -0.644854 | 0.218477  |

Sorting by values:

```
In [22]: df.sort_values(by='B')
Out[22]:
```

|            | A         | B         | C         | D         |
|------------|-----------|-----------|-----------|-----------|
| 2013-01-06 | 0.218477  | -0.644854 | 0.433885  | 1.559704  |
| 2013-01-05 | 0.952782  | -0.224539 | -0.896418 | -0.021323 |
| 2013-01-04 | -0.449553 | -0.177382 | -1.591217 | 1.281605  |
| 2013-01-01 | 0.872523  | -0.074393 | 1.629377  | -1.847811 |
| 2013-01-02 | 0.937344  | 0.165604  | -0.370979 | 0.481338  |
| 2013-01-03 | 2.534641  | 1.281051  | -0.283892 | 0.155831  |

## 5.3 Selection

**Note:** While standard Python / Numpy expressions for selecting and setting are intuitive and come in handy for interactive work, for production code, we recommend the optimized pandas data access methods, `.at`, `.iat`, `.loc` and `.iloc`.

See the indexing documentation *Indexing and Selecting Data* and *MultiIndex / Advanced Indexing*.

### 5.3.1 Getting

Selecting a single column, which yields a `Series`, equivalent to `df.A`:

```
In [23]: df['A']
Out[23]:
2013-01-01 0.872523
2013-01-02 0.937344
2013-01-03 2.534641
2013-01-04 -0.449553
2013-01-05 0.952782
2013-01-06 0.218477
Freq: D, Name: A, dtype: float64
```

Selecting via `[ ]`, which slices the rows.

```
In [24]: df[0:3]
Out[24]:
```

|            | A        | B         | C         | D         |
|------------|----------|-----------|-----------|-----------|
| 2013-01-01 | 0.872523 | -0.074393 | 1.629377  | -1.847811 |
| 2013-01-02 | 0.937344 | 0.165604  | -0.370979 | 0.481338  |
| 2013-01-03 | 2.534641 | 1.281051  | -0.283892 | 0.155831  |

```
In [25]: df['20130102':'20130104']
\\repeated slashes\\
↪
```

|            | A         | B         | C         | D        |
|------------|-----------|-----------|-----------|----------|
| 2013-01-02 | 0.937344  | 0.165604  | -0.370979 | 0.481338 |
| 2013-01-03 | 2.534641  | 1.281051  | -0.283892 | 0.155831 |
| 2013-01-04 | -0.449553 | -0.177382 | -1.591217 | 1.281605 |

### 5.3.2 Selection by Label

See more in *Selection by Label*.

For getting a cross section using a label:

```
In [26]: df.loc[dates[0]]
Out[26]:
A 0.872523
B -0.074393
C 1.629377
D -1.847811
Name: 2013-01-01 00:00:00, dtype: float64
```

Selecting on a multi-axis by label:

```
In [27]: df.loc[:, ['A', 'B']]
Out[27]:
```

|            | A         | B         |
|------------|-----------|-----------|
| 2013-01-01 | 0.872523  | -0.074393 |
| 2013-01-02 | 0.937344  | 0.165604  |
| 2013-01-03 | 2.534641  | 1.281051  |
| 2013-01-04 | -0.449553 | -0.177382 |
| 2013-01-05 | 0.952782  | -0.224539 |
| 2013-01-06 | 0.218477  | -0.644854 |

Showing label slicing, both endpoints are *included*:

```
In [28]: df.loc['20130102':'20130104', ['A', 'B']]
Out[28]:
```

|            | A         | B         |
|------------|-----------|-----------|
| 2013-01-02 | 0.937344  | 0.165604  |
| 2013-01-03 | 2.534641  | 1.281051  |
| 2013-01-04 | -0.449553 | -0.177382 |

Reduction in the dimensions of the returned object:

```
In [29]: df.loc['20130102', ['A', 'B']]
Out[29]:
```

|            | A        | B        |
|------------|----------|----------|
| 2013-01-02 | 0.937344 | 0.165604 |

Name: 2013-01-02 00:00:00, dtype: float64

For getting a scalar value:

```
In [30]: df.loc[dates[0], 'A']
Out[30]: 0.87252269539364047
```

For getting fast access to a scalar (equivalent to the prior method):

```
In [31]: df.at[dates[0], 'A']
Out[31]: 0.87252269539364047
```

### 5.3.3 Selection by Position

See more in *Selection by Position*.

Select via the position of the passed integers:

```
In [32]: df.iloc[3]
Out[32]:
```

|            | A         | B         | C         | D        |
|------------|-----------|-----------|-----------|----------|
| 2013-01-04 | -0.449553 | -0.177382 | -1.591217 | 1.281605 |

Name: 2013-01-04 00:00:00, dtype: float64

By integer slices, acting similar to numpy/python:

```
In [33]: df.iloc[3:5, 0:2]
Out [33]:
```

|            | A         | B         |
|------------|-----------|-----------|
| 2013-01-04 | -0.449553 | -0.177382 |
| 2013-01-05 | 0.952782  | -0.224539 |

By lists of integer position locations, similar to the numpy/python style:

```
In [34]: df.iloc[[1, 2, 4], [0, 2]]
Out [34]:
```

|            | A        | C         |
|------------|----------|-----------|
| 2013-01-02 | 0.937344 | -0.370979 |
| 2013-01-03 | 2.534641 | -0.283892 |
| 2013-01-05 | 0.952782 | -0.896418 |

For slicing rows explicitly:

```
In [35]: df.iloc[1:3, :]
Out [35]:
```

|            | A        | B        | C         | D        |
|------------|----------|----------|-----------|----------|
| 2013-01-02 | 0.937344 | 0.165604 | -0.370979 | 0.481338 |
| 2013-01-03 | 2.534641 | 1.281051 | -0.283892 | 0.155831 |

For slicing columns explicitly:

```
In [36]: df.iloc[:, 1:3]
Out [36]:
```

|            | B         | C         |
|------------|-----------|-----------|
| 2013-01-01 | -0.074393 | 1.629377  |
| 2013-01-02 | 0.165604  | -0.370979 |
| 2013-01-03 | 1.281051  | -0.283892 |
| 2013-01-04 | -0.177382 | -1.591217 |
| 2013-01-05 | -0.224539 | -0.896418 |
| 2013-01-06 | -0.644854 | 0.433885  |

For getting a value explicitly:

```
In [37]: df.iloc[1, 1]
Out [37]: 0.16560405473278295
```

For getting fast access to a scalar (equivalent to the prior method):

```
In [38]: df.iat[1, 1]
Out [38]: 0.16560405473278295
```

### 5.3.4 Boolean Indexing

Using a single column's values to select data.

```
In [39]: df[df.A > 0]
Out [39]:
```

|            | A        | B         | C         | D         |
|------------|----------|-----------|-----------|-----------|
| 2013-01-01 | 0.872523 | -0.074393 | 1.629377  | -1.847811 |
| 2013-01-02 | 0.937344 | 0.165604  | -0.370979 | 0.481338  |
| 2013-01-03 | 2.534641 | 1.281051  | -0.283892 | 0.155831  |

(continues on next page)

(continued from previous page)

|            |          |           |           |           |
|------------|----------|-----------|-----------|-----------|
| 2013-01-05 | 0.952782 | -0.224539 | -0.896418 | -0.021323 |
| 2013-01-06 | 0.218477 | -0.644854 | 0.433885  | 1.559704  |

## Selecting values from a DataFrame where a boolean condition is met.

```
In [40]: df[df > 0]
Out[40]:
```

|            | A        | B        | C        | D        |
|------------|----------|----------|----------|----------|
| 2013-01-01 | 0.872523 | NaN      | 1.629377 | NaN      |
| 2013-01-02 | 0.937344 | 0.165604 | NaN      | 0.481338 |
| 2013-01-03 | 2.534641 | 1.281051 | NaN      | 0.155831 |
| 2013-01-04 | NaN      | NaN      | NaN      | 1.281605 |
| 2013-01-05 | 0.952782 | NaN      | NaN      | NaN      |
| 2013-01-06 | 0.218477 | NaN      | 0.433885 | 1.559704 |

Using the `isin()` method for filtering:

```
In [41]: df2 = df.copy()

In [42]: df2['E'] = ['one', 'one', 'two', 'three', 'four', 'three']

In [43]: df2
Out[43]:
```

|            | A         | B         | C         | D         | E     |
|------------|-----------|-----------|-----------|-----------|-------|
| 2013-01-01 | 0.872523  | -0.074393 | 1.629377  | -1.847811 | one   |
| 2013-01-02 | 0.937344  | 0.165604  | -0.370979 | 0.481338  | one   |
| 2013-01-03 | 2.534641  | 1.281051  | -0.283892 | 0.155831  | two   |
| 2013-01-04 | -0.449553 | -0.177382 | -1.591217 | 1.281605  | three |
| 2013-01-05 | 0.952782  | -0.224539 | -0.896418 | -0.021323 | four  |
| 2013-01-06 | 0.218477  | -0.644854 | 0.433885  | 1.559704  | three |

```
In [44]: df2[df2['E'].isin(['two', 'four'])]
//////////
↪
```

|            | A        | B         | C         | D         | E    |
|------------|----------|-----------|-----------|-----------|------|
| 2013-01-03 | 2.534641 | 1.281051  | -0.283892 | 0.155831  | two  |
| 2013-01-05 | 0.952782 | -0.224539 | -0.896418 | -0.021323 | four |

### 5.3.5 Setting

Setting a new column automatically aligns the data by the indexes.

```
In [45]: s1 = pd.Series([1, 2, 3, 4, 5, 6], index=pd.date_range('20130102',
↳ periods=6))

In [46]: s1
Out[46]:
2013-01-02 1
2013-01-03 2
2013-01-04 3
2013-01-05 4
2013-01-06 5
2013-01-07 6
Freq: D, dtype: int64
```

(continues on next page)

(continued from previous page)

```
In [47]: df['F'] = s1
```

Setting values by label:

```
In [48]: df.at[dates[0], 'A'] = 0
```

Setting values by position:

```
In [49]: df.iat[0, 1] = 0
```

Setting by assigning with a NumPy array:

```
In [50]: df.loc[:, 'D'] = np.array([5] * len(df))
```

The result of the prior setting operations.

```
In [51]: df
Out[51]:
```

|            | A         | B         | C         | D | F   |
|------------|-----------|-----------|-----------|---|-----|
| 2013-01-01 | 0.000000  | 0.000000  | 1.629377  | 5 | NaN |
| 2013-01-02 | 0.937344  | 0.165604  | -0.370979 | 5 | 1.0 |
| 2013-01-03 | 2.534641  | 1.281051  | -0.283892 | 5 | 2.0 |
| 2013-01-04 | -0.449553 | -0.177382 | -1.591217 | 5 | 3.0 |
| 2013-01-05 | 0.952782  | -0.224539 | -0.896418 | 5 | 4.0 |
| 2013-01-06 | 0.218477  | -0.644854 | 0.433885  | 5 | 5.0 |

A where operation with setting.

```
In [52]: df2 = df.copy()
In [53]: df2[df2 > 0] = -df2
In [54]: df2
Out[54]:
```

|            | A         | B         | C         | D  | F    |
|------------|-----------|-----------|-----------|----|------|
| 2013-01-01 | 0.000000  | 0.000000  | -1.629377 | -5 | NaN  |
| 2013-01-02 | -0.937344 | -0.165604 | -0.370979 | -5 | -1.0 |
| 2013-01-03 | -2.534641 | -1.281051 | -0.283892 | -5 | -2.0 |
| 2013-01-04 | -0.449553 | -0.177382 | -1.591217 | -5 | -3.0 |
| 2013-01-05 | -0.952782 | -0.224539 | -0.896418 | -5 | -4.0 |
| 2013-01-06 | -0.218477 | -0.644854 | -0.433885 | -5 | -5.0 |

## 5.4 Missing Data

pandas primarily uses the value `np.nan` to represent missing data. It is by default not included in computations. See the *Missing Data* section.

Reindexing allows you to change/add/delete the index on a specified axis. This returns a copy of the data.

```
In [55]: df1 = df.reindex(index=dates[0:4], columns=list(df.columns) + ['E'])
In [56]: df1.loc[dates[0]:dates[1], 'E'] = 1
```

(continues on next page)

(continued from previous page)

```
In [57]: df1
Out [57]:
```

|            | A         | B         | C         | D | F   | E   |
|------------|-----------|-----------|-----------|---|-----|-----|
| 2013-01-01 | 0.000000  | 0.000000  | 1.629377  | 5 | NaN | 1.0 |
| 2013-01-02 | 0.937344  | 0.165604  | -0.370979 | 5 | 1.0 | 1.0 |
| 2013-01-03 | 2.534641  | 1.281051  | -0.283892 | 5 | 2.0 | NaN |
| 2013-01-04 | -0.449553 | -0.177382 | -1.591217 | 5 | 3.0 | NaN |

To drop any rows that have missing data.

```
In [58]: df1.dropna(how='any')
Out [58]:
```

|            | A        | B        | C         | D | F   | E   |
|------------|----------|----------|-----------|---|-----|-----|
| 2013-01-02 | 0.937344 | 0.165604 | -0.370979 | 5 | 1.0 | 1.0 |

Filling missing data.

```
In [59]: df1.fillna(value=5)
Out [59]:
```

|            | A         | B         | C         | D | F   | E   |
|------------|-----------|-----------|-----------|---|-----|-----|
| 2013-01-01 | 0.000000  | 0.000000  | 1.629377  | 5 | 5.0 | 1.0 |
| 2013-01-02 | 0.937344  | 0.165604  | -0.370979 | 5 | 1.0 | 1.0 |
| 2013-01-03 | 2.534641  | 1.281051  | -0.283892 | 5 | 2.0 | 5.0 |
| 2013-01-04 | -0.449553 | -0.177382 | -1.591217 | 5 | 3.0 | 5.0 |

To get the boolean mask where values are nan.

```
In [60]: pd.isna(df1)
Out [60]:
```

|            | A     | B     | C     | D     | F     | E     |
|------------|-------|-------|-------|-------|-------|-------|
| 2013-01-01 | False | False | False | False | True  | False |
| 2013-01-02 | False | False | False | False | False | False |
| 2013-01-03 | False | False | False | False | False | True  |
| 2013-01-04 | False | False | False | False | False | True  |

## 5.5 Operations

See the *Basic section on Binary Ops*.

### 5.5.1 Stats

Operations in general *exclude* missing data.

Performing a descriptive statistic:

```
In [61]: df.mean()
Out [61]:
```

|   |           |
|---|-----------|
| A | 0.698949  |
| B | 0.066647  |
| C | -0.179874 |
| D | 5.000000  |
| F | 3.000000  |

dtype: float64

Same operation on the other axis:

```
In [62]: df.mean(1)
Out [62]:
2013-01-01 1.657344
2013-01-02 1.346394
2013-01-03 2.106360
2013-01-04 1.156370
2013-01-05 1.766365
2013-01-06 2.001502
Freq: D, dtype: float64
```

Operating with objects that have different dimensionality and need alignment. In addition, pandas automatically broadcasts along the specified dimension.

```
In [63]: s = pd.Series([1, 3, 5, np.nan, 6, 8], index=dates).shift(2)
```

```
In [64]: s
Out [64]:
2013-01-01 NaN
2013-01-02 NaN
2013-01-03 1.0
2013-01-04 3.0
2013-01-05 5.0
2013-01-06 NaN
Freq: D, dtype: float64
```

```
In [65]: df.sub(s, axis='index')
```

```

////////////////////////////////////
↪

```

|            | A         | B         | C         | D   | F    |
|------------|-----------|-----------|-----------|-----|------|
| 2013-01-01 | NaN       | NaN       | NaN       | NaN | NaN  |
| 2013-01-02 | NaN       | NaN       | NaN       | NaN | NaN  |
| 2013-01-03 | 1.534641  | 0.281051  | -1.283892 | 4.0 | 1.0  |
| 2013-01-04 | -3.449553 | -3.177382 | -4.591217 | 2.0 | 0.0  |
| 2013-01-05 | -4.047218 | -5.224539 | -5.896418 | 0.0 | -1.0 |
| 2013-01-06 | NaN       | NaN       | NaN       | NaN | NaN  |

## 5.5.2 Apply

Applying functions to the data:

```
In [66]: df.apply(np.cumsum)
```

```
Out [66]:
```

|            | A        | B        | C         | D  | F    |
|------------|----------|----------|-----------|----|------|
| 2013-01-01 | 0.000000 | 0.000000 | 1.629377  | 5  | NaN  |
| 2013-01-02 | 0.937344 | 0.165604 | 1.258398  | 10 | 1.0  |
| 2013-01-03 | 3.471985 | 1.446655 | 0.974506  | 15 | 3.0  |
| 2013-01-04 | 3.022432 | 1.269273 | -0.616710 | 20 | 6.0  |
| 2013-01-05 | 3.975214 | 1.044734 | -1.513128 | 25 | 10.0 |
| 2013-01-06 | 4.193691 | 0.399880 | -1.079243 | 30 | 15.0 |

```
In [67]: df.apply(lambda x: x.max() - x.min())
```

```

////////////////////////////////////
↪
A 2.984194
```

(continues on next page)

(continued from previous page)

```

B 1.925905
C 3.220593
D 0.000000
F 4.000000
dtype: float64

```

### 5.5.3 Histogramming

See more at *Histogramming and Discretization*.

```
In [68]: s = pd.Series(np.random.randint(0, 7, size=10))
```

```
In [69]: s
```

```
Out [69]:
```

```

0 5
1 4
2 0
3 3
4 3
5 6
6 4
7 1
8 4
9 4
dtype: int64

```

```
In [70]: s.value_counts()
```

```

Out [70]:
4 4
3 2
6 1
5 1
1 1
0 1
dtype: int64

```

### 5.5.4 String Methods

Series is equipped with a set of string processing methods in the *str* attribute that make it easy to operate on each element of the array, as in the code snippet below. Note that pattern-matching in *str* generally uses [regular expressions](#) by default (and in some cases always uses them). See more at *Vectorized String Methods*.

```
In [71]: s = pd.Series(['A', 'B', 'C', 'Aaba', 'Baca', np.nan, 'CABA', 'dog', 'cat'])
```

```
In [72]: s.str.lower()
```

```
Out [72]:
```

```

0 a
1 b
2 c
3 aaba
4 baca
5 NaN

```

(continues on next page)

(continued from previous page)

```
6 caba
7 dog
8 cat
dtype: object
```

## 5.6 Merge

### 5.6.1 Concat

pandas provides various facilities for easily combining together Series, DataFrame, and Panel objects with various kinds of set logic for the indexes and relational algebra functionality in the case of join / merge-type operations.

See the *Merging section*.

Concatenating pandas objects together with `concat()`:

```
In [73]: df = pd.DataFrame(np.random.randn(10, 4))
```

```
In [74]: df
```

```
Out[74]:
```

|   | 0         | 1         | 2         | 3         |
|---|-----------|-----------|-----------|-----------|
| 0 | -0.291782 | 1.139424  | 2.002526  | 0.299043  |
| 1 | -2.317754 | 1.930268  | 0.394692  | 0.685290  |
| 2 | -0.455747 | 0.846805  | -1.093958 | -0.779910 |
| 3 | -0.097676 | -0.493796 | 2.357706  | -0.505366 |
| 4 | -0.434207 | 1.680201  | -0.272288 | 0.155456  |
| 5 | -1.128799 | -0.129183 | 0.933262  | 1.377561  |
| 6 | 1.955737  | 0.897844  | -0.632961 | 0.304910  |
| 7 | -0.191453 | 0.148563  | -0.264288 | -0.914179 |
| 8 | 1.398493  | -0.361695 | 1.188838  | 0.933006  |
| 9 | 0.427770  | -0.534435 | 1.122441  | -0.121105 |

```
break it into pieces
```

```
In [75]: pieces = [df[:3], df[3:7], df[7:]]
```

```
In [76]: pd.concat(pieces)
```

```
Out[76]:
```

|   | 0         | 1         | 2         | 3         |
|---|-----------|-----------|-----------|-----------|
| 0 | -0.291782 | 1.139424  | 2.002526  | 0.299043  |
| 1 | -2.317754 | 1.930268  | 0.394692  | 0.685290  |
| 2 | -0.455747 | 0.846805  | -1.093958 | -0.779910 |
| 3 | -0.097676 | -0.493796 | 2.357706  | -0.505366 |
| 4 | -0.434207 | 1.680201  | -0.272288 | 0.155456  |
| 5 | -1.128799 | -0.129183 | 0.933262  | 1.377561  |
| 6 | 1.955737  | 0.897844  | -0.632961 | 0.304910  |
| 7 | -0.191453 | 0.148563  | -0.264288 | -0.914179 |
| 8 | 1.398493  | -0.361695 | 1.188838  | 0.933006  |
| 9 | 0.427770  | -0.534435 | 1.122441  | -0.121105 |

### 5.6.2 Join

SQL style merges. See the *Database style joining* section.

```

In [77]: left = pd.DataFrame({'key': ['foo', 'foo'], 'lval': [1, 2]})

In [78]: right = pd.DataFrame({'key': ['foo', 'foo'], 'rval': [4, 5]})

In [79]: left
Out[79]:
 key lval
0 foo 1
1 foo 2

In [80]: right
Out[80]:
 key rval
0 foo 4
1 foo 5

In [81]: pd.merge(left, right, on='key')
Out[81]:
 key lval rval
0 foo 1 4
1 foo 1 5
2 foo 2 4
3 foo 2 5

```

Another example that can be given is:

```

In [82]: left = pd.DataFrame({'key': ['foo', 'bar'], 'lval': [1, 2]})

In [83]: right = pd.DataFrame({'key': ['foo', 'bar'], 'rval': [4, 5]})

In [84]: left
Out[84]:
 key lval
0 foo 1
1 bar 2

In [85]: right
Out[85]:
 key rval
0 foo 4
1 bar 5

In [86]: pd.merge(left, right, on='key')
Out[86]:
 key lval rval
0 foo 1 4
1 bar 2 5

```

## 5.6.3 Append

Append rows to a dataframe. See the *Appending* section.

```

In [87]: df = pd.DataFrame(np.random.randn(8, 4), columns=['A', 'B', 'C', 'D'])

```

(continues on next page)

(continued from previous page)

```
In [88]: df
Out[88]:
```

|   | A         | B         | C         | D         |
|---|-----------|-----------|-----------|-----------|
| 0 | 0.671126  | -1.088056 | -0.991656 | -0.872739 |
| 1 | -0.801561 | -0.896365 | -0.473303 | -0.379212 |
| 2 | -1.236540 | 0.178528  | -0.461038 | -0.376934 |
| 3 | -0.395186 | 0.716650  | 0.565508  | -0.891188 |
| 4 | -0.346659 | 0.114090  | 0.332753  | 0.695204  |
| 5 | 0.159827  | -1.997739 | -0.565975 | 1.110197  |
| 6 | 1.623927  | -0.149195 | -2.024816 | -0.304125 |
| 7 | -0.104837 | -0.968604 | 0.168592  | -1.890606 |

```
In [89]: s = df.iloc[3]
```

```
In [90]: df.append(s, ignore_index=True)
Out[90]:
```

|   | A         | B         | C         | D         |
|---|-----------|-----------|-----------|-----------|
| 0 | 0.671126  | -1.088056 | -0.991656 | -0.872739 |
| 1 | -0.801561 | -0.896365 | -0.473303 | -0.379212 |
| 2 | -1.236540 | 0.178528  | -0.461038 | -0.376934 |
| 3 | -0.395186 | 0.716650  | 0.565508  | -0.891188 |
| 4 | -0.346659 | 0.114090  | 0.332753  | 0.695204  |
| 5 | 0.159827  | -1.997739 | -0.565975 | 1.110197  |
| 6 | 1.623927  | -0.149195 | -2.024816 | -0.304125 |
| 7 | -0.104837 | -0.968604 | 0.168592  | -1.890606 |
| 8 | -0.395186 | 0.716650  | 0.565508  | -0.891188 |

## 5.7 Grouping

By “group by” we are referring to a process involving one or more of the following steps:

- **Splitting** the data into groups based on some criteria
- **Applying** a function to each group independently
- **Combining** the results into a data structure

See the *Grouping section*.

```
In [91]: df = pd.DataFrame({'A': ['foo', 'bar', 'foo', 'bar',
.....: 'foo', 'bar', 'foo', 'foo'],
.....: 'B': ['one', 'one', 'two', 'three',
.....: 'two', 'two', 'one', 'three'],
.....: 'C': np.random.randn(8),
.....: 'D': np.random.randn(8)})
.....:
```

```
In [92]: df
Out[92]:
```

|   | A   | B     | C         | D         |
|---|-----|-------|-----------|-----------|
| 0 | foo | one   | -1.204818 | 1.323211  |
| 1 | bar | one   | 1.941476  | 0.331072  |
| 2 | foo | two   | -0.516910 | -0.636676 |
| 3 | bar | three | 0.078932  | -1.165139 |
| 4 | foo | two   | 0.155286  | 0.330625  |

(continues on next page)

(continued from previous page)

```

5 bar two -0.056539 -0.223787
6 foo one 0.162013 -0.310882
7 foo three -0.095497 0.398926

```

Grouping and then applying the `sum()` function to the resulting groups.

```

In [93]: df.groupby('A').sum()
Out[93]:
 C D
A
bar 1.963869 -1.057854
foo -1.499925 1.105204

```

Grouping by multiple columns forms a hierarchical index, and again we can apply the `sum` function.

```

In [94]: df.groupby(['A', 'B']).sum()
Out[94]:
 C D
A B
bar one 1.941476 0.331072
 three 0.078932 -1.165139
 two -0.056539 -0.223787
foo one -1.042805 1.012329
 three -0.095497 0.398926
 two -0.361623 -0.306051

```

## 5.8 Reshaping

See the sections on *Hierarchical Indexing* and *Reshaping*.

### 5.8.1 Stack

```

In [95]: tuples = list(zip(*[['bar', 'bar', 'baz', 'baz',
.....: 'foo', 'foo', 'qux', 'qux'],
.....: ['one', 'two', 'one', 'two',
.....: 'one', 'two', 'one', 'two']]))
.....:

In [96]: index = pd.MultiIndex.from_tuples(tuples, names=['first', 'second'])

In [97]: df = pd.DataFrame(np.random.randn(8, 2), index=index, columns=['A', 'B'])

In [98]: df2 = df[:4]

In [99]: df2
Out[99]:
 A B
first second
bar one 1.154919 -0.581633
 two -0.097855 0.361024
baz one -0.614255 -1.629149
 two 0.166225 -0.180917

```

The `stack()` method “compresses” a level in the `DataFrame`’s columns.

```
In [100]: stacked = df2.stack()
```

```
In [101]: stacked
```

```
Out[101]:
first second
bar one A 1.154919
 B -0.581633
 two A -0.097855
 B 0.361024
baz one A -0.614255
 B -1.629149
 two A 0.166225
 B -0.180917
dtype: float64
```

With a “stacked” `DataFrame` or `Series` (having a `MultiIndex` as the index), the inverse operation of `stack()` is `unstack()`, which by default unstacks the **last level**:

```
In [102]: stacked.unstack()
```

```
Out[102]:
 A B
first second
bar one 1.154919 -0.581633
 two -0.097855 0.361024
baz one -0.614255 -1.629149
 two 0.166225 -0.180917
```

```
In [103]: stacked.unstack(1)
```

```

////////////////////////////////////
↪
second one two
first
bar A 1.154919 -0.097855
 B -0.581633 0.361024
baz A -0.614255 0.166225
 B -1.629149 -0.180917
```

```
In [104]: stacked.unstack(0)
```

```

////////////////////////////////////
↪
first bar baz
second
one A 1.154919 -0.614255
 B -0.581633 -1.629149
two A -0.097855 0.166225
 B 0.361024 -0.180917
```

## 5.8.2 Pivot Tables

See the section on *Pivot Tables*.

```
In [105]: df = pd.DataFrame({'A': ['one', 'one', 'two', 'three'] * 3,
.....: 'B': ['A', 'B', 'C'] * 4,
.....: 'C': ['foo', 'foo', 'foo', 'bar', 'bar', 'bar'] * 2,
```

(continues on next page)

(continued from previous page)

```

.....: 'D': np.random.randn(12),
.....: 'E': np.random.randn(12) })
.....:

In [106]: df
Out[106]:
 A B C D E
0 one A foo -1.369801 -0.084431
1 one B foo -1.992292 0.780136
2 two C foo -0.553642 -0.380388
3 three A bar -1.864103 0.530210
4 one B bar 0.052924 -0.586233
5 one C bar 0.301598 -1.451875
6 two A foo -1.076322 -0.504341
7 three B foo -0.894332 0.824258
8 one C foo -2.123684 0.639931
9 one A bar -0.025344 -0.674801
10 two B bar 0.288355 -0.121503
11 three C bar -0.065184 -0.870860

```

We can produce pivot tables from this data very easily:

```

In [107]: pd.pivot_table(df, values='D', index=['A', 'B'], columns=['C'])
Out[107]:
C bar foo
A B
one A -0.025344 -1.369801
 B 0.052924 -1.992292
 C 0.301598 -2.123684
three A -1.864103 NaN
 B NaN -0.894332

 C NaN -0.553642

```

## 5.9 Time Series

pandas has simple, powerful, and efficient functionality for performing resampling operations during frequency conversion (e.g., converting secondly data into 5-minutely data). This is extremely common in, but not limited to, financial applications. See the *Time Series* section.

```

In [108]: rng = pd.date_range('1/1/2012', periods=100, freq='S')

In [109]: ts = pd.Series(np.random.randint(0, 500, len(rng)), index=rng)

In [110]: ts.resample('5Min').sum()
Out[110]:
2012-01-01 28648
Freq: 5T, dtype: int64

```

Time zone representation:

```
In [111]: rng = pd.date_range('3/6/2012 00:00', periods=5, freq='D')
```

```
In [112]: ts = pd.Series(np.random.randn(len(rng)), rng)
```

```
In [113]: ts
```

```
Out[113]:
```

```
2012-03-06 -0.688273
2012-03-07 -1.190681
2012-03-08 0.241296
2012-03-09 -0.388527
2012-03-10 -1.455577
Freq: D, dtype: float64
```

```
In [114]: ts_utc = ts.tz_localize('UTC')
```

```
In [115]: ts_utc
```

```
Out[115]:
```

```
2012-03-06 00:00:00+00:00 -0.688273
2012-03-07 00:00:00+00:00 -1.190681
2012-03-08 00:00:00+00:00 0.241296
2012-03-09 00:00:00+00:00 -0.388527
2012-03-10 00:00:00+00:00 -1.455577
Freq: D, dtype: float64
```

Converting to another time zone:

```
In [116]: ts_utc.tz_convert('US/Eastern')
```

```
Out[116]:
```

```
2012-03-05 19:00:00-05:00 -0.688273
2012-03-06 19:00:00-05:00 -1.190681
2012-03-07 19:00:00-05:00 0.241296
2012-03-08 19:00:00-05:00 -0.388527
2012-03-09 19:00:00-05:00 -1.455577
Freq: D, dtype: float64
```

Converting between time span representations:

```
In [117]: rng = pd.date_range('1/1/2012', periods=5, freq='M')
```

```
In [118]: ts = pd.Series(np.random.randn(len(rng)), index=rng)
```

```
In [119]: ts
```

```
Out[119]:
```

```
2012-01-31 0.612415
2012-02-29 -0.473584
2012-03-31 -0.669215
2012-04-30 -1.750505
2012-05-31 1.238585
Freq: M, dtype: float64
```

```
In [120]: ps = ts.to_period()
```

```
In [121]: ps
```

```
Out[121]:
```

```
2012-01 0.612415
2012-02 -0.473584
2012-03 -0.669215
```

(continues on next page)

(continued from previous page)

```

2012-04 -1.750505
2012-05 1.238585
Freq: M, dtype: float64

```

```
In [122]: ps.to_timestamp()
```

```

////////////////////////////////////

```

```
↪
```

```

2012-01-01 0.612415
2012-02-01 -0.473584
2012-03-01 -0.669215
2012-04-01 -1.750505
2012-05-01 1.238585
Freq: MS, dtype: float64

```

Converting between period and timestamp enables some convenient arithmetic functions to be used. In the following example, we convert a quarterly frequency with year ending in November to 9am of the end of the month following the quarter end:

```
In [123]: prng = pd.period_range('1990Q1', '2000Q4', freq='Q-NOV')
```

```
In [124]: ts = pd.Series(np.random.randn(len(prng)), prng)
```

```
In [125]: ts.index = (prng.asfreq('M', 'e') + 1).asfreq('H', 's') + 9
```

```
In [126]: ts.head()
```

```
Out[126]:
```

```

1990-03-01 09:00 0.181307
1990-06-01 09:00 0.206330
1990-09-01 09:00 1.014639
1990-12-01 09:00 -1.049618
1991-03-01 09:00 -0.847145
Freq: H, dtype: float64

```

## 5.10 Categoricals

pandas can include categorical data in a DataFrame. For full docs, see the *categorical introduction* and the *API documentation*.

```

In [127]: df = pd.DataFrame({"id": [1, 2, 3, 4, 5, 6],
.....: "raw_grade": ['a', 'b', 'b', 'a', 'a', 'e']})
.....:

```

Convert the raw grades to a categorical data type.

```
In [128]: df["grade"] = df["raw_grade"].astype("category")
```

```
In [129]: df["grade"]
```

```
Out[129]:
```

```

0 a
1 b
2 b
3 a
4 a
5 e

```

(continues on next page)

(continued from previous page)

```
Name: grade, dtype: category
Categories (3, object): [a, b, e]
```

Rename the categories to more meaningful names (assigning to `Series.cat.categories` is inplace!).

```
In [130]: df["grade"].cat.categories = ["very good", "good", "very bad"]
```

Reorder the categories and simultaneously add the missing categories (methods under `Series.cat` return a new `Series` by default).

```
In [131]: df["grade"] = df["grade"].cat.set_categories(["very bad", "bad", "medium",
.....: "good", "very good"])
.....:

In [132]: df["grade"]
Out[132]:
0 very good
1 good
2 good
3 very good
4 very good
5 very bad
Name: grade, dtype: category
Categories (5, object): [very bad, bad, medium, good, very good]
```

Sorting is per order in the categories, not lexical order.

```
In [133]: df.sort_values(by="grade")
Out[133]:
```

|   | id | raw_grade | grade     |
|---|----|-----------|-----------|
| 5 | 6  | e         | very bad  |
| 1 | 2  | b         | good      |
| 2 | 3  | b         | good      |
| 0 | 1  | a         | very good |
| 3 | 4  | a         | very good |
| 4 | 5  | a         | very good |

Grouping by a categorical column also shows empty categories.

```
In [134]: df.groupby("grade").size()
Out[134]:
grade
very bad 1
bad 0
medium 0
good 2
very good 3
dtype: int64
```

## 5.11 Plotting

See the *Plotting* docs.

```

In [135]: ts = pd.Series(np.random.randn(1000),
.....: index=pd.date_range('1/1/2000', periods=1000))
.....:

In [136]: ts = ts.cumsum()

In [137]: ts.plot()
Out[137]: <matplotlib.axes._subplots.AxesSubplot at 0x7fd5565b1780>

```

On a DataFrame, the `plot()` method is a convenience to plot all of the columns with labels:

```

In [138]: df = pd.DataFrame(np.random.randn(1000, 4), index=ts.index,
.....: columns=['A', 'B', 'C', 'D'])
.....:

In [139]: df = df.cumsum()

In [140]: plt.figure()
Out[140]: <Figure size 640x480 with 0 Axes>

In [141]: df.plot()
Out[141]: <matplotlib.axes._subplots.
↪AxesSubplot at 0x7fd5529241d0>

```

(continues on next page)

(continued from previous page)

```
In [142]: plt.legend(loc='best')
///
↪<matplotlib.legend.Legend at 0x7fd5527f6128>
```

## 5.12 Getting Data In/Out

### 5.12.1 CSV

*Writing to a csv file.*

```
In [143]: df.to_csv('foo.csv')
```

*Reading from a csv file.*

```
In [144]: pd.read_csv('foo.csv')
```

```
Out[144]:
```

|   | Unnamed: 0 | A         | B        | C         | D         |
|---|------------|-----------|----------|-----------|-----------|

## 5.12.2 HDF5

Reading and writing to *HDFStores*.

Writing to a HDF5 Store.

```
In [145]: df.to_hdf('foo.h5', 'df')
```

Reading from a HDF5 Store.

```
In [146]: pd.read_hdf('foo.h5', 'df')
```

```
Out[146]:
```

|            | A         | B         | C         | D          |

### 5.12.3 Excel

Reading and writing to *MS Excel*.

Writing to an excel file.

```
In [147]: df.to_excel('foo.xlsx', sheet_name='Sheet1')
```

Reading from an excel file.

```
In [148]: pd.read_excel('foo.xlsx', 'Sheet1', index_col=None, na_values=['NA'])
```

```
Out[148]:
```

[1000 rows x 5 columns]

## 5.13 Gotchas

If you are attempting to perform an operation you might see an exception like:

```

>>> if pd.Series([False, True, False]):
... print("I was true")

```

(continues on next page)

(continued from previous page)

```
Traceback
...
ValueError: The truth value of an array is ambiguous. Use a.empty, a.any() or a.all().
```

See *Comparisons* for an explanation and what to do.

See *Gotchas* as well. {{ header }}

## TUTORIALS

This is a guide to many pandas tutorials, geared mainly for new users.

### 6.1 Internal Guides

pandas' own *10 Minutes to pandas*.

More complex recipes are in the *Cookbook*.

A handy pandas [cheat sheet](#).

### 6.2 Community Guides

#### 6.2.1 pandas Cookbook by Julia Evans

The goal of this 2015 cookbook (by [Julia Evans](#)) is to give you some concrete examples for getting started with pandas. These are examples with real-world data, and all the bugs and weirdness that entails. For the table of contents, see the [pandas-cookbook GitHub repository](#).

#### 6.2.2 Learn Pandas by Hernan Rojas

A set of lesson for new pandas users: <https://bitbucket.org/hrojas/learn-pandas>

#### 6.2.3 Practical data analysis with Python

This [guide](#) is an introduction to the data analysis process using the Python data ecosystem and an interesting open dataset. There are four sections covering selected topics as [munging data](#), [aggregating data](#), [visualizing data](#) and [time series](#).

#### 6.2.4 Exercises for new users

Practice your skills with real data sets and exercises. For more resources, please visit the main [repository](#).

## 6.2.5 Modern pandas

Tutorial series written in 2016 by Tom Augspurger. The source may be found in the GitHub repository [TomAugspurger/effective-pandas](#).

- [Modern Pandas](#)
- [Method Chaining](#)
- [Indexes](#)
- [Performance](#)
- [Tidy Data](#)
- [Visualization](#)
- [Timeseries](#)

## 6.2.6 Excel charts with pandas, vincent and xlsxwriter

- [Using Pandas and XlsxWriter to create Excel charts](#)

## 6.2.7 Video Tutorials

- [Pandas From The Ground Up \(2015\) \(2:24\) GitHub repo](#)
- [Introduction Into Pandas \(2016\) \(1:28\) GitHub repo](#)
- [Pandas: .head\(\) to .tail\(\) \(2016\) \(1:26\) GitHub repo](#)
- [Data analysis in Python with pandas \(2016-2018\) GitHub repo and Jupyter Notebook](#)
- [Best practices with pandas \(2018\) GitHub repo and Jupyter Notebook](#)

## 6.2.8 Various Tutorials

- [Wes McKinney's \(pandas BDFL\) blog](#)
- [Statistical analysis made easy in Python with SciPy and pandas DataFrames, by Randal Olson](#)
- [Statistical Data Analysis in Python, tutorial videos, by Christopher Fonnesbeck from SciPy 2013](#)
- [Financial analysis in Python, by Thomas Wiecki](#)
- [Intro to pandas data structures, by Greg Reda](#)
- [Pandas and Python: Top 10, by Manish Amde](#)
- [Pandas DataFrames Tutorial, by Karlijn Willems](#)
- [A concise tutorial with real life examples](#)

{{ header }}

## COOKBOOK

This is a repository for *short and sweet* examples and links for useful pandas recipes. We encourage users to add to this documentation.

Adding interesting links and/or inline examples to this section is a great *First Pull Request*.

Simplified, condensed, new-user friendly, in-line examples have been inserted where possible to augment the Stack-Overflow and GitHub links. Many of the links contain expanded information, above what the in-line examples offer.

Pandas (pd) and Numpy (np) are the only two abbreviated imported modules. The rest are kept explicitly imported for newer users.

These examples are written for Python 3. Minor tweaks might be necessary for earlier python versions.

### 7.1 Idioms

These are some neat pandas idioms

if-then/if-then-else on one column, and assignment to another one or more columns:

```
In [1]: df = pd.DataFrame({'AAA': [4, 5, 6, 7],
...: 'BBB': [10, 20, 30, 40],
...: 'CCC': [100, 50, -30, -50]})
...:

In [2]: df
Out[2]:
 AAA BBB CCC
0 4 10 100
1 5 20 50
2 6 30 -30
3 7 40 -50
```

#### 7.1.1 if-then...

An if-then on one column

```
In [3]: df.loc[df.AAA >= 5, 'BBB'] = -1

In [4]: df
Out[4]:
 AAA BBB CCC
0 4 10 100
```

(continues on next page)

(continued from previous page)

|   |   |    |     |
|---|---|----|-----|
| 1 | 5 | -1 | 50  |
| 2 | 6 | -1 | -30 |
| 3 | 7 | -1 | -50 |

An if-then with assignment to 2 columns:

```
In [5]: df.loc[df.AAA >= 5, ['BBB', 'CCC']] = 555
```

```
In [6]: df
```

```
Out [6]:
```

|   | AAA | BBB | CCC |
|---|-----|-----|-----|
| 0 | 4   | 10  | 100 |
| 1 | 5   | 555 | 555 |
| 2 | 6   | 555 | 555 |
| 3 | 7   | 555 | 555 |

Add another line with different logic, to do the -else

```
In [7]: df.loc[df.AAA < 5, ['BBB', 'CCC']] = 2000
```

```
In [8]: df
```

```
Out [8]:
```

|   | AAA | BBB  | CCC  |
|---|-----|------|------|
| 0 | 4   | 2000 | 2000 |
| 1 | 5   | 555  | 555  |
| 2 | 6   | 555  | 555  |
| 3 | 7   | 555  | 555  |

Or use pandas where after you've set up a mask

```
In [9]: df_mask = pd.DataFrame({'AAA': [True] * 4,
...: 'BBB': [False] * 4,
...: 'CCC': [True, False] * 2})
...:
```

```
In [10]: df.where(df_mask, -1000)
```

```
Out [10]:
```

|   | AAA | BBB   | CCC   |
|---|-----|-------|-------|
| 0 | 4   | -1000 | 2000  |
| 1 | 5   | -1000 | -1000 |
| 2 | 6   | -1000 | 555   |
| 3 | 7   | -1000 | -1000 |

if-then-else using numpy's where()

```
In [11]: df = pd.DataFrame({'AAA': [4, 5, 6, 7],
...: 'BBB': [10, 20, 30, 40],
...: 'CCC': [100, 50, -30, -50]})
...:
```

```
In [12]: df
```

```
Out [12]:
```

|   | AAA | BBB | CCC |
|---|-----|-----|-----|
| 0 | 4   | 10  | 100 |
| 1 | 5   | 20  | 50  |
| 2 | 6   | 30  | -30 |

(continues on next page)

(continued from previous page)

```

3 7 40 -50

In [13]: df['logic'] = np.where(df['AAA'] > 5, 'high', 'low')

In [14]: df
Out[14]:
 AAA BBB CCC logic
0 4 10 100 low
1 5 20 50 low
2 6 30 -30 high
3 7 40 -50 high

```

## 7.1.2 Splitting

Split a frame with a boolean criterion

```

In [15]: df = pd.DataFrame({'AAA': [4, 5, 6, 7],
.....: 'BBB': [10, 20, 30, 40],
.....: 'CCC': [100, 50, -30, -50]})
.....:

In [16]: df
Out[16]:
 AAA BBB CCC
0 4 10 100
1 5 20 50
2 6 30 -30
3 7 40 -50

In [17]: df[df.AAA <= 5]
Out[17]:
 AAA BBB CCC
0 4 10 100
1 5 20 50

In [18]: df[df.AAA > 5]
Out[18]:
 AAA BBB CCC
2 6 30 -30
3 7 40 -50

```

## 7.1.3 Building Criteria

Select with multi-column criteria

```

In [19]: df = pd.DataFrame({'AAA': [4, 5, 6, 7],
.....: 'BBB': [10, 20, 30, 40],
.....: 'CCC': [100, 50, -30, -50]})
.....:

In [20]: df

```

(continues on next page)

(continued from previous page)

```
Out [20]:
```

|   | AAA | BBB | CCC |
|---|-----|-----|-----|
| 0 | 4   | 10  | 100 |
| 1 | 5   | 20  | 50  |
| 2 | 6   | 30  | -30 |
| 3 | 7   | 40  | -50 |

... and (without assignment returns a Series)

```
In [21]: df.loc[(df['BBB'] < 25) & (df['CCC'] >= -40), 'AAA']
Out [21]:
```

|   | AAA |
|---|-----|
| 0 | 4   |
| 1 | 5   |

Name: AAA, dtype: int64

... or (without assignment returns a Series)

```
In [22]: df.loc[(df['BBB'] > 25) | (df['CCC'] >= -40), 'AAA']
Out [22]:
```

|   | AAA |
|---|-----|
| 0 | 4   |
| 1 | 5   |
| 2 | 6   |
| 3 | 7   |

Name: AAA, dtype: int64

... or (with assignment modifies the DataFrame.)

```
In [23]: df.loc[(df['BBB'] > 25) | (df['CCC'] >= 75), 'AAA'] = 0.1
In [24]: df
Out [24]:
```

|   | AAA | BBB | CCC |
|---|-----|-----|-----|
| 0 | 0.1 | 10  | 100 |
| 1 | 5.0 | 20  | 50  |
| 2 | 0.1 | 30  | -30 |
| 3 | 0.1 | 40  | -50 |

Select rows with data closest to certain value using argsort

```
In [25]: df = pd.DataFrame({'AAA': [4, 5, 6, 7],
.....: 'BBB': [10, 20, 30, 40],
.....: 'CCC': [100, 50, -30, -50]})
.....:

In [26]: df
Out [26]:
```

|   | AAA | BBB | CCC |
|---|-----|-----|-----|
| 0 | 4   | 10  | 100 |
| 1 | 5   | 20  | 50  |
| 2 | 6   | 30  | -30 |
| 3 | 7   | 40  | -50 |

```
In [27]: aValue = 43.0

In [28]: df.loc[(df.CCC - aValue).abs().argsort()]
Out [28]:
```

(continues on next page)

(continued from previous page)

|   | AAA | BBB | CCC |
|---|-----|-----|-----|
| 1 | 5   | 20  | 50  |
| 0 | 4   | 10  | 100 |
| 2 | 6   | 30  | -30 |
| 3 | 7   | 40  | -50 |

Dynamically reduce a list of criteria using a binary operators

```
In [29]: df = pd.DataFrame({'AAA': [4, 5, 6, 7],
.....: 'BBB': [10, 20, 30, 40],
.....: 'CCC': [100, 50, -30, -50]})
.....:
```

```
In [30]: df
```

```
Out[30]:
 AAA BBB CCC
0 4 10 100
1 5 20 50
2 6 30 -30
3 7 40 -50
```

```
In [31]: Crit1 = df.AAA <= 5.5
```

```
In [32]: Crit2 = df.BBB == 10.0
```

```
In [33]: Crit3 = df.CCC > -40.0
```

One could hard code:

```
In [34]: AllCrit = Crit1 & Crit2 & Crit3
```

... Or it can be done with a list of dynamically built criteria

```
In [35]: import functools
```

```
In [36]: CritList = [Crit1, Crit2, Crit3]
```

```
In [37]: AllCrit = functools.reduce(lambda x, y: x & y, CritList)
```

```
In [38]: df[AllCrit]
```

```
Out[38]:
 AAA BBB CCC
0 4 10 100
```

## 7.2 Selection

### 7.2.1 DataFrames

The *indexing* docs.

Using both row labels and value conditionals

```
In [39]: df = pd.DataFrame({'AAA': [4, 5, 6, 7],
.....: 'BBB': [10, 20, 30, 40],
```

(continues on next page)

(continued from previous page)

```

.....: 'CCC': [100, 50, -30, -50]})
.....:

In [40]: df
Out[40]:
 AAA BBB CCC
0 4 10 100
1 5 20 50
2 6 30 -30
3 7 40 -50

In [41]: df[(df.AAA <= 6) & (df.index.isin([0, 2, 4]))]
Out[41]:
 AAA BBB CCC
0 4 10 100
2 6 30 -30

```

Use loc for label-oriented slicing and iloc positional slicing

```

In [42]: df = pd.DataFrame({'AAA': [4, 5, 6, 7],
.....: 'BBB': [10, 20, 30, 40],
.....: 'CCC': [100, 50, -30, -50]},
.....: index=['foo', 'bar', 'boo', 'kar'])
.....:

```

There are 2 explicit slicing methods, with a third general case

1. Positional-oriented (Python slicing style : exclusive of end)
2. Label-oriented (Non-Python slicing style : inclusive of end)
3. General (Either slicing style : depends on if the slice contains labels or positions)

```

In [43]: df.loc['bar':'kar'] # Label
Out[43]:
 AAA BBB CCC
bar 5 20 50
boo 6 30 -30
kar 7 40 -50

Generic
In [44]: df.iloc[0:3]
Out[44]:
 AAA BBB CCC
foo 4 10 100
bar 5 20 50
boo 6 30 -30

In [45]: df.loc['bar':'kar']
Out[45]:
 AAA BBB CCC
bar 5 20 50
boo 6 30 -30
kar 7 40 -50

```

Ambiguity arises when an index consists of integers with a non-zero start or non-unit increment.

```
In [46]: data = {'AAA': [4, 5, 6, 7],
.....: 'BBB': [10, 20, 30, 40],
.....: 'CCC': [100, 50, -30, -50]}
.....:

In [47]: df2 = pd.DataFrame(data=data, index=[1, 2, 3, 4]) # Note index starts at 1.

In [48]: df2.iloc[1:3] # Position-oriented
Out[48]:
 AAA BBB CCC
2 5 20 50
3 6 30 -30

In [49]: df2.loc[1:3] # Label-oriented
Out[49]:
 AAA BBB CCC
1 4 10 100
2 5 20 50
3 6 30 -30
```

Using inverse operator (~) to take the complement of a mask

```
In [50]: df = pd.DataFrame({'AAA': [4, 5, 6, 7],
.....: 'BBB': [10, 20, 30, 40],
.....: 'CCC': [100, 50, -30, -50]})
.....:

In [51]: df
Out[51]:
 AAA BBB CCC
0 4 10 100
1 5 20 50
2 6 30 -30
3 7 40 -50

In [52]: df[~((df.AAA <= 6) & (df.index.isin([0, 2, 4])))]
Out[52]:
 AAA BBB CCC
1 5 20 50
3 7 40 -50
```

## 7.2.2 Panels

Extend a panel frame by transposing, adding a new dimension, and transposing back to the original dimensions

```
In [53]: rng = pd.date_range('1/1/2013', periods=100, freq='D')

In [54]: data = np.random.randn(100, 4)

In [55]: cols = ['A', 'B', 'C', 'D']

In [56]: df1 = pd.DataFrame(data, rng, cols)
```

(continues on next page)

(continued from previous page)

```

In [57]: df2 = pd.DataFrame(data, rng, cols)

In [58]: df3 = pd.DataFrame(data, rng, cols)

In [59]: pf = pd.Panel({'df1': df1, 'df2': df2, 'df3': df3})

In [60]: pf
Out[60]:
<class 'pandas.core.panel.Panel'>
Dimensions: 3 (items) x 100 (major_axis) x 4 (minor_axis)
Items axis: df1 to df3
Major_axis axis: 2013-01-01 00:00:00 to 2013-04-10 00:00:00
Minor_axis axis: A to D

In [61]: pf.loc[:, :, 'F'] = pd.DataFrame(data, rng, cols)

In [62]: pf
Out[62]:
<class 'pandas.core.panel.Panel'>
Dimensions: 3 (items) x 100 (major_axis) x 5 (minor_axis)
Items axis: df1 to df3
Major_axis axis: 2013-01-01 00:00:00 to 2013-04-10 00:00:00
Minor_axis axis: A to F

```

Mask a panel by using `np.where` and then reconstructing the panel with the new masked values

## 7.2.3 New Columns

Efficiently and dynamically creating new columns using `applymap`

```

In [63]: df = pd.DataFrame({'AAA': [1, 2, 1, 3],
.....: 'BBB': [1, 1, 2, 2],
.....: 'CCC': [2, 1, 3, 1]})
.....:

In [64]: df
Out[64]:
 AAA BBB CCC
0 1 1 2
1 2 1 1
2 1 2 3
3 3 2 1

In [65]: source_cols = df.columns # Or some subset would work too

In [66]: new_cols = [str(x) + "_cat" for x in source_cols]

In [67]: categories = {1: 'Alpha', 2: 'Beta', 3: 'Charlie'}

In [68]: df[new_cols] = df[source_cols].applymap(categories.get)

In [69]: df
Out[69]:
 AAA BBB CCC AAA_cat BBB_cat CCC_cat
0 1 1 2 Alpha Alpha Beta

```

(continues on next page)

(continued from previous page)

|   |   |   |   |         |       |         |
|---|---|---|---|---------|-------|---------|
| 1 | 2 | 1 | 1 | Beta    | Alpha | Alpha   |
| 2 | 1 | 2 | 3 | Alpha   | Beta  | Charlie |
| 3 | 3 | 2 | 1 | Charlie | Beta  | Alpha   |

Keep other columns when using min() with groupby

```
In [70]: df = pd.DataFrame({'AAA': [1, 1, 1, 2, 2, 2, 3, 3],
.....: 'BBB': [2, 1, 3, 4, 5, 1, 2, 3]})
.....:
```

```
In [71]: df
```

```
Out [71]:
```

|   | AAA | BBB |
|---|-----|-----|
| 0 | 1   | 2   |
| 1 | 1   | 1   |
| 2 | 1   | 3   |
| 3 | 2   | 4   |
| 4 | 2   | 5   |
| 5 | 2   | 1   |
| 6 | 3   | 2   |
| 7 | 3   | 3   |

Method 1 : idxmin() to get the index of the minimums

```
In [72]: df.loc[df.groupby("AAA")["BBB"].idxmin()]
```

```
Out [72]:
```

|   | AAA | BBB |
|---|-----|-----|
| 1 | 1   | 1   |
| 5 | 2   | 1   |
| 6 | 3   | 2   |

Method 2 : sort then take first of each

```
In [73]: df.sort_values(by="BBB").groupby("AAA", as_index=False).first()
```

```
Out [73]:
```

|   | AAA | BBB |
|---|-----|-----|
| 0 | 1   | 1   |
| 1 | 2   | 1   |
| 2 | 3   | 2   |

Notice the same results, with the exception of the index.

## 7.3 MultiIndexing

The *multindexing* docs.

Creating a MultiIndex from a labeled frame

```
In [74]: df = pd.DataFrame({'row': [0, 1, 2],
.....: 'One_X': [1.1, 1.1, 1.1],
.....: 'One_Y': [1.2, 1.2, 1.2],
.....: 'Two_X': [1.11, 1.11, 1.11],
.....: 'Two_Y': [1.22, 1.22, 1.22]})
.....:
```

(continues on next page)

(continued from previous page)

```

In [75]: df
Out[75]:
 row One_X One_Y Two_X Two_Y
0 0 1.1 1.2 1.11 1.22
1 1 1.1 1.2 1.11 1.22
2 2 1.1 1.2 1.11 1.22

As Labelled Index
In [76]: df = df.set_index('row')

In [77]: df
Out[77]:
 One_X One_Y Two_X Two_Y
row
0 1.1 1.2 1.11 1.22
1 1.1 1.2 1.11 1.22
2 1.1 1.2 1.11 1.22

With Hierarchical Columns
In [78]: df.columns = pd.MultiIndex.from_tuples([tuple(c.split('_'))
.....: for c in df.columns])
.....:

In [79]: df
Out[79]:
 One Two
 X Y X Y
row
0 1.1 1.2 1.11 1.22
1 1.1 1.2 1.11 1.22
2 1.1 1.2 1.11 1.22

Now stack & Reset
In [80]: df = df.stack(0).reset_index(1)

In [81]: df
Out[81]:
 level_1 X Y
row
0 One 1.10 1.20
0 Two 1.11 1.22
1 One 1.10 1.20
1 Two 1.11 1.22
2 One 1.10 1.20
2 Two 1.11 1.22

And fix the labels (Notice the label 'level_1' got added automatically)
In [82]: df.columns = ['Sample', 'All_X', 'All_Y']

In [83]: df
Out[83]:
 Sample All_X All_Y
row
0 One 1.10 1.20
0 Two 1.11 1.22
1 One 1.10 1.20
1 Two 1.11 1.22

```

(continues on next page)

(continued from previous page)

|   |     |      |      |
|---|-----|------|------|
| 2 | One | 1.10 | 1.20 |
| 2 | Two | 1.11 | 1.22 |

### 7.3.1 Arithmetic

Performing arithmetic with a MultiIndex that needs broadcasting

```
In [84]: cols = pd.MultiIndex.from_tuples([(x, y) for x in ['A', 'B', 'C']
.....: for y in ['O', 'I']])
.....:

In [85]: df = pd.DataFrame(np.random.randn(2, 6), index=['n', 'm'], columns=cols)

In [86]: df
Out[86]:
```

|   | A         |           | B         |          | C         |           |
|---|-----------|-----------|-----------|----------|-----------|-----------|
|   | O         | I         | O         | I        | O         | I         |
| n | -0.676913 | 0.322586  | -1.553378 | 0.910942 | -1.273340 | 3.100839  |
| m | -0.056376 | -0.229430 | 0.489194  | 0.683726 | 1.415411  | -0.493868 |

```
In [87]: df = df.div(df['C'], level=1)

In [88]: df
Out[88]:
```

|   | A         |          | B        |           | C   |     |
|---|-----------|----------|----------|-----------|-----|-----|
|   | O         | I        | O        | I         | O   | I   |
| n | 0.531604  | 0.104032 | 1.219924 | 0.293773  | 1.0 | 1.0 |
| m | -0.039830 | 0.464559 | 0.345620 | -1.384431 | 1.0 | 1.0 |

### 7.3.2 Slicing

Slicing a MultiIndex with xs

```
In [89]: coords = [('AA', 'one'), ('AA', 'six'), ('BB', 'one'), ('BB', 'two'),
.....: ('BB', 'six')]
.....:

In [90]: index = pd.MultiIndex.from_tuples(coords)

In [91]: df = pd.DataFrame([11, 22, 33, 44, 55], index, ['MyData'])

In [92]: df
Out[92]:
```

|    |     | MyData |
|----|-----|--------|
| AA | one | 11     |
|    | six | 22     |
| BB | one | 33     |
|    | two | 44     |
|    | six | 55     |

To take the cross section of the 1st level and 1st axis the index:

```
Note : level and axis are optional, and default to zero
In [93]: df.xs('BB', level=0, axis=0)
Out[93]:
 MyData
one 33
two 44
six 55
```

...and now the 2nd level of the 1st axis.

```
In [94]: df.xs('six', level=1, axis=0)
Out[94]:
 MyData
AA 22
BB 55
```

Slicing a MultiIndex with xs, method #2

```
In [95]: import itertools

In [96]: index = list(itertools.product(['Ada', 'Quinn', 'Violet'],
....: ['Comp', 'Math', 'Sci']))
....:

In [97]: headr = list(itertools.product(['Exams', 'Labs'], ['I', 'II']))

In [98]: indx = pd.MultiIndex.from_tuples(index, names=['Student', 'Course'])

In [99]: cols = pd.MultiIndex.from_tuples(headr) # Notice these are un-named

In [100]: data = [[70 + x + y + (x * y) % 3 for x in range(4)] for y in range(9)]

In [101]: df = pd.DataFrame(data, indx, cols)

In [102]: df
Out[102]:
 Student Course Exams Labs
 I II I II
Ada Comp 70 71 72 73

Name: A, dtype: int64
```

## 7.5.1 Expanding Data

Alignment and to-date

Rolling Computation window based on values instead of counts

Rolling Mean by Time Interval

## 7.5.2 Splitting

Splitting a frame

Create a list of dataframes, split using a delineation based on logic included in rows.

```
In [156]: df = pd.DataFrame(data={'Case': ['A', 'A', 'A', 'B', 'A', 'A', 'B', 'A',
.....: 'A'],
.....: 'Data': np.random.randn(9)})
.....:
```

```
In [157]: dfs = list(zip(*df.groupby((1 * (df['Case'] == 'B')).cumsum()
.....: .rolling(window=3, min_periods=1).median()))[-1]
.....:
```

```
In [158]: dfs[0]
```

```
Out[158]:
 Case Data
0 A 0.635872
1 A 0.620053
2 A -0.995187
3 B 1.342052
```

```
In [159]: dfs[1]
```

```
Out[159]:
 Case Data
4 A 0.291990
5 A 1.074981
6 B -0.575274
```

```
In [160]: dfs[2]
```

```
Out[160]:
 Case Data
7 A -0.748847
8 A 1.229731
```

## 7.5.3 Pivot

The *Pivot* docs.

Partial sums and subtotals

```

In [161]: df = pd.DataFrame(data={'Province': ['ON', 'QC', 'BC', 'AL', 'AL', 'MN', 'ON'],
↳ 'City': ['Toronto', 'Montreal', 'Vancouver',
 'Calgary', 'Edmonton', 'Winnipeg',
 'Windsor'],
 'Sales': [13, 6, 16, 8, 4, 3, 1]})

In [162]: table = pd.pivot_table(df, values=['Sales'], index=['Province'],
 columns=['City'], aggfunc=np.sum, margins=True)

In [163]: table.stack('City')
Out[163]:

```

| Province | City      | Sales |
|----------|-----------|-------|
| AL       | All       | 12.0  |
|          | Calgary   | 8.0   |
|          | Edmonton  | 4.0   |
| BC       | All       | 16.0  |
|          | Vancouver | 16.0  |
| MN       | All       | 3.0   |
|          | Winnipeg  | 3.0   |
| ON       | All       | 14.0  |
|          | Toronto   | 13.0  |
|          | Windsor   | 1.0   |
| QC       | All       | 6.0   |
|          | Montreal  | 6.0   |
| All      | All       | 51.0  |
|          | Calgary   | 8.0   |
|          | Edmonton  | 4.0   |
|          | Montreal  | 6.0   |
|          | Toronto   | 13.0  |
|          | Vancouver | 16.0  |
|          | Windsor   | 1.0   |
|          | Winnipeg  | 3.0   |

### Frequency table like plyr in R

```

In [164]: grades = [48, 99, 75, 80, 42, 80, 72, 68, 36, 78]

In [165]: df = pd.DataFrame({'ID': ["x%d" % r for r in range(10)],
 'Gender': ['F', 'M', 'F', 'M', 'F',
 'M', 'F', 'M', 'M', 'M'],
 'ExamYear': ['2007', '2007', '2007', '2008', '2008',
 '2008', '2008', '2009', '2009', '2009'],
 'Class': ['algebra', 'stats', 'bio', 'algebra',
 'algebra', 'stats', 'stats', 'algebra',
 'bio', 'bio'],
 'Participated': ['yes', 'yes', 'yes', 'yes', 'no',
 'yes', 'yes', 'yes', 'yes', 'yes'],
 'Passed': ['yes' if x > 50 else 'no' for x in grades],
 'Employed': [True, True, True, False,
 False, False, False, True, True, False],
 'Grade': grades})

```

(continues on next page)

(continued from previous page)

```
In [166]: df.groupby('ExamYear').agg({'Participated': lambda x: x.value_counts()['yes']
→ },
 : 'Passed': lambda x: sum(x == 'yes'),
 : 'Employed': lambda x: sum(x),
 : 'Grade': lambda x: sum(x) / len(x)})
Out[166]:
```

| ExamYear | Participated | Passed | Employed | Grade     |
|----------|--------------|--------|----------|-----------|
| 2007     | 3            | 2      | 3        | 74.000000 |
| 2008     | 3            | 3      | 0        | 68.500000 |
| 2009     | 3            | 2      | 2        | 60.666667 |

Plot pandas DataFrame with year over year data

To create year and month cross tabulation:

```
In [167]: df = pd.DataFrame({'value': np.random.randn(36)},
 : index=pd.date_range('2011-01-01', freq='M', periods=36))
 :

In [168]: pd.pivot_table(df, index=df.index.month, columns=df.index.year,
 : values='value', aggfunc='sum')
 :
Out[168]:
```

|    | 2011      | 2012      | 2013      |
|----|-----------|-----------|-----------|
| 1  | -0.548630 | 0.576933  | 0.395763  |
| 2  | 1.034493  | 0.491011  | -0.603712 |
| 3  | -1.267103 | 1.673652  | -1.162749 |
| 4  | -1.693973 | -0.665492 | -0.631144 |
| 5  | -1.310301 | 0.499177  | 0.827295  |
| 6  | 1.608492  | -0.402859 | -0.935274 |
| 7  | -0.620291 | -0.333160 | 0.107952  |
| 8  | 0.402265  | 0.801596  | -0.221593 |
| 9  | 1.804135  | -0.742853 | -0.990629 |
| 10 | -0.692932 | 0.066488  | 1.099052  |
| 11 | -0.528432 | 0.630015  | 0.383592  |
| 12 | -0.394221 | 1.563808  | 0.644267  |

## 7.5.4 Apply

Rolling Apply to Organize - Turning embedded lists into a MultiIndex frame

```
In [169]: df = pd.DataFrame(data={'A': [[2, 4, 8, 16], [100, 200], [10, 20, 30]],
 : 'B': [['a', 'b', 'c'], ['jj', 'kk'], ['ccc']]},
 : index=['I', 'II', 'III'])
 :

In [170]: def SeriesFromSubList(aList):
 : return pd.Series(aList)
 :

In [171]: df_orgz = pd.concat({ind: row.apply(SeriesFromSubList)
 : for ind, row in df.iterrows()})
 :
```

(continues on next page)

(continued from previous page)

```
In [172]: df_orgz
Out[172]:
```

|     |   | 0   | 1   | 2   | 3    |
|-----|---|-----|-----|-----|------|
| I   | A | 2   | 4   | 8   | 16.0 |
|     | B | a   | b   | c   | NaN  |
| II  | A | 100 | 200 | NaN | NaN  |
|     | B | jj  | kk  | NaN | NaN  |
| III | A | 10  | 20  | 30  | NaN  |
|     | B | ccc | NaN | NaN | NaN  |

### Rolling Apply with a DataFrame returning a Series

Rolling Apply to multiple columns where function calculates a Series before a Scalar from the Series is returned

```
In [173]: df = pd.DataFrame(data=np.random.randn(2000, 2) / 10000,
.....: index=pd.date_range('2001-01-01', periods=2000),
.....: columns=['A', 'B'])
.....:
```

```
In [174]: df
Out[174]:
```

|            | A         | B         |

## 7.6 Timeseries

Between times

Using indexer between time

Constructing a datetime range that excludes weekends and includes only certain times

Vectorized Lookup

Aggregation and plotting time series

Turn a matrix with hours in columns and days in rows into a continuous row sequence in the form of a time series.

How to rearrange a Python pandas DataFrame?

Dealing with duplicates when reindexing a timeseries to a specified frequency

Calculate the first day of the month for each entry in a DatetimeIndex

```
In [185]: dates = pd.date_range('2000-01-01', periods=5)

In [186]: dates.to_period(freq='M').to_timestamp()
Out[186]:
DatetimeIndex(['2000-01-01', '2000-01-01', '2000-01-01', '2000-01-01',
 '2000-01-01'],
 dtype='datetime64[ns]', freq=None)
```

## 7.6.1 Resampling

The *Resample* docs.

Using Grouper instead of TimeGrouper for time grouping of values

Time grouping with some missing values

Valid frequency arguments to Grouper

Grouping using a MultiIndex

Using TimeGrouper and another grouping to create subgroups, then apply a custom function

Resampling with custom periods

Resample intraday frame without adding new days

Resample minute data

Resample with groupby

## 7.7 Merge

The *Concat* docs. The *Join* docs.

Append two dataframes with overlapping index (emulate R rbind)

```
In [187]: rng = pd.date_range('2000-01-01', periods=6)

In [188]: df1 = pd.DataFrame(np.random.randn(6, 3), index=rng, columns=['A', 'B', 'C'
↳ ''])

In [189]: df2 = df1.copy()
```

Depending on df construction, ignore\_index may be needed

```
In [190]: df = df1.append(df2, ignore_index=True)

In [191]: df
Out[191]:
```

|    | A         | B         | C         |
|----|-----------|-----------|-----------|
| 0  | -0.237769 | -1.776384 | 1.566648  |

| 11 | 1.557202  | 0.604605  | 0.986813  |

Self Join of a DataFrame

```
In [192]: df = pd.DataFrame(data={'Area': ['A'] * 5 + ['C'] * 2,
.....: 'Bins': [110] * 2 + [160] * 3 + [40] * 2,
.....: 'Test_0': [0, 1, 0, 1, 2, 0, 1],
.....: 'Data': np.random.randn(7)})
.....:
```

```
In [193]: df
```

```
Out[193]:
```

|   | Area | Bins | Test_0 | Data      |
|---|------|------|--------|-----------|
| 0 | A    | 110  | 0      | -0.735630 |
| 1 | A    | 110  | 1      | 0.645093  |
| 2 | A    | 160  | 0      | -1.319750 |
| 3 | A    | 160  | 1      | -0.574086 |
| 4 | A    | 160  | 2      | 1.609964  |
| 5 | C    | 40   | 0      | 0.466171  |
| 6 | C    | 40   | 1      | -0.950616 |

```
In [194]: df['Test_1'] = df['Test_0'] - 1
```

```
In [195]: pd.merge(df, df, left_on=['Bins', 'Area', 'Test_0'],
.....: right_on=['Bins', 'Area', 'Test_1'],
.....: suffixes=('_L', '_R'))
.....:
```

```
Out[195]:
```

|   | Area | Bins | Test_0_L | Data_L    | Test_1_L | Test_0_R | Data_R    | Test_1_R |
|---|------|------|----------|-----------|----------|----------|-----------|----------|
| 0 | A    | 110  | 0        | -0.735630 | -1       | 1        | 0.645093  | 0        |
| 1 | A    | 160  | 0        | -1.319750 | -1       | 1        | -0.574086 | 0        |
| 2 | A    | 160  | 1        | -0.574086 | 0        | 2        | 1.609964  | 1        |
| 3 | C    | 40   | 0        | 0.466171  | -1       | 1        | -0.950616 | 0        |

How to set the index and join

KDB like asof join

Join with a criteria based on the values

Using searchsorted to merge based on values inside a range

## 7.8 Plotting

The *Plotting* docs.

Make Matplotlib look like R

Setting x-axis major and minor labels

Plotting multiple charts in an ipython notebook

Creating a multi-line plot

Plotting a heatmap

Annotate a time-series plot

Annotate a time-series plot #2

Generate Embedded plots in excel files using Pandas, Vincent and xlsxwriter

Boxplot for each quartile of a stratifying variable

```

In [196]: df = pd.DataFrame(
.....: {'stratifying_var': np.random.uniform(0, 100, 20),
.....: 'price': np.random.normal(100, 5, 20)})
.....:

In [197]: df['quartiles'] = pd.qcut(
.....: df['stratifying_var'],
.....: 4,
.....: labels=['0-25%', '25-50%', '50-75%', '75-100%'])
.....:

In [198]: df.boxplot(column='price', by='quartiles')
Out[198]: <matplotlib.axes._subplots.AxesSubplot at 0x7fd543b527b8>

```

## 7.9 Data In/Out

Performance comparison of SQL vs HDF5

### 7.9.1 CSV

The CSV docs

[read\\_csv in action](#)

[appending to a csv](#)

[Reading a csv chunk-by-chunk](#)

[Reading only certain rows of a csv chunk-by-chunk](#)

[Reading the first few lines of a frame](#)

[Reading a file that is compressed but not by gzip/bz2 \(the native compressed formats which read\\_csv understands\). This example shows a WinZipped file, but is a general application of opening the file within a context manager and using that handle to read. See here](#)

[Inferring dtypes from a file](#)

[Dealing with bad lines](#)

[Dealing with bad lines II](#)

[Reading CSV with Unix timestamps and converting to local timezone](#)

[Write a multi-row index CSV without writing duplicates](#)

### 7.9.1.1 Reading multiple files to create a single DataFrame

The best way to combine multiple files into a single DataFrame is to read the individual frames one by one, put all of the individual frames into a list, and then combine the frames in the list using `pd.concat()`:

```
In [199]: for i in range(3):
.....: data = pd.DataFrame(np.random.randn(10, 4))
.....: data.to_csv('file_{}.csv'.format(i))
.....:

In [200]: files = ['file_0.csv', 'file_1.csv', 'file_2.csv']

In [201]: result = pd.concat([pd.read_csv(f) for f in files], ignore_index=True)
```

You can use the same approach to read all files matching a pattern. Here is an example using `glob`:

```
In [202]: import glob

In [203]: import os

In [204]: files = glob.glob('file_*.csv')

In [205]: result = pd.concat([pd.read_csv(f) for f in files], ignore_index=True)
```

Finally, this strategy will work with the other `pd.read_*` (...) functions described in the *io docs*.

### 7.9.1.2 Parsing date components in multi-columns

Parsing date components in multi-columns is faster with a format

```
In [206]: i = pd.date_range('20000101', periods=10000)

In [207]: df = pd.DataFrame({'year': i.year, 'month': i.month, 'day': i.day})

In [208]: df.head()
```

(continues on next page)

(continued from previous page)

```

Out[208]:
 year month day
0 2000 1 1
1 2000 1 2
2 2000 1 3
3 2000 1 4
4 2000 1 5

In [209]: %timeit pd.to_datetime(df.year * 10000 + df.month * 100 + df.day, format='%Y
↪ %m%d')
.....: ds = df.apply(lambda x: "%04d%02d%02d" % (x['year'],
.....: x['month'], x['day']), axis=1)
.....: ds.head()
.....: %timeit pd.to_datetime(ds)
.....:
////////////////////////////////////
↪ 76 ms +- 526 us per loop (mean +- std. dev. of 7 runs, 100 loops each)
1.85 ms +- 128 us per loop (mean +- std. dev. of 7 runs, 1000 loops each)

```

### 7.9.1.3 Skip row between header and data

```

In [210]: data = """;;;
.....: ;;;;
.....: ;;;;
.....: ;;;;
.....: ;;;;
.....: ;;;;
.....: ;;;;
.....: ;;;;
.....: ;;;;
.....: date;Param1;Param2;Param4;Param5
.....: ;m²;°C;m²;m
.....: ;;;;
.....: 01.01.1990 00:00;1;1;2;3
.....: 01.01.1990 01:00;5;3;4;5
.....: 01.01.1990 02:00;9;5;6;7
.....: 01.01.1990 03:00;13;7;8;9
.....: 01.01.1990 04:00;17;9;10;11
.....: 01.01.1990 05:00;21;11;12;13
.....: """
.....:

```

#### Option 1: pass rows explicitly to skip rows

```

In [211]: from pandas.compat import StringIO

In [212]: pd.read_csv(StringIO(data), sep=';', skiprows=[11, 12],
.....: index_col=0, parse_dates=True, header=10)
.....:
Out[212]:
 Param1 Param2 Param4 Param5
date

```

(continues on next page)

(continued from previous page)

|                     |    |    |    |    |

## 7.9.2 SQL

The *SQL* docs

Reading from databases with SQL

## 7.9.3 Excel

The *Excel* docs

Reading from a filelike handle

Modifying formatting in XlsxWriter output

## 7.9.4 HTML

Reading HTML tables from a server that cannot handle the default request header

## 7.9.5 HDFStore

The *HDFStores* docs

Simple Queries with a Timestamp Index

Managing heterogeneous data using a linked multiple table hierarchy

Merging on-disk tables with millions of rows

Avoiding inconsistencies when writing to a store from multiple processes/threads

De-duplicating a large store by chunks, essentially a recursive reduction operation. Shows a function for taking in data from csv file and creating a store by chunks, with date parsing as well. [See here](#)

Creating a store chunk-by-chunk from a csv file

Appending to a store, while creating a unique index

Large Data work flows

Reading in a sequence of files, then providing a global unique index to a store while appending

Groupby on a HDFStore with low group density

Groupby on a HDFStore with high group density

Hierarchical queries on a HDFStore

Counting with a HDFStore

Troubleshoot HDFStore exceptions

Setting min\_itemsize with strings

Using ptrepack to create a completely-sorted-index on a store

Storing Attributes to a group node

```
In [216]: df = pd.DataFrame(np.random.randn(8, 3))

In [217]: store = pd.HDFStore('test.h5')

In [218]: store.put('df', df)

you can store an arbitrary Python object via pickle
In [219]: store.get_storer('df').attrs.my_attribute = {'A': 10}

In [220]: store.get_storer('df').attrs.my_attribute
Out[220]: {'A': 10}
```

## 7.9.6 Binary Files

pandas readily accepts NumPy record arrays, if you need to read in a binary file consisting of an array of C structs. For example, given this C program in a file called `main.c` compiled with `gcc main.c -std=gnu99` on a 64-bit machine,

```
#include <stdio.h>
#include <stdint.h>

typedef struct _Data
{
 int32_t count;
 double avg;
 float scale;
} Data;
```

(continues on next page)

(continued from previous page)

```
int main(int argc, const char *argv[])
{
 size_t n = 10;
 Data d[n];

 for (int i = 0; i < n; ++i)
 {
 d[i].count = i;
 d[i].avg = i + 1.0;
 d[i].scale = (float) i + 2.0f;
 }

 FILE *file = fopen("binary.dat", "wb");
 fwrite(&d, sizeof(Data), n, file);
 fclose(file);

 return 0;
}
```

the following Python code will read the binary file 'binary.dat' into a pandas DataFrame, where each element of the struct corresponds to a column in the frame:

```
names = 'count', 'avg', 'scale'

note that the offsets are larger than the size of the type because of
struct padding
offsets = 0, 8, 16
formats = 'i4', 'f8', 'f4'
dt = np.dtype({'names': names, 'offsets': offsets, 'formats': formats},
 align=True)
df = pd.DataFrame(np.fromfile('binary.dat', dt))
```

---

**Note:** The offsets of the structure elements may be different depending on the architecture of the machine on which the file was created. Using a raw binary file format like this for general data storage is not recommended, as it is not cross platform. We recommended either HDF5 or msgpack, both of which are supported by pandas' IO facilities.

---

## 7.10 Computation

Numerical integration (sample-based) of a time series

### 7.10.1 Correlation

Often it's useful to obtain the lower (or upper) triangular form of a correlation matrix calculated from DataFrame. `corr()`. This can be achieved by passing a boolean mask to `where` as follows:

```
In [221]: df = pd.DataFrame(np.random.random(size=(100, 5)))

In [222]: corr_mat = df.corr()

In [223]: mask = np.tril(np.ones_like(corr_mat, dtype=np.bool), k=-1)
```

(continues on next page)

(continued from previous page)

```
In [224]: corr_mat.where(mask)
Out[224]:
```

|   | 0         | 1         | 2         | 3         | 4   |
|---|-----------|-----------|-----------|-----------|-----|
| 0 | NaN       | NaN       | NaN       | NaN       | NaN |
| 1 | 0.046222  | NaN       | NaN       | NaN       | NaN |
| 2 | -0.052946 | 0.014748  | NaN       | NaN       | NaN |
| 3 | -0.112059 | 0.019629  | -0.060651 | NaN       | NaN |
| 4 | -0.079281 | -0.035202 | 0.089603  | -0.158894 | NaN |

The *method* argument within *DataFrame.corr* can accept a callable in addition to the named correlation types. Here we compute the **distance correlation** matrix for a *DataFrame* object.

```
In [225]: def distcorr(x, y):
.....: n = len(x)
.....: a = np.zeros(shape=(n, n))
.....: b = np.zeros(shape=(n, n))
.....:

In [226]: df = pd.DataFrame(np.random.normal(size=(100, 3)))

In [227]: df.corr(method=distcorr)
Out[227]:
```

|   | 0   | 1   | 2   |
|---|-----|-----|-----|
| 0 | 1.0 | NaN | NaN |
| 1 | NaN | 1.0 | NaN |
| 2 | NaN | NaN | 1.0 |

## 7.11 Timedeltas

The *Timedeltas* docs.

Using *timedeltas*

```
In [228]: import datetime

In [229]: s = pd.Series(pd.date_range('2012-1-1', periods=3, freq='D'))

In [230]: s - s.max()
Out[230]:
```

|   |         |
|---|---------|
| 0 | -2 days |
| 1 | -1 days |
| 2 | 0 days  |

```
dtype: timedelta64[ns]

In [231]: s.max() - s
Out[231]:
```

|   |        |
|---|--------|
| 0 | 2 days |
| 1 | 1 days |
| 2 | 0 days |

```
dtype: timedelta64[ns]

In [232]: s - datetime.datetime(2011, 1, 1, 3, 5)
```

(continues on next page)

(continued from previous page)

```

0 364 days 20:55:00
1 365 days 20:55:00
2 366 days 20:55:00
dtype: timedelta64[ns]

```

```
In [233]: s + datetime.timedelta(minutes=5)
```

```

////////////////////////////////////
↪
0 2012-01-01 00:05:00
1 2012-01-02 00:05:00
2 2012-01-03 00:05:00
dtype: datetime64[ns]

```

```
In [234]: datetime.datetime(2011, 1, 1, 3, 5) - s
```

```

////////////////////////////////////
↪
0 -365 days +03:05:00
1 -366 days +03:05:00
2 -367 days +03:05:00
dtype: timedelta64[ns]

```

```
In [235]: datetime.timedelta(minutes=5) + s
```

```

////////////////////////////////////
↪
0 2012-01-01 00:05:00
1 2012-01-02 00:05:00
2 2012-01-03 00:05:00
dtype: datetime64[ns]

```

### Adding and subtracting deltas and dates

```
In [236]: deltas = pd.Series([datetime.timedelta(days=i) for i in range(3)])
```

```
In [237]: df = pd.DataFrame({'A': s, 'B': deltas})
```

```
In [238]: df
```

```

Out[238]:
 A B
0 2012-01-01 0 days
1 2012-01-02 1 days
2 2012-01-03 2 days

```

```
In [239]: df['New Dates'] = df['A'] + df['B']
```

```
In [240]: df['Delta'] = df['A'] - df['New Dates']
```

```
In [241]: df
```

```

Out[241]:
 A B New Dates Delta
0 2012-01-01 0 days 2012-01-01 0 days
1 2012-01-02 1 days 2012-01-03 -1 days
2 2012-01-03 2 days 2012-01-05 -2 days

```

```
In [242]: df.dtypes
```

```

////////////////////////////////////
↪
A datetime64[ns]

```

(continues on next page)

(continued from previous page)

```

B timedelta64[ns]
New Dates datetime64[ns]
Delta timedelta64[ns]
dtype: object

```

### Another example

Values can be set to NaT using np.nan, similar to datetime

```
In [243]: y = s - s.shift()
```

```
In [244]: y
```

```

Out[244]:
0 NaT
1 1 days
2 1 days
dtype: timedelta64[ns]

```

```
In [245]: y[1] = np.nan
```

```
In [246]: y
```

```

Out[246]:
0 NaT
1 NaT
2 1 days
dtype: timedelta64[ns]

```

## 7.12 Aliasing Axis Names

To globally provide aliases for axis names, one can define these 2 functions:

```

In [247]: def set_axis_alias(cls, axis, alias):
.....: if axis not in cls._AXIS_NUMBERS:
.....: raise Exception("invalid axis [%s] for alias [%s]" % (axis, alias))
.....: cls._AXIS_ALIASES[alias] = axis
.....:

```

```

In [248]: def clear_axis_alias(cls, axis, alias):
.....: if axis not in cls._AXIS_NUMBERS:
.....: raise Exception("invalid axis [%s] for alias [%s]" % (axis, alias))
.....: cls._AXIS_ALIASES.pop(alias, None)
.....:

```

```
In [249]: set_axis_alias(pd.DataFrame, 'columns', 'myaxis2')
```

```

In [250]: df2 = pd.DataFrame(np.random.randn(3, 2), columns=['c1', 'c2'],
.....: index=['i1', 'i2', 'i3'])
.....:

```

```
In [251]: df2.sum(axis='myaxis2')
```

```

Out[251]:
i1 1.239307
i2 2.336216
i3 1.221345

```

(continues on next page)

(continued from previous page)

dtype: float64

In [252]: clear\_axis\_alias(pd.DataFrame, 'columns', 'myaxis2')

## 7.13 Creating Example Data

To create a dataframe from every combination of some given values, like R's `expand.grid()` function, we can create a dict where the keys are column names and the values are lists of the data values:

```
In [253]: def expand_grid(data_dict):
.....: rows = itertools.product(*data_dict.values())
.....: return pd.DataFrame.from_records(rows, columns=data_dict.keys())
.....:
```

```
In [254]: df = expand_grid({'height': [60, 70],
.....: 'weight': [100, 140, 180],
.....: 'sex': ['Male', 'Female']})
.....:
```

In [255]: df

Out[255]:

|    | height | weight | sex    |
|----|--------|--------|--------|
| 0  | 60     | 100    | Male   |
| 1  | 60     | 100    | Female |
| 2  | 60     | 140    | Male   |
| 3  | 60     | 140    | Female |
| 4  | 60     | 180    | Male   |
| 5  | 60     | 180    | Female |
| 6  | 70     | 100    | Male   |
| 7  | 70     | 100    | Female |
| 8  | 70     | 140    | Male   |
| 9  | 70     | 140    | Female |
| 10 | 70     | 180    | Male   |
| 11 | 70     | 180    | Female |

```
{{ header }}
```

## INTRO TO DATA STRUCTURES

We'll start with a quick, non-comprehensive overview of the fundamental data structures in pandas to get you started. The fundamental behavior about data types, indexing, and axis labeling / alignment apply across all of the objects. To get started, import NumPy and load pandas into your namespace:

```
In [1]: import numpy as np
In [2]: import pandas as pd
```

Here is a basic tenet to keep in mind: **data alignment is intrinsic**. The link between labels and data will not be broken unless done so explicitly by you.

We'll give a brief intro to the data structures, then consider all of the broad categories of functionality and methods in separate sections.

### 8.1 Series

`Series` is a one-dimensional labeled array capable of holding any data type (integers, strings, floating point numbers, Python objects, etc.). The axis labels are collectively referred to as the **index**. The basic method to create a `Series` is to call:

```
>>> s = pd.Series(data, index=index)
```

Here, `data` can be many different things:

- a Python dict
- an ndarray
- a scalar value (like 5)

The passed **index** is a list of axis labels. Thus, this separates into a few cases depending on what **data** is:

#### From ndarray

If `data` is an ndarray, **index** must be the same length as **data**. If no index is passed, one will be created having values `[0, ..., len(data) - 1]`.

```
In [3]: s = pd.Series(np.random.randn(5), index=['a', 'b', 'c', 'd', 'e'])
In [4]: s
Out[4]:
a 0.765116
b 0.410441
```

(continues on next page)

(continued from previous page)

```
c -0.184293
d -1.393422
e 0.671350
dtype: float64

In [5]: s.index
Out[5]:
Index(['a', 'b', 'c', 'd', 'e'], dtype='object')

In [6]: pd.Series(np.random.randn(5))
Out[6]:
0 0.353311
1 -0.052757
2 -0.616776
3 -1.626474
4 -0.316058
dtype: float64
```

---

**Note:** pandas supports non-unique index values. If an operation that does not support duplicate index values is attempted, an exception will be raised at that time. The reason for being lazy is nearly all performance-based (there are many instances in computations, like parts of GroupBy, where the index is not used).

---

### From dict

Series can be instantiated from dicts:

```
In [7]: d = {'b': 1, 'a': 0, 'c': 2}

In [8]: pd.Series(d)
Out[8]:
b 1
a 0
c 2
dtype: int64
```

---

**Note:** When the data is a dict, and an index is not passed, the `Series` index will be ordered by the dict's insertion order, if you're using Python version `>= 3.6` and Pandas version `>= 0.23`.

If you're using Python `< 3.6` or Pandas `< 0.23`, and an index is not passed, the `Series` index will be the lexically ordered list of dict keys.

---

In the example above, if you were on a Python version lower than 3.6 or a Pandas version lower than 0.23, the `Series` would be ordered by the lexical order of the dict keys (i.e. `['a', 'b', 'c']` rather than `['b', 'a', 'c']`).

If an index is passed, the values in data corresponding to the labels in the index will be pulled out.

```
In [9]: d = {'a': 0., 'b': 1., 'c': 2.}

In [10]: pd.Series(d)
Out[10]:
a 0.0
b 1.0
c 2.0
```

(continues on next page)

(continued from previous page)

```
dtype: float64

In [11]: pd.Series(d, index=['b', 'c', 'd', 'a'])
Out[11]:
b 1.0
c 2.0
d NaN
a 0.0
dtype: float64
```

**Note:** NaN (not a number) is the standard missing data marker used in pandas.

### From scalar value

If data is a scalar value, an index must be provided. The value will be repeated to match the length of **index**.

```
In [12]: pd.Series(5., index=['a', 'b', 'c', 'd', 'e'])
Out[12]:
a 5.0
b 5.0
c 5.0
d 5.0
e 5.0
dtype: float64
```

## 8.1.1 Series is ndarray-like

Series acts very similarly to a ndarray, and is a valid argument to most NumPy functions. However, operations such as slicing will also slice the index.

```
In [13]: s[0]
Out[13]: 0.76511565689164229

In [14]: s[:3]
Out[14]:
a 0.765116
b 0.410441
c -0.184293
dtype: float64

In [15]: s[s > s.median()]
Out[15]:
a 0.765116
e 0.671350
dtype: float64

In [16]: s[[4, 3, 1]]
Out[16]:
e 0.671350
d -1.393422
b 0.410441
```

(continues on next page)

(continued from previous page)

dtype: float64

**In [17]:** np.exp(s)

```

////////////////////////////////////
↪
a 2.149243
b 1.507482
c 0.831692
d 0.248224
e 1.956878
dtype: float64

```

**Note:** We will address array-based indexing like `s[[4, 3, 1]]` in *section*.

Like a NumPy array, a pandas Series has a `dtype`.

**In [18]:** s.dtype**Out [18]:** dtype('float64')

This is often a NumPy dtype. However, pandas and 3rd-party libraries extend NumPy's type system in a few places, in which case the dtype would be a *ExtensionDtype*. Some examples within pandas are categorical and *Nullable Integer Data Type*. See *dtypes* for more.

If you need the actual array backing a Series, use `Series.array`.

**In [19]:** s.array**Out [19]:**

&lt;PandasArray&gt;

```

[0.76511565689164229, 0.41044095243831324, -0.18429339509462103,
 -1.3934218140257773, 0.67135022495983199]

```

Length: 5, dtype: float64

Accessing the array can be useful when you need to do some operation without the index (to disable *automatic alignment*, for example).

`Series.array` will always be an *ExtensionArray*. Briefly, an *ExtensionArray* is a thin wrapper around one or more *concrete* arrays like a `numpy.ndarray`. Pandas knows how to take an *ExtensionArray* and store it in a Series or a column of a DataFrame. See *dtypes* for more.

While Series is ndarray-like, if you need an *actual* ndarray, then use `Series.to_numpy()`.

**In [20]:** s.to\_numpy()**Out [20]:** array([ 0.76511566, 0.41044095, -0.1842934 , -1.39342181, 0.67135022])

Even if the Series is backed by a *ExtensionArray*, `Series.to_numpy()` will return a NumPy ndarray.

## 8.1.2 Series is dict-like

A Series is like a fixed-size dict in that you can get and set values by index label:

**In [21]:** s['a']**Out [21]:** 0.76511565689164229**In [22]:** s['e'] = 12.

(continues on next page)

(continued from previous page)

```
In [23]: s
Out[23]:
a 0.765116
b 0.410441
c -0.184293
d -1.393422
e 12.000000
dtype: float64
```

```
In [24]: 'e' in s
///
↪ True
```

```
In [25]: 'f' in s
///
↪ False
```

If a label is not contained, an exception is raised:

```
>>> s['f']
KeyError: 'f'
```

Using the `get` method, a missing label will return `None` or specified default:

```
In [26]: s.get('f')

In [27]: s.get('f', np.nan)
Out[27]: nan
```

See also the *section on attribute access*.

### 8.1.3 Vectorized operations and label alignment with Series

When working with raw NumPy arrays, looping through value-by-value is usually not necessary. The same is true when working with Series in pandas. Series can also be passed into most NumPy methods expecting an ndarray.

```
In [28]: s + s
Out[28]:
a 1.530231
b 0.820882
c -0.368587
d -2.786844
e 24.000000
dtype: float64
```

```
In [29]: s * 2
///
↪
a 1.530231
b 0.820882
c -0.368587
d -2.786844
e 24.000000
dtype: float64
```

(continues on next page)

(continued from previous page)

```
In [30]: np.exp(s)
////////////////////////////////////
↪
a 2.149243
b 1.507482
c 0.831692
d 0.248224
e 162754.791419
dtype: float64
```

A key difference between Series and ndarray is that operations between Series automatically align the data based on label. Thus, you can write computations without giving consideration to whether the Series involved have the same labels.

```
In [31]: s[1:] + s[:-1]
Out[31]:
a NaN
b 0.820882
c -0.368587
d -2.786844
e NaN
dtype: float64
```

The result of an operation between unaligned Series will have the **union** of the indexes involved. If a label is not found in one Series or the other, the result will be marked as missing NaN. Being able to write code without doing any explicit data alignment grants immense freedom and flexibility in interactive data analysis and research. The integrated data alignment features of the pandas data structures set pandas apart from the majority of related tools for working with labeled data.

---

**Note:** In general, we chose to make the default result of operations between differently indexed objects yield the **union** of the indexes in order to avoid loss of information. Having an index label, though the data is missing, is typically important information as part of a computation. You of course have the option of dropping labels with missing data via the **dropna** function.

---

### 8.1.4 Name attribute

Series can also have a name attribute:

```
In [32]: s = pd.Series(np.random.randn(5), name='something')

In [33]: s
Out[33]:
0 -0.607083
1 1.004634
2 -0.172343
3 -0.252154
4 -0.457967
Name: something, dtype: float64

In [34]: s.name
////////////////////////////////////
↪ 'something'
```

The Series `name` will be assigned automatically in many cases, in particular when taking 1D slices of DataFrame as you will see below.

New in version 0.18.0.

You can rename a Series with the `pandas.Series.rename()` method.

```
In [35]: s2 = s.rename("different")

In [36]: s2.name
Out[36]: 'different'
```

Note that `s` and `s2` refer to different objects.

## 8.2 DataFrame

**DataFrame** is a 2-dimensional labeled data structure with columns of potentially different types. You can think of it like a spreadsheet or SQL table, or a dict of Series objects. It is generally the most commonly used pandas object. Like Series, DataFrame accepts many different kinds of input:

- Dict of 1D ndarrays, lists, dicts, or Series
- 2-D numpy.ndarray
- Structured or record ndarray
- A Series
- Another DataFrame

Along with the data, you can optionally pass **index** (row labels) and **columns** (column labels) arguments. If you pass an index and / or columns, you are guaranteeing the index and / or columns of the resulting DataFrame. Thus, a dict of Series plus a specific index will discard all data not matching up to the passed index.

If axis labels are not passed, they will be constructed from the input data based on common sense rules.

---

**Note:** When the data is a dict, and `columns` is not specified, the DataFrame columns will be ordered by the dict's insertion order, if you are using Python version `>= 3.6` and Pandas `>= 0.23`.

If you are using Python `< 3.6` or Pandas `< 0.23`, and `columns` is not specified, the DataFrame columns will be the lexically ordered list of dict keys.

---

### 8.2.1 From dict of Series or dicts

The resulting **index** will be the **union** of the indexes of the various Series. If there are any nested dicts, these will first be converted to Series. If no columns are passed, the columns will be the ordered list of dict keys.

```
In [37]: d = {'one': pd.Series([1., 2., 3.], index=['a', 'b', 'c']),
....: 'two': pd.Series([1., 2., 3., 4.], index=['a', 'b', 'c', 'd'])}
....:

In [38]: df = pd.DataFrame(d)

In [39]: df
Out[39]:
 one two
```

(continues on next page)

(continued from previous page)

```

a 1.0 1.0
b 2.0 2.0
c 3.0 3.0
d NaN 4.0

In [40]: pd.DataFrame(d, index=['d', 'b', 'a'])
\\Out [40]:
 one two
d NaN 4.0
b 2.0 2.0
a 1.0 1.0

In [41]: pd.DataFrame(d, index=['d', 'b', 'a'], columns=['two', 'three'])
\\Out [41]:
 two three
d 4.0 NaN
b 2.0 NaN
a 1.0 NaN

```

The row and column labels can be accessed respectively by accessing the **index** and **columns** attributes:

**Note:** When a particular set of columns is passed along with a dict of data, the passed columns override the keys in the dict.

```

In [42]: df.index
Out [42]: Index(['a', 'b', 'c', 'd'], dtype='object')

In [43]: df.columns
\\Out [43]: Index(['one', 'two'], dtype='object')

```

## 8.2.2 From dict of ndarrays / lists

The ndarrays must all be the same length. If an index is passed, it must clearly also be the same length as the arrays. If no index is passed, the result will be `range(n)`, where `n` is the array length.

```

In [44]: d = {'one': [1., 2., 3., 4.],
....: 'two': [4., 3., 2., 1.]}
....:

In [45]: pd.DataFrame(d)
Out [45]:
 one two
0 1.0 4.0
1 2.0 3.0
2 3.0 2.0
3 4.0 1.0

In [46]: pd.DataFrame(d, index=['a', 'b', 'c', 'd'])
\\Out [46]:
 one two
a 1.0 4.0

```

(continues on next page)

(continued from previous page)

```
b 2.0 3.0
c 3.0 2.0
d 4.0 1.0
```

### 8.2.3 From structured or record array

This case is handled identically to a dict of arrays.

```
In [47]: data = np.zeros((2,), dtype=[('A', 'i4'), ('B', 'f4'), ('C', 'a10')])

In [48]: data[:] = [(1, 2., 'Hello'), (2, 3., "World")]

In [49]: pd.DataFrame(data)
Out[49]:
 A B C
0 1 2.0 b'Hello'
1 2 3.0 b'World'

In [50]: pd.DataFrame(data, index=['first', 'second'])
Out[50]:
 A B C
first 1 2.0 b'Hello'
second 2 3.0 b'World'

In [51]: pd.DataFrame(data, columns=['C', 'A', 'B'])
Out[51]:
 C A B
0 b'Hello' 1 2.0
1 b'World' 2 3.0
```

**Note:** DataFrame is not intended to work exactly like a 2-dimensional NumPy ndarray.

### 8.2.4 From a list of dicts

```
In [52]: data2 = [{'a': 1, 'b': 2}, {'a': 5, 'b': 10, 'c': 20}]

In [53]: pd.DataFrame(data2)
Out[53]:
 a b c
0 1 2 NaN
1 5 10 20.0

In [54]: pd.DataFrame(data2, index=['first', 'second'])
Out[54]:
 a b c
first 1 2 NaN
second 5 10 20.0

In [55]: pd.DataFrame(data2, columns=['a', 'b'])
Out[55]:
 a b
0 1 2
1 5 10
```

(continues on next page)

(continued from previous page)

```

 a b
0 1 2
1 5 10

```

## 8.2.5 From a dict of tuples

You can automatically create a MultiIndexed frame by passing a tuples dictionary.

```

In [56]: pd.DataFrame({('a', 'b'): {('A', 'B'): 1, ('A', 'C'): 2},
.....: ('a', 'a'): {('A', 'C'): 3, ('A', 'B'): 4},
.....: ('a', 'c'): {('A', 'B'): 5, ('A', 'C'): 6},
.....: ('b', 'a'): {('A', 'C'): 7, ('A', 'B'): 8},
.....: ('b', 'b'): {('A', 'D'): 9, ('A', 'B'): 10}})
Out [56]:
 a b
A B 1.0 4.0 5.0 8.0 10.0
C 2.0 3.0 6.0 7.0 NaN
D NaN NaN NaN NaN 9.0

```

## 8.2.6 From a Series

The result will be a DataFrame with the same index as the input Series, and with one column whose name is the original name of the Series (only if no other column name provided).

### Missing Data

Much more will be said on this topic in the *Missing data* section. To construct a DataFrame with missing data, we use `np.nan` to represent missing values. Alternatively, you may pass a `numpy.MaskedArray` as the data argument to the DataFrame constructor, and its masked entries will be considered missing.

## 8.2.7 Alternate Constructors

### DataFrame.from\_dict

`DataFrame.from_dict` takes a dict of dicts or a dict of array-like sequences and returns a DataFrame. It operates like the DataFrame constructor except for the `orient` parameter which is 'columns' by default, but which can be set to 'index' in order to use the dict keys as row labels.

```

In [57]: pd.DataFrame.from_dict(dict([('A', [1, 2, 3]), ('B', [4, 5, 6])]))
Out [57]:
 A B
0 1 4
1 2 5
2 3 6

```

If you pass `orient='index'`, the keys will be the row labels. In this case, you can also pass the desired column names:

```

In [58]: pd.DataFrame.from_dict(dict([('A', [1, 2, 3]), ('B', [4, 5, 6])]),
.....: orient='index', columns=['one', 'two', 'three'])

```

(continues on next page)

(continued from previous page)

```
.....:
Out [58]:
 one two three
A 1 2 3
B 4 5 6
```

### DataFrame.from\_records

`DataFrame.from_records` takes a list of tuples or an ndarray with structured dtype. It works analogously to the normal `DataFrame` constructor, except that the resulting `DataFrame` index may be a specific field of the structured dtype. For example:

```
In [59]: data
Out [59]:
array([(1, 2., b'Hello'), (2, 3., b'World')],
 dtype=[('A', '<i4'), ('B', '<f4'), ('C', 'S10')])

In [60]: pd.DataFrame.from_records(data, index='C')
//////////
↪
 A B
C
b'Hello' 1 2.0
b'World' 2 3.0
```

## 8.2.8 Column selection, addition, deletion

You can treat a `DataFrame` semantically like a dict of like-indexed `Series` objects. Getting, setting, and deleting columns works with the same syntax as the analogous dict operations:

```
In [61]: df['one']
Out [61]:
a 1.0
b 2.0
c 3.0
d NaN
Name: one, dtype: float64

In [62]: df['three'] = df['one'] * df['two']

In [63]: df['flag'] = df['one'] > 2

In [64]: df
Out [64]:
 one two three flag
a 1.0 1.0 1.0 False
b 2.0 2.0 4.0 False
c 3.0 3.0 9.0 True
d NaN 4.0 NaN False
```

Columns can be deleted or popped like with a dict:

```
In [65]: del df['two']

In [66]: three = df.pop('three')
```

(continues on next page)

(continued from previous page)

```
In [67]: df
Out[67]:
```

|   | one | flag  |
|---|-----|-------|
| a | 1.0 | False |
| b | 2.0 | False |
| c | 3.0 | True  |
| d | NaN | False |

When inserting a scalar value, it will naturally be propagated to fill the column:

```
In [68]: df['foo'] = 'bar'

In [69]: df
Out[69]:
```

|   | one | flag  | foo |
|---|-----|-------|-----|
| a | 1.0 | False | bar |
| b | 2.0 | False | bar |
| c | 3.0 | True  | bar |
| d | NaN | False | bar |

When inserting a Series that does not have the same index as the DataFrame, it will be conformed to the DataFrame's index:

```
In [70]: df['one_trunc'] = df['one'][:2]

In [71]: df
Out[71]:
```

|   | one | flag  | foo | one_trunc |
|---|-----|-------|-----|-----------|
| a | 1.0 | False | bar | 1.0       |
| b | 2.0 | False | bar | 2.0       |
| c | 3.0 | True  | bar | NaN       |
| d | NaN | False | bar | NaN       |

You can insert raw ndarrays but their length must match the length of the DataFrame's index.

By default, columns get inserted at the end. The `insert` function is available to insert at a particular location in the columns:

```
In [72]: df.insert(1, 'bar', df['one'])

In [73]: df
Out[73]:
```

|   | one | bar | flag  | foo | one_trunc |
|---|-----|-----|-------|-----|-----------|
| a | 1.0 | 1.0 | False | bar | 1.0       |
| b | 2.0 | 2.0 | False | bar | 2.0       |
| c | 3.0 | 3.0 | True  | bar | NaN       |
| d | NaN | NaN | False | bar | NaN       |

## 8.2.9 Assigning New Columns in Method Chains

Inspired by `dplyr`'s `mutate` verb, DataFrame has an `assign()` method that allows you to easily create new columns that are potentially derived from existing columns.

```
In [76]: (iris.assign(sepal_ratio=iris['SepalWidth'] / iris['SepalLength'])
.....: .head())
.....:
```

In the example above, we inserted a precomputed value. We can also pass in a function of one argument to be evaluated on the DataFrame being assigned to.

`assign` **always** returns a copy of the data, leaving the original DataFrame untouched.

## 8.2. DataFrame

Since a function is passed in, the function is computed on the DataFrame being assigned to. Importantly, this is the DataFrame that's been filtered to those rows with sepal length greater than 5. The filtering happens first, and then the ratio calculations. This is an example where we didn't have a reference to the *filtered* DataFrame available.

The function signature for `assign` is simply `**kwargs`. The keys are the column names for the new fields, and the values are either a value to be inserted (for example, a `Series` or NumPy array), or a function of one argument to be called on the DataFrame. A *copy* of the original DataFrame is returned, with the new values inserted.

Changed in version 0.23.0.

Starting with Python 3.6 the order of `**kwargs` is preserved. This allows for *dependent* assignment, where an expression later in `**kwargs` can refer to a column created earlier in the same `assign()`.

```
In [79]: dfa = pd.DataFrame({"A": [1, 2, 3],
.....: "B": [4, 5, 6]})
.....:

In [80]: dfa.assign(C=lambda x: x['A'] + x['B'],
.....: D=lambda x: x['A'] + x['C'])
.....:

Out[80]:
 A B C D
0 1 4 5 6
1 2 5 7 9
2 3 6 9 12
```

In the second expression, `x['C']` will refer to the newly created column, that's equal to `dfa['A'] + dfa['B']`. To write code compatible with all versions of Python, split the assignment in two.

```
In [81]: dependent = pd.DataFrame({"A": [1, 1, 1]})

In [82]: (dependent.assign(A=lambda x: x['A'] + 1)
.....: .assign(B=lambda x: x['A'] + 2))
.....:
Out[82]:
 A B
0 2 4
1 2 4
2 2 4
```

**Warning:** Dependent assignment may subtly change the behavior of your code between Python 3.6 and older versions of Python.

If you wish write code that supports versions of python before and after 3.6, you'll need to take care when passing `assign` expressions that

- Updating an existing column
- Referring to the newly updated column in the same `assign`

For example, we'll update column "A" and then refer to it when creating "B".

```
>>> dependent = pd.DataFrame({"A": [1, 1, 1]})
>>> dependent.assign(A=lambda x: x["A"] + 1, B=lambda x: x["A"] + 2)
```

For Python 3.5 and earlier the expression creating B refers to the "old" value of A, `[1, 1, 1]`. The output is then

```
 A B
0 2 3
1 2 3
2 2 3
```

For Python 3.6 and later, the expression creating A refers to the "new" value of A, `[2, 2, 2]`, which results in

```
 A B
0 2 4
1 2 4
2 2 4
```

## 8.2.10 Indexing / Selection

The basics of indexing are as follows:

| Operation                      | Syntax                     | Result    |
|--------------------------------|----------------------------|-----------|
| Select column                  | <code>df[col]</code>       | Series    |
| Select row by label            | <code>df.loc[label]</code> | Series    |
| Select row by integer location | <code>df.iloc[loc]</code>  | Series    |
| Slice rows                     | <code>df[5:10]</code>      | DataFrame |
| Select rows by boolean vector  | <code>df[bool_vec]</code>  | DataFrame |

Row selection, for example, returns a Series whose index is the columns of the DataFrame:

```
In [83]: df.loc['b']
Out[83]:
one 2
bar 2
flag False
foo bar
one_trunc 2
Name: b, dtype: object
```

```
In [84]: df.iloc[2]
\
↩
one 3
bar 3
flag True
foo bar
one_trunc NaN
Name: c, dtype: object
```

For a more exhaustive treatment of sophisticated label-based indexing and slicing, see the *section on indexing*. We will address the fundamentals of reindexing / conforming to new sets of labels in the *section on reindexing*.

### 8.2.11 Data alignment and arithmetic

Data alignment between DataFrame objects automatically align on **both the columns and the index (row labels)**. Again, the resulting object will have the union of the column and row labels.

```
In [85]: df = pd.DataFrame(np.random.randn(10, 4), columns=['A', 'B', 'C', 'D'])
```

```
In [86]: df2 = pd.DataFrame(np.random.randn(7, 3), columns=['A', 'B', 'C'])
```

```
In [87]: df + df2
```

| Out [87] : |          |           |           |     |

| 9          | NaN      | NaN       | NaN       | NaN |

When doing an operation between DataFrame and Series, the default behavior is to align the Series **index** on the DataFrame **columns**, thus **broadcasting** row-wise. For example:

```
In [88]: df = df.iloc[0]
```

```
Out [88]:
```

|   | A         | B         | C         | D         |
|---|-----------|-----------|-----------|-----------|
| 0 | 0.000000  | 0.000000  | 0.000000  | 0.000000  |
| 1 | -0.418136 | 0.674496  | 1.339114  | 1.634480  |
| 2 | 3.003980  | 0.892402  | 1.546205  | -1.636468 |
| 3 | 0.581764  | 0.527941  | 0.010684  | -0.132101 |
| 4 | 2.290742  | -1.933553 | -0.216607 | -3.166128 |

(continues on next page)

(continued from previous page)

```

5 1.492714 -0.105121 -0.243634 -0.607707
6 0.625929 -1.701078 0.135110 -1.900465
7 -0.889407 -0.642306 0.575483 0.275011
8 1.084532 -1.179302 1.403337 -1.351607
9 1.400648 -0.269190 -1.119769 -0.382542

```

In the special case of working with time series data, and the DataFrame index also contains dates, the broadcasting will be column-wise:

```
In [89]: index = pd.date_range('1/1/2000', periods=8)
```

```
In [90]: df = pd.DataFrame(np.random.randn(8, 3), index=index, columns=list('ABC'))
```

```
In [91]: df
```

```
Out [91]:
```

```

**Warning:**

```
df - df['A']
```

is now deprecated and will be removed in a future release. The preferred way to replicate this behavior is

```
df.sub(df['A'], axis=0)
```

For explicit control over the matching and broadcasting behavior, see the section on *flexible binary operations*.

Operations with scalars are just as you would expect:

```
In [94]: df * 5 + 2
```

```
Out[94]:
```

Boolean operators work as well:

```
In [97]: df1 = pd.DataFrame({'a': [1, 0, 1], 'b': [0, 1, 1]}, dtype=bool)
In [98]: df2 = pd.DataFrame({'a': [0, 1, 1], 'b': [1, 1, 0]}, dtype=bool)
In [99]: df1 & df2
Out[99]:
 a b
0 False False
1 False True
2 True False

In [100]: df1 | df2
Out[100]:
 a b
0 True True
1 True True
2 True True

In [101]: df1 ^ df2
Out[101]:
 a b
0 True True
1 True False
2 False True

In [102]: ~df1
Out[102]:
 a b
0 False True
1 True False
2 False False
```

## 8.2.12 Transposing

To transpose, access the `T` attribute (also the `transpose` function), similar to an `ndarray`:

```
only show the first 5 rows
In [103]: df[:5].T
Out[103]:
2000-01-01 2000-01-02 2000-01-03 2000-01-04 2000-01-05
A 0.173456 0.566478 -1.104908 -0.283926 0.389501
B -0.604079 -1.011070 0.677551 -0.056689 -0.398479
C 1.204537 -0.225885 -0.284451 1.848770 -1.663322
```

## 8.2.13 DataFrame interoperability with NumPy functions

Elementwise NumPy ufuncs (`log`, `exp`, `sqrt`, ...) and various other NumPy functions can be used with no issues on `DataFrame`, assuming the data within are numeric:

```
In [104]: np.exp(df)
Out[104]:
```

(continues on next page)

(continued from previous page)

```

 A B C
2000-01-01 1.189409 0.546578 3.335213
2000-01-02 1.762050 0.363830 0.797810

2000-01-05 1.476245 0.671341 0.189508
2000-01-06 0.950022 2.810380 1.371350
2000-01-07 0.889434 2.283661 0.426058
2000-01-08 1.066487 2.949392 0.208834

```

```
In [105]: np.asarray(df)
```

```

////////////////////////////////////
↪
array([[0.17345644, -0.60407873, 1.20453659],
 [0.56647779, -1.01106975, -0.2258846],
 [-1.1049078 , 0.6775512 , -0.28445119],
 [-0.28392624, -0.05668934, 1.84876966],
 [0.38950139, -0.39847851, -1.66332151],
 [-0.05127059, 1.03331984, 0.3157955],
 [-0.11716976, 0.82577969, -0.85317866],
 [0.06437035, 1.08159914, -1.56621411]])

```

The dot method on DataFrame implements matrix multiplication:

```
In [106]: df.T.dot(df)
```

```
Out[106]:
```

```

 A B C
A 1.824632 -1.645386 -0.794554
B -1.645386 4.927766 -2.206223
C -0.794554 -2.206223 11.048100

```

Similarly, the dot method on Series implements dot product:

```
In [107]: s1 = pd.Series(np.arange(5, 10))
```

```
In [108]: s1.dot(s1)
```

```
Out[108]: 255
```

DataFrame is not intended to be a drop-in replacement for ndarray as its indexing semantics are quite different in places from a matrix.

## 8.2.14 Console display

Very large DataFrames will be truncated to display them in the console. You can also get a summary using `info()`. (Here I am reading a CSV version of the **baseball** dataset from the **plyr** R package):

```
In [109]: baseball = pd.read_csv('data/baseball.csv')
```

```
In [110]: print(baseball)
```

```

 id player year stint team lg g ab r h X2b X3b hr rbi sb_

| 99 | 89534 | alomasa02 | 2007 | 1 | NYN | NL | 8   | 22  | 1  | 3   | 1  | 0 |

Wide DataFrames will be printed across multiple rows by default:

```
In [113]: pd.DataFrame(np.random.randn(3, 12))
Out[113]:
```

|   | 0         | 1         | 2         | 3        | 4        | 5         | 6         | 7         | 8         | 9         | 10        | 11       |
|---|-----------|-----------|-----------|----------|----------|-----------|-----------|-----------|-----------|-----------|-----------|----------|
| 0 | -0.743616 | 0.835545  | -0.338730 | 0.164354 | 0.515148 | -0.750601 | -0.192540 | -1.182753 | -0.436527 | -0.817149 | 0.730668  | 1.063363 |
| 1 | -0.541534 | -0.476494 | -0.425389 | 0.359126 | 0.734102 | -0.847547 | -1.303724 | 0.930543  | 1.568026  | -0.631020 | 0.994716  | 1.323214 |
| 2 | -0.678079 | -2.105424 | -0.564226 | 0.570190 | 0.966061 | -1.294887 | 1.055618  | 0.049449  | 0.291085  | -1.262169 | -0.344360 | 0.052244 |

You can change how much to print on a single row by setting the `display.width` option:

```
In [114]: pd.set_option('display.width', 40) # default is 80
In [115]: pd.DataFrame(np.random.randn(3, 12))
Out[115]:
```

|   | 0         | 1         | 2         | 3         | 4         | 5        | 6         | 7         | 8         | 9        | 10       | 11        |
|---|-----------|-----------|-----------|-----------|-----------|----------|-----------|-----------|-----------|----------|----------|-----------|
| 0 | -0.490597 | -1.545114 | -1.341313 | -1.872716 | -1.041629 | 0.025192 | -1.490605 | -1.228780 | -0.750848 | 1.664520 | 1.682150 | -0.531331 |
| 1 | 1.303983  | 1.934970  | -0.011372 | 0.245498  | 0.468791  | 2.042893 | 2.665206  | 1.471411  | 1.235006  | 0.157700 | 0.151501 | -0.805291 |
| 2 | 1.015209  | -1.033999 | -0.606903 | -2.087113 | 0.399398  | 0.602129 | -0.759260 | -0.614225 | -0.207938 | 0.145586 | 0.619345 | -1.123601 |

You can adjust the max width of the individual columns by setting `display.max_colwidth`

```
In [116]: datafile = {'filename': ['filename_01', 'filename_02'],
.....: 'path': ["media/user_name/storage/folder_01/filename_01",
.....: "media/user_name/storage/folder_02/filename_02"]}
In [117]: pd.set_option('display.max_colwidth', 30)
In [118]: pd.DataFrame(datafile)
Out[118]:
```

|   | filename    | path                          |
|---|-------------|-------------------------------|
| 0 | filename_01 | media/user_name/storage/fo... |
| 1 | filename_02 | media/user_name/storage/fo... |

```
In [119]: pd.set_option('display.max_colwidth', 100)
In [120]: pd.DataFrame(datafile)
Out[120]:
```

|   | filename    | path                                          |
|---|-------------|-----------------------------------------------|
| 0 | filename_01 | media/user_name/storage/folder_01/filename_01 |
| 1 | filename_02 | media/user_name/storage/folder_02/filename_02 |

(continues on next page)

|   | filename    | path                                          |
|---|-------------|-----------------------------------------------|
| 0 | filename_01 | media/user_name/storage/folder_01/filename_01 |
| 1 | filename_02 | media/user_name/storage/folder_02/filename_02 |

- **minor\_axis**: axis 2, it is the **columns** of each of the DataFrames

Construction of Panels works about like you would expect:

### 8.3.1 From 3D ndarray with optional axis labels

```
In [124]: wp = pd.Panel(np.random.randn(2, 5, 4), items=['Item1', 'Item2'],
.....: major_axis=pd.date_range('1/1/2000', periods=5),
.....: minor_axis=['A', 'B', 'C', 'D'])
.....:

In [125]: wp
Out[125]:
<class 'pandas.core.panel.Panel'>
Dimensions: 2 (items) x 5 (major_axis) x 4 (minor_axis)
Items axis: Item1 to Item2
Major_axis axis: 2000-01-01 00:00:00 to 2000-01-05 00:00:00
Minor_axis axis: A to D
```

### 8.3.2 From dict of DataFrame objects

```
In [126]: data = {'Item1': pd.DataFrame(np.random.randn(4, 3)),
.....: 'Item2': pd.DataFrame(np.random.randn(4, 2))}
.....:

In [127]: pd.Panel(data)
Out[127]:
<class 'pandas.core.panel.Panel'>
Dimensions: 2 (items) x 4 (major_axis) x 3 (minor_axis)
Items axis: Item1 to Item2
Major_axis axis: 0 to 3
Minor_axis axis: 0 to 2
```

Note that the values in the dict need only be **convertible to DataFrame**. Thus, they can be any of the other valid inputs to DataFrame as per above.

One helpful factory method is `Panel.from_dict`, which takes a dictionary of DataFrames as above, and the following named parameters:

| Parameter              | Default            | Description                                                      |
|------------------------|--------------------|------------------------------------------------------------------|
| <code>intersect</code> | <code>False</code> | drops elements whose indices do not align                        |
| <code>orient</code>    | <code>items</code> | use <code>minor</code> to use DataFrames' columns as panel items |

For example, compare to the construction above:

```
In [128]: pd.Panel.from_dict(data, orient='minor')
Out[128]:
<class 'pandas.core.panel.Panel'>
Dimensions: 3 (items) x 4 (major_axis) x 2 (minor_axis)
Items axis: 0 to 2
Major_axis axis: 0 to 3
Minor_axis axis: Item1 to Item2
```

Orient is especially useful for mixed-type DataFrames. If you pass a dict of DataFrame objects with mixed-type columns, all of the data will get upcasted to `dtype=object` unless you pass `orient='minor'`:

```

In [129]: df = pd.DataFrame({'a': ['foo', 'bar', 'baz'],
.....: 'b': np.random.randn(3)})
.....:

In [130]: df
Out[130]:
 a b
0 foo 3.048888
1 bar -0.366004
2 baz -0.860411

In [131]: data = {'item1': df, 'item2': df}

In [132]: panel = pd.Panel.from_dict(data, orient='minor')

In [133]: panel['a']
Out[133]:
 item1 item2
0 foo foo
1 bar bar
2 baz baz

In [134]: panel['b']
Out[134]:
 item1 item2
0 3.048888 3.048888
1 -0.366004 -0.366004
2 -0.860411 -0.860411

In [135]: panel['b'].dtypes
Out[135]:
item1 float64
item2 float64
dtype: object

```

**Note:** Panel, being less commonly used than Series and DataFrame, has been slightly neglected feature-wise. A number of methods and options available in DataFrame are not available in Panel.

### 8.3.3 From DataFrame using `to_panel` method

`to_panel` converts a DataFrame with a two-level index to a Panel.

```

In [136]: midx = pd.MultiIndex(levels=[['one', 'two'], ['x', 'y']],
.....: codes=[[1, 1, 0, 0], [1, 0, 1, 0]])
.....:

In [137]: df = pd.DataFrame({'A': [1, 2, 3, 4], 'B': [5, 6, 7, 8]}, index=midx)

In [138]: df.to_panel()
Out[138]:
<class 'pandas.core.panel.Panel'>
Dimensions: 2 (items) x 2 (major_axis) x 2 (minor_axis)
Items axis: A to B

```

(continues on next page)

(continued from previous page)

```
Major_axis axis: one to two
Minor_axis axis: x to y
```

### 8.3.4 Item selection / addition / deletion

Similar to DataFrame functioning as a dict of Series, Panel is like a dict of DataFrames:

```
In [139]: wp['Item1']
Out[139]:
```

|            | A         | B         | C         | D         |
|------------|-----------|-----------|-----------|-----------|
| 2000-01-01 | 0.894958  | 0.726835  | -0.833648 | 0.019643  |
| 2000-01-02 | -2.386224 | -0.279027 | -0.663074 | -0.001276 |
| 2000-01-03 | 0.484556  | -0.946211 | -1.988780 | 0.574818  |
| 2000-01-04 | 0.483881  | 0.742939  | -0.117236 | -0.854805 |
| 2000-01-05 | 0.013997  | -1.628759 | 0.818533  | 1.647028  |

```
In [140]: wp['Item3'] = wp['Item1'] / wp['Item2']
```

The API for insertion and deletion is the same as for DataFrame. And as with DataFrame, if the item is a valid Python identifier, you can access it as an attribute and tab-complete it in IPython.

### 8.3.5 Transposing

A Panel can be rearranged using its `transpose` method (which does not make a copy by default unless the data are heterogeneous):

```
In [141]: wp.transpose(2, 0, 1)
Out[141]:
```

```
<class 'pandas.core.panel.Panel'>
Dimensions: 4 (items) x 3 (major_axis) x 5 (minor_axis)
Items axis: A to D
Major_axis axis: Item1 to Item3
Minor_axis axis: 2000-01-01 00:00:00 to 2000-01-05 00:00:00
```

### 8.3.6 Indexing / Selection

| Operation                     | Syntax                        | Result    |
|-------------------------------|-------------------------------|-----------|
| Select item                   | <code>wp[item]</code>         | DataFrame |
| Get slice at major_axis label | <code>wp.major_xs(val)</code> | DataFrame |
| Get slice at minor_axis label | <code>wp.minor_xs(val)</code> | DataFrame |

For example, using the earlier example data, we could do:

```
In [142]: wp['Item1']
Out[142]:
```

|            | A         | B         | C         | D         |
|------------|-----------|-----------|-----------|-----------|
| 2000-01-01 | 0.894958  | 0.726835  | -0.833648 | 0.019643  |
| 2000-01-02 | -2.386224 | -0.279027 | -0.663074 | -0.001276 |
| 2000-01-03 | 0.484556  | -0.946211 | -1.988780 | 0.574818  |
| 2000-01-04 | 0.483881  | 0.742939  | -0.117236 | -0.854805 |

(continues on next page)

(continued from previous page)

```
2000-01-05 0.013997 -1.628759 0.818533 1.647028
```

```
In [143]: wp.major_xs(wp.major_axis[2])
```

```
~~~~~
↪
      Item1      Item2      Item3
A   0.484556 -0.653553 -0.741418
B  -0.946211  0.587148 -1.611539
C  -1.988780 -0.110135  18.057711
D   0.574818  1.467666  0.391654
```

```
In [144]: wp.minor_axis
```

```
~~~~~
↪Index(['A', 'B', 'C', 'D'], dtype='object')
```

```
In [145]: wp.minor_xs('C')
```

```
~~~~~
↪
      Item1      Item2      Item3
2000-01-01 -0.833648 -0.516757    1.613230
2000-01-02 -0.663074  0.210735   -3.146484
2000-01-03 -1.988780 -0.110135  18.057711
2000-01-04 -0.117236  1.399299   -0.083782
2000-01-05  0.818533  1.394950    0.586783
```

### 8.3.7 Squeezing

Another way to change the dimensionality of an object is to squeeze a 1-len object, similar to `wp['Item1']`.

```
In [146]: wp.reindex(items=['Item1']).squeeze()
```

```
Out[146]:
      A      B      C      D
2000-01-01  0.894958  0.726835 -0.833648  0.019643
2000-01-02 -2.386224 -0.279027 -0.663074 -0.001276
2000-01-03  0.484556 -0.946211 -1.988780  0.574818
2000-01-04  0.483881  0.742939 -0.117236 -0.854805
2000-01-05  0.013997 -1.628759  0.818533  1.647028
```

```
In [147]: wp.reindex(items=['Item1'], minor=['B']).squeeze()
```

```
~~~~~
↪
2000-01-01 0.726835
2000-01-02 -0.279027
2000-01-03 -0.946211
2000-01-04 0.742939
2000-01-05 -1.628759
Freq: D, Name: B, dtype: float64
```

### 8.3.8 Conversion to DataFrame

A Panel can be represented in 2D form as a hierarchically indexed DataFrame. See the section *hierarchical indexing* for more on this. To convert a Panel to a DataFrame, use the `to_frame` method:

```
In [148]: panel = pd.Panel(np.random.randn(3, 5, 4), items=['one', 'two', 'three'],
.....: major_axis=pd.date_range('1/1/2000', periods=5),
.....: minor_axis=['a', 'b', 'c', 'd'])
.....:
```

```
In [149]: panel.to_frame()
```

```
Out[149]:
```

|            |            | one       | two       | three     |           |
|------------|------------|-----------|-----------|-----------|-----------|
| major      | minor      |           |           |           |           |
|            | 2000-01-01 | a         | 0.855351  | 0.657418  | 0.525303  |
|            |            | b         | 2.495957  | -0.393350 | -0.502215 |
|            |            | c         | 2.358398  | -1.081906 | -0.170124 |
| 2000-01-02 | d          | -0.606379 | -0.137720 | 0.011590  |           |
|            | a          | 1.456978  | -0.429064 | 0.706876  |           |
|            | b          | 0.397350  | -0.237534 | 1.392602  |           |
|            | c          | 1.021844  | 0.088512  | -1.827588 |           |
| 2000-01-03 | d          | 0.772002  | -0.535929 | -1.011012 |           |
|            | a          | 0.091345  | -1.235452 | 0.836586  |           |
|            | b          | -1.858987 | 0.701341  | -0.466161 |           |

|            | a          | 2.027639  | 1.060647  | -0.833616 |           |
|            | b          | -1.303844 | -0.736200 | -1.250272 |           |
|            | c          | 1.028453  | -2.213809 | -0.628457 |           |
|            | d          | 0.738698  | -1.653282 | 0.555431  |           |

## 8.4 Deprecate Panel

Over the last few years, pandas has increased in both breadth and depth, with new features, datatype support, and manipulation routines. As a result, supporting efficient indexing and functional routines for Series, DataFrame and Panel has contributed to an increasingly fragmented and difficult-to-understand code base.

The 3-D structure of a Panel is much less common for many types of data analysis, than the 1-D of the Series or the 2-D of the DataFrame. Going forward it makes sense for pandas to focus on these areas exclusively.

Oftentimes, one can simply use a MultiIndex DataFrame for easily working with higher dimensional data.

In addition, the xarray package was built from the ground up, specifically in order to support the multi-dimensional analysis that is one of Panel's main use cases. [Here is a link to the xarray panel-transition documentation.](#)

```
In [150]: import pandas.util.testing as tm
```

```
In [151]: p = tm.makePanel()
```

```
In [152]: p
```

```
Out[152]:
<class 'pandas.core.panel.Panel'>
Dimensions: 3 (items) x 30 (major_axis) x 4 (minor_axis)
Items axis: ItemA to ItemC
Major_axis axis: 2000-01-03 00:00:00 to 2000-02-11 00:00:00
Minor_axis axis: A to D
```

Convert to a MultiIndex DataFrame.

In [153]: p.to\_frame()

Out [153]:

|            |       | ItemA     | ItemB     | ItemC     |
|------------|-------|-----------|-----------|-----------|
| major      | minor |           |           |           |
| 2000-01-03 | A     | 1.950469  | -1.196008 | 0.108966  |

Coordinates:
 * items (items) object 'ItemA' 'ItemB' 'ItemC'
 * major_axis (major_axis) datetime64[ns] 2000-01-03 2000-01-04 ... 2000-02-11
 * minor_axis (minor_axis) object 'A' 'B' 'C' 'D'
```

You can see the full-documentation for the [xarray](#) package. `{{ header }}`

## ESSENTIAL BASIC FUNCTIONALITY

Here we discuss a lot of the essential functionality common to the pandas data structures. Here's how to create some of the objects used in the examples from the previous section:

```
In [1]: index = pd.date_range('1/1/2000', periods=8)

In [2]: s = pd.Series(np.random.randn(5), index=['a', 'b', 'c', 'd', 'e'])

In [3]: df = pd.DataFrame(np.random.randn(8, 3), index=index,
...: columns=['A', 'B', 'C'])
...:
...:

In [4]: wp = pd.Panel(np.random.randn(2, 5, 4), items=['Item1', 'Item2'],
...: major_axis=pd.date_range('1/1/2000', periods=5),
...: minor_axis=['A', 'B', 'C', 'D'])
...:
...:
```

### 9.1 Head and Tail

To view a small sample of a Series or DataFrame object, use the `head()` and `tail()` methods. The default number of elements to display is five, but you may pass a custom number.

```
In [5]: long_series = pd.Series(np.random.randn(1000))

In [6]: long_series.head()
Out[6]:
0 -0.048348
1 -1.425065
2 -1.536137
3 -1.581786
4 0.947987
dtype: float64

In [7]: long_series.tail(3)
Out[7]:
997 2.173974
998 0.708024
999 1.273601
dtype: float64
```

## 9.2 Attributes and Underlying Data

pandas objects have a number of attributes enabling you to access the metadata

- **shape**: gives the axis dimensions of the object, consistent with ndarray
- **Axis labels**
  - **Series**: *index* (only axis)
  - **DataFrame**: *index* (rows) and *columns*
  - **Panel**: *items*, *major\_axis*, and *minor\_axis*

**Note, these attributes can be safely assigned to!**

```
In [8]: df[:2]
Out[8]:
```

|            | A         | B         | C         |
|------------|-----------|-----------|-----------|
| 2000-01-01 | 0.119683  | -1.093537 | -0.016917 |
| 2000-01-02 | -0.287249 | 1.209095  | -1.186491 |

```
In [9]: df.columns = [x.lower() for x in df.columns]
In [10]: df
Out[10]:
```

|            | a         | b         | c         |
|------------|-----------|-----------|-----------|
| 2000-01-01 | 0.119683  | -1.093537 | -0.016917 |
| 2000-01-02 | -0.287249 | 1.209095  | -1.186491 |
| 2000-01-03 | 0.137204  | 1.010783  | 0.687786  |
| 2000-01-04 | 1.956740  | 0.785833  | 0.100705  |
| 2000-01-05 | -0.566641 | -1.618464 | -1.240348 |
| 2000-01-06 | -0.673001 | -0.771003 | 0.966551  |
| 2000-01-07 | -0.467656 | -1.761529 | -0.234657 |
| 2000-01-08 | 0.361709  | 0.917190  | -0.467027 |

Pandas objects (Index, Series, DataFrame) can be thought of as containers for arrays, which hold the actual data and do the actual computation. For many types, the underlying array is a `numpy.ndarray`. However, pandas and 3rd party libraries may *extend* NumPy's type system to add support for custom arrays (see *dtypes*).

To get the actual data inside a `Index` or `Series`, use the `.array` property

```
In [11]: s.array
Out[11]:
<PandasArray>
[-1.2469032832093774, 0.74141502233534617, 2.1054089214382823,
 0.68213174569083412, -0.56585958230943501]
Length: 5, dtype: float64

In [12]: s.index.array
////////////////////////////////////
↳
<PandasArray>
['a', 'b', 'c', 'd', 'e']
Length: 5, dtype: object
```

array will always be an *ExtensionArray*. The exact details of what an *ExtensionArray* is and why pandas uses them is a bit beyond the scope of this introduction. See *dtypes* for more.

If you know you need a NumPy array, use `to_numpy()` or `numpy.asarray()`.

```

In [13]: s.to_numpy()
Out[13]: array([-1.24690328, 0.74141502, 2.10540892, 0.68213175, -0.56585958])

In [14]: np.asarray(s)
Out[14]: array([-1.24690328, 0.74141502, 2.10540892, 0.68213175, -0.56585958])

```

When the Series or Index is backed by an *ExtensionArray*, `to_numpy()` may involve copying data and coercing values. See *dtypes* for more.

`to_numpy()` gives some control over the `dtype` of the resulting `numpy.ndarray`. For example, consider date-times with timezones. NumPy doesn't have a `dtype` to represent timezone-aware datetimes, so there are two possibly useful representations:

1. An object-dtype `numpy.ndarray` with `Timestamp` objects, each with the correct `tz`
2. A `datetime64[ns]` -dtype `numpy.ndarray`, where the values have been converted to UTC and the time-zone discarded

Timezones may be preserved with `dtype=object`

```

In [15]: ser = pd.Series(pd.date_range('2000', periods=2, tz="CET"))
In [16]: ser.to_numpy(dtype=object)
Out[16]: array([Timestamp('2000-01-01 00:00:00+0100', tz='CET', freq='D'),
 Timestamp('2000-01-02 00:00:00+0100', tz='CET', freq='D')], dtype=object)

```

Or thrown away with `dtype='datetime64[ns]'`

```

In [17]: ser.to_numpy(dtype="datetime64[ns]")
Out[17]: array(['1999-12-31T23:00:00.000000000', '2000-01-01T23:00:00.000000000'],
 dtype='datetime64[ns]')

```

Getting the “raw data” inside a `DataFrame` is possibly a bit more complex. When your `DataFrame` only has a single data type for all the columns, `DataFrame.to_numpy()` will return the underlying data:

```

In [18]: df.to_numpy()
Out[18]: array([[0.11968323, -1.09353724, -0.01691716],
 [-0.28724918, 1.2090954 , -1.18649058],
 [0.1372038 , 1.0107827 , 0.68778642],
 [1.95673954, 0.78583279, 0.10070456],
 [-0.56664126, -1.61846405, -1.24034782],
 [-0.67300128, -0.77100252, 0.96655126],
 [-0.46765596, -1.76152931, -0.23465705],
 [0.36170924, 0.91719033, -0.4670268]])

```

If a `DataFrame` or `Panel` contains homogeneously-typed data, the `ndarray` can actually be modified in-place, and the changes will be reflected in the data structure. For heterogeneous data (e.g. some of the `DataFrame`'s columns are not all the same `dtype`), this will not be the case. The values attribute itself, unlike the axis labels, cannot be assigned to.

**Note:** When working with heterogeneous data, the `dtype` of the resulting `ndarray` will be chosen to accommodate all of the data involved. For example, if strings are involved, the result will be of object `dtype`. If there are only floats and integers, the resulting array will be of float `dtype`.

In the past, pandas recommended `Series.values` or `DataFrame.values` for extracting the data from a `Series` or `DataFrame`. You'll still find references to these in old code bases and online. Going forward, we recommend avoiding `.values` and using `.array` or `.to_numpy()`. `.values` has the following drawbacks:

1. When your `Series` contains an *extension type*, it's unclear whether `Series.values` returns a NumPy array or the extension array. `Series.array` will always return an *ExtensionArray*, and will never copy data. `Series.to_numpy()` will always return a NumPy array, potentially at the cost of copying / coercing values.
2. When your `DataFrame` contains a mixture of data types, `DataFrame.values` may involve copying data and coercing values to a common dtype, a relatively expensive operation. `DataFrame.to_numpy()`, being a method, makes it clearer that the returned NumPy array may not be a view on the same data in the `DataFrame`.

## 9.3 Accelerated operations

pandas has support for accelerating certain types of binary numerical and boolean operations using the `numexpr` library and the `bottleneck` libraries.

These libraries are especially useful when dealing with large data sets, and provide large speedups. `numexpr` uses smart chunking, caching, and multiple cores. `bottleneck` is a set of specialized cython routines that are especially fast when dealing with arrays that have `nan`s.

Here is a sample (using 100 column x 100,000 row `DataFrames`):

| Operation                 | 0.11.0 (ms) | Prior Version (ms) | Ratio to Prior |
|---------------------------|-------------|--------------------|----------------|
| <code>df1 &gt; df2</code> | 13.32       | 125.35             | 0.1063         |
| <code>df1 * df2</code>    | 21.71       | 36.63              | 0.5928         |
| <code>df1 + df2</code>    | 22.04       | 36.50              | 0.6039         |

You are highly encouraged to install both libraries. See the section *Recommended Dependencies* for more installation info.

These are both enabled to be used by default, you can control this by setting the options:

New in version 0.20.0.

```
pd.set_option('compute.use_bottleneck', False)
pd.set_option('compute.use_numexpr', False)
```

## 9.4 Flexible binary operations

With binary operations between pandas data structures, there are two key points of interest:

- Broadcasting behavior between higher- (e.g. `DataFrame`) and lower-dimensional (e.g. `Series`) objects.
- Missing data in computations.

We will demonstrate how to manage these issues independently, though they can be handled simultaneously.

### 9.4.1 Matching / broadcasting behavior

`DataFrame` has the methods `add()`, `sub()`, `mul()`, `div()` and related functions `radd()`, `rsub()`, ... for carrying out binary operations. For broadcasting behavior, `Series` input is of primary interest. Using these functions, you can use to either match on the *index* or *columns* via the **axis** keyword:

```
In [19]: df = pd.DataFrame({
.....: 'one': pd.Series(np.random.randn(3), index=['a', 'b', 'c']),
.....: 'two': pd.Series(np.random.randn(4), index=['a', 'b', 'c', 'd']),
.....: 'three': pd.Series(np.random.randn(3), index=['b', 'c', 'd'])})
.....:
```

```
In [20]: df
```

```
Out[20]:
```

```
 one two three
a 0.491079 -0.457939 NaN
b -1.717454 1.150478 0.055990
c -0.663213 0.679724 -0.899624
d NaN -1.607408 -0.609688
```

```
In [21]: row = df.iloc[1]
```

```
In [22]: column = df['two']
```

```
In [23]: df.sub(row, axis='columns')
```

```
Out[23]:
```

```
 one two three
a 2.208533 -1.608417 NaN
b 0.000000 0.000000 0.000000
c 1.054241 -0.470753 -0.955615
d NaN -2.757886 -0.665678
```

```
In [24]: df.sub(row, axis=1)
```

```

////////////////////////////////////
↪
 one two three
a 2.208533 -1.608417 NaN
b 0.000000 0.000000 0.000000
c 1.054241 -0.470753 -0.955615
d NaN -2.757886 -0.665678
```

```
In [25]: df.sub(column, axis='index')
```

```

////////////////////////////////////
↪
 one two three
a 0.949018 0.0 NaN
b -2.867932 0.0 -1.094488
c -1.342937 0.0 -1.579349
d NaN 0.0 0.997721
```

```
In [26]: df.sub(column, axis=0)
```

```

////////////////////////////////////
↪
 one two three
a 0.949018 0.0 NaN
b -2.867932 0.0 -1.094488
c -1.342937 0.0 -1.579349
d NaN 0.0 0.997721
```

Furthermore you can align a level of a MultiIndexed DataFrame with a Series.

```
In [27]: dfmi = df.copy()
```

(continues on next page)

(continued from previous page)

[illegible]

```
In [29]: dfmi.sub(column, axis=0, level='second')
```

Out [29] :

|       |        | one       | two       | three     |
|-------|--------|-----------|-----------|-----------|
| first | second |           |           |           |
| 1     | a      | 0.949018  | 0.000000  | NaN       |
|       | b      | -2.867932 | 0.000000  | -1.094488 |
|       | c      | -1.342937 | 0.000000  | -1.579349 |
| 2     | a      | NaN       | -1.149469 | -0.151748 |

With Panel, describing the matching behavior is a bit more difficult, so the arithmetic methods instead (and perhaps confusingly?) give you the option to specify the *broadcast axis*. For example, suppose we wished to demean the data over a particular axis. This can be accomplished by taking the mean over an axis and broadcasting over the same axis:

```
In [30]: major_mean = wp.mean(axis='major')
```

```
In [31]: major_mean
```

Out [31] :

|   | Item1     | Item2     |
|---|-----------|-----------|
| A | 0.092500  | 0.170620  |
| B | -0.721563 | -0.430538 |
| C | -0.587551 | -0.157327 |
| D | -0.151985 | 0.240794  |

```
In [32]: wp.sub(major_mean, axis='major')
```

```
<class 'pandas.core.panel.Panel'>
Dimensions: 2 (items) x 5 (major_axis) x 4 (minor_axis)
Items axis: Item1 to Item2
Major_axis axis: 2000-01-01 00:00:00 to 2000-01-05 00:00:00
Minor_axis axis: A to D
```

And similarly for `axis="items"` and `axis="minor"`.

**Note:** I could be convinced to make the **axis** argument in the DataFrame methods match the broadcasting behavior of Panel. Though it would require a transition period so users can change their code...

Series and Index also support the `divmod()` builtin. This function takes the floor division and modulo operation at the same time returning a two-tuple of the same type as the left hand side. For example:

```
In [33]: s = pd.Series(np.arange(10))
```

In [34]: s

Out [34] :

|   |   |
|---|---|
| 0 | 0 |
| 1 | 1 |
| 2 | 2 |
| 3 | 3 |
| 4 | 4 |
| 5 | 5 |

(continues on next page)

(continued from previous page)

[illegible]

We can also do elementwise `divmod()`:

```
In [43]: div, rem = divmod(s, [2, 2, 3, 3, 4, 4, 5, 5, 6, 6])

In [44]: div
Out[44]:
```

(continues on next page)

(continued from previous page)

```

9 3
dtype: int64

```

## 9.4.2 Missing data / operations with fill values

In Series and DataFrame, the arithmetic functions have the option of inputting a *fill\_value*, namely a value to substitute when at most one of the values at a location are missing. For example, when adding two DataFrame objects, you may wish to treat NaN as 0 unless both DataFrames are missing that value, in which case the result will be NaN (you can later replace NaN with some other value using `fillna` if you wish).

```

In [46]: df
Out[46]:
 one two three
a 0.491079 -0.457939 NaN
b -1.717454 1.150478 0.055990

 one two three
a 0.982157 -0.915879 1.000000
b -3.434908 2.300956 0.111980
c -1.326425 1.359449 -1.799249
d NaN -3.214817 -1.219375

```

### 9.4.3 Flexible Comparisons

Series and DataFrame have the binary comparison methods `eq`, `ne`, `lt`, `gt`, `le`, and `ge` whose behavior is analogous to the binary arithmetic operations described above:

```
In [50]: df.gt(df2)
```

Out [50] :

|   | one   | two   | three |
|---|-------|-------|-------|
| a | False | False | False |
| b | False | False | False |
| c | False | False | False |
| d | False | False | False |

```
In [51]: df2.ne(df)
```

```

\\ \\ \\ \\ \\ \\ \\ \\ \\ \\ \\ \\ \\ \\ \\ \\
↔
 one two three
a False False True
b False False False
c False False False
d True False False

```

These operations produce a pandas object of the same type as the left-hand-side input that is of dtype `bool`. These `boolean` objects can be used in indexing operations, see the section on *Boolean indexing*.

### 9.4.4 Boolean Reductions

You can apply the reductions: `empty()`, `any()`, `all()`, and `bool()` to provide a way to summarize a boolean result.

```
In [52]: (df > 0).all()
```

Out [52] :

```
one False
two False
three False
dtype: bool
```

```
In [53]: (df > 0).any()
```

```

one True
Out[53]:

```

(continues on next page)

(continued from previous page)

```
two True
three True
dtype: bool
```

You can reduce to a final boolean value.

```
In [54]: (df > 0).any().any()
Out[54]: True
```

You can test if a pandas object is empty, via the `empty` property.

```
In [55]: df.empty
Out[55]: False

In [56]: pd.DataFrame(columns=list('ABC')).empty
Out[56]: True
```

To evaluate single-element pandas objects in a boolean context, use the method `bool()`:

```
In [57]: pd.Series([True]).bool()
Out[57]: True

In [58]: pd.Series([False]).bool()
Out[58]: False

In [59]: pd.DataFrame([[True]]).bool()
Out[59]: True

In [60]: pd.DataFrame([[False]]).bool()
Out[60]: False
```

**Warning:** You might be tempted to do the following:

```
>>> if df:
... pass
```

Or

```
>>> df and df2
```

These will both raise errors, as you are trying to compare multiple values.:

```
ValueError: The truth value of an array is ambiguous. Use a.empty, a.any() or a.
↳ all().
```

See *gotchas* for a more detailed discussion.

## 9.4.5 Comparing if objects are equivalent

Often you may find that there is more than one way to compute the same result. As a simple example, consider `df + df` and `df * 2`. To test that these two computations produce the same result, given the tools shown above, you might imagine using `(df + df == df * 2).all()`. But in fact, this expression is False:

```
In [61]: df + df == df * 2
Out[61]:
```

|   | one   | two  | three |
|---|-------|------|-------|
| a | True  | True | False |
| b | True  | True | True  |
| c | True  | True | True  |
| d | False | True | True  |

```
In [62]: (df + df == df * 2).all()
```

```

one False
two True
three False
dtype: bool

```

Notice that the boolean DataFrame `df + df == df * 2` contains some False values! This is because NaNs do not compare as equals:

```
In [63]: np.nan == np.nan
Out[63]: False
```

So, NDFrames (such as Series, DataFrames, and Panels) have an `equals()` method for testing equality, with NaNs in corresponding locations treated as equal.

```
In [64]: (df + df).equals(df * 2)
Out[64]: True
```

Note that the Series or DataFrame index needs to be in the same order for equality to be True:

```
In [65]: df1 = pd.DataFrame({'col': ['foo', 0, np.nan]})
In [66]: df2 = pd.DataFrame({'col': [np.nan, 0, 'foo']}, index=[2, 1, 0])
In [67]: df1.equals(df2)
Out[67]: False

In [68]: df1.equals(df2.sort_index())
\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\Out[68]: True
```

### 9.4.6 Comparing array-like objects

You can conveniently perform element-wise comparisons when comparing a pandas data structure with a scalar value:

```
In [69]: pd.Series(['foo', 'bar', 'baz']) == 'foo'
Out[69]:
0 True
1 False
2 False
dtype: bool

In [70]: pd.Index(['foo', 'bar', 'baz']) == 'foo'
Out[70]: array([True, False, False], dtype=bool)
```

Pandas also handles element-wise comparisons between different array-like objects of the same length:

```
In [71]: pd.Series(['foo', 'bar', 'baz']) == pd.Index(['foo', 'bar', 'qux'])
Out[71]:
0 True
1 True
2 False
dtype: bool

In [72]: pd.Series(['foo', 'bar', 'baz']) == np.array(['foo', 'bar', 'qux'])
Out[72]:
0 True
1 True
2 False
dtype: bool
```

Trying to compare Index or Series objects of different lengths will raise a `ValueError`:

```
In [55]: pd.Series(['foo', 'bar', 'baz']) == pd.Series(['foo', 'bar'])
ValueError: Series lengths must match to compare

In [56]: pd.Series(['foo', 'bar', 'baz']) == pd.Series(['foo'])
ValueError: Series lengths must match to compare
```

Note that this is different from the NumPy behavior where a comparison can be broadcast:

```
In [73]: np.array([1, 2, 3]) == np.array([2])
Out[73]: array([False, True, False], dtype=bool)
```

or it can return `False` if broadcasting can not be done:

```
In [74]: np.array([1, 2, 3]) == np.array([1, 2])
Out[74]: False
```

## 9.4.7 Combining overlapping data sets

A problem occasionally arising is the combination of two similar data sets where values in one are preferred over the other. An example would be two data series representing a particular economic indicator where one is considered to be of “higher quality”. However, the lower quality series might extend further back in history or have more complete data coverage. As such, we would like to combine two `DataFrame` objects where missing values in one `DataFrame` are conditionally filled with like-labeled values from the other `DataFrame`. The function implementing this operation is `combine_first()`, which we illustrate:

```
In [75]: df1 = pd.DataFrame({'A': [1., np.nan, 3., 5., np.nan],
.....: 'B': [np.nan, 2., 3., np.nan, 6.]})
.....:

In [76]: df2 = pd.DataFrame({'A': [5., 2., 4., np.nan, 3., 7.],
.....: 'B': [np.nan, np.nan, 3., 4., 6., 8.]})
.....:

In [77]: df1
Out[77]:
 A B
0 1.0 NaN
1 NaN 2.0
2 3.0 3.0
```

(continues on next page)

(continued from previous page)

```

3 5.0 NaN
4 NaN 6.0

In [78]: df2
Out[78]:
 A B
0 5.0 NaN
1 2.0 NaN
2 4.0 3.0
3 NaN 4.0
4 3.0 6.0
5 7.0 8.0

In [79]: df1.combine_first(df2)
Out[79]:
 A B
0 1.0 NaN
1 2.0 2.0
2 3.0 3.0
3 5.0 4.0
4 3.0 6.0
5 7.0 8.0

```

### 9.4.8 General DataFrame Combine

The `combine_first()` method above calls the more general `DataFrame.combine()`. This method takes another `DataFrame` and a combiner function, aligns the input `DataFrame` and then passes the combiner function pairs of `Series` (i.e., columns whose names are the same).

So, for instance, to reproduce `combine_first()` as above:

```

In [80]: def combiner(x, y):
...: np.where(pd.isna(x), y, x)
...: df1.combine(df2, combiner)
...:
Out[80]:
 A B
0 NaN NaN
1 NaN NaN
2 NaN NaN
3 NaN NaN
4 NaN NaN
5 NaN NaN

```

## 9.5 Descriptive statistics

There exists a large number of methods for computing descriptive statistics and other related operations on *Series*, *DataFrame*, and *Panel*. Most of these are aggregations (hence producing a lower-dimensional result) like `sum()`, `mean()`, and `quantile()`, but some of them, like `cumsum()` and `cumprod()`, produce an object of the same size. Generally speaking, these methods take an **axis** argument, just like `ndarray.{sum, std, ...}`, but the axis can be specified by name or integer:

- For example:

[illegible]

```

a 0.016570
b -0.170329
c -0.294371
d -1.108548
dtype: float64

```

```
Out [84] :
one NaN
two -0.235146
three NaN
dtype: float64
```

```
Out [85]:
a 0.033139
b -0.510986
c -0.883113
d -2.217096
dtype: float64
```

```
In [87]: ts_stand.std()
Out[87]:
one 1.0
```

(continued from previous page)

```
two 1.0
three 1.0
dtype: float64
```

```
In [88]: xs_stand = df.sub(df.mean(1), axis=0).div(df.std(1), axis=0)
```

```
In [89]: xs_stand.std(1)
```

```
Out [89]:
```

```
a 1.0
b 1.0
c 1.0
d 1.0
dtype: float64
```

Note that methods like `cumsum()` and `cumprod()` preserve the location of NaN values. This is somewhat different from `expanding()` and `rolling()`. For more details please see *this note*.

```
In [90]: df.cumsum()
```

```
Out [90]:
```

```
 one two three
a 0.491079 -0.457939 NaN
b -1.226375 0.692538 0.055990
c -1.889588 1.372263 -0.843634
d NaN -0.235146 -1.453322
```

Here is a quick reference summary table of common functions. Each also takes an optional `level` parameter which applies only if the object has a *hierarchical index*.

| Function              | Description                                |
|-----------------------|--------------------------------------------|
| <code>count</code>    | Number of non-NA observations              |
| <code>sum</code>      | Sum of values                              |
| <code>mean</code>     | Mean of values                             |
| <code>mad</code>      | Mean absolute deviation                    |
| <code>median</code>   | Arithmetic median of values                |
| <code>min</code>      | Minimum                                    |
| <code>max</code>      | Maximum                                    |
| <code>mode</code>     | Mode                                       |
| <code>abs</code>      | Absolute Value                             |
| <code>prod</code>     | Product of values                          |
| <code>std</code>      | Bessel-corrected sample standard deviation |
| <code>var</code>      | Unbiased variance                          |
| <code>sem</code>      | Standard error of the mean                 |
| <code>skew</code>     | Sample skewness (3rd moment)               |
| <code>kurt</code>     | Sample kurtosis (4th moment)               |
| <code>quantile</code> | Sample quantile (value at %)               |
| <code>cumsum</code>   | Cumulative sum                             |
| <code>cumprod</code>  | Cumulative product                         |
| <code>cummax</code>   | Cumulative maximum                         |
| <code>cummin</code>   | Cumulative minimum                         |

Note that by chance some NumPy methods, like `mean`, `std`, and `sum`, will exclude NAs on Series input by default:

You can select specific percentiles to include in the output:

```
In [103]: series.describe(percentiles=[.05, .25, .75, .95])
Out[103]:
count 500.000000
mean 0.059700
std 0.983662
min -2.733171
5% -1.686746
25% -0.573787
50% 0.097019
75% 0.718126
95% 1.585108
max 2.672482
dtype: float64
```

By default, the median is always included.

For a non-numerical Series object, describe() will give a simple summary of the number of unique values and most frequently occurring values:

```
In [104]: s = pd.Series(['a', 'a', 'b', 'b', 'a', 'a', np.nan, 'c', 'd', 'a'])
In [105]: s.describe()
Out[105]:
count 9
unique 4
top a
freq 5
dtype: object
```

Note that on a mixed-type DataFrame object, describe() will restrict the summary to include only numerical columns or, if none are, only categorical columns:

```
In [106]: frame = pd.DataFrame({'a': ['Yes', 'Yes', 'No', 'No'], 'b': range(4)})
In [107]: frame.describe()
Out[107]:
 b
count 4.000000
mean 1.500000
std 1.290994
min 0.000000
25% 0.750000
50% 1.500000
75% 2.250000
max 3.000000
```

This behavior can be controlled by providing a list of types as include/exclude arguments. The special value all can also be used:

```
In [108]: frame.describe(include=['object'])
Out[108]:
 a
count 4
unique 2
top Yes
freq 2
```

(continues on next page)

(continued from previous page)

```

In [109]: frame.describe(include=['number'])
////////////////////////////////////\Out [109]:
 b
count 4.000000
mean 1.500000
std 1.290994
min 0.000000
25% 0.750000
50% 1.500000
75% 2.250000
max 3.000000

In [110]: frame.describe(include='all')
////////////////////////////////////
↪
 a b
count 4 4.000000
unique 2 NaN
top Yes NaN
freq 2 NaN
mean NaN 1.500000
std NaN 1.290994
min NaN 0.000000
25% NaN 0.750000
50% NaN 1.500000
75% NaN 2.250000
max NaN 3.000000

```

That feature relies on `select_dtypes`. Refer to there for details about accepted inputs.

## 9.5.2 Index of Min/Max Values

The `idxmin()` and `idxmax()` functions on Series and DataFrame compute the index labels with the minimum and maximum corresponding values:

```

In [111]: s1 = pd.Series(np.random.randn(5))

In [112]: s1
Out [112]:
0 0.221919
1 -0.004809
2 0.286916
3 -2.649834
4 -1.202602
dtype: float64

In [113]: s1.idxmin(), s1.idxmax()
////////////////////////////////////\Out [113]:
↪ (3, 2)

In [114]: df1 = pd.DataFrame(np.random.randn(5, 3), columns=['A', 'B', 'C'])

In [115]: df1
Out [115]:

```

(continues on next page)

(continued from previous page)

```

 A B C
0 -0.115922 1.285220 1.428801
1 -0.065703 -0.379261 -1.089562
2 -0.824435 -0.576953 0.764745
3 1.260170 -1.206771 -0.614909
4 1.360334 -0.216313 -0.403728

```

```
In [116]: df1.idxmin(axis=0)
```

```

////////////////////////////////////
↪
A 2
B 3
C 1
dtype: int64

```

```
In [117]: df1.idxmax(axis=1)
```

```

////////////////////////////////////
↪
0 C
1 A
2 C
3 A
4 A
dtype: object

```

When there are multiple rows (or columns) matching the minimum or maximum value, `idxmin()` and `idxmax()` return the first matching index:

```
In [118]: df3 = pd.DataFrame([2, 1, 1, 3, np.nan], columns=['A'], index=list('edcba'))
```

```
In [119]: df3
```

```
Out[119]:
```

```

 A
e 2.0
d 1.0
c 1.0
b 3.0
a NaN

```

```
In [120]: df3['A'].idxmin()
```

```

////////////////////////////////////Out[120]: 'd'

```

---

**Note:** `idxmin` and `idxmax` are called `argmin` and `argmax` in NumPy.

---

### 9.5.3 Value counts (histogramming) / Mode

The `value_counts()` Series method and top-level function computes a histogram of a 1D array of values. It can also be used as a function on regular arrays:

```
In [121]: data = np.random.randint(0, 7, size=50)
```

```
In [122]: data
```

```
Out[122]:
```

(continues on next page)

(continued from previous page)

```

array([3, 1, 0, 5, 6, 0, 1, 1, 0, 0, 0, 1, 6, 5, 3, 0, 1, 2, 6, 3, 3, 0, 5,
 5, 5, 0, 6, 0, 0, 5, 1, 1, 3, 2, 0, 6, 5, 4, 0, 1, 3, 3, 3, 1, 6, 5,
 1, 6, 2, 3])

In [123]: s = pd.Series(data)

In [124]: s.value_counts()
Out[124]:
0 12
1 10
3 9
5 8
6 7
2 3
4 1
dtype: int64

In [125]: pd.value_counts(data)
Out[125]:
0 12
1 10
3 9
5 8
6 7
2 3
4 1
dtype: int64

```

Similarly, you can get the most frequently occurring value(s) (the mode) of the values in a Series or DataFrame:

```

In [126]: s5 = pd.Series([1, 1, 3, 3, 3, 5, 5, 7, 7, 7])

In [127]: s5.mode()
Out[127]:
0 3
1 7
dtype: int64

In [128]: df5 = pd.DataFrame({"A": np.random.randint(0, 7, size=50),
.....: "B": np.random.randint(-10, 15, size=50)})

In [129]: df5.mode()
Out[129]:
 A B
0 1 2

```

## 9.5.4 Discretization and quantiling

Continuous values can be discretized using the `cut()` (bins based on values) and `qcut()` (bins based on sample quantiles) functions:

```
In [130]: arr = np.random.randn(20)
```

(continues on next page)

(continued from previous page)

```
In [131]: factor = pd.cut(arr, 4)

In [132]: factor
Out[132]:
[(-1.601, -0.603], (-0.603, 0.391], (-0.603, 0.391], (1.385, 2.379], (-0.603, 0.391],
→..., (-0.603, 0.391], (-0.603, 0.391], (0.391, 1.385], (-0.603, 0.391], (-1.601, -0.
→603]]
Length: 20
Categories (4, interval[float64]): [(-1.601, -0.603] < (-0.603, 0.391] < (0.391, 1.
→385] <
 (1.385, 2.379]]

In [133]: factor = pd.cut(arr, [-5, -1, 0, 1, 5])

In [134]: factor
Out[134]:
[(-1, 0], (-1, 0], (-1, 0], (1, 5], (-1, 0], ..., (-1, 0], (-1, 0], (1, 5], (-1, 0],
→(-5, -1]]
Length: 20
Categories (4, interval[int64]): [(-5, -1] < (-1, 0] < (0, 1] < (1, 5]]
```

`qcut()` computes sample quantiles. For example, we could slice up some normally distributed data into equal-size quantiles like so:

```
In [135]: arr = np.random.randn(30)

In [136]: factor = pd.qcut(arr, [0, .25, .5, .75, 1])

In [137]: factor
Out[137]:
[(-0.643, -0.125], (-0.125, 0.477], (-0.125, 0.477], (-0.125, 0.477], (-2.
→ 8819999999999997, -0.643], ..., (-2.8819999999999997, -0.643], (-2.8819999999999997,
→ -0.643], (0.477, 1.57], (-2.8819999999999997, -0.643], (0.477, 1.57]]
Length: 30
Categories (4, interval[float64]): [(-2.8819999999999997, -0.643] < (-0.643, -0.125]
→ < (-0.125, 0.477] <
 (0.477, 1.57]]

In [138]: pd.value_counts(factor)
////////////////////////////////////
→
(0.477, 1.57] 8
(-2.8819999999999997, -0.643] 8
(-0.125, 0.477] 7
(-0.643, -0.125] 7
dtype: int64
```

We can also pass infinite values to define the bins:

```
In [139]: arr = np.random.randn(20)

In [140]: factor = pd.cut(arr, [-np.inf, 0, np.inf])

In [141]: factor
Out[141]:
[(0.0, inf], (-inf, 0.0], (0.0, inf], (-inf, 0.0], (0.0, inf], ..., (-inf, 0.0], (0.0,
→ inf], (0.0, inf], (0.0, inf], (-inf, 0.0]]
```

(continues on next page)

(continued from previous page)

```
Length: 20
Categories (2, interval[float64]): [(-inf, 0.0] < (0.0, inf]]
```

## 9.6 Function application

To apply your own or another library's functions to pandas objects, you should be aware of the three methods below. The appropriate method to use depends on whether your function expects to operate on an entire `DataFrame` or `Series`, row- or column-wise, or elementwise.

1. *Tablewise Function Application*: `pipe()`
2. *Row or Column-wise Function Application*: `apply()`
3. *Aggregation API*: `agg()` and `transform()`
4. *Applying Elementwise Functions*: `applymap()`

### 9.6.1 Tablewise Function Application

`DataFrames` and `Series` can of course just be passed into functions. However, if the function needs to be called in a chain, consider using the `pipe()` method. Compare the following

```
f, g, and h are functions taking and returning ``DataFrames``
>>> f(g(h(df), arg1=1), arg2=2, arg3=3)
```

with the equivalent

```
>>> (df.pipe(h)
... .pipe(g, arg1=1)
... .pipe(f, arg2=2, arg3=3))
```

Pandas encourages the second style, which is known as method chaining. `pipe` makes it easy to use your own or another library's functions in method chains, alongside pandas' methods.

In the example above, the functions `f`, `g`, and `h` each expected the `DataFrame` as the first positional argument. What if the function you wish to apply takes its data as, say, the second argument? In this case, provide `pipe` with a tuple of (callable, data\_keyword). `pipe` will route the `DataFrame` to the argument specified in the tuple.

For example, we can fit a regression using `statsmodels`. Their API expects a formula first and a `DataFrame` as the second argument, `data`. We pass in the function, keyword pair (`sm.ols`, `'data'`) to `pipe`:

```
In [142]: import statsmodels.formula.api as sm

In [143]: bb = pd.read_csv('data/baseball.csv', index_col='id')

In [144]: (bb.query('h > 0')
... .assign(ln_h=lambda df: np.log(df.h))
... .pipe((sm.ols, 'data'), 'hr ~ ln_h + year + g + C(lg)')
... .fit()
... .summary()
...)
Out[144]:
<class 'statsmodels.iolib.summary.Summary'>
```

"""

```

The pipe method is inspired by unix pipes and more recently [dplyr](#) and [magrittr](#), which have introduced the popular `(%>)` (read pipe) operator for [R](#). The implementation of pipe here is quite clean and feels right at home in python. We encourage you to view the source code of `pipe()`.

## 9.6.2 Row or Column-wise Function Application

Arbitrary functions can be applied along the axes of a DataFrame using the `apply()` method, which, like the descriptive statistics methods, takes an optional `axis` argument:

```

In [145]: df.apply(np.mean)
Out[145]:
one -0.629863
two -0.058786
three -0.484441
dtype: float64

In [146]: df.apply(np.mean, axis=1)
Out[146]:
a 0.016570
b -0.170329

```

(continues on next page)

(continued from previous page)

```
c -0.294371
d -1.108548
dtype: float64
```

```
In [147]: df.apply(lambda x: x.max() - x.min())
```

```
one 2.208533
two 2.757886
three 0.955615
dtype: float64
```

```
In [148]: df.apply(np.cumsum)
```

```
one two three
a 0.491079 -0.457939 NaN
b -1.226375 0.692538 0.055990
c -1.889588 1.372263 -0.843634
d NaN -0.235146 -1.453322
```

```
In [149]: df.apply(np.exp)
```

```
one two three
a 1.634078 0.632586 NaN
b 0.179523 3.159702 1.057587
c 0.515194 1.973334 0.406722
d NaN 0.200406 0.543521
```

The `apply()` method will also dispatch on a string method name.

```
In [150]: df.apply('mean')
```

```
Out[150]:
one -0.629863
two -0.058786
three -0.484441
dtype: float64
```

```
In [151]: df.apply('mean', axis=1)
```

```
Out[151]:
a 0.016570
b -0.170329
c -0.294371
d -1.108548
dtype: float64
```

The return type of the function passed to `apply()` affects the type of the final output from `DataFrame.apply` for the default behaviour:

- If the applied function returns a `Series`, the final output is a `DataFrame`. The columns match the index of the `Series` returned by the applied function.
- If the applied function returns any other type, the final output is a `Series`.

This default behaviour can be overridden using the `result_type`, which accepts three options: `reduce`, `broadcast`, and `expand`. These will determine how list-like return values expand (or not) to a `DataFrame`.

`apply()` combined with some cleverness can be used to answer many questions about a data set. For example, suppose we wanted to extract the date where the maximum value for each column occurred:

```
In [152]: tsdf = pd.DataFrame(np.random.randn(1000, 3), columns=['A', 'B', 'C'],
.....: index=pd.date_range('1/1/2000', periods=1000))
.....:

In [153]: tsdf.apply(lambda x: x.idxmax())
Out[153]:
A 2002-03-29
B 2000-05-20
C 2000-08-08
dtype: datetime64[ns]
```

You may also pass additional arguments and keyword arguments to the `apply()` method. For instance, consider the following function you would like to apply:

```
def subtract_and_divide(x, sub, divide=1):
 return (x - sub) / divide
```

You may then apply this function as follows:

```
df.apply(subtract_and_divide, args=(5,), divide=3)
```

Another useful feature is the ability to pass Series methods to carry out some Series operation on each column or row:

```
In [154]: tsdf
Out[154]:
```

|            | A         | B         | C         |
|------------|-----------|-----------|-----------|
| 2000-01-01 | -0.750731 | -1.390504 | 0.305933  |
| 2000-01-02 | 0.865764  | 0.466047  | 0.425618  |
| 2000-01-03 | 1.252675  | 1.633890  | 1.121654  |
| 2000-01-04 | NaN       | NaN       | NaN       |
| 2000-01-05 | NaN       | NaN       | NaN       |
| 2000-01-06 | NaN       | NaN       | NaN       |
| 2000-01-07 | NaN       | NaN       | NaN       |
| 2000-01-08 | 0.289423  | 0.186522  | -0.060746 |
| 2000-01-09 | 0.493235  | -0.340763 | 2.283378  |
| 2000-01-10 | -0.779786 | 1.652987  | 1.065328  |

```
In [155]: tsdf.apply(pd.Series.interpolate)
////////////////////////////////////
```

|            | A         | B         | C         |
|------------|-----------|-----------|-----------|
| 2000-01-01 | -0.750731 | -1.390504 | 0.305933  |
| 2000-01-02 | 0.865764  | 0.466047  | 0.425618  |
| 2000-01-03 | 1.252675  | 1.633890  | 1.121654  |
| 2000-01-04 | 1.060025  | 1.344416  | 0.885174  |
| 2000-01-05 | 0.867374  | 1.054943  | 0.648694  |
| 2000-01-06 | 0.674724  | 0.765469  | 0.412214  |
| 2000-01-07 | 0.482074  | 0.475996  | 0.175734  |
| 2000-01-08 | 0.289423  | 0.186522  | -0.060746 |
| 2000-01-09 | 0.493235  | -0.340763 | 2.283378  |
| 2000-01-10 | -0.779786 | 1.652987  | 1.065328  |

Finally, `apply()` takes an argument `raw` which is `False` by default, which converts each row or column into a Series before applying the function. When set to `True`, the passed function will instead receive an ndarray object, which has positive performance implications if you do not need the indexing functionality.

### 9.6.3 Aggregation API

New in version 0.20.0.

The aggregation API allows one to express possibly multiple aggregation operations in a single concise way. This API is similar across pandas objects, see *groupby API*, the *window functions API*, and the *resample API*. The entry point for aggregation is `DataFrame.aggregate()`, or the alias `DataFrame.agg()`.

We will use a similar starting frame from above:

```
In [156]: tsdf = pd.DataFrame(np.random.randn(10, 3), columns=['A', 'B', 'C'],
.....: index=pd.date_range('1/1/2000', periods=10))
.....:

In [157]: tsdf.iloc[3:7] = np.nan

In [158]: tsdf
Out[158]:
```

|            | A         | B         | C         |
|------------|-----------|-----------|-----------|
| 2000-01-01 | -0.935854 | -0.371887 | 0.983818  |
| 2000-01-02 | -0.901540 | 1.096046  | -1.959304 |
| 2000-01-03 | 0.352063  | -0.375253 | 0.906285  |
| 2000-01-04 | NaN       | NaN       | NaN       |
| 2000-01-05 | NaN       | NaN       | NaN       |
| 2000-01-06 | NaN       | NaN       | NaN       |
| 2000-01-07 | NaN       | NaN       | NaN       |
| 2000-01-08 | 0.186658  | 0.778072  | 0.703476  |
| 2000-01-09 | -1.244535 | 0.613626  | 1.590440  |
| 2000-01-10 | -0.355820 | 0.025667  | -0.538621 |

Using a single function is equivalent to `apply()`. You can also pass named methods as strings. These will return a `Series` of the aggregated output:

```
In [159]: tsdf.agg(np.sum)
Out[159]:
A -2.899028
B 1.766272
C 1.686094
dtype: float64

In [160]: tsdf.agg('sum')
Out[160]:
A -2.899028
B 1.766272
C 1.686094
dtype: float64

these are equivalent to a ``.sum()`` because we are aggregating
on a single function
In [161]: tsdf.sum()
Out[161]:
A -2.899028
B 1.766272
C 1.686094
dtype: float64
```

Single aggregations on a `Series` this will return a scalar value:

```
In [162]: tsdf.A.agg('sum')
Out[162]: -2.899028499662291
```

### 9.6.3.1 Aggregating with multiple functions

You can pass multiple aggregation arguments as a list. The results of each of the passed functions will be a row in the resulting `DataFrame`. These are naturally named from the aggregation function.

```
In [163]: tsdf.agg(['sum'])
Out[163]:
```

|     | A         | B        | C        |
|-----|-----------|----------|----------|
| sum | -2.899028 | 1.766272 | 1.686094 |

Multiple functions yield multiple rows:

```
In [164]: tsdf.agg(['sum', 'mean'])
Out[164]:
```

|      | A         | B        | C        |
|------|-----------|----------|----------|
| sum  | -2.899028 | 1.766272 | 1.686094 |
| mean | -0.483171 | 0.294379 | 0.281016 |

On a `Series`, multiple functions return a `Series`, indexed by the function names:

```
In [165]: tsdf.A.agg(['sum', 'mean'])
Out[165]:
```

|      |           |
|------|-----------|
| sum  | -2.899028 |
| mean | -0.483171 |

Name: A, dtype: float64

Passing a lambda function will yield a `<lambda>` named row:

```
In [166]: tsdf.A.agg(['sum', lambda x: x.mean()])
Out[166]:
```

|          |           |
|----------|-----------|
| sum      | -2.899028 |
| <lambda> | -0.483171 |

Name: A, dtype: float64

Passing a named function will yield that name for the row:

```
In [167]: def mymean(x):
.....: return x.mean()
.....:

In [168]: tsdf.A.agg(['sum', mymean])
Out[168]:
```

|        |           |
|--------|-----------|
| sum    | -2.899028 |
| mymean | -0.483171 |

Name: A, dtype: float64

### 9.6.3.2 Aggregating with a dict

Passing a dictionary of column names to a scalar or a list of scalars, to `DataFrame.agg` allows you to customize which functions are applied to which columns. Note that the results are not in any particular order, you can use an `OrderedDict` instead to guarantee ordering.

```
In [169]: tsdf.agg({'A': 'mean', 'B': 'sum'})
Out[169]:
A -0.483171
B 1.766272
dtype: float64
```

Passing a list-like will generate a DataFrame output. You will get a matrix-like output of all of the aggregators. The output will consist of all unique functions. Those that are not noted for a particular column will be NaN:

```
In [170]: tsdf.agg({'A': ['mean', 'min'], 'B': 'sum'})
Out[170]:
```

|      | A         | B        |
|------|-----------|----------|
| mean | -0.483171 | NaN      |
| min  | -1.244535 | NaN      |
| sum  | NaN       | 1.766272 |

### 9.6.3.3 Mixed Dtypes

When presented with mixed dtypes that cannot aggregate, `.agg` will only take the valid aggregations. This is similar to how `groupby .agg` works.

```
In [171]: mdf = pd.DataFrame({'A': [1, 2, 3],
.....: 'B': [1., 2., 3.],
.....: 'C': ['foo', 'bar', 'baz'],
.....: 'D': pd.date_range('20130101', periods=3)})
.....:

In [172]: mdf.dtypes
Out[172]:
A int64
B float64
C object
D datetime64[ns]
dtype: object
```

```
In [173]: mdf.agg(['min', 'sum'])
Out[173]:
```

|     | A | B   | C        | D          |
|-----|---|-----|----------|------------|
| min | 1 | 1.0 | bar      | 2013-01-01 |
| sum | 6 | 6.0 | foobabaz | NaT        |

### 9.6.3.4 Custom describe

With `.agg()` it is possible to easily create a custom describe function, similar to the built in *describe* function.

```
In [174]: from functools import partial

In [175]: q_25 = partial(pd.Series.quantile, q=0.25)

In [176]: q_25.__name__ = '25%'

In [177]: q_75 = partial(pd.Series.quantile, q=0.75)

In [178]: q_75.__name__ = '75%'
```

(continues on next page)

(continued from previous page)

```
In [179]: tsdf.agg(['count', 'mean', 'std', 'min', q_25, 'median', q_75, 'max'])
Out [179]:
```

|        | A         | B         | C         |
|--------|-----------|-----------|-----------|
| count  | 6.000000  | 6.000000  | 6.000000  |
| mean   | -0.483171 | 0.294379  | 0.281016  |
| std    | 0.651481  | 0.623389  | 1.301445  |
| min    | -1.244535 | -0.375253 | -1.959304 |
| 25%    | -0.927276 | -0.272498 | -0.228096 |
| median | -0.628680 | 0.319647  | 0.804881  |
| 75%    | 0.051038  | 0.736961  | 0.964434  |
| max    | 0.352063  | 1.096046  | 1.590440  |

## 9.6.4 Transform API

New in version 0.20.0.

The `transform()` method returns an object that is indexed the same (same size) as the original. This API allows you to provide *multiple* operations at the same time rather than one-by-one. Its API is quite similar to the `.agg` API.

We create a frame similar to the one used in the above sections.

```
In [180]: tsdf = pd.DataFrame(np.random.randn(10, 3), columns=['A', 'B', 'C'],
.....: index=pd.date_range('1/1/2000', periods=10))
.....:
```

```
In [181]: tsdf.iloc[3:7] = np.nan
```

```
In [182]: tsdf
```

```
Out [182]:
```

|            | A         | B         | C         |
|------------|-----------|-----------|-----------|
| 2000-01-01 | -1.807631 | 0.047273  | -1.674414 |
| 2000-01-02 | -0.749174 | 1.083498  | -1.732196 |
| 2000-01-03 | -1.309148 | 0.091291  | -1.254360 |
| 2000-01-04 | NaN       | NaN       | NaN       |
| 2000-01-05 | NaN       | NaN       | NaN       |
| 2000-01-06 | NaN       | NaN       | NaN       |
| 2000-01-07 | NaN       | NaN       | NaN       |
| 2000-01-08 | -1.159567 | -0.709886 | -0.221126 |
| 2000-01-09 | -1.906830 | 0.040044  | -0.685676 |
| 2000-01-10 | -0.857021 | 0.193725  | -0.470050 |

Transform the entire frame. `.transform()` allows input functions as: a NumPy function, a string function name or a user defined function.

```
In [183]: tsdf.transform(np.abs)
```

```
Out [183]:
```

|            | A        | B        | C        |
|------------|----------|----------|----------|
| 2000-01-01 | 1.807631 | 0.047273 | 1.674414 |
| 2000-01-02 | 0.749174 | 1.083498 | 1.732196 |
| 2000-01-03 | 1.309148 | 0.091291 | 1.254360 |
| 2000-01-04 | NaN      | NaN      | NaN      |
| 2000-01-05 | NaN      | NaN      | NaN      |
| 2000-01-06 | NaN      | NaN      | NaN      |
| 2000-01-07 | NaN      | NaN      | NaN      |

```

Here `transform()` received a single function; this is equivalent to a ufunc application.

```
In [186]: np.abs(tsdf)
```

```
Out [186]:
```

```

Freq: D, Name: A, dtype: float64

```

### 9.6.4.1 Transform with multiple functions

Passing multiple functions will yield a column MultiIndexed DataFrame. The first level will be the original frame column names; the second level will be the names of the transforming functions.

```

In [188]: tsdf.transform([np.abs, lambda x: x + 1])
Out [188]:

```

|            | A        |           | B        |          | C        |           |
|------------|----------|-----------|----------|----------|----------|-----------|
|            | absolute | <lambda>  | absolute | <lambda> | absolute | <lambda>  |
| 2000-01-01 | 1.807631 | -0.807631 | 0.047273 | 1.047273 | 1.674414 | -0.674414 |
| 2000-01-02 | 0.749174 | 0.250826  | 1.083498 | 2.083498 | 1.732196 | -0.732196 |
| 2000-01-03 | 1.309148 | -0.309148 | 0.091291 | 1.091291 | 1.254360 | -0.254360 |
| 2000-01-04 | NaN      | NaN       | NaN      | NaN      | NaN      | NaN       |
| 2000-01-05 | NaN      | NaN       | NaN      | NaN      | NaN      | NaN       |
| 2000-01-06 | NaN      | NaN       | NaN      | NaN      | NaN      | NaN       |
| 2000-01-07 | NaN      | NaN       | NaN      | NaN      | NaN      | NaN       |
| 2000-01-08 | 1.159567 | -0.159567 | 0.709886 | 0.290114 | 0.221126 | 0.778874  |
| 2000-01-09 | 1.906830 | -0.906830 | 0.040044 | 1.040044 | 0.685676 | 0.314324  |
| 2000-01-10 | 0.857021 | 0.142979  | 0.193725 | 1.193725 | 0.470050 | 0.529950  |

Passing multiple functions to a Series will yield a DataFrame. The resulting column names will be the transforming functions.

```

In [189]: tsdf.A.transform([np.abs, lambda x: x + 1])
Out [189]:

```

|            | absolute | <lambda>  |
|------------|----------|-----------|
| 2000-01-01 | 1.807631 | -0.807631 |
| 2000-01-02 | 0.749174 | 0.250826  |
| 2000-01-03 | 1.309148 | -0.309148 |
| 2000-01-04 | NaN      | NaN       |
| 2000-01-05 | NaN      | NaN       |
| 2000-01-06 | NaN      | NaN       |
| 2000-01-07 | NaN      | NaN       |
| 2000-01-08 | 1.159567 | -0.159567 |
| 2000-01-09 | 1.906830 | -0.906830 |
| 2000-01-10 | 0.857021 | 0.142979  |

### 9.6.4.2 Transforming with a dict

Passing a dict of functions will allow selective transforming per column.

```

In [190]: tsdf.transform({'A': np.abs, 'B': lambda x: x + 1})
Out [190]:

```

|  | A | B |
|--|---|---|
|--|---|---|

(continues on next page)

(continued from previous page)

|            |          |          |
|------------|----------|----------|
| 2000-01-01 | 1.807631 | 1.047273 |
| 2000-01-02 | 0.749174 | 2.083498 |
| 2000-01-03 | 1.309148 | 1.091291 |
| 2000-01-04 | NaN      | NaN      |
| 2000-01-05 | NaN      | NaN      |
| 2000-01-06 | NaN      | NaN      |
| 2000-01-07 | NaN      | NaN      |
| 2000-01-08 | 1.159567 | 0.290114 |
| 2000-01-09 | 1.906830 | 1.040044 |
| 2000-01-10 | 0.857021 | 1.193725 |

Passing a dict of lists will generate a MultiIndexed DataFrame with these selective transforms.

```
In [191]: tsdf.transform({'A': np.abs, 'B': [lambda x: x + 1, 'sqrt']})
Out[191]:
```

|            | A        | B        |          |
|------------|----------|----------|----------|
|            | absolute | <lambda> | sqrt     |
| 2000-01-01 | 1.807631 | 1.047273 | 0.217423 |
| 2000-01-02 | 0.749174 | 2.083498 | 1.040912 |
| 2000-01-03 | 1.309148 | 1.091291 | 0.302144 |
| 2000-01-04 | NaN      | NaN      | NaN      |
| 2000-01-05 | NaN      | NaN      | NaN      |
| 2000-01-06 | NaN      | NaN      | NaN      |
| 2000-01-07 | NaN      | NaN      | NaN      |
| 2000-01-08 | 1.159567 | 0.290114 | NaN      |
| 2000-01-09 | 1.906830 | 1.040044 | 0.200111 |
| 2000-01-10 | 0.857021 | 1.193725 | 0.440142 |

## 9.6.5 Applying Elementwise Functions

Since not all functions can be vectorized (accept NumPy arrays and return another array or value), the methods `applymap()` on `DataFrame` and analogously `map()` on `Series` accept any Python function taking a single value and returning a single value. For example:

```
In [192]: df4
Out[192]:
```

|   | one       | two       | three     |
|---|-----------|-----------|-----------|
| a | 0.491079  | -0.457939 | NaN       |
| b | -1.717454 | 1.150478  | 0.055990  |
| c | -0.663213 | 0.679724  | -0.899624 |
| d | NaN       | -1.607408 | -0.609688 |

```
In [193]: def f(x):
.....: return len(str(x))
.....:

In [194]: df4['one'].map(f)
Out[194]:
```

|   |    |
|---|----|
| a | 18 |
| b | 18 |
| c | 19 |
| d | 3  |

```
Name: one, dtype: int64

In [195]: df4.applymap(f)
```

(continues on next page)

(continued from previous page)

```

////////////////////////////////////Out[195]:
 one two three
a 18 19 3
b 18 18 19
c 19 18 19
d 3 19 19

```

`Series.map()` has an additional feature; it can be used to easily “link” or “map” values defined by a secondary series. This is closely related to *merging/joining functionality*:

```

In [196]: s = pd.Series(['six', 'seven', 'six', 'seven', 'six'],
.....: index=['a', 'b', 'c', 'd', 'e'])
.....:

In [197]: t = pd.Series({'six': 6., 'seven': 7.})

In [198]: s
Out[198]:
a six
b seven
c six
d seven
e six
dtype: object

In [199]: s.map(t)
////////////////////////////////////Out[199]:
↪
a 6.0
b 7.0
c 6.0
d 7.0
e 6.0
dtype: float64

```

## 9.7 Reindexing and altering labels

`reindex()` is the fundamental data alignment method in pandas. It is used to implement nearly all other features relying on label-alignment functionality. To *reindex* means to conform the data to match a given set of labels along a particular axis. This accomplishes several things:

- Reorders the existing data to match a new set of labels
- Inserts missing value (NA) markers in label locations where no data for that label existed
- If specified, **fill** data for missing labels using logic (highly relevant to working with time series data)

Here is a simple example:

```

In [200]: s = pd.Series(np.random.randn(5), index=['a', 'b', 'c', 'd', 'e'])

In [201]: s
Out[201]:
a 0.973238
b -0.188607

```

(continues on next page)

(continued from previous page)

```
c -1.599855
d 1.150115
e 0.326748
dtype: float64
```

```
In [202]: s.reindex(['e', 'b', 'f', 'd'])
```

```
Out [202]:
```

```
e 0.326748
b -0.188607
f NaN
d 1.150115
dtype: float64
```

Here, the `f` label was not contained in the Series and hence appears as `NaN` in the result.

With a `DataFrame`, you can simultaneously reindex the index and columns:

```
In [203]: df
```

```
Out [203]:
```

```
 one two three
a 0.491079 -0.457939 NaN
b -1.717454 1.150478 0.055990
c -0.663213 0.679724 -0.899624
d NaN -1.607408 -0.609688
```

```
In [204]: df.reindex(index=['c', 'f', 'b'], columns=['three', 'two', 'one'])
```

```
Out [204]:
```

```
 three two one
c -0.899624 0.679724 -0.663213
f NaN NaN NaN
b 0.055990 1.150478 -1.717454
```

You may also use `reindex` with an `axis` keyword:

```
In [205]: df.reindex(['c', 'f', 'b'], axis='index')
```

```
Out [205]:
```

```
 one two three
c -0.663213 0.679724 -0.899624
f NaN NaN NaN
b -1.717454 1.150478 0.055990
```

Note that the `Index` objects containing the actual axis labels can be **shared** between objects. So if we have a `Series` and a `DataFrame`, the following can be done:

```
In [206]: rs = s.reindex(df.index)
```

```
In [207]: rs
```

```
Out [207]:
```

```
a 0.973238
b -0.188607
c -1.599855
d 1.150115
dtype: float64
```

(continues on next page)

(continued from previous page)

```
In [208]: rs.index is df.index
Out[208]: True
```

This means that the reindexed Series's index is the same Python object as the DataFrame's index.

New in version 0.21.0.

`DataFrame.reindex()` also supports an “axis-style” calling convention, where you specify a single labels argument and the axis it applies to.

```
In [209]: df.reindex(['c', 'f', 'b'], axis='index')
Out[209]:
```

|   | one       | two      | three     |
|---|-----------|----------|-----------|
| c | -0.663213 | 0.679724 | -0.899624 |
| f | NaN       | NaN      | NaN       |
| b | -1.717454 | 1.150478 | 0.055990  |

```
In [210]: df.reindex(['three', 'two', 'one'], axis='columns')
Out[210]:
```

|   | three     | two       | one       |
|---|-----------|-----------|-----------|
| a | NaN       | -0.457939 | 0.491079  |
| b | 0.055990  | 1.150478  | -1.717454 |
| c | -0.899624 | 0.679724  | -0.663213 |
| d | -0.609688 | -1.607408 | NaN       |

**See also:**

*MultiIndex / Advanced Indexing* is an even more concise way of doing reindexing.

**Note:** When writing performance-sensitive code, there is a good reason to spend some time becoming a reindexing ninja: **many operations are faster on pre-aligned data**. Adding two unaligned DataFrames internally triggers a reindexing step. For exploratory analysis you will hardly notice the difference (because `reindex` has been heavily optimized), but when CPU cycles matter sprinkling a few explicit `reindex` calls here and there can have an impact.

## 9.7.1 Reindexing to align with another object

You may wish to take an object and reindex its axes to be labeled the same as another object. While the syntax for this is straightforward albeit verbose, it is a common enough operation that the `reindex_like()` method is available to make this simpler:

```
In [211]: df2
Out[211]:
```

|   | one       | two       |
|---|-----------|-----------|
| a | 0.491079  | -0.457939 |
| b | -1.717454 | 1.150478  |
| c | -0.663213 | 0.679724  |

```
In [212]: df3
Out[212]:
```

|   | one      | two       |
|---|----------|-----------|
| a | 1.120941 | -0.915360 |

(continues on next page)

(continued from previous page)

```
b -1.087591 0.693057
c -0.033350 0.222303
```

```
In [213]: df.reindex_like(df2)
```

```
////////////////////////////////////
↪
 one two
a 0.491079 -0.457939
b -1.717454 1.150478
c -0.663213 0.679724
```

## 9.7.2 Aligning objects with each other with `align`

The `align()` method is the fastest way to simultaneously align two objects. It supports a `join` argument (related to *joining and merging*):

- `join='outer'`: take the union of the indexes (default)
- `join='left'`: use the calling object's index
- `join='right'`: use the passed object's index
- `join='inner'`: intersect the indexes

It returns a tuple with both of the reindexed Series:

```
In [214]: s = pd.Series(np.random.randn(5), index=['a', 'b', 'c', 'd', 'e'])
```

```
In [215]: s1 = s[:4]
```

```
In [216]: s2 = s[1:]
```

```
In [217]: s1.align(s2)
```

```
Out[217]:
```

```
(a -0.638423
 b 1.987089
 c 1.202333
 d -0.294015
 e NaN
dtype: float64, a NaN
 b 1.987089
 c 1.202333
 d -0.294015
 e 1.178496
dtype: float64)
```

```
In [218]: s1.align(s2, join='inner')
```

```
////////////////////////////////////
↪
(b 1.987089
 c 1.202333
 d -0.294015
dtype: float64, b 1.987089
 c 1.202333
 d -0.294015
dtype: float64)
```

(continues on next page)

(continued from previous page)

```
In [219]: s1.align(s2, join='left')
```

```

////////////////////////////////////
↪
(a -0.638423
 b 1.987089
 c 1.202333
 d -0.294015
 dtype: float64, a NaN
 b 1.987089
 c 1.202333
 d -0.294015
 dtype: float64)

```

For DataFrames, the join method will be applied to both the index and the columns by default:

```
In [220]: df.align(df2, join='inner')
```

```
Out [220]:
```

```

(
 one two
a 0.491079 -0.457939
b -1.717454 1.150478
c -0.663213 0.679724, one two
a 0.491079 -0.457939
b -1.717454 1.150478
c -0.663213 0.679724)

```

You can also pass an axis option to only align on the specified axis:

```
In [221]: df.align(df2, join='inner', axis=0)
```

```
Out [221]:
```

```

(
 one two three
a 0.491079 -0.457939 NaN
b -1.717454 1.150478 0.055990
c -0.663213 0.679724 -0.899624, one two
a 0.491079 -0.457939
b -1.717454 1.150478
c -0.663213 0.679724)

```

If you pass a Series to `DataFrame.align()`, you can choose to align both objects either on the DataFrame's index or columns using the `axis` argument:

```
In [222]: df.align(df2.iloc[0], axis=1)
```

```
Out [222]:
```

```

(
 one three two
a 0.491079 NaN -0.457939
b -1.717454 0.055990 1.150478
c -0.663213 -0.899624 0.679724
d NaN -0.609688 -1.607408, one 0.491079
three NaN
two -0.457939
Name: a, dtype: float64)

```

### 9.7.3 Filling while reindexing

`reindex()` takes an optional parameter `method` which is a filling method chosen from the following table:

| Method           | Action                            |
|------------------|-----------------------------------|
| pad / ffill      | Fill values forward               |
| bfill / backfill | Fill values backward              |
| nearest          | Fill from the nearest index value |

We illustrate these fill methods on a simple Series:

```
In [223]: rng = pd.date_range('1/3/2000', periods=8)
```

```
In [224]: ts = pd.Series(np.random.randn(8), index=rng)
```

```
In [225]: ts2 = ts[[0, 3, 6]]
```

```
In [226]: ts
```

Out [226] :

```

2000-01-04 0.393647
2000-01-05 0.393647
2000-01-06 0.393647
2000-01-07 -0.222918
2000-01-08 -0.222918
2000-01-09 -0.222918
2000-01-10 NaN
Freq: D, dtype: float64
```

```
In [231]: ts2.reindex(ts.index, method='nearest')
```

```
2000-01-03 -0.350059
2000-01-04 -0.350059
2000-01-05 0.393647
2000-01-06 0.393647
2000-01-07 0.393647
2000-01-08 -0.222918
2000-01-09 -0.222918
2000-01-10 -0.222918
Freq: D, dtype: float64
```

These methods require that the indexes are **ordered** increasing or decreasing.

Note that the same result could have been achieved using *fillna* (except for `method='nearest'`) or *interpolate*:

```
In [232]: ts2.reindex(ts.index).fillna(method='ffill')
```

```
Out [232]:
2000-01-03 -0.350059
2000-01-04 -0.350059
2000-01-05 -0.350059
2000-01-06 0.393647
2000-01-07 0.393647
2000-01-08 0.393647
2000-01-09 -0.222918
2000-01-10 -0.222918
Freq: D, dtype: float64
```

`reindex()` will raise a `ValueError` if the index is not monotonically increasing or decreasing. `fillna()` and `interpolate()` will not perform any checks on the order of the index.

### 9.7.4 Limits on filling while reindexing

The `limit` and `tolerance` arguments provide additional control over filling while reindexing. `Limit` specifies the maximum count of consecutive matches:

```
In [233]: ts2.reindex(ts.index, method='ffill', limit=1)
```

```
Out [233]:
```

(continues on next page)

(continued from previous page)

```
2000-01-03 -0.350059
2000-01-04 -0.350059
2000-01-05 NaN
2000-01-06 0.393647
2000-01-07 0.393647
2000-01-08 NaN
2000-01-09 -0.222918
2000-01-10 -0.222918
Freq: D, dtype: float64
```

In contrast, tolerance specifies the maximum distance between the index and indexer values:

```
In [234]: ts2.reindex(ts.index, method='ffill', tolerance='1 day')
Out [234]:
2000-01-03 -0.350059
2000-01-04 -0.350059
2000-01-05 NaN
2000-01-06 0.393647
2000-01-07 0.393647
2000-01-08 NaN
2000-01-09 -0.222918
2000-01-10 -0.222918
Freq: D, dtype: float64
```

Notice that when used on a `DatetimeIndex`, `TimedeltaIndex` or `PeriodIndex`, `tolerance` will be coerced into a `Timedelta` if possible. This allows you to specify `tolerance` with appropriate strings.

### 9.7.5 Dropping labels from an axis

A method closely related to `reindex` is the `drop()` function. It removes a set of labels from an axis:

```
In [235]: df
Out[235]:
```

|   | one       | two       | three     |
|---|-----------|-----------|-----------|
| a | 0.491079  | -0.457939 | NaN       |
| b | -1.717454 | 1.150478  | 0.055990  |
| c | -0.663213 | 0.679724  | -0.899624 |
| d | NaN       | -1.607408 | -0.609688 |

```
In [236]: df.drop(['a', 'd'], axis=0)
↩
```

|   | one       | two      | three     |
|---|-----------|----------|-----------|
| b | -1.717454 | 1.150478 | 0.055990  |
| c | -0.663213 | 0.679724 | -0.899624 |

```
In [237]: df.drop(['one'], axis=1)
↩
```

|   | two       | three     |
|---|-----------|-----------|
| a | -0.457939 | NaN       |
| b | 1.150478  | 0.055990  |
| c | 0.679724  | -0.899624 |
| d | -1.607408 | -0.609688 |

Note that the following also works, but is a bit less obvious / clean:

```
In [238]: df.reindex(df.index.difference(['a', 'd']))
Out[238]:
```

|   | one       | two      | three     |
|---|-----------|----------|-----------|
| b | -1.717454 | 1.150478 | 0.055990  |
| c | -0.663213 | 0.679724 | -0.899624 |

## 9.7.6 Renaming / mapping labels

The `rename()` method allows you to relabel an axis based on some mapping (a dict or Series) or an arbitrary function.

```
In [239]: s
Out[239]:
```

| a | -0.638423 |
|---|-----------|
| b | 1.987089  |
| c | 1.202333  |
| d | -0.294015 |
| e | 1.178496  |

dtype: float64

```
In [240]: s.rename(str.upper)
Out[240]:
```

| A | -0.638423 |
|---|-----------|
| B | 1.987089  |
| C | 1.202333  |
| D | -0.294015 |
| E | 1.178496  |

dtype: float64

If you pass a function, it must return a value when called with any of the labels (and must produce a set of unique values). A dict or Series can also be used:

```
In [241]: df.rename(columns={'one': 'foo', 'two': 'bar'},
.....: index={'a': 'apple', 'b': 'banana', 'd': 'durian'})
Out[241]:
```

|        | foo       | bar       | three     |
|--------|-----------|-----------|-----------|
| apple  | 0.491079  | -0.457939 | NaN       |
| banana | -1.717454 | 1.150478  | 0.055990  |
| c      | -0.663213 | 0.679724  | -0.899624 |
| durian | NaN       | -1.607408 | -0.609688 |

If the mapping doesn't include a column/index label, it isn't renamed. Note that extra labels in the mapping don't throw an error.

New in version 0.21.0.

`DataFrame.rename()` also supports an “axis-style” calling convention, where you specify a single mapper and the axis to apply that mapping to.

```
In [242]: df.rename({'one': 'foo', 'two': 'bar'}, axis='columns')
Out[242]:
```

|   | foo       | bar       | three     |
|---|-----------|-----------|-----------|
| a | 0.491079  | -0.457939 | NaN       |
| b | -1.717454 | 1.150478  | 0.055990  |
| c | -0.663213 | 0.679724  | -0.899624 |

(continues on next page)

(continued from previous page)

```

d NaN -1.607408 -0.609688

In [243]: df.rename({'a': 'apple', 'b': 'banana', 'd': 'durian'}, axis='index')
///
↪

```

|        | one       | two       | three     |
|--------|-----------|-----------|-----------|
| apple  | 0.491079  | -0.457939 | NaN       |
| banana | -1.717454 | 1.150478  | 0.055990  |
| c      | -0.663213 | 0.679724  | -0.899624 |
| durian | NaN       | -1.607408 | -0.609688 |

The `rename()` method also provides an `inplace` named parameter that is by default `False` and copies the underlying data. Pass `inplace=True` to rename the data in place.

New in version 0.18.0.

Finally, `rename()` also accepts a scalar or list-like for altering the `Series.name` attribute.

```

In [244]: s.rename("scalar-name")
Out[244]:
a -0.638423
b 1.987089
c 1.202333
d -0.294015
e 1.178496
Name: scalar-name, dtype: float64

```

New in version 0.24.0.

The methods `rename_axis()` and `rename_axis()` allow specific names of a *MultiIndex* to be changed (as opposed to the labels).

```

In [245]: df = pd.DataFrame({'x': [1, 2, 3, 4, 5, 6],
.....: 'y': [10, 20, 30, 40, 50, 60]},
.....: index=pd.MultiIndex.from_product([['a', 'b', 'c'], [1, 2]],
↪ names=['let', 'num']))

In [246]: df
Out[246]:

```

|   |   | x | y  |
|---|---|---|----|
| a | 1 | 1 | 10 |
|   | 2 | 2 | 20 |
| b | 1 | 3 | 30 |
|   | 2 | 4 | 40 |
| c | 1 | 5 | 50 |
|   | 2 | 6 | 60 |

```

In [247]: df.rename_axis(index={'let': 'abc'})
///
↪

```

|     |     | x | y  |
|-----|-----|---|----|
| abc | num |   |    |
| a   | 1   | 1 | 10 |
|     | 2   | 2 | 20 |

(continues on next page)

(continued from previous page)

```

b 1 3 30
 2 4 40
c 1 5 50
 2 6 60

```

```
In [248]: df.rename_axis(index=str.upper)
```

```

////////////////////////////////////

```

```
↪
```

```

 x y
LET NUM
a 1 1 10
 2 2 20
b 1 3 30
 2 4 40
c 1 5 50
 2 6 60

```

## 9.8 Iteration

The behavior of basic iteration over pandas objects depends on the type. When iterating over a Series, it is regarded as array-like, and basic iteration produces the values. Other data structures, like DataFrame and Panel, follow the dict-like convention of iterating over the “keys” of the objects.

In short, basic iteration (`for i in object`) produces:

- **Series:** values
- **DataFrame:** column labels
- **Panel:** item labels

Thus, for example, iterating over a DataFrame gives you the column names:

```

In [249]: df = pd.DataFrame({'col1': np.random.randn(3),
.....: 'col2': np.random.randn(3)}, index=['a', 'b', 'c'])
.....:

In [250]: for col in df:
.....: print(col)
.....:
col1
col2

```

Pandas objects also have the dict-like `iteritems()` method to iterate over the (key, value) pairs.

To iterate over the rows of a DataFrame, you can use the following methods:

- `iterrows()`: Iterate over the rows of a DataFrame as (index, Series) pairs. This converts the rows to Series objects, which can change the dtypes and has some performance implications.
- `itertuples()`: Iterate over the rows of a DataFrame as namedtuples of the values. This is a lot faster than `iterrows()`, and is in most cases preferable to use to iterate over the values of a DataFrame.

**Warning:** Iterating through pandas objects is generally **slow**. In many cases, iterating manually over the rows is not needed and can be avoided with one of the following approaches:

- Look for a *vectorized* solution: many operations can be performed using built-in methods or NumPy functions, (boolean) indexing, ...
- When you have a function that cannot work on the full DataFrame/Series at once, it is better to use `apply()` instead of iterating over the values. See the docs on *function application*.
- If you need to do iterative manipulations on the values but performance is important, consider writing the inner loop with cython or numba. See the *enhancing performance* section for some examples of this approach.

**Warning:** You should **never modify** something you are iterating over. This is not guaranteed to work in all cases. Depending on the data types, the iterator returns a copy and not a view, and writing to it will have no effect!

For example, in the following case setting the value has no effect:

```
In [251]: df = pd.DataFrame({'a': [1, 2, 3], 'b': ['a', 'b', 'c']})

In [252]: for index, row in df.iterrows():
.....: row['a'] = 10
.....:

In [253]: df
Out[253]:
 a b
0 1 a
1 2 b
2 3 c
```

### 9.8.1 iteritems

Consistent with the dict-like interface, `iteritems()` iterates through key-value pairs:

- **Series:** (index, scalar value) pairs
- **DataFrame:** (column, Series) pairs
- **Panel:** (item, DataFrame) pairs

For example:

```
In [254]: for item, frame in wp.iteritems():
.....: print(item)
.....: print(frame)
.....:
```

Item1

|            | A         | B         | C         | D         |
|------------|-----------|-----------|-----------|-----------|
| 2000-01-01 | -1.339362 | -1.481140 | -1.709077 | -0.530151 |
| 2000-01-02 | 0.410069  | -1.476497 | 0.119285  | -0.969678 |
| 2000-01-03 | 0.053252  | 1.045977  | -0.866711 | 0.815461  |
| 2000-01-04 | 2.153828  | -0.840474 | -1.003657 | -0.397531 |
| 2000-01-05 | -0.815288 | -0.855682 | 0.522406  | 0.321976  |

Item2

|            | A         | B         | C         | D         |
|------------|-----------|-----------|-----------|-----------|
| 2000-01-01 | -0.943681 | -1.339727 | -0.546112 | -0.991064 |
| 2000-01-02 | 0.758942  | -0.125619 | 1.193632  | -1.114847 |
| 2000-01-03 | -0.421906 | -0.836575 | 0.713583  | 1.837874  |

(continues on next page)

(continued from previous page)

```
2000-01-04 0.220064 -0.039839 -0.298747 0.854274
2000-01-05 1.239680 0.189073 -1.848990 0.617732
```

### 9.8.2 iterrows

`iterrows()` allows you to iterate through the rows of a `DataFrame` as `Series` objects. It returns an iterator yielding each index value along with a `Series` containing the data in each row:

```
In [255]: for row_index, row in df.iterrows():
.....: print(row_index, row, sep='\n')
.....:
0
a 1
b a
Name: 0, dtype: object
1
a 2
b b
Name: 1, dtype: object
2
a 3
b c
Name: 2, dtype: object
```

**Note:** Because `iterrows()` returns a `Series` for each row, it does **not** preserve dtypes across the rows (dtypes are preserved across columns for `DataFrames`). For example,

```
In [256]: df_orig = pd.DataFrame([[1, 1.5]], columns=['int', 'float'])

In [257]: df_orig.dtypes
Out[257]:
int int64
float float64
dtype: object

In [258]: row = next(df_orig.iterrows())[1]

In [259]: row
Out[259]:
int 1.0
float 1.5
Name: 0, dtype: float64
```

All values in `row`, returned as a `Series`, are now upcasted to floats, also the original integer value in column `x`:

```
In [260]: row['int'].dtype
Out[260]: dtype('float64')

In [261]: df_orig['int'].dtype
Out[261]: dtype('int64')
```

To preserve dtypes while iterating over the rows, it is better to use `itertuples()` which returns `namedtuples` of the values and which is generally much faster than `iterrows()`.

For instance, a contrived way to transpose the DataFrame would be:

```
In [262]: df2 = pd.DataFrame({'x': [1, 2, 3], 'y': [4, 5, 6]})

In [263]: print(df2)
 x y
0 1 4
1 2 5
2 3 6

In [264]: print(df2.T)
\\repeated slashes\\ 0 1 2
x 1 2 3
y 4 5 6

In [265]: df2_t = pd.DataFrame({idx: values for idx, values in df2.iterrows()})

In [266]: print(df2_t)
 0 1 2
x 1 2 3
y 4 5 6
```

### 9.8.3 itertuples

The `itertuples()` method will return an iterator yielding a `namedtuple` for each row in the `DataFrame`. The first element of the tuple will be the row's corresponding index value, while the remaining values are the row values.

For instance:

```
In [267]: for row in df.itertuples():
.....: print(row)
.....:
Pandas(Index=0, a=1, b='a')
Pandas(Index=1, a=2, b='b')
Pandas(Index=2, a=3, b='c')
```

This method does not convert the row to a Series object; it merely returns the values inside a namedtuple. Therefore, `itertuples()` preserves the data type of the values and is generally faster as `iterrows()`.

**Note:** The column names will be renamed to positional names if they are invalid Python identifiers, repeated, or start with an underscore. With a large number of columns (>255), regular tuples are returned.

## 9.9 .dt accessor

`Series` has an accessor to succinctly return datetime like properties for the *values* of the `Series`, if it is a date-time/period like `Series`. This will return a `Series`, indexed like the existing `Series`.

```
datetime
In [268]: s = pd.Series(pd.date_range('20130101 09:10:12', periods=4))

In [269]: s
Out[269]:
```

(continues on next page)

(continued from previous page)

```

0 2013-01-01 09:10:12
1 2013-01-02 09:10:12
2 2013-01-03 09:10:12
3 2013-01-04 09:10:12
dtype: datetime64[ns]

```

```
In [270]: s.dt.hour
```

```

0 9
1 9
2 9
3 9
dtype: int64

```

```
In [271]: s.dt.second
```

```

0 12
1 12
2 12
3 12
dtype: int64

```

```
In [272]: s.dt.day
```

```

0 1
1 2
2 3
3 4
dtype: int64

```

This enables nice expressions like this:

```
In [273]: s[s.dt.day == 2]
```

```

Out[273]:
1 2013-01-02 09:10:12
dtype: datetime64[ns]

```

You can easily produces tz aware transformations:

```
In [274]: stz = s.dt.tz_localize('US/Eastern')
```

```
In [275]: stz
```

```

Out[275]:
0 2013-01-01 09:10:12-05:00
1 2013-01-02 09:10:12-05:00
2 2013-01-03 09:10:12-05:00
3 2013-01-04 09:10:12-05:00
dtype: datetime64[ns, US/Eastern]

```

```
In [276]: stz.dt.tz
```

```

<DstTzInfo 'US/Eastern' LMT-1 day, 19:04:00 STD>

```

You can also chain these types of operations:

```
In [277]: s.dt.tz_localize('UTC').dt.tz_convert('US/Eastern')
Out[277]:
0 2013-01-01 04:10:12-05:00
1 2013-01-02 04:10:12-05:00
2 2013-01-03 04:10:12-05:00
3 2013-01-04 04:10:12-05:00
dtype: datetime64[ns, US/Eastern]
```

You can also format datetime values as strings with `Series.dt.strftime()` which supports the same format as the standard `strftime()`.

```
DatetimeIndex
In [278]: s = pd.Series(pd.date_range('20130101', periods=4))

In [279]: s
Out[279]:
0 2013-01-01
1 2013-01-02
2 2013-01-03
3 2013-01-04
dtype: datetime64[ns]

In [280]: s.dt.strftime('%Y/%m/%d')
Out[280]:
0 2013/01/01
1 2013/01/02
2 2013/01/03
3 2013/01/04
dtype: object
```

```
PeriodIndex
In [281]: s = pd.Series(pd.period_range('20130101', periods=4))

In [282]: s
Out[282]:
0 2013-01-01
1 2013-01-02
2 2013-01-03
3 2013-01-04
dtype: period[D]

In [283]: s.dt.strftime('%Y/%m/%d')
Out[283]:
0 2013/01/01
1 2013/01/02
2 2013/01/03
3 2013/01/04
dtype: object
```

The `.dt` accessor works for period and timedelta dtypes.

```
period
In [284]: s = pd.Series(pd.period_range('20130101', periods=4, freq='D'))

In [285]: s
```

|   | days | hours | minutes | seconds | milliseconds | microseconds | nanoseconds |
|---|------|-------|---------|---------|--------------|--------------|-------------|
| 0 | 1    | 0     | 0       | 5       | 0            | 0            | 0           |
| 1 | 1    | 0     | 0       | 6       | 0            | 0            | 0           |
| 2 | 1    | 0     | 0       | 7       | 0            | 0            | 0           |
| 3 | 1    | 0     | 0       | 8       | 0            | 0            | 0           |

**Note:** `Series.dt` will raise a `TypeError` if you access with a non-datetime-like values.

## 9.10 Vectorized string methods

`Series` is equipped with a set of string processing methods that make it easy to operate on each element of the array. Perhaps most importantly, these methods exclude missing/NA values automatically. These are accessed via the `Series`'s `str` attribute and generally have names matching the equivalent (scalar) built-in string methods. For example:

```
In [293]: s = pd.Series(['A', 'B', 'C', 'Aaba', 'Baca', np.nan, 'CABA', 'dog',
→, 'cat'])

In [294]: s.str.lower()
Out[294]:
0 a
1 b
2 c
3 aaba
4 baca
5 NaN
6 caba
7 dog
8 cat
dtype: object
```

Powerful pattern-matching methods are provided as well, but note that pattern-matching generally uses [regular expressions](#) by default (and in some cases always uses them).

Please see *Vectorized String Methods* for a complete description.

## 9.11 Sorting

Pandas supports three kinds of sorting: sorting by index labels, sorting by column values, and sorting by a combination of both.

### 9.11.1 By Index

The `Series.sort_index()` and `DataFrame.sort_index()` methods are used to sort a pandas object by its index levels.

```
In [295]: df = pd.DataFrame({
.....: 'one': pd.Series(np.random.randn(3), index=['a', 'b', 'c']),
.....: 'two': pd.Series(np.random.randn(4), index=['a', 'b', 'c', 'd']),
.....: 'three': pd.Series(np.random.randn(3), index=['b', 'c', 'd'])})
```

(continues on next page)

(continued from previous page)

```

.....:

In [296]: unsorted_df = df.reindex(index=['a', 'd', 'c', 'b'],
.....: columns=['three', 'two', 'one'])
.....:

In [297]: unsorted_df
Out[297]:
 three two one
a NaN 0.237012 -0.200147
d -0.725224 0.191147 NaN
c 0.131799 0.935521 0.847987
b -0.135232 0.716850 0.471782

DataFrame
In [298]: unsorted_df.sort_index()
////////////////////////////////////
↪
 three two one
a NaN 0.237012 -0.200147
b -0.135232 0.716850 0.471782
c 0.131799 0.935521 0.847987
d -0.725224 0.191147 NaN

In [299]: unsorted_df.sort_index(ascending=False)
////////////////////////////////////
↪
 three two one
d -0.725224 0.191147 NaN
c 0.131799 0.935521 0.847987
b -0.135232 0.716850 0.471782
a NaN 0.237012 -0.200147

In [300]: unsorted_df.sort_index(axis=1)
////////////////////////////////////
↪

a -0.200147 NaN 0.237012
d NaN -0.725224 0.191147
c 0.847987 0.131799 0.935521
b 0.471782 -0.135232 0.716850

Series
In [301]: unsorted_df['three'].sort_index()
////////////////////////////////////
↪
a NaN
b -0.135232
c 0.131799
d -0.725224
Name: three, dtype: float64

```

### 9.11.2 By Values

The `Series.sort_values()` method is used to sort a *Series* by its values. The `DataFrame.sort_values()` method is used to sort a *DataFrame* by its column or row values. The optional `by` parameter to `DataFrame`.

`sort_values()` may used to specify one or more columns to use to determine the sorted order.

```
In [302]: df1 = pd.DataFrame({'one': [2, 1, 1, 1],
.....: 'two': [1, 3, 2, 4],
.....: 'three': [5, 4, 3, 2]})
.....:

In [303]: df1.sort_values(by='two')
Out[303]:
```

|   | one | two | three |
|---|-----|-----|-------|
| 0 | 2   | 1   | 5     |
| 2 | 1   | 2   | 3     |
| 1 | 1   | 3   | 4     |
| 3 | 1   | 4   | 2     |

The `by` parameter can take a list of column names, e.g.:

```
In [304]: df1[['one', 'two', 'three']].sort_values(by=['one', 'two'])
Out[304]:
```

|   | one | two | three |
|---|-----|-----|-------|
| 2 | 1   | 2   | 3     |
| 1 | 1   | 3   | 4     |
| 3 | 1   | 4   | 2     |
| 0 | 2   | 1   | 5     |

These methods have special treatment of NA values via the `na_position` argument:

```
In [305]: s[2] = np.nan

In [306]: s.sort_values()
Out[306]:
```

|   |      |
|---|------|
| 0 | A    |
| 3 | Aaba |
| 1 | B    |
| 4 | Baca |
| 6 | CABA |
| 8 | cat  |
| 7 | dog  |
| 2 | NaN  |
| 5 | NaN  |

dtype: object

```
In [307]: s.sort_values(na_position='first')
```

////////////////////////////////////

```
↪
```

|   |      |
|---|------|
| 2 | NaN  |
| 5 | NaN  |
| 0 | A    |
| 3 | Aaba |
| 1 | B    |
| 4 | Baca |
| 6 | CABA |
| 8 | cat  |
| 7 | dog  |

dtype: object

### 9.11.3 By Indexes and Values

New in version 0.23.0.

Strings passed as the `by` parameter to `DataFrame.sort_values()` may refer to either columns or index level names.

```
Build MultiIndex
In [308]: idx = pd.MultiIndex.from_tuples([('a', 1), ('a', 2), ('a', 2),
.....: ('b', 2), ('b', 1), ('b', 1)])
.....:

In [309]: idx.names = ['first', 'second']

Build DataFrame
In [310]: df_multi = pd.DataFrame({'A': np.arange(6, 0, -1)},
.....: index=idx)
.....:

In [311]: df_multi
Out[311]:
```

|       |        | A |
|-------|--------|---|
| first | second |   |
| a     | 1      | 6 |
|       | 2      | 5 |
|       | 2      | 4 |
| b     | 2      | 3 |
|       | 1      | 2 |
|       | 1      | 1 |

Sort by 'second' (index) and 'A' (column)

```
In [312]: df_multi.sort_values(by=['second', 'A'])
Out[312]:
```

|       |        | A |
|-------|--------|---|
| first | second |   |
| b     | 1      | 1 |
|       | 1      | 2 |
| a     | 1      | 6 |
| b     | 2      | 3 |
| a     | 2      | 4 |
|       | 2      | 5 |

**Note:** If a string matches both a column name and an index level name then a warning is issued and the column takes precedence. This will result in an ambiguity error in a future version.

### 9.11.4 searchsorted

Series has the `searchsorted()` method, which works similarly to `numpy.ndarray.searchsorted()`.

```
In [313]: ser = pd.Series([1, 2, 3])

In [314]: ser.searchsorted([0, 3])
Out[314]: array([0, 2])
```

(continues on next page)

(continued from previous page)

```
In [315]: ser.searchsorted([0, 4])
Out[315]: array([0, 3])

In [316]: ser.searchsorted([1, 3], side='right')
Out[316]: array([1, 3])

In [317]: ser.searchsorted([1, 3], side='left')
Out[317]: array([0, 2])

In [318]: ser = pd.Series([3, 1, 2])

In [319]: ser.searchsorted([0, 3], sorter=np.argsort(ser))
Out[319]: array([0, 2])
```

### 9.11.5 smallest / largest values

`Series` has the `nsmallest()` and `nlargest()` methods which return the smallest or largest  $n$  values. For a large `Series` this can be much faster than sorting the entire `Series` and calling `head(n)` on the result.

```
In [320]: s = pd.Series(np.random.permutation(10))

In [321]: s
Out[321]:
0 3
1 1
2 5
3 7
4 6
5 0
6 9
7 8
8 2
9 4
dtype: int64

In [322]: s.sort_values()
Out[322]:
5 0
1 1
8 2
0 3
9 4
2 5
4 6
3 7
7 8
6 9
dtype: int64

In [323]: s.nsmallest(3)
Out[323]:
5 0
1 1
8 2
dtype: int64
```

(continues on next page)

(continued from previous page)

```

5 0
1 1
8 2
dtype: int64

```

```
In [324]: s.nlargest(3)
```

```

////////////////////////////////////
↪
6 9
7 8
3 7
dtype: int64

```

DataFrame also has the `nlargest` and `nsmallest` methods.

```
In [325]: df = pd.DataFrame({'a': [-2, -1, 1, 10, 8, 11, -1],
.....: 'b': list('abdceff'),
.....: 'c': [1.0, 2.0, 4.0, 3.2, np.nan, 3.0, 4.0]})
.....:
```

```
In [326]: df.nlargest(3, 'a')
```

```
Out[326]:
 a b c
5 11 f 3.0
3 10 c 3.2
4 8 e NaN
```

```
In [327]: df.nlargest(5, ['a', 'c'])
```

```

////////////////////////////////////Out[327]:
 a b c
5 11 f 3.0
3 10 c 3.2
4 8 e NaN
2 1 d 4.0
6 -1 f 4.0

```

```
In [328]: df.nsmallest(3, 'a')
```

```

////////////////////////////////////
↪
 a b c
0 -2 a 1.0
1 -1 b 2.0
6 -1 f 4.0

```

```
In [329]: df.nsmallest(5, ['a', 'c'])
```

```

////////////////////////////////////
↪
 a b c
0 -2 a 1.0
1 -1 b 2.0
6 -1 f 4.0
2 1 d 4.0
4 8 e NaN

```

### 9.11.6 Sorting by a MultiIndex column

You must be explicit about sorting when the column is a MultiIndex, and fully specify all levels to `by`.

```
In [330]: df1.columns = pd.MultiIndex.from_tuples([('a', 'one'),
.....: ('a', 'two'),
.....: ('b', 'three')])
.....:

In [331]: df1.sort_values(by=('a', 'two'))
Out[331]:
```

|   | a   | b   |       |
|---|-----|-----|-------|
|   | one | two | three |
| 0 | 2   | 1   | 5     |
| 2 | 1   | 2   | 3     |
| 1 | 1   | 3   | 4     |
| 3 | 1   | 4   | 2     |

## 9.12 Copying

The `copy()` method on pandas objects copies the underlying data (though not the axis indexes, since they are immutable) and returns a new object. Note that **it is seldom necessary to copy objects**. For example, there are only a handful of ways to alter a DataFrame *in-place*:

- Inserting, deleting, or modifying a column.
- Assigning to the `index` or `columns` attributes.
- For homogeneous data, directly modifying the values via the `values` attribute or advanced indexing.

To be clear, no pandas method has the side effect of modifying your data; almost every method returns a new object, leaving the original object untouched. If the data is modified, it is because you did so explicitly.

## 9.13 dtypes

For the most part, pandas uses NumPy arrays and dtypes for Series or individual columns of a DataFrame. NumPy provides support for `float`, `int`, `bool`, `timedelta64[ns]` and `datetime64[ns]` (note that NumPy does not support timezone-aware datetimes).

Pandas and third-party libraries *extend* NumPy's type system in a few places. This section describes the extensions pandas has made internally. See *Extension Types* for how to write your own extension that works with pandas. See *Extension Data Types* for a list of third-party libraries that have implemented an extension.

The following table lists all of pandas extension types. See the respective documentation sections for more on each type.

| Kind of Data        | Data Type        | Scalar    | Array                    | Documentation                     |
|---------------------|------------------|-----------|--------------------------|-----------------------------------|
| tz-aware date-time  | DatetimeTZDtype  | Timestamp | arrays.<br>DatetimeArray | <i>Time Zone Handling</i>         |
| Categorical         | CategoricalDtype | (none)    | Categorical              | categorical                       |
| period (time spans) | PeriodDtype      | Period    | arrays.<br>PeriodArray   | <i>Time Span Representation</i>   |
| sparse              | SparseDtype      | (none)    | arrays.<br>SparseArray   | sparse                            |
| intervals           | IntervalDtype    | Interval  | arrays.<br>IntervalArray | <i>IntervalIndex</i>              |
| nullable integer    | Int64Dtype, ...  | (none)    | arrays.<br>IntegerArray  | <i>Nullable Integer Data Type</i> |

Pandas uses the object dtype for storing strings.

Finally, arbitrary objects may be stored using the object dtype, but should be avoided to the extent possible (for performance and interoperability with other libraries and methods. See *object conversion*).

A convenient dtypes attribute for DataFrame returns a Series with the data type of each column.

```
In [332]: dft = pd.DataFrame({'A': np.random.rand(3),
.....: 'B': 1,
.....: 'C': 'foo',
.....: 'D': pd.Timestamp('20010102'),
.....: 'E': pd.Series([1.0] * 3).astype('float32'),
.....: 'F': False,
.....: 'G': pd.Series([1] * 3, dtype='int8')})
.....:
```

```
In [333]: dft
```

```
Out [333]:
```

|   | A        | B | C   | D          | E   | F     | G |
|---|----------|---|-----|------------|-----|-------|---|
| 0 | 0.140868 | 1 | foo | 2001-01-02 | 1.0 | False | 1 |
| 1 | 0.016430 | 1 | foo | 2001-01-02 | 1.0 | False | 1 |
| 2 | 0.616327 | 1 | foo | 2001-01-02 | 1.0 | False | 1 |

```
In [334]: dft.dtypes
```

```

////////////////////////////////////
↪
A float64
B int64
C object
D datetime64[ns]
E float32
F bool
G int8
dtype: object
```

On a Series object, use the dtype attribute.

```
In [335]: dft['A'].dtype
Out [335]: dtype('float64')
```

If a pandas object contains data with multiple dtypes *in a single column*, the dtype of the column will be chosen to accommodate all of the data types (object is the most general).

```
these ints are coerced to floats
In [336]: pd.Series([1, 2, 3, 4, 5, 6.])
Out[336]:
0 1.0
1 2.0
2 3.0
3 4.0
4 5.0
5 6.0
dtype: float64

string data forces an ``object`` dtype
In [337]: pd.Series([1, 2, 3, 6., 'foo'])
Out[337]:
0 1
1 2
2 3
3 6
4 foo
dtype: object
```

The number of columns of each type in a DataFrame can be found by calling `get_dtype_counts()`.

```
In [338]: dft.get_dtype_counts()
Out[338]:
float64 1
float32 1
int64 1
int8 1
datetime64[ns] 1
bool 1
object 1
dtype: int64
```

Numeric dtypes will propagate and can coexist in DataFrames. If a dtype is passed (either directly via the `dtype` keyword, a passed `ndarray`, or a passed `Series`, then it will be preserved in DataFrame operations. Furthermore, different numeric dtypes will **NOT** be combined. The following example will give you a taste.

```
In [339]: df1 = pd.DataFrame(np.random.randn(8, 1), columns=['A'], dtype='float32')

In [340]: df1
Out[340]:
 A
0 0.241459
1 -1.905493
2 0.875040
3 0.397489
4 0.016893
5 -0.230517
6 -0.105347
7 -0.154539

In [341]: df1.dtypes
Out[341]:
A float32
```

(continues on next page)

(continued from previous page)

```
dtype: object

In [342]: df2 = pd.DataFrame({'A': pd.Series(np.random.randn(8), dtype='float16'),
.....: 'B': pd.Series(np.random.randn(8)),
.....: 'C': pd.Series(np.array(np.random.randn(8),
.....: dtype='uint8'))})

In [343]: df2
Out[343]:
```

|   | A         | B        | C   |
|---|-----------|----------|-----|
| 0 | -0.581055 | 1.778026 | 0   |
| 1 | -1.198242 | 1.251536 | 1   |
| 2 | 0.199097  | 0.618643 | 0   |
| 3 | 0.476074  | 0.159498 | 0   |
| 4 | -0.023560 | 1.263693 | 0   |
| 5 | 0.360596  | 0.711871 | 255 |
| 6 | 0.545898  | 0.638791 | 0   |
| 7 | 0.570801  | 0.535610 | 0   |

```

In [344]: df2.dtypes
//////////

C uint8
dtype: object
```

### 9.13.1 defaults

By default integer types are `int64` and float types are `float64`, *regardless* of platform (32-bit or 64-bit). The following will all result in `int64` dtypes.

[illegible]

Note that Numpy will choose *platform-dependent* types when creating arrays. The following **WILL** result in `int32` on 32-bit platform.

```
In [348]: frame = pd.DataFrame(np.array([1, 2]))
```

### 9.13.2 upcasting

Types can potentially be *upcasted* when combined with other types, meaning they are promoted from the current type (e.g. int to float).

```
In [349]: df3 = df1.reindex_like(df2).fillna(value=0.0) + df2
```

```
In [350]: df3
```

```
Out [350]:
```

|   | A         | B        | C     |
|---|-----------|----------|-------|
| 0 | -0.339596 | 1.778026 | 0.0   |
| 1 | -3.103735 | 1.251536 | 1.0   |
| 2 | 1.074136  | 0.618643 | 0.0   |
| 3 | 0.873563  | 0.159498 | 0.0   |
| 4 | -0.006667 | 1.263693 | 0.0   |
| 5 | 0.130079  | 0.711871 | 255.0 |
| 6 | 0.440551  | 0.638791 | 0.0   |
| 7 | 0.416261  | 0.535610 | 0.0   |

```
In [351]: df3.dtypes
```

```

////////////////////////////////////
↪
A float32
B float64
C float64
dtype: object

```

`DataFrame.to_numpy()` will return the *lower-common-denominator* of the dtypes, meaning the dtype that can accommodate **ALL** of the types in the resulting homogeneous typed NumPy array. This can force some *upcasting*.

```
In [352]: df3.to_numpy().dtype
```

```
Out [352]: dtype('float64')
```

### 9.13.3 astype

You can use the `astype()` method to explicitly convert dtypes from one to another. These will by default return a copy, even if the dtype was unchanged (pass `copy=False` to change this behavior). In addition, they will raise an exception if the `astype` operation is invalid.

Upcasting is always according to the **numpy** rules. If two different dtypes are involved in an operation, then the more *general* one will be used as the result of the operation.

```
In [353]: df3
```

```
Out [353]:
```

|   | A         | B        | C     |
|---|-----------|----------|-------|
| 0 | -0.339596 | 1.778026 | 0.0   |
| 1 | -3.103735 | 1.251536 | 1.0   |
| 2 | 1.074136  | 0.618643 | 0.0   |
| 3 | 0.873563  | 0.159498 | 0.0   |
| 4 | -0.006667 | 1.263693 | 0.0   |
| 5 | 0.130079  | 0.711871 | 255.0 |
| 6 | 0.440551  | 0.638791 | 0.0   |
| 7 | 0.416261  | 0.535610 | 0.0   |

```
In [354]: df3.dtypes
```

```

////////////////////////////////////
↪

```

(continues on next page)

(continued from previous page)

```
A float32
B float64
C float64
dtype: object
```

```
conversion of dtypes
```

```
In [355]: df3.astype('float32').dtypes
```

---

```
A float32
B float32
C float32
dtype: object
```

Convert a subset of columns to a specified type using `astype()`.

```
In [356]: dft = pd.DataFrame({'a': [1, 2, 3], 'b': [4, 5, 6], 'c': [7, 8, 9]})
```

```
In [357]: dft[['a', 'b']] = dft[['a', 'b']].astype(np.uint8)
```

```
In [358]: dft
```

Out [358] :

|   | a | b | c |
|---|---|---|---|
| 0 | 1 | 4 | 7 |
| 1 | 2 | 5 | 8 |
| 2 | 3 | 6 | 9 |

```
In [359]: dft.dtypes
```

```
Out[359]:
```

```
a uint8
```

```
b uint8
```

```
c int64
```

```
dtype: object
```

New in version 0.19.0.

Convert certain columns to a specific dtype by passing a dict to `astype()`.

```
In [360]: dft1 = pd.DataFrame({'a': [1, 0, 1], 'b': [4, 5, 6], 'c': [7, 8, 9]})
```

```
In [361]: dft1 = dft1.astype({'a': np.bool, 'c': np.float64})
```

```
In [362]: dft1
```

Out [362] :

|   | a     | b | c   |
|---|-------|---|-----|
| 0 | True  | 4 | 7.0 |
| 1 | False | 5 | 8.0 |
| 2 | True  | 6 | 9.0 |

```
In [363]: dft1.dtypes
```

```
Out[363]:
```

```
a bool
```

```
b int64
```

|   |         |
|---|---------|
| c | float64 |
|---|---------|

```
dtype: object
```

**Note:** When trying to convert a subset of columns to a specified type using `astype()` and `loc()`, upcasting occurs. `loc()` tries to fit in what we are assigning to the current dtypes, while `[]` will overwrite them taking the dtype from the right hand side. Therefore the following piece of code produces the unintended result.

```
In [364]: dft = pd.DataFrame({'a': [1, 2, 3], 'b': [4, 5, 6], 'c': [7, 8, 9]})

In [365]: dft.loc[:, ['a', 'b']].astype(np.uint8).dtypes
Out[365]:
a uint8
b uint8
dtype: object

In [366]: dft.loc[:, ['a', 'b']] = dft.loc[:, ['a', 'b']].astype(np.uint8)

In [367]: dft.dtypes
Out[367]:
a int64
b int64
c int64
dtype: object
```

### 9.13.4 object conversion

pandas offers various functions to try to force conversion of types from the `object` dtype to other types. In cases where the data is already of the correct type, but stored in an `object` array, the `DataFrame.infer_objects()` and `Series.infer_objects()` methods can be used to soft convert to the correct type.

```
In [368]: import datetime

In [369]: df = pd.DataFrame([[1, 2],
.....: ['a', 'b'],
.....: [datetime.datetime(2016, 3, 2),
.....: datetime.datetime(2016, 3, 2)]]))

In [370]: df = df.T

In [371]: df
Out[371]:
```

|   | 0 | 1 | 2                   |
|---|---|---|---------------------|
| 0 | 1 | a | 2016-03-02 00:00:00 |
| 1 | 2 | b | 2016-03-02 00:00:00 |

```
In [372]: df.dtypes
//////////
↪
0 object
1 object
2 object
dtype: object
```

Because the data was transposed the original inference stored all columns as object, which `infer_objects` will correct.

```
In [373]: df.infer_objects().dtypes
Out[373]:
0 int64
1 object
2 datetime64[ns]
dtype: object
```

The following functions are available for one dimensional object arrays or scalars to perform hard conversion of objects to a specified type:

- `to_numeric()` (conversion to numeric dtypes)

```
In [374]: m = ['1.1', 2, 3]

In [375]: pd.to_numeric(m)
Out[375]: array([1.1, 2. , 3.])
```

- `to_datetime()` (conversion to datetime objects)

```
In [376]: import datetime

In [377]: m = ['2016-07-09', datetime.datetime(2016, 3, 2)]

In [378]: pd.to_datetime(m)
Out[378]: DatetimeIndex(['2016-07-09', '2016-03-02'], dtype='datetime64[ns]',
↳ freq=None)
```

- `to_timedelta()` (conversion to timedelta objects)

```
In [379]: m = ['5us', pd.Timedelta('1day')]

In [380]: pd.to_timedelta(m)
Out[380]: TimedeltaIndex(['0 days 00:00:00.000005', '1 days 00:00:00'], dtype=
↳ 'timedelta64[ns]', freq=None)
```

To force a conversion, we can pass in an `errors` argument, which specifies how pandas should deal with elements that cannot be converted to desired dtype or object. By default, `errors='raise'`, meaning that any errors encountered will be raised during the conversion process. However, if `errors='coerce'`, these errors will be ignored and pandas will convert problematic elements to `pd.NaT` (for datetime and timedelta) or `np.nan` (for numeric). This might be useful if you are reading in data which is mostly of the desired dtype (e.g. numeric, datetime), but occasionally has non-conforming elements intermixed that you want to represent as missing:

```
In [381]: import datetime

In [382]: m = ['apple', datetime.datetime(2016, 3, 2)]

In [383]: pd.to_datetime(m, errors='coerce')
Out[383]: DatetimeIndex(['NaT', '2016-03-02'], dtype='datetime64[ns]', freq=None)

In [384]: m = ['apple', 2, 3]

In [385]: pd.to_numeric(m, errors='coerce')
Out[385]: array([nan, 2., 3.])

In [386]: m = ['apple', pd.Timedelta('1day')]
```

(continues on next page)

(continued from previous page)

```
In [387]: pd.to_timedelta(m, errors='coerce')
Out[387]: TimedeltaIndex([NaT, '1 days'], dtype='timedelta64[ns]', freq=None)
```

The `errors` parameter has a third option of `errors='ignore'`, which will simply return the passed in data if it encounters any errors with the conversion to a desired data type:

```
In [388]: import datetime

In [389]: m = ['apple', datetime.datetime(2016, 3, 2)]

In [390]: pd.to_datetime(m, errors='ignore')
Out[390]: Index(['apple', '2016-03-02 00:00:00'], dtype='object')

In [391]: m = ['apple', 2, 3]

In [392]: pd.to_numeric(m, errors='ignore')
Out[392]: array(['apple', 2, 3], dtype=object)

In [393]: m = ['apple', pd.Timedelta('1day')]

In [394]: pd.to_timedelta(m, errors='ignore')
Out[394]: array(['apple', Timedelta('1 days 00:00:00')], dtype=object)
```

In addition to object conversion, `to_numeric()` provides another argument `downcast`, which gives the option of downcasting the newly (or already) numeric data to a smaller dtype, which can conserve memory:

```
In [395]: m = ['1', 2, 3]

In [396]: pd.to_numeric(m, downcast='integer') # smallest signed int dtype
Out[396]: array([1, 2, 3], dtype=int8)

In [397]: pd.to_numeric(m, downcast='signed') # same as 'integer'
Out[397]: array([1, 2, 3], dtype=int8)

In [398]: pd.to_numeric(m, downcast='unsigned') # smallest unsigned int dtype
Out[398]: array([1, 2, 3], dtype=uint8)

In [399]: pd.to_numeric(m, downcast='float') # smallest float dtype
Out[399]: array([1., 2., 3.], dtype=float32)
```

As these methods apply only to one-dimensional arrays, lists or scalars; they cannot be used directly on multi-dimensional objects such as DataFrames. However, with `apply()`, we can “apply” the function over each column efficiently:

```
In [400]: import datetime

In [401]: df = pd.DataFrame([
.....: ['2016-07-09', datetime.datetime(2016, 3, 2)] * 2, dtype='O'
.....:])

In [402]: df
Out[402]:
```

|   | 0          | 1                   |
|---|------------|---------------------|
| 0 | 2016-07-09 | 2016-03-02 00:00:00 |

(continues on next page)

(continued from previous page)

```

1 2016-07-09 2016-03-02 00:00:00

In [403]: df.apply(pd.to_datetime)
//////////
↪
 0 1
0 2016-07-09 2016-03-02
1 2016-07-09 2016-03-02

In [404]: df = pd.DataFrame([[1.1, 2, 3]] * 2, dtype='O')

In [405]: df
Out[405]:
 0 1 2
0 1.1 2 3
1 1.1 2 3

In [406]: df.apply(pd.to_numeric)
//////////Out[406]:
 0 1 2
0 1.1 2 3
1 1.1 2 3

In [407]: df = pd.DataFrame(['5us', pd.Timedelta('1day')] * 2, dtype='O')

In [408]: df
Out[408]:
 0 1
0 5us 1 days 00:00:00
1 5us 1 days 00:00:00

In [409]: df.apply(pd.to_timedelta)
//////////Out[409]:
↪
 0 1
0 00:00:00.000005 1 days
1 00:00:00.000005 1 days

```

### 9.13.5 gotchas

Performing selection operations on integer type data can easily upcast the data to floating. The dtype of the input data will be preserved in cases where nans are not introduced. See also *Support for integer NA*.

```

In [410]: dfi = df3.astype('int32')

In [411]: dfi['E'] = 1

In [412]: dfi
Out[412]:
 A B C E
0 0 1 0 1
1 -3 1 1 1
2 1 0 0 1
3 0 0 0 1
4 0 1 0 1

```

(continues on next page)

(continued from previous page)

```

5 0 0 255 1
6 0 0 0 1
7 0 0 0 1

```

```
In [413]: dfi.dtypes
```

```

////////////////////////////////////
↪
A int32

dtype: object

```

## 9.14 Selecting columns based on dtype

The `select_dtypes()` method implements subsetting of columns based on their dtype.

First, let's create a DataFrame with a slew of different dtypes:

```

In [423]: df = pd.DataFrame({'string': list('abc'),
.....: 'int64': list(range(1, 4)),
.....: 'uint8': np.arange(3, 6).astype('u1'),
.....: 'float64': np.arange(4.0, 7.0),
.....: 'bool1': [True, False, True],
.....: 'bool2': [False, True, False],
.....: 'dates': pd.date_range('now', periods=3),
.....: 'category': pd.Series(list("ABC")).astype('category')})

In [424]: df['tdeltas'] = df.dates.diff()

In [425]: df['uint64'] = np.arange(3, 6).astype('u8')

In [426]: df['other_dates'] = pd.date_range('20130101', periods=3)

In [427]: df['tz_aware_dates'] = pd.date_range('20130101', periods=3, tz='US/Eastern')

In [428]: df
Out[428]:
 string int64 uint8 float64 bool1 bool2 dates category_
↪tdeltas uint64 other_dates tz_aware_dates
0 a 1 3 4.0 True False 2019-01-11 16:36:43.084272 A
↪NaT 3 2013-01-01 2013-01-01 00:00:00-05:00
1 b 2 4 5.0 False True 2019-01-12 16:36:43.084272 B 1
↪days 4 2013-01-02 2013-01-02 00:00:00-05:00
2 c 3 5 6.0 True False 2019-01-13 16:36:43.084272 C 1
↪days 5 2013-01-03 2013-01-03 00:00:00-05:00

```

And the dtypes:

```

In [429]: df.dtypes
Out[429]:
string object

```

(continues on next page)

(continued from previous page)

```

int64 int64
uint8 uint8
float64 float64
bool1 bool
bool2 bool
dates datetime64[ns]
category category
tdeltas timedelta64[ns]
uint64 uint64
other_dates datetime64[ns]
tz_aware_dates datetime64[ns, US/Eastern]
dtype: object

```

`select_dtypes()` has two parameters `include` and `exclude` that allow you to say “give me the columns *with* these dtypes” (`include`) and/or “give the columns *without* these dtypes” (`exclude`).

For example, to select `bool` columns:

```

In [430]: df.select_dtypes(include=[bool])
Out[430]:
 bool1 bool2
0 True False
1 False True
2 True False

```

You can also pass the name of a dtype in the [NumPy dtype hierarchy](#):

```

In [431]: df.select_dtypes(include=['bool'])
Out[431]:
 bool1 bool2
0 True False
1 False True
2 True False

```

`select_dtypes()` also works with generic dtypes as well.

For example, to select all numeric and boolean columns while excluding unsigned integers:

```

In [432]: df.select_dtypes(include=['number', 'bool'], exclude=['unsignedinteger'])
Out[432]:
 int64 float64 bool1 bool2 tdeltas
0 1 4.0 True False NaT
1 2 5.0 False True 1 days
2 3 6.0 True False 1 days

```

To select string columns you must use the `object` dtype:

```

In [433]: df.select_dtypes(include=['object'])
Out[433]:
 string
0 a
1 b
2 c

```

To see all the child dtypes of a generic dtype like `numpy.number` you can define a function that returns a tree of child dtypes:

```
In [434]: def subdtypes(dtype):
.....: subs = dtype.__subclasses__()
.....: if not subs:
.....: return dtype
.....: return [dtype, [subdtypes(dt) for dt in subs]]
.....:
```

All NumPy dtypes are subclasses of `numpy.generic`:

```
In [435]: subdtypes(np.generic)
Out[435]:
[numpy.generic,
 [[numpy.number,
 [[numpy.integer,
 [[numpy.signedinteger,
 [numpy.int8,
 numpy.int16,
 numpy.int32,
 numpy.int64,
 numpy.int64,
 numpy.timedelta64]],
 [numpy.unsignedinteger,
 [numpy.uint8,
 numpy.uint16,
 numpy.uint32,
 numpy.uint64,
 numpy.uint64]]]],
 [numpy.inexact,
 [[numpy.floating,
 [numpy.float16, numpy.float32, numpy.float64, numpy.float128]],
 [numpy.complexfloating,
 [numpy.complex64, numpy.complex128, numpy.complex256]]]]]],
 [numpy.flexible,
 [[numpy.character, [numpy.bytes_, numpy.str_]],
 [numpy.void, [numpy.record]]]],
 numpy.bool_,
 numpy.datetime64,
 numpy.object_]]
```

**Note:** Pandas also defines the types `category`, and `datetime64[ns, tz]`, which are not integrated into the normal NumPy hierarchy and won't show up with the above function.

```
{{ header }}
```

## WORKING WITH TEXT DATA

Series and Index are equipped with a set of string processing methods that make it easy to operate on each element of the array. Perhaps most importantly, these methods exclude missing/NA values automatically. These are accessed via the `str` attribute and generally have names matching the equivalent (scalar) built-in string methods:

```
In [1]: s = pd.Series(['A', 'B', 'C', 'Aaba', 'Baca', np.nan, 'CABA', 'dog', 'cat'])
```

```
In [2]: s.str.lower()
```

```
Out[2]:
```

```
0 a
1 b
2 c
3 aaba
4 baca
5 NaN
6 caba
7 dog
8 cat
dtype: object
```

```
In [3]: s.str.upper()
```

```
////////////////////////////////////
↪
0 A
1 B
2 C
3 AABA
4 BACA
5 NaN
6 CABA
7 DOG
8 CAT
dtype: object
```

```
In [4]: s.str.len()
```

```
////////////////////////////////////
↪
0 1.0
1 1.0
2 1.0
3 4.0
4 4.0
5 NaN
6 4.0
7 3.0
```

(continues on next page)

(continued from previous page)

```
8 3.0
dtype: float64
```

```
In [5]: idx = pd.Index([' jack', 'jill ', ' jesse ', 'frank'])

In [6]: idx.str.strip()
Out[6]: Index(['jack', 'jill', 'jesse', 'frank'], dtype='object')

In [7]: idx.str.lstrip()
Out[7]: Index(['jack', 'jill', 'jesse', 'frank'], dtype='object')

In [8]: idx.str.rstrip()
Out[8]: Index([' jack', 'jill ', ' jesse ', 'frank'], dtype='object')
```

The string methods on Index are especially useful for cleaning up or transforming DataFrame columns. For instance, you may have columns with leading or trailing whitespace:

```
In [9]: df = pd.DataFrame(np.random.randn(3, 2),
...: columns=[' Column A ', ' Column B '], index=range(3))
...:

In [10]: df
Out[10]:
 Column A Column B
0 -0.061542 0.528296
1 -0.952849 2.392803
2 -1.524186 2.642204
```

Since `df.columns` is an Index object, we can use the `.str` accessor

```
In [11]: df.columns.str.strip()
Out[11]: Index(['Column A', 'Column B'], dtype='object')

In [12]: df.columns.str.lower()
Out[12]: Index(['column a', 'column b'], dtype='object')
```

These string methods can then be used to clean up the columns as needed. Here we are removing leading and trailing white spaces, lower casing all names, and replacing any remaining white spaces with underscores:

```
In [13]: df.columns = df.columns.str.strip().str.lower().str.replace(' ', '_')

In [14]: df
Out[14]:
 column_a column_b
0 -0.061542 0.528296
1 -0.952849 2.392803
2 -1.524186 2.642204
```

**Note:** If you have a Series where lots of elements are repeated (i.e. the number of unique elements in the Series is a lot smaller than the length of the Series), it can be faster to convert the original Series to one of type category and then use `.str.<method>` or `.dt.<property>` on that. The performance difference comes from the fact that, for Series of type category, the string operations are done on the `.categories` and not on

each element of the Series.

Please note that a Series of type `category` with string `.categories` has some limitations in comparison of Series of type `string` (e.g. you can't add strings to each other: `s + " " + s` won't work if `s` is a Series of type `category`). Also, `.str` methods which operate on elements of type `list` are not available on such a Series.

## 10.1 Splitting and Replacing Strings

Methods like `split` return a Series of lists:

```
In [15]: s2 = pd.Series(['a_b_c', 'c_d_e', np.nan, 'f_g_h'])

In [16]: s2.str.split('_')
Out[16]:
0 [a, b, c]
1 [c, d, e]
2 NaN
3 [f, g, h]
dtype: object
```

Elements in the split lists can be accessed using `get` or `[]` notation:

```
In [17]: s2.str.split('_').str.get(1)
Out[17]:
0 b
1 d
2 NaN
3 g
dtype: object

In [18]: s2.str.split('_').str[1]
Out[18]:
0 b
1 d
2 NaN
3 g
dtype: object
```

It is easy to expand this to return a DataFrame using `expand`.

```
In [19]: s2.str.split('_', expand=True)
Out[19]:
 0 1 2
0 a b c
1 c d e
2 NaN NaN NaN
3 f g h
```

It is also possible to limit the number of splits:

```
In [20]: s2.str.split('_', expand=True, n=1)
Out[20]:
 0 1
0 a b_c
1 c d_e
```

(continues on next page)

(continued from previous page)

```
2 NaN NaN
3 f g_h
```

`rsplit` is similar to `split` except it works in the reverse direction, i.e., from the end of the string to the beginning of the string:

```
In [21]: s2.str.rsplit('_', expand=True, n=1)
Out[21]:
 0 1
0 a_b c
1 c_d e
2 NaN NaN
3 f_g h
```

`replace` by default replaces regular expressions:

```
In [22]: s3 = pd.Series(['A', 'B', 'C', 'Aaba', 'Baca',
.....: '', np.nan, 'CABA', 'dog', 'cat'])
.....:
```

```
In [23]: s3
```

```
Out[23]:
0 A
1 B
2 C
3 Aaba
4 Baca
5
6 NaN
7 CABA
8 dog
9 cat
dtype: object
```

```
In [24]: s3.str.replace('^.a|dog', 'XX-XX ', case=False)
```

```

////////////////////////////////////
↪
0 A
1 B
2 C
3 XX-XX ba
4 XX-XX ca
5
6 NaN
7 XX-XX BA
8 XX-XX
9 XX-XX t
dtype: object
```

Some caution must be taken to keep regular expressions in mind! For example, the following code will cause trouble because of the regular expression meaning of `$`:

```
Consider the following badly formatted financial data
In [25]: dollars = pd.Series(['12', '-$10', '$10,000'])

This does what you'd naively expect:
```

(continues on next page)

(continued from previous page)

```

In [26]: dollars.str.replace('$', '')
Out[26]:
0 12
1 -10
2 10,000
dtype: object

But this doesn't:
In [27]: dollars.str.replace('-$', '-')
Out[27]:
0 12
1 -10
2 $10,000
dtype: object

We need to escape the special character (for >1 len patterns)
In [28]: dollars.str.replace(r'\-$', '-')
Out[28]:
0 12
1 -10
2 $10,000
dtype: object

```

New in version 0.23.0.

If you do want literal replacement of a string (equivalent to `str.replace()`), you can set the optional `regex` parameter to `False`, rather than escaping each character. In this case both `pat` and `repl` must be strings:

```

These lines are equivalent
In [29]: dollars.str.replace(r'\-$', '-')
Out[29]:
0 12
1 -10
2 $10,000
dtype: object

In [30]: dollars.str.replace('-', '-', regex=False)
Out[30]:
0 12
1 -10
2 $10,000
dtype: object

```

New in version 0.20.0.

The `replace` method can also take a callable as replacement. It is called on every `pat` using `re.sub()`. The callable should expect one positional argument (a regex object) and return a string.

```

Reverse every lowercase alphabetic word
In [31]: pat = r'[a-z]+'

In [32]: def repl(m):
...: return m.group(0)[::-1]
...:

In [33]: pd.Series(['foo 123', 'bar baz', np.nan]).str.replace(pat, repl)

```

(continues on next page)

(continued from previous page)

```

Out[33]:
0 oof 123
1 rab zab
2 NaN
dtype: object

Using regex groups
In [34]: pat = r"(?P<one>\w+) (?P<two>\w+) (?P<three>\w+)"

In [35]: def repl(m):
....: return m.group('two').swapcase()
....:

In [36]: pd.Series(['Foo Bar Baz', np.nan]).str.replace(pat, repl)
Out[36]:
0 bAR
1 NaN
dtype: object

```

New in version 0.20.0.

The `replace` method also accepts a compiled regular expression object from `re.compile()` as a pattern. All flags should be included in the compiled regular expression object.

```

In [37]: import re

In [38]: regex_pat = re.compile(r'^.a[dog]', flags=re.IGNORECASE)

In [39]: s3.str.replace(regex_pat, 'XX-XX ')
Out[39]:
0 A
1 B
2 C
3 XX-XX ba
4 XX-XX ca
5
6 NaN
7 XX-XX BA
8 XX-XX
9 XX-XX t
dtype: object

```

Including a `flags` argument when calling `replace` with a compiled regular expression object will raise a `ValueError`.

```

In [40]: s3.str.replace(regex_pat, 'XX-XX ', flags=re.IGNORECASE)

ValueError: case and flags cannot be set when pat is a compiled regex

```

## 10.2 Concatenation

There are several ways to concatenate a `Series` or `Index`, either with itself or others, all based on `cat()`, resp. `Index.str.cat`.

## 10.2.1 Concatenating a single Series into a string

The content of a Series (or Index) can be concatenated:

```
In [41]: s = pd.Series(['a', 'b', 'c', 'd'])

In [42]: s.str.cat(sep=',')
Out[42]: 'a,b,c,d'
```

If not specified, the keyword `sep` for the separator defaults to the empty string, `sep=''`:

```
In [43]: s.str.cat()
Out[43]: 'abcd'
```

By default, missing values are ignored. Using `na_rep`, they can be given a representation:

```
In [44]: t = pd.Series(['a', 'b', np.nan, 'd'])

In [45]: t.str.cat(sep=',')
Out[45]: 'a,b,d'

In [46]: t.str.cat(sep=',', na_rep='-')
Out[46]: 'a,b,-,d'
```

## 10.2.2 Concatenating a Series and something list-like into a Series

The first argument to `cat()` can be a list-like object, provided that it matches the length of the calling Series (or Index).

```
In [47]: s.str.cat(['A', 'B', 'C', 'D'])
Out[47]:
0 aA
1 bB
2 cC
3 dD
dtype: object
```

Missing values on either side will result in missing values in the result as well, *unless* `na_rep` is specified:

```
In [48]: s.str.cat(t)
Out[48]:
0 aa
1 bb
2 NaN
3 dd
dtype: object

In [49]: s.str.cat(t, na_rep='-')
Out[49]:
0 aa
1 bb
2 c-
3 dd
dtype: object
```

### 10.2.3 Concatenating a Series and something array-like into a Series

New in version 0.23.0.

The parameter `others` can also be two-dimensional. In this case, the number of rows must match the lengths of the calling Series (or Index).

```
In [50]: d = pd.concat([t, s], axis=1)

In [51]: s
Out[51]:
0 a
1 b
2 c
3 d
dtype: object

In [52]: d
Out[52]:
 0 1
0 a a
1 b b
2 NaN c
3 d d

In [53]: s.str.cat(d, na_rep='-')
Out[53]:
0 aaa
1 bbb
2 c-c
3 ddd
dtype: object
```

### 10.2.4 Concatenating a Series and an indexed object into a Series, with alignment

New in version 0.23.0.

For concatenation with a Series or DataFrame, it is possible to align the indexes before concatenation by setting the `join-keyword`.

```
In [54]: u = pd.Series(['b', 'd', 'a', 'c'], index=[1, 3, 0, 2])

In [55]: s
Out[55]:
0 a
1 b
2 c
3 d
dtype: object

In [56]: u
Out[56]:
1 b
3 d
0 a
2 c
```

(continues on next page)

(continued from previous page)

dtype: object

**In [57]:** s.str.cat(u)

```

////////////////////////////////////

```

```

↪

```

```

0 ab
1 bd
2 ca
3 dc

```

dtype: object

**In [58]:** s.str.cat(u, join='left')

```

////////////////////////////////////

```

```

↪

```

```

0 aa
1 bb
2 cc
3 dd

```

dtype: object

**Warning:** If the `join` keyword is not passed, the method `cat()` will currently fall back to the behavior before version 0.23.0 (i.e. no alignment), but a `FutureWarning` will be raised if any of the involved indexes differ, since this default will change to `join='left'` in a future version.

The usual options are available for `join` (one of `'left'`, `'outer'`, `'inner'`, `'right'`). In particular, alignment also means that the different lengths do not need to coincide anymore.

**In [59]:** v = pd.Series(['z', 'a', 'b', 'd', 'e'], index=[-1, 0, 1, 3, 4])**In [60]:** s**Out [60]:**

```

0 a
1 b
2 c
3 d

```

dtype: object

**In [61]:** v

```

////////////////////////////////////Out [61]:

```

```

-1 z
0 a
1 b
3 d
4 e

```

dtype: object

**In [62]:** s.str.cat(v, join='left', na\_rep='-')

```

////////////////////////////////////

```

```

↪

```

```

0 aa
1 bb
2 c-
3 dd

```

dtype: object

(continues on next page)

(continued from previous page)

```
In [63]: s.str.cat(v, join='outer', na_rep='-')
//////////
↪
-1 -z
0 aa
1 bb
2 c-
3 dd
4 -e
dtype: object
```

The same alignment can be used when `others` is a `DataFrame`:

[illegible]

### 10.2.5 Concatenating a Series and many objects into a Series

Several array-like items (specifically: `Series`, `Index`, and 1-dimensional variants of `np.ndarray`) can be combined in a list-like container (including iterators, `dict`-views, etc.).

```
In [68]: s
Out[68]:
0 a
1 b
2 c
3 d
dtype: object

In [69]: u
```

(continues on next page)

(continued from previous page)

```
\\Out [69]:
```

```
1 b
3 d
0 a
2 c
dtype: object
```

```
In [70]: s.str.cat([u, u.to_numpy()], join='left')
```

```
\\Out [70]:
0 aab
1 bbd
2 cca
3 ddc
dtype: object
```

All elements without an index (e.g. `np.ndarray`) within the passed list-like must match in length to the calling Series (or Index), but Series and Index may have arbitrary length (as long as alignment is not disabled with `join=None`):

```
In [71]: v
```

```
Out [71]:
```

```
-1 z
0 a
1 b
3 d
4 e
dtype: object
```

```
In [72]: s.str.cat([v, u, u.to_numpy()], join='outer', na_rep='-')
```

```
\\Out [72]:
```

```
-1 -z--
0 aaab
1 bbbd
2 c-ca
3 dddc
4 -e--
dtype: object
```

If using `join='right'` on a list-like of others that contains different indexes, the union of these indexes will be used as the basis for the final concatenation:

```
In [73]: u.loc[[3]]
```

```
Out [73]:
```

```
3 d
dtype: object
```

```
In [74]: v.loc[[-1, 0]]
```

```
\\Out [74]:
```

```
-1 z
0 a
dtype: object
```

```
In [75]: s.str.cat([u.loc[[3]], v.loc[[-1, 0]]], join='right', na_rep='-')
```

```
\\Out [75]:
```

```
-1 --z
```

(continues on next page)

(continued from previous page)

```

0 a-a
3 dd-
dtype: object

```

## 10.3 Indexing with `.str`

You can use `[]` notation to directly index by position locations. If you index past the end of the string, the result will be a NaN.

```

In [76]: s = pd.Series(['A', 'B', 'C', 'Aaba', 'Baca', np.nan,
.....: 'CABA', 'dog', 'cat'])
.....:

```

```

In [77]: s.str[0]

```

```

Out[77]:
0 A
1 B
2 C
3 A
4 B
5 NaN
6 C
7 d
8 c
dtype: object

```

```

In [78]: s.str[1]

```

```

////////////////////////////////////
↪
0 NaN
1 NaN
2 NaN
3 a
4 a
5 NaN
6 A
7 o
8 a
dtype: object

```

## 10.4 Extracting Substrings

### 10.4.1 Extract first match in each subject (extract)

**Warning:** In version 0.18.0, `extract` gained the `expand` argument. When `expand=False` it returns a Series, Index, or DataFrame, depending on the subject and regular expression pattern (same behavior as pre-0.18.0). When `expand=True` it always returns a DataFrame, which is more consistent and less confusing from the perspective of a user. `expand=True` is the default since version 0.23.0.

The `extract` method accepts a [regular expression](#) with at least one capture group.

Extracting a regular expression with more than one group returns a `DataFrame` with one column per group.

```
In [79]: pd.Series(['a1', 'b2', 'c3']).str.extract(r'([ab])(\d)', expand=False)
Out[79]:
```

|   | 0   | 1   |
|---|-----|-----|
| 0 | a   | 1   |
| 1 | b   | 2   |
| 2 | NaN | NaN |

Elements that do not match return a row filled with `NaN`. Thus, a `Series` of messy strings can be “converted” into a like-indexed `Series` or `DataFrame` of cleaned-up or more useful strings, without necessitating `get()` to access tuples or `re.match` objects. The `dtype` of the result is always `object`, even if no match is found and the result only contains `NaN`.

Named groups like

```
In [80]: pd.Series(['a1', 'b2', 'c3']).str.extract(r'(?P<letter>[ab])(?P<digit>\d)',
.....: expand=False)
.....:
Out[80]:
```

|   | letter | digit |
|---|--------|-------|
| 0 | a      | 1     |
| 1 | b      | 2     |
| 2 | NaN    | NaN   |

and optional groups like

```
In [81]: pd.Series(['a1', 'b2', '3']).str.extract(r'([ab])?(\d)', expand=False)
Out[81]:
```

|   | 0   | 1 |
|---|-----|---|
| 0 | a   | 1 |
| 1 | b   | 2 |
| 2 | NaN | 3 |

can also be used. Note that any capture group names in the regular expression will be used for column names; otherwise capture group numbers will be used.

Extracting a regular expression with one group returns a `DataFrame` with one column if `expand=True`.

```
In [82]: pd.Series(['a1', 'b2', 'c3']).str.extract(r'[ab](\d)', expand=True)
Out[82]:
```

|   | 0   |
|---|-----|
| 0 | 1   |
| 1 | 2   |
| 2 | NaN |

It returns a `Series` if `expand=False`.

```
In [83]: pd.Series(['a1', 'b2', 'c3']).str.extract(r'[ab](\d)', expand=False)
Out[83]:
```

|   | 0   |
|---|-----|
| 0 | 1   |
| 1 | 2   |
| 2 | NaN |

dtype: object

Calling on an `Index` with a regex with exactly one capture group returns a `DataFrame` with one column if `expand=True`.

```
In [84]: s = pd.Series(["a1", "b2", "c3"], ["A11", "B22", "C33"])

In [85]: s
Out[85]:
A11 a1
B22 b2
C33 c3
dtype: object

In [86]: s.index.str.extract("(?P<letter>[a-zA-Z])", expand=True)
Out[86]:
letter
0 A
1 B
2 C
```

It returns an Index if `expand=False`.

```
In [87]: s.index.str.extract("(?P<letter>[a-zA-Z])", expand=False)
Out[87]: Index(['A', 'B', 'C'], dtype='object', name='letter')
```

Calling on an Index with a regex with more than one capture group returns a DataFrame if `expand=True`.

```
In [88]: s.index.str.extract("(?P<letter>[a-zA-Z])([0-9]+)", expand=True)
Out[88]:
letter 1
0 A 11
1 B 22
2 C 33
```

It raises `ValueError` if `expand=False`.

```
>>> s.index.str.extract("(?P<letter>[a-zA-Z])([0-9]+)", expand=False)
ValueError: only one regex group is supported with Index
```

The table below summarizes the behavior of `extract` (`expand=False`) (input subject in first column, number of groups in regex in first row)

|        | 1 group | >1 group   |
|--------|---------|------------|
| Index  | Index   | ValueError |
| Series | Series  | DataFrame  |

## 10.4.2 Extract all matches in each subject (`extractall`)

New in version 0.18.0.

Unlike `extract` (which returns only the first match),

```
In [89]: s = pd.Series(["a1a2", "b1", "c1"], index=["A", "B", "C"])

In [90]: s
Out[90]:
A a1a2
B b1
C c1
```

(continues on next page)

(continued from previous page)

```
dtype: object

In [91]: two_groups = '(?P<letter>[a-z])(?P<digit>[0-9])'

In [92]: s.str.extract(two_groups, expand=True)
Out[92]:
```

|   | letter | digit |
|---|--------|-------|
| A | a      | 1     |
| B | b      | 1     |
| C | c      | 1     |

the `extractall` method returns every match. The result of `extractall` is always a `DataFrame` with a `MultiIndex` on its rows. The last level of the `MultiIndex` is named `match` and indicates the order in the subject.

```
In [93]: s.str.extractall(two_groups)
Out[93]:
```

|   |       | letter | digit |
|---|-------|--------|-------|
|   | match |        |       |
| A | 0     | a      | 1     |
|   | 1     | a      | 2     |
| B | 0     | b      | 1     |
| C | 0     | c      | 1     |

When each subject string in the `Series` has exactly one match,

```
In [94]: s = pd.Series(['a3', 'b3', 'c2'])

In [95]: s
Out[95]:
```

|   |    |
|---|----|
| 0 | a3 |
| 1 | b3 |
| 2 | c2 |

dtype: object

then `extractall(pat).xs(0, level='match')` gives the same result as `extract(pat)`.

```
In [96]: extract_result = s.str.extract(two_groups, expand=True)

In [97]: extract_result
Out[97]:
```

|   | letter | digit |
|---|--------|-------|
| 0 | a      | 3     |
| 1 | b      | 3     |
| 2 | c      | 2     |

```
In [98]: extractall_result = s.str.extractall(two_groups)

In [99]: extractall_result
Out[99]:
```

|   |       | letter | digit |
|---|-------|--------|-------|
|   | match |        |       |
| 0 | 0     | a      | 3     |
| 1 | 0     | b      | 3     |
| 2 | 0     | c      | 2     |

(continues on next page)

(continued from previous page)

```
In [100]: extractall_result.xs(0, level="match")
```

```

////////////////////////////////////
↪
 letter digit
0 a 3
1 b 3
2 c 2

```

Index also supports `.str.extractall`. It returns a `DataFrame` which has the same result as a `Series.str.extractall` with a default index (starts from 0).

New in version 0.19.0.

```
In [101]: pd.Index(["ala2", "b1", "c1"]).str.extractall(two_groups)
```

```
Out[101]:
```

```

 letter digit
match
0 0 a 1
 1 a 2
1 0 b 1
2 0 c 1

```

```
In [102]: pd.Series(["ala2", "b1", "c1"]).str.extractall(two_groups)
```

```

////////////////////////////////////
↪
 letter digit
match
0 0 a 1
 1 a 2
1 0 b 1
2 0 c 1

```

## 10.5 Testing for Strings that Match or Contain a Pattern

You can check whether elements contain a pattern:

```
In [103]: pattern = r'[0-9][a-z]'
```

```
In [104]: pd.Series(['1', '2', '3a', '3b', '03c']).str.contains(pattern)
```

```
Out[104]:
```

```

0 False
1 False
2 True
3 True
4 True
dtype: bool

```

Or whether elements match a pattern:

```
In [105]: pd.Series(['1', '2', '3a', '3b', '03c']).str.match(pattern)
```

```
Out[105]:
```

```

0 False
1 False
2 True

```

(continues on next page)

(continued from previous page)

```
3 True
4 False
dtype: bool
```

The distinction between `match` and `contains` is strictness: `match` relies on strict `re.match`, while `contains` relies on `re.search`.

Methods like `match`, `contains`, `startswith`, and `endswith` take an extra `na` argument so missing values can be considered `True` or `False`:

```
In [106]: s4 = pd.Series(['A', 'B', 'C', 'Aaba', 'Baca', np.nan, 'CABA', 'dog', 'cat',
→])

In [107]: s4.str.contains('A', na=False)
Out[107]:
0 True
1 False
2 False
3 True
4 False
5 False
6 True
7 False
8 False
dtype: bool
```

## 10.6 Creating Indicator Variables

You can extract dummy variables from string columns. For example if they are separated by a `'|'`:

```
In [108]: s = pd.Series(['a', 'a|b', np.nan, 'a|c'])

In [109]: s.str.get_dummies(sep='|')
Out[109]:
 a b c
0 1 0 0
1 1 1 0
2 0 0 0
3 1 0 1
```

String Index also supports `get_dummies` which returns a `MultiIndex`.

New in version 0.18.1.

```
In [110]: idx = pd.Index(['a', 'a|b', np.nan, 'a|c'])

In [111]: idx.str.get_dummies(sep='|')
Out[111]:
MultiIndex(levels=[[0, 1], [0, 1], [0, 1]],
 labels=[[1, 1, 0, 1], [0, 1, 0, 0], [0, 0, 0, 1]],
 names=['a', 'b', 'c'])
```

See also `get_dummies()`.

## 10.7 Method Summary

| Method                       | Description                                                                                                                                |
|------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------|
| <code>cat()</code>           | Concatenate strings                                                                                                                        |
| <code>split()</code>         | Split strings on delimiter                                                                                                                 |
| <code>rsplit()</code>        | Split strings on delimiter working from the end of the string                                                                              |
| <code>get()</code>           | Index into each element (retrieve i-th element)                                                                                            |
| <code>join()</code>          | Join strings in each element of the Series with passed separator                                                                           |
| <code>get_dummies()</code>   | Split strings on the delimiter returning DataFrame of dummy variables                                                                      |
| <code>contains()</code>      | Return boolean array if each string contains pattern/regex                                                                                 |
| <code>replace()</code>       | Replace occurrences of pattern/regex/string with some other string or the return value of a callable given the occurrence                  |
| <code>repeat()</code>        | Duplicate values ( <code>s.str.repeat(3)</code> equivalent to <code>x * 3</code> )                                                         |
| <code>pad()</code>           | Add whitespace to left, right, or both sides of strings                                                                                    |
| <code>center()</code>        | Equivalent to <code>str.center</code>                                                                                                      |
| <code>ljust()</code>         | Equivalent to <code>str.ljust</code>                                                                                                       |
| <code>rjust()</code>         | Equivalent to <code>str.rjust</code>                                                                                                       |
| <code>zfill()</code>         | Equivalent to <code>str.zfill</code>                                                                                                       |
| <code>wrap()</code>          | Split long strings into lines with length less than a given width                                                                          |
| <code>slice()</code>         | Slice each string in the Series                                                                                                            |
| <code>slice_replace()</code> | Replace slice in each string with passed value                                                                                             |
| <code>count()</code>         | Count occurrences of pattern                                                                                                               |
| <code>startswith()</code>    | Equivalent to <code>str.startswith(pat)</code> for each element                                                                            |
| <code>endswith()</code>      | Equivalent to <code>str.endswith(pat)</code> for each element                                                                              |
| <code>findall()</code>       | Compute list of all occurrences of pattern/regex for each string                                                                           |
| <code>match()</code>         | Call <code>re.match</code> on each element, returning matched groups as list                                                               |
| <code>extract()</code>       | Call <code>re.search</code> on each element, returning DataFrame with one row for each element and one column for each regex capture group |
| <code>extractall()</code>    | Call <code>re.findall</code> on each element, returning DataFrame with one row for each match and one column for each regex capture group  |
| <code>len()</code>           | Compute string lengths                                                                                                                     |
| <code>strip()</code>         | Equivalent to <code>str.strip</code>                                                                                                       |
| <code>rstrip()</code>        | Equivalent to <code>str.rstrip</code>                                                                                                      |
| <code>lstrip()</code>        | Equivalent to <code>str.lstrip</code>                                                                                                      |
| <code>partition()</code>     | Equivalent to <code>str.partition</code>                                                                                                   |
| <code>rpartition()</code>    | Equivalent to <code>str.rpartition</code>                                                                                                  |
| <code>lower()</code>         | Equivalent to <code>str.lower</code>                                                                                                       |
| <code>upper()</code>         | Equivalent to <code>str.upper</code>                                                                                                       |
| <code>find()</code>          | Equivalent to <code>str.find</code>                                                                                                        |
| <code>rfind()</code>         | Equivalent to <code>str.rfind</code>                                                                                                       |
| <code>index()</code>         | Equivalent to <code>str.index</code>                                                                                                       |
| <code>rindex()</code>        | Equivalent to <code>str.rindex</code>                                                                                                      |
| <code>capitalize()</code>    | Equivalent to <code>str.capitalize</code>                                                                                                  |
| <code>swapcase()</code>      | Equivalent to <code>str.swapcase</code>                                                                                                    |
| <code>normalize()</code>     | Return Unicode normal form. Equivalent to <code>unicodedata.normalize</code>                                                               |
| <code>translate()</code>     | Equivalent to <code>str.translate</code>                                                                                                   |
| <code>isalnum()</code>       | Equivalent to <code>str.isalnum</code>                                                                                                     |
| <code>isalpha()</code>       | Equivalent to <code>str.isalpha</code>                                                                                                     |
| <code>isdigit()</code>       | Equivalent to <code>str.isdigit</code>                                                                                                     |
| <code>isspace()</code>       | Equivalent to <code>str.isspace</code>                                                                                                     |

## OPTIONS AND SETTINGS

### 11.1 Overview

pandas has an options system that lets you customize some aspects of its behaviour, display-related options being those the user is most likely to adjust.

Options have a full “dotted-style”, case-insensitive name (e.g. `display.max_rows`). You can get/set options directly as attributes of the top-level `options` attribute:

```
In [1]: import pandas as pd

In [2]: pd.options.display.max_rows
Out[2]: 60

In [3]: pd.options.display.max_rows = 999

In [4]: pd.options.display.max_rows
Out[4]: 999
```

The API is composed of 5 relevant functions, available directly from the `pandas` namespace:

- `get_option()` / `set_option()` - get/set the value of a single option.
- `reset_option()` - reset one or more options to their default value.
- `describe_option()` - print the descriptions of one or more options.
- `option_context()` - execute a codeblock with a set of options that revert to prior settings after execution.

**Note:** Developers can check out [pandas/core/config.py](#) for more information.

All of the functions above accept a regexp pattern (`re.search` style) as an argument, and so passing in a substring will work - as long as it is unambiguous:

```
In [5]: pd.get_option("display.max_rows")
Out[5]: 999

In [6]: pd.set_option("display.max_rows", 101)

In [7]: pd.get_option("display.max_rows")
Out[7]: 101

In [8]: pd.set_option("max_r", 102)

In [9]: pd.get_option("display.max_rows")
Out[9]: 102
```

The following will **not work** because it matches multiple option names, e.g. `display.max_colwidth`, `display.max_rows`, `display.max_columns`:

```
In [10]: try:
.....: pd.get_option("column")
.....: except KeyError as e:
.....: print(e)
.....:
'Pattern matched multiple keys'
```

**Note:** Using this form of shorthand may cause your code to break if new options with similar names are added in future versions.

You can get a list of available options and their descriptions with `describe_option`. When called with no argument `describe_option` will print out the descriptions for all available options.

## 11.2 Getting and Setting Options

As described above, `get_option()` and `set_option()` are available from the pandas namespace. To change an option, call `set_option('option regex', new_value)`.

```
In [11]: pd.get_option('mode.sim_interactive')
Out[11]: False

In [12]: pd.set_option('mode.sim_interactive', True)

In [13]: pd.get_option('mode.sim_interactive')
Out[13]: True
```

**Note:** The option ‘mode.sim\_interactive’ is mostly used for debugging purposes.

All options also have a default value, and you can use `reset_option` to do just that:

```
In [14]: pd.get_option("display.max_rows")
Out[14]: 60

In [15]: pd.set_option("display.max_rows", 999)

In [16]: pd.get_option("display.max_rows")
Out[16]: 999

In [17]: pd.reset_option("display.max_rows")

In [18]: pd.get_option("display.max_rows")
Out[18]: 60
```

It’s also possible to reset multiple options at once (using a regex):

```
In [19]: pd.reset_option("^display")
```

`option_context` context manager has been exposed through the top-level API, allowing you to execute code with given option values. Option values are restored automatically when you exit the *with* block:

```
In [20]: with pd.option_context("display.max_rows", 10, "display.max_columns", 5):
.....: print(pd.get_option("display.max_rows"))
.....: print(pd.get_option("display.max_columns"))
```

(continues on next page)

(continued from previous page)

```

.....:
10
5

In [21]: print(pd.get_option("display.max_rows"))
\\\\"60

In [22]: print(pd.get_option("display.max_columns"))
\\\\"0

```

## 11.3 Setting Startup Options in python/ipython Environment

Using startup scripts for the python/ipython environment to import pandas and set options makes working with pandas more efficient. To do this, create a .py or .ipy script in the startup directory of the desired profile. An example where the startup folder is in a default ipython profile can be found at:

```
$IPYTHONDIR/profile_default/startup
```

More information can be found in the [ipython documentation](#). An example startup script for pandas is displayed below:

```

import pandas as pd
pd.set_option('display.max_rows', 999)
pd.set_option('precision', 5)

```

## 11.4 Frequently Used Options

The following is a walk-through of the more frequently used display options.

`display.max_rows` and `display.max_columns` sets the maximum number of rows and columns displayed when a frame is pretty-printed. Truncated lines are replaced by an ellipsis.

```

In [23]: df = pd.DataFrame(np.random.randn(7, 2))

In [24]: pd.set_option('max_rows', 7)

In [25]: df
Out[25]:
 0 1
0 -0.228248 -2.069612
1 0.610144 0.423497
2 1.117887 -0.274242
3 1.741812 -0.447501
4 -1.255427 0.938164
5 -0.468346 -1.254720
6 0.124824 0.756502

In [26]: pd.set_option('max_rows', 5)

In [27]: df
Out[27]:

```

(continues on next page)

(continued from previous page)

```

 0 1
0 -0.228248 -2.069612
1 0.610144 0.423497
..
5 -0.468346 -1.254720
6 0.124824 0.756502

```

```
[7 rows x 2 columns]
```

```
In [28]: pd.reset_option('max_rows')
```

`display.expand_frame_repr` allows for the representation of dataframes to stretch across pages, wrapped over the full column vs row-wise.

```
In [29]: df = pd.DataFrame(np.random.randn(5, 10))
```

```
In [30]: pd.set_option('expand_frame_repr', True)
```

```
In [31]: df
```

```
Out[31]:
```

```

 0 1 2 3 4 5 6 7 8 9
0 0.241440 0.497426 4.108693 0.821121 1.531760 -1.985846 0.365054 0.774082 -0.364479 -0.875979

`display.max_info_rows: df.info()` will usually show null-counts for each column. For large frames this can be quite slow. `max_info_rows` and `max_info_cols` limit this null check only to frames with smaller dimensions than specified. Note that you can specify the option `df.info(null_counts=True)` to override on showing a particular frame.

```

In [55]: df = pd.DataFrame(np.random.choice([0, 1, np.nan], size=(10, 10)))

## 11.5 Available Options

|                                  | Option   | Default                                                                                      | Function |
|----------------------------------|----------|----------------------------------------------------------------------------------------------|----------|
| display.chop_threshold           | None     | If set to a float value, all float values smaller then the given threshold will be displayed |          |
| display.colheader_justify        | right    | Controls the justification of column headers. used by DataFrameFormatter.                    |          |
| display.column_space             | 12       | No description available.                                                                    |          |
| display.date_dayfirst            | False    | When True, prints and parses dates with the day first, eg 20/01/2005                         |          |
| display.date_yearfirst           | False    | When True, prints and parses dates with the year first, eg 2005/01/20                        |          |
| display.encoding                 | UTF-8    | Defaults to the detected encoding of the console. Specifies the encoding to be used for      |          |
| display.expand_frame_repr        | True     | Whether to print out the full DataFrame repr for wide DataFrames across multiple lines       |          |
| display.float_format             | None     | The callable should accept a floating point number and return a string with the desired      |          |
| display.large_repr               | truncate | For DataFrames exceeding max_rows/max_cols, the repr (and HTML repr) can show                |          |
| display.latex.repr               | False    | Whether to produce a latex DataFrame representation for jupyter frontends that support       |          |
| display.latex.escape             | True     | Escapes special characters in DataFrames, when using the to_latex method.                    |          |
| display.latex.longtable          | False    | Specifies if the to_latex method of a DataFrame uses the longtable format.                   |          |
| display.latex.multicolumn        | True     | Combines columns when using a MultiIndex                                                     |          |
| display.latex.multicolumn_format | ‘l’      | Alignment of multicolumn labels                                                              |          |
| display.latex.multirow           | False    | Combines rows when using a MultiIndex. Centered instead of top-aligned, separated            |          |
| display.max_columns              | 0 or 20  | max_rows and max_columns are used in __repr__() methods to decide if to_string() or          |          |
| display.max_colwidth             | 50       | The maximum width in characters of a column in the repr of a pandas data structure.          |          |

Table 1 – continued from previous page

|                                         | Option   | Default | Function                                                                                                                               |
|-----------------------------------------|----------|---------|----------------------------------------------------------------------------------------------------------------------------------------|
| display.max_info_columns                | 100      |         | max_info_columns is used in DataFrame.info method to decide if per column information should be displayed.                             |
| display.max_info_rows                   | 1690785  |         | df.info() will usually show null-counts for each column. For large frames this can be a problem.                                       |
| display.max_rows                        | 60       |         | This sets the maximum number of rows pandas should output when printing out various objects.                                           |
| display.max_seq_items                   | 100      |         | when pretty-printing a long sequence, no more than max_seq_items will be printed. 100 is a reasonable default.                         |
| display.memory_usage                    | True     |         | This specifies if the memory usage of a DataFrame should be displayed when the df.info() method is called.                             |
| display.multi_sparse                    | True     |         | “Sparsify” MultiIndex display (don’t display repeated elements in outer levels within a group).                                        |
| display.notebook_repr_html              | True     |         | When True, IPython notebook will use html representation for pandas objects (if it is available).                                      |
| display.pprint_nest_depth               | 3        |         | Controls the number of nested levels to process when pretty-printing.                                                                  |
| display.precision                       | 6        |         | Floating point output precision in terms of number of places after the decimal, for regular floats.                                    |
| display.show_dimensions                 | truncate |         | Whether to print out dimensions at the end of DataFrame repr. If ‘truncate’ is specified, only the first few dimensions will be shown. |
| display.width                           | 80       |         | Width of the display in characters. In case python/IPython is running in a terminal the width is determined by the terminal width.     |
| display.html.table_schema               | False    |         | Whether to publish a Table Schema representation for frontends that support it.                                                        |
| display.html.border                     | 1        |         | A border=value attribute is inserted in the <table> tag for the DataFrame HTML representation.                                         |
| display.html.use_mathjax                | True     |         | When True, Jupyter notebook will process table contents using MathJax, rendering mathematical expressions.                             |
| io.excel.xls.writer                     | xlwt     |         | The default Excel writer engine for ‘xls’ files.                                                                                       |
| io.excel.xlsm.writer                    | openpyxl |         | The default Excel writer engine for ‘xlsm’ files. Available options: ‘openpyxl’ (the default), ‘xlwt’, ‘xlsxwriter’.                   |
| io.excel.xlsx.writer                    | openpyxl |         | The default Excel writer engine for ‘xlsx’ files.                                                                                      |
| io.hdf.default_format                   | None     |         | default format writing format, if None, then put will default to ‘fixed’ and append will default to ‘append’.                          |
| io.hdf.dropna_table                     | True     |         | drop ALL nan rows when appending to a table                                                                                            |
| io.parquet.engine                       | None     |         | The engine to use as a default for parquet reading and writing. If None then try ‘pyarrow’, ‘fastparquet’, or ‘dask’.                  |
| mode.chained_assignment                 | warn     |         | Controls SettingWithCopyWarning: ‘raise’, ‘warn’, or None. Raise an exception on chained assignment.                                   |
| mode.sim_interactive                    | False    |         | Whether to simulate interactive mode for purposes of testing.                                                                          |
| mode.use_inf_as_na                      | False    |         | True means treat None, NaN, -INF, INF as NA (old way), False means None and NaN are distinct.                                          |
| compute.use_bottleneck                  | True     |         | Use the bottleneck library to accelerate computation if it is installed.                                                               |
| compute.use_numexpr                     | True     |         | Use the numexpr library to accelerate computation if it is installed.                                                                  |
| plotting.matplotlib.register_converters | True     |         | Register custom converters with matplotlib. Set to False to de-register.                                                               |

## 11.6 Number Formatting

pandas also allows you to set how numbers are displayed in the console. This option is not set through the `set_options` API.

Use the `set_eng_float_format` function to alter the floating-point formatting of pandas objects to produce a particular format.

For instance:

```
In [79]: import numpy as np

In [80]: pd.set_eng_float_format(accuracy=3, use_eng_prefix=True)

In [81]: s = pd.Series(np.random.randn(5), index=['a', 'b', 'c', 'd', 'e'])

In [82]: s / 1.e3
Out[82]:
a -606.343u
b 795.472u
c 811.825u
d 49.229u
e -1.554m
dtype: float64
```

(continues on next page)

(continued from previous page)

```
In [83]: s / 1.e6
```

```

////////////////////////////////////Out [83]:
↪
a -606.343n
b 795.472n
c 811.825n
d 49.229n
e -1.554u
dtype: float64

```

To round floats on a case-by-case basis, you can also use `round()` and `round()`.

## 11.7 Unicode Formatting

**Warning:** Enabling this option will affect the performance for printing of DataFrame and Series (about 2 times slower). Use only when it is actually required.

Some East Asian countries use Unicode characters whose width corresponds to two Latin characters. If a DataFrame or Series contains these characters, the default output mode may not align them properly.

**Note:** Screen captures are attached for each output to show the actual results.

```
In [84]: df = pd.DataFrame({'u': ['UK', u''], u': ['Alice', u'']})
```

```
In [85]: df
```

```
Out[85]:
```

```

0 UK Alice
1

```

```
>>> df = pd.DataFrame({'u': ['UK', u'日本'], u': ['Alice', u'しのぶ']})
```

```
>>> df
```

```

 名前 国籍
0 Alice UK
1 のぶ 日本

```

Enabling `display.unicode.east_asian_width` allows pandas to check each character's "East Asian Width" property. These characters can be aligned properly by setting this option to `True`. However, this will result in longer render times than the standard `len` function.

```
In [86]: pd.set_option('display.unicode.east_asian_width', True)
```

```
In [87]: df
```

```
Out[87]:
```

```

0 UK Alice
1

```

```
>>> pd.set_option('display.unicode.east_asian_width', True)
>>> df
 名前 国籍
0 Alice UK
1 し の ぶ 日本
```

In addition, Unicode characters whose width is “Ambiguous” can either be 1 or 2 characters wide depending on the terminal setting or encoding. The option `display.unicode.ambiguous_as_wide` can be used to handle the ambiguity.

By default, an “Ambiguous” character’s width, such as “`¡`” (inverted exclamation) in the example below, is taken to be 1.

```
In [88]: df = pd.DataFrame({'a': ['xxx', u'¡¡'], 'b': ['yyy', u'¡¡']})
In [89]: df
Out[89]:
 a b
0 xxx yyy
1 ¡¡ ¡¡
```

```
>>> df = pd.DataFrame({'a': ['xxx', u'¡¡'], 'b': ['yyy', u'¡¡']})
>>> df
 a b
0 xxx yyy
1 ¡¡ ¡¡
```

Enabling `display.unicode.ambiguous_as_wide` makes pandas interpret these characters’ widths to be 2. (Note that this option will only be effective when `display.unicode.east_asian_width` is enabled.)

However, setting this option incorrectly for your terminal will cause these characters to be aligned incorrectly:

```
In [90]: pd.set_option('display.unicode.ambiguous_as_wide', True)
In [91]: df
Out[91]:
 a b
0 xxx yyy
1 ¡¡ ¡¡
```

```
>>> pd.set_option('display.unicode.ambiguous_as_wide', True)
>>> df
 a b
0 xxx yyy
1 ¡¡ ¡¡
```

## 11.8 Table Schema Display

New in version 0.20.0.

`DataFrame` and `Series` will publish a Table Schema representation by default. False by default, this can be enabled globally with the `display.html.table_schema` option:

```
In [92]: pd.set_option('display.html.table_schema', True)
```

Only `'display.max_rows'` are serialized and published. `{{ header }}`

## INDEXING AND SELECTING DATA

The axis labeling information in pandas objects serves many purposes:

- Identifies data (i.e. provides *metadata*) using known indicators, important for analysis, visualization, and interactive console display.
- Enables automatic and explicit data alignment.
- Allows intuitive getting and setting of subsets of the data set.

In this section, we will focus on the final point: namely, how to slice, dice, and generally get and set subsets of pandas objects. The primary focus will be on Series and DataFrame as they have received more development attention in this area.

---

**Note:** The Python and NumPy indexing operators `[]` and attribute operator `.` provide quick and easy access to pandas data structures across a wide range of use cases. This makes interactive work intuitive, as there's little new to learn if you already know how to deal with Python dictionaries and NumPy arrays. However, since the type of the data to be accessed isn't known in advance, directly using standard operators has some optimization limits. For production code, we recommended that you take advantage of the optimized pandas data access methods exposed in this chapter.

---

**Warning:** Whether a copy or a reference is returned for a setting operation, may depend on the context. This is sometimes called `chained assignment` and should be avoided. See *Returning a View versus Copy*.

**Warning:** Indexing on an integer-based Index with floats has been clarified in 0.18.0, for a summary of the changes, see *here*.

See the *MultiIndex / Advanced Indexing* for `MultiIndex` and more advanced indexing documentation.

See the *cookbook* for some advanced strategies.

### 12.1 Different Choices for Indexing

Object selection has had a number of user-requested additions in order to support more explicit location based indexing. Pandas now supports three types of multi-axis indexing.

- `.loc` is primarily label based, but may also be used with a boolean array. `.loc` will raise `KeyError` when the items are not found. Allowed inputs are:

- A single label, e.g. 5 or 'a' (Note that 5 is interpreted as a *label* of the index. This use is **not** an integer position along the index.).
- A list or array of labels ['a', 'b', 'c'].
- A slice object with labels 'a': 'f' (Note that contrary to usual python slices, **both** the start and the stop are included, when present in the index! See *Slicing with labels*.).
- A boolean array
- A callable function with one argument (the calling Series, DataFrame or Panel) and that returns valid output for indexing (one of the above).

New in version 0.18.1.

See more at *Selection by Label*.

- `.iloc` is primarily integer position based (from 0 to `length-1` of the axis), but may also be used with a boolean array. `.iloc` will raise `IndexError` if a requested indexer is out-of-bounds, except *slice* indexers which allow out-of-bounds indexing. (this conforms with Python/NumPy *slice* semantics). Allowed inputs are:
  - An integer e.g. 5.
  - A list or array of integers [4, 3, 0].
  - A slice object with ints 1:7.
  - A boolean array.
  - A callable function with one argument (the calling Series, DataFrame or Panel) and that returns valid output for indexing (one of the above).

New in version 0.18.1.

See more at *Selection by Position*, *Advanced Indexing* and *Advanced Hierarchical*.

- `.loc`, `.iloc`, and also `[]` indexing can accept a callable as indexer. See more at *Selection By Callable*.

Getting values from an object with multi-axes selection uses the following notation (using `.loc` as an example, but the following applies to `.iloc` as well). Any of the axes accessors may be the null slice `:`. Axes left out of the specification are assumed to be `:`, e.g. `p.loc['a']` is equivalent to `p.loc['a', :, :]`.

| Object Type | Indexers                                                       |
|-------------|----------------------------------------------------------------|
| Series      | <code>s.loc[indexer]</code>                                    |
| DataFrame   | <code>df.loc[row_indexer, column_indexer]</code>               |
| Panel       | <code>p.loc[item_indexer, major_indexer, minor_indexer]</code> |

## 12.2 Basics

As mentioned when introducing the data structures in the *last section*, the primary function of indexing with `[]` (a.k.a. `__getitem__` for those familiar with implementing class behavior in Python) is selecting out lower-dimensional slices. The following table shows return type values when indexing pandas objects with `[]`:

| Object Type | Selection                    | Return Value Type                       |
|-------------|------------------------------|-----------------------------------------|
| Series      | <code>series[label]</code>   | scalar value                            |
| DataFrame   | <code>frame[colname]</code>  | Series corresponding to colname         |
| Panel       | <code>panel[itemname]</code> | DataFrame corresponding to the itemname |

Here we construct a simple time series data set to use for illustrating the indexing functionality:

```
In [1]: dates = pd.date_range('1/1/2000', periods=8)

In [2]: df = pd.DataFrame(np.random.randn(8, 4),
 ...: index=dates, columns=['A', 'B', 'C', 'D'])
 ...:

In [3]: df
Out[3]:
```

|            | A         | B         | C         | D         |
|------------|-----------|-----------|-----------|-----------|
| 2000-01-01 | -1.157426 | -0.096491 | 0.999344  | -1.482012 |
| 2000-01-02 | 0.189291  | 0.926828  | -0.029095 | 1.776600  |
| 2000-01-03 | -1.334294 | 2.085399  | -0.633036 | 0.208208  |
| 2000-01-04 | -1.723333 | -0.355486 | -0.143959 | 0.177635  |
| 2000-01-05 | 1.071746  | -0.516876 | -0.382709 | 0.888600  |
| 2000-01-06 | -0.156260 | -0.720254 | -0.837161 | -0.426902 |
| 2000-01-07 | -0.354174 | 0.510804  | 0.156535  | 0.294767  |
| 2000-01-08 | -1.448608 | -1.191084 | -0.128338 | -0.687717 |

```
In [4]: panel = pd.Panel({'one': df, 'two': df - df.mean()})

In [5]: panel
Out[5]:
```

```
<class 'pandas.core.panel.Panel'>
Dimensions: 2 (items) x 8 (major_axis) x 4 (minor_axis)
Items axis: one to two
Major_axis axis: 2000-01-01 00:00:00 to 2000-01-08 00:00:00
Minor_axis axis: A to D
```

**Note:** None of the indexing functionality is time series specific unless specifically stated.

Thus, as per above, we have the most basic indexing using []:

```
In [6]: s = df['A']

In [7]: s[dates[5]]
Out[7]: -0.15625969875302725

In [8]: panel['two']
\\Out[8]:
```

|            | A         | B         | C         | D         |
|------------|-----------|-----------|-----------|-----------|
| 2000-01-01 | -0.543294 | -0.176846 | 1.124147  | -1.575659 |
| 2000-01-02 | 0.803423  | 0.846473  | 0.095708  | 1.682953  |
| 2000-01-03 | -0.720162 | 2.005044  | -0.508234 | 0.114560  |
| 2000-01-04 | -1.109201 | -0.435841 | -0.019156 | 0.083987  |
| 2000-01-05 | 1.685878  | -0.597231 | -0.257907 | 0.794953  |
| 2000-01-06 | 0.457873  | -0.800609 | -0.712359 | -0.520549 |
| 2000-01-07 | 0.259958  | 0.430449  | 0.281337  | 0.201120  |
| 2000-01-08 | -0.834476 | -1.271439 | -0.003536 | -0.781364 |

You can pass a list of columns to [] to select columns in that order. If a column is not contained in the DataFrame, an exception will be raised. Multiple columns can also be set in this manner:

```
In [9]: df
Out[9]:
```

(continues on next page)

(continued from previous page)

```

 A B C D
2000-01-01 -1.157426 -0.096491 0.999344 -1.482012

2000-01-08 -1.448608 -1.191084 -0.128338 -0.687717

```

```
In [10]: df[['B', 'A']] = df[['A', 'B']]
```

```
In [11]: df
```

```
Out[11]:
```

```

 A B C D
2000-01-01 -0.096491 -1.157426 0.999344 -1.482012
2000-01-02 0.926828 0.189291 -0.029095 1.776600
2000-01-03 2.085399 -1.334294 -0.633036 0.208208
2000-01-04 -0.355486 -1.723333 -0.143959 0.177635
2000-01-05 -0.516876 1.071746 -0.382709 0.888600
2000-01-06 -0.720254 -0.156260 -0.837161 -0.426902
2000-01-07 0.510804 -0.354174 0.156535 0.294767
2000-01-08 -1.191084 -1.448608 -0.128338 -0.687717

```

You may find this useful for applying a transform (in-place) to a subset of the columns.

**Warning:** pandas aligns all AXES when setting Series and DataFrame from `.loc`, and `.iloc`.

This will **not** modify `df` because the column alignment is before value assignment.

```
In [12]: df[['A', 'B']]
```

```
Out[12]:
```

```

 A B

```

The correct way to swap column values is by using raw values:

```
In [17]: sa = pd.Series([1, 2, 3], index=list('abc'))

In [18]: dfa = df.copy()
```

```
In [19]: sa.b
Out[19]: 2

In [20]: dfa.A
Out[20]:
2000-01-01 -1.157426
2000-01-02 0.189291
2000-01-03 -1.334294
2000-01-04 -1.723333
2000-01-05 1.071746
2000-01-06 -0.156260
2000-01-07 -0.354174
2000-01-08 -1.448608
Freq: D, Name: A, dtype: float64

In [21]: panel.one
Out[21]:

2000-01-05 4 -0.516876 -0.382709 0.888600
2000-01-06 5 -0.720254 -0.837161 -0.426902
2000-01-07 6 0.510804 0.156535 0.294767
2000-01-08 7 -1.191084 -0.128338 -0.687717

```

**Warning:**

- You can use this access only if the index element is a valid Python identifier, e.g. `s.1` is not allowed. See [here for an explanation of valid identifiers](#).
- The attribute will not be available if it conflicts with an existing method name, e.g. `s.min` is not allowed.
- Similarly, the attribute will not be available if it conflicts with any of the following list: `index`, `major_axis`, `minor_axis`, `items`.
- In any of these cases, standard indexing will still work, e.g. `s['1']`, `s['min']`, and `s['index']` will access the corresponding element or column.

If you are using the IPython environment, you may also use tab-completion to see these accessible attributes.

You can also assign a dict to a row of a DataFrame:

```

In [28]: x = pd.DataFrame({'x': [1, 2, 3], 'y': [3, 4, 5]})

In [29]: x.iloc[1] = {'x': 9, 'y': 99}

```

(continues on next page)

(continued from previous page)

```
In [30]: x
Out[30]:
```

|   | x | y  |
|---|---|----|
| 0 | 1 | 3  |
| 1 | 9 | 99 |
| 2 | 3 | 5  |

You can use attribute access to modify an existing element of a Series or column of a DataFrame, but be careful; if you try to use attribute access to create a new column, it creates a new attribute rather than a new column. In 0.21.0 and later, this will raise a UserWarning:

```
In [1]: df = pd.DataFrame({'one': [1., 2., 3.]})
In [2]: df.two = [4, 5, 6]
UserWarning: Pandas doesn't allow Series to be assigned into nonexistent columns -
↳see https://pandas.pydata.org/pandas-docs/stable/indexing.html#attribute_access
In [3]: df
Out[3]:
```

|   | one |
|---|-----|
| 0 | 1.0 |
| 1 | 2.0 |
| 2 | 3.0 |

## 12.4 Slicing ranges

The most robust and consistent way of slicing ranges along arbitrary axes is described in the *Selection by Position* section detailing the `.iloc` method. For now, we explain the semantics of slicing using the `[]` operator.

With Series, the syntax works exactly as with an ndarray, returning a slice of the values and the corresponding labels:

```
In [31]: s[:5]
Out[31]:
```

| 2000-01-01 | -1.157426 |
|------------|-----------|
| 2000-01-02 | 0.189291  |
| 2000-01-03 | -1.334294 |
| 2000-01-04 | -1.723333 |
| 2000-01-05 | 1.071746  |

Freq: D, Name: A, dtype: float64

```
In [32]: s[::2]
Out[32]:
```

| 2000-01-01 | -1.157426 |
|------------|-----------|
| 2000-01-03 | -1.334294 |
| 2000-01-05 | 1.071746  |
| 2000-01-07 | -0.354174 |

Freq: 2D, Name: A, dtype: float64

```
In [33]: s[::-1]
Out[33]:
```

| 2000-01-08 | -1.448608 |
|------------|-----------|
| 2000-01-07 | -0.354174 |
| 2000-01-06 | -0.156260 |
| 2000-01-05 | 1.071746  |

(continues on next page)

(continued from previous page)

```

2000-01-04 -1.723333
2000-01-03 -1.334294
2000-01-02 0.189291
2000-01-01 -1.157426
Freq: -1D, Name: A, dtype: float64

```

Note that setting works as well:

```

In [34]: s2 = s.copy()

In [35]: s2[:5] = 0

In [36]: s2
Out[36]:
2000-01-01 0.000000
2000-01-02 0.000000
2000-01-03 0.000000
2000-01-04 0.000000
2000-01-05 0.000000
2000-01-06 -0.156260
2000-01-07 -0.354174
2000-01-08 -1.448608
Freq: D, Name: A, dtype: float64

```

With DataFrame, slicing inside of `[]` **slices the rows**. This is provided largely as a convenience since it is such a common operation.

```

In [37]: df[:3]
Out[37]:
 A B C D
2000-01-01 -1.157426 -0.096491 0.999344 -1.482012
2000-01-02 0.189291 0.926828 -0.029095 1.776600
2000-01-03 -1.334294 2.085399 -0.633036 0.208208

In [38]: df[::-1]
Out[38]:
 A B C D
2000-01-08 -1.448608 -1.191084 -0.128338 -0.687717
2000-01-07 -0.354174 0.510804 0.156535 0.294767
2000-01-06 -0.156260 -0.720254 -0.837161 -0.426902
2000-01-05 1.071746 -0.516876 -0.382709 0.888600
2000-01-04 -1.723333 -0.355486 -0.143959 0.177635
2000-01-03 -1.334294 2.085399 -0.633036 0.208208
2000-01-02 0.189291 0.926828 -0.029095 1.776600
2000-01-01 -1.157426 -0.096491 0.999344 -1.482012

```

## 12.5 Selection By Label

**Warning:** Whether a copy or a reference is returned for a setting operation, may depend on the context. This is sometimes called `chained assignment` and should be avoided. See *Returning a View versus Copy*.

**Warning:**

.loc is strict when you present slicers that are not compatible (or convertible) with the index type. For example using integers in a DatetimeIndex. These will raise a `TypeError`.

```
In [39]: df1 = pd.DataFrame(np.random.randn(5, 4),
.....: columns=list('ABCD'),
.....: index=pd.date_range('20130101', periods=5))
.....:
```

```
In [40]: df1
```

```
Out [40]:
```

|            | A         | B         | C         | D         |
|------------|-----------|-----------|-----------|-----------|
| 2013-01-01 | -2.100928 | 1.025928  | -0.007973 | -1.336035 |
| 2013-01-02 | 0.915382  | -0.130655 | 0.022627  | -1.425459 |
| 2013-01-03 | 0.271939  | 0.169543  | 0.692513  | -1.231139 |
| 2013-01-04 | 1.692870  | 0.783855  | -0.721626 | 1.698994  |
| 2013-01-05 | -0.349882 | 1.586451  | 1.454199  | 0.149458  |

```
In [4]: df1.loc[2:3]
```

```
TypeError: cannot do slice indexing on <class 'pandas.tseries.index.DatetimeIndex'>
↪ with these indexers [2] of <type 'int'>
```

String likes in slicing *can* be convertible to the type of the index and lead to natural slicing.

```
In [41]: df1.loc['20130102':'20130104']
```

```
Out [41]:
```

|            | A        | B         | C         | D         |
|------------|----------|-----------|-----------|-----------|
| 2013-01-02 | 0.915382 | -0.130655 | 0.022627  | -1.425459 |
| 2013-01-03 | 0.271939 | 0.169543  | 0.692513  | -1.231139 |
| 2013-01-04 | 1.692870 | 0.783855  | -0.721626 | 1.698994  |

**Warning:** Starting in 0.21.0, pandas will show a `FutureWarning` if indexing with a list with missing labels. In the future this will raise a `KeyError`. See *list-like Using loc with missing keys in a list is Deprecated*.

pandas provides a suite of methods in order to have **purely label based indexing**. This is a strict inclusion based protocol. Every label asked for must be in the index, or a `KeyError` will be raised. When slicing, both the start bound **AND** the stop bound are *included*, if present in the index. Integers are valid labels, but they refer to the label **and not the position**.

The `.loc` attribute is the primary access method. The following are valid inputs:

- A single label, e.g. 5 or 'a' (Note that 5 is interpreted as a *label* of the index. This use is **not** an integer position along the index.).
- A list or array of labels ['a', 'b', 'c'].
- A slice object with labels 'a': 'f' (Note that contrary to usual python slices, **both** the start and the stop are included, when present in the index! See *Slicing with labels*.).
- A boolean array.
- A callable, see *Selection By Callable*.

```
In [42]: s1 = pd.Series(np.random.randn(6), index=list('abcdef'))
```

```
In [43]: s1
```

## Chapter 12. Indexing and Selecting Data

(continued from previous page)

```
a 1.695493 1.632303 -1.726092 0.486227
b -0.625187 0.386616 -0.048112 -2.598355
d 0.573428 0.697186 -2.442512 -1.423556
```

Accessing via label slices:

```
In [51]: df1.loc['d':, 'A':'C']
Out[51]:
```

|   | A         | B         | C         |
|---|-----------|-----------|-----------|
| d | 0.573428  | 0.697186  | -2.442512 |
| e | -0.304997 | 0.672794  | 0.954090  |
| f | 0.015720  | -0.815293 | 0.164562  |

For getting a cross section using a label (equivalent to `df.xs('a')`):

```
In [52]: df1.loc['a']
Out[52]:
```

|   | A        | B        | C         | D        |
|---|----------|----------|-----------|----------|
| a | 1.695493 | 1.632303 | -1.726092 | 0.486227 |

Name: a, dtype: float64

For getting values with a boolean array:

```
In [53]: df1.loc['a'] > 0
Out[53]:
```

|   | A    | B    | C     | D    |
|---|------|------|-------|------|
| a | True | True | False | True |

Name: a, dtype: bool

```
In [54]: df1.loc[:, df1.loc['a'] > 0]
Out[54]:
```

|   | A         | B         | D         |
|---|-----------|-----------|-----------|
| a | 1.695493  | 1.632303  | 0.486227  |
| b | -0.625187 | 0.386616  | -2.598355 |
| c | -0.871135 | -0.209156 | 0.449006  |
| d | 0.573428  | 0.697186  | -1.423556 |
| e | -0.304997 | 0.672794  | 1.323584  |
| f | 0.015720  | -0.815293 | 0.576599  |

For getting a value explicitly (equivalent to deprecated `df.get_value('a', 'A')`):

```
this is also equivalent to ``df1.at['a', 'A']``
In [55]: df1.loc['a', 'A']
Out[55]: 1.6954931738440173
```

## 12.5.1 Slicing with labels

When using `.loc` with slices, if both the start and the stop labels are present in the index, then elements *located* between the two (including them) are returned:

```
In [56]: s = pd.Series(list('abcde'), index=[0, 3, 2, 5, 4])
In [57]: s.loc[3:5]
Out[57]:
3 b
2 c
5 d
dtype: object
```

If at least one of the two is absent, but the index is sorted, and can be compared against start and stop labels, then slicing will still work as expected, by selecting labels which *rank* between the two:

```
In [58]: s.sort_index()
Out[58]:
0 a
2 c
3 b
4 e
5 d
dtype: object

In [59]: s.sort_index().loc[1:6]
Out[59]:
2 c
3 b
4 e
5 d
dtype: object
```

However, if at least one of the two is absent *and* the index is not sorted, an error will be raised (since doing otherwise would be computationally expensive, as well as potentially ambiguous for mixed type indexes). For instance, in the above example, `s.loc[1:6]` would raise `KeyError`.

## 12.6 Selection By Position

**Warning:** Whether a copy or a reference is returned for a setting operation, may depend on the context. This is sometimes called `chained assignment` and should be avoided. See *Returning a View versus Copy*.

Pandas provides a suite of methods in order to get **purely integer based indexing**. The semantics follow closely Python and NumPy slicing. These are 0-based indexing. When slicing, the start bounds is *included*, while the upper bound is *excluded*. Trying to use a non-integer, even a **valid** label will raise an `IndexError`.

The `.iloc` attribute is the primary access method. The following are valid inputs:

- An integer e.g. 5.
- A list or array of integers [4, 3, 0].
- A slice object with ints 1:7.
- A boolean array.
- A callable, see *Selection By Callable*.

$\hookrightarrow -0.27389806372914649$

| 4 | 0.259405 |

```
In [87]: dfl.iloc[4:6]
```

A single indexer that is out of bounds will raise an `IndexError`. A list of indexers where any element is out of bounds will raise an `IndexError`.

```
>>> dfl.iloc[[4, 5, 6]]
IndexError: positional indexers are out-of-bounds
```

```
>>> dfl.iloc[:, 4]
IndexError: single positional indexer is out-of-bounds
```

## 12.7 Selection By Callable

New in version 0.18.1.

`.loc`, `.iloc`, and also `[]` indexing can accept a callable as indexer. The callable must be a function with one argument (the calling Series, DataFrame or Panel) and that returns valid output for indexing.

```
In [88]: df1 = pd.DataFrame(np.random.randn(6, 4),
...: index=list('abcdef'),
...: columns=list('ABCD'))
...:
```

```
In [89]: df1
```

Out [89] :

## 12.8 IX Indexer is Deprecated

**Warning:** Starting in 0.20.0, the `.ix` indexer is deprecated, in favor of the more strict `.iloc` and `.loc` indexers.

`.ix` offers a lot of magic on the inference of what the user wants to do. To wit, `.ix` can decide to index *positionally* OR via *labels* depending on the data type of the index. This has caused quite a bit of user confusion over the years.

The recommended methods of indexing are:

- `.loc` if you want to *label* index.
- `.iloc` if you want to *positionally* index.

```
In [97]: dfd = pd.DataFrame({'A': [1, 2, 3],
.....: 'B': [4, 5, 6]},
.....: index=list('abc'))
.....:

In [98]: dfd
Out[98]:
 A B
a 1 4
b 2 5
c 3 6
```

Previous behavior, where you wish to get the 0th and the 2nd elements from the index in the 'A' column.

```
In [3]: dfd.ix[[0, 2], 'A']
Out[3]:
a 1
c 3
Name: A, dtype: int64
```

Using `.loc`. Here we will select the appropriate indexes from the index, then use *label* indexing.

```
In [99]: dfd.loc[dfd.index[[0, 2]], 'A']
Out[99]:
a 1
```

(continues on next page)

(continued from previous page)

```
c 3
Name: A, dtype: int64
```

This can also be expressed using `.iloc`, by explicitly getting locations on the indexers, and using *positional* indexing to select things.

```
In [100]: dfd.iloc[[0, 2], dfd.columns.get_loc('A')]
Out[100]:
a 1
c 3
Name: A, dtype: int64
```

For getting *multiple* indexers, using `.get_indexer`:

```
In [101]: dfd.iloc[[0, 2], dfd.columns.get_indexer(['A', 'B'])]
Out[101]:
 A B
a 1 4
c 3 6
```

## 12.9 Indexing with list with missing labels is Deprecated

**Warning:** Starting in 0.21.0, using `.loc` or `[]` with a list with one or more missing labels, is deprecated, in favor of `.reindex`.

In prior versions, using `.loc[list-of-labels]` would work as long as *at least 1* of the keys was found (otherwise it would raise a `KeyError`). This behavior is deprecated and will show a warning message pointing to this section. The recommended alternative is to use `.reindex()`.

For example.

```
In [102]: s = pd.Series([1, 2, 3])

In [103]: s
Out[103]:
0 1
1 2
2 3
dtype: int64
```

Selection with all keys found is unchanged.

```
In [104]: s.loc[[1, 2]]
Out[104]:
1 2
2 3
dtype: int64
```

Previous Behavior

```
In [4]: s.loc[[1, 2, 3]]
Out[4]:
```

(continues on next page)

(continued from previous page)

```
1 2.0
2 3.0
3 NaN
dtype: float64
```

### Current Behavior

```
In [4]: s.loc[[1, 2, 3]]
Passing list-likes to .loc with any non-matching elements will raise
KeyError in the future, you can use .reindex() as an alternative.

See the documentation here:
http://pandas.pydata.org/pandas-docs/stable/indexing.html#deprecate-loc-reindex-
→listlike

Out[4]:
1 2.0
2 3.0
3 NaN
dtype: float64
```

## 12.9.1 Reindexing

The idiomatic way to achieve selecting potentially not-found elements is via `.reindex()`. See also the section on *reindexing*.

```
In [105]: s.reindex([1, 2, 3])
Out[105]:
1 2.0
2 3.0
3 NaN
dtype: float64
```

Alternatively, if you want to select only *valid* keys, the following is idiomatic and efficient; it is guaranteed to preserve the dtype of the selection.

```
In [106]: labels = [1, 2, 3]

In [107]: s.loc[s.index.intersection(labels)]
Out[107]:
1 2
2 3
dtype: int64
```

Having a duplicated index will raise for a `.reindex()`:

```
In [108]: s = pd.Series(np.arange(4), index=['a', 'a', 'b', 'c'])

In [109]: labels = ['c', 'd']
```

```
In [17]: s.reindex(labels)
ValueError: cannot reindex from a duplicate axis
```

Generally, you can intersect the desired labels with the current axis, and then reindex.

```
In [110]: s.loc[s.index.intersection(labels)].reindex(labels)
Out[110]:
c 3.0
d NaN
dtype: float64
```

However, this would *still* raise if your resulting index is duplicated.

```
In [41]: labels = ['a', 'd']

In [42]: s.loc[s.index.intersection(labels)].reindex(labels)
ValueError: cannot reindex from a duplicate axis
```

## 12.10 Selecting Random Samples

A random selection of rows or columns from a Series, DataFrame, or Panel with the `sample()` method. The method will sample rows by default, and accepts a specific number of rows/columns to return, or a fraction of rows.

```
In [111]: s = pd.Series([0, 1, 2, 3, 4, 5])

When no arguments are passed, returns 1 row.
In [112]: s.sample()
Out[112]:
0 0
dtype: int64

One may specify either a number of rows:
In [113]: s.sample(n=3)
Out[113]:
2 2
1 1
5 5
dtype: int64

Or a fraction of the rows:
In [114]: s.sample(frac=0.5)
Out[114]:
0 0
2 2
3 3
dtype: int64
```

By default, `sample` will return each row at most once, but one can also sample with replacement using the `replace` option:

```
In [115]: s = pd.Series([0, 1, 2, 3, 4, 5])

Without replacement (default):
In [116]: s.sample(n=6, replace=False)
Out[116]:
3 3
2 2
4 4
0 0
```

(continues on next page)

(continued from previous page)

```

5 5
1 1
dtype: int64

With replacement:
In [117]: s.sample(n=6, replace=True)
Out[117]:
0 0
2 2
0 0
3 3
1 1
2 2
dtype: int64

```

By default, each row has an equal probability of being selected, but if you want rows to have different probabilities, you can pass the `sample` function sampling weights as `weights`. These weights can be a list, a NumPy array, or a Series, but they must be of the same length as the object you are sampling. Missing values will be treated as a weight of zero, and `inf` values are not allowed. If weights do not sum to 1, they will be re-normalized by dividing all weights by the sum of the weights. For example:

```

In [118]: s = pd.Series([0, 1, 2, 3, 4, 5])

In [119]: example_weights = [0, 0, 0.2, 0.2, 0.2, 0.4]

In [120]: s.sample(n=3, weights=example_weights)
Out[120]:
5 5
4 4
3 3
dtype: int64

Weights will be re-normalized automatically
In [121]: example_weights2 = [0.5, 0, 0, 0, 0, 0]

In [122]: s.sample(n=1, weights=example_weights2)
Out[122]:
0 0
dtype: int64

```

When applied to a DataFrame, you can use a column of the DataFrame as sampling weights (provided you are sampling rows and not columns) by simply passing the name of the column as a string.

```

In [123]: df2 = pd.DataFrame({'coll': [9, 8, 7, 6],
.....: 'weight_column': [0.5, 0.4, 0.1, 0]})

In [124]: df2.sample(n=3, weights='weight_column')
Out[124]:
 coll weight_column
0 9 0.5
2 7 0.1
1 8 0.4

```

`sample` also allows users to sample columns instead of rows using the `axis` argument.

```
In [125]: df3 = pd.DataFrame({'col1': [1, 2, 3], 'col2': [2, 3, 4]})
```

```
In [126]: df3.sample(n=1, axis=1)
```

Out [126] :

|   | coll |
|---|------|
| 0 | 1    |
| 1 | 2    |
| 2 | 3    |

Finally, one can also set a seed for sample's random number generator using the `random_state` argument, which will accept either an integer (as a seed) or a NumPy RandomState object.

```
In [127]: df4 = pd.DataFrame({'col1': [1, 2, 3], 'col2': [2, 3, 4]})
```

```
With a given seed, the sample will always draw the same rows.
```

```
In [128]: df4.sample(n=2, random_state=2)
```

Out [128]:

|   | col1 | col2 |
|---|------|------|
| 2 | 3    | 4    |
| 1 | 2    | 3    |

```
In [129]: df4.sample(n=2, random_state=2)
```

```
\\Out[129]:
```

|   | col1 | col2 |
|---|------|------|
| 2 | 3    | 4    |
| 1 | 2    | 3    |

## 12.11 Setting With Enlargement

The `.loc/[]` operations can perform enlargement when setting a non-existent key for that axis.

In the `Series` case this is effectively an appending operation.

```
In [130]: se = pd.Series([1, 2, 3])
```

```
In [131]: se
```

Out [131]:

```
0 1
1 2
2 3
dtype: int64
```

```
In [132]: se[5] = 5.
```

```
In [133]: se
```

Out [133]:

```
0 1.0
1 2.0
2 3.0
5 5.0
dtype: float64
```

A DataFrame can be enlarged on either axis via `.loc`.

```
In [134]: dfi = pd.DataFrame(np.arange(6).reshape(3, 2),
.....: columns=['A', 'B'])
.....:
```

```
In [135]: dfi
Out[135]:
```

|   | A | B |
|---|---|---|
| 0 | 0 | 1 |
| 1 | 2 | 3 |
| 2 | 4 | 5 |

```
In [136]: dfi.loc[:, 'C'] = dfi.loc[:, 'A']
```

```
In [137]: dfi
Out[137]:
```

|   | A | B | C |
|---|---|---|---|
| 0 | 0 | 1 | 0 |
| 1 | 2 | 3 | 2 |
| 2 | 4 | 5 | 4 |

This is like an append operation on the DataFrame.

```
In [138]: dfi.loc[3] = 5

In [139]: dfi
Out[139]:
```

|   | A | B | C |
|---|---|---|---|
| 0 | 0 | 1 | 0 |
| 1 | 2 | 3 | 2 |
| 2 | 4 | 5 | 4 |
| 3 | 5 | 5 | 5 |

## 12.12 Fast scalar value getting and setting

Since indexing with `[]` must handle a lot of cases (single-label access, slicing, boolean indexing, etc.), it has a bit of overhead in order to figure out what you're asking for. If you only want to access a scalar value, the fastest way is to use the `at` and `iat` methods, which are implemented on all of the data structures.

Similarly to `loc`, `at` provides **label** based scalar lookups, while, `iat` provides **integer** based lookups analogously to `iloc`

[illegible]

You can also set using these same indexers.

```
In [143]: df.at[dates[5], 'E'] = 7

In [144]: df.iat[3, 0] = 7
```

at may enlarge the object in-place as above if the indexer is missing.

```
In [145]: df.at[dates[-1] + 1, 0] = 7

In [146]: df
Out[146]:
```

|            | A         | B         | C         | D         | E   | 0   |
|------------|-----------|-----------|-----------|-----------|-----|-----|
| 2000-01-01 | -1.157426 | -0.096491 | 0.999344  | -1.482012 | NaN | NaN |
| 2000-01-02 | 0.189291  | 0.926828  | -0.029095 | 1.776600  | NaN | NaN |
| 2000-01-03 | -1.334294 | 2.085399  | -0.633036 | 0.208208  | NaN | NaN |
| 2000-01-04 | 7.000000  | -0.355486 | -0.143959 | 0.177635  | NaN | NaN |
| 2000-01-05 | 1.071746  | -0.516876 | -0.382709 | 0.888600  | NaN | NaN |
| 2000-01-06 | -0.156260 | -0.720254 | -0.837161 | -0.426902 | 7.0 | NaN |
| 2000-01-07 | -0.354174 | 0.510804  | 0.156535  | 0.294767  | NaN | NaN |
| 2000-01-08 | -1.448608 | -1.191084 | -0.128338 | -0.687717 | NaN | NaN |
| 2000-01-09 | NaN       | NaN       | NaN       | NaN       | NaN | 7.0 |

## 12.13 Boolean indexing

Another common operation is the use of boolean vectors to filter the data. The operators are: | for or, & for and, and ~ for not. These **must** be grouped by using parentheses, since by default Python will evaluate an expression such as `df.A > 2 & df.B < 3` as `df.A > (2 & df.B) < 3`, while the desired evaluation order is `(df.A > 2) & (df.B < 3)`.

Using a boolean vector to index a Series works exactly as in a NumPy ndarray:

```
In [147]: s = pd.Series(range(-3, 4))

In [148]: s
Out[148]:
```

|   |    |
|---|----|
| 0 | -3 |
| 1 | -2 |
| 2 | -1 |
| 3 | 0  |
| 4 | 1  |
| 5 | 2  |
| 6 | 3  |

```
dtype: int64

In [149]: s[s > 0]
Out[149]:
```

|   |   |
|---|---|
| 4 | 1 |
| 5 | 2 |
| 6 | 3 |

```
dtype: int64

In [150]: s[(s < -1) | (s > 0.5)]
Out[150]:
```

|   |    |
|---|----|
| 0 | -3 |
| 1 | -2 |
| 4 | 1  |
| 5 | 2  |
| 6 | 3  |

```
dtype: int64
```

(continues on next page)

(continued from previous page)

```
In [151]: s[~(s < 0)]
```

```

////////////////////////////////////
↪
3 0
4 1
5 2
6 3
dtype: int64

```

You may select rows from a DataFrame using a boolean vector the same length as the DataFrame's index (for example, something derived from one of the columns of the DataFrame):

```
In [152]: df[df['A'] > 0]
```

```
Out [152]:
```

|            | A        | B         | C         | D        | E   | 0   |
|------------|----------|-----------|-----------|----------|-----|-----|
| 2000-01-02 | 0.189291 | 0.926828  | -0.029095 | 1.776600 | NaN | NaN |
| 2000-01-04 | 7.000000 | -0.355486 | -0.143959 | 0.177635 | NaN | NaN |
| 2000-01-05 | 1.071746 | -0.516876 | -0.382709 | 0.888600 | NaN | NaN |

List comprehensions and map method of Series can also be used to produce more complex criteria:

```
In [153]: df2 = pd.DataFrame({'a': ['one', 'one', 'two', 'three', 'two', 'one', 'six'],
↪ 'b': ['x', 'y', 'y', 'x', 'y', 'x', 'x'],
 'c': np.random.randn(7)})
```

```
only want 'two' or 'three'
```

```
In [154]: criterion = df2['a'].map(lambda x: x.startswith('t'))
```

```
In [155]: df2[criterion]
```

```
Out [155]:
```

|   | a     | b | c        |
|---|-------|---|----------|
| 2 | two   | y | 0.344065 |
| 3 | three | x | 1.275247 |
| 4 | two   | y | 1.303763 |

```
equivalent but slower
```

```
In [156]: df2[[x.startswith('t') for x in df2['a']]]
```

```

////////////////////////////////////
↪
 a b c
2 two y 0.344065
3 three x 1.275247
4 two y 1.303763

```

```
Multiple criteria
```

```
In [157]: df2[criterion & (df2['b'] == 'x')]
```

```

////////////////////////////////////
↪
 a b c
3 three x 1.275247

```

With the choice methods *Selection by Label*, *Selection by Position*, and *Advanced Indexing* you may select along more than one axis using boolean vectors combined with other indexing expressions.

```
In [158]: df2.loc[criterion & (df2['b'] == 'x'), 'b':'c']
Out[158]:
 b c
3 x 1.275247
```

## 12.14 Indexing with isin

Consider the `isin()` method of `Series`, which returns a boolean vector that is true wherever the `Series` elements exist in the passed list. This allows you to select rows where one or more columns have values you want:

```
In [159]: s = pd.Series(np.arange(5), index=np.arange(5)[::-1], dtype='int64')

In [160]: s
Out[160]:
4 0
3 1
2 2
1 3
0 4
dtype: int64

In [161]: s.isin([2, 4, 6])
Out[161]:
4 False
3 False
2 True
1 False
0 True
dtype: bool

In [162]: s[s.isin([2, 4, 6])]
Out[162]:
2 2
0 4
dtype: int64
```

The same method is available for `Index` objects and is useful for the cases when you don't know which of the sought labels are in fact present:

```
In [163]: s[s.index.isin([2, 4, 6])]
Out[163]:
4 0
2 2
dtype: int64

compare it to the following
In [164]: s.reindex([2, 4, 6])
Out[164]:
2 2.0
4 0.0
6 NaN
dtype: float64
```

In addition to that, `MultiIndex` allows selecting a separate level to use in the membership check:

```

In [165]: s_mi = pd.Series(np.arange(6),
.....: index=pd.MultiIndex.from_product([[0, 1], ['a', 'b', 'c
↳ ']]))
.....:

In [166]: s_mi
Out[166]:
0 a 0
 b 1
 c 2
1 a 3
 b 4
 c 5
dtype: int64

In [167]: s_mi.iloc[s_mi.index.isin([(1, 'a'), (2, 'b'), (0, 'c')])]
Out[167]:
↳
0 c 2
1 a 3
dtype: int64

In [168]: s_mi.iloc[s_mi.index.isin(['a', 'c', 'e'], level=1)]
↳
0 a 0
 c 2
1 a 3
 c 5
dtype: int64

```

DataFrame also has an `isin()` method. When calling `isin`, pass a set of values as either an array or dict. If values is an array, `isin` returns a DataFrame of booleans that is the same shape as the original DataFrame, with True wherever the element is in the sequence of values.

```

In [169]: df = pd.DataFrame({'vals': [1, 2, 3, 4], 'ids': ['a', 'b', 'f', 'n'],
.....: 'ids2': ['a', 'n', 'c', 'n']})
.....:

In [170]: values = ['a', 'b', 1, 3]

In [171]: df.isin(values)
Out[171]:
 vals ids ids2
0 True True True
1 False True False
2 True False False
3 False False False

```

Oftentimes you'll want to match certain values with certain columns. Just make values a dict where the key is the column, and the value is a list of items you want to check for.

```

In [172]: values = {'ids': ['a', 'b'], 'vals': [1, 3]}

In [173]: df.isin(values)
Out[173]:
 vals ids ids2

```

(continues on next page)

(continued from previous page)

```

0 True True False
1 False True False
2 True False False
3 False False False

```

Combine `DataFrame`'s `isin` with the `any()` and `all()` methods to quickly select subsets of your data that meet a given criteria. To select a row where each column meets its own criterion:

```

In [174]: values = {'ids': ['a', 'b'], 'ids2': ['a', 'c'], 'vals': [1, 3]}

In [175]: row_mask = df.isin(values).all(1)

In [176]: df[row_mask]
Out[176]:
 vals ids ids2
0 1 a a

```

## 12.15 The `where()` Method and Masking

Selecting values from a `Series` with a boolean vector generally returns a subset of the data. To guarantee that selection output has the same shape as the original data, you can use the `where` method in `Series` and `DataFrame`.

To return only the selected rows:

```

In [177]: s[s > 0]
Out[177]:
3 1
2 2
1 3
0 4
dtype: int64

```

To return a `Series` of the same shape as the original:

```

In [178]: s.where(s > 0)
Out[178]:
4 NaN
3 1.0
2 2.0
1 3.0
0 4.0
dtype: float64

```

Selecting values from a `DataFrame` with a boolean criterion now also preserves input data shape. `where` is used under the hood as the implementation. The code below is equivalent to `df[df < 0]`.

```

In [179]: df[df < 0]
Out[179]:
 A B C D
2000-01-01 -0.986205 -1.719758 -2.230079 -0.439106
2000-01-02 -2.397242 NaN NaN -0.237058
2000-01-03 -1.482014 NaN -0.782186 NaN
2000-01-04 -0.480306 -1.051903 -0.987736 -0.182060
2000-01-05 -0.379467 NaN -0.138556 NaN

```

(continues on next page)

(continued from previous page)

```

2000-01-06 -0.514897 -0.117796 -0.108906 -1.142649
2000-01-07 -1.349120 NaN -0.128845 -1.352644
2000-01-08 NaN NaN NaN -1.495080

```

In addition, `where` takes an optional `other` argument for replacement of values where the condition is False, in the returned copy.

```

In [180]: df.where(df < 0, -df)
Out[180]:
 A B C D
2000-01-01 -0.986205 -1.719758 -2.230079 -0.439106
2000-01-02 -2.397242 -0.124508 -1.493995 -0.237058
2000-01-03 -1.482014 -0.429889 -0.782186 -0.389666
2000-01-04 -0.480306 -1.051903 -0.987736 -0.182060
2000-01-05 -0.379467 -0.273248 -0.138556 -0.881904
2000-01-06 -0.514897 -0.117796 -0.108906 -1.142649
2000-01-07 -1.349120 -0.316880 -0.128845 -1.352644
2000-01-08 -0.161458 -0.739064 -0.165377 -1.495080

```

You may wish to set values based on some boolean criteria. This can be done intuitively like so:

```

In [181]: s2 = s.copy()

In [182]: s2[s2 < 0] = 0

In [183]: s2
Out[183]:
4 0
3 1
2 2
1 3
0 4
dtype: int64

In [184]: df2 = df.copy()

In [185]: df2[df2 < 0] = 0

In [186]: df2
Out[186]:
 A B C D
2000-01-01 0.000000 0.000000 0.000000 0.000000
2000-01-02 0.000000 0.124508 1.493995 0.000000
2000-01-03 0.000000 0.429889 0.000000 0.389666
2000-01-04 0.000000 0.000000 0.000000 0.000000
2000-01-05 0.000000 0.273248 0.000000 0.881904
2000-01-06 0.000000 0.000000 0.000000 0.000000
2000-01-07 0.000000 0.316880 0.000000 0.000000
2000-01-08 0.161458 0.739064 0.165377 0.000000

```

By default, `where` returns a modified copy of the data. There is an optional parameter `inplace` so that the original data can be modified without creating a copy:

```

In [187]: df_orig = df.copy()

In [188]: df_orig.where(df > 0, -df, inplace=True)

```

(continues on next page)

(continued from previous page)

```
In [189]: df_orig
Out[189]:
```

|            | A        | B        | C        | D        |
|------------|----------|----------|----------|----------|
| 2000-01-01 | 0.986205 | 1.719758 | 2.230079 | 0.439106 |
| 2000-01-02 | 2.397242 | 0.124508 | 1.493995 | 0.237058 |
| 2000-01-03 | 1.482014 | 0.429889 | 0.782186 | 0.389666 |
| 2000-01-04 | 0.480306 | 1.051903 | 0.987736 | 0.182060 |
| 2000-01-05 | 0.379467 | 0.273248 | 0.138556 | 0.881904 |
| 2000-01-06 | 0.514897 | 0.117796 | 0.108906 | 1.142649 |
| 2000-01-07 | 1.349120 | 0.316880 | 0.128845 | 1.352644 |
| 2000-01-08 | 0.161458 | 0.739064 | 0.165377 | 1.495080 |

**Note:** The signature for `DataFrame.where()` differs from `numpy.where()`. Roughly `df1.where(m, df2)` is equivalent to `np.where(m, df1, df2)`.

```
In [190]: df.where(df < 0, -df) == np.where(df < 0, df, -df)
Out[190]:
```

|            | A    | B    | C    | D    |
|------------|------|------|------|------|
| 2000-01-01 | True | True | True | True |
| 2000-01-02 | True | True | True | True |
| 2000-01-03 | True | True | True | True |
| 2000-01-04 | True | True | True | True |
| 2000-01-05 | True | True | True | True |
| 2000-01-06 | True | True | True | True |
| 2000-01-07 | True | True | True | True |
| 2000-01-08 | True | True | True | True |

### alignment

Furthermore, `where` aligns the input boolean condition (ndarray or DataFrame), such that partial selection with setting is possible. This is analogous to partial setting via `.loc` (but on the contents rather than the axis labels).

```
In [191]: df2 = df.copy()
In [192]: df2[df2[1:4] > 0] = 3
In [193]: df2
Out[193]:
```

|            | A         | B         | C         | D         |
|------------|-----------|-----------|-----------|-----------|
| 2000-01-01 | -0.986205 | -1.719758 | -2.230079 | -0.439106 |
| 2000-01-02 | -2.397242 | 3.000000  | 3.000000  | -0.237058 |
| 2000-01-03 | -1.482014 | 3.000000  | -0.782186 | 3.000000  |
| 2000-01-04 | -0.480306 | -1.051903 | -0.987736 | -0.182060 |
| 2000-01-05 | -0.379467 | 0.273248  | -0.138556 | 0.881904  |
| 2000-01-06 | -0.514897 | -0.117796 | -0.108906 | -1.142649 |
| 2000-01-07 | -1.349120 | 0.316880  | -0.128845 | -1.352644 |
| 2000-01-08 | 0.161458  | 0.739064  | 0.165377  | -1.495080 |

Where can also accept `axis` and `level` parameters to align the input when performing the `where`.

```
In [194]: df2 = df.copy()
In [195]: df2.where(df2 > 0, df2['A'], axis='index')
Out[195]:
```

(continues on next page)

(continued from previous page)

|            | A         | B         | C         | D         |
|------------|-----------|-----------|-----------|-----------|
| 2000-01-01 | -0.986205 | -0.986205 | -0.986205 | -0.986205 |
| 2000-01-02 | -2.397242 | 0.124508  | 1.493995  | -2.397242 |
| 2000-01-03 | -1.482014 | 0.429889  | -1.482014 | 0.389666  |
| 2000-01-04 | -0.480306 | -0.480306 | -0.480306 | -0.480306 |
| 2000-01-05 | -0.379467 | 0.273248  | -0.379467 | 0.881904  |
| 2000-01-06 | -0.514897 | -0.514897 | -0.514897 | -0.514897 |
| 2000-01-07 | -1.349120 | 0.316880  | -1.349120 | -1.349120 |
| 2000-01-08 | 0.161458  | 0.739064  | 0.165377  | 0.161458  |

This is equivalent to (but faster than) the following.

```
In [196]: df2 = df.copy()

In [197]: df.apply(lambda x, y: x.where(x > 0, y), y=df['A'])
Out[197]:
```

|            | A         | B         | C         | D         |
|------------|-----------|-----------|-----------|-----------|
| 2000-01-01 | -0.986205 | -0.986205 | -0.986205 | -0.986205 |
| 2000-01-02 | -2.397242 | 0.124508  | 1.493995  | -2.397242 |
| 2000-01-03 | -1.482014 | 0.429889  | -1.482014 | 0.389666  |
| 2000-01-04 | -0.480306 | -0.480306 | -0.480306 | -0.480306 |
| 2000-01-05 | -0.379467 | 0.273248  | -0.379467 | 0.881904  |
| 2000-01-06 | -0.514897 | -0.514897 | -0.514897 | -0.514897 |
| 2000-01-07 | -1.349120 | 0.316880  | -1.349120 | -1.349120 |
| 2000-01-08 | 0.161458  | 0.739064  | 0.165377  | 0.161458  |

New in version 0.18.1.

Where can accept a callable as condition and other arguments. The function must be with one argument (the calling Series or DataFrame) and that returns valid output as condition and other argument.

```
In [198]: df3 = pd.DataFrame({'A': [1, 2, 3],
.....: 'B': [4, 5, 6],
.....: 'C': [7, 8, 9]})
.....:

In [199]: df3.where(lambda x: x > 4, lambda x: x + 10)
Out[199]:
```

|   | A  | B  | C |
|---|----|----|---|
| 0 | 11 | 14 | 7 |
| 1 | 12 | 5  | 8 |
| 2 | 13 | 6  | 9 |

## 12.15.1 Mask

`mask()` is the inverse boolean operation of `where`.

```
In [200]: s.mask(s >= 0)
Out[200]:
```

|   |     |
|---|-----|
| 4 | NaN |
| 3 | NaN |
| 2 | NaN |
| 1 | NaN |
| 0 | NaN |

dtype: float64

(continues on next page)

(continued from previous page)

```
In [201]: df.mask(df >= 0)
Out[201]:
```

|            | A         | B         | C         | D         |
|------------|-----------|-----------|-----------|-----------|
| 2000-01-01 | -0.986205 | -1.719758 | -2.230079 | -0.439106 |
| 2000-01-02 | -2.397242 | NaN       | NaN       | -0.237058 |
| 2000-01-03 | -1.482014 | NaN       | -0.782186 | NaN       |
| 2000-01-04 | -0.480306 | -1.051903 | -0.987736 | -0.182060 |
| 2000-01-05 | -0.379467 | NaN       | -0.138556 | NaN       |
| 2000-01-06 | -0.514897 | -0.117796 | -0.108906 | -1.142649 |
| 2000-01-07 | -1.349120 | NaN       | -0.128845 | -1.352644 |
| 2000-01-08 | NaN       | NaN       | NaN       | -1.495080 |

## 12.16 The query() Method

*DataFrame* objects have a `query()` method that allows selection using an expression.

You can get the value of the frame where column `b` has values between the values of columns `a` and `c`. For example:

```
In [202]: n = 10
In [203]: df = pd.DataFrame(np.random.rand(n, 3), columns=list('abc'))
In [204]: df
Out[204]:
```

|   | a        | b        | c        |
|---|----------|----------|----------|
| 0 | 0.564354 | 0.446221 | 0.031135 |
| 1 | 0.902823 | 0.612305 | 0.538181 |
| 2 | 0.663245 | 0.164731 | 0.782808 |
| 3 | 0.194429 | 0.253263 | 0.923684 |
| 4 | 0.698026 | 0.425477 | 0.840259 |
| 5 | 0.739830 | 0.738261 | 0.105783 |
| 6 | 0.214871 | 0.824421 | 0.246428 |
| 7 | 0.821225 | 0.243330 | 0.650292 |
| 8 | 0.373653 | 0.171969 | 0.479279 |
| 9 | 0.450277 | 0.365091 | 0.217416 |

```
pure python
In [205]: df[(df.a < df.b) & (df.b < df.c)]
Out[205]:
```

|   | a        | b        | c        |
|---|----------|----------|----------|
| 3 | 0.194429 | 0.253263 | 0.923684 |

```
query
In [206]: df.query('(a < b) & (b < c)')
Out[206]:
```

|   | a        | b        | c        |
|---|----------|----------|----------|
| 3 | 0.194429 | 0.253263 | 0.923684 |

Do the same thing but fall back on a named index if there is no column with the name `a`.

```
In [207]: df = pd.DataFrame(np.random.randint(n / 2, size=(n, 2)), columns=list('bc'))

In [208]: df.index.name = 'a'

In [209]: df
Out[209]:
```

|   | b | c |
|---|---|---|
| a |   |   |
| 0 | 4 | 0 |
| 1 | 3 | 1 |
| 2 | 4 | 3 |
| 3 | 0 | 2 |
| 4 | 1 | 4 |
| 5 | 4 | 4 |
| 6 | 4 | 2 |
| 7 | 2 | 0 |
| 8 | 0 | 0 |
| 9 | 1 | 3 |

```
In [210]: df.query('a < b and b < c')
Empty DataFrame
Columns: [b, c]
Index: []
```

If instead you don't want to or cannot name your index, you can use the name `index` in your query expression:

```
In [211]: df = pd.DataFrame(np.random.randint(n, size=(n, 2)), columns=list('bc'))

In [212]: df
Out[212]:
```

|   | b | c |
|---|---|---|
| 0 | 4 | 5 |
| 1 | 4 | 1 |
| 2 | 0 | 8 |
| 3 | 4 | 7 |
| 4 | 0 | 0 |
| 5 | 8 | 5 |
| 6 | 1 | 2 |
| 7 | 4 | 3 |
| 8 | 1 | 0 |
| 9 | 6 | 3 |

```
In [213]: df.query('index < b < c')
//////////
↪
```

|   | b | c |
|---|---|---|
| 0 | 4 | 5 |
| 3 | 4 | 7 |

**Note:** If the name of your index overlaps with a column name, the column name is given precedence. For example,

```
In [214]: df = pd.DataFrame({'a': np.random.randint(5, size=5)})
In [215]: df.index.name = 'a'
```

(continues on next page)

(continued from previous page)

```
In [216]: df.query('a > 2') # uses the column 'a', not the index
Out[216]:
 a
0 4
1 4
2 3
```

You can still use the index in a query expression by using the special identifier ‘index’:

```
In [217]: df.query('index > 2')
Out[217]:
 a
3 1
4 1
```

If for some reason you have a column named `index`, then you can refer to the index as `ilevel_0` as well, but at this point you should consider renaming your columns to something less ambiguous.

### 12.16.1 MultiIndex query() Syntax

You can also use the levels of a DataFrame with a *MultiIndex* as if they were columns in the frame:

```
In [218]: n = 10

In [219]: colors = np.random.choice(['red', 'green'], size=n)

In [220]: foods = np.random.choice(['eggs', 'ham'], size=n)

In [221]: colors
Out[221]:
array(['red', 'red', 'green', 'green', 'red', 'red', 'green', 'green',
 'green', 'red'],
 dtype='<U5')

In [222]: foods
Out[222]:
array(['eggs', 'ham', 'ham', 'ham', 'ham', 'ham', 'eggs', 'eggs', 'ham',
 'eggs'],
 dtype='<U4')

In [223]: index = pd.MultiIndex.from_arrays([colors, foods], names=['color', 'food'])

In [224]: df = pd.DataFrame(np.random.randn(n, 2), index=index)

In [225]: df
Out[225]:
 color food
0 red eggs 0.397240 1.722883
1 red ham 0.634589 1.761948
```

(continues on next page)

(continued from previous page)

```

green ham 1.191222 -0.748678
 ham -0.013401 -0.982325
red ham 0.272726 1.042615
 ham 0.267082 0.191461
green eggs -0.435659 -0.035917
 eggs 0.194931 0.970348
 ham 2.187055 0.383666
red eggs -0.812383 -0.497327

```

```
In [226]: df.query('color == "red"')
```

```

////////////////////////////////////
↪
 0 1
color food
red eggs 0.397240 1.722883
 ham 0.634589 1.761948
 ham 0.272726 1.042615
 ham 0.267082 0.191461
 eggs -0.812383 -0.497327

```

If the levels of the `MultiIndex` are unnamed, you can refer to them using special names:

```
In [227]: df.index.names = [None, None]
```

```
In [228]: df
```

```
Out[228]:
```

```

 0 1
red eggs 0.397240 1.722883
 ham 0.634589 1.761948
green ham 1.191222 -0.748678
 ham -0.013401 -0.982325
red ham 0.272726 1.042615
 ham 0.267082 0.191461
green eggs -0.435659 -0.035917
 eggs 0.194931 0.970348
 ham 2.187055 0.383666
red eggs -0.812383 -0.497327

```

```
In [229]: df.query('ilevel_0 == "red"')
```

```

////////////////////////////////////
↪
 0 1
red eggs 0.397240 1.722883
 ham 0.634589 1.761948
 ham 0.272726 1.042615
 ham 0.267082 0.191461
 eggs -0.812383 -0.497327

```

The convention is `ilevel_0`, which means “index level 0” for the 0th level of the index.

## 12.16.2 `query()` Use Cases

A use case for `query()` is when you have a collection of `DataFrame` objects that have a subset of column names (or index levels/names) in common. You can pass the same query to both frames *without* having to specify which frame you’re interested in querying

```

In [230]: df = pd.DataFrame(np.random.rand(n, 3), columns=list('abc'))

In [231]: df
Out[231]:
 a b c
0 0.483974 0.645639 0.413412
1 0.611039 0.585546 0.848970
2 0.523271 0.811649 0.517849
3 0.947506 0.143525 0.055154
4 0.934891 0.214973 0.271028
5 0.832143 0.777114 0.572133
6 0.304056 0.712288 0.960006
7 0.965451 0.803696 0.866318
8 0.965355 0.383391 0.647743
9 0.639263 0.218103 0.886788

In [232]: df2 = pd.DataFrame(np.random.rand(n + 2, 3), columns=df.columns)

In [233]: df2
Out[233]:
 a b c
0 0.563472 0.298326 0.361543
1 0.021200 0.761846 0.279478
2 0.274321 0.127032 0.025433
3 0.789059 0.154680 0.999703
4 0.195936 0.042450 0.475367
5 0.970329 0.053024 0.293762
6 0.877607 0.352530 0.300746
7 0.259895 0.666779 0.920354
8 0.861035 0.176572 0.638339
9 0.083984 0.834057 0.673247
10 0.190267 0.647251 0.586836
11 0.395322 0.575815 0.184662

In [234]: expr = '0.0 <= a <= c <= 0.5'

In [235]: map(lambda frame: frame.query(expr), [df, df2])
Out[235]: <map at 0x7fd542e41240>

```

### 12.16.3 query() Python versus pandas Syntax Comparison

Full numpy-like syntax:

```

In [236]: df = pd.DataFrame(np.random.randint(n, size=(n, 3)), columns=list('abc'))

In [237]: df
Out[237]:
 a b c
0 4 1 0
1 9 3 7
2 6 7 9
3 1 9 4
4 6 9 9
5 1 1 2
6 6 6 6
7 9 6 3

```

(continues on next page)

(continued from previous page)

```
8 0 7 9
9 3 8 3
```

```
In [238]: df.query('(a < b) & (b < c)')
```

```

////////////////////////////////////
↪
 a b c
2 6 7 9
8 0 7 9
```

```
In [239]: df[(df.a < df.b) & (df.b < df.c)]
```

```

////////////////////////////////////
↪
 a b c
2 6 7 9
8 0 7 9
```

Slightly nicer by removing the parentheses (by binding making comparison operators bind tighter than `&` and `|`).

```
In [240]: df.query('a < b & b < c')
```

```
Out[240]:
 a b c
2 6 7 9
8 0 7 9
```

Use English instead of symbols:

```
In [241]: df.query('a < b and b < c')
```

```
Out[241]:
 a b c
2 6 7 9
8 0 7 9
```

Pretty close to how you might write it on paper:

```
In [242]: df.query('a < b < c')
```

```
Out[242]:
 a b c
2 6 7 9
8 0 7 9
```

## 12.16.4 The `in` and `not in` operators

`query()` also supports special use of Python's `in` and `not in` comparison operators, providing a succinct syntax for calling the `isin` method of a `Series` or `DataFrame`.

```
get all rows where columns "a" and "b" have overlapping values
In [243]: df = pd.DataFrame({'a': list('aabbccddeeff'), 'b': list('aaaabbbbccccc'),
.....: 'c': np.random.randint(5, size=12),
.....: 'd': np.random.randint(9, size=12)})
.....:

In [244]: df
Out[244]:
 a b c d
```

(continues on next page)

(continued from previous page)

```

0 a a 1 5
1 a a 1 1
2 b a 4 1
3 b a 4 3
4 c b 4 5
5 c b 0 0
6 d b 0 4
7 d b 3 3
8 e c 4 5
9 e c 2 0
10 f c 2 2
11 f c 4 7

```

```
In [245]: df.query('a in b')
```

```

////////////////////////////////////
↪
 a b c d
0 a a 1 5
1 a a 1 1
2 b a 4 1
3 b a 4 3
4 c b 4 5
5 c b 0 0

```

```
How you'd do it in pure Python
```

```
In [246]: df[df.a.isin(df.b)]
```

```

////////////////////////////////////
↪
 a b c d
0 a a 1 5
1 a a 1 1
2 b a 4 1
3 b a 4 3
4 c b 4 5
5 c b 0 0

```

```
In [247]: df.query('a not in b')
```

```

////////////////////////////////////
↪
 a b c d
6 d b 0 4
7 d b 3 3
8 e c 4 5
9 e c 2 0
10 f c 2 2
11 f c 4 7

```

```
pure Python
```

```
In [248]: df[~df.a.isin(df.b)]
```

```

////////////////////////////////////
↪
 a b c d
6 d b 0 4
7 d b 3 3
8 e c 4 5
9 e c 2 0
10 f c 2 2

```

(continues on next page)

(continued from previous page)

```
11 f c 4 7
```

You can combine this with other expressions for very succinct queries:

```
rows where cols a and b have overlapping values
and col c's values are less than col d's
In [249]: df.query('a in b and c < d')
Out[249]:
 a b c d
0 a a 1 5
4 c b 4 5

pure Python
In [250]: df[df.b.isin(df.a) & (df.c < df.d)]
Out[250]:
 a b c d
0 a a 1 5
4 c b 4 5
6 d b 0 4
8 e c 4 5
11 f c 4 7
```

**Note:** Note that `in` and `not in` are evaluated in Python, since `numexpr` has no equivalent of this operation. However, **only the `in/not in` expression itself** is evaluated in vanilla Python. For example, in the expression

```
df.query('a in b + c + d')
```

`(b + c + d)` is evaluated by `numexpr` and *then* the `in` operation is evaluated in plain Python. In general, any operations that can be evaluated using `numexpr` will be.

### 12.16.5 Special use of the `==` operator with `list` objects

Comparing a list of values to a column using `==`/`!=` works similarly to `in/not in`.

```
In [251]: df.query('b == ["a", "b", "c"]')
Out[251]:
 a b c d
0 a a 1 5
1 a a 1 1
2 b a 4 1
3 b a 4 3
4 c b 4 5
5 c b 0 0
6 d b 0 4
7 d b 3 3
8 e c 4 5
9 e c 2 0
10 f c 2 2
11 f c 4 7
```

```
pure Python
In [252]: df[df.b.isin(["a", "b", "c"])]
```

(continues on next page)

(continued from previous page)

```

 a b c d
0 a a 1 5
1 a a 1 1
2 b a 4 1
3 b a 4 3
4 c b 4 5
5 c b 0 0
6 d b 0 4
7 d b 3 3
8 e c 4 5
9 e c 2 0
10 f c 2 2
11 f c 4 7

```

```
In [253]: df.query('c == [1, 2]')
```

```

////////////////////////////////////
↪
 a b c d
0 a a 1 5

## 12.16.6 Boolean Operators

You can negate boolean expressions with the word `not` or the `~` operator.

```
In [258]: df = pd.DataFrame(np.random.rand(n, 3), columns=list('abc'))
```

```
In [259]: df['bools'] = np.random.rand(len(df)) > 0.5
```

```
In [260]: df.query('~bools')
```

```
Out[260]:
```

```

 a b c bools
0 0.499604 0.981560 0.137759 False
4 0.104751 0.782568 0.977198 False
7 0.973197 0.245000 0.977406 False
9 0.805940 0.451425 0.070470 False

```

```
In [261]: df.query('not bools')
```

```

////////////////////////////////////
↪
 a b c bools
0 0.499604 0.981560 0.137759 False
4 0.104751 0.782568 0.977198 False
7 0.973197 0.245000 0.977406 False
9 0.805940 0.451425 0.070470 False

```

```
In [262]: df.query('not bools') == df[~df.bools]
```

```

////////////////////////////////////
↪
 a b c bools
0 True True True True
4 True True True True
7 True True True True
9 True True True True

```

Of course, expressions can be arbitrarily complex too:

```
short query syntax
```

```
In [263]: shorter = df.query('a < b < c and (not bools) or bools > 2')
```

```
equivalent in pure Python
```

```
In [264]: longer = df[(df.a < df.b) & (df.b < df.c) & (~df.bools) | (df.bools > 2)]
```

```
In [265]: shorter
```

(continues on next page)

(continued from previous page)

```
Out [265]:
```

|   | a        | b        | c        | bools |
|---|----------|----------|----------|-------|
| 4 | 0.104751 | 0.782568 | 0.977198 | False |

```
In [266]: longer
```

```
Out [266]:
```

|   | a        | b        | c        | bools |
|---|----------|----------|----------|-------|
| 4 | 0.104751 | 0.782568 | 0.977198 | False |

```
In [267]: shorter == longer
```

|   | a    | b    | c    | bools |
|---|------|------|------|-------|
| 4 | True | True | True | True  |

### 12.16.7 Performance of query ()

`DataFrame.query()` using `numexpr` is slightly faster than Python for large frames.

**Note:** You will only see the performance benefits of using the `numexpr` engine with `DataFrame.query()` if your frame has more than approximately 200,000 rows.

This plot was created using a `DataFrame` with 3 columns each containing floating point values generated using `numpy.random.randn()`.

## 12.17 Duplicate Data

If you want to identify and remove duplicate rows in a `DataFrame`, there are two methods that will help: `duplicated` and `drop_duplicates`. Each takes as an argument the columns to use to identify duplicated rows.

- `duplicated` returns a boolean vector whose length is the number of rows, and which indicates whether a row is duplicated.
- `drop_duplicates` removes duplicate rows.

By default, the first observed row of a duplicate set is considered unique, but each method has a `keep` parameter to specify targets to be kept.

- `keep='first'` (default): mark / drop duplicates except for the first occurrence.
- `keep='last'`: mark / drop duplicates except for the last occurrence.
- `keep=False`: mark / drop all duplicates.

```
In [268]: df2 = pd.DataFrame({'a': ['one', 'one', 'two', 'two', 'two', 'three', 'four'],
...: 'b': ['x', 'y', 'x', 'y', 'x', 'x', 'x'],
...: 'c': np.random.randn(7)})

In [269]: df2
Out[269]:
```

|   | a   | b | c         |
|---|-----|---|-----------|
| 0 | one | x | -0.086643 |
| 1 | one | y | -0.862428 |
| 2 | two | x | 1.155986  |
| 3 | two | y | -0.583644 |

(continues on next page)

(continued from previous page)

```

4 two x -1.416461
5 three x 0.799196
6 four x -2.063856

```

```
In [270]: df2.duplicated('a')
```

```

0 False
1 True
2 False
3 True
4 True
5 False
6 False
dtype: bool

```

```
In [271]: df2.duplicated('a', keep='last')
```

```

0 True
1 False
2 True
3 True
4 False
5 False
6 False
dtype: bool

```

```
In [272]: df2.duplicated('a', keep=False)
```

```

0 True
1 True
2 True
3 True
4 True
5 False
6 False
dtype: bool

```

```
In [273]: df2.drop_duplicates('a')
```

```

 a b c
0 one x -0.086643
2 two x 1.155986
5 three x 0.799196
6 four x -2.063856

```

```
In [274]: df2.drop_duplicates('a', keep='last')
```

```

 a b c
1 one y -0.862428
4 two x -1.416461
5 three x 0.799196
6 four x -2.063856

```

(continues on next page)

(continued from previous page)

```
In [275]: df2.drop_duplicates('a', keep=False)
```

```

////////////////////////////////////
↪
 a b c
5 three x 0.799196
6 four x -2.063856

```

Also, you can pass a list of columns to identify duplications.

```
In [276]: df2.duplicated(['a', 'b'])
```

```
Out[276]:
0 False
1 False
2 False
3 False
4 True
5 False
6 False
dtype: bool
```

```
In [277]: df2.drop_duplicates(['a', 'b'])
```

```

////////////////////////////////////
↪
 a b c
0 one x -0.086643
1 one y -0.862428
2 two x 1.155986
3 two y -0.583644
5 three x 0.799196
6 four x -2.063856

```

To drop duplicates by index value, use `Index.duplicated` then perform slicing. The same set of options are available for the `keep` parameter.

```
In [278]: df3 = pd.DataFrame({'a': np.arange(6),
.....: 'b': np.random.randn(6)},
.....: index=['a', 'a', 'b', 'c', 'b', 'a'])
.....:
```

```
In [279]: df3
```

```
Out[279]:
 a b
a 0 -0.457673
a 1 0.315795
b 2 -0.013959
c 3 -0.376069
b 4 -0.715356
a 5 1.802760
```

```
In [280]: df3.index.duplicated()
```

```

////////////////////////////////////
↪array([False, True, False, False, True, True], dtype=bool)

```

```
In [281]: df3[~df3.index.duplicated()]
```

```

////////////////////////////////////
↪

```

(continues on next page)

(continued from previous page)

```

a b
a 0 -0.457673
b 2 -0.013959
c 3 -0.376069

```

```
In [282]: df3[~df3.index.duplicated(keep='last')]
```

```

////////////////////////////////////
↪
a b
c 3 -0.376069
b 4 -0.715356
a 5 1.802760

```

```
In [283]: df3[~df3.index.duplicated(keep=False)]
```

```

////////////////////////////////////
↪
a b
c 3 -0.376069

```

## 12.18 Dictionary-like get () method

Each of Series, DataFrame, and Panel have a `get` method which can return a default value.

```
In [284]: s = pd.Series([1, 2, 3], index=['a', 'b', 'c'])
```

```
In [285]: s.get('a') # equivalent to s['a']
```

```
Out[285]: 1
```

```
In [286]: s.get('x', default=-1)
```

```
\\\\\\\\\\\\\\\\\\\\Out[286]: -1
```

## 12.19 The lookup () Method

Sometimes you want to extract a set of values given a sequence of row labels and column labels, and the `lookup` method allows for this and returns a NumPy array. For instance:

```
In [287]: dflookup = pd.DataFrame(np.random.rand(20, 4), columns = ['A', 'B', 'C', 'D']
↪)
```

```
In [288]: dflookup.lookup(list(range(0, 10, 2)), ['B', 'C', 'A', 'B', 'D'])
```

```
Out[288]: array([0.85612986, 0.02825952, 0.99403226, 0.02263787, 0.37166623])
```

## 12.20 Index objects

The pandas *Index* class and its subclasses can be viewed as implementing an *ordered multiset*. Duplicates are allowed. However, if you try to convert an *Index* object with duplicate entries into a *set*, an exception will be raised.

*Index* also provides the infrastructure necessary for lookups, data alignment, and reindexing. The easiest way to create an *Index* directly is to pass a list or other sequence to *Index*:

```
In [289]: index = pd.Index(['e', 'd', 'a', 'b'])

In [290]: index
Out[290]: Index(['e', 'd', 'a', 'b'], dtype='object')

In [291]: 'd' in index
Out[291]: True
```

You can also pass a name to be stored in the index:

```
In [292]: index = pd.Index(['e', 'd', 'a', 'b'], name='something')

In [293]: index.name
Out[293]: 'something'
```

The name, if set, will be shown in the console display:

```
In [294]: index = pd.Index(list(range(5)), name='rows')

In [295]: columns = pd.Index(['A', 'B', 'C'], name='cols')

In [296]: df = pd.DataFrame(np.random.randn(5, 3), index=index, columns=columns)

In [297]: df
Out[297]:
cols A B C
rows
0 -1.539526 0.083551 1.819217
1 -0.556258 -1.013751 0.804958
2 1.138849 -0.913212 2.047493
3 -0.894783 1.059103 -0.605857
4 -1.096832 0.217643 2.122047

In [298]: df['A']
Out[298]:
rows
0 -1.539526
1 -0.556258
2 1.138849
3 -0.894783
4 -1.096832
Name: A, dtype: float64
```

## 12.20.1 Setting metadata

Indexes are “mostly immutable”, but it is possible to set and change their metadata, like the index `name` (or, for `MultiIndex`, levels and codes).

You can use the `rename`, `set_names`, `set_levels`, and `set_codes` to set these attributes directly. They default to returning a copy; however, you can specify `inplace=True` to have the data change in place.

See *Advanced Indexing* for usage of `MultiIndexes`.

```
In [299]: ind = pd.Index([1, 2, 3])
```

(continues on next page)

(continued from previous page)

```

In [300]: ind.rename("apple")
Out[300]: Int64Index([1, 2, 3], dtype='int64', name='apple')

In [301]: ind
Out[301]: Int64Index([1, 2, 3], dtype='int64', name='apple')

In [302]: ind.set_names(["apple"], inplace=True)

In [303]: ind.name = "bob"

In [304]: ind
Out[304]: Int64Index([1, 2, 3], dtype='int64', name='bob')

```

set\_names, set\_levels, and set\_codes also take an optional *level* argument

```

In [305]: index = pd.MultiIndex.from_product([range(3), ['one', 'two']], names=['first', 'second'])

In [306]: index
Out[306]:
MultiIndex(levels=[[0, 1, 2], ['one', 'two']],
 labels=[[0, 0, 1, 1, 2, 2], [0, 1, 0, 1, 0, 1]],
 names=['first', 'second'])

In [307]: index.levels[1]
Out[307]:
Index(['one', 'two'], dtype='object', name='second')

In [308]: index.set_levels(["a", "b"], level=1)
Out[308]:
MultiIndex(levels=[[0, 1, 2], ['a', 'b']],
 labels=[[0, 0, 1, 1, 2, 2], [0, 1, 0, 1, 0, 1]],
 names=['first', 'second'])

```

## 12.20.2 Set operations on Index objects

The two main operations are union (`|`) and intersection (`&`). These can be directly called as instance methods or used via overloaded operators. Difference is provided via the `.difference()` method.

```

In [309]: a = pd.Index(['c', 'b', 'a'])
In [310]: b = pd.Index(['c', 'e', 'd'])

In [311]: a | b
Out[311]: Index(['a', 'b', 'c', 'd', 'e'], dtype='object')

In [312]: a & b
Out[312]: Index(['c'], dtype='object')

In [313]: a.difference(b)
Out[313]: Index(['a', 'b'], dtype='object')

```

Also available is the `symmetric_difference (^)` operation, which returns elements that appear in either `idx1` or `idx2`, but not in both. This is equivalent to the Index created by `idx1.difference(idx2).union(idx2.difference(idx1))`, with duplicates dropped.

[illegible]

**Note:** The resulting index from a set operation will be sorted in ascending order.

### 12.20.3 Missing values

**Important:** Even though `Index` can hold missing values (`NaN`), it should be avoided if you do not want any unexpected results. For example, some operations exclude missing values implicitly.

`Index.fillna` fills missing values with specified scalar value.

[illegible]

## 12.21 Set / Reset Index

Occasionally you will load or create a data set into a DataFrame and want to add an index after you've already done so. There are a couple of different ways.

### 12.21.1 Set an index

`DataFrame` has a `set_index()` method which takes a column name (for a regular `Index`) or a list of column names (for a `MultiIndex`). To create a new, re-indexed `DataFrame`:

```
In [324]: data
Out[324]:
```

|   | a   | b   | c | d   |
|---|-----|-----|---|-----|
| 0 | bar | one | z | 1.0 |
| 1 | bar | two | y | 2.0 |
| 2 | foo | one | x | 3.0 |
| 3 | foo | two | w | 4.0 |

```
In [325]: indexed1 = data.set_index('c')

In [326]: indexed1
Out[326]:
```

|   | a   | b   | d   |
|---|-----|-----|-----|
| c |     |     |     |
| z | bar | one | 1.0 |
| y | bar | two | 2.0 |
| x | foo | one | 3.0 |
| w | foo | two | 4.0 |

```
In [327]: indexed2 = data.set_index(['a', 'b'])

In [328]: indexed2
Out[328]:
```

|     |     | c | d   |
|-----|-----|---|-----|
| a   | b   |   |     |
| bar | one | z | 1.0 |
|     | two | y | 2.0 |
| foo | one | x | 3.0 |
|     | two | w | 4.0 |

The `append` keyword option allow you to keep the existing index and append the given columns to a `MultiIndex`:

```
In [329]: frame = data.set_index('c', drop=False)

In [330]: frame = frame.set_index(['a', 'b'], append=True)

In [331]: frame
Out[331]:
```

|   |     | c   | d     |
|---|-----|-----|-------|
| c | a   | b   |       |
| z | bar | one | z 1.0 |
| y | bar | two | y 2.0 |
| x | foo | one | x 3.0 |
| w | foo | two | w 4.0 |

Other options in `set_index` allow you not drop the index columns or to add the index in-place (without creating a new object):

```
In [332]: data.set_index('c', drop=False)
Out[332]:
```

|   | a   | b   | c | d   |
|---|-----|-----|---|-----|
| c |     |     |   |     |
| z | bar | one | z | 1.0 |

(continues on next page)

(continued from previous page)

```
y bar two y 2.0
x foo one x 3.0
w foo two w 4.0
```

```
In [333]: data.set_index(['a', 'b'], inplace=True)
```

```
In [334]: data
```

```
Out [334]:
```

|     |     | c | d   |
|-----|-----|---|-----|
| a   | b   |   |     |
| bar | one | z | 1.0 |
|     | two | y | 2.0 |
| foo | one | x | 3.0 |
|     | two | w | 4.0 |

## 12.21.2 Reset the index

As a convenience, there is a new function on DataFrame called `reset_index()` which transfers the index values into the DataFrame's columns and sets a simple integer index. This is the inverse operation of `set_index()`.

```
In [335]: data
```

```
Out [335]:
```

|     |     | c | d   |
|-----|-----|---|-----|
| a   | b   |   |     |
| bar | one | z | 1.0 |
|     | two | y | 2.0 |
| foo | one | x | 3.0 |
|     | two | w | 4.0 |

```
In [336]: data.reset_index()
```

```
////////////////////////////////////
```

```
↪
```

```

 a b c d
0 bar one z 1.0
1 bar two y 2.0
2 foo one x 3.0
3 foo two w 4.0
```

The output is more similar to a SQL table or a record array. The names for the columns derived from the index are the ones stored in the `names` attribute.

You can use the `level` keyword to remove only a portion of the index:

```
In [337]: frame
```

```
Out [337]:
```

|   |     | c   | d     |
|---|-----|-----|-------|
| c | a   | b   |       |
| z | bar | one | z 1.0 |
| y | bar | two | y 2.0 |
| x | foo | one | x 3.0 |
| w | foo | two | w 4.0 |

```
In [338]: frame.reset_index(level=1)
```

```
////////////////////////////////////
```

```
↪
```

(continues on next page)

(continued from previous page)

```

 a c d
c b
z one bar z 1.0
y two bar y 2.0
x one foo x 3.0
w two foo w 4.0

```

`reset_index` takes an optional parameter `drop` which if true simply discards the index, instead of putting index values in the DataFrame's columns.

### 12.21.3 Adding an ad hoc index

If you create an index yourself, you can just assign it to the `index` field:

```
data.index = index
```

## 12.22 Returning a view versus a copy

When setting values in a pandas object, care must be taken to avoid what is called `chained indexing`. Here is an example.

```

In [339]: dfmi = pd.DataFrame([list('abcd'),
.....: list('efgh'),
.....: list('ijkl'),
.....: list('mnop')],
.....: columns=pd.MultiIndex.from_product([['one', 'two'],
.....: ['first', 'second']]))
In [340]: dfmi
Out[340]:
 one two
first second first second
0 a b c d
1 e f g h
2 i j k l
3 m n o p

```

Compare these two access methods:

```

In [341]: dfmi['one']['second']
Out[341]:
0 b
1 f
2 j
3 n
Name: second, dtype: object

```

```

In [342]: dfmi.loc[:, ('one', 'second')]
Out[342]:
0 b

```

(continues on next page)

(continued from previous page)

```

1 f
2 j
3 n
Name: (one, second), dtype: object

```

These both yield the same results, so which should you use? It is instructive to understand the order of operations on these and why method 2 (`.loc`) is much preferred over method 1 (chained `[]`).

`dfmi['one']` selects the first level of the columns and returns a DataFrame that is singly-indexed. Then another Python operation `dfmi_with_one['second']` selects the series indexed by 'second'. This is indicated by the variable `dfmi_with_one` because pandas sees these operations as separate events. e.g. separate calls to `__getitem__`, so it has to treat them as linear operations, they happen one after another.

Contrast this to `df.loc[:, ('one', 'second')]` which passes a nested tuple of `(slice(None), ('one', 'second'))` to a single call to `__getitem__`. This allows pandas to deal with this as a single entity. Furthermore this order of operations *can* be significantly faster, and allows one to index *both* axes if so desired.

### 12.22.1 Why does assignment fail when using chained indexing?

The problem in the previous section is just a performance issue. What's up with the `SettingWithCopy` warning? We don't **usually** throw warnings around when you do something that might cost a few extra milliseconds!

But it turns out that assigning to the product of chained indexing has inherently unpredictable results. To see this, think about how the Python interpreter executes this code:

```

dfmi.loc[:, ('one', 'second')] = value
becomes
dfmi.loc.__setitem__((slice(None), ('one', 'second'))), value)

```

But this code is handled differently:

```

dfmi['one']['second'] = value
becomes
dfmi.__getitem__('one').__setitem__('second', value)

```

See that `__getitem__` in there? Outside of simple cases, it's very hard to predict whether it will return a view or a copy (it depends on the memory layout of the array, about which pandas makes no guarantees), and therefore whether the `__setitem__` will modify `dfmi` or a temporary object that gets thrown out immediately afterward. **That's** what `SettingWithCopy` is warning you about!

---

**Note:** You may be wondering whether we should be concerned about the `loc` property in the first example. But `dfmi.loc` is guaranteed to be `dfmi` itself with modified indexing behavior, so `dfmi.loc.__getitem__` / `dfmi.loc.__setitem__` operate on `dfmi` directly. Of course, `dfmi.loc.__getitem__(idx)` may be a view or a copy of `dfmi`.

---

Sometimes a `SettingWithCopy` warning will arise at times when there's no obvious chained indexing going on. **These** are the bugs that `SettingWithCopy` is designed to catch! Pandas is probably trying to warn you that you've done this:

```

def do_something(df):
 foo = df[['bar', 'baz']] # Is foo a view? A copy? Nobody knows!
 # ... many lines here ...
 # We don't know whether this will modify df or not!

```

(continues on next page)

(continued from previous page)

```
foo['quux'] = value
return foo
```

Yikes!

## 12.22.2 Evaluation order matters

When you use chained indexing, the order and type of the indexing operation partially determine whether the result is a slice into the original object, or a copy of the slice.

Pandas has the `SettingWithCopyWarning` because assigning to a copy of a slice is frequently not intentional, but a mistake caused by chained indexing returning a copy where a slice was expected.

If you would like pandas to be more or less trusting about assignment to a chained indexing expression, you can set the `option.mode.chained_assignment` to one of these values:

- 'warn', the default, means a `SettingWithCopyWarning` is printed.
- 'raise' means pandas will raise a `SettingWithCopyException` you have to deal with.
- None will suppress the warnings entirely.

```
In [343]: dfb = pd.DataFrame({'a': ['one', 'one', 'two',
.....: 'three', 'two', 'one', 'six'],
.....: 'c': np.arange(7)})
.....:

This will show the SettingWithCopyWarning
but the frame values will be set
In [344]: dfb['c'][dfb.a.str.startswith('o')] = 42
```

This however is operating on a copy and will not work.

```
>>> pd.set_option('mode.chained_assignment','warn')
>>> dfb[dfb.a.str.startswith('o')]['c'] = 42
Traceback (most recent call last):
...
SettingWithCopyWarning:
 A value is trying to be set on a copy of a slice from a DataFrame.
 Try using .loc[row_index,col_indexer] = value instead
```

A chained assignment can also crop up in setting in a mixed dtype frame.

---

**Note:** These setting rules apply to all of `.loc/.iloc`.

---

This is the correct access method:

```
In [345]: dfc = pd.DataFrame({'A': ['aaa', 'bbb', 'ccc'], 'B': [1, 2, 3]})

In [346]: dfc.loc[0, 'A'] = 11

In [347]: dfc
Out[347]:
 A B
0 11 1
```

(continues on next page)

(continued from previous page)

```
1 bbb 2
2 ccc 3
```

This *can* work at times, but it is not guaranteed to, and therefore should be avoided:

```
In [348]: dfc = dfc.copy()

In [349]: dfc['A'][0] = 111

In [350]: dfc
Out[350]:
 A B
0 111 1
1 bbb 2
2 ccc 3
```

This will **not** work at all, and so should be avoided:

```
>>> pd.set_option('mode.chained_assignment', 'raise')
>>> dfc.loc[0]['A'] = 1111
Traceback (most recent call last):
...
SettingWithCopyException:
 A value is trying to be set on a copy of a slice from a DataFrame.
 Try using .loc[row_index,col_indexer] = value instead
```

**Warning:** The chained assignment warnings / exceptions are aiming to inform the user of a possibly invalid assignment. There may be false positives; situations where a chained assignment is inadvertently reported.

{{ header }}

## MULTIINDEX / ADVANCED INDEXING

This section covers *indexing with a MultiIndex* and *other advanced indexing features*.

See the *Indexing and Selecting Data* for general indexing documentation.

**Warning:** Whether a copy or a reference is returned for a setting operation may depend on the context. This is sometimes called `chained assignment` and should be avoided. See *Returning a View versus Copy*.

See the *cookbook* for some advanced strategies.

### 13.1 Hierarchical indexing (MultiIndex)

Hierarchical / Multi-level indexing is very exciting as it opens the door to some quite sophisticated data analysis and manipulation, especially for working with higher dimensional data. In essence, it enables you to store and manipulate data with an arbitrary number of dimensions in lower dimensional data structures like `Series` (1d) and `DataFrame` (2d).

In this section, we will show what exactly we mean by “hierarchical” indexing and how it integrates with all of the pandas indexing functionality described above and in prior sections. Later, when discussing *group by* and *pivoting and reshaping data*, we’ll show non-trivial applications to illustrate how it aids in structuring data for analysis.

See the *cookbook* for some advanced strategies.

Changed in version 0.24.0: `MultiIndex.labels` has been renamed to `MultiIndex.codes` and `MultiIndex.set_labels` to `MultiIndex.set_codes`.

#### 13.1.1 Creating a MultiIndex (hierarchical index) object

The `MultiIndex` object is the hierarchical analogue of the standard `Index` object which typically stores the axis labels in pandas objects. You can think of `MultiIndex` as an array of tuples where each tuple is unique. A `MultiIndex` can be created from a list of arrays (using `MultiIndex.from_arrays()`), an array of tuples (using `MultiIndex.from_tuples()`), a crossed set of iterables (using `MultiIndex.from_product()`), or a `DataFrame` (using `MultiIndex.from_frame()`). The `Index` constructor will attempt to return a `MultiIndex` when it is passed a list of tuples. The following examples demonstrate different ways to initialize `MultiIndexes`.

```
In [1]: arrays = [['bar', 'bar', 'baz', 'baz', 'foo', 'foo', 'qux', 'qux'],
...: ['one', 'two', 'one', 'two', 'one', 'two', 'one', 'two']]
...:
```

(continues on next page)

(continued from previous page)

```

In [2]: tuples = list(zip(*arrays))

In [3]: tuples
Out[3]:
[('bar', 'one'),
 ('bar', 'two'),
 ('baz', 'one'),
 ('baz', 'two'),
 ('foo', 'one'),
 ('foo', 'two'),
 ('qux', 'one'),
 ('qux', 'two')]

In [4]: index = pd.MultiIndex.from_tuples(tuples, names=['first', 'second'])

In [5]: index
Out[5]:
MultiIndex(levels=[['bar', 'baz', 'foo', 'qux'], ['one', 'two']],
 labels=[[0, 0, 1, 1, 2, 2, 3, 3], [0, 1, 0, 1, 0, 1, 0, 1]],
 names=['first', 'second'])

In [6]: s = pd.Series(np.random.randn(8), index=index)

In [7]: s
Out[7]:
first second
bar one 0.942109
 two -0.407508
baz one 1.587919
 two 1.435895
foo one -0.175078
 two 0.867816
qux one 0.468178
 two -1.685124
dtype: float64

```

When you want every pairing of the elements in two iterables, it can be easier to use the `MultiIndex.from_product()` method:

```

In [8]: iterables = [['bar', 'baz', 'foo', 'qux'], ['one', 'two']]

In [9]: pd.MultiIndex.from_product(iterables, names=['first', 'second'])
Out[9]:
MultiIndex(levels=[['bar', 'baz', 'foo', 'qux'], ['one', 'two']],
 labels=[[0, 0, 1, 1, 2, 2, 3, 3], [0, 1, 0, 1, 0, 1, 0, 1]],
 names=['first', 'second'])

```

You can also construct a `MultiIndex` from a `DataFrame` directly, using the method `MultiIndex.from_frame()`. This is a complementary method to `MultiIndex.to_frame()`.

New in version 0.24.0.

```

In [10]: df = pd.DataFrame([['bar', 'one'], ['bar', 'two'],
.....: ['foo', 'one'], ['foo', 'two']],
.....: columns=['first', 'second'])
.....:

```

(continues on next page)

(continued from previous page)

```
In [11]: pd.MultiIndex.from_frame(df)
Out[11]:
MultiIndex(levels=[['bar', 'foo'], ['one', 'two']],
 labels=[[0, 0, 1, 1], [0, 1, 0, 1]],
 names=['first', 'second'])
```

As a convenience, you can pass a list of arrays directly into Series or DataFrame to construct a MultiIndex automatically:

```
In [12]: arrays = [np.array(['bar', 'bar', 'baz', 'baz', 'foo', 'foo', 'qux', 'qux']),
.....: np.array(['one', 'two', 'one', 'two', 'one', 'two', 'one', 'two'])]
.....:

In [13]: s = pd.Series(np.random.randn(8), index=arrays)

In [14]: s
Out[14]:
bar one -0.715173
 two -0.996344
baz one 1.188569
 two 0.394180
foo one 0.815692
 two -1.205161
qux one 0.025782
 two -1.296148
dtype: float64

In [15]: df = pd.DataFrame(np.random.randn(8, 4), index=arrays)

In [16]: df
Out[16]:
```

|     |     | 0         | 1         | 2         | 3         |
|-----|-----|-----------|-----------|-----------|-----------|
| bar | one | 1.406445  | 1.230370  | -1.090473 | -0.579002 |
|     | two | 0.222923  | -1.577340 | 0.799953  | 0.724337  |
| baz | one | 1.128994  | 0.263834  | 0.890175  | 2.168279  |
|     | two | -0.768915 | -0.847295 | 0.948498  | 0.032017  |
| foo | one | 1.009777  | 0.556461  | -0.003874 | -0.412964 |
|     | two | -2.040932 | -1.217551 | -0.564874 | 0.186890  |
| qux | one | -0.225831 | -2.563809 | 1.937454  | -0.266082 |
|     | two | 0.013594  | 0.225764  | -0.973096 | 0.430530  |

All of the MultiIndex constructors accept a names argument which stores string names for the levels themselves. If no names are provided, None will be assigned:

```
In [17]: df.index.names
Out[17]: FrozenList([None, None])
```

This index can back any axis of a pandas object, and the number of levels of the index is up to you:

```
In [18]: df = pd.DataFrame(np.random.randn(3, 8), index=['A', 'B', 'C'],
.....: columns=index)
.....:

In [19]: df
Out[19]:
```

|   | first | second | bar | two | baz | one | two | foo | one | two | qux | one | two |
|---|-------|--------|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|
| A |       |        |     |     |     |     |     |     |     |     |     |     |     |
| B |       |        |     |     |     |     |     |     |     |     |     |     |     |
| C |       |        |     |     |     |     |     |     |     |     |     |     |     |

(continues on next page)

(continued from previous page)

```
A -0.555669 0.709978 -0.985197 1.585585 -1.351187 -1.854533 -0.614166 -0.488757
B -0.240837 -0.847627 0.693226 0.548476 0.876179 1.243335 -1.452421 -1.229657
C -1.575771 -0.115320 -2.210900 -1.030585 -0.104524 0.203529 1.126258 0.346519
```

```
In [20]: pd.DataFrame(np.random.randn(6, 6), index=index[:6], columns=index[:6])
```

```

first bar baz foo
second one two one two one two
first second
bar one 0.542277 0.536008 0.216746 -0.015647 -0.822166 -1.020749
 two -0.135523 2.230234 -0.264817 -0.325985 -0.967942 0.364592
baz one -0.847950 1.141273 0.543339 -0.346907 1.586351 1.505383
 two -0.696523 -0.074421 -1.350381 -0.203836 -0.483924 -1.226262
foo one -0.915461 -0.394608 0.121120 1.415075 1.225750 0.705866
 two 0.520779 1.387268 -0.210920 0.881870 1.327766 1.380304
```

We’ve “sparsified” the higher levels of the indexes to make the console output a bit easier on the eyes. Note that how the index is displayed can be controlled using the `multi_sparse` option in `pandas.set_options()`:

```
In [21]: with pd.option_context('display.multi_sparse', False):
.....: df
.....:
```

It’s worth keeping in mind that there’s nothing preventing you from using tuples as atomic labels on an axis:

```
In [22]: pd.Series(np.random.randn(8), index=tuples)
```

```
Out [22]:
```

```
(bar, one) -1.208973
(bar, two) 1.677210
(baz, one) -0.094166
(baz, two) -0.343880
(foo, one) -0.925297
(foo, two) -0.396784
(qux, one) -0.489528
(qux, two) -0.255701
dtype: float64
```

The reason that the `MultiIndex` matters is that it can allow you to do grouping, selection, and reshaping operations as we will describe below and in subsequent areas of the documentation. As you will see in later sections, you can find yourself working with hierarchically-indexed data without creating a `MultiIndex` explicitly yourself. However, when loading data from a file, you may wish to generate your own `MultiIndex` when preparing the data set.

### 13.1.2 Reconstructing the level labels

The method `get_level_values()` will return a vector of the labels for each location at a particular level:

```
In [23]: index.get_level_values(0)
```

```
Out [23]: Index(['bar', 'bar', 'baz', 'baz', 'foo', 'foo', 'qux', 'qux'], dtype='object',
↳ name='first')
```

```
In [24]: index.get_level_values('second')
```

```

↳ Index(['one', 'two', 'one', 'two', 'one', 'two', 'one', 'two'], dtype='object',
↳ name='second')
```

This is done to avoid a recomputation of the levels in order to make slicing highly performant. If you want to see only the used levels, you can use the `get_level_values()` method.

```
In [31]: df[['foo', 'qux']].columns.to_numpy()
Out [31]: array([('foo', 'one'), ('foo', 'two'), ('qux', 'one'), ('qux', 'two')],
↳dtype=object)

for a specific level
In [32]: df[['foo', 'qux']].columns.get_level_values(0)
Out [32]: Index(['foo', 'foo', 'qux', 'qux'], dtype='object', name='first')
```

To reconstruct the `MultiIndex` with only the used levels, the `remove_unused_levels()` method may be used. New in version 0.20.0.

```
In [33]: df[['foo', 'qux']].columns.remove_unused_levels()
Out [33]:
MultiIndex(levels=[['foo', 'qux'], ['one', 'two']],
 labels=[[0, 0, 1, 1], [0, 1, 0, 1]],
 names=['first', 'second'])
```

### 13.1.5 Data alignment and using `reindex`

Operations between differently-indexed objects having `MultiIndex` on the axes will work as you expect; data alignment will work the same as an `Index` of tuples:

```
In [34]: s + s[:-2]
Out [34]:
bar one -1.430346
 two -1.992687
baz one 2.377138
 two 0.788360
foo one 1.631383
 two -2.410322
qux one NaN
 two NaN
dtype: float64

In [35]: s + s[:,2]
Out [35]:
bar one -1.430346
 two NaN
baz one 2.377138
 two NaN
foo one 1.631383
 two NaN
qux one 0.051564
 two NaN
dtype: float64
```

The `reindex()` method of `Series/DataFrames` can be called with another `MultiIndex`, or even a list or array of tuples:

```
In [36]: s.reindex(index[:3])
Out[36]:
first second
bar one -0.715173
 two -0.996344
baz one 1.188569
dtype: float64

In [37]: s.reindex([('foo', 'two'), ('bar', 'one'), ('qux', 'one'), ('baz', 'one')])
\//\
↪
foo two -1.205161
bar one -0.715173
qux one 0.025782
baz one 1.188569
dtype: float64
```

## 13.2 Advanced indexing with hierarchical index

Syntactically integrating `MultiIndex` in advanced indexing with `.loc` is a bit challenging, but we've made every effort to do so. In general, `MultiIndex` keys take the form of tuples. For example, the following works as you would expect:

```
In [38]: df = df.T

In [39]: df
Out[39]:
```

|       |        | A         | B         | C         |
|-------|--------|-----------|-----------|-----------|
| first | second |           |           |           |
| bar   | one    | -0.555669 | -0.240837 | -1.575771 |
|       | two    | 0.709978  | -0.847627 | -0.115320 |
| baz   | one    | -0.985197 | 0.693226  | -0.210900 |
|       | two    | 1.585585  | 0.548476  | -1.030585 |
| foo   | one    | -1.351187 | 0.876179  | -0.104524 |
|       | two    | -1.854533 | 1.243335  | 0.203529  |
| gux   | one    | -0.614166 | -1.452421 | 1.126258  |
|       | two    | -0.488757 | -1.229657 | 0.346519  |

```
In [40]: df.loc[('bar', 'two')]
Out[40]:
A 0.709978
B -0.847627
C -0.115320
Name: (bar, two), dtype: float64
```

Note that `df.loc['bar', 'two']` would also work in this example, but this shorthand notation can lead to ambiguity in general.

If you also want to index a specific column with `.loc`, you must use a tuple like this:

```
In [41]: df.loc[('bar', 'two'), 'A']
Out[41]: 0.70997753591798507
```

You don't have to specify all levels of the `MultiIndex` by passing only the first elements of the tuple. For example, you can use “partial” indexing to get all elements with `bar` in the first level as follows:

```
df.loc['bar']
```

This is a shortcut for the slightly more verbose notation `df.loc[('bar',),]` (equivalent to `df.loc['bar',]` in this example).

“Partial” slicing also works quite nicely.

```
In [42]: df.loc['baz':'foo']
Out[42]:
```

|       |        | A         | B        | C         |
|-------|--------|-----------|----------|-----------|
| first | second |           |          |           |
| baz   | one    | -0.985197 | 0.693226 | -2.210900 |
|       | two    | 1.585585  | 0.548476 | -1.030585 |
| foo   | one    | -1.351187 | 0.876179 | -0.104524 |
|       | two    | -1.854533 | 1.243335 | 0.203529  |

You can slice with a ‘range’ of values, by providing a slice of tuples.

```
In [43]: df.loc[('baz', 'two'):('qux', 'one')]
Out[43]:
```

|       |        | A         | B         | C         |
|-------|--------|-----------|-----------|-----------|
| first | second |           |           |           |
| baz   | two    | 1.585585  | 0.548476  | -1.030585 |
| foo   | one    | -1.351187 | 0.876179  | -0.104524 |
|       | two    | -1.854533 | 1.243335  | 0.203529  |
| qux   | one    | -0.614166 | -1.452421 | 1.126258  |

```
In [44]: df.loc[('baz', 'two'):'foo']
```

```

////////////////////////////////////
↪

```

|       |        | A         | B        | C         |
|-------|--------|-----------|----------|-----------|
| first | second |           |          |           |
| baz   | two    | 1.585585  | 0.548476 | -1.030585 |
| foo   | one    | -1.351187 | 0.876179 | -0.104524 |
|       | two    | -1.854533 | 1.243335 | 0.203529  |

Passing a list of labels or tuples works similar to reindexing:

```
In [45]: df.loc[[('bar', 'two'), ('qux', 'one')]]
Out[45]:
```

|       |        | A         | B         | C         |
|-------|--------|-----------|-----------|-----------|
| first | second |           |           |           |
| bar   | two    | 0.709978  | -0.847627 | -0.115320 |
| qux   | one    | -0.614166 | -1.452421 | 1.126258  |

**Note:** It is important to note that tuples and lists are not treated identically in pandas when it comes to indexing. Whereas a tuple is interpreted as one multi-level key, a list is used to specify several keys. Or in other words, tuples go horizontally (traversing levels), lists go vertically (scanning levels).

Importantly, a list of tuples indexes several complete `MultiIndex` keys, whereas a tuple of lists refer to several values within a level:

```
In [46]: s = pd.Series([1, 2, 3, 4, 5, 6],
.....: index=pd.MultiIndex.from_product([["A", "B"], ["c", "d", "e
↪"]]))
.....:
```

(continues on next page)

(continued from previous page)

```

In [47]: s.loc[("A", "c"), ("B", "d")] # list of tuples
Out[47]:
A c 1
B d 5
dtype: int64

In [48]: s.loc[["A", "B"], ["c", "d"]] # tuple of lists
Out[48]:
A c 1
 d 2
B c 4
 d 5
dtype: int64

```

### 13.2.1 Using slicers

You can slice a `MultiIndex` by providing multiple indexers.

You can provide any of the selectors as if you are indexing by label, see *Selection by Label*, including slices, lists of labels, labels, and boolean indexers.

You can use `slice(None)` to select all the contents of *that* level. You do not need to specify all the *deeper* levels, they will be implied as `slice(None)`.

As usual, **both sides** of the slicers are included as this is label indexing.

**Warning:** You should specify all axes in the `.loc` specifier, meaning the indexer for the **index** and for the **columns**. There are some ambiguous cases where the passed indexer could be mis-interpreted as indexing *both* axes, rather than into say the `MultiIndex` for the rows.

You should do this:

```
df.loc[(slice('A1', 'A3'), ...), :] # noqa: E999
```

You should **not** do this:

```
df.loc[(slice('A1', 'A3'), ...)] # noqa: E999
```

```

In [49]: def mklbl(prefix, n):
....: return ["%s%s" % (prefix, i) for i in range(n)]
....:

In [50]: miindex = pd.MultiIndex.from_product([mklbl('A', 4),
....: mklbl('B', 2),
....: mklbl('C', 4),
....: mklbl('D', 2)])
....:

In [51]: micolumns = pd.MultiIndex.from_tuples([('a', 'foo'), ('a', 'bar'),
....: ('b', 'foo'), ('b', 'bah')],
....: names=['lv10', 'lv11'])
....:

In [52]: dfmi = pd.DataFrame(np.arange(len(miindex) * len(micolumns))

```

 D1 253 252 255 254
```

You can use `pandas.IndexSlice` to facilitate a more natural syntax using `:`, rather than using `slice(None)`.

```

In [55]: idx = pd.IndexSlice

In [56]: dfmi.loc[idx[:, :, ['C1', 'C3']], idx[:, 'foo']]
Out [56]:
 lvl0 a b
 lvl1 foo foo
A0 B0 C1 D0 8 10
 D1 12 14
```

It is possible to perform quite complicated selections using this method on multiple axes at the same time.

```
In [57]: dfmi.loc['A1', (slice(None), 'foo')]
```

```
Out[57]:
```

| lvl0 |    |    |  | a   | b   |
|------|----|----|--|-----|-----|
| lvl1 |    |    |  | foo | foo |
| B0   | C0 | D0 |  | 64  | 66  |
|      |    | D1 |  | 68  | 70  |
|      | C1 | D0 |  | 72  | 74  |
|      |    | D1 |  | 76  | 78  |
|      | C2 | D0 |  | 80  | 82  |
|      |    | D1 |  | 84  | 86  |
|      | C3 | D0 |  | 88  | 90  |
|      |    | D1 |  | 92  | 94  |
| B1   | C0 | D0 |  | 96  | 98  |
|      |    | D1 |  | 100 | 102 |
|      | C1 | D0 |  | 104 | 106 |
|      |    | D1 |  | 108 | 110 |

```

Using a boolean indexer you can provide selection related to the *values*.

```

In [59]: mask = dfmi[['a', 'foo']] > 200

In [60]: dfmi.loc[idx[mask, :], ['C1', 'C3']], idx[:, 'foo']]
Out[60]:
lvl0 a b
lvl1 foo foo
A3 B0 C1 D1 204 206
 C3 D0 216 218
 D1 220 222
 B1 C1 D0 232 234
 D1 236 238
 C3 D0 248 250
 D1 252 254

```

You can also specify the `axis` argument to `.loc` to interpret the passed slicers on a single axis.

```

In [61]: dfmi.loc(axis=0)[:, :, ['C1', 'C3']]
Out[61]:
lvl0 a b
lvl1 bar foo bah foo

```

## 13.2.2 Cross-section

The `xs()` method of `DataFrame` additionally takes a `level` argument to make selecting data at a particular level of a `MultiIndex` easier.

```
In [68]: df
Out[68]:
```

|       |        | A         | B         | C         |
|-------|--------|-----------|-----------|-----------|
| first | second |           |           |           |
| bar   | one    | -0.555669 | -0.240837 | -1.575771 |
|       | two    | 0.709978  | -0.847627 | -0.115320 |
| baz   | one    | -0.985197 | 0.693226  | -2.210900 |
|       | two    | 1.585585  | 0.548476  | -1.030585 |
| foo   | one    | -1.351187 | 0.876179  | -0.104524 |
|       | two    | -1.854533 | 1.243335  | 0.203529  |
| qux   | one    | -0.614166 | -1.452421 | 1.126258  |
|       | two    | -0.488757 | -1.229657 | 0.346519  |

```
In [69]: df.xs('one', level='second')
```

```

////////////////////////////////////
↪
 A B C
first
bar -0.555669 -0.240837 -1.575771
baz -0.985197 0.693226 -2.210900
foo -1.351187 0.876179 -0.104524
qux -0.614166 -1.452421 1.126258
```

```
using the slicers
```

```
In [70]: df.loc[(slice(None), 'one'), :]
```

```
Out[70]:
```

|       |        | A         | B         | C         |
|-------|--------|-----------|-----------|-----------|
| first | second |           |           |           |
| bar   | one    | -0.555669 | -0.240837 | -1.575771 |
| baz   | one    | -0.985197 | 0.693226  | -2.210900 |
| foo   | one    | -1.351187 | 0.876179  | -0.104524 |
| qux   | one    | -0.614166 | -1.452421 | 1.126258  |

You can also select on the columns with `xs`, by providing the `axis` argument.

```
In [71]: df = df.T
```

```
In [72]: df.xs('one', level='second', axis=1)
```

```
Out[72]:
```

(continues on next page)

(continued from previous page)

| first | bar       | baz       | foo       | qux       |
|-------|-----------|-----------|-----------|-----------|
| A     | -0.555669 | -0.985197 | -1.351187 | -0.614166 |
| B     | -0.240837 | 0.693226  | 0.876179  | -1.452421 |
| C     | -1.575771 | -2.210900 | -0.104524 | 1.126258  |

```
using the slicers
In [73]: df.loc[:, (slice(None), 'one')]
Out[73]:
```

| first  | bar       | baz       | foo       | qux       |
|--------|-----------|-----------|-----------|-----------|
| second | one       | one       | one       | one       |
| A      | -0.555669 | -0.985197 | -1.351187 | -0.614166 |
| B      | -0.240837 | 0.693226  | 0.876179  | -1.452421 |
| C      | -1.575771 | -2.210900 | -0.104524 | 1.126258  |

xs also allows selection with multiple keys.

```
In [74]: df.xs(('one', 'bar'), level=('second', 'first'), axis=1)
Out[74]:
```

| first  | bar       |
|--------|-----------|
| second | one       |
| A      | -0.555669 |
| B      | -0.240837 |
| C      | -1.575771 |

```
using the slicers
In [75]: df.loc[:, ('bar', 'one')]
Out[75]:
```

|   |           |
|---|-----------|
| A | -0.555669 |
| B | -0.240837 |
| C | -1.575771 |

Name: (bar, one), dtype: float64

You can pass `drop_level=False` to `xs` to retain the level that was selected.

```
In [76]: df.xs('one', level='second', axis=1, drop_level=False)
Out[76]:
```

| first  | bar       | baz       | foo       | qux       |
|--------|-----------|-----------|-----------|-----------|
| second | one       | one       | one       | one       |
| A      | -0.555669 | -0.985197 | -1.351187 | -0.614166 |
| B      | -0.240837 | 0.693226  | 0.876179  | -1.452421 |
| C      | -1.575771 | -2.210900 | -0.104524 | 1.126258  |

Compare the above with the result using `drop_level=True` (the default value).

```
In [77]: df.xs('one', level='second', axis=1, drop_level=True)
Out[77]:
```

| first | bar       | baz       | foo       | qux       |
|-------|-----------|-----------|-----------|-----------|
| A     | -0.555669 | -0.985197 | -1.351187 | -0.614166 |
| B     | -0.240837 | 0.693226  | 0.876179  | -1.452421 |
| C     | -1.575771 | -2.210900 | -0.104524 | 1.126258  |

### 13.2.3 Advanced reindexing and alignment

Using the parameter `level` in the `reindex()` and `align()` methods of pandas objects is useful to broadcast values across a level. For instance:

```

In [78]: midx = pd.MultiIndex(levels=[['zero', 'one'], ['x', 'y']],
.....: codes=[[1, 1, 0, 0], [1, 0, 1, 0]])
.....:

In [79]: df = pd.DataFrame(np.random.randn(4, 2), index=midx)

In [80]: df
Out[80]:
 0 1
one y 0.725523 0.786553
 x 0.688945 -0.262157
zero y -0.571851 -0.840027
 x 1.588489 -1.850730

In [81]: df2 = df.mean(level=0)

In [82]: df2
Out[82]:
 0 1
one 0.707234 0.262198
zero 0.508319 -1.345378

In [83]: df2.reindex(df.index, level=0)
Out[83]:
 0 1
one y 0.707234 0.262198
 x 0.707234 0.262198
zero y 0.508319 -1.345378
 x 0.508319 -1.345378

aligning
In [84]: df_aligned, df2_aligned = df.align(df2, level=0)

In [85]: df_aligned
Out[85]:
 0 1
one y 0.725523 0.786553
 x 0.688945 -0.262157
zero y -0.571851 -0.840027
 x 1.588489 -1.850730

In [86]: df2_aligned
Out[86]:
 0 1
one y 0.707234 0.262198
 x 0.707234 0.262198
zero y 0.508319 -1.345378
 x 0.508319 -1.345378

```

### 13.2.4 Swapping levels with `swaplevel`

The `swaplevel()` method can switch the order of two levels:

```
In [87]: df[:5]
Out[87]:
```

```
 0 1
one y 0.725523 0.786553
 x 0.688945 -0.262157
zero y -0.571851 -0.840027
 x 1.588489 -1.850730
```

```
In [88]: df[:5].swaplevel(0, 1, axis=0)
```

```

////////////////////////////////////
↪
 0 1
y one 0.725523 0.786553
x one 0.688945 -0.262157
y zero -0.571851 -0.840027
x zero 1.588489 -1.850730
```

### 13.2.5 Reordering levels with `reorder_levels`

The `reorder_levels()` method generalizes the `swaplevel` method, allowing you to permute the hierarchical index levels in one step:

```
In [89]: df[:5].reorder_levels([1, 0], axis=0)
```

```
Out[89]:
 0 1
y one 0.725523 0.786553
x one 0.688945 -0.262157
y zero -0.571851 -0.840027
x zero 1.588489 -1.850730
```

### 13.2.6 Renaming names of an `Index` or `MultiIndex`

The `rename()` method is used to rename the labels of a `MultiIndex`, and is typically used to rename the columns of a `DataFrame`. The `columns` argument of `rename` allows a dictionary to be specified that includes only the columns you wish to rename.

```
In [90]: df.rename(columns={0: "col0", 1: "col1"})
```

```
Out[90]:
 col0 col1
one y 0.725523 0.786553
 x 0.688945 -0.262157
zero y -0.571851 -0.840027
 x 1.588489 -1.850730
```

This method can also be used to rename specific labels of the main index of the `DataFrame`.

```
In [91]: df.rename(index={"one": "two", "y": "z"})
```

```
Out[91]:
 0 1
two z 0.725523 0.786553
 x 0.688945 -0.262157
zero z -0.571851 -0.840027
 x 1.588489 -1.850730
```

The `rename_axis()` method is used to rename the name of a `Index` or `MultiIndex`. In particular, the names of the levels of a `MultiIndex` can be specified, which is useful if `reset_index()` is later used to move the values from the `MultiIndex` to a column.

```
In [92]: df.rename_axis(index=['abc', 'def'])
```

```
Out [92]:
```

```

 0 1
abc def
one y 0.725523 0.786553
 x 0.688945 -0.262157
zero y -0.571851 -0.840027
 x 1.588489 -1.850730
```

Note that the columns of a `DataFrame` are an index, so that using `rename_axis` with the `columns` argument will change the name of that index.

```
In [93]: df.rename_axis(columns="Cols").columns
```

```
Out [93]: RangeIndex(start=0, stop=2, step=1, name='Cols')
```

Both `rename` and `rename_axis` support specifying a dictionary, `Series` or a mapping function to map labels/names to new values.

## 13.3 Sorting a MultiIndex

For `MultiIndex`-ed objects to be indexed and sliced effectively, they need to be sorted. As with any index, you can use `sort_index()`.

```
In [94]: import random
```

```
In [95]: random.shuffle(tuples)
```

```
In [96]: s = pd.Series(np.random.randn(8), index=pd.MultiIndex.from_tuples(tuples))
```

```
In [97]: s
```

```
Out [97]:
```

```

qux one -0.254441
foo one -1.128470
baz two -1.939811
 one 0.855476
qux two 1.955892
foo two 0.263358
bar one -0.266644
 two 0.782349
dtype: float64
```

```
In [98]: s.sort_index()
```

```

////////////////////////////////////
↪
bar one -0.266644
 two 0.782349
baz one 0.855476
 two -1.939811
foo one -1.128470
 two 0.263358
qux one -0.254441
```

(continues on next page)

(continued from previous page)

```

 two 1.955892
dtype: float64

```

```
In [99]: s.sort_index(level=0)
```

```

////////////////////////////////////
↪
bar one -0.266644
 two 0.782349
baz one 0.855476
 two -1.939811
foo one -1.128470
 two 0.263358
qux one -0.254441
 two 1.955892
dtype: float64

```

```
In [100]: s.sort_index(level=1)
```

```

////////////////////////////////////
↪
bar one -0.266644
baz one 0.855476
foo one -1.128470
qux one -0.254441
bar two 0.782349
baz two -1.939811
foo two 0.263358
qux two 1.955892
dtype: float64

```

You may also pass a level name to `sort_index` if the `MultiIndex` levels are named.

```
In [101]: s.index.set_names(['L1', 'L2'], inplace=True)
```

```
In [102]: s.sort_index(level='L1')
```

```

Out[102]:
L1 L2
bar one -0.266644
 two 0.782349
baz one 0.855476
 two -1.939811
foo one -1.128470
 two 0.263358
qux one -0.254441
 two 1.955892
dtype: float64

```

```
In [103]: s.sort_index(level='L2')
```

```

////////////////////////////////////
↪
L1 L2
bar one -0.266644
baz one 0.855476
foo one -1.128470
qux one -0.254441
bar two 0.782349
baz two -1.939811
foo two 0.263358

```

(continues on next page)

(continued from previous page)

```
qux two 1.955892
dtype: float64
```

On higher dimensional objects, you can sort any of the other axes by level if they have a `MultiIndex`:

```
In [104]: df.T.sort_index(level=1, axis=1)
Out[104]:
```

|   | one       | zero      | one      | zero      |
|---|-----------|-----------|----------|-----------|
|   | x         | x         | y        | y         |
| 0 | 0.688945  | 1.588489  | 0.725523 | -0.571851 |
| 1 | -0.262157 | -1.850730 | 0.786553 | -0.840027 |

Indexing will work even if the data are not sorted, but will be rather inefficient (and show a `PerformanceWarning`). It will also return a copy of the data rather than a view:

```
In [105]: dfm = pd.DataFrame({'jim': [0, 0, 1, 1],
.....: 'joe': ['x', 'x', 'z', 'y'],
.....: 'jolie': np.random.rand(4)})
.....:

In [106]: dfm = dfm.set_index(['jim', 'joe'])

In [107]: dfm
Out[107]:
```

| jim | joe | jolie    |
|-----|-----|----------|
| 0   | x   | 0.495305 |
|     | x   | 0.738373 |
| 1   | z   | 0.212994 |
|     | y   | 0.243827 |

```
In [4]: dfm.loc[(1, 'z')]
PerformanceWarning: indexing past lexsort depth may impact performance.

Out[4]:
```

| jim | joe | jolie   |
|-----|-----|---------|
| 1   | z   | 0.64094 |

Furthermore, if you try to index something that is not fully lexsorted, this can raise:

```
In [5]: dfm.loc[(0, 'y'):(1, 'z')]
UnsortedIndexError: 'Key length (2) was greater than MultiIndex lexsort depth (1)'
```

The `is_lexsorted()` method on a `MultiIndex` shows if the index is sorted, and the `lexsort_depth` property returns the sort depth:

```
In [108]: dfm.index.is_lexsorted()
Out[108]: False

In [109]: dfm.index.lexsort_depth
Out[109]: 1
```

```
In [110]: dfm = dfm.sort_index()
```

(continues on next page)

```
In [114]: dfm.loc[(0, 'y'):(1, 'z')]
Out[114]:
```

|         |          |
|---------|----------|
|         | jolie    |
| jim joe |          |
| 1 y     | 0.243827 |
| z       | 0.212994 |

[illegible]

(continued from previous page)

```
In [122]: ser.take(positions)
\\Out [122]:
0 1.420032
9 0.720240
3 -1.937897
dtype: float64
```

For DataFrames, the given indices should be a 1d list or ndarray that specifies row or column positions.

```
In [123]: frm = pd.DataFrame(np.random.randn(5, 3))
```

```
In [124]: frm.take([1, 4, 3])
```

```
Out [124]:
 0 1 2
1 0.374636 1.533061 0.264930
4 -1.033614 -1.729078 0.550414
3 0.325945 -0.650153 0.076307
```

```
In [125]: frm.take([0, 2], axis=1)
```

```
\\Out [125]:
 0 2
0 0.559686 -0.717803
1 0.374636 0.264930
2 0.625505 -0.675251
3 0.325945 0.076307
4 -1.033614 0.550414
```

It is important to note that the `take` method on pandas objects are not intended to work on boolean indices and may return unexpected results.

```
In [126]: arr = np.random.randn(10)
```

```
In [127]: arr.take([False, False, True, True])
```

```
Out [127]: array([1.16319769, 1.16319769, -1.4061546 , -1.4061546])
```

```
In [128]: arr[[0, 1]]
```

```
\\Out [128]:
array([1.16319769, -1.4061546])
```

```
In [129]: ser = pd.Series(np.random.randn(10))
```

```
In [130]: ser.take([False, False, True, True])
```

```
Out [130]:
0 -0.485505
0 -0.485505
1 0.257638
1 0.257638
dtype: float64
```

```
In [131]: ser.iloc[[0, 1]]
```

```
\\Out [131]:
0 -0.485505
1 0.257638
dtype: float64
```

Finally, as a small note on performance, because the `take` method handles a narrower range of inputs, it can offer performance that is a good deal faster than fancy indexing.

```
In [132]: arr = np.random.randn(10000, 5)

In [133]: indexer = np.arange(10000)

In [134]: random.shuffle(indexer)

In [135]: %timeit arr[indexer]
.....: %timeit arr.take(indexer, axis=0)
.....:
180 us +- 17.5 us per loop (mean +- std. dev. of 7 runs, 1000 loops each)
49.4 us +- 737 ns per loop (mean +- std. dev. of 7 runs, 10000 loops each)
```

## 13.5 Index Types

We have discussed `MultiIndex` in the previous sections pretty extensively. Documentation about `DatetimeIndex` and `PeriodIndex` are shown *here*, and documentation about `TimedeltaIndex` is found *here*.

In the following sub-sections we will highlight some other index types.

### 13.5.1 CategoricalIndex

`CategoricalIndex` is a type of index that is useful for supporting indexing with duplicates. This is a container around a `Categorical` and allows efficient indexing and storage of an index with a large number of duplicated elements.

```
In [136]: from pandas.api.types import CategoricalDtype

In [137]: df = pd.DataFrame({'A': np.arange(6),
.....: 'B': list('aabbca')})
.....:

In [138]: df['B'] = df['B'].astype(CategoricalDtype(list('cab')))

In [139]: df
Out[139]:
 A B
0 0 a
1 1 a
2 2 b
3 3 b
4 4 c
5 5 a

In [140]: df.dtypes
Out[140]:
A int64
B category
dtype: object
```

(continues on next page)

(continued from previous page)

```
In [141]: df.B.cat.categories
```

[illegible]

Setting the index will create a `CategoricalIndex`.

```
In [142]: df2 = df.set_index('B')
```

```
In [143]: df2.index
```

```
Out[143]: CategoricalIndex(['a', 'a', 'b', 'b', 'c', 'a'], categories=['c', 'a', 'b'],
↳ ordered=False, name='B', dtype='category')
```

Indexing with `__getitem__/.iloc/.loc` works similarly to an `Index` with duplicates. The indexers **must** be in the category or the operation will raise a `KeyError`.

```
In [144]: df2.loc['a']
```

Out [144] :

A

B

|   |   |
|---|---|
| a | 0 |
|---|---|

|   |   |
|---|---|
| a | 1 |
|---|---|

|   |   |
|---|---|
| a | 5 |
|---|---|

The CategoricalIndex is **preserved** after indexing:

```
In [145]: df2.loc['a'].index
```

```
Out[145]: CategoricalIndex(['a', 'a', 'a'], categories=['c', 'a', 'b'], ordered=False,
↪ name='B', dtype='category')
```

Sorting the index will sort by the order of the categories (recall that we created the index with `CategoricalDtype(list('cab'))`, so the sorted order is cab).

```
In [146]: df2.sort_index()
```

Out [146] :

A

B

C 4

|   |   |
|---|---|
| a | 0 |
|---|---|

|   |   |
|---|---|
| a | 1 |
|---|---|

|   |   |
|---|---|
| a | 5 |
|---|---|

b 2

b 3

Groupby operations on the index will preserve the index nature as well.

```
In [147]: df2.groupby(level=0).sum()
```

Out [147]:

A

B

C 4

a 6

b 5

```
In [148]: df2.groupby(level=0).sum().index
```

```
Out[148]: CategoricalIndex(['c', 'a', 'b'],
categories=['c', 'a', 'b'], ordered=False, name='B', dtype='category')
```

Reindexing operations will return a resulting index based on the type of the passed indexer. Passing a list will return a plain-old Index; indexing with a Categorical will return a CategoricalIndex, indexed according to the categories of the **passed** Categorical dtype. This allows one to arbitrarily index these even with values **not** in the categories, similarly to how you can reindex **any** pandas index.

```
In [149]: df2.reindex(['a', 'e'])
Out[149]:
 A
B
a 0.0
a 1.0
a 5.0
e NaN

In [150]: df2.reindex(['a', 'e']).index
Out[150]: Index(['a', 'a', 'a', 'e'], dtype='object', name='B')

In [151]: df2.reindex(pd.Categorical(['a', 'e'], categories=list('abcde')))
Out[151]:
 A
B
a 0.0
a 1.0
a 5.0
e NaN

In [152]: df2.reindex(pd.Categorical(['a', 'e'], categories=list('abcde'))).index
Out[152]: CategoricalIndex(['a', 'a', 'a', 'e'], categories=['a', 'b', 'c', 'd', 'e'], ordered=False, name='B', dtype='category')
```

**Warning:** Reshaping and Comparison operations on a CategoricalIndex must have the same categories or a TypeError will be raised.

```
In [9]: df3 = pd.DataFrame({'A': np.arange(6), 'B': pd.Series(list('aabbca')).
 ↳ astype('category')})

In [11]: df3 = df3.set_index('B')

In [11]: df3.index
Out[11]: CategoricalIndex([u'a', u'a', u'b', u'b', u'c', u'a'], categories=[u'a', u'b', u'c'], ordered=False, name=u'B', dtype='category')

In [12]: pd.concat([df2, df3])
TypeError: categories must match existing categories when appending
```

## 13.5.2 Int64Index and RangeIndex

**Warning:** Indexing on an integer-based Index with floats has been clarified in 0.18.0, for a summary of the changes, see [here](#).

`Int64Index` is a fundamental basic index in pandas. This is an immutable array implementing an ordered, sliceable set. Prior to 0.18.0, the `Int64Index` would provide the default index for all `NDFrame` objects.

`RangeIndex` is a sub-class of `Int64Index` added in version 0.18.0, now providing the default index for all `NDFrame` objects. `RangeIndex` is an optimized version of `Int64Index` that can represent a monotonic ordered set. These are analogous to Python [range types](#).

### 13.5.3 Float64Index

By default a `Float64Index` will be automatically created when passing floating, or mixed-integer-floating values in index creation. This enables a pure label-based slicing paradigm that makes `[]`, `ix`, `loc` for scalar indexing and slicing work exactly the same.

```
In [153]: indexf = pd.Index([1.5, 2, 3, 4.5, 5])

In [154]: indexf
Out[154]: Float64Index([1.5, 2.0, 3.0, 4.5, 5.0], dtype='float64')

In [155]: sf = pd.Series(range(5), index=indexf)

In [156]: sf
Out[156]:
1.5 0
2.0 1
3.0 2
4.5 3
5.0 4
dtype: int64
```

Scalar selection for `[]`, `.loc` will always be label based. An integer will match an equal float index (e.g. 3 is equivalent to 3.0).

```
In [157]: sf[3]
Out[157]: 2

In [158]: sf[3.0]
Out[158]: 2

In [159]: sf.loc[3]
Out[159]: 2

In [160]: sf.loc[3.0]
Out[160]: 2
```

The only positional indexing is via `iloc`.

```
In [161]: sf.iloc[3]
Out[161]: 3
```

A scalar index that is not found will raise a `KeyError`. Slicing is primarily on the values of the index when using `[]`, `ix`, `loc`, and **always** positional when using `iloc`. The exception is when the slice is boolean, in which case it will always be positional.

```
In [162]: sf[2:4]
Out[162]:
2.0 1
```

(continues on next page)

(continued from previous page)

[illegible]

In float indexes, slicing using floats is allowed.

```
In [165]: sf[2.1:4.6]
Out[165]:
3.0 2
4.5 3
dtype: int64

In [166]: sf.loc[2.1:4.6]
Out[166]:
3.0 2
4.5 3
dtype: int64
```

In non-float indexes, slicing using floats will raise a `TypeError`.

```
In [1]: pd.Series(range(5))[3.5]
TypeError: the label [3.5] is not a proper indexer for this index type (Int64Index)
```

```
In [1]: pd.Series(range(5))[3.5:4.5]
TypeError: the slice start [3.5] is not a proper indexer for this index type_
↪ (Int64Index)
```

**Warning:** Using a scalar float indexer for `.iloc` has been removed in 0.18.0, so the following will raise a `TypeError`:

```
In [3]: pd.Series(range(5)).iloc[3.0]
TypeError: cannot do positional indexing on <class 'pandas.indexes.range.RangeIndex
↪'> with these indexers [3.0] of <type 'float'>
```

Here is a typical use-case for using this type of indexing. Imagine that you have a somewhat irregular timedelta-like indexing scheme, but the data is recorded as floats. This could, for example, be millisecond offsets.

[illegible]

(continues on next page)

```
columns=list('AB'))])
```

```
In [168]: dfir
```

```
Out[168]:
```

|        | A         | B         |
|--------|-----------|-----------|
| 0.0    | -0.153376 | 0.663156  |
| 250.0  | 0.275422  | -0.064285 |
| 500.0  | -0.625785 | 0.465218  |
| 750.0  | 0.556269  | -0.723352 |
| 1000.0 | 0.707619  | 0.156870  |
| 1000.4 | 1.283519  | 0.227837  |
| 1250.5 | -0.298442 | -0.173607 |
| 1500.6 | 0.574110  | -1.347191 |
| 1750.7 | 1.503203  | 1.050886  |
| 2000.8 | -0.761489 | -0.250566 |
| 2250.9 | -0.861955 | -0.798510 |

[illegible]

```
In [172]: dfir[0:1000]
Out[172]:
```

|       | A         | B         |
|-------|-----------|-----------|
| 0.0   | -0.153376 | 0.663156  |
| 250.0 | 0.275422  | -0.064285 |
| 500.0 | -0.625785 | 0.465218  |
| 750.0 | 0.556269  | -0.723352 |

(continued from previous page)

```
1000.0 0.707619 0.156870
```

If you need integer based selection, you should use `iloc`:

```
In [173]: dfir.iloc[0:5]
Out[173]:
```

|        | A         | B         |
|--------|-----------|-----------|
| 0.0    | -0.153376 | 0.663156  |
| 250.0  | 0.275422  | -0.064285 |
| 500.0  | -0.625785 | 0.465218  |
| 750.0  | 0.556269  | -0.723352 |
| 1000.0 | 0.707619  | 0.156870  |

### 13.5.4 IntervalIndex

New in version 0.20.0.

`IntervalIndex` together with its own dtype, `IntervalDtype` as well as the `Interval` scalar type, allow first-class support in pandas for interval notation.

The `IntervalIndex` allows some unique indexing and is also used as a return type for the categories in `cut()` and `qcut()`.

**Warning:** These indexing behaviors are provisional and may change in a future version of pandas.

An `IntervalIndex` can be used in `Series` and in `DataFrame` as the index.

```
In [174]: df = pd.DataFrame({'A': [1, 2, 3, 4]},
.....: index=pd.IntervalIndex.from_breaks([0, 1, 2, 3, 4]))
.....:

In [175]: df
Out[175]:
```

| A        |
|----------|
| (0, 1] 1 |
| (1, 2] 2 |
| (2, 3] 3 |
| (3, 4] 4 |

Label based indexing via `.loc` along the edges of an interval works as you would expect, selecting that particular interval.

```
In [176]: df.loc[2]
Out[176]:
```

| A |
|---|
| 2 |

Name: (1, 2], dtype: int64

```
In [177]: df.loc[[2, 3]]
Out[177]:
```

| A        |
|----------|
| (1, 2] 2 |
| (2, 3] 3 |

If you select a label *contained* within an interval, this will also select the interval.

```

In [178]: df.loc[2.5]
Out[178]:
A 3
Name: (2, 3], dtype: int64

In [179]: df.loc[[2.5, 3.5]]
Out[179]:
A
(2, 3] 3
(3, 4] 4

```

Interval and IntervalIndex are used by cut and qcut:

```

In [180]: c = pd.cut(range(4), bins=2)

In [181]: c
Out[181]:
[(-0.003, 1.5], (-0.003, 1.5], (1.5, 3.0], (1.5, 3.0]]
Categories (2, interval[float64]): [(-0.003, 1.5] < (1.5, 3.0]]

In [182]: c.categories
Out[182]:
IntervalIndex([(-0.003, 1.5], (1.5, 3.0]],
 closed='right',
 dtype='interval[float64]')

```

Furthermore, IntervalIndex allows one to bin *other* data with these same bins, with NaN representing a missing value similar to other dtypes.

```

In [183]: pd.cut([0, 3, 5, 1], bins=c.categories)
Out[183]:
[(-0.003, 1.5], (1.5, 3.0], NaN, (-0.003, 1.5]]
Categories (2, interval[float64]): [(-0.003, 1.5] < (1.5, 3.0]]

```

### 13.5.4.1 Generating Ranges of Intervals

If we need intervals on a regular frequency, we can use the `interval_range()` function to create an IntervalIndex using various combinations of start, end, and periods. The default frequency for `interval_range` is a 1 for numeric intervals, and calendar day for datetime-like intervals:

```

In [184]: pd.interval_range(start=0, end=5)
Out[184]:
IntervalIndex([(0, 1], (1, 2], (2, 3], (3, 4], (4, 5]],
 closed='right',
 dtype='interval[int64]')

In [185]: pd.interval_range(start=pd.Timestamp('2017-01-01'), periods=4)
Out[185]:
IntervalIndex([(2017-01-01, 2017-01-02], (2017-01-02, 2017-01-03], (2017-01-03, 2017-
 01-04], (2017-01-04, 2017-01-05]],
 closed='right',
 dtype='interval[datetime64[ns]]')

```

(continues on next page)

(continued from previous page)

```
In [186]: pd.interval_range(end=pd.Timedelta('3 days'), periods=3)
IntervalIndex([(0 days 00:00:00, 1 days 00:00:00], (1 days 00:00:00, 2 days 00:00:00],
 (2 days 00:00:00, 3 days 00:00:00]],
 closed='right',
 dtype='interval[timedelta64[ns]]')
```

The `freq` parameter can be used to specify non-default frequencies, and can utilize a variety of *frequency aliases* with datetime-like intervals:

```
In [187]: pd.interval_range(start=0, periods=5, freq=1.5)
Out[187]:
IntervalIndex([(0.0, 1.5], (1.5, 3.0], (3.0, 4.5], (4.5, 6.0], (6.0, 7.5]],
 closed='right',
 dtype='interval[float64]')

In [188]: pd.interval_range(start=pd.Timestamp('2017-01-01'), periods=4, freq='W')
IntervalIndex([(2017-01-01, 2017-01-08], (2017-01-08, 2017-01-15], (2017-01-15, 2017-
 01-22], (2017-01-22, 2017-01-29]],
 closed='right',
 dtype='interval[datetime64[ns]]')

In [189]: pd.interval_range(start=pd.Timedelta('0 days'), periods=3, freq='9H')
IntervalIndex([(0 days 00:00:00, 0 days 09:00:00], (0 days 09:00:00, 0 days 18:00:00],
 (0 days 18:00:00, 1 days 03:00:00]],
 closed='right',
 dtype='interval[timedelta64[ns]]')
```

Additionally, the `closed` parameter can be used to specify which side(s) the intervals are closed on. Intervals are closed on the right side by default.

```
In [190]: pd.interval_range(start=0, end=4, closed='both')
Out[190]:
IntervalIndex([[0, 1], [1, 2], [2, 3], [3, 4]],
 closed='both',
 dtype='interval[int64]')

In [191]: pd.interval_range(start=0, end=4, closed='neither')
IntervalIndex([(0, 1), (1, 2), (2, 3), (3, 4)],
 closed='neither',
 dtype='interval[int64]')
```

New in version 0.23.0.

Specifying `start`, `end`, and `periods` will generate a range of evenly spaced intervals from `start` to `end` inclusively, with `periods` number of elements in the resulting `IntervalIndex`:

```
In [192]: pd.interval_range(start=0, end=6, periods=4)
Out[192]:
IntervalIndex([(0.0, 1.5], (1.5, 3.0], (3.0, 4.5], (4.5, 6.0]],
```

(continues on next page)

(continued from previous page)

```

 closed='right',
 dtype='interval[float64]')

In [193]: pd.interval_range(pd.Timestamp('2018-01-01'),
 : pd.Timestamp('2018-02-28'), periods=3)
 :
////////////////////////////////////
↪
IntervalIndex([(2018-01-01, 2018-01-20 08:00:00], (2018-01-20 08:00:00, 2018-02-08_
↪16:00:00], (2018-02-08 16:00:00, 2018-02-28]],
 closed='right',
 dtype='interval[datetime64[ns]]')

```

## 13.6 Miscellaneous indexing FAQ

### 13.6.1 Integer indexing

Label-based indexing with integer axis labels is a thorny topic. It has been discussed heavily on mailing lists and among various members of the scientific Python community. In pandas, our general viewpoint is that labels matter more than integer locations. Therefore, with an integer axis index *only* label-based indexing is possible with the standard tools like `.loc`. The following code will generate exceptions:

```

In [194]: s = pd.Series(range(5))

In [195]: s[-1]

KeyError Traceback (most recent call last)
<ipython-input-195-76c3dce40054> in <module>
----> 1 s[-1]

/pandas/pandas/core/series.py in __getitem__(self, key)
 866 key = com.apply_if_callable(key, self)
 867 try:
--> 868 result = self.index.get_value(self, key)
 869
 870 if not is_scalar(result):

/pandas/pandas/core/indexes/base.py in get_value(self, series, key)

↪Int64HashTable.get_item()

```

(continues on next page)

(continued from previous page)

```
/pandas/pandas/_libs/hashtable_class_helper.pxi in pandas._libs.hashtable.
↳ Int64HashTable.get_item()
```

```
KeyError: -1
```

```
In [196]: df = pd.DataFrame(np.random.randn(5, 4))
```

```
In [197]: df
```

Out [197] :

|   | 0         | 1         | 2         | 3         |
|---|-----------|-----------|-----------|-----------|
| 0 | -0.781941 | 0.824456  | -1.451860 | 0.341576  |
| 1 | 0.709434  | -0.099138 | -2.270327 | -0.587698 |
| 2 | 0.013096  | 0.681939  | 0.102295  | -0.806798 |
| 3 | -0.405558 | 0.029793  | -1.797748 | 0.689181  |
| 4 | -2.024254 | 2.085931  | 0.450769  | 1.501304  |

```
In [198]: df.loc[-2:]
```

|   | 0         | 1         | 2         | 3         |
|---|-----------|-----------|-----------|-----------|
| 0 | -0.781941 | 0.824456  | -1.451860 | 0.341576  |
| 1 | 0.709434  | -0.099138 | -2.270327 | -0.587698 |
| 2 | 0.013096  | 0.681939  | 0.102295  | -0.806798 |
| 3 | -0.405558 | 0.029793  | -1.797748 | 0.689181  |
| 4 | -2.024254 | 2.085931  | 0.450769  | 1.501304  |

This deliberate decision was made to prevent ambiguities and subtle bugs (many users reported finding bugs when the API change was made to stop “falling back” on position-based indexing).

### 13.6.2 Non-monotonic indexes require exact matches

If the index of a `Series` or `DataFrame` is monotonically increasing or decreasing, then the bounds of a label-based slice can be outside the range of the index, much like slice indexing a normal Python `list`. Monotonicity of an index can be tested with the `is_monotonically_increasing()` and `is_monotonically_decreasing()` attributes.

```
In [199]: df = pd.DataFrame(index=[2, 3, 3, 4, 5], columns=['data'],
↳ data=list(range(5)))
```

```
In [200]: df.index.is_monotonic_increasing
```

```
Out[200]: True
```

```
no rows 0 or 1, but still returns rows 2, 3 (both of them), and 4:
```

```
In [201]: df.loc[0:4, :]
```

```
\\Out[201]:
```

|   | data |
|---|------|
| 2 | 0    |
| 3 | 1    |
| 3 | 2    |
| 4 | 3    |

```
slice is are outside the index, so empty DataFrame is returned
```

```
In [202]: df.loc[13:15, :]
```

```
\\Out[202]:
```

Empty DataFrame

(continues on next page)

```
Columns: [data]
Index: []
```

(continued from previous page)

```
a 2.774316
b -0.877422
c 1.144724
d 0.577204
e 0.460418
f -0.394649
dtype: float64
```

Suppose we wished to slice from `c` to `e`, using integers this would be accomplished as such:

```
In [212]: s[2:5]
Out[212]:
c 1.144724
d 0.577204
e 0.460418
dtype: float64
```

However, if you only had `c` and `e`, determining the next element in the index can be somewhat complicated. For example, the following does not work:

```
s.loc['c':'e' + 1]
```

A very common use case is to limit a time series to start and end at two specific dates. To enable this, we made the design to make label-based slicing include both endpoints:

```
In [213]: s.loc['c':'e']
Out[213]:
c 1.144724
d 0.577204
e 0.460418
dtype: float64
```

This is most definitely a “practicality beats purity” sort of thing, but it is something to watch out for if you expect label-based slicing to behave exactly in the way that standard Python integer slicing works.

## 13.6.4 Indexing potentially changes underlying Series dtype

The different indexing operation can potentially change the dtype of a Series.

```
In [214]: series1 = pd.Series([1, 2, 3])

In [215]: series1.dtype
Out[215]: dtype('int64')

In [216]: res = series1.reindex([0, 4])

In [217]: res.dtype
Out[217]: dtype('float64')

In [218]: res
Out[218]:
0 1.0
4 NaN
dtype: float64
```

```
In [219]: series2 = pd.Series([True])
In [220]: series2.dtype
Out[220]: dtype('bool')

In [221]: res = series2.reindex_like(series1)

In [222]: res.dtype
Out[222]: dtype('O')

In [223]: res
\\Out[223]:
0 True
1 NaN
2 NaN
dtype: object
```

This is because the (re)indexing operations above silently inserts NaNs and the `dtype` changes accordingly. This can cause some issues when using numpy ufuncs such as `numpy.logical_and`.

See the [this old issue](#) for a more detailed discussion. {{ header }}

## COMPUTATIONAL TOOLS

### 14.1 Statistical Functions

#### 14.1.1 Percent Change

`Series`, `DataFrame`, and `Panel` all have a method `pct_change()` to compute the percent change over a given number of periods (using `fill_method` to fill NA/null values *before* computing the percent change).

```
In [1]: ser = pd.Series(np.random.randn(8))
```

```
In [2]: ser.pct_change()
```

```
Out [2]:
0 NaN
1 -0.348936
2 -0.026376
3 0.081126
4 0.318782
5 -2.147899
6 -1.371373
7 0.357070
dtype: float64
```

```
In [3]: df = pd.DataFrame(np.random.randn(10, 4))
```

```
In [4]: df.pct_change(periods=3)
```

```
Out [4]:
 0 1 2 3
0 NaN NaN NaN NaN
1 NaN NaN NaN NaN
2 NaN NaN NaN NaN
3 3.024922 0.705266 -79.616581 149.889894
4 0.408779 1.000074 -3.774982 -0.911056
5 -4.935972 -4.326987 -4.525734 1.968868
6 -0.689585 -0.701729 -1.216839 -1.286671
7 6.906300 -1.460166 -0.731611 13.661560
8 -2.515096 -1.974306 -1.209768 -3.160704
9 -0.812018 -0.000037 3.715428 -2.348990
```

#### 14.1.2 Covariance

`Series.cov()` can be used to compute covariance between series (excluding missing values).

```
In [5]: s1 = pd.Series(np.random.randn(1000))
In [6]: s2 = pd.Series(np.random.randn(1000))
In [7]: s1.cov(s2)
Out[7]: -0.00079988177100508802
```

Analogously, `DataFrame.cov()` to compute pairwise covariances among the series in the `DataFrame`, also excluding NA/null values.

**Note:** Assuming the missing data are missing at random this results in an estimate for the covariance matrix which is unbiased. However, for many applications this estimate may not be acceptable because the estimated covariance matrix is not guaranteed to be positive semi-definite. This could lead to estimated correlations having absolute values which are greater than one, and/or a non-invertible covariance matrix. See [Estimation of covariance matrices](#) for more details.

```
In [8]: frame = pd.DataFrame(np.random.randn(1000, 5),
...: columns=['a', 'b', 'c', 'd', 'e'])
...:

In [9]: frame.cov()
Out[9]:
```

|   | a         | b         | c         | d         | e         |
|---|-----------|-----------|-----------|-----------|-----------|
| a | 1.027398  | -0.007341 | -0.024844 | -0.021018 | -0.013558 |
| b | -0.007341 | 1.070581  | 0.008770  | -0.060699 | -0.018320 |
| c | -0.024844 | 0.008770  | 0.996535  | 0.066856  | -0.034870 |
| d | -0.021018 | -0.060699 | 0.066856  | 1.037899  | 0.003609  |
| e | -0.013558 | -0.018320 | -0.034870 | 0.003609  | 1.100988  |

`DataFrame.cov` also supports an optional `min_periods` keyword that specifies the required minimum number of observations for each column pair in order to have a valid result.

```
In [10]: frame = pd.DataFrame(np.random.randn(20, 3), columns=['a', 'b', 'c'])

In [11]: frame.loc[frame.index[:5], 'a'] = np.nan

In [12]: frame.loc[frame.index[5:10], 'b'] = np.nan

In [13]: frame.cov()
Out[13]:
```

|   | a         | b         | c         |
|---|-----------|-----------|-----------|
| a | 1.280953  | -0.470434 | -0.479275 |
| b | -0.470434 | 0.952343  | 0.182053  |
| c | -0.479275 | 0.182053  | 1.244097  |

```
In [14]: frame.cov(min_periods=12)
//////////
↪
```

|   | a         | b        | c         |
|---|-----------|----------|-----------|
| a | 1.280953  | NaN      | -0.479275 |
| b | NaN       | 0.952343 | 0.182053  |
| c | -0.479275 | 0.182053 | 1.244097  |

### 14.1.3 Correlation

Correlation may be computed using the `corr()` method. Using the `method` parameter, several methods for computing correlations are provided:

| Method name          | Description                           |
|----------------------|---------------------------------------|
| pearson<br>(default) | Standard correlation coefficient      |
| kendall              | Kendall Tau correlation coefficient   |
| spearman             | Spearman rank correlation coefficient |

All of these are currently computed using pairwise complete observations. Wikipedia has articles covering the above correlation coefficients:

- [Pearson correlation coefficient](#)
- [Kendall rank correlation coefficient](#)
- [Spearman's rank correlation coefficient](#)

**Note:** Please see the *caveats* associated with this method of calculating correlation matrices in the *covariance section*.

```
In [15]: frame = pd.DataFrame(np.random.randn(1000, 5),
.....: columns=['a', 'b', 'c', 'd', 'e'])
.....:

In [16]: frame.iloc[:,2] = np.nan

Series with Series
In [17]: frame['a'].corr(frame['b'])
Out[17]: -0.063204214056691327

In [18]: frame['a'].corr(frame['b'], method='spearman')
Out[18]: -0.059948303793215175

Pairwise correlation of DataFrame columns
In [19]: frame.corr()
Out[19]:
```

|   | a         | b         | c         | d         | e         |
|---|-----------|-----------|-----------|-----------|-----------|
| a | 1.000000  | -0.063204 | 0.024497  | -0.129131 | 0.025662  |
| b | -0.063204 | 1.000000  | 0.027601  | 0.044030  | 0.043048  |
| c | 0.024497  | 0.027601  | 1.000000  | -0.038875 | -0.019944 |
| d | -0.129131 | 0.044030  | -0.038875 | 1.000000  | -0.051578 |
| e | 0.025662  | 0.043048  | -0.019944 | -0.051578 | 1.000000  |

Note that non-numeric columns will be automatically excluded from the correlation calculation.

Like `cov`, `corr` also supports the optional `min_periods` keyword:

```
In [20]: frame = pd.DataFrame(np.random.randn(20, 3), columns=['a', 'b', 'c'])

In [21]: frame.loc[frame.index[:5], 'a'] = np.nan

In [22]: frame.loc[frame.index[5:10], 'b'] = np.nan

In [23]: frame.corr()
```

(continues on next page)

(continued from previous page)

Out [23]:

|   | a        | b         | c         |
|---|----------|-----------|-----------|
| a | 1.000000 | 0.207934  | 0.228834  |
| b | 0.207934 | 1.000000  | -0.158902 |
| c | 0.228834 | -0.158902 | 1.000000  |

In [24]: frame.corr(min\_periods=12)

```

////////////////////////////////////

```

↪

|   | a        | b         | c         |
|---|----------|-----------|-----------|
| a | 1.000000 | NaN       | 0.228834  |
| b | NaN      | 1.000000  | -0.158902 |
| c | 0.228834 | -0.158902 | 1.000000  |

New in version 0.24.0.

The method argument can also be a callable for a generic correlation calculation. In this case, it should be a single function that produces a single value from two ndarray inputs. Suppose we wanted to compute the correlation based on histogram intersection:

# histogram intersection

In [25]: def histogram\_intersection(a, b):

```

.....: return np.minimum(np.true_divide(a, a.sum()),
.....: np.true_divide(b, b.sum())).sum()
.....:

```

In [26]: frame.corr(method=histogram\_intersection)

Out [26]:

|   | a          | b         | c          |
|---|------------|-----------|------------|
| a | 1.000000   | -3.100565 | -27.605999 |
| b | -3.100565  | 1.000000  | -8.782364  |
| c | -27.605999 | -8.782364 | 1.000000   |

A related method `corrwith()` is implemented on `DataFrame` to compute the correlation between like-labeled Series contained in different `DataFrame` objects.

In [27]: index = ['a', 'b', 'c', 'd', 'e']

In [28]: columns = ['one', 'two', 'three', 'four']

In [29]: df1 = pd.DataFrame(np.random.randn(5, 4), index=index, columns=columns)

In [30]: df2 = pd.DataFrame(np.random.randn(4, 4), index=index[:4], columns=columns)

In [31]: df1.corrwith(df2)

Out [31]:

```

one 0.063419
two 0.736453
three -0.081154
four 0.749461
dtype: float64

```

In [32]: df2.corrwith(df1, axis=1)

```

////////////////////////////////////

```

↪

```

a 0.042790
b -0.018607

```

(continues on next page)

(continued from previous page)

```
c -0.833176
d 0.926166
e NaN
dtype: float64
```

### 14.1.4 Data ranking

The `rank()` method produces a data ranking with ties being assigned the mean of the ranks (by default) for the group:

```
In [33]: s = pd.Series(np.random.randn(5), index=list('abcde'))

In [34]: s['d'] = s['b'] # so there's a tie

In [35]: s.rank()
Out[35]:
a 1.0
b 4.5
c 2.0
d 4.5
e 3.0
dtype: float64
```

`rank()` is also a `DataFrame` method and can rank either the rows (`axis=0`) or the columns (`axis=1`). `NaN` values are excluded from the ranking.

```
In [36]: df = pd.DataFrame(np.random.randn(10, 6))

In [37]: df[4] = df[2][:5] # some ties

In [38]: df
Out[38]:
```

|   | 0         | 1         | 2         | 3         | 4         | 5         |
|---|-----------|-----------|-----------|-----------|-----------|-----------|
| 0 | 0.510018  | -1.779081 | 0.202659  | -1.616651 | 0.202659  | 1.664382  |
| 1 | -0.975431 | -1.713425 | -0.387278 | 0.610810  | -0.387278 | 0.796303  |
| 2 | 0.306241  | 0.246291  | -0.344366 | -1.739973 | -0.344366 | 1.031902  |
| 3 | -0.417855 | 0.303383  | 0.613276  | -0.816931 | 0.613276  | 0.181888  |
| 4 | 0.705822  | -1.347610 | 0.772669  | 0.613000  | 0.772669  | 0.477587  |
| 5 | -0.802468 | -1.893147 | 1.440578  | 1.999440  | NaN       | 0.487140  |
| 6 | 0.062935  | -0.201690 | -0.620078 | -1.168259 | NaN       | -0.220455 |
| 7 | 0.172867  | 0.836662  | 1.035598  | -0.603920 | NaN       | 0.411587  |
| 8 | 0.019935  | 0.593362  | -0.664809 | -1.143994 | NaN       | -1.352719 |
| 9 | -0.674355 | -1.554639 | 1.138247  | 1.722682  | NaN       | -0.035174 |

```
In [39]: df.rank(1)
Out[39]:
```

|   | 0   | 1   | 2   | 3   | 4   | 5   |
|---|-----|-----|-----|-----|-----|-----|
| 0 | 5.0 | 1.0 | 3.5 | 2.0 | 3.5 | 6.0 |
| 1 | 2.0 | 1.0 | 3.5 | 5.0 | 3.5 | 6.0 |
| 2 | 5.0 | 4.0 | 2.5 | 1.0 | 2.5 | 6.0 |
| 3 | 2.0 | 4.0 | 5.5 | 1.0 | 5.5 | 3.0 |
| 4 | 4.0 | 1.0 | 5.5 | 3.0 | 5.5 | 2.0 |
| 5 | 2.0 | 1.0 | 4.0 | 5.0 | NaN | 3.0 |
| 6 | 5.0 | 4.0 | 2.0 | 1.0 | NaN | 3.0 |
| 7 | 2.0 | 4.0 | 5.0 | 1.0 | NaN | 3.0 |

(continues on next page)

(continued from previous page)

|   |     |     |     |     |     |     |
|---|-----|-----|-----|-----|-----|-----|
| 8 | 4.0 | 5.0 | 3.0 | 2.0 | NaN | 1.0 |
| 9 | 2.0 | 1.0 | 4.0 | 5.0 | NaN | 3.0 |

`rank` optionally takes a parameter `ascending` which by default is `true`; when `false`, data is reverse-ranked, with larger values assigned a smaller rank.

`rank` supports different tie-breaking methods, specified with the `method` parameter:

- `average` : average rank of tied group
- `min` : lowest rank in the group
- `max` : highest rank in the group
- `first` : ranks assigned in the order they appear in the array

## 14.2 Window Functions

For working with data, a number of window functions are provided for computing common *window* or *rolling* statistics. Among these are count, sum, mean, median, correlation, variance, covariance, standard deviation, skewness, and kurtosis.

The `rolling()` and `expanding()` functions can be used directly from `DataFrameGroupBy` objects, see the *groupby docs*.

**Note:** The API for window statistics is quite similar to the way one works with `GroupBy` objects, see the documentation *here*.

We work with `rolling`, `expanding` and `exponentially weighted` data through the corresponding objects, `Rolling`, `Expanding` and `EWM`.

```
In [40]: s = pd.Series(np.random.randn(1000),
.....: index=pd.date_range('1/1/2000', periods=1000))
.....:

In [41]: s = s.cumsum()

In [42]: s
Out[42]:

2002-09-26 -69.508790

```

```
Freq: D, Length: 1000, dtype: float64
```

These are created from methods on Series and DataFrame.

```

In [43]: r = s.rolling(window=60)

In [44]: r
Out[44]: Rolling [window=60,center=False,axis=0]

```

These object provide tab-completion of the available methods and properties.

```
In [14]: r.<TAB> # noqa: E225, E999
r.agg r.apply r.count r.exclusions r.max r.median r.
↪name
r.aggreate r.skew r.sum r.kurt r.mean r.min r.
↪quantile r.std r.var
```

Generally these methods all have the same interface. They all accept the following arguments:

- window: size of moving window
- min\_periods: threshold of non-null data points to require (otherwise result is NA)
- center: boolean, whether to set the labels at the center (default is False)

We can then call methods on these rolling objects. These return like-indexed objects:

```
In [45]: r.mean()
Out[45]:
2000-01-01 NaN

2002-09-26 -68.272557
Freq: D, Length: 1000, dtype: float64
```

[illegible]

They can also be applied to DataFrame objects. This is really just syntactic sugar for applying the moving window operator to all of the DataFrame's columns:

```
In [48]: df = pd.DataFrame(np.random.randn(1000, 4),
.....: index=pd.date_range('1/1/2000', periods=1000),
.....: columns=['A', 'B', 'C', 'D'])
.....:

In [49]: df = df.cumsum()

In [50]: df.rolling(window=60).sum().plot(subplots=True)
Out[50]:
array([<matplotlib.axes._subplots.AxesSubplot object at 0x7fd54a123e48>,
 <matplotlib.axes._subplots.AxesSubplot object at 0x7fd54a128470>,
 <matplotlib.axes._subplots.AxesSubplot object at 0x7fd54acd4438>,
 <matplotlib.axes._subplots.AxesSubplot object at 0x7fd54aac34a8>],
 dtype=object)
```

### 14.2.1 Method Summary

We provide a number of common statistical functions:

| Method                  | Description                                |
|-------------------------|--------------------------------------------|
| <code>count()</code>    | Number of non-null observations            |
| <code>sum()</code>      | Sum of values                              |
| <code>mean()</code>     | Mean of values                             |
| <code>median()</code>   | Arithmetic median of values                |
| <code>min()</code>      | Minimum                                    |
| <code>max()</code>      | Maximum                                    |
| <code>std()</code>      | Bessel-corrected sample standard deviation |
| <code>var()</code>      | Unbiased variance                          |
| <code>skew()</code>     | Sample skewness (3rd moment)               |
| <code>kurt()</code>     | Sample kurtosis (4th moment)               |
| <code>quantile()</code> | Sample quantile (value at %)               |
| <code>apply()</code>    | Generic apply                              |
| <code>cov()</code>      | Unbiased covariance (binary)               |
| <code>corr()</code>     | Correlation (binary)                       |

The `apply()` function takes an extra `func` argument and performs generic rolling computations. The `func` argu-

ment should be a single function that produces a single value from an ndarray input. Suppose we wanted to compute the mean absolute deviation on a rolling basis:

```
In [51]: def mad(x):
...: return np.fabs(x - x.mean()).mean()
...:

In [52]: s.rolling(window=60).apply(mad, raw=True).plot(style='k')
Out[52]: <matplotlib.axes._subplots.AxesSubplot at 0x7fd54ac6d320>
```

## 14.2.2 Rolling Windows

Passing `win_type` to `.rolling` generates a generic rolling window computation, that is weighted according to the `win_type`. The following methods are available:

| Method              | Description    |
|---------------------|----------------|
| <code>sum()</code>  | Sum of values  |
| <code>mean()</code> | Mean of values |

The weights used in the window are specified by the `win_type` keyword. The list of recognized types are the `scipy.signal` window functions:

- `boxcar`

- triang
- blackman
- hamming
- bartlett
- parzen
- bohman
- blackmanharris
- nuttall
- barthann
- kaiser (needs beta)
- gaussian (needs std)
- general\_gaussian (needs power, width)
- slepian (needs width).

```
In [53]: ser = pd.Series(np.random.randn(10),
.....: index=pd.date_range('1/1/2000', periods=10))
.....:

In [54]: ser.rolling(window=5, win_type='triang').mean()
Out[54]:
2000-01-01 NaN
2000-01-02 NaN
2000-01-03 NaN
2000-01-04 NaN
2000-01-05 0.505229
2000-01-06 0.179026
2000-01-07 -0.161393
2000-01-08 -0.522180
2000-01-09 -0.788461
2000-01-10 -1.188481
Freq: D, dtype: float64
```

Note that the boxcar window is equivalent to `mean()`.

```
In [55]: ser.rolling(window=5, win_type='boxcar').mean()
Out[55]:
2000-01-01 NaN
2000-01-02 NaN
2000-01-03 NaN
2000-01-04 NaN
2000-01-05 0.319390
2000-01-06 0.184067
2000-01-07 0.032535
2000-01-08 -0.647038
2000-01-09 -0.909053
2000-01-10 -0.956596
Freq: D, dtype: float64
```

```
In [56]: ser.rolling(window=5).mean()
```

////////////////////////////////////

↪

(continues on next page)

(continued from previous page)

```

2000-01-01 NaN
2000-01-02 NaN
2000-01-03 NaN
2000-01-04 NaN
2000-01-05 0.319390
2000-01-06 0.184067
2000-01-07 0.032535
2000-01-08 -0.647038
2000-01-09 -0.909053
2000-01-10 -0.956596
Freq: D, dtype: float64

```

For some windowing functions, additional parameters must be specified:

```

In [57]: ser.rolling(window=5, win_type='gaussian').mean(std=0.1)
Out[57]:
2000-01-01 NaN
2000-01-02 NaN
2000-01-03 NaN
2000-01-04 NaN
2000-01-05 0.817239
2000-01-06 0.276334
2000-01-07 -0.679009
2000-01-08 -0.533527
2000-01-09 0.281637
2000-01-10 -2.580626
Freq: D, dtype: float64

```

**Note:** For `.sum()` with a `win_type`, there is no normalization done to the weights for the window. Passing custom weights of `[1, 1, 1]` will yield a different result than passing weights of `[2, 2, 2]`, for example. When passing a `win_type` instead of explicitly specifying the weights, the weights are already normalized so that the largest weight is 1.

In contrast, the nature of the `.mean()` calculation is such that the weights are normalized with respect to each other. Weights of `[1, 1, 1]` and `[2, 2, 2]` yield the same result.

### 14.2.3 Time-aware Rolling

New in version 0.19.0.

New in version 0.19.0 are the ability to pass an offset (or convertible) to a `.rolling()` method and have it produce variable sized windows based on the passed time window. For each time point, this includes all preceding values occurring within the indicated time delta.

This can be particularly useful for a non-regular time frequency index.

```

In [58]: dft = pd.DataFrame({'B': [0, 1, 2, np.nan, 4]},
.....: index=pd.date_range('20130101 09:00:00',
.....: periods=5,
.....: freq='s'))

In [59]: dft
Out[59]:

```

(continues on next page)

|            |          | B   |
|------------|----------|-----|
| 2013-01-01 | 09:00:00 | 0.0 |
| 2013-01-01 | 09:00:01 | 1.0 |
| 2013-01-01 | 09:00:02 | 2.0 |
| 2013-01-01 | 09:00:03 | NaN |
| 2013-01-01 | 09:00:04 | 4.0 |

Out [60]:

| 2013-01-01 | 09:00:04 | 4.0 |

Out [62] :

|            |          | B   |
|------------|----------|-----|
| 2013-01-01 | 09:00:00 | 0.0 |
| 2013-01-01 | 09:00:01 | 1.0 |
| 2013-01-01 | 09:00:02 | 3.0 |
| 2013-01-01 | 09:00:03 | 2.0 |
| 2013-01-01 | 09:00:04 | 4.0 |

1. *Journal of Management Studies*, 1996, 33, 1, 1-14.

Out [64]:

|                     |     |
|---------------------|-----|
|                     | B   |
| foo                 |     |
| 2013-01-01 09:00:00 | 0.0 |
| 2013-01-01 09:00:02 | 1.0 |
| 2013-01-01 09:00:03 | 2.0 |

(continued from previous page)

|            |          |     |
|------------|----------|-----|
| 2013-01-01 | 09:00:05 | NaN |
| 2013-01-01 | 09:00:06 | 4.0 |

```
In [65]: dft.rolling(2).sum()
```

|            |          | B   |
|------------|----------|-----|
| foo        |          |     |
| 2013-01-01 | 09:00:00 | NaN |
| 2013-01-01 | 09:00:02 | 1.0 |
| 2013-01-01 | 09:00:03 | 3.0 |
| 2013-01-01 | 09:00:05 | NaN |
| 2013-01-01 | 09:00:06 | NaN |

Using the time-specification generates variable windows for this sparse data.

```
In [66]: dft.rolling('2s').sum()
```

Out [66] :

|            |          | B   |
|------------|----------|-----|
| foo        |          |     |
| 2013-01-01 | 09:00:00 | 0.0 |
| 2013-01-01 | 09:00:02 | 1.0 |
| 2013-01-01 | 09:00:03 | 3.0 |
| 2013-01-01 | 09:00:05 | NaN |
| 2013-01-01 | 09:00:06 | 4.0 |

Furthermore, we now allow an optional `on` parameter to specify a column (rather than the default of the index) in a `DataFrame`.

```
In [67]: dft = dft.reset_index()
```

```
In [68]: dft
```

Out [68] :

|   |                     | foo | B |
|---|---------------------|-----|---|
| 0 | 2013-01-01 09:00:00 | 0.0 |   |
| 1 | 2013-01-01 09:00:02 | 1.0 |   |
| 2 | 2013-01-01 09:00:03 | 2.0 |   |
| 3 | 2013-01-01 09:00:05 | NaN |   |
| 4 | 2013-01-01 09:00:06 | 4.0 |   |

```
In [69]: dft.rolling('2s', on='foo').sum()
```

|   |            |          | foo | B |
|---|------------|----------|-----|---|
| 0 | 2013-01-01 | 09:00:00 | 0.0 |   |
| 1 | 2013-01-01 | 09:00:02 | 1.0 |   |
| 2 | 2013-01-01 | 09:00:03 | 3.0 |   |
| 3 | 2013-01-01 | 09:00:05 | NaN |   |
| 4 | 2013-01-01 | 09:00:06 | 4.0 |   |

### 14.2.4 Rolling Window Endpoints

New in version 0.20.0.

The inclusion of the interval endpoints in rolling window calculations can be specified with the `closed` parameter:

| closed  | Description          | Default for        |
|---------|----------------------|--------------------|
| right   | close right endpoint | time-based windows |
| left    | close left endpoint  |                    |
| both    | close both endpoints | fixed windows      |
| neither | open endpoints       |                    |

For example, having the right endpoint open is useful in many problems that require that there is no contamination from present information back to past information. This allows the rolling window to compute statistics “up to that point in time”, but not including that point in time.

```
In [70]: df = pd.DataFrame({'x': 1},
.....: index=[pd.Timestamp('20130101 09:00:01'),
.....: pd.Timestamp('20130101 09:00:02'),
.....: pd.Timestamp('20130101 09:00:03'),
.....: pd.Timestamp('20130101 09:00:04'),
.....: pd.Timestamp('20130101 09:00:06')])
.....:

In [71]: df["right"] = df.rolling('2s', closed='right').x.sum() # default

In [72]: df["both"] = df.rolling('2s', closed='both').x.sum()

In [73]: df["left"] = df.rolling('2s', closed='left').x.sum()

In [74]: df["neither"] = df.rolling('2s', closed='neither').x.sum()

In [75]: df
Out[75]:
```

|                     | x | right | both | left | neither |
|---------------------|---|-------|------|------|---------|
| 2013-01-01 09:00:01 | 1 | 1.0   | 1.0  | NaN  | NaN     |
| 2013-01-01 09:00:02 | 1 | 2.0   | 2.0  | 1.0  | 1.0     |
| 2013-01-01 09:00:03 | 1 | 2.0   | 3.0  | 2.0  | 1.0     |
| 2013-01-01 09:00:04 | 1 | 2.0   | 3.0  | 2.0  | 1.0     |
| 2013-01-01 09:00:06 | 1 | 1.0   | 2.0  | 1.0  | NaN     |

Currently, this feature is only implemented for time-based windows. For fixed windows, the closed parameter cannot be set and the rolling window will always have both endpoints closed.

### 14.2.5 Time-aware Rolling vs. Resampling

Using `.rolling()` with a time-based index is quite similar to *resampling*. They both operate and perform reductive operations on time-indexed pandas objects.

When using `.rolling()` with an offset. The offset is a time-delta. Take a backwards-in-time looking window, and aggregate all of the values in that window (including the end-point, but not the start-point). This is the new value at that point in the result. These are variable sized windows in time-space for each point of the input. You will get a same sized result as the input.

When using `.resample()` with an offset. Construct a new index that is the frequency of the offset. For each frequency bin, aggregate points from the input within a backwards-in-time looking window that fall in that bin. The result of this aggregation is the output for that frequency point. The windows are fixed size in the frequency space. Your result will have the shape of a regular frequency between the min and the max of the original input object.

To summarize, `.rolling()` is a time-based window operation, while `.resample()` is a frequency-based window operation.

## 14.2.8 Computing rolling pairwise covariances and correlations

**Warning:** Prior to version 0.20.0 if `pairwise=True` was passed, a `Panel` would be returned. This will now return a 2-level `MultiIndexed DataFrame`, see the [whatsnew here](#).

In financial data analysis and other fields it's common to compute covariance and correlation matrices for a collection of time series. Often one is also interested in moving-window covariance and correlation matrices. This can be done by passing the `pairwise` keyword argument, which in the case of `DataFrame` inputs will yield a `MultiIndexed DataFrame` whose index are the dates in question. In the case of a single `DataFrame` argument the `pairwise` argument can even be omitted:

**Note:** Missing values are ignored and each entry is computed using the pairwise complete observations. Please see the [covariance section](#) for *caveats* associated with this method of calculating covariance and correlation matrices.

```
In [82]: covs = (df[['B', 'C', 'D']].rolling(window=50)
.....: .cov(df[['A', 'B', 'C']], pairwise=True))
.....:

In [83]: covs.loc['2002-09-22':]
Out[83]:

 D -0.455928 0.180482 -0.649316 1.000000

```

You can efficiently retrieve the time series of correlations between two columns by reshaping and indexing:

```
In [86]: correls.unstack(1)[('A', 'C')].plot()
```

```
Out [86]: <matplotlib.axes._subplots.AxesSubplot at 0x7fd54adfc4a8>
```

## 14.3 Aggregation

Once the `Rolling`, `Expanding` or `EWM` objects have been created, several methods are available to perform multiple computations on the data. These operations are similar to the *aggregating API*, *groupby API*, and *resample API*.

```
In [87]: dfa = pd.DataFrame(np.random.randn(1000, 3),
.....: index=pd.date_range('1/1/2000', periods=1000),
.....: columns=['A', 'B', 'C'])
.....:

In [88]: r = dfa.rolling(window=60, min_periods=1)

In [89]: r
Out[89]: Rolling [window=60,min_periods=1,center=False,axis=0]
```

We can aggregate by passing a function to the entire `DataFrame`, or select a `Series` (or multiple `Series`) via standard `__getitem__`.

```
In [90]: r.aggregate(np.sum)
Out[90]:
```

|            | A        | B         | C         |
|------------|----------|-----------|-----------|
| 2000-01-01 | 1.305250 | -0.261154 | -0.411249 |

[1000 rows x 2 columns]

```

As you can see, the result of the aggregation will have the selected columns, or all columns if none are selected.

### 14.3.1 Applying multiple functions

With windowed Series you can also pass a list of functions to do aggregation with, outputting a DataFrame:

```

In [93]: r['A'].agg([np.sum, np.mean, np.std])
Out [93]:

```

|            | sum       | mean      | std      |
|------------|-----------|-----------|----------|
| 2000-01-01 | 1.305250  | 1.305250  | NaN      |
| 2000-01-02 | 1.408833  | 0.704416  | 0.849707 |

```

[1000 rows x 3 columns]

On a windowed DataFrame, you can pass a list of functions to apply to each column, which produces an aggregated result with a hierarchical index:

```
In [94]: r.agg([np.sum, np.mean])
```

```
Out [94]:
```

|            | A         |           | B         |           | C         |           |
|------------|-----------|-----------|-----------|-----------|-----------|-----------|
|            | sum       | mean      | sum       | mean      | sum       | mean      |
| 2000-01-01 | 1.305250  | 1.305250  | -0.261154 | -0.261154 | -0.411249 | -0.411249 |

(continued from previous page)

[1000 rows x 6 columns]

Passing a dict of functions has different behavior by default, see the next section.

### 14.3.2 Applying different functions to DataFrame columns

By passing a dict to `aggregate` you can apply a different aggregation to the columns of a `DataFrame`:

```
In [95]: r.agg({'A': np.sum, 'B': lambda x: np.std(x, ddof=1)})
```

```
Out [95]:
```

|            | A         | B        |
|------------|-----------|----------|
| 2000-01-01 | 1.305250  | NaN      |
| 2000-01-02 | 1.408833  | 2.121302 |
| 2000-01-03 | -0.138202 | 2.321877 |
| 2000-01-04 | -0.154923 | 2.118371 |
| 2000-01-05 | 0.269332  | 1.837455 |
| 2000-01-06 | 0.121619  | 1.644346 |

## 14.4 Expanding Windows

A common alternative to rolling statistics is to use an *expanding* window, which yields the value of the statistic with all the data available up to that point in time.

These follow a similar interface to `.rolling`, with the `.expanding` method returning an `Expanding` object.

As these calculations are a special case of rolling statistics, they are implemented in pandas such that the following

two calls are equivalent:

```
In [98]: df.rolling(window=len(df), min_periods=1).mean()[5]
```

```
Out [98]:
```

```

 A B C D
2000-01-01 1.854776 1.324020 -0.329349 -1.988498
2000-01-02 2.490598 0.707260 -0.120063 -1.941828
2000-01-03 2.270376 0.306459 -0.320107 -1.840187
2000-01-04 2.301363 0.063160 -0.376001 -1.881649
2000-01-05 2.298072 0.373701 -0.398629 -1.556853

```

```
In [99]: df.expanding(min_periods=1).mean()[5]
```

```

////////////////////////////////////
↪
 A B C D
2000-01-01 1.854776 1.324020 -0.329349 -1.988498
2000-01-02 2.490598 0.707260 -0.120063 -1.941828
2000-01-03 2.270376 0.306459 -0.320107 -1.840187
2000-01-04 2.301363 0.063160 -0.376001 -1.881649
2000-01-05 2.298072 0.373701 -0.398629 -1.556853

```

These have a similar set of methods to `.rolling` methods.

### 14.4.1 Method Summary

| Function                | Description                     |
|-------------------------|---------------------------------|
| <code>count()</code>    | Number of non-null observations |
| <code>sum()</code>      | Sum of values                   |
| <code>mean()</code>     | Mean of values                  |
| <code>median()</code>   | Arithmetic median of values     |
| <code>min()</code>      | Minimum                         |
| <code>max()</code>      | Maximum                         |
| <code>std()</code>      | Unbiased standard deviation     |
| <code>var()</code>      | Unbiased variance               |
| <code>skew()</code>     | Unbiased skewness (3rd moment)  |
| <code>kurt()</code>     | Unbiased kurtosis (4th moment)  |
| <code>quantile()</code> | Sample quantile (value at %)    |
| <code>apply()</code>    | Generic apply                   |
| <code>cov()</code>      | Unbiased covariance (binary)    |
| <code>corr()</code>     | Correlation (binary)            |

Aside from not having a `window` parameter, these functions have the same interfaces as their `.rolling` counterparts. Like above, the parameters they all accept are:

- `min_periods`: threshold of non-null data points to require. Defaults to minimum needed to compute statistic. No NaNs will be output once `min_periods` non-null data points have been seen.
- `center`: boolean, whether to set the labels at the center (default is False).

**Note:** The output of the `.rolling` and `.expanding` methods do not return a NaN if there are at least `min_periods` non-null values in the current window. For example:

```

In [100]: sn = pd.Series([1, 2, np.nan, 3, np.nan, 4])

In [101]: sn
Out[101]:
0 1.0
1 2.0
2 NaN
3 3.0
4 NaN
5 4.0
dtype: float64

In [102]: sn.rolling(2).max()
Out[102]:
0 NaN
1 2.0
2 NaN
3 NaN
4 NaN
5 NaN
dtype: float64

In [103]: sn.rolling(2, min_periods=1).max()
Out[103]:
0 1.0
1 2.0
2 2.0
3 3.0
4 3.0
5 4.0
dtype: float64

```

In case of expanding functions, this differs from `cumsum()`, `cumprod()`, `cummax()`, and `cummin()`, which return NaN in the output wherever a NaN is encountered in the input. In order to match the output of `cumsum` with expanding, use `fillna()`:

```

In [104]: sn.expanding().sum()
Out[104]:
0 1.0
1 3.0
2 3.0
3 6.0
4 6.0
5 10.0
dtype: float64

In [105]: sn.cumsum()
Out[105]:
0 1.0
1 3.0
2 NaN
3 6.0
4 NaN
5 10.0

```

(continues on next page)

(continued from previous page)

```
dtype: float64
```

```
In [106]: sn.cumsum().fillna(method='ffill')
```

---

|   |     |
|---|-----|
| 0 | 1.0 |
|---|-----|

|   |     |
|---|-----|
| 1 | 3.0 |
|---|-----|

|   |     |
|---|-----|
| 2 | 3.0 |
|---|-----|

|   |     |
|---|-----|
| 3 | 6.0 |
|---|-----|

|   |     |
|---|-----|
| 4 | 6.0 |
|---|-----|

|   |      |
|---|------|
| 5 | 10.0 |
|---|------|

```
dtype: float64
```

An expanding window statistic will be more stable (and less responsive) than its rolling window counterpart as the increasing window size decreases the relative impact of an individual data point. As an example, here is the `mean()` output for the previous time series dataset:

```
In [107]: s.plot(style='k--')
```

```
Out[107]: <matplotlib.axes._subplots.AxesSubplot at 0x7fd55293ca90>
```

```
In [108]: s.expanding().mean().plot(style='k')
```

```
Out[108]:
```

```
↪<matplotlib.axes._subplots.AxesSubplot at 0x7fd55293ca90>
```

## 14.5 Exponentially Weighted Windows

A related set of functions are exponentially weighted versions of several of the above statistics. A similar interface to `.rolling` and `.expanding` is accessed through the `.ewm` method to receive an EWM object. A number of expanding EW (exponentially weighted) methods are provided:

| Function            | Description                  |
|---------------------|------------------------------|
| <code>mean()</code> | EW moving average            |
| <code>var()</code>  | EW moving variance           |
| <code>std()</code>  | EW moving standard deviation |
| <code>corr()</code> | EW moving correlation        |
| <code>cov()</code>  | EW moving covariance         |

In general, a weighted moving average is calculated as

$$y_t = \frac{\sum_{i=0}^t w_i x_{t-i}}{\sum_{i=0}^t w_i},$$

where  $x_t$  is the input,  $y_t$  is the result and the  $w_i$  are the weights.

The EW functions support two variants of exponential weights. The default, `adjust=True`, uses the weights  $w_i = (1 - \alpha)^i$  which gives

$$y_t = \frac{x_t + (1 - \alpha)x_{t-1} + (1 - \alpha)^2x_{t-2} + \dots + (1 - \alpha)^tx_0}{1 + (1 - \alpha) + (1 - \alpha)^2 + \dots + (1 - \alpha)^t}$$

When `adjust=False` is specified, moving averages are calculated as

$$\begin{aligned} y_0 &= x_0 \\ y_t &= (1 - \alpha)y_{t-1} + \alpha x_t, \end{aligned}$$

which is equivalent to using weights

$$w_i = \begin{cases} \alpha(1 - \alpha)^i & \text{if } i < t \\ (1 - \alpha)^i & \text{if } i = t. \end{cases}$$

---

**Note:** These equations are sometimes written in terms of  $\alpha' = 1 - \alpha$ , e.g.

$$y_t = \alpha' y_{t-1} + (1 - \alpha')x_t.$$

---

The difference between the above two variants arises because we are dealing with series which have finite history. Consider a series of infinite history:

$$y_t = \frac{x_t + (1 - \alpha)x_{t-1} + (1 - \alpha)^2x_{t-2} + \dots}{1 + (1 - \alpha) + (1 - \alpha)^2 + \dots}$$

Noting that the denominator is a geometric series with initial term equal to 1 and a ratio of  $1 - \alpha$  we have

$$\begin{aligned} y_t &= \frac{x_t + (1 - \alpha)x_{t-1} + (1 - \alpha)^2x_{t-2} + \dots}{\frac{1}{1 - (1 - \alpha)}} \\ &= [x_t + (1 - \alpha)x_{t-1} + (1 - \alpha)^2x_{t-2} + \dots]\alpha \\ &= \alpha x_t + [(1 - \alpha)x_{t-1} + (1 - \alpha)^2x_{t-2} + \dots]\alpha \\ &= \alpha x_t + (1 - \alpha)[x_{t-1} + (1 - \alpha)x_{t-2} + \dots]\alpha \\ &= \alpha x_t + (1 - \alpha)y_{t-1} \end{aligned}$$

which shows the equivalence of the above two variants for infinite series. When `adjust=True` we have  $y_0 = x_0$  and from the last representation above we have  $y_t = \alpha x_t + (1 - \alpha)y_{t-1}$ , therefore there is an assumption that  $x_0$  is not an ordinary value but rather an exponentially weighted moment of the infinite series up to that point.

One must have  $0 < \alpha \leq 1$ , and while since version 0.18.0 it has been possible to pass  $\alpha$  directly, it's often easier to think about either the **span**, **center of mass (com)** or **half-life** of an EW moment:

$$\alpha = \begin{cases} \frac{2}{s+1}, & \text{for span } s \geq 1 \\ \frac{1}{1+c}, & \text{for center of mass } c \geq 0 \\ 1 - \exp^{-\frac{\log 0.5}{h}}, & \text{for half-life } h > 0 \end{cases}$$

One must specify precisely one of **span**, **center of mass**, **half-life** and **alpha** to the EW functions:

- **Span** corresponds to what is commonly called an “N-day EW moving average”.
- **Center of mass** has a more physical interpretation and can be thought of in terms of span:  $c = (s - 1)/2$ .
- **Half-life** is the period of time for the exponential weight to reduce to one half.
- **Alpha** specifies the smoothing factor directly.

Here is an example for a univariate time series:

```

In [109]: s.plot(style='k--')
Out[109]: <matplotlib.axes._subplots.AxesSubplot at 0x7fd543bdc3c8>

In [110]: s.ewm(span=20).mean().plot(style='k')
Out[110]:
\\Out[110]:
↪<matplotlib.axes._subplots.AxesSubplot at 0x7fd543bdc3c8>

```

EWM has a `min_periods` argument, which has the same meaning it does for all the `.expanding` and `.rolling` methods: no output values will be set until at least `min_periods` non-null values are encountered in the (expanding) window.

EWM also has an `ignore_na` argument, which determines how intermediate null values affect the calculation of the weights. When `ignore_na=False` (the default), weights are calculated based on absolute positions, so that intermediate null values affect the result. When `ignore_na=True`, weights are calculated by ignoring intermediate null values. For example, assuming `adjust=True`, if `ignore_na=False`, the weighted average of 3, NaN, 5 would be calculated as

$$\frac{(1 - \alpha)^2 \cdot 3 + 1 \cdot 5}{(1 - \alpha)^2 + 1}.$$

Whereas if `ignore_na=True`, the weighted average would be calculated as

$$\frac{(1 - \alpha) \cdot 3 + 1 \cdot 5}{(1 - \alpha) + 1}.$$

The `var()`, `std()`, and `cov()` functions have a `bias` argument, specifying whether the result should contain biased or unbiased statistics. For example, if `bias=True`, `ewmvar(x)` is calculated as `ewmvar(x) = ewm(x**2) - ewm(x)**2`; whereas if `bias=False` (the default), the biased variance statistics are scaled by debiasing factors

$$\frac{\left(\sum_{i=0}^t w_i\right)^2}{\left(\sum_{i=0}^t w_i\right)^2 - \sum_{i=0}^t w_i^2}.$$

(For  $w_i = 1$ , this reduces to the usual  $N/(N - 1)$  factor, with  $N = t + 1$ .) See [Weighted Sample Variance](#) on Wikipedia for further details. {{ header }}

## WORKING WITH MISSING DATA

In this section, we will discuss missing (also referred to as NA) values in pandas.

---

**Note:** The choice of using NaN internally to denote missing data was largely for simplicity and performance reasons. It differs from the MaskedArray approach of, for example, `scikits.timeseries`. We are hopeful that NumPy will soon be able to provide a native NA type solution (similar to R) performant enough to be used in pandas.

---

See the *cookbook* for some advanced strategies.

### 15.1 Values considered “missing”

As data comes in many shapes and forms, pandas aims to be flexible with regard to handling missing data. While NaN is the default missing value marker for reasons of computational speed and convenience, we need to be able to easily detect this value with data of different types: floating point, integer, boolean, and general object. In many cases, however, the Python None will arise and we wish to also consider that “missing” or “not available” or “NA”.

---

**Note:** If you want to consider `inf` and `-inf` to be “NA” in computations, you can set `pandas.options.mode.use_inf_as_na = True`.

---

```
In [1]: df = pd.DataFrame(np.random.randn(5, 3), index=['a', 'c', 'e', 'f', 'h'],
...: columns=['one', 'two', 'three'])
...:
...:

In [2]: df['four'] = 'bar'

In [3]: df['five'] = df['one'] > 0

In [4]: df
Out[4]:
 one two three four five
a -1.347359 -0.129210 -0.903942 bar False
c 0.892813 0.310267 0.727182 bar True
e 0.205146 0.243977 1.123362 bar True
f -1.429867 -0.924164 -0.716660 bar False
h 1.330055 -0.418604 -0.399835 bar True

In [5]: df2 = df.reindex(['a', 'b', 'c', 'd', 'e', 'f', 'g', 'h'])

In [6]: df2
```

(continues on next page)

(continued from previous page)

```
Out [6]:
```

|   | one       | two       | three     | four | five  |
|---|-----------|-----------|-----------|------|-------|
| a | -1.347359 | -0.129210 | -0.903942 | bar  | False |
| b | NaN       | NaN       | NaN       | NaN  | NaN   |
| c | 0.892813  | 0.310267  | 0.727182  | bar  | True  |
| d | NaN       | NaN       | NaN       | NaN  | NaN   |
| e | 0.205146  | 0.243977  | 1.123362  | bar  | True  |
| f | -1.429867 | -0.924164 | -0.716660 | bar  | False |
| g | NaN       | NaN       | NaN       | NaN  | NaN   |
| h | 1.330055  | -0.418604 | -0.399835 | bar  | True  |

To make detecting missing values easier (and across different array dtypes), pandas provides the `isna()` and `notna()` functions, which are also methods on Series and DataFrame objects:

```
In [7]: df2['one']
Out [7]:
```

|   |           |
|---|-----------|
| a | -1.347359 |
| b | NaN       |
| c | 0.892813  |
| d | NaN       |
| e | 0.205146  |
| f | -1.429867 |
| g | NaN       |
| h | 1.330055  |

Name: one, dtype: float64

```
In [8]: pd.isna(df2['one'])
```

```

////////////////////////////////////
↪
a False
b True
c False
d True
e False
f False
g True
h False
Name: one, dtype: bool
```

```
In [9]: df2['four'].notna()
```

```

////////////////////////////////////
↪
a True
b False
c True
d False
e True
f True
g False
h True
Name: four, dtype: bool
```

```
In [10]: df2.isna()
```

```

////////////////////////////////////
↪
 one two three four five
```

(continues on next page)

(continued from previous page)

```

a False False False False False
b True True True True True
c False False False False False
d True True True True True
e False False False False False
f False False False False False
g True True True True True
h False False False False False

```

**Warning:** One has to be mindful that in Python (and NumPy), the nan 's don't compare equal, but None 's **do**. Note that pandas/NumPy uses the fact that `np.nan != np.nan`, and treats None like `np.nan`.

```

In [11]: None == None # noqa: E711
Out[11]: True

In [12]: np.nan == np.nan
\\Out[12]: False

```

So as compared to above, a scalar equality comparison versus a None/`np.nan` doesn't provide useful information.

```

In [13]: df2['one'] == np.nan
Out[13]:
a False
b False
c False
d False
e False
f False
g False
h False
Name: one, dtype: bool

```

### 15.1.1 Integer Dtypes and Missing Data

Because NaN is a float, a column of integers with even one missing values is cast to floating-point dtype (see *Support for integer NA* for more). Pandas provides a nullable integer array, which can be used by explicitly requesting the dtype:

```

In [14]: pd.Series([1, 2, np.nan, 4], dtype=pd.Int64Dtype())
Out[14]:
0 1
1 2
2 NaN
3 4
dtype: Int64

```

Alternatively, the string alias `dtype='Int64'` (note the capital "I") can be used.

See *Nullable Integer Data Type* for more.

### 15.1.2 Datetimes

For `datetime64[ns]` types, `NaT` represents missing values. This is a pseudo-native sentinel value that can be represented by NumPy in a singular dtype (`datetime64[ns]`). pandas objects provide compatibility between `NaT` and `NaN`.

```
In [15]: df2 = df.copy()

In [16]: df2['timestamp'] = pd.Timestamp('20120101')

In [17]: df2
Out[17]:
```

|   | one       | two       | three     | four | five  | timestamp  |
|---|-----------|-----------|-----------|------|-------|------------|
| a | -1.347359 | -0.129210 | -0.903942 | bar  | False | 2012-01-01 |
| c | 0.892813  | 0.310267  | 0.727182  | bar  | True  | 2012-01-01 |
| e | 0.205146  | 0.243977  | 1.123362  | bar  | True  | 2012-01-01 |
| f | -1.429867 | -0.924164 | -0.716660 | bar  | False | 2012-01-01 |
| h | 1.330055  | -0.418604 | -0.399835 | bar  | True  | 2012-01-01 |

```
In [18]: df2.loc[['a', 'c', 'h'], ['one', 'timestamp']] = np.nan

In [19]: df2
Out[19]:
```

|   | one       | two       | three     | four | five  | timestamp  |
|---|-----------|-----------|-----------|------|-------|------------|
| a | NaN       | -0.129210 | -0.903942 | bar  | False | NaT        |
| c | NaN       | 0.310267  | 0.727182  | bar  | True  | NaT        |
| e | 0.205146  | 0.243977  | 1.123362  | bar  | True  | 2012-01-01 |
| f | -1.429867 | -0.924164 | -0.716660 | bar  | False | 2012-01-01 |
| h | NaN       | -0.418604 | -0.399835 | bar  | True  | NaT        |

```
In [20]: df2.get_dtype_counts()
//
```

|                |   |
|----------------|---|
| float64        | 3 |
| object         | 1 |
| bool           | 1 |
| datetime64[ns] | 1 |
| dtype: int64   |   |

### 15.1.3 Inserting missing data

You can insert missing values by simply assigning to containers. The actual missing value used will be chosen based on the dtype.

For example, numeric containers will always use NaN regardless of the missing value type chosen:

```
In [21]: s = pd.Series([1, 2, 3])

In [22]: s.loc[0] = None

In [23]: s
Out[23]:
0 NaN
1 2.0
2 3.0
dtype: float64
```

Likewise, datetime containers will always use NaT.

For object containers, pandas will use the value given:

```
In [24]: s = pd.Series(["a", "b", "c"])
In [25]: s.loc[0] = None
In [26]: s.loc[1] = np.nan
In [27]: s
Out[27]:
0 None
1 NaN
2 c
dtype: object
```

### 15.1.4 Calculations with missing data

Missing values propagate naturally through arithmetic operations between pandas objects.

```
In [28]: a
Out[28]:
 one two
a NaN -0.129210
c NaN 0.310267
e 0.205146 0.243977
f -1.429867 -0.924164
h -1.429867 -0.418604

In [29]: b
////////////////////////////////////
↪
 one two three
a NaN -0.129210 -0.903942
c NaN 0.310267 0.727182
e 0.205146 0.243977 1.123362
f -1.429867 -0.924164 -0.716660
h NaN -0.418604 -0.399835

In [30]: a + b
////////////////////////////////////
↪
 one three two
a NaN NaN -0.258421
c NaN NaN 0.620534
e 0.410292 NaN 0.487954
f -2.859734 NaN -1.848327
h NaN NaN -0.837207
```

The descriptive statistics and computational methods discussed in the *data structure overview* (and listed *here* and *here*) are all written to account for missing data. For example:

- When summing data, NA (missing) values will be treated as zero.
- If the data are all NA, the result will be 0.
- Cumulative methods like `cumsum()` and `cumprod()` ignore NA values by default, but preserve them in the resulting arrays. To override this behaviour and include NA values, use `skipna=False`.

```
In [31]: df
Out[31]:
```

|   | one       | two       | three     |
|---|-----------|-----------|-----------|
| a | NaN       | -0.129210 | -0.903942 |
| c | NaN       | 0.310267  | 0.727182  |
| e | 0.205146  | 0.243977  | 1.123362  |
| f | -1.429867 | -0.924164 | -0.716660 |
| h | NaN       | -0.418604 | -0.399835 |

[illegible]

```
In [33]: df.mean(1)
\\//
↪
a -0.516576

e 0.524162
f -1.023564
h -0.409219
dtype: float64
```

```
In [34]: df.cumsum()
```

```
|||||
```

|   | one       | two       | three     |
|---|-----------|-----------|-----------|
| a | NaN       | -0.129210 | -0.903942 |
| c | NaN       | 0.181057  | -0.176760 |
| e | 0.205146  | 0.425034  | 0.946601  |
| f | -1.224721 | -0.499130 | 0.229941  |
| h | NaN       | -0.917733 | -0.169894 |

```
In [35]: df.cumsum(skipna=False)
//////////
↪
 one two three
a NaN -0.129210 -0.903942
c NaN 0.181057 -0.176760
e NaN 0.425034 0.946601
f NaN -0.499130 0.229941
h NaN -0.917733 -0.169894
```

## 15.2 Sum/Prod of Empties/Nans

**Warning:** This behavior is now standard as of v0.22.0 and is consistent with the default in `numpy`; previously `sum/prod` of all-NA or empty `Series/DataFrames` would return `NaN`. See *v0.22.0 whatsnew* for more.

The sum of an empty or all-NA Series or column of a DataFrame is 0.

```
In [36]: pd.Series([np.nan]).sum()
Out[36]: 0.0
```

(continues on next page)

(continued from previous page)

```
In [37]: pd.Series([]).sum()
\\Out[37]: 0.0
```

The product of an empty or all-NA Series or column of a DataFrame is 1.

```
In [38]: pd.Series([np.nan]).prod()
Out[38]: 1.0

In [39]: pd.Series([]).prod()
\\Out[39]: 1.0
```

## 15.3 NA values in GroupBy

NA groups in GroupBy are automatically excluded. This behavior is consistent with R, for example:

```
In [40]: df
Out[40]:
```

|   | one       | two       | three     |
|---|-----------|-----------|-----------|
| a | NaN       | -0.129210 | -0.903942 |
| c | NaN       | 0.310267  | 0.727182  |
| e | 0.205146  | 0.243977  | 1.123362  |
| f | -1.429867 | -0.924164 | -0.716660 |
| h | NaN       | -0.418604 | -0.399835 |

```
In [41]: df.groupby('one').mean()
\\Out[41]:
```

|           | two       | three     |
|-----------|-----------|-----------|
| one       |           |           |
| -1.429867 | -0.924164 | -0.716660 |
| 0.205146  | 0.243977  | 1.123362  |

See the groupby section [here](#) for more information.

### 15.3.1 Cleaning / filling missing data

pandas objects are equipped with various data manipulation methods for dealing with missing data.

## 15.4 Filling missing values: fillna

fillna() can “fill in” NA values with non-NA data in a couple of ways, which we illustrate:

**Replace NA with a scalar value**

```
In [42]: df2
Out[42]:
```

|   | one       | two       | three     | four | five  | timestamp  |
|---|-----------|-----------|-----------|------|-------|------------|
| a | NaN       | -0.129210 | -0.903942 | bar  | False | NaT        |
| c | NaN       | 0.310267  | 0.727182  | bar  | True  | NaT        |
| e | 0.205146  | 0.243977  | 1.123362  | bar  | True  | 2012-01-01 |
| f | -1.429867 | -0.924164 | -0.716660 | bar  | False | 2012-01-01 |

(continues on next page)

(continued from previous page)

```
h NaN -0.418604 -0.399835 bar True NaT
```

```
In [43]: df2.fillna(0)
```

```

////////////////////////////////////
↪
 one two three four five timestamp
a 0.000000 -0.129210 -0.903942 bar False 0
c 0.000000 0.310267 0.727182 bar True 0
e 0.205146 0.243977 1.123362 bar True 2012-01-01 00:00:00
f -1.429867 -0.924164 -0.716660 bar False 2012-01-01 00:00:00
h 0.000000 -0.418604 -0.399835 bar True 0

```

```
In [44]: df2['one'].fillna('missing')
```

```

////////////////////////////////////
↪
a missing
c missing
e 0.205146
f -1.42987
h missing
Name: one, dtype: object

```

### Fill gaps forward or backward

Using the same filling arguments as *reindexing*, we can propagate non-NA values forward or backward:

```
In [45]: df
```

```
Out [45]:
 one two three
a NaN -0.129210 -0.903942
c NaN 0.310267 0.727182
e 0.205146 0.243977 1.123362
f -1.429867 -0.924164 -0.716660
h NaN -0.418604 -0.399835

```

```
In [46]: df.fillna(method='pad')
```

```

////////////////////////////////////
↪
 one two three
a NaN -0.129210 -0.903942
c NaN 0.310267 0.727182
e 0.205146 0.243977 1.123362
f -1.429867 -0.924164 -0.716660
h -1.429867 -0.418604 -0.399835

```

### Limit the amount of filling

If we only want consecutive gaps filled up to a certain number of data points, we can use the *limit* keyword:

```
In [47]: df
```

```
Out [47]:
 one two three
a NaN -0.129210 -0.903942
c NaN 0.310267 0.727182
e NaN NaN NaN
f NaN NaN NaN
h NaN -0.418604 -0.399835

```

(continues on next page)

(continued from previous page)

```
In [48]: df.fillna(method='pad', limit=1)
```

```

////////////////////////////////////
↪
 one two three
a NaN -0.129210 -0.903942
c NaN 0.310267 0.727182
e NaN 0.310267 0.727182
f NaN NaN NaN
h NaN -0.418604 -0.399835

```

To remind you, these are the available filling methods:

| Method           | Action               |
|------------------|----------------------|
| pad / ffill      | Fill values forward  |
| bfill / backfill | Fill values backward |

With time series data, using pad/ffill is extremely common so that the “last known value” is available at every time point.

`ffill()` is equivalent to `fillna(method='ffill')` and `bfill()` is equivalent to `fillna(method='bfill')`

## 15.5 Filling with a PandasObject

You can also fillna using a dict or Series that is alignable. The labels of the dict or index of the Series must match the columns of the frame you wish to fill. The use case of this is to fill a DataFrame with the mean of that column.

```
In [49]: dff = pd.DataFrame(np.random.randn(10, 3), columns=list('ABC'))
```

```
In [50]: dff.iloc[3:5, 0] = np.nan
```

```
In [51]: dff.iloc[4:6, 1] = np.nan
```

```
In [52]: dff.iloc[5:8, 2] = np.nan
```

```
In [53]: dff
```

```
Out [53]:
```

```

 A B C
0 0.973213 0.151970 0.912544
1 -1.941888 0.040945 -0.772060
2 1.154696 -0.044806 -0.322667
3 NaN -1.658882 0.471216
4 NaN NaN 1.200994
5 -0.376308 NaN NaN

7 -0.723439 -1.197455 NaN
8 -0.357026 0.739897 -1.087057
9 0.209877 0.663146 0.282573

```

```
In [54]: dff.fillna(dff.mean())
```

```

////////////////////////////////////
↪

```

(continues on next page)

(continued from previous page)

```

 A B C
0 0.973213 0.151970 0.912544
1 -1.941888 0.040945 -0.772060
2 1.154696 -0.044806 -0.322667
3 -0.274585 -1.658882 0.471216
4 -0.274585 -0.086492 1.200994
5 -0.376308 -0.086492 0.097935
6 -1.135807 0.613248 0.097935
7 -0.723439 -1.197455 0.097935
8 -0.357026 0.739897 -1.087057
9 0.209877 0.663146 0.282573

```

```
In [55]: dff.fillna(dff.mean()['B':'C'])
```

```

////////////////////////////////////
↪
 A B C
0 0.973213 0.151970 0.912544
1 -1.941888 0.040945 -0.772060
2 1.154696 -0.044806 -0.322667
3 NaN -1.658882 0.471216
4 NaN -0.086492 1.200994
5 -0.376308 -0.086492 0.097935
6 -1.135807 0.613248 0.097935
7 -0.723439 -1.197455 0.097935
8 -0.357026 0.739897 -1.087057
9 0.209877 0.663146 0.282573

```

Same result as above, but is aligning the ‘fill’ value which is a Series in this case.

```
In [56]: dff.where(pd.notna(dff), dff.mean(), axis='columns')
```

```
Out [56]:
```

```

 A B C
0 0.973213 0.151970 0.912544
1 -1.941888 0.040945 -0.772060
2 1.154696 -0.044806 -0.322667
3 -0.274585 -1.658882 0.471216
4 -0.274585 -0.086492 1.200994
5 -0.376308 -0.086492 0.097935
6 -1.135807 0.613248 0.097935
7 -0.723439 -1.197455 0.097935
8 -0.357026 0.739897 -1.087057
9 0.209877 0.663146 0.282573

```

## 15.6 Dropping axis labels with missing data: dropna

You may wish to simply exclude labels from a data set which refer to missing data. To do this, use `dropna()`:

```
In [57]: df
```

```
Out [57]:
```

```

 one two three
a NaN -0.129210 -0.903942
c NaN 0.310267 0.727182
e NaN 0.000000 0.000000
f NaN 0.000000 0.000000

```

(continues on next page)

(continued from previous page)

```
h NaN -0.418604 -0.399835
```

```
In [58]: df.dropna(axis=0)
```

```
Empty DataFrame
Columns: [one, two, three]
Index: []
```

```
In [59]: df.dropna(axis=1)
```

```
 two three
a -0.129210 -0.903942
c 0.310267 0.727182
e 0.000000 0.000000
f 0.000000 0.000000
h -0.418604 -0.399835
```

```
In [60]: df['one'].dropna()
```

```
Series([], Name: one, dtype: float64)
```

An equivalent `dropna()` is available for Series. `DataFrame.dropna` has considerably more options than `Series.dropna`, which can be examined *in the API*.

## 15.7 Interpolation

New in version 0.21.0: The `limit_area` keyword argument was added.

Both Series and DataFrame objects have `interpolate()` that, by default, performs linear interpolation at missing data points.

```
In [61]: ts
```

```
Out [61]:
```

```
2000-01-31 0.469112
2000-02-29 NaN
2000-03-31 NaN
2000-04-28 NaN
2000-05-31 NaN
2000-06-30 NaN
2000-07-31 NaN
2000-08-31 NaN
2000-09-29 NaN
2000-10-31 NaN
2000-11-30 NaN
2000-12-29 NaN
2001-01-31 NaN
2001-02-28 NaN
2001-03-30 NaN
2001-04-30 NaN
2001-05-31 NaN
2001-06-29 NaN
2001-07-31 NaN
2001-08-31 NaN
```

(continues on next page)

```
<matplotlib.figure.Figure at 0x7fd503e9f8c0>
↳<matplotlib.axes._subplots.AxesSubplot at 0x7fd503effcf8>
```

Index aware interpolation is available via the `method` keyword:

```
In [65]: ts2
```

```
Out[65]:
```

```
2000-01-31 0.469112
2000-02-29 NaN
2002-07-31 -5.689738
2005-01-31 NaN
2008-04-30 -8.916232
dtype: float64
```

```
In [66]: ts2.interpolate()
```

```

////////////////////////////////////
↪
2000-01-31 0.469112
2000-02-29 -2.610313
2002-07-31 -5.689738
2005-01-31 -7.302985
2008-04-30 -8.916232
dtype: float64
```

```
In [67]: ts2.interpolate(method='time')
```

```

////////////////////////////////////
↪
```

(continues on next page)

(continued from previous page)

```

2000-01-31 0.469112
2000-02-29 0.273272
2002-07-31 -5.689738
2005-01-31 -7.095568
2008-04-30 -8.916232
dtype: float64

```

For a floating-point index, use `method='values'`:

```

In [68]: ser
Out[68]:
0.0 0.0
1.0 NaN
10.0 10.0
dtype: float64

In [69]: ser.interpolate()
Out[69]:
0.0 0.0
1.0 5.0
10.0 10.0
dtype: float64

In [70]: ser.interpolate(method='values')
Out[70]:
0.0 0.0
1.0 1.0
10.0 10.0
dtype: float64

```

You can also interpolate with a DataFrame:

```

In [71]: df = pd.DataFrame({'A': [1, 2.1, np.nan, 4.7, 5.6, 6.8],
.....: 'B': [.25, np.nan, np.nan, 4, 12.2, 14.4]})
.....:

In [72]: df
Out[72]:
 A B
0 1.0 0.25
1 2.1 NaN
2 NaN NaN
3 4.7 4.00
4 5.6 12.20
5 6.8 14.40

In [73]: df.interpolate()
Out[73]:
 A B
0 1.0 0.25
1 2.1 1.50
2 3.4 2.75
3 4.7 4.00
4 5.6 12.20
5 6.8 14.40

```

The `method` argument gives access to fancier interpolation methods. If you have `scipy` installed, you can pass the name of a 1-d interpolation routine to `method`. You'll want to consult the full [scipy interpolation documentation](#) and reference [guide](#) for details. The appropriate interpolation method will depend on the type of data you are working with.

- If you are dealing with a time series that is growing at an increasing rate, `method='quadratic'` may be appropriate.
- If you have values approximating a cumulative distribution function, then `method='pchip'` should work well.
- To fill missing values with goal of smooth plotting, consider `method='akima'`.

**Warning:** These methods require `scipy`.

```
In [74]: df.interpolate(method='barycentric')
```

```
Out [74]:
```

|   | A    | B      |
|---|------|--------|
| 0 | 1.00 | 0.250  |
| 1 | 2.10 | -7.660 |
| 2 | 3.53 | -4.515 |
| 3 | 4.70 | 4.000  |
| 4 | 5.60 | 12.200 |
| 5 | 6.80 | 14.400 |

```
In [75]: df.interpolate(method='pchip')
```

```
////////////////////////////////////
```

```
↪
```

|   | A       | B         |
|---|---------|-----------|
| 0 | 1.00000 | 0.250000  |
| 1 | 2.10000 | 0.672808  |
| 2 | 3.43454 | 1.928950  |
| 3 | 4.70000 | 4.000000  |
| 4 | 5.60000 | 12.200000 |
| 5 | 6.80000 | 14.400000 |

```
In [76]: df.interpolate(method='akima')
```

```
////////////////////////////////////
```

```
↪
```

|   | A        | B         |
|---|----------|-----------|
| 0 | 1.000000 | 0.250000  |
| 1 | 2.100000 | -0.873316 |
| 2 | 3.406667 | 0.320034  |
| 3 | 4.700000 | 4.000000  |
| 4 | 5.600000 | 12.200000 |
| 5 | 6.800000 | 14.400000 |

When interpolating via a polynomial or spline approximation, you must also specify the degree or order of the approximation:

```
In [77]: df.interpolate(method='spline', order=2)
```

```
Out [77]:
```

|   | A        | B         |
|---|----------|-----------|
| 0 | 1.000000 | 0.250000  |
| 1 | 2.100000 | -0.428598 |
| 2 | 3.404545 | 1.206900  |

(continues on next page)

(continued from previous page)

|   |          |           |
|---|----------|-----------|
| 3 | 4.700000 | 4.000000  |
| 4 | 5.600000 | 12.200000 |
| 5 | 6.800000 | 14.400000 |

```
In [78]: df.interpolate(method='polynomial', order=2)
```

|   | A        | B         |
|---|----------|-----------|
| 0 | 1.000000 | 0.250000  |
| 1 | 2.100000 | -2.703846 |
| 2 | 3.451351 | -1.453846 |
| 3 | 4.700000 | 4.000000  |
| 4 | 5.600000 | 12.200000 |
| 5 | 6.800000 | 14.400000 |

Compare several methods:

```
In [79]: np.random.seed(2)
```

```
In [80]: ser = pd.Series(np.arange(1, 10.1, .25)**2 + np.random.randn(37))
```

```
In [81]: bad = np.array([4, 13, 14, 15, 16, 17, 18, 20, 29])
```

```
In [82]: ser[bad] = np.nan
```

```
In [83]: methods = ['linear', 'quadratic', 'cubic']
```

```
In [84]: df = pd.DataFrame({m: ser.interpolate(method=m) for m in methods})
```

```
In [85]: df.plot()
```

```
Out [85]: <matplotlib.axes._subplots.AxesSubplot at 0x7fd542efada0>
```

Another use case is interpolation at *new* values. Suppose you have 100 observations from some distribution. And let's suppose that you're particularly interested in what's happening around the middle. You can mix pandas' `reindex` and `interpolate` methods to interpolate at the new values.

```
In [86]: ser = pd.Series(np.sort(np.random.uniform(size=100)))

interpolate at new_index
In [87]: new_index = ser.index | pd.Index([49.25, 49.5, 49.75, 50.25, 50.5, 50.75])

In [88]: interp_s = ser.reindex(new_index).interpolate(method='pchip')

In [89]: interp_s[49:51]
Out[89]:
49.00 0.471410
49.25 0.476841
49.50 0.481780
49.75 0.485998
50.00 0.489266
50.25 0.491814
50.50 0.493995
50.75 0.495763
51.00 0.497074
dtype: float64
```

Like other pandas fill methods, `interpolate()` accepts a `limit` keyword argument. Use this argument to limit

the number of consecutive NaN values filled since the last valid observation:

```
In [90]: ser = pd.Series([np.nan, np.nan, 5, np.nan, np.nan,
.....: np.nan, 13, np.nan, np.nan])
.....:
```

```
fill all consecutive values in a forward direction
```

```
In [91]: ser.interpolate()
```

Out [91]:

```
0 NaN
1 NaN
2 5.0
3 7.0
4 9.0
5 11.0
6 13.0
7 13.0
8 13.0
dtype: float64
```

```
fill one consecutive value in a forward direction
```

```
In [92]: ser.interpolate(limit=1)
```

```
0 NaN
1 NaN
2 5.0
3 7.0
4 NaN
5 NaN
6 13.0
7 13.0
8 NaN
dtype: float64
```

By default, NaN values are filled in a forward direction. Use `limit_direction` parameter to fill backward or from both directions.

```
fill one consecutive value backwards
```

```
In [93]: ser.interpolate(limit=1, limit_direction='backward')
```

Out [93]:

```
0 NaN
1 5.0
2 5.0
3 NaN
4 NaN
5 11.0
6 13.0
7 NaN
8 NaN
dtype: float64
```

```
fill one consecutive value in both directions
```

```
In [94]: ser.interpolate(limit=1, limit_direction='both')
```

[illegible]

(continues on next page)

(continued from previous page)

```

2 5.0
3 7.0
4 NaN
5 11.0
6 13.0
7 13.0
8 NaN
dtype: float64

```

```

fill all consecutive values in both directions
In [95]: ser.interpolate(limit_direction='both')

```

```

////////////////////////////////////
↪
0 5.0
1 5.0
2 5.0
3 7.0
4 9.0
5 11.0
6 13.0
7 13.0
8 13.0
dtype: float64

```

By default, NaN values are filled whether they are inside (surrounded by) existing valid values, or outside existing valid values. Introduced in v0.23 the `limit_area` parameter restricts filling to either inside or outside values.

```

fill one consecutive inside value in both directions
In [96]: ser.interpolate(limit_direction='both', limit_area='inside', limit=1)
Out[96]:

```

```

0 NaN
1 NaN
2 5.0
3 7.0
4 NaN
5 11.0
6 13.0
7 NaN
8 NaN
dtype: float64

```

```

fill all consecutive outside values backward

```

```

In [97]: ser.interpolate(limit_direction='backward', limit_area='outside')

```

```

////////////////////////////////////

2 5.0
3 NaN
4 NaN
5 NaN
6 13.0
7 13.0
8 13.0
dtype: float64
```

## 15.8 Replacing Generic Values

Often times we want to replace arbitrary values with other values.

`replace()` in `Series` and `replace()` in `DataFrame` provides an efficient yet flexible way to perform such replacements.

For a Series, you can replace a single value or a list of values by another value:

```
In [99]: ser = pd.Series([0., 1., 2., 3., 4.])

In [100]: ser.replace(0, 5)
Out[100]:
0 5.0
1 1.0
2 2.0
3 3.0
4 4.0
dtype: float64
```

You can replace a list of values by a list of other values:

```
In [101]: ser.replace([0, 1, 2, 3, 4], [4, 3, 2, 1, 0])
Out[101]:
0 4.0
1 3.0
2 2.0
3 1.0
4 0.0
dtype: float64
```

You can also specify a mapping dict:

```
In [102]: ser.replace({0: 10, 1: 100})
Out[102]:
0 10.0
1 100.0
2 2.0
3 3.0
```

(continues on next page)

(continued from previous page)

```
4 4.0
dtype: float64
```

For a DataFrame, you can specify individual values by column:

```
In [103]: df = pd.DataFrame({'a': [0, 1, 2, 3, 4], 'b': [5, 6, 7, 8, 9]})

In [104]: df.replace({'a': 0, 'b': 5}, 100)
Out[104]:
```

|   | a   | b   |
|---|-----|-----|
| 0 | 100 | 100 |
| 1 | 1   | 6   |
| 2 | 2   | 7   |
| 3 | 3   | 8   |
| 4 | 4   | 9   |

Instead of replacing with specified values, you can treat all given values as missing and interpolate over them:

```
In [105]: ser.replace([1, 2, 3], method='pad')
Out[105]:
```

|   |     |
|---|-----|
| 0 | 0.0 |
| 1 | 0.0 |
| 2 | 0.0 |
| 3 | 0.0 |
| 4 | 4.0 |

dtype: float64

## 15.9 String/Regular Expression Replacement

**Note:** Python strings prefixed with the `r` character such as `r'hello world'` are so-called “raw” strings. They have different semantics regarding backslashes than strings without this prefix. Backslashes in raw strings will be interpreted as an escaped backslash, e.g., `r'\' == '\\'`. You should [read about them](#) if this is unclear.

Replace the ‘.’ with NaN (str -> str):

```
In [106]: d = {'a': list(range(4)), 'b': list('ab..'), 'c': ['a', 'b', np.nan, 'd']}

In [107]: df = pd.DataFrame(d)

In [108]: df.replace('.', np.nan)
Out[108]:
```

|   | a | b   | c   |
|---|---|-----|-----|
| 0 | 0 | a   | a   |
| 1 | 1 | b   | b   |
| 2 | 2 | NaN | NaN |
| 3 | 3 | NaN | d   |

Now do it with a regular expression that removes surrounding whitespace (regex -> regex):

```
In [109]: df.replace(r'\s*\.\s*', np.nan, regex=True)
Out[109]:
```

|  | a | b | c |
|--|---|---|---|
|--|---|---|---|

(continues on next page)

(continued from previous page)

```
0 0 a a
1 1 b b
2 2 NaN NaN
3 3 NaN d
```

Replace a few different values (list -> list):

```
In [110]: df.replace(['a', '.'], ['b', np.nan])
```

```
Out[110]:
 a b c
0 0 b b
1 1 b b
2 2 NaN NaN
3 3 NaN d
```

list of regex -> list of regex:

```
In [111]: df.replace([r'\.', r'(a)'], ['dot', '\1stuff'], regex=True)
```

```
Out[111]:
 a b c
0 0 {stuff {stuff
1 1 b b
2 2 dot NaN
3 3 dot d
```

Only search in column 'b' (dict -> dict):

```
In [112]: df.replace({'b': '.'}, {'b': np.nan})
```

```
Out[112]:
 a b c
0 0 a a
1 1 b b
2 2 NaN NaN
3 3 NaN d
```

Same as the previous example, but use a regular expression for searching instead (dict of regex -> dict):

```
In [113]: df.replace({'b': r'\s*\.\s*'}, {'b': np.nan}, regex=True)
```

```
Out[113]:
 a b c
0 0 a a
1 1 b b
2 2 NaN NaN
3 3 NaN d
```

You can pass nested dictionaries of regular expressions that use `regex=True`:

```
In [114]: df.replace({'b': {'b': r'.'}}, regex=True)
```

```
Out[114]:
 a b c
0 0 a a
1 1 b b
2 2 . NaN
3 3 . d
```

Alternatively, you can pass the nested dictionary like so:

```
In [115]: df.replace(regex={'b': {r'\s*\.\s*': np.nan}})
Out[115]:
```

|   | a | b   | c   |
|---|---|-----|-----|
| 0 | 0 | a   | a   |
| 1 | 1 | b   | b   |
| 2 | 2 | NaN | NaN |
| 3 | 3 | NaN | d   |

You can also use the group of a regular expression match when replacing (dict of regex -> dict of regex), this works for lists as well.

```
In [116]: df.replace({'b': r'\s*(\.)\s*'}, {'b': r'\lty'}, regex=True)
Out[116]:
```

|   | a | b   | c   |
|---|---|-----|-----|
| 0 | 0 | a   | a   |
| 1 | 1 | b   | b   |
| 2 | 2 | .ty | NaN |
| 3 | 3 | .ty | d   |

You can pass a list of regular expressions, of which those that match will be replaced with a scalar (list of regex -> regex).

```
In [117]: df.replace([r'\s*\.\s*', r'a|b'], np.nan, regex=True)
Out[117]:
```

|   | a | b   | c   |
|---|---|-----|-----|
| 0 | 0 | NaN | NaN |
| 1 | 1 | NaN | NaN |
| 2 | 2 | NaN | NaN |
| 3 | 3 | NaN | d   |

All of the regular expression examples can also be passed with the `to_replace` argument as the `regex` argument. In this case the `value` argument must be passed explicitly by name or `regex` must be a nested dictionary. The previous example, in this case, would then be:

```
In [118]: df.replace(regex=[r'\s*\.\s*', r'a|b'], value=np.nan)
Out[118]:
```

|   | a | b   | c   |
|---|---|-----|-----|
| 0 | 0 | NaN | NaN |
| 1 | 1 | NaN | NaN |
| 2 | 2 | NaN | NaN |
| 3 | 3 | NaN | d   |

This can be convenient if you do not want to pass `regex=True` every time you want to use a regular expression.

**Note:** Anywhere in the above `replace` examples that you see a regular expression a compiled regular expression is valid as well.

## 15.10 Numeric Replacement

`replace()` is similar to `fillna()`.

```
In [119]: df = pd.DataFrame(np.random.randn(10, 2))
```

(continues on next page)

(continued from previous page)

```
In [120]: df[np.random.rand(df.shape[0]) > 0.5] = 1.5
```

```
In [121]: df.replace(1.5, np.nan)
```

```
Out [121]:
```

|   | 0         | 1         |
|---|-----------|-----------|
| 0 | -0.844214 | -1.021415 |
| 1 | 0.432396  | -0.323580 |
| 2 | 0.423825  | 0.799180  |
| 3 | 1.262614  | 0.751965  |
| 4 | NaN       | NaN       |
| 5 | NaN       | NaN       |
| 6 | -0.498174 | -1.060799 |
| 7 | 0.591667  | -0.183257 |
| 8 | 1.019855  | -1.482465 |
| 9 | NaN       | NaN       |

Replacing more than one value is possible by passing a list.

```
In [122]: df00 = df.iloc[0, 0]
```

```
In [123]: df.replace([1.5, df00], [np.nan, 'a'])
```

```
Out [123]:
```

|   | 0         | 1         |
|---|-----------|-----------|
| 0 | a         | -1.02141  |
| 1 | 0.432396  | -0.32358  |
| 2 | 0.423825  | 0.79918   |
| 3 | 1.26261   | 0.751965  |
| 4 | NaN       | NaN       |
| 5 | NaN       | NaN       |
| 6 | -0.498174 | -1.0608   |
| 7 | 0.591667  | -0.183257 |
| 8 | 1.01985   | -1.48247  |
| 9 | NaN       | NaN       |

```
In [124]: df[1].dtype
```

```
dtype('float64')
```

You can also operate on the DataFrame in place:

```
In [125]: df.replace(1.5, np.nan, inplace=True)
```

**Warning:** When replacing multiple bool or datetime64 objects, the first argument to replace (to\_replace) must match the type of the value being replaced. For example,

```
>>> s = pd.Series([True, False, True])
>>> s.replace({'a string': 'new value', True: False}) # raises
TypeError: Cannot compare types 'ndarray(dtype=bool)' and 'str'
```

will raise a TypeError because one of the dict keys is not of the correct type for replacement.

However, when replacing a *single* object such as,

```
In [126]: s = pd.Series([True, False, True])

In [127]: s.replace('a string', 'another string')
Out[127]:
0 True
1 False
2 True
dtype: bool
```

the original `NDFrame` object will be returned untouched. We’re working on unifying this API, but for backwards compatibility reasons we cannot break the latter behavior. See [GH6354](#) for more details.

### 15.10.1 Missing data casting rules and indexing

While pandas supports storing arrays of integer and boolean type, these types are not capable of storing missing data. Until we can switch to using a native NA type in NumPy, we’ve established some “casting rules”. When a reindexing operation introduces missing data, the Series will be cast according to the rules introduced in the table below.

| data type | Cast to |
|-----------|---------|
| integer   | float   |
| boolean   | object  |
| float     | no cast |
| object    | no cast |

For example:

```
In [128]: s = pd.Series(np.random.randn(5), index=[0, 2, 4, 6, 7])

In [129]: s > 0
Out[129]:
0 True
2 True
4 True
6 True
7 True
dtype: bool

In [130]: (s > 0).dtype
Out[130]: dtype('bool')

In [131]: crit = (s > 0).reindex(list(range(8)))

In [132]: crit
Out[132]:
0 True
1 NaN
2 True
3 NaN
4 True
5 NaN
6 True
7 True
```

(continues on next page)

(continued from previous page)

dtype: object

In [133]: crit.dtype

```

////////////////////////////////////
->dtype('O')
```

Ordinarily NumPy will complain if you try to use an object array (even if it contains boolean values) instead of a boolean array to get or set values from an ndarray (e.g. selecting values based on some criteria). If a boolean vector contains NAs, an exception will be generated:

In [134]: reindexed = s.reindex(list(range(8))).fillna(0)

In [135]: reindexed[crit]

```

ValueError Traceback (most recent call last)
<ipython-input-135-0dac417a4890> in <module>
----> 1 reindexed[crit]
```

```

/pandas/pandas/core/series.py in __getitem__(self, key)
 906 key = list(key)
 907
--> 908 if com.is_bool_indexer(key):
 909 key = check_bool_indexer(self.index, key)
 910
```

```

/pandas/pandas/core/common.py in is_bool_indexer(key)
 122 if not lib.is_bool_array(key):
 123 if isna(key).any():
--> 124 raise ValueError(na_msg)
 125 return False
 126 return True
```

ValueError: cannot index with vector containing NA / NaN values

However, these can be filled in using `fillna()` and it will work fine:

In [136]: reindexed[crit.fillna(False)]

Out[136]:

```

0 0.126504
2 0.696198
4 0.697416
6 0.601516
7 0.003659
dtype: float64
```

In [137]: reindexed[crit.fillna(True)]

```

////////////////////////////////////Out [137]:
```

```

->
0 0.126504
1 0.000000
2 0.696198
3 0.000000
4 0.697416
5 0.000000
6 0.601516
7 0.003659
dtype: float64
```

Pandas provides a nullable integer dtype, but you must explicitly request it when creating the series or column. Notice that we use a capital “I” in the `dtype="Int64"`.

```
In [138]: s = pd.Series([0, 1, np.nan, 3, 4], dtype="Int64")
```

```
In [139]: s
```

```
Out[139]:
0 0
1 1
2 NaN
3 3
4 4
dtype: Int64
```

See *Nullable Integer Data Type* for more. `{{ header }}`

## GROUP BY: SPLIT-APPLY-COMBINE

By “group by” we are referring to a process involving one or more of the following steps:

- **Splitting** the data into groups based on some criteria.
- **Applying** a function to each group independently.
- **Combining** the results into a data structure.

Out of these, the split step is the most straightforward. In fact, in many situations we may wish to split the data set into groups and do something with those groups. In the apply step, we might wish to one of the following:

- **Aggregation:** compute a summary statistic (or statistics) for each group. Some examples:
  - Compute group sums or means.
  - Compute group sizes / counts.
- **Transformation:** perform some group-specific computations and return a like-indexed object. Some examples:
  - Standardize data (zscore) within a group.
  - Filling NAs within groups with a value derived from each group.
- **Filtration:** discard some groups, according to a group-wise computation that evaluates True or False. Some examples:
  - Discard data that belongs to groups with only a few members.
  - Filter out data based on the group sum or mean.
- Some combination of the above: GroupBy will examine the results of the apply step and try to return a sensibly combined result if it doesn’t fit into either of the above two categories.

Since the set of object instance methods on pandas data structures are generally rich and expressive, we often simply want to invoke, say, a DataFrame function on each group. The name GroupBy should be quite familiar to those who have used a SQL-based tool (or `itertools`), in which you can write code like:

```
SELECT Column1, Column2, mean(Column3), sum(Column4)
FROM SomeTable
GROUP BY Column1, Column2
```

We aim to make operations like this natural and easy to express using pandas. We’ll address each area of GroupBy functionality then provide some non-trivial examples / use cases.

See the *cookbook* for some advanced strategies.

## 16.1 Splitting an object into groups

pandas objects can be split on any of their axes. The abstract definition of grouping is to provide a mapping of labels to group names. To create a GroupBy object (more on what the GroupBy object is later), you may do the following:

```
In [1]: df = pd.DataFrame([('bird', 'Falconiformes', 389.0),
...: ('bird', 'Psittaciformes', 24.0),
...: ('mammal', 'Carnivora', 80.2),
...: ('mammal', 'Primates', np.nan),
...: ('mammal', 'Carnivora', 58)],
...: index=['falcon', 'parrot', 'lion', 'monkey', 'leopard'],
...: columns=('class', 'order', 'max_speed'))
...:
```

```
In [2]: df
Out[2]:
```

|         | class  | order          | max_speed |
|---------|--------|----------------|-----------|
| falcon  | bird   | Falconiformes  | 389.0     |
| parrot  | bird   | Psittaciformes | 24.0      |
| lion    | mammal | Carnivora      | 80.2      |
| monkey  | mammal | Primates       | NaN       |
| leopard | mammal | Carnivora      | 58.0      |

```
default is axis=0
In [3]: grouped = df.groupby('class')

In [4]: grouped = df.groupby('order', axis='columns')

In [5]: grouped = df.groupby(['class', 'order'])
```

The mapping can be specified many different ways:

- A Python function, to be called on each of the axis labels.
- A list or NumPy array of the same length as the selected axis.
- A dict or Series, providing a label → group name mapping.
- For DataFrame objects, a string indicating a column to be used to group. Of course `df.groupby('A')` is just syntactic sugar for `df.groupby(df['A'])`, but it makes life simpler.
- For DataFrame objects, a string indicating an index level to be used to group.
- A list of any of the above things.

Collectively we refer to the grouping objects as the **keys**. For example, consider the following DataFrame:

**Note:** A string passed to `groupby` may refer to either a column or an index level. If a string matches both a column name and an index level name, a `ValueError` will be raised.

```
In [6]: df = pd.DataFrame({'A': ['foo', 'bar', 'foo', 'bar',
...: 'foo', 'bar', 'foo', 'foo'],
...: 'B': ['one', 'one', 'two', 'three',
...: 'two', 'two', 'one', 'three'],
...: 'C': np.random.randn(8),
...: 'D': np.random.randn(8)})
...:
```

(continues on next page)

(continued from previous page)

```
In [7]: df
Out[7]:
```

|   | A   | B     | C         | D         |
|---|-----|-------|-----------|-----------|
| 0 | foo | one   | 0.309727  | 1.154671  |
| 1 | bar | one   | 0.679393  | -1.013749 |
| 2 | foo | two   | -0.079173 | 2.056747  |
| 3 | bar | three | -0.588213 | -1.164318 |
| 4 | foo | two   | -1.547004 | -0.032813 |
| 5 | bar | two   | -0.262632 | -1.132973 |
| 6 | foo | one   | -0.217040 | -2.325318 |
| 7 | foo | three | -1.617562 | -1.366944 |

On a DataFrame, we obtain a GroupBy object by calling `groupby()`. We could naturally group by either the A or B columns, or both:

```
In [8]: grouped = df.groupby('A')
In [9]: grouped = df.groupby(['A', 'B'])
```

New in version 0.24.

If we also have a MultiIndex on columns A and B, we can group by all but the specified columns

```
In [10]: df2 = df.set_index(['A', 'B'])
In [11]: grouped = df2.groupby(level=df2.index.names.difference(['B']))
In [12]: grouped.sum()
Out[12]:
```

|     | C         | D         |
|-----|-----------|-----------|
| A   |           |           |
| bar | -0.171452 | -3.311039 |
| foo | -3.151052 | -0.513657 |

These will split the DataFrame on its index (rows). We could also split by the columns:

```
In [13]: def get_letter_type(letter):
.....: if letter.lower() in 'aeiou':
.....: return 'vowel'
.....: else:
.....: return 'consonant'
.....:
In [14]: grouped = df.groupby(get_letter_type, axis=1)
```

pandas *Index* objects support duplicate values. If a non-unique index is used as the group key in a groupby operation, all values for the same index value will be considered to be in one group and thus the output of aggregation functions will only contain unique index values:

```
In [15]: lst = [1, 2, 3, 1, 2, 3]
In [16]: s = pd.Series([1, 2, 3, 10, 20, 30], lst)
In [17]: grouped = s.groupby(level=0)
In [18]: grouped.first()
Out[18]:
```

(continues on next page)

(continued from previous page)

```
1 1
2 2
3 3
dtype: int64

In [19]: grouped.last()
Out[19]:
1 10
2 20
3 30
dtype: int64

In [20]: grouped.sum()
Out[20]:
1 11
2 22
3 33
dtype: int64
```

Note that **no splitting occurs** until it's needed. Creating the `GroupBy` object only verifies that you've passed a valid mapping.

**Note:** Many kinds of complicated data manipulations can be expressed in terms of GroupBy operations (though can't be guaranteed to be the most efficient). You can get quite creative with the label mapping functions.

### 16.1.1 GroupBy sorting

By default the group keys are sorted during the `groupby` operation. You may however pass `sort=False` for potential speedups:

```
In [21]: df2 = pd.DataFrame({'X': ['B', 'B', 'A', 'A'], 'Y': [1, 2, 3, 4]})

In [22]: df2.groupby(['X']).sum()
Out[22]:
 Y
X
A 7
B 3

In [23]: df2.groupby(['X'], sort=False).sum()
Out[23]:
 Y
X
B 3
A 7
```

Note that `groupby` will preserve the order in which *observations* are sorted *within* each group. For example, the groups created by `groupby()` below are in the order they appeared in the original `DataFrame`:

```
In [24]: df3 = pd.DataFrame({'X': ['A', 'B', 'A', 'B'], 'Y': [1, 4, 3, 2]})

In [25]: df3.groupby(['X']).get_group('A')
```

(continues on next page)

(continued from previous page)

```

Out [25]:
 X Y
0 A 1
2 A 3

In [26]: df3.groupby(['X']).get_group('B')
Out [26]:
 X Y
1 B 4
3 B 2

```

## 16.1.2 GroupBy object attributes

The `groups` attribute is a dict whose keys are the computed unique groups and corresponding values being the axis labels belonging to each group. In the above example we have:

```

In [27]: df.groupby('A').groups
Out [27]:
{'bar': Int64Index([1, 3, 5], dtype='int64'),
 'foo': Int64Index([0, 2, 4, 6, 7], dtype='int64')}

In [28]: df.groupby(get_letter_type, axis=1).groups
Out [28]:
{'consonant': Index(['B', 'C', 'D'], dtype='object'),
 'vowel': Index(['A'], dtype='object')}

```

Calling the standard Python `len` function on the `GroupBy` object just returns the length of the `groups` dict, so it is largely just a convenience:

```

In [29]: grouped = df.groupby(['A', 'B'])

In [30]: grouped.groups
Out [30]:
{('bar', 'one'): Int64Index([1], dtype='int64'),
 ('bar', 'three'): Int64Index([3], dtype='int64'),
 ('bar', 'two'): Int64Index([5], dtype='int64'),
 ('foo', 'one'): Int64Index([0, 6], dtype='int64'),
 ('foo', 'three'): Int64Index([7], dtype='int64'),
 ('foo', 'two'): Int64Index([2, 4], dtype='int64')}

In [31]: len(grouped)
Out [31]: 6

```

`GroupBy` will tab complete column names (and other attributes):

```

In [32]: df
Out [32]:
 height weight gender
2000-01-01 53.800784 170.315467 male
2000-01-02 46.106283 185.215838 male
2000-01-03 39.051035 166.673532 male
2000-01-04 55.257272 162.359058 male
2000-01-05 68.250588 155.274718 female

```

(continues on next page)

(continued from previous page)

```

### 16.1.3 GroupBy with MultiIndex

With *hierarchically-indexed data*, it's quite natural to group by one of the levels of the hierarchy.

Let's create a Series with a two-level MultiIndex.

```

In [35]: arrays = [['bar', 'bar', 'baz', 'baz', 'foo', 'foo', 'qux', 'qux'],
.....: ['one', 'two', 'one', 'two', 'one', 'two', 'one', 'two']]
.....:

In [36]: index = pd.MultiIndex.from_arrays(arrays, names=['first', 'second'])

In [37]: s = pd.Series(np.random.randn(8), index=index)

In [38]: s
Out[38]:
first second
bar one 0.038465
 two -1.804693
baz one -0.071490
 two 0.092567
foo one 0.221205
 two 2.196410
qux one 1.888169
 two 0.208277
dtype: float64

```

We can then group by one of the levels in `s`.

```

In [39]: grouped = s.groupby(level=0)

In [40]: grouped.sum()
Out[40]:
first
bar -1.766227
baz 0.021077

```

(continues on next page)

```
foo 2.417615
qux 2.096446
dtype: float64
```

```
In [41]: s.groupby(level='second').sum()
Out[41]:
second
one 2.076349
two 0.692561
dtype: float64
```

```
In [42]: s.sum(level='second')
Out[42]:
second
one 2.076349
two 0.692561
dtype: float64
```

```
In [43]: s
Out[43]:
```

| first | second | third |           |
|-------|--------|-------|-----------|
| bar   | doo    | one   | -2.944966 |
|       |        | two   | -1.039147 |
| baz   | bee    | one   | 0.425584  |
|       |        | two   | -0.610963 |
| foo   | bop    | one   | 1.094359  |
|       |        | two   | -0.681384 |
| qux   | bop    | one   | 1.288235  |
|       |        | two   | -0.867184 |

```
dtype: float64
```

```
In [44]: s.groupby(level=['first', 'second']).sum()
```

```
\\//
```

```
↪
```

| first | second |           |
|-------|--------|-----------|
| bar   | doo    | -3.984113 |
| baz   | bee    | -0.185378 |
| foo   | bop    | 0.412975  |
| qux   | bop    | 0.421051  |

```
dtype: float64
```

Index level names may be supplied as keys.

---

```
In [45]: s.groupby(['first', 'second']).sum()
Out[45]:
```

| first | second |           |
|-------|--------|-----------|
| bar   | doo    | -3.984113 |
| baz   | bee    | -0.185378 |

16.1. Splitting an object into groups 477

(continued from previous page)

```
foo bop 0.412975
qux bop 0.421051
dtype: float64
```

More on the `sum` function and aggregation later.

### 16.1.4 Grouping DataFrame with Index Levels and Columns

A DataFrame may be grouped by a combination of columns and index levels by specifying the column names as strings and the index levels as `pd.Grouper` objects.

```
In [46]: arrays = [['bar', 'bar', 'baz', 'baz', 'foo', 'foo', 'qux', 'qux'],
.....: ['one', 'two', 'one', 'two', 'one', 'two', 'one', 'two']]
.....:

In [47]: index = pd.MultiIndex.from_arrays(arrays, names=['first', 'second'])

In [48]: df = pd.DataFrame({'A': [1, 1, 1, 1, 2, 2, 3, 3],
.....: 'B': np.arange(8)},
.....: index=index)
.....:

In [49]: df
Out[49]:
```

|       |        | A | B |
|-------|--------|---|---|
| first | second |   |   |
| bar   | one    | 1 | 0 |
|       | two    | 1 | 1 |
| baz   | one    | 1 | 2 |
|       | two    | 1 | 3 |
| foo   | one    | 2 | 4 |
|       | two    | 2 | 5 |
| qux   | one    | 3 | 6 |
|       | two    | 3 | 7 |

The following example groups `df` by the second index level and the A column.

```
In [50]: df.groupby([pd.Grouper(level=1), 'A']).sum()
Out[50]:
```

|        |   | B |
|--------|---|---|
| second | A |   |
| one    | 1 | 2 |
|        | 2 | 4 |
|        | 3 | 6 |
| two    | 1 | 4 |
|        | 2 | 5 |
|        | 3 | 7 |

Index levels may also be specified by name.

```
In [51]: df.groupby([pd.Grouper(level='second'), 'A']).sum()
Out[51]:
```

|        |   | B |
|--------|---|---|
| second | A |   |
| one    | 1 | 2 |

(continues on next page)

(continued from previous page)

|     |   |   |
|-----|---|---|
|     | 2 | 4 |
|     | 3 | 6 |
| two | 1 | 4 |
|     | 2 | 5 |
|     | 3 | 7 |

New in version 0.20.

Index level names may be specified as keys directly to `groupby`.

```
In [52]: df.groupby(['second', 'A']).sum()
Out[52]:
```

|        |   | B |
|--------|---|---|
| second | A |   |
| one    | 1 | 2 |
|        | 2 | 4 |
|        | 3 | 6 |
| two    | 1 | 4 |
|        | 2 | 5 |
|        | 3 | 7 |

### 16.1.5 DataFrame column selection in GroupBy

Once you have created the `GroupBy` object from a `DataFrame`, you might want to do something different for each of the columns. Thus, using `[]` similar to getting a column from a `DataFrame`, you can do:

```
In [53]: grouped = df.groupby(['A'])
In [54]: grouped_C = grouped['C']
In [55]: grouped_D = grouped['D']
```

This is mainly syntactic sugar for the alternative and much more verbose:

```
In [56]: df['C'].groupby(df['A'])
Out[56]: <pandas.core.groupby.generic.SeriesGroupBy object at 0x7fd532e70fd0>
```

Additionally this method avoids recomputing the internal grouping information derived from the passed key.

## 16.2 Iterating through groups

With the `GroupBy` object in hand, iterating through the grouped data is very natural and functions similarly to `itertools.groupby()`:

```
In [57]: grouped = df.groupby('A')

In [58]: for name, group in grouped:
...: print(name)
...: print(group)
...:

bar
 A B C D
1 bar one -0.070623 2.022515
```

(continues on next page)

(continued from previous page)

```

3 bar three 1.237975 -0.072396
5 bar two 0.218653 0.894831
foo
 A B C D
0 foo one 0.569529 0.621574
2 foo two 2.673393 0.228612
4 foo two 0.285588 -0.282797
6 foo one 0.445458 1.022252
7 foo three -0.140933 0.333401

```

In the case of grouping by multiple keys, the group name will be a tuple:

```

In [59]: for name, group in df.groupby(['A', 'B']):
...: print(name)
...: print(group)
...:
('bar', 'one')
 A B C D
1 bar one -0.070623 2.022515
('bar', 'three')
 A B C D
3 bar three 1.237975 -0.072396
('bar', 'two')
 A B C D
5 bar two 0.218653 0.894831
('foo', 'one')
 A B C D
0 foo one 0.569529 0.621574
6 foo one 0.445458 1.022252
('foo', 'three')
 A B C D
7 foo three -0.140933 0.333401
('foo', 'two')
 A B C D
2 foo two 2.673393 0.228612
4 foo two 0.285588 -0.282797

```

See *Iterating through groups*.

## 16.3 Selecting a group

A single group can be selected using `get_group()`:

```

In [60]: grouped.get_group('bar')
Out[60]:
 A B C D
1 bar one -0.070623 2.022515
3 bar three 1.237975 -0.072396
5 bar two 0.218653 0.894831

```

Or for an object grouped on multiple columns:

```

In [61]: df.groupby(['A', 'B']).get_group(('bar', 'one'))
Out[61]:

```

(continues on next page)

|   | A   | B   | C         | D        |
|---|-----|-----|-----------|----------|
| 1 | bar | one | -0.070623 | 2.022515 |

```
In [62]: grouped = df.groupby('A')

In [63]: grouped.agg(np.sum)
Out[63]:
```

|     | C        | D        |
|-----|----------|----------|
| A   |          |          |
| bar | 1.386005 | 2.844951 |
| foo | 3.833036 | 1.923042 |

```
In [64]: grouped = df.groupby(['A', 'B'])

In [65]: grouped.agg(np.sum)
Out[65]:
```

|     |       | C         | D         |
|-----|-------|-----------|-----------|
| A   | B     |           |           |
| bar | one   | -0.070623 | 2.022515  |
|     | three | 1.237975  | -0.072396 |
|     | two   | 0.218653  | 0.894831  |
| foo | one   | 1.014987  | 1.643826  |
|     | three | -0.140933 | 0.333401  |
|     | two   | 2.958981  | -0.054185 |

```
In [66]: grouped = df.groupby(['A', 'B'], as_index=False)

In [67]: grouped.aggregate(np.sum)
Out[67]:
```

|   | A   | B     | C         | D         |
|---|-----|-------|-----------|-----------|
| 0 | bar | one   | -0.070623 | 2.022515  |
| 1 | bar | three | 1.237975  | -0.072396 |
| 2 | bar | two   | 0.218653  | 0.894831  |
| 3 | foo | one   | 1.014987  | 1.643826  |
| 4 | foo | three | -0.140933 | 0.333401  |
| 5 | foo | two   | 2.958981  | -0.054185 |

```
In [68]: df.groupby('A', as_index=False).sum()
//////////
↪
```

|   | A   | C        | D        |
|---|-----|----------|----------|
| 0 | bar | 1.386005 | 2.844951 |
| 1 | foo | 3.833036 | 1.923042 |

Note that you could use the `reset_index` DataFrame function to achieve the same result as the column names are stored in the resulting MultiIndex:

```
In [69]: df.groupby(['A', 'B']).sum().reset_index()
```

```
Out [69]:
```

|   | A   | B     | C         | D         |
|---|-----|-------|-----------|-----------|
| 0 | bar | one   | -0.070623 | 2.022515  |
| 1 | bar | three | 1.237975  | -0.072396 |
| 2 | bar | two   | 0.218653  | 0.894831  |
| 3 | foo | one   | 1.014987  | 1.643826  |
| 4 | foo | three | -0.140933 | 0.333401  |
| 5 | foo | two   | 2.958981  | -0.054185 |

Another simple aggregation example is to compute the size of each group. This is included in GroupBy as the `size` method. It returns a Series whose index are the group names and whose values are the sizes of each group.

```
In [70]: grouped.size()
```

```
Out [70]:
```

| A   | B     | size |
|-----|-------|------|
| bar | one   | 1    |
|     | three | 1    |
|     | two   | 1    |
| foo | one   | 2    |
|     | three | 1    |
|     | two   | 2    |

dtype: int64

```
In [71]: grouped.describe()
```

```
Out [71]:
```

|   | C     |           |          |           |           |           |           |           | D     |
|---|-------|-----------|----------|-----------|-----------|-----------|-----------|-----------|-------|

**Note:** Aggregation functions **will not** return the groups that you are aggregating over if they are named *columns*, when `as_index=True`, the default. The grouped columns will be the **indices** of the returned object.

Passing `as_index=False` **will** return the groups that you are aggregating over, if they are named *columns*.

Aggregating functions are the ones that reduce the dimension of the returned objects. Some common aggregating functions are tabulated below:

| Function                | Description                                |
|-------------------------|--------------------------------------------|
| <code>mean()</code>     | Compute mean of groups                     |
| <code>sum()</code>      | Compute sum of group values                |
| <code>size()</code>     | Compute group sizes                        |
| <code>count()</code>    | Compute count of group                     |
| <code>std()</code>      | Standard deviation of groups               |
| <code>var()</code>      | Compute variance of groups                 |
| <code>sem()</code>      | Standard error of the mean of groups       |
| <code>describe()</code> | Generates descriptive statistics           |
| <code>first()</code>    | Compute first of group values              |
| <code>last()</code>     | Compute last of group values               |
| <code>nth()</code>      | Take nth value, or a subset if n is a list |
| <code>min()</code>      | Compute min of group values                |
| <code>max()</code>      | Compute max of group values                |

The aggregating functions above will exclude NA values. Any function which reduces a `Series` to a scalar value is an aggregation function and will work, a trivial example is `df.groupby('A').agg(lambda ser: 1)`. Note that `nth()` can act as a reducer *or* a filter, see [here](#).

### 16.4.1 Applying multiple functions at once

With grouped `Series` you can also pass a list or dict of functions to do aggregation with, outputting a `DataFrame`:

```
In [72]: grouped = df.groupby('A')
In [73]: grouped['C'].agg([np.sum, np.mean, np.std])
Out[73]:
```

|     | sum      | mean     | std      |
|-----|----------|----------|----------|
| A   |          |          |          |
| bar | 1.386005 | 0.462002 | 0.687402 |
| foo | 3.833036 | 0.766607 | 1.099183 |

On a grouped `DataFrame`, you can pass a list of functions to apply to each column, which produces an aggregated result with a hierarchical index:

```
In [74]: grouped.agg([np.sum, np.mean, np.std])
Out[74]:
```

|     | C        |          |          | D        |          |          |
|-----|----------|----------|----------|----------|----------|----------|
|     | sum      | mean     | std      | sum      | mean     | std      |
| A   |          |          |          |          |          |          |
| bar | 1.386005 | 0.462002 | 0.687402 | 2.844951 | 0.948317 | 1.048479 |
| foo | 3.833036 | 0.766607 | 1.099183 | 1.923042 | 0.384608 | 0.483510 |

The resulting aggregations are named for the functions themselves. If you need to rename, then you can add in a chained operation for a `Series` like this:

```
In [75]: (grouped['C'].agg([np.sum, np.mean, np.std])
.....: .rename(columns={'sum': 'foo',
.....: 'mean': 'bar',
.....: 'std': 'baz'}))
Out[75]:
```

|     | foo      | bar      | baz      |
|-----|----------|----------|----------|
| A   |          |          |          |
| bar | 1.386005 | 0.462002 | 0.687402 |
| foo | 3.833036 | 0.766607 | 1.099183 |

(continues on next page)

(continued from previous page)

```
A
bar 1.386005 0.462002 0.687402
foo 3.833036 0.766607 1.099183
```

For a grouped DataFrame, you can rename in a similar manner:

```
In [76]: (grouped.agg([np.sum, np.mean, np.std])
.....: .rename(columns={'sum': 'foo',
.....: 'mean': 'bar',
.....: 'std': 'baz'}))
.....:
Out[76]:
```

|     | C        |          |          | D        |          |          |
|-----|----------|----------|----------|----------|----------|----------|
|     | foo      | bar      | baz      | foo      | bar      | baz      |
| A   |          |          |          |          |          |          |
| bar | 1.386005 | 0.462002 | 0.687402 | 2.844951 | 0.948317 | 1.048479 |
| foo | 3.833036 | 0.766607 | 1.099183 | 1.923042 | 0.384608 | 0.483510 |

## 16.4.2 Applying different functions to DataFrame columns

By passing a dict to `aggregate` you can apply a different aggregation to the columns of a DataFrame:

```
In [77]: grouped.agg({'C': np.sum,
.....: 'D': lambda x: np.std(x, ddof=1)})
.....:
Out[77]:
```

|     | C        | D        |
|-----|----------|----------|
| A   |          |          |
| bar | 1.386005 | 1.048479 |
| foo | 3.833036 | 0.483510 |

The function names can also be strings. In order for a string to be valid it must be either implemented on `GroupBy` or available via *dispatching*:

```
In [78]: grouped.agg({'C': 'sum', 'D': 'std'})
Out[78]:
```

|     | C        | D        |
|-----|----------|----------|
| A   |          |          |
| bar | 1.386005 | 1.048479 |
| foo | 3.833036 | 0.483510 |

**Note:** If you pass a dict to `aggregate`, the ordering of the output columns is non-deterministic. If you want to be sure the output columns will be in a specific order, you can use an `OrderedDict`. Compare the output of the following two commands:

```
In [79]: from collections import OrderedDict

In [80]: grouped.agg({'D': 'std', 'C': 'mean'})
Out[80]:
```

|     | D        | C        |
|-----|----------|----------|
| A   |          |          |
| bar | 1.048479 | 0.462002 |

(continues on next page)

(continued from previous page)

```
foo 0.483510 0.766607
```

```
In [81]: grouped.agg(OrderedDict([('D', 'std'), ('C', 'mean')]))
```

```

////////////////////////////////////
↪
 D C
A
bar 1.048479 0.462002
foo 0.483510 0.766607
```

### 16.4.3 Cython-optimized aggregation functions

Some common aggregations, currently only `sum`, `mean`, `std`, and `sem`, have optimized Cython implementations:

```
In [82]: df.groupby('A').sum()
```

```
Out [82]:
 C D
A
bar 1.386005 2.844951
foo 3.833036 1.923042
```

```
In [83]: df.groupby(['A', 'B']).mean()
```

```

////////////////////////////////////
↪
 C D
A B
bar one -0.070623 2.022515
 three 1.237975 -0.072396
 two 0.218653 0.894831
foo one 0.507494 0.821913
 three -0.140933 0.333401
 two 1.479491 -0.027093
```

Of course `sum` and `mean` are implemented on pandas objects, so the above code would work even without the special versions via dispatching (see below).

## 16.5 Transformation

The `transform` method returns an object that is indexed the same (same size) as the one being grouped. The transform function must:

- Return a result that is either the same size as the group chunk or broadcastable to the size of the group chunk (e.g., a scalar, `grouped.transform(lambda x: x.iloc[-1])`).
- Operate column-by-column on the group chunk. The transform is applied to the first group chunk using `chunk.apply`.
- Not perform in-place operations on the group chunk. Group chunks should be treated as immutable, and changes to a group chunk may produce unexpected results. For example, when using `fillna`, `inplace` must be `False` (`grouped.transform(lambda x: x.fillna(inplace=False))`).
- (Optionally) operates on the entire group chunk. If this is supported, a fast path is used starting from the *second* chunk.

For example, suppose we wished to standardize the data within each group:

```
In [84]: index = pd.date_range('10/1/1999', periods=1100)

In [85]: ts = pd.Series(np.random.normal(0.5, 2, 1100), index)

In [86]: ts = ts.rolling(window=100, min_periods=100).mean().dropna()

In [87]: ts.head()
Out[87]:
2000-01-08 0.349399
2000-01-09 0.339073
2000-01-10 0.372710
2000-01-11 0.382315
2000-01-12 0.375697
Freq: D, dtype: float64

In [88]: ts.tail()
↩
2002-09-30 0.214789
2002-10-01 0.219466
2002-10-02 0.274490
2002-10-03 0.310372
2002-10-04 0.308196
Freq: D, dtype: float64

In [89]: transformed = (ts.groupby(lambda x: x.year)
.....: .transform(lambda x: (x - x.mean()) / x.std()))
.....:
```

We would expect the result to now have mean 0 and standard deviation 1 within each group, which we can easily check:

```
Original Data
In [90]: grouped = ts.groupby(lambda x: x.year)

In [91]: grouped.mean()
Out[91]:
2000 0.436457
2001 0.360175
2002 0.543804
dtype: float64

In [92]: grouped.std()
Out[92]:
2000 0.104504
2001 0.104016
2002 0.179309
dtype: float64

Transformed Data
In [93]: grouped_trans = transformed.groupby(lambda x: x.year)

In [94]: grouped_trans.mean()
Out[94]:
2000 -1.212277e-15
2001 6.995926e-16
2002 1.117437e-15
```

(continues on next page)

(continued from previous page)

dtype: float64

In [95]: grouped\_trans.std()

Out [95]:

```

2000 1.0
2001 1.0
2002 1.0
dtype: float64

```

We can also visually compare the original and transformed data sets.

In [96]: compare = pd.DataFrame({'Original': ts, 'Transformed': transformed})

In [97]: compare.plot()

Out [97]: &lt;matplotlib.axes.\_subplots.AxesSubplot at 0x7fd541f48e80&gt;

Transformation functions that have lower dimension outputs are broadcast to match the shape of the input array.

In [98]: ts.groupby(lambda x: x.year).transform(lambda x: x.max() - x.min())

Out [98]:

```

2000-01-08 0.458485
2000-01-09 0.458485

```

## 16.5.1 New syntax to window and resample operations

New in version 0.18.1.

Working with the resample, expanding or rolling operations on the groupby level used to require the application of helper functions. However, now it is possible to use `resample()`, `expanding()` and `rolling()` as methods on groupbys.

The example below will apply the `rolling()` method on the samples of the column B based on the groups of column A.

```
In [115]: df_re = pd.DataFrame({'A': [1] * 10 + [5] * 10,
.....: 'B': np.arange(20)})
.....:
```

```
In [116]: df_re
```

```
Out[116]:
```

|    | A | B  |
|----|---|----|
| 0  | 1 | 0  |
| 1  | 1 | 1  |
| 2  | 1 | 2  |
| 3  | 1 | 3  |
| 4  | 1 | 4  |
| 5  | 1 | 5  |
| 6  | 1 | 6  |
| 7  | 1 | 7  |
| 8  | 1 | 8  |
| 9  | 1 | 9  |
| 10 | 5 | 10 |
| 11 | 5 | 11 |
| 12 | 5 | 12 |
| 13 | 5 | 13 |
| 14 | 5 | 14 |
| 15 | 5 | 15 |
| 16 | 5 | 16 |
| 17 | 5 | 17 |
| 18 | 5 | 18 |
| 19 | 5 | 19 |

```
In [117]: df_re.groupby('A').rolling(4).B.mean()
```

```
////////////////////////////////////
```

```
↪
```

|   | A  |      |
|---|----|------|
| 1 | 0  | NaN  |
|   | 1  | NaN  |
|   | 2  | NaN  |
|   | 3  | 1.5  |
|   | 4  | 2.5  |
|   | 5  | 3.5  |
|   | 6  | 4.5  |
|   | 7  | 5.5  |
|   | 8  | 6.5  |
|   | 9  | 7.5  |
| 5 | 10 | NaN  |
|   | 11 | NaN  |

## 16.6 Filtration

The `filter` method returns a subset of the original object. Suppose we want to take only elements that belong to groups with a group sum greater than 2.

```
In [122]: sf = pd.Series([1, 1, 2, 3, 3, 3])
In [123]: sf.groupby(sf).filter(lambda x: x.sum() > 2)
Out[123]:
3 3
4 3
5 3
dtype: int64
```

The argument of `filter` must be a function that, applied to the group as a whole, returns `True` or `False`.

Another useful operation is filtering out elements that belong to groups with only a couple members.

```
In [124]: dff = pd.DataFrame({'A': np.arange(8), 'B': list('aabbbbcc')})
In [125]: dff.groupby('B').filter(lambda x: len(x) > 2)
Out[125]:
 A B
2 2 b
3 3 b
4 4 b
5 5 b
```

Alternatively, instead of dropping the offending groups, we can return a like-indexed objects where the groups that do not pass the filter are filled with NaNs.

```
In [126]: dff.groupby('B').filter(lambda x: len(x) > 2, dropna=False)
Out[126]:
 A B
0 NaN NaN
```

(continues on next page)

(continued from previous page)

```

1 NaN NaN
2 2.0 b
3 3.0 b
4 4.0 b
5 5.0 b
6 NaN NaN
7 NaN NaN

```

For DataFrames with multiple columns, filters should explicitly specify a column as the filter criterion.

```

In [127]: dff['C'] = np.arange(8)

In [128]: dff.groupby('B').filter(lambda x: len(x['C']) > 2)
Out[128]:
 A B C
2 2 b 2
3 3 b 3
4 4 b 4
5 5 b 5

```

**Note:** Some functions when applied to a groupby object will act as a **filter** on the input, returning a reduced shape of the original (and potentially eliminating groups), but with the index unchanged. Passing `as_index=False` will not affect these transformation methods.

For example: `head`, `tail`.

```

In [129]: dff.groupby('B').head(2)
Out[129]:
 A B C
0 0 a 0
1 1 a 1
2 2 b 2
3 3 b 3
6 6 c 6
7 7 c 7

```

## 16.7 Dispatching to instance methods

When doing an aggregation or transformation, you might just want to call an instance method on each data group. This is pretty easy to do by passing lambda functions:

```

In [130]: grouped = df.groupby('A')

In [131]: grouped.agg(lambda x: x.std())
Out[131]:
 C D
A
bar 0.687402 1.048479
foo 1.099183 0.483510

```

But, it's rather verbose and can be untidy if you need to pass additional arguments. Using a bit of metaprogramming cleverness, `GroupBy` now has the ability to “dispatch” method calls to the groups:

```
In [132]: grouped.std()
```

```
Out[132]:
```

|     | C        | D        |
|-----|----------|----------|
| A   |          |          |
| bar | 0.687402 | 1.048479 |
| foo | 1.099183 | 0.483510 |

What is actually happening here is that a function wrapper is being generated. When invoked, it takes any passed arguments and invokes the function with any arguments on each group (in the above example, the `std` function). The results are then combined together much in the style of `agg` and `transform` (it actually uses `apply` to infer the gluing, documented next). This enables some operations to be carried out rather succinctly:

```
In [133]: tsdf = pd.DataFrame(np.random.randn(1000, 3),
.....: index=pd.date_range('1/1/2000', periods=1000),
.....: columns=['A', 'B', 'C'])
.....:
```

```
In [134]: tsdf.iloc[:,2] = np.nan
```

```
In [135]: grouped = tsdf.groupby(lambda x: x.year)
```

```
In [136]: grouped.fillna(method='pad')
```

```
Out[136]:
```

|            | A         | B         | C         |
|------------|-----------|-----------|-----------|
| 2000-01-01 | NaN       | NaN       | NaN       |

```

```
[1000 rows x 3 columns]
```

In this example, we chopped the collection of time series into yearly chunks then independently called *fillna* on the groups.

The `nlargest` and `nsmallest` methods work on Series style groupbys:

```
In [137]: s = pd.Series([9, 8, 7, 5, 19, 1, 4.2, 3.3])
```

```
In [138]: g = pd.Series(list('abababab'))
```

```
In [139]: gb = s.groupby(g)
```

```
In [140]: gb.nlargest(3)
```

```
Out[140]:
a 4 19.0
 0 9.0
 2 7.0
b 1 8.0
 3 5.0
 7 3.3
dtype: float64
```

```
In [141]: gb.nsmallest(3)
```

```

////////////////////////////////////
↪
a 6 4.2
 2 7.0

```

(continues on next page)

(continued from previous page)

```

0 9.0
b 5 1.0
 7 3.3
 3 5.0
dtype: float64

```

## 16.8 Flexible apply

Some operations on the grouped data might not fit into either the aggregate or transform categories. Or, you may simply want GroupBy to infer how to combine the results. For these, use the `apply` function, which can be substituted for both `aggregate` and `transform` in many standard use cases. However, `apply` can handle some exceptional use cases, for example:

```

In [142]: df
Out[142]:
 A B C D
0 foo one 0.569529 0.621574
1 bar one -0.070623 2.022515
2 foo two 2.673393 0.228612
3 bar three 1.237975 -0.072396
4 foo two 0.285588 -0.282797
5 bar two 0.218653 0.894831
6 foo one 0.445458 1.022252
7 foo three -0.140933 0.333401

In [143]: grouped = df.groupby('A')

could also just call .describe()
In [144]: grouped['C'].apply(lambda x: x.describe())
Out[144]:
A
bar count 3.000000
 mean 0.462002
 std 0.687402
 min -0.070623
 25% 0.074015
 50% 0.218653
 75% 0.728314
 max 1.237975
foo count 5.000000
 mean 0.766607
 std 1.099183
 min -0.140933
 25% 0.285588
 50% 0.445458
 75% 0.569529
 max 2.673393
Name: C, dtype: float64

```

The dimension of the returned result can also change:

```

In [145]: grouped = df.groupby('A')['C']

In [146]: def f(group):

```

(continues on next page)

(continued from previous page)

```

.....: return pd.DataFrame({'original': group,
.....: 'demeaned': group - group.mean() })
.....:
In [147]: grouped.apply(f)
Out[147]:
 original demeaned
0 0.569529 -0.197078
1 -0.070623 -0.532625
2 2.673393 1.906786
3 1.237975 0.775973
4 0.285588 -0.481019
5 0.218653 -0.243349
6 0.445458 -0.321149
7 -0.140933 -0.907540

```

`apply` on a `Series` can operate on a returned value from the applied function, that is itself a series, and possibly upcast the result to a `DataFrame`:

```

In [148]: def f(x):
.....: return pd.Series([x, x ** 2], index=['x', 'x^2'])
.....:

In [149]: s = pd.Series(np.random.rand(5))

In [150]: s
Out[150]:
0 0.154124
1 0.643928
2 0.399339
3 0.801210
4 0.691231
dtype: float64

In [151]: s.apply(f)
Out[151]:
 x x^2
0 0.154124 0.023754
1 0.643928 0.414644
2 0.399339 0.159471
3 0.801210 0.641937
4 0.691231 0.477800

```

**Note:** `apply` can act as a reducer, transformer, *or* filter function, depending on exactly what is passed to it. So depending on the path taken, and exactly what you are grouping. Thus the grouped columns(s) may be included in the output as well as set the indices.

**Warning:** In the current implementation `apply` calls `func` twice on the first group to decide whether it can take a fast or slow code path. This can lead to unexpected behavior if `func` has side-effects, as they will take effect twice for the first group.

```

In [152]: d = pd.DataFrame({"a": ["x", "y"], "b": [1, 2]})

In [153]: def identity(df):
.....: print(df)
.....: return df
.....:

In [154]: d.groupby("a").apply(identity)
a b
0 x 1
a b
0 x 1
a b
1 y 2
Out[154]:
a b
0 x 1
1 y 2

```

## 16.9 Other useful features

### 16.9.1 Automatic exclusion of “nuisance” columns

Again consider the example DataFrame we’ve been looking at:

```

In [155]: df
Out[155]:
 A B C D
0 foo one 0.569529 0.621574
1 bar one -0.070623 2.022515
2 foo two 2.673393 0.228612
3 bar three 1.237975 -0.072396
4 foo two 0.285588 -0.282797
5 bar two 0.218653 0.894831
6 foo one 0.445458 1.022252
7 foo three -0.140933 0.333401

```

Suppose we wish to compute the standard deviation grouped by the A column. There is a slight problem, namely that we don’t care about the data in column B. We refer to this as a “nuisance” column. If the passed aggregation function can’t be applied to some columns, the troublesome columns will be (silently) dropped. Thus, this does not pose any problems:

```

In [156]: df.groupby('A').std()
Out[156]:
 C D
A
bar 0.687402 1.048479
foo 1.099183 0.483510

```

Note that `df.groupby('A').colname.std()` is more efficient than `df.groupby('A').std().colname`, so if the result of an aggregation function is only interesting over one column (here `colname`), it may be filtered *before* applying the aggregation function.

**Note:** Any object column, also if it contains numerical values such as `Decimal` objects, is considered as a “nuisance” columns. They are excluded from aggregate functions automatically in `groupby`.

If you do wish to include decimal or object columns in an aggregation with other non-nuisance data types, you must do so explicitly.

```
In [157]: from decimal import Decimal

In [158]: df_dec = pd.DataFrame(
.....: {'id': [1, 2, 1, 2],
.....: 'int_column': [1, 2, 3, 4],
.....: 'dec_column': [Decimal('0.50'), Decimal('0.15'),
.....: Decimal('0.25'), Decimal('0.40')]}
.....:)
.....:

Decimal columns can be sum'd explicitly by themselves...
In [159]: df_dec.groupby(['id'])['dec_column'].sum()
Out[159]:
dec_column
id
1 0.75
2 0.55

...but cannot be combined with standard data types or they will be excluded
In [160]: df_dec.groupby(['id'])['int_column', 'dec_column'].sum()
Out[160]:
int_column
id
1 4
2 6

Use .agg function to aggregate over standard and "nuisance" data types
at the same time
In [161]: df_dec.groupby(['id']).agg({'int_column': 'sum', 'dec_column': 'sum'})
Out[161]:
int_column dec_column
id
1 4 0.75
2 6 0.55
```

## 16.9.2 Handling of (un)observed Categorical values

When using a `Categorical` grouper (as a single grouper, or as part of multiple groupers), the `observed` keyword controls whether to return a cartesian product of all possible groupers values (`observed=False`) or only those that are observed groupers (`observed=True`).

Show all values:

```
In [162]: pd.Series([1, 1, 1]).groupby(pd.Categorical(['a', 'a', 'a'],
.....: categories=['a', 'b']),
.....: observed=False).count()
```

(continues on next page)

(continued from previous page)

```
.....:
Out [162]:
a 3
b 0
dtype: int64
```

Show only the observed values:

```
In [163]: pd.Series([1, 1, 1]).groupby(pd.Categorical(['a', 'a', 'a'],
.....: categories=['a', 'b']),
.....: observed=True).count()
.....:
Out [163]:
a 3
dtype: int64
```

The returned dtype of the grouped will *always* include *all* of the categories that were grouped.

```
In [164]: s = pd.Series([1, 1, 1]).groupby(pd.Categorical(['a', 'a', 'a'],
.....: categories=['a', 'b']),
.....: observed=False).count()
.....:

In [165]: s.index.dtype
Out [165]: CategoricalDtype(categories=['a', 'b'], ordered=False)
```

### 16.9.3 NA and NaT group handling

If there are any NaN or NaT values in the grouping key, these will be automatically excluded. In other words, there will never be an “NA group” or “NaT group”. This was not the case in older versions of pandas, but users were generally discarding the NA group anyway (and supporting it was an implementation headache).

### 16.9.4 Grouping with ordered factors

Categorical variables represented as instance of pandas’s `Categorical` class can be used as group keys. If so, the order of the levels will be preserved:

```
In [166]: data = pd.Series(np.random.randn(100))

In [167]: factor = pd.qcut(data, [0, .25, .5, .75, 1.])

In [168]: data.groupby(factor).mean()
Out [168]:
(-2.465, -0.727] -1.276356
(-0.727, -0.175] -0.474861
(-0.175, 0.492] 0.178580
(0.492, 2.724] 1.329015
dtype: float64
```

### 16.9.5 Grouping with a Grouper specification

You may need to specify a bit more data to properly group. You can use the `pd.Grouper` to provide this local control.

```
In [169]: import datetime

In [170]: df = pd.DataFrame({'Branch': 'A A A A A A B'.split(),
.....: 'Buyer': 'Carl Mark Carl Carl Joe Joe Joe Carl'.split(),
.....: 'Quantity': [1, 3, 5, 1, 8, 1, 9, 3],
.....: 'Date': [
.....: datetime.datetime(2013, 1, 1, 13, 0),
.....: datetime.datetime(2013, 1, 1, 13, 5),
.....: datetime.datetime(2013, 10, 1, 20, 0),
.....: datetime.datetime(2013, 10, 2, 10, 0),
.....: datetime.datetime(2013, 10, 1, 20, 0),
.....: datetime.datetime(2013, 10, 2, 10, 0),
.....: datetime.datetime(2013, 12, 2, 12, 0),
.....: datetime.datetime(2013, 12, 2, 14, 0)]
.....: })

In [171]: df
Out[171]:
```

|   | Branch | Buyer | Quantity | Date                |
|---|--------|-------|----------|---------------------|
| 0 | A      | Carl  | 1        | 2013-01-01 13:00:00 |
| 1 | A      | Mark  | 3        | 2013-01-01 13:05:00 |
| 2 | A      | Carl  | 5        | 2013-10-01 20:00:00 |
| 3 | A      | Carl  | 1        | 2013-10-02 10:00:00 |
| 4 | A      | Joe   | 8        | 2013-10-01 20:00:00 |
| 5 | A      | Joe   | 1        | 2013-10-02 10:00:00 |
| 6 | A      | Joe   | 9        | 2013-12-02 12:00:00 |
| 7 | B      | Carl  | 3        | 2013-12-02 14:00:00 |

Groupby a specific column with the desired frequency. This is like resampling.

```
In [172]: df.groupby([pd.Grouper(freq='1M', key='Date'), 'Buyer']).sum()
Out[172]:
```

| Date       | Buyer | Quantity |
|------------|-------|----------|
| 2013-01-31 | Carl  | 1        |
|            | Mark  | 3        |
| 2013-10-31 | Carl  | 6        |
|            | Joe   | 9        |
| 2013-12-31 | Carl  | 3        |
|            | Joe   | 9        |

You have an ambiguous specification in that you have a named index and a column that could be potential groupers.

```
In [173]: df = df.set_index('Date')

In [174]: df['Date'] = df.index + pd.offsets.MonthEnd(2)

In [175]: df.groupby([pd.Grouper(freq='6M', key='Date'), 'Buyer']).sum()
Out[175]:
```

| Date       | Buyer | Quantity |
|------------|-------|----------|
| 2013-02-28 | Carl  | 1        |
|            | Mark  | 3        |
| 2014-02-28 | Carl  | 9        |
|            | Joe   | 18       |

(continues on next page)

(continued from previous page)

```
In [176]: df.groupby([pd.Grouper(freq='6M', level='Date'), 'Buyer']).sum()
```

| Quantity   |       |    |
|------------|-------|----|
| Date       | Buyer |    |
| 2013-01-31 | Carl  | 1  |
|            | Mark  | 3  |
| 2014-01-31 | Carl  | 9  |
|            | Joe   | 18 |

### 16.9.6 Taking the first rows of each group

Just like for a DataFrame or Series you can call head and tail on a groupby:

```
In [177]: df = pd.DataFrame([[1, 2], [1, 4], [5, 6]], columns=['A', 'B'])
```

```
In [178]: df
```

Out[178]:

|   | A | B |
|---|---|---|
| 0 | 1 | 2 |
| 1 | 1 | 4 |
| 2 | 5 | 6 |

```
In [179]: g = df.groupby('A')
```

```
In [180]: g.head(1)
```

Out[180]:

|   |   |   |
|---|---|---|
|   | A | B |
| 0 | 1 | 2 |
| 2 | 5 | 6 |

```
In [181]: g.tail(1)
```

```
\\Out[181]:
```

|   | A | B |
|---|---|---|
| 1 | 1 | 4 |
| 2 | 5 | 6 |

This shows the first or last n rows from each group.

### 16.9.7 Taking the nth row of each group

To select from a DataFrame or Series the `n`th item, use `nth()`. This is a reduction method, and will return a single row (or no row) per group if you pass an int for `n`:

```
In [182]: df = pd.DataFrame([[1, np.nan], [1, 4], [5, 6]], columns=['A', 'B'])
```

```
In [183]: g = df.groupby('A')
```

```
In [184]: g.nth(0)
```

Out[184]:

(continues on next page)

(continued from previous page)

```

5 6.0

In [185]: g.nth(-1)
\\Out[185]:
 B
A
1 4.0
5 6.0

In [186]: g.nth(1)
\\Out[186]:
↪ B
A
1 4.0

```

If you want to select the *nth* not-null item, use the `dropna` kwarg. For a `DataFrame` this should be either `'any'` or `'all'` just like you would pass to `dropna`:

```

nth(0) is the same as g.first()
In [187]: g.nth(0, dropna='any')
Out[187]:
 B
A
1 4.0
5 6.0

In [188]: g.first()
\\Out[188]:
 B
A
1 4.0
5 6.0

nth(-1) is the same as g.last()
In [189]: g.nth(-1, dropna='any') # NaNs denote group exhausted when using dropna
\\Out[189]:
↪ B
A
1 4.0
5 6.0

In [190]: g.last()
\\Out[190]:
↪ B
A
1 4.0
5 6.0

In [191]: g.B.nth(0, dropna='all')
\\Out[191]:
↪ B
A
1 4.0

```

(continues on next page)

(continued from previous page)

```
5 6.0
Name: B, dtype: float64
```

As with other methods, passing `as_index=False`, will achieve a filtration, which returns the grouped row.

```
In [192]: df = pd.DataFrame([[1, np.nan], [1, 4], [5, 6]], columns=['A', 'B'])

In [193]: g = df.groupby('A', as_index=False)

In [194]: g.nth(0)
Out[194]:
```

|   | A | B   |
|---|---|-----|
| 0 | 1 | NaN |
| 2 | 5 | 6.0 |

```

In [195]: g.nth(-1)
\\Out[195]:
```

|   | A | B   |
|---|---|-----|
| 1 | 1 | 4.0 |
| 2 | 5 | 6.0 |

You can also select multiple rows from each group by specifying multiple `nth` values as a list of ints.

```
In [196]: business_dates = pd.date_range(start='4/1/2014', end='6/30/2014', freq='B')

In [197]: df = pd.DataFrame(1, index=business_dates, columns=['a', 'b'])

get the first, 4th, and last date index for each month
In [198]: df.groupby([df.index.year, df.index.month]).nth([0, 3, -1])
Out[198]:
```

|      |   | a | b |
|------|---|---|---|
| 2014 | 4 | 1 | 1 |
|      | 4 | 1 | 1 |
|      | 4 | 1 | 1 |
|      | 5 | 1 | 1 |
|      | 5 | 1 | 1 |
|      | 5 | 1 | 1 |
|      | 6 | 1 | 1 |
|      | 6 | 1 | 1 |
|      | 6 | 1 | 1 |

### 16.9.8 Enumerate group items

To see the order in which each row appears within its group, use the `cumcount` method:

```
In [199]: dfg = pd.DataFrame(list('aaabba'), columns=['A'])

In [200]: dfg
Out[200]:
 A
0 a
1 a
2 a
3 b
4 b
```

(continues on next page)

(continued from previous page)

```
5 a
```

```
In [201]: dfg.groupby('A').cumcount()
```

```
\////////////////////////////////////Out[201]:\n\n0 0\n1 1\n2 2\n3 0\n4 1\n5 3\ndtype: int64
```

```
In [202]: dfg.groupby('A').cumcount(ascending=False)
```

```
\%%%\n↪\n\n0 3\n1 2\n2 1\n3 1\n4 0\n5 0\ndtype: int64
```

### 16.9.9 Enumerate groups

## New in version 0.20.2.

To see the ordering of the groups (as opposed to the order of rows within a group given by `cumcount`) you can use `ngroup()`.

Note that the numbers given to the groups match the order in which the groups would be seen when iterating over the `groupby` object, not the order they are first observed.

```
In [203]: dfg = pd.DataFrame(list('aaabba'), columns=['A'])

In [204]: dfg
Out[204]:
 A
0 a
1 a
2 a
3 b
4 b
5 a

In [205]: dfg.groupby('A').ngroup()
Out[205]:
0 0
1 0
2 0
3 1
4 1
5 0
dtype: int64
```

(continues on next page)

(continued from previous page)

```
In [206]: dfg.groupby('A').ngroup(ascending=False)
```

```
////////////////////////////////////
```

```
↪
```

```
0 1
```

```
1 1
```

```
2 1
```

```
3 0
```

```
4 0
```

```
5 1
```

```
dtype: int64
```

## 16.9.10 Plotting

Groupby also works with some plotting methods. For example, suppose we suspect that some features in a DataFrame may differ by group, in this case, the values in column 1 where the group is “B” are 3 higher on average.

```
In [207]: np.random.seed(1234)
```

```
In [208]: df = pd.DataFrame(np.random.randn(50, 2))
```

```
In [209]: df['g'] = np.random.choice(['A', 'B'], size=50)
```

```
In [210]: df.loc[df['g'] == 'B', 1] += 3
```

We can easily visualize this with a boxplot:

```
In [211]: df.groupby('g').boxplot()
```

```
Out[211]:
```

```
A AxesSubplot(0.1,0.15;0.363636x0.75)
```

```
B AxesSubplot(0.536364,0.15;0.363636x0.75)
```

```
dtype: object
```

The result of calling `boxplot` is a dictionary whose keys are the values of our grouping column `g` (“A” and “B”). The values of the resulting dictionary can be controlled by the `return_type` keyword of `boxplot`. See the [visualization documentation](#) for more.

**Warning:** For historical reasons, `df.groupby("g").boxplot()` is not equivalent to `df.boxplot(by="g")`. See [here](#) for an explanation.

### 16.9.11 Piping function calls

New in version 0.21.0.

Similar to the functionality provided by `DataFrame` and `Series`, functions that take `GroupBy` objects can be chained together using a `pipe` method to allow for a cleaner, more readable syntax. To read about `.pipe` in general terms, see [here](#).

Combining `.groupby` and `.pipe` is often useful when you need to reuse `GroupBy` objects.

As an example, imagine having a `DataFrame` with columns for stores, products, revenue and quantity sold. We’d like to do a groupwise calculation of *prices* (i.e. revenue/quantity) per store and per product. We could do this in a multi-step operation, but expressing it in terms of piping can make the code more readable. First we set the data:

```
In [212]: n = 1000

In [213]: df = pd.DataFrame({'Store': np.random.choice(['Store_1', 'Store_2'], n),
.....: 'Product': np.random.choice(['Product_1',
.....: 'Product_2'], n),
.....: 'Revenue': (np.random.random(n) * 50 + 10).round(2),
.....: 'Quantity': np.random.randint(1, 10, size=n)})
.....:

In [214]: df.head(2)
Out[214]:
```

|   | Store   | Product   | Revenue | Quantity |
|---|---------|-----------|---------|----------|
| 0 | Store_2 | Product_1 | 26.12   | 1        |
| 1 | Store_2 | Product_1 | 28.86   | 1        |

Now, to find prices per store/product, we can simply do:

```
In [215]: (df.groupby(['Store', 'Product'])
.....: .pipe(lambda grp: grp.Revenue.sum() / grp.Quantity.sum())
.....: .unstack().round(2))
.....:
Out[215]:
```

| Product | Product_1 | Product_2 |
|---------|-----------|-----------|
| Store   |           |           |
| Store_1 | 6.82      | 7.05      |
| Store_2 | 6.30      | 6.64      |

Piping can also be expressive when you want to deliver a grouped object to some arbitrary function, for example:

```
In [216]: def mean(groupby):
.....: return groupby.mean()
.....:

In [217]: df.groupby(['Store', 'Product']).pipe(mean)
Out[217]:
```

|         |           | Revenue   | Quantity |
|---------|-----------|-----------|----------|
| Store   | Product   |           |          |
| Store_1 | Product_1 | 34.622727 | 5.075758 |
|         | Product_2 | 35.482815 | 5.029630 |
| Store_2 | Product_1 | 32.972837 | 5.237589 |
|         | Product_2 | 34.684360 | 5.224000 |

where `mean` takes a `GroupBy` object and finds the mean of the `Revenue` and `Quantity` columns respectively for each `Store-Product` combination. The `mean` function can be any function that takes in a `GroupBy` object; the `.pipe` will pass the `GroupBy` object as a parameter into the function you specify.

## 16.10 Examples

### 16.10.1 Regrouping by factor

Regroup columns of a `DataFrame` according to their sum, and sum the aggregated ones.

```
In [218]: df = pd.DataFrame({'a': [1, 0, 0], 'b': [0, 1, 0],
.....: 'c': [1, 0, 0], 'd': [2, 3, 4]})
```

(continues on next page)

```
.....:

In [219]: df
Out[219]:
 a b c d
0 1 0 1 2
1 0 1 0 3
2 0 0 0 4

In [220]: df.groupby(df.sum(), axis=1).sum()
Out[220]:
 1 9
0 2 2
1 1 3
2 0 4
```

[illegible]

### 16.10.3 Groupby by Indexer to ‘resample’ data

Resampling produces new hypothetical samples (resamples) from already existing observed data or from a model that generates data. These new samples are similar to the pre-existing samples.

In order to resample to work on indices that are non-datetime-like, the following procedure can be utilized.

In the following examples, `df.index // 5` returns a binary array which is used to determine what gets selected for the groupby operation.

**Note:** The below example shows how we can downsample by consolidation of samples into fewer samples. Here by using `df.index // 5`, we are aggregating the samples in bins. By applying `std()` function, we aggregate the information contained in many samples into a small subset of values which is their standard deviation thereby reducing the number of samples.

```
In [225]: df = pd.DataFrame(np.random.randn(10, 2))

In [226]: df
Out[226]:
```

|   | 0         | 1         |
|---|-----------|-----------|
| 0 | -0.793893 | 0.321153  |
| 1 | 0.342250  | 1.618906  |
| 2 | -0.975807 | 1.918201  |
| 3 | -0.810847 | -1.405919 |
| 4 | -1.977759 | 0.461659  |
| 5 | 0.730057  | -1.316938 |
| 6 | -0.751328 | 0.528290  |
| 7 | -0.257759 | -1.081009 |
| 8 | 0.505895  | -1.701948 |
| 9 | -1.006349 | 0.020208  |

```
In [227]: df.index // 5
↪ Int64Index([0, 0, 0, 0, 0, 1, 1, 1, 1, 1], dtype='int64')
```

```
In [228]: df.groupby(df.index // 5).std()
↪
```

|   | 0        | 1        |
|---|----------|----------|
| 0 | 0.823647 | 1.312912 |
| 1 | 0.760109 | 0.942941 |

### 16.10.4 Returning a Series to propagate names

Group DataFrame columns, compute a set of metrics and return a named Series. The Series name is used as the name for the column index. This is especially useful in conjunction with reshaping operations such as stacking in which the column index name will be used as the name of the inserted column:

```
In [229]: df = pd.DataFrame({'a': [0, 0, 0, 0, 1, 1, 1, 1, 2, 2, 2, 2],
.....: 'b': [0, 0, 1, 1, 0, 0, 1, 1, 0, 0, 1, 1],
.....: 'c': [1, 0, 1, 0, 1, 0, 1, 0, 1, 0, 1, 0],
.....: 'd': [0, 0, 0, 1, 0, 0, 0, 1, 0, 0, 0, 1]})
.....:
```

(continues on next page)

(continued from previous page)

```
In [230]: def compute_metrics(x):
.....: result = {'b_sum': x['b'].sum(), 'c_mean': x['c'].mean()}
.....: return pd.Series(result, name='metrics')
.....:
```

```
In [231]: result = df.groupby('a').apply(compute_metrics)
```

```
In [232]: result
```

```
Out[232]:
metrics b_sum c_mean
a
0 2.0 0.5
1 2.0 0.5
2 2.0 0.5
```

```
In [233]: result.stack()
```

```

////////////////////////////////////
↪
a metrics
0 b_sum 2.0
 c_mean 0.5
1 b_sum 2.0
 c_mean 0.5
2 b_sum 2.0
 c_mean 0.5
dtype: float64
```

```
{{ header }}
```

## MERGE, JOIN, AND CONCATENATE

pandas provides various facilities for easily combining together Series, DataFrame, and Panel objects with various kinds of set logic for the indexes and relational algebra functionality in the case of join / merge-type operations.

### 17.1 Concatenating objects

The `concat()` function (in the main pandas namespace) does all of the heavy lifting of performing concatenation operations along an axis while performing optional set logic (union or intersection) of the indexes (if any) on the other axes. Note that I say “if any” because there is only a single possible axis of concatenation for Series.

Before diving into all of the details of `concat` and what it can do, here is a simple example:

```
In [1]: df1 = pd.DataFrame({'A': ['A0', 'A1', 'A2', 'A3'],
...: 'B': ['B0', 'B1', 'B2', 'B3'],
...: 'C': ['C0', 'C1', 'C2', 'C3'],
...: 'D': ['D0', 'D1', 'D2', 'D3']},
...: index=[0, 1, 2, 3])
...:

In [2]: df2 = pd.DataFrame({'A': ['A4', 'A5', 'A6', 'A7'],
...: 'B': ['B4', 'B5', 'B6', 'B7'],
...: 'C': ['C4', 'C5', 'C6', 'C7'],
...: 'D': ['D4', 'D5', 'D6', 'D7']},
...: index=[4, 5, 6, 7])
...:

In [3]: df3 = pd.DataFrame({'A': ['A8', 'A9', 'A10', 'A11'],
...: 'B': ['B8', 'B9', 'B10', 'B11'],
...: 'C': ['C8', 'C9', 'C10', 'C11'],
...: 'D': ['D8', 'D9', 'D10', 'D11']},
...: index=[8, 9, 10, 11])
...:

In [4]: frames = [df1, df2, df3]

In [5]: result = pd.concat(frames)
```

| df1 |     |     |     |     | Result |     |     |     |     |
|-----|-----|-----|-----|-----|--------|-----|-----|-----|-----|
|     | A   | B   | C   | D   |        | A   | B   | C   | D   |
| 0   | A0  | B0  | C0  | D0  | 0      | A0  | B0  | C0  | D0  |
| 1   | A1  | B1  | C1  | D1  | 1      | A1  | B1  | C1  | D1  |
| 2   | A2  | B2  | C2  | D2  | 2      | A2  | B2  | C2  | D2  |
| 3   | A3  | B3  | C3  | D3  | 3      | A3  | B3  | C3  | D3  |
| df2 |     |     |     |     | 4      | A4  | B4  | C4  | D4  |
|     | A   | B   | C   | D   | 5      | A5  | B5  | C5  | D5  |
| 4   | A4  | B4  | C4  | D4  | 6      | A6  | B6  | C6  | D6  |
| 5   | A5  | B5  | C5  | D5  | 7      | A7  | B7  | C7  | D7  |
| 6   | A6  | B6  | C6  | D6  | 8      | A8  | B8  | C8  | D8  |
| 7   | A7  | B7  | C7  | D7  | 9      | A9  | B9  | C9  | D9  |
| df3 |     |     |     |     | 10     | A10 | B10 | C10 | D10 |
|     | A   | B   | C   | D   | 11     | A11 | B11 | C11 | D11 |
| 8   | A8  | B8  | C8  | D8  |        |     |     |     |     |
| 9   | A9  | B9  | C9  | D9  |        |     |     |     |     |
| 10  | A10 | B10 | C10 | D10 |        |     |     |     |     |
| 11  | A11 | B11 | C11 | D11 |        |     |     |     |     |

Like its sibling function on ndarrays, `numpy.concatenate`, `pandas.concat` takes a list or dict of homogeneously-typed objects and concatenates them with some configurable handling of “what to do with the other axes”:

```
pd.concat(objs, axis=0, join='outer', join_axes=None, ignore_index=False,
 keys=None, levels=None, names=None, verify_integrity=False,
 copy=True)
```

- `objs` : a sequence or mapping of Series, DataFrame, or Panel objects. If a dict is passed, the sorted keys will be used as the `keys` argument, unless it is passed, in which case the values will be selected (see below). Any None objects will be dropped silently unless they are all None in which case a `ValueError` will be raised.
- `axis` : {0, 1, ...}, default 0. The axis to concatenate along.
- `join` : {'inner', 'outer'}, default 'outer'. How to handle indexes on other axis(es). Outer for union and inner for intersection.
- `ignore_index` : boolean, default False. If True, do not use the index values on the concatenation axis. The resulting axis will be labeled 0, ..., n - 1. This is useful if you are concatenating objects where the concatenation axis does not have meaningful indexing information. Note the index values on the other axes are still respected in the join.
- `join_axes` : list of Index objects. Specific indexes to use for the other n - 1 axes instead of performing inner/outer set logic.
- `keys` : sequence, default None. Construct hierarchical index using the passed keys as the outermost level. If multiple levels passed, should contain tuples.
- `levels` : list of sequences, default None. Specific levels (unique values) to use for constructing a MultiIndex. Otherwise they will be inferred from the keys.
- `names` : list, default None. Names for the levels in the resulting hierarchical index.

- `verify_integrity`: boolean, default False. Check whether the new concatenated axis contains duplicates. This can be very expensive relative to the actual data concatenation.
- `copy`: boolean, default True. If False, do not copy data unnecessarily.

Without a little bit of context many of these arguments don't make much sense. Let's revisit the above example. Suppose we wanted to associate specific keys with each of the pieces of the chopped up DataFrame. We can do this using the `keys` argument:

```
In [6]: result = pd.concat(frames, keys=['x', 'y', 'z'])
```

| df1 |     |     |     |     | Result |    |     |     |     |     |
|-----|-----|-----|-----|-----|--------|----|-----|-----|-----|-----|
|     | A   | B   | C   | D   |        |    | A   | B   | C   | D   |
| 0   | A0  | B0  | C0  | D0  | x      | 0  | A0  | B0  | C0  | D0  |
| 1   | A1  | B1  | C1  | D1  | x      | 1  | A1  | B1  | C1  | D1  |
| 2   | A2  | B2  | C2  | D2  | x      | 2  | A2  | B2  | C2  | D2  |
| 3   | A3  | B3  | C3  | D3  | x      | 3  | A3  | B3  | C3  | D3  |
| df2 |     |     |     |     | y      | 4  | A4  | B4  | C4  | D4  |
| 4   | A4  | B4  | C4  | D4  | y      | 5  | A5  | B5  | C5  | D5  |
| 5   | A5  | B5  | C5  | D5  | y      | 6  | A6  | B6  | C6  | D6  |
| 6   | A6  | B6  | C6  | D6  | y      | 7  | A7  | B7  | C7  | D7  |
| 7   | A7  | B7  | C7  | D7  | z      | 8  | A8  | B8  | C8  | D8  |
| df3 |     |     |     |     | z      | 9  | A9  | B9  | C9  | D9  |
| 8   | A8  | B8  | C8  | D8  | z      | 10 | A10 | B10 | C10 | D10 |
| 9   | A9  | B9  | C9  | D9  | z      | 11 | A11 | B11 | C11 | D11 |
| 10  | A10 | B10 | C10 | D10 |        |    |     |     |     |     |
| 11  | A11 | B11 | C11 | D11 |        |    |     |     |     |     |

As you can see (if you've read the rest of the documentation), the resulting object's index has a *hierarchical index*. This means that we can now select out each chunk by key:

```
In [7]: result.loc['y']
Out[7]:
```

|   | A  | B  | C  | D  |
|---|----|----|----|----|
| 4 | A4 | B4 | C4 | D4 |
| 5 | A5 | B5 | C5 | D5 |
| 6 | A6 | B6 | C6 | D6 |
| 7 | A7 | B7 | C7 | D7 |

It's not a stretch to see how this can be very useful. More detail on this functionality below.

**Note:** It is worth noting that `concat()` (and therefore `append()`) makes a full copy of the data, and that constantly reusing this function can create a significant performance hit. If you need to use the operation over several datasets, use a list comprehension.

```
frames = [process_your_file(f) for f in files]
result = pd.concat(frames)
```

### 17.1.1 Set logic on the other axes

When gluing together multiple DataFrames, you have a choice of how to handle the other axes (other than the one being concatenated). This can be done in the following three ways:

- Take the union of them all, `join='outer'`. This is the default option as it results in zero information loss.
- Take the intersection, `join='inner'`.
- Use a specific index, as passed to the `join_axes` argument.

Here is an example of each of these methods. First, the default `join='outer'` behavior:

```
In [8]: df4 = pd.DataFrame({'B': ['B2', 'B3', 'B6', 'B7'],
...: 'D': ['D2', 'D3', 'D6', 'D7'],
...: 'F': ['F2', 'F3', 'F6', 'F7']},
...: index=[2, 3, 6, 7])
...:
In [9]: result = pd.concat([df1, df4], axis=1, sort=False)
```

| df1 |  |  |  |  | df4 |  |  |  | Result |  |  |  |  |  |  |  |
|-----|--|--|--|--|-----|--|--|--|--------|--|--|--|--|--|--|--|

|     |  |  |  |  |     |  |  |  |        |  |  |  |  |  |  |  |
|     |  |  |  |  |     |  |  |  |        |  |  |  |  |  |  |  |
|     |  |  |  |  |     |  |  |  |        |  |  |  |  |  |  |  |
|     |  |  |  |  |     |  |  |  |        |  |  |  |  |  |  |  |
|     |  |  |  |  |     |  |  |  |        |  |  |  |  |  |  |  |
|     |  |  |  |  |     |  |  |  |        |  |  |  |  |  |  |  |
|     |  |  |  |  |     |  |  |  |        |  |  |  |  |  |  |  |
|     |  |  |  |  |     |  |  |  |        |  |  |  |  |  |  |  |
|     |  |  |  |  |     |  |  |  |        |  |  |  |  |  |  |  |
|     |  |  |  |  |     |  |  |  |        |  |  |  |  |  |  |  |

**Warning:** Changed in version 0.23.0.

The default behavior with `join='outer'` is to sort the other axis (columns in this case). In a future version of pandas, the default will be to not sort. We specified `sort=False` to opt in to the new behavior now.

Here is the same thing with `join='inner'`:

```
In [10]: result = pd.concat([df1, df4], axis=1, join='inner')
```

| df1 |    |    |    |    | df4 |    |    |    | Result |    |    |    |    |    |    |    |
|-----|----|----|----|----|-----|----|----|----|--------|----|----|----|----|----|----|----|
|     | A  | B  | C  | D  |     | B  | D  | F  |        | A  | B  | C  | D  | B  | D  | F  |
| 0   | A0 | B0 | C0 | D0 | 2   | B2 | D2 | F2 | 2      | A2 | B2 | C2 | D2 | B2 | D2 | F2 |
| 1   | A1 | B1 | C1 | D1 | 3   | B3 | D3 | F3 | 3      | A3 | B3 | C3 | D3 | B3 | D3 | F3 |
| 2   | A2 | B2 | C2 | D2 | 6   | B6 | D6 | F6 |        |    |    |    |    |    |    |    |
| 3   | A3 | B3 | C3 | D3 | 7   | B7 | D7 | F7 |        |    |    |    |    |    |    |    |

Lastly, suppose we just wanted to reuse the *exact index* from the original DataFrame:

```
In [11]: result = pd.concat([df1, df4], axis=1, join_axes=[df1.index])
```

| df1 |    |    |    |    | df4 |    |    |    | Result |    |    |    |    |     |     |     |
|-----|----|----|----|----|-----|----|----|----|--------|----|----|----|----|-----|-----|-----|
|     | A  | B  | C  | D  |     | B  | D  | F  |        | A  | B  | C  | D  | B   | D   | F   |
| 0   | A0 | B0 | C0 | D0 | 2   | B2 | D2 | F2 | 0      | A0 | B0 | C0 | D0 | NaN | NaN | NaN |
| 1   | A1 | B1 | C1 | D1 | 3   | B3 | D3 | F3 | 1      | A1 | B1 | C1 | D1 | NaN | NaN | NaN |
| 2   | A2 | B2 | C2 | D2 | 6   | B6 | D6 | F6 | 2      | A2 | B2 | C2 | D2 | B2  | D2  | F2  |
| 3   | A3 | B3 | C3 | D3 | 7   | B7 | D7 | F7 | 3      | A3 | B3 | C3 | D3 | B3  | D3  | F3  |

### 17.1.2 Concatenating using `append`

A useful shortcut to `concat()` are the `append()` instance methods on `Series` and `DataFrame`. These methods actually predated `concat`. They concatenate along `axis=0`, namely the index:

```
In [12]: result = df1.append(df2)
```

| df1 |    |    |    |    | Result |    |    |    |    |
|-----|----|----|----|----|--------|----|----|----|----|
|     | A  | B  | C  | D  |        | A  | B  | C  | D  |
| 0   | A0 | B0 | C0 | D0 | 0      | A0 | B0 | C0 | D0 |
| 1   | A1 | B1 | C1 | D1 | 1      | A1 | B1 | C1 | D1 |
| 2   | A2 | B2 | C2 | D2 | 2      | A2 | B2 | C2 | D2 |
| 3   | A3 | B3 | C3 | D3 | 3      | A3 | B3 | C3 | D3 |
| df2 |    |    |    |    | 4      | A4 | B4 | C4 | D4 |
|     | A  | B  | C  | D  | 5      | A5 | B5 | C5 | D5 |
| 4   | A4 | B4 | C4 | D4 | 6      | A6 | B6 | C6 | D6 |
| 5   | A5 | B5 | C5 | D5 | 7      | A7 | B7 | C7 | D7 |
| 6   | A6 | B6 | C6 | D6 |        |    |    |    |    |
| 7   | A7 | B7 | C7 | D7 |        |    |    |    |    |

In the case of `DataFrame`, the indexes must be disjoint but the columns do not need to be:

```
In [13]: result = df1.append(df4, sort=False)
```

| df1 |    |    |    |    | Result |     |    |     |    |     |
|-----|----|----|----|----|--------|-----|----|-----|----|-----|
|     | A  | B  | C  | D  |        | A   | B  | C   | D  | F   |
| 0   | A0 | B0 | C0 | D0 | 0      | A0  | B0 | C0  | D0 | NaN |
| 1   | A1 | B1 | C1 | D1 | 1      | A1  | B1 | C1  | D1 | NaN |
| 2   | A2 | B2 | C2 | D2 | 2      | A2  | B2 | C2  | D2 | NaN |
| 3   | A3 | B3 | C3 | D3 | 3      | A3  | B3 | C3  | D3 | NaN |
| df4 |    |    |    |    | 2      | NaN | B2 | NaN | D2 | F2  |
|     | B  | D  | F  |    | 3      | NaN | B3 | NaN | D3 | F3  |
| 2   | B2 | D2 | F2 |    | 6      | NaN | B6 | NaN | D6 | F6  |
| 3   | B3 | D3 | F3 |    | 7      | NaN | B7 | NaN | D7 | F7  |
| 6   | B6 | D6 | F6 |    |        |     |    |     |    |     |
| 7   | B7 | D7 | F7 |    |        |     |    |     |    |     |

append may take multiple objects to concatenate:

```
In [14]: result = df1.append([df2, df3])
```

| df1 |     |     |     |     | Result |     |     |     |     |
|-----|-----|-----|-----|-----|--------|-----|-----|-----|-----|
|     | A   | B   | C   | D   |        | A   | B   | C   | D   |
| 0   | A0  | B0  | C0  | D0  | 0      | A0  | B0  | C0  | D0  |
| 1   | A1  | B1  | C1  | D1  | 1      | A1  | B1  | C1  | D1  |
| 2   | A2  | B2  | C2  | D2  | 2      | A2  | B2  | C2  | D2  |
| 3   | A3  | B3  | C3  | D3  | 3      | A3  | B3  | C3  | D3  |
| df2 |     |     |     |     | 4      | A4  | B4  | C4  | D4  |
|     | A   | B   | C   | D   | 5      | A5  | B5  | C5  | D5  |
| 4   | A4  | B4  | C4  | D4  | 6      | A6  | B6  | C6  | D6  |
| 5   | A5  | B5  | C5  | D5  | 7      | A7  | B7  | C7  | D7  |
| 6   | A6  | B6  | C6  | D6  | 8      | A8  | B8  | C8  | D8  |
| 7   | A7  | B7  | C7  | D7  | 9      | A9  | B9  | C9  | D9  |
| df3 |     |     |     |     | 10     | A10 | B10 | C10 | D10 |
|     | A   | B   | C   | D   | 11     | A11 | B11 | C11 | D11 |
| 8   | A8  | B8  | C8  | D8  |        |     |     |     |     |
| 9   | A9  | B9  | C9  | D9  |        |     |     |     |     |
| 10  | A10 | B10 | C10 | D10 |        |     |     |     |     |
| 11  | A11 | B11 | C11 | D11 |        |     |     |     |     |

**Note:** Unlike the `append()` method, which appends to the original list and returns `None`, `append()` here **does not** modify `df1` and returns its copy with `df2` appended.

### 17.1.3 Ignoring indexes on the concatenation axis

For `DataFrame` objects which don't have a meaningful index, you may wish to append them and ignore the fact that they may have overlapping indexes. To do this, use the `ignore_index` argument:

```
In [15]: result = pd.concat([df1, df4], ignore_index=True, sort=False)
```

| df1 |    |    |    |    | Result |     |     |     |    |     |
|-----|----|----|----|----|--------|-----|-----|-----|----|-----|
|     | A  | B  | C  | D  |        | A   | B   | C   | D  | F   |
| 0   | A0 | B0 | C0 | D0 | 0      | A0  | B0  | C0  | D0 | NaN |
| 1   | A1 | B1 | C1 | D1 | 1      | A1  | B1  | C1  | D1 | NaN |
| 2   | A2 | B2 | C2 | D2 | 2      | A2  | B2  | C2  | D2 | NaN |
| 3   | A3 | B3 | C3 | D3 | 3      | A3  | B3  | C3  | D3 | NaN |
| df4 |    |    |    |    | 4      | NaN | B2  | NaN | D2 | F2  |
|     | B  | D  | F  |    | 5      | NaN | B3  | NaN | D3 | F3  |
| 2   | B2 | D2 | F2 | 6  | NaN    | B6  | NaN | D6  | F6 |     |
| 3   | B3 | D3 | F3 | 7  | NaN    | B7  | NaN | D7  | F7 |     |
| 6   | B6 | D6 | F6 |    |        |     |     |     |    |     |
| 7   | B7 | D7 | F7 |    |        |     |     |     |    |     |

This is also a valid argument to `DataFrame.append()`:

```
In [16]: result = df1.append(df4, ignore_index=True, sort=False)
```

| df1 |    |    |    |    | Result |     |     |     |    |     |
|-----|----|----|----|----|--------|-----|-----|-----|----|-----|
|     | A  | B  | C  | D  |        | A   | B   | C   | D  | F   |
| 0   | A0 | B0 | C0 | D0 | 0      | A0  | B0  | C0  | D0 | NaN |
| 1   | A1 | B1 | C1 | D1 | 1      | A1  | B1  | C1  | D1 | NaN |
| 2   | A2 | B2 | C2 | D2 | 2      | A2  | B2  | C2  | D2 | NaN |
| 3   | A3 | B3 | C3 | D3 | 3      | A3  | B3  | C3  | D3 | NaN |
| df4 |    |    |    |    | 4      | NaN | B2  | NaN | D2 | F2  |
|     | B  | D  | F  |    | 5      | NaN | B3  | NaN | D3 | F3  |
| 2   | B2 | D2 | F2 | 6  | NaN    | B6  | NaN | D6  | F6 |     |
| 3   | B3 | D3 | F3 | 7  | NaN    | B7  | NaN | D7  | F7 |     |
| 6   | B6 | D6 | F6 |    |        |     |     |     |    |     |
| 7   | B7 | D7 | F7 |    |        |     |     |     |    |     |

### 17.1.4 Concatenating with mixed ndims

You can concatenate a mix of `Series` and `DataFrame` objects. The `Series` will be transformed to `DataFrame` with the column name as the name of the `Series`.

```
In [17]: s1 = pd.Series(['X0', 'X1', 'X2', 'X3'], name='X')
```

```
In [18]: result = pd.concat([df1, s1], axis=1)
```

| df1 |    |    |    |    | s1 |    | Result |    |    |    |    |    |
|-----|----|----|----|----|----|----|--------|----|----|----|----|----|
|     | A  | B  | C  | D  |    | X  |        | A  | B  | C  | D  | X  |
| 0   | A0 | B0 | C0 | D0 | 0  | X0 | 0      | A0 | B0 | C0 | D0 | X0 |
| 1   | A1 | B1 | C1 | D1 | 1  | X1 | 1      | A1 | B1 | C1 | D1 | X1 |
| 2   | A2 | B2 | C2 | D2 | 2  | X2 | 2      | A2 | B2 | C2 | D2 | X2 |
| 3   | A3 | B3 | C3 | D3 | 3  | X3 | 3      | A3 | B3 | C3 | D3 | X3 |

**Note:** Since we're concatenating a Series to a DataFrame, we could have achieved the same result with `DataFrame.assign()`. To concatenate an arbitrary number of pandas objects (DataFrame or Series), use `concat`.

If unnamed Series are passed they will be numbered consecutively.

```
In [19]: s2 = pd.Series(['_0', '_1', '_2', '_3'])
```

```
In [20]: result = pd.concat([df1, s2, s2, s2], axis=1)
```

| df1 |    |    |    |    | s2 |    | Result |    |    |    |    |    |    |    |
|-----|----|----|----|----|----|----|--------|----|----|----|----|----|----|----|
|     | A  | B  | C  | D  |    |    |        | A  | B  | C  | D  | 0  | 1  | 2  |
| 0   | A0 | B0 | C0 | D0 | 0  | _0 | 0      | A0 | B0 | C0 | D0 | _0 | _0 | _0 |
| 1   | A1 | B1 | C1 | D1 | 1  | _1 | 1      | A1 | B1 | C1 | D1 | _1 | _1 | _1 |
| 2   | A2 | B2 | C2 | D2 | 2  | _2 | 2      | A2 | B2 | C2 | D2 | _2 | _2 | _2 |
| 3   | A3 | B3 | C3 | D3 | 3  | _3 | 3      | A3 | B3 | C3 | D3 | _3 | _3 | _3 |

Passing `ignore_index=True` will drop all name references.

```
In [21]: result = pd.concat([df1, s1], axis=1, ignore_index=True)
```

| df1 |    |    |    |    | s1 |    | Result |    |    |    |    |    |
|-----|----|----|----|----|----|----|--------|----|----|----|----|----|
|     | A  | B  | C  | D  |    | X  |        | 0  | 1  | 2  | 3  | 4  |
| 0   | A0 | B0 | C0 | D0 | 0  | X0 | 0      | A0 | B0 | C0 | D0 | X0 |
| 1   | A1 | B1 | C1 | D1 | 1  | X1 | 1      | A1 | B1 | C1 | D1 | X1 |
| 2   | A2 | B2 | C2 | D2 | 2  | X2 | 2      | A2 | B2 | C2 | D2 | X2 |
| 3   | A3 | B3 | C3 | D3 | 3  | X3 | 3      | A3 | B3 | C3 | D3 | X3 |

### 17.1.5 More concatenating with group keys

A fairly common use of the `keys` argument is to override the column names when creating a new `DataFrame` based on existing `Series`. Notice how the default behaviour consists on letting the resulting `DataFrame` inherit the parent `Series`' name, when these existed.

```
In [22]: s3 = pd.Series([0, 1, 2, 3], name='foo')
```

```
In [23]: s4 = pd.Series([0, 1, 2, 3])
```

```
In [24]: s5 = pd.Series([0, 1, 4, 5])
```

```
In [25]: pd.concat([s3, s4, s5], axis=1)
```

```
Out[25]:
 foo 0 1
0 0 0 0
1 1 1 1
2 2 2 4
3 3 3 5
```

Through the `keys` argument we can override the existing column names.

```
In [26]: pd.concat([s3, s4, s5], axis=1, keys=['red', 'blue', 'yellow'])
```

```
Out[26]:
 red blue yellow
0 0 0 0
1 1 1 1
2 2 2 4
3 3 3 5
```

Let's consider a variation of the very first example presented:

```
In [27]: result = pd.concat(frames, keys=['x', 'y', 'z'])
```

| df1 |     |     |     |     | Result |    |     |     |     |     |
|-----|-----|-----|-----|-----|--------|----|-----|-----|-----|-----|
|     | A   | B   | C   | D   |        |    | A   | B   | C   | D   |
| 0   | A0  | B0  | C0  | D0  | x      | 0  | A0  | B0  | C0  | D0  |
| 1   | A1  | B1  | C1  | D1  | x      | 1  | A1  | B1  | C1  | D1  |
| 2   | A2  | B2  | C2  | D2  | x      | 2  | A2  | B2  | C2  | D2  |
| 3   | A3  | B3  | C3  | D3  | x      | 3  | A3  | B3  | C3  | D3  |
| df2 |     |     |     |     |        |    |     |     |     |     |
|     | A   | B   | C   | D   |        |    |     |     |     |     |
| 4   | A4  | B4  | C4  | D4  | y      | 4  | A4  | B4  | C4  | D4  |
| 5   | A5  | B5  | C5  | D5  | y      | 5  | A5  | B5  | C5  | D5  |
| 6   | A6  | B6  | C6  | D6  | y      | 6  | A6  | B6  | C6  | D6  |
| 7   | A7  | B7  | C7  | D7  | y      | 7  | A7  | B7  | C7  | D7  |
| df3 |     |     |     |     |        |    |     |     |     |     |
|     | A   | B   | C   | D   |        |    |     |     |     |     |
| 8   | A8  | B8  | C8  | D8  | z      | 8  | A8  | B8  | C8  | D8  |
| 9   | A9  | B9  | C9  | D9  | z      | 9  | A9  | B9  | C9  | D9  |
| 10  | A10 | B10 | C10 | D10 | z      | 10 | A10 | B10 | C10 | D10 |
| 11  | A11 | B11 | C11 | D11 | z      | 11 | A11 | B11 | C11 | D11 |

You can also pass a dict to `concat` in which case the dict keys will be used for the `keys` argument (unless other keys are specified):

```
In [28]: pieces = {'x': df1, 'y': df2, 'z': df3}
```

```
In [29]: result = pd.concat(pieces)
```

| df1 |     |     |     |     | Result |    |     |     |     |     |
|-----|-----|-----|-----|-----|--------|----|-----|-----|-----|-----|
|     | A   | B   | C   | D   |        |    | A   | B   | C   | D   |
| 0   | A0  | B0  | C0  | D0  | x      | 0  | A0  | B0  | C0  | D0  |
| 1   | A1  | B1  | C1  | D1  | x      | 1  | A1  | B1  | C1  | D1  |
| 2   | A2  | B2  | C2  | D2  | x      | 2  | A2  | B2  | C2  | D2  |
| 3   | A3  | B3  | C3  | D3  | x      | 3  | A3  | B3  | C3  | D3  |
| df2 |     |     |     |     | y      | 4  | A4  | B4  | C4  | D4  |

| 3   | A3  | B3  | C3  | D3  | z      | 11 | A11 | B11 | C11 | D11 |
| df2 |     |     |     |     | y      | 4  | A4  | B4  | C4  | D4  |
|     | A   | B   | C   | D   | y      | 5  | A5  | B5  | C5  | D5  |
| 4   | A4  | B4  | C4  | D4  | y      | 6  | A6  | B6  | C6  | D6  |
| 5   | A5  | B5  | C5  | D5  | y      | 7  | A7  | B7  | C7  | D7  |
| 6   | A6  | B6  | C6  | D6  |        |    |     |     |     |     |
| 7   | A7  | B7  | C7  | D7  |        |    |     |     |     |     |
| df3 |     |     |     |     |        |    |     |     |     |     |
|     | A   | B   | C   | D   |        |    |     |     |     |     |
| 8   | A8  | B8  | C8  | D8  |        |    |     |     |     |     |
| 9   | A9  | B9  | C9  | D9  |        |    |     |     |     |     |
| 10  | A10 | B10 | C10 | D10 |        |    |     |     |     |     |
| 11  | A11 | B11 | C11 | D11 |        |    |     |     |     |     |

The MultiIndex created has levels that are constructed from the passed keys and the index of the DataFrame pieces:

```
In [31]: result.index.levels
Out[31]: FrozenList([['z', 'y'], [4, 5, 6, 7, 8, 9, 10, 11]])
```

If you wish to specify other levels (as will occasionally be the case), you can do so using the `levels` argument:

```
In [32]: result = pd.concat(pieces, keys=['x', 'y', 'z'],
.....: levels=['z', 'y', 'x', 'w'],
.....: names=['group_key'])
.....:
```

| df1 |     |     |     |     | Result |    |     |     |     |     |
|-----|-----|-----|-----|-----|--------|----|-----|-----|-----|-----|
|     | A   | B   | C   | D   |        |    | A   | B   | C   | D   |
| 0   | A0  | B0  | C0  | D0  | x      | 0  | A0  | B0  | C0  | D0  |
| 1   | A1  | B1  | C1  | D1  | x      | 1  | A1  | B1  | C1  | D1  |
| 2   | A2  | B2  | C2  | D2  | x      | 2  | A2  | B2  | C2  | D2  |
| 3   | A3  | B3  | C3  | D3  | x      | 3  | A3  | B3  | C3  | D3  |
| df2 |     |     |     |     | y      | 4  | A4  | B4  | C4  | D4  |
| 4   | A4  | B4  | C4  | D4  | y      | 5  | A5  | B5  | C5  | D5  |
| 5   | A5  | B5  | C5  | D5  | y      | 6  | A6  | B6  | C6  | D6  |
| 6   | A6  | B6  | C6  | D6  | y      | 7  | A7  | B7  | C7  | D7  |
| 7   | A7  | B7  | C7  | D7  | z      | 8  | A8  | B8  | C8  | D8  |
| df3 |     |     |     |     | z      | 9  | A9  | B9  | C9  | D9  |
|     | A   | B   | C   | D   | z      | 10 | A10 | B10 | C10 | D10 |
| 8   | A8  | B8  | C8  | D8  | z      | 11 | A11 | B11 | C11 | D11 |
| 9   | A9  | B9  | C9  | D9  |        |    |     |     |     |     |
| 10  | A10 | B10 | C10 | D10 |        |    |     |     |     |     |
| 11  | A11 | B11 | C11 | D11 |        |    |     |     |     |     |

```
In [33]: result.index.levels
Out[33]: FrozenList([['z', 'y', 'x', 'w'], [0, 1, 2, 3, 4, 5, 6, 7, 8, 9, 10, 11]])
```

This is fairly esoteric, but it is actually necessary for implementing things like `GroupBy` where the order of a categorical variable is meaningful.

### 17.1.6 Appending rows to a DataFrame

While not especially efficient (since a new object must be created), you can append a single row to a `DataFrame` by passing a `Series` or dict to `append`, which returns a new `DataFrame` as above.

```
In [34]: s2 = pd.Series(['X0', 'X1', 'X2', 'X3'], index=['A', 'B', 'C', 'D'])
In [35]: result = df1.append(s2, ignore_index=True)
```

| df1 |    |    |    |    | Result |    |    |    |    |
|-----|----|----|----|----|--------|----|----|----|----|
|     | A  | B  | C  | D  |        | A  | B  | C  | D  |
| 0   | A0 | B0 | C0 | D0 | 0      | A0 | B0 | C0 | D0 |
| 1   | A1 | B1 | C1 | D1 | 1      | A1 | B1 | C1 | D1 |
| 2   | A2 | B2 | C2 | D2 | 2      | A2 | B2 | C2 | D2 |
| 3   | A3 | B3 | C3 | D3 | 3      | A3 | B3 | C3 | D3 |
| s2  |    |    |    |    | 4      | X0 | X1 | X2 | X3 |
|     | A  |    |    | X0 |        |    |    |    |    |
|     | B  |    |    | X1 |        |    |    |    |    |
|     | C  |    |    | X2 |        |    |    |    |    |
|     | D  |    |    | X3 |        |    |    |    |    |

You should use `ignore_index` with this method to instruct `DataFrame` to discard its index. If you wish to preserve the index, you should construct an appropriately-indexed `DataFrame` and append or concatenate those objects.

You can also pass a list of dicts or Series:

```
In [36]: dicts = [{'A': 1, 'B': 2, 'C': 3, 'X': 4},
.....: {'A': 5, 'B': 6, 'C': 7, 'Y': 8}]
.....:

In [37]: result = df1.append(dicts, ignore_index=True, sort=False)
```

| df1   |    |    |    |     | Result |    |    |    |     |     |     |
|-------|----|----|----|-----|--------|----|----|----|-----|-----|-----|
|       | A  | B  | C  | D   |        | A  | B  | C  | D   | X   | Y   |
| 0     | A0 | B0 | C0 | D0  | 0      | A0 | B0 | C0 | D0  | NaN | NaN |
| 1     | A1 | B1 | C1 | D1  | 1      | A1 | B1 | C1 | D1  | NaN | NaN |
| 2     | A2 | B2 | C2 | D2  | 2      | A2 | B2 | C2 | D2  | NaN | NaN |
| 3     | A3 | B3 | C3 | D3  | 3      | A3 | B3 | C3 | D3  | NaN | NaN |
| dicts |    |    |    |     | 4      | 1  | 2  | 3  | NaN | 4.0 | NaN |
|       | A  | B  | C  | X   | Y      | 5  | 5  | 6  | 7   | NaN | 8.0 |
| 0     | 1  | 2  | 3  | 4.0 | NaN    |    |    |    |     |     |     |
| 1     | 5  | 6  | 7  | NaN | 8.0    |    |    |    |     |     |     |

## 17.2 Database-style DataFrame or named Series joining/merging

pandas has full-featured, **high performance** in-memory join operations idiomatically very similar to relational databases like SQL. These methods perform significantly better (in some cases well over an order of magnitude better) than other open source implementations (like `base::merge.data.frame` in R). The reason for this is careful algorithmic design and the internal layout of the data in `DataFrame`.

See the *cookbook* for some advanced strategies.

Users who are familiar with SQL but new to pandas might be interested in a *comparison with SQL*.

pandas provides a single function, `merge()`, as the entry point for all standard database join operations between `DataFrame` or named `Series` objects:

```
pd.merge(left, right, how='inner', on=None, left_on=None, right_on=None,
 left_index=False, right_index=False, sort=True,
 suffixes=('_x', '_y'), copy=True, indicator=False,
 validate=None)
```

- `left`: A `DataFrame` or named `Series` object.
- `right`: Another `DataFrame` or named `Series` object.
- `on`: Column or index level names to join on. Must be found in both the left and right `DataFrame` and/or `Series` objects. If not passed and `left_index` and `right_index` are `False`, the intersection of the columns in the `DataFrames` and/or `Series` will be inferred to be the join keys.
- `left_on`: Columns or index levels from the left `DataFrame` or `Series` to use as keys. Can either be column names, index level names, or arrays with length equal to the length of the `DataFrame` or `Series`.
- `right_on`: Columns or index levels from the right `DataFrame` or `Series` to use as keys. Can either be column names, index level names, or arrays with length equal to the length of the `DataFrame` or `Series`.
- `left_index`: If `True`, use the index (row labels) from the left `DataFrame` or `Series` as its join key(s). In the case of a `DataFrame` or `Series` with a `MultiIndex` (hierarchical), the number of levels must match the number of join keys from the right `DataFrame` or `Series`.
- `right_index`: Same usage as `left_index` for the right `DataFrame` or `Series`.
- `how`: One of `'left'`, `'right'`, `'outer'`, `'inner'`. Defaults to `inner`. See below for more detailed description of each method.
- `sort`: Sort the result `DataFrame` by the join keys in lexicographical order. Defaults to `True`, setting to `False` will improve performance substantially in many cases.
- `suffixes`: A tuple of string suffixes to apply to overlapping columns. Defaults to `('_x', '_y')`.
- `copy`: Always copy data (default `True`) from the passed `DataFrame` or named `Series` objects, even when reindexing is not necessary. Cannot be avoided in many cases but may improve performance / memory usage. The cases where copying can be avoided are somewhat pathological but this option is provided nonetheless.
- `indicator`: Add a column to the output `DataFrame` called `_merge` with information on the source of each row. `_merge` is Categorical-type and takes on a value of `left_only` for observations whose merge key only appears in `'left'` `DataFrame` or `Series`, `right_only` for observations whose merge key only appears in `'right'` `DataFrame` or `Series`, and `both` if the observation's merge key is found in both.
- `validate`: string, default `None`. If specified, checks if merge is of specified type.
  - `"one_to_one"` or `"1:1"`: checks if merge keys are unique in both left and right datasets.
  - `"one_to_many"` or `"1:m"`: checks if merge keys are unique in left dataset.
  - `"many_to_one"` or `"m:1"`: checks if merge keys are unique in right dataset.
  - `"many_to_many"` or `"m:m"`: allowed, but does not result in checks.

New in version 0.21.0.

---

**Note:** Support for specifying index levels as the `on`, `left_on`, and `right_on` parameters was added in version 0.23.0. Support for merging named `Series` objects was added in version 0.24.0.

---

The return type will be the same as `left`. If `left` is a `DataFrame` or named `Series` and `right` is a subclass of `DataFrame`, the return type will still be `DataFrame`.

`merge` is a function in the pandas namespace, and it is also available as a `DataFrame` instance method `merge()`, with the calling `DataFrame` being implicitly considered the left object in the join.

The related `join()` method, uses `merge` internally for the index-on-index (by default) and column(s)-on-index join. If you are joining on index only, you may wish to use `DataFrame.join` to save yourself some typing.

### 17.2.1 Brief primer on merge methods (relational algebra)

Experienced users of relational databases like SQL will be familiar with the terminology used to describe join operations between two SQL-table like structures (`DataFrame` objects). There are several cases to consider which are very important to understand:

- **one-to-one** joins: for example when joining two `DataFrame` objects on their indexes (which must contain unique values).
- **many-to-one** joins: for example when joining an index (unique) to one or more columns in a different `DataFrame`.
- **many-to-many** joins: joining columns on columns.

**Note:** When joining columns on columns (potentially a many-to-many join), any indexes on the passed `DataFrame` objects **will be discarded**.

It is worth spending some time understanding the result of the **many-to-many** join case. In SQL / standard relational algebra, if a key combination appears more than once in both tables, the resulting table will have the **Cartesian product** of the associated data. Here is a very basic example with one unique key combination:

```
In [38]: left = pd.DataFrame({'key': ['K0', 'K1', 'K2', 'K3'],
.....: 'A': ['A0', 'A1', 'A2', 'A3'],
.....: 'B': ['B0', 'B1', 'B2', 'B3']})
.....:

In [39]: right = pd.DataFrame({'key': ['K0', 'K1', 'K2', 'K3'],
.....: 'C': ['C0', 'C1', 'C2', 'C3'],
.....: 'D': ['D0', 'D1', 'D2', 'D3']})
.....:

In [40]: result = pd.merge(left, right, on='key')
```

| left |     |    |    | right |     |    |    | Result |     |    |    |    |    |
|------|-----|----|----|-------|-----|----|----|--------|-----|----|----|----|----|
|      | key | A  | B  |       | key | C  | D  |        | key | A  | B  | C  | D  |
| 0    | K0  | A0 | B0 | 0     | K0  | C0 | D0 | 0      | K0  | A0 | B0 | C0 | D0 |
| 1    | K1  | A1 | B1 | 1     | K1  | C1 | D1 | 1      | K1  | A1 | B1 | C1 | D1 |
| 2    | K2  | A2 | B2 | 2     | K2  | C2 | D2 | 2      | K2  | A2 | B2 | C2 | D2 |
| 3    | K3  | A3 | B3 | 3     | K3  | C3 | D3 | 3      | K3  | A3 | B3 | C3 | D3 |

Here is a more complicated example with multiple join keys. Only the keys appearing in `left` and `right` are present (the intersection), since `how='inner'` by default.

```
In [41]: left = pd.DataFrame({'key1': ['K0', 'K0', 'K1', 'K2'],
.....: 'key2': ['K0', 'K1', 'K0', 'K1']},
```

(continues on next page)

(continued from previous page)

```

.....: 'A': ['A0', 'A1', 'A2', 'A3'],
.....: 'B': ['B0', 'B1', 'B2', 'B3']})
.....:
In [42]: right = pd.DataFrame({'key1': ['K0', 'K1', 'K1', 'K2'],
.....: 'key2': ['K0', 'K0', 'K0', 'K0'],
.....: 'C': ['C0', 'C1', 'C2', 'C3'],
.....: 'D': ['D0', 'D1', 'D2', 'D3']})
.....:
In [43]: result = pd.merge(left, right, on=['key1', 'key2'])

```

| left |      |      |    |    | right |      |      |    |    | Result |      |      |    |    |    |    |
|------|------|------|----|----|-------|------|------|----|----|--------|------|------|----|----|----|----|
|      | key1 | key2 | A  | B  |       | key1 | key2 | C  | D  |        | key1 | key2 | A  | B  | C  | D  |
| 0    | K0   | K0   | A0 | B0 | 0     | K0   | K0   | C0 | D0 | 0      | K0   | K0   | A0 | B0 | C0 | D0 |
| 1    | K0   | K1   | A1 | B1 | 1     | K1   | K0   | C1 | D1 | 1      | K1   | K0   | A2 | B2 | C1 | D1 |
| 2    | K1   | K0   | A2 | B2 | 2     | K1   | K0   | C2 | D2 | 2      | K1   | K0   | A2 | B2 | C2 | D2 |
| 3    | K2   | K1   | A3 | B3 | 3     | K2   | K0   | C3 | D3 |        |      |      |    |    |    |    |

The `how` argument to `merge` specifies how to determine which keys are to be included in the resulting table. If a key combination **does not appear** in either the left or right tables, the values in the joined table will be NA. Here is a summary of the `how` options and their SQL equivalent names:

| Merge method | SQL Join Name    | Description                               |
|--------------|------------------|-------------------------------------------|
| left         | LEFT OUTER JOIN  | Use keys from left frame only             |
| right        | RIGHT OUTER JOIN | Use keys from right frame only            |
| outer        | FULL OUTER JOIN  | Use union of keys from both frames        |
| inner        | INNER JOIN       | Use intersection of keys from both frames |

```
In [44]: result = pd.merge(left, right, how='left', on=['key1', 'key2'])
```

| left |      |      |    |    | right |      |      |    |    | Result |      |      |    |    |     |     |
|------|------|------|----|----|-------|------|------|----|----|--------|------|------|----|----|-----|-----|
|      | key1 | key2 | A  | B  |       | key1 | key2 | C  | D  |        | key1 | key2 | A  | B  | C   | D   |
| 0    | K0   | K0   | A0 | B0 | 0     | K0   | K0   | C0 | D0 | 0      | K0   | K0   | A0 | B0 | C0  | D0  |
| 1    | K0   | K1   | A1 | B1 | 1     | K1   | K0   | C1 | D1 | 1      | K0   | K1   | A1 | B1 | NaN | NaN |
| 2    | K1   | K0   | A2 | B2 | 2     | K1   | K0   | C2 | D2 | 2      | K1   | K0   | A2 | B2 | C1  | D1  |
| 3    | K2   | K1   | A3 | B3 | 3     | K2   | K0   | C3 | D3 | 3      | K1   | K0   | A2 | B2 | C2  | D2  |
|      |      |      |    |    |       |      |      |    |    | 4      | K2   | K1   | A3 | B3 | NaN | NaN |

```
In [45]: result = pd.merge(left, right, how='right', on=['key1', 'key2'])
```

| left |      |      |    |    | right |      |      |    |    | Result |      |      |     |     |    |    |
|------|------|------|----|----|-------|------|------|----|----|--------|------|------|-----|-----|----|----|
|      | key1 | key2 | A  | B  |       | key1 | key2 | C  | D  |        | key1 | key2 | A   | B   | C  | D  |
| 0    | K0   | K0   | A0 | B0 | 0     | K0   | K0   | C0 | D0 | 0      | K0   | K0   | A0  | B0  | C0 | D0 |
| 1    | K0   | K1   | A1 | B1 | 1     | K1   | K0   | C1 | D1 | 1      | K1   | K0   | A2  | B2  | C1 | D1 |
| 2    | K1   | K0   | A2 | B2 | 2     | K1   | K0   | C2 | D2 | 2      | K1   | K0   | A2  | B2  | C2 | D2 |
| 3    | K2   | K1   | A3 | B3 | 3     | K2   | K0   | C3 | D3 | 3      | K2   | K0   | NaN | NaN | C3 | D3 |

```
In [46]: result = pd.merge(left, right, how='outer', on=['key1', 'key2'])
```

| left       |    |    |    |    | right      |    |    |    |    | Result       |    |    |     |     |     |     |
|------------|----|----|----|----|------------|----|----|----|----|--------------|----|----|-----|-----|-----|-----|
|            |    |    |    |    |            |    |    |    |    |              |    |    |     |     |     |     |
| key1key2AB |    |    |    |    | key1key2CD |    |    |    |    | key1key2ABCD |    |    |     |     |     |     |
| 0          | K0 | K0 | A0 | B0 | 0          | K0 | K0 | C0 | D0 | 0            | K0 | K0 | A0  | B0  | C0  | D0  |
| 1          | K0 | K1 | A1 | B1 | 1          | K1 | K0 | C1 | D1 | 1            | K0 | K1 | A1  | B1  | NaN | NaN |
| 2          | K1 | K0 | A2 | B2 | 2          | K1 | K0 | C2 | D2 | 2            | K1 | K0 | A2  | B2  | C1  | D1  |
| 3          | K2 | K1 | A3 | B3 | 3          | K2 | K0 | C3 | D3 | 3            | K1 | K0 | A2  | B2  | C2  | D2  |
|            |    |    |    |    |            |    |    |    |    | 4            | K2 | K1 | A3  | B3  | NaN | NaN |
|            |    |    |    |    |            |    |    |    |    | 5            | K2 | K0 | NaN | NaN | C3  | D3  |

```
In [47]: result = pd.merge(left, right, how='inner', on=['key1', 'key2'])
```

| left |      |      |    |    | right |      |      |    |    | Result |      |      |    |    |    |    |
|------|------|------|----|----|-------|------|------|----|----|--------|------|------|----|----|----|----|
|      | key1 | key2 | A  | B  |       | key1 | key2 | C  | D  |        | key1 | key2 | A  | B  | C  | D  |
| 0    | K0   | K0   | A0 | B0 | 0     | K0   | K0   | C0 | D0 | 0      | K0   | K0   | A0 | B0 | C0 | D0 |
| 1    | K0   | K1   | A1 | B1 | 1     | K1   | K0   | C1 | D1 | 1      | K1   | K0   | A2 | B2 | C1 | D1 |
| 2    | K1   | K0   | A2 | B2 | 2     | K1   | K0   | C2 | D2 | 2      | K1   | K0   | A2 | B2 | C2 | D2 |
| 3    | K2   | K1   | A3 | B3 | 3     | K2   | K0   | C3 | D3 |        |      |      |    |    |    |    |

Here is another example with duplicate join keys in DataFrames:

```
In [48]: left = pd.DataFrame({'A': [1, 2], 'B': [2, 2]})
```

```
In [49]: right = pd.DataFrame({'A': [4, 5, 6], 'B': [2, 2, 2]})
```

```
In [50]: result = pd.merge(left, right, on='B', how='outer')
```

| left |   |   | right |   |   | Result |   |     |   |
|------|---|---|-------|---|---|--------|---|-----|---|
|      | A | B |       | A | B | A_x    | B | A_y |   |
| 0    | 1 | 2 | 0     | 4 | 2 | 0      | 1 | 2   | 4 |
| 1    | 2 | 2 | 1     | 5 | 2 | 1      | 1 | 2   | 5 |
|      |   |   | 2     | 6 | 2 | 2      | 1 | 2   | 6 |
|      |   |   |       |   |   | 3      | 2 | 2   | 4 |
|      |   |   |       |   |   | 4      | 2 | 2   | 5 |
|      |   |   |       |   |   | 5      | 2 | 2   | 6 |

**Warning:** Joining / merging on duplicate keys can cause a returned frame that is the multiplication of the row dimensions, which may result in memory overflow. It is the user's responsibility to manage duplicate values in keys before joining large DataFrames.

## 17.2.2 Checking for duplicate keys

New in version 0.21.0.

Users can use the `validate` argument to automatically check whether there are unexpected duplicates in their merge keys. Key uniqueness is checked before merge operations and so should protect against memory overflows. Checking key uniqueness is also a good way to ensure user data structures are as expected.

In the following example, there are duplicate values of `B` in the right DataFrame. As this is not a one-to-one merge – as specified in the `validate` argument – an exception will be raised.

```
In [51]: left = pd.DataFrame({'A' : [1,2], 'B' : [1, 2]})
```

```
In [52]: right = pd.DataFrame({'A' : [4,5,6], 'B': [2, 2, 2]})
```

```
In [53]: result = pd.merge(left, right, on='B', how='outer', validate="one_to_one")
...
MergeError: Merge keys are not unique in right dataset; not a one-to-one merge
```

If the user is aware of the duplicates in the right DataFrame but wants to ensure there are no duplicates in the left DataFrame, one can use the `validate='one_to_many'` argument instead, which will not raise an exception.

```
In [53]: pd.merge(left, right, on='B', how='outer', validate="one_to_many")
```

```
Out [53]:
 A_x B A_y
0 1 1 NaN
1 2 2 4.0
2 2 2 5.0
3 2 2 6.0
```

## 17.2.3 The merge indicator

`merge()` accepts the argument `indicator`. If `True`, a Categorical-type column called `_merge` will be added to the output object that takes on values:

| Observation Origin              | _merge value |
|---------------------------------|--------------|
| Merge key only in 'left' frame  | left_only    |
| Merge key only in 'right' frame | right_only   |
| Merge key in both frames        | both         |

```
In [54]: df1 = pd.DataFrame({'coll': [0, 1], 'col_left': ['a', 'b']})
In [55]: df2 = pd.DataFrame({'coll': [1, 2, 2], 'col_right': [2, 2, 2]})
In [56]: pd.merge(df1, df2, on='coll', how='outer', indicator=True)
Out[56]:
```

|   | coll | col_left | col_right | _merge     |
|---|------|----------|-----------|------------|
| 0 | 0    | a        | NaN       | left_only  |
| 1 | 1    | b        | 2.0       | both       |
| 2 | 2    | NaN      | 2.0       | right_only |
| 3 | 2    | NaN      | 2.0       | right_only |

The `indicator` argument will also accept string arguments, in which case the indicator function will use the value of the passed string as the name for the indicator column.

```
In [57]: pd.merge(df1, df2, on='coll', how='outer', indicator='indicator_column')
Out[57]:
```

|   | coll | col_left | col_right | indicator_column |
|---|------|----------|-----------|------------------|
| 0 | 0    | a        | NaN       | left_only        |
| 1 | 1    | b        | 2.0       | both             |
| 2 | 2    | NaN      | 2.0       | right_only       |
| 3 | 2    | NaN      | 2.0       | right_only       |

## 17.2.4 Merge Dtypes

New in version 0.19.0.

Merging will preserve the dtype of the join keys.

```
In [58]: left = pd.DataFrame({'key': [1], 'v1': [10]})
In [59]: left
Out[59]:
```

|   | key | v1 |
|---|-----|----|
| 0 | 1   | 10 |

```
In [60]: right = pd.DataFrame({'key': [1, 2], 'v1': [20, 30]})
In [61]: right
Out[61]:
```

|   | key | v1 |
|---|-----|----|
| 0 | 1   | 20 |
| 1 | 2   | 30 |

We are able to preserve the join keys:

```
In [62]: pd.merge(left, right, how='outer')
Out[62]:
```

|  | key | v1 |
|--|-----|----|
|--|-----|----|

(continues on next page)

(continued from previous page)

```

0 1 10
1 1 20
2 2 30

In [63]: pd.merge(left, right, how='outer').dtypes
Out [63]:
key int64
v1 int64
dtype: object

```

Of course if you have missing values that are introduced, then the resulting dtype will be upcast.

```

In [64]: pd.merge(left, right, how='outer', on='key')
Out [64]:
 key v1_x v1_y
0 1 10.0 20
1 2 NaN 30

In [65]: pd.merge(left, right, how='outer', on='key').dtypes
Out [65]:
key int64
v1_x float64
v1_y int64
dtype: object

```

New in version 0.20.0.

Merging will preserve category dtypes of the mergands. See also the section on *categoricals*.

The left frame.

```

In [66]: from pandas.api.types import CategoricalDtype

In [67]: X = pd.Series(np.random.choice(['foo', 'bar'], size=(10,)))

In [68]: X = X.astype(CategoricalDtype(categories=['foo', 'bar']))

In [69]: left = pd.DataFrame({'X': X,
.....: 'Y': np.random.choice(['one', 'two', 'three'],
.....: size=(10,))})
.....:

In [70]: left
Out [70]:
 X Y
0 foo one
1 foo three
2 foo one
3 bar one
4 foo two
5 foo one
6 foo three
7 bar two
8 bar three
9 foo three

In [71]: left.dtypes

```

(continues on next page)

(continued from previous page)

```

////////////////////////////////////
↪
X category
Y object
dtype: object

```

The right frame.

```

In [72]: right = pd.DataFrame({'X': pd.Series(['foo', 'bar'],
.....: dtype=CategoricalDtype(['foo', 'bar'])),
.....: 'Z': [1, 2]})
.....:

In [73]: right
Out[73]:
 X Z
0 foo 1
1 bar 2

In [74]: right.dtypes
Out[74]:
X category
Z int64
dtype: object

```

The merged result:

```

In [75]: result = pd.merge(left, right, how='outer')

In [76]: result
Out[76]:
 X Y Z
0 foo one 1
1 foo three 1
2 foo one 1
3 foo two 1
4 foo one 1
5 foo three 1
6 foo three 1
7 bar one 2
8 bar two 2
9 bar three 2

In [77]: result.dtypes
Out[77]:
X category
Y object
Z int64
dtype: object

```

**Note:** The category dtypes must be *exactly* the same, meaning the same categories and the ordered attribute. Otherwise the result will coerce to `object` dtype.

**Note:** Merging on category dtypes that are the same can be quite performant compared to object dtype merging.

## 17.2.5 Joining on index

`DataFrame.join()` is a convenient method for combining the columns of two potentially differently-indexed DataFrames into a single result DataFrame. Here is a very basic example:

```
In [78]: left = pd.DataFrame({'A': ['A0', 'A1', 'A2'],
.....: 'B': ['B0', 'B1', 'B2']},
.....: index=['K0', 'K1', 'K2'])
.....:

In [79]: right = pd.DataFrame({'C': ['C0', 'C2', 'C3'],
.....: 'D': ['D0', 'D2', 'D3']},
.....: index=['K0', 'K2', 'K3'])
.....:

In [80]: result = left.join(right)
```

| left |    |    | right |    |    | Result |    |    |     |     |
|------|----|----|-------|----|----|--------|----|----|-----|-----|
|      | A  | B  |       | C  | D  |        | A  | B  | C   | D   |
| K0   | A0 | B0 | K0    | C0 | D0 | K0     | A0 | B0 | C0  | D0  |
| K1   | A1 | B1 | K2    | C2 | D2 | K1     | A1 | B1 | NaN | NaN |
| K2   | A2 | B2 | K3    | C3 | D3 | K2     | A2 | B2 | C2  | D2  |

```
In [81]: result = left.join(right, how='outer')
```

| left |    |    | right |    |    | Result |     |     |     |     |
|------|----|----|-------|----|----|--------|-----|-----|-----|-----|
|      | A  | B  |       | C  | D  |        | A   | B   | C   | D   |
| K0   | A0 | B0 | K0    | C0 | D0 | K0     | A0  | B0  | C0  | D0  |
| K1   | A1 | B1 | K2    | C2 | D2 | K1     | A1  | B1  | NaN | NaN |
| K2   | A2 | B2 | K3    | C3 | D3 | K2     | A2  | B2  | C2  | D2  |
|      |    |    |       |    |    | K3     | NaN | NaN | C3  | D3  |

The same as above, but with `how='inner'`.

```
In [82]: result = left.join(right, how='inner')
```

| left |    |    | right |    |    | Result |    |    |    |    |
|------|----|----|-------|----|----|--------|----|----|----|----|
|      | A  | B  |       | C  | D  |        | A  | B  | C  | D  |
| K0   | A0 | B0 | K0    | C0 | D0 | K0     | A0 | B0 | C0 | D0 |
| K1   | A1 | B1 | K2    | C2 | D2 |        |    |    |    |    |
| K2   | A2 | B2 | K3    | C3 | D3 | K2     | A2 | B2 | C2 | D2 |

The data alignment here is on the indexes (row labels). This same behavior can be achieved using `merge` plus additional arguments instructing it to use the indexes:

```
In [83]: result = pd.merge(left, right, left_index=True, right_index=True, how='outer')
↪')
```

| left |    |    | right |    |    | Result |     |     |     |     |
|------|----|----|-------|----|----|--------|-----|-----|-----|-----|
|      | A  | B  |       | C  | D  |        | A   | B   | C   | D   |
| K0   | A0 | B0 | K0    | C0 | D0 | K0     | A0  | B0  | C0  | D0  |
| K1   | A1 | B1 | K2    | C2 | D2 | K1     | A1  | B1  | NaN | NaN |
| K2   | A2 | B2 | K3    | C3 | D3 | K2     | A2  | B2  | C2  | D2  |
|      |    |    |       |    |    | K3     | NaN | NaN | C3  | D3  |

```
In [84]: result = pd.merge(left, right, left_index=True, right_index=True, how='inner')
↪');
```

| left |    |    | right |    |    | Result |    |    |    |    |
|------|----|----|-------|----|----|--------|----|----|----|----|
|      | A  | B  |       | C  | D  |        | A  | B  | C  | D  |
| K0   | A0 | B0 | K0    | C0 | D0 | K0     | A0 | B0 | C0 | D0 |
| K1   | A1 | B1 | K2    | C2 | D2 |        |    |    |    |    |
| K2   | A2 | B2 | K3    | C3 | D3 | K2     | A2 | B2 | C2 | D2 |

## 17.2.6 Joining key columns on an index

`join()` takes an optional `on` argument which may be a column or multiple column names, which specifies that the passed `DataFrame` is to be aligned on that column in the `DataFrame`. These two function calls are completely equivalent:

```
left.join(right, on=key_or_keys)
pd.merge(left, right, left_on=key_or_keys, right_index=True,
 how='left', sort=False)
```

Obviously you can choose whichever form you find more convenient. For many-to-one joins (where one of the `DataFrame`'s is already indexed by the join key), using `join` may be more convenient. Here is a simple example:

```
In [85]: left = pd.DataFrame({'A': ['A0', 'A1', 'A2', 'A3'],
.....: 'B': ['B0', 'B1', 'B2', 'B3'],
.....: 'key': ['K0', 'K1', 'K0', 'K1']})
.....:
```

(continues on next page)

(continued from previous page)

```
In [86]: right = pd.DataFrame({'C': ['C0', 'C1'],
.....: 'D': ['D0', 'D1']},
.....: index=['K0', 'K1'])
.....:
```

```
In [87]: result = left.join(right, on='key')
```

| left                                                                                                                                                                                                                                                                              |    |    |     | right |    |   | Result |   |    |    |    |   |    |    |    |   |    |    |    |   |    |    |    |                                                                                                                                           |  |  |  |   |   |    |    |    |    |    |    |                                                                                                                                                                                                                                                                                                                                                                                               |  |  |  |  |  |  |   |   |     |   |   |   |    |    |    |    |    |   |    |    |    |    |    |   |    |    |    |    |    |   |    |    |    |    |    |
|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|----|----|-----|-------|----|---|--------|---|----|----|----|---|----|----|----|---|----|----|----|---|----|----|----|-------------------------------------------------------------------------------------------------------------------------------------------|--|--|--|---|---|----|----|----|----|----|----|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|--|--|--|--|--|--|---|---|-----|---|---|---|----|----|----|----|----|---|----|----|----|----|----|---|----|----|----|----|----|---|----|----|----|----|----|

| 1                                                                                                                                                                                                                                                                                 | A1 | B1 | K1  | C1    | D1 |   |        |   |    |    |    |   |    |    |    |   |    |    |    |   |    |    |    |                                                                                                                                           |  |  |  |   |   |    |    |    |    |    |    |                                                                                                                                                                                                                                                                                                                                                                                               |  |  |  |  |  |  |   |   |     |   |   |   |    |    |    |    |    |   |    |    |    |    |    |   |    |    |    |    |    |   |    |    |    |    |    |
| 2                                                                                                                                                                                                                                                                                 | A2 | B2 | K0  | C0    | D0 |   |        |   |    |    |    |   |    |    |    |   |    |    |    |   |    |    |    |                                                                                                                                           |  |  |  |   |   |    |    |    |    |    |    |                                                                                                                                                                                                                                                                                                                                                                                               |  |  |  |  |  |  |   |   |     |   |   |   |    |    |    |    |    |   |    |    |    |    |    |   |    |    |    |    |    |   |    |    |    |    |    |
| 3                                                                                                                                                                                                                                                                                 | A3 | B3 | K1  | C1    | D1 |   |        |   |    |    |    |   |    |    |    |   |    |    |    |   |    |    |    |                                                                                                                                           |  |  |  |   |   |    |    |    |    |    |    |                                                                                                                                                                                                                                                                                                                                                                                               |  |  |  |  |  |  |   |   |     |   |   |   |    |    |    |    |    |   |    |    |    |    |    |   |    |    |    |    |    |   |    |    |    |    |    |

the passed DataFrame must have a MultiIndex:

To join on multiple keys,

```
In [89]: left = pd.DataFrame({'A': ['A0', 'A1', 'A2', 'A3'],
.....: 'B': ['B0', 'B1', 'B2', 'B3'],
.....: 'key1': ['K0', 'K0', 'K1', 'K2'],
.....: 'key2': ['K0', 'K1', 'K0', 'K1']})
.....:

In [90]: index = pd.MultiIndex.from_tuples([('K0', 'K0'), ('K1', 'K0'),
.....: ('K2', 'K0'), ('K2', 'K1')])
.....:

In [91]: right = pd.DataFrame({'C': ['C0', 'C1', 'C2', 'C3'],
.....: 'D': ['D0', 'D1', 'D2', 'D3']},
.....: index=index)
.....:
```

Now this can be joined by passing the two key column names:

```
In [92]: result = left.join(right, on=['key1', 'key2'])
```

| left |    |    |      | right |    |    |    | Result |   |    |    |      |      |     |     |
|------|----|----|------|-------|----|----|----|--------|---|----|----|------|------|-----|-----|
|      | A  | B  | key1 | key2  |    |    | C  | D      |   | A  | B  | key1 | key2 | C   | D   |
| 0    | A0 | B0 | K0   | K0    | K0 | K0 | C0 | D0     | 0 | A0 | B0 | K0   | K0   | C0  | D0  |
| 1    | A1 | B1 | K0   | K1    | K1 | K0 | C1 | D1     | 1 | A1 | B1 | K0   | K1   | NaN | NaN |
| 2    | A2 | B2 | K1   | K0    | K2 | K0 | C2 | D2     | 2 | A2 | B2 | K1   | K0   | C1  | D1  |
| 3    | A3 | B3 | K2   | K1    | K2 | K1 | C3 | D3     | 3 | A3 | B3 | K2   | K1   | C3  | D3  |

The default for `DataFrame.join` is to perform a left join (essentially a “VLOOKUP” operation, for Excel users), which uses only the keys found in the calling `DataFrame`. Other join types, for example inner join, can be just as easily performed:

```
In [93]: result = left.join(right, on=['key1', 'key2'], how='inner')
```

| left |    |    |      |      | right |    |    |    | Result |    |    |      |      |    |    |
|------|----|----|------|------|-------|----|----|----|--------|----|----|------|------|----|----|
|      | A  | B  | key1 | key2 |       |    | C  | D  |        | A  | B  | key1 | key2 | C  | D  |
| 0    | A0 | B0 | K0   | K0   | K0    | K0 | C0 | D0 | 0      | A0 | B0 | K0   | K0   | C0 | D0 |
| 1    | A1 | B1 | K0   | K1   | K1    | K0 | C1 | D1 |        |    |    |      |      |    |    |
| 2    | A2 | B2 | K1   | K0   | K2    | K0 | C2 | D2 | 2      | A2 | B2 | K1   | K0   | C1 | D1 |
| 3    | A3 | B3 | K2   | K1   | K2    | K1 | C3 | D3 | 3      | A3 | B3 | K2   | K1   | C3 | D3 |

As you can see, this drops any rows where there was no match.

### 17.2.7 Joining a single Index to a MultiIndex

You can join a singly-indexed `DataFrame` with a level of a `MultiIndexed DataFrame`. The level will match on the name of the index of the singly-indexed frame against a level name of the `MultiIndexed` frame.

```
In [94]: left = pd.DataFrame({'A': ['A0', 'A1', 'A2'],
.....: 'B': ['B0', 'B1', 'B2']},
.....: index=pd.Index(['K0', 'K1', 'K2'], name='key'))
.....:

In [95]: index = pd.MultiIndex.from_tuples([('K0', 'Y0'), ('K1', 'Y1'),
.....: ('K2', 'Y2'), ('K2', 'Y3')],
.....: names=['key', 'Y'])
.....:

In [96]: right = pd.DataFrame({'C': ['C0', 'C1', 'C2', 'C3'],
.....: 'D': ['D0', 'D1', 'D2', 'D3']},
.....: index=index)
.....:

In [97]: result = left.join(right, how='inner')
```

| left |    |    | right |    |    |    | Result |    |    |    |    |    |
|------|----|----|-------|----|----|----|--------|----|----|----|----|----|
|      | A  | B  |       |    | C  | D  |        |    | A  | B  | C  | D  |
| K0   | A0 | B0 | K0    | Y0 | C0 | D0 | K0     | Y0 | A0 | B0 | C0 | D0 |
| K1   | A1 | B1 | K1    | Y1 | C1 | D1 | K1     | Y1 | A1 | B1 | C1 | D1 |
| K2   | A2 | B2 | K2    | Y2 | C2 | D2 | K2     | Y2 | A2 | B2 | C2 | D2 |
|      |    |    | K2    | Y3 | C3 | D3 | K2     | Y3 | A2 | B2 | C3 | D3 |

This is equivalent but less verbose and more memory efficient / faster than this.

```
In [98]: result = pd.merge(left.reset_index(), right.reset_index(),
.....: on=['key'], how='inner').set_index(['key', 'Y'])
.....:
```

| left |    |    | right |    |    |    | Result |    |    |    |    |    |
|------|----|----|-------|----|----|----|--------|----|----|----|----|----|
|      | A  | B  |       |    | C  | D  |        |    | A  | B  | C  | D  |
| K0   | A0 | B0 | K0    | Y0 | C0 | D0 | K0     | Y0 | A0 | B0 | C0 | D0 |
| K1   | A1 | B1 | K1    | Y1 | C1 | D1 | K1     | Y1 | A1 | B1 | C1 | D1 |
| K2   | A2 | B2 | K2    | Y2 | C2 | D2 | K2     | Y2 | A2 | B2 | C2 | D2 |
|      |    |    | K2    | Y3 | C3 | D3 | K2     | Y3 | A2 | B2 | C3 | D3 |

## 17.2.8 Joining with two MultiIndexes

This is supported in a limited way, provided that the index for the right argument is completely used in the join, and is a subset of the indices in the left argument, as in this example:

```
In [99]: leftindex = pd.MultiIndex.from_product([list('abc'), list('xy'), [1, 2]],
.....: names=['abc', 'xy', 'num'])
.....:

In [100]: left = pd.DataFrame({'v1': range(12)}, index=leftindex)

In [101]: left
Out[101]:
 v1
abc xy num
a x 1 0
 2 1
 y 1 2
 2 3
b x 1 4
 2 5
 y 1 6
 2 7
c x 1 8
 2 9
 y 1 10
 2 11

In [102]: rightindex = pd.MultiIndex.from_product([list('abc'), list('xy')],
```

(continues on next page)

```

.....: names=['abc', 'xy'])
.....:
In [103]: right = pd.DataFrame({'v2': [100 * i for i in range(1, 7)]},
→index=rightindex)

```

```
In [104]: right
```

Out [104]:

a    x    100

y 200

|   |   |     |
|---|---|-----|
| b | x | 300 |
|---|---|-----|

|   |     |
|---|-----|
| y | 400 |
|---|-----|

|   |   |     |
|---|---|-----|
| C | x | 500 |
|---|---|-----|

y 600

```
In [105]: left.join(right, on=['abc', 'xy'], how='inner')
```

|    | v1       | v2       |

|---|----|-----|
| 2 | 11 | 600 |
|---|----|-----|

If that condition is not satisfied, a join with two multi-indexes can be done using the following code.

```
In [106]: leftindex = pd.MultiIndex.from_tuples([('K0', 'X0'), ('K0', 'X1'),
.....: ('K1', 'X2')],
.....: names=['key', 'X'])
```

```
In [107]: left = pd.DataFrame({'A': ['A0', 'A1', 'A2'],
.....: 'B': ['B0', 'B1', 'B2']},
.....: index=leftindex)
.....:
```

```
In [108]: rightindex = pd.MultiIndex.from_tuples([('K0', 'Y0'), ('K1', 'Y1'),
.....: ('K2', 'Y2'), ('K2', 'Y3')],
.....: names=['key', 'Y'])
```

```
In [109]: right = pd.DataFrame({'C': ['C0', 'C1', 'C2', 'C3'],
.....: 'D': ['D0', 'D1', 'D2', 'D3']},
.....: index=rightindex)
.....:
```

(continues on next page)

(continued from previous page)

```
In [110]: result = pd.merge(left.reset_index(), right.reset_index(),
.....: on='key', how='inner').set_index(['key', 'X', 'Y'])
.....:
```

| left |    |    |    | right |    |    |    | Result |    |    |    |    |    |    |
|------|----|----|----|-------|----|----|----|--------|----|----|----|----|----|----|
|      |    | A  | B  |       |    | C  | D  |        |    | A  | B  | C  | D  |    |

| K0   | X1 | A1 | B1 | K1    | Y1 | C1 | D1 | K0     | X1 | Y0 | A1 | B1 | C0 | D0 |
| K1   | X2 | A2 | B2 | K2    | Y2 | C2 | D2 | K1     | X2 | Y1 | A2 | B2 | C1 | D1 |
|      |    |    |    | K2    | Y3 | C3 | D3 |        |    |    |    |    |    |    |

## 17.2.9 Merging on a combination of columns and index levels

New in version 0.23.

Strings passed as the `on`, `left_on`, and `right_on` parameters may refer to either column names or index level names. This enables merging DataFrame instances on a combination of index levels and columns without resetting indexes.

```
In [111]: left_index = pd.Index(['K0', 'K0', 'K1', 'K2'], name='key1')
In [112]: left = pd.DataFrame({'A': ['A0', 'A1', 'A2', 'A3'],
.....: 'B': ['B0', 'B1', 'B2', 'B3'],
.....: 'key2': ['K0', 'K1', 'K0', 'K1']},
.....: index=left_index)
.....:
In [113]: right_index = pd.Index(['K0', 'K1', 'K2', 'K2'], name='key1')
In [114]: right = pd.DataFrame({'C': ['C0', 'C1', 'C2', 'C3'],
.....: 'D': ['D0', 'D1', 'D2', 'D3'],
.....: 'key2': ['K0', 'K0', 'K0', 'K1']},
.....: index=right_index)
.....:
In [115]: result = left.merge(right, on=['key1', 'key2'])
```

| left |    |    |      | right |    |    | Result |    |    |      |    |    |
|------|----|----|------|-------|----|----|--------|----|----|------|----|----|
|      | A  | B  | key2 |       | C  | D  |        | A  | B  | key2 | C  | D  |
| K0   | A0 | B0 | K0   | K0    | C0 | D0 | K0     | A0 | B0 | K0   | C0 | D0 |
| K0   | A1 | B1 | K1   | K1    | C1 | D1 | K0     |    |    |      |    |    |
| K1   | A2 | B2 | K0   | K2    | C2 | D2 | K0     | A2 | B2 | K0   | C1 | D1 |
| K2   | A3 | B3 | K1   | K2    | C3 | D3 | K1     | A3 | B3 | K1   | C3 | D3 |

**Note:** When DataFrames are merged on a string that matches an index level in both frames, the index level is

preserved as an index level in the resulting DataFrame.

**Note:** When DataFrames are merged using only some of the levels of a *MultiIndex*, the extra levels will be dropped from the resulting merge. In order to preserve those levels, use `reset_index` on those level names to move those levels to columns prior to doing the merge.

**Note:** If a string matches both a column name and an index level name, then a warning is issued and the column takes precedence. This will result in an ambiguity error in a future version.

### 17.2.10 Overlapping value columns

The merge `suffixes` argument takes a tuple of list of strings to append to overlapping column names in the input DataFrames to disambiguate the result columns:

```
In [116]: left = pd.DataFrame({'k': ['K0', 'K1', 'K2'], 'v': [1, 2, 3]})
In [117]: right = pd.DataFrame({'k': ['K0', 'K0', 'K3'], 'v': [4, 5, 6]})
In [118]: result = pd.merge(left, right, on='k')
```

| left |    |   | right |    |   | Result |    |     |     |
|------|----|---|-------|----|---|--------|----|-----|-----|
|      | k  | v |       | k  | v |        | k  | v_x | v_y |
| 0    | K0 | 1 | 0     | K0 | 4 | 0      | K0 | 1   | 4   |
| 1    | K1 | 2 | 1     | K0 | 5 | 1      | K0 | 1   | 5   |
| 2    | K2 | 3 | 2     | K3 | 6 |        |    |     |     |

```
In [119]: result = pd.merge(left, right, on='k', suffixes=['_l', '_r'])
```

| left |    |   | right |    |   | Result |    |     |     |
|------|----|---|-------|----|---|--------|----|-----|-----|
|      | k  | v |       | k  | v |        | k  | v_l | v_r |
| 0    | K0 | 1 | 0     | K0 | 4 | 0      | K0 | 1   | 4   |
| 1    | K1 | 2 | 1     | K0 | 5 | 1      | K0 | 1   | 5   |
| 2    | K2 | 3 | 2     | K3 | 6 |        |    |     |     |

`DataFrame.join()` has `lsuffix` and `rsuffix` arguments which behave similarly.

```
In [120]: left = left.set_index('k')
In [121]: right = right.set_index('k')
In [122]: result = left.join(right, lsuffix='_l', rsuffix='_r')
```

| left |   | right |   | Result |     |     |
|------|---|-------|---|--------|-----|-----|
|      | v |       | v |        | v_l | v_r |
| K0   | 1 | K0    | 4 | K0     | 1   | 4.0 |
| K1   | 2 | K0    | 5 | K0     | 1   | 5.0 |
| K2   | 3 | K3    | 6 | K1     | 2   | NaN |
|      |   |       |   | K2     | 3   | NaN |

### 17.2.11 Joining multiple DataFrame or Panel objects

A list or tuple of DataFrames can also be passed to `join()` to join them together on their indexes.

```
In [123]: right2 = pd.DataFrame({'v': [7, 8, 9]}, index=['K1', 'K1', 'K2'])
```

```
In [124]: result = left.join([right, right2])
```

| left |   | right |   | right2 |   | Result |     |     |     |
|------|---|-------|---|--------|---|--------|-----|-----|-----|
|      | v |       | v |        | v |        | v_x | v_y | v   |
| K0   | 1 | K0    | 4 | K1     | 7 | K0     | 1   | 4.0 | NaN |
| K1   | 2 | K0    | 5 | K1     | 8 | K0     | 1   | 5.0 | NaN |
| K2   | 3 | K3    | 6 | K2     | 9 | K1     | 2   | NaN | 7.0 |
|      |   |       |   |        |   | K1     | 2   | NaN | 8.0 |
|      |   |       |   |        |   | K2     | 3   | NaN | 9.0 |

### 17.2.12 Merging together values within Series or DataFrame columns

Another fairly common situation is to have two like-indexed (or similarly indexed) Series or DataFrame objects and wanting to “patch” values in one object from values for matching indices in the other. Here is an example:

```
In [125]: df1 = pd.DataFrame([[np.nan, 3., 5.], [-4.6, np.nan, np.nan],
.....: [np.nan, 7., np.nan]])
```

```
In [126]: df2 = pd.DataFrame([[-42.6, np.nan, -8.2], [-5., 1.6, 4]],
.....: index=[1, 2])
```

For this, use the `combine_first()` method:

```
In [127]: result = df1.combine_first(df2)
```

| df1 |      |     |     | df2 |       |     |      | Result |      |     |      |
|-----|------|-----|-----|-----|-------|-----|------|--------|------|-----|------|
|     | 0    | 1   | 2   |     | 0     | 1   | 2    |        | 0    | 1   | 2    |
| 0   | NaN  | 3.0 | 5.0 | 1   | -42.6 | NaN | -8.2 | 0      | NaN  | 3.0 | 5.0  |
| 1   | -4.6 | NaN | NaN | 2   | -5.0  | 1.6 | 4.0  | 1      | -4.6 | NaN | -8.2 |
| 2   | NaN  | 7.0 | NaN |     |       |     |      | 2      | -5.0 | 7.0 | 4.0  |

Note that this method only takes values from the right DataFrame if they are missing in the left DataFrame. A related method, `update()`, alters non-NA values in place:

```
In [128]: df1.update(df2)
```

| df1 |      |     |     | df2 |       |     |      | Result |       |     |      |
|-----|------|-----|-----|-----|-------|-----|------|--------|-------|-----|------|
|     | 0    | 1   | 2   |     | 0     | 1   | 2    |        | 0     | 1   | 2    |
| 0   | NaN  | 3.0 | 5.0 | 1   | -42.6 | NaN | -8.2 | 0      | NaN   | 3.0 | 5.0  |
| 1   | -4.6 | NaN | NaN | 2   | -5.0  | 1.6 | 4.0  | 1      | -42.6 | NaN | -8.2 |
| 2   | NaN  | 7.0 | NaN |     |       |     |      | 2      | -5.0  | 1.6 | 4.0  |

## 17.3 Timeseries friendly merging

### 17.3.1 Merging Ordered Data

A `merge_ordered()` function allows combining time series and other ordered data. In particular it has an optional `fill_method` keyword to fill/interpolate missing data:

```
In [129]: left = pd.DataFrame({'k': ['K0', 'K1', 'K1', 'K2'],
.....: 'lv': [1, 2, 3, 4],
.....: 's': ['a', 'b', 'c', 'd']})
.....:

In [130]: right = pd.DataFrame({'k': ['K1', 'K2', 'K4'],
.....: 'rv': [1, 2, 3]})
.....:

In [131]: pd.merge_ordered(left, right, fill_method='ffill', left_by='s')
Out[131]:
 k lv s rv
0 K0 1.0 a NaN
1 K1 1.0 a 1.0
2 K2 1.0 a 2.0
3 K4 1.0 a 3.0
4 K1 2.0 b 1.0
5 K2 2.0 b 2.0
6 K4 2.0 b 3.0
7 K1 3.0 c 1.0
8 K2 3.0 c 2.0
9 K4 3.0 c 3.0
10 K1 NaN d 1.0
11 K2 4.0 d 2.0
12 K4 4.0 d 3.0
```

## 17.3.2 Merging AsOf

New in version 0.19.0.

A `merge_asof()` is similar to an ordered left-join except that we match on nearest key rather than equal keys. For each row in the left DataFrame, we select the last row in the right DataFrame whose on key is less than the left's key. Both DataFrames must be sorted by the key.

Optionally an asof merge can perform a group-wise merge. This matches the `by` key equally, in addition to the nearest match on the `on` key.

For example; we might have `trades` and `quotes` and we want to asof merge them.

```
In [132]: trades = pd.DataFrame({
.....: 'time': pd.to_datetime(['20160525 13:30:00.023',
.....: '20160525 13:30:00.038',
.....: '20160525 13:30:00.048',

| 7 | 2016-05-25 13:30:00.075 | MSFT   | 52.01  | 52.03  |

By default we are taking the asof of the quotes.

```
In [136]: pd.merge_asof(trades, quotes,
.....: on='time',
.....: by='ticker')
.....:
```

Out [136]:

|   | time                    | ticker | price  | quantity | bid    | ask    |
|---|-------------------------|--------|--------|----------|--------|--------|
| 0 | 2016-05-25 13:30:00.023 | MSFT   | 51.95  | 75       | 51.95  | 51.96  |
| 1 | 2016-05-25 13:30:00.038 | MSFT   | 51.95  | 155      | 51.97  | 51.98  |
| 2 | 2016-05-25 13:30:00.048 | GOOG   | 720.77 | 100      | 720.50 | 720.93 |
| 3 | 2016-05-25 13:30:00.048 | GOOG   | 720.92 | 100      | 720.50 | 720.93 |
| 4 | 2016-05-25 13:30:00.048 | AAPL   | 98.00  | 100      | NaN    | NaN    |

We only asof within 2ms between the quote time and the trade time.

```
In [137]: pd.merge_asof(trades, quotes,
.....: on='time',
.....: by='ticker',
.....: tolerance=pd.Timedelta('2ms'))
.....:
```

Out [137]:

|   | time                    | ticker | price  | quantity | bid    | ask    |
|---|-------------------------|--------|--------|----------|--------|--------|
| 0 | 2016-05-25 13:30:00.023 | MSFT   | 51.95  | 75       | 51.95  | 51.96  |
| 1 | 2016-05-25 13:30:00.038 | MSFT   | 51.95  | 155      | NaN    | NaN    |
| 2 | 2016-05-25 13:30:00.048 | GOOG   | 720.77 | 100      | 720.50 | 720.93 |
| 3 | 2016-05-25 13:30:00.048 | GOOG   | 720.92 | 100      | 720.50 | 720.93 |
| 4 | 2016-05-25 13:30:00.048 | AAPL   | 98.00  | 100      | NaN    | NaN    |

We only asof within 10ms between the quote time and the trade time and we exclude exact matches on time. Note that though we exclude the exact matches (of the quotes), prior quotes **do** propagate to that point in time.

```
In [138]: pd.merge_asof(trades, quotes,
.....: on='time',
.....: by='ticker',
.....: tolerance=pd.Timedelta('10ms'),
.....: allow_exact_matches=False)
.....:
```

Out [138]:

|   | time                    | ticker | price  | quantity | bid   | ask   |
|---|-------------------------|--------|--------|----------|-------|-------|
| 0 | 2016-05-25 13:30:00.023 | MSFT   | 51.95  | 75       | NaN   | NaN   |
| 1 | 2016-05-25 13:30:00.038 | MSFT   | 51.95  | 155      | 51.97 | 51.98 |
| 2 | 2016-05-25 13:30:00.048 | GOOG   | 720.77 | 100      | NaN   | NaN   |
| 3 | 2016-05-25 13:30:00.048 | GOOG   | 720.92 | 100      | NaN   | NaN   |
| 4 | 2016-05-25 13:30:00.048 | AAPL   | 98.00  | 100      | NaN   | NaN   |

## RESHAPING AND PIVOT TABLES

### 18.1 Reshaping by pivoting DataFrame objects

# Pivot

Data is often stored in so-called “stacked” or “record” format:

```
In [1]: df
Out[1]:
```

|   | date       | variable | value     |
|---|------------|----------|-----------|
| 0 | 2000-01-03 | A        | -0.494734 |
| 1 | 2000-01-04 | A        | 0.133468  |

(continues on next page)

(continued from previous page)

```

2 2000-01-05 A 1.823068
3 2000-01-03 B -1.036726
4 2000-01-04 B -0.821608
5 2000-01-05 B 1.747339
6 2000-01-03 C -0.259191
7 2000-01-04 C 0.888706
8 2000-01-05 C 0.029082
9 2000-01-03 D -2.466061
10 2000-01-04 D 2.161473
11 2000-01-05 D -0.223723

```

For the curious here is how the above DataFrame was created:

```

import pandas.util.testing as tm

tm.N = 3

def unpivot(frame):
 N, K = frame.shape
 data = {'value': frame.to_numpy().ravel('F'),
 'variable': np.asarray(frame.columns).repeat(N),
 'date': np.tile(np.asarray(frame.index), K)}
 return pd.DataFrame(data, columns=['date', 'variable', 'value'])

df = unpivot(tm.makeTimeDataFrame())

```

To select out everything for variable A we could do:

```

In [2]: df[df['variable'] == 'A']
Out[2]:
 date variable value
0 2000-01-03 A -0.494734
1 2000-01-04 A 0.133468
2 2000-01-05 A 1.823068

```

But suppose we wish to do time series operations with the variables. A better representation would be where the columns are the unique variables and an index of dates identifies individual observations. To reshape the data into this form, we use the `DataFrame.pivot()` method (also implemented as a top level function `pivot()`):

```

In [3]: df.pivot(index='date', columns='variable', values='value')
Out[3]:
variable A B C D
date
2000-01-03 -0.494734 -1.036726 -0.259191 -2.466061
2000-01-04 0.133468 -0.821608 0.888706 2.161473
2000-01-05 1.823068 1.747339 0.029082 -0.223723

```

If the `values` argument is omitted, and the input DataFrame has more than one column of values which are not used as column or index inputs to `pivot`, then the resulting “pivoted” DataFrame will have *hierarchical columns* whose topmost level indicates the respective value column:

```

In [4]: df['value2'] = df['value'] * 2

In [5]: pivoted = df.pivot(index='date', columns='variable')

```

(continues on next page)

(continued from previous page)

```
In [6]: pivoted
Out [6]:
```

|            | value     |           |           |           | value2    |           |           |           |
|------------|-----------|-----------|-----------|-----------|-----------|-----------|-----------|-----------|
| variable   | A         | B         | C         | D         | A         | B         | C         |           |
| date       |           |           |           |           |           |           |           |           |
| 2000-01-03 | -0.494734 | -1.036726 | -0.259191 | -2.466061 | -0.989467 | -2.073452 | -0.518382 | -4.932122 |
| 2000-01-04 | 0.133468  | -0.821608 | 0.888706  | 2.161473  | 0.266936  | -1.643215 | 1.777411  | 4.322947  |
| 2000-01-05 | 1.823068  | 1.747339  | 0.029082  | -0.223723 | 3.646136  | 3.494679  | 0.058164  | -0.447445 |

You can then select subsets from the pivoted DataFrame:

```
In [7]: pivoted['value2']
Out [7]:
```

| variable   | A         | B         | C         | D         |
|------------|-----------|-----------|-----------|-----------|
| date       |           |           |           |           |
| 2000-01-03 | -0.989467 | -2.073452 | -0.518382 | -4.932122 |
| 2000-01-04 | 0.266936  | -1.643215 | 1.777411  | 4.322947  |
| 2000-01-05 | 3.646136  | 3.494679  | 0.058164  | -0.447445 |

Note that this returns a view on the underlying data in the case where the data are homogeneously-typed.

**Note:** `pivot()` will error with a `ValueError: Index contains duplicate entries, cannot reshape if the index/column pair is not unique`. In this case, consider using `pivot_table()` which is a generalization of `pivot` that can handle duplicate values for one index/column pair.

## 18.2 Reshaping by stacking and unstacking

# Stack

Closely related to the `pivot()` method are the related `stack()` and `unstack()` methods available on `Series` and `DataFrame`. These methods are designed to work together with `MultiIndex` objects (see the section on *hierarchical indexing*). Here are essentially what these methods do:

- `stack`: “pivot” a level of the (possibly hierarchical) column labels, returning a `DataFrame` with an index with a new inner-most level of row labels.
- `unstack`: (inverse operation of `stack`) “pivot” a level of the (possibly hierarchical) row index to the column axis, producing a reshaped `DataFrame` with a new inner-most level of column labels.

# Unstack

The clearest way to explain is by example. Let's take a prior example data set from the hierarchical indexing section:

```
In [8]: tuples = list(zip(*(['bar', 'bar', 'baz', 'baz',
...: 'foo', 'foo', 'qux', 'qux'],
...: ['one', 'two', 'one', 'two',
...: 'one', 'two', 'one', 'two'])))
...:
In [9]: index = pd.MultiIndex.from_tuples(tuples, names=['first', 'second'])
In [10]: df = pd.DataFrame(np.random.randn(8, 2), index=index, columns=['A', 'B'])
In [11]: df2 = df[:4]
In [12]: df2
Out[12]:
```

|       |        | A         | B         |
|-------|--------|-----------|-----------|
| first | second |           |           |
| bar   | one    | -0.266261 | 1.185342  |
|       | two    | -1.406596 | -0.485618 |

(continues on next page)

(continued from previous page)

|     |     |          |           |
|-----|-----|----------|-----------|
| baz | one | 1.137925 | -0.119747 |
|     | two | 0.965647 | 0.853345  |

The `stack` function “compresses” a level in the `DataFrame`’s columns to produce either:

- A `Series`, in the case of a simple column `Index`.
- A `DataFrame`, in the case of a `MultiIndex` in the columns.

If the columns have a `MultiIndex`, you can choose which level to stack. The stacked level becomes the new lowest level in a `MultiIndex` on the columns:

```
In [13]: stacked = df2.stack()
```

```
In [14]: stacked
```

Out [14]:

| first | second |   |           |
|-------|--------|---|-----------|
| bar   | one    | A | -0.266261 |
|       |        | B | 1.185342  |
|       | two    | A | -1.406596 |
|       |        | B | -0.485618 |
| baz   | one    | A | 1.137925  |
|       |        | B | -0.119747 |
|       | two    | A | 0.965647  |
|       |        | B | 0.853345  |

```
dtype: float64
```

With a “stacked” DataFrame or Series (having a MultiIndex as the index), the inverse operation of `stack` is `unstack`, which by default unstacks the **last level**:

```
In [15]: stacked.unstack()
```

Out [15]:

|       |        | A         | B         |
|-------|--------|-----------|-----------|
| first | second |           |           |
| bar   | one    | -0.266261 | 1.185342  |
|       | two    | -1.406596 | -0.485618 |
| baz   | one    | 1.137925  | -0.119747 |
|       | two    | 0.965647  | 0.853345  |

```
In [16]: stacked.unstack(1)
```

```

↪
second one two
first
bar A -0.266261 -1.406596
 B 1.185342 -0.485618
baz A 1.137925 0.965647
 B -0.119747 0.853345

```

```
In [17]: stacked.unstack(0)
```

|     |        |           |           |
|-----|--------|-----------|-----------|
| ↩   | first  | bar       | baz       |
|     | second |           |           |
| one | A      | -0.266261 | 1.137925  |
|     | B      | 1.185342  | -0.119747 |
| two | A      | -1.406596 | 0.965647  |
|     | B      | -0.485618 | 0.853345  |

# Unstack(1)

If the indexes have names, you can use the level names instead of specifying the level numbers:

```
In [18]: stacked.unstack('second')
Out[18]:
second one two
first
bar A -0.266261 -1.406596
 B 1.185342 -0.485618
baz A 1.137925 0.965647
 B -0.119747 0.853345
```

# Unstack(0)

Notice that the `stack` and `unstack` methods implicitly sort the index levels involved. Hence a call to `stack` and then `unstack`, or vice versa, will result in a **sorted** copy of the original DataFrame or Series:

```
In [19]: index = pd.MultiIndex.from_product([[2, 1], ['a', 'b']])
In [20]: df = pd.DataFrame(np.random.randn(4), index=index, columns=['A'])

In [21]: df
Out[21]:
 A
2 a -0.564401
 b -1.235396
1 a 0.203387
 b 0.929991

In [22]: all(df.unstack().stack() == df.sort_index())
Out[22]: True
```

The above code will raise a `TypeError` if the call to `sort_index` is removed.

## 18.2.1 Multiple Levels

You may also stack or unstack more than one level at a time by passing a list of levels, in which case the end result is as if each level in the list were processed individually.

```
In [23]: columns = pd.MultiIndex.from_tuples([
.....: ('A', 'cat', 'long'), ('B', 'cat', 'long'),
.....: ('A', 'dog', 'short'), ('B', 'dog', 'short')],
.....: names=['exp', 'animal', 'hair_length'])
.....:

In [24]: df = pd.DataFrame(np.random.randn(4, 4), columns=columns)

In [25]: df
Out[25]:
```

| exp         | A         |           | B         |           |
|-------------|-----------|-----------|-----------|-----------|
| animal      | cat       | cat       | dog       | dog       |
| hair_length | long      | long      | short     | short     |
| 0           | 0.538890  | 1.514500  | 1.129305  | -2.463576 |
| 1           | 0.043231  | 2.128053  | -0.284454 | -0.310703 |
| 2           | -0.234404 | -0.365981 | -1.319911 | 0.370235  |
| 3           | -0.855109 | 0.260821  | -0.629389 | 0.072991  |

```
In [26]: df.stack(level=['animal', 'hair_length'])
//////////
↪
exp A B
animal hair_length
0 cat long 0.538890 1.514500
 dog short 1.129305 -2.463576
1 cat long 0.043231 2.128053
 dog short -0.284454 -0.310703
2 cat long -0.234404 -0.365981
 dog short -1.319911 0.370235
3 cat long -0.855109 0.260821
 dog short -0.629389 0.072991
```

The list of levels can contain either level names or level numbers (but not a mixture of the two).

```
df.stack(level=['animal', 'hair_length'])
from above is equivalent to:
In [27]: df.stack(level=[1, 2])
Out[27]:
```

| exp    | A           |       | B         |           |
|--------|-------------|-------|-----------|-----------|
| animal | hair_length |       |           |           |
| 0      | cat         | long  | 0.538890  | 1.514500  |
|        | dog         | short | 1.129305  | -2.463576 |
| 1      | cat         | long  | 0.043231  | 2.128053  |
|        | dog         | short | -0.284454 | -0.310703 |
| 2      | cat         | long  | -0.234404 | -0.365981 |
|        | dog         | short | -1.319911 | 0.370235  |
| 3      | cat         | long  | -0.855109 | 0.260821  |
|        | dog         | short | -0.629389 | 0.072991  |

## 18.2.2 Missing Data

These functions are intelligent about handling missing data and do not expect each subgroup within the hierarchical index to have the same set of labels. They also can handle the index being unsorted (but you can make it sorted by calling `sort_index`, of course). Here is a more complex example:

```
In [28]: columns = pd.MultiIndex.from_tuples([('A', 'cat'), ('B', 'dog'),
.....: ('B', 'cat'), ('A', 'dog')],
.....: names=['exp', 'animal'])

In [29]: index = pd.MultiIndex.from_product([('bar', 'baz', 'foo', 'qux'),
.....: ('one', 'two')],
.....: names=['first', 'second'])

In [30]: df = pd.DataFrame(np.random.randn(8, 4), index=index, columns=columns)

In [31]: df2 = df.iloc[[0, 1, 2, 4, 5, 7]]

In [32]: df2
Out[32]:
exp A B A
animal cat dog cat dog
first second
bar one -0.971685 0.530934 0.215132 0.475668
 two 1.913078 -1.689378 0.285952 0.181144
baz one -1.023210 0.673676 -0.040334 -0.278373
foo one 0.929725 -0.674426 -0.969159 0.685328
 two -0.592525 -1.029536 0.775670 1.489639
qux two -1.142265 -0.563112 -1.075990 -0.356460
```

As mentioned above, `stack` can be called with a `level` argument to select which level in the columns to stack:

```
In [33]: df2.stack('exp')
Out[33]:
animal cat dog
first second exp
bar one A -0.971685 0.475668
 two B 0.215132 0.530934
 two A 1.913078 0.181144
 two B 0.285952 -1.689378
baz one A -1.023210 -0.278373
 one B -0.040334 0.673676
foo one A 0.929725 0.685328
 one B -0.969159 -0.674426
 two A -0.592525 1.489639
 two B 0.775670 -1.029536
qux two A -1.142265 -0.356460
 two B -1.075990 -0.563112

In [34]: df2.stack('animal')
//////////
↪
exp A B
first second animal
bar one cat -0.971685 0.215132
 one dog 0.475668 0.530934
```

(continues on next page)

(continued from previous page)

|     |     |     |           |           |
|-----|-----|-----|-----------|-----------|
|     | two | cat | 1.913078  | 0.285952  |
|     |     | dog | 0.181144  | -1.689378 |
| baz | one | cat | -1.023210 | -0.040334 |
|     |     | dog | -0.278373 | 0.673676  |
| foo | one | cat | 0.929725  | -0.969159 |
|     |     | dog | 0.685328  | -0.674426 |
|     | two | cat | -0.592525 | 0.775670  |
|     |     | dog | 1.489639  | -1.029536 |
| qux | two | cat | -1.142265 | -1.075990 |
|     |     | dog | -0.356460 | -0.563112 |

Unstacking can result in missing values if subgroups do not have the same set of labels. By default, missing values will be replaced with the default fill value for that data type, NaN for float, NaT for datetimelike, etc. For integer types, by default data will be converted to float and missing values will be set to NaN.

```
In [35]: df3 = df.iloc[[0, 1, 4, 7], [1, 2]]
```

```
In [36]: df3
```

```
Out [36]:
```

```
exp B
animal dog cat
first second
bar one 0.530934 0.215132
 two -1.689378 0.285952
foo one -0.674426 -0.969159
qux two -0.563112 -1.075990
```

```
In [37]: df3.unstack()
```

```

////////////////////////////////////
↪
exp B
animal dog cat
second one two one two
first
bar 0.530934 -1.689378 0.215132 0.285952
foo -0.674426 NaN -0.969159 NaN
qux NaN -0.563112 NaN -1.075990
```

New in version 0.18.0.

Alternatively, `unstack` takes an optional `fill_value` argument, for specifying the value of missing data.

```
In [38]: df3.unstack(fill_value=-1e9)
```

```
Out [38]:
```

```
exp B
animal dog cat
second one two one two
first
bar 5.309336e-01 -1.689378e+00 2.151317e-01 2.859519e-01
foo -6.744258e-01 -1.000000e+09 -9.691591e-01 -1.000000e+09
qux -1.000000e+09 -5.631121e-01 -1.000000e+09 -1.075990e+00
```

### 18.2.3 With a MultiIndex

Unstacking when the columns are a `MultiIndex` is also careful about doing the right thing:

```
In [39]: df[:3].unstack(0)
```

```
Out [39]:
```

```
exp A B
animal cat dog
first bar bar baz
second
one -0.971685 -1.02321 0.530934 0.673676 0.215132 -0.040334 0.475668 -0.278373
two 1.913078 NaN -1.689378 NaN 0.285952 NaN 0.181144 NaN
```

```
In [40]: df2.unstack(1)
```

```

////////////////////////////////////
↪
exp A B A
animal cat dog dog
second one two one two
first
bar -0.971685 1.913078 0.530934 -1.689378 0.215132 0.285952 0.475668 0.181144
baz -1.023210 NaN 0.673676 NaN -0.040334 NaN -0.278373 NaN
foo 0.929725 -0.592525 -0.674426 -1.029536 -0.969159 0.775670 0.685328 1.489639
qux NaN -1.142265 NaN -0.563112 NaN -1.075990 NaN -0.356460
```

## 18.3 Reshaping by Melt

# Melt

The top-level `melt()` function and the corresponding `DataFrame.melt()` are useful to massage a `DataFrame` into a format where one or more columns are *identifier variables*, while all other columns, considered *measured variables*, are “unpivoted” to the row axis, leaving just two non-identifier columns, “variable” and “value”. The names of those columns can be customized by supplying the `var_name` and `value_name` parameters.

For instance,

```
In [41]: cheese = pd.DataFrame({'first': ['John', 'Mary'],
.....: 'last': ['Doe', 'Bo'],
.....: 'height': [5.5, 6.0],
.....: 'weight': [130, 150]})
.....:

In [42]: cheese
Out[42]:
```

|   | first | last | height | weight |
|---|-------|------|--------|--------|
| 0 | John  | Doe  | 5.5    | 130    |
| 1 | Mary  | Bo   | 6.0    | 150    |

```

In [43]: cheese.melt(id_vars=['first', 'last'])
Out[43]:
```

|   | first | last | variable | value |
|---|-------|------|----------|-------|
| 0 | John  | Doe  | height   | 5.5   |
| 1 | Mary  | Bo   | height   | 6.0   |
| 2 | John  | Doe  | weight   | 130.0 |
| 3 | Mary  | Bo   | weight   | 150.0 |

```

In [44]: cheese.melt(id_vars=['first', 'last'], var_name='quantity')
Out[44]:
```

|   | first | last | quantity | value |
|---|-------|------|----------|-------|
| 0 | John  | Doe  | height   | 5.5   |
| 1 | Mary  | Bo   | height   | 6.0   |
| 2 | John  | Doe  | weight   | 130.0 |
| 3 | Mary  | Bo   | weight   | 150.0 |

Another way to transform is to use the `wide_to_long()` panel data convenience function. It is less flexible than `melt()`, but more user-friendly.

```
In [45]: dft = pd.DataFrame({'A1970': {0: "a", 1: "b", 2: "c"},
.....: "A1980": {0: "d", 1: "e", 2: "f"},
.....: "B1970": {0: 2.5, 1: 1.2, 2: .7},
.....: "B1980": {0: 3.2, 1: 1.3, 2: .1},
.....: "X": dict(zip(range(3), np.random.randn(3)))
.....: })

In [46]: dft["id"] = dft.index

In [47]: dft
Out[47]:
```

|   | A1970 | A1980 | B1970 | B1980 | X         | id |
|---|-------|-------|-------|-------|-----------|----|
| 0 | a     | d     | 2.5   | 3.2   | -0.440518 | 0  |
| 1 | b     | e     | 1.2   | 1.3   | -0.522015 | 1  |
| 2 | c     | f     | 0.7   | 0.1   | -0.777022 | 2  |

```

In [48]: pd.wide_to_long(dft, ["A", "B"], i="id", j="year")

```

(continues on next page)

(continued from previous page)

```

////////////////////////////////////
↪
 X A B
id year
0 1970 -0.440518 a 2.5
1 1970 -0.522015 b 1.2
2 1970 -0.777022 c 0.7

1 1980 -0.522015 e 1.3
2 1980 -0.777022 f 0.1

```

## 18.4 Combining with stats and GroupBy

It should be no shock that combining `pivot / stack / unstack` with `GroupBy` and the basic `Series` and `DataFrame` statistical functions can produce some very expressive and fast data manipulations.

```

In [49]: df
Out[49]:
exp A B A
animal cat dog cat dog

## 18.5 Pivot tables

While `pivot()` provides general purpose pivoting with various data types (strings, numerics, etc.), pandas also provides `pivot_table()` for pivoting with aggregation of numeric data.

The function `pivot_table()` can be used to create spreadsheet-style pivot tables. See the *cookbook* for some advanced strategies.

It takes a number of arguments:

- `data`: a `DataFrame` object.
- `values`: a column or a list of columns to aggregate.
- `index`: a column, Grouper, array which has the same length as data, or list of them. Keys to group by on the pivot table index. If an array is passed, it is being used as the same manner as column values.
- `columns`: a column, Grouper, array which has the same length as data, or list of them. Keys to group by on the pivot table column. If an array is passed, it is being used as the same manner as column values.
- `aggfunc`: function to use for aggregation, defaulting to `numpy.mean`.

Consider a data set like this:

```
In [54]: import datetime
```

```
In [55]: df = pd.DataFrame({'A': ['one', 'one', 'two', 'three'] * 6,
.....: 'B': ['A', 'B', 'C'] * 8,
.....: 'C': ['foo', 'foo', 'foo', 'bar', 'bar', 'bar'] * 4,
.....: 'D': np.random.randn(24),
.....: 'E': np.random.randn(24),
.....: 'F': [datetime.datetime(2013, i, 1) for i in range(1, 13)]
.....: + [datetime.datetime(2013, i, 15) for i in range(1, 13)]})
.....:
```

```
In [56]: df
```

(continues on next page)

(continued from previous page)

```

Out [56]:
 A B C D E F
0 one A foo 2.031024 0.587067 2013-01-01
1 one B foo -1.930326 1.146514 2013-02-01
2 two C foo 0.559927 0.301133 2013-03-01
3 three A bar -0.334458 -0.756871 2013-04-01
4 one B bar -1.814223 -0.924987 2013-05-01
5 one C bar 0.567246 -1.308765 2013-06-01
6 two A foo -0.050949 -0.067550 2013-07-01
7 three B foo 1.643538 -1.602353 2013-08-01
8 one C foo 0.208607 -0.161546 2013-09-01
9 one A bar 0.473890 -2.408852 2013-10-01
10 two B bar -0.348543 -1.442058 2013-11-01
11 three C bar 0.446942 1.936009 2013-12-01
12 one A foo 0.958559 0.316644 2013-01-15
13 one B foo -0.618469 1.161859 2013-02-15
14 two C foo -1.342978 -0.297691 2013-03-15
15 three A bar 1.452769 -0.634789 2013-04-15
16 one B bar 0.278106 0.348131 2013-05-15
17 one C bar 1.605078 0.746067 2013-06-15
18 two A foo 0.853331 -0.920981 2013-07-15
19 three B foo -0.211112 -0.904811 2013-08-15
20 one C foo -0.616888 -1.011468 2013-09-15
21 one A bar -2.780856 -1.397577 2013-10-15
22 two B bar 0.682771 -0.515555 2013-11-15
23 three C bar -0.678234 -2.299810 2013-12-15

```

We can produce pivot tables from this data very easily:

```

In [57]: pd.pivot_table(df, values='D', index=['A', 'B'], columns=['C'])
Out [57]:
C bar foo
A B
one A -1.153483 1.494791
 B -0.768059 -1.274398
 C 1.086162 -0.204141
three A 0.559156 NaN
 B NaN 0.716213
 C -0.115646 NaN
two A NaN 0.401191
 B 0.167114 NaN
 C NaN -0.391525

In [58]: pd.pivot_table(df, values='D', index=['B'], columns=['A', 'C'], aggfunc=np.
→sum)
→
A one three two
C bar foo bar foo bar foo
B
A -2.306965 2.989583 1.118312 NaN NaN 0.802382
B -1.536118 -2.548796 NaN 1.432426 0.334228 NaN
C 2.172325 -0.408281 -0.231291 NaN NaN -0.783051

In [59]: pd.pivot_table(df, values=['D', 'E'], index=['B'], columns=['A', 'C'],
.....: aggfunc=np.sum)
.....:

```

(continues on next page)

(continued from previous page)

```

////////////////////////////////////
↪
 D E
↪
A one three two one
↪three
C bar foo bar foo bar foo bar foo
↪ bar foo bar foo
B
↪
A -2.306965 2.989583 1.118312 NaN NaN 0.802382 -3.806429 0.903711 -1.
↪391660 NaN NaN -0.988531
B -1.536118 -2.548796 NaN 1.432426 0.334228 NaN -0.576856 2.308373
↪ NaN -2.507164 -1.957613 NaN
C 2.172325 -0.408281 -0.231291 NaN NaN -0.783051 -0.562698 -1.173014 -0.
↪363801 NaN NaN 0.003442

```

The result object is a DataFrame having potentially hierarchical indexes on the rows and columns. If the values column name is not given, the pivot table will include all of the data that can be aggregated in an additional level of hierarchy in the columns:

```

In [60]: pd.pivot_table(df, index=['A', 'B'], columns=['C'])
Out [60]:

```

```

 D E
C bar foo bar foo
A B
one A -1.153483 1.494791 -1.903214 0.451855
 B -0.768059 -1.274398 -0.288428 1.154187
 C 1.086162 -0.204141 -0.281349 -0.586507
three A 0.559156 NaN -0.695830 NaN
 B NaN 0.716213 NaN -1.253582
 C -0.115646 NaN -0.181900 NaN
two A NaN 0.401191 NaN -0.494265
 B 0.167114 NaN -0.978806 NaN
 C NaN -0.391525 NaN 0.001721

```

Also, you can use Grouper for index and columns keywords. For detail of Grouper, see *Grouping with a Grouper specification*.

```

In [61]: pd.pivot_table(df, values='D', index=pd.Grouper(freq='M', key='F'),
.....: columns='C')
.....:

```

```

Out [61]:
C bar foo
F
2013-01-31 NaN 1.494791
2013-02-28 NaN -1.274398
2013-03-31 NaN -0.391525
2013-04-30 0.559156 NaN
2013-05-31 -0.768059 NaN
2013-06-30 1.086162 NaN
2013-07-31 NaN 0.401191
2013-08-31 NaN 0.716213
2013-09-30 NaN -0.204141
2013-10-31 -1.153483 NaN
2013-11-30 0.167114 NaN
2013-12-31 -0.115646 NaN

```

You can render a nice output of the table omitting the missing values by calling `to_string` if you wish:

```
In [62]: table = pd.pivot_table(df, index=['A', 'B'], columns=['C'])
```

```
In [63]: print(table.to_string(na_rep=''))
```

|       |   | D         |           | E         |           |
|-------|---|-----------|-----------|-----------|-----------|
| C     |   | bar       | foo       | bar       | foo       |
| one   | A | -1.153483 | 1.494791  | -1.903214 | 0.451855  |
|       | B | -0.768059 | -1.274398 | -0.288428 | 1.154187  |
|       | C | 1.086162  | -0.204141 | -0.281349 | -0.586507 |
| three | A | 0.559156  |           | -0.695830 |           |
|       | B |           | 0.716213  |           | -1.253582 |
|       | C | -0.115646 |           | -0.181900 |           |
| two   | A |           | 0.401191  |           | -0.494265 |
|       | B | 0.167114  |           | -0.978806 |           |
|       | C |           | -0.391525 |           | 0.001721  |

Note that `pivot_table` is also available as an instance method on `DataFrame`, i.e. `DataFrame.pivot_table()`.

### 18.5.1 Adding margins

If you pass `margins=True` to `pivot_table`, special `All` columns and rows will be added with partial group aggregates across the categories on the rows and columns:

```
In [64]: df.pivot_table(index=['A', 'B'], columns='C', margins=True, aggfunc=np.std)
```

```
Out [64]:
```

|       |   | D        |          |          |          | E        |          |
|-------|---|----------|----------|----------|----------|----------|----------|
| C     |   | bar      | foo      | All      | bar      | foo      | All      |
| one   | A | 2.301453 | 0.758347 | 2.072449 | 0.715080 | 0.191218 | 1.425279 |
|       | B | 1.479500 | 0.927623 | 1.049728 | 0.900230 | 0.010851 | 0.981779 |
|       | C | 0.733858 | 0.583713 | 0.920896 | 1.452986 | 0.600986 | 0.924747 |
| three | A | 1.263761 | NaN      | 1.263761 | 0.086326 | NaN      | 0.086326 |
|       | B | NaN      | 1.311435 | 1.311435 | NaN      | 0.493236 | 0.493236 |
|       | C | 0.795620 | NaN      | 0.795620 | 2.995176 | NaN      | 2.995176 |
| two   | A | NaN      | 0.639422 | 0.639422 | NaN      | 0.603467 | 0.603467 |
|       | B | 0.729249 | NaN      | 0.729249 | 0.655136 | NaN      | 0.655136 |
|       | C | NaN      | 1.345557 | 1.345557 | NaN      | 0.423433 | 0.423433 |
| All   |   | 1.267693 | 1.167231 | 1.169402 | 1.247258 | 0.873904 | 1.073866 |

## 18.6 Cross tabulations

Use `crosstab()` to compute a cross-tabulation of two (or more) factors. By default `crosstab` computes a frequency table of the factors unless an array of values and an aggregation function are passed.

It takes a number of arguments

- `index`: array-like, values to group by in the rows.
- `columns`: array-like, values to group by in the columns.
- `values`: array-like, optional, array of values to aggregate according to the factors.
- `aggfunc`: function, optional, If no values array is passed, computes a frequency table.

- `rownames`: sequence, default `None`, must match number of row arrays passed.
- `colnames`: sequence, default `None`, if passed, must match number of column arrays passed.
- `margins`: boolean, default `False`, Add row/column margins (subtotals)
- `normalize`: boolean, { 'all', 'index', 'columns' }, or {0,1}, default `False`. Normalize by dividing all values by the sum of values.

Any `Series` passed will have their name attributes used unless row or column names for the cross-tabulation are specified

For example:

```
In [65]: foo, bar, dull, shiny, one, two = 'foo', 'bar', 'dull', 'shiny', 'one', 'two'
In [66]: a = np.array([foo, foo, bar, bar, foo, foo], dtype=object)
In [67]: b = np.array([one, one, two, one, two, one], dtype=object)
In [68]: c = np.array([dull, dull, shiny, dull, dull, shiny], dtype=object)
In [69]: pd.crosstab(a, [b, c], rownames=['a'], colnames=['b', 'c'])
Out[69]:
```

|     | one  |       | two  |       |
|-----|------|-------|------|-------|
| c   | dull | shiny | dull | shiny |
| a   |      |       |      |       |
| bar | 1    | 0     | 0    | 1     |
| foo | 2    | 1     | 1    | 0     |

If `crosstab` receives only two `Series`, it will provide a frequency table.

```
In [70]: df = pd.DataFrame({'A': [1, 2, 2, 2, 2], 'B': [3, 3, 4, 4, 4],
.....: 'C': [1, 1, np.nan, 1, 1]})
.....:
In [71]: df
Out[71]:
```

|   | A | B | C   |
|---|---|---|-----|
| 0 | 1 | 3 | 1.0 |
| 1 | 2 | 3 | 1.0 |
| 2 | 2 | 4 | NaN |
| 3 | 2 | 4 | 1.0 |
| 4 | 2 | 4 | 1.0 |

```
In [72]: pd.crosstab(df.A, df.B)
Out[72]:
```

|   | 3 | 4 |
|---|---|---|
| A |   |   |
| 1 | 1 | 0 |
| 2 | 1 | 3 |

Any input passed containing `Categorical` data will have **all** of its categories included in the cross-tabulation, even if the actual data does not contain any instances of a particular category.

```
In [73]: foo = pd.Categorical(['a', 'b'], categories=['a', 'b', 'c'])
In [74]: bar = pd.Categorical(['d', 'e'], categories=['d', 'e', 'f'])
```

(continues on next page)

(continued from previous page)

```
In [75]: pd.crosstab(foo, bar)
Out[75]:
col_0 d e
row_0
a 1 0
b 0 1
```

## 18.6.1 Normalization

New in version 0.18.1.

Frequency tables can also be normalized to show percentages rather than counts using the `normalize` argument:

```
In [76]: pd.crosstab(df.A, df.B, normalize=True)
Out[76]:
B 3 4
A
1 0.2 0.0
2 0.2 0.6
```

`normalize` can also normalize values within each row or within each column:

```
In [77]: pd.crosstab(df.A, df.B, normalize='columns')
Out[77]:
B 3 4
A
1 0.5 0.0
2 0.5 1.0
```

`crosstab` can also be passed a third `Series` and an aggregation function (`aggfunc`) that will be applied to the values of the third `Series` within each group defined by the first two `Series`:

```
In [78]: pd.crosstab(df.A, df.B, values=df.C, aggfunc=np.sum)
Out[78]:
B 3 4
A
1 1.0 NaN
2 1.0 2.0
```

## 18.6.2 Adding Margins

Finally, one can also add margins or normalize this output.

```
In [79]: pd.crosstab(df.A, df.B, values=df.C, aggfunc=np.sum, normalize=True,
.....: margins=True)
Out[79]:
B 3 4 All
A
1 0.25 0.0 0.25
2 0.25 0.5 0.75
All 0.50 0.5 1.00
```

## 18.7 Tiling

The `cut()` function computes groupings for the values of the input array and is often used to transform continuous variables to discrete or categorical variables:

```
In [80]: ages = np.array([10, 15, 13, 12, 23, 25, 28, 59, 60])

In [81]: pd.cut(ages, bins=3)
Out[81]:
[(9.95, 26.667], (9.95, 26.667], (9.95, 26.667], (9.95, 26.667], (9.95, 26.667], (9.
↪95, 26.667], (26.667, 43.333], (43.333, 60.0], (43.333, 60.0]]
Categories (3, interval[float64]): [(9.95, 26.667] < (26.667, 43.333] < (43.333, 60.
↪0]]
```

If the `bins` keyword is an integer, then equal-width bins are formed. Alternatively we can specify custom bin-edges:

```
In [82]: c = pd.cut(ages, bins=[0, 18, 35, 70])

In [83]: c
Out[83]:
[(0, 18], (0, 18], (0, 18], (0, 18], (18, 35], (18, 35], (18, 35], (35, 70], (35, 70]]
Categories (3, interval[int64]): [(0, 18] < (18, 35] < (35, 70]]
```

New in version 0.20.0.

If the `bins` keyword is an `IntervalIndex`, then these will be used to bin the passed data.:

```
pd.cut([25, 20, 50], bins=c.categories)
```

## 18.8 Computing indicator / dummy variables

To convert a categorical variable into a “dummy” or “indicator” `DataFrame`, for example a column in a `DataFrame` (a `Series`) which has `k` distinct values, can derive a `DataFrame` containing `k` columns of 1s and 0s using `get_dummies()`:

```
In [84]: df = pd.DataFrame({'key': list('bbacab'), 'data1': range(6)})

In [85]: pd.get_dummies(df['key'])
Out[85]:
 a b c
0 0 1 0
1 0 1 0
2 1 0 0
3 0 0 1
4 1 0 0
5 0 1 0
```

Sometimes it’s useful to prefix the column names, for example when merging the result with the original `DataFrame`:

```
In [86]: dummies = pd.get_dummies(df['key'], prefix='key')

In [87]: dummies
Out[87]:
 key_a key_b key_c
```

(continues on next page)

(continued from previous page)

```

0 0 1 0
1 0 1 0
2 1 0 0
3 0 0 1
4 1 0 0
5 0 1 0

```

```
In [88]: df[['data1']].join(dummies)
```

```

=====
↪
 data1 key_a key_b key_c
0 0 0 1 0
1 1 0 1 0
2 2 1 0 0
3 3 0 0 1
4 4 1 0 0
5 5 0 1 0

```

This function is often used along with discretization functions like `cut`:

```
In [89]: values = np.random.randn(10)
```

```
In [90]: values
```

```
Out[90]:
```

```
array([1.10259296, -1.56366988, -0.81214265, -0.97020413, 0.83347632,
 -1.12573161, 1.12464315, -1.50716649, 1.01881441, 0.46509623])
```

```
In [91]: bins = [0, 0.2, 0.4, 0.6, 0.8, 1]
```

```
In [92]: pd.get_dummies(pd.cut(values, bins))
```

```
Out[92]:
```

```

(0.0, 0.2] (0.2, 0.4] (0.4, 0.6] (0.6, 0.8] (0.8, 1.0]
0 0 0 0 0 0
1 0 0 0 0 0
2 0 0 0 0 0
3 0 0 0 0 0
4 0 0 0 0 1
5 0 0 0 0 0
6 0 0 0 0 0
7 0 0 0 0 0
8 0 0 0 0 0
9 0 0 1 0 0

```

See also `Series.str.get_dummies`.

`get_dummies()` also accepts a `DataFrame`. By default all categorical variables (categorical in the statistical sense, those with *object* or *categorical* dtype) are encoded as dummy variables.

```
In [93]: df = pd.DataFrame({'A': ['a', 'b', 'a'], 'B': ['c', 'c', 'b'],
.....: 'C': [1, 2, 3]})
.....:
```

```
In [94]: pd.get_dummies(df)
```

```
Out[94]:
```

```

 C A_a A_b B_b B_c
0 1 1 0 0 1
1 2 0 1 0 1

```

(continues on next page)

(continued from previous page)

|   |   |   |   |   |   |
|---|---|---|---|---|---|
| 2 | 3 | 1 | 0 | 1 | 0 |
|---|---|---|---|---|---|

All non-object columns are included untouched in the output. You can control the columns that are encoded with the `columns` keyword.

```
In [95]: pd.get_dummies(df, columns=['A'])
```

```
Out[95]:
```

|   | B | C | A_a | A_b |
|---|---|---|-----|-----|
| 0 | c | 1 | 1   | 0   |
| 1 | c | 2 | 0   | 1   |
| 2 | b | 3 | 1   | 0   |

Notice that the `B` column is still included in the output, it just hasn't been encoded. You can drop `B` before calling `get_dummies` if you don't want to include it in the output.

As with the `Series` version, you can pass values for the `prefix` and `prefix_sep`. By default the column name is used as the prefix, and `'_'` as the prefix separator. You can specify `prefix` and `prefix_sep` in 3 ways:

- string: Use the same value for `prefix` or `prefix_sep` for each column to be encoded.
- list: Must be the same length as the number of columns being encoded.
- dict: Mapping column name to prefix.

```
In [96]: simple = pd.get_dummies(df, prefix='new_prefix')
```

```
In [97]: simple
```

```
Out[97]:
```

|   | C | new_prefix_a | new_prefix_b | new_prefix_b | new_prefix_c |
|---|---|--------------|--------------|--------------|--------------|
| 0 | 1 | 1            | 0            | 0            | 1            |
| 1 | 2 | 0            | 1            | 0            | 1            |
| 2 | 3 | 1            | 0            | 1            | 0            |

```
In [98]: from_list = pd.get_dummies(df, prefix=['from_A', 'from_B'])
```

```
In [99]: from_list
```

```
Out[99]:
```

|   | C | from_A_a | from_A_b | from_B_b | from_B_c |
|---|---|----------|----------|----------|----------|
| 0 | 1 | 1        | 0        | 0        | 1        |
| 1 | 2 | 0        | 1        | 0        | 1        |
| 2 | 3 | 1        | 0        | 1        | 0        |

```
In [100]: from_dict = pd.get_dummies(df, prefix={'B': 'from_B', 'A': 'from_A'})
```

```
In [101]: from_dict
```

```
Out[101]:
```

|   | C | from_A_a | from_A_b | from_B_b | from_B_c |
|---|---|----------|----------|----------|----------|
| 0 | 1 | 1        | 0        | 0        | 1        |
| 1 | 2 | 0        | 1        | 0        | 1        |
| 2 | 3 | 1        | 0        | 1        | 0        |

New in version 0.18.0.

Sometimes it will be useful to only keep `k-1` levels of a categorical variable to avoid collinearity when feeding the result to statistical models. You can switch to this mode by turn on `drop_first`.

```
In [102]: s = pd.Series(list('abcaa'))
```

(continues on next page)

(continued from previous page)

```

In [103]: pd.get_dummies(s)
Out[103]:
 a b c
0 1 0 0
1 0 1 0
2 0 0 1
3 1 0 0
4 1 0 0

In [104]: pd.get_dummies(s, drop_first=True)
Out[104]:
 b c
0 0 0
1 1 0
2 0 1
3 0 0
4 0 0

```

When a column contains only one level, it will be omitted in the result.

```

In [105]: df = pd.DataFrame({'A': list('aaaaa'), 'B': list('ababc')})

In [106]: pd.get_dummies(df)
Out[106]:
 A_a B_a B_b B_c
0 1 1 0 0
1 1 0 1 0
2 1 1 0 0
3 1 0 1 0
4 1 0 0 1

In [107]: pd.get_dummies(df, drop_first=True)
Out[107]:
 B_b B_c
0 0 0
1 1 0
2 0 0
3 1 0
4 0 1

```

By default new columns will have `np.uint8` dtype. To choose another dtype, use the `dtype` argument:

```

In [108]: df = pd.DataFrame({'A': list('abc'), 'B': [1.1, 2.2, 3.3]})

In [109]: pd.get_dummies(df, dtype=bool).dtypes
Out[109]:
B float64
A_a bool
A_b bool
A_c bool
dtype: object

```

New in version 0.23.0.

## 18.9 Factorizing values

To encode 1-d values as an enumerated type use `factorize()`:

```
In [110]: x = pd.Series(['A', 'A', np.nan, 'B', 3.14, np.inf])

In [111]: x
Out[111]:
0 A
1 A
2 NaN
3 B
4 3.14
5 inf
dtype: object

In [112]: labels, uniques = pd.factorize(x)

In [113]: labels
Out[113]: array([0, 0, -1, 1, 2, 3])

In [114]: uniques
Out[114]: Index(['A', 'B', 3.14, inf],
dtype='object')
```

Note that `factorize` is similar to `numpy.unique`, but differs in its handling of NaN:

**Note:** The following `numpy.unique` will fail under Python 3 with a `TypeError` because of an ordering bug. See also [here](#).

```
In [1]: x = pd.Series(['A', 'A', np.nan, 'B', 3.14, np.inf])
In [2]: pd.factorize(x, sort=True)
Out[2]:
(array([2, 2, -1, 3, 0, 1]),
 Index([3.14, inf, u'A', u'B'], dtype='object'))

In [3]: np.unique(x, return_inverse=True)[::-1]
Out[3]: (array([3, 3, 0, 4, 1, 2]), array([nan, 3.14, inf, 'A', 'B'], dtype=object))
```

**Note:** If you just want to handle one column as a categorical variable (like R's factor), you can use `df["cat_col"] = pd.Categorical(df["col"])` or `df["cat_col"] = df["col"].astype("category")`. For full docs on *Categorical*, see the *Categorical introduction* and the API documentation.

### 18.10 Examples

In this section, we will review frequently asked questions and examples. The column names and relevant column values are named to correspond with how this DataFrame will be pivoted in the answers below.

```
In [115]: np.random.seed([3, 1415])
```

(continues on next page)

(continued from previous page)

```

In [116]: n = 20

In [117]: cols = np.array(['key', 'row', 'item', 'col'])

In [118]: df = cols + pd.DataFrame((np.random.randint(5, size=(n, 4))
.....: // [2, 1, 2, 1]).astype(str))
.....:

In [119]: df.columns = cols

In [120]: df = df.join(pd.DataFrame(np.random.rand(n, 2).round(2)).add_prefix('val'))

In [121]: df
Out[121]:
 key row item col val0 val1
0 key0 row3 item1 col3 0.81 0.04
1 key1 row2 item1 col2 0.44 0.07
2 key1 row0 item1 col0 0.77 0.01
3 key0 row4 item0 col2 0.15 0.59
4 key1 row0 item2 col1 0.81 0.64
5 key1 row2 item2 col4 0.13 0.88
6 key2 row4 item1 col3 0.88 0.39
7 key1 row4 item1 col1 0.10 0.07
8 key1 row0 item2 col4 0.65 0.02
9 key1 row2 item0 col2 0.35 0.61
10 key2 row0 item2 col1 0.40 0.85
11 key2 row4 item1 col2 0.64 0.25
12 key0 row2 item2 col3 0.50 0.44
13 key0 row4 item1 col4 0.24 0.46
14 key1 row3 item2 col3 0.28 0.11
15 key0 row3 item1 col1 0.31 0.23
16 key0 row0 item2 col3 0.86 0.01
17 key0 row4 item0 col3 0.64 0.21
18 key2 row2 item2 col0 0.13 0.45
19 key0 row2 item0 col4 0.37 0.70

```

### 18.10.1 Pivoting with Single Aggregations

Suppose we wanted to pivot `df` such that the `col` values are columns, `row` values are the index, and the mean of `val0` are the values? In particular, the resulting DataFrame should look like:

---

**Note:** col col0 col1 col2 col3 col4 row row0 0.77 0.605 NaN 0.860 0.65 row2 0.13 NaN 0.395 0.500 0.25 row3 NaN 0.310 NaN 0.545 NaN row4 NaN 0.100 0.395 0.760 0.24

---

This solution uses `pivot_table()`. Also note that `aggfunc='mean'` is the default. It is included here to be explicit.

```

In [122]: df.pivot_table(
.....: values='val0', index='row', columns='col', aggfunc='mean')
.....:
Out[122]:
col col0 col1 col2 col3 col4
row

```

(continues on next page)

(continued from previous page)

|      |      |       |       |       |      |
|------|------|-------|-------|-------|------|
| row0 | 0.77 | 0.605 | NaN   | 0.860 | 0.65 |
| row2 | 0.13 | NaN   | 0.395 | 0.500 | 0.25 |
| row3 | NaN  | 0.310 | NaN   | 0.545 | NaN  |
| row4 | NaN  | 0.100 | 0.395 | 0.760 | 0.24 |

Note that we can also replace the missing values by using the `fill_value` parameter.

```
In [123]: df.pivot_table(
.....: values='val0', index='row', columns='col', aggfunc='mean', fill_value=0)
.....:
Out[123]:
```

| col  | col0 | col1  | col2  | col3  | col4 |
|------|------|-------|-------|-------|------|
| row  |      |       |       |       |      |
| row0 | 0.77 | 0.605 | 0.000 | 0.860 | 0.65 |
| row2 | 0.13 | 0.000 | 0.395 | 0.500 | 0.25 |
| row3 | 0.00 | 0.310 | 0.000 | 0.545 | 0.00 |
| row4 | 0.00 | 0.100 | 0.395 | 0.760 | 0.24 |

Also note that we can pass in other aggregation functions as well. For example, we can also pass in `sum`.

```
In [124]: df.pivot_table(
.....: values='val0', index='row', columns='col', aggfunc='sum', fill_value=0)
.....:
Out[124]:
```

| col  | col0 | col1 | col2 | col3 | col4 |
|------|------|------|------|------|------|
| row  |      |      |      |      |      |
| row0 | 0.77 | 1.21 | 0.00 | 0.86 | 0.65 |
| row2 | 0.13 | 0.00 | 0.79 | 0.50 | 0.50 |
| row3 | 0.00 | 0.31 | 0.00 | 1.09 | 0.00 |
| row4 | 0.00 | 0.10 | 0.79 | 1.52 | 0.24 |

Another aggregation we can do is calculate the frequency in which the columns and rows occur together a.k.a. “cross tabulation”. To do this, we can pass `size` to the `aggfunc` parameter.

```
In [125]: df.pivot_table(index='row', columns='col', fill_value=0, aggfunc='size')
Out[125]:
```

| col  | col0 | col1 | col2 | col3 | col4 |
|------|------|------|------|------|------|
| row  |      |      |      |      |      |
| row0 | 1    | 2    | 0    | 1    | 1    |
| row2 | 1    | 0    | 2    | 1    | 2    |
| row3 | 0    | 1    | 0    | 2    | 0    |
| row4 | 0    | 1    | 2    | 2    | 1    |

## 18.10.2 Pivoting with Multiple Aggregations

We can also perform multiple aggregations. For example, to perform both a `sum` and `mean`, we can pass in a list to the `aggfunc` argument.

```
In [126]: df.pivot_table(
.....: values='val0', index='row', columns='col', aggfunc=['mean', 'sum'])
.....:
Out[126]:
```

|     | mean |      |      |      |      | sum  |      |      |      |      |
|-----|------|------|------|------|------|------|------|------|------|------|
| col | col0 | col1 | col2 | col3 | col4 | col0 | col1 | col2 | col3 | col4 |
| row |      |      |      |      |      |      |      |      |      |      |

(continues on next page)

(continued from previous page)

|      |      |       |       |       |      |      |      |      |      |      |
|------|------|-------|-------|-------|------|------|------|------|------|------|
| row0 | 0.77 | 0.605 | NaN   | 0.860 | 0.65 | 0.77 | 1.21 | NaN  | 0.86 | 0.65 |
| row2 | 0.13 | NaN   | 0.395 | 0.500 | 0.25 | 0.13 | NaN  | 0.79 | 0.50 | 0.50 |
| row3 | NaN  | 0.310 | NaN   | 0.545 | NaN  | NaN  | 0.31 | NaN  | 1.09 | NaN  |
| row4 | NaN  | 0.100 | 0.395 | 0.760 | 0.24 | NaN  | 0.10 | 0.79 | 1.52 | 0.24 |

Note to aggregate over multiple value columns, we can pass in a list to the `values` parameter.

```
In [127]: df.pivot_table(
.....: values=['val0', 'val1'], index='row', columns='col', aggfunc=['mean'])
.....:
Out[127]:
```

|      | mean val0 |       |       |       |      | mean val1 |       |      |       |      |
|------|-----------|-------|-------|-------|------|-----------|-------|------|-------|------|
| col  | col0      | col1  | col2  | col3  | col4 | col0      | col1  | col2 | col3  | col4 |
| row  |           |       |       |       |      |           |       |      |       |      |
| row0 | 0.77      | 0.605 | NaN   | 0.860 | 0.65 | 0.01      | 0.745 | NaN  | 0.010 | 0.02 |
| row2 | 0.13      | NaN   | 0.395 | 0.500 | 0.25 | 0.45      | NaN   | 0.34 | 0.440 | 0.79 |
| row3 | NaN       | 0.310 | NaN   | 0.545 | NaN  | NaN       | 0.230 | NaN  | 0.075 | NaN  |
| row4 | NaN       | 0.100 | 0.395 | 0.760 | 0.24 | NaN       | 0.070 | 0.42 | 0.300 | 0.46 |

Note to subdivide over multiple columns we can pass in a list to the `columns` parameter.

```
In [128]: df.pivot_table(
.....: values=['val0'], index='row', columns=['item', 'col'], aggfunc=['mean'])
.....:
Out[128]:
```

|      | mean val0 |       |      |      |       |      |      |      |      |       |      |      |
|------|-----------|-------|------|------|-------|------|------|------|------|-------|------|------|
| item | item0     | item1 |      |      | item2 |      |      |      |      |       |      |      |
| col  | col2      | col3  | col4 | col0 | col1  | col2 | col3 | col4 | col0 | col1  | col3 | col4 |
| row  |           |       |      |      |       |      |      |      |      |       |      |      |
| row0 | NaN       | NaN   | NaN  | 0.77 | NaN   | NaN  | NaN  | NaN  | NaN  | 0.605 | 0.86 | 0.65 |
| row2 | 0.35      | NaN   | 0.37 | NaN  | NaN   | 0.44 | NaN  | NaN  | 0.13 | NaN   | 0.50 | 0.13 |
| row3 | NaN       | NaN   | NaN  | NaN  | 0.31  | NaN  | 0.81 | NaN  | NaN  | NaN   | 0.28 | NaN  |
| row4 | 0.15      | 0.64  | NaN  | NaN  | 0.10  | 0.64 | 0.88 | 0.24 | NaN  | NaN   | NaN  | NaN  |

```
{{ header }}
```

## TIME SERIES / DATE FUNCTIONALITY

pandas contains extensive capabilities and features for working with time series data for all domains. Using the NumPy `datetime64` and `timedelta64` dtypes, pandas has consolidated a large number of features from other Python libraries like `scikits.timeseries` as well as created a tremendous amount of new functionality for manipulating time series data.

For example, pandas supports:

## Parsing time series information from various sources and formats

```
In [1]: import datetime

In [2]: dti = pd.to_datetime(['1/1/2018', np.datetime64('2018-01-01'),
...: datetime.datetime(2018, 1, 1)])
...:

In [3]: dti
Out[3]: DatetimeIndex(['2018-01-01', '2018-01-01', '2018-01-01'], dtype=
↳ 'datetime64[ns]', freq=None)
```

### Generate sequences of fixed-frequency dates and time spans

```
In [4]: dti = pd.date_range('2018-01-01', periods=3, freq='H')
In [5]: dti
Out[5]:
DatetimeIndex(['2018-01-01 00:00:00', '2018-01-01 01:00:00',
 '2018-01-01 02:00:00'],
 dtype='datetime64[ns]', freq='H')
```

## Manipulating and converting date times with timezone information

```
In [6]: dti = dti.tz_localize('UTC')

In [7]: dti
Out[7]:
DatetimeIndex(['2018-01-01 00:00:00+00:00', '2018-01-01 01:00:00+00:00',
 '2018-01-01 02:00:00+00:00'],
 dtype='datetime64[ns, UTC]', freq='H')

In [8]: dti.tz_convert('US/Pacific')
//////////
↳
DatetimeIndex(['2017-12-31 16:00:00-08:00', '2017-12-31 17:00:00-08:00',
 '2017-12-31 18:00:00-08:00'],
 dtype='datetime64[ns, US/Pacific]', freq='H')
```

## Resampling or converting a time series to a particular frequency

```
In [9]: idx = pd.date_range('2018-01-01', periods=5, freq='H')
```

```
In [10]: ts = pd.Series(range(len(idx)), index=idx)
```

```
In [11]: ts
```

Out[11]:

|                     |   |
|---------------------|---|
| 2018-01-01 00:00:00 | 0 |
|---------------------|---|

|                     |   |
|---------------------|---|
| 2018-01-01 01:00:00 | 1 |
|---------------------|---|

|                     |   |
|---------------------|---|
| 2018-01-01 02:00:00 | 2 |
|---------------------|---|

|                     |   |
|---------------------|---|
| 2018-01-01 03:00:00 | 3 |
|---------------------|---|

|                     |   |
|---------------------|---|
| 2018-01-01 04:00:00 | 4 |
|---------------------|---|

```
Freq: H, dtype: int64
```

```
In [12]: ts.resample('2H').mean()
```

|                     |     |
|---------------------|-----|
| 2018-01-01 00:00:00 | 0.5 |
|---------------------|-----|

|                     |     |
|---------------------|-----|
| 2018-01-01 02:00:00 | 2.5 |
|---------------------|-----|

|                     |     |
|---------------------|-----|
| 2018-01-01 04:00:00 | 4.0 |
|---------------------|-----|

```
Freq: 2H, dtype: float64
```

## Performing date and time arithmetic with absolute or relative time increments

```
In [13]: friday = pd.Timestamp('2018-01-05')
```

```
In [14]: friday.day_name()
```

```
Out[14]: 'Friday'
```

```
Add 1 day
```

```
In [15]: saturday = friday + pd.Timedelta('1 day')
```

```
In [16]: saturday.day_name()
```

```
Out[16]: 'Saturday'
```

```
Add 1 business day (Friday --> Monday)
```

```
In [17]: monday = friday + pd.offsets.BDay()
```

```
In [18]: monday.day_name()
```

```
Out[18]: 'Monday'
```

pandas provides a relatively compact and self-contained set of tools for performing the above tasks and more.

## 19.1 Overview

pandas captures 4 general time related concepts:

1. **Date times:** A specific date and time with timezone support. Similar to `datetime.datetime` from the standard library.
2. **Time deltas:** An absolute time duration. Similar to `datetime.timedelta` from the standard library.
3. **Time spans:** A span of time defined by a point in time and its associated frequency.
4. **Date offsets:** A relative time duration that respects calendar arithmetic. Similar to `dateutil.relativedelta.relativedelta` from the `dateutil` package.

| Concept      | Scalar Class | Array Class    | pandas Data Type                     | Primary Creation Method         |
|--------------|--------------|----------------|--------------------------------------|---------------------------------|
| Date times   | Timestamp    | DatetimeIndex  | datetime64[ns] or datetime64[ns, tz] | to_datetime or date_range       |
| Time deltas  | Timedelta    | TimedeltaIndex | timedelta64[ns]                      | to_timedelta or timedelta_range |
| Time spans   | Period       | PeriodIndex    | period[freq]                         | Period or period_range          |
| Date offsets | DateOffset   | None           | None                                 | DateOffset                      |

For time series data, it's conventional to represent the time component in the index of a Series or DataFrame so manipulations can be performed with respect to the time element.

```
In [19]: pd.Series(range(3), index=pd.date_range('2000', freq='D', periods=3))
Out[19]:
2000-01-01 0
2000-01-02 1
2000-01-03 2
Freq: D, dtype: int64
```

However, Series and DataFrame can directly also support the time component as data itself.

```
In [20]: pd.Series(pd.date_range('2000', freq='D', periods=3))
Out[20]:
0 2000-01-01
1 2000-01-02
2 2000-01-03
dtype: datetime64[ns]
```

Series and DataFrame have extended data type support and functionality for datetime, timedelta and Period data when passed into those constructors. DateOffset data however will be stored as object data.

```
In [21]: pd.Series(pd.period_range('1/1/2011', freq='M', periods=3))
Out[21]:
0 2011-01
1 2011-02
2 2011-03
dtype: period[M]

In [22]: pd.Series([pd.DateOffset(1), pd.DateOffset(2)])
Out[22]:
0 <DateOffset>
1 <2 * DateOffsets>
dtype: object

In [23]: pd.Series(pd.date_range('1/1/2011', freq='M', periods=3))
Out[23]:
0 2011-01-31
1 2011-02-28
2 2011-03-31
dtype: datetime64[ns]
```

Lastly, pandas represents null date times, time deltas, and time spans as NaT which is useful for representing missing or null date like values and behaves similar as np.nan does for float data.

```

In [24]: pd.Timestamp(pd.NaT)
Out[24]: NaT

In [25]: pd.Timedelta(pd.NaT)
Out[25]: NaT

In [26]: pd.Period(pd.NaT)
Out[26]: NaT

Equality acts as np.nan would
In [27]: pd.NaT == pd.NaT
Out[27]: False

```

## 19.2 Timestamps vs. Time Spans

Timestamped data is the most basic type of time series data that associates values with points in time. For pandas objects it means using the points in time.

```

In [28]: pd.Timestamp(datetime.datetime(2012, 5, 1))
Out[28]: Timestamp('2012-05-01 00:00:00')

In [29]: pd.Timestamp('2012-05-01')
Out[29]: Timestamp('2012-05-01 00:00:00')

In [30]: pd.Timestamp(2012, 5, 1)
Out[30]: Timestamp('2012-05-01 00:00:00')

```

However, in many cases it is more natural to associate things like change variables with a time span instead. The span represented by `Period` can be specified explicitly, or inferred from datetime string format.

For example:

```

In [31]: pd.Period('2011-01')
Out[31]: Period('2011-01', 'M')

In [32]: pd.Period('2012-05', freq='D')
Out[32]: Period('2012-05-01', 'D')

```

Timestamp and Period can serve as an index. Lists of Timestamp and Period are automatically coerced to `DatetimeIndex` and `PeriodIndex` respectively.

```

In [33]: dates = [pd.Timestamp('2012-05-01'),
....: pd.Timestamp('2012-05-02'),
....: pd.Timestamp('2012-05-03')]
....:

In [34]: ts = pd.Series(np.random.randn(3), dates)

In [35]: type(ts.index)
Out[35]: pandas.core.indexes.datetimes.DatetimeIndex

In [36]: ts.index
Out[36]: DatetimeIndex(['2012-05-01', '2012-05-02', '2012-05-03'], dtype='datetime64[ns]', freq=None)

```

(continues on next page)

(continued from previous page)

```

In [37]: ts
\\repeated backslashes\\
↪
2012-05-01 1.212707
2012-05-02 -2.219105
2012-05-03 0.930394
dtype: float64

In [38]: periods = [pd.Period('2012-01'), pd.Period('2012-02'), pd.Period('2012-03')]

In [39]: ts = pd.Series(np.random.randn(3), periods)

In [40]: type(ts.index)
Out[40]: pandas.core.indexes.period.PeriodIndex

In [41]: ts.index
\\repeated backslashes\\Out[41]: PeriodIndex(['2012-01',
↪ '2012-02', '2012-03'], dtype='period[M]', freq='M')

In [42]: ts
\\repeated backslashes\\
↪
2012-01 0.703754
2012-02 0.580511
2012-03 -0.135776
Freq: M, dtype: float64

```

pandas allows you to capture both representations and convert between them. Under the hood, pandas represents timestamps using instances of `Timestamp` and sequences of timestamps using instances of `DatetimeIndex`. For regular time spans, pandas uses `Period` objects for scalar values and `PeriodIndex` for sequences of spans. Better support for irregular intervals with arbitrary start and end points are forth-coming in future releases.

## 19.3 Converting to Timestamps

To convert a `Series` or list-like object of date-like objects e.g. strings, epochs, or a mixture, you can use the `to_datetime` function. When passed a `Series`, this returns a `Series` (with the same index), while a list-like is converted to a `DatetimeIndex`:

```
In [43]: pd.to_datetime(pd.Series(['Jul 31, 2009', '2010-01-10', None]))
Out[43]:
0 2009-07-31
1 2010-01-10
2 NaT
dtype: datetime64[ns]

In [44]: pd.to_datetime(['2005/11/23', '2010.12.31'])
Out[44]:
DatetimeIndex(['2005-11-23', '2010-12-31'], dtype='datetime64[ns]', freq=None)
```

If you use dates which start with the day first (i.e. European style), you can pass the `dayfirst` flag:

```
In [45]: pd.to_datetime(['04-01-2012 10:00'], dayfirst=True)
Out[45]: DatetimeIndex(['2012-01-04 10:00:00'], dtype='datetime64[ns]', freq=None)
```

(continues on next page)

(continued from previous page)

```
In [46]: pd.to_datetime(['14-01-2012', '01-14-2012'], dayfirst=True)
Out[46]: DatetimeIndex(['2012-01-14', '2012-01-14'], dtype='datetime64[ns]', freq=None)
```

**Warning:** You see in the above example that `dayfirst` isn't strict, so if a date can't be parsed with the day being first it will be parsed as if `dayfirst` were `False`.

If you pass a single string to `to_datetime`, it returns a single `Timestamp`. `Timestamp` can also accept string input, but it doesn't accept string parsing options like `dayfirst` or `format`, so use `to_datetime` if these are required.

```
In [47]: pd.to_datetime('2010/11/12')
Out[47]: Timestamp('2010-11-12 00:00:00')

In [48]: pd.Timestamp('2010/11/12')
Out[48]: Timestamp('2010-11-12 00:00:00')
```

You can also use the `DatetimeIndex` constructor directly:

```
In [49]: pd.DatetimeIndex(['2018-01-01', '2018-01-03', '2018-01-05'])
Out[49]: DatetimeIndex(['2018-01-01', '2018-01-03', '2018-01-05'], dtype=
 'datetime64[ns]', freq=None)
```

The string `'infer'` can be passed in order to set the frequency of the index as the inferred frequency upon creation:

```
In [50]: pd.DatetimeIndex(['2018-01-01', '2018-01-03', '2018-01-05'], freq='infer')
Out[50]: DatetimeIndex(['2018-01-01', '2018-01-03', '2018-01-05'], dtype=
 'datetime64[ns]', freq='2D')
```

### 19.3.1 Providing a Format Argument

In addition to the required datetime string, a `format` argument can be passed to ensure specific parsing. This could also potentially speed up the conversion considerably.

```
In [51]: pd.to_datetime('2010/11/12', format='%Y/%m/%d')
Out[51]: Timestamp('2010-11-12 00:00:00')

In [52]: pd.to_datetime('12-11-2010 00:00', format='%d-%m-%Y %H:%M')
Out[52]: Timestamp('2010-11-12 00:00:00')
```

For more information on the choices available when specifying the `format` option, see the [Python `datetime` documentation](#).

### 19.3.2 Assembling Datetime from Multiple DataFrame Columns

New in version 0.18.1.

You can also pass a `DataFrame` of integer or string columns to assemble into a `Series` of `Timestamps`.

```
In [53]: df = pd.DataFrame({'year': [2015, 2016],
.....: 'month': [2, 3],
.....: 'day': [4, 5],
.....: 'hour': [2, 3]})
.....:
```

```
In [54]: pd.to_datetime(df)
```

```
Out[54]:
```

```
0 2015-02-04 02:00:00
1 2016-03-05 03:00:00
dtype: datetime64[ns]
```

You can pass only the columns that you need to assemble.

```
In [55]: pd.to_datetime(df[['year', 'month', 'day']])
```

```
Out[55]:
```

```
0 2015-02-04
1 2016-03-05
dtype: datetime64[ns]
```

`pd.to_datetime` looks for standard designations of the datetime component in the column names, including:

- **required:** year, month, day
- **optional:** hour, minute, second, millisecond, microsecond, nanosecond

### 19.3.3 Invalid Data

The default behavior, `errors='raise'`, is to raise when unparseable:

```
In [2]: pd.to_datetime(['2009/07/31', 'asd'], errors='raise')
ValueError: Unknown string format
```

Pass `errors='ignore'` to return the original input when unparseable:

```
In [56]: pd.to_datetime(['2009/07/31', 'asd'], errors='ignore')
Out[56]: Index(['2009/07/31', 'asd'], dtype='object')
```

Pass `errors='coerce'` to convert unparseable data to NaT (not a time):

```
In [57]: pd.to_datetime(['2009/07/31', 'asd'], errors='coerce')
Out[57]: DatetimeIndex(['2009-07-31', 'NaT'], dtype='datetime64[ns]', freq=None)
```

### 19.3.4 Epoch Timestamps

pandas supports converting integer or float epoch times to `Timestamp` and `DatetimeIndex`. The default unit is nanoseconds, since that is how `Timestamp` objects are stored internally. However, epochs are often stored in another unit which can be specified. These are computed from the starting point specified by the `origin` parameter.

```
In [58]: pd.to_datetime([1349720105, 1349806505, 1349892905,
.....: 1349979305, 1350065705], unit='s')
.....:
Out[58]:
DatetimeIndex(['2012-10-08 18:15:05', '2012-10-09 18:15:05',
 '2012-10-10 18:15:05', '2012-10-11 18:15:05',
```

(continues on next page)

(continued from previous page)

```

 '2012-10-12 18:15:05'],
 dtype='datetime64[ns]', freq=None)

In [59]: pd.to_datetime([1349720105100, 1349720105200, 1349720105300,
 : 1349720105400, 1349720105500], unit='ms')
 :
DatetimeIndex(['2012-10-08 18:15:05.100000', '2012-10-08 18:15:05.200000',
 : '2012-10-08 18:15:05.300000', '2012-10-08 18:15:05.400000',
 : '2012-10-08 18:15:05.500000'],
 dtype='datetime64[ns]', freq=None)

```

**Note:** Epoch times will be rounded to the nearest nanosecond.

**Warning:** Conversion of float epoch times can lead to inaccurate and unexpected results. Python floats have about 15 digits precision in decimal. Rounding during conversion from float to high precision Timestamp is unavoidable. The only way to achieve exact precision is to use a fixed-width types (e.g. an int64).

```

In [60]: pd.to_datetime([1490195805.433, 1490195805.433502912], unit='s')
Out [60]: DatetimeIndex(['2017-03-22 15:16:45.433000088', '2017-03-22 15:16:45.
→433502913'], dtype='datetime64[ns]', freq=None)

In [61]: pd.to_datetime(1490195805433502912, unit='ns')
→Timestamp('2017-03-22 15:16:45.433502912')

```

See also:

*Using the origin Parameter*

### 19.3.5 From Timestamps to Epoch

To invert the operation from above, namely, to convert from a Timestamp to a ‘unix’ epoch:

```

In [62]: stamps = pd.date_range('2012-10-08 18:15:05', periods=4, freq='D')

In [63]: stamps
Out [63]:
DatetimeIndex(['2012-10-08 18:15:05', '2012-10-09 18:15:05',
 : '2012-10-10 18:15:05', '2012-10-11 18:15:05'],
 dtype='datetime64[ns]', freq='D')

```

We subtract the epoch (midnight at January 1, 1970 UTC) and then floor divide by the “unit” (1 second).

```

In [64]: (stamps - pd.Timestamp("1970-01-01")) // pd.Timedelta('1s')
Out [64]: Int64Index([1349720105, 1349806505, 1349892905, 1349979305], dtype='int64')

```

### 19.3.6 Using the origin Parameter

New in version 0.20.0.

Using the `origin` parameter, one can specify an alternative starting point for creation of a `DatetimeIndex`. For example, to use 1960-01-01 as the starting date:

```
In [65]: pd.to_datetime([1, 2, 3], unit='D', origin=pd.Timestamp('1960-01-01'))
Out [65]: DatetimeIndex(['1960-01-02', '1960-01-03', '1960-01-04'], dtype=
↳ 'datetime64[ns]', freq=None)
```

The default is set at `origin='unix'`, which defaults to 1970-01-01 00:00:00. Commonly called ‘unix epoch’ or POSIX time.

```
In [66]: pd.to_datetime([1, 2, 3], unit='D')
Out [66]: DatetimeIndex(['1970-01-02', '1970-01-03', '1970-01-04'], dtype=
↳ 'datetime64[ns]', freq=None)
```

## 19.4 Generating Ranges of Timestamps

To generate an index with timestamps, you can use either the `DatetimeIndex` or `Index` constructor and pass in a list of datetime objects:

```
In [67]: dates = [datetime.datetime(2012, 5, 1),
.....: datetime.datetime(2012, 5, 2),
.....: datetime.datetime(2012, 5, 3)]
.....:

Note the frequency information
In [68]: index = pd.DatetimeIndex(dates)

In [69]: index
Out [69]: DatetimeIndex(['2012-05-01', '2012-05-02', '2012-05-03'], dtype=
↳ 'datetime64[ns]', freq=None)

Automatically converted to DatetimeIndex
In [70]: index = pd.Index(dates)

In [71]: index
Out [71]: DatetimeIndex(['2012-05-01', '2012-05-02', '2012-05-03'], dtype=
↳ 'datetime64[ns]', freq=None)
```

In practice this becomes very cumbersome because we often need a very long index with a large number of timestamps. If we need timestamps on a regular frequency, we can use the `date_range()` and `bdate_range()` functions to create a `DatetimeIndex`. The default frequency for `date_range` is a **calendar day** while the default for `bdate_range` is a **business day**:

```
In [72]: start = datetime.datetime(2011, 1, 1)

In [73]: end = datetime.datetime(2012, 1, 1)

In [74]: index = pd.date_range(start, end)

In [75]: index
Out [75]:
DatetimeIndex(['2011-01-01', '2011-01-02', '2011-01-03', '2011-01-04',
 '2011-01-05', '2011-01-06', '2011-01-07', '2011-01-08',
 '2011-01-09', '2011-01-10',
 ...
```

(continues on next page)

(continued from previous page)

```

 '2011-12-23', '2011-12-24', '2011-12-25', '2011-12-26',
 '2011-12-27', '2011-12-28', '2011-12-29', '2011-12-30',
 '2011-12-31', '2012-01-01'],
 dtype='datetime64[ns]', length=366, freq='D')

In [76]: index = pd.bdate_range(start, end)

In [77]: index
Out[77]:
DatetimeIndex(['2011-01-03', '2011-01-04', '2011-01-05', '2011-01-06',
 '2011-01-07', '2011-01-10', '2011-01-11', '2011-01-12',
 '2011-01-13', '2011-01-14',
 ...
 '2011-12-19', '2011-12-20', '2011-12-21', '2011-12-22',
 '2011-12-23', '2011-12-26', '2011-12-27', '2011-12-28',
 '2011-12-29', '2011-12-30'],
 dtype='datetime64[ns]', length=260, freq='B')
```

Convenience functions like `date_range` and `bdate_range` can utilize a variety of *frequency aliases*:

```

In [78]: pd.date_range(start, periods=1000, freq='M')
Out[78]:
DatetimeIndex(['2011-01-31', '2011-02-28', '2011-03-31', '2011-04-30',
 '2011-05-31', '2011-06-30', '2011-07-31', '2011-08-31',
 '2011-09-30', '2011-10-31',
 ...
 '2093-07-31', '2093-08-31', '2093-09-30', '2093-10-31',
 '2093-11-30', '2093-12-31', '2094-01-31', '2094-02-28',
 '2094-03-31', '2094-04-30'],
 dtype='datetime64[ns]', length=1000, freq='M')

In [79]: pd.bdate_range(start, periods=250, freq='BQS')
↪
DatetimeIndex(['2011-01-03', '2011-04-01', '2011-07-01', '2011-10-03',
 '2012-01-02', '2012-04-02', '2012-07-02', '2012-10-01',
 '2013-01-01', '2013-04-01',
 ...
 '2071-01-01', '2071-04-01', '2071-07-01', '2071-10-01',
 '2072-01-01', '2072-04-01', '2072-07-01', '2072-10-03',
 '2073-01-02', '2073-04-03'],
 dtype='datetime64[ns]', length=250, freq='BQS-JAN')
```

`date_range` and `bdate_range` make it easy to generate a range of dates using various combinations of parameters like `start`, `end`, `periods`, and `freq`. The start and end dates are strictly inclusive, so dates outside of those specified will not be generated:

```

In [80]: pd.date_range(start, end, freq='BM')
Out[80]:
DatetimeIndex(['2011-01-31', '2011-02-28', '2011-03-31', '2011-04-29',
 '2011-05-31', '2011-06-30', '2011-07-29', '2011-08-31',
 '2011-09-30', '2011-10-31', '2011-11-30', '2011-12-30'],
 dtype='datetime64[ns]', freq='BM')

In [81]: pd.date_range(start, end, freq='W')
↪
```

(continues on next page)

```
DatetimeIndex(['2011-01-02', '2011-01-09', '2011-01-16', '2011-01-23',
 '2011-01-30', '2011-02-06', '2011-02-13', '2011-02-20',
 '2011-02-27', '2011-03-06', '2011-03-13', '2011-03-20',
 '2011-03-27', '2011-04-03', '2011-04-10', '2011-04-17',
 '2011-04-24', '2011-05-01', '2011-05-08', '2011-05-15',
 '2011-05-22', '2011-05-29', '2011-06-05', '2011-06-12',
 '2011-06-19', '2011-06-26', '2011-07-03', '2011-07-10',
 '2011-07-17', '2011-07-24', '2011-07-31', '2011-08-07',
 '2011-08-14', '2011-08-21', '2011-08-28', '2011-09-04',
 '2011-09-11', '2011-09-18', '2011-09-25', '2011-10-02',
 '2011-10-09', '2011-10-16', '2011-10-23', '2011-10-30',
 '2011-11-06', '2011-11-13', '2011-11-20', '2011-11-27',
 '2011-12-04', '2011-12-11', '2011-12-18', '2011-12-25',
 '2012-01-01'],
 dtype='datetime64[ns]', freq='W-SUN')
```

```
↪ DatetimeIndex(['2011-12-05', '2011-12-06', '2011-12-07', '2011-12-08',
 '2011-12-09', '2011-12-12', '2011-12-13', '2011-12-14',
 '2011-12-15', '2011-12-16', '2011-12-19', '2011-12-20',

 '2011-12-27', '2011-12-28', '2011-12-29', '2011-12-30'],
 dtype='datetime64[ns]', freq='B')
```

```

DatetimeIndex(['2011-01-03', '2011-01-04', '2011-01-05', '2011-01-06',
 '2011-01-07', '2011-01-10', '2011-01-11', '2011-01-12',
 '2011-01-13', '2011-01-14', '2011-01-17', '2011-01-18',
 '2011-01-19', '2011-01-20', '2011-01-21', '2011-01-24',
 '2011-01-25', '2011-01-26', '2011-01-27', '2011-01-28'],
 dtype='datetime64[ns]', freq='B')

```

```
Out[84]:
DatetimeIndex(['2018-01-01', '2018-01-02', '2018-01-03', '2018-01-04',
 '2018-01-05'],
 dtype='datetime64[ns]', freq=None)
```

```

DatetimeIndex(['2018-01-01 00:00:00', '2018-01-01 10:40:00',
 '2018-01-01 21:20:00', '2018-01-02 08:00:00',
 '2018-01-02 18:40:00', '2018-01-03 05:20:00',
 '2018-01-03 16:00:00', '2018-01-04 02:40:00',
 '2018-01-04 13:20:00', '2018-01-05 00:00:00'],
 dtype='datetime64[ns]', freq=None)

```

## 19.4.1 Custom Frequency Ranges

**Warning:** This functionality was originally exclusive to `cdate_range`, which is deprecated as of version 0.21.0 in favor of `bdate_range`. Note that `cdate_range` only utilizes the `weekmask` and `holidays` parameters when custom business day, 'C', is passed as the frequency string. Support has been expanded with `bdate_range` to work with any custom frequency string.

New in version 0.21.0.

`bdate_range` can also generate a range of custom frequency dates by using the `weekmask` and `holidays` parameters. These parameters will only be used if a custom frequency string is passed.

```
In [86]: weekmask = 'Mon Wed Fri'

In [87]: holidays = [datetime.datetime(2011, 1, 5), datetime.datetime(2011, 3, 14)]

In [88]: pd.bdate_range(start, end, freq='C', weekmask=weekmask, holidays=holidays)
Out[88]:
DatetimeIndex(['2011-01-03', '2011-01-07', '2011-01-10', '2011-01-12',
 '2011-01-14', '2011-01-17', '2011-01-19', '2011-01-21',
 '2011-01-24', '2011-01-26',
 ...,
 '2011-12-09', '2011-12-12', '2011-12-14', '2011-12-16',
 '2011-12-19', '2011-12-21', '2011-12-23', '2011-12-26',
 '2011-12-28', '2011-12-30'],
 dtype='datetime64[ns]', length=154, freq='C')

In [89]: pd.bdate_range(start, end, freq='CBMS', weekmask=weekmask)
Out[89]:
DatetimeIndex(['2011-01-03', '2011-02-02', '2011-03-02', '2011-04-01',
 '2011-05-02', '2011-06-01', '2011-07-01', '2011-08-01',
 '2011-09-02', '2011-10-03', '2011-11-02', '2011-12-02'],
 dtype='datetime64[ns]', freq='CBMS')
```

See also:

*Custom Business Days*

## 19.5 Timestamp Limitations

Since pandas represents timestamps in nanosecond resolution, the time span that can be represented using a 64-bit integer is limited to approximately 584 years:

```
In [90]: pd.Timestamp.min
Out[90]: Timestamp('1677-09-21 00:12:43.145225')

In [91]: pd.Timestamp.max
Out[91]: Timestamp('2262-04-11 23:47:16.854775807')
```

See also:

*Representing Out-of-Bounds Spans*

## 19.6.1 Partial String Indexing

Dates and strings that parse to timestamps can be passed as indexing parameters:

```
In [97]: ts['1/31/2011']
Out[97]: 0.31350344977403782

In [98]: ts[datetime.datetime(2011, 12, 25):]
Out[98]:
2011-12-30 -0.62564
Freq: BM, dtype: float64

In [99]: ts['10/31/2011':'12/31/2011']
Out[99]:
2011-10-31 -0.042894
2011-11-30 1.321441
2011-12-30 -0.625640
Freq: BM, dtype: float64
```

To provide convenience for accessing longer time series, you can also pass in the year or year and month as strings:

```
In [100]: ts['2011']
Out[100]:
2011-01-31 0.313503
2011-02-28 1.055889
2011-03-31 0.714651
2011-04-29 0.612442
2011-05-31 -0.170038
2011-06-30 -0.828809
2011-07-29 0.458806
2011-08-31 0.764740
2011-09-30 1.917429
2011-10-31 -0.042894
2011-11-30 1.321441
2011-12-30 -0.625640
Freq: BM, dtype: float64

In [101]: ts['2011-6']
Out[101]:
2011-06-30 -0.828809
Freq: BM, dtype: float64
```

This type of slicing will work on a `DataFrame` with a `DatetimeIndex` as well. Since the partial string selection is a form of label slicing, the endpoints **will be** included. This would include matching times on an included date:

```
In [102]: dft = pd.DataFrame(np.random.randn(100000, 1), columns=['A'],
.....: index=pd.date_range('20130101', periods=100000, freq='T
.....: ↪'))
.....:

In [103]: dft
Out[103]:
 A
2013-01-01 00:00:00 0.480217
2013-01-01 00:01:00 0.791875
2013-01-01 00:02:00 1.414514
```

(continues on next page)

(continued from previous page)

```
2013-01-01 00:03:00 -0.801147
2013-01-01 00:04:00 0.462656
2013-01-01 00:05:00 -0.534906
2013-01-01 00:06:00 0.782687

```

```
[751 rows x 1 columns]
```

New in version 0.18.0.

DatetimeIndex partial string indexing also works on a DataFrame with a MultiIndex:

```

In [109]: dft2 = pd.DataFrame(np.random.randn(20, 1),
.....: columns=['A'],
.....: index=pd.MultiIndex.from_product(
.....: [pd.date_range('20130101', periods=10, freq='12H'),
.....: ['a', 'b']]))
.....:

```

```
In [110]: dft2
```

```

Out[110]:
 A
2013-01-01 00:00:00 a 0.030508
 b 0.201088
2013-01-01 12:00:00 a -0.822650
 b -0.159673
2013-01-02 00:00:00 a 0.715939
 b 0.635435
2013-01-02 12:00:00 a 0.071542
 b 0.539646
2013-01-03 00:00:00 a -0.743837
 b 1.319587
2013-01-03 12:00:00 a -0.501123
 b -0.492347

2013-01-05 00:00:00 a 0.048871
 b -0.400048
2013-01-05 12:00:00 a 1.325801
 b 0.651751

```

```
In [111]: dft2.loc['2013-01-05']
```

```

////////////////////////////////////
↪
 A
2013-01-05 00:00:00 a 0.048871
 b -0.400048
2013-01-05 12:00:00 a 1.325801
 b 0.651751

```

```
In [112]: idx = pd.IndexSlice
```

```
In [113]: dft2 = dft2.swaplevel(0, 1).sort_index()
```

```
In [114]: dft2.loc[idx[:, '2013-01-05'], :]
```

```

Out[114]:
 A

```

(continues on next page)

```
In [123]: dft_minute = pd.DataFrame({'a': [1, 2, 3], 'b': [4, 5, 6]},
.....: index=series_minute.index)
.....:

In [124]: dft_minute['2011-12-31 23']
Out[124]:
```

|                     | a | b |
|---------------------|---|---|
| 2011-12-31 23:59:00 | 1 | 4 |

**Warning:** However, if the string is treated as an exact match, the selection in DataFrame's [] will be column-wise and not row-wise, see *Indexing Basics*. For example `dft_minute['2011-12-31 23:59']` will raise `KeyError` as '2012-12-31 23:59' has the same resolution as the index and there is no column with such name:

To *always* have unambiguous selection, whether the row is treated as a slice or a single selection, use `.loc`.

```
In [125]: dft_minute.loc['2011-12-31 23:59']
Out[125]:
```

|                     | a | b |
|---------------------|---|---|
| 2011-12-31 23:59:00 | 1 | 4 |

Name: 2011-12-31 23:59:00, dtype: int64

Note also that `DatetimeIndex` resolution cannot be less precise than day.

```
In [126]: series_monthly = pd.Series([1, 2, 3],
.....: pd.DatetimeIndex(['2011-12', '2012-01', '2012-02
↪']))
.....:

In [127]: series_monthly.index.resolution
Out[127]: 'day'

In [128]: series_monthly['2011-12'] # returns Series
Out[128]:
```

| 2011-12-01 | 1 |
|------------|---|

dtype: int64

### 19.6.3 Exact Indexing

As discussed in previous section, indexing a `DatetimeIndex` with a partial string depends on the “accuracy” of the period, in other words how specific the interval is in relation to the resolution of the index. In contrast, indexing with `Timestamp` or `datetime` objects is exact, because the objects have exact meaning. These also follow the semantics of *including both endpoints*.

These `Timestamp` and `datetime` objects have exact hours, minutes, and seconds, even though they were not explicitly specified (they are 0).

```
In [129]: dft[datetime.datetime(2013, 1, 1):datetime.datetime(2013, 2, 28)]
Out[129]:
```

|                     | A        |
|---------------------|----------|
| 2013-01-01 00:00:00 | 0.480217 |
| 2013-01-01 00:01:00 | 0.791875 |
| 2013-01-01 00:02:00 | 1.414514 |

## 19.6.4 Truncating & Fancy Indexing

A `truncate()` convenience function is provided that is similar to slicing. Note that `truncate` assumes a 0 value for any unspecified date component in a `DatetimeIndex` in contrast to slicing which returns any partially matching dates:

```
In [131]: rng2 = pd.date_range('2011-01-01', '2012-01-01', freq='W')
```

```
In [132]: ts2 = pd.Series(np.random.randn(len(rng2)), index=rng2)
```

```
In [133]: ts2.truncate(before='2011-11', after='2011-12')
```

```
Out[133]:
```

```

2011-11-06 0.524645
2011-11-13 0.027878
2011-11-20 -0.914186
2011-11-27 0.672453
Freq: W-SUN, dtype: float64

```

```
In [134]: ts2['2011-11':'2011-12']
```

```

////////////////////////////////////

```

```

↪
2011-11-06 0.524645
2011-11-13 0.027878
2011-11-20 -0.914186
2011-11-27 0.672453
2011-12-04 -0.698538
2011-12-11 1.048716
2011-12-18 0.158099
2011-12-25 1.605115
Freq: W-SUN, dtype: float64

```

Even complicated fancy indexing that breaks the `DatetimeIndex` frequency regularity will result in a `DatetimeIndex`, although frequency is lost:

```
In [135]: ts2[[0, 2, 6]].index
```

```

Out[135]: DatetimeIndex(['2011-01-02', '2011-01-16', '2011-02-13'], dtype=
↪ 'datetime64[ns]', freq=None)

```

## 19.7 Iterating through groups

With the Resampler object in hand, iterating through the grouped data is very natural and functions similarly to `itertools.groupby()`:

```
In [136]: small = pd.Series(
.....: range(6),
.....: index=pd.to_datetime(['2017-01-01T00:00:00',
.....: '2017-01-01T00:30:00',
.....: '2017-01-01T00:31:00',
.....: '2017-01-01T01:00:00',
.....: '2017-01-01T03:00:00',
.....: '2017-01-01T03:05:00']))
.....:)
.....:

In [137]: resampled = small.resample('H')

In [138]: for name, group in resampled:
.....: print("Group: ", name)
.....: print("-" * 27)
.....: print(group, end="\n\n")
.....:
Group: 2017-01-01 00:00:00

2017-01-01 00:00:00 0
2017-01-01 00:30:00 1
2017-01-01 00:31:00 2
dtype: int64

Group: 2017-01-01 01:00:00

2017-01-01 01:00:00 3
dtype: int64

Group: 2017-01-01 02:00:00

Series([], dtype: int64)

Group: 2017-01-01 03:00:00

2017-01-01 03:00:00 4
2017-01-01 03:05:00 5
dtype: int64
```

See *Iterating through groups* or `Resampler.__iter__` for more.

## 19.8 Time/Date Components

There are several time/date properties that one can access from `Timestamp` or a collection of timestamps like a `DatetimeIndex`.

| Property         | Description                                                       |
|------------------|-------------------------------------------------------------------|
| year             | The year of the datetime                                          |
| month            | The month of the datetime                                         |
| day              | The days of the datetime                                          |
| hour             | The hour of the datetime                                          |
| minute           | The minutes of the datetime                                       |
| second           | The seconds of the datetime                                       |
| microsecond      | The microseconds of the datetime                                  |
| nanosecond       | The nanoseconds of the datetime                                   |
| date             | Returns datetime.date (does not contain timezone information)     |
| time             | Returns datetime.time (does not contain timezone information)     |
| timetz           | Returns datetime.time as local time with timezone information     |
| dayofyear        | The ordinal day of year                                           |
| weekofyear       | The week ordinal of the year                                      |
| week             | The week ordinal of the year                                      |
| dayofweek        | The number of the day of the week with Monday=0, Sunday=6         |
| weekday          | The number of the day of the week with Monday=0, Sunday=6         |
| weekday_name     | The name of the day in a week (ex: Friday)                        |
| quarter          | Quarter of the date: Jan-Mar = 1, Apr-Jun = 2, etc.               |
| days_in_month    | The number of days in the month of the datetime                   |
| is_month_start   | Logical indicating if first day of month (defined by frequency)   |
| is_month_end     | Logical indicating if last day of month (defined by frequency)    |
| is_quarter_start | Logical indicating if first day of quarter (defined by frequency) |
| is_quarter_end   | Logical indicating if last day of quarter (defined by frequency)  |
| is_year_start    | Logical indicating if first day of year (defined by frequency)    |
| is_year_end      | Logical indicating if last day of year (defined by frequency)     |
| is_leap_year     | Logical indicating if the date belongs to a leap year             |

Furthermore, if you have a `Series` with datetimelike values, then you can access these properties via the `.dt` accessor, as detailed in the section on *.dt accessors*.

## 19.9 DateOffset Objects

In the preceding examples, frequency strings (e.g. 'D') were used to specify a frequency that defined:

- how the date times in `DatetimeIndex` were spaced when using `date_range()`
- the frequency of a `Period` or `PeriodIndex`

These frequency strings map to a `DateOffset` object and its subclasses. A `DateOffset` is similar to a `Timedelta` that represents a duration of time but follows specific calendar duration rules. For example, a `Timedelta` day will always increment datetimes by 24 hours, while a `DateOffset` day will increment datetimes to the same time the next day whether a day represents 23, 24 or 25 hours due to daylight savings time. However, all `DateOffset` subclasses that are an hour or smaller (`Hour`, `Minute`, `Second`, `Milli`, `Micro`, `Nano`) behave like `Timedelta` and respect absolute time.

The basic `DateOffset` acts similar to `dateutil.relativedelta` ([relativedelta documentation](#)) that shifts a date time by the corresponding calendar duration specified. The arithmetic operator (+) or the `apply` method can be used to perform the shift.

```
This particular day contains a day light savings time transition
In [139]: ts = pd.Timestamp('2016-10-30 00:00:00', tz='Europe/Helsinki')
```

(continues on next page)

(continued from previous page)

```

Respects absolute time
In [140]: ts + pd.Timedelta(days=1)
Out[140]: Timestamp('2016-10-30 23:00:00+0200', tz='Europe/Helsinki')

Respects calendar time
In [141]: ts + pd.DateOffset(days=1)
Out[141]: Timestamp('2016-10-31 00:00:00+0200', tz='Europe/Helsinki')

In [142]: friday = pd.Timestamp('2018-01-05')

In [143]: friday.day_name()
Out[143]: 'Friday'

Add 2 business days (Friday --> Tuesday)
In [144]: two_business_days = 2 * pd.offsets.BDay()

In [145]: two_business_days.apply(friday)
Out[145]: Timestamp('2018-01-09 00:00:00')

In [146]: friday + two_business_days
Out[146]: Timestamp('2018-01-09 00:00:00')

In [147]: (friday + two_business_days).day_name()
Out[147]: 'Tuesday'

```

Most `DateOffsets` have associated frequency strings, or offset aliases, that can be passed into `freq` keyword arguments. The available date offsets and associated frequency strings can be found below:

| Date Offset                                        | Frequency String | Description                                        |
|----------------------------------------------------|------------------|----------------------------------------------------|
| <i>DateOffset</i>                                  | None             | Generic offset class, defaults to 1 calendar day   |
| <i>BDay</i> or <i>BusinessDay</i>                  | 'B'              | business day (weekday)                             |
| <i>CDay</i> or <i>CustomBusinessDay</i>            | 'C'              | custom business day                                |
| <i>Week</i>                                        | 'W'              | one week, optionally anchored on a day of the week |
| <i>WeekOfMonth</i>                                 | 'WOM'            | the x-th day of the y-th week of each month        |
| <i>LastWeekOfMonth</i>                             | 'LWOM'           | the x-th day of the last week of each month        |
| <i>MonthEnd</i>                                    | 'M'              | calendar month end                                 |
| <i>MonthBegin</i>                                  | 'MS'             | calendar month begin                               |
| <i>BMonthEnd</i> or <i>BusinessMonthEnd</i>        | 'BM'             | business month end                                 |
| <i>BMonthBegin</i> or <i>BusinessMonthBegin</i>    | 'BMS'            | business month begin                               |
| <i>CBMonthEnd</i> or <i>CustomBusinessMonthEnd</i> | 'CBM'            | custom business month end                          |

Continued on next page

Table 1 – continued from previous page

| Date Offset                                                  | Frequency String | Description                                           |
|--------------------------------------------------------------|------------------|-------------------------------------------------------|
| <i>CBMonthBegin</i><br>or<br><i>CustomBusinessMonthBegin</i> | 'CBMS'           | custom business month begin                           |
| <i>SemiMonthEnd</i>                                          | 'SM'             | 15th (or other day_of_month) and calendar month end   |
| <i>SemiMonthBegin</i>                                        | 'SMS'            | 15th (or other day_of_month) and calendar month begin |
| <i>QuarterEnd</i>                                            | 'Q'              | calendar quarter end                                  |
| <i>QuarterBegin</i>                                          | 'QS'             | calendar quarter begin                                |
| <i>BQuarterEnd</i>                                           | 'BQ'             | business quarter end                                  |
| <i>BQuarterBegin</i>                                         | 'BQS'            | business quarter begin                                |
| <i>FY5253Quarter</i>                                         | 'REQ'            | retail (aka 52-53 week) quarter                       |
| <i>YearEnd</i>                                               | 'A'              | calendar year end                                     |
| <i>YearBegin</i>                                             | 'AS' or<br>'BYS' | calendar year begin                                   |
| <i>BYearEnd</i>                                              | 'BA'             | business year end                                     |
| <i>BYearBegin</i>                                            | 'BAS'            | business year begin                                   |
| <i>FY5253</i>                                                | 'RE'             | retail (aka 52-53 week) year                          |
| <i>Easter</i>                                                | None             | Easter holiday                                        |
| <i>BusinessHour</i>                                          | 'BH'             | business hour                                         |
| <i>CustomBusinessHour</i>                                    | 'CBH'            | custom business hour                                  |
| <i>Day</i>                                                   | 'D'              | one absolute day                                      |
| <i>Hour</i>                                                  | 'H'              | one hour                                              |
| <i>Minute</i>                                                | 'T' or 'min'     | one minute                                            |
| <i>Second</i>                                                | 'S'              | one second                                            |
| <i>Milli</i>                                                 | 'L' or 'ms'      | one millisecond                                       |
| <i>Micro</i>                                                 | 'U' or 'us'      | one microsecond                                       |
| <i>Nano</i>                                                  | 'N'              | one nanosecond                                        |

`DateOffsets` additionally have `rollforward()` and `rollback()` methods for moving a date forward or backward respectively to a valid offset date relative to the offset. For example, business offsets will roll dates that land on the weekends (Saturday and Sunday) forward to Monday since business offsets operate on the weekdays.

```
In [148]: ts = pd.Timestamp('2018-01-06 00:00:00')

In [149]: ts.day_name()
Out[149]: 'Saturday'

BusinessHour's valid offset dates are Monday through Friday
In [150]: offset = pd.offsets.BusinessHour(start='09:00')

Bring the date to the closest offset date (Monday)
In [151]: offset.rollforward(ts)
Out[151]: Timestamp('2018-01-08 09:00:00')

Date is brought to the closest offset date first and then the hour is added
In [152]: ts + offset
Out[152]: Timestamp('2018-01-08 10:00:00')
```

These operations preserve time (hour, minute, etc) information by default. To reset time to midnight, use `normalize()` before or after applying the operation (depending on whether you want the time information included in the operation).

[illegible]

### 19.9.1 Parametric Offsets

Some of the offsets can be “parameterized” when created to result in different behaviors. For example, the `Week` offset for generating weekly data accepts a `weekday` parameter which results in the generated dates always lying on a particular day of the week:

```
In [162]: d = datetime.datetime(2008, 8, 18, 9, 0)

In [163]: d
Out[163]: datetime.datetime(2008, 8, 18, 9, 0)

In [164]: d + pd.offsets.Week()
Out[164]: Timestamp('2008-08-25_
↳09:00:00')
```

```
In [165]: d + pd.offsets.Week(weekday=4)
Out[165]: Timestamp('2008-08-22 09:00:00')
```

```
In [166]: (d + pd.offsets.Week(weekday=4)).weekday()
Out[166]: 4
```

```
In [167]: d - pd.offsets.Week()
Out[167]: Timestamp('2008-08-11 09:00:00')
```

The `normalize` option will be effective for addition and subtraction.

```
In [168]: d + pd.offsets.Week(normalize=True)
Out[168]: Timestamp('2008-08-25 00:00:00')
```

(continues on next page)

(continued from previous page)

```
In [169]: d - pd.offsets.Week(normalize=True)
Out[169]: Timestamp('2008-08-11 00:00:00')
```

Another example is parameterizing YearEnd with the specific ending month:

```
In [170]: d + pd.offsets.YearEnd()
Out[170]: Timestamp('2008-12-31 09:00:00')

In [171]: d + pd.offsets.YearEnd(month=6)
Out[171]: Timestamp('2009-06-30 09:00:00')
```

## 19.9.2 Using Offsets with Series / DatetimeIndex

Offsets can be used with either a Series or DatetimeIndex to apply the offset to each element.

```
In [172]: rng = pd.date_range('2012-01-01', '2012-01-03')

In [173]: s = pd.Series(rng)

In [174]: rng
Out[174]: DatetimeIndex(['2012-01-01', '2012-01-02', '2012-01-03'], dtype=
↳ 'datetime64[ns]', freq='D')

In [175]: rng + pd.DateOffset(months=2)
Out[175]: DatetimeIndex(['2012-03-01', '2012-03-02', '2012-03-03'], dtype='datetime64[ns]',
↳ freq='D')

In [176]: s + pd.DateOffset(months=2)
Out[176]:
0 2012-03-01
1 2012-03-02
2 2012-03-03
dtype: datetime64[ns]

In [177]: s - pd.DateOffset(months=2)
Out[177]:
0 2011-11-01
1 2011-11-02
2 2011-11-03
dtype: datetime64[ns]
```

If the offset class maps directly to a Timedelta (Day, Hour, Minute, Second, Micro, Milli, Nano) it can be used exactly like a Timedelta - see the *Timedelta* section for more examples.

```
In [178]: s - pd.offsets.Day(2)
Out[178]:
0 2011-12-30
1 2011-12-31
2 2012-01-01
dtype: datetime64[ns]
```

(continues on next page)

(continued from previous page)

```
In [179]: td = s - pd.Series(pd.date_range('2011-12-29', '2011-12-31'))

In [180]: td
Out[180]:
0 3 days
1 3 days
2 3 days
dtype: timedelta64[ns]

In [181]: td + pd.offsets.Minute(15)
Out[181]:
0 3 days 00:15:00
1 3 days 00:15:00
2 3 days 00:15:00
dtype: timedelta64[ns]
```

Note that some offsets (such as `BQuarterEnd`) do not have a vectorized implementation. They can still be used but may calculate significantly slower and will show a `PerformanceWarning`

```
In [182]: rng + pd.offsets.BQuarterEnd()
Out[182]: DatetimeIndex(['2012-03-30', '2012-03-30', '2012-03-30'], dtype=
↳ 'datetime64[ns]', freq='D')
```

### 19.9.3 Custom Business Days

The `CDay` or `CustomBusinessDay` class provides a parametric `BusinessDay` class which can be used to create customized business day calendars which account for local holidays and local weekend conventions.

As an interesting example, let's look at Egypt where a Friday-Saturday weekend is observed.

```
In [183]: weekmask_egypt = 'Sun Mon Tue Wed Thu'

They also observe International Workers' Day so let's
add that for a couple of years
In [184]: holidays = ['2012-05-01',
.....: datetime.datetime(2013, 5, 1),
.....: np.datetime64('2014-05-01')]
.....:

In [185]: bday_egypt = pd.offsets.CustomBusinessDay(holidays=holidays,
.....: weekmask=weekmask_egypt)
.....:

In [186]: dt = datetime.datetime(2013, 4, 30)

In [187]: dt + 2 * bday_egypt
Out[187]: Timestamp('2013-05-05 00:00:00')
```

Let's map to the weekday names:

```
In [188]: dts = pd.date_range(dt, periods=5, freq=bday_egypt)

In [189]: pd.Series(dts.weekday, dts).map(
.....: pd.Series('Mon Tue Wed Thu Fri Sat Sun'.split()))
.....:
```

(continues on next page)

(continued from previous page)

```
Out [189]:
2013-04-30 Tue
2013-05-02 Thu
2013-05-05 Sun
2013-05-06 Mon
2013-05-07 Tue
Freq: C, dtype: object
```

Holiday calendars can be used to provide the list of holidays. See the *holiday calendar* section for more information.

```
In [190]: from pandas.tseries.holiday import USFederalHolidayCalendar

In [191]: bday_us = pd.offsets.CustomBusinessDay(calendar=USFederalHolidayCalendar())

Friday before MLK Day
In [192]: dt = datetime.datetime(2014, 1, 17)

Tuesday after MLK Day (Monday is skipped because it's a holiday)
In [193]: dt + bday_us
Out [193]: Timestamp('2014-01-21 00:00:00')
```

Monthly offsets that respect a certain holiday calendar can be defined in the usual way.

```
In [194]: bmth_us = pd.offsets.CustomBusinessMonthBegin(
.....: calendar=USFederalHolidayCalendar())
.....:

Skip new years
In [195]: dt = datetime.datetime(2013, 12, 17)

In [196]: dt + bmth_us
Out [196]: Timestamp('2014-01-02 00:00:00')

Define date index with custom offset
In [197]: pd.date_range(start='20100101', end='20120101', freq=bmth_us)
Out [197]:
DatetimeIndex(['2010-01-04', '2010-02-01', '2010-03-01', '2010-04-01',
 '2010-05-03', '2010-06-01', '2010-07-01', '2010-08-02',
 '2010-09-01', '2010-10-01', '2010-11-01', '2010-12-01',
 '2011-01-03', '2011-02-01', '2011-03-01', '2011-04-01',
 '2011-05-02', '2011-06-01', '2011-07-01', '2011-08-01',
 '2011-09-01', '2011-10-03', '2011-11-01', '2011-12-01'],
 dtype='datetime64[ns]', freq='CBMS')
```

**Note:** The frequency string ‘C’ is used to indicate that a CustomBusinessDay DateOffset is used, it is important to note that since CustomBusinessDay is a parameterised type, instances of CustomBusinessDay may differ and this is not detectable from the ‘C’ frequency string. The user therefore needs to ensure that the ‘C’ frequency string is used consistently within the user’s application.

## 19.9.4 Business Hour

The BusinessHour class provides a business hour representation on BusinessDay, allowing to use specific start and end times.

By default, `BusinessHour` uses 9:00 - 17:00 as business hours. Adding `BusinessHour` will increment `Timestamp` by hourly frequency. If target `Timestamp` is out of business hours, move to the next business hour then increment it. If the result exceeds the business hours end, the remaining hours are added to the next business day.

```
In [198]: bh = pd.offsets.BusinessHour()

In [199]: bh
Out[199]: <BusinessHour: BH=09:00-17:00>

2014-08-01 is Friday
In [200]: pd.Timestamp('2014-08-01 10:00').weekday()
Out[200]: 4

In [201]: pd.Timestamp('2014-08-01 10:00') + bh
Out[201]: Timestamp('2014-08-01 11:00:00')

Below example is the same as: pd.Timestamp('2014-08-01 09:00') + bh
In [202]: pd.Timestamp('2014-08-01 08:00') + bh
Out[202]: Timestamp('2014-08-01 10:00:00')

If the results is on the end time, move to the next business day
In [203]: pd.Timestamp('2014-08-01 16:00') + bh
Out[203]: Timestamp('2014-08-04 09:00:00')

Remainings are added to the next day
In [204]: pd.Timestamp('2014-08-01 16:30') + bh
Out[204]: Timestamp('2014-08-04 09:30:00')

Adding 2 business hours
In [205]: pd.Timestamp('2014-08-01 10:00') + pd.offsets.BusinessHour(2)
Out[205]: Timestamp('2014-08-01 12:00:00')

Subtracting 3 business hours
In [206]: pd.Timestamp('2014-08-01 10:00') + pd.offsets.BusinessHour(-3)
Out[206]: Timestamp('2014-07-31 15:00:00')
```

You can also specify start and end time by keywords. The argument must be a `str` with an `hour:minute` representation or a `datetime.time` instance. Specifying seconds, microseconds and nanoseconds as business hour results in `ValueError`.

```
In [207]: bh = pd.offsets.BusinessHour(start='11:00', end=datetime.time(20, 0))

In [208]: bh
Out[208]: <BusinessHour: BH=11:00-20:00>

In [209]: pd.Timestamp('2014-08-01 13:00') + bh
Out[209]: Timestamp('2014-08-01 14:00:00')

In [210]: pd.Timestamp('2014-08-01 09:00') + bh
Out[210]: Timestamp('2014-08-01 12:00:00')
```

(continues on next page)

(continued from previous page)

```
In [211]: pd.Timestamp('2014-08-01 18:00') + bh
\\Out[211]: Timestamp('2014-08-01 19:00:00')
```

Passing start time later than end represents midnight business hour. In this case, business hour exceeds midnight and overlap to the next day. Valid business hours are distinguished by whether it started from valid BusinessDay.

```
In [212]: bh = pd.offsets.BusinessHour(start='17:00', end='09:00')

In [213]: bh
Out[213]: <BusinessHour: BH=17:00-09:00>

In [214]: pd.Timestamp('2014-08-01 17:00') + bh
\\Out[214]: Timestamp('2014-08-01 18:00:00')

In [215]: pd.Timestamp('2014-08-01 23:00') + bh
\\Out[215]: Timestamp('2014-08-02 00:00:00')

Although 2014-08-02 is Saturday,
it is valid because it starts from 08-01 (Friday).
In [216]: pd.Timestamp('2014-08-02 04:00') + bh
\\Out[216]: Timestamp('2014-08-02 05:00:00')

Although 2014-08-04 is Monday,
it is out of business hours because it starts from 08-03 (Sunday).
In [217]: pd.Timestamp('2014-08-04 04:00') + bh
\\Out[217]: Timestamp('2014-08-04 18:00:00')
```

Applying BusinessHour.rollforward and rollback to out of business hours results in the next business hour start or previous day's end. Different from other offsets, BusinessHour.rollforward may output different results from apply by definition.

This is because one day's business hour end is equal to next day's business hour start. For example, under the default business hours (9:00 - 17:00), there is no gap (0 minutes) between 2014-08-01 17:00 and 2014-08-04 09:00.

```
This adjusts a Timestamp to business hour edge
In [218]: pd.offsets.BusinessHour().rollback(pd.Timestamp('2014-08-02 15:00'))
Out[218]: Timestamp('2014-08-01 17:00:00')

In [219]: pd.offsets.BusinessHour().rollforward(pd.Timestamp('2014-08-02 15:00'))
\\Out[219]: Timestamp('2014-08-04 09:00:00')

It is the same as BusinessHour().apply(pd.Timestamp('2014-08-01 17:00')).
And it is the same as BusinessHour().apply(pd.Timestamp('2014-08-04 09:00'))
In [220]: pd.offsets.BusinessHour().apply(pd.Timestamp('2014-08-02 15:00'))
\\Out[220]: Timestamp('2014-08-04 10:00:00')

BusinessDay results (for reference)
In [221]: pd.offsets.BusinessHour().rollforward(pd.Timestamp('2014-08-02'))
\\Out[221]: Timestamp('2014-08-04 09:00:00')
```

(continues on next page)

(continued from previous page)

[illegible]

`BusinessHour` regards Saturday and Sunday as holidays. To use arbitrary holidays, you can use `CustomBusinessHour` offset, as explained in the following subsection.

### 19.9.5 Custom Business Hour

New in version 0.18.1.

The `CustomBusinessHour` is a mixture of `BusinessHour` and `CustomBusinessDay` which allows you to specify arbitrary holidays. `CustomBusinessHour` works as the same as `BusinessHour` except that it skips specified custom holidays.

```
In [223]: from pandas.tseries.holiday import USFederalHolidayCalendar

In [224]: bhour_us = pd.offsets.
↳CustomBusinessHour(calendar=USFederalHolidayCalendar())

Friday before MLK Day
In [225]: dt = datetime.datetime(2014, 1, 17, 15)

In [226]: dt + bhour_us
Out[226]: Timestamp('2014-01-17 16:00:00')

Tuesday after MLK Day (Monday is skipped because it's a holiday)
In [227]: dt + bhour_us * 2
Out[227]: Timestamp('2014-01-21 09:00:00')
```

You can use keyword arguments supported by either `BusinessHour` and `CustomBusinessDay`.

```
In [228]: bhour_mon = pd.offsets.CustomBusinessHour(start='10:00',
.....: weekmask='Tue Wed Thu Fri')
.....:

Monday is skipped because it's a holiday, business hour starts from 10:00
In [229]: dt + bhour_mon * 2
Out[229]: Timestamp('2014-01-21 10:00:00')
```

### 19.9.6 Offset Aliases

A number of string aliases are given to useful common time series frequencies. We will refer to these aliases as *offset aliases*.

(continued from previous page)

```

 '2011-01-01 09:20:00', '2011-01-01 11:40:00',
 '2011-01-01 14:00:00', '2011-01-01 16:20:00',
 '2011-01-01 18:40:00', '2011-01-01 21:00:00'],
 dtype='datetime64[ns]', freq='140T')

In [233]: pd.date_range(start, periods=10, freq='1D10U')
///
↪
DatetimeIndex(['2011-01-01 00:00:00', '2011-01-02 00:00:00.000010',
 '2011-01-03 00:00:00.000020', '2011-01-04 00:00:00.000030',
 '2011-01-05 00:00:00.000040', '2011-01-06 00:00:00.000050',
 '2011-01-07 00:00:00.000060', '2011-01-08 00:00:00.000070',
 '2011-01-09 00:00:00.000080', '2011-01-10 00:00:00.000090'],
 dtype='datetime64[ns]', freq='86400000010U')

```

## 19.9.8 Anchored Offsets

For some frequencies you can specify an anchoring suffix:

| Alias       | Description                                             |
|-------------|---------------------------------------------------------|
| W-SUN       | weekly frequency (Sundays). Same as 'W'                 |
| W-MON       | weekly frequency (Mondays)                              |
| W-TUE       | weekly frequency (Tuesdays)                             |
| W-WED       | weekly frequency (Wednesdays)                           |
| W-THU       | weekly frequency (Thursdays)                            |
| W-FRI       | weekly frequency (Fridays)                              |
| W-SAT       | weekly frequency (Saturdays)                            |
| (B)Q(S)-DEC | quarterly frequency, year ends in December. Same as 'Q' |
| (B)Q(S)-JAN | quarterly frequency, year ends in January               |
| (B)Q(S)-FEB | quarterly frequency, year ends in February              |
| (B)Q(S)-MAR | quarterly frequency, year ends in March                 |
| (B)Q(S)-APR | quarterly frequency, year ends in April                 |
| (B)Q(S)-MAY | quarterly frequency, year ends in May                   |
| (B)Q(S)-JUN | quarterly frequency, year ends in June                  |
| (B)Q(S)-JUL | quarterly frequency, year ends in July                  |
| (B)Q(S)-AUG | quarterly frequency, year ends in August                |
| (B)Q(S)-SEP | quarterly frequency, year ends in September             |
| (B)Q(S)-OCT | quarterly frequency, year ends in October               |
| (B)Q(S)-NOV | quarterly frequency, year ends in November              |

Continued on next page

Table 2 – continued from previous page

| Alias       | Description                                             |
|-------------|---------------------------------------------------------|
| (B)A(S)-DEC | annual frequency, anchored end of December. Same as 'A' |
| (B)A(S)-JAN | annual frequency, anchored end of January               |
| (B)A(S)-FEB | annual frequency, anchored end of February              |
| (B)A(S)-MAR | annual frequency, anchored end of March                 |
| (B)A(S)-APR | annual frequency, anchored end of April                 |
| (B)A(S)-MAY | annual frequency, anchored end of May                   |
| (B)A(S)-JUN | annual frequency, anchored end of June                  |
| (B)A(S)-JUL | annual frequency, anchored end of July                  |
| (B)A(S)-AUG | annual frequency, anchored end of August                |
| (B)A(S)-SEP | annual frequency, anchored end of September             |
| (B)A(S)-OCT | annual frequency, anchored end of October               |
| (B)A(S)-NOV | annual frequency, anchored end of November              |

These can be used as arguments to `date_range`, `bdate_range`, constructors for `DatetimeIndex`, as well as various other timeseries-related functions in pandas.

### 19.9.9 Anchored Offset Semantics

For those offsets that are anchored to the start or end of specific frequency (`MonthEnd`, `MonthBegin`, `WeekEnd`, etc), the following rules apply to rolling forward and backwards.

When `n` is not 0, if the given date is not on an anchor point, it snapped to the next(previous) anchor point, and moved `|n|-1` additional steps forwards or backwards.

```
In [234]: pd.Timestamp('2014-01-02') + pd.offsets.MonthBegin(n=1)
Out[234]: Timestamp('2014-02-01 00:00:00')
```

```
In [235]: pd.Timestamp('2014-01-02') + pd.offsets.MonthEnd(n=1)
Out[235]: Timestamp('2014-01-31 00:00:00')
```

```
In [236]: pd.Timestamp('2014-01-02') - pd.offsets.MonthBegin(n=1)
Out[236]: Timestamp('2014-01-01 00:00:00')
```

```
In [237]: pd.Timestamp('2014-01-02') - pd.offsets.MonthEnd(n=1)
Out[237]: Timestamp('2013-12-31 00:00:00')
```

```
In [238]: pd.Timestamp('2014-01-02') + pd.offsets.MonthBegin(n=4)
Out[238]: Timestamp('2014-05-01 00:00:00')
```

(continues on next page)

(continued from previous page)

```
In [239]: pd.Timestamp('2014-01-02') - pd.offsets.MonthBegin(n=4)
\\Out[239]: Timestamp('2013-10-01 00:00:00')
```

If the given date *is* on an anchor point, it is moved  $|n|$  points forwards or backwards.

```
In [240]: pd.Timestamp('2014-01-01') + pd.offsets.MonthBegin(n=1)
Out[240]: Timestamp('2014-02-01 00:00:00')

In [241]: pd.Timestamp('2014-01-31') + pd.offsets.MonthEnd(n=1)
\\Out[241]: Timestamp('2014-02-28 00:00:00')

In [242]: pd.Timestamp('2014-01-01') - pd.offsets.MonthBegin(n=1)
\\Out[242]: Timestamp('2013-12-01 00:00:00')

In [243]: pd.Timestamp('2014-01-31') - pd.offsets.MonthEnd(n=1)
\\Out[243]: Timestamp('2013-12-31 00:00:00')

In [244]: pd.Timestamp('2014-01-01') + pd.offsets.MonthBegin(n=4)
\\Out[244]: Timestamp('2014-05-01 00:00:00')

In [245]: pd.Timestamp('2014-01-31') - pd.offsets.MonthBegin(n=4)
\\Out[245]: Timestamp('2013-10-01 00:00:00')
```

For the case when  $n=0$ , the date is not moved if on an anchor point, otherwise it is rolled forward to the next anchor point.

```
In [246]: pd.Timestamp('2014-01-02') + pd.offsets.MonthBegin(n=0)
Out[246]: Timestamp('2014-02-01 00:00:00')

In [247]: pd.Timestamp('2014-01-02') + pd.offsets.MonthEnd(n=0)
\\Out[247]: Timestamp('2014-01-31 00:00:00')

In [248]: pd.Timestamp('2014-01-01') + pd.offsets.MonthBegin(n=0)
\\Out[248]: Timestamp('2014-01-01 00:00:00')

In [249]: pd.Timestamp('2014-01-31') + pd.offsets.MonthEnd(n=0)
\\Out[249]: Timestamp('2014-01-31 00:00:00')
```

## 19.9.10 Holidays / Holiday Calendars

Holidays and calendars provide a simple way to define holiday rules to be used with `CustomBusinessDay` or in other analysis that requires a predefined set of holidays. The `AbstractHolidayCalendar` class provides all the necessary methods to return a list of holidays and only rules need to be defined in a specific holiday calendar class. Furthermore, the `start_date` and `end_date` class attributes determine over what date range holidays are generated. These should be overwritten on the `AbstractHolidayCalendar` class to have the range apply to all calendar subclasses. `USFederalHolidayCalendar` is the only calendar that exists and primarily serves as an example for developing other calendars.

For holidays that occur on fixed dates (e.g., US Memorial Day or July 4th) an observance rule determines when that holiday is observed if it falls on a weekend or some other non-observed day. Defined observance rules are:

| Rule                   | Description                                          |
|------------------------|------------------------------------------------------|
| nearest_workday        | move Saturday to Friday and Sunday to Monday         |
| sunday_to_monday       | move Sunday to following Monday                      |
| next_monday_or_tuesday | move Saturday to Monday and Sunday/Monday to Tuesday |
| previous_friday        | move Saturday and Sunday to previous Friday          |
| next_monday            | move Saturday and Sunday to following Monday         |

An example of how holidays and holiday calendars are defined:

```
In [250]: from pandas.tseries.holiday import Holiday, USMemorialDay, \
.....: AbstractHolidayCalendar, nearest_workday, MO
.....:

In [251]: class ExampleCalendar(AbstractHolidayCalendar):
.....: rules = [
.....: USMemorialDay,
.....: Holiday('July 4th', month=7, day=4, observance=nearest_workday),
.....: Holiday('Columbus Day', month=10, day=1,
.....: offset=pd.DateOffset(weekday=MO(2)))]
.....:

In [252]: cal = ExampleCalendar()

In [253]: cal.holidays(datetime.datetime(2012, 1, 1), datetime.datetime(2012, 12, 31))
Out[253]: DatetimeIndex(['2012-05-28', '2012-07-04', '2012-10-08'], dtype=
->'datetime64[ns]', freq=None)
```

**hint** weekday=MO(2) is same as 2 \* Week(weekday=2)

Using this calendar, creating an index or doing offset arithmetic skips weekends and holidays (i.e., Memorial Day/July 4th). For example, the below defines a custom business day offset using the ExampleCalendar. Like any other offset, it can be used to create a DatetimeIndex or added to datetime or Timestamp objects.

```
In [254]: pd.date_range(start='7/1/2012', end='7/10/2012',
.....: freq=pd.offsets.CDay(calendar=cal)).to_pydatetime()
.....:
Out[254]:
array([datetime.datetime(2012, 7, 2, 0, 0),
 datetime.datetime(2012, 7, 3, 0, 0),
 datetime.datetime(2012, 7, 5, 0, 0),
 datetime.datetime(2012, 7, 6, 0, 0),
 datetime.datetime(2012, 7, 9, 0, 0),
 datetime.datetime(2012, 7, 10, 0, 0)], dtype=object)

In [255]: offset = pd.offsets.CustomBusinessDay(calendar=cal)

In [256]: datetime.datetime(2012, 5, 25) + offset
Out[256]: Timestamp('2012-05-29 00:00:00')

In [257]: datetime.datetime(2012, 7, 3) + offset
Out[257]: Timestamp('2012-07-05 00:00:00')

In [258]: datetime.datetime(2012, 7, 3) + 2 * offset
Out[258]: Timestamp('2012-07-06 00:00:00')
(continues on next page)
```

(continued from previous page)

```
In [259]: datetime.datetime(2012, 7, 6) + offset
\\.....
↳Timestamp('2012-07-09 00:00:00')
```

Ranges are defined by the `start_date` and `end_date` class attributes of `AbstractHolidayCalendar`. The defaults are shown below.

```
In [260]: AbstractHolidayCalendar.start_date
Out[260]: Timestamp('1970-01-01 00:00:00')

In [261]: AbstractHolidayCalendar.end_date
\\.....Out[261]: Timestamp('2030-12-31 00:00:00')
```

These dates can be overwritten by setting the attributes as `datetime`/`Timestamp`/`string`.

```
In [262]: AbstractHolidayCalendar.start_date = datetime.datetime(2012, 1, 1)

In [263]: AbstractHolidayCalendar.end_date = datetime.datetime(2012, 12, 31)

In [264]: cal.holidays()
Out[264]: DatetimeIndex(['2012-05-28', '2012-07-04', '2012-10-08'], dtype=
↳'datetime64[ns]', freq=None)
```

Every calendar class is accessible by name using the `get_calendar` function which returns a holiday class instance. Any imported calendar class will automatically be available by this function. Also, `HolidayCalendarFactory` provides an easy interface to create calendars that are combinations of calendars or calendars with additional rules.

```
In [265]: from pandas.tseries.holiday import get_calendar, HolidayCalendarFactory, \
.....: USLaborDay
.....:

In [266]: cal = get_calendar('ExampleCalendar')

In [267]: cal.rules
Out[267]:
[Holiday: MemorialDay (month=5, day=31, offset=<DateOffset: weekday=MO(-1)>),
 Holiday: July 4th (month=7, day=4, observance=<function nearest_workday at
↳0x7fd508b19730>),
 Holiday: Columbus Day (month=10, day=1, offset=<DateOffset: weekday=MO(+2)>)]

In [268]: new_cal = HolidayCalendarFactory('NewExampleCalendar', cal, USLaborDay)

In [269]: new_cal.rules
Out[269]:
[Holiday: Labor Day (month=9, day=1, offset=<DateOffset: weekday=MO(+1)>),
 Holiday: MemorialDay (month=5, day=31, offset=<DateOffset: weekday=MO(-1)>),
 Holiday: July 4th (month=7, day=4, observance=<function nearest_workday at
↳0x7fd508b19730>),
 Holiday: Columbus Day (month=10, day=1, offset=<DateOffset: weekday=MO(+2)>)]
```

## 19.10 Time Series-Related Instance Methods

### 19.10.1 Shifting / Lagging

One may want to *shift* or *lag* the values in a time series back and forward in time. The method for this is `shift()`, which is available on all of the pandas objects.

```
In [270]: ts = pd.Series(range(len(rng)), index=rng)
```

```
In [271]: ts = ts[:5]
```

```
In [272]: ts.shift(1)
```

```
Out[272]:
2012-01-01 NaN
2012-01-02 0.0
2012-01-03 1.0
Freq: D, dtype: float64
```

The `shift` method accepts an `freq` argument which can accept a `DateOffset` class or other `timedelta`-like object or also an *offset alias*:

```
In [273]: ts.shift(5, freq=pd.offsets.BDay())
```

```
Out[273]:
2012-01-06 0
2012-01-09 1
2012-01-10 2
Freq: B, dtype: int64
```

```
In [274]: ts.shift(5, freq='BM')
```

```
Out[274]:
2012-05-31 0
2012-05-31 1
2012-05-31 2
Freq: D, dtype: int64
```

Rather than changing the alignment of the data and the index, `DataFrame` and `Series` objects also have a `tshift()` convenience method that changes all the dates in the index by a specified number of offsets:

```
In [275]: ts.tshift(5, freq='D')
```

```
Out[275]:
2012-01-06 0
2012-01-07 1
2012-01-08 2
Freq: D, dtype: int64
```

Note that with `tshift`, the leading entry is no longer `NaN` because the data is not being realigned.

### 19.10.2 Frequency Conversion

The primary function for changing frequencies is the `asfreq()` method. For a `DatetimeIndex`, this is basically just a thin, but convenient wrapper around `reindex()` which generates a `date_range` and calls `reindex`.

```
In [276]: dr = pd.date_range('1/1/2010', periods=3, freq=3 * pd.offsets.BDay())
```

(continues on next page)

(continued from previous page)

```
In [277]: ts = pd.Series(np.random.randn(3), index=dr)
```

```
In [278]: ts
```

Out [278] :

```
2010-01-01 -0.014261
2010-01-06 -0.760069
2010-01-11 0.028879
Freq: 3B, dtype: float64
```

```
In [279]: ts.asfreq(pd.offsets.BDay())
```

```
2010-01-01 -0.014261
2010-01-04 NaN
2010-01-05 NaN
2010-01-06 -0.760069
2010-01-07 NaN
2010-01-08 NaN
2010-01-11 0.028879
Freq: B, dtype: float64
```

`asfreq` provides a further convenience so you can specify an interpolation method for any gaps that may appear after the frequency conversion.

```
In [280]: ts.asfreq(pd.offsets.BDay(), method='pad')
```

Out [280] :

```
2010-01-01 -0.014261
2010-01-04 -0.014261
2010-01-05 -0.014261
2010-01-06 -0.760069
2010-01-07 -0.760069
2010-01-08 -0.760069
2010-01-11 0.028879
Freq: B, dtype: float64
```

### 19.10.3 Filling Forward / Backward

Related to `asfreq` and `reindex` is `fillna()`, which is documented in the *missing data section*.

### 19.10.4 Converting to Python Datetimes

`DatetimeIndex` can be converted to an array of Python native `datetime.datetime` objects using the `to_pydatetime` method.

## 19.11 Resampling

**Warning:** The interface to `.resample` has changed in 0.18.0 to be more groupby-like and hence more flexible. See the *whatsnew docs* for a comparison with prior versions.

Pandas has a simple, powerful, and efficient functionality for performing resampling operations during frequency conversion (e.g., converting secondly data into 5-minutely data). This is extremely common in, but not limited to, financial applications.

`resample()` is a time-based groupby, followed by a reduction method on each of its groups. See some *cookbook examples* for some advanced strategies.

Starting in version 0.18.1, the `resample()` function can be used directly from `DataFrameGroupBy` objects, see the *groupby docs*.

**Note:** `.resample()` is similar to using a `rolling()` operation with a time-based offset, see a discussion *here*.

### 19.11.1 Basics

```
In [281]: rng = pd.date_range('1/1/2012', periods=100, freq='S')

In [282]: ts = pd.Series(np.random.randint(0, 500, len(rng)), index=rng)

In [283]: ts.resample('5Min').sum()
Out[283]:
2012-01-01 25003
Freq: 5T, dtype: int64
```

The `resample` function is very flexible and allows you to specify many different parameters to control the frequency conversion and resampling operation.

Any function available via *dispatching* is available as a method of the returned object, including `sum`, `mean`, `std`, `sem`, `max`, `min`, `median`, `first`, `last`, `ohlc`:

```
In [284]: ts.resample('5Min').mean()
Out[284]:
2012-01-01 250.03
Freq: 5T, dtype: float64

In [285]: ts.resample('5Min').ohlc()
Out[285]:
open high low close
2012-01-01 114 499 0 381

In [286]: ts.resample('5Min').max()
Out[286]:
2012-01-01 499
Freq: 5T, dtype: int64
```

For downsampling, `closed` can be set to 'left' or 'right' to specify which end of the interval is closed:

```
In [287]: ts.resample('5Min', closed='right').mean()
Out[287]:
2011-12-31 23:55:00 114.00000
2012-01-01 00:00:00 251.40404
Freq: 5T, dtype: float64
```

```
In [288]: ts.resample('5Min', closed='left').mean()
```

(continues on next page)

(continued from previous page)

```
2012-01-01 250.03
Freq: 5T, dtype: float64
```

Parameters like `label` and `loffset` are used to manipulate the resulting labels. `label` specifies whether the result is labeled with the beginning or the end of the interval. `loffset` performs a time adjustment on the output labels.

```
In [289]: ts.resample('5Min').mean() # by default label='left'
Out[289]:
2012-01-01 250.03
Freq: 5T, dtype: float64

In [290]: ts.resample('5Min', label='left').mean()
Out[290]:
2012-01-01 250.03
Freq: 5T, dtype: float64

In [291]: ts.resample('5Min', label='left', loffset='1s').mean()
Out[291]:
2012-01-01 00:00:01 250.03
dtype: float64
```

**Note:** The default values for `label` and `closed` is 'left' for all frequency offsets except for 'M', 'A', 'Q', 'BM', 'BA', 'BQ', and 'W' which all have a default of 'right'.

```
In [292]: rng2 = pd.date_range('1/1/2012', end='3/31/2012', freq='D')
In [293]: ts2 = pd.Series(range(len(rng2)), index=rng2)

default: label='right', closed='right'
In [294]: ts2.resample('M').max()
Out[294]:
2012-01-31 30
2012-02-29 59
2012-03-31 90
Freq: M, dtype: int64

default: label='left', closed='left'
In [295]: ts2.resample('SM').max()
Out[295]:
2011-12-31 13
2012-01-15 29
2012-01-31 44
2012-02-15 58
2012-02-29 73
2012-03-15 89
2012-03-31 90
Freq: SM-15, dtype: int64

In [296]: ts2.resample('SM', label='right', closed='right').max()
Out[296]:
2012-01-15 14.0
2012-01-31 30.0
```

(continues on next page)

want to use a method to fill these values, e.g. `fill_method` is `None`, then intermediate values will be filled with `NaN`.

Since `resample` is a time-based groupby, the following is a method to efficiently resample only the groups that are not all `NaN`.

```
In [300]: rng = pd.date_range('2014-1-1', periods=100, freq='D') + pd.Timedelta('1s')
In [301]: ts = pd.Series(range(100), index=rng)
```

If we want to resample to the full range of the series:

```
In [302]: ts.resample('3T').sum()
```

Out[302]:

```

### 19.11.4 Aggregation

Similar to the *aggregating API*, *groupby API*, and the *window functions API*, a `Resampler` can be selectively resampled.

Resampling a `DataFrame`, the default will be to act on all columns with the same function.

```

In [307]: df = pd.DataFrame(np.random.randn(1000, 3),
.....: index=pd.date_range('1/1/2012', freq='S', periods=1000),
.....: columns=['A', 'B', 'C'])
.....:

In [308]: r = df.resample('3T')

In [309]: r.mean()
Out[309]:

```

A
B
C

```
In [314]: r.agg({'A': np.sum,
.....: 'B': lambda x: np.std(x, ddof=1)})
.....:
Out[314]:
```

|                     | A         | B        |
|---------------------|-----------|----------|
| 2012-01-01 00:00:00 | -6.080538 | 0.929504 |
| 2012-01-01 00:03:00 | -4.229885 | 0.945142 |
| 2012-01-01 00:06:00 | -6.934007 | 0.992286 |
| 2012-01-01 00:09:00 | 2.873238  | 0.990177 |
| 2012-01-01 00:12:00 | -2.000302 | 0.976255 |
| 2012-01-01 00:15:00 | -0.816366 | 1.037785 |

The function names can also be strings. In order for a string to be valid it must be implemented on the resampled object:

```
In [315]: r.agg({'A': 'sum', 'B': 'std'})
Out[315]:
```

|                     | A         | B        |
|---------------------|-----------|----------|
| 2012-01-01 00:00:00 | -6.080538 | 0.929504 |
| 2012-01-01 00:03:00 | -4.229885 | 0.945142 |
| 2012-01-01 00:06:00 | -6.934007 | 0.992286 |
| 2012-01-01 00:09:00 | 2.873238  | 0.990177 |
| 2012-01-01 00:12:00 | -2.000302 | 0.976255 |
| 2012-01-01 00:15:00 | -0.816366 | 1.037785 |

Furthermore, you can also specify multiple aggregation functions for each column separately.

```
In [316]: r.agg({'A': ['sum', 'std'], 'B': ['mean', 'std']})
Out[316]:
```

|                     | A         |          | B         |          |
|---------------------|-----------|----------|-----------|----------|
|                     | sum       | std      | mean      | std      |
| 2012-01-01 00:00:00 | -6.080538 | 1.063125 | -0.032439 | 0.929504 |
| 2012-01-01 00:03:00 | -4.229885 | 0.967564 | 0.121188  | 0.945142 |
| 2012-01-01 00:06:00 | -6.934007 | 1.026984 | 0.061784  | 0.992286 |
| 2012-01-01 00:09:00 | 2.873238  | 0.961662 | 0.076245  | 0.990177 |
| 2012-01-01 00:12:00 | -2.000302 | 0.951884 | -0.044745 | 0.976255 |
| 2012-01-01 00:15:00 | -0.816366 | 0.879981 | -0.148956 | 1.037785 |

If a DataFrame does not have a datetimelike index, but instead you want to resample based on datetimelike column in the frame, it can be passed to the `on` keyword.

```
In [317]: df = pd.DataFrame({'date': pd.date_range('2015-01-01', freq='W', periods=5),
.....: 'a': np.arange(5)},
.....: index=pd.MultiIndex.from_arrays([

date
2015-01-31 6
2015-02-28 4

```

Similarly, if you instead want to resample by a datetimelike level of `MultiIndex`, its name or location can be passed to the `level` keyword.

```
In [320]: df.resample('M', level='d').sum()
```

```

Out [320]:
 a
d
2015-01-31 6
2015-02-28 4

```

## 19.12 Time Span Representation

Regular intervals of time are represented by `Period` objects in pandas while sequences of `Period` objects are collected in a `PeriodIndex`, which can be created with the convenience function `period_range`.

### 19.12.1 Period

A `Period` represents a span of time (e.g., a day, a month, a quarter, etc). You can specify the span via `freq` keyword using a frequency alias like below. Because `freq` represents a span of `Period`, it cannot be negative like “-3D”.

```
In [321]: pd.Period('2012', freq='A-DEC')
```

```
Out [321]: Period('2012', 'A-DEC')
```

```
In [322]: pd.Period('2012-1-1', freq='D')
```

```

////////////////////////////////////Out [322]: Period('2012-01-01', 'D')

```

```
In [323]: pd.Period('2012-1-1 19:00', freq='H')
```

```

////////////////////////////////////Out [323]:
↪Period('2012-01-01 19:00', 'H')

```

```
In [324]: pd.Period('2012-1-1 19:00', freq='5H')
```

```

////////////////////////////////////
↪Period('2012-01-01 19:00', '5H')

```

Adding and subtracting integers from periods shifts the period by its own frequency. Arithmetic is not allowed between `Period` with different `freq` (span).

```
In [325]: p = pd.Period('2012', freq='A-DEC')
```

```
In [326]: p + 1
```

```
Out [326]: Period('2013', 'A-DEC')
```

(continues on next page)

(continued from previous page)

```

In [327]: p - 3
\\Out[327]: Period('2009', 'A-DEC')

In [328]: p = pd.Period('2012-01', freq='2M')

In [329]: p + 2
Out[329]: Period('2012-05', '2M')

In [330]: p - 1
\\Out[330]: Period('2011-11', '2M')

In [331]: p == pd.Period('2012-01', freq='3M')
\\-----
↪-----
IncompatibleFrequency Traceback (most recent call last)
<ipython-input-331-4b67dc0b596c> in <module>
----> 1 p == pd.Period('2012-01', freq='3M')

/pandas/pandas/_libs/tslibs/period.pyx in pandas._libs.tslibs.period._Period.__
↪richcmp__()

IncompatibleFrequency: Input has different freq=3M from Period(freq=2M)

```

If Period freq is daily or higher (D, H, T, S, L, U, N), offsets and timedelta-like can be added if the result can have the same freq. Otherwise, ValueError will be raised.

```

In [332]: p = pd.Period('2014-07-01 09:00', freq='H')

In [333]: p + pd.offsets.Hour(2)
Out[333]: Period('2014-07-01 11:00', 'H')

In [334]: p + datetime.timedelta(minutes=120)
\\Out[334]: Period('2014-07-01 11:00', 'H')

In [335]: p + np.timedelta64(7200, 's')
\\Out[335]: ↪Period('2014-07-01 11:00', 'H')

```

```

In [1]: p + pd.offsets.Minute(5)
Traceback
...
ValueError: Input has different freq from Period(freq=H)

```

If Period has other frequencies, only the same offsets can be added. Otherwise, ValueError will be raised.

```

In [336]: p = pd.Period('2014-07', freq='M')

In [337]: p + pd.offsets.MonthEnd(3)
Out[337]: Period('2014-10', 'M')

```

```

In [1]: p + pd.offsets.MonthBegin(3)
Traceback
...
ValueError: Input has different freq from Period(freq=M)

```

Taking the difference of Period instances with the same frequency will return the number of frequency units between

them:

```
In [338]: pd.Period('2012', freq='A-DEC') - pd.Period('2002', freq='A-DEC')
Out [338]: <10 * YearEnds: month=12>
```

### 19.12.2 PeriodIndex and period\_range

Regular sequences of Period objects can be collected in a PeriodIndex, which can be constructed using the period\_range convenience function:

```
In [339]: prng = pd.period_range('1/1/2011', '1/1/2012', freq='M')

In [340]: prng
Out [340]:
PeriodIndex(['2011-01', '2011-02', '2011-03', '2011-04', '2011-05', '2011-06',
 '2011-07', '2011-08', '2011-09', '2011-10', '2011-11', '2011-12',
 '2012-01'],
 dtype='period[M]', freq='M')
```

The PeriodIndex constructor can also be used directly:

```
In [341]: pd.PeriodIndex(['2011-1', '2011-2', '2011-3'], freq='M')
Out [341]: PeriodIndex(['2011-01', '2011-02', '2011-03'], dtype='period[M]', freq='M')
```

Passing multiplied frequency outputs a sequence of Period which has multiplied span.

```
In [342]: pd.period_range(start='2014-01', freq='3M', periods=4)
Out [342]: PeriodIndex(['2014-01', '2014-04', '2014-07', '2014-10'], dtype='period[3M]',
 freq='3M')
```

If start or end are Period objects, they will be used as anchor endpoints for a PeriodIndex with frequency matching that of the PeriodIndex constructor.

```
In [343]: pd.period_range(start=pd.Period('2017Q1', freq='Q'),
 : end=pd.Period('2017Q2', freq='Q'), freq='M')
 :
Out [343]: PeriodIndex(['2017-03', '2017-04', '2017-05', '2017-06'], dtype='period[M]',
 freq='M')
```

Just like DatetimeIndex, a PeriodIndex can also be used to index pandas objects:

```
In [344]: ps = pd.Series(np.random.randn(len(prng)), prng)

In [345]: ps
Out [345]:
2011-01 0.818145
2011-02 0.267439
2011-03 -0.133309
2011-04 0.662254
2011-05 -0.688393
2011-06 -0.731718
2011-07 -1.190946
2011-08 -1.889384
2011-09 0.171033
2011-10 0.368582
2011-11 0.356459
```

(continues on next page)

(continued from previous page)

```

2011-12 0.556248
2012-01 -0.148709
Freq: M, dtype: float64

```

PeriodIndex supports addition and subtraction with the same rule as Period.

```
In [346]: idx = pd.period_range('2014-07-01 09:00', periods=5, freq='H')
```

```
In [347]: idx
```

```
Out [347]:
```

```

PeriodIndex(['2014-07-01 09:00', '2014-07-01 10:00', '2014-07-01 11:00',
 '2014-07-01 12:00', '2014-07-01 13:00'],
 dtype='period[H]', freq='H')

```

```
In [348]: idx + pd.offsets.Hour(2)
```

```

////////////////////////////////////~
↪
PeriodIndex(['2014-07-01 11:00', '2014-07-01 12:00', '2014-07-01 13:00',
 '2014-07-01 14:00', '2014-07-01 15:00'],
 dtype='period[H]', freq='H')

```

```
In [349]: idx = pd.period_range('2014-07', periods=5, freq='M')
```

```
In [350]: idx
```

```

Out [350]: PeriodIndex(['2014-07', '2014-08', '2014-09', '2014-10', '2014-11'], dtype=
↪ 'period[M]', freq='M')

```

```
In [351]: idx + pd.offsets.MonthEnd(3)
```

```

////////////////////////////////////~
↪ PeriodIndex(['2014-10', '2014-11', '2014-12', '2015-01', '2015-02'], dtype=
↪ 'period[M]', freq='M')

```

PeriodIndex has its own dtype named period, refer to *Period Dtypes*.

### 19.12.3 Period Dtypes

New in version 0.19.0.

PeriodIndex has a custom period dtype. This is a pandas extension dtype similar to the *timezone aware dtype* (datetime64[ns, tz]).

The period dtype holds the freq attribute and is represented with period[freq] like period[D] or period[M], using *frequency strings*.

```
In [352]: pi = pd.period_range('2016-01-01', periods=3, freq='M')
```

```
In [353]: pi
```

```
Out [353]: PeriodIndex(['2016-01', '2016-02', '2016-03'], dtype='period[M]', freq='M')
```

```
In [354]: pi.dtype
```

```

////////////////////////////////////~Out [354]: ↪
↪ period[M]

```

The period dtype can be used in `.astype(...)`. It allows one to change the freq of a PeriodIndex like `.asfreq()` and convert a DatetimeIndex to PeriodIndex like `to_period()`:

```
change monthly freq to daily freq
In [355]: pi.astype('period[D]')
Out[355]: PeriodIndex(['2016-01-31', '2016-02-29', '2016-03-31'], dtype='period[D]',
↳freq='D')

convert to DatetimeIndex
In [356]: pi.astype('datetime64[ns]')
Out[356]: DatetimeIndex(['2016-01-01', '2016-02-01', '2016-03-01'], dtype='datetime64[ns]',
↳freq='MS')

convert to PeriodIndex
In [357]: dti = pd.date_range('2011-01-01', freq='M', periods=3)

In [358]: dti
Out[358]: DatetimeIndex(['2011-01-31', '2011-02-28', '2011-03-31'], dtype=
↳'datetime64[ns]', freq='M')

In [359]: dti.astype('period[M]')
Out[359]: PeriodIndex(['2011-01', '2011-02', '2011-03'], dtype='period[M]', freq='M')
```

### 19.12.4 PeriodIndex Partial String Indexing

You can pass in dates and strings to Series and DataFrame with PeriodIndex, in the same manner as DatetimeIndex. For details, refer to *DatetimeIndex Partial String Indexing*.

```
In [360]: ps['2011-01']
Out[360]: 0.81814541276591313

In [361]: ps[datetime.datetime(2011, 12, 25):]
Out[361]:
2011-12 0.556248
2012-01 -0.148709
Freq: M, dtype: float64

In [362]: ps['10/31/2011':'12/31/2011']
Out[362]:
2011-10 0.368582
2011-11 0.356459
2011-12 0.556248
Freq: M, dtype: float64
```

Passing a string representing a lower frequency than PeriodIndex returns partial sliced data.

```
In [363]: ps['2011']
Out[363]:
2011-01 0.818145
2011-02 0.267439
2011-03 -0.133309
2011-04 0.662254
2011-05 -0.688393
2011-06 -0.731718
2011-07 -1.190946
2011-08 -1.889384
```

(continues on next page)

(continued from previous page)

```

2011-09 0.171033
2011-10 0.368582
2011-11 0.356459
2011-12 0.556248
Freq: M, dtype: float64

```

```

In [364]: dfp = pd.DataFrame(np.random.randn(600, 1),
.....: columns=['A'],
.....: index=pd.period_range('2013-01-01 9:00',
.....: periods=600,
.....: freq='T'))
.....:

```

```
In [365]: dfp
```

```
Out[365]:
```

```

### 19.12.5 Frequency Conversion and Resampling with PeriodIndex

The frequency of Period and PeriodIndex can be converted via the `asfreq` method. Let's start with the fiscal year 2011, ending in December:

```

In [368]: p = pd.Period('2011', freq='A-DEC')

In [369]: p
Out[369]: Period('2011', 'A-DEC')

```

We can convert it to a monthly frequency. Using the `how` parameter, we can specify whether to return the starting or

ending month:

```
In [370]: p.asfreq('M', how='start')
Out[370]: Period('2011-01', 'M')

In [371]: p.asfreq('M', how='end')
Out[371]: Period('2011-12', 'M')
```

The shorthands 's' and 'e' are provided for convenience:

```
In [372]: p.asfreq('M', 's')
Out[372]: Period('2011-01', 'M')

In [373]: p.asfreq('M', 'e')
Out[373]: Period('2011-12', 'M')
```

Converting to a “super-period” (e.g., annual frequency is a super-period of quarterly frequency) automatically returns the super-period that includes the input period:

```
In [374]: p = pd.Period('2011-12', freq='M')

In [375]: p.asfreq('A-NOV')
Out[375]: Period('2012', 'A-NOV')
```

Note that since we converted to an annual frequency that ends the year in November, the monthly period of December 2011 is actually in the 2012 A-NOV period.

Period conversions with anchored frequencies are particularly useful for working with various quarterly data common to economics, business, and other fields. Many organizations define quarters relative to the month in which their fiscal year starts and ends. Thus, first quarter of 2011 could start in 2010 or a few months into 2011. Via anchored frequencies, pandas works for all quarterly frequencies Q-JAN through Q-DEC.

Q-DEC define regular calendar quarters:

```
In [376]: p = pd.Period('2012Q1', freq='Q-DEC')

In [377]: p.asfreq('D', 's')
Out[377]: Period('2012-01-01', 'D')

In [378]: p.asfreq('D', 'e')
Out[378]: Period('2012-03-31', 'D')
```

Q-MAR defines fiscal year end in March:

```
In [379]: p = pd.Period('2011Q4', freq='Q-MAR')

In [380]: p.asfreq('D', 's')
Out[380]: Period('2011-01-01', 'D')

In [381]: p.asfreq('D', 'e')
Out[381]: Period('2011-03-31', 'D')
```

## 19.13 Converting Between Representations

Timestamped data can be converted to PeriodIndex-ed data using `to_period` and vice-versa using `to_timestamp`:

```
In [388]: ps.to_timestamp('D', how='s')
Out[388]:
2012-01-01 0.886762
2012-02-01 0.034219
2012-03-01 -0.120191
2012-04-01 -1.448144
2012-05-01 -0.316413
Freq: MS, dtype: float64
```

```
In [389]: prng = pd.period_range('1990Q1', '2000Q4', freq='Q-NOV')

In [390]: ts = pd.Series(np.random.randn(len(prng)), prng)

In [391]: ts.index = (prng.asfreq('M', 'e') + 1).asfreq('H', 's') + 9

In [392]: ts.head()
Out[392]:
```

643

(continued from previous page)

```

1990-03-01 09:00 1.136089
1990-06-01 09:00 0.413044
1990-09-01 09:00 -0.815750
1990-12-01 09:00 0.473114
1991-03-01 09:00 -0.242094
Freq: H, dtype: float64

```

## 19.14 Representing Out-of-Bounds Spans

If you have data that is outside of the Timestamp bounds, see *Timestamp limitations*, then you can use a PeriodIndex and/or Series of Periods to do computations.

```

In [393]: span = pd.period_range('1215-01-01', '1381-01-01', freq='D')

In [394]: span
Out[394]:
PeriodIndex(['1215-01-01', '1215-01-02', '1215-01-03', '1215-01-04',
 '1215-01-05', '1215-01-06', '1215-01-07', '1215-01-08',
 '1215-01-09', '1215-01-10',
 ...,
 '1380-12-23', '1380-12-24', '1380-12-25', '1380-12-26',
 '1380-12-27', '1380-12-28', '1380-12-29', '1380-12-30',
 '1380-12-31', '1381-01-01'],
 dtype='period[D]', length=60632, freq='D')

```

To convert from an int64 based YYYYMMDD representation.

```

In [395]: s = pd.Series([20121231, 20141130, 99991231])

In [396]: s
Out[396]:
0 20121231
1 20141130
2 99991231
dtype: int64

In [397]: def conv(x):
.....: return pd.Period(year=x // 10000, month=x // 100 % 100,
.....: day=x % 100, freq='D')
.....:

In [398]: s.apply(conv)
Out[398]:
0 2012-12-31
1 2014-11-30
2 9999-12-31
dtype: period[D]

In [399]: s.apply(conv)[2]
\\Out[399]:
↪Period('9999-12-31', 'D')

```

These can easily be converted to a PeriodIndex:

```
In [400]: span = pd.PeriodIndex(s.apply(conv))

In [401]: span
Out[401]: PeriodIndex(['2012-12-31', '2014-11-30', '9999-12-31'], dtype='period[D]',
↪ freq='D')
```

## 19.15 Time Zone Handling

Pandas provides rich support for working with timestamps in different time zones using `pytz` and `dateutil` libraries. `dateutil` currently is only supported for fixed offset and `tzfile` zones. The default library is `pytz`. Support for `dateutil` is provided for compatibility with other applications e.g. if you use `dateutil` in other Python packages.

### 19.15.1 Working with Time Zones

By default, pandas objects are time zone unaware:

```
In [402]: rng = pd.date_range('3/6/2012 00:00', periods=15, freq='D')

In [403]: rng.tz is None
Out[403]: True
```

To supply the time zone, you can use the `tz` keyword to `date_range` and other functions. `Dateutil` time zone strings are distinguished from `pytz` time zones by starting with `dateutil/`.

- In `pytz` you can find a list of common (and less common) time zones using `from pytz import common_timezones, all_timezones`.
- `dateutil` uses the OS timezones so there isn't a fixed list available. For common zones, the names are the same as `pytz`.

```
In [404]: import dateutil

pytz
In [405]: rng_pytz = pd.date_range('3/6/2012 00:00', periods=10, freq='D',
.....: tz='Europe/London')
.....:

In [406]: rng_pytz.tz
Out[406]: <DstTzInfo 'Europe/London' LMT-1 day, 23:59:00 STD>

dateutil
In [407]: rng_dateutil = pd.date_range('3/6/2012 00:00', periods=10, freq='D',
.....: tz='dateutil/Europe/London')
.....:

In [408]: rng_dateutil.tz
Out[408]: tzfile('/usr/share/zoneinfo/Europe/London')

dateutil - utc special case
In [409]: rng_utc = pd.date_range('3/6/2012 00:00', periods=10, freq='D',
.....: tz=dateutil.tz.tzutc())
.....:
```

(continues on next page)

(continued from previous page)

```
In [410]: rng_utc.tz
Out[410]: tzutc()
```

Note that the UTC timezone is a special case in `dateutil` and should be constructed explicitly as an instance of `dateutil.tz.tzutc`. You can also construct other timezones explicitly first, which gives you more control over which time zone is used:

```
In [411]: import pytz

pytz
In [412]: tz_pytz = pytz.timezone('Europe/London')

In [413]: rng_pytz = pd.date_range('3/6/2012 00:00', periods=10, freq='D',
.....: tz=tz_pytz)
.....:

In [414]: rng_pytz.tz == tz_pytz
Out[414]: True

dateutil
In [415]: tz_dateutil = dateutil.tz.gettz('Europe/London')

In [416]: rng_dateutil = pd.date_range('3/6/2012 00:00', periods=10, freq='D',
.....: tz=tz_dateutil)
.....:

In [417]: rng_dateutil.tz == tz_dateutil
Out[417]: True
```

Timestamps, like Python's `datetime.datetime` object can be either time zone naive or time zone aware. Naive time series and `DatetimeIndex` objects can be *localized* using `tz_localize`:

```
In [418]: ts = pd.Series(np.random.randn(len(rng)), rng)

In [419]: ts_utc = ts.tz_localize('UTC')

In [420]: ts_utc
Out[420]:
2012-03-06 00:00:00+00:00 -0.592233
2012-03-07 00:00:00+00:00 -1.554700
2012-03-08 00:00:00+00:00 1.127087
2012-03-09 00:00:00+00:00 0.883420
2012-03-10 00:00:00+00:00 0.504273
2012-03-11 00:00:00+00:00 0.693315
2012-03-12 00:00:00+00:00 -0.062018
2012-03-13 00:00:00+00:00 -1.193184
2012-03-14 00:00:00+00:00 0.096275
2012-03-15 00:00:00+00:00 -0.116311
2012-03-16 00:00:00+00:00 -0.359970
2012-03-17 00:00:00+00:00 -1.278410
2012-03-18 00:00:00+00:00 -0.877575
2012-03-19 00:00:00+00:00 -0.852171
2012-03-20 00:00:00+00:00 2.579281
Freq: D, dtype: float64
```

Again, you can explicitly construct the timezone object first. You can use the `tz_convert` method to convert pandas objects to convert tz-aware data to another time zone:

```
In [421]: ts_utc.tz_convert('US/Eastern')
```

```
Out [421]:
```

```
2012-03-05 19:00:00-05:00 -0.592233
2012-03-06 19:00:00-05:00 -1.554700
2012-03-07 19:00:00-05:00 1.127087
2012-03-08 19:00:00-05:00 0.883420
2012-03-09 19:00:00-05:00 0.504273
2012-03-10 19:00:00-05:00 0.693315
2012-03-11 20:00:00-04:00 -0.062018
2012-03-12 20:00:00-04:00 -1.193184
2012-03-13 20:00:00-04:00 0.096275
2012-03-14 20:00:00-04:00 -0.116311
2012-03-15 20:00:00-04:00 -0.359970
2012-03-16 20:00:00-04:00 -1.278410
2012-03-17 20:00:00-04:00 -0.877575
2012-03-18 20:00:00-04:00 -0.852171
2012-03-19 20:00:00-04:00 2.579281
Freq: D, dtype: float64
```

**Warning:** Be wary of conversions between libraries. For some zones `pytz` and `dateutil` have different definitions of the zone. This is more of a problem for unusual timezones than for ‘standard’ zones like `US/Eastern`.

**Warning:** Be aware that a timezone definition across versions of timezone libraries may not be considered equal. This may cause problems when working with stored data that is localized using one version and operated on with a different version. See [here](#) for how to handle such a situation.

**Warning:** It is incorrect to pass a timezone directly into the `datetime.datetime` constructor (e.g., `datetime.datetime(2011, 1, 1, tz=timezone('US/Eastern'))`). Instead, the `datetime` needs to be localized using the `localize` method on the `timezone`.

Under the hood, all timestamps are stored in UTC. Scalar values from a `DatetimeIndex` with a time zone will have their fields (day, hour, minute) localized to the time zone. However, timestamps with the same UTC value are still considered to be equal even if they are in different time zones:

```
In [422]: rng_eastern = rng_utc.tz_convert('US/Eastern')
```

```
In [423]: rng_berlin = rng_utc.tz_convert('Europe/Berlin')
```

```
In [424]: rng_eastern[5]
```

```
Out [424]: Timestamp('2012-03-10 19:00:00-0500', tz='US/Eastern', freq='D')
```

```
In [425]: rng_berlin[5]
```

```
Out [425]: Timestamp('2012-03-11 01:00:00+0100', tz='Europe/Berlin', freq='D')
```

```
In [426]: rng_eastern[5] == rng_berlin[5]
```

```
Out [426]: True
```

Like `Series`, `DataFrame`, and `DatetimeIndex`; `Timestamp` objects can be converted to other time zones

using `tz_convert`:

```
In [427]: rng_eastern[5]
Out[427]: Timestamp('2012-03-10 19:00:00-0500', tz='US/Eastern', freq='D')

In [428]: rng_berlin[5]
Out[428]: Timestamp('2012-03-11 01:00:00+0100', tz='Europe/Berlin', freq='D')

In [429]: rng_eastern[5].tz_convert('Europe/Berlin')
Out[429]: Timestamp('2012-03-11 01:00:00+0100', tz='Europe/Berlin')
```

Localization of Timestamp functions just like `DatetimeIndex` and `Series`:

```
In [430]: rng[5]
Out[430]: Timestamp('2012-03-11 00:00:00', freq='D')

In [431]: rng[5].tz_localize('Asia/Shanghai')
Out[431]: Timestamp('2012-03-11 00:00:00+0800', tz='Asia/Shanghai')
```

Operations between `Series` in different time zones will yield `UTC Series`, aligning the data on the `UTC timestamps`:

```
In [432]: eastern = ts_utc.tz_convert('US/Eastern')

In [433]: berlin = ts_utc.tz_convert('Europe/Berlin')

In [434]: result = eastern + berlin

In [435]: result
Out[435]:
2012-03-06 00:00:00+00:00 -1.184465

'2012-03-16 00:00:00+00:00', '2012-03-17 00:00:00+00:00',
'2012-03-18 00:00:00+00:00', '2012-03-19 00:00:00+00:00',
'2012-03-20 00:00:00+00:00'],
dtype='datetime64[ns, UTC]', freq='D')
```

To remove timezone from tz-aware `DatetimeIndex`, use `tz_localize(None)` or `tz_convert(None)`. `tz_localize(None)` will remove timezone holding local time representations. `tz_convert(None)` will remove timezone after converting to UTC time.

### 19.15.3 Nonexistent Times when Localizing

A DST transition may also shift the local time ahead by 1 hour creating nonexistent local times. The behavior of localizing a timeseries with nonexistent times can be controlled by the `nonexistent` argument. The following options are available:

- `'raise'`: Raises a `pytz.NonExistentTimeError` (the default behavior)
- `'NaT'`: Replaces nonexistent times with `NaT`
- `'shift_forward'`: Shifts nonexistent times forward to the closest real time
- `'shift_backward'`: Shifts nonexistent times backward to the closest real time
- `timedelta` object: Shifts nonexistent times by the `timedelta` duration

```
In [453]: dti = pd.date_range(start='2015-03-29 02:30:00', periods=3, freq='H')

2:30 is a nonexistent time
```

Localization of nonexistent times will raise an error by default.

```
In [2]: dti.tz_localize('Europe/Warsaw')
NonExistentTimeError: 2015-03-29 02:30:00
```

Transform nonexistent times to NaT or shift the times.

```
In [454]: dti
Out[454]:
DatetimeIndex(['2015-03-29 02:30:00', '2015-03-29 03:30:00',
 '2015-03-29 04:30:00'],
 dtype='datetime64[ns]', freq='H')

In [455]: dti.tz_localize('Europe/Warsaw', nonexistent='shift_forward')
DatetimeIndex(['2015-03-29 03:00:00+02:00', '2015-03-29 03:30:00+02:00',
 '2015-03-29 04:30:00+02:00'],
 dtype='datetime64[ns, Europe/Warsaw]', freq='H')

In [456]: dti.tz_localize('Europe/Warsaw', nonexistent='shift_backward')
DatetimeIndex(['2015-03-29 01:59:59.999999999+01:00',
 '2015-03-29 03:30:00+02:00',
 '2015-03-29 04:30:00+02:00'],
 dtype='datetime64[ns, Europe/Warsaw]', freq='H')

In [457]: dti.tz_localize('Europe/Warsaw', nonexistent=pd.Timedelta(1, unit='H'))
DatetimeIndex(['2015-03-29 03:30:00+02:00', '2015-03-29 03:30:00+02:00',
 '2015-03-29 04:30:00+02:00'],
 dtype='datetime64[ns, Europe/Warsaw]', freq='H')

In [458]: dti.tz_localize('Europe/Warsaw', nonexistent='NaT')
DatetimeIndex(['NaT', '2015-03-29 03:30:00+02:00',
 '2015-03-29 04:30:00+02:00'],
 dtype='datetime64[ns, Europe/Warsaw]', freq='H')
```

## 19.15.4 TZ Aware Dtypes

Series/DatetimeIndex with a timezone **naive** value are represented with a dtype of `datetime64[ns]`.

```
In [459]: s_naive = pd.Series(pd.date_range('20130101', periods=3))

In [460]: s_naive
Out[460]:
0 2013-01-01
1 2013-01-02
```

(continues on next page)

(continued from previous page)

```
2 2013-01-03
dtype: datetime64[ns]
```

Series/DatetimeIndex with a **timezone aware** value are represented with a dtype of `datetime64[ns, tz]`.

```
In [461]: s_aware = pd.Series(pd.date_range('20130101', periods=3, tz='US/Eastern'))
```

```
In [462]: s_aware
```

```
Out [462]:
0 2013-01-01 00:00:00-05:00
1 2013-01-02 00:00:00-05:00
2 2013-01-03 00:00:00-05:00
dtype: datetime64[ns, US/Eastern]
```

Both of these Series can be manipulated via the `.dt` accessor, see [here](#).

For example, to localize and convert a naive stamp to timezone aware.

```
In [463]: s_naive.dt.tz_localize('UTC').dt.tz_convert('US/Eastern')
```

```
Out [463]:
0 2012-12-31 19:00:00-05:00
1 2013-01-01 19:00:00-05:00
2 2013-01-02 19:00:00-05:00
dtype: datetime64[ns, US/Eastern]
```

Further more you can `.astype(...)` timezone aware (and naive). This operation is effectively a localize AND convert on a naive stamp, and a convert on an aware stamp.

```
localize and convert a naive timezone
```

```
In [464]: s_naive.astype('datetime64[ns, US/Eastern]')
```

```
Out [464]:
0 2012-12-31 19:00:00-05:00
1 2013-01-01 19:00:00-05:00
2 2013-01-02 19:00:00-05:00
dtype: datetime64[ns, US/Eastern]
```

```
make an aware tz naive
```

```
In [465]: s_aware.astype('datetime64[ns]')
```

```
Out [465]:
0 2013-01-01 05:00:00
1 2013-01-02 05:00:00
2 2013-01-03 05:00:00
dtype: datetime64[ns]
```

```
convert to a new timezone
```

```
In [466]: s_aware.astype('datetime64[ns, CET]')
```

```
Out [466]:
0 2013-01-01 06:00:00+01:00
1 2013-01-02 06:00:00+01:00
2 2013-01-03 06:00:00+01:00
dtype: datetime64[ns, CET]
```

**Note:** Using `Series.to_numpy()` on a Series, returns a NumPy array of the data. NumPy does not currently

support timezones (even though it is *printing* in the local timezone!), therefore an object array of Timestamps is returned for timezone aware data:

```
In [467]: s_naive.to_numpy()
Out[467]:
array(['2013-01-01T00:00:00.000000000', '2013-01-02T00:00:00.000000000',
 '2013-01-03T00:00:00.000000000'], dtype='datetime64[ns]')

In [468]: s_aware.to_numpy()
////////////////////////////////////
↳ array([Timestamp('2013-01-01 00:00:00-0500', tz='US/Eastern', freq='D'),
 Timestamp('2013-01-02 00:00:00-0500', tz='US/Eastern', freq='D'),
 Timestamp('2013-01-03 00:00:00-0500', tz='US/Eastern', freq='D')],
 dtype=object)
```

```
In [469]: pd.Series(s_aware.to_numpy())
Out[469]:
0 2013-01-01 00:00:00-05:00
1 2013-01-02 00:00:00-05:00
2 2013-01-03 00:00:00-05:00
dtype: datetime64[ns, US/Eastern]
```

```
In [470]: s_aware.to_numpy(dtype='datetime64[ns]')
Out[470]:
array(['2013-01-01T05:00:00.000000000', '2013-01-02T05:00:00.000000000',
 '2013-01-03T05:00:00.000000000'], dtype='datetime64[ns]')
```

## TIME DELTAS

Timedeltas are differences in times, expressed in difference units, e.g. days, hours, minutes, seconds. They can be both positive and negative.

Timedelta is a subclass of `datetime.timedelta`, and behaves in a similar manner, but allows compatibility with `np.timedelta64` types as well as a host of custom representation, parsing, and attributes.

### 20.1 Parsing

You can construct a `Timedelta` scalar through various arguments:

```
In [1]: import datetime

strings
In [2]: pd.Timedelta('1 days')
Out[2]: Timedelta('1 days 00:00:00')

In [3]: pd.Timedelta('1 days 00:00:00')
Out[3]: Timedelta('1 days 00:00:00')

In [4]: pd.Timedelta('1 days 2 hours')
Out[4]: Timedelta('1 days 02:00:00')

In [5]: pd.Timedelta('-1 days 2 min 3us')
Out[5]: Timedelta('-2 days +23:57:59.999997')

like datetime.timedelta
note: these MUST be specified as keyword arguments
In [6]: pd.Timedelta(days=1, seconds=1)
Out[6]: Timedelta('1 days 00:00:01')

integers with a unit
In [7]: pd.Timedelta(1, unit='d')
Out[7]: Timedelta('1 days 00:00:00')

from a datetime.timedelta/np.timedelta64
In [8]: pd.Timedelta(datetime.timedelta(days=1, seconds=1))
Out[8]: Timedelta('1 days 00:00:01')
```

(continues on next page)

(continued from previous page)

```

In [9]: pd.Timedelta(np.timedelta64(1, 'ms'))
\\////////////////////////////////////
↪Timedelta('0 days 00:00:00.001000')

negative Timedeltas have this string repr
to be more consistent with datetime.timedelta conventions
In [10]: pd.Timedelta('-1us')
\\////////////////////////////////////
↪Timedelta('-1 days +23:59:59.999999')

a NaT
In [11]: pd.Timedelta('nan')
\\////////////////////////////////////
↪NaT

In [12]: pd.Timedelta('nat')
\\////////////////////////////////////
↪NaT

ISO 8601 Duration strings
In [13]: pd.Timedelta('P0DT0H1M0S')
\\////////////////////////////////////
↪Timedelta('0 days 00:01:00')

In [14]: pd.Timedelta('P0DT0H0M0.000000123S')
\\////////////////////////////////////
↪Timedelta('0 days 00:00:00.000000')

```

New in version 0.23.0: Added constructor for ISO 8601 Duration strings

*DateOffsets* (Day, Hour, Minute, Second, Milli, Micro, Nano) can also be used in construction.

```

In [15]: pd.Timedelta(pd.offsets.Second(2))
Out[15]: Timedelta('0 days 00:00:02')

```

Further, operations among the scalars yield another scalar *Timedelta*.

```

In [16]: pd.Timedelta(pd.offsets.Day(2)) + pd.Timedelta(pd.offsets.Second(2)) + \
....: pd.Timedelta('00:00:00.000123')
....:
Out[16]: Timedelta('2 days 00:00:02.000123')

```

### 20.1.1 to\_timedelta

Using the top-level `pd.to_timedelta`, you can convert a scalar, array, list, or *Series* from a recognized *timedelta* format / value into a *Timedelta* type. It will construct *Series* if the input is a *Series*, a scalar if the input is scalar-like, otherwise it will output a *TimedeltaIndex*.

You can parse a single string to a *Timedelta*:

```

In [17]: pd.to_timedelta('1 days 06:05:01.00003')
Out[17]: Timedelta('1 days 06:05:01.000030')

```

(continues on next page)

(continued from previous page)

```
In [18]: pd.to_timedelta('15.5us')
Out[18]: Timedelta('0 days 00:00:00.000015')
```

or a list/array of strings:

```
In [19]: pd.to_timedelta(['1 days 06:05:01.00003', '15.5us', 'nan'])
Out[19]: TimedeltaIndex(['1 days 06:05:01.000030', '0 days 00:00:00.000015', NaT],
 dtype='timedelta64[ns]', freq=None)
```

The unit keyword argument specifies the unit of the Timedelta:

```
In [20]: pd.to_timedelta(np.arange(5), unit='s')
Out[20]: TimedeltaIndex(['00:00:00', '00:00:01', '00:00:02', '00:00:03', '00:00:04'],
 dtype='timedelta64[ns]', freq=None)

In [21]: pd.to_timedelta(np.arange(5), unit='d')
Out[21]: TimedeltaIndex(['0 days', '1 days', '2 days', '3 days', '4 days'],
 dtype='timedelta64[ns]', freq=None)
```

## 20.1.2 Timedelta limitations

Pandas represents Timedeltas in nanosecond resolution using 64 bit integers. As such, the 64 bit integer limits determine the Timedelta limits.

```
In [22]: pd.Timedelta.min
Out[22]: Timedelta('-106752 days +00:12:43.145224')

In [23]: pd.Timedelta.max
Out[23]: Timedelta('106751 days +23:47:16.854775')
```

## 20.2 Operations

You can operate on Series/DataFrames and construct `timedelta64[ns]` Series through subtraction operations on `datetime64[ns]` Series, or Timestamps.

```
In [24]: s = pd.Series(pd.date_range('2012-1-1', periods=3, freq='D'))
In [25]: td = pd.Series([pd.Timedelta(days=i) for i in range(3)])
In [26]: df = pd.DataFrame({'A': s, 'B': td})

In [27]: df
Out[27]:
 A B
0 2012-01-01 0 days
1 2012-01-02 1 days
2 2012-01-03 2 days

In [28]: df['C'] = df['A'] + df['B']
```

(continues on next page)

(continued from previous page)

**In [29]:** df**Out[29]:**

|   | A          | B      | C          |
|---|------------|--------|------------|
| 0 | 2012-01-01 | 0 days | 2012-01-01 |
| 1 | 2012-01-02 | 1 days | 2012-01-03 |
| 2 | 2012-01-03 | 2 days | 2012-01-05 |

**In [30]:** df.dtypes

```

A datetime64[ns]
B timedelta64[ns]
C datetime64[ns]
dtype: object

```

**In [31]:** s - s.max()

```

-2 days
-1 days
 0 days
dtype: timedelta64[ns]

```

**In [32]:** s - datetime.datetime(2011, 1, 1, 3, 5)

```

364 days 20:55:00
365 days 20:55:00
366 days 20:55:00
dtype: timedelta64[ns]

```

**In [33]:** s + datetime.timedelta(minutes=5)

```

2012-01-01 00:05:00
2012-01-02 00:05:00
2012-01-03 00:05:00
dtype: datetime64[ns]

```

**In [34]:** s + pd.offsets.Minute(5)

```

2012-01-01 00:05:00
2012-01-02 00:05:00
2012-01-03 00:05:00
dtype: datetime64[ns]

```

**In [35]:** s + pd.offsets.Minute(5) + pd.offsets.Milli(5)

```

2012-01-01 00:05:00.005
2012-01-02 00:05:00.005
2012-01-03 00:05:00.005
dtype: datetime64[ns]

```

Operations with scalars from a `timedelta64[ns]` series:

```
In [36]: y = s - s[0]
```

```
In [37]: y
```

```
Out[37]:
```

```
0 0 days
1 1 days
2 2 days
dtype: timedelta64[ns]
```

Series of timedeltas with NaT values are supported:

```
In [38]: y = s - s.shift()
```

```
In [39]: y
```

```
Out[39]:
```

```
0 NaT
1 1 days
2 1 days
dtype: timedelta64[ns]
```

Elements can be set to NaT using `np.nan` analogously to datetimes:

```
In [40]: y[1] = np.nan
```

```
In [41]: y
```

```
Out[41]:
```

```
0 NaT
1 NaT
2 1 days
dtype: timedelta64[ns]
```

Operands can also appear in a reversed order (a singular object operated with a Series):

```
In [42]: s.max() - s
```

```
Out[42]:
```

```
0 2 days
1 1 days
2 0 days
dtype: timedelta64[ns]
```

```
In [43]: datetime.datetime(2011, 1, 1, 3, 5) - s
```

```
Out[43]:
```

```
0 -365 days +03:05:00
1 -366 days +03:05:00
2 -367 days +03:05:00
dtype: timedelta64[ns]
```

```
In [44]: datetime.timedelta(minutes=5) + s
```

```
Out[44]:
```

```
0 2012-01-01 00:05:00
1 2012-01-02 00:05:00
2 2012-01-03 00:05:00
dtype: datetime64[ns]
```

`min`, `max` and the corresponding `idxmin`, `idxmax` operations are supported on frames:

```

In [45]: A = s - pd.Timestamp('20120101') - pd.Timedelta('00:05:05')

In [46]: B = s - pd.Series(pd.date_range('2012-1-2', periods=3, freq='D'))

In [47]: df = pd.DataFrame({'A': A, 'B': B})

In [48]: df
Out[48]:
 A B
0 -1 days +23:54:55 -1 days
1 0 days 23:54:55 -1 days
2 1 days 23:54:55 -1 days

In [49]: df.min()
Out[49]:
A -1 days +23:54:55
B -1 days +00:00:00
dtype: timedelta64[ns]

In [50]: df.min(axis=1)
Out[50]:
0 -1 days
1 -1 days
2 -1 days
dtype: timedelta64[ns]

In [51]: df.idxmin()
Out[51]:
A 0
B 0
dtype: int64

In [52]: df.idxmax()
Out[52]:
A 2
B 0
dtype: int64

```

min, max, idxmin, idxmax operations are supported on Series as well. A scalar result will be a Timedelta.

```

In [53]: df.min().max()
Out[53]: Timedelta('-1 days +23:54:55')

In [54]: df.min(axis=1).min()
Out[54]: Timedelta('-1 days +00:00:00')

In [55]: df.min().idxmax()
Out[55]: 'A'

In [56]: df.min(axis=1).idxmin()
Out[56]: 0

```

You can fillna on timedeltas. Integers will be interpreted as seconds. You can pass a timedelta to get a particular value.

```
In [57]: y.fillna(0)
Out[57]:
0 0 days
1 0 days
2 1 days
dtype: timedelta64[ns]

In [58]: y.fillna(10)
Out[58]:
0 0 days 00:00:10
1 0 days 00:00:10
2 1 days 00:00:00
dtype: timedelta64[ns]

In [59]: y.fillna(pd.Timedelta('-1 days, 00:00:05'))
Out[59]:
0 -1 days +00:00:05
1 -1 days +00:00:05
2 1 days 00:00:00
dtype: timedelta64[ns]
```

You can also negate, multiply and use `abs` on `Timedeltas`:

[illegible]

## 20.3 Reductions

Numeric reduction operation for `timedelta64[ns]` will return `Timedelta` objects. As usual `NaT` are skipped during evaluation.

```
In [65]: y2 = pd.Series(pd.to_timedelta(['-1 days +00:00:05', 'nat',
.....: '-1 days +00:00:05', '1 days']))
.....:

In [66]: y2
Out[66]:
0 -1 days +00:00:05
1 NaT
```

(continues on next page)

(continued from previous page)

```
2 -1 days +00:00:05
3 1 days 00:00:00
dtype: timedelta64[ns]
```

```
In [67]: y2.mean()
~~~~~
↪Timedelta('-1 days +16:00:03.333333')
```

```
In [68]: y2.median()
~~~~~
↪Timedelta('-1 days +00:00:05')
```

```
In [69]: y2.quantile(.1)
~~~~~
↪Timedelta('-1 days +00:00:05')
```

```
In [70]: y2.sum()
~~~~~
↪Timedelta('-1 days +00:00:10')
```

## 20.4 Frequency Conversion

Timedelta Series, TimedeltaIndex, and Timedelta scalars can be converted to other ‘frequencies’ by dividing by another timedelta, or by astyping to a specific timedelta type. These operations yield Series and propagate NaT -> nan. Note that division by the NumPy scalar is true division, while astyping is equivalent of floor division.

```
In [71]: december = pd.Series(pd.date_range('20121201', periods=4))
```

```
In [72]: january = pd.Series(pd.date_range('20130101', periods=4))
```

```
In [73]: td = january - december
```

```
In [74]: td[2] += datetime.timedelta(minutes=5, seconds=3)
```

```
In [75]: td[3] = np.nan
```

```
In [76]: td
```

```
Out[76]:
```

```
0 31 days 00:00:00
1 31 days 00:00:00
2 31 days 00:05:03
3 NaT
dtype: timedelta64[ns]
```

```
to days
```

```
In [77]: td / np.timedelta64(1, 'D')
```

```
~~~~~
↪
0   31.000000
1   31.000000
2   31.003507
3           NaN
dtype: float64
```

(continues on next page)

(continued from previous page)

```
In [78]: td.astype('timedelta64[D]')
```

```

////////////////////////////////////
↪
0      31.0
1      31.0
2      31.0
3       NaN
dtype: float64

```

```
# to seconds
```

```
In [79]: td / np.timedelta64(1, 's')
```

```

////////////////////////////////////
↪
0      2678400.0
1      2678400.0
2      2678703.0
3           NaN
dtype: float64

```

```
In [80]: td.astype('timedelta64[s]')
```

```

////////////////////////////////////
↪
0      2678400.0
1      2678400.0
2      2678703.0
3           NaN
dtype: float64

```

```
# to months (these are constant months)
```

```
In [81]: td / np.timedelta64(1, 'M')
```

```

////////////////////////////////////
↪
0      1.018501
1      1.018501
2      1.018617
3           NaN
dtype: float64

```

Dividing or multiplying a `timedelta64[ns]` Series by an integer or integer Series yields another `timedelta64[ns]` dtypes Series.

```
In [82]: td * -1
```

```
Out[82]:
```

```

0      -31 days +00:00:00
1      -31 days +00:00:00
2      -32 days +23:54:57
3                NaT
dtype: timedelta64[ns]

```

```
In [83]: td * pd.Series([1, 2, 3, 4])
```

```

////////////////////////////////////
↪
0      31 days 00:00:00
1      62 days 00:00:00
2      93 days 00:15:09
3                NaT
dtype: timedelta64[ns]

```

Rounded division (floor-division) of a `timedelta64 [ns]` Series by a scalar `Timedelta` gives a series of integers.

```
In [84]: td // pd.Timedelta(days=3, hours=4)
Out[84]:
0      9.0
1      9.0
2      9.0
3      NaN
dtype: float64

In [85]: pd.Timedelta(days=3, hours=4) // td
Out[85]:
0      0.0
1      0.0
2      0.0
3      NaN
dtype: float64
```

The `mod (%)` and `divmod` operations are defined for `Timedelta` when operating with another `timedelta`-like or with a numeric argument.

```
In [86]: pd.Timedelta(hours=37) % datetime.timedelta(hours=2)
Out[86]: Timedelta('0 days 01:00:00')

# divmod against a timedelta-like returns a pair (int, Timedelta)
In [87]: divmod(datetime.timedelta(hours=2), pd.Timedelta(minutes=11))
Out[87]: (10, Timedelta('0 days 00:10:00'))

# divmod against a numeric returns a pair (Timedelta, Timedelta)
In [88]: divmod(pd.Timedelta(hours=25), 864000000000000)
Out[88]: (Timedelta('0 days 00:00:00.000000'), Timedelta('0 days 01:00:00'))
```

## 20.5 Attributes

You can access various components of the `Timedelta` or `TimedeltaIndex` directly using the attributes `days`, `seconds`, `microseconds`, `nanoseconds`. These are identical to the values returned by `datetime.timedelta`, in that, for example, the `.seconds` attribute represents the number of seconds  $\geq 0$  and  $< 1$  day. These are signed according to whether the `Timedelta` is signed.

These operations can also be directly accessed via the `.dt` property of the `Series` as well.

---

**Note:** Note that the attributes are NOT the displayed values of the `Timedelta`. Use `.components` to retrieve the displayed values.

---

For a `Series`:

```
In [89]: td.dt.days
Out[89]:
0      31.0
1      31.0
2      31.0
3      NaN
dtype: float64
```

(continues on next page)

(continued from previous page)

```
In [90]: td.dt.seconds
\\Out [90]:
0      0.0
1      0.0
2     303.0
3      NaN
dtype: float64
```

You can access the value of the fields for a scalar `Timedelta` directly.

```
In [91]: tds = pd.Timedelta('31 days 5 min 3 sec')

In [92]: tds.days
Out [92]: 31

In [93]: tds.seconds
\\Out [93]: 303

In [94]: (-tds).seconds
\\Out [94]: 86097
```

You can use the `.components` property to access a reduced form of the `timedelta`. This returns a `DataFrame` indexed similarly to the `Series`. These are the *displayed* values of the `Timedelta`.

```
In [95]: td.dt.components
Out [95]:
   days  hours  minutes  seconds  milliseconds  microseconds  nanoseconds
0  31.0    0.0     0.0     0.0             0.0             0.0             0.0
1  31.0    0.0     0.0     0.0             0.0             0.0             0.0
2  31.0    0.0     5.0     3.0             0.0             0.0             0.0
3   NaN    NaN     NaN     NaN             NaN             NaN             NaN

In [96]: td.dt.components.seconds
\\Out [96]:
↪
0      0.0
1      0.0
2      3.0
3      NaN
Name: seconds, dtype: float64
```

You can convert a `Timedelta` to an [ISO 8601 Duration](#) string with the `.isoformat` method

New in version 0.20.0.

```
In [97]: pd.Timedelta(days=6, minutes=50, seconds=3,
....:                  milliseconds=10, microseconds=10,
....:                  nanoseconds=12).isoformat()
Out [97]: 'P6DT0H50M3.010010012S'
```

## 20.6 TimedeltaIndex

To generate an index with time delta, you can use either the `TimedeltaIndex` or the `timedelta_range()` constructor.

Using `TimedeltaIndex` you can pass string-like, `Timedelta`, `timedelta`, or `np.timedelta64` objects. Passing `np.nan`/`pd.NaT`/`nat` will represent missing values.

```
In [98]: pd.TimedeltaIndex(['1 days', '1 days, 00:00:05', np.timedelta64(2, 'D'),
.....:                     datetime.timedelta(days=2, seconds=2)])
.....:
Out[98]:
TimedeltaIndex(['1 days 00:00:00', '1 days 00:00:05', '2 days 00:00:00',
               '2 days 00:00:02'],
              dtype='timedelta64[ns]', freq=None)
```

The string 'infer' can be passed in order to set the frequency of the index as the inferred frequency upon creation:

```
In [99]: pd.TimedeltaIndex(['0 days', '10 days', '20 days'], freq='infer')
Out[99]: TimedeltaIndex(['0 days', '10 days', '20 days'], dtype='timedelta64[ns]',
    freq='10D')
```

### 20.6.1 Generating Ranges of Time Deltas

Similar to `date_range()`, you can construct regular ranges of a `TimedeltaIndex` using `timedelta_range()`. The default frequency for `timedelta_range` is calendar day:

```
In [100]: pd.timedelta_range(start='1 days', periods=5)
Out[100]: TimedeltaIndex(['1 days', '2 days', '3 days', '4 days', '5 days'], dtype=
↳ 'timedelta64[ns]', freq='D')
```

Various combinations of `start`, `end`, and `periods` can be used with `timedelta_range`:

```
In [101]: pd.timedelta_range(start='1 days', end='5 days')
Out[101]: TimedeltaIndex(['1 days', '2 days', '3 days', '4 days', '5 days'], dtype=
↳ 'timedelta64[ns]', freq='D')

In [102]: pd.timedelta_range(end='10 days', periods=4)
////////////////////////////////////
↳ TimedeltaIndex(['7 days', '8 days', '9 days', '10 days'], dtype='timedelta64[ns]',
↳ freq='D')
```

The `freq` parameter can passed a variety of *frequency aliases*:

```
In [103]: pd.timedelta_range(start='1 days', end='2 days', freq='30T')
Out[103]:
TimedeltaIndex(['1 days 00:00:00', '1 days 00:30:00', '1 days 01:00:00',
                '1 days 01:30:00', '1 days 02:00:00', '1 days 02:30:00',
                '1 days 03:00:00', '1 days 03:30:00', '1 days 04:00:00',
                '1 days 04:30:00', '1 days 05:00:00', '1 days 05:30:00',
                '1 days 06:00:00', '1 days 06:30:00', '1 days 07:00:00',
                '1 days 07:30:00', '1 days 08:00:00', '1 days 08:30:00',
                '1 days 09:00:00', '1 days 09:30:00', '1 days 10:00:00',
                '1 days 10:30:00', '1 days 11:00:00', '1 days 11:30:00',
                '1 days 12:00:00', '1 days 12:30:00', '1 days 13:00:00',
```

(continues on next page)

(continued from previous page)

```

        '1 days 13:30:00', '1 days 14:00:00', '1 days 14:30:00',
        '1 days 15:00:00', '1 days 15:30:00', '1 days 16:00:00',
        '1 days 16:30:00', '1 days 17:00:00', '1 days 17:30:00',
        '1 days 18:00:00', '1 days 18:30:00', '1 days 19:00:00',
        '1 days 19:30:00', '1 days 20:00:00', '1 days 20:30:00',
        '1 days 21:00:00', '1 days 21:30:00', '1 days 22:00:00',
        '1 days 22:30:00', '1 days 23:00:00', '1 days 23:30:00',
        '2 days 00:00:00'],
        dtype='timedelta64[ns]', freq='30T')

In [104]: pd.timedelta_range(start='1 days', periods=5, freq='2D5H')
//////////////////////////////////////////////////////////////////////////////////////////////////////////////////////////////////
↪
TimedeltaIndex(['1 days 00:00:00', '3 days 05:00:00', '5 days 10:00:00',
               '7 days 15:00:00', '9 days 20:00:00'],
               dtype='timedelta64[ns]', freq='53H')

```

New in version 0.23.0.

Specifying start, end, and periods will generate a range of evenly spaced timesteps from start to end inclusively, with periods number of elements in the resulting TimedeltaIndex:

```

In [105]: pd.timedelta_range('0 days', '4 days', periods=5)
Out[105]: TimedeltaIndex(['0 days', '1 days', '2 days', '3 days', '4 days'], dtype=
↪ 'timedelta64[ns]', freq=None)

In [106]: pd.timedelta_range('0 days', '4 days', periods=10)
//////////////////////////////////////////////////////////////////////////////////////////////////////////////////////////////////
↪
TimedeltaIndex(['0 days 00:00:00', '0 days 10:40:00', '0 days 21:20:00',
               '1 days 08:00:00', '1 days 18:40:00', '2 days 05:20:00',
               '2 days 16:00:00', '3 days 02:40:00', '3 days 13:20:00',
               '4 days 00:00:00'],
               dtype='timedelta64[ns]', freq=None)

```

## 20.6.2 Using the TimedeltaIndex

Similarly to other of the datetime-like indices, DatetimeIndex and PeriodIndex, you can use TimedeltaIndex as the index of pandas objects.

```

In [107]: s = pd.Series(np.arange(100),
        .....:          index=pd.timedelta_range('1 days', periods=100, freq='h'))
        .....:

In [108]: s
Out[108]:
1 days 00:00:00    0
1 days 01:00:00    1
1 days 02:00:00    2
1 days 03:00:00    3
1 days 04:00:00    4
1 days 05:00:00    5
1 days 06:00:00    6
1 days 07:00:00    7
1 days 08:00:00    8

```

(continues on next page)

(continued from previous page)

```
1 days 09:00:00    9
1 days 10:00:00   10
1 days 11:00:00   11
1 days 12:00:00   12
1 days 13:00:00   13
1 days 14:00:00   14
1 days 15:00:00   15
1 days 16:00:00   16
1 days 17:00:00   17
1 days 18:00:00   18
1 days 19:00:00   19
1 days 20:00:00   20
1 days 21:00:00   21
1 days 22:00:00   22
1 days 23:00:00   23
2 days 00:00:00   24
2 days 01:00:00   25
2 days 02:00:00   26
2 days 03:00:00   27
2 days 04:00:00   28
2 days 05:00:00   29
..

5 days 01:00:00   97
5 days 02:00:00   98
5 days 03:00:00   99
Freq: H, Length: 100, dtype: int64
```

Selections work similarly, with coercion on string-likes and slices:

(continued from previous page)

```

\\
↪1

```

Furthermore you can use partial string selection and the range will be inferred:

```

In [112]: s['1 day':'1 day 5 hours']
Out[112]:
1 days 00:00:00    0
1 days 01:00:00    1
1 days 02:00:00    2
1 days 03:00:00    3
1 days 04:00:00    4
1 days 05:00:00    5
Freq: H, dtype: int64

```

### 20.6.3 Operations

Finally, the combination of `TimedeltaIndex` with `DatetimeIndex` allow certain combination operations that are NaT preserving:

```

In [113]: tdi = pd.TimedeltaIndex(['1 days', pd.NaT, '2 days'])

In [114]: tdi.to_list()
Out[114]: [Timedelta('1 days 00:00:00'), NaT, Timedelta('2 days 00:00:00')]

In [115]: dti = pd.date_range('20130101', periods=3)

In [116]: dti.to_list()
Out[116]:
[Timestamp('2013-01-01 00:00:00', freq='D'),
 Timestamp('2013-01-02 00:00:00', freq='D'),
 Timestamp('2013-01-03 00:00:00', freq='D')]

In [117]: (dti + tdi).to_list()
\\
↪[Timestamp('2013-01-02 00:00:00'), NaT, Timestamp('2013-01-05 00:00:00')]

In [118]: (dti - tdi).to_list()
\\
↪[Timestamp('2012-12-31 00:00:00'), NaT, Timestamp('2013-01-01 00:00:00')]

```

### 20.6.4 Conversions

Similarly to frequency conversion on a `Series` above, you can convert these indices to yield another `Index`.

```

In [119]: tdi / np.timedelta64(1, 's')
Out[119]: Float64Index([86400.0, nan, 172800.0], dtype='float64')

In [120]: tdi.astype('timedelta64[s]')
\\
↪Float64Index([86400.0, nan, 172800.0], dtype='float64')
Out[120]:

```

Scalars type ops work as well. These can potentially return a *different* type of index.

```

# adding or timedelta and date -> datelike
In [121]: tdi + pd.Timestamp('20130101')
Out[121]: DatetimeIndex(['2013-01-02', 'NaT', '2013-01-03'], dtype='datetime64[ns]',
↳freq=None)

# subtraction of a date and a timedelta -> datelike
# note that trying to subtract a date from a Timedelta will raise an exception
In [122]: (pd.Timestamp('20130101') - tdi).to_list()
Out[122]: [Timestamp('2012-12-31 00:00:00'), NaT, Timestamp('2012-12-30 00:00:00')]

# timedelta + timedelta -> timedelta
In [123]: tdi + pd.Timedelta('10 days')
Out[123]: TimedeltaIndex(['11 days', 'NaT', '12 days'], dtype='timedelta64[ns]', freq=None)

# division can result in a Timedelta if the divisor is an integer
In [124]: tdi / 2
Out[124]: TimedeltaIndex(['0 days 12:00:00', 'NaT', '1 days 00:00:00'], dtype='timedelta64[ns]',
↳freq=None)

# or a Float64Index if the divisor is a Timedelta
In [125]: tdi / tdi[0]
Out[125]: Float64Index([1.0, nan, 2.0], dtype='float64')

```

## 20.7 Resampling

Similar to *timeseries resampling*, we can resample with a `TimedeltaIndex`.

```

In [126]: s.resample('D').mean()
Out[126]:
1 days    11.5
2 days    35.5
3 days    59.5
4 days    83.5
5 days    97.5
Freq: D, dtype: float64

```

```
{{ header }}
```

## CATEGORICAL DATA

This is an introduction to pandas categorical data type, including a short comparison with R's `factor`.

*Categoricals* are a pandas data type corresponding to categorical variables in statistics. A categorical variable takes on a limited, and usually fixed, number of possible values (*categories*; *levels* in R). Examples are gender, social class, blood type, country affiliation, observation time or rating via Likert scales.

In contrast to statistical categorical variables, categorical data might have an order (e.g. 'strongly agree' vs 'agree' or 'first observation' vs. 'second observation'), but numerical operations (additions, divisions, ...) are not possible.

All values of categorical data are either in *categories* or *np.nan*. Order is defined by the order of *categories*, not lexical order of the values. Internally, the data structure consists of a *categories* array and an integer array of *codes* which point to the real value in the *categories* array.

The categorical data type is useful in the following cases:

- A string variable consisting of only a few different values. Converting such a string variable to a categorical variable will save some memory, see *here*.
- The lexical order of a variable is not the same as the logical order ("one", "two", "three"). By converting to a categorical and specifying an order on the categories, sorting and min/max will use the logical order instead of the lexical order, see *here*.
- As a signal to other Python libraries that this column should be treated as a categorical variable (e.g. to use suitable statistical methods or plot types).

See also the *API docs on categoricals*.

## 21.1 Object Creation

### 21.1.1 Series Creation

Categorical Series or columns in a DataFrame can be created in several ways:

By specifying `dtype="category"` when constructing a Series:

```
In [1]: s = pd.Series(["a", "b", "c", "a"], dtype="category")

In [2]: s
Out[2]:
0      a
1      b
2      c
3      a
```

(continues on next page)

(continued from previous page)

```
dtype: category
Categories (3, object): [a, b, c]
```

By converting an existing Series or column to a category dtype:

```
In [3]: df = pd.DataFrame({"A": ["a", "b", "c", "a"]})

In [4]: df["B"] = df["A"].astype('category')

In [5]: df
Out[5]:
   A B
0  a a
1  b b
2  c c
3  a a
```

By using special functions, such as `cut()`, which groups data into discrete bins. See the *example on tiling* in the docs.

```
In [6]: df = pd.DataFrame({'value': np.random.randint(0, 100, 20)})

In [7]: labels = ["{0} - {1}".format(i, i + 9) for i in range(0, 100, 10)]

In [8]: df['group'] = pd.cut(df.value, range(0, 105, 10), right=False, labels=labels)

In [9]: df.head(10)
Out[9]:
   value  group
0     59  50 - 59
1     54  50 - 59
2      2    0 - 9
3     71  70 - 79
4     83  80 - 89
5     80  80 - 89
6     65  60 - 69
7     73  70 - 79
8     96  90 - 99
9     55  50 - 59
```

By passing a `pandas.Categorical` object to a Series or assigning it to a DataFrame.

```
In [10]: raw_cat = pd.Categorical(["a", "b", "c", "a"], categories=["b", "c", "d"],
....:                             ordered=False)
....:

In [11]: s = pd.Series(raw_cat)

In [12]: s
Out[12]:
0    NaN
1     b
2     c
3    NaN
dtype: category
Categories (3, object): [b, c, d]
```

(continues on next page)

(continued from previous page)

```
In [13]: df = pd.DataFrame({"A": ["a", "b", "c", "a"]})
In [14]: df["B"] = raw_cat
In [15]: df
Out[15]:
   A    B
0  a  NaN
1  b    b
2  c    c
3  a  NaN
```

Categorical data has a specific *category dtype*:

```
In [16]: df.dtypes
Out[16]:
A      object
B    category
dtype: object
```

## 21.1.2 DataFrame Creation

Similar to the previous section where a single column was converted to categorical, all columns in a `DataFrame` can be batch converted to categorical either during or after construction.

This can be done during construction by specifying `dtype="category"` in the `DataFrame` constructor:

```
In [17]: df = pd.DataFrame({'A': list('abca'), 'B': list('bccd')}, dtype="category")
In [18]: df.dtypes
Out[18]:
A    category
B    category
dtype: object
```

Note that the categories present in each column differ; the conversion is done column by column, so only labels present in a given column are categories:

```
In [19]: df['A']
Out[19]:
0    a
1    b
2    c
3    a
Name: A, dtype: category
Categories (3, object): [a, b, c]

In [20]: df['B']
Out[20]:
0    b
1    c
2    c
3    d
```

(continues on next page)

(continued from previous page)

```
Name: B, dtype: category
Categories (3, object): [b, c, d]
```

New in version 0.23.0.

Analogously, all columns in an existing `DataFrame` can be batch converted using `DataFrame.astype()`:

```
In [21]: df = pd.DataFrame({'A': list('abca'), 'B': list('bccd')})
In [22]: df_cat = df.astype('category')
In [23]: df_cat.dtypes
Out[23]:
A      category
B      category
dtype: object
```

This conversion is likewise done column by column:

```
In [24]: df_cat['A']
Out[24]:
0      a
1      b
2      c
3      a
Name: A, dtype: category
Categories (3, object): [a, b, c]

In [25]: df_cat['B']
Out[25]:
0      b
1      c
2      c
3      d
Name: B, dtype: category
Categories (3, object): [b, c, d]
```

### 21.1.3 Controlling Behavior

In the examples above where we passed `dtype='category'`, we used the default behavior:

1. Categories are inferred from the data.
2. Categories are unordered.

To control those behaviors, instead of passing `'category'`, use an instance of `CategoricalDtype`.

```
In [26]: from pandas.api.types import CategoricalDtype
In [27]: s = pd.Series(["a", "b", "c", "a"])
In [28]: cat_type = CategoricalDtype(categories=["b", "c", "d"],
.....:                                     ordered=True)
.....:
```

(continues on next page)

(continued from previous page)

```
In [29]: s_cat = s.astype(cat_type)

In [30]: s_cat
Out[30]:
0      NaN
1         b
2         c
3      NaN
dtype: category
Categories (3, object): [b < c < d]
```

Similarly, a `CategoricalDtype` can be used with a `DataFrame` to ensure that categories are consistent among all columns.

```
In [31]: from pandas.api.types import CategoricalDtype

In [32]: df = pd.DataFrame({'A': list('abca'), 'B': list('bccd')})

In [33]: cat_type = CategoricalDtype(categories=list('abcd'),
....:                                ordered=True)
....:

In [34]: df_cat = df.astype(cat_type)

In [35]: df_cat['A']
Out[35]:
0    a
1    b
2    c
3    a
Name: A, dtype: category
Categories (4, object): [a < b < c < d]

In [36]: df_cat['B']
Out[36]:
0    b
1    c
2    c
3    d
Name: B, dtype: category
Categories (4, object): [a < b < c < d]
```

**Note:** To perform table-wise conversion, where all labels in the entire DataFrame are used as categories for each column, the `categories` parameter can be determined programmatically by `categories = pd.unique(df.to_numpy().ravel())`.

If you already have `codes` and `categories`, you can use the `from_codes()` constructor to save the factorize step during normal constructor mode:

[illegible]

### 21.1.4 Regaining Original Data

To get back to the original Series or NumPy array, use `Series.astype(original_dtype)` or `np.asarray(categorical)`:

```
In [39]: s = pd.Series(["a", "b", "c", "a"])

In [40]: s
Out[40]:
0    a
1    b
2    c
3    a
dtype: object

In [41]: s2 = s.astype('category')

In [42]: s2
Out[42]:
0    a
1    b
2    c
3    a
dtype: category
Categories (3, object): [a, b, c]

In [43]: s2.astype(str)
Out[43]:
0    a
1    b
2    c
3    a
dtype: object

In [44]: np.asarray(s2)
array(['a', 'b', 'c', 'a'], dtype=object)
```

---

**Note:** In contrast to R's *factor* function, categorical data is not converting input values to strings; categories will end up the same data type as the original values.

---

---

**Note:** In contrast to R's *factor* function, there is currently no way to assign/change labels at creation time. Use *categories* to change the categories after creation time.

---

## 21.2 CategoricalDtype

Changed in version 0.21.0.

A categorical's type is fully described by

1. `categories`: a sequence of unique values and no missing values

2. `ordered`: a boolean

This information can be stored in a `CategoricalDtype`. The `categories` argument is optional, which implies that the actual categories should be inferred from whatever is present in the data when the `pandas.Categorical` is created. The categories are assumed to be unordered by default.

```
In [45]: from pandas.api.types import CategoricalDtype

In [46]: CategoricalDtype(['a', 'b', 'c'])
Out[46]: CategoricalDtype(categories=['a', 'b', 'c'], ordered=None)

In [47]: CategoricalDtype(['a', 'b', 'c'], ordered=True)
Out[47]: CategoricalDtype(categories=['a', 'b', 'c'], ordered=True)

In [48]: CategoricalDtype()
Out[48]: CategoricalDtype(categories=None, ordered=None)
```

A `CategoricalDtype` can be used in any place pandas expects a *dtype*. For example `pandas.read_csv()`, `pandas.DataFrame.astype()`, or in the `Series` constructor.

**Note:** As a convenience, you can use the string `'category'` in place of a `CategoricalDtype` when you want the default behavior of the categories being unordered, and equal to the set values present in the array. In other words, `dtype='category'` is equivalent to `dtype=CategoricalDtype()`.

### 21.2.1 Equality Semantics

Two instances of `CategoricalDtype` compare equal whenever they have the same categories and order. When comparing two unordered categoricals, the order of the categories is not considered.

```
In [49]: c1 = CategoricalDtype(['a', 'b', 'c'], ordered=False)

# Equal, since order is not considered when ordered=False
In [50]: c1 == CategoricalDtype(['b', 'c', 'a'], ordered=False)
Out[50]: True

# Unequal, since the second CategoricalDtype is ordered
In [51]: c1 == CategoricalDtype(['a', 'b', 'c'], ordered=True)
Out[51]: False
```

All instances of `CategoricalDtype` compare equal to the string `'category'`.

```
In [52]: c1 == 'category'
Out[52]: True
```

**Warning:** Since `dtype='category'` is essentially `CategoricalDtype(None, False)`, and since all instances `CategoricalDtype` compare equal to `'category'`, all instances of `CategoricalDtype` compare equal to a `CategoricalDtype(None, False)`, regardless of categories or ordered.

## 21.3 Description

Using `describe()` on categorical data will produce similar output to a `Series` or `DataFrame` of type `string`.

```
In [53]: cat = pd.Categorical(["a", "c", "c", np.nan], categories=["b", "a", "c"])

In [54]: df = pd.DataFrame({"cat": cat, "s": ["a", "c", "c", np.nan]})

In [55]: df.describe()
Out[55]:
```

|        | cat | s |
|--------|-----|---|
| count  | 3   | 3 |
| unique | 2   | 2 |
| top    | c   | c |
| freq   | 2   | 2 |

```
In [56]: df["cat"].describe()
Out[56]:
```

|        |   |
|--------|---|
| count  | 3 |
| unique | 2 |
| top    | c |
| freq   | 2 |

```
Name: cat, dtype: object
```

## 21.4 Working with categories

Categorical data has a *categories* and a *ordered* property, which list their possible values and whether the ordering matters or not. These properties are exposed as `s.cat.categories` and `s.cat.ordered`. If you don't manually specify categories and ordering, they are inferred from the passed arguments.

```
In [57]: s = pd.Series(["a", "b", "c", "a"], dtype="category")
In [58]: s.cat.categories
Out[58]: Index(['a', 'b', 'c'], dtype='object')
In [59]: s.cat.ordered
Out[59]: False
```

It's also possible to pass in the categories in a specific order:

```
In [60]: s = pd.Series(pd.Categorical(["a", "b", "c", "a"],
....:                                categories=["c", "b", "a"]))
....:

In [61]: s.cat.categories
Out[61]: Index(['c', 'b', 'a'], dtype='object')

In [62]: s.cat.ordered
Out[62]: False
```

**Note:** New categorical data are **not** automatically ordered. You must explicitly pass `ordered=True` to indicate an ordered `Categorical`.

(continued from previous page)

```

In [71]: s = s.cat.rename_categories([1, 2, 3])

In [72]: s
Out[72]:
0    1
1    2
2    3
3    1
dtype: category
Categories (3, int64): [1, 2, 3]

# You can also pass a dict-like object to map the renaming
In [73]: s = s.cat.rename_categories({1: 'x', 2: 'y', 3: 'z'})

In [74]: s
Out[74]:
0    x
1    y
2    z
3    x
dtype: category
Categories (3, object): [x, y, z]

```

---

**Note:** In contrast to R's *factor*, categorical data can have categories of other types than string.

---

---

**Note:** Be aware that assigning new categories is an inplace operation, while most other operations under `Series.cat` per default return a new `Series` of dtype *category*.

---

Categories must be unique or a *ValueError* is raised:

```

In [75]: try:
.....:     s.cat.categories = [1, 1, 1]
.....: except ValueError as e:
.....:     print("ValueError:", str(e))
.....:
ValueError: Categorical categories must be unique

```

Categories must also not be NaN or a *ValueError* is raised:

```

In [76]: try:
.....:     s.cat.categories = [1, 2, np.nan]
.....: except ValueError as e:
.....:     print("ValueError:", str(e))
.....:
ValueError: Categorical categories cannot be null

```

## 21.4.2 Appending new categories

Appending categories can be done by using the `add_categories()` method:

```

In [77]: s = s.cat.add_categories([4])

In [78]: s.cat.categories
Out[78]: Index(['x', 'y', 'z', 4], dtype='object')

In [79]: s
\\Out[79]:
0      x
1      y
2      z
3      x
dtype: category
Categories (4, object): [x, y, z, 4]

```

### 21.4.3 Removing categories

Removing categories can be done by using the `remove_categories()` method. Values which are removed are replaced by `np.nan`:

```

In [80]: s = s.cat.remove_categories([4])

In [81]: s
Out[81]:
0      x
1      y
2      z
3      x
dtype: category
Categories (3, object): [x, y, z]

```

### 21.4.4 Removing unused categories

Removing unused categories can also be done:

```

In [82]: s = pd.Series(pd.Categorical(["a", "b", "a"],
....:                                categories=["a", "b", "c", "d"]))
....:

In [83]: s
Out[83]:
0      a
1      b
2      a
dtype: category
Categories (4, object): [a, b, c, d]

In [84]: s.cat.remove_unused_categories()
\\Out[84]:
→
0      a
1      b
2      a
dtype: category
Categories (2, object): [a, b]

```

### 21.4.5 Setting categories

If you want to do remove and add new categories in one step (which has some speed advantage), or simply set the categories to a predefined scale, use `set_categories()`.

```
In [85]: s = pd.Series(["one", "two", "four", "-"], dtype="category")

In [86]: s
Out[86]:
0      one
1      two
2     four
3        -
dtype: category
Categories (4, object): [-, four, one, two]

In [87]: s = s.cat.set_categories(["one", "two", "three", "four"])

In [88]: s
Out[88]:
0      one
1      two
2     four
3      NaN
dtype: category
Categories (4, object): [one, two, three, four]
```

---

**Note:** Be aware that `Categorical.set_categories()` cannot know whether some category is omitted intentionally or because it is misspelled or (under Python3) due to a type difference (e.g., NumPy S1 dtype and Python strings). This can result in surprising behaviour!

---

## 21.5 Sorting and Order

If categorical data is ordered (`s.cat.ordered == True`), then the order of the categories has a meaning and certain operations are possible. If the categorical is unordered, `.min()` / `.max()` will raise a `TypeError`.

```
In [89]: s = pd.Series(pd.Categorical(["a", "b", "c", "a"], ordered=False))

In [90]: s.sort_values(inplace=True)

In [91]: s = pd.Series(["a", "b", "c", "a"]).astype(
.....:     CategoricalDtype(ordered=True)
.....: )
.....:

In [92]: s.sort_values(inplace=True)

In [93]: s
Out[93]:
0      a
3      a
1      b
2      c
```

(continues on next page)

(continued from previous page)

```
dtype: category
Categories (3, object): [a < b < c]
```

```
In [94]: s.min(), s.max()
```

```
Out[94]:
```

You can set categorical data to be ordered by using `as_ordered()` or unordered by using `as_unordered()`. These will by default return a *new* object.

```
In [95]: s.cat.as_ordered()
```

Out [95] :

|   |   |
|---|---|
| 0 | a |
|---|---|

3 a

|   |   |
|---|---|
| 1 | b |
|---|---|

2 c

```
dtype: category
```

```
Categories (3, object): [a < b < c]
```

```
In [96]: s.cat.as_unordered()
```

```
\\Out[96]:
```

|   |   |
|---|---|
| 0 | a |
|---|---|

3 a

|   |   |
|---|---|
| 1 | b |
|---|---|

2 c

```
dtype: category
```

```
Categories (3, object): [a, b, c]
```

Sorting will use the order defined by categories, not any lexical order present on the data type. This is even true for strings and numeric data:

```
In [97]: s = pd.Series([1, 2, 3, 1], dtype="category")
```

```
In [98]: s = s.cat.set_categories([2, 3, 1], ordered=True)
```

In [99]: S

Out [99] :

|   |   |
|---|---|
| 0 | 1 |
|---|---|

|   |   |
|---|---|
| 1 | 2 |
|---|---|

|   |   |
|---|---|
| 2 | 3 |
|---|---|

|   |   |
|---|---|
| 3 | 1 |
|---|---|

```
dtype: category
```

```
Categories (3, int64): [2 < 3 < 1]

|---|---|

```
dtype: category
```

```
Categories (3, int64): [2 < 3 < 1]
```

(continues on next page)

(continued from previous page)

```
In [102]: s.min(), s.max()
\\Out[102]:
↪ (2, 1)
```

## 21.5.1 Reordering

Reordering the categories is possible via the `Categorical.reorder_categories()` and the `Categorical.set_categories()` methods. For `Categorical.reorder_categories()`, all old categories must be included in the new categories and no new categories are allowed. This will necessarily make the sort order the same as the categories order.

```
In [103]: s = pd.Series([1, 2, 3, 1], dtype="category")

In [104]: s = s.cat.reorder_categories([2, 3, 1], ordered=True)

In [105]: s
Out[105]:
0    1
1    2
2    3
3    1
dtype: category
Categories (3, int64): [2 < 3 < 1]

In [106]: s.sort_values(inplace=True)

In [107]: s
Out[107]:
1    2
2    3
0    1
3    1
dtype: category
Categories (3, int64): [2 < 3 < 1]

In [108]: s.min(), s.max()
\\Out[108]:
↪ (2, 1)
```

**Note:** Note the difference between assigning new categories and reordering the categories: the first renames categories and therefore the individual values in the `Series`, but if the first position was sorted last, the renamed value will still be sorted last. Reordering means that the way values are sorted is different afterwards, but not that individual values in the `Series` are changed.

**Note:** If the `Categorical` is not ordered, `Series.min()` and `Series.max()` will raise `TypeError`. Numeric operations like `+`, `-`, `*`, `/` and operations based on them (e.g. `Series.median()`, which would need to compute the mean between two values if the length of an array is even) do not work and raise a `TypeError`.

## 21.5.2 Multi Column Sorting

A categorical dtyped column will participate in a multi-column sort in a similar manner to other columns. The ordering of the categorical is determined by the `categories` of that column.

```
In [109]: dfs = pd.DataFrame({'A': pd.Categorical(list('bbeebbaa'),
.....:                                     categories=['e', 'a', 'b'],
.....:                                     ordered=True),
.....:                       'B': [1, 2, 1, 2, 2, 1, 2, 1]})
.....:

In [110]: dfs.sort_values(by=['A', 'B'])
Out[110]:
```

|   | A | B |
|---|---|---|
| 2 | e | 1 |
| 3 | e | 2 |
| 7 | a | 1 |
| 6 | a | 2 |
| 0 | b | 1 |
| 5 | b | 1 |
| 1 | b | 2 |
| 4 | b | 2 |

Reordering the `categories` changes a future sort.

```
In [111]: dfs['A'] = dfs['A'].cat.reorder_categories(['a', 'b', 'e'])

In [112]: dfs.sort_values(by=['A', 'B'])
Out[112]:
```

|   | A | B |
|---|---|---|
| 7 | a | 1 |
| 6 | a | 2 |
| 0 | b | 1 |
| 5 | b | 1 |
| 1 | b | 2 |
| 4 | b | 2 |
| 2 | e | 1 |
| 3 | e | 2 |

## 21.6 Comparisons

Comparing categorical data with other objects is possible in three cases:

- Comparing equality (`==` and `!=`) to a list-like object (list, Series, array, ...) of the same length as the categorical data.
- All comparisons (`==`, `!=`, `>`, `>=`, `<`, and `<=`) of categorical data to another categorical Series, when `ordered=True` and the `categories` are the same.
- All comparisons of a categorical data to a scalar.

All other comparisons, especially “non-equality” comparisons of two categoricals with different categories or a categorical with any list-like object, will raise a `TypeError`.

**Note:** Any “non-equality” comparisons of categorical data with a Series, `np.array`, list or categorical data with different categories or ordering will raise a `TypeError` because custom categories ordering could be interpreted

in two ways: one with taking into account the ordering and one without.

---

```
In [113]: cat = pd.Series([1, 2, 3]).astype(
.....:     CategoricalDtype([3, 2, 1], ordered=True)
.....: )
.....:

In [114]: cat_base = pd.Series([2, 2, 2]).astype(
.....:     CategoricalDtype([3, 2, 1], ordered=True)
.....: )
.....:

In [115]: cat_base2 = pd.Series([2, 2, 2]).astype(
.....:     CategoricalDtype(ordered=True)
.....: )
.....:

In [116]: cat
Out[116]:
0    1
1    2
2    3
dtype: category
Categories (3, int64): [3 < 2 < 1]

In [117]: cat_base
Out[117]:
0    2
1    2
2    2
dtype: category
Categories (3, int64): [3 < 2 < 1]

In [118]: cat_base2
Out[118]:
0    2
1    2
2    2
dtype: category
Categories (1, int64): [2]
```

Comparing to a categorical with the same categories and ordering or to a scalar works:

```
In [119]: cat > cat_base
Out[119]:
0    True
1   False
2   False
dtype: bool

In [120]: cat > 2
Out[120]:
0    True
1   False
2   False
```

(continues on next page)

(continued from previous page)

```
dtype: bool
```

Equality comparisons work with any list-like object of same length and scalars:

```
In [121]: cat == cat_base
Out[121]:
0    False
1     True
2    False
dtype: bool

In [122]: cat == np.array([1, 2, 3])
Out[122]:
0     True
1     True
2     True
dtype: bool

In [123]: cat == 2
Out[123]:
0    False
1     True
2    False
dtype: bool
```

This doesn't work because the categories are not the same:

```
In [124]: try:
.....:     cat > cat_base2
.....: except TypeError as e:
.....:     print("TypeError:", str(e))
.....:
TypeError: Categoricals can only be compared if 'categories' are the same. Categoricals
are different lengths
```

If you want to do a “non-equality” comparison of a categorical series with a list-like object which is not categorical data, you need to be explicit and convert the categorical data back to the original values:

```
In [125]: base = np.array([1, 2, 3])

In [126]: try:
.....:     cat > base
.....: except TypeError as e:
.....:     print("TypeError:", str(e))
.....:
TypeError: Cannot compare a Categorical for op __gt__ with type <class 'numpy.ndarray'>.
If you want to compare values, use 'np.asarray(cat) <op> other'.

In [127]: np.asarray(cat) > base
Out[127]: array([False, False, False], dtype=bool)
```

When you compare two unordered categoricals with the same categories, the order is not considered:

```
In [128]: c1 = pd.Categorical(['a', 'b'], categories=['a', 'b'], ordered=False)
In [129]: c2 = pd.Categorical(['a', 'b'], categories=['b', 'a'], ordered=False)
In [130]: c1 == c2
Out[130]: array([ True,  True], dtype=bool)
```

## 21.7 Operations

Apart from `Series.min()`, `Series.max()` and `Series.mode()`, the following operations are possible with categorical data:

Series methods like `Series.value_counts()` will use all categories, even if some categories are not present in the data:

```
In [131]: s = pd.Series(pd.Categorical(["a", "b", "c", "c"],
.....:                               categories=["c", "a", "b", "d"]))
.....:
.....:
In [132]: s.value_counts()
Out[132]:
c    2
b    1
a    1
d    0
dtype: int64
```

Groupby will also show “unused” categories:

```
In [133]: cats = pd.Categorical(["a", "b", "b", "b", "c", "c", "c"],
.....:                           categories=["a", "b", "c", "d"])
.....:
In [134]: df = pd.DataFrame({"cats": cats, "values": [1, 2, 2, 2, 3, 4, 5]})

In [135]: df.groupby("cats").mean()
Out[135]:
      values
cats
a         1.0
b         2.0
c         4.0
d         NaN

In [136]: cats2 = pd.Categorical(["a", "a", "b", "b"], categories=["a", "b", "c"])

In [137]: df2 = pd.DataFrame({"cats": cats2,
.....:                        "B": ["c", "d", "c", "d"],
.....:                        "values": [1, 2, 3, 4]})
.....:

In [138]: df2.groupby(["cats", "B"]).mean()
Out[138]:
      values
cats B
```

(continues on next page)

(continued from previous page)

|   |   |     |
|---|---|-----|
| a | c | 1.0 |
|   | d | 2.0 |
| b | c | 3.0 |
|   | d | 4.0 |
| c | c | NaN |
|   | d | NaN |

Pivot tables:

```
In [139]: raw_cat = pd.Categorical(["a", "a", "b", "b"], categories=["a", "b", "c"])

In [140]: df = pd.DataFrame({"A": raw_cat,
.....:                      "B": ["c", "d", "c", "d"],
.....:                      "values": [1, 2, 3, 4]})
.....:

In [141]: pd.pivot_table(df, values='values', index=['A', 'B'])
Out[141]:
      values
A B
a c        1
  d        2
b c        3
  d        4
```

## 21.8 Data munging

The optimized pandas data access methods `.loc`, `.iloc`, `.at`, and `.iat`, work as normal. The only difference is the return type (for getting) and that only values already in *categories* can be assigned.

### 21.8.1 Getting

If the slicing operation returns either a `DataFrame` or a column of type `Series`, the `category` dtype is preserved.

```
In [142]: idx = pd.Index(["h", "i", "j", "k", "l", "m", "n"])

In [143]: cats = pd.Series(["a", "b", "b", "b", "c", "c", "c"],
.....:                     dtype="category", index=idx)
.....:

In [144]: values = [1, 2, 2, 2, 3, 4, 5]

In [145]: df = pd.DataFrame({"cats": cats, "values": values}, index=idx)

In [146]: df.iloc[2:4, :]
Out[146]:
      cats  values
j      b        2
k      b        2

In [147]: df.iloc[2:4, :].dtypes
Out[147]:
cats      category
```

(continues on next page)

(continued from previous page)

```

values      int64
dtype: object

In [148]: df.loc["h":"j", "cats"]
///////////////////////////////////////////////////
↪
h      a
i      b
j      b
Name: cats, dtype: category
Categories (3, object): [a, b, c]

In [149]: df[df["cats"] == "b"]
///////////////////////////////////////////////////
↪
   cats  values
i      b        2
j      b        2
k      b        2

```

An example where the category type is not preserved is if you take one single row: the resulting `Series` is of dtype `object`:

```

# get the complete "h" row as a Series
In [150]: df.loc["h", :]
Out[150]:
cats      a
values    1
Name: h, dtype: object

```

Returning a single item from categorical data will also return the value, not a categorical of length “1”.

```

In [151]: df.iat[0, 0]
Out[151]: 'a'

In [152]: df["cats"].cat.categories = ["x", "y", "z"]

In [153]: df.at["h", "cats"] # returns a string
Out[153]: 'x'

```

---

**Note:** This is in contrast to R’s `factor` function, where `factor(c(1, 2, 3))[1]` returns a single value *factor*.

---

To get a single value `Series` of type `category`, you pass in a list with a single value:

```

In [154]: df.loc[["h"], "cats"]
Out[154]:
h      x
Name: cats, dtype: category
Categories (3, object): [x, y, z]

```

## 21.8.2 String and datetime accessors

The accessors `.dt` and `.str` will work if the `s.cat.categories` are of an appropriate type:

```

In [155]: str_s = pd.Series(list('aabb'))

In [156]: str_cat = str_s.astype('category')

In [157]: str_cat
Out[157]:
0      a
1      a
2      b
3      b
dtype: category
Categories (2, object): [a, b]

In [158]: str_cat.str.contains("a")
Out[158]:
0      True
1      True
2     False
3     False
dtype: bool

In [159]: date_s = pd.Series(pd.date_range('1/1/2015', periods=5))

In [160]: date_cat = date_s.astype('category')

In [161]: date_cat
Out[161]:
0    2015-01-01
1    2015-01-02
2    2015-01-03
3    2015-01-04
4    2015-01-05
dtype: category
Categories (5, datetime64[ns]): [2015-01-01, 2015-01-02, 2015-01-03, 2015-01-04, 2015-01-05]

In [162]: date_cat.dt.day
Out[162]:
0      1
1      2
2      3
3      4
4      5
dtype: int64

```

---

**Note:** The returned Series (or DataFrame) is of the same type as if you used the `.str.<method>` / `.dt.<method>` on a Series of that type (and not of type `category`!).

---

That means, that the returned values from methods and properties on the accessors of a `Series` and the returned values from methods and properties on the accessors of this `Series` transformed to one of type `category` will be equal:

```
In [163]: ret_s = str_s.str.contains("a")
```

(continues on next page)

(continued from previous page)

```
In [164]: ret_cat = str_cat.str.contains("a")
```

```
In [165]: ret_s.dtype == ret_cat.dtype
```

```
Out[165]: True
```

```
In [166]: ret_s == ret_cat
```

```
\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\Out[166]:
```

|   |      |
|---|------|
| 0 | True |
|---|------|

|   |      |
|---|------|
| 2 | True |
|---|------|

```
dtype: bool
```

**Note:** The work is done on the `categories` and then a new `Series` is constructed. This has some performance implication if you have a `Series` of type `string`, where lots of elements are repeated (i.e. the number of unique elements in the `Series` is a lot smaller than the length of the `Series`). In this case it can be faster to convert the original `Series` to one of type `category` and use `.str.<method>` or `.dt.<property>` on that.

### 21.8.3 Setting

Setting values in a categorical column (or `Series`) works as long as the value is included in the *categories*:

```
In [167]: idx = pd.Index(["h", "i", "j", "k", "l", "m", "n"])
```

```
In [168]: cats = pd.Categorical(["a", "a", "a", "a", "a", "a", "a"],
.....:                          categories=["a", "b"])
.....:
```

```
In [169]: values = [1, 1, 1, 1, 1, 1, 1]
```

```
In [170]: df = pd.DataFrame({"cats": cats, "values": values}, index=idx)
```

```
In [171]: df.iloc[2:4, :] = [{"b", 2}, {"b", 2}]
```

```
In [172]: df
```

Out [172]:

| cats | values |
|------|--------|
|------|--------|

i b 2

|   |   |   |
|---|---|---|
| k | b | 2 |
|---|---|---|

|   |   |   |
|---|---|---|
| m | a | 1 |
|---|---|---|

```
In [173]: try:
```

```
df.iloc[2:4, :] = [{"c", 3}, {"c", 3}]
```

```
.....: except ValueError as e:
```

```
.....: print("ValueError:", str(e))
```

[illegible]

Setting values by assigning categorical data will also check that the *categories* match:

```
In [174]: df.loc["j":"k", "cats"] = pd.Categorical(["a", "a"], categories=["a", "b"])

In [175]: df
Out[175]:
   cats  values
h     a        1
i     a        1
j     a        2
k     a        2
l     a        1
m     a        1
n     a        1

In [176]: try:
.....:     df.loc["j":"k", "cats"] = pd.Categorical(["b", "b"],
.....:                                                categories=["a", "b", "c"])
.....: except ValueError as e:
.....:     print("ValueError:", str(e))
.....:
////////////////////////////////////
↪Cannot set a Categorical with another, without identical categories
```

Assigning a Categorical to parts of a column of other types will use the values:

```
In [177]: df = pd.DataFrame({"a": [1, 1, 1, 1, 1], "b": ["a", "a", "a", "a", "a"]})

In [178]: df.loc[1:2, "a"] = pd.Categorical(["b", "b"], categories=["a", "b"])

In [179]: df.loc[2:3, "b"] = pd.Categorical(["b", "b"], categories=["a", "b"])

In [180]: df
Out[180]:
   a  b
0  1  a
1  b  a
2  b  b
3  1  b
4  1  a

In [181]: df.dtypes
Out[181]:
a    object
b    object
dtype: object
```

## 21.8.4 Merging

You can concat two DataFrames containing categorical data together, but the categories of these categoricals need to be the same:

```
In [182]: cat = pd.Series(["a", "b"], dtype="category")

In [183]: vals = [1, 2]
```

(continues on next page)

(continued from previous page)

```

In [184]: df = pd.DataFrame({"cats": cat, "vals": vals})

In [185]: res = pd.concat([df, df])

In [186]: res
Out[186]:
   cats  vals
0     a     1
1     b     2
0     a     1
1     b     2

In [187]: res.dtypes
Out[187]:
cats      category
vals      int64
dtype: object

```

In this case the categories are not the same, and therefore an error is raised:

```

In [188]: df_different = df.copy()

In [189]: df_different["cats"].cat.categories = ["c", "d"]

In [190]: try:
.....:     pd.concat([df, df_different])
.....: except ValueError as e:
.....:     print("ValueError:", str(e))
.....:

```

The same applies to `df.append(df_different)`.

See also the section on *merge dtypes* for notes about preserving merge dtypes and performance.

## 21.8.5 Unioning

New in version 0.19.0.

If you want to combine categoricals that do not necessarily have the same categories, the `union_categoricals()` function will combine a list-like of categoricals. The new categories will be the union of the categories being combined.

```

In [191]: from pandas.api.types import union_categoricals

In [192]: a = pd.Categorical(["b", "c"])

In [193]: b = pd.Categorical(["a", "b"])

In [194]: union_categoricals([a, b])
Out[194]:
[b, c, a, b]
Categories (3, object): [b, c, a]

```

By default, the resulting categories will be ordered as they appear in the data. If you want the categories to be lexsorted, use `sort_categories=True` argument.

```
In [195]: union_categoricals([a, b], sort_categories=True)
Out[195]:
[b, c, a, b]
Categories (3, object): [a, b, c]
```

`union_categoricals` also works with the “easy” case of combining two categoricals of the same categories and order information (e.g. what you could also append for).

```
In [196]: a = pd.Categorical(["a", "b"], ordered=True)
In [197]: b = pd.Categorical(["a", "b", "a"], ordered=True)
In [198]: union_categoricals([a, b])
Out[198]:
[a, b, a, b, a]
Categories (2, object): [a < b]
```

The below raises `TypeError` because the categories are ordered and not identical.

```
In [1]: a = pd.Categorical(["a", "b"], ordered=True)
In [2]: b = pd.Categorical(["a", "b", "c"], ordered=True)
In [3]: union_categoricals([a, b])
Out[3]:
TypeError: to union ordered Categoricals, all categories must be the same
```

New in version 0.20.0.

Ordered categoricals with different categories or orderings can be combined by using the `ignore_ordered=True` argument.

```
In [199]: a = pd.Categorical(["a", "b", "c"], ordered=True)
In [200]: b = pd.Categorical(["c", "b", "a"], ordered=True)
In [201]: union_categoricals([a, b], ignore_order=True)
Out[201]:
[a, b, c, c, b, a]
Categories (3, object): [a, b, c]
```

`union_categoricals()` also works with a `CategoricalIndex`, or `Series` containing categorical data, but note that the resulting array will always be a plain `Categorical`:

```
In [202]: a = pd.Series(["b", "c"], dtype='category')
In [203]: b = pd.Series(["a", "b"], dtype='category')
In [204]: union_categoricals([a, b])
Out[204]:
[b, c, a, b]
Categories (3, object): [b, c, a]
```

**Note:** `union_categoricals` may recode the integer codes for categories when combining categoricals. This is likely what you want, but if you are relying on the exact numbering of the categories, be aware.

```
In [205]: c1 = pd.Categorical(["b", "c"])
```

(continues on next page)

(continued from previous page)

```

In [206]: c2 = pd.Categorical(["a", "b"])

In [207]: c1
Out[207]:
[b, c]
Categories (2, object): [b, c]

# "b" is coded to 0
In [208]: c1.codes
Out[208]: array([0, 1], dtype=int8)

In [209]: c2
Out[209]:
↪
[a, b]
Categories (2, object): [a, b]

# "b" is coded to 1
In [210]: c2.codes
Out[210]: array([0, 1], dtype=int8)

In [211]: c = union_categoricals([c1, c2])

In [212]: c
Out[212]:
[b, c, a, b]
Categories (3, object): [b, c, a]

# "b" is coded to 0 throughout, same as c1, different from c2
In [213]: c.codes
Out[213]: array([0, 1, 2, 0], dtype=int8)

```

## 21.8.6 Concatenation

This section describes concatenations specific to category dtype. See *Concatenating objects* for general description.

By default, Series or DataFrame concatenation which contains the same categories results in category dtype, otherwise results in object dtype. Use `.astype` or `union_categoricals` to get category result.

```

# same categories
In [214]: s1 = pd.Series(['a', 'b'], dtype='category')

In [215]: s2 = pd.Series(['a', 'b', 'a'], dtype='category')

In [216]: pd.concat([s1, s2])
Out[216]:
0    a
1    b
0    a
1    b
2    a
dtype: category

```

(continues on next page)

(continued from previous page)

```
Categories (2, object): [a, b]

# different categories
In [217]: s3 = pd.Series(['b', 'c'], dtype='category')

In [218]: pd.concat([s1, s3])
Out[218]:
0      a
1      b
0      b
1      c
dtype: object

In [219]: pd.concat([s1, s3]).astype('category')
Out[219]:
0      a
1      b
0      b
1      c
dtype: category
Categories (3, object): [a, b, c]

In [220]: union_categoricals([s1.array, s3.array])
Out[220]:
0      a
1      b
0      b
1      c
dtype: category
Categories (3, object): [a, b, c]
```

Following table summarizes the results of Categoricals related concatenations.

| arg1     | arg2                                                   | result                     |
|----------|--------------------------------------------------------|----------------------------|
| category | category (identical categories)                        | category                   |
| category | category (different categories, both not ordered)      | object (dtype is inferred) |
| category | category (different categories, either one is ordered) | object (dtype is inferred) |
| category | not category                                           | object (dtype is inferred) |

## 21.9 Getting Data In/Out

You can write data that contains `category` dtypes to a `HDFStore`. See *here* for an example and caveats.

It is also possible to write data to and reading data from *Stata* format files. See [here](#) for an example and caveats.

Writing to a CSV file will convert the data, effectively removing any information about the categorical (categories and ordering). So if you read back the CSV file you have to convert the relevant columns back to *category* and assign the right categories and categories ordering.

```
In [221]: import io

In [222]: s = pd.Series(pd.Categorical(['a', 'b', 'b', 'a', 'a', 'd']))

# rename the categories
In [223]: s.cat.categories = ["very good", "good", "bad"]

# reorder the categories and add missing categories
```

(continues on next page)

(continued from previous page)

```

In [224]: s = s.cat.set_categories(["very bad", "bad", "medium", "good", "very good"])

In [225]: df = pd.DataFrame({"cats": s, "vals": [1, 2, 3, 4, 5, 6]})

In [226]: csv = io.StringIO()

In [227]: df.to_csv(csv)

In [228]: df2 = pd.read_csv(io.StringIO(csv.getvalue()))

In [229]: df2.dtypes
Out[229]:
Unnamed: 0      int64
cats           object
vals           int64
dtype: object

In [230]: df2["cats"]
Out[230]:
0    very good
1         good
2         good
3    very good
4    very good
5         bad
Name: cats, dtype: object

# Redo the category
In [231]: df2["cats"] = df2["cats"].astype("category")

In [232]: df2["cats"].cat.set_categories(["very bad", "bad", "medium",
.....:                                "good", "very good"],
.....:                                inplace=True)
.....:

In [233]: df2.dtypes
Out[233]:
Unnamed: 0      int64
cats           category
vals           int64
dtype: object

In [234]: df2["cats"]
Out[234]:
0    very good
1         good
2         good
3    very good
4    very good
5         bad
Name: cats, dtype: category
Categories (5, object): [very bad, bad, medium, good, very good]

```

The same holds for writing to a SQL database with `to_sql`.

## 21.10 Missing Data

pandas primarily uses the value `np.nan` to represent missing data. It is by default not included in computations. See the *Missing Data section*.

Missing values should **not** be included in the Categorical's `categories`, only in the `values`. Instead, it is understood that NaN is different, and is always a possibility. When working with the Categorical's `codes`, missing values will always have a code of `-1`.

```
In [235]: s = pd.Series(["a", "b", np.nan, "a"], dtype="category")

# only two categories
In [236]: s
Out[236]:
0      a
1      b
2     NaN
3      a
dtype: category
Categories (2, object): [a, b]

In [237]: s.cat.codes
Out[237]:
0      0
1      1
2     -1
3      0
dtype: int8
```

Methods for working with missing data, e.g. `isna()`, `fillna()`, `dropna()`, all work normally:

```
In [238]: s = pd.Series(["a", "b", np.nan], dtype="category")

In [239]: s
Out[239]:
0      a
1      b
2     NaN
dtype: category
Categories (2, object): [a, b]

In [240]: pd.isna(s)
Out[240]:
0    False
1    False
2     True
dtype: bool

In [241]: s.fillna("a")
Out[241]:
0      a
1      b
2      a
dtype: category
Categories (2, object): [a, b]
```

## 21.11 Differences to R's *factor*

The following differences to R's *factor* functions can be observed:

- R's *levels* are named *categories*.
- R's *levels* are always of type string, while *categories* in pandas can be of any dtype.
- It's not possible to specify labels at creation time. Use `s.cat.rename_categories(new_labels)` afterwards.
- In contrast to R's *factor* function, using categorical data as the sole input to create a new categorical series will *not* remove unused categories but create a new categorical series which is equal to the passed in one!
- R allows for missing values to be included in its *levels* (pandas' *categories*). Pandas does not allow *NaN* categories, but missing values can still be in the *values*.

## 21.12 Gotchas

### 21.12.1 Memory Usage

The memory usage of a `Categorical` is proportional to the number of categories plus the length of the data. In contrast, an `object` dtype is a constant times the length of the data.

```
In [242]: s = pd.Series(['foo', 'bar'] * 1000)

# object dtype
In [243]: s.nbytes
Out[243]: 16000

# category dtype
In [244]: s.astype('category').nbytes
\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\Out[244]: 2016
```

---

**Note:** If the number of categories approaches the length of the data, the `Categorical` will use nearly the same or more memory than an equivalent `object` dtype representation.

```
In [245]: s = pd.Series(['foo%04d' % i for i in range(2000)])

# object dtype
In [246]: s.nbytes
Out[246]: 16000

# category dtype
In [247]: s.astype('category').nbytes
\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\Out[247]: 20000
```

### 21.12.2 *Categorical* is not a *numpy* array

Currently, categorical data and the underlying `Categorical` is implemented as a Python object and not as a low-level NumPy array dtype. This leads to some problems.

NumPy itself doesn't know about the new *dtype*:

```
In [248]: try:
.....:     np.dtype("category")
.....: except TypeError as e:
.....:     print("TypeError:", str(e))
.....:
TypeError: data type "category" not understood

In [249]: dtype = pd.Categorical(["a"]).dtype

In [250]: try:
.....:     np.dtype(dtype)
.....: except TypeError as e:
.....:     print("TypeError:", str(e))
.....:
TypeError: data type not understood
```

Dtype comparisons work:

```
In [251]: dtype == np.str_
Out[251]: False

In [252]: np.str_ == dtype
\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\Out[252]: False
```

To check if a Series contains Categorical data, use `hasattr(s, 'cat')`:

```
In [253]: hasattr(pd.Series(['a'], dtype='category'), 'cat')
Out[253]: True

In [254]: hasattr(pd.Series(['a']), 'cat')
\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\Out[254]: False
```

Using NumPy functions on a Series of type category should not work as *Categoricals* are not numeric data (even in the case that `.categories` is numeric).

```
In [255]: s = pd.Series(pd.Categorical([1, 2, 3, 4]))

In [256]: try:
.....:     np.sum(s)
.....: except TypeError as e:
.....:     print("TypeError:", str(e))
.....:
TypeError: Categorical cannot perform the operation sum
```

---

**Note:** If such a function works, please file a bug at <https://github.com/pandas-dev/pandas!>

---

### 21.12.3 dtype in apply

Pandas currently does not preserve the dtype in apply functions: If you apply along rows you get a *Series* of object *dtype* (same as getting a row -> getting one element will return a basic type) and applying along columns will also convert to object. NaN values are unaffected. You can use `fillna` to handle missing values before applying a function.

```
In [257]: df = pd.DataFrame({"a": [1, 2, 3, 4],
.....:                      "b": ["a", "b", "c", "d"],
.....:                      "cats": pd.Categorical([1, 2, 3, 2])})
.....:

In [258]: df.apply(lambda row: type(row["cats"]), axis=1)
Out [258]:
0    <class 'int'>
1    <class 'int'>
2    <class 'int'>
3    <class 'int'>
dtype: object

In [259]: df.apply(lambda col: col.dtype, axis=0)
////////////////////////////////////
a    int64
b    object
cats  category
dtype: object
```

### 21.12.4 Categorical Index

`CategoricalIndex` is a type of index that is useful for supporting indexing with duplicates. This is a container around a `Categorical` and allows efficient indexing and storage of an index with a large number of duplicated elements. See the *advanced indexing docs* for a more detailed explanation.

Setting the index will create a `CategoricalIndex`:

```
In [260]: cats = pd.Categorical([1, 2, 3, 4], categories=[4, 2, 3, 1])

In [261]: strings = ["a", "b", "c", "d"]

In [262]: values = [4, 2, 3, 1]

In [263]: df = pd.DataFrame({"strings": strings, "values": values}, index=cats)

In [264]: df.index
Out[264]: CategoricalIndex([1, 2, 3, 4], categories=[4, 2, 3, 1], ordered=False,
↳ dtype='category')

# This now sorts by the categories order
In [265]: df.sort_index()
↳
strings  values
4        d      1
2        b      2
3        c      3
1        a      4
```

### 21.12.5 Side Effects

Constructing a `Series` from a `Categorical` will not copy the input `Categorical`. This means that changes to the `Series` will in most cases change the original `Categorical`:

```
In [266]: cat = pd.Categorical([1, 2, 3, 10], categories=[1, 2, 3, 4, 10])

In [267]: s = pd.Series(cat, name="cat")

In [268]: cat
Out[268]:
[1, 2, 3, 10]
Categories (5, int64): [1, 2, 3, 4, 10]

In [269]: s.iloc[0:2] = 10

In [270]: cat
Out[270]:
[10, 10, 3, 10]
Categories (5, int64): [1, 2, 3, 4, 10]

In [271]: df = pd.DataFrame(s)

In [272]: df["cat"].cat.categories = [1, 2, 3, 4, 5]

In [273]: cat
Out[273]:
[5, 5, 3, 5]
Categories (5, int64): [1, 2, 3, 4, 5]
```

Use `copy=True` to prevent such a behaviour or simply don't reuse Categoricals:

```
In [274]: cat = pd.Categorical([1, 2, 3, 10], categories=[1, 2, 3, 4, 10])

In [275]: s = pd.Series(cat, name="cat", copy=True)

In [276]: cat
Out[276]:
[1, 2, 3, 10]
Categories (5, int64): [1, 2, 3, 4, 10]

In [277]: s.iloc[0:2] = 10

In [278]: cat
Out[278]:
[1, 2, 3, 10]
Categories (5, int64): [1, 2, 3, 4, 10]
```

---

**Note:** This also happens in some cases when you supply a NumPy array instead of a Categorical: using an int array (e.g. `np.array([1, 2, 3, 4])`) will exhibit the same behavior, while using a string array (e.g. `np.array(["a", "b", "c", "a"])`) will not.

---

{{ header }}

## NULLABLE INTEGER DATA TYPE

New in version 0.24.0.

In [Missing Data](#), we saw that pandas primarily uses `NaN` to represent missing data. Because `NaN` is a float, this forces an array of integers with any missing values to become floating point. In some cases, this may not matter much. But if your integer column is, say, an identifier, casting to float can be problematic. Some integers cannot even be represented as floating point numbers.

Pandas can represent integer data with possibly missing values using `arrays.IntegerArray`. This is an *extension types* implemented within pandas. It is not the default dtype for integers, and will not be inferred; you must explicitly pass the dtype into `array()` or `Series`:

```
In [1]: arr = pd.array([1, 2, np.nan], dtype=pd.Int64Dtype())

In [2]: arr
Out[2]:
<IntegerArray>
[1, 2, NaN]
Length: 3, dtype: Int64
```

Or the string alias `"Int64"` (note the capital `"I"`, to differentiate from NumPy's `'int64'` dtype:

```
In [3]: pd.array([1, 2, np.nan], dtype="Int64")
Out[3]:
<IntegerArray>
[1, 2, NaN]
Length: 3, dtype: Int64
```

This array can be stored in a `DataFrame` or `Series` like any NumPy array.

```
In [4]: pd.Series(arr)
Out[4]:
0      1
1      2
2     NaN
dtype: Int64
```

You can also pass the list-like object to the `Series` constructor with the dtype.

```
In [5]: s = pd.Series([1, 2, np.nan], dtype="Int64")

In [6]: s
Out[6]:
0      1
1      2
```

(continues on next page)

(continued from previous page)

```
2      NaN
dtype: Int64
```

By default (if you don't specify `dtype`), NumPy is used, and you'll end up with a `float64` dtype Series:

```
In [7]: pd.Series([1, 2, np.nan])
Out[7]:
0      1.0
1      2.0
2      NaN
dtype: float64
```

Operations involving an integer array will behave similar to NumPy arrays. Missing values will be propagated, and and the data will be coerced to another dtype if needed.

```
# arithmetic
In [8]: s + 1
Out[8]:
0      2
1      3
2      NaN
dtype: Int64

# comparison
In [9]: s == 1
Out[9]:
0      True
1     False
2     False
dtype: bool

# indexing
In [10]: s.iloc[1:3]
Out[10]:
1      2
2      NaN
dtype: Int64

# operate with other dtypes
In [11]: s + s.iloc[1:3].astype('Int8')
Out[11]:
0      NaN
1      4
2      NaN
dtype: Int64

# coerce when needed
In [12]: s + 0.01
Out[12]:
0      1.01
1      2.01
2      NaN
dtype: float64
```

These dtypes can operate as part of of DataFrame.

```
In [13]: df = pd.DataFrame({'A': s, 'B': [1, 1, 3], 'C': list('aab')})

In [14]: df
Out[14]:
```

|   | A   | B | C |
|---|-----|---|---|
| 0 | 1   | 1 | a |
| 1 | 2   | 1 | a |
| 2 | NaN | 3 | b |

```
In [15]: df.dtypes
Out[15]:
A      Int64
B      int64
C      object
dtype: object
```

These dtypes can be merged & reshaped & casted.

```
In [16]: pd.concat([df[['A']], df[['B', 'C']], axis=1).dtypes
Out[16]:
A      Int64
B      int64
C      object
dtype: object

In [17]: df['A'].astype(float)
Out[17]:
```

|   | A   |
|---|-----|
| 0 | 1.0 |
| 1 | 2.0 |
| 2 | NaN |

```
Name: A, dtype: float64
```

Reduction and groupby operations such as 'sum' work as well.

```
In [18]: df.sum()
Out[18]:
A      3
B      5
C      aab
dtype: object

In [19]: df.groupby('B').A.sum()
Out[19]:
```

| B | A |
|---|---|
| 1 | 3 |
| 3 | 0 |

```
Name: A, dtype: Int64
```

{{ header }}

## VISUALIZATION

We use the standard convention for referencing the matplotlib API:

```
In [1]: import matplotlib.pyplot as plt
In [2]: plt.close('all')
```

We provide the basics in pandas to easily create decent looking plots. See the *ecosystem* section for visualization libraries that go beyond the basics documented here.

---

**Note:** All calls to `np.random` are seeded with 123456.

---

### 23.1 Basic Plotting: `plot`

We will demonstrate the basics, see the *cookbook* for some advanced strategies.

The `plot` method on Series and DataFrame is just a simple wrapper around `plt.plot()`:

```
In [3]: ts = pd.Series(np.random.randn(1000),
...:                  index=pd.date_range('1/1/2000', periods=1000))
...:
In [4]: ts = ts.cumsum()
In [5]: ts.plot()
Out[5]: <matplotlib.axes._subplots.AxesSubplot at 0x7fd5309570b8>
```

If the index consists of dates, it calls `gcf().autofmt_xdate()` to try to format the x-axis nicely as per above.

On `DataFrame`, `plot()` is a convenience to plot all of the columns with labels:

```
In [6]: df = pd.DataFrame(np.random.randn(1000, 4),
...:                       index=ts.index, columns=list('ABCD'))
...:

In [7]: df = df.cumsum()

In [8]: plt.figure();

In [9]: df.plot();
```

You can plot one column versus another using the *x* and *y* keywords in `plot()`:

```
In [10]: df3 = pd.DataFrame(np.random.randn(1000, 2), columns=['B', 'C']).cumsum()
In [11]: df3['A'] = pd.Series(list(range(len(df))))
In [12]: df3.plot(x='A', y='B')
Out[12]: <matplotlib.axes._subplots.AxesSubplot at 0x7fd5099f3c88>
```

---

**Note:** For more formatting and styling options, see *formatting* below.

---

## 23.2 Other Plots

Plotting methods allow for a handful of plot styles other than the default line plot. These methods can be provided as the `kind` keyword argument to `plot()`, and include:

- `'bar'` or `'barh'` for bar plots
- `'hist'` for histogram
- `'box'` for boxplot
- `'kde'` or `'density'` for density plots
- `'area'` for area plots
- `'scatter'` for scatter plots
- `'hexbin'` for hexagonal bin plots
- `'pie'` for pie plots

For example, a bar plot can be created the following way:

```
In [13]: plt.figure();
In [14]: df.iloc[5].plot(kind='bar');
```

You can also create these other plots using the methods `DataFrame.plot.<kind>` instead of providing the `kind` keyword argument. This makes it easier to discover plot methods and the specific arguments they use:

```
In [15]: df = pd.DataFrame()

In [16]: df.plot.<TAB> # noqa: E225, E999
df.plot.area      df.plot.barh      df.plot.density  df.plot.hist      df.plot.line
↳ df.plot.scatter
df.plot.bar        df.plot.box        df.plot.hexbin   df.plot.kde        df.plot.pie
```

In addition to these `kind`s, there are the `DataFrame.hist()`, and `DataFrame.boxplot()` methods, which use a separate interface.

Finally, there are several *plotting functions* in `pandas.plotting` that take a `Series` or `DataFrame` as an argument. These include:

- *Scatter Matrix*
- *Andrews Curves*
- *Parallel Coordinates*

- *Lag Plot*
- *Autocorrelation Plot*
- *Bootstrap Plot*
- *RadViz*

Plots may also be adorned with *errorbars* or *tables*.

### 23.2.1 Bar plots

For labeled, non-time series data, you may wish to produce a bar plot:

```
In [17]: plt.figure();  
In [18]: df.iloc[5].plot.bar()  
Out[18]: <matplotlib.axes._subplots.AxesSubplot at 0x7fd509f3d898>  
In [19]: plt.axhline(0, color='k');
```

Calling a `DataFrame`'s `plot.bar()` method produces a multiple bar plot:

```
In [20]: df2 = pd.DataFrame(np.random.rand(10, 4), columns=['a', 'b', 'c', 'd'])  
In [21]: df2.plot.bar();
```

To produce a stacked bar plot, pass `stacked=True`:

```
In [22]: df2.plot.bar(stacked=True);
```

To get horizontal bar plots, use the `barh` method:

```
In [23]: df2.plot.barh(stacked=True);
```

### 23.2.2 Histograms

Histograms can be drawn by using the `DataFrame.plot.hist()` and `Series.plot.hist()` methods.

```
In [24]: df4 = pd.DataFrame({'a': np.random.randn(1000) + 1, 'b': np.random.
↳randn(1000),
      ....:                  'c': np.random.randn(1000) - 1}, columns=['a', 'b', 'c'])
      ....:

In [25]: plt.figure();

In [26]: df4.plot.hist(alpha=0.5)
Out [26]: <matplotlib.axes._subplots.AxesSubplot at 0x7fd50c7e0e10>
```

A histogram can be stacked using `stacked=True`. Bin size can be changed using the `bins` keyword.

```
In [27]: plt.figure();
```

```
In [28]: df4.plot.hist(stacked=True, bins=20)
```

```
Out [28]: <matplotlib.axes._subplots.AxesSubplot at 0x7fd50c7ba8d0>
```

You can pass other keywords supported by matplotlib `hist`. For example, horizontal and cumulative histograms can be drawn by `orientation='horizontal'` and `cumulative=True`.

```
In [29]: plt.figure();
```

```
In [30]: df4['a'].plot.hist(orientation='horizontal', cumulative=True)
```

```
Out [30]: <matplotlib.axes._subplots.AxesSubplot at 0x7fd50a31c1d0>
```

See the [hist](#) method and the [matplotlib hist documentation](#) for more.

The existing interface `DataFrame.hist` to plot histogram still can be used.

```
In [31]: plt.figure();
```

```
In [32]: df['A'].diff().hist()
```

```
Out [32]: <matplotlib.axes._subplots.AxesSubplot at 0x7fd50886c2e8>
```

`DataFrame.hist()` plots the histograms of the columns on multiple subplots:

```
In [33]: plt.figure()
Out[33]: <Figure size 640x480 with 0 Axes>

In [34]: df.diff().hist(color='k', alpha=0.5, bins=50)
Out[34]:
array([[<matplotlib.axes._subplots.AxesSubplot object at 0x7fd509fc38d0>,
        <matplotlib.axes._subplots.AxesSubplot object at 0x7fd509851b38>],
       [<matplotlib.axes._subplots.AxesSubplot object at 0x7fd5093d5da0>,
        <matplotlib.axes._subplots.AxesSubplot object at 0x7fd5082bf048>]],
      dtype=object)
```

The `by` keyword can be specified to plot grouped histograms:

```
In [35]: data = pd.Series(np.random.randn(1000))

In [36]: data.hist(by=np.random.randint(0, 4, 1000), figsize=(6, 4))
Out[36]:
array([[<matplotlib.axes._subplots.AxesSubplot object at 0x7fd5096385f8>,
        <matplotlib.axes._subplots.AxesSubplot object at 0x7fd50a270860>],
       [<matplotlib.axes._subplots.AxesSubplot object at 0x7fd50a23cac8>,
        <matplotlib.axes._subplots.AxesSubplot object at 0x7fd50936ed30>]],
      dtype=object)
```

### 23.2.3 Box Plots

Boxplot can be drawn calling `Series.plot.box()` and `DataFrame.plot.box()`, or `DataFrame.boxplot()` to visualize the distribution of values within each column.

For instance, here is a boxplot representing five trials of 10 observations of a uniform random variable on  $[0,1)$ .

```
In [37]: df = pd.DataFrame(np.random.rand(10, 5), columns=['A', 'B', 'C', 'D', 'E'])
In [38]: df.plot.box()
Out[38]: <matplotlib.axes._subplots.AxesSubplot at 0x7fd50a350160>
```

Boxplot can be colored by passing `color` keyword. You can pass a dict whose keys are `boxes`, `whiskers`, `medians` and `caps`. If some keys are missing in the dict, default colors are used for the corresponding artists. Also, boxplot has `sym` keyword to specify fliers style.

When you pass other type of arguments via `color` keyword, it will be directly passed to matplotlib for all the `boxes`, `whiskers`, `medians` and `caps` colorization.

The colors are applied to every boxes to be drawn. If you want more complicated colorization, you can get each drawn artists by passing `return_type`.

```
In [39]: color = {'boxes': 'DarkGreen', 'whiskers': 'DarkOrange',
.....:           'medians': 'DarkBlue', 'caps': 'Gray'}
.....:

In [40]: df.plot.box(color=color, sym='r+')
Out [40]: <matplotlib.axes._subplots.AxesSubplot at 0x7fd508d42198>
```

Also, you can pass other keywords supported by matplotlib `boxplot`. For example, horizontal and custom-positioned boxplot can be drawn by `vert=False` and `positions` keywords.

```
In [41]: df.plot.box(ver=False, positions=[1, 4, 5, 6, 8])
Out[41]: <matplotlib.axes._subplots.AxesSubplot at 0x7fd508d59ac8>
```

See the `boxplot` method and the [matplotlib boxplot documentation](#) for more.

The existing interface `DataFrame.boxplot` to plot boxplot still can be used.

```
In [42]: df = pd.DataFrame(np.random.rand(10, 5))
```

```
In [43]: plt.figure();
```

```
In [44]: bp = df.boxplot()
```

You can create a stratified boxplot using the `by` keyword argument to create groupings. For instance,

```
In [45]: df = pd.DataFrame(np.random.rand(10, 2), columns=['Col1', 'Col2'])
In [46]: df['X'] = pd.Series(['A', 'A', 'A', 'A', 'A', 'B', 'B', 'B', 'B', 'B'])
In [47]: plt.figure();
In [48]: bp = df.boxplot(by='X')
```

You can also pass a subset of columns to plot, as well as group by multiple columns:

```
In [49]: df = pd.DataFrame(np.random.rand(10, 3), columns=['Col1', 'Col2', 'Col3'])
In [50]: df['X'] = pd.Series(['A', 'A', 'A', 'A', 'A', 'B', 'B', 'B', 'B', 'B'])
In [51]: df['Y'] = pd.Series(['A', 'B', 'A', 'B', 'A', 'B', 'A', 'B', 'A', 'B'])
In [52]: plt.figure();
In [53]: bp = df.boxplot(column=['Col1', 'Col2'], by=['X', 'Y'])
```

**Warning:** The default changed from 'dict' to 'axes' in version 0.19.0.

In `boxplot`, the return type can be controlled by the `return_type`, keyword. The valid choices are {"axes", "dict", "both", None}. Faceting, created by `DataFrame.boxplot` with the `by` keyword, will affect the output type as well:

| <code>return_type=</code> | Faceted | Output type                |
|---------------------------|---------|----------------------------|
| None                      | No      | axes                       |
| None                      | Yes     | 2-D ndarray of axes        |
| 'axes'                    | No      | axes                       |
| 'axes'                    | Yes     | Series of axes             |
| 'dict'                    | No      | dict of artists            |
| 'dict'                    | Yes     | Series of dicts of artists |
| 'both'                    | No      | namedtuple                 |
| 'both'                    | Yes     | Series of namedtuples      |

`Groupby.boxplot` always returns a `Series` of `return_type`.

```

In [54]: np.random.seed(1234)

In [55]: df_box = pd.DataFrame(np.random.randn(50, 2))

In [56]: df_box['g'] = np.random.choice(['A', 'B'], size=50)

In [57]: df_box.loc[df_box['g'] == 'B', 1] += 3

In [58]: bp = df_box.boxplot(by='g')

```

The subplots above are split by the numeric columns first, then the value of the `g` column. Below the subplots are first split by the value of `g`, then by the numeric columns.

```

In [59]: bp = df_box.groupby('g').boxplot()

```

### 23.2.4 Area Plot

You can create area plots with `Series.plot.area()` and `DataFrame.plot.area()`. Area plots are stacked by default. To produce stacked area plot, each column must be either all positive or all negative values.

When input data contains *NaN*, it will be automatically filled by 0. If you want to drop or fill by different values, use `dataframe.dropna()` or `dataframe.fillna()` before calling `plot`.

```
In [60]: df = pd.DataFrame(np.random.rand(10, 4), columns=['a', 'b', 'c', 'd'])
In [61]: df.plot.area();
```

To produce an unstacked plot, pass `stacked=False`. Alpha value is set to 0.5 unless otherwise specified:

```
In [62]: df.plot.area(stacked=False);
```

### 23.2.5 Scatter Plot

Scatter plot can be drawn by using the `DataFrame.plot.scatter()` method. Scatter plot requires numeric columns for the x and y axes. These can be specified by the `x` and `y` keywords.

```
In [63]: df = pd.DataFrame(np.random.rand(50, 4), columns=['a', 'b', 'c', 'd'])
```

```
In [64]: df.plot.scatter(x='a', y='b');
```

To plot multiple column groups in a single axes, repeat `plot` method specifying target `ax`. It is recommended to specify `color` and `label` keywords to distinguish each groups.

```
In [65]: ax = df.plot.scatter(x='a', y='b', color='DarkBlue', label='Group 1');  
In [66]: df.plot.scatter(x='c', y='d', color='DarkGreen', label='Group 2', ax=ax);
```

The keyword `c` may be given as the name of a column to provide colors for each point:

```
In [67]: df.plot.scatter(x='a', y='b', c='c', s=50);
```

You can pass other keywords supported by matplotlib `scatter`. The example below shows a bubble chart using a column of the `DataFrame` as the bubble size.

```
In [68]: df.plot.scatter(x='a', y='b', s=df['c'] * 200);
```

See the `scatter` method and the [matplotlib scatter documentation](#) for more.

### 23.2.6 Hexagonal Bin Plot

You can create hexagonal bin plots with `DataFrame.plot.hexbin()`. Hexbin plots can be a useful alternative to scatter plots if your data are too dense to plot each point individually.

```
In [69]: df = pd.DataFrame(np.random.randn(1000, 2), columns=['a', 'b'])
In [70]: df['b'] = df['b'] + np.arange(1000)
In [71]: df.plot.hexbin(x='a', y='b', gridsize=25)
Out[71]: <matplotlib.axes._subplots.AxesSubplot at 0x7fd54c49f978>
```

A useful keyword argument is `gridsize`; it controls the number of hexagons in the x-direction, and defaults to 100. A larger `gridsize` means more, smaller bins.

By default, a histogram of the counts around each  $(x, y)$  point is computed. You can specify alternative aggregations by passing values to the `C` and `reduce_C_function` arguments. `C` specifies the value at each  $(x, y)$  point and `reduce_C_function` is a function of one argument that reduces all the values in a bin to a single number (e.g. mean, max, sum, std). In this example the positions are given by columns `a` and `b`, while the value is given by column `z`. The bins are aggregated with NumPy's `max` function.

```
In [72]: df = pd.DataFrame(np.random.randn(1000, 2), columns=['a', 'b'])
In [73]: df['b'] = df['b'] + np.arange(1000)
In [74]: df['z'] = np.random.uniform(0, 3, 1000)
In [75]: df.plot.hexbin(x='a', y='b', C='z', reduce_C_function=np.max, gridsize=25)
Out[75]: <matplotlib.axes._subplots.AxesSubplot at 0x7fd5099d9cc0>
```

See the `hexbin` method and the `matplotlib hexbin` documentation for more.

### 23.2.7 Pie plot

You can create a pie plot with `DataFrame.plot.pie()` or `Series.plot.pie()`. If your data includes any `NaN`, they will be automatically filled with 0. A `ValueError` will be raised if there are any negative values in your data.

```
In [76]: series = pd.Series(3 * np.random.rand(4),
.....:                     index=['a', 'b', 'c', 'd'], name='series')
.....:

In [77]: series.plot.pie(figsize=(6, 6))
Out[77]: <matplotlib.axes._subplots.AxesSubplot at 0x7fd50a677dd8>
```

For pie plots it's best to use square figures, i.e. a figure aspect ratio 1. You can create the figure with equal width and height, or force the aspect ratio to be equal after plotting by calling `ax.set_aspect('equal')` on the returned axes object.

Note that pie plot with `DataFrame` requires that you either specify a target column by the `y` argument or `subplots=True`. When `y` is specified, pie plot of selected column will be drawn. If `subplots=True` is specified, pie plots for each column are drawn as subplots. A legend will be drawn in each pie plots by default; specify `legend=False` to hide it.

```
In [78]: df = pd.DataFrame(3 * np.random.rand(4, 2),
.....:                    index=['a', 'b', 'c', 'd'], columns=['x', 'y'])
.....:
```

```
In [79]: df.plot.pie(subplots=True, figsize=(8, 4))
```

```
Out [79]:
array([<matplotlib.axes._subplots.AxesSubplot object at 0x7fd50a677be0>,
```

(continues on next page)

(continued from previous page)

```
<matplotlib.axes._subplots.AxesSubplot object at 0x7fd50c82ca90>],  
dtype=object)
```

You can use the `labels` and `colors` keywords to specify the labels and colors of each wedge.

**Warning:** Most pandas plots use the `label` and `color` arguments (note the lack of “s” on those). To be consistent with `matplotlib.pyplot.pie()` you must use `labels` and `colors`.

If you want to hide wedge labels, specify `labels=None`. If `fontsize` is specified, the value will be applied to wedge labels. Also, other keywords supported by `matplotlib.pyplot.pie()` can be used.

```
In [80]: series.plot.pie(labels=['AA', 'BB', 'CC', 'DD'], colors=['r', 'g', 'b', 'c'],  
.....:                 autopct='%0.2f', fontsize=20, figsize=(6, 6))  
.....:  
Out [80]: <matplotlib.axes._subplots.AxesSubplot at 0x7fd50c951630>
```

If you pass values whose sum total is less than 1.0, matplotlib draws a semicircle.

```
In [81]: series = pd.Series([0.1] * 4, index=['a', 'b', 'c', 'd'], name='series2')
In [82]: series.plot.pie(figsize=(6, 6))
Out [82]: <matplotlib.axes._subplots.AxesSubplot at 0x7fd50a0f5b00>
```

See the [matplotlib pie documentation](#) for more.

## 23.3 Plotting with Missing Data

Pandas tries to be pragmatic about plotting `DataFrames` or `Series` that contain missing data. Missing values are dropped, left out, or filled depending on the plot type.

| Plot Type      | NaN Handling            |
|----------------|-------------------------|
| Line           | Leave gaps at NaNs      |
| Line (stacked) | Fill 0's                |
| Bar            | Fill 0's                |
| Scatter        | Drop NaNs               |
| Histogram      | Drop NaNs (column-wise) |
| Box            | Drop NaNs (column-wise) |
| Area           | Fill 0's                |
| KDE            | Drop NaNs (column-wise) |
| Hexbin         | Drop NaNs               |
| Pie            | Fill 0's                |

If any of these defaults are not what you want, or if you want to be explicit about how missing values are handled, consider using `fillna()` or `dropna()` before plotting.

## 23.4 Plotting Tools

These functions can be imported from `pandas.plotting` and take a `Series` or `DataFrame` as an argument.

### 23.4.1 Scatter Matrix Plot

You can create a scatter plot matrix using the `scatter_matrix` method in `pandas.plotting`:

```
In [83]: from pandas.plotting import scatter_matrix

In [84]: df = pd.DataFrame(np.random.randn(1000, 4), columns=['a', 'b', 'c', 'd'])

In [85]: scatter_matrix(df, alpha=0.2, figsize=(6, 6), diagonal='kde')
Out[85]:
array([[<matplotlib.axes._subplots.AxesSubplot object at 0x7fd5309d6320>,
        <matplotlib.axes._subplots.AxesSubplot object at 0x7fd5309db080>,
        <matplotlib.axes._subplots.AxesSubplot object at 0x7fd5082c5d30>,
        <matplotlib.axes._subplots.AxesSubplot object at 0x7fd503f23438>],
        [<matplotlib.axes._subplots.AxesSubplot object at 0x7fd503fa7ba8>,
        <matplotlib.axes._subplots.AxesSubplot object at 0x7fd503db1048>,
        <matplotlib.axes._subplots.AxesSubplot object at 0x7fd503de8668>,
        <matplotlib.axes._subplots.AxesSubplot object at 0x7fd508092160>],
        [<matplotlib.axes._subplots.AxesSubplot object at 0x7fd508092438>,
        <matplotlib.axes._subplots.AxesSubplot object at 0x7fd508191fd0>,
        <matplotlib.axes._subplots.AxesSubplot object at 0x7fd5083b45f8>,
        <matplotlib.axes._subplots.AxesSubplot object at 0x7fd5083ff3c8>],
        [<matplotlib.axes._subplots.AxesSubplot object at 0x7fd5088258d0>,
        <matplotlib.axes._subplots.AxesSubplot object at 0x7fd50878e400>,
        <matplotlib.axes._subplots.AxesSubplot object at 0x7fd508c2dda0>,
        <matplotlib.axes._subplots.AxesSubplot object at 0x7fd508c0e940>]],
        dtype=object)
```

### 23.4.2 Density Plot

You can create density plots using the `Series.plot.kde()` and `DataFrame.plot.kde()` methods.

```
In [86]: ser = pd.Series(np.random.randn(1000))
```

```
In [87]: ser.plot.kde()
```

```
Out [87]: <matplotlib.axes._subplots.AxesSubplot at 0x7fd541cf4358>
```

### 23.4.3 Andrews Curves

Andrews curves allow one to plot multivariate data as a large number of curves that are created using the attributes of samples as coefficients for Fourier series, see the [Wikipedia entry](#) for more information. By coloring these curves differently for each class it is possible to visualize data clustering. Curves belonging to samples of the same class will usually be closer together and form larger structures.

**Note:** The “Iris” dataset is available [here](#).

```
In [88]: from pandas.plotting import andrews_curves

In [89]: data = pd.read_csv('data/iris.data')

In [90]: plt.figure()
Out[90]: <Figure size 640x480 with 0 Axes>

In [91]: andrews_curves(data, 'Name')
Out[91]: <matplotlib.axes._subplots.
AxesSubplot at 0x7fd5085fef98>
```

### 23.4.5 Lag Plot

Lag plots are used to check if a data set or time series is random. Random data should not exhibit any structure in the lag plot. Non-random structure implies that the underlying data are not random. The `lag` argument may be passed, and when `lag=1` the plot is essentially `data[:-1]` vs. `data[1:]`.

```
In [96]: from pandas.plotting import lag_plot

In [97]: plt.figure()
Out[97]: <Figure size 640x480 with 0 Axes>

In [98]: spacing = np.linspace(-99 * np.pi, 99 * np.pi, num=1000)

In [99]: data = pd.Series(0.1 * np.random.rand(1000) + 0.9 * np.sin(spacing))

In [100]: lag_plot(data)
Out[100]: <matplotlib.axes._subplots.AxesSubplot at 0x7fd508ffd6a0>
```

### 23.4.6 Autocorrelation Plot

Autocorrelation plots are often used for checking randomness in time series. This is done by computing autocorrelations for data values at varying time lags. If time series is random, such autocorrelations should be near zero for any and all time-lag separations. If time series is non-random then one or more of the autocorrelations will be significantly non-zero. The horizontal lines displayed in the plot correspond to 95% and 99% confidence bands. The dashed line is 99% confidence band. See the [Wikipedia entry](#) for more about autocorrelation plots.

```
In [101]: from pandas.plotting import autocorrelation_plot

In [102]: plt.figure()
Out[102]: <Figure size 640x480 with 0 Axes>

In [103]: spacing = np.linspace(-9 * np.pi, 9 * np.pi, num=1000)

In [104]: data = pd.Series(0.7 * np.random.rand(1000) + 0.3 * np.sin(spacing))

In [105]: autocorrelation_plot(data)
Out[105]: <matplotlib.axes._subplots.AxesSubplot at 0x7fd508ffdl0>
```

### 23.4.7 Bootstrap Plot

Bootstrap plots are used to visually assess the uncertainty of a statistic, such as mean, median, midrange, etc. A random subset of a specified size is selected from a data set, the statistic in question is computed for this subset and the process is repeated a specified number of times. Resulting plots and histograms are what constitutes the bootstrap plot.

```
In [106]: from pandas.plotting import bootstrap_plot
In [107]: data = pd.Series(np.random.rand(1000))
In [108]: bootstrap_plot(data, size=50, samples=500, color='grey')
Out[108]: <Figure size 640x480 with 6 Axes>
```

### 23.4.8 RadViz

RadViz is a way of visualizing multi-variate data. It is based on a simple spring tension minimization algorithm. Basically you set up a bunch of points in a plane. In our case they are equally spaced on a unit circle. Each point represents a single attribute. You then pretend that each sample in the data set is attached to each of these points by a spring, the stiffness of which is proportional to the numerical value of that attribute (they are normalized to unit interval). The point in the plane, where our sample settles to (where the forces acting on our sample are at an equilibrium) is where a dot representing our sample will be drawn. Depending on which class that sample belongs to it will be colored differently. See the R package [Radviz](#) for more information.

**Note:** The “Iris” dataset is available [here](#).

```
In [109]: from pandas.plotting import radviz

In [110]: data = pd.read_csv('data/iris.data')

In [111]: plt.figure()
Out[111]: <Figure size 640x480 with 0 Axes>

In [112]: radviz(data, 'Name')
Out[112]: <matplotlib.axes._subplots.
AxesSubplot at 0x7fd5081180b8>
```

## 23.5 Plot Formatting

### 23.5.1 Setting the plot style

From version 1.5 and up, matplotlib offers a range of pre-configured plotting styles. Setting the style can be used to easily give plots the general look that you want. Setting the style is as easy as calling `matplotlib.style.use(my_plot_style)` before creating your plot. For example you could write `matplotlib.style.use('ggplot')` for ggplot-style plots.

You can see the various available style names at `matplotlib.style.available` and it's very easy to try them out.

### 23.5.2 General plot style arguments

Most plotting methods have a set of keyword arguments that control the layout and formatting of the returned plot:

```
In [113]: plt.figure();
In [114]: ts.plot(style='k--', label='Series');
```

For each kind of plot (e.g. *line*, *bar*, *scatter*) any additional arguments keywords are passed along to the corresponding matplotlib function (`ax.plot()`, `ax.bar()`, `ax.scatter()`). These can be used to control additional styling, beyond what pandas provides.

### 23.5.3 Controlling the Legend

You may set the `legend` argument to `False` to hide the legend, which is shown by default.

```
In [115]: df = pd.DataFrame(np.random.randn(1000, 4),
.....:                      index=ts.index, columns=list('ABCD'))
.....:

In [116]: df = df.cumsum()

In [117]: df.plot(legend=False)
Out[117]: <matplotlib.axes._subplots.AxesSubplot at 0x7fd5083e9470>
```

### 23.5.4 Scales

You may pass `logy` to get a log-scale Y axis.

```
In [118]: ts = pd.Series(np.random.randn(1000),
.....:                  index=pd.date_range('1/1/2000', periods=1000))
.....:

In [119]: ts = np.exp(ts.cumsum())

In [120]: ts.plot(logy=True)
Out[120]: <matplotlib.axes._subplots.AxesSubplot at 0x7fd508483390>
```

See also the `logx` and `loglog` keyword arguments.

### 23.5.5 Plotting on a Secondary Y-axis

To plot data on a secondary y-axis, use the `secondary_y` keyword:

```
In [121]: df.A.plot()
Out[121]: <matplotlib.axes._subplots.AxesSubplot at 0x7fd509ccdf98>

In [122]: df.B.plot(secondary_y=True, style='g')
Out[122]:
<matplotlib.axes._subplots.AxesSubplot at 0x7fd509384cf8>
```

To plot some columns in a DataFrame, give the column names to the `secondary_y` keyword:

```
In [123]: plt.figure()
Out[123]: <Figure size 640x480 with 0 Axes>

In [124]: ax = df.plot(secondary_y=['A', 'B'])

In [125]: ax.set_ylabel('CD scale')
Out[125]: Text(0, 0.5, 'CD scale')

In [126]: ax.right_ax.set_ylabel('AB scale')
Out[126]: Text(0, 0.5, 'AB scale')
```

Note that the columns plotted on the secondary y-axis is automatically marked with “(right)” in the legend. To turn off the automatic marking, use the `mark_right=False` keyword:

```
In [127]: plt.figure()
Out[127]: <Figure size 640x480 with 0 Axes>

In [128]: df.plot(secondary_y=['A', 'B'], mark_right=False)
Out[128]: <matplotlib.axes._subplots.
AxesSubplot at 0x7fd50a590a20>
```

### 23.5.6 Suppressing Tick Resolution Adjustment

pandas includes automatic tick resolution adjustment for regular frequency time-series data. For limited cases where pandas cannot infer the frequency information (e.g., in an externally created `twinx`), you can choose to suppress this behavior for alignment purposes.

Here is the default behavior, notice how the x-axis tick labeling is performed:

```
In [129]: plt.figure()
Out[129]: <Figure size 640x480 with 0 Axes>

In [130]: df.A.plot()
////////////////////////////////////Out[130]: <matplotlib.axes._subplots.
->AxesSubplot at 0x7fd50a3d0b70>
```

Using the `x_compat` parameter, you can suppress this behavior:

```
In [131]: plt.figure()
Out[131]: <Figure size 640x480 with 0 Axes>

In [132]: df.A.plot(x_compat=True)
Out[132]: <matplotlib.axes._subplots.
AxesSubplot at 0x7fd50a2d7828>
```

If you have more than one plot that needs to be suppressed, the use method in `pandas.plotting.plot_params` can be used in a *with statement*:

```
In [133]: plt.figure()
Out[133]: <Figure size 640x480 with 0 Axes>

In [134]: with pd.plotting.plot_params.use('x_compat', True):
.....:     df.A.plot(color='r')
.....:     df.B.plot(color='g')
.....:     df.C.plot(color='b')
.....:
```

### 23.5.7 Automatic Date Tick Adjustment

New in version 0.20.0.

`TimedeltaIndex` now uses the native matplotlib tick locator methods, it is useful to call the automatic date tick adjustment from matplotlib for figures whose ticklabels overlap.

See the `autofmt_xdate` method and the [matplotlib documentation](#) for more.

### 23.5.8 Subplots

Each `Series` in a `DataFrame` can be plotted on a different axis with the `subplots` keyword:

```
In [135]: df.plot(subplots=True, figsize=(6, 6));
```

### 23.5.9 Using Layout and Targeting Multiple Axes

The layout of subplots can be specified by the `layout` keyword. It can accept `(rows, columns)`. The `layout` keyword can be used in `hist` and `boxplot` also. If the input is invalid, a `ValueError` will be raised.

The number of axes which can be contained by rows x columns specified by `layout` must be larger than the number of required subplots. If `layout` can contain more axes than required, blank axes are not drawn. Similar to a NumPy array's `reshape` method, you can use `-1` for one dimension to automatically calculate the number of rows or columns needed, given the other.

```
In [136]: df.plot(subplots=True, layout=(2, 3), figsize=(6, 6), sharex=False);
```

The above example is identical to using:

```
In [137]: df.plot(subplots=True, layout=(2, -1), figsize=(6, 6), sharex=False);
```

The required number of columns (3) is inferred from the number of series to plot and the given number of rows (2).

You can pass multiple axes created beforehand as list-like via `ax` keyword. This allows more complicated layouts. The passed axes must be the same number as the subplots being drawn.

When multiple axes are passed via the `ax` keyword, `layout`, `sharex` and `sharey` keywords don't affect to the output. You should explicitly pass `sharex=False` and `sharey=False`, otherwise you will see a warning.

```
In [138]: fig, axes = plt.subplots(4, 4, figsize=(6, 6))
In [139]: plt.subplots_adjust(wspace=0.5, hspace=0.5)
In [140]: target1 = [axes[0][0], axes[1][1], axes[2][2], axes[3][3]]
```

(continues on next page)

(continued from previous page)

```

In [141]: target2 = [axes[3][0], axes[2][1], axes[1][2], axes[0][3]]

In [142]: df.plot(subplots=True, ax=target1, legend=False, sharex=False,
→sharey=False);

In [143]: (-df).plot(subplots=True, ax=target2, legend=False,
.....:               sharex=False, sharey=False);
.....:
.....:

```

Another option is passing an `ax` argument to `Series.plot()` to plot on a particular axis:

```

In [144]: fig, axes = plt.subplots(nrows=2, ncols=2)

In [145]: df['A'].plot(ax=axes[0, 0]);

```

(continues on next page)

(continued from previous page)

```

In [146]: axes[0, 0].set_title('A');
In [147]: df['B'].plot(ax=axes[0, 1]);
In [148]: axes[0, 1].set_title('B');
In [149]: df['C'].plot(ax=axes[1, 0]);
In [150]: axes[1, 0].set_title('C');
In [151]: df['D'].plot(ax=axes[1, 1]);
In [152]: axes[1, 1].set_title('D');

```

### 23.5.10 Plotting With Error Bars

Plotting with error bars is supported in `DataFrame.plot()` and `Series.plot()`.

Horizontal and vertical error bars can be supplied to the `xerr` and `yerr` keyword arguments to `plot()`. The error values can be specified using a variety of formats:

- As a `DataFrame` or `dict` of errors with column names matching the `columns` attribute of the plotting

DataFrame or matching the name attribute of the Series.

- As a str indicating which of the columns of plotting DataFrame contain the error values.
- As raw values (list, tuple, or np.ndarray). Must be the same length as the plotting DataFrame/Series.

Asymmetrical error bars are also supported, however raw error values must be provided in this case. For a M length Series, a Mx2 array should be provided indicating lower and upper (or left and right) errors. For a MxN DataFrame, asymmetrical errors should be in a Mx2xN array.

Here is an example of one way to easily plot group means with standard deviations from the raw data.

```
# Generate the data
In [153]: ix3 = pd.MultiIndex.from_arrays([
.....:     ['a', 'a', 'a', 'a', 'b', 'b', 'b', 'b'],
.....:     ['foo', 'foo', 'bar', 'bar', 'foo', 'foo', 'bar', 'bar']],
.....:     names=['letter', 'word'])
.....:

In [154]: df3 = pd.DataFrame({'data1': [3, 2, 4, 3, 2, 4, 3, 2],
.....:                        'data2': [6, 5, 7, 5, 4, 5, 6, 5]}, index=ix3)
.....:

# Group by index labels and take the means and standard deviations
# for each group
In [155]: gp3 = df3.groupby(level=('letter', 'word'))

In [156]: means = gp3.mean()

In [157]: errors = gp3.std()

In [158]: means
Out[158]:
```

| letter | word | data1 | data2 |
|--------|------|-------|-------|
| a      | bar  | 3.5   | 6.0   |
|        | foo  | 2.5   | 5.5   |
| b      | bar  | 2.5   | 5.5   |
|        | foo  | 3.0   | 4.5   |

```

In [159]: errors
////////////////////////////////////
↪
      data1      data2
letter word
a      bar  0.707107  1.414214
      foo  0.707107  0.707107
b      bar  0.707107  0.707107
      foo  1.414214  0.707107

# Plot
In [160]: fig, ax = plt.subplots()

In [161]: means.plot.bar(yerr=errors, ax=ax, capsize=4)
Out[161]: <matplotlib.axes._subplots.AxesSubplot at 0x7fd501b71ef0>

```

### 23.5.11 Plotting Tables

Plotting with matplotlib table is now supported in `DataFrame.plot()` and `Series.plot()` with a `table` keyword. The `table` keyword can accept `bool`, `DataFrame` or `Series`. The simple way to draw a table is to specify `table=True`. Data will be transposed to meet matplotlib's default layout.

```
In [162]: fig, ax = plt.subplots(1, 1)

In [163]: df = pd.DataFrame(np.random.rand(5, 3), columns=['a', 'b', 'c'])

In [164]: ax.get_xaxis().set_visible(False)    # Hide Ticks

In [165]: df.plot(table=True, ax=ax)
Out[165]: <matplotlib.axes._subplots.AxesSubplot at 0x7fd501eb2a20>
```

Also, you can pass a different DataFrame or Series to the `table` keyword. The data will be drawn as displayed in print method (not transposed automatically). If required, it should be transposed manually as seen in the example below.

```
In [166]: fig, ax = plt.subplots(1, 1)

In [167]: ax.get_xaxis().set_visible(False)    # Hide Ticks

In [168]: df.plot(table=np.round(df.T, 2), ax=ax)
Out[168]: <matplotlib.axes._subplots.AxesSubplot at 0x7fd50206e940>
```

There also exists a helper function `pandas.plotting.table`, which creates a table from `DataFrame` or `Series`, and adds it to an `matplotlib.Axes` instance. This function can accept keywords which the `matplotlib` `table` has.

```
In [169]: from pandas.plotting import table

In [170]: fig, ax = plt.subplots(1, 1)

In [171]: table(ax, np.round(df.describe(), 2),
.....:         loc='upper right', colWidths=[0.2, 0.2, 0.2])
.....:
Out[171]: <matplotlib.table.Table at 0x7fd501c03908>

In [172]: df.plot(ax=ax, ylim=(0, 2), legend=None)
Out[172]: <matplotlib.axes._
↳subplots.AxesSubplot at 0x7fd501b35f60>
```

**Note:** You can get table instances on the axes using `axes.tables` property for further decorations. See the [matplotlib table documentation](#) for more.

### 23.5.12 Colormaps

A potential issue when plotting a large number of columns is that it can be difficult to distinguish some series due to repetition in the default colors. To remedy this, `DataFrame` plotting supports the use of the `colormap` argument, which accepts either a Matplotlib [colormap](#) or a string that is a name of a colormap registered with Matplotlib. A visualization of the default matplotlib colormaps is available [here](#).

As matplotlib does not directly support colormaps for line-based plots, the colors are selected based on an even spacing determined by the number of columns in the `DataFrame`. There is no consideration made for background color, so some colormaps will produce lines that are not easily visible.

To use the `cubehelix` colormap, we can pass `colormap='cubehelix'`.

```
In [173]: df = pd.DataFrame(np.random.randn(1000, 10), index=ts.index)
In [174]: df = df.cumsum()
In [175]: plt.figure()
Out[175]: <Figure size 640x480 with 0 Axes>
```

(continues on next page)

(continued from previous page)

```
In [176]: df.plot(colormap='cubehelix')
Out[176]: <matplotlib.axes._subplots.
AxesSubplot at 0x7fd5021c6588>
```

Alternatively, we can pass the colormap itself:

```
In [177]: from matplotlib import cm

In [178]: plt.figure()
Out[178]: <Figure size 640x480 with 0 Axes>

In [179]: df.plot(colormap=cm.cubehelix)
Out[179]: <matplotlib.axes._subplots.
AxesSubplot at 0x7fd501ec5208>
```

Colormaps can also be used other plot types, like bar charts:

```
In [180]: dd = pd.DataFrame(np.random.randn(10, 10)).applymap(abs)
In [181]: dd = dd.cumsum()
In [182]: plt.figure()
Out[182]: <Figure size 640x480 with 0 Axes>
In [183]: dd.plot.bar(colormap='Greens')
Out[183]: <matplotlib.axes._subplots.
AxesSubplot at 0x7fd5018a53c8>
```

Parallel coordinates charts:

```
In [184]: plt.figure()
Out[184]: <Figure size 640x480 with 0 Axes>

In [185]: parallel_coordinates(data, 'Name', colormap='gist_rainbow')
Out[185]: <matplotlib.axes._subplots.
AxesSubplot at 0x7fd50177aac8>
```

Andrews curves charts:

```
In [186]: plt.figure()
Out[186]: <Figure size 640x480 with 0 Axes>

In [187]: andrews_curves(data, 'Name', colormap='winter')
Out[187]: <matplotlib.axes._subplots.
AxesSubplot at 0x7fd5015c4f60>
```

## 23.6 Plotting directly with matplotlib

In some situations it may still be preferable or necessary to prepare plots directly with matplotlib, for instance when a certain type of plot or customization is not (yet) supported by pandas. `Series` and `DataFrame` objects behave like arrays and can therefore be passed directly to matplotlib functions without explicit casts.

pandas also automatically registers formatters and locators that recognize date indices, thereby extending date and time support to practically all plot types available in matplotlib. Although this formatting does not provide the same level of refinement you would get when plotting via pandas, it can be faster when plotting a large number of points.

```
In [188]: price = pd.Series(np.random.randn(150).cumsum(),
.....:                     index=pd.date_range('2000-1-1', periods=150, freq='B'))
.....:

In [189]: ma = price.rolling(20).mean()

In [190]: mstd = price.rolling(20).std()

In [191]: plt.figure()
Out[191]: <Figure size 640x480 with 0 Axes>

In [192]: plt.plot(price.index, price, 'k')
```

(continues on next page)

(continued from previous page)

```

\\Out[192]: [<matplotlib.lines.Line2D at 0x7fd50134e400>]
↪0x7fd50134e400>]

In [193]: plt.plot(ma.index, ma, 'b')
\\
↪ [<matplotlib.lines.Line2D at 0x7fd5513a99b0>]

In [194]: plt.fill_between(mstd.index, ma - 2 * mstd, ma + 2 * mstd,
.....:                    color='b', alpha=0.2)
.....:
.....:
\\
↪ <matplotlib.collections.PolyCollection at 0x7fd5013765c0>

```

## 23.7 Trellis plotting interface

**Warning:** The `rplot` trellis plotting interface has been **removed**. Please use external packages like [seaborn](#) for similar but more refined functionality and refer to our 0.18.1 documentation [here](#) for how to convert to using it.

## STYLING

*New in version 0.17.1*

Provisional: This is a new feature and still under development. We'll be adding features and possibly making breaking changes in future releases. We'd love to hear your feedback.

This document is written as a Jupyter Notebook, and can be viewed or downloaded [here](#).

You can apply **conditional formatting**, the visual styling of a DataFrame depending on the data within, by using the `DataFrame.style` property. This is a property that returns a `Styler` object, which has useful methods for formatting and displaying DataFrames.

The styling is accomplished using CSS. You write “style functions” that take scalars, DataFrames or Series, and return *like-indexed* DataFrames or Series with CSS “attribute: value” pairs for the values. These functions can be incrementally passed to the `Styler` which collects the styles before rendering.

### 24.1 Building Styles

Pass your style functions into one of the following methods:

- `Styler.applymap`: elementwise
- `Styler.apply`: column-/row-/table-wise

Both of those methods take a function (and some other keyword arguments) and applies your function to the DataFrame in a certain way. `Styler.applymap` works through the DataFrame elementwise. `Styler.apply` passes each column or row into your DataFrame one-at-a-time or the entire table at once, depending on the `axis` keyword argument. For columnwise use `axis=0`, rowwise use `axis=1`, and for the entire table at once use `axis=None`.

For `Styler.applymap` your function should take a scalar and return a single string with the CSS attribute-value pair.

For `Styler.apply` your function should take a Series or DataFrame (depending on the `axis` parameter), and return a Series or DataFrame with an identical shape where each value is a string with a CSS attribute-value pair.

Let's see some examples.

```
[2]: import pandas as pd
import numpy as np

np.random.seed(24)
df = pd.DataFrame({'A': np.linspace(1, 10, 10)})
df = pd.concat([df, pd.DataFrame(np.random.randn(10, 4), columns=list('BCDE'))],
               axis=1)
df.iloc[0, 2] = np.nan
```

Here's a boring example of rendering a DataFrame, without any (visible) styles:

```
[3]: df.style
[3]: <pandas.io.formats.style.Styler at 0x7f895bf262b0>
```

*Note:* The `DataFrame.style` attribute is a property that returns a `Styler` object. `Styler` has a `_repr_html_` method defined on it so they are rendered automatically. If you want the actual HTML back for further processing or for writing to file call the `.render()` method which returns a string.

The above output looks very similar to the standard DataFrame HTML representation. But we've done some work behind the scenes to attach CSS classes to each cell. We can view these by calling the `.render` method.

```
[4]: df.style.highlight_null().render().split('\n')[:10]
[4]: ['<style type="text/css" >',
      '#T_73b38f98_15bf_11e9_96a7_77e674dc3417row0_col2 {',
      '    background-color: red;',
      '}</style><table id="T_73b38f98_15bf_11e9_96a7_77e674dc3417" ><thead>    <tr>
      <th class="blank level0" ></th>    <th class="col_heading level0 col0" >
      <th class="col_heading level0 col1" >B</th>    <th class="col_
      heading level0 col2" >C</th>    <th class="col_heading level0 col3" >D</th>
      <th class="col_heading level0 col4" >E</th>    </tr></thead><tbody>',
      '    <tr>',
      '        <th id="T_73b38f98_15bf_11e9_96a7_77e674dc3417level0_row0"
      class="row_heading level0 row0" >0</th>',
      '        <td id="T_73b38f98_15bf_11e9_96a7_77e674dc3417row0_col0"
      class="data row0 col0" >1</td>',
      '        <td id="T_73b38f98_15bf_11e9_96a7_77e674dc3417row0_col1"
      class="data row0 col1" >1.32921</td>',
      '        <td id="T_73b38f98_15bf_11e9_96a7_77e674dc3417row0_col2"
      class="data row0 col2" >nan</td>',
      '        <td id="T_73b38f98_15bf_11e9_96a7_77e674dc3417row0_col3"
      class="data row0 col3" >-0.31628</td>']
```

The `row0_col2` is the identifier for that particular cell. We've also prepended each row/column identifier with a UUID unique to each DataFrame so that the style from one doesn't collide with the styling from another within the same notebook or page (you can set the `uuid` if you'd like to tie together the styling of two DataFrames).

When writing style functions, you take care of producing the CSS attribute / value pairs you want. Pandas matches those up with the CSS classes that identify each cell.

Let's write a simple style function that will color negative numbers red and positive numbers black.

```
[5]: def color_negative_red(val):
      """
      Takes a scalar and returns a string with
      the css property `color: red` for negative
      strings, black otherwise.
      """
      color = 'red' if val < 0 else 'black'
      return 'color: %s' % color
```

In this case, the cell's style depends only on its own value. That means we should use the `Styler.applymap` method which works elementwise.

```
[6]: s = df.style.applymap(color_negative_red)
      s
```

```
[6]: <pandas.io.formats.style.Styler at 0x7f89677387f0>
```

Notice the similarity with the standard `df.applymap`, which operates on DataFrames elementwise. We want you to be able to reuse your existing knowledge of how to interact with DataFrames.

Notice also that our function returned a string containing the CSS attribute and value, separated by a colon just like in a `<style>` tag. This will be a common theme.

Finally, the input shapes matched. `Styler.applymap` calls the function on each scalar input, and the function returns a scalar output.

Now suppose you wanted to highlight the maximum value in each column. We can't use `.applymap` anymore since that operated elementwise. Instead, we'll turn to `.apply` which operates columnwise (or rowwise using the `axis` keyword). Later on we'll see that something like `highlight_max` is already defined on `Styler` so you wouldn't need to write this yourself.

```
[7]: def highlight_max(s):
    '''
    highlight the maximum in a Series yellow.
    '''
    is_max = s == s.max()
    return ['background-color: yellow' if v else '' for v in is_max]
```

```
[8]: df.style.apply(highlight_max)
```

```
[8]: <pandas.io.formats.style.Styler at 0x7f8959669dd8>
```

In this case the input is a `Series`, one column at a time. Notice that the output shape of `highlight_max` matches the input shape, an array with `len(s)` items.

We encourage you to use method chains to build up a style piecewise, before finally rendering at the end of the chain.

```
[9]: df.style.\
    applymap(color_negative_red).\
    apply(highlight_max)

[9]: <pandas.io.formats.style.Styler at 0x7f8959669e10>
```

Above we used `Styler.apply` to pass in each column one at a time.

Debugging Tip: If you're having trouble writing your style function, try just passing it into `DataFrame.apply`. Internally, `Styler.apply` uses `DataFrame.apply` so the result should be the same.

What if you wanted to highlight just the maximum value in the entire table? Use `.apply(function, axis=None)` to indicate that your function wants the entire table, not one column or row at a time. Let's try that next.

We'll rewrite our `highlight_max` to handle either `Series` (from `.apply(axis=0 or 1)`) or `DataFrames` (from `.apply(axis=None)`). We'll also allow the color to be adjustable, to demonstrate that `.apply`, and `.applymap` pass along keyword arguments.

```
[10]: def highlight_max(data, color='yellow'):
    '''
    highlight the maximum in a Series or DataFrame
    '''
    attr = 'background-color: {}'.format(color)
    if data.ndim == 1: # Series from .apply(axis=0) or axis=1
        is_max = data == data.max()
        return [attr if v else '' for v in is_max]
```

(continues on next page)

(continued from previous page)

```

else: # from .apply(axis=None)
    is_max = data == data.max().max()
    return pd.DataFrame(np.where(is_max, attr, ''),
                        index=data.index, columns=data.columns)

```

When using `Styler.apply(func, axis=None)`, the function must return a `DataFrame` with the same index and column labels.

```
[11]: df.style.apply(highlight_max, color='darkorange', axis=None)
```

```
[11]: <pandas.io.formats.style.Styler at 0x7f8959669cf8>
```

### 24.1.1 Building Styles Summary

Style functions should return strings with one or more CSS attribute: value delimited by semicolons. Use

- `Styler.applymap(func)` for elementwise styles
- `Styler.apply(func, axis=0)` for columnwise styles
- `Styler.apply(func, axis=1)` for rowwise styles
- `Styler.apply(func, axis=None)` for tablewise styles

And crucially the input and output shapes of `func` must match. If `x` is the input then `func(x).shape == x.shape`.

## 24.2 Finer Control: Slicing

Both `Styler.apply`, and `Styler.applymap` accept a `subset` keyword. This allows you to apply styles to specific rows or columns, without having to code that logic into your `style` function.

The value passed to `subset` behaves similar to slicing a `DataFrame`.

- A scalar is treated as a column label
- A list (or series or numpy array)
- A tuple is treated as `(row_indexer, column_indexer)`

Consider using `pd.IndexSlice` to construct the tuple for the last one.

```
[12]: df.style.apply(highlight_max, subset=['B', 'C', 'D'])
```

```
[12]: <pandas.io.formats.style.Styler at 0x7f8959669710>
```

For row and column slicing, any valid indexer to `.loc` will work.

```
[13]: df.style.applymap(color_negative_red,
                        subset=pd.IndexSlice[2:5, ['B', 'D']])
```

```
[13]: <pandas.io.formats.style.Styler at 0x7f89596694e0>
```

Only label-based slicing is supported right now, not positional.

If your style function uses a `subset` or `axis` keyword argument, consider wrapping your function in a `functools.partial`, partialing out that keyword.

```
my_func2 = functools.partial(my_func, subset=42)
```

## 24.3 Finer Control: Display Values

We distinguish the *display* value from the *actual* value in `Styler`. To control the display value, the text is printed in each cell, use `Styler.format`. Cells can be formatted according to a *format spec string* or a callable that takes a single value and returns a string.

```
[14]: df.style.format("{:.2%}")
[14]: <pandas.io.formats.style.Styler at 0x7f8959612ba8>
```

Use a dictionary to format specific columns.

```
[15]: df.style.format({'B': "{:0<4.0f}", 'D': '{:+.2f}'})
[15]: <pandas.io.formats.style.Styler at 0x7f8959669d68>
```

Or pass in a callable (or dictionary of callables) for more flexible handling.

```
[16]: df.style.format({'B': lambda x: "±{:.2f}".format(abs(x))})
[16]: <pandas.io.formats.style.Styler at 0x7f8959612fd0>
```

## 24.4 Builtin Styles

Finally, we expect certain styling functions to be common enough that we’ve included a few “built-in” to the `Styler`, so you don’t have to write them yourself.

```
[17]: df.style.highlight_null(null_color='red')
[17]: <pandas.io.formats.style.Styler at 0x7f89596128d0>
```

You can create “heatmaps” with the `background_gradient` method. These require `matplotlib`, and we’ll use `Seaborn` to get a nice colormap.

```
[18]: import seaborn as sns

cm = sns.light_palette("green", as_cmap=True)

s = df.style.background_gradient(cmap=cm)
s

/opt/conda/envs/pandas/lib/python3.6/site-packages/matplotlib/colors.py:512:
↳RuntimeWarning: invalid value encountered in less
  xa[xa < 0] = -1
[18]: <pandas.io.formats.style.Styler at 0x7f89585760b8>
```

`Styler.background_gradient` takes the keyword arguments `low` and `high`. Roughly speaking these extend the range of your data by `low` and `high` percent so that when we convert the colors, the colormap’s entire range isn’t used. This is useful so that you can actually read the text still.

```
[19]: # Uses the full color range
df.loc[:4].style.background_gradient(cmap='viridis')
```

```
[19]: <pandas.io.formats.style.Styler at 0x7f8959612c18>
```

```
[20]: # Compress the color range
(df.loc[:4]
 .style
 .background_gradient(cmap='viridis', low=.5, high=0)
 .highlight_null('red'))
```

```
[20]: <pandas.io.formats.style.Styler at 0x7f8949736eb8>
```

There's also `.highlight_min` and `.highlight_max`.

```
[21]: df.style.highlight_max(axis=0)
```

```
[21]: <pandas.io.formats.style.Styler at 0x7f8959612780>
```

Use `Styler.set_properties` when the style doesn't actually depend on the values.

```
[22]: df.style.set_properties(**{'background-color': 'black',
                                'color': 'lawngreen',
                                'border-color': 'white'})
```

```
[22]: <pandas.io.formats.style.Styler at 0x7f89495eb240>
```

## 24.4.1 Bar charts

You can include “bar charts” in your `DataFrame`.

```
[23]: df.style.bar(subset=['A', 'B'], color='#d65f5f')
```

```
[23]: <pandas.io.formats.style.Styler at 0x7f8949736b00>
```

New in version 0.20.0 is the ability to customize further the bar chart: You can now have the `df.style.bar` be centered on zero or midpoint value (in addition to the already existing way of having the min value at the left side of the cell), and you can pass a list of `[color_negative, color_positive]`.

Here's how you can change the above with the new `align='mid'` option:

```
[24]: df.style.bar(subset=['A', 'B'], align='mid', color=['#d65f5f', '#5fba7d'])
```

```
[24]: <pandas.io.formats.style.Styler at 0x7f89495ebac8>
```

The following example aims to give a highlight of the behavior of the new align options:

```
[25]: import pandas as pd
from IPython.display import HTML

# Test series
test1 = pd.Series([-100, -60, -30, -20], name='All Negative')
test2 = pd.Series([10, 20, 50, 100], name='All Positive')
test3 = pd.Series([-10, -5, 0, 90], name='Both Pos and Neg')

head = """
<table>
  <thead>
```

(continues on next page)

(continued from previous page)

```

        <th>Align</th>
        <th>All Negative</th>
        <th>All Positive</th>
        <th>Both Neg and Pos</th>
    </thead>
</tbody>

"""

aligns = ['left', 'zero', 'mid']
for align in aligns:
    row = "<tr><th>{}</th>".format(align)
    for serie in [test1, test2, test3]:
        s = serie.copy()
        s.name = ''
        row += "<td>{}</td>".format(s.to_frame().style.bar(align=align,
                                                                color=['#d65f5f', '#5fba7d',
                                                                width=100).render())
        row += "</tr>"
    head += row

head += """
</tbody>
</table>"""

```

HTML (head)

[25]: &lt;IPython.core.display.HTML object&gt;

## 24.5 Sharing Styles

Say you have a lovely style built up for a DataFrame, and now you want to apply the same style to a second DataFrame. Export the style with `df1.style.export`, and import it on the second DataFrame with `df2.style.set`

```
[26]: df2 = -df
      style1 = df.style.applymap(color_negative_red)
      style1
```

[26]: &lt;pandas.io.formats.style.Styler at 0x7f89495ebfd0&gt;

```
[27]: style2 = df2.style
      style2.use(style1.export())
      style2
```

[27]: &lt;pandas.io.formats.style.Styler at 0x7f89495a2128&gt;

Notice that you're able share the styles even though they're data aware. The styles are re-evaluated on the new DataFrame they've been used upon.

## 24.6 Other Options

You’ve seen a few methods for data-driven styling. `Styler` also provides a few other options for styles that don’t depend on the data.

- precision
- captions
- table-wide styles
- hiding the index or columns

Each of these can be specified in two ways:

- A keyword argument to `Styler.__init__`
- A call to one of the `.set_` or `.hide_` methods, e.g. `.set_caption` or `.hide_columns`

The best method to use depends on the context. Use the `Styler` constructor when building many styled `DataFrames` that should all share the same properties. For interactive use, the `.set_` and `.hide_` methods are more convenient.

### 24.6.1 Precision

You can control the precision of floats using pandas’ regular `display.precision` option.

```
[28]: with pd.option_context('display.precision', 2):
      html = (df.style
              .applymap(color_negative_red)
              .apply(highlight_max))
      html
[28]: <pandas.io.formats.style.Styler at 0x7f894959f6d8>
```

Or through a `set_precision` method.

```
[29]: df.style\
      .applymap(color_negative_red)\
      .apply(highlight_max)\
      .set_precision(2)
[29]: <pandas.io.formats.style.Styler at 0x7f89495a2eb8>
```

Setting the precision only affects the printed number; the full-precision values are always passed to your style functions. You can always use `df.round(2).style` if you’d prefer to round from the start.

### 24.6.2 Captions

Regular table captions can be added in a few ways.

```
[30]: df.style.set_caption('Colormaps, with a caption.')\
      .background_gradient(cmap=cm)
[30]: <pandas.io.formats.style.Styler at 0x7f894959f9e8>
```

### 24.6.3 Table Styles

The next option you have are “table styles”. These are styles that apply to the table as a whole, but don’t look at the data. Certain sytlings, including pseudo-selectors like `:hover` can only be used this way.

```
[31]: from IPython.display import HTML

def hover(hover_color="#ffff99"):
    return dict(selector="tr:hover",
                props=[("background-color", "%s" % hover_color)])

styles = [
    hover(),
    dict(selector="th", props=[("font-size", "150%"),
                                ("text-align", "center")]),
    dict(selector="caption", props=[("caption-side", "bottom")])
]
html = (df.style.set_table_styles(styles)
        .set_caption("Hover to highlight."))
html

[31]: <pandas.io.formats.style.Styler at 0x7f894959fa20>
```

`table_styles` should be a list of dictionaries. Each dictionary should have the `selector` and `props` keys. The value for `selector` should be a valid CSS selector. Recall that all the styles are already attached to an `id`, unique to each `Styler`. This selector is in addition to that `id`. The value for `props` should be a list of tuples of ('attribute', 'value').

`table_styles` are extremely flexible, but not as fun to type out by hand. We hope to collect some useful ones either in pandas, or preferable in a new package that *builds on top* the tools here.

### 24.6.4 Hiding the Index or Columns

The index can be hidden from rendering by calling `Styler.hide_index`. Columns can be hidden from rendering by calling `Styler.hide_columns` and passing in the name of a column, or a slice of columns.

```
[32]: df.style.hide_index()

[32]: <pandas.io.formats.style.Styler at 0x7f894959f908>

[33]: df.style.hide_columns(['C', 'D'])

[33]: <pandas.io.formats.style.Styler at 0x7f894959ff28>
```

### 24.6.5 CSS Classes

Certain CSS classes are attached to cells.

- Index and Column names include `index_name` and `level<k>` where `k` is its level in a `MultiIndex`
- Index label cells include
  - `row_heading`
  - `row<n>` where `n` is the numeric position of the row
  - `level<k>` where `k` is the level in a `MultiIndex`

- Column label cells include
  - `col_heading`
  - `col<n>` where `n` is the numeric position of the column
  - `level<k>` where `k` is the level in a `MultiIndex`
- Blank cells include `blank`
- Data cells include `data`

## 24.6.6 Limitations

- `DataFrame` only (use `Series.to_frame().style`)
- The index and columns must be unique
- No large repr, and performance isn't great; this is intended for summary `DataFrames`
- You can only style the *values*, not the index or columns
- You can only apply styles, you can't insert new HTML entities

Some of these will be addressed in the future.

## 24.6.7 Terms

- Style function: a function that's passed into `Styler.apply` or `Styler.applymap` and returns values like `'css attribute: value'`
- Builtin style functions: style functions that are methods on `Styler`
- table style: a dictionary with the two keys `selector` and `props`. `selector` is the CSS selector that `props` will apply to. `props` is a list of `(attribute, value)` tuples. A list of table styles passed into `Styler`.

## 24.7 Fun stuff

Here are a few interesting examples.

`Styler` interacts pretty well with widgets. If you're viewing this online instead of running the notebook yourself, you're missing out on interactively adjusting the color palette.

```
[34]: from IPython.html import widgets
      @widgets.interact
      def f(h_neg=(0, 359, 1), h_pos=(0, 359), s=(0., 99.9), l=(0., 99.9)):
          return df.style.background_gradient(
              cmap=sns.palettes.diverging_palette(h_neg=h_neg, h_pos=h_pos, s=s, l=l,
                                                  as_cmap=True)
          )

      <pandas.io.formats.style.Styler at 0x7f89495eb630>
```

```
[35]: def magnify():
      return [dict(selector="th",
                  props=[("font-size", "4pt")]),
              dict(selector="td",
                  props=[('padding', "0em 0em")]),
```

(continues on next page)

(continued from previous page)

```

dict(selector="th:hover",
      props=[("font-size", "12pt")]),
dict(selector="tr:hover td:hover",
      props=[('max-width', '200px'),
              ('font-size', '12pt')])
]

```

```

[36]: np.random.seed(25)
      cmap = cmap=sns.diverging_palette(5, 250, as_cmap=True)
      bigdf = pd.DataFrame(np.random.randn(20, 25)).cumsum()

      bigdf.style.background_gradient(cmap, axis=1)\
        .set_properties(**{'max-width': '80px', 'font-size': '1pt'})\
        .set_caption("Hover to magnify")\
        .set_precision(2)\
        .set_table_styles(magnify())
[36]: <pandas.io.formats.style.Styler at 0x7f8959612b38>

```

## 24.8 Export to Excel

*New in version 0.20.0*

Experimental: This is a new feature and still under development. We'll be adding features and possibly making breaking changes in future releases. We'd love to hear your feedback.

Some support is available for exporting styled DataFrames to Excel worksheets using the OpenPyXL or XlsxWriter engines. CSS2.2 properties handled include:

- background-color
- border-style, border-width, border-color and their {top, right, bottom, left variants}
- color
- font-family
- font-style
- font-weight
- text-align
- text-decoration
- vertical-align
- white-space: nowrap
- Only CSS2 named colors and hex colors of the form #rgb or #rrggbb are currently supported.
- The following pseudo CSS properties are also available to set excel specific style properties:
  - number-format

```

[37]: df.style.\
      applymap(color_negative_red).\
      apply(highlight_max).\
      to_excel('styled.xlsx', engine='openpyxl')

```

A screenshot of the output:

|    | A | B  | C         | D         | E         | F         |
|----|---|----|-----------|-----------|-----------|-----------|
| 1  |   | A  | B         | C         | D         | E         |
| 2  | 0 | 1  | 1.329212  |           | -0.31628  | -0.99081  |
| 3  | 1 | 2  | -1.070816 | -1.438713 | 0.564417  | 0.295722  |
| 4  | 2 | 3  | -1.626404 | 0.219565  | 0.678805  | 1.889273  |
| 5  | 3 | 4  | 0.961538  | 0.104011  | -0.481165 | 0.850229  |
| 6  | 4 | 5  | 1.453425  | 1.057737  | 0.165562  | 0.515018  |
| 7  | 5 | 6  | -1.336936 | 0.562861  | 1.392855  | -0.063328 |
| 8  | 6 | 7  | 0.121668  | 1.207603  | -0.00204  | 1.627796  |
| 9  | 7 | 8  | 0.354493  | 1.037528  | -0.385684 | 0.519818  |
| 10 | 8 | 9  | 1.686583  | -1.325963 | 1.428984  | -2.089354 |
| 11 | 9 | 10 | -0.12982  | 0.631523  | -0.586538 | 0.29072   |

## 24.9 Extensibility

The core of pandas is, and will remain, its “high-performance, easy-to-use data structures”. With that in mind, we hope that `DataFrame.style` accomplishes two goals

- Provide an API that is pleasing to use interactively and is “good enough” for many tasks
- Provide the foundations for dedicated libraries to build on

If you build a great library on top of this, let us know and we’ll [link](#) to it.

### 24.9.1 Subclassing

If the default template doesn’t quite suit your needs, you can subclass `Styler` and extend or override the template. We’ll show an example of extending the default template to insert a custom header before each table.

```
[38]: from jinja2 import Environment, ChoiceLoader, FileSystemLoader
      from IPython.display import HTML
      from pandas.io.formats.style import Styler
```

We’ll use the following template:

```
[39]: with open("templates/myhtml.tpl") as f:
      print(f.read())

{% extends "html.tpl" %}
{% block table %}
<h1>{{ table_title|default("My Table") }}</h1>
{{ super() }}
{% endblock table %}
```

Now that we’ve created a template, we need to set up a subclass of `Styler` that knows about it.

```
[40]: class MyStyler(Styler):
      env = Environment(
```

(continues on next page)

(continued from previous page)

```

        loader=ChoiceLoader([
            FileSystemLoader("templates"), # contains ours
            Styler.loader, # the default
        ])
    )
    template = env.get_template("myhtml.tpl")

```

Notice that we include the original loader in our environment's loader. That's because we extend the original template, so the Jinja environment needs to be able to find it.

Now we can use that custom styler. It's `__init__` takes a DataFrame.

```

[41]: MyStyler(df)
[41]: <__main__.MyStyler at 0x7f894959f080>

```

Our custom template accepts a `table_title` keyword. We can provide the value in the `.render` method.

```

[42]: HTML(MyStyler(df).render(table_title="Extending Example"))
[42]: <IPython.core.display.HTML object>

```

For convenience, we provide the `Styler.from_custom_template` method that does the same as the custom subclass.

```

[43]: EasyStyler = Styler.from_custom_template("templates", "myhtml.tpl")
      EasyStyler(df)
[43]: <pandas.io.formats.style.Styler.from_custom_template.<locals>.MyStyler at 0x7f894095ecc0>

```

Here's the template structure:

```

[44]: with open("template_structure.html") as f:
      structure = f.read()

      HTML(structure)
[44]: <IPython.core.display.HTML object>

```

See the template in the [GitHub repo](#) for more details. {{ header }}

## IO TOOLS (TEXT, CSV, HDF5, ...)

The pandas I/O API is a set of top level reader functions accessed like `pandas.read_csv()` that generally return a pandas object. The corresponding writer functions are object methods that are accessed like `DataFrame.to_csv()`. Below is a table containing available readers and writers.

| Format Type | Data Description     | Reader                      | Writer                    |
|-------------|----------------------|-----------------------------|---------------------------|
| text        | CSV                  | <code>read_csv</code>       | <code>to_csv</code>       |
| text        | JSON                 | <code>read_json</code>      | <code>to_json</code>      |
| text        | HTML                 | <code>read_html</code>      | <code>to_html</code>      |
| text        | Local clipboard      | <code>read_clipboard</code> | <code>to_clipboard</code> |
| binary      | MS Excel             | <code>read_excel</code>     | <code>to_excel</code>     |
| binary      | HDF5 Format          | <code>read_hdf</code>       | <code>to_hdf</code>       |
| binary      | Feather Format       | <code>read_feather</code>   | <code>to_feather</code>   |
| binary      | Parquet Format       | <code>read_parquet</code>   | <code>to_parquet</code>   |
| binary      | Msgpack              | <code>read_msgpack</code>   | <code>to_msgpack</code>   |
| binary      | Stata                | <code>read_stata</code>     | <code>to_stata</code>     |
| binary      | SAS                  | <code>read_sas</code>       |                           |
| binary      | Python Pickle Format | <code>read_pickle</code>    | <code>to_pickle</code>    |
| SQL         | SQL                  | <code>read_sql</code>       | <code>to_sql</code>       |
| SQL         | Google Big Query     | <code>read_gbq</code>       | <code>to_gbq</code>       |

Here is an informal performance comparison for some of these IO methods.

---

**Note:** For examples that use the `StringIO` class, make sure you import it according to your Python version, i.e. `from StringIO import StringIO` for Python 2 and `from io import StringIO` for Python 3.

---

### 25.1 CSV & Text files

The workhorse function for reading text files (a.k.a. flat files) is `read_csv()`. See the *cookbook* for some advanced strategies.

#### 25.1.1 Parsing options

`read_csv()` accepts the following common arguments:

### 25.1.1.1 Basic

**filepath\_or\_buffer** [various] Either a path to a file (a `str`, `pathlib.Path`, or `py._path.local.LocalPath`), URL (including `http`, `ftp`, and `S3` locations), or any object with a `read()` method (such as an open file or `StringIO`).

**sep** [str, defaults to `,` for `read_csv()`, `\t` for `read_table()`] Delimiter to use. If `sep` is `None`, the C engine cannot automatically detect the separator, but the Python parsing engine can, meaning the latter will be used and automatically detect the separator by Python's builtin sniffer tool, `csv.Sniffer`. In addition, separators longer than 1 character and different from `'\s+'` will be interpreted as regular expressions and will also force the use of the Python parsing engine. Note that regex delimiters are prone to ignoring quoted data. Regex example: `'\\r\\t'`.

**delimiter** [str, default `None`] Alternative argument name for `sep`.

**delim\_whitespace** [boolean, default `False`] Specifies whether or not whitespace (e.g. `' '` or `'\t'`) will be used as the delimiter. Equivalent to setting `sep='\\s+'`. If this option is set to `True`, nothing should be passed in for the `delimiter` parameter.

New in version 0.18.1: support for the Python parser.

### 25.1.1.2 Column and Index Locations and Names

**header** [int or list of ints, default `'infer'`] Row number(s) to use as the column names, and the start of the data. Default behavior is to infer the column names: if no names are passed the behavior is identical to `header=0` and column names are inferred from the first line of the file, if column names are passed explicitly then the behavior is identical to `header=None`. Explicitly pass `header=0` to be able to replace existing names.

The header can be a list of ints that specify row locations for a `MultiIndex` on the columns e.g. `[0, 1, 3]`. Intervening rows that are not specified will be skipped (e.g. 2 in this example is skipped). Note that this parameter ignores commented lines and empty lines if `skip_blank_lines=True`, so `header=0` denotes the first line of data rather than the first line of the file.

**names** [array-like, default `None`] List of column names to use. If file contains no header row, then you should explicitly pass `header=None`. Duplicates in this list will cause a `UserWarning` to be issued.

**index\_col** [int or sequence or `False`, default `None`] Column to use as the row labels of the `DataFrame`. If a sequence is given, a `MultiIndex` is used. If you have a malformed file with delimiters at the end of each line, you might consider `index_col=False` to force pandas to *not* use the first column as the index (row names).

**usecols** [list-like or callable, default `None`] Return a subset of the columns. If list-like, all elements must either be positional (i.e. integer indices into the document columns) or strings that correspond to column names provided either by the user in `names` or inferred from the document header row(s). For example, a valid list-like `usecols` parameter would be `[0, 1, 2]` or `['foo', 'bar', 'baz']`.

Element order is ignored, so `usecols=[0, 1]` is the same as `[1, 0]`. To instantiate a `DataFrame` from data with element order preserved use `pd.read_csv(data, usecols=['foo', 'bar'])[['foo', 'bar']]` for columns in `['foo', 'bar']` order or `pd.read_csv(data, usecols=['foo', 'bar'])[['bar', 'foo']]` for `['bar', 'foo']` order.

If callable, the callable function will be evaluated against the column names, returning names where the callable function evaluates to `True`:

```
In [1]: from pandas.compat import StringIO, BytesIO

In [2]: data = ('col1,col2,col3\n'
...:          'a,b,1\n'
...:          'a,b,2\n')
```

(continues on next page)

(continued from previous page)

```

...:         'c,d,3')
...:

In [3]: pd.read_csv(StringIO(data))
Out[3]:
   col1 col2 col3
0     a    b     1
1     a    b     2
2     c    d     3

In [4]: pd.read_csv(StringIO(data), usecols=lambda x: x.upper() in ['COL1', 'COL3
Out[4]:
   col1 col3
0     a     1
1     a     2
2     c     3

```

Using this parameter results in much faster parsing time and lower memory usage.

**squeeze** [boolean, default False] If the parsed data only contains one column then return a Series.

**prefix** [str, default None] Prefix to add to column numbers when no header, e.g. 'X' for X0, X1, ...

**mangle\_dupe\_cols** [boolean, default True] Duplicate columns will be specified as 'X', 'X.1'... 'X.N', rather than 'X'... 'X'. Passing in False will cause data to be overwritten if there are duplicate names in the columns.

### 25.1.1.3 General Parsing Configuration

**dtype** [Type name or dict of column -> type, default None] Data type for data or columns. E.g. {'a': np.float64, 'b': np.int32} (unsupported with engine='python'). Use *str* or *object* together with suitable *na\_values* settings to preserve and not interpret dtype.

New in version 0.20.0: support for the Python parser.

**engine** [{ 'c', 'python' }] Parser engine to use. The C engine is faster while the Python engine is currently more feature-complete.

**converters** [dict, default None] Dict of functions for converting values in certain columns. Keys can either be integers or column labels.

**true\_values** [list, default None] Values to consider as True.

**false\_values** [list, default None] Values to consider as False.

**skipinitialspace** [boolean, default False] Skip spaces after delimiter.

**skiprows** [list-like or integer, default None] Line numbers to skip (0-indexed) or number of lines to skip (int) at the start of the file.

If callable, the callable function will be evaluated against the row indices, returning True if the row should be skipped and False otherwise:

```

In [5]: data = ('col1,col2,col3\n'
...:           'a,b,1\n'
...:           'a,b,2\n'
...:           'c,d,3')
...:

```

(continues on next page)

(continued from previous page)

```

In [6]: pd.read_csv(StringIO(data))
Out[6]:
   col1 col2 col3
0     a    b    1
1     a    b    2
2     c    d    3

In [7]: pd.read_csv(StringIO(data), skiprows=lambda x: x % 2 != 0)
Out[7]:
   col1 col2 col3
0     a    b    2

```

**skipfooter** [int, default 0] Number of lines at bottom of file to skip (unsupported with engine='c').

**nrows** [int, default None] Number of rows of file to read. Useful for reading pieces of large files.

**low\_memory** [boolean, default True] Internally process the file in chunks, resulting in lower memory use while parsing, but possibly mixed type inference. To ensure no mixed types either set `False`, or specify the type with the `dtype` parameter. Note that the entire file is read into a single `DataFrame` regardless, use the `chunksize` or `iterator` parameter to return the data in chunks. (Only valid with C parser)

**memory\_map** [boolean, default False] If a filepath is provided for `filepath_or_buffer`, map the file object directly onto memory and access the data directly from there. Using this option can improve performance because there is no longer any I/O overhead.

#### 25.1.1.4 NA and Missing Data Handling

**na\_values** [scalar, str, list-like, or dict, default None] Additional strings to recognize as NA/NaN. If dict passed, specific per-column NA values. See *na values const* below for a list of the values interpreted as NaN by default.

**keep\_default\_na** [boolean, default True] Whether or not to include the default NaN values when parsing the data. Depending on whether *na\_values* is passed in, the behavior is as follows:

- If *keep\_default\_na* is `True`, and *na\_values* are specified, *na\_values* is appended to the default NaN values used for parsing.
- If *keep\_default\_na* is `True`, and *na\_values* are not specified, only the default NaN values are used for parsing.
- If *keep\_default\_na* is `False`, and *na\_values* are specified, only the NaN values specified *na\_values* are used for parsing.
- If *keep\_default\_na* is `False`, and *na\_values* are not specified, no strings will be parsed as NaN.

Note that if *na\_filter* is passed in as `False`, the *keep\_default\_na* and *na\_values* parameters will be ignored.

**na\_filter** [boolean, default True] Detect missing value markers (empty strings and the value of *na\_values*). In data without any NAs, passing *na\_filter=False* can improve the performance of reading a large file.

**verbose** [boolean, default False] Indicate number of NA values placed in non-numeric columns.

**skip\_blank\_lines** [boolean, default True] If `True`, skip over blank lines rather than interpreting as NaN values.

#### 25.1.1.5 Datetime Handling

**parse\_dates** [boolean or list of ints or names or list of lists or dict, default False.]

- If `True` -> try parsing the index.
- If `[1, 2, 3]` -> try parsing columns 1, 2, 3 each as a separate date column.
- If `[[1, 3]]` -> combine columns 1 and 3 and parse as a single date column.
- If `{'foo': [1, 3]}` -> parse columns 1, 3 as date and call result 'foo'. A fast-path exists for iso8601-formatted dates.

**infer\_datetime\_format** [boolean, default `False`] If `True` and `parse_dates` is enabled for a column, attempt to infer the datetime format to speed up the processing.

**keep\_date\_col** [boolean, default `False`] If `True` and `parse_dates` specifies combining multiple columns then keep the original columns.

**date\_parser** [function, default `None`] Function to use for converting a sequence of string columns to an array of datetime instances. The default uses `dateutil.parser.parser` to do the conversion. Pandas will try to call `date_parser` in three different ways, advancing to the next if an exception occurs: 1) Pass one or more arrays (as defined by `parse_dates`) as arguments; 2) concatenate (row-wise) the string values from the columns defined by `parse_dates` into a single array and pass that; and 3) call `date_parser` once for each row using one or more strings (corresponding to the columns defined by `parse_dates`) as arguments.

**dayfirst** [boolean, default `False`] DD/MM format dates, international and European format.

#### 25.1.1.6 Iteration

**iterator** [boolean, default `False`] Return *TextFileReader* object for iteration or getting chunks with `get_chunk()`.

**chunksize** [int, default `None`] Return *TextFileReader* object for iteration. See *iterating and chunking* below.

#### 25.1.1.7 Quoting, Compression, and File Format

**compression** [{`'infer'`, `'gzip'`, `'bz2'`, `'zip'`, `'xz'`, `None`}, default `'infer'`] For on-the-fly decompression of on-disk data. If `'infer'`, then use `gzip`, `bz2`, `zip`, or `xz` if `filepath_or_buffer` is a string ending in `'gz'`, `'bz2'`, `'zip'`, or `'xz'`, respectively, and no decompression otherwise. If using `'zip'`, the ZIP file must contain only one data file to be read in. Set to `None` for no decompression.

New in version 0.18.1: support for `'zip'` and `'xz'` compression.

Changed in version 0.24.0: `'infer'` option added and set to default.

**thousands** [str, default `None`] Thousands separator.

**decimal** [str, default `'.'`] Character to recognize as decimal point. E.g. use `'.'` for European data.

**float\_precision** [string, default `None`] Specifies which converter the C engine should use for floating-point values. The options are `None` for the ordinary converter, `high` for the high-precision converter, and `round_trip` for the round-trip converter.

**lineterminator** [str (length 1), default `None`] Character to break file into lines. Only valid with C parser.

**quotechar** [str (length 1)] The character used to denote the start and end of a quoted item. Quoted items can include the delimiter and it will be ignored.

**quoting** [int or `csv.QUOTE_*` instance, default 0] Control field quoting behavior per `csv.QUOTE_*` constants. Use one of `QUOTE_MINIMAL` (0), `QUOTE_ALL` (1), `QUOTE_NONNUMERIC` (2) or `QUOTE_NONE` (3).

**doublequote** [boolean, default `True`] When `quotechar` is specified and `quoting` is not `QUOTE_NONE`, indicate whether or not to interpret two consecutive `quotechar` elements **inside** a field as a single `quotechar` element.

**escapechar** [str (length 1), default None] One-character string used to escape delimiter when quoting is QUOTE\_NONE.

**comment** [str, default None] Indicates remainder of line should not be parsed. If found at the beginning of a line, the line will be ignored altogether. This parameter must be a single character. Like empty lines (as long as `skip_blank_lines=True`), fully commented lines are ignored by the parameter *header* but not by *skiprows*. For example, if `comment='#'`, parsing `'#empty\na,b,c\n1,2,3'` with *header=0* will result in `'a,b,c'` being treated as the header.

**encoding** [str, default None] Encoding to use for UTF when reading/writing (e.g. `'utf-8'`). [List of Python standard encodings](#).

**dialect** [str or `csv.Dialect` instance, default None] If provided, this parameter will override values (default or not) for the following parameters: *delimiter*, *doublequote*, *escapechar*, *skipinitialspace*, *quotechar*, and *quoting*. If it is necessary to override values, a `ParserWarning` will be issued. See `csv.Dialect` documentation for more details.

**tupleize\_cols** [boolean, default False]

Deprecated since version 0.21.0.

This argument will be removed and will always convert to `MultiIndex`

Leave a list of tuples on columns as is (default is to convert to a `MultiIndex` on the columns).

### 25.1.1.8 Error Handling

**error\_bad\_lines** [boolean, default True] Lines with too many fields (e.g. a csv line with too many commas) will by default cause an exception to be raised, and no `DataFrame` will be returned. If False, then these “bad lines” will be dropped from the `DataFrame` that is returned. See *bad lines* below.

**warn\_bad\_lines** [boolean, default True] If `error_bad_lines` is False, and `warn_bad_lines` is True, a warning for each “bad line” will be output.

## 25.1.2 Specifying column data types

You can indicate the data type for the whole `DataFrame` or individual columns:

```
In [8]: data = ('a,b,c,d\n'
...:          '1,2,3,4\n'
...:          '5,6,7,8\n'
...:          '9,10,11')
...:

In [9]: print(data)
a,b,c,d
1,2,3,4
5,6,7,8
9,10,11

In [10]: df = pd.read_csv(StringIO(data), dtype=object)

In [11]: df
Out[11]:
   a  b  c  d
0  1  2  3  4
1  5  6  7  8
```

(continues on next page)

(continued from previous page)

```

2   9   10   11   NaN

In [12]: df['a'][0]
Out[12]:
1
→ '1'

In [13]: df = pd.read_csv(StringIO(data),
.....:                    dtype={'b': object, 'c': np.float64, 'd': 'Int64'})
.....:

In [14]: df.dtypes
Out[14]:
a      int64
b      object
c     float64
d      Int64
dtype: object

```

Fortunately, pandas offers more than one way to ensure that your column(s) contain only one dtype. If you're unfamiliar with these concepts, you can see [here](#) to learn more about dtypes, and [here](#) to learn more about object conversion in pandas.

For instance, you can use the `converters` argument of `read_csv()`:

```

In [15]: data = ("col_1\n"
.....:          "1\n"
.....:          "2\n"
.....:          "'A'\n"
.....:          "4.22")
.....:

In [16]: df = pd.read_csv(StringIO(data), converters={'col_1': str})

In [17]: df
Out[17]:
   col_1
0      1
1      2
2     'A'
3    4.22

In [18]: df['col_1'].apply(type).value_counts()
Out[18]:
<class 'str'>      4
Name: col_1, dtype: int64

```

Or you can use the `to_numeric()` function to coerce the dtypes after reading in the data,

```

In [19]: df2 = pd.read_csv(StringIO(data))

In [20]: df2['col_1'] = pd.to_numeric(df2['col_1'], errors='coerce')

In [21]: df2
Out[21]:
   col_1
0    1.00
1    2.00

```

(continues on next page)

(continued from previous page)

```

2      NaN
3      4.22

In [22]: df2['col_1'].apply(type).value_counts()
\\Out[22]:
<class 'float'>      4
Name: col_1, dtype: int64

```

which will convert all valid parsing to floats, leaving the invalid parsing as NaN.

Ultimately, how you deal with reading in columns containing mixed dtypes depends on your specific needs. In the case above, if you wanted to NaN out the data anomalies, then `to_numeric()` is probably your best option. However, if you wanted for all the data to be coerced, no matter the type, then using the `converters` argument of `read_csv()` would certainly be worth trying.

New in version 0.20.0: support for the Python parser.

The `dtype` option is supported by the ‘python’ engine.

**Note:** In some cases, reading in abnormal data with columns containing mixed dtypes will result in an inconsistent dataset. If you rely on pandas to infer the dtypes of your columns, the parsing engine will go and infer the dtypes for different chunks of the data, rather than the whole dataset at once. Consequently, you can end up with column(s) with mixed dtypes. For example,

```

In [23]: col_1 = list(range(500000)) + ['a', 'b'] + list(range(500000))

In [24]: df = pd.DataFrame({'col_1': col_1})

In [25]: df.to_csv('foo.csv')

In [26]: mixed_df = pd.read_csv('foo.csv')

In [27]: mixed_df['col_1'].apply(type).value_counts()
Out[27]:
<class 'int'>      737858
<class 'str'>     262144
Name: col_1, dtype: int64

In [28]: mixed_df['col_1'].dtype
\\Out[28]:
dtype('O')

```

will result with `mixed_df` containing an `int` dtype for certain chunks of the column, and `str` for others due to the mixed dtypes from the data that was read in. It is important to note that the overall column will be marked with a dtype of object, which is used for columns with mixed dtypes.

### 25.1.3 Specifying Categorical dtype

New in version 0.19.0.

Categorical columns can be parsed directly by specifying `dtype='category'` or `dtype=CategoricalDtype(categories, ordered)`.

```

In [29]: data = ('col1,col2,col3\n'
.....:         'a,b,1\n'
.....:         'a,b,2\n'
.....:         'c,d,3')
.....:

In [30]: pd.read_csv(StringIO(data))
Out[30]:
   col1 col2 col3
0     a    b    1
1     a    b    2
2     c    d    3

In [31]: pd.read_csv(StringIO(data)).dtypes
Out[31]:
col1      object
col2      object
col3      int64
dtype: object

In [32]: pd.read_csv(StringIO(data), dtype='category').dtypes
Out[32]:
col1      category
col2      category
col3      category
dtype: object

```

Individual columns can be parsed as a Categorical using a dict specification:

```

In [33]: pd.read_csv(StringIO(data), dtype={'col1': 'category'}).dtypes
Out[33]:
col1      category
col2      object
col3      int64
dtype: object

```

New in version 0.21.0.

Specifying `dtype='category'` will result in an unordered Categorical whose categories are the unique values observed in the data. For more control on the categories and order, create a CategoricalDtype ahead of time, and pass that for that column's dtype.

```

In [34]: from pandas.api.types import CategoricalDtype

In [35]: dtype = CategoricalDtype(['d', 'c', 'b', 'a'], ordered=True)

In [36]: pd.read_csv(StringIO(data), dtype={'col1': dtype}).dtypes
Out[36]:
col1      category
col2      object
col3      int64
dtype: object

```

When using `dtype=CategoricalDtype`, “unexpected” values outside of `dtype.categories` are treated as missing values.

```
In [37]: dtype = CategoricalDtype(['a', 'b', 'd']) # No 'c'

In [38]: pd.read_csv(StringIO(data), dtype={'col1': dtype}).col1
Out[38]:
0      a
1      a
2     NaN
Name: col1, dtype: category
Categories (3, object): [a, b, d]
```

This matches the behavior of `Categorical.set_categories()`.

---

**Note:** With `dtype='category'`, the resulting categories will always be parsed as strings (object dtype). If the categories are numeric they can be converted using the `to_numeric()` function, or as appropriate, another converter such as `to_datetime()`.

When `dtype` is a `CategoricalDtype` with homogeneous categories (all numeric, all datetimes, etc.), the conversion is done automatically.

```
In [39]: df = pd.read_csv(StringIO(data), dtype='category')

In [40]: df.dtypes
Out[40]:
col1    category
col2    category
col3    category
dtype: object

In [41]: df['col3']
Out[41]:
0      1
1      2
2      3
Name: col3, dtype: category
Categories (3, object): [1, 2, 3]

In [42]: df['col3'].cat.categories = pd.to_numeric(df['col3'].cat.categories)

In [43]: df['col3']
Out[43]:
0      1
1      2
2      3
Name: col3, dtype: category
Categories (3, int64): [1, 2, 3]
```

---

## 25.1.4 Naming and Using Columns

### 25.1.4.1 Handling column names

A file may or may not have a header row. pandas assumes the first row should be used as the column names:

```
In [44]: data = ('a,b,c\n'
.....:         '1,2,3\n')
```

(continues on next page)

(continued from previous page)

```
.....:      '4,5,6\n'
.....:      '7,8,9')
```

```
In [45]: print(data)
a,b,c
1,2,3
4,5,6
7,8,9
```

```
In [46]: pd.read_csv(StringIO(data))
\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\Out[46]:
```

|   | a | b | c |
|---|---|---|---|
| 0 | 1 | 2 | 3 |
| 1 | 4 | 5 | 6 |
| 2 | 7 | 8 | 9 |

By specifying the `names` argument in conjunction with `header` you can indicate other names to use and whether or not to throw away the header row (if any):

```
In [47]: print(data)
a,b,c
1,2,3
4,5,6
7,8,9
```

```
In [48]: pd.read_csv(StringIO(data), names=['foo', 'bar', 'baz'], header=0)
\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\Out[48]:
   foo  bar  baz
0     1    2    3
1     4    5    6
2     7    8    9
```

```
In [49]: pd.read_csv(StringIO(data), names=['foo', 'bar', 'baz'], header=None)
/////////////////////////////////////////////////
↪
   foo bar baz
0    a  b   c
1    1  2   3
2    4  5   6
3    7  8   9
```

If the header is in a row other than the first, pass the row number to `header_r`. This will skip the preceding rows:

```
In [50]: data = ('skip this skip it\n'
.....:          'a,b,c\n'
.....:          '1,2,3\n'
.....:          '4,5,6\n'
.....:          '7,8,9')
.....:

In [51]: pd.read_csv(StringIO(data), header=1)
Out[51]:
```

|   | a | b | c |
|---|---|---|---|
| 0 | 1 | 2 | 3 |
| 1 | 4 | 5 | 6 |
| 2 | 7 | 8 | 9 |

**Note:** Default behavior is to infer the column names: if no names are passed the behavior is identical to `header=0` and column names are inferred from the first non-blank line of the file, if column names are passed explicitly then the behavior is identical to `header=None`.

---

### 25.1.5 Duplicate names parsing

If the file or header contains duplicate names, pandas will by default distinguish between them so as to prevent overwriting data:

```
In [52]: data = ('a,b,a\n'
.....:          '0,1,2\n'
.....:          '3,4,5')
.....:

In [53]: pd.read_csv(StringIO(data))
Out[53]:
```

|   | a | b | a.1 |
|---|---|---|-----|
| 0 | 0 | 1 | 2   |
| 1 | 3 | 4 | 5   |

There is no more duplicate data because `mangle_dupe_cols=True` by default, which modifies a series of duplicate columns 'X', ..., 'X' to become 'X', 'X.1', ..., 'X.N'. If `mangle_dupe_cols=False`, duplicate data can arise:

```
In [2]: data = 'a,b,a\n0,1,2\n3,4,5'
In [3]: pd.read_csv(StringIO(data), mangle_dupe_cols=False)
Out[3]:
```

|   | a | b | a |
|---|---|---|---|
| 0 | 2 | 1 | 2 |
| 1 | 5 | 4 | 5 |

To prevent users from encountering this problem with duplicate data, a `ValueError` exception is raised if `mangle_dupe_cols != True`:

```
In [2]: data = 'a,b,a\n0,1,2\n3,4,5'
In [3]: pd.read_csv(StringIO(data), mangle_dupe_cols=False)
...
ValueError: Setting mangle_dupe_cols=False is not supported yet
```

#### 25.1.5.1 Filtering columns (`usecols`)

The `usecols` argument allows you to select any subset of the columns in a file, either using the column names, position numbers or a callable:

New in version 0.20.0: support for callable `usecols` arguments

```
In [54]: data = 'a,b,c,d\n1,2,3,foo\n4,5,6,bar\n7,8,9,baz'

In [55]: pd.read_csv(StringIO(data))
Out[55]:
```

|   | a | b | c | d   |
|---|---|---|---|-----|
| 0 | 1 | 2 | 3 | foo |
| 1 | 4 | 5 | 6 | bar |

(continues on next page)

(continued from previous page)

```

2  7  8  9  baz

In [56]: pd.read_csv(StringIO(data), usecols=['b', 'd'])
Out[56]:
   b  d
0  2  foo
1  5  bar
2  8  baz

In [57]: pd.read_csv(StringIO(data), usecols=[0, 2, 3])
Out[57]:
   a  c  d
0  1  3  foo
1  4  6  bar
2  7  9  baz

In [58]: pd.read_csv(StringIO(data), usecols=lambda x: x.upper() in ['A', 'C'])
Out[58]:
   a  c
0  1  3
1  4  6
2  7  9

```

The `usecols` argument can also be used to specify which columns not to use in the final result:

```

In [59]: pd.read_csv(StringIO(data), usecols=lambda x: x not in ['a', 'c'])
Out[59]:
   b  d
0  2  foo
1  5  bar
2  8  baz

```

In this case, the callable is specifying that we exclude the “a” and “c” columns from the output.

## 25.1.6 Comments and Empty Lines

### 25.1.6.1 Ignoring line comments and empty lines

If the `comment` parameter is specified, then completely commented lines will be ignored. By default, completely blank lines will be ignored as well.

```

In [60]: data = ('\\n'
.....:          'a,b,c\\n'
.....:          '\\n'
.....:          '# commented line\\n'
.....:          '1,2,3\\n'
.....:          '\\n'
.....:          '4,5,6')

In [61]: print(data)

a,b,c

```

(continues on next page)

(continued from previous page)

```
# commented line
1,2,3

4,5,6

In [62]: pd.read_csv(StringIO(data), comment='#')
Out[62]:
   a  b  c
0  1  2  3
1  4  5  6
```

If `skip_blank_lines=False`, then `read_csv` will not ignore blank lines:

```
In [63]: data = ('a,b,c\n'
.....:          '\n'
.....:          '1,2,3\n'
.....:          '\n'
.....:          '\n'
.....:          '4,5,6')
.....:

In [64]: pd.read_csv(StringIO(data), skip_blank_lines=False)
Out[64]:
   a  b  c
0 NaN NaN NaN
1 1.0 2.0 3.0
2 NaN NaN NaN
3 NaN NaN NaN
4 4.0 5.0 6.0
```

**Warning:** The presence of ignored lines might create ambiguities involving line numbers; the parameter `header` uses row numbers (ignoring commented/empty lines), while `skiprows` uses line numbers (including commented/empty lines):

```
In [65]: data = ('#comment\n'
.....:          'a,b,c\n'
.....:          'A,B,C\n'
.....:          '1,2,3')
.....:

In [66]: pd.read_csv(StringIO(data), comment='#', header=1)
Out[66]:
   A  B  C
0  1  2  3

In [67]: data = ('A,B,C\n'
.....:          '#comment\n'
.....:          'a,b,c\n'
.....:          '1,2,3')
.....:

In [68]: pd.read_csv(StringIO(data), comment='#', skiprows=2)
Out[68]:
   a  b  c
0  1  2  3
```

If both `header` and `skiprows` are specified, `header` will be relative to the end of `skiprows`. For example:

```
In [69]: data = ('# empty\n'
.....:         '# second empty line\n'
.....:         '# third emptyline\n'
.....:         'X,Y,Z\n'
.....:         '1,2,3\n'
.....:         'A,B,C\n'
.....:         '1,2.,4.\n'
.....:         '5.,NaN,10.0\n')
.....:

In [70]: print(data)
# empty
# second empty line
# third emptyline
X,Y,Z
1,2,3
A,B,C
1,2.,4.
5.,NaN,10.0

In [71]: pd.read_csv(StringIO(data), comment='#', skiprows=4, header=1)
////////////////////////////////////Out [71]:
↪
   A    B    C
0  1.0  2.0  4.0
1  5.0  NaN 10.0
```

### 25.1.6.2 Comments

Sometimes comments or meta data may be included in a file:

```
In [72]: print(open('tmp.csv').read())
ID,level,category
Patient1,123000,x # really unpleasant
Patient2,23000,y # wouldn't take his medicine
Patient3,1234018,z # awesome
```

By default, the parser includes the comments in the output:

```
In [73]: df = pd.read_csv('tmp.csv')

In [74]: df
Out[74]:
   ID    level                category
0  Patient1  123000      x # really unpleasant
1  Patient2   23000  y # wouldn't take his medicine
2  Patient3 1234018      z # awesome
```

We can suppress the comments using the `comment` keyword:

```
In [75]: df = pd.read_csv('tmp.csv', comment='#')
```

```
In [76]: df
```

```
Out[76]:
```

|   | ID       | level   | category |
|---|----------|---------|----------|
| 0 | Patient1 | 123000  | x        |
| 1 | Patient2 | 23000   | y        |
| 2 | Patient3 | 1234018 | z        |

## 25.1.7 Dealing with Unicode Data

The `encoding` argument should be used for encoded unicode data, which will result in byte strings being decoded to unicode in the result:

```
In [77]: data = (b'word,length\n'
.....:          b'Tr\xc3\xa4umen,7\n'
.....:          b'Gr\xc3\xbc\xc3\xfe,5')
.....:
```

```
In [78]: data = data.decode('utf8').encode('latin-1')
```

```
In [79]: df = pd.read_csv(BytesIO(data), encoding='latin-1')
```

```
In [80]: df
```

```
Out[80]:
```

|   | word    | length |
|---|---------|--------|
| 0 | Träumen | 7      |
| 1 | Grüße   | 5      |

```
In [81]: df['word'][1]
```

```
Out[81]: 'Grüße'
```

Some formats which encode all characters as multiple bytes, like UTF-16, won't parse correctly at all without specifying the encoding. [Full list of Python standard encodings](#).

## 25.1.8 Index columns and trailing delimiters

If a file has one more column of data than the number of column names, the first column will be used as the `DataFrame`'s row names:

```
In [82]: data = ('a,b,c\n'
.....:          '4,apple,bat,5.7\n'
.....:          '8,orange,cow,10')
.....:
```

```
In [83]: pd.read_csv(StringIO(data))
```

```
Out[83]:
```

|   | a      | b   | c    |
|---|--------|-----|------|
| 4 | apple  | bat | 5.7  |
| 8 | orange | cow | 10.0 |

```
In [84]: data = ('index,a,b,c\n'
.....:          '4,apple,bat,5.7\n'
.....:          '8,orange,cow,10')
```

(continues on next page)

(continued from previous page)

```
.....:

In [85]: pd.read_csv(StringIO(data), index_col=0)
Out[85]:
```

|       | a      | b   | c    |
|-------|--------|-----|------|
| index |        |     |      |
| 4     | apple  | bat | 5.7  |
| 8     | orange | cow | 10.0 |

Ordinarily, you can achieve this behavior using the `index_col` option.

There are some exception cases when a file has been prepared with delimiters at the end of each data line, confusing the parser. To explicitly disable the index column inference and discard the last column, pass `index_col=False`:

```
In [86]: data = ('a,b,c\n'
.....:          '4,apple,bat,\n'
.....:          '8,orange,cow,')
.....:

In [87]: print(data)
a,b,c
4,apple,bat,
8,orange,cow,

In [88]: pd.read_csv(StringIO(data))
Out[88]:
   a      b      c
4  apple  bat  NaN
8  orange  cow  NaN
```

```
In [89]: pd.read_csv(StringIO(data), index_col=False)
////////////////////////////////////
↪
   a      b      c
0  4  apple  bat
1  8 orange  cow
```

If a subset of data is being parsed using the `usecols` option, the `index_col` specification is based on that subset, not the original data.

```
In [90]: data = ('a,b,c\n'
....:           '4,apple,bat,\n'
....:           '8,orange,cow,')
....:

In [91]: print(data)
a,b,c
4,apple,bat,
8,orange,cow,

In [92]: pd.read_csv(StringIO(data), usecols=['b', 'c'])
Out[92]:
   b  c
4  bat NaN
8  cow NaN

In [93]: pd.read_csv(StringIO(data), usecols=['b', 'c'], index_col=0)
```

(continues on next page)

(continued from previous page)

```

Out[93]:
      b    c
4  bat NaN
8  cow NaN

```

## 25.1.9 Date Handling

### 25.1.9.1 Specifying Date Columns

To better facilitate working with datetime data, `read_csv()` uses the keyword arguments `parse_dates` and `date_parser` to allow users to specify a variety of columns and date/time formats to turn the input text data into datetime objects.

The simplest case is to just pass in `parse_dates=True`:

```

# Use a column as an index, and parse it as dates.
In [94]: df = pd.read_csv('foo.csv', index_col=0, parse_dates=True)

In [95]: df
Out[95]:
      A  B  C
date
2009-01-01  a  1  2
2009-01-02  b  3  4
2009-01-03  c  4  5

# These are Python datetime objects
In [96]: df.index
Out[96]:
DatetimeIndex(['2009-01-01', '2009-01-02', '2009-01-03'], dtype='datetime64[ns]',
              name='date', freq=None)

```

It is often the case that we may want to store date and time data separately, or store various date fields separately. the `parse_dates` keyword can be used to specify a combination of columns to parse the dates and/or times from.

You can specify a list of column lists to `parse_dates`, the resulting date columns will be prepended to the output (so as to not affect the existing column order) and the new column names will be the concatenation of the component column names:

```

In [97]: print(open('tmp.csv').read())
KORD,19990127, 19:00:00, 18:56:00, 0.8100
KORD,19990127, 20:00:00, 19:56:00, 0.0100
KORD,19990127, 21:00:00, 20:56:00, -0.5900
KORD,19990127, 21:00:00, 21:18:00, -0.9900
KORD,19990127, 22:00:00, 21:56:00, -0.5900
KORD,19990127, 23:00:00, 22:56:00, -0.5900

In [98]: df = pd.read_csv('tmp.csv', header=None, parse_dates=[[1, 2], [1, 3]])

In [99]: df
Out[99]:
      1_2      1_3    0    4
0 1999-01-27 19:00:00 1999-01-27 18:56:00 KORD 0.81
1 1999-01-27 20:00:00 1999-01-27 19:56:00 KORD 0.01
2 1999-01-27 21:00:00 1999-01-27 20:56:00 KORD -0.59

```

(continues on next page)

(continued from previous page)

```

3 1999-01-27 21:00:00 1999-01-27 21:18:00 KORD -0.99
4 1999-01-27 22:00:00 1999-01-27 21:56:00 KORD -0.59
5 1999-01-27 23:00:00 1999-01-27 22:56:00 KORD -0.59

```

By default the parser removes the component date columns, but you can choose to retain them via the `keep_date_col` keyword:

```

In [100]: df = pd.read_csv('tmp.csv', header=None, parse_dates=[[1, 2], [1, 3]],
.....:                  keep_date_col=True)
.....:

In [101]: df
Out[101]:
```

|   | 1_2                 | 1_3                 | 0    | 1        | 2        | 3        | 4     |
|---|---------------------|---------------------|------|----------|----------|----------|-------|
| 0 | 1999-01-27 19:00:00 | 1999-01-27 18:56:00 | KORD | 19990127 | 19:00:00 | 18:56:00 | 0.81  |
| 1 | 1999-01-27 20:00:00 | 1999-01-27 19:56:00 | KORD | 19990127 | 20:00:00 | 19:56:00 | 0.01  |
| 2 | 1999-01-27 21:00:00 | 1999-01-27 20:56:00 | KORD | 19990127 | 21:00:00 | 20:56:00 | -0.59 |
| 3 | 1999-01-27 21:00:00 | 1999-01-27 21:18:00 | KORD | 19990127 | 21:00:00 | 21:18:00 | -0.99 |
| 4 | 1999-01-27 22:00:00 | 1999-01-27 21:56:00 | KORD | 19990127 | 22:00:00 | 21:56:00 | -0.59 |
| 5 | 1999-01-27 23:00:00 | 1999-01-27 22:56:00 | KORD | 19990127 | 23:00:00 | 22:56:00 | -0.59 |

Note that if you wish to combine multiple columns into a single date column, a nested list must be used. In other words, `parse_dates=[1, 2]` indicates that the second and third columns should each be parsed as separate date columns while `parse_dates=[[1, 2]]` means the two columns should be parsed into a single column.

You can also use a dict to specify custom name columns:

```

In [102]: date_spec = {'nominal': [1, 2], 'actual': [1, 3]}

In [103]: df = pd.read_csv('tmp.csv', header=None, parse_dates=date_spec)

In [104]: df
Out[104]:
```

|   | nominal             | actual              | 0    | 4     |
|---|---------------------|---------------------|------|-------|
| 0 | 1999-01-27 19:00:00 | 1999-01-27 18:56:00 | KORD | 0.81  |
| 1 | 1999-01-27 20:00:00 | 1999-01-27 19:56:00 | KORD | 0.01  |
| 2 | 1999-01-27 21:00:00 | 1999-01-27 20:56:00 | KORD | -0.59 |
| 3 | 1999-01-27 21:00:00 | 1999-01-27 21:18:00 | KORD | -0.99 |
| 4 | 1999-01-27 22:00:00 | 1999-01-27 21:56:00 | KORD | -0.59 |
| 5 | 1999-01-27 23:00:00 | 1999-01-27 22:56:00 | KORD | -0.59 |

It is important to remember that if multiple text columns are to be parsed into a single date column, then a new column is prepended to the data. The `index_col` specification is based off of this new set of columns rather than the original data columns:

```

In [105]: date_spec = {'nominal': [1, 2], 'actual': [1, 3]}

In [106]: df = pd.read_csv('tmp.csv', header=None, parse_dates=date_spec,
.....:                  index_col=0) # index is the nominal column
.....:

In [107]: df
Out[107]:
```

|                     | nominal             | actual | 0    | 4 |
|---------------------|---------------------|--------|------|---|
| 1999-01-27 19:00:00 | 1999-01-27 18:56:00 | KORD   | 0.81 |   |

(continues on next page)

(continued from previous page)

```

1999-01-27 20:00:00 1999-01-27 19:56:00 KORD 0.01
1999-01-27 21:00:00 1999-01-27 20:56:00 KORD -0.59
1999-01-27 21:00:00 1999-01-27 21:18:00 KORD -0.99
1999-01-27 22:00:00 1999-01-27 21:56:00 KORD -0.59
1999-01-27 23:00:00 1999-01-27 22:56:00 KORD -0.59

```

**Note:** If a column or index contains an unparseable date, the entire column or index will be returned unaltered as an object data type. For non-standard datetime parsing, use `to_datetime()` after `pd.read_csv`.

**Note:** `read_csv` has a `fast_path` for parsing datetime strings in iso8601 format, e.g. “2000-01-01T00:01:02+00:00” and similar variations. If you can arrange for your data to store datetimes in this format, load times will be significantly faster, ~20x has been observed.

**Note:** When passing a dict as the `parse_dates` argument, the order of the columns prepended is not guaranteed, because *dict* objects do not impose an ordering on their keys. On Python 2.7+ you may use `collections.OrderedDict` instead of a regular *dict* if this matters to you. Because of this, when using a dict for ‘`parse_dates`’ in conjunction with the `index_col` argument, it’s best to specify `index_col` as a column label rather than as an index on the resulting frame.

### 25.1.9.2 Date Parsing Functions

Finally, the parser allows you to specify a custom `date_parser` function to take full advantage of the flexibility of the date parsing API:

```

In [108]: df = pd.read_csv('tmp.csv', header=None, parse_dates=date_spec,
.....:                    date_parser=pd.io.date_converters.parse_date_time)
.....:

In [109]: df
Out[109]:
      nominal      actual    0    4
0 1999-01-27 19:00:00 1999-01-27 18:56:00 KORD 0.81
1 1999-01-27 20:00:00 1999-01-27 19:56:00 KORD 0.01
2 1999-01-27 21:00:00 1999-01-27 20:56:00 KORD -0.59
3 1999-01-27 21:00:00 1999-01-27 21:18:00 KORD -0.99
4 1999-01-27 22:00:00 1999-01-27 21:56:00 KORD -0.59
5 1999-01-27 23:00:00 1999-01-27 22:56:00 KORD -0.59

```

Pandas will try to call the `date_parser` function in three different ways. If an exception is raised, the next one is tried:

1. `date_parser` is first called with one or more arrays as arguments, as defined using `parse_dates` (e.g., `date_parser(['2013', '2013'], ['1', '2'])`).
2. If #1 fails, `date_parser` is called with all the columns concatenated row-wise into a single array (e.g., `date_parser(['2013 1', '2013 2'])`).
3. If #2 fails, `date_parser` is called once for every row with one or more string arguments from the columns indicated with `parse_dates` (e.g., `date_parser('2013', '1')` for the first row, `date_parser('2013', '2')` for the second, etc.).

Note that performance-wise, you should try these methods of parsing dates in order:

1. Try to infer the format using `infer_datetime_format=True` (see section below).
2. If you know the format, use `pd.to_datetime(): date_parser=lambda x: pd.to_datetime(x, format=...)`.
3. If you have a really non-standard format, use a custom `date_parser` function. For optimal performance, this should be vectorized, i.e., it should accept arrays as arguments.

You can explore the date parsing functionality in `date_converters.py` and add your own. We would love to turn this module into a community supported set of date/time parsers. To get you started, `date_converters.py` contains functions to parse dual date and time columns, year/month/day columns, and year/month/day/hour/minute/second columns. It also contains a `generic_parser` function so you can curry it with a function that deals with a single date rather than the entire array.

### 25.1.9.3 Inferring Datetime Format

If you have `parse_dates` enabled for some or all of your columns, and your datetime strings are all formatted the same way, you may get a large speed up by setting `infer_datetime_format=True`. If set, pandas will attempt to guess the format of your datetime strings, and then use a faster means of parsing the strings. 5-10x parsing speeds have been observed. pandas will fallback to the usual parsing if either the format cannot be guessed or the format that was guessed cannot properly parse the entire column of strings. So in general, `infer_datetime_format` should not have any negative consequences if enabled.

Here are some examples of datetime strings that can be guessed (All representing December 30th, 2011 at 00:00:00):

- “20111230”
- “2011/12/30”
- “20111230 00:00:00”
- “12/30/2011 00:00:00”
- “30/Dec/2011 00:00:00”
- “30/December/2011 00:00:00”

Note that `infer_datetime_format` is sensitive to `dayfirst`. With `dayfirst=True`, it will guess “01/12/2011” to be December 1st. With `dayfirst=False` (default) it will guess “01/12/2011” to be January 12th.

```
# Try to infer the format for the index column
In [110]: df = pd.read_csv('foo.csv', index_col=0, parse_dates=True,
.....:                    infer_datetime_format=True)
.....:

In [111]: df
Out[111]:
```

|            | A | B | C |
|------------|---|---|---|
| date       |   |   |   |
| 2009-01-01 | a | 1 | 2 |
| 2009-01-02 | b | 3 | 4 |
| 2009-01-03 | c | 4 | 5 |

### 25.1.9.4 International Date Formats

While US date formats tend to be MM/DD/YYYY, many international formats use DD/MM/YYYY instead. For convenience, a `dayfirst` keyword is provided:

```
In [112]: print(open('tmp.csv').read())
date,value,cat
1/6/2000,5,a
2/6/2000,10,b
3/6/2000,15,c

In [113]: pd.read_csv('tmp.csv', parse_dates=[0])
Out[113]:
   date  value cat
0 2000-01-06     5  a
1 2000-02-06    10  b
2 2000-03-06    15  c

In [114]: pd.read_csv('tmp.csv', dayfirst=True, parse_dates=[0])
Out[114]:
   date  value cat
0 2000-06-01     5  a
1 2000-06-02    10  b
2 2000-06-03    15  c
```

### 25.1.10 Specifying method for floating-point conversion

The parameter `float_precision` can be specified in order to use a specific floating-point converter during parsing with the C engine. The options are the ordinary converter, the high-precision converter, and the round-trip converter (which is guaranteed to round-trip values after writing to a file). For example:

[illegible]

### 25.1.11 Thousand Separators

For large numbers that have been written with a thousands separator, you can set the `thousands` keyword to a string of length 1 so that integers will be parsed correctly:

By default, numbers with a thousands separator will be parsed as strings:

[illegible]

The `thousands` keyword allows integers to be parsed correctly:

```
In [124]: print(open('tmp.csv').read())
ID|level|category
Patient1|123,000|x
Patient2|23,000|y
Patient3|1,234,018|z

In [125]: df = pd.read_csv('tmp.csv', sep='|', thousands=',')

In [126]: df
Out[126]:
```

|   | ID       | level   | category |
|---|----------|---------|----------|
| 0 | Patient1 | 123000  | x        |
| 1 | Patient2 | 23000   | y        |
| 2 | Patient3 | 1234018 | z        |

```
In [127]: df.level.dtype
dtype('int64')
```

### 25.1.12 NA Values

To control which values are parsed as missing values (which are signified by `NaN`), specify a string in `na_values`. If you specify a list of strings, then all values in it are considered to be missing values. If you specify a number (a `float`, like `5.0` or an `integer` like `5`), the corresponding equivalent values will also imply a missing value (in this case effectively `[5.0, 5]` are recognized as `NaN`).

To completely override the default values that are recognized as missing, specify `keep_default_na=False`.

The default NaN recognized values are ['-1.#IND', '1.#QNAN', '1.#IND', '-1.#QNAN', '#N/A N/A', '#N/A', 'N/A', 'n/a', 'NA', '#NA', 'NULL', 'null', 'NaN', '-NaN', 'nan', '-nan', ''].

Let us consider some examples:

```
pd.read_csv('path_to_file.csv', na_values=[5])
```

In the example above 5 and 5.0 will be recognized as NaN, in addition to the defaults. A string will first be interpreted as a numerical 5, then as a NaN.

```
pd.read_csv('path_to_file.csv', keep_default_na=False, na_values=[""])
```

Above, only an empty field will be recognized as NaN.

```
pd.read_csv('path_to_file.csv', keep_default_na=False, na_values=["NA", "0"])
```

Above, both NA and 0 as strings are NaN.

```
pd.read_csv('path_to_file.csv', na_values=["Nope"])
```

The default values, in addition to the string "Nope" are recognized as NaN.

### 25.1.13 Infinity

inf like values will be parsed as `np.inf` (positive infinity), and `-inf` as `-np.inf` (negative infinity). These will ignore the case of the value, meaning `Inf`, will also be parsed as `np.inf`.

### 25.1.14 Returning Series

Using the `squeeze` keyword, the parser will return output with a single column as a `Series`:

```
In [128]: print(open('tmp.csv').read())
level
Patient1,123000
Patient2,23000
Patient3,1234018

In [129]: output = pd.read_csv('tmp.csv', squeeze=True)

In [130]: output
Out[130]:
Patient1      123000
Patient2       23000
Patient3     1234018
Name: level, dtype: int64

In [131]: type(output)
////////////////////////////////////Out
↳pandas.core.series.Series
```

### 25.1.15 Boolean values

The common values `True`, `False`, `TRUE`, and `FALSE` are all recognized as boolean. Occasionally you might want to recognize other values as being boolean. To do this, use the `true_values` and `false_values` options as follows:

```
In [132]: data = ('a,b,c\n'
.....:          '1,Yes,2\n'
.....:          '3,No,4')
.....:
```

(continues on next page)

```
In [133]: print(data)
a,b,c
1,Yes,2
3,No,4

In [134]: pd.read_csv(StringIO(data))
\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\Out[134]:
```

|   | a | b   | c |
|---|---|-----|---|
| 0 | 1 | Yes | 2 |
| 1 | 3 | No  | 4 |

```
In [135]: pd.read_csv(StringIO(data), true_values=['Yes'], false_values=['No'])
\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\Out[135]:
```

|   | a | b     | c |
|---|---|-------|---|
| 0 | 1 | True  | 2 |
| 1 | 3 | False | 4 |

Some files may have malformed lines with too few fields or too many. Lines with too few fields will have NA values filled in the trailing fields. Lines with too many fields will raise an error by default:

```
In [136]: data = ('a,b,c\n'
.....:          '1,2,3\n'
.....:          '4,5,6,7\n'
.....:          '8,9,10')
.....:

In [137]: pd.read_csv(StringIO(data))

/pandas/pandas/_libs/parsers.pyx in pandas._libs.parsers.TextReader._read_rows()

/pandas/pandas/_libs/parsers.pyx in pandas._libs.parsers.TextReader._tokenize_rows()

/pandas/pandas/_libs/parsers.pyx in pandas._libs.parsers.raise_parser_error()

ParserError: Error tokenizing data. C error: Expected 3 fields in line 3, saw 4

```

You can elect to skip bad lines:

```

In [29]: pd.read_csv(StringIO(data), error_bad_lines=False)
Skipping line 3: expected 3 fields, saw 4

Out[29]:
   a  b  c
0  1  2  3
1  8  9 10

```

You can also use the `usecols` parameter to eliminate extraneous column data that appear in some lines but not others:

```

In [30]: pd.read_csv(StringIO(data), usecols=[0, 1, 2])

Out[30]:
   a  b  c
0  1  2  3
1  4  5  6
2  8  9 10

```

### 25.1.17 Dialect

The `dialect` keyword gives greater flexibility in specifying the file format. By default it uses the Excel dialect but you can specify either the dialect name or a `csv.Dialect` instance.

Suppose you had data with unenclosed quotes:

```

In [138]: print(data)
label1,label2,label3

```

(continues on next page)

(continued from previous page)

```
index1,"a,c,e
index2,b,d,f
```

By default, `read_csv` uses the Excel dialect and treats the double quote as the quote character, which causes it to fail when it finds a newline before it finds the closing double quote.

We can get around this using `dialect`:

```
In [139]: import csv

In [140]: dia = csv.excel()

In [141]: dia.quoting = csv.QUOTE_NONE

In [142]: pd.read_csv(StringIO(data), dialect=dia)
Out[142]:
   label1 label2 label3
index1    "a      c      e
index2     b      d      f
```

All of the dialect options can be specified separately by keyword arguments:

```
In [143]: data = 'a,b,c~1,2,3~4,5,6'

In [144]: pd.read_csv(StringIO(data), lineterminator='~')
Out[144]:
   a  b  c
0  1  2  3
1  4  5  6
```

Another common dialect option is `skipinitialspace`, to skip any whitespace after a delimiter:

```
In [145]: data = 'a, b, c\n1, 2, 3\n4, 5, 6'

In [146]: print(data)
a, b, c
1, 2, 3
4, 5, 6

In [147]: pd.read_csv(StringIO(data), skipinitialspace=True)
\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\Out[147]:
   a  b  c
0  1  2  3
1  4  5  6
```

The parsers make every attempt to “do the right thing” and not be fragile. Type inference is a pretty big deal. If a column can be coerced to integer dtype without altering the contents, the parser will do so. Any non-numeric columns will come through as object dtype as with the rest of pandas objects.

### 25.1.18 Quoting and Escape Characters

Quotes (and other escape characters) in embedded fields can be handled in any number of ways. One way is to use backslashes; to properly parse this data, you should pass the `escapechar` option:

```
In [148]: data = 'a,b\n"hello, \\"Bob\\", nice to see you",5'

In [149]: print(data)
a,b
"hello, \"Bob\", nice to see you",5

In [150]: pd.read_csv(StringIO(data), escapechar='\\')
\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\Out[150]:
          a    b
0 hello, "Bob", nice to see you 5
```

### 25.1.19 Files with Fixed Width Columns

While `read_csv()` reads delimited data, the `read_fwf()` function works with data files that have known and fixed column widths. The function parameters to `read_fwf` are largely the same as `read_csv` with two extra parameters, and a different usage of the `delimiter` parameter:

- **colspecs**: A list of pairs (tuples) giving the extents of the fixed-width fields of each line as half-open intervals (i.e., [from, to[ ). String value 'infer' can be used to instruct the parser to try detecting the column specifications from the first 100 rows of the data. Default behavior, if not specified, is to infer.
- **widths**: A list of field widths which can be used instead of 'colspecs' if the intervals are contiguous.
- **delimiter**: Characters to consider as filler characters in the fixed-width file. Can be used to specify the filler character of the fields if it is not spaces (e.g., '~').

Consider a typical fixed-width data file:

```
In [151]: print(open('bar.csv').read())
```

|        |            |            |         |
|--------|------------|------------|---------|
| id8141 | 360.242940 | 149.910199 | 11950.7 |
| id1594 | 444.953632 | 166.985655 | 11788.4 |
| id1849 | 364.136849 | 183.628767 | 11806.2 |
| id1230 | 413.836124 | 184.375703 | 11916.8 |
| id1948 | 502.953953 | 173.237159 | 12468.3 |

In order to parse this file into a `DataFrame`, we simply need to supply the column specifications to the `read_fwf` function along with the file name:

```
# Column specifications are a list of half-intervals
In [152]: colspecs = [(0, 6), (8, 20), (21, 33), (34, 43)]

In [153]: df = pd.read_fwf('bar.csv', colspecs=colspecs, header=None, index_col=0)

In [154]: df
Out[154]:
```

|        | 1          | 2          | 3       |
|--------|------------|------------|---------|
| 0      |            |            |         |
| id8141 | 360.242940 | 149.910199 | 11950.7 |
| id1594 | 444.953632 | 166.985655 | 11788.4 |
| id1849 | 364.136849 | 183.628767 | 11806.2 |
| id1230 | 413.836124 | 184.375703 | 11916.8 |
| id1948 | 502.953953 | 173.237159 | 12468.3 |

Note how the parser automatically picks column names X.<column number> when `header=None` argument is specified. Alternatively, you can supply just the column widths for contiguous columns:

```
# Widths are a list of integers
In [155]: widths = [6, 14, 13, 10]

In [156]: df = pd.read_fwf('bar.csv', widths=widths, header=None)

In [157]: df
Out[157]:
```

|   | 0      | 1          | 2          | 3       |
|---|--------|------------|------------|---------|
| 0 | id8141 | 360.242940 | 149.910199 | 11950.7 |
| 1 | id1594 | 444.953632 | 166.985655 | 11788.4 |
| 2 | id1849 | 364.136849 | 183.628767 | 11806.2 |
| 3 | id1230 | 413.836124 | 184.375703 | 11916.8 |
| 4 | id1948 | 502.953953 | 173.237159 | 12468.3 |

The parser will take care of extra white spaces around the columns so it's ok to have extra separation between the columns in the file.

By default, `read_fwf` will try to infer the file's `colspecs` by using the first 100 rows of the file. It can do it only in cases when the columns are aligned and correctly separated by the provided `delimiter` (default delimiter is whitespace).

```
In [158]: df = pd.read_fwf('bar.csv', header=None, index_col=0)

In [159]: df
Out[159]:
```

|        | 1          | 2          | 3          |         |
|--------|------------|------------|------------|---------|
| 0      | id8141     | 360.242940 | 149.910199 | 11950.7 |
| id1594 | 444.953632 | 166.985655 | 11788.4    |         |
| id1849 | 364.136849 | 183.628767 | 11806.2    |         |
| id1230 | 413.836124 | 184.375703 | 11916.8    |         |
| id1948 | 502.953953 | 173.237159 | 12468.3    |         |

New in version 0.20.0.

`read_fwf` supports the `dtype` parameter for specifying the types of parsed columns to be different from the inferred type.

```
In [160]: pd.read_fwf('bar.csv', header=None, index_col=0).dtypes
Out[160]:
1    float64
2    float64
3    float64
dtype: object

In [161]: pd.read_fwf('bar.csv', header=None, dtype={2: 'object'}).dtypes
Out[161]:
0    object
1    float64
2    object
3    float64
dtype: object
```

## 25.1.20 Indexes

### 25.1.20.1 Files with an “implicit” index column

Consider a file with one less entry in the header than the number of data column:

```
In [162]: print(open('foo.csv').read())
A,B,C
20090101,a,1,2
20090102,b,3,4
20090103,c,4,5
```

In this special case, `read_csv` assumes that the first column is to be used as the index of the `DataFrame`:

```
In [163]: pd.read_csv('foo.csv')
Out[163]:
```

|          | A | B | C |
|----------|---|---|---|
| 20090101 | a | 1 | 2 |
| 20090102 | b | 3 | 4 |
| 20090103 | c | 4 | 5 |

Note that the dates weren’t automatically parsed. In that case you would need to do as before:

```
In [164]: df = pd.read_csv('foo.csv', parse_dates=True)

In [165]: df.index
Out[165]: DatetimeIndex(['2009-01-01', '2009-01-02', '2009-01-03'], dtype=
↳ 'datetime64[ns]', freq=None)
```

### 25.1.20.2 Reading an index with a `MultiIndex`

Suppose you have data indexed by two columns:

```
In [166]: print(open('data/minindex_ex.csv').read())
year,indiv,zit,xit
1977,"A",1.2,.6
1977,"B",1.5,.5
1977,"C",1.7,.8
1978,"A",.2,.06
1978,"B",.7,.2
1978,"C",.8,.3
1978,"D",.9,.5
1978,"E",1.4,.9
1979,"C",.2,.15
1979,"D",.14,.05
1979,"E",.5,.15
1979,"F",1.2,.5
1979,"G",3.4,1.9
1979,"H",5.4,2.7
1979,"I",6.4,1.2
```

The `index_col` argument to `read_csv` can take a list of column numbers to turn multiple columns into a `MultiIndex` for the index of the returned object:

```
In [167]: df = pd.read_csv("data/minindex_ex.csv", index_col=[0, 1])
```

(continues on next page)

(continued from previous page)

**In [168]:** df**Out[168]:**

|      |       | zit  | xit  |
|------|-------|------|------|
| year | indiv |      |      |
| 1977 | A     | 1.20 | 0.60 |
|      | B     | 1.50 | 0.50 |
|      | C     | 1.70 | 0.80 |
| 1978 | A     | 0.20 | 0.06 |
|      | B     | 0.70 | 0.20 |
|      | C     | 0.80 | 0.30 |
|      | D     | 0.90 | 0.50 |
|      | E     | 1.40 | 0.90 |
| 1979 | C     | 0.20 | 0.15 |
|      | D     | 0.14 | 0.05 |
|      | E     | 0.50 | 0.15 |
|      | F     | 1.20 | 0.50 |
|      | G     | 3.40 | 1.90 |
|      | H     | 5.40 | 2.70 |
|      | I     | 6.40 | 1.20 |

**In [169]:** df.loc[1978]

```

////////////////////////////////////

```

```

↪

```

|       | zit | xit  |
|-------|-----|------|
| indiv |     |      |
| A     | 0.2 | 0.06 |
| B     | 0.7 | 0.20 |
| C     | 0.8 | 0.30 |
| D     | 0.9 | 0.50 |
| E     | 1.4 | 0.90 |

### 25.1.20.3 Reading columns with a MultiIndex

By specifying list of row locations for the `header` argument, you can read in a `MultiIndex` for the columns. Specifying non-consecutive rows will skip the intervening rows.

**In [170]:** `from pandas.util.testing import makeCustomDataframe as mkdf`**In [171]:** `df = mkdf(5, 3, r_idx_nlevels=2, c_idx_nlevels=4)`**In [172]:** `df.to_csv('mi.csv')`**In [173]:** `print(open('mi.csv').read())`

```

C0,,C_10_g0,C_10_g1,C_10_g2
C1,,C_11_g0,C_11_g1,C_11_g2
C2,,C_12_g0,C_12_g1,C_12_g2
C3,,C_13_g0,C_13_g1,C_13_g2
R0,R1,,,
R_10_g0,R_11_g0,R0C0,R0C1,R0C2
R_10_g1,R_11_g1,R1C0,R1C1,R1C2
R_10_g2,R_11_g2,R2C0,R2C1,R2C2
R_10_g3,R_11_g3,R3C0,R3C1,R3C2
R_10_g4,R_11_g4,R4C0,R4C1,R4C2

```

(continues on next page)

(continued from previous page)

```
In [174]: pd.read_csv('mi.csv', header=[0, 1, 2, 3], index_col=[0, 1])
```

```

////////////////////////////////////
↪
C0          C_10_g0 C_10_g1 C_10_g2
C1          C_11_g0 C_11_g1 C_11_g2
C2          C_12_g0 C_12_g1 C_12_g2
C3          C_13_g0 C_13_g1 C_13_g2
R0          R1
R_10_g0 R_11_g0      R0C0      R0C1      R0C2
R_10_g1 R_11_g1      R1C0      R1C1      R1C2
R_10_g2 R_11_g2      R2C0      R2C1      R2C2
R_10_g3 R_11_g3      R3C0      R3C1      R3C2
R_10_g4 R_11_g4      R4C0      R4C1      R4C2

```

`read_csv` is also able to interpret a more common format of multi-columns indices.

```
In [175]: print(open('mi2.csv').read())
```

```

,a,a,a,b,c,c
,q,r,s,t,u,v
one,1,2,3,4,5,6
two,7,8,9,10,11,12

```

```
In [176]: pd.read_csv('mi2.csv', header=[0, 1], index_col=0)
```

```

////////////////////////////////////\Out[176]:
      a      b      c
q  r  s  t  u  v
one 1  2  3  4  5  6
two 7  8  9 10 11 12

```

Note: If an `index_col` is not specified (e.g. you don't have an index, or wrote it with `df.to_csv(..., index=False)`), then any names on the columns index will be *lost*.

### 25.1.21 Automatically “sniffing” the delimiter

`read_csv` is capable of inferring delimited (not necessarily comma-separated) files, as pandas uses the `csv.Sniffer` class of the `csv` module. For this, you have to specify `sep=None`.

```
In [177]: print(open('tmp2.csv').read())
```

```

## 25.1.22 Reading multiple files to create a single DataFrame

It's best to use `concat()` to combine multiple files. See the *cookbook* for an example.

## 25.1.23 Iterating through files chunk by chunk

Suppose you wish to iterate through a (potentially very large) file lazily rather than reading the entire file into memory, such as the following:

```
In [179]: print(open('tmp.csv').read())
|0|1|2|3
0|1.1214905765122583|-1.1011663421613171|-1.2725711408453018|0.8434589457722285
1|0.8739661419816901|-1.1622548707272122|0.12618578996106738|0.5057848504967111
2|0.6695152369722812|0.4833977900441433|-0.4383565886430891|-0.13952146077085656
3|1.6678766138462109|0.906356209978661|0.8603041052486606|-0.009413710135323125
4|-0.8075485015292924|-0.7848128653629299|-1.3155155066668116|0.6875244729698119
5|-0.1572352664979729|0.30339976035788174|-0.36340691002502046|-0.5526511482544121
6|0.41442095212262187|0.17517103850750262|-0.5295157789486404|-0.06745694327155764
7|1.058814717443789|-0.11789792502832808|-1.8534207864364352|-0.7018494437516053
8|0.26239634172416604|-1.7245959745828128|0.2765803759042711|1.0730241342647273

In [180]: table = pd.read_csv('tmp.csv', sep='|')

In [181]: table
Out[181]:
   Unnamed: 0      0      1      2      3
0          0  1.121491 -1.101166 -1.272571  0.843459
1          1  0.873966 -1.162255  0.126186  0.505785
2          2  0.669515  0.483398 -0.438357 -0.139521
3          3  1.667877  0.906356  0.860304 -0.009414
4          4 -0.807549 -0.784813 -1.315516  0.687524
5          5 -0.157235  0.303400 -0.363407 -0.552651
6          6  0.414421  0.175171 -0.529516 -0.067457
7          7  1.058815 -0.117898 -1.853421 -0.701849
8          8  0.262396 -1.724596  0.276580  1.073024
9          9  0.635285 -2.178548  0.312044  1.572378
```

By specifying a `chunksize` to `read_csv`, the return value will be an iterable object of type `TextFileReader`:

```
In [182]: reader = pd.read_csv('tmp.csv', sep='|', chunksize=4)

In [183]: reader
Out[183]: <pandas.io.parsers.TextFileReader at 0x7fd542e5ac18>

In [184]: for chunk in reader:
.....:     print(chunk)
.....:
```

|    | 0          | 1         | 2         | 3         | Unnamed: 0 |
|----|------------|-----------|-----------|-----------|------------|
| 0  | 0          | 1.121491  | -1.101166 | -1.272571 | 0.843459   |
| 1  | 1          | 0.873966  | -1.162255 | 0.126186  | 0.505785   |
| 2  | 2          | 0.669515  | 0.483398  | -0.438357 | -0.139521  |
| 3  | 3          | 1.667877  | 0.906356  | 0.860304  | -0.009414  |
| 4  | Unnamed: 0 | 0         | 1         | 2         | 3          |
| 5  | 4          | -0.807549 | -0.784813 | -1.315516 | 0.687524   |
| 6  | 5          | -0.157235 | 0.303400  | -0.363407 | -0.552651  |
| 7  | 6          | 0.414421  | 0.175171  | -0.529516 | -0.067457  |
| 8  | 7          | 1.058815  | -0.117898 | -1.853421 | -0.701849  |
| 9  | Unnamed: 0 | 0         | 1         | 2         | 3          |
| 10 | 8          | 0.262396  | -1.724596 | 0.276580  | 1.073024   |
| 11 | 9          | 0.635285  | -2.178548 | 0.312044  | 1.572378   |

Specifying `iterator=True` will also return the `TextFileReader` object:

```
In [185]: reader = pd.read_csv('tmp.csv', sep='|', iterator=True)

In [186]: reader.get_chunk(5)
Out[186]:
```

|   | 0 | 1         | 2         | 3         | Unnamed: 0 |
|---|---|-----------|-----------|-----------|------------|
| 0 | 0 | 1.121491  | -1.101166 | -1.272571 | 0.843459   |
| 1 | 1 | 0.873966  | -1.162255 | 0.126186  | 0.505785   |
| 2 | 2 | 0.669515  | 0.483398  | -0.438357 | -0.139521  |
| 3 | 3 | 1.667877  | 0.906356  | 0.860304  | -0.009414  |
| 4 | 4 | -0.807549 | -0.784813 | -1.315516 | 0.687524   |

### 25.1.24 Specifying the parser engine

Under the hood pandas uses a fast and efficient parser implemented in C as well as a Python implementation which is currently more feature-complete. Where possible pandas uses the C parser (specified as `engine='c'`), but may fall back to Python if C-unsupported options are specified. Currently, C-unsupported options include:

- `sep` other than a single character (e.g. regex separators)
- `skipfooter`
- `sep=None` with `delim_whitespace=False`

Specifying any of the above options will produce a `ParserWarning` unless the python engine is selected explicitly using `engine='python'`.

### 25.1.25 Reading remote files

You can pass in a URL to a CSV file:

```
df = pd.read_csv('https://download.bls.gov/pub/time.series/cu/cu.item',
                 sep='\t')
```

S3 URLs are handled as well but require installing the [S3Fs](#) library:

```
df = pd.read_csv('s3://pandas-test/tips.csv')
```

If your S3 bucket requires credentials you will need to set them as environment variables or in the `~/.aws/credentials` config file, refer to the [S3Fs documentation on credentials](#).

## 25.1.26 Writing out Data

### 25.1.26.1 Writing to CSV format

The `Series` and `DataFrame` objects have an instance method `to_csv` which allows storing the contents of the object as a comma-separated-values file. The function takes a number of arguments. Only the first is required.

- `path_or_buf`: A string path to the file to write or a `StringIO`
- `sep`: Field delimiter for the output file (default “,”)
- `na_rep`: A string representation of a missing value (default “”)
- `float_format`: Format string for floating point numbers
- `columns`: Columns to write (default `None`)
- `header`: Whether to write out the column names (default `True`)
- `index`: whether to write row (index) names (default `True`)
- `index_label`: Column label(s) for index column(s) if desired. If `None` (default), and `header` and `index` are `True`, then the index names are used. (A sequence should be given if the `DataFrame` uses `MultiIndex`).
- `mode`: Python write mode, default ‘w’
- `encoding`: a string representing the encoding to use if the contents are non-ASCII, for Python versions prior to 3
- `line_terminator`: Character sequence denoting line end (default ‘\n’)
- `quoting`: Set quoting rules as in `csv` module (default `csv.QUOTE_MINIMAL`). Note that if you have set a *float\_format* then floats are converted to strings and `csv.QUOTE_NONNUMERIC` will treat them as non-numeric
- `quotechar`: Character used to quote fields (default “”)
- `doublequote`: Control quoting of `quotechar` in fields (default `True`)
- `escapechar`: Character used to escape `sep` and `quotechar` when appropriate (default `None`)
- `chunksize`: Number of rows to write at a time
- `tupleize_cols`: If `False` (default), write as a list of tuples, otherwise write in an expanded line format suitable for `read_csv`
- `date_format`: Format string for datetime objects

### 25.1.26.2 Writing a formatted string

The `DataFrame` object has an instance method `to_string` which allows control over the string representation of the object. All arguments are optional:

- `buf` default `None`, for example a `StringIO` object
- `columns` default `None`, which columns to write
- `col_space` default `None`, minimum width of each column.
- `na_rep` default `NaN`, representation of NA value
- `formatters` default `None`, a dictionary (by column) of functions each of which takes a single argument and returns a formatted string
- `float_format` default `None`, a function which takes a single (float) argument and returns a formatted string; to be applied to floats in the `DataFrame`.
- `sparsify` default `True`, set to `False` for a `DataFrame` with a hierarchical index to print every `MultiIndex` key at each row.
- `index_names` default `True`, will print the names of the indices
- `index` default `True`, will print the index (ie, row labels)
- `header` default `True`, will print the column labels
- `justify` default `left`, will print column headers left- or right-justified

The `Series` object also has a `to_string` method, but with only the `buf`, `na_rep`, `float_format` arguments. There is also a `length` argument which, if set to `True`, will additionally output the length of the `Series`.

## 25.2 JSON

Read and write JSON format files and strings.

### 25.2.1 Writing JSON

A `Series` or `DataFrame` can be converted to a valid JSON string. Use `to_json` with optional parameters:

- `path_or_buf`: the pathname or buffer to write the output This can be `None` in which case a JSON string is returned
- `orient`:
  - Series:**
    - default is `index`
    - allowed values are `{split, records, index}`
  - DataFrame:**
    - default is `columns`
    - allowed values are `{split, records, index, columns, values, table}`

The format of the JSON string

|         |                                                                      |
|---------|----------------------------------------------------------------------|
| split   | dict like {index -> [index], columns -> [columns], data -> [values]} |
| records | list like [{column -> value}, ... , {column -> value}]               |
| index   | dict like {index -> {column -> value}}                               |
| columns | dict like {column -> {index -> value}}                               |
| values  | just the values array                                                |

- `date_format` : string, type of date conversion, 'epoch' for timestamp, 'iso' for ISO8601.
- `double_precision` : The number of decimal places to use when encoding floating point values, default 10.
- `force_ascii` : force encoded string to be ASCII, default True.
- `date_unit` : The time unit to encode to, governs timestamp and ISO8601 precision. One of 's', 'ms', 'us' or 'ns' for seconds, milliseconds, microseconds and nanoseconds respectively. Default 'ms'.
- `default_handler` : The handler to call if an object cannot otherwise be converted to a suitable format for JSON. Takes a single argument, which is the object to convert, and returns a serializable object.
- `lines` : If records orient, then will write each record per line as json.

Note NaN's, NaT's and None will be converted to null and datetime objects will be converted based on the `date_format` and `date_unit` parameters.

```
In [187]: dfj = pd.DataFrame(np.random.randn(5, 2), columns=list('AB'))
In [188]: json = dfj.to_json()
In [189]: json
Out[189]: '{"A":{"0":2.0027932898,"1":-1.1284197337,"2":-0.2671230751,"3":0.0590811856,"4":0.2126018166},"B":{"0":0.009310115,"1":-1.2591311739,"2":1.7549089729,"3":0.9464922966,"4":-0.5276761509}}'
```

### 25.2.1.1 Orient Options

There are a number of different options for the format of the resulting JSON file / string. Consider the following DataFrame and Series:

```
In [190]: dfjo = pd.DataFrame(dict(A=range(1, 4), B=range(4, 7), C=range(7, 10)),
.....:                        columns=list('ABC'), index=list('xyz'))
.....:
In [191]: dfjo
Out[191]:
   A  B  C
x  1  4  7
y  2  5  8
z  3  6  9

In [192]: sjo = pd.Series(dict(x=15, y=16, z=17), name='D')
In [193]: sjo
Out[193]:
x    15
y    16
```

(continues on next page)

(continued from previous page)

```
z      17
Name: D, dtype: int64
```

**Column oriented** (the default for `DataFrame`) serializes the data as nested JSON objects with column labels acting as the primary index:

```
In [194]: dfjo.to_json(orient="columns")
Out[194]: '{"A":{"x":1,"y":2,"z":3},"B":{"x":4,"y":5,"z":6},"C":{"x":7,"y":8,"z":9}}'
```

# Not available for Series

**Index oriented** (the default for `Series`) similar to column oriented but the index labels are now primary:

[illegible]

**Record oriented** serializes the data to a JSON array of column -> value records, index labels are not included. This is useful for passing `DataFrame` data to plotting libraries, for example the JavaScript library `d3.js`:

[illegible]

**Value oriented** is a bare-bones option which serializes to nested JSON arrays of values only, column and index labels are not included:

```
In [199]: dfjo.to_json(orient="values")
Out[199]: '[[1,4,7],[2,5,8],[3,6,9]]'

# Not available for Series
```

**Split oriented** serializes to a JSON object containing separate entries for values, index and columns. Name is also included for `Series`:

```
In [200]: dfjo.to_json(orient="split")
Out[200]: '{"columns":["A","B","C"],"index":["x","y","z"],"data":[[1,4,7],[2,5,8],[3,
↪6,9]]}'

In [201]: sjo.to_json(orient="split")
////////////////////////////////////////////////////////////////////////////////////////////////
↪ '{"name":"D","index":["x","y","z"],"data":[15,16,17]}'
```

**Table oriented** serializes to the JSON **Table Schema**, allowing for the preservation of metadata including but not limited to dtypes and index names.

**Note:** Any orient option that encodes to a JSON object will not preserve the ordering of index and column labels during round-trip serialization. If you wish to preserve label ordering use the *split* option as it uses ordered containers.

### 25.2.1.2 Date Handling

Writing in ISO date format:

```
In [202]: dfd = pd.DataFrame(np.random.randn(5, 2), columns=list('AB'))

In [203]: dfd['date'] = pd.Timestamp('20130101')

In [204]: dfd = dfd.sort_index(1, ascending=False)

In [205]: json = dfd.to_json(date_format='iso')

In [206]: json
Out[206]: '{"date":{"0":"2013-01-01T00:00:00.000Z","1":"2013-01-01T00:00:00.000Z","2":
↳ "2013-01-01T00:00:00.000Z","3":"2013-01-01T00:00:00.000Z","4":"2013-01-01T00:00:00.
↳ 000Z"},"B":{"0":0.3903383957,"1":-0.5223681486,"2":2.0249145293,"3":2.1144885256,"4
↳ ":0.5337588359},"A":{"0":-1.0954121534,"1":-0.147141856,"2":0.6305826658,"3":1.
↳ 5730764249,"4":0.6200376615}}'
```

Writing in ISO date format, with microseconds:

```
In [207]: json = dfd.to_json(date_format='iso', date_unit='us')

In [208]: json
Out[208]: '{"date":{"0":"2013-01-01T00:00:00.000000Z","1":"2013-01-01T00:00:00.000000Z
↳ ","2":"2013-01-01T00:00:00.000000Z","3":"2013-01-01T00:00:00.000000Z","4":"2013-01-
↳ 01T00:00:00.000000Z"},"B":{"0":0.3903383957,"1":-0.5223681486,"2":2.0249145293,"3
↳ ":2.1144885256,"4":0.5337588359},"A":{"0":-1.0954121534,"1":-0.147141856,"2":0.
↳ 6305826658,"3":1.5730764249,"4":0.6200376615}}'
```

Epoch timestamps, in seconds:

```
In [209]: json = dfd.to_json(date_format='epoch', date_unit='s')

In [210]: json
Out[210]: '{"date":{"0":1356998400,"1":1356998400,"2":1356998400,"3":1356998400,"4
↳ ":1356998400},"B":{"0":0.3903383957,"1":-0.5223681486,"2":2.0249145293,"3":2.
↳ 1144885256,"4":0.5337588359},"A":{"0":-1.0954121534,"1":-0.147141856,"2":0.
↳ 6305826658,"3":1.5730764249,"4":0.6200376615}}'
```

Writing to a file, with a date index and a date column:

```
In [211]: dfj2 = dfj.copy()

In [212]: dfj2['date'] = pd.Timestamp('20130101')

In [213]: dfj2['ints'] = list(range(5))

In [214]: dfj2['bools'] = True

In [215]: dfj2.index = pd.date_range('20130101', periods=5)

In [216]: dfj2.to_json('test.json')

In [217]: with open('test.json') as fh:
.....:     print(fh.read())
.....:
{"A":{"1356998400000":2.0027932898,"1357084800000":-1.1284197337,"1357171200000":-0.
↳ 2671230751,"1357257600000":0.0590811856,"1357344000000":0.2126018166},"B":{"1356998400000":0.009310115,"1357084800000":-1.2591311739,"1357171200000":1.
↳ 7549089729,"1357257600000":0.9464922966,"1357344000000":0.5276761509},"date":{"
↳ 1356998400000":1356998400000,"1357084800000":1356998400000,"1357171200000":
↳ 1356998400000,"1357257600000":1356998400000,"1357344000000":1356998400000},"ints":
↳ {"1356998400000":0,"1357084800000":1,"1357171200000":2,"1357257600000":3,
↳ "1357344000000":4},"bools":{"1356998400000":true,"1357084800000":true,"1357171200000
↳ ":true,"1357257600000":true,"1357344000000":true}}
```

### 25.2.1.3 Fallback Behavior

If the JSON serializer cannot handle the container contents directly it will fall back in the following manner:

- if the dtype is unsupported (e.g. `np.complex`) then the `default_handler`, if provided, will be called for each value, otherwise an exception is raised.
- if an object is unsupported it will attempt the following:
  - check if the object has defined a `toDict` method and call it. A `toDict` method should return a dict which will then be JSON serialized.
  - invoke the `default_handler` if one was provided.
  - convert the object to a dict by traversing its contents. However this will often fail with an `OverflowError` or give unexpected results.

In general the best approach for unsupported objects or dtypes is to provide a `default_handler`. For example:

```
>>> DataFrame([1.0, 2.0, complex(1.0, 2.0)]).to_json() # raises
RuntimeError: Unhandled numpy dtype 15
```

can be dealt with by specifying a simple `default_handler`:

```
In [218]: pd.DataFrame([1.0, 2.0, complex(1.0, 2.0)]).to_json(default_handler=str)
Out [218]: '{"0":{"0":"(1+0j)", "1":"(2+0j)", "2":"(1+2j)"} }'
```

## 25.2.2 Reading JSON

Reading a JSON string to pandas object can take a number of parameters. The parser will try to parse a `DataFrame` if `typ` is not supplied or is `None`. To explicitly force `Series` parsing, pass `typ=series`

- `filepath_or_buffer`: a **VALID** JSON string or file handle / `StringIO`. The string could be a URL. Valid URL schemes include `http`, `ftp`, `S3`, and `file`. For file URLs, a host is expected. For instance, a local file could be `file://localhost/path/to/table.json`
- `typ`: type of object to recover (series or frame), default 'frame'
- `orient`:

#### Series :

- default is `index`
- allowed values are `{split, records, index}`

#### DataFrame

- default is `columns`
- allowed values are `{split, records, index, columns, values, table}`

The format of the JSON string

|         |                                                                      |
|---------|----------------------------------------------------------------------|
| split   | dict like {index -> [index], columns -> [columns], data -> [values]} |
| records | list like [{column -> value}, ... , {column -> value}]               |
| index   | dict like {index -> {column -> value}}                               |
| columns | dict like {column -> {index -> value}}                               |
| values  | just the values array                                                |
| table   | adhering to the JSON <a href="#">Table Schema</a>                    |

- `dtype` : if `True`, infer dtypes, if a dict of column to dtype, then use those, if `False`, then don't infer dtypes at all, default is `True`, apply only to the data.
- `convert_axes` : boolean, try to convert the axes to the proper dtypes, default is `True`
- `convert_dates` : a list of columns to parse for dates; If `True`, then try to parse date-like columns, default is `True`.
- `keep_default_dates` : boolean, default `True`. If parsing dates, then parse the default date-like columns.
- `numpy` : direct decoding to NumPy arrays. default is `False`; Supports numeric data only, although labels may be non-numeric. Also note that the JSON ordering **MUST** be the same for each term if `numpy=True`.
- `precise_float` : boolean, default `False`. Set to enable usage of higher precision (`strtod`) function when decoding string to double values. Default (`False`) is to use fast but less precise builtin functionality.
- `date_unit` : string, the timestamp unit to detect if converting dates. Default `None`. By default the timestamp precision will be detected, if this is not desired then pass one of 's', 'ms', 'us' or 'ns' to force timestamp precision to seconds, milliseconds, microseconds or nanoseconds respectively.
- `lines` : reads file as one json object per line.
- `encoding` : The encoding to use to decode py3 bytes.
- `chunksize` : when used in combination with `lines=True`, return a `JsonReader` which reads in `chunksize` lines per iteration.

The parser will raise one of `ValueError/TypeError/AssertionError` if the JSON is not parseable.

If a non-default `orient` was used when encoding to JSON be sure to pass the same option here so that decoding produces sensible results, see *Orient Options* for an overview.

### 25.2.2.1 Data Conversion

The default of `convert_axes=True`, `dtype=True`, and `convert_dates=True` will try to parse the axes, and all of the data into appropriate types, including dates. If you need to override specific dtypes, pass a dict to `dtype`. `convert_axes` should only be set to `False` if you need to preserve string-like numbers (e.g. '1', '2') in an axes.

**Note:** Large integer values may be converted to dates if `convert_dates=True` and the data and / or column labels appear 'date-like'. The exact threshold depends on the `date_unit` specified. 'date-like' means that the column label meets one of the following criteria:

- it ends with '\_at'
- it ends with '\_time'
- it begins with 'timestamp'
- it is 'modified'
- it is 'date'

**Warning:** When reading JSON data, automatic coercing into dtypes has some quirks:

- an index can be reconstructed in a different order from serialization, that is, the returned order is not guaranteed to be the same as before serialization
- a column that was `float` data will be converted to `integer` if it can be done safely, e.g. a column of 1.
- `bool` columns will be converted to `integer` on reconstruction

Thus there are times where you may want to specify specific dtypes via the `dtype` keyword argument.

Reading from a JSON string:

```
In [219]: pd.read_json(json)
```

```
Out [219]:
```

|   | date       | B         | A         |
|---|------------|-----------|-----------|
| 0 | 2013-01-01 | 0.390338  | -1.095412 |
| 1 | 2013-01-01 | -0.522368 | -0.147142 |
| 2 | 2013-01-01 | 2.024915  | 0.630583  |
| 3 | 2013-01-01 | 2.114489  | 1.573076  |
| 4 | 2013-01-01 | 0.533759  | 0.620038  |

Reading from a file:

```
In [220]: pd.read_json('test.json')
```

```
Out [220]:
```

|            | A         | B         | date       | ints | bools |
|------------|-----------|-----------|------------|------|-------|
| 2013-01-01 | 2.002793  | 0.009310  | 2013-01-01 | 0    | True  |
| 2013-01-02 | -1.128420 | -1.259131 | 2013-01-01 | 1    | True  |
| 2013-01-03 | -0.267123 | 1.754909  | 2013-01-01 | 2    | True  |
| 2013-01-04 | 0.059081  | 0.946492  | 2013-01-01 | 3    | True  |
| 2013-01-05 | 0.212602  | -0.527676 | 2013-01-01 | 4    | True  |

Don't convert any data (but still convert axes and dates):

```
In [221]: pd.read_json('test.json', dtype=object).dtypes
```

```
Out [221]:
```

```
A      object
B      object
date    object
ints    object
bools   object
dtype: object
```

Specify dtypes for conversion:

```
In [222]: pd.read_json('test.json', dtype={'A': 'float32', 'bools': 'int8'}).dtypes
```

```
Out [222]:
```

```
A      float32
B      float64
date    datetime64[ns]
ints      int64
bools      int8
dtype: object
```

Preserve string indices:

```

In [223]: si = pd.DataFrame(np.zeros((4, 4)), columns=list(range(4)),
.....:                      index=[str(i) for i in range(4)])
.....:

In [224]: si
Out[224]:
   0    1    2    3
0  0.0  0.0  0.0  0.0
1  0.0  0.0  0.0  0.0
2  0.0  0.0  0.0  0.0
3  0.0  0.0  0.0  0.0

In [225]: si.index
\\////////////////////////////////////////////////////////////////////////////////////////////////////////////////////////////////////////////////////////////////////////////////////////////////////////////////////////////////////////////////////////////////Out [230]:
↪Index(['0', '1', '2', '3'], dtype='object')

In [226]: si.columns
\\////////////////////////////////////////////////////////////////////////////////////////////////////////////////////////////////////////////////////////////////////////////////////////////////////////////////////////////////////////////////////////////////
↪Int64Index([0, 1, 2, 3], dtype='int64')

In [227]: json = si.to_json()

In [228]: sij = pd.read_json(json, convert_axes=False)

In [229]: sij
Out[229]:
   0  1  2  3
0  0  0  0  0
1  0  0  0  0
2  0  0  0  0
3  0  0  0  0

In [230]: sij.index
\\////////////////////////////////////////////////////////////////////////////////////////////////////////////////////////////////////////////////////////////////////////////////////////////////////////////////////////////////////////////////////////////////Out [230]:
↪Index(['0', '1', '2', '3'], dtype='object')

In [231]: sij.columns
\\////////////////////////////////////////////////////////////////////////////////////////////////////////////////////////////////////////////////////////////////////////////////////////////////////////////////////////////////////////////////////////////////
↪Index(['0', '1', '2', '3'], dtype='object')

```

Dates written in nanoseconds need to be read back in nanoseconds:

```

In [232]: json = dfj2.to_json(date_unit='ns')

# Try to parse timestamps as milliseconds -> Won't Work
In [233]: dfju = pd.read_json(json, date_unit='ms')

In [234]: dfju
Out[234]:
           A           B           date  ints  bools
1356998400000000000  2.002793  0.009310  1356998400000000000    0   True
1357084800000000000 -1.128420 -1.259131  1356998400000000000    1   True
1357171200000000000 -0.267123  1.754909  1356998400000000000    2   True
1357257600000000000  0.059081  0.946492  1356998400000000000    3   True
1357344000000000000  0.212602 -0.527676  1356998400000000000    4   True

# Let pandas detect the correct precision

```

(continues on next page)

(continued from previous page)

```
In [235]: dfju = pd.read_json(json)

In [236]: dfju
Out[236]:
```

|            | A         | B         | date       | ints | bools |
|------------|-----------|-----------|------------|------|-------|
| 2013-01-01 | 2.002793  | 0.009310  | 2013-01-01 | 0    | True  |
| 2013-01-02 | -1.128420 | -1.259131 | 2013-01-01 | 1    | True  |
| 2013-01-03 | -0.267123 | 1.754909  | 2013-01-01 | 2    | True  |
| 2013-01-04 | 0.059081  | 0.946492  | 2013-01-01 | 3    | True  |
| 2013-01-05 | 0.212602  | -0.527676 | 2013-01-01 | 4    | True  |

```
# Or specify that all timestamps are in nanoseconds
In [237]: dfju = pd.read_json(json, date_unit='ns')

In [238]: dfju
Out[238]:
```

|            | A         | B         | date       | ints | bools |
|------------|-----------|-----------|------------|------|-------|
| 2013-01-01 | 2.002793  | 0.009310  | 2013-01-01 | 0    | True  |
| 2013-01-02 | -1.128420 | -1.259131 | 2013-01-01 | 1    | True  |
| 2013-01-03 | -0.267123 | 1.754909  | 2013-01-01 | 2    | True  |
| 2013-01-04 | 0.059081  | 0.946492  | 2013-01-01 | 3    | True  |
| 2013-01-05 | 0.212602  | -0.527676 | 2013-01-01 | 4    | True  |

### 25.2.2.2 The Numpy Parameter

**Note:** This supports numeric data only. Index and columns labels may be non-numeric, e.g. strings, dates etc.

If `numpy=True` is passed to `read_json` an attempt will be made to sniff an appropriate dtype during deserialization and to subsequently decode directly to NumPy arrays, bypassing the need for intermediate Python objects.

This can provide speedups if you are deserialising a large amount of numeric data:

```
In [239]: randfloats = np.random.uniform(-100, 1000, 10000)

In [240]: randfloats.shape = (1000, 10)

In [241]: dffloats = pd.DataFrame(randfloats, columns=list('ABCDEFGHIJ'))

In [242]: jsonfloats = dffloats.to_json()
```

```
In [243]: %timeit pd.read_json(jsonfloats)
11.1 ms +- 347 us per loop (mean +- std. dev. of 7 runs, 100 loops each)
```

```
In [244]: %timeit pd.read_json(jsonfloats, numpy=True)
8.36 ms +- 265 us per loop (mean +- std. dev. of 7 runs, 100 loops each)
```

The speedup is less noticeable for smaller datasets:

```
In [245]: jsonfloats = dffloats.head(100).to_json()
```

```
In [246]: %timeit pd.read_json(jsonfloats)
7.71 ms +- 163 us per loop (mean +- std. dev. of 7 runs, 100 loops each)
```

```
In [247]: %timeit pd.read_json(jsonfloats, numpy=True)
6.92 ms +- 441 us per loop (mean +- std. dev. of 7 runs, 100 loops each)
```

**Warning:** Direct NumPy decoding makes a number of assumptions and may fail or produce unexpected output if these assumptions are not satisfied:

- data is numeric.
- data is uniform. The dtype is sniffed from the first value decoded. A `ValueError` may be raised, or incorrect output may be produced if this condition is not satisfied.
- labels are ordered. Labels are only read from the first container, it is assumed that each subsequent row / column has been encoded in the same order. This should be satisfied if the data was encoded using `to_json` but may not be the case if the JSON is from another source.

### 25.2.3 Normalization

pandas provides a utility function to take a dict or list of dicts and *normalize* this semi-structured data into a flat table.

```
In [248]: from pandas.io.json import json_normalize
```

```
In [249]: data = [{'id': 1, 'name': {'first': 'Coleen', 'last': 'Volk'}},
.....:           {'name': {'given': 'Mose', 'family': 'Regner'}},
.....:           {'id': 2, 'name': 'Faye Raker'}]
.....:
```

```
In [250]: json_normalize(data)
```

```
Out[250]:
```

|   | id  | name       | name.family | name.first | name.given | name.last |
|---|-----|------------|-------------|------------|------------|-----------|
| 0 | 1.0 | NaN        | NaN         | Coleen     | NaN        | Volk      |
| 1 | NaN | NaN        | Regner      | NaN        | Mose       | NaN       |
| 2 | 2.0 | Faye Raker | NaN         | NaN        | NaN        | NaN       |

```
In [251]: data = [{'state': 'Florida',

## 25.2.4 Line delimited json

New in version 0.19.0.

pandas is able to read and write line-delimited json files that are common in data processing pipelines using Hadoop or Spark.

New in version 0.21.0.

For line-delimited json files, pandas can also return an iterator which reads in `chunksize` lines at a time. This can be useful for large files or to read from a stream.

```
In [253]: jsonl = '''
.....:      {"a": 1, "b": 2}
.....:      {"a": 3, "b": 4}
.....: '''
.....:

In [254]: df = pd.read_json(jsonl, lines=True)

In [255]: df
Out[255]:
   a  b
0  1  2
1  3  4

In [256]: df.to_json(orient='records', lines=True)
Out[256]: '{"a":1,"b":2}\n{"a":3,"b":4}'

# reader is an iterator that returns `chunksize` lines each iteration
In [257]: reader = pd.read_json(StringIO(jsonl), lines=True, chunksize=1)

In [258]: reader
Out[258]: <pandas.io.json.json.JsonReader at 0x7fd531df4e48>

In [259]: for chunk in reader:
.....:     print(chunk)
.....:
Empty DataFrame
Columns: []
Index: []
   a  b
0  1  2
   a  b
1  3  4
```

## 25.2.5 Table Schema

New in version 0.20.0.

[Table Schema](#) is a spec for describing tabular datasets as a JSON object. The JSON includes information on the field names, types, and other attributes. You can use the `orient=table` to build a JSON string with two fields, `schema` and `data`.

```
In [260]: df = pd.DataFrame({'A': [1, 2, 3],
.....:                      'B': ['a', 'b', 'c'],
.....:                      'C': pd.date_range('2016-01-01', freq='d', periods=3)},
```

(continues on next page)

(continued from previous page)

```

.....:
.....:
index=pd.Index(range(3), name='idx'))

In [261]: df
Out[261]:
   A  B      C
idx
0   1  a 2016-01-01
1   2  b 2016-01-02
2   3  c 2016-01-03

In [262]: df.to_json(orient='table', date_format="iso")
////////////////////////////////////
↪ '{"schema": {"fields":[{"name":"idx","type":"integer"}, {"name":"A","type":"integer"}
↪ , {"name":"B","type":"string"}, {"name":"C","type":"datetime"}], "primaryKey":["idx"],
↪ "pandas_version":"0.20.0"}, "data": [{"idx":0, "A":1, "B":"a", "C":"2016-01-
↪ 01T00:00:00.000Z"}, {"idx":1, "A":2, "B":"b", "C":"2016-01-02T00:00:00.000Z"}, {"idx":2,
↪ "A":3, "B":"c", "C":"2016-01-03T00:00:00.000Z"}]}'

```

The schema field contains the `fields` key, which itself contains a list of column name to type pairs, including the `Index` or `MultiIndex` (see below for a list of types). The schema field also contains a `primaryKey` field if the (Multi)index is unique.

The second field, `data`, contains the serialized data with the `records` orient. The index is included, and any datetimes are ISO 8601 formatted, as required by the Table Schema spec.

The full list of types supported are described in the Table Schema spec. This table shows the mapping from pandas types:

| Pandas type     | Table Schema type |
|-----------------|-------------------|
| int64           | integer           |
| float64         | number            |
| bool            | boolean           |
| datetime64[ns]  | datetime          |
| timedelta64[ns] | duration          |
| categorical     | any               |
| object          | str               |

A few notes on the generated table schema:

- The `schema` object contains a `pandas_version` field. This contains the version of pandas' dialect of the schema, and will be incremented with each revision.
- All dates are converted to UTC when serializing. Even timezone naive values, which are treated as UTC with an offset of 0.

```
In [263]: from pandas.io.json import build_table_schema

In [264]: s = pd.Series(pd.date_range('2016', periods=4))

In [265]: build_table_schema(s)
Out[265]:
{'fields': [{'name': 'index', 'type': 'integer'},
             {'name': 'values', 'type': 'datetime'}],
 'primaryKey': ['index'],
 'pandas_version': '0.20.0'}
```

- datetimes with a timezone (before serializing), include an additional field `tz` with the time zone name (e.g. 'US/Central').

```
In [266]: s_tz = pd.Series(pd.date_range('2016', periods=12,
.....:                                     tz='US/Central'))
.....:

In [267]: build_table_schema(s_tz)
Out[267]:
{'fields': [{'name': 'index', 'type': 'integer'},
             {'name': 'values', 'type': 'datetime', 'tz': 'US/Central'}],
 'primaryKey': ['index'],
 'pandas_version': '0.20.0'}
```

- Periods are converted to timestamps before serialization, and so have the same behavior of being converted to UTC. In addition, periods will contain an additional field `freq` with the period's frequency, e.g. 'A-DEC'.

```
In [268]: s_per = pd.Series(1, index=pd.period_range('2016', freq='A-DEC',
.....:                                               periods=4))
.....:

In [269]: build_table_schema(s_per)
Out[269]:
{'fields': [{'name': 'index', 'type': 'datetime', 'freq': 'A-DEC'},
             {'name': 'values', 'type': 'integer'}],
 'primaryKey': ['index'],
 'pandas_version': '0.20.0'}
```

- Categoricals use the any type and an enum constraint listing the set of possible values. Additionally, an ordered field is included:

```
In [270]: s_cat = pd.Series(pd.Categorical(['a', 'b', 'a']))

In [271]: build_table_schema(s_cat)
Out[271]:
{'fields': [{'name': 'index', 'type': 'integer'},
             {'name': 'values',
              'type': 'any',
              'constraints': {'enum': ['a', 'b']},
              'ordered': False}],
 'primaryKey': ['index'],
 'pandas_version': '0.20.0'}
```

- A `primaryKey` field, containing an array of labels, is included *if the index is unique*:

```
In [272]: s_dupe = pd.Series([1, 2], index=[1, 1])

In [273]: build_table_schema(s_dupe)
Out[273]:
{'fields': [{'name': 'index', 'type': 'integer'},
             {'name': 'values', 'type': 'integer'}],
 'pandas_version': '0.20.0'}
```

- The `primaryKey` behavior is the same with `MultiIndex`s, but in this case the `primaryKey` is an array:

```
In [274]: s_multi = pd.Series(1, index=pd.MultiIndex.from_product([('a', 'b'),
.....:                                                                (0, 1)]))
.....:
```

(continues on next page)

(continued from previous page)

```
In [275]: build_table_schema(s_multi)
Out[275]:
{'fields': [{'name': 'level_0', 'type': 'string'},
             {'name': 'level_1', 'type': 'integer'},
             {'name': 'values', 'type': 'integer'}],
 'primaryKey': FrozenList(['level_0', 'level_1']),
 'pandas_version': '0.20.0'}
```

- The default naming roughly follows these rules:
  - For series, the `object.name` is used. If that's none, then the name is values
  - For DataFrames, the stringified version of the column name is used
  - For Index (not MultiIndex), `index.name` is used, with a fallback to `index` if that is None.
  - For MultiIndex, `mi.names` is used. If any level has no name, then `level_<i>` is used.

New in version 0.23.0.

`read_json` also accepts `orient='table'` as an argument. This allows for the preservation of metadata such as dtypes and index names in a round-trippable manner.

```
In [276]: df = pd.DataFrame({'foo': [1, 2, 3, 4],
.....:                     'bar': ['a', 'b', 'c', 'd'],
.....:                     'baz': pd.date_range('2018-01-01', freq='d',
↳ periods=4),
.....:                     'qux': pd.Categorical(['a', 'b', 'c', 'c'])
.....:                     }, index=pd.Index(range(4), name='idx'))
.....:
```

```
In [277]: df
```

```
Out[277]:
   foo bar      baz qux
idx
0     1  a 2018-01-01  a
1     2  b 2018-01-02  b
2     3  c 2018-01-03  c
3     4  d 2018-01-04  c
```

```
In [278]: df.dtypes
```

```

////////////////////////////////////
↳
foo      int64
bar      object
baz      datetime64[ns]
qux      category
dtype: object
```

```
In [279]: df.to_json('test.json', orient='table')
```

```
In [280]: new_df = pd.read_json('test.json', orient='table')
```

```
In [281]: new_df
```

```
Out[281]:
   foo bar      baz qux
idx
0     1  a 2018-01-01  a
```

(continues on next page)

(continued from previous page)

```

1      2      b 2018-01-02      b
2      3      c 2018-01-03      c
3      4      d 2018-01-04      c

```

```
In [282]: new_df.dtypes
```

```

////////////////////////////////////
↪
foo      int64
bar      object
baz      datetime64[ns]
qux      category
dtype: object

```

Please note that the literal string ‘index’ as the name of an *Index* is not round-trippable, nor are any names beginning with ‘level\_’ within a *MultiIndex*. These are used by default in *DataFrame.to\_json()* to indicate missing values and the subsequent read cannot distinguish the intent.

```
In [283]: df.index.name = 'index'
```

```
In [284]: df.to_json('test.json', orient='table')
```

```
In [285]: new_df = pd.read_json('test.json', orient='table')
```

```
In [286]: print(new_df.index.name)
```

```
None
```

## 25.3 HTML

### 25.3.1 Reading HTML Content

**Warning:** We **highly encourage** you to read the *HTML Table Parsing gotchas* below regarding the issues surrounding the BeautifulSoup4/html5lib/lxml parsers.

The top-level `read_html()` function can accept an HTML string/file/URL and will parse HTML tables into list of pandas *DataFrames*. Let’s look at a few examples.

**Note:** `read_html` returns a list of *DataFrame* objects, even if there is only a single table contained in the HTML content.

Read a URL with no options:

```
In [287]: url = 'https://www.fdic.gov/bank/individual/failed/banklist.html'
```

```
In [288]: dfs = pd.read_html(url)
```

```
In [289]: dfs
```

```
Out[289]:
```

|       | Bank Name             | City         | ST           |  |

[505 rows x 7 columns]
```

---

**Note:** The following examples are not run by the IPython evaluator due to the fact that having so many network-accessing functions slows down the documentation build. If you spot an error or an example that doesn't run, please do not hesitate to report it over on [pandas GitHub issues page](#).

---

Read a URL and match a table that contains specific text:

```
match = 'Metcalf Bank'
df_list = pd.read_html(url, match=match)
```

Specify a header row (by default `<th>` or `<td>` elements located within a `<thead>` are used to form the column index, if multiple rows are contained within `<thead>` then a `MultiIndex` is created); if specified, the header row is taken from the data minus the parsed header elements (`<th>` elements).

```
dfs = pd.read_html(url, header=0)
```

Specify an index column:

```
dfs = pd.read_html(url, index_col=0)
```

Specify a number of rows to skip:

```
dfs = pd.read_html(url, skiprows=0)
```

Specify a number of rows to skip using a list (`xrange` (Python 2 only) works as well):

```
dfs = pd.read_html(url, skiprows=range(2))
```

Specify an HTML attribute:

```
dfs1 = pd.read_html(url, attrs={'id': 'table'})
dfs2 = pd.read_html(url, attrs={'class': 'sortable'})
print(np.array_equal(dfs1[0], dfs2[0])) # Should be True
```

Specify values that should be converted to NaN:

```
dfs = pd.read_html(url, na_values=['No Acquirer'])
```

New in version 0.19.

Specify whether to keep the default set of NaN values:

```
dfs = pd.read_html(url, keep_default_na=False)
```

New in version 0.19.

Specify converters for columns. This is useful for numerical text data that has leading zeros. By default columns that are numerical are cast to numeric types and the leading zeros are lost. To avoid this, we can convert these columns to strings.

```
url_mcc = 'https://en.wikipedia.org/wiki/Mobile_country_code'
dfs = pd.read_html(url_mcc, match='Telekom Albania', header=0,
                    converters={'MNC': str})
```

New in version 0.19.

Use some combination of the above:

```
dfs = pd.read_html(url, match='Metcalfe Bank', index_col=0)
```

Read in pandas to\_html output (with some loss of floating point precision):

```
df = pd.DataFrame(np.random.randn(2, 2))
s = df.to_html(float_format='{0:.40g}'.format)
dfin = pd.read_html(s, index_col=0)
```

The lxml backend will raise an error on a failed parse if that is the only parser you provide. If you only have a single parser you can provide just a string, but it is considered good practice to pass a list with one string if, for example, the function expects a sequence of strings. You may use:

```
dfs = pd.read_html(url, 'Metcalfe Bank', index_col=0, flavor=['lxml'])
```

Or you could pass flavor='lxml' without a list:

```
dfs = pd.read_html(url, 'Metcalfe Bank', index_col=0, flavor='lxml')
```

However, if you have bs4 and html5lib installed and pass None or ['lxml', 'bs4'] then the parse will most likely succeed. Note that *as soon as a parse succeeds, the function will return*.

```
dfs = pd.read_html(url, 'Metcalfe Bank', index_col=0, flavor=['lxml', 'bs4'])
```

## 25.3.2 Writing to HTML files

DataFrame objects have an instance method to\_html which renders the contents of the DataFrame as an HTML table. The function arguments are as in the method to\_string described above.

**Note:** Not all of the possible options for DataFrame.to\_html are shown here for brevity's sake. See to\_html() for the full set of options.

```
In [295]: df = pd.DataFrame(np.random.randn(2, 2))
```

```
In [296]: df
```

```
Out[296]:
           0           1
0 -1.050304  1.131622
1 -0.692581 -1.174172
```

```
In [297]: print(df.to_html()) # raw html
```

```
\\////////////////////////////////////////////////////////////////////////////////////////////////////////////////////////////////<table_
↪border="1" class="dataframe">
```

(continues on next page)

(continued from previous page)

```

<thead>
  <tr style="text-align: right;">
    <th></th>
    <th>0</th>
    <th>1</th>
  </tr>
</thead>
<tbody>
  <tr>
    <th>0</th>
    <td>-1.050304</td>
    <td>1.131622</td>
  </tr>
  <tr>
    <th>1</th>
    <td>-0.692581</td>
    <td>-1.174172</td>
  </tr>
</tbody>
</table>

```

HTML:

The columns argument will limit the columns shown:

```

In [298]: print(df.to_html(columns=[0]))
<table border="1" class="dataframe">
  <thead>
    <tr style="text-align: right;">
      <th></th>
      <th>0</th>
    </tr>
  </thead>
  <tbody>
    <tr>
      <th>0</th>
      <td>-1.050304</td>
    </tr>
    <tr>
      <th>1</th>
      <td>-0.692581</td>
    </tr>
  </tbody>
</table>

```

HTML:

float\_format takes a Python callable to control the precision of floating point values:

```

In [299]: print(df.to_html(float_format='{0:.10f}'.format))
<table border="1" class="dataframe">
  <thead>
    <tr style="text-align: right;">
      <th></th>
      <th>0</th>
      <th>1</th>
    </tr>

```

(continues on next page)

(continued from previous page)

```

</thead>
<tbody>
  <tr>
    <th>0</th>
    <td>-1.0503044154</td>
    <td>1.1316218324</td>
  </tr>
  <tr>
    <th>1</th>
    <td>-0.6925807265</td>
    <td>-1.1741715747</td>
  </tr>
</tbody>
</table>

```

HTML:

`bold_rows` will make the row labels bold by default, but you can turn that off:

```

In [300]: print(df.to_html(bold_rows=False))
<table border="1" class="dataframe">
  <thead>
    <tr style="text-align: right;">
      <th></th>
      <th>0</th>
      <th>1</th>
    </tr>
  </thead>
  <tbody>
    <tr>
      <td>0</td>
      <td>-1.050304</td>
      <td>1.131622</td>
    </tr>
    <tr>
      <td>1</td>
      <td>-0.692581</td>
      <td>-1.174172</td>
    </tr>
  </tbody>
</table>

```

The `classes` argument provides the ability to give the resulting HTML table CSS classes. Note that these classes are *appended* to the existing 'dataframe' class.

```

In [301]: print(df.to_html(classes=['awesome_table_class', 'even_more_awesome_class
→']))
<table border="1" class="dataframe awesome_table_class even_more_awesome_class">
  <thead>
    <tr style="text-align: right;">
      <th></th>
      <th>0</th>
      <th>1</th>
    </tr>
  </thead>
  <tbody>
    <tr>

```

(continues on next page)

(continued from previous page)

```

        <th>0</th>
        <td>-1.050304</td>
        <td>1.131622</td>
    </tr>
    <tr>
        <th>1</th>
        <td>-0.692581</td>
        <td>-1.174172</td>
    </tr>
</tbody>
</table>

```

The `render_links` argument provides the ability to add hyperlinks to cells that contain URLs.

New in version 0.24.

```

In [302]: url_df = pd.DataFrame({
.....:     'name': ['Python', 'Pandas'],
.....:     'url': ['https://www.python.org/', 'http://pandas.pydata.org']}})
.....:

In [303]: print(url_df.to_html(render_links=True))
<table border="1" class="dataframe">
  <thead>
    <tr style="text-align: right;">
      <th></th>
      <th>name</th>
      <th>url</th>
    </tr>
  </thead>
  <tbody>
    <tr>
      <th>0</th>
      <td>Python</td>

### 25.3.3 HTML Table Parsing Gotchas

There are some versioning issues surrounding the libraries that are used to parse HTML tables in the top-level pandas io function `read_html`.

#### Issues with `lxml`

- Benefits
  - `lxml` is very fast.
  - `lxml` requires Cython to install correctly.
- Drawbacks
  - `lxml` does *not* make any guarantees about the results of its parse *unless* it is given **strictly valid markup**.
  - In light of the above, we have chosen to allow you, the user, to use the `lxml` backend, but **this backend will use `html5lib` if `lxml` fails to parse**
  - It is therefore *highly recommended* that you install both `BeautifulSoup4` and `html5lib`, so that you will still get a valid result (provided everything else is valid) even if `lxml` fails.

#### Issues with `BeautifulSoup4` using `lxml` as a backend

- The above issues hold here as well since `BeautifulSoup4` is essentially just a wrapper around a parser backend.

#### Issues with `BeautifulSoup4` using `html5lib` as a backend

- Benefits
  - `html5lib` is far more lenient than `lxml` and consequently deals with *real-life markup* in a much saner way rather than just, e.g., dropping an element without notifying you.
  - `html5lib` *generates valid HTML5 markup from invalid markup automatically*. This is extremely important for parsing HTML tables, since it guarantees a valid document. However, that does NOT mean that it is “correct”, since the process of fixing markup does not have a single definition.
  - `html5lib` is pure Python and requires no additional build steps beyond its own installation.
- Drawbacks
  - The biggest drawback to using `html5lib` is that it is slow as molasses. However consider the fact that many tables on the web are not big enough for the parsing algorithm runtime to matter. It is more likely that the bottleneck will be in the process of reading the raw text from the URL over the web, i.e., IO (input-output). For very large tables, this might not be true.

## 25.4 Excel files

The `read_excel()` method can read Excel 2003 (`.xls`) and Excel 2007+ (`.xlsx`) files using the `xlrd` Python module. The `to_excel()` instance method is used for saving a `DataFrame` to Excel. Generally the semantics are similar to working with `csv` data. See the *cookbook* for some advanced strategies.

## 25.4.1 Reading Excel Files

In the most basic use-case, `read_excel` takes a path to an Excel file, and the `sheet_name` indicating which sheet to parse.

```
# Returns a DataFrame
pd.read_excel('path_to_file.xls', sheet_name='Sheet1')
```

### 25.4.1.1 ExcelFile class

To facilitate working with multiple sheets from the same file, the `ExcelFile` class can be used to wrap the file and can be passed into `read_excel`. There will be a performance benefit for reading multiple sheets as the file is read into memory only once.

```
xlsx = pd.ExcelFile('path_to_file.xls')
df = pd.read_excel(xlsx, 'Sheet1')
```

The `ExcelFile` class can also be used as a context manager.

```
with pd.ExcelFile('path_to_file.xls') as xls:
    df1 = pd.read_excel(xls, 'Sheet1')
    df2 = pd.read_excel(xls, 'Sheet2')
```

The `sheet_names` property will generate a list of the sheet names in the file.

The primary use-case for an `ExcelFile` is parsing multiple sheets with different parameters:

```
data = {}
# For when Sheet1's format differs from Sheet2
with pd.ExcelFile('path_to_file.xls') as xls:
    data['Sheet1'] = pd.read_excel(xls, 'Sheet1', index_col=None,
                                  na_values=['NA'])
    data['Sheet2'] = pd.read_excel(xls, 'Sheet2', index_col=1)
```

Note that if the same parsing parameters are used for all sheets, a list of sheet names can simply be passed to `read_excel` with no loss in performance.

```
# using the ExcelFile class
data = {}
with pd.ExcelFile('path_to_file.xls') as xls:
    data['Sheet1'] = pd.read_excel(xls, 'Sheet1', index_col=None,
                                  na_values=['NA'])
    data['Sheet2'] = pd.read_excel(xls, 'Sheet2', index_col=None,
                                  na_values=['NA'])

# equivalent using the read_excel function
data = pd.read_excel('path_to_file.xls', ['Sheet1', 'Sheet2'],
                    index_col=None, na_values=['NA'])
```

### 25.4.1.2 Specifying Sheets

---

**Note:** The second argument is `sheet_name`, not to be confused with `ExcelFile.sheet_names`.

---

---

**Note:** An `ExcelFile`'s attribute `sheet_names` provides access to a list of sheets.

---

- The arguments `sheet_name` allows specifying the sheet or sheets to read.
- The default value for `sheet_name` is 0, indicating to read the first sheet
- Pass a string to refer to the name of a particular sheet in the workbook.
- Pass an integer to refer to the index of a sheet. Indices follow Python convention, beginning at 0.
- Pass a list of either strings or integers, to return a dictionary of specified sheets.
- Pass a `None` to return a dictionary of all available sheets.

```
# Returns a DataFrame
pd.read_excel('path_to_file.xls', 'Sheet1', index_col=None, na_values=['NA'])
```

Using the sheet index:

```
# Returns a DataFrame
pd.read_excel('path_to_file.xls', 0, index_col=None, na_values=['NA'])
```

Using all default values:

```
# Returns a DataFrame
pd.read_excel('path_to_file.xls')
```

Using `None` to get all sheets:

```
# Returns a dictionary of DataFrames
pd.read_excel('path_to_file.xls', sheet_name=None)
```

Using a list to get multiple sheets:

```
# Returns the 1st and 4th sheet, as a dictionary of DataFrames.
pd.read_excel('path_to_file.xls', sheet_name=['Sheet1', 3])
```

`read_excel` can read more than one sheet, by setting `sheet_name` to either a list of sheet names, a list of sheet positions, or `None` to read all sheets. Sheets can be specified by sheet index or sheet name, using an integer or string, respectively.

### 25.4.1.3 Reading a `MultiIndex`

`read_excel` can read a `MultiIndex` index, by passing a list of columns to `index_col` and a `MultiIndex` column by passing a list of rows to `header`. If either the index or columns have serialized level names those will be read in as well by specifying the rows/columns that make up the levels.

For example, to read in a `MultiIndex` index without names:

```
In [307]: df = pd.DataFrame({'a': [1, 2, 3, 4], 'b': [5, 6, 7, 8]},
.....:                      index=pd.MultiIndex.from_product([['a', 'b'], ['c', 'd
↳ ']]))
.....:

In [308]: df.to_excel('path_to_file.xlsx')

In [309]: df = pd.read_excel('path_to_file.xlsx', index_col=[0, 1])
```

(continues on next page)

(continued from previous page)

```
In [310]: df
Out[310]:
```

|     | a | b |
|-----|---|---|
| a c | 1 | 5 |
| d   | 2 | 6 |
| b c | 3 | 7 |
| d   | 4 | 8 |

If the index has level names, they will be parsed as well, using the same parameters.

```
In [311]: df.index = df.index.set_names(['lvl1', 'lvl2'])
In [312]: df.to_excel('path_to_file.xlsx')
In [313]: df = pd.read_excel('path_to_file.xlsx', index_col=[0, 1])

In [314]: df
Out[314]:
```

| lvl1 | lvl2 | a | b |
|------|------|---|---|
| a    | c    | 1 | 5 |
|      | d    | 2 | 6 |
| b    | c    | 3 | 7 |
|      | d    | 4 | 8 |

If the source file has both MultiIndex index and columns, lists specifying each should be passed to `index_col` and `header`:

```
In [315]: df.columns = pd.MultiIndex.from_product(['a', 'b', 'd'],
.....:                                           names=['c1', 'c2'])
.....:

In [316]: df.to_excel('path_to_file.xlsx')

In [317]: df = pd.read_excel('path_to_file.xlsx', index_col=[0, 1], header=[0, 1])

In [318]: df
Out[318]:
```

| c1   | a    |     |
|------|------|-----|
| c2   | b    | d   |
| lvl1 | lvl2 |     |
| a    | c    | 1 5 |
|      | d    | 2 6 |
| b    | c    | 3 7 |
|      | d    | 4 8 |

#### 25.4.1.4 Parsing Specific Columns

It is often the case that users will insert columns to do temporary computations in Excel and you may not want to read in those columns. `read_excel` takes a `usecols` keyword to allow you to specify a subset of columns to parse.

Deprecated since version 0.24.0.

Passing in an integer for `usecols` has been deprecated. Please pass in a list of ints from 0 to `usecols` inclusive instead.

If `usecols` is an integer, then it is assumed to indicate the last column to be parsed.

```
pd.read_excel('path_to_file.xls', 'Sheet1', usecols=2)
```

You can also specify a comma-delimited set of Excel columns and ranges as a string:

```
pd.read_excel('path_to_file.xls', 'Sheet1', usecols='A,C:E')
```

If `usecols` is a list of integers, then it is assumed to be the file column indices to be parsed.

```
pd.read_excel('path_to_file.xls', 'Sheet1', usecols=[0, 2, 3])
```

Element order is ignored, so `usecols=[0, 1]` is the same as `[1, 0]`.

New in version 0.24.

If `usecols` is a list of strings, it is assumed that each string corresponds to a column name provided either by the user in names or inferred from the document header row(s). Those strings define which columns will be parsed:

```
pd.read_excel('path_to_file.xls', 'Sheet1', usecols=['foo', 'bar'])
```

Element order is ignored, so `usecols=['baz', 'joe']` is the same as `['joe', 'baz']`.

New in version 0.24.

If `usecols` is callable, the callable function will be evaluated against the column names, returning names where the callable function evaluates to `True`.

```
pd.read_excel('path_to_file.xls', 'Sheet1', usecols=lambda x: x.isalpha())
```

### 25.4.1.5 Parsing Dates

Datetime-like values are normally automatically converted to the appropriate dtype when reading the excel file. But if you have a column of strings that *look* like dates (but are not actually formatted as dates in excel), you can use the `parse_dates` keyword to parse those strings to datetimes:

```
pd.read_excel('path_to_file.xls', 'Sheet1', parse_dates=['date_strings'])
```

### 25.4.1.6 Cell Converters

It is possible to transform the contents of Excel cells via the `converters` option. For instance, to convert a column to boolean:

```
pd.read_excel('path_to_file.xls', 'Sheet1', converters={'MyBools': bool})
```

This options handles missing values and treats exceptions in the converters as missing data. Transformations are applied cell by cell rather than to the column as a whole, so the array dtype is not guaranteed. For instance, a column of integers with missing values cannot be transformed to an array with integer dtype, because `NaN` is strictly a float. You can manually mask missing data to recover integer dtype:

```
def cfun(x):
    return int(x) if x else -1

pd.read_excel('path_to_file.xls', 'Sheet1', converters={'MyInts': cfun})
```

### 25.4.1.7 dtype Specifications

New in version 0.20.

As an alternative to converters, the type for an entire column can be specified using the *dtype* keyword, which takes a dictionary mapping column names to types. To interpret data with no type inference, use the type `str` or `object`.

```
pd.read_excel('path_to_file.xls', dtype={'MyInts': 'int64', 'MyText': str})
```

## 25.4.2 Writing Excel Files

### 25.4.2.1 Writing Excel Files to Disk

To write a `DataFrame` object to a sheet of an Excel file, you can use the `to_excel` instance method. The arguments are largely the same as `to_csv` described above, the first argument being the name of the excel file, and the optional second argument the name of the sheet to which the `DataFrame` should be written. For example:

```
df.to_excel('path_to_file.xlsx', sheet_name='Sheet1')
```

Files with a `.xls` extension will be written using `xlwt` and those with a `.xlsx` extension will be written using `xlsxwriter` (if available) or `openpyxl`.

The `DataFrame` will be written in a way that tries to mimic the REPL output. The `index_label` will be placed in the second row instead of the first. You can place it in the first row by setting the `merge_cells` option in `to_excel()` to `False`:

```
df.to_excel('path_to_file.xlsx', index_label='label', merge_cells=False)
```

In order to write separate `DataFrames` to separate sheets in a single Excel file, one can pass an `ExcelWriter`.

```
with pd.ExcelWriter('path_to_file.xlsx') as writer:
    df1.to_excel(writer, sheet_name='Sheet1')
    df2.to_excel(writer, sheet_name='Sheet2')
```

**Note:** Wringing a little more performance out of `read_excel` Internally, Excel stores all numeric data as floats. Because this can produce unexpected behavior when reading in data, pandas defaults to trying to convert integers to floats if it doesn't lose information (`1.0 --> 1`). You can pass `convert_float=False` to disable this behavior, which may give a slight performance improvement.

### 25.4.2.2 Writing Excel Files to Memory

Pandas supports writing Excel files to buffer-like objects such as `StringIO` or `BytesIO` using `ExcelWriter`.

```
# Safe import for either Python 2.x or 3.x
try:
    from io import BytesIO
except ImportError:
    from cStringIO import StringIO as BytesIO

bio = BytesIO()

# By setting the 'engine' in the ExcelWriter constructor.
```

(continues on next page)

(continued from previous page)

```
writer = pd.ExcelWriter(bio, engine='xlsxwriter')
df.to_excel(writer, sheet_name='Sheet1')

# Save the workbook
writer.save()

# Seek to the beginning and read to copy the workbook to a variable in memory
bio.seek(0)
workbook = bio.read()
```

---

**Note:** engine is optional but recommended. Setting the engine determines the version of workbook produced. Setting engine='xlrd' will produce an Excel 2003-format workbook (xls). Using either 'openpyxl' or 'xlsxwriter' will produce an Excel 2007-format workbook (xlsx). If omitted, an Excel 2007-formatted workbook is produced.

---

### 25.4.3 Excel writer engines

Pandas chooses an Excel writer via two methods:

1. the engine keyword argument
2. the filename extension (via the default specified in config options)

By default, pandas uses the `XlsxWriter` for `.xlsx`, `openpyxl` for `.xlsm`, and `xlwt` for `.xls` files. If you have multiple engines installed, you can set the default engine through *setting the config options* `io.excel.xlsx.writer` and `io.excel.xls.writer`. pandas will fall back on `openpyxl` for `.xlsx` files if `XlsxWriter` is not available.

To specify which writer you want to use, you can pass an engine keyword argument to `to_excel` and to `ExcelWriter`. The built-in engines are:

- openpyxl: version 2.4 or higher is required
- xlsxwriter
- xlwt

```
# By setting the 'engine' in the DataFrame and Panel 'to_excel()' methods.
df.to_excel('path_to_file.xlsx', sheet_name='Sheet1', engine='xlsxwriter')

# By setting the 'engine' in the ExcelWriter constructor.
writer = pd.ExcelWriter('path_to_file.xlsx', engine='xlsxwriter')

# Or via pandas configuration.
from pandas import options                                     # noqa: E402
options.io.excel.xlsx.writer = 'xlsxwriter'

df.to_excel('path_to_file.xlsx', sheet_name='Sheet1')
```

### 25.4.4 Style and Formatting

The look and feel of Excel worksheets created from pandas can be modified using the following parameters on the `DataFrame`'s `to_excel` method.

- float\_format : Format string for floating point numbers (default None).

- `freeze_panes` : A tuple of two integers representing the bottommost row and rightmost column to freeze. Each of these parameters is one-based, so (1, 1) will freeze the first row and first column (default `None`).

## 25.5 Clipboard

A handy way to grab data is to use the `read_clipboard()` method, which takes the contents of the clipboard buffer and passes them to the `read_csv` method. For instance, you can copy the following text to the clipboard (CTRL-C on many operating systems):

|   |   |   |   |
|---|---|---|---|
|   | A | B | C |
| x | 1 | 4 | p |
| y | 2 | 5 | q |
| z | 3 | 6 | r |

And then import the data directly to a `DataFrame` by calling:

```
clipdf = pd.read_clipboard()
```

```
In [319]: clipdf
Out[319]:
```

|   | A | B | C |
|---|---|---|---|
| x | 1 | 4 | p |
| y | 2 | 5 | q |
| z | 3 | 6 | r |

The `to_clipboard` method can be used to write the contents of a `DataFrame` to the clipboard. Following which you can paste the clipboard contents into other applications (CTRL-V on many operating systems). Here we illustrate writing a `DataFrame` into clipboard and reading it back.

[illegible]

(continues on next page)

(continued from previous page)

```

129         if PY2:
130             text = text.decode('utf-8')
--> 131         clipboard_set(text)
132         return
133     except TypeError:

/pandas/pandas/io/clipboard/clipboards.py in __call__(self, *args, **kwargs)
134
135     def __call__(self, *args, **kwargs):
--> 136         raise PyperclipException(EXCEPT_MSG)
137
138         if PY2:

PyperclipException:
Pyperclip could not find a copy/paste mechanism for your system.
For more information, please visit https://pyperclip.readthedocs.org

In [323]: pd.read_clipboard()
////////////////////////////////////
-----
PyperclipException                                Traceback (most recent call last)
<ipython-input-323-8cbad928c47b> in <module>
----> 1 pd.read_clipboard()

/pandas/pandas/io/clipboard/clipboards.py in read_clipboard(sep, **kwargs)
35     from pandas.io.clipboard import clipboard_get
36     from pandas.io.parsers import read_csv
--> 37     text = clipboard_get()
38
39     # try to decode (if needed on PY3)

/pandas/pandas/io/clipboard/clipboards.py in __call__(self, *args, **kwargs)
134
135     def __call__(self, *args, **kwargs):
--> 136         raise PyperclipException(EXCEPT_MSG)
137
138         if PY2:

PyperclipException:
Pyperclip could not find a copy/paste mechanism for your system.
For more information, please visit https://pyperclip.readthedocs.org

```

We can see that we got the same content back, which we had earlier written to the clipboard.

---

**Note:** You may need to install `xclip` or `xsel` (with `gtk`, `PyQt5`, `PyQt4` or `qtpy`) on Linux to use these methods.

---

## 25.6 Pickling

All pandas objects are equipped with `to_pickle` methods which use Python's `cPickle` module to save data structures to disk using the pickle format.

```

In [324]: df
Out[324]:

```

(continues on next page)

(continued from previous page)

```

      0      1      2
0 -0.053113  0.348832 -0.162729
1 -1.269943 -0.481824 -0.235455
2 -0.487288  2.083314 -0.237314
3  1.106767  1.355168  0.178975
4 -0.047906 -0.719700  1.016059

```

```
In [325]: df.to_pickle('foo.pkl')
```

The `read_pickle` function in the pandas namespace can be used to load any pickled pandas object (or any other pickled object) from file:

```
In [326]: pd.read_pickle('foo.pkl')
```

```
Out[326]:
```

```

      0      1      2
0 -0.053113  0.348832 -0.162729
1 -1.269943 -0.481824 -0.235455
2 -0.487288  2.083314 -0.237314
3  1.106767  1.355168  0.178975
4 -0.047906 -0.719700  1.016059

```

**Warning:** Loading pickled data received from untrusted sources can be unsafe.

See: <https://docs.python.org/3/library/pickle.html>

**Warning:** Several internal refactoring have been done while still preserving compatibility with pickles created with older versions of pandas. However, for such cases, pickled `DataFrames`, `Series` etc, must be read with `pd.read_pickle`, rather than `pickle.load`.

See [here](#) and [here](#) for some examples of compatibility-breaking changes. See [this question](#) for a detailed explanation.

## 25.6.1 Compressed pickle files

New in version 0.20.0.

`read_pickle()`, `DataFrame.to_pickle()` and `Series.to_pickle()` can read and write compressed pickle files. The compression types of `gzip`, `bz2`, `xz` are supported for reading and writing. The `zip` file format only supports reading and must contain only one data file to be read.

The compression type can be an explicit parameter or be inferred from the file extension. If 'infer', then use `gzip`, `bz2`, `zip`, or `xz` if filename ends in `'.gz'`, `'.bz2'`, `'.zip'`, or `'.xz'`, respectively.

```
In [327]: df = pd.DataFrame({
.....:     'A': np.random.randn(1000),
.....:     'B': 'foo',
.....:     'C': pd.date_range('20130101', periods=1000, freq='s')})
.....:
```

```
In [328]: df
```

```
Out[328]:
```

```

      A      B      C

```

(continues on next page)

(continued from previous page)

```

## 25.7 msgpack

pandas supports the msgpack format for object serialization. This is a lightweight portable binary format, similar to binary JSON, that is highly space efficient, and provides good performance both on the writing (serialization), and reading (deserialization).

**Warning:** This is a very new feature of pandas. We intend to provide certain optimizations in the io of the msgpack data. Since this is marked as an EXPERIMENTAL LIBRARY, the storage format may not be stable until a future release.

```

In [341]: df = pd.DataFrame(np.random.rand(5, 2), columns=list('AB'))
In [342]: df.to_msgpack('foo.msg')
In [343]: pd.read_msgpack('foo.msg')
Out[343]:
      A      B
0  0.459984  0.554090
1  0.948600  0.694894
2  0.526870  0.845380
3  0.165345  0.493407
4  0.722574  0.248189

In [344]: s = pd.Series(np.random.rand(5), index=pd.date_range('20130101', periods=5))

```

You can pass a list of objects and you will receive them back on deserialization.

```

In [345]: pd.to_msgpack('foo.msg', df, 'foo', np.array([1, 2, 3]), s)
In [346]: pd.read_msgpack('foo.msg')
Out[346]:
[
      A      B
0  0.459984  0.554090
1  0.948600  0.694894
2  0.526870  0.845380
3  0.165345  0.493407
4  0.722574  0.248189, 'foo', array([1, 2, 3]), 2013-01-01    0.774451
2013-01-02    0.059825
2013-01-03    0.245682
2013-01-04    0.537556
2013-01-05    0.844230
Freq: D, dtype: float64]

```

You can pass `iterator=True` to iterate over the unpacked results:

```
In [347]: for o in pd.read_msgpack('foo.msg', iterator=True):
.....:     print(o)
.....:
```

|   | A        | B        |
|---|----------|----------|
| 0 | 0.459984 | 0.554090 |
| 1 | 0.948600 | 0.694894 |
| 2 | 0.526870 | 0.845380 |
| 3 | 0.165345 | 0.493407 |
| 4 | 0.722574 | 0.248189 |

```
foo
[1 2 3]
2013-01-01    0.774451
2013-01-02    0.059825
2013-01-03    0.245682
2013-01-04    0.537556
2013-01-05    0.844230
Freq: D, dtype: float64
```

You can pass `append=True` to the writer to append to an existing pack:

```
In [348]: df.to_msgpack('foo.msg', append=True)

In [349]: pd.read_msgpack('foo.msg')
Out[349]:
```

|   | A        | B        |
|---|----------|----------|
| 0 | 0.459984 | 0.554090 |
| 1 | 0.948600 | 0.694894 |
| 2 | 0.526870 | 0.845380 |
| 3 | 0.165345 | 0.493407 |
| 4 | 0.722574 | 0.248189 |

```
'foo', array([1, 2, 3]), 2013-01-01    0.774451
2013-01-02    0.059825
2013-01-03    0.245682
2013-01-04    0.537556
2013-01-05    0.844230
Freq: D, dtype: float64,
A      B
0  0.459984  0.554090
1  0.948600  0.694894
2  0.526870  0.845380
3  0.165345  0.493407
4  0.722574  0.248189]
```

Unlike other io methods, `to_msgpack` is available on both a per-object basis, `df.to_msgpack()` and using the top-level `pd.to_msgpack(...)` where you can pack arbitrary collections of Python lists, dicts, scalars, while intermixing pandas objects.

```
In [350]: pd.to_msgpack('foo2.msg', {'dict': [{'df': df}, {'string': 'foo'},
.....:                                     {'scalar': 1.}, {'s': s}])
.....:
```

```
In [351]: pd.read_msgpack('foo2.msg')
Out[351]:
```

```
{'dict': ({'df':
0  0.459984  0.554090
1  0.948600  0.694894
2  0.526870  0.845380
3  0.165345  0.493407
```

(continues on next page)

(continued from previous page)

```

4  0.722574  0.248189},
{'string': 'foo'},
{'scalar': 1.0},
{'s': 2013-01-01    0.774451
2013-01-02    0.059825
2013-01-03    0.245682
2013-01-04    0.537556
2013-01-05    0.844230
Freq: D, dtype: float64}}

```

## 25.7.1 Read/Write API

Msgpacks can also be read from and written to strings.

```

In [352]: df.to_msgpack()
Out [352]: b'\x84\xa3typ\xadbloc_
↪manager\xa5klass\xa9DataFrame\xa4axes\x92\x86\xa3typ\xa5index\xa5klass\xa5Index\xa4name\xc0\xa5dtype
↪index\xa5klass\xaaRangeIndex\xa4name\xc0\xa5start\x00\xa4stop\x05\xa4step\x01\xa6blocks\x91\x86\xa
↪\xb0v\xa34\xeeZ\xee?\xf7\xe6\xd7\xd7\x1d\xdc\xe0?(Y\xf21\x04*\xc5?\xf7\x00
↪"\xe5R\x1f\xe7?\xa2\x9d\x13[\x1a\xbb\xe1?R&h8\x93<\xe6?P8\xe0@[\r\xeb?
↪\nM\xff\xba\xfb\x93\xdf?\xe0\xd52\x99\xaa\xc4\xcf?
↪\xa5shape\x92\x02\x05\xa5dtype\xa7float64\xa5klass\xaaFloatBlock\xa8compress\xc0'

```

Furthermore you can concatenate the strings to produce a list of the original objects.

```

In [353]: pd.read_msgpack(df.to_msgpack() + s.to_msgpack())
Out [353]:
[
  A      B
0  0.459984  0.554090
1  0.948600  0.694894
2  0.526870  0.845380
3  0.165345  0.493407
4  0.722574  0.248189, 2013-01-01    0.774451
2013-01-02    0.059825
2013-01-03    0.245682
2013-01-04    0.537556
2013-01-05    0.844230
Freq: D, dtype: float64]

```

## 25.8 HDF5 (PyTables)

`HDFStore` is a dict-like object which reads and writes pandas using the high performance HDF5 format using the excellent [PyTables](#) library. See the *cookbook* for some advanced strategies

**Warning:** pandas requires `PyTables >= 3.0.0`. There is a indexing bug in `PyTables < 3.2` which may appear when querying stores using an index. If you see a subset of results being returned, upgrade to `PyTables >= 3.2`. Stores created previously will need to be rewritten using the updated version.

```

In [354]: store = pd.HDFStore('store.h5')

```

(continues on next page)

(continued from previous page)

```
In [355]: print(store)
<class 'pandas.io.pytables.HDFStore'>
File path: store.h5
```

Objects can be written to the file just like adding key-value pairs to a dict:

```
In [356]: index = pd.date_range('1/1/2000', periods=8)

In [357]: s = pd.Series(np.random.randn(5), index=['a', 'b', 'c', 'd', 'e'])

In [358]: df = pd.DataFrame(np.random.randn(8, 3), index=index,
.....:                      columns=['A', 'B', 'C'])
.....:

In [359]: wp = pd.Panel(np.random.randn(2, 5, 4), items=['Item1', 'Item2'],
.....:                  major_axis=pd.date_range('1/1/2000', periods=5),
.....:                  minor_axis=['A', 'B', 'C', 'D'])
.....:

# store.put('s', s) is an equivalent method
In [360]: store['s'] = s

In [361]: store['df'] = df

In [362]: store['wp'] = wp

# the type of stored data
In [363]: store.root.wp._v_attrs.pandas_type
Out[363]: 'wide'

In [364]: store
\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\Out[364]:
<class 'pandas.io.pytables.HDFStore'>
File path: store.h5
```

In a current or later Python session, you can retrieve stored objects:

```
# store.get('df') is an equivalent method
In [365]: store['df']
Out[365]:
```

|            | A         | B         | C         |
|------------|-----------|-----------|-----------|
| 2000-01-01 | -0.274852 | -0.667027 | -0.688782 |

| 2000-01-03 | -0.999591 | -0.320658 | -1.922640 |
| 2000-01-04 | 0.894171  | -1.539066 | -0.114019 |
| 2000-01-05 | 0.780874  | 0.757320  | -2.110838 |
| 2000-01-06 | -0.704558 | -0.929182 | -1.452159 |
| 2000-01-07 | 1.018959  | -0.087476 | -2.051015 |
| 2000-01-08 | 0.554322  | -1.234633 | 0.463419  |

```
# dotted (attribute) access provides get as well
In [366]: store.df
\\\\"
↪
```

|            | A         | B         | C         |
|------------|-----------|-----------|-----------|
| 2000-01-01 | -0.274852 | -0.667027 | -0.688782 |
| 2000-01-02 | 0.621607  | -1.300199 | 0.050119  |

(continues on next page)

(continued from previous page)

```

2000-01-03 -0.999591 -0.320658 -1.922640
2000-01-04  0.894171 -1.539066 -0.114019
2000-01-05  0.780874  0.757320 -2.110838
2000-01-06 -0.704558 -0.929182 -1.452159
2000-01-07  1.018959 -0.087476 -2.051015
2000-01-08  0.554322 -1.234633  0.463419

```

Deletion of the object specified by the key:

```

# store.remove('wp') is an equivalent method
In [367]: del store['wp']

In [368]: store
Out[368]:
<class 'pandas.io.pytables.HDFStore'>
File path: store.h5

```

Closing a Store and using a context manager:

```

In [369]: store.close()

In [370]: store
Out[370]:
<class 'pandas.io.pytables.HDFStore'>
File path: store.h5

In [371]: store.is_open
Out[371]: False

# Working with, and automatically closing the store using a context manager
In [372]: with pd.HDFStore('store.h5') as store:
.....:     store.keys()
.....:

```

## 25.8.1 Read/Write API

HDFStore supports an top-level API using `read_hdf` for reading and `to_hdf` for writing, similar to how `read_csv` and `to_csv` work.

```

In [373]: df_t1 = pd.DataFrame({'A': list(range(5)), 'B': list(range(5))})

In [374]: df_t1.to_hdf('store_t1.h5', 'table', append=True)

In [375]: pd.read_hdf('store_t1.h5', 'table', where=['index>2'])
Out[375]:
   A  B
3  3  3
4  4  4

```

HDFStore will by default not drop rows that are all missing. This behavior can be changed by setting `dropna=True`.

```

In [376]: df_with_missing = pd.DataFrame({'col1': [0, np.nan, 2],
.....:                                     'col2': [1, np.nan, np.nan]})
.....:

```

(continues on next page)

(continued from previous page)

```

In [377]: df_with_missing
Out[377]:
   col1  col2
0    0.0    1.0
1    NaN    NaN
2    2.0    NaN

In [378]: df_with_missing.to_hdf('file.h5', 'df_with_missing',
.....:                          format='table', mode='w')
.....:

In [379]: pd.read_hdf('file.h5', 'df_with_missing')
Out[379]:
   col1  col2
0    0.0    1.0
1    NaN    NaN
2    2.0    NaN

In [380]: df_with_missing.to_hdf('file.h5', 'df_with_missing',
.....:                          format='table', mode='w', dropna=True)
.....:

Major_axis axis: 2 to 2
Minor_axis axis: A to C
```

## 25.8.2 Fixed Format

The examples above show storing using `put`, which write the HDF5 to PyTables in a fixed array format, called the *fixed* format. These types of stores are **not** appendable once written (though you can simply remove them and rewrite). Nor are they **queryable**; they must be retrieved in their entirety. They also do not support dataframes with non-unique column names. The *fixed* format stores offer very fast writing and slightly faster reading than *table* stores. This format is specified by default when using `put` or `to_hdf` or by `format='fixed'` or `format='f'`.

**Warning:** A fixed format will raise a `TypeError` if you try to retrieve using a `where`:

```
>>> pd.DataFrame(np.random.randn(10, 2)).to_hdf('test_fixed.h5', 'df')
>>> pd.read_hdf('test_fixed.h5', 'df', where='index>5')
TypeError: cannot pass a where specification when reading a fixed format.
        this store must be selected in its entirety
```

## 25.8.3 Table Format

`HDFStore` supports another PyTables format on disk, the *table* format. Conceptually a table is shaped very much like a `DataFrame`, with rows and columns. A table may be appended to in the same or other sessions. In addition, delete and query type operations are supported. This format is specified by `format='table'` or `format='t'` to append or `put` or `to_hdf`.

This format can be set as an option as well `pd.set_option('io.hdf.default_format', 'table')` to enable `put`/`append`/`to_hdf` to by default store in the *table* format.

```
In [388]: store = pd.HDFStore('store.h5')

In [389]: df1 = df[0:4]

In [390]: df2 = df[4:]

# append data (creates a table automatically)
In [391]: store.append('df', df1)

In [392]: store.append('df', df2)

In [393]: store
Out[393]:
<class 'pandas.io.pytables.HDFStore'>
File path: store.h5

# select the entire object
```

(continues on next page)

(continued from previous page)

```

In [394]: store.select('df')
Out [394]:
      A      B      C
2000-01-01 -0.274852 -0.667027 -0.688782
2000-01-02  0.621607 -1.300199  0.050119
2000-01-03 -0.999591 -0.320658 -1.922640
2000-01-04  0.894171 -1.539066 -0.114019
2000-01-05  0.780874  0.757320 -2.110838
2000-01-06 -0.704558 -0.929182 -1.452159
2000-01-07  1.018959 -0.087476 -2.051015
2000-01-08  0.554322 -1.234633  0.463419

# the type of stored data
In [395]: store.root.df._v_attrs.pandas_type
Out [395]:
'frame_table'

```

**Note:** You can also create a table by passing `format='table'` or `format='t'` to a put operation.

## 25.8.4 Hierarchical Keys

Keys to a store can be specified as a string. These can be in a hierarchical path-name like format (e.g. `foo/bar/bah`), which will generate a hierarchy of sub-stores (or Groups in PyTables parlance). Keys can be specified without the leading `/` and are **always** absolute (e.g. `'foo'` refers to `'/foo'`). Removal operations can remove everything in the sub-store and **below**, so be *careful*.

```

In [396]: store.put('foo/bar/bah', df)

In [397]: store.append('food/orange', df)

In [398]: store.append('food/apple', df)

In [399]: store
Out [399]:
<class 'pandas.io.pytables.HDFStore'>
File path: store.h5

# a list of keys are returned
In [400]: store.keys()
Out [400]:
['/df',
'/food/apple', '/food/orange', '/foo/bar/bah']

# remove all nodes under this level
In [401]: store.remove('food')

In [402]: store
Out [402]:
<class 'pandas.io.pytables.HDFStore'>
File path: store.h5

```

You can walk through the group hierarchy using the `walk` method which will yield a tuple for each group key along with the relative keys of its contents.

New in version 0.24.0.

```
In [403]: for (path, subgroups, subkeys) in store.walk():
.....:     for subgroup in subgroups:
.....:         print('GROUP: {}'.format(path, subgroup))
.....:     for subkey in subkeys:
.....:         key = '/'.join([path, subkey])
.....:         print('KEY: {}'.format(key))
.....:         print(store.get(key))
.....:
```

```
GROUP: /foo
```

```
KEY: /df
```

|            | A         | B         | C         |
|------------|-----------|-----------|-----------|
| 2000-01-01 | -0.274852 | -0.667027 | -0.688782 |
| 2000-01-02 | 0.621607  | -1.300199 | 0.050119  |
| 2000-01-03 | -0.999591 | -0.320658 | -1.922640 |
| 2000-01-04 | 0.894171  | -1.539066 | -0.114019 |
| 2000-01-05 | 0.780874  | 0.757320  | -2.110838 |
| 2000-01-06 | -0.704558 | -0.929182 | -1.452159 |
| 2000-01-07 | 1.018959  | -0.087476 | -2.051015 |
| 2000-01-08 | 0.554322  | -1.234633 | 0.463419  |

```
GROUP: /foo/bar
```

```
KEY: /foo/bar/bah
```

|            | A         | B         | C         |
|------------|-----------|-----------|-----------|
| 2000-01-01 | -0.274852 | -0.667027 | -0.688782 |
| 2000-01-02 | 0.621607  | -1.300199 | 0.050119  |
| 2000-01-03 | -0.999591 | -0.320658 | -1.922640 |
| 2000-01-04 | 0.894171  | -1.539066 | -0.114019 |
| 2000-01-05 | 0.780874  | 0.757320  | -2.110838 |
| 2000-01-06 | -0.704558 | -0.929182 | -1.452159 |
| 2000-01-07 | 1.018959  | -0.087476 | -2.051015 |
| 2000-01-08 | 0.554322  | -1.234633 | 0.463419  |

**Warning:** Hierarchical keys cannot be retrieved as dotted (attribute) access as described above for items stored under the root node.

```
In [8]: store.foo.bar.bah
```

```
AttributeError: 'HDFStore' object has no attribute 'foo'
```

```
# you can directly access the actual PyTables node but using the root node
```

```
In [9]: store.root.foo.bar.bah
```

```
Out[9]:
```

```
/foo/bar/bah (Group) ''
```

```
  children := ['block0_items' (Array), 'block0_values' (Array), 'axis0' (Array),
  ↪ 'axis1' (Array)]
```

Instead, use explicit string based keys:

```
In [404]: store['foo/bar/bah']
```

```
Out[404]:
```

|            | A         | B         | C         |
|------------|-----------|-----------|-----------|
| 2000-01-01 | -0.274852 | -0.667027 | -0.688782 |
| 2000-01-02 | 0.621607  | -1.300199 | 0.050119  |
| 2000-01-03 | -0.999591 | -0.320658 | -1.922640 |
| 2000-01-04 | 0.894171  | -1.539066 | -0.114019 |
| 2000-01-05 | 0.780874  | 0.757320  | -2.110838 |
| 2000-01-06 | -0.704558 | -0.929182 | -1.452159 |
| 2000-01-07 | 1.018959  | -0.087476 | -2.051015 |
| 2000-01-08 | 0.554322  | -1.234633 | 0.463419  |

## 25.8.5 Storing Types

### 25.8.5.1 Storing Mixed Types in a Table

Storing mixed-dtype data is supported. Strings are stored as a fixed-width using the maximum size of the appended column. Subsequent attempts at appending longer strings will raise a `ValueError`.

Passing `min_itemsize={'values': size}` as a parameter to append will set a larger minimum for the string columns. Storing floats, strings, ints, bools, `datetime64` are currently supported. For string columns, passing `nan_rep = 'nan'` to append will change the default nan representation on disk (which converts to/from `np.nan`), this defaults to `nan`.

```
In [405]: df_mixed = pd.DataFrame({'A': np.random.randn(8),
.....:                             'B': np.random.randn(8),
.....:                             'C': np.array(np.random.randn(8), dtype='float32'),
.....:                             'string': 'string',
.....:                             'int': 1,
.....:                             'bool': True,
.....:                             'datetime64': pd.Timestamp('20010102')},
.....:                             index=list(range(8)))

In [406]: df_mixed.loc[df_mixed.index[3:5],
.....:                  ['A', 'B', 'string', 'datetime64']] = np.nan
.....:

In [407]: store.append('df_mixed', df_mixed, min_itemsize={'values': 50})

In [408]: df_mixed1 = store.select('df_mixed')

In [409]: df_mixed1
Out[409]:
```

|   | A         | B         | C         | string | int | bool | datetime64 |

### 25.8.5.2 Storing MultiIndex DataFrames

Storing MultiIndex DataFrames as tables is very similar to storing/selecting from homogeneous index DataFrames.

```

In [412]: index = pd.MultiIndex(levels=[['foo', 'bar', 'baz', 'qux'],
.....:                                ['one', 'two', 'three']],
.....:                           codes=[[0, 0, 0, 1, 1, 2, 2, 3, 3, 3],
.....:                                [0, 1, 2, 0, 1, 1, 2, 0, 1, 2]],
.....:                           names=['foo', 'bar'])
.....:

```

```

In [413]: df_mi = pd.DataFrame(np.random.randn(10, 3), index=index,
.....:                          columns=['A', 'B', 'C'])
.....:

```

```

In [414]: df_mi

```

```

Out[414]:
           A         B         C
foo bar
foo one    0.909453  1.434186  2.485565
   two    0.319459  0.828792 -0.221890
   three  0.693093 -0.446442  0.030712

   two     0.599256 -0.954386  1.269314

```

## 25.8.6 Querying

### 25.8.6.1 Querying a Table

`select` and `delete` operations have an optional criterion that can be specified to select/delete only a subset of the data. This allows one to have a very large on-disk table and retrieve only a portion of the data.

A query is specified using the `Term` class under the hood, as a boolean expression.

- `index` and `columns` are supported indexers of a `DataFrames`.
- `major_axis`, `minor_axis`, and `items` are supported indexers of the `Panel`.
- if `data_columns` are specified, these can be used as additional indexers.

Valid comparison operators are:

`=`, `==`, `!=`, `>`, `>=`, `<`, `<=`

Valid boolean expressions are combined with:

- `|` : or
- `&` : and
- `( and )` : for grouping

These rules are similar to how boolean expressions are used in pandas for indexing.

---

#### Note:

- `=` will be automatically expanded to the comparison operator `==`
  - `~` is the not operator, but can only be used in very limited circumstances
  - If a list/tuple of expressions is passed they will be combined via `&`
- 

The following are valid expressions:

- `'index >= date'`
- `"columns = ['A', 'D']"`

- `"columns in ['A', 'D']"`
- `'columns = A'`
- `'columns == A'`
- `"~(columns = ['A', 'B'])"`
- `'index > df.index[3] & string = "bar"'`
- `'(index > df.index[3] & index <= df.index[6]) | string = "bar"'`
- `"ts >= Timestamp('2012-02-01')"`
- `"major_axis>=20130101"`

The indexers are on the left-hand side of the sub-expression:

`columns,major_axis,ts`

The right-hand side of the sub-expression (after a comparison operator) can be:

- functions that will be evaluated, e.g. `Timestamp('2012-02-01')`
- strings, e.g. `"bar"`
- date-like, e.g. `20130101`, or `"20130101"`
- lists, e.g. `"['A', 'B']"`
- variables that are defined in the local names space, e.g. `date`

---

**Note:** Passing a string to a query by interpolating it into the query expression is not recommended. Simply assign the string of interest to a variable and use that variable in an expression. For example, do this

```
string = "HolyMoly"
store.select('df', 'index == string')
```

instead of this

```
string = "HolyMoly"
store.select('df', 'index == %s' % string)
```

The latter will **not** work and will raise a `SyntaxError`. Note that there's a single quote followed by a double quote in the string variable.

If you *must* interpolate, use the `'%r'` format specifier

```
store.select('df', 'index == %r' % string)
```

which will quote string.

---

Here are some examples:

```
In [418]: dfq = pd.DataFrame(np.random.randn(10, 4), columns=list('ABCD'),
.....:                      index=pd.date_range('20130101', periods=10))
.....:
In [419]: store.append('dfq', dfq, format='table', data_columns=True)
```

Use boolean expressions, with in-line function evaluation.

Items axis: Item1 to Item2
```

```
Major_axis axis: 2000-01-03 00:00:00 to 2000-01-03 00:00:00
```

```
Minor_axis axis: A to B
```

**Note:** select will raise a ValueError if the query expression has an unknown variable reference. Usually this means that you are trying to select on a column that is **not** a data\_column.

select will raise a SyntaxError if the query expression is not valid.

### 25.8.6.2 Using timedelta64[ns]

You can store and query using the timedelta64[ns] type. Terms can be specified in the format: <float>(<unit>), where float may be signed (and fractional), and unit can be D, s, ms, us, ns for the timedelta. Here's an example:

```
In [428]: from datetime import timedelta
```

```
In [429]: dftd = pd.DataFrame({'A': pd.Timestamp('20130101'),
```

(continues on next page)

(continued from previous page)

```

.....:                                     'B': [pd.Timestamp('20130101') + timedelta(days=i,
.....:                                                                 seconds=10)
.....:                                     for i in range(10)]]}
.....:
In [430]: dftd['C'] = dftd['A'] - dftd['B']

In [431]: dftd
Out[431]:

```

|   | A                              | B                  | C |
|---|--------------------------------|--------------------|---|
| 0 | 2013-01-01 2013-01-01 00:00:10 | -1 days +23:59:50  |   |
| 1 | 2013-01-01 2013-01-02 00:00:10 | -2 days +23:59:50  |   |
| 2 | 2013-01-01 2013-01-03 00:00:10 | -3 days +23:59:50  |   |
| 3 | 2013-01-01 2013-01-04 00:00:10 | -4 days +23:59:50  |   |
| 4 | 2013-01-01 2013-01-05 00:00:10 | -5 days +23:59:50  |   |
| 5 | 2013-01-01 2013-01-06 00:00:10 | -6 days +23:59:50  |   |

| 9 | 2013-01-01 2013-01-10 00:00:10 | -10 days +23:59:50 |   |

### 25.8.6.3 Indexing

You can create/modify an index for a table with `create_table_index` after data is already in the table (after and append/put operation). Creating a table index is **highly** encouraged. This will speed your queries a great deal when you use a select with the indexed dimension as the where.

**Note:** Indexes are automatically created on the indexables and any data columns you specify. This behavior can be turned off by passing `index=False` to `append`.

```

# we have automatically already created an index (in the first section)
In [434]: i = store.root.df.table.cols.index.index

In [435]: i.optlevel, i.kind
Out[435]: (6, 'medium')

# change an index by passing new parameters
In [436]: store.create_table_index('df', optlevel=9, kind='full')

In [437]: i = store.root.df.table.cols.index.index

```

(continues on next page)

(continued from previous page)

```
In [438]: i.optlevel, i.kind
Out[438]: (9, 'full')
```

Oftentimes when appending large amounts of data to a store, it is useful to turn off index creation for each append, then recreate at the end.

```
In [439]: df_1 = pd.DataFrame(np.random.randn(10, 2), columns=list('AB'))
In [440]: df_2 = pd.DataFrame(np.random.randn(10, 2), columns=list('AB'))
In [441]: st = pd.HDFStore('appends.h5', mode='w')
In [442]: st.append('df', df_1, data_columns=['B'], index=False)
In [443]: st.append('df', df_2, data_columns=['B'], index=False)
In [444]: st.get_storer('df').table
Out[444]:
/df/table (Table(20,)) ''
  description := {
    "index": Int64Col(shape=(), dflt=0, pos=0),
    "values_block_0": Float64Col(shape=(1,), dflt=0.0, pos=1),
    "B": Float64Col(shape=(), dflt=0.0, pos=2)}
  byteorder := 'little'
  chunkshape := (2730,)
```

Then create the index when finished appending.

```
In [445]: st.create_table_index('df', columns=['B'], optlevel=9, kind='full')
In [446]: st.get_storer('df').table
Out[446]:
/df/table (Table(20,)) ''
  description := {
    "index": Int64Col(shape=(), dflt=0, pos=0),
    "values_block_0": Float64Col(shape=(1,), dflt=0.0, pos=1),
    "B": Float64Col(shape=(), dflt=0.0, pos=2)}
  byteorder := 'little'
  chunkshape := (2730,)
  autoindex := True
  colindexes := {
    "B": Index(9, full, shuffle, zlib(1)).is_csi=True}
In [447]: st.close()
```

See [here](#) for how to create a completely-sorted-index (CSI) on an existing store.

#### 25.8.6.4 Query via Data Columns

You can designate (and index) certain columns that you want to be able to perform queries (other than the *indexable* columns, which you can always query). For instance say you want to perform this common operation, on-disk, and return just the frame that matches this query. You can specify `data_columns = True` to force all columns to be `data_columns`.

```

In [448]: df_dc = df.copy()

In [449]: df_dc['string'] = 'foo'

In [450]: df_dc.loc[df_dc.index[4:6], 'string'] = np.nan

In [451]: df_dc.loc[df_dc.index[7:9], 'string'] = 'bar'

In [452]: df_dc['string2'] = 'cool'

In [453]: df_dc.loc[df_dc.index[1:3], ['B', 'C']] = 1.0

In [454]: df_dc
Out[454]:
           A          B          C string string2
2000-01-01 -0.274852 -0.667027 -0.688782    foo    cool
2000-01-02  0.621607  1.000000  1.000000    foo    cool
2000-01-03 -0.999591  1.000000  1.000000    foo    cool
2000-01-04  0.894171 -1.539066 -0.114019    foo    cool
2000-01-05  0.780874  0.757320 -2.110838   NaN    cool
2000-01-06 -0.704558 -0.929182 -1.452159   NaN    cool
2000-01-07  1.018959 -0.087476 -2.051015    foo    cool
2000-01-08  0.554322 -1.234633  0.463419    bar    cool

# on-disk operations
In [455]: store.append('df_dc', df_dc, data_columns=['B', 'C', 'string', 'string2'])

In [456]: store.select('df_dc', where='B > 0')
Out[456]:
           A          B          C string string2
2000-01-02  0.621607  1.000000  1.000000    foo    cool
2000-01-03 -0.999591  1.000000  1.000000    foo    cool
2000-01-05  0.780874  0.757320 -2.110838   NaN    cool

# getting creative
In [457]: store.select('df_dc', 'B > 0 & C > 0 & string == foo')
\
↪
           A          B          C string string2

2000-01-03 -0.999591  1.0    1.0    foo    cool

# this is in-memory version of this type of selection
In [458]: df_dc[(df_dc.B > 0) & (df_dc.C > 0) & (df_dc.string == 'foo')]
\
↪
           A          B          C string string2
2000-01-02  0.621607  1.0    1.0    foo    cool
2000-01-03 -0.999591  1.0    1.0    foo    cool

# we have automagically created this index and the B/C/string/string2
# columns are stored separately as ``PyTables`` columns
In [459]: store.root.df_dc.table
\
↪
/df_dc/table (Table(8,)) ''
description := {

```

(continues on next page)

(continued from previous page)

```

"index": Int64Col(shape=(), dflt=0, pos=0),
"values_block_0": Float64Col(shape=(1,), dflt=0.0, pos=1),
"B": Float64Col(shape=(), dflt=0.0, pos=2),
"C": Float64Col(shape=(), dflt=0.0, pos=3),
"string": StringCol(itemsizes=3, shape=(), dflt=b'', pos=4),
"string2": StringCol(itemsizes=4, shape=(), dflt=b'', pos=5)}
byteorder := 'little'
chunkshape := (1680,)
autoindex := True
colindexes := {
    "index": Index(6, medium, shuffle, zlib(1)).is_csi=False,
    "B": Index(6, medium, shuffle, zlib(1)).is_csi=False,
    "C": Index(6, medium, shuffle, zlib(1)).is_csi=False,
    "string": Index(6, medium, shuffle, zlib(1)).is_csi=False,
    "string2": Index(6, medium, shuffle, zlib(1)).is_csi=False}

```

There is some performance degradation by making lots of columns into *data columns*, so it is up to the user to designate these. In addition, you cannot change data columns (nor indexables) after the first append/put operation (Of course you can simply read in the data and create a new table!).

### 25.8.6.5 Iterator

You can pass `iterator=True` or `chunksize=number_in_a_chunk` to select and `select_as_multiple` to return an iterator on the results. The default is 50,000 rows returned in a chunk.

```

In [460]: for df in store.select('df', chunksize=3):
.....:     print(df)
.....:

```

```

      A      B      C
2000-01-01 -0.274852 -0.667027 -0.688782
2000-01-02  0.621607 -1.300199  0.050119
2000-01-03 -0.999591 -0.320658 -1.922640
      A      B      C
2000-01-04  0.894171 -1.539066 -0.114019
2000-01-05  0.780874  0.757320 -2.110838
2000-01-06 -0.704558 -0.929182 -1.452159
      A      B      C
2000-01-07  1.018959 -0.087476 -2.051015
2000-01-08  0.554322 -1.234633  0.463419

```

**Note:** You can also use the iterator with `read_hdf` which will open, then automatically close the store when finished iterating.

```

for df in pd.read_hdf('store.h5', 'df', chunksize=3):
    print(df)

```

Note, that the `chunksize` keyword applies to the **source** rows. So if you are doing a query, then the `chunksize` will subdivide the total rows in the table and the query applied, returning an iterator on potentially unequal sized chunks.

Here is a recipe for generating a query and using it to create equal sized return chunks.

```

In [461]: dfeq = pd.DataFrame({'number': np.arange(1, 11)})

```

(continues on next page)

(continued from previous page)

```

In [462]: dfreq
Out[462]:
  number
0      1
1      2
2      3
3      4
4      5
5      6
6      7
7      8
8      9
9     10

In [463]: store.append('dfreq', dfreq, data_columns=['number'])

In [464]: def chunks(l, n):
.....:     return [l[i:i + n] for i in range(0, len(l), n)]
.....:

In [465]: evens = [2, 4, 6, 8, 10]

In [466]: coordinates = store.select_as_coordinates('dfreq', 'number=evens')

In [467]: for c in chunks(coordinates, 2):
.....:     print(store.select('dfreq', where=c))
.....:
  number
1      2
3      4
  number
5      6
7      8
  number
9     10

```

### 25.8.6.6 Advanced Queries

#### Select a Single Column

To retrieve a single indexable or data column, use the method `select_column`. This will, for example, enable you to get the index very quickly. These return a `Series` of the result, indexed by the row number. These do not currently accept the `where` selector.

```

In [468]: store.select_column('df_dc', 'index')
Out[468]:
0    2000-01-01
1    2000-01-02
2    2000-01-03
3    2000-01-04
4    2000-01-05
5    2000-01-06
6    2000-01-07
7    2000-01-08

```

(continues on next page)

(continued from previous page)

Name: index, dtype: datetime64[ns]

In [469]: store.select\_column('df\_dc', 'string')

```

////////////////////////////////////

```

↪

```

0    foo
1    foo

## Selecting coordinates

Sometimes you want to get the coordinates (a.k.a the index locations) of your query. This returns an `Int64Index` of the resulting locations. These coordinates can also be passed to subsequent where operations.

```

In [470]: df_coord = pd.DataFrame(np.random.randn(1000, 2),
.....:                           index=pd.date_range('20000101', periods=1000))
.....:

```

In [471]: store.append('df\_coord', df\_coord)

In [472]: c = store.select\_as\_coordinates('df\_coord', 'index &gt; 20020101')

In [473]: c

Out[473]:

```

Int64Index([732, 733, 734, 735, 736, 737, 738, 739, 740, 741,
...
          990, 991, 992, 993, 994, 995, 996, 997, 998, 999],
dtype='int64', length=268)

```

In [474]: store.select('df\_coord', where=c)

```

////////////////////////////////////

```

↪

```

## Selecting using a where mask

Sometime your query can involve creating a list of rows to select. Usually this mask would be a resulting index from an indexing operation. This example selects the months of a datetimeindex which are 5.

```

In [475]: df_mask = pd.DataFrame(np.random.randn(1000, 2),
.....:                           index=pd.date_range('20000101', periods=1000))

```

(continues on next page)

(continued from previous page)

```

.....:

In [476]: store.append('df_mask', df_mask)

In [477]: c = store.select_column('df_mask', 'index')

In [478]: where = c[pd.DatetimeIndex(c).month == 5].index

In [479]: store.select('df_mask', where=where)
Out[479]:

## Storer Object

If you want to inspect the stored object, retrieve via `get_storer`. You could use this programmatically to say get the number of rows in an object.

```

In [480]: store.get_storer('df_dc').nrows
Out[480]: 8

```

### 25.8.6.7 Multiple Table Queries

The methods `append_to_multiple` and `select_as_multiple` can perform appending/selecting from multiple tables at once. The idea is to have one table (call it the selector table) that you index most/all of the columns, and perform your queries. The other table(s) are data tables with an index matching the selector table's index. You can then perform a very fast query on the selector table, yet get lots of data back. This method is similar to having a very wide table, but enables more efficient queries.

The `append_to_multiple` method splits a given single DataFrame into multiple tables according to `d`, a dictionary that maps the table names to a list of 'columns' you want in that table. If `None` is used in place of a list, that table will have the remaining unspecified columns of the given DataFrame. The argument `selector` defines which table is the selector table (which you can make queries from). The argument `dropna` will drop rows from the input DataFrame to ensure tables are synchronized. This means that if a row for one of the tables being written to is entirely `np.NaN`, that row will be dropped from all tables.

If `dropna` is `False`, **THE USER IS RESPONSIBLE FOR SYNCHRONIZING THE TABLES**. Remember that entirely `np.NaN` rows are not written to the HDFStore, so if you choose to call `dropna=False`, some tables may have more rows than others, and therefore `select_as_multiple` may not work or it may return unexpected results.

```

In [481]: df_mt = pd.DataFrame(np.random.randn(8, 6),
.....:                        index=pd.date_range('1/1/2000', periods=8),
.....:                        columns=['A', 'B', 'C', 'D', 'E', 'F'])
.....:

In [482]: df_mt['foo'] = 'bar'

```

(continues on next page)

(continued from previous page)

```

In [483]: df_mt.loc[df_mt.index[1], ('A', 'B')] = np.nan

# you can also create the tables individually
In [484]: store.append_to_multiple({'df1_mt': ['A', 'B'], 'df2_mt': None},
.....:                             df_mt, selector='df1_mt')
.....:

In [485]: store

### 25.8.7 Delete from a Table

You can delete from a table selectively by specifying a `where`. In deleting rows, it is important to understand the PyTables deletes rows by erasing the rows, then **moving** the following data. Thus deleting can potentially be a very expensive operation depending on the orientation of your data. This is especially true in higher dimensional objects (Panel and Panel4D). To get optimal performance, it's worthwhile to have the dimension you are deleting be the first of the indexables.

Data is ordered (on the disk) in terms of the `indexables`. Here's a simple use case. You store panel-type data, with dates in the `major_axis` and ids in the `minor_axis`. The data is then interleaved like this:

- **date\_1**
  - id\_1
  - id\_2
  - .
  - id\_n
- **date\_2**
  - id\_1
  - .
  - id\_n

It should be clear that a delete operation on the `major_axis` will be fairly quick, as one chunk is removed, then the following data moved. On the other hand a delete operation on the `minor_axis` will be very expensive. In this case it would almost certainly be faster to rewrite the table using a `where` that selects all but the missing data.

```
# returns the number of rows deleted
In [489]: store.remove('wp', 'major_axis > 20000102')
Out[489]: 12

In [490]: store.select('wp')
\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\Out[490]:
<class 'pandas.core.panel.Panel'>
Dimensions: 2 (items) x 2 (major_axis) x 4 (minor_axis)
Items axis: Item1 to Item2
Major_axis axis: 2000-01-01 00:00:00 to 2000-01-02 00:00:00
Minor_axis axis: A to D
```

**Warning:** Please note that HDF5 **DOES NOT RECLAIM SPACE** in the h5 files automatically. Thus, repeatedly deleting (or removing nodes) and adding again, **WILL TEND TO INCREASE THE FILE SIZE**.

To *repack and clean* the file, use *ptrepack*.

## 25.8.8 Notes & Caveats

### 25.8.8.1 Compression

PyTables allows the stored data to be compressed. This applies to all kinds of stores, not just tables. Two parameters are used to control compression: `complevel` and `complib`.

**complevel** specifies if and how hard data is to be compressed. `complevel=0` and `complevel=None` disables compression and `0 < complevel < 10` enables compression.

**complib** specifies which compression library to use. If nothing is specified the default library `zlib` is used. A compression library usually optimizes for either good compression rates or speed and the results will depend on the type of data. Which type of compression to choose depends on your specific needs and data. The list of supported compression libraries:

- **zlib:** The default compression library. A classic in terms of compression, achieves good compression rates but is somewhat slow.

- `lzo`: Fast compression and decompression.
- `bzip2`: Good compression rates.
- `blosc`: Fast compression and decompression.

New in version 0.20.2: Support for alternative blosc compressors:

- `blosc:blosclz` This is the default compressor for `blosc`
- `blosc:lz4`: A compact, very popular and fast compressor.
- `blosc:lz4hc`: A tweaked version of LZ4, produces better compression ratios at the expense of speed.
- `blosc:snappy`: A popular compressor used in many places.
- `blosc:zlib`: A classic; somewhat slower than the previous ones, but achieving better compression ratios.
- `blosc:zstd`: An extremely well balanced codec; it provides the best compression ratios among the others above, and at reasonably fast speed.

If `complib` is defined as something other than the listed libraries a `ValueError` exception is issued.

---

**Note:** If the library specified with the `complib` option is missing on your platform, compression defaults to `zlib` without further ado.

---

Enable compression for all objects within the file:

```
store_compressed = pd.HDFStore('store_compressed.h5', complevel=9,
                               complib='blosc:blosclz')
```

Or on-the-fly compression (this only applies to tables) in stores where compression is not enabled:

```
store.append('df', df, complib='zlib', complevel=5)
```

### 25.8.8.2 ptrepack

`PyTables` offers better write performance when tables are compressed after they are written, as opposed to turning on compression at the very beginning. You can use the supplied `PyTables` utility `ptrepack`. In addition, `ptrepack` can change compression levels after the fact.

```
ptrepack --chunkshape=auto --propindexes --complevel=9 --complib=blosc in.h5 out.h5
```

Furthermore `ptrepack in.h5 out.h5` will *repack* the file to allow you to reuse previously deleted space. Alternatively, one can simply remove the file and write again, or use the `copy` method.

### 25.8.8.3 Caveats

**Warning:** `HDFStore` is **not-threadsafe for writing**. The underlying `PyTables` only supports concurrent reads (via threading or processes). If you need reading and writing *at the same time*, you need to serialize these operations in a single thread in a single process. You will corrupt your data otherwise. See the [\(GH2397\)](#) for more information.

- If you use locks to manage write access between multiple processes, you may want to use `fsync()` before releasing write locks. For convenience you can use `store.flush(fsyntax=True)` to do this for you.
- Once a `table` is created its items (`Panel`) / columns (`DataFrame`) are fixed; only exactly the same columns can be appended
- Be aware that timezones (e.g., `pytz.timezone('US/Eastern')`) are not necessarily equal across time-zone versions. So if data is localized to a specific timezone in the `HDFStore` using one version of a timezone library and that data is updated with another version, the data will be converted to UTC since these timezones are not considered equal. Either use the same version of timezone library or use `tz_convert` with the updated timezone definition.

**Warning:** `PyTables` will show a `NaturalNameWarning` if a column name cannot be used as an attribute selector. *Natural* identifiers contain only letters, numbers, and underscores, and may not begin with a number. Other identifiers cannot be used in a `where` clause and are generally a bad idea.

## 25.8.9 DataTypes

`HDFStore` will map an object dtype to the `PyTables` underlying dtype. This means the following types are known to work:

| Type                                               | Represents missing values |
|----------------------------------------------------|---------------------------|
| floating: float64, float32, float16                | np.nan                    |
| integer: int64, int32, int8, uint64, uint32, uint8 |                           |
| boolean                                            |                           |
| datetime64[ns]                                     | NaT                       |
| timedelta64[ns]                                    | NaT                       |
| categorical: see the section below                 |                           |
| object: strings                                    | np.nan                    |

unicode columns are not supported, and **WILL FAIL**.

### 25.8.9.1 Categorical Data

You can write data that contains `category` dtypes to a `HDFStore`. Queries work the same as if it was an object array. However, the `category` typed data is stored in a more efficient manner.

```
In [491]: dfcat = pd.DataFrame({'A': pd.Series(list('aabbcdab')).astype('category'),
.....:                        'B': np.random.randn(8)})
.....:
```

```
In [492]: dfcat
```

```
Out[492]:
```

```
   A      B
0  a -1.429797
1  a  0.621996
2  b -1.431952
3  b  0.426694
4  c -0.468803
5  d -0.992122
6  b -0.972611
7  a -0.730214
```

(continues on next page)

(continued from previous page)

```

In [493]: dfcat.dtypes
////////////////////////////////////Out [493]:
↪
A      category
B      float64
dtype: object

In [494]: cstore = pd.HDFStore('cats.h5', mode='w')

In [495]: cstore.append('dfcat', dfcat, format='table', data_columns=['A'])

In [496]: result = cstore.select('dfcat', where="A in ['b', 'c']")

In [497]: result
Out[497]:
   A      B
2  b -1.431952
3  b  0.426694
4  c -0.468803
6  b -0.972611

In [498]: result.dtypes
////////////////////////////////////Out [498]:
↪
A      category
B      float64
dtype: object

```

### 25.8.9.2 String Columns

#### min\_itemsize

The underlying implementation of `HDFStore` uses a fixed column width (`itemsize`) for string columns. A string column `itemsize` is calculated as the maximum of the length of data (for that column) that is passed to the `HDFStore`, **in the first append**. Subsequent appends, may introduce a string for a column **larger** than the column can hold, an `Exception` will be raised (otherwise you could have a silent truncation of these columns, leading to loss of information). In the future we may relax this and allow a user-specified truncation to occur.

Pass `min_itemsize` on the first table creation to a-priori specify the minimum length of a particular string column. `min_itemsize` can be an integer, or a dict mapping a column name to an integer. You can pass `values` as a key to allow all *indexables* or *data\_columns* to have this `min_itemsize`.

Passing a `min_itemsize` dict will cause all passed columns to be created as *data\_columns* automatically.

---

**Note:** If you are not passing any `data_columns`, then the `min_itemsize` will be the maximum of the length of any string passed

---

```

In [499]: dfs = pd.DataFrame({'A': 'foo', 'B': 'bar'}, index=list(range(5)))

In [500]: dfs
Out[500]:
   A      B
0  foo  bar

```

(continues on next page)

(continued from previous page)

```

1  foo  bar
2  foo  bar
3  foo  bar
4  foo  bar

# A and B have a size of 30
In [501]: store.append('dfs', dfs, min_itemsize=30)

In [502]: store.get_storer('dfs').table
Out[502]:
/dfs/table (Table(5,)) ''
  description := {
    "index": Int64Col(shape=(), dflt=0, pos=0),
    "values_block_0": StringCol(itemsized=30, shape=(2,), dflt=b'', pos=1)}
  byteorder := 'little'
  chunkshape := (963,)
  autoindex := True
  colindexes := {
    "index": Index(6, medium, shuffle, zlib(1)).is_csi=False}

# A is created as a data_column with a size of 30
# B is size is calculated
In [503]: store.append('dfs2', dfs, min_itemsize={'A': 30})

In [504]: store.get_storer('dfs2').table
Out[504]:
/dfs2/table (Table(5,)) ''
  description := {
    "index": Int64Col(shape=(), dflt=0, pos=0),
    "values_block_0": StringCol(itemsized=3, shape=(1,), dflt=b'', pos=1),
    "A": StringCol(itemsized=30, shape=(), dflt=b'', pos=2)}
  byteorder := 'little'
  chunkshape := (1598,)
  autoindex := True
  colindexes := {
    "index": Index(6, medium, shuffle, zlib(1)).is_csi=False,
    "A": Index(6, medium, shuffle, zlib(1)).is_csi=False}

```

**nan\_rep**

String columns will serialize a `np.nan` (a missing value) with the `nan_rep` string representation. This defaults to the string value `nan`. You could inadvertently turn an actual `nan` value into a missing value.

```

In [505]: dfss = pd.DataFrame({'A': ['foo', 'bar', 'nan']})

In [506]: dfss
Out[506]:
   A
0  foo
1  bar
2  nan

In [507]: store.append('dfss', dfss)

In [508]: store.select('dfss')
Out[508]:
   A

```

(continues on next page)

(continued from previous page)

```

0  foo
1  bar
2  NaN

# here you need to specify a different nan rep
In [509]: store.append('dfss2', dfss, nan_rep='_nan_')

In [510]: store.select('dfss2')
Out[510]:
      A
0  foo
1  bar
2  nan

```

### 25.8.10 External Compatibility

HDFStore writes table format objects in specific formats suitable for producing loss-less round trips to pandas objects. For external compatibility, HDFStore can read native PyTables format tables.

It is possible to write an HDFStore object that can easily be imported into R using the rhdf5 library ([Package website](#)). Create a table format store like this:

```

In [511]: df_for_r = pd.DataFrame({"first": np.random.rand(100),
.....:                           "second": np.random.rand(100),
.....:                           "class": np.random.randint(0, 2, (100, ))},
.....:                           index=range(100))
.....:

In [512]: df_for_r.head()
Out[512]:
      first  second  class
0  0.566639  0.308612     0
1  0.104893  0.415039     1
2  0.740523  0.005893     0
3  0.091274  0.905068     0
4  0.545799  0.335621     0

In [513]: store_export = pd.HDFStore('export.h5')

In [514]: store_export.append('df_for_r', df_for_r, data_columns=df_dc.columns)

In [515]: store_export
Out[515]:
<class 'pandas.io.pytables.HDFStore'>
File path: export.h5

```

In R this file can be read into a `data.frame` object using the `rhdf5` library. The following example function reads the corresponding column names and data values from the values and assembles them into a `data.frame`:

```

# Load values and column names for all datasets from corresponding nodes and
# insert them into one data.frame object.

library(rhdf5)

loadhdf5data <- function(h5File) {

```

(continues on next page)

(continued from previous page)

```

listing <- h5ls(h5File)
# Find all data nodes, values are stored in *_values and corresponding column
# titles in *_items
data_nodes <- grep("_values", listing$name)
name_nodes <- grep("_items", listing$name)
data_paths = paste(listing$group[data_nodes], listing$name[data_nodes], sep = "/")
name_paths = paste(listing$group[name_nodes], listing$name[name_nodes], sep = "/")
columns = list()
for (idx in seq(data_paths)) {
  # NOTE: matrices returned by h5read have to be transposed to obtain
  # required Fortran order!
  data <- data.frame(t(h5read(h5File, data_paths[idx])))
  names <- t(h5read(h5File, name_paths[idx]))
  entry <- data.frame(data)
  colnames(entry) <- names
  columns <- append(columns, entry)
}

data <- data.frame(columns)

return(data)
}

```

Now you can import the DataFrame into R:

```

> data = loadhdf5data("transfer.hdf5")
> head(data)
      first      second class
1 0.4170220047 0.3266449      0
2 0.7203244934 0.5270581      0
3 0.0001143748 0.8859421      1
4 0.3023325726 0.3572698      1
5 0.1467558908 0.9085352      1
6 0.0923385948 0.6233601      1

```

**Note:** The R function lists the entire HDF5 file's contents and assembles the `data.frame` object from all matching nodes, so use this only as a starting point if you have stored multiple DataFrame objects to a single HDF5 file.

### 25.8.11 Performance

- tables format come with a writing performance penalty as compared to fixed stores. The benefit is the ability to append/delete and query (potentially very large amounts of data). Write times are generally longer as compared with regular stores. Query times can be quite fast, especially on an indexed axis.
- You can pass `chunksize=<int>` to `append`, specifying the write chunksize (default is 50000). This will significantly lower your memory usage on writing.
- You can pass `expectedrows=<int>` to the first `append`, to set the TOTAL number of expected rows that PyTables will expect. This will optimize read/write performance.
- Duplicate rows can be written to tables, but are filtered out in selection (with the last items being selected; thus a table is unique on major, minor pairs)

- A `PerformanceWarning` will be raised if you are attempting to store types that will be pickled by PyTables (rather than stored as endemic types). See [Here](#) for more information and some solutions.

## 25.9 Feather

New in version 0.20.0.

Feather provides binary columnar serialization for data frames. It is designed to make reading and writing data frames efficient, and to make sharing data across data analysis languages easy.

Feather is designed to faithfully serialize and de-serialize DataFrames, supporting all of the pandas dtypes, including extension dtypes such as categorical and datetime with tz.

Several caveats.

- This is a newer library, and the format, though stable, is not guaranteed to be backward compatible to the earlier versions.
- The format will NOT write an `Index`, or `MultiIndex` for the `DataFrame` and will raise an error if a non-default one is provided. You can `.reset_index()` to store the index or `.reset_index(drop=True)` to ignore it.
- Duplicate column names and non-string columns names are not supported
- Non supported types include `Period` and actual Python object types. These will raise a helpful error message on an attempt at serialization.

See the [Full Documentation](#).

```
In [516]: df = pd.DataFrame({'a': list('abc'),
.....:                      'b': list(range(1, 4)),
.....:                      'c': np.arange(3, 6).astype('u1'),
.....:                      'd': np.arange(4.0, 7.0, dtype='float64'),
.....:                      'e': [True, False, True],
.....:                      'f': pd.Categorical(list('abc')),
.....:                      'g': pd.date_range('20130101', periods=3),
.....:                      'h': pd.date_range('20130101', periods=3, tz='US/Eastern
→'),
.....:                      'i': pd.date_range('20130101', periods=3, freq='ns')})
.....:
.....:
```

```
In [517]: df
```

```
Out[517]:

## 25.10 Parquet

New in version 0.21.0.

**Apache Parquet** provides a partitioned binary columnar serialization for data frames. It is designed to make reading and writing data frames efficient, and to make sharing data across data analysis languages easy. Parquet can use a variety of compression techniques to shrink the file size as much as possible while still maintaining good read performance.

Parquet is designed to faithfully serialize and de-serialize `DataFrame` s, supporting all of the pandas dtypes, including extension dtypes such as datetime with tz.

Several caveats.

- Duplicate column names and non-string columns names are not supported.

- The `pyarrow` engine always writes the index to the output, but `fastparquet` only writes non-default indexes. This extra column can cause problems for non-Pandas consumers that are not expecting it. You can force including or omitting indexes with the `index` argument, regardless of the underlying engine.
- Index level names, if specified, must be strings.
- Categorical dtypes can be serialized to parquet, but will de-serialize as `object` dtype.
- Non supported types include `Period` and actual Python object types. These will raise a helpful error message on an attempt at serialization.

You can specify an engine to direct the serialization. This can be one of `pyarrow`, or `fastparquet`, or `auto`. If the engine is NOT specified, then the `pd.options.io.parquet.engine` option is checked; if this is also `auto`, then `pyarrow` is tried, and falling back to `fastparquet`.

See the documentation for [pyarrow](#) and [fastparquet](#).

---

**Note:** These engines are very similar and should read/write nearly identical parquet format files. Currently `pyarrow` does not support `timedelta` data, `fastparquet`  $\geq 0.1.4$  supports timezone aware datetimes. These libraries differ by having different underlying dependencies (`fastparquet` by using `numba`, while `pyarrow` uses a c-library).

---

```
In [523]: df = pd.DataFrame({'a': list('abc'),
.....:                      'b': list(range(1, 4)),
.....:                      'c': np.arange(3, 6).astype('u1'),
.....:                      'd': np.arange(4.0, 7.0, dtype='float64'),
.....:                      'e': [True, False, True],
.....:                      'f': pd.date_range('20130101', periods=3),
.....:                      'g': pd.date_range('20130101', periods=3, tz='US/Eastern
↪')})
.....:

In [524]: df
Out[524]:
   a  b  c   d     e         f         g
0  a  1  3  4.0  True 2013-01-01 2013-01-01 00:00:00-05:00
1  b  2  4  5.0 False 2013-01-02 2013-01-02 00:00:00-05:00
2  c  3  5  6.0  True 2013-01-03 2013-01-03 00:00:00-05:00

In [525]: df.dtypes
↪
a          object
b          int64
c          uint8
d          float64
e           bool
f    datetime64[ns]
g    datetime64[ns, US/Eastern]
dtype: object
```

Write to a parquet file.

```
In [526]: df.to_parquet('example_pa.parquet', engine='pyarrow')

In [527]: df.to_parquet('example_fp.parquet', engine='fastparquet')
```

Read from a parquet file.

```
In [528]: result = pd.read_parquet('example_fp.parquet', engine='fastparquet')

In [529]: result = pd.read_parquet('example_pa.parquet', engine='pyarrow')

In [530]: result.dtypes
Out[530]:
a                object
b                int64
c                uint8
d                float64
e                 bool
f      datetime64[ns]
g      datetime64[ns, US/Eastern]
dtype: object
```

Read only certain columns of a parquet file.

```
In [531]: result = pd.read_parquet('example_fp.parquet',
.....:                             engine='fastparquet', columns=['a', 'b'])
.....:

In [532]: result.dtypes
Out[532]:
a      object
b      int64
dtype: object
```

## 25.10.1 Handling Indexes

Serializing a DataFrame to parquet may include the implicit index as one or more columns in the output file. Thus, this code:

```
In [533]: df = pd.DataFrame({'a': [1, 2], 'b': [3, 4]})

In [534]: df.to_parquet('test.parquet', engine='pyarrow')
```

creates a parquet file with *three* columns if you use pyarrow for serialization: a, b, and `__index_level_0__`. If you're using fastparquet, the index *may or may not* be written to the file.

This unexpected extra column causes some databases like Amazon Redshift to reject the file, because that column doesn't exist in the target table.

If you want to omit a dataframe's indexes when writing, pass `index=False` to `to_parquet()`:

```
In [535]: df.to_parquet('test.parquet', index=False)
```

This creates a parquet file with just the two expected columns, a and b. If your DataFrame has a custom index, you won't get it back when you load this file into a DataFrame.

Passing `index=True` will *always* write the index, even if that's not the underlying engine's default behavior.

## 25.10.2 Partitioning Parquet files

New in version 0.24.0.

Parquet supports partitioning of data based on the values of one or more columns.

```
In [536]: df = pd.DataFrame({'a': [0, 0, 1, 1], 'b': [0, 1, 0, 1]})

In [537]: df.to_parquet(fname='test', engine='pyarrow',
.....:                  partition_cols=['a'], compression=None)
.....:
```

The *fname* specifies the parent directory to which data will be saved. The *partition\_cols* are the column names by which the dataset will be partitioned. Columns are partitioned in the order they are given. The partition splits are determined by the unique values in the partition columns. The above example creates a partitioned dataset that may look like:

```
test
├── a=0
│   ├── 0bac803e32dc42ae83fddfd029cbdebc.parquet
│   └── ...
└── a=1
    ├── e6ab24a4f45147b49b54a662f0c412a3.parquet
    └── ...
```

## 25.11 SQL Queries

The `pandas.io.sql` module provides a collection of query wrappers to both facilitate data retrieval and to reduce dependency on DB-specific API. Database abstraction is provided by SQLAlchemy if installed. In addition you will need a driver library for your database. Examples of such drivers are [psycopg2](#) for PostgreSQL or [pymysql](#) for MySQL. For [SQLite](#) this is included in Python's standard library by default. You can find an overview of supported drivers for each SQL dialect in the [SQLAlchemy docs](#).

If SQLAlchemy is not installed, a fallback is only provided for sqlite (and for mysql for backwards compatibility, but this is deprecated and will be removed in a future version). This mode requires a Python database adapter which respect the [Python DB-API](#).

See also some *cookbook examples* for some advanced strategies.

The key functions are:

|                                                             |                                                        |

### 25.11.1 pandas.read\_sql\_table

`pandas.read_sql_table(table_name, con, schema=None, index_col=None, coerce_float=True, parse_dates=None, columns=None, chunksize=None)`  
Read SQL database table into a DataFrame.

Given a table name and a SQLAlchemy connectable, returns a DataFrame. This function does not support DBAPI connections.

#### Parameters

**table\_name** [string] Name of SQL table in database.

**con** [SQLAlchemy connectable (or database string URI)] SQLite DBAPI connection mode not

supported.

**schema** [string, default None] Name of SQL schema in database to query (if database flavor supports this). Uses default schema if None (default).

**index\_col** [string or list of strings, optional, default: None] Column(s) to set as index(MultiIndex).

**coerce\_float** [boolean, default True] Attempts to convert values of non-string, non-numeric objects (like decimal.Decimal) to floating point. Can result in loss of Precision.

**parse\_dates** [list or dict, default: None]

- List of column names to parse as dates.
- Dict of {column\_name: format string} where format string is strftime compatible in case of parsing string times or is one of (D, s, ns, ms, us) in case of parsing integer timestamps.
- Dict of {column\_name: arg dict}, where the arg dict corresponds to the keyword arguments of `pandas.to_datetime()` Especially useful with databases without native Datetime support, such as SQLite.

**columns** [list, default: None] List of column names to select from SQL table

**chunksize** [int, default None] If specified, returns an iterator where *chunksize* is the number of rows to include in each chunk.

#### Returns

**DataFrame**

See also:

**read\_sql\_query** Read SQL query into a DataFrame.

`read_sql`

#### Notes

Any datetime values with time zone information will be converted to UTC.

### 25.11.2 pandas.read\_sql\_query

`pandas.read_sql_query(sql, con, index_col=None, coerce_float=True, params=None, parse_dates=None, chunksize=None)`

Read SQL query into a DataFrame.

Returns a DataFrame corresponding to the result set of the query string. Optionally provide an *index\_col* parameter to use one of the columns as the index, otherwise default integer index will be used.

#### Parameters

**sql** [string SQL query or SQLAlchemy Selectable (select or text object)] SQL query to be executed.

**con** [SQLAlchemy connectable(engine/connection), database string URI,] or sqlite3 DBAPI2 connection Using SQLAlchemy makes it possible to use any DB supported by that library. If a DBAPI2 object, only sqlite3 is supported.

**index\_col** [string or list of strings, optional, default: None] Column(s) to set as index(MultiIndex).

**coerce\_float** [boolean, default True] Attempts to convert values of non-string, non-numeric objects (like decimal.Decimal) to floating point. Useful for SQL result sets.

**params** [list, tuple or dict, optional, default: None] List of parameters to pass to execute method. The syntax used to pass parameters is database driver dependent. Check your database driver documentation for which of the five syntax styles, described in PEP 249's paramstyle, is supported. Eg. for psycopg2, uses %(name)s so use params={'name' : 'value'}

**parse\_dates** [list or dict, default: None]

- List of column names to parse as dates.
- Dict of {column\_name: format string} where format string is strftime compatible in case of parsing string times, or is one of (D, s, ns, ms, us) in case of parsing integer timestamps.
- Dict of {column\_name: arg dict}, where the arg dict corresponds to the keyword arguments of `pandas.to_datetime()` Especially useful with databases without native Datetime support, such as SQLite.

**chunksize** [int, default None] If specified, return an iterator where *chunksize* is the number of rows to include in each chunk.

#### Returns

**DataFrame**

See also:

**read\_sql\_table** Read SQL database table into a DataFrame.

*read\_sql*

#### Notes

Any datetime values with time zone information parsed via the *parse\_dates* parameter will be converted to UTC.

### 25.11.3 pandas.read\_sql

`pandas.read_sql(sql, con, index_col=None, coerce_float=True, params=None, parse_dates=None, columns=None, chunksize=None)`

Read SQL query or database table into a DataFrame.

This function is a convenience wrapper around `read_sql_table` and `read_sql_query` (for backward compatibility). It will delegate to the specific function depending on the provided input. A SQL query will be routed to `read_sql_query`, while a database table name will be routed to `read_sql_table`. Note that the delegated function might have more specific notes about their functionality not listed here.

#### Parameters

**sql** [string or SQLAlchemy Selectable (select or text object)] SQL query to be executed or a table name.

**con** [SQLAlchemy connectable (engine/connection) or database string URI] or DBAPI2 connection (fallback mode)

Using SQLAlchemy makes it possible to use any DB supported by that library. If a DBAPI2 object, only sqlite3 is supported.

**index\_col** [string or list of strings, optional, default: None] Column(s) to set as index(MultiIndex).

**coerce\_float** [boolean, default True] Attempts to convert values of non-string, non-numeric objects (like decimal.Decimal) to floating point, useful for SQL result sets.

**params** [list, tuple or dict, optional, default: None] List of parameters to pass to execute method. The syntax used to pass parameters is database driver dependent. Check your database driver documentation for which of the five syntax styles, described in PEP 249's paramstyle, is supported. Eg. for psycopg2, uses %(name)s so use params={'name' : 'value'}

**parse\_dates** [list or dict, default: None]

- List of column names to parse as dates.
- Dict of {column\_name: format string} where format string is strftime compatible in case of parsing string times, or is one of (D, s, ns, ms, us) in case of parsing integer timestamps.
- Dict of {column\_name: arg dict}, where the arg dict corresponds to the keyword arguments of `pandas.to_datetime()` Especially useful with databases without native Datetime support, such as SQLite.

**columns** [list, default: None] List of column names to select from SQL table (only used when reading a table).

**chunksize** [int, default None] If specified, return an iterator where *chunksize* is the number of rows to include in each chunk.

#### Returns

**DataFrame**

See also:

**read\_sql\_table** Read SQL database table into a DataFrame.

**read\_sql\_query** Read SQL query into a DataFrame.

### 25.11.4 pandas.DataFrame.to\_sql

`DataFrame.to_sql(name, con, schema=None, if_exists='fail', index=True, index_label=None, chunksize=None, dtype=None, method=None)`

Write records stored in a DataFrame to a SQL database.

Databases supported by SQLAlchemy [?] are supported. Tables can be newly created, appended to, or overwritten.

#### Parameters

**name** [string] Name of SQL table.

**con** [sqlalchemy.engine.Engine or sqlite3.Connection] Using SQLAlchemy makes it possible to use any DB supported by that library. Legacy support is provided for sqlite3.Connection objects.

**schema** [string, optional] Specify the schema (if database flavor supports this). If None, use default schema.

**if\_exists** [{‘fail’, ‘replace’, ‘append’}, default ‘fail’] How to behave if the table already exists.

- fail: Raise a ValueError.
- replace: Drop the table before inserting new values.
- append: Insert new values to the existing table.

**index** [bool, default True] Write DataFrame index as a column. Uses *index\_label* as the column name in the table.

**index\_label** [string or sequence, default None] Column label for index column(s). If None is given (default) and *index* is True, then the index names are used. A sequence should be given if the DataFrame uses MultiIndex.

**chunksize** [int, optional] Rows will be written in batches of this size at a time. By default, all rows will be written at once.

**dtype** [dict, optional] Specifying the datatype for columns. The keys should be the column names and the values should be the SQLAlchemy types or strings for the sqlite3 legacy mode.

**method** [{None, ‘multi’, callable}, default None] Controls the SQL insertion clause used:

- None : Uses standard SQL INSERT clause (one per row).
- ‘multi’: Pass multiple values in a single INSERT clause.
- callable with signature (pd\_table, conn, keys, data\_iter).

Details and a sample callable implementation can be found in the section *insert method*.

New in version 0.24.0.

#### Raises

**ValueError** When the table already exists and *if\_exists* is ‘fail’ (the default).

See also:

**read\_sql** Read a DataFrame from a table.

#### Notes

Timezone aware datetime columns will be written as `Timestamp with timezone` type with SQLAlchemy if supported by the database. Otherwise, the datetimes will be stored as timezone unaware timestamps local to the original timezone.

New in version 0.24.0.

#### References

[?], [?]

#### Examples

Create an in-memory SQLite database.

```
>>> from sqlalchemy import create_engine
>>> engine = create_engine('sqlite://', echo=False)
```

Create a table from scratch with 3 rows.

```
>>> df = pd.DataFrame({'name' : ['User 1', 'User 2', 'User 3']})
>>> df
   name
0  User 1
1  User 2
2  User 3
```

```
>>> df.to_sql('users', con=engine)
>>> engine.execute("SELECT * FROM users").fetchall()
[(0, 'User 1'), (1, 'User 2'), (2, 'User 3')]
```

```
>>> df1 = pd.DataFrame({'name' : ['User 4', 'User 5']})
>>> df1.to_sql('users', con=engine, if_exists='append')
>>> engine.execute("SELECT * FROM users").fetchall()
[(0, 'User 1'), (1, 'User 2'), (2, 'User 3'),
 (0, 'User 4'), (1, 'User 5')]
```

Overwrite the table with just df1.

```
>>> df1.to_sql('users', con=engine, if_exists='replace',
...           index_label='id')
>>> engine.execute("SELECT * FROM users").fetchall()
[(0, 'User 4'), (1, 'User 5')]
```

Specify the dtype (especially useful for integers with missing values). Notice that while pandas is forced to store the data as floating point, the database supports nullable integers. When fetching the data with Python, we get back integer scalars.

```
>>> df = pd.DataFrame({"A": [1, None, 2]})
>>> df
   A
0  1.0
1  NaN
2  2.0
```

```
>>> from sqlalchemy.types import Integer
>>> df.to_sql('integers', con=engine, index=False,
...          dtype={"A": Integer()})
```

```
>>> engine.execute("SELECT * FROM integers").fetchall()
[(1,), (None,), (2,)]
```

**Note:** The function `read_sql()` is a convenience wrapper around `read_sql_table()` and `read_sql_query()` (and for backward compatibility) and will delegate to specific function depending on the provided input (database table name or sql query). Table names do not need to be quoted if they have special characters.

In the following example, we use the [SQLite](#) SQL database engine. You can use a temporary SQLite database where data are stored in “memory”.

To connect with SQLAlchemy you use the `create_engine()` function to create an engine object from database URI. You only need to create the engine once per database you are connecting to. For more information on `create_engine()` and the URI formatting, see the examples below and the SQLAlchemy [documentation](#)

```
In [538]: from sqlalchemy import create_engine

# Create your engine.
In [539]: engine = create_engine('sqlite:///memory:')
```

If you want to manage your own connections you can pass one of those instead:

```
with engine.connect() as conn, conn.begin():
    data = pd.read_sql_table('data', conn)
```

## 25.11.5 Writing DataFrames

Assuming the following data is in a DataFrame `data`, we can insert it into the database using `to_sql()`.

| id | Date       | Col_1 | Col_2 | Col_3 |
|----|------------|-------|-------|-------|
| 26 | 2012-10-18 | X     | 25.7  | True  |
| 42 | 2012-10-19 | Y     | -12.4 | False |
| 63 | 2012-10-20 | Z     | 5.73  | True  |

```
In [540]: data
Out[540]:
   id      Date Col_1  Col_2  Col_3
0  26 2010-10-18     X   27.50   True
1  42 2010-10-19     Y  -12.50  False
2  63 2010-10-20     Z    5.73   True

In [541]: data.to_sql('data', engine)
```

With some databases, writing large DataFrames can result in errors due to packet size limitations being exceeded. This can be avoided by setting the `chunksize` parameter when calling `to_sql`. For example, the following writes `data` to the database in batches of 1000 rows at a time:

```
In [542]: data.to_sql('data_chunked', engine, chunksize=1000)
```

### 25.11.5.1 SQL data types

`to_sql()` will try to map your data to an appropriate SQL data type based on the dtype of the data. When you have columns of dtype `object`, pandas will try to infer the data type.

You can always override the default type by specifying the desired SQL type of any of the columns by using the `dtype` argument. This argument needs a dictionary mapping column names to SQLAlchemy types (or strings for the `sqlite3` fallback mode). For example, specifying to use the sqlalchemy `String` type instead of the default `Text` type for string columns:

```
In [543]: from sqlalchemy.types import String

In [544]: data.to_sql('data_dtype', engine, dtype={'Col_1': String})
```

---

**Note:** Due to the limited support for `timedelta`'s in the different database flavors, columns with type `timedelta64` will be written as integer values as nanoseconds to the database and a warning will be raised.

---

**Note:** Columns of `category` dtype will be converted to the dense representation as you would get with `np.asarray(categorical)` (e.g. for string categories this gives an array of strings). Because of this, reading the database table back in does **not** generate a categorical.

## 25.11.6 Datetime data types

Using SQLAlchemy, `to_sql()` is capable of writing datetime data that is timezone naive or timezone aware. However, the resulting data stored in the database ultimately depends on the supported data type for datetime data of the database system being used.

The following table lists supported data types for datetime data for some common databases. Other database dialects may have different data types for datetime data.

| Database   | SQL Datetime Types                    | Timezone Support |
|------------|---------------------------------------|------------------|
| SQLite     | TEXT                                  | No               |
| MySQL      | TIMESTAMP or DATETIME                 | No               |
| PostgreSQL | TIMESTAMP or TIMESTAMP WITH TIME ZONE | Yes              |

When writing timezone aware data to databases that do not support timezones, the data will be written as timezone naive timestamps that are in local time with respect to the timezone.

`read_sql_table()` is also capable of reading datetime data that is timezone aware or naive. When reading `TIMESTAMP WITH TIME ZONE` types, pandas will convert the data to UTC.

### 25.11.6.1 Insertion Method

New in version 0.24.0.

The parameter `method` controls the SQL insertion clause used. Possible values are:

- `None`: Uses standard SQL `INSERT` clause (one per row).
- `'multi'`: Pass multiple values in a single `INSERT` clause. It uses a *special* SQL syntax not supported by all backends. This usually provides better performance for analytic databases like *Presto* and *Redshift*, but has worse performance for traditional SQL backend if the table contains many columns. For more information check the SQLAlchemy [documentation](#).
- callable with signature `(pd_table, conn, keys, data_iter)`: This can be used to implement a more performant insertion method based on specific backend dialect features.

Example of a callable using PostgreSQL `COPY` clause:

```
# Alternative to_sql() *method* for DBs that support COPY FROM
import csv
from io import StringIO

def psql_insert_copy(table, conn, keys, data_iter):
    # gets a DBAPI connection that can provide a cursor
    dbapi_conn = conn.connection
    with dbapi_conn.cursor() as cur:
        s_buf = StringIO()
        writer = csv.writer(s_buf)
        writer.writerows(data_iter)
        s_buf.seek(0)
```

(continues on next page)

(continued from previous page)

```

columns = ', '.join("{}{}".format(k) for k in keys)
if table.schema:
    table_name = '{}.{}'.format(table.schema, table.name)
else:
    table_name = table.name

sql = 'COPY {} (()) FROM STDIN WITH CSV'.format(
    table_name, columns)
cur.copy_expert(sql=sql, file=s_buf)

```

## 25.11.7 Reading Tables

`read_sql_table()` will read a database table given the table name and optionally a subset of columns to read.

**Note:** In order to use `read_sql_table()`, you **must** have the SQLAlchemy optional dependency installed.

```
In [545]: pd.read_sql_table('data', engine)
```

```
Out[545]:
```

|   | index | id | Date       | Col_1 | Col_2  | Col_3 |
|---|-------|----|------------|-------|--------|-------|
| 0 | 0     | 26 | 2010-10-18 | X     | 27.50  | True  |
| 1 | 1     | 42 | 2010-10-19 | Y     | -12.50 | False |
| 2 | 2     | 63 | 2010-10-20 | Z     | 5.73   | True  |

You can also specify the name of the column as the DataFrame index, and specify a subset of columns to be read.

```
In [546]: pd.read_sql_table('data', engine, index_col='id')
```

```
Out[546]:
```

|    | index | Date       | Col_1 | Col_2  | Col_3 |
|----|-------|------------|-------|--------|-------|
| id |       |            |       |        |       |
| 26 | 0     | 2010-10-18 | X     | 27.50  | True  |
| 42 | 1     | 2010-10-19 | Y     | -12.50 | False |
| 63 | 2     | 2010-10-20 | Z     | 5.73   | True  |

```
In [547]: pd.read_sql_table('data', engine, columns=['Col_1', 'Col_2'])
```

```

////////////////////////////////////
↪
   Col_1  Col_2
0      X  27.50
1      Y -12.50
2      Z   5.73

```

And you can explicitly force columns to be parsed as dates:

```
In [548]: pd.read_sql_table('data', engine, parse_dates=['Date'])
```

```
Out[548]:
```

|   | index | id | Date       | Col_1 | Col_2  | Col_3 |
|---|-------|----|------------|-------|--------|-------|
| 0 | 0     | 26 | 2010-10-18 | X     | 27.50  | True  |
| 1 | 1     | 42 | 2010-10-19 | Y     | -12.50 | False |
| 2 | 2     | 63 | 2010-10-20 | Z     | 5.73   | True  |

If needed you can explicitly specify a format string, or a dict of arguments to pass to `pandas.to_datetime()`:

```
pd.read_sql_table('data', engine, parse_dates={'Date': '%Y-%m-%d'})
pd.read_sql_table('data', engine,
                  parse_dates={'Date': {'format': '%Y-%m-%d %H:%M:%S'}})
```

You can check if a table exists using `has_table()`

### 25.11.8 Schema support

Reading from and writing to different schema's is supported through the `schema` keyword in the `read_sql_table()` and `to_sql()` functions. Note however that this depends on the database flavor (sqlite does not have schema's). For example:

```
df.to_sql('table', engine, schema='other_schema')
pd.read_sql_table('table', engine, schema='other_schema')
```

### 25.11.9 Querying

You can query using raw SQL in the `read_sql_query()` function. In this case you must use the SQL variant appropriate for your database. When using SQLAlchemy, you can also pass SQLAlchemy Expression language constructs, which are database-agnostic.

```
In [549]: pd.read_sql_query('SELECT * FROM data', engine)
Out[549]:
```

|   | index | id | Date                       | Col_1 | Col_2  | Col_3 |
|---|-------|----|----------------------------|-------|--------|-------|
| 0 | 0     | 26 | 2010-10-18 00:00:00.000000 | X     | 27.50  | 1     |
| 1 | 1     | 42 | 2010-10-19 00:00:00.000000 | Y     | -12.50 | 0     |
| 2 | 2     | 63 | 2010-10-20 00:00:00.000000 | Z     | 5.73   | 1     |

Of course, you can specify a more “complex” query.

```
In [550]: pd.read_sql_query("SELECT id, Col_1, Col_2 FROM data WHERE id = 42;",
                             ↪engine)
Out[550]:
```

|   | id | Col_1 | Col_2 |
|---|----|-------|-------|
| 0 | 42 | Y     | -12.5 |

The `read_sql_query()` function supports a `chunksize` argument. Specifying this will return an iterator through chunks of the query result:

```
In [551]: df = pd.DataFrame(np.random.randn(20, 3), columns=list('abc'))
In [552]: df.to_sql('data_chunks', engine, index=False)
```

```
In [553]: for chunk in pd.read_sql_query("SELECT * FROM data_chunks",
      .....:                             engine, chunksize=5):
      .....:     print(chunk)
      .....:
```

|   | a         | b         | c         |
|---|-----------|-----------|-----------|
| 0 | -0.175453 | -0.809833 | 1.537958  |
| 1 | -0.833349 | 2.502008  | -1.016559 |

| 3 | 1.737293  | -1.555844 | -0.600872 |
| 4 | 1.153956  | 0.330173  | 0.649107  |

|   | a         | b         | c         |
|---|-----------|-----------|-----------|
| 0 | 1.282816  | -0.402091 | 0.654118  |
| 1 | -0.502296 | -0.116233 | -0.812102 |
| 2 | -1.798362 | -1.926876 | -1.277219 |
| 3 | -0.658800 | 0.811340  | -1.228702 |
| 4 | -1.195364 | 0.211111  | 0.244740  |

You can also run a plain query without creating a `DataFrame` with `execute()`. This is useful for queries that don't return values, such as `INSERT`. This is functionally equivalent to calling `execute` on the SQLAlchemy engine or db connection object. Again, you must use the SQL syntax variant appropriate for your database.

```
from pandas.io import sql
sql.execute('SELECT * FROM table_name', engine)
sql.execute('INSERT INTO table_name VALUES(?, ?, ?)', engine,
            params=[('id', 1, 12.2, True)])
```

### 25.11.10 Engine connection examples

To connect with SQLAlchemy you use the `create_engine()` function to create an engine object from database URI. You only need to create the engine once per database you are connecting to.

```
from sqlalchemy import create_engine

engine = create_engine('postgresql://scott:tiger@localhost:5432/mydatabase')

engine = create_engine('mysql+mysqldb://scott:tiger@localhost/foo')

engine = create_engine('oracle://scott:tiger@127.0.0.1:1521/sidname')

engine = create_engine('mssql+pyodbc://mydsn')

# sqlite://<nohostname>/<path>
# where <path> is relative:
engine = create_engine('sqlite:///foo.db')

# or absolute, starting with a slash:
engine = create_engine('sqlite:///absolute/path/to/foo.db')
```

For more information see the examples the SQLAlchemy [documentation](#)

### 25.11.11 Advanced SQLAlchemy queries

You can use SQLAlchemy constructs to describe your query.

Use `sqlalchemy.text()` to specify query parameters in a backend-neutral way

```
In [554]: import sqlalchemy as sa

In [555]: pd.read_sql(sa.text('SELECT * FROM data where Col_1=:coll1'),
.....:               engine, params={'coll1': 'X'})
.....:
Out[555]:
```

|   | index | id | Date                       | Col_1 | Col_2 | Col_3 |
|---|-------|----|----------------------------|-------|-------|-------|
| 0 | 0     | 26 | 2010-10-18 00:00:00.000000 | X     | 27.5  | 1     |

If you have an SQLAlchemy description of your database you can express where conditions using SQLAlchemy expressions

```
In [556]: metadata = sa.MetaData()

In [557]: data_table = sa.Table('data', metadata,
.....:                          sa.Column('index', sa.Integer),
.....:                          sa.Column('Date', sa.DateTime),
.....:                          sa.Column('Col_1', sa.String),
.....:                          sa.Column('Col_2', sa.Float),
.....:                          sa.Column('Col_3', sa.Boolean),
.....:                          )

In [558]: pd.read_sql(sa.select([data_table]).where(data_table.c.Col_3 is True),
→engine)
Out[558]:
Empty DataFrame
Columns: [index, Date, Col_1, Col_2, Col_3]
Index: []
```

You can combine SQLAlchemy expressions with parameters passed to `read_sql()` using `sqlalchemy.bindparam()`

```
In [559]: import datetime as dt

In [560]: expr = sa.select([data_table]).where(data_table.c.Date > sa.bindparam('date
→'))

In [561]: pd.read_sql(expr, engine, params={'date': dt.datetime(2010, 10, 18)})
Out[561]:
```

|   | index | Date       | Col_1 | Col_2  | Col_3 |
|---|-------|------------|-------|--------|-------|
| 0 | 1     | 2010-10-19 | Y     | -12.50 | False |
| 1 | 2     | 2010-10-20 | Z     | 5.73   | True  |

### 25.11.12 Sqlite fallback

The use of `sqlite` is supported without using SQLAlchemy. This mode requires a Python database adapter which respect the [Python DB-API](#).

You can create connections like so:

```
import sqlite3
con = sqlite3.connect(':memory:')
```

And then issue the following queries:

```
data.to_sql('data', con)
pd.read_sql_query("SELECT * FROM data", con)
```

## 25.12 Google BigQuery

**Warning:** Starting in 0.20.0, pandas has split off Google BigQuery support into the separate package `pandas-gbq`. You can `pip install pandas-gbq` to get it.

The `pandas-gbq` package provides functionality to read/write from Google BigQuery.

`pandas` integrates with this external package. If `pandas-gbq` is installed, you can use the pandas methods `pd.read_gbq` and `DataFrame.to_gbq`, which will call the respective functions from `pandas-gbq`.

Full documentation can be found [here](#).

## 25.13 Stata Format

### 25.13.1 Writing to Stata format

The method `to_stata()` will write a `DataFrame` into a `.dta` file. The format version of this file is always 115 (Stata 12).

```
In [562]: df = pd.DataFrame(np.random.randn(10, 2), columns=list('AB'))
In [563]: df.to_stata('stata.dta')
```

*Stata* data files have limited data type support; only strings with 244 or fewer characters, `int8`, `int16`, `int32`, `float32` and `float64` can be stored in `.dta` files. Additionally, *Stata* reserves certain values to represent missing data. Exporting a non-missing value that is outside of the permitted range in *Stata* for a particular data type will retype the variable to the next larger size. For example, `int8` values are restricted to lie between -127 and 100 in *Stata*, and so variables with values above 100 will trigger a conversion to `int16`. `nan` values in floating points data types are stored as the basic missing data type (`.` in *Stata*).

---

**Note:** It is not possible to export missing data values for integer data types.

---

The *Stata* writer gracefully handles other data types including `int64`, `bool`, `uint8`, `uint16`, `uint32` by casting to the smallest supported type that can represent the data. For example, data with a type of `uint8` will be cast to `int8` if all values are less than 100 (the upper bound for non-missing `int8` data in *Stata*), or, if values are outside of this range, the variable is cast to `int16`.

**Warning:** Conversion from `int64` to `float64` may result in a loss of precision if `int64` values are larger than  $2^{53}$ .

**Warning:** `StataWriter` and `to_stata()` only support fixed width strings containing up to 244 characters, a limitation imposed by the version 115 dta file format. Attempting to write *Stata* dta files with strings longer than 244 characters raises a `ValueError`.

### 25.13.2 Reading from Stata format

The top-level function `read_stata` will read a dta file and return either a `DataFrame` or a `StataReader` that can be used to read the file incrementally.

```
In [564]: pd.read_stata('stata.dta')
Out[564]:
```

|   | index | A         | B         |
|---|-------|-----------|-----------|
| 0 | 0     | 0.552113  | -1.686920 |
| 1 | 1     | 0.845778  | -0.913166 |
| 2 | 2     | -0.986607 | 0.710558  |
| 3 | 3     | -0.130151 | -1.140741 |
| 4 | 4     | -0.411941 | 0.326399  |
| 5 | 5     | 2.595523  | 0.926898  |
| 6 | 6     | -0.835681 | 0.666860  |
| 7 | 7     | 1.034252  | -0.027252 |
| 8 | 8     | 1.408774  | -0.359164 |
| 9 | 9     | 0.721177  | -0.001537 |

Specifying a `chunksize` yields a `StataReader` instance that can be used to read `chunksize` lines from the file at a time. The `StataReader` object can be used as an iterator.

```
In [565]: reader = pd.read_stata('stata.dta', chunksize=3)

In [566]: for df in reader:
.....:     print(df.shape)
.....:
(3, 3)
(3, 3)
(3, 3)
(1, 3)
```

For more fine-grained control, use `iterator=True` and specify `chunksize` with each call to `read()`.

```
In [567]: reader = pd.read_stata('stata.dta', iterator=True)

In [568]: chunk1 = reader.read(5)

In [569]: chunk2 = reader.read(5)
```

Currently the index is retrieved as a column.

The parameter `convert_categoricals` indicates whether value labels should be read and used to create a `Categorical` variable from them. Value labels can also be retrieved by the function `value_labels`, which requires `read()` to be called before use.

The parameter `convert_missing` indicates whether missing value representations in Stata should be preserved. If `False` (the default), missing values are represented as `np.nan`. If `True`, missing values are represented using `StataMissingValue` objects, and columns containing missing values will have object data type.

**Note:** `read_stata()` and `StataReader` support .dta formats 113-115 (Stata 10-12), 117 (Stata 13), and 118

(Stata 14).

---

**Note:** Setting `preserve_dtypes=False` will upcast to the standard pandas data types: `int64` for all integer types and `float64` for floating point data. By default, the Stata data types are preserved when importing.

---

### 25.13.2.1 Categorical Data

Categorical data can be exported to *Stata* data files as value labeled data. The exported data consists of the underlying category codes as integer data values and the categories as value labels. *Stata* does not have an explicit equivalent to a `Categorical` and information about *whether* the variable is ordered is lost when exporting.

**Warning:** *Stata* only supports string value labels, and so `str` is called on the categories when exporting data. Exporting `Categorical` variables with non-string categories produces a warning, and can result a loss of information if the `str` representations of the categories are not unique.

Labeled data can similarly be imported from *Stata* data files as `Categorical` variables using the keyword argument `convert_categoricals` (True by default). The keyword argument `order_categoricals` (True by default) determines whether imported `Categorical` variables are ordered.

**Note:** When importing categorical data, the values of the variables in the *Stata* data file are not preserved since `Categorical` variables always use integer data types between `-1` and `n-1` where `n` is the number of categories. If the original values in the *Stata* data file are required, these can be imported by setting `convert_categoricals=False`, which will import original data (but not the variable labels). The original values can be matched to the imported categorical data since there is a simple mapping between the original *Stata* data values and the category codes of imported `Categorical` variables: missing values are assigned code `-1`, and the smallest original value is assigned `0`, the second smallest is assigned `1` and so on until the largest original value is assigned the code `n-1`.

---

**Note:** *Stata* supports partially labeled series. These series have value labels for some but not all data values. Importing a partially labeled series will produce a `Categorical` with string categories for the values that are labeled and numeric categories for values with no label.

---

## 25.14 SAS Formats

The top-level function `read_sas()` can read (but not write) SAS *xport* (.XPT) and (since v0.18.0) *SAS7BDAT* (.sas7bdat) format files.

SAS files only contain two value types: ASCII text and floating point values (usually 8 bytes but sometimes truncated). For *xport* files, there is no automatic type conversion to integers, dates, or categoricals. For *SAS7BDAT* files, the format codes may allow date variables to be automatically converted to dates. By default the whole file is read and returned as a `DataFrame`.

Specify a `chunksize` or use `iterator=True` to obtain reader objects (`XportReader` or `SAS7BDATReader`) for incrementally reading the file. The reader objects also have attributes that contain additional information about the file and its variables.

Read a SAS7BDAT file:

```
df = pd.read_sas('sas_data.sas7bdat')
```

Obtain an iterator and read an XPORT file 100,000 lines at a time:

```
def do_something(chunk):
    pass

rdr = pd.read_sas('sas_xport.xpt', chunk=100000)
for chunk in rdr:
    do_something(chunk)
```

The [specification](#) for the xport file format is available from the SAS web site.

No official documentation is available for the SAS7BDAT format.

## 25.15 Other file formats

pandas itself only supports IO with a limited set of file formats that map cleanly to its tabular data model. For reading and writing other file formats into and from pandas, we recommend these packages from the broader community.

### 25.15.1 netCDF

[xarray](#) provides data structures inspired by the pandas `DataFrame` for working with multi-dimensional datasets, with a focus on the netCDF file format and easy conversion to and from pandas.

## 25.16 Performance Considerations

This is an informal comparison of various IO methods, using pandas 0.20.3. Timings are machine dependent and small differences should be ignored.

```
In [1]: sz = 1000000
In [2]: df = pd.DataFrame({'A': np.random.randn(sz), 'B': [1] * sz})

In [3]: df.info()
<class 'pandas.core.frame.DataFrame'>
RangeIndex: 1000000 entries, 0 to 999999
Data columns (total 2 columns):
A      1000000 non-null float64
B      1000000 non-null int64
dtypes: float64(1), int64(1)
memory usage: 15.3 MB
```

Given the next test set:

```
from numpy.random import randn

sz = 1000000
df = pd.DataFrame({'A': randn(sz), 'B': [1] * sz})
```

(continues on next page)

(continued from previous page)

```
def test_sql_write(df):
    if os.path.exists('test.sql'):
        os.remove('test.sql')
    sql_db = sqlite3.connect('test.sql')
    df.to_sql(name='test_table', con=sql_db)
    sql_db.close()

def test_sql_read():
    sql_db = sqlite3.connect('test.sql')
    pd.read_sql_query("select * from test_table", sql_db)
    sql_db.close()

def test_hdf_fixed_write(df):
    df.to_hdf('test_fixed.hdf', 'test', mode='w')

def test_hdf_fixed_read():
    pd.read_hdf('test_fixed.hdf', 'test')

def test_hdf_fixed_write_compress(df):
    df.to_hdf('test_fixed_compress.hdf', 'test', mode='w', complib='blosc')

def test_hdf_fixed_read_compress():
    pd.read_hdf('test_fixed_compress.hdf', 'test')

def test_hdf_table_write(df):
    df.to_hdf('test_table.hdf', 'test', mode='w', format='table')

def test_hdf_table_read():
    pd.read_hdf('test_table.hdf', 'test')

def test_hdf_table_write_compress(df):
    df.to_hdf('test_table_compress.hdf', 'test', mode='w',
              complib='blosc', format='table')

def test_hdf_table_read_compress():
    pd.read_hdf('test_table_compress.hdf', 'test')

def test_csv_write(df):
    df.to_csv('test.csv', mode='w')

def test_csv_read():
    pd.read_csv('test.csv', index_col=0)

def test_feather_write(df):
    df.to_feather('test.feather')
```

(continues on next page)

(continued from previous page)

```

def test_feather_read():
    pd.read_feather('test.feather')

def test_pickle_write(df):
    df.to_pickle('test.pkl')

def test_pickle_read():
    pd.read_pickle('test.pkl')

def test_pickle_write_compress(df):
    df.to_pickle('test.pkl.compress', compression='xz')

def test_pickle_read_compress():
    pd.read_pickle('test.pkl.compress', compression='xz')

```

When writing, the top-three functions in terms of speed are `test_pickle_write`, `test_feather_write` and `test_hdf_fixed_write_compress`.

```

In [14]: %timeit test_sql_write(df)
2.37 s ± 36.6 ms per loop (mean ± std. dev. of 7 runs, 1 loop each)

In [15]: %timeit test_hdf_fixed_write(df)

## ENHANCING PERFORMANCE

In this part of the tutorial, we will investigate how to speed up certain functions operating on pandas `DataFrames` using three different techniques: Cython, Numba and `pandas.eval()`. We will see a speed improvement of ~200 when we use Cython and Numba on a test function operating row-wise on the `DataFrame`. Using `pandas.eval()` we will speed up a sum by an order of ~2.

### 26.1 Cython (Writing C extensions for pandas)

For many use cases writing pandas in pure Python and NumPy is sufficient. In some computationally heavy applications however, it can be possible to achieve sizable speed-ups by offloading work to [cython](#).

This tutorial assumes you have refactored as much as possible in Python, for example by trying to remove for-loops and making use of NumPy vectorization. It's always worth optimising in Python first.

This tutorial walks through a “typical” process of cythonizing a slow computation. We use an [example from the Cython documentation](#) but in the context of pandas. Our final cythonized solution is around 100 times faster than the pure Python solution.

#### 26.1.1 Pure python

We have a `DataFrame` to which we want to apply a function row-wise.

```
In [1]: df = pd.DataFrame({'a': np.random.randn(1000),
...:                      'b': np.random.randn(1000),
...:                      'N': np.random.randint(100, 1000, (1000)),
...:                      'x': 'x'})
...:
```

```
In [2]: df
```

```
Out[2]:
```

|   | a         | b         | N   | x |
|---|-----------|-----------|-----|---|
| 0 | -0.052526 | -0.465341 | 342 | x |
| 1 | 1.343970  | -0.709572 | 865 | x |
| 2 | 0.180262  | 0.169150  | 879 | x |
| 3 | 1.602940  | -0.602105 | 993 | x |
| 4 | 0.357233  | 0.886264  | 969 | x |
| 5 | 1.203043  | -0.947506 | 480 | x |
| 6 | 1.142005  | -1.010341 | 816 | x |
| 7 | 0.002293  | 0.508020  | 711 | x |
| 8 | 1.283408  | -0.856512 | 461 | x |
| 9 | -1.259051 | 0.577789  | 434 | x |

(continues on next page)

990    0.623282   -1.961655    295    x
991  -1.695224    1.141042    398    x
992  -1.841635   -0.686226    509    x
993  -0.805841    0.947042    837    x
994  -0.243984    1.487879    676    x
995  -0.318964   -1.975936    668    x
996  -1.608481    1.093351    522    x
997  -0.327760    0.294133    992    x
998  -0.273733    0.678038    386    x
999  -0.412327   -0.074951    841    x

[1000 rows x 4 columns]
```

Here's the function in pure Python:

```
In [3]: def f(x):
...:     return x * (x - 1)
...:

In [4]: def integrate_f(a, b, N):
...:     s = 0
...:     dx = (b - a) / N
...:     for i in range(N):
...:         s += f(a + i * dx)
...:     return s * dx
...:
```

We achieve our result by using `apply` (row-wise):

```
In [7]: %timeit df.apply(lambda x: integrate_f(x['a'], x['b'], x['N']), axis=1)
10 loops, best of 3: 174 ms per loop
```

But clearly this isn't fast enough for us. Let's take a look and see where the time is spent during this operation (limited to the most time consuming four calls) using the `prun` `ipython` magic function:

```
In [5]: %prun -l 4 df.apply(lambda x: integrate_f(x['a'], x['b'], x['N']), axis=1)
680947 function calls (675927 primitive calls) in 4.438 seconds

Ordered by: internal time
List reduced from 219 to 4 due to restriction <4>

ncalls  tottime  percall  cumtime  percall filename:lineno(function)
    1000     1.849     0.002     3.609     0.004 <ipython-input-4-c2a74e076cf0>
->:1(integrate_f)
    561154     1.760     0.000     1.760     0.000 <ipython-input-3-c138bdd570e3>:1(f)
     3000     0.093     0.000     0.582     0.000 base.py:4258(get_value)
10104/5084     0.050     0.000     0.082     0.000 {built-in method builtins.len}
```

By far the majority of time is spent inside either `integrate_f` or `f`, hence we'll concentrate our efforts cythonizing these two functions.

**Note:** In Python 2 replacing the `range` with its generator counterpart (`xrange`) would mean the `range` line would vanish. In Python 3 `range` is already a generator.

## 26.1.2 Plain Cython

First we're going to need to import the Cython magic function to `ipython`:

```
In [6]: %load_ext Cython
```

Now, let's simply copy our functions over to Cython as is (the suffix is here to distinguish between function versions):

```
In [7]: %%cython
...: def f_plain(x):
...:     return x * (x - 1)
...: def integrate_f_plain(a, b, N):
...:     s = 0
...:     dx = (b - a) / N
...:     for i in range(N):
```

(continues on next page)

(continued from previous page)

```

...:         s += f_plain(a + i * dx)
...:     return s * dx
...:

```

**Note:** If you're having trouble pasting the above into your ipython, you may need to be using bleeding edge ipython for paste to play well with cell magics.

```

In [4]: %timeit df.apply(lambda x: integrate_f_plain(x['a'], x['b'], x['N']), axis=1)
10 loops, best of 3: 85.5 ms per loop

```

Already this has shaved a third off, not too bad for a simple copy and paste.

### 26.1.3 Adding type

We get another huge improvement simply by providing type information:

```

In [8]: %%cython
...: cdef double f_typed(double x) except? -2:
...:     return x * (x - 1)
...: cpdef double integrate_f_typed(double a, double b, int N):
...:     cdef int i
...:     cdef double s, dx
...:     s = 0
...:     dx = (b - a) / N
...:     for i in range(N):
...:         s += f_typed(a + i * dx)
...:     return s * dx
...:

```

```

In [4]: %timeit df.apply(lambda x: integrate_f_typed(x['a'], x['b'], x['N']), axis=1)
10 loops, best of 3: 20.3 ms per loop

```

Now, we're talking! It's now over ten times faster than the original python implementation, and we haven't *really* modified the code. Let's have another look at what's eating up time:

```

In [9]: %prun -l 4 df.apply(lambda x: integrate_f_typed(x['a'], x['b'], x['N']),
→axis=1)
119791 function calls (114771 primitive calls) in 0.814 seconds

Ordered by: internal time
List reduced from 216 to 4 due to restriction <4>

ncalls  tottime  percall  cumtime  percall  filename:lineno(function)
   3000    0.091    0.000    0.576    0.000  base.py:4258(get_value)
10104/5084    0.050    0.000    0.082    0.000  {built-in method builtins.len}
   3000    0.043    0.000    0.657    0.000  series.py:865(__getitem__)
   9264    0.042    0.000    0.111    0.000  {built-in method builtins.getattr}

```

### 26.1.4 Using ndarray

It's calling series... a lot! It's creating a Series from each row, and get-ting from both the index and the series (three times for each row). Function calls are expensive in Python, so maybe we could minimize these by cythonizing the

apply part.

**Note:** We are now passing ndarrays into the Cython function, fortunately Cython plays very nicely with NumPy.

```
In [10]: %%cython
...: cimport numpy as np
...: import numpy as np
...: cdef double f_typed(double x) except? -2:
...:     return x * (x - 1)
...: cpdef double integrate_f_typed(double a, double b, int N):
...:     cdef int i
...:     cdef double s, dx
...:     s = 0
...:     dx = (b - a) / N
...:     for i in range(N):
...:         s += f_typed(a + i * dx)
...:     return s * dx
...: cpdef np.ndarray[double] apply_integrate_f(np.ndarray col_a, np.ndarray col_
↪b, np.ndarray col_N):
...:     assert (col_a.dtype == np.float and col_b.dtype == np.float and col_N.
↪dtype == np.int)
...:     cdef Py_ssize_t i, n = len(col_N)
...:     assert (len(col_a) == len(col_b) == n)
...:     cdef np.ndarray[double] res = np.empty(n)
...:     for i in range(len(col_a)):
...:         res[i] = integrate_f_typed(col_a[i], col_b[i], col_N[i])
...:     return res
...:
```

The implementation is simple, it creates an array of zeros and loops over the rows, applying our `integrate_f_typed`, and putting this in the zeros array.

**Warning:** You can **not** pass a Series directly as a ndarray typed parameter to a Cython function. Instead pass the actual ndarray using the `Series.to_numpy()`. The reason is that the Cython definition is specific to an ndarray and not the passed Series.

So, do not do this:

```
apply_integrate_f(df['a'], df['b'], df['N'])
```

But rather, use `Series.to_numpy()` to get the underlying ndarray:

```
apply_integrate_f(df['a'].to_numpy(),
                  df['b'].to_numpy(),
                  df['N'].to_numpy())
```

**Note:** Loops like this would be *extremely* slow in Python, but in Cython looping over NumPy arrays is *fast*.

```
In [4]: %timeit apply_integrate_f(df['a'].values, df['b'].values, df['N'].values)
1000 loops, best of 3: 1.25 ms per loop
```

We've gotten another big improvement. Let's check again where the time is spent:

```
In [11]: %prun -l 4 apply_integrate_f(df['a'].values, df['b'].values, df['N'].values)
          197 function calls in 0.003 seconds

Ordered by: internal time
List reduced from 53 to 4 due to restriction <4>

ncalls  tottime  percall  cumtime  percall filename:lineno(function)
      1    0.001    0.001    0.001    0.001 {built-in method _cython_magic_
↪b27681d1a5192061751d3e2e163b9c72.apply_integrate_f}
      3    0.000    0.000    0.001    0.000 frame.py:2882(__getitem__)
      3    0.000    0.000    0.000    0.000 managers.py:963(iget)
      1    0.000    0.000    0.003    0.003 <string>:1(<module>)
```

As one might expect, the majority of the time is now spent in `apply_integrate_f`, so if we wanted to make anymore efficiencies we must continue to concentrate our efforts here.

### 26.1.5 More advanced techniques

There is still hope for improvement. Here's an example of using some more advanced Cython techniques:

```
In [12]: %%cython
.....: cimport cython
.....: cimport numpy as np
.....: import numpy as np
.....: cdef double f_typed(double x) except? -2:
.....:     return x * (x - 1)
.....: cpdef double integrate_f_typed(double a, double b, int N):
.....:     cdef int i
.....:     cdef double s, dx
.....:     s = 0
.....:     dx = (b - a) / N
.....:     for i in range(N):
.....:         s += f_typed(a + i * dx)
.....:     return s * dx
.....: @cython.boundscheck(False)
.....: @cython.wraparound(False)
.....: cpdef np.ndarray[double] apply_integrate_f_wrap(np.ndarray[double] col_a, np.
↪ndarray[double] col_b, np.ndarray[int] col_N):
.....:     cdef int i, n = len(col_N)
.....:     assert len(col_a) == len(col_b) == n
.....:     cdef np.ndarray[double] res = np.empty(n)
.....:     for i in range(n):
.....:         res[i] = integrate_f_typed(col_a[i], col_b[i], col_N[i])
.....:     return res
.....:
```

```
In [4]: %timeit apply_integrate_f_wrap(df['a'].values, df['b'].values, df['N'].values)
1000 loops, best of 3: 987 us per loop
```

Even faster, with the caveat that a bug in our Cython code (an off-by-one error, for example) might cause a segfault because memory access isn't checked. For more about `boundscheck` and `wraparound`, see the Cython docs on [compiler directives](#).

## 26.2 Using Numba

A recent alternative to statically compiling Cython code, is to use a *dynamic jit-compiler*, Numba.

Numba gives you the power to speed up your applications with high performance functions written directly in Python. With a few annotations, array-oriented and math-heavy Python code can be just-in-time compiled to native machine instructions, similar in performance to C, C++ and Fortran, without having to switch languages or Python interpreters.

Numba works by generating optimized machine code using the LLVM compiler infrastructure at import time, runtime, or statically (using the included pycc tool). Numba supports compilation of Python to run on either CPU or GPU hardware, and is designed to integrate with the Python scientific software stack.

---

**Note:** You will need to install Numba. This is easy with `conda`, by using: `conda install numba`, see *installing using miniconda*.

---

---

**Note:** As of Numba version 0.20, pandas objects cannot be passed directly to Numba-compiled functions. Instead, one must pass the NumPy array underlying the pandas object to the Numba-compiled function as demonstrated below.

---

### 26.2.1 Jit

We demonstrate how to use Numba to just-in-time compile our code. We simply take the plain Python code from above and annotate with the `@jit` decorator.

```
import numba

@numba.jit
def f_plain(x):
    return x * (x - 1)

@numba.jit
def integrate_f_numba(a, b, N):
    s = 0
    dx = (b - a) / N
    for i in range(N):
        s += f_plain(a + i * dx)
    return s * dx

@numba.jit
def apply_integrate_f_numba(col_a, col_b, col_N):
    n = len(col_N)
    result = np.empty(n, dtype='float64')
    assert len(col_a) == len(col_b) == n
    for i in range(n):
        result[i] = integrate_f_numba(col_a[i], col_b[i], col_N[i])
    return result

def compute_numba(df):
    result = apply_integrate_f_numba(df['a'].values, df['b'].values,
```

(continues on next page)

(continued from previous page)

```
df['N'].values)
return pd.Series(result, index=df.index, name='result')
```

Note that we directly pass NumPy arrays to the Numba function. `compute_numba` is just a wrapper that provides a nicer interface by passing/returning pandas objects.

```
In [4]: %timeit compute_numba(df)
1000 loops, best of 3: 798 us per loop
```

In this example, using Numba was faster than Cython.

## 26.2.2 Vectorize

Numba can also be used to write vectorized functions that do not require the user to explicitly loop over the observations of a vector; a vectorized function will be applied to each row automatically. Consider the following toy example of doubling each observation:

```
import numba

def double_every_value_nonumba(x):
    return x * 2

@numba.vectorize
def double_every_value_withnumba(x):
    return x * 2
```

```
# Custom function without numba
In [5]: %timeit df['coll_doubled'] = df.a.apply(double_every_value_nonumba)
1000 loops, best of 3: 797 us per loop

# Standard implementation (faster than a custom function)
In [6]: %timeit df['coll_doubled'] = df.a*2
1000 loops, best of 3: 233 us per loop

# Custom function with numba
In [7]: %timeit df['coll_doubled'] = double_every_value_withnumba(df.a.values)
1000 loops, best of 3: 145 us per loop
```

## 26.2.3 Caveats

---

**Note:** Numba will execute on any function, but can only accelerate certain classes of functions.

---

Numba is best at accelerating functions that apply numerical functions to NumPy arrays. When passed a function that only uses operations it knows how to accelerate, it will execute in `nopython` mode.

If Numba is passed a function that includes something it doesn't know how to work with – a category that currently includes sets, lists, dictionaries, or string functions – it will revert to `object` mode. In `object` mode, Numba will execute but your code will not speed up significantly. If you would prefer that Numba throw an error if it cannot compile a function in a way that speeds up your code, pass Numba the argument `nopython=True` (e.g. `@numba.jit(nopython=True)`). For more on troubleshooting Numba modes, see the [Numba troubleshooting page](#).

Read more in the [Numba docs](#).

## 26.3 Expression Evaluation via `eval()`

The top-level function `pandas.eval()` implements expression evaluation of *Series* and *DataFrame* objects.

---

**Note:** To benefit from using `eval()` you need to install `numexpr`. See the *recommended dependencies section* for more details.

---

The point of using `eval()` for expression evaluation rather than plain Python is two-fold: 1) large *DataFrame* objects are evaluated more efficiently and 2) large arithmetic and boolean expressions are evaluated all at once by the underlying engine (by default `numexpr` is used for evaluation).

---

**Note:** You should not use `eval()` for simple expressions or for expressions involving small *DataFrames*. In fact, `eval()` is many orders of magnitude slower for smaller expressions/objects than plain ol' Python. A good rule of thumb is to only use `eval()` when you have a *DataFrame* with more than 10,000 rows.

---

`eval()` supports all arithmetic expressions supported by the engine in addition to some extensions available only in pandas.

---

**Note:** The larger the frame and the larger the expression the more speedup you will see from using `eval()`.

---

### 26.3.1 Supported Syntax

These operations are supported by `pandas.eval()`:

- Arithmetic operations except for the left shift (`<<`) and right shift (`>>`) operators, e.g., `df + 2 * pi / s ** 4 % 42 - the_golden_ratio`
- Comparison operations, including chained comparisons, e.g., `2 < df < df2`
- Boolean operations, e.g., `df < df2 and df3 < df4 or not df_bool`
- list and tuple literals, e.g., `[1, 2]` or `(1, 2)`
- Attribute access, e.g., `df.a`
- Subscript expressions, e.g., `df[0]`
- Simple variable evaluation, e.g., `pd.eval('df')` (this is not very useful)
- Math functions: *sin*, *cos*, *exp*, *log*, *expm1*, *log1p*, *sqrt*, *sinh*, *cosh*, *tanh*, *arcsin*, *arccos*, *arctan*, *arccosh*, *arcsinh*, *arctanh*, *abs*, *arctan2* and *log10*.

This Python syntax is **not** allowed:

- Expressions
  - Function calls other than math functions.
  - `is/is not` operations
  - `if` expressions
  - `lambda` expressions

- list/set/dict comprehensions
  - Literal dict and set expressions
  - yield expressions
  - Generator expressions
  - Boolean expressions consisting of only scalar values
- Statements
    - Neither `simple` nor `compound` statements are allowed. This includes things like `for`, `while`, and `if`.

## 26.3.2 `eval()` Examples

`pandas.eval()` works well with expressions containing large arrays.

First let's create a few decent-sized arrays to play with:

```
In [13]: nrows, ncols = 20000, 100

In [14]: df1, df2, df3, df4 = [pd.DataFrame(np.random.randn(nrows, ncols)) for _ in
↳ range(4)]
```

Now let's compare adding them together using plain ol' Python versus `eval()`:

```
In [15]: %timeit df1 + df2 + df3 + df4
18.8 ms +- 463 us per loop (mean +- std. dev. of 7 runs, 10 loops each)
```

```
In [16]: %timeit pd.eval('df1 + df2 + df3 + df4')
6.33 ms +- 184 us per loop (mean +- std. dev. of 7 runs, 100 loops each)
```

Now let's do the same thing but with comparisons:

```
In [17]: %timeit (df1 > 0) & (df2 > 0) & (df3 > 0) & (df4 > 0)
171 ms +- 3.08 ms per loop (mean +- std. dev. of 7 runs, 10 loops each)
```

```
In [18]: %timeit pd.eval('(df1 > 0) & (df2 > 0) & (df3 > 0) & (df4 > 0)')
11.3 ms +- 1.01 ms per loop (mean +- std. dev. of 7 runs, 100 loops each)
```

`eval()` also works with unaligned pandas objects:

```
In [19]: s = pd.Series(np.random.randn(50))

In [20]: %timeit df1 + df2 + df3 + df4 + s
82.3 ms +- 4.69 ms per loop (mean +- std. dev. of 7 runs, 10 loops each)
```

```
In [21]: %timeit pd.eval('df1 + df2 + df3 + df4 + s')
7.27 ms +- 416 us per loop (mean +- std. dev. of 7 runs, 100 loops each)
```

---

**Note:** Operations such as

```
1 and 2 # would parse to 1 & 2, but should evaluate to 2
3 or 4  # would parse to 3 | 4, but should evaluate to 3
~1      # this is okay, but slower when using eval
```

should be performed in Python. An exception will be raised if you try to perform any boolean/bitwise operations with scalar operands that are not of type `bool` or `np.bool_`. Again, you should perform these kinds of operations in plain Python.

### 26.3.3 The `DataFrame.eval` method

In addition to the top level `pandas.eval()` function you can also evaluate an expression in the “context” of a `DataFrame`.

```
In [22]: df = pd.DataFrame(np.random.randn(5, 2), columns=['a', 'b'])

In [23]: df.eval('a + b')
Out[23]:
0    -3.248550
1     0.404003
2    -0.257494
3     2.986745
4     2.550393
dtype: float64
```

Any expression that is a valid `pandas.eval()` expression is also a valid `DataFrame.eval()` expression, with the added benefit that you don’t have to prefix the name of the `DataFrame` to the column(s) you’re interested in evaluating.

In addition, you can perform assignment of columns within an expression. This allows for *formulaic evaluation*. The assignment target can be a new column name or an existing column name, and it must be a valid Python identifier.

New in version 0.18.0.

The `inplace` keyword determines whether this assignment will be performed on the original `DataFrame` or return a copy with the new column.

**Warning:** For backwards compatibility, `inplace` defaults to `True` if not specified. This will change in a future version of pandas - if your code depends on an `inplace` assignment you should update to explicitly set `inplace=True`.

```
In [24]: df = pd.DataFrame(dict(a=range(5), b=range(5, 10)))

In [25]: df.eval('c = a + b', inplace=True)

In [26]: df.eval('d = a + b + c', inplace=True)

In [27]: df.eval('a = 1', inplace=True)

In [28]: df
Out[28]:
   a  b  c  d
0  1  5  5 10
1  1  6  7 14
2  1  7  9 18
3  1  8 11 22
4  1  9 13 26
```

When `inplace` is set to `False`, a copy of the `DataFrame` with the new or modified columns is returned and the original frame is unchanged.

```
In [29]: df
Out[29]:
```

|   | a | b | c  | d  |
|---|---|---|----|----|
| 0 | 1 | 5 | 5  | 10 |
| 1 | 1 | 6 | 7  | 14 |
| 2 | 1 | 7 | 9  | 18 |
| 3 | 1 | 8 | 11 | 22 |
| 4 | 1 | 9 | 13 | 26 |

```
In [30]: df.eval('e = a - c', inplace=False)
```

```
////////////////////////////////////
```

↪

|   | a | b | c  | d  | e   |
|---|---|---|----|----|-----|
| 0 | 1 | 5 | 5  | 10 | -4  |
| 1 | 1 | 6 | 7  | 14 | -6  |
| 2 | 1 | 7 | 9  | 18 | -8  |
| 3 | 1 | 8 | 11 | 22 | -10 |
| 4 | 1 | 9 | 13 | 26 | -12 |

```
In [31]: df
```

```
////////////////////////////////////
```

↪

|   | a | b | c  | d  |
|---|---|---|----|----|
| 0 | 1 | 5 | 5  | 10 |
| 1 | 1 | 6 | 7  | 14 |
| 2 | 1 | 7 | 9  | 18 |
| 3 | 1 | 8 | 11 | 22 |
| 4 | 1 | 9 | 13 | 26 |

New in version 0.18.0.

As a convenience, multiple assignments can be performed by using a multi-line string.

```
In [32]: df.eval("""
.....: c = a + b
.....: d = a + b + c
.....: a = 1""", inplace=False)
.....:
```

```
Out[32]:
```

|   | a | b | c  | d  |
|---|---|---|----|----|
| 0 | 1 | 5 | 6  | 12 |
| 1 | 1 | 6 | 7  | 14 |
| 2 | 1 | 7 | 8  | 16 |
| 3 | 1 | 8 | 9  | 18 |
| 4 | 1 | 9 | 10 | 20 |

The equivalent in standard Python would be

```
In [33]: df = pd.DataFrame(dict(a=range(5), b=range(5, 10)))
```

```
In [34]: df['c'] = df.a + df.b
```

```
In [35]: df['d'] = df.a + df.b + df.c
```

```
In [36]: df['a'] = 1
```

(continues on next page)

(continued from previous page)

```
In [37]: df
Out[37]:
```

|   | a | b | c  | d  |
|---|---|---|----|----|
| 0 | 1 | 5 | 5  | 10 |
| 1 | 1 | 6 | 7  | 14 |
| 2 | 1 | 7 | 9  | 18 |
| 3 | 1 | 8 | 11 | 22 |
| 4 | 1 | 9 | 13 | 26 |

New in version 0.18.0.

The `query` method gained the `inplace` keyword which determines whether the query modifies the original frame.

```
In [38]: df = pd.DataFrame(dict(a=range(5), b=range(5, 10)))
```

```
In [39]: df.query('a > 2')
```

```
Out[39]:
```

|   | a | b |
|---|---|---|
| 3 | 3 | 8 |
| 4 | 4 | 9 |

```
In [40]: df.query('a > 2', inplace=True)
```

```
In [41]: df
```

```
Out[41]:
```

|   | a | b |
|---|---|---|
| 3 | 3 | 8 |
| 4 | 4 | 9 |

**Warning:** Unlike with `eval`, the default value for `inplace` for `query` is `False`. This is consistent with prior versions of pandas.

## 26.3.4 Local Variables

You must *explicitly reference* any local variable that you want to use in an expression by placing the `@` character in front of the name. For example,

```
In [42]: df = pd.DataFrame(np.random.randn(5, 2), columns=list('ab'))
```

```
In [43]: newcol = np.random.randn(len(df))
```

```
In [44]: df.eval('b + @newcol')
```

```
Out[44]:
```

|   |           |
|---|-----------|
| 0 | 1.522643  |
| 1 | -2.443206 |
| 2 | -0.218394 |
| 3 | 0.689813  |
| 4 | 0.759309  |

dtype: float64

```
In [45]: df.query('b < @newcol')
```

```
Out[45]:
```

(continues on next page)

(continued from previous page)

```
      a      b
2 -0.722128 -1.354853
3 -0.037539 -0.966599
```

If you don't prefix the local variable with `@`, pandas will raise an exception telling you the variable is undefined.

When using `DataFrame.eval()` and `DataFrame.query()`, this allows you to have a local variable and a `DataFrame` column with the same name in an expression.

```
In [46]: a = np.random.randn()

In [47]: df.query('@a < a')
Out[47]:
Empty DataFrame
Columns: [a, b]
Index: []

In [48]: df.loc[a < df.a] # same as the previous expression
Out[48]:
Empty DataFrame
Columns: [a, b]
Index: []
```

With `pandas.eval()` you cannot use the `@` prefix *at all*, because it isn't defined in that context. pandas will let you know this if you try to use `@` in a top-level call to `pandas.eval()`. For example,

```
In [49]: a, b = 1, 2

In [50]: pd.eval('@a + b')
Traceback (most recent call last):

  File "/opt/conda/envs/pandas/lib/python3.6/site-packages/IPython/core/
↳ interactiveshell.py", line 3267, in run_code
    exec(code_obj, self.user_global_ns, self.user_ns)

  File "<ipython-input-50-af17947a194f>", line 1, in <module>
    pd.eval('@a + b')

  File "/pandas/pandas/core/computation/eval.py", line 286, in eval
    _check_for_locals(expr, level, parser)

  File "/pandas/pandas/core/computation/eval.py", line 153, in _check_for_locals
    raise SyntaxError(msg)

  File "<string>", line unknown
SyntaxError: The '@' prefix is not allowed in top-level eval calls,
please refer to your variables by name without the '@' prefix
```

In this case, you should simply refer to the variables like you would in standard Python.

```
In [51]: pd.eval('a + b')
Out[51]: 3
```

## 26.3.5 `pandas.eval()` Parsers

There are two different parsers and two different engines you can use as the backend.

The default 'pandas' parser allows a more intuitive syntax for expressing query-like operations (comparisons, conjunctions and disjunctions). In particular, the precedence of the `&` and `|` operators is made equal to the precedence of the corresponding boolean operations `and` and `or`.

For example, the above conjunction can be written without parentheses. Alternatively, you can use the 'python' parser to enforce strict Python semantics.

```
In [52]: expr = '(df1 > 0) & (df2 > 0) & (df3 > 0) & (df4 > 0) '
In [53]: x = pd.eval(expr, parser='python')
In [54]: expr_no_parens = 'df1 > 0 & df2 > 0 & df3 > 0 & df4 > 0'
In [55]: y = pd.eval(expr_no_parens, parser='pandas')
In [56]: np.all(x == y)
Out[56]: True
```

The same expression can be “anded” together with the word `and` as well:

```
In [57]: expr = '(df1 > 0) & (df2 > 0) & (df3 > 0) & (df4 > 0) '
In [58]: x = pd.eval(expr, parser='python')
In [59]: expr_with_and = 'df1 > 0 and df2 > 0 and df3 > 0 and df4 > 0'
In [60]: y = pd.eval(expr_with_and, parser='pandas')
In [61]: np.all(x == y)
Out[61]: True
```

The `and` and `or` operators here have the same precedence that they would in vanilla Python.

### 26.3.6 pandas.eval() Backends

There’s also the option to make `eval()` operate identical to plain ol’ Python.

**Note:** Using the 'python' engine is generally *not* useful, except for testing other evaluation engines against it. You will achieve **no** performance benefits using `eval()` with `engine='python'` and in fact may incur a performance hit.

You can see this by using `pandas.eval()` with the 'python' engine. It is a bit slower (not by much) than evaluating the same expression in Python

```
In [62]: %timeit df1 + df2 + df3 + df4
7.92 ms +- 489 us per loop (mean +- std. dev. of 7 runs, 100 loops each)
```

```
In [63]: %timeit pd.eval('df1 + df2 + df3 + df4', engine='python')
8.74 ms +- 463 us per loop (mean +- std. dev. of 7 runs, 100 loops each)
```

### 26.3.7 pandas.eval() Performance

`eval()` is intended to speed up certain kinds of operations. In particular, those operations involving complex expressions with large `DataFrame`/`Series` objects should see a significant performance benefit. Here is a plot showing

the running time of `pandas.eval()` as function of the size of the frame involved in the computation. The two lines are two different engines.

---

**Note:** Operations with smallish objects (around 15k-20k rows) are faster using plain Python:

---

This plot was created using a DataFrame with 3 columns each containing floating point values generated using `numpy.random.randn()`.

### 26.3.8 Technical Minutia Regarding Expression Evaluation

Expressions that would result in an object dtype or involve datetime operations (because of NaT) must be evaluated in Python space. The main reason for this behavior is to maintain backwards compatibility with versions of NumPy < 1.7. In those versions of NumPy a call to `ndarray.astype(str)` will truncate any strings that are more than 60

## SPARSE DATA STRUCTURES

---

**Note:** The `SparsePanel` class has been removed in 0.19.0

---

We have implemented “sparse” versions of `Series` and `DataFrame`. These are not sparse in the typical “mostly 0”. Rather, you can view these objects as being “compressed” where any data matching a specific value (`NaN` / missing value, though any value can be chosen) is omitted. A special `SparseIndex` object tracks where data has been “sparsified”. This will make much more sense with an example. All of the standard pandas data structures have a `to_sparse` method:

```
In [1]: ts = pd.Series(np.random.randn(10))
In [2]: ts[2:-2] = np.nan
In [3]: sts = ts.to_sparse()
In [4]: sts
Out[4]:
0    1.485629
1    0.328995
2         NaN
3         NaN
4         NaN
5         NaN
6         NaN
7         NaN
8   -0.305795
9    0.163245
dtype: Sparse[float64, nan]
BlockIndex
Block locations: array([0, 8], dtype=int32)
Block lengths: array([2, 2], dtype=int32)
```

The `to_sparse` method takes a `kind` argument (for the sparse index, see below) and a `fill_value`. So if we had a mostly zero `Series`, we could convert it to sparse with `fill_value=0`:

```
In [5]: ts.fillna(0).to_sparse(fill_value=0)
Out[5]:
0    1.485629
1    0.328995
2    0.000000
3    0.000000
4    0.000000
5    0.000000
```

(continues on next page)

(continued from previous page)

```

6      0.000000
7      0.000000
8     -0.305795
9      0.163245
dtype: Sparse[float64, 0]
BlockIndex
Block locations: array([0, 8], dtype=int32)
Block lengths: array([2, 2], dtype=int32)

```

The sparse objects exist for memory efficiency reasons. Suppose you had a large, mostly NA DataFrame:

```

In [6]: df = pd.DataFrame(np.random.randn(10000, 4))

In [7]: df.iloc[:9998] = np.nan

In [8]: sdf = df.to_sparse()

```

```

In [9]: sdf
Out[9]:

```

|      | 0   | 1   | 2   | 3   |
|------|-----|-----|-----|-----|

9993      NaN      NaN      NaN      NaN
9994      NaN      NaN      NaN      NaN
9995      NaN      NaN      NaN      NaN
9996      NaN      NaN      NaN      NaN
9997      NaN      NaN      NaN      NaN
9998 -0.269621  0.625865 -0.161406  1.133638
9999  0.662879 -1.076637 -1.589441 -0.531743

```

```
[10000 rows x 4 columns]
```

```
In [10]: sdf.density
```

```

////////////////////////////////////
↪0.0002

```

As you can see, the density (% of values that have not been “compressed”) is extremely low. This sparse object takes up much less memory on disk (pickled) and in the Python interpreter. Functionally, their behavior should be nearly identical to their dense counterparts.

Any sparse object can be converted back to the standard dense form by calling `to_dense`:

```
In [11]: sts.to_dense()
```

```
Out[11]:
```

```

0      1.485629
1      0.328995
2          NaN
3          NaN
4          NaN
5          NaN
6          NaN
7          NaN
8     -0.305795
9      0.163245
dtype: float64

```

## 27.1 Sparse Accessor

New in version 0.24.0.

(continued from previous page)

```

In [29]: s.to_sparse()
\\Out [29]:
0      True
1     False
2      True
dtype: Sparse[bool, False]
BlockIndex
Block locations: array([0, 2], dtype=int32)
Block lengths: array([1, 1], dtype=int32)

```

You can change the dtype using `.astype()`, the result is also sparse. Note that `.astype()` also affects to the `fill_value` to keep its dense representation.

```

In [30]: s = pd.Series([1, 0, 0, 0, 0])

```

```

In [31]: s

```

```

Out [31]:
0      1
1      0
2      0
3      0
4      0
dtype: int64

```

```

In [32]: ss = s.to_sparse()

```

```

In [33]: ss

```

```

Out [33]:
0      1
1      0
2      0
3      0
4      0
dtype: Sparse[int64, 0]
BlockIndex
Block locations: array([0], dtype=int32)
Block lengths: array([1], dtype=int32)

```

```

In [34]: ss.astype(np.float64)

```

```

\\Out [34]:
↪
0      1.0
1      0.0
2      0.0
3      0.0
4      0.0
dtype: Sparse[float64, 0.0]
BlockIndex
Block locations: array([0], dtype=int32)
Block lengths: array([1], dtype=int32)

```

It raises if any value cannot be coerced to specified dtype.

```

In [1]: ss = pd.Series([1, np.nan, np.nan]).to_sparse()

```

```

Out [1]:
0      1.0

```

(continues on next page)

(continued from previous page)

```

1      NaN
2      NaN
dtype: float64
BlockIndex
Block locations: array([0], dtype=int32)
Block lengths: array([1], dtype=int32)

In [2]: ss.astype(np.int64)
Out[2]:
ValueError: unable to coerce current fill_value nan to int64 dtype

```

## 27.5 Sparse Calculation

You can apply NumPy *ufuncs* to SparseArray and get a SparseArray as a result.

```

In [35]: arr = pd.SparseArray([1., np.nan, np.nan, -2., np.nan])

In [36]: np.abs(arr)
Out[36]:
[1.0, nan, nan, 2.0, nan]
Fill: nan
IntIndex
Indices: array([0, 3], dtype=int32)

```

The *ufunc* is also applied to `fill_value`. This is needed to get the correct dense result.

```

In [37]: arr = pd.SparseArray([1., -1, -1, -2., -1], fill_value=-1)

In [38]: np.abs(arr)
Out[38]:
[1.0, 1, 1, 2.0, 1]
Fill: 1
IntIndex
Indices: array([0, 3], dtype=int32)

In [39]: np.abs(arr).to_dense()
Out[39]:
array([ 1.,  1.,  1.,  2.,  1.])

```

## 27.6 Interaction with scipy.sparse

### 27.6.1 SparseDataFrame

New in version 0.20.0.

Pandas supports creating sparse dataframes directly from `scipy.sparse` matrices.

```

In [40]: from scipy.sparse import csr_matrix

In [41]: arr = np.random.random(size=(1000, 5))

```

(continues on next page)

(continued from previous page)

```

In [42]: arr[arr < .9] = 0

In [43]: sp_arr = csr_matrix(arr)

In [44]: sp_arr
Out[44]:
<1000x5 sparse matrix of type '<class 'numpy.float64'>'
      with 464 stored elements in Compressed Sparse Row format>

In [45]: sdf = pd.SparseDataFrame(sp_arr)

In [46]: sdf
Out[46]:

```

|     | 0        | 1        | 2        | 3        | 4        |
|-----|----------|----------|----------|----------|----------|
| 0   | NaN      | 0.921245 | NaN      | NaN      | NaN      |
| 1   | NaN      | NaN      | NaN      | NaN      | NaN      |
| 2   | NaN      | NaN      | NaN      | NaN      | NaN      |
| 3   | NaN      | NaN      | NaN      | NaN      | NaN      |
| 4   | NaN      | NaN      | NaN      | 0.936826 | 0.918174 |
| 5   | NaN      | 0.989695 | NaN      | NaN      | 0.906931 |
| 6   | NaN      | NaN      | NaN      | NaN      | NaN      |
| 7   | NaN      | NaN      | NaN      | NaN      | NaN      |
| 8   | NaN      | NaN      | NaN      | 0.931992 | NaN      |
| 9   | NaN      | NaN      | 0.988575 | NaN      | NaN      |
| 10  | NaN      | NaN      | NaN      | NaN      | NaN      |
| 11  | NaN      | NaN      | NaN      | NaN      | NaN      |
| 12  | NaN      | NaN      | NaN      | NaN      | NaN      |
| 13  | NaN      | NaN      | NaN      | NaN      | 0.942330 |
| 14  | NaN      | NaN      | NaN      | NaN      | NaN      |
| 15  | NaN      | NaN      | NaN      | NaN      | NaN      |
| 16  | NaN      | NaN      | NaN      | NaN      | 0.986490 |
| 17  | NaN      | NaN      | NaN      | NaN      | NaN      |
| 18  | NaN      | NaN      | NaN      | NaN      | NaN      |
| 19  | NaN      | NaN      | NaN      | NaN      | NaN      |

999      NaN      NaN      NaN      NaN      NaN

```

```
[1000 rows x 5 columns]
```

All sparse formats are supported, but matrices that are not in `COO` format will be converted, copying data as needed. To convert a `SparseDataFrame` back to sparse SciPy matrix in COO format, you can use the `SparseDataFrame.to_coo()` method:

```

In [47]: sdf.to_coo()
Out[47]:
<1000x5 sparse matrix of type '<class 'numpy.float64''>'
    with 464 stored elements in COO format>

```

## 27.6.2 SparseSeries

A `SparseSeries.to_coo()` method is implemented for transforming a `SparseSeries` indexed by a `MultiIndex` to a `scipy.sparse.coo_matrix`.

The method requires a `MultiIndex` with two or more levels.

```

In [48]: s = pd.Series([3.0, np.nan, 1.0, 3.0, np.nan, np.nan])

In [49]: s.index = pd.MultiIndex.from_tuples([(1, 2, 'a', 0),
.....:                                     (1, 2, 'a', 1),
.....:                                     (1, 1, 'b', 0),
.....:                                     (1, 1, 'b', 1),
.....:                                     (2, 1, 'b', 0),
.....:                                     (2, 1, 'b', 1)],
.....:                                     names=['A', 'B', 'C', 'D'])

In [50]: s
Out[50]:
A B C D
1 2 a 0    3.0
    1    NaN
    1 b 0    1.0
    1    3.0

```

(continues on next page)

In the example below, we transform the `SparseSeries` to a sparse representation of a 2-d array by specifying that the first and second `MultiIndex` levels define labels for the rows and the third and fourth levels define labels for the columns. We also specify that the column and row labels should be sorted in the final sparse representation.

Specifying different row and column labels (and not sorting them) yields a different sparse matrix:

(continues on next page)

(continued from previous page)

```
In [59]: A
Out[59]:
<3x2 sparse matrix of type '<class 'numpy.float64'>'
      with 3 stored elements in COOrdinate format>
```

```
In [60]: A.todense()
```

```
matrix([[ 3.,  0.],
        [ 1.,  3.],
        [ 0.,  0.]])
```

```
In [61]: rows
```

```
matrix([[1, 2, 'a'), (1, 1, 'b'), (2, 1, 'b')])
```

```
In [62]: columns
```

```
matrix([[0, 1]])
```

A convenience method `SparseSeries.from_coo()` is implemented for creating a `SparseSeries` from a `scipy.sparse.coo_matrix`.

```
In [63]: from scipy import sparse
```

```
In [64]: A = sparse.coo_matrix((([3.0, 1.0, 2.0], ([1, 0, 0], [0, 2, 3])),
      ....:                    shape=(3, 4))
      ....:
```

```
In [65]: A
```

```
Out[65]:
<3x4 sparse matrix of type '<class 'numpy.float64'>'
      with 3 stored elements in COOrdinate format>
```

```
In [66]: A.todense()
```

```
matrix([[ 0.,  0.,  1.,  2.],
        [ 3.,  0.,  0.,  0.],
        [ 0.,  0.,  0.,  0.]])
```

The default behaviour (with `dense_index=False`) simply returns a `SparseSeries` containing only the non-null entries.

```
In [67]: ss = pd.SparseSeries.from_coo(A)
```

```
In [68]: ss
```

```
Out[68]:
0 2 1.0
  3 2.0
1 0 3.0
dtype: Sparse[float64, nan]
BlockIndex
Block locations: array([0], dtype=int32)
Block lengths: array([3], dtype=int32)
```

Specifying `dense_index=True` will result in an index that is the Cartesian product of the row and columns coordinates of the matrix. Note that this will consume a significant amount of memory (relative to `dense_index=False`) if the sparse matrix is large (and sparse) enough.

```
In [69]: ss_dense = pd.SparseSeries.from_coo(A, dense_index=True)
```

```
In [70]: ss_dense
```

```
Out[70]:
```

```
0 0 NaN
```

```
   1 NaN
```

```
   2 1.0
```

```
   3 2.0
```

```
1 0 3.0
```

```
   1 NaN
```

```
   2 NaN
```

```
   3 NaN
```

```
2 0 NaN
```

```
   1 NaN
```

```
   2 NaN
```

```
   3 NaN
```

```
dtype: Sparse[float64, nan]
```

```
BlockIndex
```

```
Block locations: array([2], dtype=int32)
```

```
Block lengths: array([3], dtype=int32)
```

```
{{ header }}
```

## FREQUENTLY ASKED QUESTIONS (FAQ)

### 28.1 DataFrame memory usage

The memory usage of a DataFrame (including the index) is shown when calling the `info()`. A configuration option, `display.memory_usage` (see *the list of options*), specifies if the DataFrame's memory usage will be displayed when invoking the `df.info()` method.

For example, the memory usage of the DataFrame below is shown when calling `info()`:

```
In [1]: dtypes = ['int64', 'float64', 'datetime64[ns]', 'timedelta64[ns]',
...:             'complex128', 'object', 'bool']
...:
In [2]: n = 5000

In [3]: data = {t: np.random.randint(100, size=n).astype(t) for t in dtypes}

In [4]: df = pd.DataFrame(data)

In [5]: df['categorical'] = df['object'].astype('category')

In [6]: df.info()
<class 'pandas.core.frame.DataFrame'>
RangeIndex: 5000 entries, 0 to 4999
Data columns (total 8 columns):
int64          5000 non-null int64
float64        5000 non-null float64
datetime64[ns] 5000 non-null datetime64[ns]
timedelta64[ns] 5000 non-null timedelta64[ns]
complex128      5000 non-null complex128
object         5000 non-null object
bool           5000 non-null bool
categorical     5000 non-null category
dtypes: bool(1), category(1), complex128(1), datetime64[ns](1), float64(1), int64(1),
→object(1), timedelta64[ns](1)
memory usage: 289.1+ KB
```

The + symbol indicates that the true memory usage could be higher, because pandas does not count the memory used by values in columns with `dtype=object`.

Passing `memory_usage='deep'` will enable a more accurate memory usage report, accounting for the full usage of the contained objects. This is optional as it can be expensive to do this deeper introspection.

```
In [7]: df.info(memory_usage='deep')
<class 'pandas.core.frame.DataFrame'>
RangeIndex: 5000 entries, 0 to 4999
Data columns (total 8 columns):
int64          5000 non-null int64
float64        5000 non-null float64
datetime64[ns] 5000 non-null datetime64[ns]
timedelta64[ns] 5000 non-null timedelta64[ns]
complex128     5000 non-null complex128
object         5000 non-null object
bool           5000 non-null bool
categorical    5000 non-null category
dtypes: bool(1), category(1), complex128(1), datetime64[ns](1), float64(1), int64(1),
      ↪ object(1), timedelta64[ns](1)
memory usage: 425.6 KB
```

By default the display option is set to `True` but can be explicitly overridden by passing the `memory_usage` argument when invoking `df.info()`.

The memory usage of each column can be found by calling the `memory_usage()` method. This returns a `Series` with an index represented by column names and memory usage of each column shown in bytes. For the `DataFrame` above, the memory usage of each column and the total memory usage can be found with the `memory_usage` method:

```
In [8]: df.memory_usage()
```

Out [8]:

|                 |       |
|-----------------|-------|
| Index           | 80    |
| int64           | 40000 |
| float64         | 40000 |
| datetime64[ns]  | 40000 |
| timedelta64[ns] | 40000 |
| complex128      | 80000 |
| object          | 40000 |
| bool            | 5000  |
| categorical     | 10920 |
| dtype: int64    |       |

```
# total memory usage of dataframe
```

```
In [9]: df.memory_usage().sum()
```

↪ 296000

By default the memory usage of the `DataFrame`'s index is shown in the returned `Series`, the memory usage of the index can be suppressed by passing the `index=False` argument:

```
In [10]: df.memory_usage(index=False)
```

Out[10]:

```
int64      40000
float64     40000
datetime64[ns] 40000
timedelta64[ns] 40000
complex128  80000
object     40000
bool        5000
categorical 10920
dtype: int64
```

The memory usage displayed by the `info()` method utilizes the `memory_usage()` method to determine the memory usage of a `DataFrame` while also formatting the output in human-readable units (base-2 representation; i.e. 1KB

= 1024 bytes).

See also *Categorical Memory Usage*.

## 28.2 Using If/Truth Statements with pandas

pandas follows the NumPy convention of raising an error when you try to convert something to a `bool`. This happens in an `if`-statement or when using the boolean operations: `and`, `or`, and `not`. It is not clear what the result of the following code should be:

```
>>> if pd.Series([False, True, False]):
...     pass
```

Should it be `True` because it's not zero-length, or `False` because there are `False` values? It is unclear, so instead, pandas raises a `ValueError`:

```
>>> if pd.Series([False, True, False]):
...     print("I was true")
Traceback
...
ValueError: The truth value of an array is ambiguous. Use a.empty, a.any() or a.all().
```

You need to explicitly choose what you want to do with the `DataFrame`, e.g. use `any()`, `all()` or `empty()`. Alternatively, you might want to compare if the pandas object is `None`:

```
>>> if pd.Series([False, True, False]) is not None:
...     print("I was not None")
I was not None
```

Below is how to check if any of the values are `True`:

```
>>> if pd.Series([False, True, False]).any():
...     print("I am any")
I am any
```

To evaluate single-element pandas objects in a boolean context, use the method `bool()`:

```
In [11]: pd.Series([True]).bool()
Out[11]: True

In [12]: pd.Series([False]).bool()
\\Out[12]: False

In [13]: pd.DataFrame([[True]]).bool()
\\Out[13]: True

In [14]: pd.DataFrame([[False]]).bool()
\\Out[14]: False
```

### 28.2.1 Bitwise boolean

Bitwise boolean operators like `==` and `!=` return a boolean `Series`, which is almost always what you want anyways.

```
>>> s = pd.Series(range(5))
>>> s == 4
0    False
1    False
2    False
3    False
4     True
dtype: bool
```

See *boolean comparisons* for more examples.

### 28.2.2 Using the in operator

Using the Python `in` operator on a `Series` tests for membership in the index, not membership among the values.

```
In [15]: s = pd.Series(range(5), index=list('abcde'))

In [16]: 2 in s
Out[16]: False

In [17]: 'b' in s
\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\Out[17]: True
```

If this behavior is surprising, keep in mind that using `in` on a Python dictionary tests keys, not values, and `Series` are dict-like. To test for membership in the values, use the method `isin()`:

```
In [18]: s.isin([2])
Out[18]:
a    False
b    False
c     True
d    False
e    False
dtype: bool

In [19]: s.isin([2]).any()
Out[19]: True
```

For DataFrames, likewise, `in` applies to the column axis, testing for membership in the list of column names.

### 28.3 NaN, Integer NA values and NA type promotions

### 28.3.1 Choice of NA representation

For lack of NA (missing) support from the ground up in NumPy and Python in general, we were given the difficult choice between either:

- A *masked array* solution: an array of data and an array of boolean values indicating whether a value is there or is missing.
- Using a special sentinel value, bit pattern, or set of sentinel values to denote NA across the dtypes.

For many reasons we chose the latter. After years of production use it has proven, at least in my opinion, to be the best decision given the state of affairs in NumPy and Python in general. The special value `NaN` (Not-A-Number) is used

(continued from previous page)

```

Out [27]:
a      1
b      2
c      3
d      4
e      5
dtype: Int64

In [28]: s_int.dtype
Out [28]: Int64Dtype()

In [29]: s2_int = s_int.reindex(['a', 'b', 'c', 'f', 'u'])

In [30]: s2_int
Out [30]:
a      1
b      2
c      3
f      NaN
u      NaN
dtype: Int64

In [31]: s2_int.dtype
Out [31]:
Int64Dtype()

```

See *Nullable Integer Data Type* for more.

### 28.3.3 NA type promotions

When introducing NAs into an existing `Series` or `DataFrame` via `reindex()` or some other means, boolean and integer types will be promoted to a different dtype in order to store the NAs. The promotions are summarized in this table:

| Typeclass | Promotion dtype for storing NAs |
|-----------|---------------------------------|
| floating  | no change                       |
| object    | no change                       |
| integer   | cast to float64                 |
| boolean   | cast to object                  |

While this may seem like a heavy trade-off, I have found very few cases where this is an issue in practice i.e. storing values greater than  $2^{*}53$ . Some explanation for the motivation is in the next section.

### 28.3.4 Why not make NumPy like R?

Many people have suggested that NumPy should simply emulate the NA support present in the more domain-specific statistical programming language [R](#). Part of the reason is the NumPy type hierarchy:

| Typeclass                          | Dtypes                                                                                     |
|------------------------------------|--------------------------------------------------------------------------------------------|
| <code>numpy.floating</code>        | <code>float16</code> , <code>float32</code> , <code>float64</code> , <code>float128</code> |
| <code>numpy.integer</code>         | <code>int8</code> , <code>int16</code> , <code>int32</code> , <code>int64</code>           |
| <code>numpy.unsignedinteger</code> | <code>uint8</code> , <code>uint16</code> , <code>uint32</code> , <code>uint64</code>       |
| <code>numpy.object_</code>         | <code>object_</code>                                                                       |
| <code>numpy.bool_</code>           | <code>bool_</code>                                                                         |
| <code>numpy.character</code>       | <code>string_</code> , <code>unicode_</code>                                               |

The R language, by contrast, only has a handful of built-in data types: `integer`, `numeric` (floating-point), `character`, and `boolean`. NA types are implemented by reserving special bit patterns for each type to be used as the missing value. While doing this with the full NumPy type hierarchy would be possible, it would be a more substantial trade-off (especially for the 8- and 16-bit data types) and implementation undertaking.

An alternate approach is that of using masked arrays. A masked array is an array of data with an associated boolean *mask* denoting whether each value should be considered NA or not. I am personally not in love with this approach as I feel that overall it places a fairly heavy burden on the user and the library implementer. Additionally, it exacts a fairly high performance cost when working with numerical data compared with the simple approach of using `NaN`. Thus, I have chosen the Pythonic “practicality beats purity” approach and traded integer NA capability for a much simpler approach of using a special value in float and object arrays to denote NA, and promoting integer arrays to floating when NAs must be introduced.

## 28.4 Differences with NumPy

For `Series` and `DataFrame` objects, `var()` normalizes by  $N-1$  to produce unbiased estimates of the sample variance, while NumPy’s `var` normalizes by  $N$ , which measures the variance of the sample. Note that `cov()` normalizes by  $N-1$  in both pandas and NumPy.

## 28.5 Thread-safety

As of pandas 0.11, pandas is not 100% thread safe. The known issues relate to the `copy()` method. If you are doing a lot of copying of `DataFrame` objects shared among threads, we recommend holding locks inside the threads where the data copying occurs.

See [this link](#) for more information.

## 28.6 Byte-Ordering Issues

Occasionally you may have to deal with data that were created on a machine with a different byte order than the one on which you are running Python. A common symptom of this issue is an error like::

```
Traceback
...
ValueError: Big-endian buffer not supported on little-endian compiler
```

To deal with this issue you should convert the underlying NumPy array to the native system byte order *before* passing it to `Series` or `DataFrame` constructors using something similar to the following:

```
In [32]: x = np.array(list(range(10)), '>i4') # big endian
In [33]: newx = x.byteswap().newbyteorder() # force native byteorder
In [34]: s = pd.Series(newx)
```

See the [NumPy documentation on byte order](#) for more details. {{ header }}

## RPY2 / R INTERFACE

**Warning:** Up to pandas 0.19, a `pandas.rpy` module existed with functionality to convert between pandas and rpy2 objects. This functionality now lives in the rpy2 project itself. See the [updating section](#) of the previous documentation for a guide to port your code from the removed `pandas.rpy` to rpy2 functions.

rpy2 is an interface to R running embedded in a Python process, and also includes functionality to deal with pandas DataFrames. Converting data frames back and forth between rpy2 and pandas should be largely automated (no need to convert explicitly, it will be done on the fly in most rpy2 functions). To convert explicitly, the functions are `pandas2ri.py2ri()` and `pandas2ri.ri2py()`.

See also the documentation of the rpy2 project: <https://rpy2.readthedocs.io>.

In the remainder of this page, a few examples of explicit conversion is given. The pandas conversion of rpy2 needs first to be activated:

```
In [1]: from rpy2.robjects import pandas2ri
...: pandas2ri.activate()
...:
```

### 29.1 Transferring R data sets into Python

Once the pandas conversion is activated (`pandas2ri.activate()`), many conversions of R to pandas objects will be done automatically. For example, to obtain the ‘iris’ dataset as a pandas DataFrame:

```
In [2]: from rpy2.robjects import r
In [3]: r.data('iris')
In [4]: r['iris'].head()
Out[4]:
```

|   | Sepal.Length | Sepal.Width | Petal.Length | Petal.Width | Species |
|---|--------------|-------------|--------------|-------------|---------|
| 0 | 5.1          | 3.5         | 1.4          | 0.2         | setosa  |
| 1 | 4.9          | 3.0         | 1.4          | 0.2         | setosa  |
| 2 | 4.7          | 3.2         | 1.3          | 0.2         | setosa  |
| 3 | 4.6          | 3.1         | 1.5          | 0.2         | setosa  |
| 4 | 5.0          | 3.6         | 1.4          | 0.2         | setosa  |

If the pandas conversion was not activated, the above could also be accomplished by explicitly converting it with the `pandas2ri.ri2py` function (`pandas2ri.ri2py(r['iris'])`).

## 29.2 Converting DataFrames into R objects

The `pandas2ri.py2ri` function support the reverse operation to convert DataFrames into the equivalent R object (that is, **data.frame**):

```
In [5]: df = pd.DataFrame({'A': [1, 2, 3], 'B': [4, 5, 6], 'C': [7, 8, 9]},
...:                      index=["one", "two", "three"])
...:

In [6]: r_dataframe = pandas2ri.py2ri(df)

In [7]: print(type(r_dataframe))
Out[7]: <class 'rpy2.robjjects.vectors.DataFrame'>

In [8]: print(r_dataframe)
Out[8]:
      A B C
one  1 4 7
two  2 5 8
three 3 6 9
```

The DataFrame's index is stored as the `rownames` attribute of the `data.frame` instance. `{{ header }}`

## PANDAS ECOSYSTEM

Increasingly, packages are being built on top of pandas to address specific needs in data preparation, analysis and visualization. This is encouraging because it means pandas is not only helping users to handle their data tasks but also that it provides a better starting point for developers to build powerful and more focused data tools. The creation of libraries that complement pandas' functionality also allows pandas development to remain focused around its original requirements.

This is an inexhaustive list of projects that build on pandas in order to provide tools in the PyData space. For a list of projects that depend on pandas, see the [libraries.io usage page for pandas](#) or [search pypi for pandas](#).

We'd like to make it easier for users to find these projects, if you know of other substantial projects that you feel should be on this list, please let us know.

### 30.1 Statistics and Machine Learning

#### 30.1.1 Statsmodels

Statsmodels is the prominent Python “statistics and econometrics library” and it has a long-standing special relationship with pandas. Statsmodels provides powerful statistics, econometrics, analysis and modeling functionality that is out of pandas' scope. Statsmodels leverages pandas objects as the underlying data container for computation.

#### 30.1.2 sklearn-pandas

Use pandas DataFrames in your [scikit-learn](#) ML pipeline.

#### 30.1.3 Featuretools

Featuretools is a Python library for automated feature engineering built on top of pandas. It excels at transforming temporal and relational datasets into feature matrices for machine learning using reusable feature engineering “primitives”. Users can contribute their own primitives in Python and share them with the rest of the community.

### 30.2 Visualization

#### 30.2.1 Altair

Altair is a declarative statistical visualization library for Python. With Altair, you can spend more time understanding your data and its meaning. Altair's API is simple, friendly and consistent and built on top of the powerful Vega-Lite

JSON specification. This elegant simplicity produces beautiful and effective visualizations with a minimal amount of code. Altair works with Pandas DataFrames.

### 30.2.2 Bokeh

Bokeh is a Python interactive visualization library for large datasets that natively uses the latest web technologies. Its goal is to provide elegant, concise construction of novel graphics in the style of Protovis/D3, while delivering high-performance interactivity over large data to thin clients.

### 30.2.3 seaborn

Seaborn is a Python visualization library based on [matplotlib](#). It provides a high-level, dataset-oriented interface for creating attractive statistical graphics. The plotting functions in seaborn understand pandas objects and leverage pandas grouping operations internally to support concise specification of complex visualizations. Seaborn also goes beyond matplotlib and pandas with the option to perform statistical estimation while plotting, aggregating across observations and visualizing the fit of statistical models to emphasize patterns in a dataset.

### 30.2.4 yhat/ggpy

Hadley Wickham's [ggplot2](#) is a foundational exploratory visualization package for the R language. Based on “[The Grammar of Graphics](#)” it provides a powerful, declarative and extremely general way to generate bespoke plots of any kind of data. It's really quite incredible. Various implementations to other languages are available, but a faithful implementation for Python users has long been missing. Although still young (as of Jan-2014), the [yhat/ggpy](#) project has been progressing quickly in that direction.

### 30.2.5 IPython Vega

[IPython Vega](#) leverages [Vega](#) to create plots within Jupyter Notebook.

### 30.2.6 Plotly

Plotly's [Python API](#) enables interactive figures and web shareability. Maps, 2D, 3D, and live-streaming graphs are rendered with WebGL and [D3.js](#). The library supports plotting directly from a pandas DataFrame and cloud-based collaboration. Users of [matplotlib](#), [ggplot for Python](#), and [Seaborn](#) can convert figures into interactive web-based plots. Plots can be drawn in [IPython Notebooks](#), edited with R or MATLAB, modified in a GUI, or embedded in apps and dashboards. Plotly is free for unlimited sharing, and has [cloud](#), [offline](#), or [on-premise](#) accounts for private use.

### 30.2.7 QtPandas

Spun off from the main pandas library, the [qtpandas](#) library enables DataFrame visualization and manipulation in PyQt4 and PySide applications.

## 30.3 IDE

### 30.3.1 IPython

IPython is an interactive command shell and distributed computing environment. IPython tab completion works with Pandas methods and also attributes like DataFrame columns.

### 30.3.2 Jupyter Notebook / Jupyter Lab

Jupyter Notebook is a web application for creating Jupyter notebooks. A Jupyter notebook is a JSON document containing an ordered list of input/output cells which can contain code, text, mathematics, plots and rich media. Jupyter notebooks can be converted to a number of open standard output formats (HTML, HTML presentation slides, LaTeX, PDF, ReStructuredText, Markdown, Python) through ‘Download As’ in the web interface and `jupyter convert` in a shell.

Pandas DataFrames implement `_repr_html_` and `_repr_latex` methods which are utilized by Jupyter Notebook for displaying (abbreviated) HTML or LaTeX tables. LaTeX output is properly escaped. (Note: HTML tables may or may not be compatible with non-HTML Jupyter output formats.)

See *Options and Settings* and *Available Options* for pandas `display` settings.

### 30.3.3 quantopian/qgrid

qgrid is “an interactive grid for sorting and filtering DataFrames in IPython Notebook” built with SlickGrid.

### 30.3.4 Spyder

Spyder is a cross-platform PyQt-based IDE combining the editing, analysis, debugging and profiling functionality of a software development tool with the data exploration, interactive execution, deep inspection and rich visualization capabilities of a scientific environment like MATLAB or Rstudio.

Its **Variable Explorer** allows users to view, manipulate and edit pandas `Index`, `Series`, and `DataFrame` objects like a “spreadsheet”, including copying and modifying values, sorting, displaying a “heatmap”, converting data types and more. Pandas objects can also be renamed, duplicated, new columns added, copied/pasted to/from the clipboard (as TSV), and saved/loaded to/from a file. Spyder can also import data from a variety of plain text and binary files or the clipboard into a new pandas `DataFrame` via a sophisticated import wizard.

Most pandas classes, methods and data attributes can be autocompleted in Spyder’s **Editor** and **IPython Console**, and Spyder’s **Help pane** can retrieve and render Numpydoc documentation on pandas objects in rich text with Sphinx both automatically and on-demand.

## 30.4 API

### 30.4.1 pandas-datareader

pandas-datareader is a remote data access library for pandas (PyPI:pandas-datareader). It is based on functionality that was located in `pandas.io.data` and `pandas.io.wb` but was split off in v0.19. See more in the [pandas-datareader docs](#):

The following data feeds are available:

- [Google Finance](#)
- [Tiingo](#)
- [Morningstar](#)
- [IEX](#)
- [Robinhood](#)
- [Enigma](#)
- [Quandl](#)
- [FRED](#)
- [Fama/French](#)
- [World Bank](#)
- [OECD](#)
- [Eurostat](#)
- [TSP Fund Data](#)
- [Nasdaq Trader Symbol Definitions](#)
- [Stooq Index Data](#)
- [MOEX Data](#)

### 30.4.2 [quandl/Python](#)

Quandl API for Python wraps the Quandl REST API to return Pandas DataFrames with timeseries indexes.

### 30.4.3 [pydatastream](#)

PyDatastream is a Python interface to the [Thomson Dataworks Enterprise \(DWE/Datastream\)](#) SOAP API to return indexed Pandas DataFrames or Panels with financial data. This package requires valid credentials for this API (non free).

### 30.4.4 [pandaSDMX](#)

pandaSDMX is a library to retrieve and acquire statistical data and metadata disseminated in [SDMX 2.1](#), an ISO-standard widely used by institutions such as statistics offices, central banks, and international organisations. pandaSDMX can expose datasets and related structural metadata including data flows, code-lists, and data structure definitions as pandas Series or MultiIndexed DataFrames.

### 30.4.5 [fredapi](#)

fredapi is a Python interface to the [Federal Reserve Economic Data \(FRED\)](#) provided by the Federal Reserve Bank of St. Louis. It works with both the FRED database and ALFRED database that contains point-in-time data (i.e. historic data revisions). fredapi provides a wrapper in Python to the FRED HTTP API, and also provides several convenient methods for parsing and analyzing point-in-time data from ALFRED. fredapi makes use of pandas and returns data in a Series or DataFrame. This module requires a FRED API key that you can obtain for free on the FRED website.

## 30.5 Domain Specific

### 30.5.1 Geopandas

Geopandas extends pandas data objects to include geographic information which support geometric operations. If your work entails maps and geographical coordinates, and you love pandas, you should take a close look at Geopandas.

### 30.5.2 xarray

xarray brings the labeled data power of pandas to the physical sciences by providing N-dimensional variants of the core pandas data structures. It aims to provide a pandas-like and pandas-compatible toolkit for analytics on multi-dimensional arrays, rather than the tabular data for which pandas excels.

## 30.6 Out-of-core

### 30.6.1 Blaze

Blaze provides a standard API for doing computations with various in-memory and on-disk backends: NumPy, Pandas, SQLAlchemy, MongoDB, PyTables, PySpark.

### 30.6.2 Dask

Dask is a flexible parallel computing library for analytics. Dask provides a familiar `DataFrame` interface for out-of-core, parallel and distributed computing.

### 30.6.3 Dask-ML

Dask-ML enables parallel and distributed machine learning using Dask alongside existing machine learning libraries like Scikit-Learn, XGBoost, and TensorFlow.

### 30.6.4 Odo

Odo provides a uniform API for moving data between different formats. It uses pandas own `read_csv` for CSV IO and leverages many existing packages such as PyTables, h5py, and pymongo to move data between non pandas formats. Its graph based approach is also extensible by end users for custom formats that may be too specific for the core of odo.

### 30.6.5 Ray

Pandas on Ray is an early stage `DataFrame` library that wraps Pandas and transparently distributes the data and computation. The user does not need to know how many cores their system has, nor do they need to specify how to distribute the data. In fact, users can continue using their previous Pandas notebooks while experiencing a considerable speedup from Pandas on Ray, even on a single machine. Only a modification of the import statement is needed, as we demonstrate below. Once you've changed your import statement, you're ready to use Pandas on Ray just like you would Pandas.

```
# import pandas as pd
import ray.dataframe as pd
```

## 30.6.6 Vaex

Increasingly, packages are being built on top of pandas to address specific needs in data preparation, analysis and visualization. Vaex is a python library for Out-of-Core DataFrames (similar to Pandas), to visualize and explore big tabular datasets. It can calculate statistics such as mean, sum, count, standard deviation etc, on an N-dimensional grid up to a billion ( $10^9$ ) objects/rows per second. Visualization is done using histograms, density plots and 3d volume rendering, allowing interactive exploration of big data. Vaex uses memory mapping, zero memory copy policy and lazy computations for best performance (no memory wasted).

- `vaex.from_pandas`
- `vaex.to_pandas_df`

## 30.7 Data validation

### 30.7.1 Engarde

Engarde is a lightweight library used to explicitly state your assumptions about your datasets and check that they're *actually* true.

## 30.8 Extension Data Types

Pandas provides an interface for defining *extension types* to extend NumPy's type system. The following libraries implement that interface to provide types not found in NumPy or pandas, which work well with pandas' data containers.

### 30.8.1 cyberpandas

Cyberpandas provides an extension type for storing arrays of IP Addresses. These arrays can be stored inside pandas' Series and DataFrame.

## 30.9 Accessors

A directory of projects providing *extension accessors*. This is for users to discover new accessors and for library authors to coordinate on the namespace.

| Library     | Accessor | Classes           |
|-------------|----------|-------------------|
| cyberpandas | ip       | Series            |
| pdvega      | vgplot   | Series, DataFrame |

```
{{ header }}
```

## COMPARISON WITH R / R LIBRARIES

Since `pandas` aims to provide a lot of the data manipulation and analysis functionality that people use `R` for, this page was started to provide a more detailed look at the `R` language and its many third party libraries as they relate to `pandas`. In comparisons with `R` and CRAN libraries, we care about the following things:

- **Functionality / flexibility:** what can/cannot be done with each tool
- **Performance:** how fast are operations. Hard numbers/benchmarks are preferable
- **Ease-of-use:** Is one tool easier/harder to use (you may have to be the judge of this, given side-by-side code comparisons)

This page is also here to offer a bit of a translation guide for users of these `R` packages.

For transfer of `DataFrame` objects from `pandas` to `R`, one option is to use `HDF5` files, see *External Compatibility* for an example.

### 31.1 Quick Reference

We'll start off with a quick reference guide pairing some common `R` operations using `dplyr` with `pandas` equivalents.

#### 31.1.1 Querying, Filtering, Sampling

| R                                                   | pandas                                                          |
|-----------------------------------------------------|-----------------------------------------------------------------|
| <code>dim(df)</code>                                | <code>df.shape</code>                                           |
| <code>head(df)</code>                               | <code>df.head()</code>                                          |
| <code>slice(df, 1:10)</code>                        | <code>df.iloc[:9]</code>                                        |
| <code>filter(df, col1 == 1, col2 == 1)</code>       | <code>df.query('col1 == 1 &amp; col2 == 1')</code>              |
| <code>df[df\$col1 == 1 &amp; df\$col2 == 1,]</code> | <code>df[(df.col1 == 1) &amp; (df.col2 == 1)]</code>            |
| <code>select(df, col1, col2)</code>                 | <code>df[['col1', 'col2']]</code>                               |
| <code>select(df, col1:col3)</code>                  | <code>df.loc[:, 'col1':'col3']</code>                           |
| <code>select(df, -(col1:col3))</code>               | <code>df.drop(cols_to_drop, axis=1)</code> but see <sup>1</sup> |
| <code>distinct(select(df, col1))</code>             | <code>df[['col1']].drop_duplicates()</code>                     |
| <code>distinct(select(df, col1, col2))</code>       | <code>df[['col1', 'col2']].drop_duplicates()</code>             |
| <code>sample_n(df, 10)</code>                       | <code>df.sample(n=10)</code>                                    |
| <code>sample_frac(df, 0.01)</code>                  | <code>df.sample(frac=0.01)</code>                               |

---

<sup>1</sup> `R`'s shorthand for a subrange of columns (`select(df, col1:col3)`) can be approached cleanly in `pandas`, if you have the list of columns, for example `df[cols[1:3]]` or `df.drop(cols[1:3])`, but doing this by column name is a bit messy.

### 31.1.2 Sorting

| R                                    | pandas                                               |
|--------------------------------------|------------------------------------------------------|
| <code>arrange(df, col1, col2)</code> | <code>df.sort_values(['col1', 'col2'])</code>        |
| <code>arrange(df, desc(col1))</code> | <code>df.sort_values('col1', ascending=False)</code> |

### 31.1.3 Transforming

| R                                       | pandas                                                         |
|-----------------------------------------|----------------------------------------------------------------|
| <code>select(df, col_one = col1)</code> | <code>df.rename(columns={'col1': 'col_one'})['col_one']</code> |
| <code>rename(df, col_one = col1)</code> | <code>df.rename(columns={'col1': 'col_one'})</code>            |
| <code>mutate(df, c=a-b)</code>          | <code>df.assign(c=df.a-df.b)</code>                            |

### 31.1.4 Grouping and Summarizing

| R                                                       | pandas                                                |
|---------------------------------------------------------|-------------------------------------------------------|
| <code>summary(df)</code>                                | <code>df.describe()</code>                            |
| <code>gdf &lt;- group_by(df, col1)</code>               | <code>gdf = df.groupby('col1')</code>                 |
| <code>summarise(gdf, avg=mean(col1, na.rm=TRUE))</code> | <code>df.groupby('col1').agg({'col1': 'mean'})</code> |
| <code>summarise(gdf, total=sum(col1))</code>            | <code>df.groupby('col1').sum()</code>                 |

## 31.2 Base R

### 31.2.1 Slicing with R's `c`

R makes it easy to access `data.frame` columns by name

```
df <- data.frame(a=rnorm(5), b=rnorm(5), c=rnorm(5), d=rnorm(5), e=rnorm(5))
df[, c("a", "c", "e")]
```

or by integer location

```
df <- data.frame(matrix(rnorm(1000), ncol=100))
df[, c(1:10, 25:30, 40, 50:100)]
```

Selecting multiple columns by name in pandas is straightforward

```
In [1]: df = pd.DataFrame(np.random.randn(10, 3), columns=list('abc'))

In [2]: df[['a', 'c']]
Out[2]:
```

|   | a         | c         |
|---|-----------|-----------|
| 0 | -0.287968 | 1.187667  |
| 1 | -1.306271 | -1.308312 |
| 2 | -0.362413 | 0.608241  |

(continues on next page)

(continued from previous page)

```

3 -0.184284 -1.655681
4  0.681877  1.832548
5  0.722909 -0.553662
6 -1.124419  1.609726
7 -1.427167 -0.072162
8 -0.176493  1.923560
9 -0.995568 -0.296664

```

```
In [3]: df.loc[:, ['a', 'c']]
```

```

↪
      a      c
0 -0.287968  1.187667
1 -1.306271 -1.308312
2 -0.362413  0.608241
3 -0.184284 -1.655681
4  0.681877  1.832548
5  0.722909 -0.553662
6 -1.124419  1.609726
7 -1.427167 -0.072162
8 -0.176493  1.923560
9 -0.995568 -0.296664

```

Selecting multiple noncontiguous columns by integer location can be achieved with a combination of the `iloc` indexer attribute and `numpy.r_`.

```
In [4]: named = list('abcdefg')
```

```
In [5]: n = 30
```

```
In [6]: columns = named + np.arange(len(named), n).tolist()
```

```
In [7]: df = pd.DataFrame(np.random.randn(n, n), columns=columns)
```

```
In [8]: df.iloc[:, np.r_[:10, 24:30]]
```

```
Out[8]:
```

```

      a      b      c      d      e      f      g      7
↪      8      9      24      25      26      27      28      29

```

## 31.2.2 aggregate

In R you may want to split data into subsets and compute the mean for each. Using a data.frame called `df` and splitting it into groups by `by1` and by `by2`:

```

df <- data.frame(
    v1 = c(1, 3, 5, 7, 8, 3, 5, NA, 4, 5, 7, 9),
    v2 = c(11, 33, 55, 77, 88, 33, 55, NA, 44, 55, 77, 99),
    by1 = c("red", "blue", 1, 2, NA, "big", 1, 2, "red", 1, NA, 12),
    by2 = c("wet", "dry", 99, 95, NA, "damp", 95, 99, "red", 99, NA, NA))
aggregate(x=df[, c("v1", "v2")], by=list(mydf2$by1, mydf2$by2), FUN = mean)

```

The `groupby()` method is similar to base R `aggregate` function.

```

In [9]: df = pd.DataFrame(
...:     {'v1': [1, 3, 5, 7, 8, 3, 5, np.nan, 4, 5, 7, 9],
...:      'v2': [11, 33, 55, 77, 88, 33, 55, np.nan, 44, 55, 77, 99],
...:      'by1': ["red", "blue", 1, 2, np.nan, "big", 1, 2, "red", 1, np.nan, 12],
...:      'by2': ["wet", "dry", 99, 95, np.nan, "damp", 95, 99, "red", 99, np.nan,
...:              np.nan]})
...:
In [10]: g = df.groupby(['by1', 'by2'])

In [11]: g[['v1', 'v2']].mean()
Out[11]:
```

|      |      | v1  | v2   |
|------|------|-----|------|
| by1  | by2  |     |      |
| 1    | 95   | 5.0 | 55.0 |
|      | 99   | 5.0 | 55.0 |
| 2    | 95   | 7.0 | 77.0 |
|      | 99   | NaN | NaN  |
| big  | damp | 3.0 | 33.0 |
| blue | dry  | 3.0 | 33.0 |
| red  | red  | 4.0 | 44.0 |
|      | wet  | 1.0 | 11.0 |

For more details and examples see *the groupby documentation*.

### 31.2.3 match / %in%

A common way to select data in R is using `%in%` which is defined using the function `match`. The operator `%in%` is used to return a logical vector indicating if there is a match or not:

```

s <- 0:4
s %in% c(2,4)

```

The `isin()` method is similar to R `%in%` operator:

```

In [12]: s = pd.Series(np.arange(5), dtype=np.float32)

In [13]: s.isin([2, 4])
Out[13]:
```

|   |       |
|---|-------|
| 0 | False |
| 1 | False |
| 2 | True  |
| 3 | False |
| 4 | True  |

dtype: bool

The `match` function returns a vector of the positions of matches of its first argument in its second:

```

s <- 0:4
match(s, c(2,4))

```

For more details and examples see *the reshaping documentation*.

### 31.2.4 tapply

`tapply` is similar to `aggregate`, but data can be in a ragged array, since the subclass sizes are possibly irregular. Using a data.frame called `baseball`, and retrieving information based on the array `team`:

```
baseball <-
  data.frame(team = gl(5, 5,
    labels = paste("Team", LETTERS[1:5])),
    player = sample(letters, 25),
    batting.average = runif(25, .200, .400))

tapply(baseball$batting.average, baseball$team,
  max)
```

In pandas we may use `pivot_table()` method to handle this:

```
In [14]: import random

In [15]: import string

In [16]: baseball = pd.DataFrame(
.....:     {'team': ["team %d" % (x + 1) for x in range(5)] * 5,
.....:       'player': random.sample(list(string.ascii_lowercase), 25),
.....:       'batting avg': np.random.uniform(.200, .400, 25)})
.....:

In [17]: baseball.pivot_table(values='batting avg', columns='team', aggfunc=np.max)
Out[17]:
team      team 1    team 2    team 3    team 4    team 5
batting avg  0.283274  0.38365  0.389401  0.397145  0.371601
```

For more details and examples see *the reshaping documentation*.

### 31.2.5 subset

The `query()` method is similar to the base R `subset` function. In R you might want to get the rows of a data.frame where one column's values are less than another column's values:

```
df <- data.frame(a=rnorm(10), b=rnorm(10))
subset(df, a <= b)
df[df$a <= df$b,] # note the comma
```

In pandas, there are a few ways to perform subsetting. You can use `query()` or pass an expression as if it were an index/slice as well as standard boolean indexing:

```
In [18]: df = pd.DataFrame({'a': np.random.randn(10), 'b': np.random.randn(10)})

In [19]: df.query('a <= b')
Out[19]:
   a         b
1 -1.204278  1.931881
2 -0.454758  1.070978
3 -0.283183  0.632277
5 -1.762922  1.286535
7 -0.189083  1.030371
```

(continues on next page)

(continued from previous page)

**In [20]:** df[df.a <= df.b]

```

////////////////////////////////////
↪
      a      b
1 -1.204278  1.931881
2 -0.454758  1.070978
3 -0.283183  0.632277
5 -1.762922  1.286535
7 -0.189083  1.030371

```

**In [21]:** df.loc[df.a <= df.b]

```

////////////////////////////////////
↪
      a      b
1 -1.204278  1.931881
2 -0.454758  1.070978
3 -0.283183  0.632277
5 -1.762922  1.286535
7 -0.189083  1.030371

```

For more details and examples see *the query documentation*.

### 31.2.6 with

An expression using a data.frame called `df` in R with the columns `a` and `b` would be evaluated using `with` like so:

```

df <- data.frame(a=rnorm(10), b=rnorm(10))
with(df, a + b)
df$a + df$b # same as the previous expression

```

In pandas the equivalent expression, using the `eval()` method, would be:

**In [22]:** df = pd.DataFrame({'a': np.random.randn(10), 'b': np.random.randn(10)})**In [23]:** df.eval('a + b')

```

Out[23]:
0    -1.477377
1     0.797915
2    -0.081443
3     0.314410
4    -1.296904
5    -2.067580
6     1.062894
7    -0.924963
8     0.834764
9     1.557189
dtype: float64

```

**In [24]:** df.a + df.b # same as the previous expression

```

////////////////////////////////////
↪
0    -1.477377
1     0.797915
2    -0.081443
3     0.314410

```

(continues on next page)

(continued from previous page)

```

4    -1.296904
5    -2.067580
6     1.062894
7    -0.924963
8     0.834764
9     1.557189
dtype: float64

```

In certain cases `eval()` will be much faster than evaluation in pure Python. For more details and examples see *the eval documentation*.

## 31.3 plyr

`plyr` is an R library for the split-apply-combine strategy for data analysis. The functions revolve around three data structures in R, `a` for arrays, `l` for lists, and `d` for `data.frame`. The table below shows how these data structures could be mapped in Python.

| R          | Python                        |
|------------|-------------------------------|
| array      | list                          |
| lists      | dictionary or list of objects |
| data.frame | dataframe                     |

### 31.3.1 ddply

An expression using a `data.frame` called `df` in R where you want to summarize `x` by month:

```

require(plyr)
df <- data.frame(
  x = runif(120, 1, 168),
  y = runif(120, 7, 334),
  z = runif(120, 1.7, 20.7),
  month = rep(c(5, 6, 7, 8), 30),
  week = sample(1:4, 120, TRUE)
)

ddply(df, .(month, week), summarize,
      mean = round(mean(x), 2),
      sd = round(sd(x), 2))

```

In pandas the equivalent expression, using the `groupby()` method, would be:

```

In [25]: df = pd.DataFrame({'x': np.random.uniform(1., 168., 120),
.....:                    'y': np.random.uniform(7., 334., 120),
.....:                    'z': np.random.uniform(1.7, 20.7, 120),
.....:                    'month': [5, 6, 7, 8] * 30,
.....:                    'week': np.random.randint(1, 4, 120)})

In [26]: grouped = df.groupby(['month', 'week'])

In [27]: grouped['x'].agg([np.mean, np.std])
Out[27]:

```

(continues on next page)

(continued from previous page)

|       |      | mean       | std       |
|-------|------|------------|-----------|
| month | week |            |           |
| 5     | 1    | 86.725172  | 44.280928 |
|       | 2    | 44.659494  | 48.697885 |
|       | 3    | 84.886403  | 61.326188 |
| 6     | 1    | 96.894893  | 46.820060 |
|       | 2    | 72.186856  | 49.274792 |
|       | 3    | 90.537846  | 45.975009 |
| 7     | 1    | 84.099059  | 46.008288 |
|       | 2    | 109.657020 | 44.530491 |
|       | 3    | 86.625297  | 41.023494 |
| 8     | 1    | 88.411595  | 46.621045 |
|       | 2    | 99.187963  | 52.104145 |
|       | 3    | 81.025281  | 50.016413 |

For more details and examples see *the groupby documentation*.

## 31.4 reshape / reshape2

### 31.4.1 melt.array

An expression using a 3 dimensional array called `a` in R where you want to melt it into a data.frame:

```
a <- array(c(1:23, NA), c(2,3,4))
data.frame(melt(a))
```

In Python, since `a` is a list, you can simply use list comprehension.

```
In [28]: a = np.array(list(range(1, 24)) + [np.NaN]).reshape(2, 3, 4)

In [29]: pd.DataFrame([tuple(list(x) + [val]) for x, val in np.ndenumerate(a)])
Out[29]:
   0  1  2    3
0  0  0  0  1.0
1  0  0  1  2.0
2  0  0  2  3.0
3  0  0  3  4.0
4  0  1  0  5.0
5  0  1  1  6.0
6  0  1  2  7.0
7  0  1  3  8.0
8  0  2  0  9.0
9  0  2  1 10.0
10 0  2  2 11.0
11 0  2  3 12.0
12 1  0  0 13.0
13 1  0  1 14.0
14 1  0  2 15.0
15 1  0  3 16.0
16 1  1  0 17.0
17 1  1  1 18.0
18 1  1  2 19.0
19 1  1  3 20.0
20 1  2  0 21.0
```

(continues on next page)

(continued from previous page)

```

21  1  2  1  22.0
22  1  2  2  23.0
23  1  2  3   NaN

```

### 31.4.2 melt.list

An expression using a list called `a` in R where you want to melt it into a data.frame:

```

a <- as.list(c(1:4, NA))
data.frame(melt(a))

```

In Python, this list would be a list of tuples, so `DataFrame()` method would convert it to a dataframe as required.

```

In [30]: a = list(enumerate(list(range(1, 5)) + [np.NaN]))

In [31]: pd.DataFrame(a)
Out[31]:
   0  1
0  0  1.0
1  1  2.0
2  2  3.0
3  3  4.0
4  4  NaN

```

For more details and examples see *the Into to Data Structures documentation*.

### 31.4.3 melt.data.frame

An expression using a data.frame called `cheese` in R where you want to reshape the data.frame:

```

cheese <- data.frame(
  first = c('John', 'Mary'),
  last = c('Doe', 'Bo'),
  height = c(5.5, 6.0),
  weight = c(130, 150)
)
melt(cheese, id=c("first", "last"))

```

In Python, the `melt()` method is the R equivalent:

```

In [32]: cheese = pd.DataFrame({'first': ['John', 'Mary'],
....:                          'last': ['Doe', 'Bo'],
....:                          'height': [5.5, 6.0],
....:                          'weight': [130, 150]})
....:

In [33]: pd.melt(cheese, id_vars=['first', 'last'])
Out[33]:
  first last variable  value
0  John  Doe   height    5.5
1  Mary  Bo   height    6.0
2  John  Doe  weight   130.0
3  Mary  Bo  weight   150.0

```

(continues on next page)

(continued from previous page)

```
In [34]: cheese.set_index(['first', 'last']).stack() # alternative way
//////////
↪
first last
John Doe height 5.5
      weight 130.0
Mary Bo height 6.0
      weight 150.0
dtype: float64
```

For more details and examples see *the reshaping documentation*.

### 31.4.4 cast

In R `acast` is an expression using a `data.frame` called `df` in R to cast into a higher dimensional array:

```
df <- data.frame(
  x = runif(12, 1, 168),
  y = runif(12, 7, 334),
  z = runif(12, 1.7, 20.7),
  month = rep(c(5,6,7),4),
  week = rep(c(1,2), 6)
)

mdf <- melt(df, id=c("month", "week"))
acast(mdf, week ~ month ~ variable, mean)
```

In Python the best way is to make use of `pivot_table()`:

```
In [35]: df = pd.DataFrame({'x': np.random.uniform(1., 168., 12),
.....:                    'y': np.random.uniform(7., 334., 12),
.....:                    'z': np.random.uniform(1.7, 20.7, 12),
.....:                    'month': [5, 6, 7] * 4,
.....:                    'week': [1, 2] * 6})
.....:

In [36]: mdf = pd.melt(df, id_vars=['month', 'week'])

In [37]: pd.pivot_table(mdf, values='value', index=['variable', 'week'],
.....:                  columns=['month'], aggfunc=np.mean)
.....:

Out[37]:
```

|          |      | 5          | 6          | 7          |
|----------|------|------------|------------|------------|
| variable | week |            |            |            |
| x        | 1    | 141.589929 | 39.695390  | 52.449418  |
|          | 2    | 35.392851  | 53.847264  | 115.984939 |
| y        | 1    | 77.445477  | 204.863780 | 241.691953 |
|          | 2    | 167.211992 | 152.693647 | 59.314503  |
| z        | 1    | 5.787666   | 14.865190  | 8.592594   |
|          | 2    | 16.012928  | 8.442993   | 10.590114  |

Similarly for `dcast` which uses a `data.frame` called `df` in R to aggregate information based on `Animal` and `FeedType`:

```
df <- data.frame(
  Animal = c('Animal1', 'Animal2', 'Animal3', 'Animal2', 'Animal1',
            'Animal2', 'Animal3'),
  FeedType = c('A', 'B', 'A', 'A', 'B', 'B', 'A'),
  Amount = c(10, 7, 4, 2, 5, 6, 2)
)

dcast(df, Animal ~ FeedType, sum, fill=NaN)
# Alternative method using base R
with(df, tapply(Amount, list(Animal, FeedType), sum))
```

Python can approach this in two different ways. Firstly, similar to above using `pivot_table()`:

```
In [38]: df = pd.DataFrame({
.....:     'Animal': ['Animal1', 'Animal2', 'Animal3', 'Animal2', 'Animal1',
.....:                'Animal2', 'Animal3'],
.....:     'FeedType': ['A', 'B', 'A', 'A', 'B', 'B', 'A'],
.....:     'Amount': [10, 7, 4, 2, 5, 6, 2],
.....: })
.....:

In [39]: df.pivot_table(values='Amount', index='Animal', columns='FeedType',
.....:                    aggfunc='sum')
.....:

Out [39]:
FeedType      A      B
Animal
Animal1    10.0    5.0
Animal2     2.0   13.0
Animal3     6.0    NaN
```

The second approach is to use the `groupby()` method:

```
In [40]: df.groupby(['Animal', 'FeedType'])['Amount'].sum()
Out [40]:
Animal  FeedType
Animal1  A         10
         B          5
Animal2  A          2
         B         13
Animal3  A          6
Name: Amount, dtype: int64
```

For more details and examples see *the reshaping documentation* or *the groupby documentation*.

### 31.4.5 factor

pandas has a data type for categorical data.

```
cut(c(1,2,3,4,5,6), 3)
factor(c(1,2,3,2,2,3))
```

In pandas this is accomplished with `pd.cut` and `astype("category")`:

```
In [41]: pd.cut(pd.Series([1, 2, 3, 4, 5, 6]), 3)
Out [41]:
```

(continues on next page)

(continued from previous page)

```
0      (0.995, 2.667]
1      (0.995, 2.667]
2      (2.667, 4.333]
3      (2.667, 4.333]
4      (4.333, 6.0]
5      (4.333, 6.0]
dtype: category
Categories (3, interval[float64]): [(0.995, 2.667] < (2.667, 4.333] < (4.333, 6.0]]
```

```
In [42]: pd.Series([1, 2, 3, 2, 2, 3]).astype("category")
```

```
0    1
1    2
2    3
3    2
4    2
5    3
dtype: category
Categories (3, int64): [1, 2, 3]
```

For more details and examples see *categorical introduction* and the *API documentation*. There is also a documentation regarding the *differences to R's factor*. `{{ header }}`

## COMPARISON WITH SQL

Since many potential pandas users have some familiarity with **SQL**, this page is meant to provide some examples of how various SQL operations would be performed using pandas.

If you're new to pandas, you might want to first read through *10 Minutes to pandas* to familiarize yourself with the library.

As is customary, we import pandas and NumPy as follows:

```
In [1]: import pandas as pd
In [2]: import numpy as np
```

Most of the examples will utilize the `tips` dataset found within pandas tests. We'll read the data into a `DataFrame` called `tips` and assume we have a database table of the same name and structure.

```
In [3]: url = ('https://raw.githubusercontent.com/pandas-dev/
...:         '/pandas/master/pandas/tests/data/tips.csv')
...:

In [4]: tips = pd.read_csv(url)

In [5]: tips.head()
Out[5]:
```

|   | total_bill | tip  | sex    | smoker | day | time   | size |
|---|------------|------|--------|--------|-----|--------|------|
| 0 | 16.99      | 1.01 | Female | No     | Sun | Dinner | 2    |
| 1 | 10.34      | 1.66 | Male   | No     | Sun | Dinner | 3    |
| 2 | 21.01      | 3.50 | Male   | No     | Sun | Dinner | 3    |
| 3 | 23.68      | 3.31 | Male   | No     | Sun | Dinner | 2    |
| 4 | 24.59      | 3.61 | Female | No     | Sun | Dinner | 4    |

### 32.1 SELECT

In SQL, selection is done using a comma-separated list of columns you'd like to select (or a `*` to select all columns):

```
SELECT total_bill, tip, smoker, time
FROM tips
LIMIT 5;
```

With pandas, column selection is done by passing a list of column names to your `DataFrame`:

```
In [6]: tips[['total_bill', 'tip', 'smoker', 'time']].head(5)
Out[6]:
```

|   | total_bill | tip  | smoker | time   |
|---|------------|------|--------|--------|
| 0 | 16.99      | 1.01 | No     | Dinner |
| 1 | 10.34      | 1.66 | No     | Dinner |
| 2 | 21.01      | 3.50 | No     | Dinner |
| 3 | 23.68      | 3.31 | No     | Dinner |
| 4 | 24.59      | 3.61 | No     | Dinner |

Calling the DataFrame without the list of column names would display all columns (akin to SQL's \*).

## 32.2 WHERE

Filtering in SQL is done via a WHERE clause.

```
SELECT *
FROM tips
WHERE time = 'Dinner'
LIMIT 5;
```

DataFrames can be filtered in multiple ways; the most intuitive of which is using [boolean indexing](#).

```
In [7]: tips[tips['time'] == 'Dinner'].head(5)
Out[7]:
```

|   | total_bill | tip  | sex    | smoker | day | time   | size |
|---|------------|------|--------|--------|-----|--------|------|
| 0 | 16.99      | 1.01 | Female | No     | Sun | Dinner | 2    |
| 1 | 10.34      | 1.66 | Male   | No     | Sun | Dinner | 3    |
| 2 | 21.01      | 3.50 | Male   | No     | Sun | Dinner | 3    |
| 3 | 23.68      | 3.31 | Male   | No     | Sun | Dinner | 2    |
| 4 | 24.59      | 3.61 | Female | No     | Sun | Dinner | 4    |

The above statement is simply passing a Series of True/False objects to the DataFrame, returning all rows with True.

```
In [8]: is_dinner = tips['time'] == 'Dinner'

In [9]: is_dinner.value_counts()
Out[9]:
True      176
False      68
Name: time, dtype: int64

In [10]: tips[is_dinner].head(5)
Out[10]:
```

|   | total_bill | tip  | sex    | smoker | day | time   | size |
|---|------------|------|--------|--------|-----|--------|------|
| 0 | 16.99      | 1.01 | Female | No     | Sun | Dinner | 2    |
| 1 | 10.34      | 1.66 | Male   | No     | Sun | Dinner | 3    |
| 2 | 21.01      | 3.50 | Male   | No     | Sun | Dinner | 3    |
| 3 | 23.68      | 3.31 | Male   | No     | Sun | Dinner | 2    |
| 4 | 24.59      | 3.61 | Female | No     | Sun | Dinner | 4    |

Just like SQL's OR and AND, multiple conditions can be passed to a DataFrame using | (OR) and & (AND).

```
-- tips of more than $5.00 at Dinner meals
SELECT *
```

(continues on next page)

(continued from previous page)

```
FROM tips
WHERE time = 'Dinner' AND tip > 5.00;
```

```
# tips of more than $5.00 at Dinner meals
In [11]: tips[(tips['time'] == 'Dinner') & (tips['tip'] > 5.00)]
Out[11]:
```

|     | total_bill | tip   | sex    | smoker | day | time   | size |
|-----|------------|-------|--------|--------|-----|--------|------|
| 23  | 39.42      | 7.58  | Male   | No     | Sat | Dinner | 4    |
| 44  | 30.40      | 5.60  | Male   | No     | Sun | Dinner | 4    |
| 47  | 32.40      | 6.00  | Male   | No     | Sun | Dinner | 4    |
| 52  | 34.81      | 5.20  | Female | No     | Sun | Dinner | 4    |
| 59  | 48.27      | 6.73  | Male   | No     | Sat | Dinner | 4    |
| 116 | 29.93      | 5.07  | Male   | No     | Sun | Dinner | 4    |
| 155 | 29.85      | 5.14  | Female | No     | Sun | Dinner | 5    |
| 170 | 50.81      | 10.00 | Male   | Yes    | Sat | Dinner | 3    |
| 172 | 7.25       | 5.15  | Male   | Yes    | Sun | Dinner | 2    |
| 181 | 23.33      | 5.65  | Male   | Yes    | Sun | Dinner | 2    |
| 183 | 23.17      | 6.50  | Male   | Yes    | Sun | Dinner | 4    |
| 211 | 25.89      | 5.16  | Male   | Yes    | Sat | Dinner | 4    |
| 212 | 48.33      | 9.00  | Male   | No     | Sat | Dinner | 4    |
| 214 | 28.17      | 6.50  | Female | Yes    | Sat | Dinner | 3    |
| 239 | 29.03      | 5.92  | Male   | No     | Sat | Dinner | 3    |

```
-- tips by parties of at least 5 diners OR bill total was more than $45
SELECT *
FROM tips
WHERE size >= 5 OR total_bill > 45;
```

```
# tips by parties of at least 5 diners OR bill total was more than $45
In [12]: tips[(tips['size'] >= 5) | (tips['total_bill'] > 45)]
Out[12]:
```

|     | total_bill | tip   | sex    | smoker | day  | time   | size |
|-----|------------|-------|--------|--------|------|--------|------|
| 59  | 48.27      | 6.73  | Male   | No     | Sat  | Dinner | 4    |
| 125 | 29.80      | 4.20  | Female | No     | Thur | Lunch  | 6    |
| 141 | 34.30      | 6.70  | Male   | No     | Thur | Lunch  | 6    |
| 142 | 41.19      | 5.00  | Male   | No     | Thur | Lunch  | 5    |
| 143 | 27.05      | 5.00  | Female | No     | Thur | Lunch  | 6    |
| 155 | 29.85      | 5.14  | Female | No     | Sun  | Dinner | 5    |
| 156 | 48.17      | 5.00  | Male   | No     | Sun  | Dinner | 6    |
| 170 | 50.81      | 10.00 | Male   | Yes    | Sat  | Dinner | 3    |
| 182 | 45.35      | 3.50  | Male   | Yes    | Sun  | Dinner | 3    |
| 185 | 20.69      | 5.00  | Male   | No     | Sun  | Dinner | 5    |
| 187 | 30.46      | 2.00  | Male   | Yes    | Sun  | Dinner | 5    |
| 212 | 48.33      | 9.00  | Male   | No     | Sat  | Dinner | 4    |
| 216 | 28.15      | 3.00  | Male   | Yes    | Sat  | Dinner | 5    |

NULL checking is done using the `notna()` and `isna()` methods.

```
In [13]: frame = pd.DataFrame({'col1': ['A', 'B', np.NaN, 'C', 'D'],
.....:                        'col2': ['F', np.NaN, 'G', 'H', 'I']})
.....:

In [14]: frame
Out[14]:
```

|   | col1 | col2 |
|---|------|------|
| 0 | A    | F    |
| 1 | B    | NaN  |
| 2 | NaN  | G    |
| 3 | C    | H    |
| 4 | D    | I    |

(continues on next page)

(continued from previous page)

|   |     |     |
|---|-----|-----|
| 0 | A   | F   |
| 1 | B   | NaN |
| 2 | NaN | G   |
| 3 | C   | H   |
| 4 | D   | I   |

Assume we have a table of the same structure as our DataFrame above. We can see only the records where `col2` IS NULL with the following query:

```
SELECT *
FROM frame
WHERE col2 IS NULL;
```

```
In [15]: frame[frame['col2'].isna()]
Out[15]:
   col1 col2
1     B  NaN
```

Getting items where `col1` IS NOT NULL can be done with `notna()`.

```
SELECT *
FROM frame
WHERE col1 IS NOT NULL;
```

```
In [16]: frame[frame['col1'].notna()]
Out[16]:
   col1 col2
0     A    F
1     B  NaN
3     C    H
4     D    I
```

## 32.3 GROUP BY

In pandas, SQL's GROUP BY operations are performed using the similarly named `groupby()` method. `groupby()` typically refers to a process where we'd like to split a dataset into groups, apply some function (typically aggregation), and then combine the groups together.

A common SQL operation would be getting the count of records in each group throughout a dataset. For instance, a query getting us the number of tips left by sex:

```
SELECT sex, count(*)
FROM tips
GROUP BY sex;
/*
Female      87
Male       157
*/
```

The pandas equivalent would be:

```
In [17]: tips.groupby('sex').size()
Out[17]:
```

(continues on next page)

(continued from previous page)

```
sex
Female      87
Male       157
dtype: int64
```

Notice that in the pandas code we used `size()` and not `count()`. This is because `count()` applies the function to each column, returning the number of not null records within each.

```
In [18]: tips.groupby('sex').count()
Out[18]:
```

|        | total_bill | tip | smoker | day | time | size |
|--------|------------|-----|--------|-----|------|------|
| sex    |            |     |        |     |      |      |
| Female | 87         | 87  | 87     | 87  | 87   | 87   |
| Male   | 157        | 157 | 157    | 157 | 157  | 157  |

Alternatively, we could have applied the `count()` method to an individual column:

```
In [19]: tips.groupby('sex')['total_bill'].count()
Out[19]:
```

| sex    | total_bill |
|--------|------------|
| Female | 87         |
| Male   | 157        |

Name: total\_bill, dtype: int64

Multiple functions can also be applied at once. For instance, say we'd like to see how tip amount differs by day of the week - `agg()` allows you to pass a dictionary to your grouped DataFrame, indicating which functions to apply to specific columns.

```
SELECT day, AVG(tip), COUNT(*)
FROM tips
GROUP BY day;
/*
Fri    2.734737    19
Sat    2.993103    87
Sun    3.255132    76
Thur   2.771452    62
*/
```

```
In [20]: tips.groupby('day').agg({'tip': np.mean, 'day': np.size})
Out[20]:
```

|      | tip      | day |
|------|----------|-----|
| day  |          |     |
| Fri  | 2.734737 | 19  |
| Sat  | 2.993103 | 87  |
| Sun  | 3.255132 | 76  |
| Thur | 2.771452 | 62  |

Grouping by more than one column is done by passing a list of columns to the `groupby()` method.

```
SELECT smoker, day, COUNT(*), AVG(tip)
FROM tips
GROUP BY smoker, day;
/*
smoker day
No      Fri      4    2.812500
        Sat     45    3.102889
```

(continues on next page)

(continued from previous page)

```

        Sun      57  3.167895
        Thur     45  2.673778
Yes      Fri     15  2.714000
        Sat     42  2.875476
        Sun     19  3.516842
        Thur    17  3.030000
*/

```

```

In [21]: tips.groupby(['smoker', 'day']).agg({'tip': [np.size, np.mean]})
Out[21]:

```

|        |      | tip  |          |
|--------|------|------|----------|
|        |      | size | mean     |
| smoker | day  |      |          |
| No     | Fri  | 4.0  | 2.812500 |
|        | Sat  | 45.0 | 3.102889 |
|        | Sun  | 57.0 | 3.167895 |
|        | Thur | 45.0 | 2.673778 |
| Yes    | Fri  | 15.0 | 2.714000 |
|        | Sat  | 42.0 | 2.875476 |
|        | Sun  | 19.0 | 3.516842 |
|        | Thur | 17.0 | 3.030000 |

## 32.4 JOIN

JOINS can be performed with `join()` or `merge()`. By default, `join()` will join the DataFrames on their indices. Each method has parameters allowing you to specify the type of join to perform (LEFT, RIGHT, INNER, FULL) or the columns to join on (column names or indices).

```

In [22]: df1 = pd.DataFrame({'key': ['A', 'B', 'C', 'D'],
    ....:                    'value': np.random.randn(4)})
    ....:

In [23]: df2 = pd.DataFrame({'key': ['B', 'D', 'D', 'E'],
    ....:                    'value': np.random.randn(4)})
    ....:

```

Assume we have two database tables of the same name and structure as our DataFrames.

Now let's go over the various types of JOINS.

### 32.4.1 INNER JOIN

```

SELECT *
FROM df1
INNER JOIN df2
  ON df1.key = df2.key;

```

```

# merge performs an INNER JOIN by default
In [24]: pd.merge(df1, df2, on='key')
Out[24]:
   key  value_x  value_y
0    B  0.512365 -0.875472

```

(continues on next page)

(continued from previous page)

```
1  D -0.115234  0.189158
2  D -0.115234  1.427408
```

`merge()` also offers parameters for cases when you'd like to join one DataFrame's column with another DataFrame's index.

```
In [25]: indexed_df2 = df2.set_index('key')

In [26]: pd.merge(df1, indexed_df2, left_on='key', right_index=True)
Out[26]:
```

|   | key | value_x   | value_y   |
|---|-----|-----------|-----------|
| 1 | B   | 0.512365  | -0.875472 |
| 3 | D   | -0.115234 | 0.189158  |
| 3 | D   | -0.115234 | 1.427408  |

## 32.4.2 LEFT OUTER JOIN

```
-- show all records from df1
SELECT *
FROM df1
LEFT OUTER JOIN df2
  ON df1.key = df2.key;
```

```
# show all records from df1
In [27]: pd.merge(df1, df2, on='key', how='left')
Out[27]:
```

|   | key | value_x   | value_y   |
|---|-----|-----------|-----------|
| 0 | A   | -0.022008 | NaN       |
| 1 | B   | 0.512365  | -0.875472 |
| 2 | C   | -0.979461 | NaN       |
| 3 | D   | -0.115234 | 0.189158  |
| 4 | D   | -0.115234 | 1.427408  |

## 32.4.3 RIGHT JOIN

```
-- show all records from df2
SELECT *
FROM df1
RIGHT OUTER JOIN df2
  ON df1.key = df2.key;
```

```
# show all records from df2
In [28]: pd.merge(df1, df2, on='key', how='right')
Out[28]:
```

|   | key | value_x   | value_y   |
|---|-----|-----------|-----------|
| 0 | B   | 0.512365  | -0.875472 |
| 1 | D   | -0.115234 | 0.189158  |
| 2 | D   | -0.115234 | 1.427408  |
| 3 | E   | NaN       | 0.683190  |

### 32.4.4 FULL JOIN

pandas also allows for FULL JOINS, which display both sides of the dataset, whether or not the joined columns find a match. As of writing, FULL JOINS are not supported in all RDBMS (MySQL).

```
-- show all records from both tables
SELECT *
FROM df1
FULL OUTER JOIN df2
  ON df1.key = df2.key;
```

```
# show all records from both frames
In [29]: pd.merge(df1, df2, on='key', how='outer')
Out[29]:
```

|   | key | value_x   | value_y   |
|---|-----|-----------|-----------|
| 0 | A   | -0.022008 | NaN       |
| 1 | B   | 0.512365  | -0.875472 |
| 2 | C   | -0.979461 | NaN       |
| 3 | D   | -0.115234 | 0.189158  |
| 4 | D   | -0.115234 | 1.427408  |
| 5 | E   | NaN       | 0.683190  |

## 32.5 UNION

UNION ALL can be performed using `concat()`.

```
In [30]: df1 = pd.DataFrame({'city': ['Chicago', 'San Francisco', 'New York City'],
.....:                      'rank': range(1, 4)})
.....:

In [31]: df2 = pd.DataFrame({'city': ['Chicago', 'Boston', 'Los Angeles'],
.....:                      'rank': [1, 4, 5]})
.....:
```

```
SELECT city, rank
FROM df1
UNION ALL
SELECT city, rank
FROM df2;
/*
      city  rank
San Francisco  2
New York City  3
      Chicago  1
      Boston   4
Los Angeles   5
*/
```

```
In [32]: pd.concat([df1, df2])
Out[32]:
```

|   | city          | rank |
|---|---------------|------|
| 0 | Chicago       | 1    |
| 1 | San Francisco | 2    |

(continues on next page)

(continued from previous page)

|   |               |   |
|---|---------------|---|
| 2 | New York City | 3 |
| 0 | Chicago       | 1 |
| 1 | Boston        | 4 |
| 2 | Los Angeles   | 5 |

SQL's UNION is similar to UNION ALL, however UNION will remove duplicate rows.

```
SELECT city, rank
FROM df1
UNION
SELECT city, rank
FROM df2;
-- notice that there is only one Chicago record this time
/*
      city  rank
      Chicago    1
San Francisco    2
New York City    3
      Boston    4
      Los Angeles 5
*/
```

In pandas, you can use `concat()` in conjunction with `drop_duplicates()`.

```
In [33]: pd.concat([df1, df2]).drop_duplicates()
```

```
Out[33]:
      city  rank
0   Chicago    1
1 San Francisco  2
2 New York City  3
1   Boston    4
2  Los Angeles  5
```

## 32.6 Pandas equivalents for some SQL analytic and aggregate functions

### 32.6.1 Top N rows with offset

```
-- MySQL
SELECT * FROM tips
ORDER BY tip DESC
LIMIT 10 OFFSET 5;
```

```
In [34]: tips.nlargest(10 + 5, columns='tip').tail(10)
```

```
Out[34]:
   total_bill  tip  sex smoker  day  time  size
183    23.17  6.50  Male   Yes  Sun  Dinner    4
214    28.17  6.50  Female Yes  Sat  Dinner    3
47     32.40  6.00  Male   No   Sun  Dinner    4
239    29.03  5.92  Male   No   Sat  Dinner    3
88     24.71  5.85  Male   No  Thur  Lunch    2
181    23.33  5.65  Male   Yes  Sun  Dinner    2
```

(continues on next page)

(continued from previous page)

|     |       |      |        |     |      |        |   |
|-----|-------|------|--------|-----|------|--------|---|
| 44  | 30.40 | 5.60 | Male   | No  | Sun  | Dinner | 4 |
| 52  | 34.81 | 5.20 | Female | No  | Sun  | Dinner | 4 |
| 85  | 34.83 | 5.17 | Female | No  | Thur | Lunch  | 4 |
| 211 | 25.89 | 5.16 | Male   | Yes | Sat  | Dinner | 4 |

### 32.6.2 Top N rows per group

```
-- Oracle's ROW_NUMBER() analytic function
SELECT * FROM (
  SELECT
    t.*,
    ROW_NUMBER() OVER(PARTITION BY day ORDER BY total_bill DESC) AS rn
  FROM tips t
)
WHERE rn < 3
ORDER BY day, rn;
```

```
In [35]: (tips.assign(rn=tips.sort_values(['total_bill'], ascending=False)
.....:               .groupby(['day'])
.....:               .cumcount() + 1)
.....:       .query('rn < 3')
.....:       .sort_values(['day', 'rn']))
.....:
```

```
Out[35]:
```

|     | total_bill | tip   | sex    | smoker | day  | time   | size | rn |
|-----|------------|-------|--------|--------|------|--------|------|----|
| 95  | 40.17      | 4.73  | Male   | Yes    | Fri  | Dinner | 4    | 1  |
| 90  | 28.97      | 3.00  | Male   | Yes    | Fri  | Dinner | 2    | 2  |
| 170 | 50.81      | 10.00 | Male   | Yes    | Sat  | Dinner | 3    | 1  |
| 212 | 48.33      | 9.00  | Male   | No     | Sat  | Dinner | 4    | 2  |
| 156 | 48.17      | 5.00  | Male   | No     | Sun  | Dinner | 6    | 1  |
| 182 | 45.35      | 3.50  | Male   | Yes    | Sun  | Dinner | 3    | 2  |
| 197 | 43.11      | 5.00  | Female | Yes    | Thur | Lunch  | 4    | 1  |
| 142 | 41.19      | 5.00  | Male   | No     | Thur | Lunch  | 5    | 2  |

the same using `rank(method='first')` function

```
In [36]: (tips.assign(rnk=tips.groupby(['day'])['total_bill']
.....:               .rank(method='first', ascending=False))
.....:       .query('rnk < 3')
.....:       .sort_values(['day', 'rnk']))
.....:
```

```
Out[36]:
```

|     | total_bill | tip   | sex    | smoker | day  | time   | size | rnk |
|-----|------------|-------|--------|--------|------|--------|------|-----|
| 95  | 40.17      | 4.73  | Male   | Yes    | Fri  | Dinner | 4    | 1.0 |
| 90  | 28.97      | 3.00  | Male   | Yes    | Fri  | Dinner | 2    | 2.0 |
| 170 | 50.81      | 10.00 | Male   | Yes    | Sat  | Dinner | 3    | 1.0 |
| 212 | 48.33      | 9.00  | Male   | No     | Sat  | Dinner | 4    | 2.0 |
| 156 | 48.17      | 5.00  | Male   | No     | Sun  | Dinner | 6    | 1.0 |
| 182 | 45.35      | 3.50  | Male   | Yes    | Sun  | Dinner | 3    | 2.0 |
| 197 | 43.11      | 5.00  | Female | Yes    | Thur | Lunch  | 4    | 1.0 |
| 142 | 41.19      | 5.00  | Male   | No     | Thur | Lunch  | 5    | 2.0 |

```
-- Oracle's RANK() analytic function
SELECT * FROM (
```

(continues on next page)

(continued from previous page)

```

SELECT
  t.*,
  RANK() OVER(PARTITION BY sex ORDER BY tip) AS rnk
FROM tips t
WHERE tip < 2
)
WHERE rnk < 3
ORDER BY sex, rnk;

```

Let's find tips with (rank < 3) per gender group for (tips < 2). Notice that when using `rank(method='min')` function `rnk_min` remains the same for the same *tip* (as Oracle's RANK() function)

```

In [37]: (tips[tips['tip'] < 2]
....:      .assign(rnk_min=tips.groupby(['sex'])['tip']
....:              .rank(method='min'))
....:      .query('rnk_min < 3')
....:      .sort_values(['sex', 'rnk_min']))
....:
Out[37]:
   total_bill  tip  sex smoker  day  time  size  rnk_min
67         3.07  1.00 Female   Yes  Sat  Dinner     1     1.0
92         5.75  1.00 Female   Yes  Fri  Dinner     2     1.0
111         7.25  1.00 Female   No   Sat  Dinner     1     1.0
236        12.60  1.00 Male    Yes  Sat  Dinner     2     1.0
237        32.83  1.17 Male    Yes  Sat  Dinner     2     2.0

```

## 32.7 UPDATE

```

UPDATE tips
SET tip = tip*2
WHERE tip < 2;

```

```

In [38]: tips.loc[tips['tip'] < 2, 'tip'] *= 2

```

## 32.8 DELETE

```

DELETE FROM tips
WHERE tip > 9;

```

In pandas we select the rows that should remain, instead of deleting them

```

In [39]: tips = tips.loc[tips['tip'] <= 9]

```

```
{{ header }}
```

## COMPARISON WITH SAS

For potential users coming from SAS this page is meant to demonstrate how different SAS operations would be performed in pandas.

If you're new to pandas, you might want to first read through *10 Minutes to pandas* to familiarize yourself with the library.

As is customary, we import pandas and NumPy as follows:

```
In [1]: import pandas as pd
```

```
In [2]: import numpy as np
```

---

**Note:** Throughout this tutorial, the pandas `DataFrame` will be displayed by calling `df.head()`, which displays the first N (default 5) rows of the `DataFrame`. This is often used in interactive work (e.g. [Jupyter notebook](#) or terminal) - the equivalent in SAS would be:

```
proc print data=df(obs=5);  
run;
```

### 33.1 Data Structures

#### 33.1.1 General Terminology Translation

| pandas                 | SAS         |
|------------------------|-------------|
| <code>DataFrame</code> | data set    |
| column                 | variable    |
| row                    | observation |
| <code>groupby</code>   | BY-group    |
| NaN                    | .           |

#### 33.1.2 `DataFrame` / `Series`

A `DataFrame` in pandas is analogous to a SAS data set - a two-dimensional data source with labeled columns that can be of different types. As will be shown in this document, almost any operation that can be applied to a data set using SAS's `DATA` step, can also be accomplished in pandas.

A `Series` is the data structure that represents one column of a `DataFrame`. SAS doesn't have a separate data structure for a single column, but in general, working with a `Series` is analogous to referencing a column in the `DATA` step.

### 33.1.3 Index

Every `DataFrame` and `Series` has an `Index` - which are labels on the *rows* of the data. SAS does not have an exactly analogous concept. A data set's rows are essentially unlabeled, other than an implicit integer index that can be accessed during the `DATA` step (`_N_`).

In pandas, if no index is specified, an integer index is also used by default (first row = 0, second row = 1, and so on). While using a labeled `Index` or `MultiIndex` can enable sophisticated analyses and is ultimately an important part of pandas to understand, for this comparison we will essentially ignore the `Index` and just treat the `DataFrame` as a collection of columns. Please see the *indexing documentation* for much more on how to use an `Index` effectively.

## 33.2 Data Input / Output

### 33.2.1 Constructing a DataFrame from Values

A SAS data set can be built from specified values by placing the data after a `datalines` statement and specifying the column names.

```
data df;
  input x y;
  datalines;
1 2
3 4
5 6
;
run;
```

A pandas `DataFrame` can be constructed in many different ways, but for a small number of values, it is often convenient to specify it as a Python dictionary, where the keys are the column names and the values are the data.

```
In [3]: df = pd.DataFrame({'x': [1, 3, 5], 'y': [2, 4, 6]})

In [4]: df
Out[4]:
   x  y
0  1  2
1  3  4
2  5  6
```

### 33.2.2 Reading External Data

Like SAS, pandas provides utilities for reading in data from many formats. The `tips` dataset, found within the pandas tests (`csv`) will be used in many of the following examples.

SAS provides `PROC IMPORT` to read csv data into a data set.

```
proc import datafile='tips.csv' dbms=csv out=tips replace;
  getnames=yes;
run;
```

The pandas method is `read_csv()`, which works similarly.

```
In [5]: url = ('https://raw.githubusercontent.com/pandas-dev/'
...:         'pandas/master/pandas/tests/data/tips.csv')
...:

In [6]: tips = pd.read_csv(url)

In [7]: tips.head()
Out[7]:
```

|   | total_bill | tip  | sex    | smoker | day | time   | size |
|---|------------|------|--------|--------|-----|--------|------|
| 0 | 16.99      | 1.01 | Female | No     | Sun | Dinner | 2    |
| 1 | 10.34      | 1.66 | Male   | No     | Sun | Dinner | 3    |
| 2 | 21.01      | 3.50 | Male   | No     | Sun | Dinner | 3    |
| 3 | 23.68      | 3.31 | Male   | No     | Sun | Dinner | 2    |
| 4 | 24.59      | 3.61 | Female | No     | Sun | Dinner | 4    |

Like `PROC IMPORT`, `read_csv` can take a number of parameters to specify how the data should be parsed. For example, if the data was instead tab delimited, and did not have column names, the pandas command would be:

```
tips = pd.read_csv('tips.csv', sep='\t', header=None)

# alternatively, read_table is an alias to read_csv with tab delimiter
tips = pd.read_table('tips.csv', header=None)
```

In addition to text/csv, pandas supports a variety of other data formats such as Excel, HDF5, and SQL databases. These are all read via a `pd.read_*` function. See the *IO documentation* for more details.

### 33.2.3 Exporting Data

The inverse of `PROC IMPORT` in SAS is `PROC EXPORT`

```
proc export data=tips outfile='tips2.csv' dbms=csv;
run;
```

Similarly in pandas, the opposite of `read_csv` is `to_csv()`, and other data formats follow a similar api.

```
tips.to_csv('tips2.csv')
```

## 33.3 Data Operations

### 33.3.1 Operations on Columns

In the DATA step, arbitrary math expressions can be used on new or existing columns.

```
data tips;
  set tips;
  total_bill = total_bill - 2;
  new_bill = total_bill / 2;
run;
```

pandas provides similar vectorized operations by specifying the individual `Series` in the `DataFrame`. New columns can be assigned in the same way.

```
In [8]: tips['total_bill'] = tips['total_bill'] - 2
In [9]: tips['new_bill'] = tips['total_bill'] / 2.0
In [10]: tips.head()
Out[10]:
```

|   | total_bill | tip  | sex    | smoker | day | time   | size | new_bill |
|---|------------|------|--------|--------|-----|--------|------|----------|
| 0 | 14.99      | 1.01 | Female | No     | Sun | Dinner | 2    | 7.495    |
| 1 | 8.34       | 1.66 | Male   | No     | Sun | Dinner | 3    | 4.170    |
| 2 | 19.01      | 3.50 | Male   | No     | Sun | Dinner | 3    | 9.505    |
| 3 | 21.68      | 3.31 | Male   | No     | Sun | Dinner | 2    | 10.840   |
| 4 | 22.59      | 3.61 | Female | No     | Sun | Dinner | 4    | 11.295   |

### 33.3.2 Filtering

Filtering in SAS is done with an `if` or `where` statement, on one or more columns.

```
data tips;
  set tips;
  if total_bill > 10;
run;

data tips;
  set tips;
  where total_bill > 10;
  /* equivalent in this case - where happens before the
     DATA step begins and can also be used in PROC statements */
run;
```

DataFrames can be filtered in multiple ways; the most intuitive of which is using *boolean indexing*

```
In [11]: tips[tips['total_bill'] > 10].head()
Out[11]:
```

|   | total_bill | tip  | sex    | smoker | day | time   | size |
|---|------------|------|--------|--------|-----|--------|------|
| 0 | 14.99      | 1.01 | Female | No     | Sun | Dinner | 2    |
| 2 | 19.01      | 3.50 | Male   | No     | Sun | Dinner | 3    |
| 3 | 21.68      | 3.31 | Male   | No     | Sun | Dinner | 2    |
| 4 | 22.59      | 3.61 | Female | No     | Sun | Dinner | 4    |
| 5 | 23.29      | 4.71 | Male   | No     | Sun | Dinner | 4    |

### 33.3.3 If/Then Logic

In SAS, `if/then` logic can be used to create new columns.

```
data tips;
  set tips;
  format bucket $4.;

  if total_bill < 10 then bucket = 'low';
  else bucket = 'high';
run;
```

The same operation in pandas can be accomplished using the `where` method from numpy.

```
In [12]: tips['bucket'] = np.where(tips['total_bill'] < 10, 'low', 'high')
```

```
In [13]: tips.head()
```

```
Out[13]:
```

|   | total_bill | tip  | sex    | smoker | day | time   | size | bucket |
|---|------------|------|--------|--------|-----|--------|------|--------|
| 0 | 14.99      | 1.01 | Female | No     | Sun | Dinner | 2    | high   |
| 1 | 8.34       | 1.66 | Male   | No     | Sun | Dinner | 3    | low    |
| 2 | 19.01      | 3.50 | Male   | No     | Sun | Dinner | 3    | high   |
| 3 | 21.68      | 3.31 | Male   | No     | Sun | Dinner | 2    | high   |
| 4 | 22.59      | 3.61 | Female | No     | Sun | Dinner | 4    | high   |

### 33.3.4 Date Functionality

SAS provides a variety of functions to do operations on date/datetime columns.

```
data tips;
  set tips;
  format date1 date2 date1_plusmonth mmddyy10.;
  date1 = mdy(1, 15, 2013);
  date2 = mdy(2, 15, 2015);
  date1_year = year(date1);
  date2_month = month(date2);
  * shift date to beginning of next interval;
  date1_next = intnx('MONTH', date1, 1);
  * count intervals between dates;
  months_between = intck('MONTH', date1, date2);
run;
```

The equivalent pandas operations are shown below. In addition to these functions pandas supports other Time Series features not available in Base SAS (such as resampling and custom offsets) - see the *timeseries documentation* for more details.

```
In [14]: tips['date1'] = pd.Timestamp('2013-01-15')
```

```
In [15]: tips['date2'] = pd.Timestamp('2015-02-15')
```

```
In [16]: tips['date1_year'] = tips['date1'].dt.year
```

```
In [17]: tips['date2_month'] = tips['date2'].dt.month
```

```
In [18]: tips['date1_next'] = tips['date1'] + pd.offsets.MonthBegin()
```

```
In [19]: tips['months_between'] = (
.....:     tips['date2'].dt.to_period('M') - tips['date1'].dt.to_period('M'))
.....:
```

```
In [20]: tips[['date1', 'date2', 'date1_year', 'date2_month',
.....:         'date1_next', 'months_between']].head()
.....:
```

```
Out[20]:
```

|   | date1      | date2      | date1_year | date2_month | date1_next | months_between   |
|---|------------|------------|------------|-------------|------------|------------------|
| 0 | 2013-01-15 | 2015-02-15 | 2013       | 2           | 2013-02-01 | <25 * MonthEnds> |
| 1 | 2013-01-15 | 2015-02-15 | 2013       | 2           | 2013-02-01 | <25 * MonthEnds> |
| 2 | 2013-01-15 | 2015-02-15 | 2013       | 2           | 2013-02-01 | <25 * MonthEnds> |
| 3 | 2013-01-15 | 2015-02-15 | 2013       | 2           | 2013-02-01 | <25 * MonthEnds> |
| 4 | 2013-01-15 | 2015-02-15 | 2013       | 2           | 2013-02-01 | <25 * MonthEnds> |

### 33.3.5 Selection of Columns

SAS provides keywords in the DATA step to select, drop, and rename columns.

```
data tips;
  set tips;
  keep sex total_bill tip;
run;

data tips;
  set tips;
  drop sex;
run;

data tips;
  set tips;
  rename total_bill=total_bill_2;
run;
```

The same operations are expressed in pandas below.

```
# keep
In [21]: tips[['sex', 'total_bill', 'tip']].head()
Out[21]:
   sex  total_bill  tip
0  Female      14.99  1.01
1   Male       8.34  1.66
2   Male      19.01  3.50
3   Male      21.68  3.31
4  Female      22.59  3.61

# drop
In [22]: tips.drop('sex', axis=1).head()
////////////////////////////////////
↪
   total_bill  tip  smoker  day  time  size
0      14.99  1.01     No  Sun  Dinner    2
1       8.34  1.66     No  Sun  Dinner    3
2      19.01  3.50     No  Sun  Dinner    3
3      21.68  3.31     No  Sun  Dinner    2
4      22.59  3.61     No  Sun  Dinner    4

# rename
In [23]: tips.rename(columns={'total_bill': 'total_bill_2'}).head()
////////////////////////////////////
↪
   total_bill_2  tip  sex  smoker  day  time  size
0      14.99  1.01  Female     No  Sun  Dinner    2
1       8.34  1.66   Male     No  Sun  Dinner    3
2      19.01  3.50   Male     No  Sun  Dinner    3
3      21.68  3.31   Male     No  Sun  Dinner    2
4      22.59  3.61  Female     No  Sun  Dinner    4
```

### 33.3.6 Sorting by Values

Sorting in SAS is accomplished via PROC SORT

```
proc sort data=tips;
    by sex total_bill;
run;
```

pandas objects have a `sort_values()` method, which takes a list of columns to sort by.

```
In [24]: tips = tips.sort_values(['sex', 'total_bill'])

In [25]: tips.head()
Out[25]:
```

|     | total_bill | tip  | sex    | smoker | day  | time   | size |
|-----|------------|------|--------|--------|------|--------|------|
| 67  | 1.07       | 1.00 | Female | Yes    | Sat  | Dinner | 1    |
| 92  | 3.75       | 1.00 | Female | Yes    | Fri  | Dinner | 2    |
| 111 | 5.25       | 1.00 | Female | No     | Sat  | Dinner | 1    |
| 145 | 6.35       | 1.50 | Female | No     | Thur | Lunch  | 2    |
| 135 | 6.51       | 1.25 | Female | No     | Thur | Lunch  | 2    |

## 33.4 String Processing

### 33.4.1 Length

SAS determines the length of a character string with the `LENGTHN` and `LENGTHC` functions. `LENGTHN` excludes trailing blanks and `LENGTHC` includes trailing blanks.

```
data _null_;
set tips;
put (LENGTHN(time));
put (LENGTHC(time));
run;
```

Python determines the length of a character string with the `len` function. `len` includes trailing blanks. Use `len` and `rstrip` to exclude trailing blanks.

```
In [26]: tips['time'].str.len().head()
Out[26]:
```

|     |   |
|-----|---|
| 67  | 6 |
| 92  | 6 |
| 111 | 6 |
| 145 | 5 |
| 135 | 5 |

Name: time, dtype: int64

```
In [27]: tips['time'].str.rstrip().str.len().head()
Out[27]:
```

|     |   |
|-----|---|
| 67  | 6 |
| 92  | 6 |
| 111 | 6 |
| 145 | 5 |
| 135 | 5 |

Name: time, dtype: int64

### 33.4.2 Find

SAS determines the position of a character in a string with the **FINDW** function. **FINDW** takes the string defined by the first argument and searches for the first position of the substring you supply as the second argument.

```
data _null_;
set tips;
put (FINDW(sex, 'ale'));
run;
```

Python determines the position of a character in a string with the `find` function. `find` searches for the first position of the substring. If the substring is found, the function returns its position. Keep in mind that Python indexes are zero-based and the function will return -1 if it fails to find the substring.

```
In [28]: tips['sex'].str.find("ale").head()
Out[28]:
67      3
92      3
111     3
145     3
135     3
Name: sex, dtype: int64
```

### 33.4.3 Substring

SAS extracts a substring from a string based on its position with the **SUBSTR** function.

```
data _null_;
set tips;
put (substr(sex,1,1));
run;
```

With pandas you can use `[]` notation to extract a substring from a string by position locations. Keep in mind that Python indexes are zero-based.

```
In [29]: tips['sex'].str[0:1].head()
Out[29]:
67      F
92      F
111     F
145     F
135     F
Name: sex, dtype: object
```

### 33.4.4 Scan

The SAS **SCAN** function returns the *n*th word from a string. The first argument is the string you want to parse and the second argument specifies which word you want to extract.

```
data firstlast;
input String $60.;
First_Name = scan(string, 1);
Last_Name = scan(string, -1);
datalines2;
```

(continues on next page)

(continued from previous page)

```
John Smith;
Jane Cook;
;;;
run;
```

Python extracts a substring from a string based on its text by using regular expressions. There are much more powerful approaches, but this just shows a simple approach.

```
In [30]: firstlast = pd.DataFrame({'String': ['John Smith', 'Jane Cook']})

In [31]: firstlast['First_Name'] = firstlast['String'].str.split(" ", expand=True)[0]

In [32]: firstlast['Last_Name'] = firstlast['String'].str.rsplit(" ", expand=True)[0]

In [33]: firstlast
Out[33]:
```

|   | String     | First_Name | Last_Name |
|---|------------|------------|-----------|
| 0 | John Smith | John       | Smith     |
| 1 | Jane Cook  | Jane       | Cook      |

### 33.4.5 Uppcase, Lowcase, and Propcase

The SAS `UPCASE` `LOWCASE` and `PROPCASE` functions change the case of the argument.

```
data firstlast;
input String $60.;
string_up = UPCASE(string);
string_low = LOWCASE(string);
string_prop = PROPCASE(string);
datalines2;
John Smith;
Jane Cook;
;;;
run;
```

The equivalent Python functions are `upper`, `lower`, and `title`.

```
In [34]: firstlast = pd.DataFrame({'String': ['John Smith', 'Jane Cook']})

In [35]: firstlast['string_up'] = firstlast['String'].str.upper()

In [36]: firstlast['string_low'] = firstlast['String'].str.lower()

In [37]: firstlast['string_prop'] = firstlast['String'].str.title()

In [38]: firstlast
Out[38]:
```

|   | String     | string_up  | string_low | string_prop |
|---|------------|------------|------------|-------------|
| 0 | John Smith | JOHN SMITH | john smith | John Smith  |
| 1 | Jane Cook  | JANE COOK  | jane cook  | Jane Cook   |

## 33.5 Merging

The following tables will be used in the merge examples

```
In [39]: df1 = pd.DataFrame({'key': ['A', 'B', 'C', 'D'],
.....:                      'value': np.random.randn(4)})
.....:

In [40]: df1
Out[40]:
   key  value
0    A  0.943856
1    B  0.810496
2    C  0.686163
3    D -1.672422

In [41]: df2 = pd.DataFrame({'key': ['B', 'D', 'D', 'E'],
.....:                      'value': np.random.randn(4)})
.....:

In [42]: df2
Out[42]:
   key  value
0    B -1.038680
1    D -0.288663
2    D -0.798926
3    E -1.770844
```

In SAS, data must be explicitly sorted before merging. Different types of joins are accomplished using the `in=` dummy variables to track whether a match was found in one or both input frames.

```
proc sort data=df1;
  by key;
run;

proc sort data=df2;
  by key;
run;

data left_join inner_join right_join outer_join;
  merge df1(in=a) df2(in=b);

  if a and b then output inner_join;
  if a then output left_join;
  if b then output right_join;
  if a or b then output outer_join;
run;
```

pandas DataFrames have a `merge()` method, which provides similar functionality. Note that the data does not have to be sorted ahead of time, and different join types are accomplished via the `how` keyword.

```
In [43]: inner_join = df1.merge(df2, on='key', how='inner')

In [44]: inner_join
Out[44]:
   key  value_x  value_y
0    B  0.810496 -1.038680
```

(continues on next page)

(continued from previous page)

```

1   D -1.672422 -0.288663
2   D -1.672422 -0.798926

In [45]: left_join = df1.merge(df2, on=['key'], how='left')

In [46]: left_join
Out[46]:
   key  value_x  value_y
0   A  0.943856      NaN
1   B  0.810496 -1.038680
2   C  0.686163      NaN
3   D -1.672422 -0.288663
4   D -1.672422 -0.798926

In [47]: right_join = df1.merge(df2, on=['key'], how='right')

In [48]: right_join
Out[48]:
   key  value_x  value_y
0   B  0.810496 -1.038680
1   D -1.672422 -0.288663
2   D -1.672422 -0.798926
3   E         NaN -1.770844

In [49]: outer_join = df1.merge(df2, on=['key'], how='outer')

In [50]: outer_join
Out[50]:
   key  value_x  value_y
0   A  0.943856      NaN
1   B  0.810496 -1.038680
2   C  0.686163      NaN
3   D -1.672422 -0.288663
4   D -1.672422 -0.798926
5   E         NaN -1.770844

```

## 33.6 Missing Data

Like SAS, pandas has a representation for missing data - which is the special float value NaN (not a number). Many of the semantics are the same, for example missing data propagates through numeric operations, and is ignored by default for aggregations.

```

In [51]: outer_join
Out[51]:
   key  value_x  value_y
0   A  0.943856      NaN
1   B  0.810496 -1.038680
2   C  0.686163      NaN
3   D -1.672422 -0.288663
4   D -1.672422 -0.798926
5   E         NaN -1.770844

In [52]: outer_join['value_x'] + outer_join['value_y']

```

(continues on next page)

(continued from previous page)

```

0      NaN
1  -0.228184
2      NaN
3  -1.961084
4  -2.471348
5      NaN
dtype: float64

```

```
In [53]: outer_join['value_x'].sum()
```

```

////////////////////////////////////
↪ -0.90432756186221441

```

One difference is that missing data cannot be compared to its sentinel value. For example, in SAS you could do this to filter missing values.

```

data outer_join_nulls;
    set outer_join;
    if value_x = .;
run;

data outer_join_no_nulls;
    set outer_join;
    if value_x ^= .;
run;

```

Which doesn't work in pandas. Instead, the `pd.isna` or `pd.notna` functions should be used for comparisons.

```
In [54]: outer_join[pd.isna(outer_join['value_x'])]
```

```
Out[54]:
```

```

   key  value_x  value_y
5    E      NaN -1.770844

```

```
In [55]: outer_join[pd.notna(outer_join['value_x'])]
```

```

////////////////////////////////////Out[55]:

```

```

   key  value_x  value_y
0    A  0.943856      NaN
1    B  0.810496 -1.038680
2    C  0.686163      NaN
3    D -1.672422 -0.288663
4    D -1.672422 -0.798926

```

pandas also provides a variety of methods to work with missing data - some of which would be challenging to express in SAS. For example, there are methods to drop all rows with any missing values, replacing missing values with a specified value, like the mean, or forward filling from previous rows. See the *missing data documentation* for more.

```
In [56]: outer_join.dropna()
```

```
Out[56]:
```

```

   key  value_x  value_y
1    B  0.810496 -1.038680
3    D -1.672422 -0.288663
4    D -1.672422 -0.798926

```

```
In [57]: outer_join.fillna(method='ffill')
```

```

////////////////////////////////////
↪
   key  value_x  value_y

```

(continues on next page)

(continued from previous page)

```

0   A   0.943856      NaN
1   B   0.810496  -1.038680
2   C   0.686163  -1.038680
3   D  -1.672422  -0.288663
4   D  -1.672422  -0.798926
5   E  -1.672422  -1.770844

```

```
In [58]: outer_join['value_x'].fillna(outer_join['value_x'].mean())
```

```

////////////////////////////////////

```

```

→
0   0.943856
1   0.810496
2   0.686163
3  -1.672422
4  -1.672422
5  -0.180866
Name: value_x, dtype: float64

```

## 33.7 GroupBy

### 33.7.1 Aggregation

SAS's PROC SUMMARY can be used to group by one or more key variables and compute aggregations on numeric columns.

```

proc summary data=tips nway;
  class sex smoker;
  var total_bill tip;
  output out=tips_summed sum=;
run;

```

pandas provides a flexible `groupby` mechanism that allows similar aggregations. See the *groupby documentation* for more details and examples.

```
In [59]: tips_summed = tips.groupby(['sex', 'smoker'])['total_bill', 'tip'].sum()
```

```
In [60]: tips_summed.head()
```

```

Out [60]:

```

|        |        | total_bill | tip    |
|--------|--------|------------|--------|
| sex    | smoker |            |        |
| Female | No     | 869.68     | 149.77 |
|        | Yes    | 527.27     | 96.74  |
| Male   | No     | 1725.75    | 302.00 |
|        | Yes    | 1217.07    | 183.07 |

### 33.7.2 Transformation

In SAS, if the group aggregations need to be used with the original frame, it must be merged back together. For example, to subtract the mean for each observation by smoker group.

```

proc summary data=tips missing nway;
  class smoker;
  var total_bill;
  output out=smoker_means mean(total_bill)=group_bill;
run;

proc sort data=tips;
  by smoker;
run;

data tips;
  merge tips(in=a) smoker_means(in=b);
  by smoker;
  adj_total_bill = total_bill - group_bill;
  if a and b;
run;

```

pandas groupby provides a transform mechanism that allows these type of operations to be succinctly expressed in one operation.

```

In [61]: gb = tips.groupby('smoker')['total_bill']

In [62]: tips['adj_total_bill'] = tips['total_bill'] - gb.transform('mean')

In [63]: tips.head()
Out[63]:
   total_bill  tip  sex smoker  day  time  size  adj_total_bill
67         1.07  1.00 Female   Yes  Sat  Dinner    1        -17.686344
92         3.75  1.00 Female   Yes  Fri  Dinner    2        -15.006344
111        5.25  1.00 Female    No  Sat  Dinner    1        -11.938278
145         6.35  1.50 Female    No  Thur  Lunch    2        -10.838278
135         6.51  1.25 Female    No  Thur  Lunch    2        -10.678278

```

### 33.7.3 By Group Processing

In addition to aggregation, pandas groupby can be used to replicate most other by group processing from SAS. For example, this DATA step reads the data by sex/smoker group and filters to the first entry for each.

```

proc sort data=tips;
  by sex smoker;
run;

data tips_first;
  set tips;
  by sex smoker;
  if FIRST.sex or FIRST.smoker then output;
run;

```

In pandas this would be written as:

```

In [64]: tips.groupby(['sex', 'smoker']).first()
Out[64]:
   total_bill  tip  day  time  size  adj_total_bill
sex  smoker
Female No         5.25  1.00  Sat  Dinner    1        -11.938278

```

(continues on next page)

(continued from previous page)

|      |     |      |      |      |        |   |            |
|------|-----|------|------|------|--------|---|------------|
|      | Yes | 1.07 | 1.00 | Sat  | Dinner | 1 | -17.686344 |
| Male | No  | 5.51 | 2.00 | Thur | Lunch  | 2 | -11.678278 |
|      | Yes | 5.25 | 5.15 | Sun  | Dinner | 2 | -13.506344 |

## 33.8 Other Considerations

### 33.8.1 Disk vs Memory

pandas operates exclusively in memory, where a SAS data set exists on disk. This means that the size of data able to be loaded in pandas is limited by your machine's memory, but also that the operations on that data may be faster.

If out of core processing is needed, one possibility is the [dask.dataframe](#) library (currently in development) which provides a subset of pandas functionality for an on-disk DataFrame

### 33.8.2 Data Interop

pandas provides a `read_sas()` method that can read SAS data saved in the XPORT or SAS7BDAT binary format.

```
libname xportout xport 'transport-file.xpt';
data xportout.tips;
    set tips(rename=(total_bill=tbill));
    * xport variable names limited to 6 characters;
run;
```

```
df = pd.read_sas('transport-file.xpt')
df = pd.read_sas('binary-file.sas7bdat')
```

You can also specify the file format directly. By default, pandas will try to infer the file format based on its extension.

```
df = pd.read_sas('transport-file.xpt', format='xport')
df = pd.read_sas('binary-file.sas7bdat', format='sas7bdat')
```

XPORT is a relatively limited format and the parsing of it is not as optimized as some of the other pandas readers. An alternative way to interop data between SAS and pandas is to serialize to csv.

```
# version 0.17, 10M rows

In [8]: %time df = pd.read_sas('big.xpt')
Wall time: 14.6 s

In [9]: %time df = pd.read_csv('big.csv')
Wall time: 4.86 s
```

```
{{ header }}
```

## COMPARISON WITH STATA

For potential users coming from [Stata](#) this page is meant to demonstrate how different Stata operations would be performed in pandas.

If you're new to pandas, you might want to first read through *10 Minutes to pandas* to familiarize yourself with the library.

As is customary, we import pandas and NumPy as follows. This means that we can refer to the libraries as `pd` and `np`, respectively, for the rest of the document.

```
In [1]: import pandas as pd
```

```
In [2]: import numpy as np
```

---

**Note:** Throughout this tutorial, the pandas `DataFrame` will be displayed by calling `df.head()`, which displays the first N (default 5) rows of the `DataFrame`. This is often used in interactive work (e.g. [Jupyter notebook](#) or terminal) – the equivalent in Stata would be:

```
list in 1/5
```

---

### 34.1 Data Structures

#### 34.1.1 General Terminology Translation

|                        |                     |
|------------------------|---------------------|
| pandas                 | Stata               |
| <code>DataFrame</code> | data set            |
| column                 | variable            |
| row                    | observation         |
| <code>groupby</code>   | <code>bysort</code> |
| NaN                    | .                   |

#### 34.1.2 `DataFrame` / `Series`

A `DataFrame` in pandas is analogous to a Stata data set – a two-dimensional data source with labeled columns that can be of different types. As will be shown in this document, almost any operation that can be applied to a data set in Stata can also be accomplished in pandas.

A `Series` is the data structure that represents one column of a `DataFrame`. Stata doesn't have a separate data structure for a single column, but in general, working with a `Series` is analogous to referencing a column of a data set in Stata.

### 34.1.3 Index

Every `DataFrame` and `Series` has an `Index` – labels on the *rows* of the data. Stata does not have an exactly analogous concept. In Stata, a data set's rows are essentially unlabeled, other than an implicit integer index that can be accessed with `_n`.

In pandas, if no index is specified, an integer index is also used by default (first row = 0, second row = 1, and so on). While using a labeled `Index` or `MultiIndex` can enable sophisticated analyses and is ultimately an important part of pandas to understand, for this comparison we will essentially ignore the `Index` and just treat the `DataFrame` as a collection of columns. Please see the *indexing documentation* for much more on how to use an `Index` effectively.

## 34.2 Data Input / Output

### 34.2.1 Constructing a DataFrame from Values

A Stata data set can be built from specified values by placing the data after an `input` statement and specifying the column names.

```
input x y
1 2
3 4
5 6
end
```

A pandas `DataFrame` can be constructed in many different ways, but for a small number of values, it is often convenient to specify it as a Python dictionary, where the keys are the column names and the values are the data.

```
In [3]: df = pd.DataFrame({'x': [1, 3, 5], 'y': [2, 4, 6]})

In [4]: df
Out[4]:
```

|   | x | y |
|---|---|---|
| 0 | 1 | 2 |
| 1 | 3 | 4 |
| 2 | 5 | 6 |

### 34.2.2 Reading External Data

Like Stata, pandas provides utilities for reading in data from many formats. The `tips` data set, found within the pandas tests (`csv`) will be used in many of the following examples.

Stata provides `import delimited` to read `csv` data into a data set in memory. If the `tips.csv` file is in the current working directory, we can import it as follows.

```
import delimited tips.csv
```

The pandas method is `read_csv()`, which works similarly. Additionally, it will automatically download the data set if presented with a url.

```
In [5]: url = ('https://raw.githubusercontent.com/pandas-dev'
...:         '/pandas/master/pandas/tests/data/tips.csv')
...:

In [6]: tips = pd.read_csv(url)

In [7]: tips.head()
Out[7]:
```

|   | total_bill | tip  | sex    | smoker | day | time   | size |
|---|------------|------|--------|--------|-----|--------|------|
| 0 | 16.99      | 1.01 | Female | No     | Sun | Dinner | 2    |
| 1 | 10.34      | 1.66 | Male   | No     | Sun | Dinner | 3    |
| 2 | 21.01      | 3.50 | Male   | No     | Sun | Dinner | 3    |
| 3 | 23.68      | 3.31 | Male   | No     | Sun | Dinner | 2    |
| 4 | 24.59      | 3.61 | Female | No     | Sun | Dinner | 4    |

Like `import delimited`, `read_csv()` can take a number of parameters to specify how the data should be parsed. For example, if the data were instead tab delimited, did not have column names, and existed in the current working directory, the pandas command would be:

```
tips = pd.read_csv('tips.csv', sep='\t', header=None)

# alternatively, read_table is an alias to read_csv with tab delimiter
tips = pd.read_table('tips.csv', header=None)
```

Pandas can also read Stata data sets in `.dta` format with the `read_stata()` function.

```
df = pd.read_stata('data.dta')
```

In addition to text/csv and Stata files, pandas supports a variety of other data formats such as Excel, SAS, HDF5, Parquet, and SQL databases. These are all read via a `pd.read_*` function. See the *IO documentation* for more details.

### 34.2.3 Exporting Data

The inverse of `import delimited` in Stata is `export delimited`

```
export delimited tips2.csv
```

Similarly in pandas, the opposite of `read_csv` is `DataFrame.to_csv()`.

```
tips.to_csv('tips2.csv')
```

Pandas can also export to Stata file format with the `DataFrame.to_stata()` method.

```
tips.to_stata('tips2.dta')
```

## 34.3 Data Operations

### 34.3.1 Operations on Columns

In Stata, arbitrary math expressions can be used with the `generate` and `replace` commands on new or existing columns. The `drop` command drops the column from the data set.

```

replace total_bill = total_bill - 2
generate new_bill = total_bill / 2
drop new_bill

```

pandas provides similar vectorized operations by specifying the individual Series in the DataFrame. New columns can be assigned in the same way. The `DataFrame.drop()` method drops a column from the DataFrame.

```

In [8]: tips['total_bill'] = tips['total_bill'] - 2

In [9]: tips['new_bill'] = tips['total_bill'] / 2

In [10]: tips.head()
Out[10]:
   total_bill  tip  sex smoker  day  time  size  new_bill
0      14.99  1.01 Female    No  Sun  Dinner     2     7.495
1       8.34  1.66  Male    No  Sun  Dinner     3     4.170
2      19.01  3.50  Male    No  Sun  Dinner     3     9.505
3      21.68  3.31  Male    No  Sun  Dinner     2    10.840
4      22.59  3.61 Female    No  Sun  Dinner     4    11.295

In [11]: tips = tips.drop('new_bill', axis=1)

```

### 34.3.2 Filtering

Filtering in Stata is done with an `if` clause on one or more columns.

```
list if total_bill > 10
```

DataFrames can be filtered in multiple ways; the most intuitive of which is using *boolean indexing*.

```

In [12]: tips[tips['total_bill'] > 10].head()
Out[12]:
   total_bill  tip  sex smoker  day  time  size
0      14.99  1.01 Female    No  Sun  Dinner     2
2      19.01  3.50  Male    No  Sun  Dinner     3
3      21.68  3.31  Male    No  Sun  Dinner     2
4      22.59  3.61 Female    No  Sun  Dinner     4
5      23.29  4.71  Male    No  Sun  Dinner     4

```

### 34.3.3 If/Then Logic

In Stata, an `if` clause can also be used to create new columns.

```

generate bucket = "low" if total_bill < 10
replace bucket = "high" if total_bill >= 10

```

The same operation in pandas can be accomplished using the `where` method from numpy.

```

In [13]: tips['bucket'] = np.where(tips['total_bill'] < 10, 'low', 'high')

In [14]: tips.head()
Out[14]:
   total_bill  tip  sex smoker  day  time  size bucket
0      14.99  1.01 Female    No  Sun  Dinner     2   high

```

(continues on next page)

(continued from previous page)

|   |       |      |        |    |     |        |   |      |
|---|-------|------|--------|----|-----|--------|---|------|
| 1 | 8.34  | 1.66 | Male   | No | Sun | Dinner | 3 | low  |
| 2 | 19.01 | 3.50 | Male   | No | Sun | Dinner | 3 | high |
| 3 | 21.68 | 3.31 | Male   | No | Sun | Dinner | 2 | high |
| 4 | 22.59 | 3.61 | Female | No | Sun | Dinner | 4 | high |

### 34.3.4 Date Functionality

Stata provides a variety of functions to do operations on date/datetime columns.

```

generate date1 = mdy(1, 15, 2013)
generate date2 = date("Feb152015", "MDY")

generate date1_year = year(date1)
generate date2_month = month(date2)

* shift date to beginning of next month
generate date1_next = mdy(month(date1) + 1, 1, year(date1)) if month(date1) != 12
replace date1_next = mdy(1, 1, year(date1) + 1) if month(date1) == 12
generate months_between = mofd(date2) - mofd(date1)

list date1 date2 date1_year date2_month date1_next months_between

```

The equivalent pandas operations are shown below. In addition to these functions, pandas supports other Time Series features not available in Stata (such as time zone handling and custom offsets) – see the *timeseries documentation* for more details.

```

In [15]: tips['date1'] = pd.Timestamp('2013-01-15')

In [16]: tips['date2'] = pd.Timestamp('2015-02-15')

In [17]: tips['date1_year'] = tips['date1'].dt.year

In [18]: tips['date2_month'] = tips['date2'].dt.month

In [19]: tips['date1_next'] = tips['date1'] + pd.offsets.MonthBegin()

In [20]: tips['months_between'] = (tips['date2'].dt.to_period('M')
....:                               - tips['date1'].dt.to_period('M'))
....:

In [21]: tips[['date1', 'date2', 'date1_year', 'date2_month', 'date1_next',
....:           'months_between']].head()
....:

Out[21]:
   date1      date2  date1_year  date2_month  date1_next  months_between
0 2013-01-15 2015-02-15        2013          2 2013-02-01  <25 * MonthEnds>
1 2013-01-15 2015-02-15        2013          2 2013-02-01  <25 * MonthEnds>
2 2013-01-15 2015-02-15        2013          2 2013-02-01  <25 * MonthEnds>
3 2013-01-15 2015-02-15        2013          2 2013-02-01  <25 * MonthEnds>
4 2013-01-15 2015-02-15        2013          2 2013-02-01  <25 * MonthEnds>

```

### 34.3.5 Selection of Columns

Stata provides keywords to select, drop, and rename columns.

```

keep sex total_bill tip

drop sex

rename total_bill total_bill_2

```

The same operations are expressed in pandas below. Note that in contrast to Stata, these operations do not happen in place. To make these changes persist, assign the operation back to a variable.

```

# keep
In [22]: tips[['sex', 'total_bill', 'tip']].head()
Out[22]:
   sex  total_bill  tip
0  Female      14.99  1.01
1   Male       8.34  1.66
2   Male      19.01  3.50
3   Male      21.68  3.31
4  Female      22.59  3.61

# drop
In [23]: tips.drop('sex', axis=1).head()
Out[23]:
   total_bill  tip  smoker  day  time  size
0      14.99  1.01     No  Sun  Dinner    2
1       8.34  1.66     No  Sun  Dinner    3
2      19.01  3.50     No  Sun  Dinner    3
3      21.68  3.31     No  Sun  Dinner    2
4      22.59  3.61     No  Sun  Dinner    4

# rename
In [24]: tips.rename(columns={'total_bill': 'total_bill_2'}).head()
Out[24]:
   total_bill_2  tip  sex  smoker  day  time  size
0      14.99  1.01  Female     No  Sun  Dinner    2
1       8.34  1.66   Male     No  Sun  Dinner    3
2      19.01  3.50   Male     No  Sun  Dinner    3
3      21.68  3.31   Male     No  Sun  Dinner    2
4      22.59  3.61  Female     No  Sun  Dinner    4

```

### 34.3.6 Sorting by Values

Sorting in Stata is accomplished via `sort`

```
sort sex total_bill
```

pandas objects have a `DataFrame.sort_values()` method, which takes a list of columns to sort by.

```

In [25]: tips = tips.sort_values(['sex', 'total_bill'])
In [26]: tips.head()
Out[26]:
   total_bill  tip  sex  smoker  day  time  size
67       1.07  1.00  Female     Yes  Sat  Dinner    1

```

(continues on next page)

|     |      |      |        |     |      |        |   |
|-----|------|------|--------|-----|------|--------|---|
| 92  | 3.75 | 1.00 | Female | Yes | Fri  | Dinner | 2 |
| 111 | 5.25 | 1.00 | Female | No  | Sat  | Dinner | 1 |
| 145 | 6.35 | 1.50 | Female | No  | Thur | Lunch  | 2 |
| 135 | 6.51 | 1.25 | Female | No  | Thur | Lunch  | 2 |

### 34.4.1 Finding Length of String

### 34.4.1 Finding Length of String

```
generate strlen_time = strlen(time)
generate ustrlen_time = ustrlen(time)
```

```
In [27]: tips['time'].str.len().head()
Out[27]:
67      6
92      6
111     6
145     5
135     5
Name: time, dtype: int64

In [28]: tips['time'].str.rstrip().str.len().head()
Out[28]:
67      6
92      6
111     6
145     5
135     5
Name: time, dtype: int64
```

```
generate str_position = strpos(sex, "ale")
```

```
In [29]: tips['sex'].str.find("ale").head()
Out[29]:
67      3
```

### 34.4. String Processing

(continued from previous page)

```

92      3
111     3
145     3
135     3
Name: sex, dtype: int64

```

### 34.4.3 Extracting Substring by Position

Stata extracts a substring from a string based on its position with the `substr()` function.

```
generate short_sex = substr(sex, 1, 1)
```

With pandas you can use `[]` notation to extract a substring from a string by position locations. Keep in mind that Python indexes are zero-based.

```

In [30]: tips['sex'].str[0:1].head()
Out[30]:
67      F
92      F
111     F
145     F
135     F
Name: sex, dtype: object

```

### 34.4.4 Extracting nth Word

The Stata `word()` function returns the *nth* word from a string. The first argument is the string you want to parse and the second argument specifies which word you want to extract.

```

clear
input str20 string
"John Smith"
"Jane Cook"
end

generate first_name = word(name, 1)
generate last_name = word(name, -1)

```

Python extracts a substring from a string based on its text by using regular expressions. There are much more powerful approaches, but this just shows a simple approach.

```

In [31]: firstlast = pd.DataFrame({'string': ['John Smith', 'Jane Cook']})

In [32]: firstlast['First_Name'] = firstlast['string'].str.split(" ", expand=True)[0]

In [33]: firstlast['Last_Name'] = firstlast['string'].str.rsplit(" ", expand=True)[0]

In [34]: firstlast
Out[34]:
      string First_Name Last_Name
0  John Smith      John      John
1  Jane Cook      Jane      Jane

```

### 34.4.5 Changing Case

The Stata `strupper()`, `strlower()`, `strproper()`, `ustrupper()`, `ustrlower()`, and `ustrtitle()` functions change the case of ASCII and Unicode strings, respectively.

```
clear
input str20 string
"John Smith"
"Jane Cook"
end

generate upper = strupper(string)
generate lower = strlower(string)
generate title = strproper(string)
list
```

The equivalent Python functions are `upper`, `lower`, and `title`.

```
In [35]: firstlast = pd.DataFrame({'string': ['John Smith', 'Jane Cook']})

In [36]: firstlast['upper'] = firstlast['string'].str.upper()

In [37]: firstlast['lower'] = firstlast['string'].str.lower()

In [38]: firstlast['title'] = firstlast['string'].str.title()

In [39]: firstlast
Out[39]:
```

|   | string     | upper      | lower      | title      |
|---|------------|------------|------------|------------|
| 0 | John Smith | JOHN SMITH | john smith | John Smith |
| 1 | Jane Cook  | JANE COOK  | jane cook  | Jane Cook  |

## 34.5 Merging

The following tables will be used in the merge examples

```
In [40]: df1 = pd.DataFrame({'key': ['A', 'B', 'C', 'D'],
.....:                      'value': np.random.randn(4)})
.....:

In [41]: df1
Out[41]:
```

|   | key | value     |
|---|-----|-----------|
| 0 | A   | -1.479749 |
| 1 | B   | -0.851762 |
| 2 | C   | -0.663538 |
| 3 | D   | -0.270669 |

```
In [42]: df2 = pd.DataFrame({'key': ['B', 'D', 'D', 'E'],
.....:                      'value': np.random.randn(4)})
.....:

In [43]: df2
Out[43]:
```

|  | key | value |
|--|-----|-------|
|--|-----|-------|

(continues on next page)

(continued from previous page)

|   |   |          |
|---|---|----------|
| 0 | B | 1.354348 |
| 1 | D | 0.158096 |
| 2 | D | 0.480507 |
| 3 | E | 2.012318 |

In Stata, to perform a merge, one data set must be in memory and the other must be referenced as a file name on disk. In contrast, Python must have both `DataFrames` already in memory.

By default, Stata performs an outer join, where all observations from both data sets are left in memory after the merge. One can keep only observations from the initial data set, the merged data set, or the intersection of the two by using the values created in the `_merge` variable.

```
* First create df2 and save to disk
clear
input str1 key
B
D
D
E
end
generate value = rnormal()
save df2.dta

* Now create df1 in memory
clear
input str1 key
A
B
C
D
end
generate value = rnormal()

preserve

* Left join
merge 1:n key using df2.dta
keep if _merge == 1

* Right join
restore, preserve
merge 1:n key using df2.dta
keep if _merge == 2

* Inner join
restore, preserve
merge 1:n key using df2.dta
keep if _merge == 3

* Outer join
restore
merge 1:n key using df2.dta
```

pandas `DataFrames` have a `DataFrame.merge()` method, which provides similar functionality. Note that different join types are accomplished via the `how` keyword.

```
In [44]: inner_join = df1.merge(df2, on=['key'], how='inner')
```

```
In [45]: inner_join
```

```
Out[45]:
```

|   | key | value_x   | value_y  |
|---|-----|-----------|----------|
| 0 | B   | -0.851762 | 1.354348 |
| 1 | D   | -0.270669 | 0.158096 |
| 2 | D   | -0.270669 | 0.480507 |

```
In [46]: left_join = df1.merge(df2, on=['key'], how='left')
```

```
In [47]: left_join
```

```
Out[47]:
```

|   | key | value_x   | value_y  |
|---|-----|-----------|----------|
| 0 | A   | -1.479749 | NaN      |
| 1 | B   | -0.851762 | 1.354348 |
| 2 | C   | -0.663538 | NaN      |
| 3 | D   | -0.270669 | 0.158096 |
| 4 | D   | -0.270669 | 0.480507 |

```
In [48]: right_join = df1.merge(df2, on=['key'], how='right')
```

```
In [49]: right_join
```

```
Out[49]:
```

|   | key | value_x   | value_y  |
|---|-----|-----------|----------|
| 0 | B   | -0.851762 | 1.354348 |
| 1 | D   | -0.270669 | 0.158096 |
| 2 | D   | -0.270669 | 0.480507 |
| 3 | E   | NaN       | 2.012318 |

```
In [50]: outer_join = df1.merge(df2, on=['key'], how='outer')
```

```
In [51]: outer_join
```

```
Out[51]:
```

|   | key | value_x   | value_y  |
|---|-----|-----------|----------|
| 0 | A   | -1.479749 | NaN      |
| 1 | B   | -0.851762 | 1.354348 |
| 2 | C   | -0.663538 | NaN      |
| 3 | D   | -0.270669 | 0.158096 |
| 4 | D   | -0.270669 | 0.480507 |
| 5 | E   | NaN       | 2.012318 |

## 34.6 Missing Data

Like Stata, pandas has a representation for missing data – the special float value NaN (not a number). Many of the semantics are the same; for example missing data propagates through numeric operations, and is ignored by default for aggregations.

```
In [52]: outer_join
```

```
Out[52]:
```

|   | key | value_x   | value_y  |
|---|-----|-----------|----------|
| 0 | A   | -1.479749 | NaN      |
| 1 | B   | -0.851762 | 1.354348 |
| 2 | C   | -0.663538 | NaN      |
| 3 | D   | -0.270669 | 0.158096 |

(continues on next page)

(continued from previous page)

|   |   |           |          |
|---|---|-----------|----------|
| 4 | D | -0.270669 | 0.480507 |
| 5 | E | NaN       | 2.012318 |

```
In [53]: outer_join['value_x'] + outer_join['value_y']
```

```
0      NaN
1    0.502585
2      NaN
3   -0.112572
4    0.209838
5      NaN
dtype: float64
```

```
In [54]: outer_join['value_x'].sum()
```

$\rightarrow -3.5363859435752811$

One difference is that missing data cannot be compared to its sentinel value. For example, in Stata you could do this to filter missing values.

```
* Keep missing values
list if value_x == .
* Keep non-missing values
list if value_x != .
```

This doesn't work in pandas. Instead, the `pd.isna()` or `pd.notna()` functions should be used for comparisons.

```
In [55]: outer_join[pd.isna(outer_join['value_x'])]
```

Out [55] :

|   | key | value_x | value_y  |
|---|-----|---------|----------|
| 5 | E   | NaN     | 2.012318 |

```
In [56]: outer_join[pd.notna(outer_join['value_x'])]
```

```
Out[56]:
```

|   | key | value_x   | value_y  |
|---|-----|-----------|----------|
| 0 | A   | -1.479749 | NaN      |
| 1 | B   | -0.851762 | 1.354348 |
| 2 | C   | -0.663538 | NaN      |
| 3 | D   | -0.270669 | 0.158096 |
| 4 | D   | -0.270669 | 0.480507 |

Pandas also provides a variety of methods to work with missing data – some of which would be challenging to express in Stata. For example, there are methods to drop all rows with any missing values, replacing missing values with a specified value, like the mean, or forward filling from previous rows. See the *missing data documentation* for more.

```
# Drop rows with any missing value
```

```
In [57]: outer_join.dropna()
```

Out [57]:

|   | key | value_x   | value_y  |
|---|-----|-----------|----------|
| 1 | B   | -0.851762 | 1.354348 |
| 3 | D   | -0.270669 | 0.158096 |
| 4 | D   | -0.270669 | 0.480507 |

```
# Fill forwards
```

```
In [58]: outer_join.fillna(method='ffill')
```

(continues on next page)

(continued from previous page)

```

////////////////////////////////////

```

## 34.7 GroupBy

### 34.7.1 Aggregation

Stata's `collapse` can be used to group by one or more key variables and compute aggregations on numeric columns.

```
collapse (sum) total_bill tip, by(sex smoker)
```

pandas provides a flexible `groupby` mechanism that allows similar aggregations. See the *groupby documentation* for more details and examples.

```

In [60]: tips_summed = tips.groupby(['sex', 'smoker'])['total_bill', 'tip'].sum()

In [61]: tips_summed.head()
Out [61]:
           total_bill    tip
sex  smoker
Female No           869.68  149.77
      Yes           527.27   96.74
Male   No          1725.75  302.00
      Yes          1217.07  183.07

```

### 34.7.2 Transformation

In Stata, if the group aggregations need to be used with the original data set, one would usually use `bysort` with `egen()`. For example, to subtract the mean for each observation by smoker group.

```
bysort sex smoker: egen group_bill = mean(total_bill)
generate adj_total_bill = total_bill - group_bill
```

pandas `groupby` provides a `transform` mechanism that allows these type of operations to be succinctly expressed in one operation.

```
In [62]: gb = tips.groupby('smoker')['total_bill']

In [63]: tips['adj_total_bill'] = tips['total_bill'] - gb.transform('mean')

In [64]: tips.head()
Out[64]:
```

|     | total_bill | tip  | sex    | smoker | day  | time   | size | adj_total_bill |
|-----|------------|------|--------|--------|------|--------|------|----------------|
| 67  | 1.07       | 1.00 | Female | Yes    | Sat  | Dinner | 1    | -17.686344     |
| 92  | 3.75       | 1.00 | Female | Yes    | Fri  | Dinner | 2    | -15.006344     |
| 111 | 5.25       | 1.00 | Female | No     | Sat  | Dinner | 1    | -11.938278     |
| 145 | 6.35       | 1.50 | Female | No     | Thur | Lunch  | 2    | -10.838278     |
| 135 | 6.51       | 1.25 | Female | No     | Thur | Lunch  | 2    | -10.678278     |

### 34.7.3 By Group Processing

In addition to aggregation, pandas `groupby` can be used to replicate most other `bysort` processing from Stata. For example, the following example lists the first observation in the current sort order by sex/smoker group.

```
bysort sex smoker: list if _n == 1
```

In pandas this would be written as:

```
In [65]: tips.groupby(['sex', 'smoker']).first()
Out[65]:
```

|        |        | total_bill | tip  | day  | time   | size | adj_total_bill |
|--------|--------|------------|------|------|--------|------|----------------|
| sex    | smoker |            |      |      |        |      |                |
|        |        |            |      |      |        |      |                |
| Female | No     | 5.25       | 1.00 | Sat  | Dinner | 1    | -11.938278     |
|        | Yes    | 1.07       | 1.00 | Sat  | Dinner | 1    | -17.686344     |
| Male   | No     | 5.51       | 2.00 | Thur | Lunch  | 2    | -11.678278     |
|        | Yes    | 5.25       | 5.15 | Sun  | Dinner | 2    | -13.506344     |

## 34.8 Other Considerations

### 34.8.1 Disk vs Memory

Pandas and Stata both operate exclusively in memory. This means that the size of data able to be loaded in pandas is limited by your machine's memory. If out of core processing is needed, one possibility is the [dask.dataframe](#) library, which provides a subset of pandas functionality for an on-disk `DataFrame`.

```
{{ header }}
```

## API REFERENCE

This page gives an overview of all public pandas objects, functions and methods. All classes and functions exposed in `pandas.*` namespace are public.

Some subpackages are public which include `pandas.errors`, `pandas.plotting`, and `pandas.testing`. Public functions in `pandas.io` and `pandas.tseries` submodules are mentioned in the documentation. `pandas.api.types` subpackage holds some public functions related to data types in pandas.

**Warning:** The `pandas.core`, `pandas.compat`, and `pandas.util` top-level modules are PRIVATE. Stable functionality in such modules is not guaranteed.

## 35.1 Input/Output

### 35.1.1 Pickling

---

|                                               |                                                       |
|-----------------------------------------------|-------------------------------------------------------|
| <code>read_pickle(path[, compression])</code> | Load pickled pandas object (or any object) from file. |
|-----------------------------------------------|-------------------------------------------------------|

---

#### 35.1.1.1 `pandas.read_pickle`

`pandas.read_pickle(path, compression='infer')`  
Load pickled pandas object (or any object) from file.

**Warning:** Loading pickled data received from untrusted sources can be unsafe. See [here](#).

#### Parameters

**path** [str] File path where the pickled object will be loaded.

**compression** [{ 'infer', 'gzip', 'bz2', 'zip', 'xz', None }, default 'infer'] For on-the-fly decompression of on-disk data. If 'infer', then use gzip, bz2, xz or zip if path ends in '.gz', '.bz2', '.xz', or '.zip' respectively, and no decompression otherwise. Set to None for no decompression.

New in version 0.20.0.

#### Returns

**unpickled** [same type as object stored in file]

See also:

**DataFrame.to\_pickle** Pickle (serialize) DataFrame object to file.

**Series.to\_pickle** Pickle (serialize) Series object to file.

**read\_hdf** Read HDF5 file into a DataFrame.

**read\_sql** Read SQL query or database table into a DataFrame.

**read\_parquet** Load a parquet object, returning a DataFrame.

## Examples

```
>>> original_df = pd.DataFrame({"foo": range(5), "bar": range(5, 10)})
>>> original_df
   foo  bar
0    0    5
1    1    6
2    2    7
3    3    8
4    4    9
>>> pd.to_pickle(original_df, "./dummy.pkl")
```

```
>>> unpickled_df = pd.read_pickle("./dummy.pkl")
>>> unpickled_df
   foo  bar
0    0    5
1    1    6
2    2    7
3    3    8
4    4    9
```

```
>>> import os
>>> os.remove("./dummy.pkl")
```

### 35.1.2 Flat File

|                                                              |                                                             |
|--------------------------------------------------------------|-------------------------------------------------------------|
| <code>read_table(filepath_or_buffer[, sep, ...])</code>      | (DEPRECATED) Read general delimited file into DataFrame.    |
| <code>read_csv(filepath_or_buffer[, sep, ...])</code>        | Read a comma-separated values (csv) file into DataFrame.    |
| <code>read_fwf(filepath_or_buffer[, colspecs, ...])</code>   | Read a table of fixed-width formatted lines into DataFrame. |
| <code>read_msgpack(path_or_buf[, encoding, iterator])</code> | Load msgpack pandas object from the specified file path     |

### 35.1.2.1 pandas.read\_table

```
pandas.read_table(filepath_or_buffer, sep=False, delimiter=None, header='infer', names=None,
                  index_col=None, usecols=None, squeeze=False, prefix=None, man-
                  gle_dupe_cols=True, dtype=None, engine=None, converters=None,
                  true_values=None, false_values=None, skipinitialspace=False, skiprows=None,
                  skipfooter=0, nrows=None, na_values=None, keep_default_na=True,
                  na_filter=True, verbose=False, skip_blank_lines=True, parse_dates=False,
                  infer_datetime_format=False, keep_date_col=False, date_parser=None, day-
                  first=False, iterator=False, chunksize=None, compression='infer', thou-
                  sands=None, decimal=b'.', lineterminator=None, quotechar='"', quot-
                  ing=0, doublequote=True, escapechar=None, comment=None, encod-
                  ing=None, dialect=None, tupleize_cols=None, error_bad_lines=True,
                  warn_bad_lines=True, delim_whitespace=False, low_memory=True, mem-
                  ory_map=False, float_precision=None)
```

Read general delimited file into DataFrame.

Deprecated since version 0.24.0.

Use `pandas.read_csv()` instead, passing `sep='\t'` if necessary.

Also supports optionally iterating or breaking of the file into chunks.

Additional help can be found in the online docs for [IO Tools](#).

#### Parameters

**filepath\_or\_buffer** [str, path object, or file-like object] Any valid string path is acceptable. The string could be a URL. Valid URL schemes include http, ftp, s3, and file. For file URLs, a host is expected. A local file could be: `file://localhost/path/to/table.csv`.

If you want to pass in a path object, pandas accepts either `pathlib.Path` or `py._path.local.LocalPath`.

By file-like object, we refer to objects with a `read()` method, such as a file handler (e.g. via builtin `open` function) or `StringIO`.

**sep** [str, default '\t' (tab-stop)] Delimiter to use. If `sep` is `None`, the C engine cannot automatically detect the separator, but the Python parsing engine can, meaning the latter will be used and automatically detect the separator by Python's builtin sniffer tool, `csv.Sniffer`. In addition, separators longer than 1 character and different from `'\s+'` will be interpreted as regular expressions and will also force the use of the Python parsing engine. Note that regex delimiters are prone to ignoring quoted data. Regex example: `'\r\t'`.

**delimiter** [str, default `None`] Alias for `sep`.

**header** [int, list of int, default 'infer'] Row number(s) to use as the column names, and the start of the data. Default behavior is to infer the column names: if no names are passed the behavior is identical to `header=0` and column names are inferred from the first line of the file, if column names are passed explicitly then the behavior is identical to `header=None`. Explicitly pass `header=0` to be able to replace existing names. The header can be a list of integers that specify row locations for a multi-index on the columns e.g. `[0,1,3]`. Intervening rows that are not specified will be skipped (e.g. 2 in this example is skipped). Note that this parameter ignores commented lines and empty lines if `skip_blank_lines=True`, so `header=0` denotes the first line of data rather than the first line of the file.

**names** [array-like, optional] List of column names to use. If file contains no header row, then you should explicitly pass `header=None`. Duplicates in this list will cause a `UserWarning` to be issued.

**index\_col** [int, sequence or bool, optional] Column to use as the row labels of the DataFrame. If a sequence is given, a MultiIndex is used. If you have a malformed file with delimiters at the end of each line, you might consider `index_col=False` to force pandas to not use the first column as the index (row names).

**usecols** [list-like or callable, optional] Return a subset of the columns. If list-like, all elements must either be positional (i.e. integer indices into the document columns) or strings that correspond to column names provided either by the user in *names* or inferred from the document header row(s). For example, a valid list-like *usecols* parameter would be `[0, 1, 2]` or `['foo', 'bar', 'baz']`. Element order is ignored, so `usecols=[0, 1]` is the same as `[1, 0]`. To instantiate a DataFrame from data with element order preserved use `pd.read_csv(data, usecols=['foo', 'bar'])[['foo', 'bar']]` for columns in `['foo', 'bar']` order or `pd.read_csv(data, usecols=['foo', 'bar'])[['bar', 'foo']]` for `['bar', 'foo']` order.

If callable, the callable function will be evaluated against the column names, returning names where the callable function evaluates to True. An example of a valid callable argument would be `lambda x: x.upper() in ['AAA', 'BBB', 'DDD']`. Using this parameter results in much faster parsing time and lower memory usage.

**squeeze** [bool, default False] If the parsed data only contains one column then return a Series.

**prefix** [str, optional] Prefix to add to column numbers when no header, e.g. 'X' for X0, X1, ...

**mangle\_dupe\_cols** [bool, default True] Duplicate columns will be specified as 'X', 'X.1', ... 'X.N', rather than 'X'...'X'. Passing in False will cause data to be overwritten if there are duplicate names in the columns.

**dtype** [Type name or dict of column -> type, optional] Data type for data or columns. E.g. `{ 'a': np.float64, 'b': np.int32, 'c': 'Int64' }` Use *str* or *object* together with suitable *na\_values* settings to preserve and not interpret dtype. If converters are specified, they will be applied INSTEAD of dtype conversion.

**engine** [{ 'c', 'python' }, optional] Parser engine to use. The C engine is faster while the python engine is currently more feature-complete.

**converters** [dict, optional] Dict of functions for converting values in certain columns. Keys can either be integers or column labels.

**true\_values** [list, optional] Values to consider as True.

**false\_values** [list, optional] Values to consider as False.

**skipinitialspace** [bool, default False] Skip spaces after delimiter.

**skiprows** [list-like, int or callable, optional] Line numbers to skip (0-indexed) or number of lines to skip (int) at the start of the file.

If callable, the callable function will be evaluated against the row indices, returning True if the row should be skipped and False otherwise. An example of a valid callable argument would be `lambda x: x in [0, 2]`.

**skipfooter** [int, default 0] Number of lines at bottom of file to skip (Unsupported with engine='c').

**nrows** [int, optional] Number of rows of file to read. Useful for reading pieces of large files.

**na\_values** [scalar, str, list-like, or dict, optional] Additional strings to recognize as NA/NaN. If dict passed, specific per-column NA values. By default the following values are interpreted as NaN: `''`, `#N/A`, `#N/A N/A`, `#NA`, `-1.#IND`, `-1.#QNAN`, `-NaN`, `-nan`, `1.#IND`, `1.#QNAN`, `N/A`, `NA`, `NULL`, `NaN`, `n/a`, `nan`, `null`.

**keep\_default\_na** [bool, default True] Whether or not to include the default NaN values when parsing the data. Depending on whether *na\_values* is passed in, the behavior is as follows:

- If *keep\_default\_na* is True, and *na\_values* are specified, *na\_values* is appended to the default NaN values used for parsing.
- If *keep\_default\_na* is True, and *na\_values* are not specified, only the default NaN values are used for parsing.
- If *keep\_default\_na* is False, and *na\_values* are specified, only the NaN values specified *na\_values* are used for parsing.
- If *keep\_default\_na* is False, and *na\_values* are not specified, no strings will be parsed as NaN.

Note that if *na\_filter* is passed in as False, the *keep\_default\_na* and *na\_values* parameters will be ignored.

**na\_filter** [bool, default True] Detect missing value markers (empty strings and the value of *na\_values*). In data without any NAs, passing *na\_filter*=False can improve the performance of reading a large file.

**verbose** [bool, default False] Indicate number of NA values placed in non-numeric columns.

**skip\_blank\_lines** [bool, default True] If True, skip over blank lines rather than interpreting as NaN values.

**parse\_dates** [bool or list of int or names or list of lists or dict, default False] The behavior is as follows:

- boolean. If True -> try parsing the index.
- list of int or names. e.g. If [1, 2, 3] -> try parsing columns 1, 2, 3 each as a separate date column.
- list of lists. e.g. If [[1, 3]] -> combine columns 1 and 3 and parse as a single date column.
- dict, e.g. { 'foo' : [1, 3] } -> parse columns 1, 3 as date and call result 'foo'

If a column or index contains an unparseable date, the entire column or index will be returned unaltered as an object data type. For non-standard datetime parsing, use `pd.to_datetime` after `pd.read_csv`

Note: A fast-path exists for iso8601-formatted dates.

**infer\_datetime\_format** [bool, default False] If True and *parse\_dates* is enabled, pandas will attempt to infer the format of the datetime strings in the columns, and if it can be inferred, switch to a faster method of parsing them. In some cases this can increase the parsing speed by 5-10x.

**keep\_date\_col** [bool, default False] If True and *parse\_dates* specifies combining multiple columns then keep the original columns.

**date\_parser** [function, optional] Function to use for converting a sequence of string columns to an array of datetime instances. The default uses `dateutil.parser.parser` to do the conversion. Pandas will try to call *date\_parser* in three different ways, advancing to the next if an exception occurs: 1) Pass one or more arrays (as defined by *parse\_dates*) as arguments; 2) concatenate (row-wise) the string values from the columns defined by *parse\_dates* into a single array and pass that; and 3) call *date\_parser* once for each row using one or more strings (corresponding to the columns defined by *parse\_dates*) as arguments.

**dayfirst** [bool, default False] DD/MM format dates, international and European format.

**iterator** [bool, default False] Return TextFileReader object for iteration or getting chunks with `get_chunk()`.

**chunksize** [int, optional] Return TextFileReader object for iteration. See the [IO Tools docs](#) for more information on `iterator` and `chunksize`.

**compression** [{ 'infer', 'gzip', 'bz2', 'zip', 'xz', None }, default 'infer'] For on-the-fly decompression of on-disk data. If 'infer' and *filepath\_or\_buffer* is path-like, then detect compression from the following extensions: '.gz', '.bz2', '.zip', or '.xz' (otherwise no decompression). If using 'zip', the ZIP file must contain only one data file to be read in. Set to None for no decompression.

New in version 0.18.1: support for 'zip' and 'xz' compression.

**thousands** [str, optional] Thousands separator.

**decimal** [str, default '.'] Character to recognize as decimal point (e.g. use ',' for European data).

**lineterminator** [str (length 1), optional] Character to break file into lines. Only valid with C parser.

**quotechar** [str (length 1), optional] The character used to denote the start and end of a quoted item. Quoted items can include the delimiter and it will be ignored.

**quoting** [int or csv.QUOTE\_\* instance, default 0] Control field quoting behavior per `csv.QUOTE_*` constants. Use one of `QUOTE_MINIMAL` (0), `QUOTE_ALL` (1), `QUOTE_NONNUMERIC` (2) or `QUOTE_NONE` (3).

**doublequote** [bool, default True] When `quotechar` is specified and quoting is not `QUOTE_NONE`, indicate whether or not to interpret two consecutive `quotechar` elements INSIDE a field as a single `quotechar` element.

**escapechar** [str (length 1), optional] One-character string used to escape other characters.

**comment** [str, optional] Indicates remainder of line should not be parsed. If found at the beginning of a line, the line will be ignored altogether. This parameter must be a single character. Like empty lines (as long as `skip_blank_lines=True`), fully commented lines are ignored by the parameter *header* but not by *skiprows*. For example, if `comment='#'`, parsing `#empty\na,b,c\n1,2,3` with `header=0` will result in 'a,b,c' being treated as the header.

**encoding** [str, optional] Encoding to use for UTF when reading/writing (ex. 'utf-8'). [List of Python standard encodings](#).

**dialect** [str or csv.Dialect, optional] If provided, this parameter will override values (default or not) for the following parameters: *delimiter*, *doublequote*, *escapechar*, *skipinitialspace*, *quotechar*, and *quoting*. If it is necessary to override values, a `ParserWarning` will be issued. See `csv.Dialect` documentation for more details.

**tupleize\_cols** [bool, default False] Leave a list of tuples on columns as is (default is to convert to a `MultiIndex` on the columns).

Deprecated since version 0.21.0: This argument will be removed and will always convert to `MultiIndex`

**error\_bad\_lines** [bool, default True] Lines with too many fields (e.g. a csv line with too many commas) will by default cause an exception to be raised, and no `DataFrame` will be returned. If False, then these “bad lines” will dropped from the `DataFrame` that is returned.

**warn\_bad\_lines** [bool, default True] If `error_bad_lines` is False, and `warn_bad_lines` is True, a warning for each “bad line” will be output.

**delim\_whitespace** [bool, default False] Specifies whether or not whitespace (e.g. ' ' or ' ') will be used as the sep. Equivalent to setting `sep='\s+'`. If this option is set to True, nothing should be passed in for the `delimiter` parameter.

New in version 0.18.1: support for the Python parser.

**low\_memory** [bool, default True] Internally process the file in chunks, resulting in lower memory use while parsing, but possibly mixed type inference. To ensure no mixed types either set False, or specify the type with the `dtype` parameter. Note that the entire file is read into a single DataFrame regardless, use the `chunksize` or `iterator` parameter to return the data in chunks. (Only valid with C parser).

**memory\_map** [bool, default False] If a filepath is provided for `filepath_or_buffer`, map the file object directly onto memory and access the data directly from there. Using this option can improve performance because there is no longer any I/O overhead.

**float\_precision** [str, optional] Specifies which converter the C engine should use for floating-point values. The options are *None* for the ordinary converter, *high* for the high-precision converter, and *round\_trip* for the round-trip converter.

### Returns

**DataFrame or TextParser** A comma-separated values (csv) file is returned as two-dimensional data structure with labeled axes.

See also:

**to\_csv** Write DataFrame to a comma-separated values (csv) file.

**read\_csv** Read a comma-separated values (csv) file into DataFrame.

**read\_fwf** Read a table of fixed-width formatted lines into DataFrame.

### Examples

```
>>> pd.read_table('data.csv') # doctest: +SKIP
```

#### 35.1.2.2 pandas.read\_csv

`pandas.read_csv` (*filepath\_or\_buffer*, *sep*=', ', *delimiter*=None, *header*='infer', *names*=None, *index\_col*=None, *usecols*=None, *squeeze*=False, *prefix*=None, *mangle\_dupe\_cols*=True, *dtype*=None, *engine*=None, *converters*=None, *true\_values*=None, *false\_values*=None, *skipinitialspace*=False, *skiprows*=None, *skipfooter*=0, *nrows*=None, *na\_values*=None, *keep\_default\_na*=True, *na\_filter*=True, *verbose*=False, *skip\_blank\_lines*=True, *parse\_dates*=False, *infer\_datetime\_format*=False, *keep\_date\_col*=False, *date\_parser*=None, *dayfirst*=False, *iterator*=False, *chunksize*=None, *compression*='infer', *thousands*=None, *decimal*=b'.', *lineterminator*=None, *quotechar*='\"', *quoting*=0, *doublequote*=True, *escapechar*=None, *comment*=None, *encoding*=None, *dialect*=None, *tupleize\_cols*=None, *error\_bad\_lines*=True, *warn\_bad\_lines*=True, *delim\_whitespace*=False, *low\_memory*=True, *memory\_map*=False, *float\_precision*=None)

Read a comma-separated values (csv) file into DataFrame.

Also supports optionally iterating or breaking of the file into chunks.

Additional help can be found in the online docs for [IO Tools](#).

### Parameters

**filepath\_or\_buffer** [str, path object, or file-like object] Any valid string path is acceptable. The string could be a URL. Valid URL schemes include http, ftp, s3, and file. For file URLs, a host is expected. A local file could be: `file://localhost/path/to/table.csv`.

If you want to pass in a path object, pandas accepts either `pathlib.Path` or `py._path.local.LocalPath`.

By file-like object, we refer to objects with a `read()` method, such as a file handler (e.g. via builtin `open` function) or `StringIO`.

**sep** [str, default ‘,’] Delimiter to use. If `sep` is `None`, the C engine cannot automatically detect the separator, but the Python parsing engine can, meaning the latter will be used and automatically detect the separator by Python’s builtin sniffer tool, `csv.Sniffer`. In addition, separators longer than 1 character and different from ‘\s+’ will be interpreted as regular expressions and will also force the use of the Python parsing engine. Note that regex delimiters are prone to ignoring quoted data. Regex example: ‘\r\t’.

**delimiter** [str, default `None`] Alias for `sep`.

**header** [int, list of int, default ‘infer’] Row number(s) to use as the column names, and the start of the data. Default behavior is to infer the column names: if no names are passed the behavior is identical to `header=0` and column names are inferred from the first line of the file, if column names are passed explicitly then the behavior is identical to `header=None`. Explicitly pass `header=0` to be able to replace existing names. The header can be a list of integers that specify row locations for a multi-index on the columns e.g. `[0,1,3]`. Intervening rows that are not specified will be skipped (e.g. 2 in this example is skipped). Note that this parameter ignores commented lines and empty lines if `skip_blank_lines=True`, so `header=0` denotes the first line of data rather than the first line of the file.

**names** [array-like, optional] List of column names to use. If file contains no header row, then you should explicitly pass `header=None`. Duplicates in this list will cause a `UserWarning` to be issued.

**index\_col** [int, sequence or bool, optional] Column to use as the row labels of the `DataFrame`. If a sequence is given, a `MultiIndex` is used. If you have a malformed file with delimiters at the end of each line, you might consider `index_col=False` to force pandas to not use the first column as the index (row names).

**usecols** [list-like or callable, optional] Return a subset of the columns. If list-like, all elements must either be positional (i.e. integer indices into the document columns) or strings that correspond to column names provided either by the user in *names* or inferred from the document header row(s). For example, a valid list-like *usecols* parameter would be `[0, 1, 2]` or `['foo', 'bar', 'baz']`. Element order is ignored, so `usecols=[0, 1]` is the same as `[1, 0]`. To instantiate a `DataFrame` from data with element order preserved use `pd.read_csv(data, usecols=['foo', 'bar'])[['foo', 'bar']]` for columns in `['foo', 'bar']` order or `pd.read_csv(data, usecols=['foo', 'bar'])[['bar', 'foo']]` for `['bar', 'foo']` order.

If callable, the callable function will be evaluated against the column names, returning names where the callable function evaluates to `True`. An example of a valid callable argument would be `lambda x: x.upper() in ['AAA', 'BBB', 'DDD']`. Using this parameter results in much faster parsing time and lower memory usage.

**squeeze** [bool, default `False`] If the parsed data only contains one column then return a `Series`.

**prefix** [str, optional] Prefix to add to column numbers when no header, e.g. ‘X’ for X0, X1, ...

**mangle\_dupe\_cols** [bool, default `True`] Duplicate columns will be specified as ‘X’, ‘X.1’, ... ‘X.N’, rather than ‘X’...‘X’. Passing in `False` will cause data to be overwritten if there are duplicate names in the columns.

**dtype** [Type name or dict of column -> type, optional] Data type for data or columns. E.g. {'a': np.float64, 'b': np.int32, 'c': 'Int64'} Use *str* or *object* together with suitable *na\_values* settings to preserve and not interpret dtype. If converters are specified, they will be applied INSTEAD of dtype conversion.

**engine** [{ 'c', 'python' }, optional] Parser engine to use. The C engine is faster while the python engine is currently more feature-complete.

**converters** [dict, optional] Dict of functions for converting values in certain columns. Keys can either be integers or column labels.

**true\_values** [list, optional] Values to consider as True.

**false\_values** [list, optional] Values to consider as False.

**skipinitialspace** [bool, default False] Skip spaces after delimiter.

**skiprows** [list-like, int or callable, optional] Line numbers to skip (0-indexed) or number of lines to skip (int) at the start of the file.

If callable, the callable function will be evaluated against the row indices, returning True if the row should be skipped and False otherwise. An example of a valid callable argument would be `lambda x: x in [0, 2]`.

**skipfooter** [int, default 0] Number of lines at bottom of file to skip (Unsupported with engine='c').

**nrows** [int, optional] Number of rows of file to read. Useful for reading pieces of large files.

**na\_values** [scalar, str, list-like, or dict, optional] Additional strings to recognize as NA/NaN. If dict passed, specific per-column NA values. By default the following values are interpreted as NaN: ' ', '#N/A', '#N/A N/A', '#NA', '-1.#IND', '-1.#QNAN', '-NaN', '-nan', '1.#IND', '1.#QNAN', 'N/A', 'NA', 'NULL', 'NaN', 'n/a', 'nan', 'null'.

**keep\_default\_na** [bool, default True] Whether or not to include the default NaN values when parsing the data. Depending on whether *na\_values* is passed in, the behavior is as follows:

- If *keep\_default\_na* is True, and *na\_values* are specified, *na\_values* is appended to the default NaN values used for parsing.
- If *keep\_default\_na* is True, and *na\_values* are not specified, only the default NaN values are used for parsing.
- If *keep\_default\_na* is False, and *na\_values* are specified, only the NaN values specified *na\_values* are used for parsing.
- If *keep\_default\_na* is False, and *na\_values* are not specified, no strings will be parsed as NaN.

Note that if *na\_filter* is passed in as False, the *keep\_default\_na* and *na\_values* parameters will be ignored.

**na\_filter** [bool, default True] Detect missing value markers (empty strings and the value of *na\_values*). In data without any NAs, passing *na\_filter*=False can improve the performance of reading a large file.

**verbose** [bool, default False] Indicate number of NA values placed in non-numeric columns.

**skip\_blank\_lines** [bool, default True] If True, skip over blank lines rather than interpreting as NaN values.

**parse\_dates** [bool or list of int or names or list of lists or dict, default False] The behavior is as follows:

- boolean. If True -> try parsing the index.
- list of int or names. e.g. If [1, 2, 3] -> try parsing columns 1, 2, 3 each as a separate date column.
- list of lists. e.g. If [[1, 3]] -> combine columns 1 and 3 and parse as a single date column.
- dict, e.g. {'foo' : [1, 3]} -> parse columns 1, 3 as date and call result 'foo'

If a column or index contains an unparseable date, the entire column or index will be returned unaltered as an object data type. For non-standard datetime parsing, use `pd.to_datetime` after `pd.read_csv`

Note: A fast-path exists for iso8601-formatted dates.

**infer\_datetime\_format** [bool, default False] If True and *parse\_dates* is enabled, pandas will attempt to infer the format of the datetime strings in the columns, and if it can be inferred, switch to a faster method of parsing them. In some cases this can increase the parsing speed by 5-10x.

**keep\_date\_col** [bool, default False] If True and *parse\_dates* specifies combining multiple columns then keep the original columns.

**date\_parser** [function, optional] Function to use for converting a sequence of string columns to an array of datetime instances. The default uses `dateutil.parser.parser` to do the conversion. Pandas will try to call *date\_parser* in three different ways, advancing to the next if an exception occurs: 1) Pass one or more arrays (as defined by *parse\_dates*) as arguments; 2) concatenate (row-wise) the string values from the columns defined by *parse\_dates* into a single array and pass that; and 3) call *date\_parser* once for each row using one or more strings (corresponding to the columns defined by *parse\_dates*) as arguments.

**dayfirst** [bool, default False] DD/MM format dates, international and European format.

**iterator** [bool, default False] Return `TextFileReader` object for iteration or getting chunks with `get_chunk()`.

**chunksize** [int, optional] Return `TextFileReader` object for iteration. See the [IO Tools docs](#) for more information on *iterator* and *chunksize*.

**compression** [{ 'infer', 'gzip', 'bz2', 'zip', 'xz', None }, default 'infer'] For on-the-fly decompression of on-disk data. If 'infer' and *filepath\_or\_buffer* is path-like, then detect compression from the following extensions: '.gz', '.bz2', '.zip', or '.xz' (otherwise no decompression). If using 'zip', the ZIP file must contain only one data file to be read in. Set to None for no decompression.

New in version 0.18.1: support for 'zip' and 'xz' compression.

**thousands** [str, optional] Thousands separator.

**decimal** [str, default '.'] Character to recognize as decimal point (e.g. use ',' for European data).

**lineterminator** [str (length 1), optional] Character to break file into lines. Only valid with C parser.

**quotechar** [str (length 1), optional] The character used to denote the start and end of a quoted item. Quoted items can include the delimiter and it will be ignored.

**quoting** [int or csv.QUOTE\_\* instance, default 0] Control field quoting behavior per `csv.QUOTE_*` constants. Use one of `QUOTE_MINIMAL` (0), `QUOTE_ALL` (1), `QUOTE_NONNUMERIC` (2) or `QUOTE_NONE` (3).

**doublequote** [bool, default True] When quotechar is specified and quoting is not QUOTE\_NONE, indicate whether or not to interpret two consecutive quotechar elements INSIDE a field as a single quotechar element.

**escapechar** [str (length 1), optional] One-character string used to escape other characters.

**comment** [str, optional] Indicates remainder of line should not be parsed. If found at the beginning of a line, the line will be ignored altogether. This parameter must be a single character. Like empty lines (as long as skip\_blank\_lines=True), fully commented lines are ignored by the parameter *header* but not by *skiprows*. For example, if comment='#', parsing #empty\na,b,c\n1,2,3 with header=0 will result in 'a,b,c' being treated as the header.

**encoding** [str, optional] Encoding to use for UTF when reading/writing (ex. 'utf-8'). [List of Python standard encodings](#).

**dialect** [str or csv.Dialect, optional] If provided, this parameter will override values (default or not) for the following parameters: *delimiter*, *doublequote*, *escapechar*, *skipinitialspace*, *quotechar*, and *quoting*. If it is necessary to override values, a ParserWarning will be issued. See csv.Dialect documentation for more details.

**tupleize\_cols** [bool, default False] Leave a list of tuples on columns as is (default is to convert to a MultiIndex on the columns).

Deprecated since version 0.21.0: This argument will be removed and will always convert to MultiIndex

**error\_bad\_lines** [bool, default True] Lines with too many fields (e.g. a csv line with too many commas) will by default cause an exception to be raised, and no DataFrame will be returned. If False, then these “bad lines” will be dropped from the DataFrame that is returned.

**warn\_bad\_lines** [bool, default True] If error\_bad\_lines is False, and warn\_bad\_lines is True, a warning for each “bad line” will be output.

**delim\_whitespace** [bool, default False] Specifies whether or not whitespace (e.g. ' ' or ' ') will be used as the sep. Equivalent to setting sep='\s+'. If this option is set to True, nothing should be passed in for the *delimiter* parameter.

New in version 0.18.1: support for the Python parser.

**low\_memory** [bool, default True] Internally process the file in chunks, resulting in lower memory use while parsing, but possibly mixed type inference. To ensure no mixed types either set False, or specify the type with the *dtype* parameter. Note that the entire file is read into a single DataFrame regardless, use the *chunksize* or *iterator* parameter to return the data in chunks. (Only valid with C parser).

**memory\_map** [bool, default False] If a filepath is provided for *filepath\_or\_buffer*, map the file object directly onto memory and access the data directly from there. Using this option can improve performance because there is no longer any I/O overhead.

**float\_precision** [str, optional] Specifies which converter the C engine should use for floating-point values. The options are *None* for the ordinary converter, *high* for the high-precision converter, and *round\_trip* for the round-trip converter.

## Returns

**DataFrame or TextParser** A comma-separated values (csv) file is returned as two-dimensional data structure with labeled axes.

See also:

**to\_csv** Write DataFrame to a comma-separated values (csv) file.

**read\_csv** Read a comma-separated values (csv) file into DataFrame.

**read\_fwf** Read a table of fixed-width formatted lines into DataFrame.

### Examples

```
>>> pd.read_csv('data.csv') # doctest: +SKIP
```

#### 35.1.2.3 pandas.read\_fwf

`pandas.read_fwf(filepath_or_buffer, colspecs='infer', widths=None, infer_nrows=100, **kwargs)`

Read a table of fixed-width formatted lines into DataFrame.

Also supports optionally iterating or breaking of the file into chunks.

Additional help can be found in the [online docs for IO Tools](#).

##### Parameters

**filepath\_or\_buffer** [str, path object, or file-like object] Any valid string path is acceptable. The string could be a URL. Valid URL schemes include http, ftp, s3, and file. For file URLs, a host is expected. A local file could be: `file://localhost/path/to/table.csv`.

If you want to pass in a path object, pandas accepts either `pathlib.Path` or `py._path.local.LocalPath`.

By file-like object, we refer to objects with a `read()` method, such as a file handler (e.g. via builtin `open` function) or `StringIO`.

**colspecs** [list of tuple (int, int) or 'infer'. optional] A list of tuples giving the extents of the fixed-width fields of each line as half-open intervals (i.e., [from, to[ ). String value 'infer' can be used to instruct the parser to try detecting the column specifications from the first 100 rows of the data which are not being skipped via `skiprows` (default='infer').

**widths** [list of int, optional] A list of field widths which can be used instead of 'colspecs' if the intervals are contiguous.

**infer\_nrows** [int, default 100] The number of rows to consider when letting the parser determine the *colspecs*.

New in version 0.24.0.

**\*\*kwargs** [optional] Optional keyword arguments can be passed to `TextFileReader`.

##### Returns

**DataFrame or TextParser** A comma-separated values (csv) file is returned as two-dimensional data structure with labeled axes.

See also:

**to\_csv** Write DataFrame to a comma-separated values (csv) file.

**read\_csv** Read a comma-separated values (csv) file into DataFrame.

### Examples

```
>>> pd.read_fwf('data.csv') # doctest: +SKIP
```

### 35.1.2.4 pandas.read\_msgpack

`pandas.read_msgpack(path_or_buf, encoding='utf-8', iterator=False, **kwargs)`

Load msgpack pandas object from the specified file path

THIS IS AN EXPERIMENTAL LIBRARY and the storage format may not be stable until a future release.

#### Parameters

**path\_or\_buf** [string File path, BytesIO like or string]

**encoding** [Encoding for decoding msgpack str type]

**iterator** [boolean, if True, return an iterator to the unpacker] (default is False)

#### Returns

**obj** [same type as object stored in file]

### 35.1.3 Clipboard

---

`read_clipboard([sep])`

Read text from clipboard and pass to read\_csv.

---

#### 35.1.3.1 pandas.read\_clipboard

`pandas.read_clipboard(sep='\s+', **kwargs)`

Read text from clipboard and pass to read\_csv. See read\_csv for the full argument list

#### Parameters

**sep** [str, default '\s+'] A string or regex delimiter. The default of 's+' denotes one or more whitespace characters.

#### Returns

**parsed** [DataFrame]

### 35.1.4 Excel

---

`read_excel(io[, sheet_name, header, names, ...])`

Read an Excel file into a pandas DataFrame.

`ExcelFile.parse([sheet_name, header, names, ...])`

Parse specified sheet(s) into a DataFrame

---

#### 35.1.4.1 pandas.read\_excel

`pandas.read_excel(io, sheet_name=0, header=0, names=None, index_col=None, parse_cols=None, usecols=None, squeeze=False, dtype=None, engine=None, converters=None, true_values=None, false_values=None, skiprows=None, nrows=None, na_values=None, keep_default_na=True, verbose=False, parse_dates=False, date_parser=None, thousands=None, comment=None, skip_footer=0, skip_footer=0, convert_float=True, mangle_dupe_cols=True, **kws)`

Read an Excel file into a pandas DataFrame.

Support both *xls* and *xlsx* file extensions from a local filesystem or URL. Support an option to read a single sheet or a list of sheets.

#### Parameters

**io** [str, file descriptor, pathlib.Path, ExcelFile or xlrd.Book] The string could be a URL. Valid URL schemes include http, ftp, s3, gcs, and file. For file URLs, a host is expected. For instance, a local file could be /path/to/workbook.xlsx.

**sheet\_name** [str, int, list, or None, default 0] Strings are used for sheet names. Integers are used in zero-indexed sheet positions. Lists of strings/integers are used to request multiple sheets. Specify None to get all sheets.

Available cases:

- Defaults to 0: 1st sheet as a *DataFrame*
- 1: 2nd sheet as a *DataFrame*
- "Sheet1": Load sheet with name "Sheet1"
- [0, 1, "Sheet5"]: Load first, second and sheet named "Sheet5" as a dict of *DataFrame*
- None: All sheets.

**header** [int, list of int, default 0] Row (0-indexed) to use for the column labels of the parsed *DataFrame*. If a list of integers is passed those row positions will be combined into a *MultiIndex*. Use None if there is no header.

**names** [array-like, default None] List of column names to use. If file contains no header row, then you should explicitly pass header=None.

**index\_col** [int, list of int, default None] Column (0-indexed) to use as the row labels of the *DataFrame*. Pass None if there is no such column. If a list is passed, those columns will be combined into a *MultiIndex*. If a subset of data is selected with *usecols*, *index\_col* is based on the subset.

**parse\_cols** [int or list, default None] Alias of *usecols*.

Deprecated since version 0.21.0: Use *usecols* instead.

**usecols** [int, str, list-like, or callable default None] Return a subset of the columns. \* If None, then parse all columns. \* If int, then indicates last column to be parsed.

Deprecated since version 0.24.0: Pass in a list of int instead from 0 to *usecols* inclusive.

- If str, then indicates comma separated list of Excel column letters and column ranges (e.g. "A:E" or "A,C,E:F"). Ranges are inclusive of both sides.
- If list of int, then indicates list of column numbers to be parsed.
- If list of string, then indicates list of column names to be parsed.

New in version 0.24.0.

- If callable, then evaluate each column name against it and parse the column if the callable returns *True*.

New in version 0.24.0.

**squeeze** [bool, default False] If the parsed data only contains one column then return a *Series*.

**dtype** [Type name or dict of column -> type, default None] Data type for data or columns. E.g. {'a': np.float64, 'b': np.int32} Use *object* to preserve data as stored in Excel and not interpret dtype. If converters are specified, they will be applied INSTEAD of dtype conversion.

New in version 0.20.0.

**engine** [str, default None] If io is not a buffer or path, this must be set to identify io. Acceptable values are None or xlrld.

**converters** [dict, default None] Dict of functions for converting values in certain columns. Keys can either be integers or column labels, values are functions that take one input argument, the Excel cell content, and return the transformed content.

**true\_values** [list, default None] Values to consider as True.

New in version 0.19.0.

**false\_values** [list, default None] Values to consider as False.

New in version 0.19.0.

**skiprows** [list-like] Rows to skip at the beginning (0-indexed).

**nrows** [int, default None] Number of rows to parse.

New in version 0.23.0.

**na\_values** [scalar, str, list-like, or dict, default None] Additional strings to recognize as NA/NaN. If dict passed, specific per-column NA values. By default the following values are interpreted as NaN: ‘’, ‘#N/A’, ‘#N/A N/A’, ‘#NA’, ‘-1.#IND’, ‘-1.#QNAN’, ‘-NaN’, ‘-nan’, ‘1.#IND’, ‘1.#QNAN’, ‘N/A’, ‘NA’, ‘NULL’, ‘NaN’, ‘n/a’, ‘nan’, ‘null’.

**keep\_default\_na** [bool, default True] If na\_values are specified and keep\_default\_na is False the default NaN values are overridden, otherwise they’re appended to.

**verbose** [bool, default False] Indicate number of NA values placed in non-numeric columns.

**parse\_dates** [bool, list-like, or dict, default False] The behavior is as follows:

- bool. If True -> try parsing the index.
- list of int or names. e.g. If [1, 2, 3] -> try parsing columns 1, 2, 3 each as a separate date column.
- list of lists. e.g. If [[1, 3]] -> combine columns 1 and 3 and parse as a single date column.
- dict, e.g. {‘foo’: [1, 3]} -> parse columns 1, 3 as date and call result ‘foo’

If a column or index contains an unparseable date, the entire column or index will be returned unaltered as an object data type. For non-standard datetime parsing, use `pd.to_datetime` after `pd.read_csv`

Note: A fast-path exists for iso8601-formatted dates.

**date\_parser** [function, optional] Function to use for converting a sequence of string columns to an array of datetime instances. The default uses `dateutil.parser.parser` to do the conversion. Pandas will try to call `date_parser` in three different ways, advancing to the next if an exception occurs: 1) Pass one or more arrays (as defined by `parse_dates`) as arguments; 2) concatenate (row-wise) the string values from the columns defined by `parse_dates` into a single array and pass that; and 3) call `date_parser` once for each row using one or more strings (corresponding to the columns defined by `parse_dates`) as arguments.

**thousands** [str, default None] Thousands separator for parsing string columns to numeric. Note that this parameter is only necessary for columns stored as TEXT in Excel, any numeric columns will automatically be parsed, regardless of display format.

**comment** [str, default None] Comments out remainder of line. Pass a character or characters to this argument to indicate comments in the input file. Any data between the comment string and the end of the current line is ignored.

**skip\_footer** [int, default 0] Alias of *skipfooter*.

Deprecated since version 0.23.0: Use *skipfooter* instead.

**skipfooter** [int, default 0] Rows at the end to skip (0-indexed).

**convert\_float** [bool, default True] Convert integral floats to int (i.e., 1.0 → 1). If False, all numeric data will be read in as floats: Excel stores all numbers as floats internally.

**mangle\_dupe\_cols** [bool, default True] Duplicate columns will be specified as 'X', 'X.1', ... 'X.N', rather than 'X'...'X'. Passing in False will cause data to be overwritten if there are duplicate names in the columns.

**\*\*kwargs** [optional] Optional keyword arguments can be passed to `TextFileReader`.

### Returns

**DataFrame or dict of DataFrames** DataFrame from the passed in Excel file. See notes in `sheet_name` argument for more information on when a dict of DataFrames is returned.

See also:

**to\_excel** Write DataFrame to an Excel file.

**to\_csv** Write DataFrame to a comma-separated values (csv) file.

**read\_csv** Read a comma-separated values (csv) file into DataFrame.

**read\_fwf** Read a table of fixed-width formatted lines into DataFrame.

### Examples

The file can be read using the file name as string or an open file object:

```
>>> pd.read_excel('tmp.xlsx', index_col=0) # doctest: +SKIP
   Name  Value
0  string1     1
1  string2     2
2  #Comment     3
```

```
>>> pd.read_excel(open('tmp.xlsx', 'rb'),
...               sheet_name='Sheet3') # doctest: +SKIP
   Unnamed: 0   Name  Value
0           0  string1     1
1           1  string2     2
2           2  #Comment     3
```

Index and header can be specified via the `index_col` and `header` arguments

```
>>> pd.read_excel('tmp.xlsx', index_col=None, header=None) # doctest: +SKIP
   0      1      2
0 NaN      Name  Value
1 0.0  string1     1
2 1.0  string2     2
3 2.0  #Comment     3
```

Column types are inferred but can be explicitly specified

```
>>> pd.read_excel('tmp.xlsx', index_col=0,
...               dtype={'Name': str, 'Value': float}) # doctest: +SKIP
```

|   | Name     | Value |
|---|----------|-------|
| 0 | string1  | 1.0   |
| 1 | string2  | 2.0   |
| 2 | #Comment | 3.0   |

True, False, and NA values, and thousands separators have defaults, but can be explicitly specified, too. Supply the values you would like as strings or lists of strings!

```
>>> pd.read_excel('tmp.xlsx', index_col=0,
...               na_values=['string1', 'string2']) # doctest: +SKIP
```

|   | Name     | Value |
|---|----------|-------|
| 0 | NaN      | 1     |
| 1 | NaN      | 2     |
| 2 | #Comment | 3     |

Comment lines in the excel input file can be skipped using the *comment* kwarg

```
>>> pd.read_excel('tmp.xlsx', index_col=0, comment='#') # doctest: +SKIP
```

|   | Name    | Value |
|---|---------|-------|
| 0 | string1 | 1.0   |
| 1 | string2 | 2.0   |
| 2 | None    | NaN   |

### 35.1.4.2 pandas.ExcelFile.parse

`ExcelFile.parse(sheet_name=0, header=0, names=None, index_col=None, usecols=None, squeeze=False, converters=None, true_values=None, false_values=None, skiprows=None, nrows=None, na_values=None, parse_dates=False, date_parser=None, thousands=None, comment=None, skipfooter=0, convert_float=True, mangle_dupe_cols=True, **kwargs)`

Parse specified sheet(s) into a DataFrame

Equivalent to `read_excel(ExcelFile, ...)` See the `read_excel` docstring for more info on accepted parameters

`ExcelWriter(path[, engine, date_format, ...])`

Class for writing DataFrame objects into excel sheets, default is to use xlwt for xls, openpyxl for xlsx.

### 35.1.4.3 pandas.ExcelWriter

`class pandas.ExcelWriter(path, engine=None, date_format=None, datetime_format=None, mode='w', **engine_kwargs)`

Class for writing DataFrame objects into excel sheets, default is to use xlwt for xls, openpyxl for xlsx. See `DataFrame.to_excel` for typical usage.

#### Parameters

**path** [string] Path to xls or xlsx file.

**engine** [string (optional)] Engine to use for writing. If None, defaults to `io.excel.<extension>.writer`. NOTE: can only be passed as a keyword argument.

**date\_format** [string, default None] Format string for dates written into Excel files (e.g. 'YYYY-MM-DD')

**datetime\_format** [string, default None] Format string for datetime objects written into Excel files (e.g. 'YYYY-MM-DD HH:MM:SS')

**mode** [{ 'w' or 'a' }, default 'w'] File mode to use (write or append).

**.. versionadded:: 0.24.0**

## Notes

None of the methods and properties are considered public.

For compatibility with CSV writers, ExcelWriter serializes lists and dicts to strings before writing.

## Examples

Default usage:

```
>>> with ExcelWriter('path_to_file.xlsx') as writer:
...     df.to_excel(writer)
```

To write to separate sheets in a single file:

```
>>> with ExcelWriter('path_to_file.xlsx') as writer:
...     df1.to_excel(writer, sheet_name='Sheet1')
...     df2.to_excel(writer, sheet_name='Sheet2')
```

You can set the date format or datetime format:

```
>>> with ExcelWriter('path_to_file.xlsx',
...                   date_format='YYYY-MM-DD',
...                   datetime_format='YYYY-MM-DD HH:MM:SS') as writer:
...     df.to_excel(writer)
```

You can also append to an existing Excel file:

```
>>> with ExcelWriter('path_to_file.xlsx', mode='a') as writer:
...     df.to_excel(writer, sheet_name='Sheet3')
```

### 35.1.5 JSON

---

|                                                                |                                         |
|----------------------------------------------------------------|-----------------------------------------|
| <code>read_json([path_or_buf, orient, typ, dtype, ...])</code> | Convert a JSON string to pandas object. |
|----------------------------------------------------------------|-----------------------------------------|

---

### 35.1.5.1 pandas.read\_json

`pandas.read_json` (*path\_or\_buf=None, orient=None, typ='frame', dtype=True, convert\_axes=True, convert\_dates=True, keep\_default\_dates=True, numpy=False, precise\_float=False, date\_unit=None, encoding=None, lines=False, chunksize=None, compression='infer'*)

Convert a JSON string to pandas object.

#### Parameters

**path\_or\_buf** [a valid JSON string or file-like, default: None] The string could be a URL. Valid URL schemes include http, ftp, s3, gcs, and file. For file URLs, a host is expected. For instance, a local file could be `file://localhost/path/to/table.json`

**orient** [string,] Indication of expected JSON string format. Compatible JSON strings can be produced by `to_json()` with a corresponding orient value. The set of possible orients is:

- 'split': dict like {index -> [index], columns -> [columns], data -> [values]}
- 'records' : list like [{column -> value}, ... , {column -> value}]
- 'index': dict like {index -> {column -> value}}
- 'columns': dict like {column -> {index -> value}}
- 'values': just the values array

The allowed and default values depend on the value of the *typ* parameter.

- when `typ == 'series'`,
  - allowed orients are {'split', 'records', 'index'}
  - default is 'index'
  - The Series index must be unique for orient 'index'.
- when `typ == 'frame'`,
  - allowed orients are {'split', 'records', 'index', 'columns', 'values', 'table'}
  - default is 'columns'
  - The DataFrame index must be unique for orients 'index' and 'columns'.
  - The DataFrame columns must be unique for orients 'index', 'columns', and 'records'.

New in version 0.23.0: 'table' as an allowed value for the *orient* argument

**typ** [type of object to recover (series or frame), default 'frame']

**dtype** [boolean or dict, default True] If True, infer dtypes, if a dict of column to dtype, then use those, if False, then don't infer dtypes at all, applies only to the data.

**convert\_axes** [boolean, default True] Try to convert the axes to the proper dtypes.

**convert\_dates** [boolean, default True] List of columns to parse for dates; If True, then try to parse datelike columns default is True; a column label is datelike if

- it ends with '\_at',
- it ends with '\_time',

- it begins with 'timestamp',
- it is 'modified', or
- it is 'date'

**keep\_default\_dates** [boolean, default True] If parsing dates, then parse the default datelike columns

**numpy** [boolean, default False] Direct decoding to numpy arrays. Supports numeric data only, but non-numeric column and index labels are supported. Note also that the JSON ordering MUST be the same for each term if numpy=True.

**precise\_float** [boolean, default False] Set to enable usage of higher precision (strtod) function when decoding string to double values. Default (False) is to use fast but less precise builtin functionality

**date\_unit** [string, default None] The timestamp unit to detect if converting dates. The default behaviour is to try and detect the correct precision, but if this is not desired then pass one of 's', 'ms', 'us' or 'ns' to force parsing only seconds, milliseconds, microseconds or nanoseconds respectively.

**encoding** [str, default is 'utf-8'] The encoding to use to decode py3 bytes.

New in version 0.19.0.

**lines** [boolean, default False] Read the file as a json object per line.

New in version 0.19.0.

**chunksize** [integer, default None] Return JsonReader object for iteration. See the [line-delimited json docs](#) for more information on `chunksize`. This can only be passed if `lines=True`. If this is None, the file will be read into memory all at once.

New in version 0.21.0.

**compression** [{ 'infer', 'gzip', 'bz2', 'zip', 'xz', None }, default 'infer'] For on-the-fly decompression of on-disk data. If 'infer', then use gzip, bz2, zip or xz if `path_or_buf` is a string ending in '.gz', '.bz2', '.zip', or '.xz', respectively, and no decompression otherwise. If using 'zip', the ZIP file must contain only one data file to be read in. Set to None for no decompression.

New in version 0.21.0.

## Returns

**result** [Series or DataFrame, depending on the value of *typ*.]

## See also:

`DataFrame.to_json`

## Notes

Specific to `orient='table'`, if a `DataFrame` with a literal `Index` name of `index` gets written with `to_json()`, the subsequent read operation will incorrectly set the `Index` name to `None`. This is because `index` is also used by `DataFrame.to_json()` to denote a missing `Index` name, and the subsequent `read_json()` operation cannot distinguish between the two. The same limitation is encountered with a `MultiIndex` and any names beginning with 'level\_'.

## Examples

```
>>> df = pd.DataFrame([[ 'a', 'b'], [ 'c', 'd']],
...                    index=[ 'row 1', 'row 2'],
...                    columns=[ 'col 1', 'col 2'])
```

Encoding/decoding a Dataframe using 'split' formatted JSON:

```
>>> df.to_json(orient='split')
'{"columns":["col 1","col 2"],
  "index":["row 1","row 2"],
  "data":[["a","b"],["c","d"]]} '
>>> pd.read_json(_, orient='split')
   col 1 col 2
row 1    a    b
row 2    c    d
```

Encoding/decoding a Dataframe using 'index' formatted JSON:

```
>>> df.to_json(orient='index')
'{"row 1":{"col 1":"a","col 2":"b"},"row 2":{"col 1":"c","col 2":"d"}} '
>>> pd.read_json(_, orient='index')
   col 1 col 2
row 1    a    b
row 2    c    d
```

Encoding/decoding a Dataframe using 'records' formatted JSON. Note that index labels are not preserved with this encoding.

```
>>> df.to_json(orient='records')
'[{"col 1":"a","col 2":"b"}, {"col 1":"c","col 2":"d"}] '
>>> pd.read_json(_, orient='records')
   col 1 col 2
0      a    b
1      c    d
```

Encoding with Table Schema

```
>>> df.to_json(orient='table')
'{"schema": {"fields": [{"name": "index", "type": "string"},
                        {"name": "col 1", "type": "string"},
                        {"name": "col 2", "type": "string"}],
             "primaryKey": "index",
             "pandas_version": "0.20.0"},
  "data": [{"index": "row 1", "col 1": "a", "col 2": "b"},
            {"index": "row 2", "col 1": "c", "col 2": "d"}]}'
```

---

*json\_normalize*(data[, record\_path, meta, ...])

Normalize semi-structured JSON data into a flat table.

---

*build\_table\_schema*(data[, index, ...])

Create a Table schema from data.

---

### 35.1.5.2 pandas.io.json.json\_normalize

`pandas.io.json.json_normalize`(data, record\_path=None, meta=None, meta\_prefix=None, record\_prefix=None, errors='raise', sep='.')

Normalize semi-structured JSON data into a flat table.

**Parameters**

**data** [dict or list of dicts] Unserialized JSON objects

**record\_path** [string or list of strings, default None] Path in each object to list of records. If not passed, data will be assumed to be an array of records

**meta** [list of paths (string or list of strings), default None] Fields to use as metadata for each record in resulting table

**meta\_prefix** [string, default None]

**record\_prefix** [string, default None] If True, prefix records with dotted (?) path, e.g. foo.bar.field if path to records is ['foo', 'bar']

**errors** [{ 'raise', 'ignore' }, default 'raise']

- 'ignore' : will ignore KeyError if keys listed in meta are not always present
- 'raise' : will raise KeyError if keys listed in meta are not always present

New in version 0.20.0.

**sep** [string, default '.'] Nested records will generate names separated by sep, e.g., for sep='.', { 'foo' : { 'bar' : 0 } } -> foo.bar

New in version 0.20.0.

**Returns**

**frame** [DataFrame]

**Examples**

```
>>> from pandas.io.json import json_normalize
>>> data = [{ 'id': 1, 'name': { 'first': 'Coleen', 'last': 'Volk' },
...         { 'name': { 'given': 'Mose', 'family': 'Regner' } },
...         { 'id': 2, 'name': 'Faye Raker' }]
>>> json_normalize(data)
   id      name name.family name.first name.given name.last
0  1.0      NaN      NaN      Coleen      NaN      Volk
1  NaN      NaN      Regner      NaN      Mose      NaN
2  2.0  Faye Raker      NaN      NaN      NaN      NaN
```

```
>>> data = [{ 'state': 'Florida',
...         'shortname': 'FL',
...         'info': {
...             'governor': 'Rick Scott'
...         },
...         'counties': [{ 'name': 'Dade', 'population': 12345 },
...                       { 'name': 'Broward', 'population': 40000 },
...                       { 'name': 'Palm Beach', 'population': 60000 } ] },
...         { 'state': 'Ohio',
...         'shortname': 'OH',
...         'info': {
...             'governor': 'John Kasich'
...         },
...         'counties': [{ 'name': 'Summit', 'population': 1234 },
...                       { 'name': 'Cuyahoga', 'population': 1337 } ] } ]
>>> result = json_normalize(data, 'counties', ['state', 'shortname',
```

(continues on next page)

(continued from previous page)

```

...                                     ['info', 'governor'])
>>> result
      name  population info.governor  state shortname
0      Dade      12345    Rick Scott  Florida        FL
1  Broward      40000    Rick Scott  Florida        FL
2  Palm Beach    60000    Rick Scott  Florida        FL
3    Summit       1234   John Kasich    Ohio        OH
4   Cuyahoga       1337   John Kasich    Ohio        OH

```

```

>>> data = {'A': [1, 2]}
>>> json_normalize(data, 'A', record_prefix='Prefix.')
Prefix.0
0         1
1         2

```

### 35.1.5.3 pandas.io.json.build\_table\_schema

`pandas.io.json.build_table_schema` (*data*, *index=True*, *primary\_key=None*, *version=True*)

Create a Table schema from data.

#### Parameters

**data** [Series, DataFrame]

**index** [bool, default True] Whether to include `data.index` in the schema.

**primary\_key** [bool or None, default True] column names to designate as the primary key. The default *None* will set *'primaryKey'* to the index level or levels if the index is unique.

**version** [bool, default True] Whether to include a field *pandas\_version* with the version of pandas that generated the schema.

#### Returns

**schema** [dict]

#### Notes

See *\_as\_json\_table\_type* for conversion types. Timedeltas are converted to ISO8601 duration format with 9 decimal places after the seconds field for nanosecond precision.

Categoricals are converted to the *any* dtype, and use the *enum* field constraint to list the allowed values. The *ordered* attribute is included in an *ordered* field.

#### Examples

```

>>> df = pd.DataFrame(
...     {'A': [1, 2, 3],
...      'B': ['a', 'b', 'c'],
...      'C': pd.date_range('2016-01-01', freq='d', periods=3),
...     }, index=pd.Index(range(3), name='idx'))
>>> build_table_schema(df)
{'fields': [{'name': 'idx', 'type': 'integer'},
{'name': 'A', 'type': 'integer'},

```

(continues on next page)

(continued from previous page)

```
{'name': 'B', 'type': 'string'},
{'name': 'C', 'type': 'datetime'}],
'pandas_version': '0.20.0',
'primaryKey': ['idx']}
```

## 35.1.6 HTML

`read_html(io[, match, flavor, header, ...])`

Read HTML tables into a list of DataFrame objects.

### 35.1.6.1 pandas.read\_html

`pandas.read_html(io, match='.+', flavor=None, header=None, index_col=None, skiprows=None, attrs=None, parse_dates=False, tupleize_cols=None, thousands=',', encoding=None, decimal='.', converters=None, na_values=None, keep_default_na=True, displayed_only=True)`

Read HTML tables into a list of DataFrame objects.

#### Parameters

- io** [str or file-like] A URL, a file-like object, or a raw string containing HTML. Note that lxml only accepts the http, ftp and file url protocols. If you have a URL that starts with 'https' you might try removing the 's'.
- match** [str or compiled regular expression, optional] The set of tables containing text matching this regex or string will be returned. Unless the HTML is extremely simple you will probably need to pass a non-empty string here. Defaults to `‘.+’` (match any non-empty string). The default value will return all tables contained on a page. This value is converted to a regular expression so that there is consistent behavior between BeautifulSoup and lxml.
- flavor** [str or None, container of strings] The parsing engine to use. `‘bs4’` and `‘html5lib’` are synonymous with each other, they are both there for backwards compatibility. The default of None tries to use lxml to parse and if that fails it falls back on bs4 + html5lib.
- header** [int or list-like or None, optional] The row (or list of rows for a *MultiIndex*) to use to make the columns headers.
- index\_col** [int or list-like or None, optional] The column (or list of columns) to use to create the index.
- skiprows** [int or list-like or slice or None, optional] 0-based. Number of rows to skip after parsing the column integer. If a sequence of integers or a slice is given, will skip the rows indexed by that sequence. Note that a single element sequence means ‘skip the nth row’ whereas an integer means ‘skip n rows’.
- attrs** [dict or None, optional] This is a dictionary of attributes that you can pass to use to identify the table in the HTML. These are not checked for validity before being passed to lxml or BeautifulSoup. However, these attributes must be valid HTML table attributes to work correctly. For example,

```
attrs = {'id': 'table'}
```

is a valid attribute dictionary because the `‘id’` HTML tag attribute is a valid HTML attribute for any HTML tag as per [this document](#).

```
attrs = {'asdf': 'table'}
```

is *not* a valid attribute dictionary because ‘asdf’ is not a valid HTML attribute even if it is a valid XML attribute. Valid HTML 4.01 table attributes can be found [here](#). A working draft of the HTML 5 spec can be found [here](#). It contains the latest information on table attributes for the modern web.

**parse\_dates** [bool, optional] See `read_csv()` for more details.

**tupleize\_cols** [bool, optional] If `False` try to parse multiple header rows into a *MultiIndex*, otherwise return raw tuples. Defaults to `False`.

Deprecated since version 0.21.0: This argument will be removed and will always convert to *MultiIndex*

**thousands** [str, optional] Separator to use to parse thousands. Defaults to `' , '`.

**encoding** [str or None, optional] The encoding used to decode the web page. Defaults to `None`. “None” preserves the previous encoding behavior, which depends on the underlying parser library (e.g., the parser library will try to use the encoding provided by the document).

**decimal** [str, default `'.'`] Character to recognize as decimal point (e.g. use `','` for European data).

New in version 0.19.0.

**converters** [dict, default `None`] Dict of functions for converting values in certain columns. Keys can either be integers or column labels, values are functions that take one input argument, the cell (not column) content, and return the transformed content.

New in version 0.19.0.

**na\_values** [iterable, default `None`] Custom NA values

New in version 0.19.0.

**keep\_default\_na** [bool, default `True`] If `na_values` are specified and `keep_default_na` is `False` the default NaN values are overridden, otherwise they’re appended to

New in version 0.19.0.

**displayed\_only** [bool, default `True`] Whether elements with “display: none” should be parsed

New in version 0.23.0.

## Returns

**dfs** [list of DataFrames]

See also:

`pandas.read_csv`

## Notes

Before using this function you should read the *gotchas about the HTML parsing libraries*.

Expect to do some cleanup after you call this function. For example, you might need to manually assign column names if the column names are converted to NaN when you pass the `header=0` argument. We try to assume as little as possible about the structure of the table and push the idiosyncrasies of the HTML contained in the table to the user.

This function searches for `<table>` elements and only for `<tr>` and `<th>` rows and `<td>` elements within each `<tr>` or `<th>` element in the table. `<td>` stands for “table data”. This function attempts to properly

handle `colspan` and `rowspan` attributes. If the function has a `<thead>` argument, it is used to construct the header, otherwise the function attempts to find the header within the body (by putting rows with only `<th>` elements into the header).

New in version 0.21.0.

Similar to `read_csv()` the `header` argument is applied **after** `skiprows` is applied.

This function will *always* return a list of `DataFrame` or it will fail, e.g., it will *not* return an empty list.

## Examples

See the `read_html` documentation in the *IO* section of the docs for some examples of reading in HTML tables.

### 35.1.7 HDFStore: PyTables (HDF5)

|                                                              |                                                                                                        |
|--------------------------------------------------------------|--------------------------------------------------------------------------------------------------------|
| <code>read_hdf(path_or_buf[, key, mode])</code>              | Read from the store, close it if we opened it.                                                         |
| <code>HDFStore.put(key, value[, format, append])</code>      | Store object in HDFStore                                                                               |
| <code>HDFStore.append(key, value[, format, ...])</code>      | Append to Table in file.                                                                               |
| <code>HDFStore.get(key)</code>                               | Retrieve pandas object stored in file                                                                  |
| <code>HDFStore.select(key[, where, start, stop, ...])</code> | Retrieve pandas object stored in file, optionally based on where criteria                              |
| <code>HDFStore.info()</code>                                 | Print detailed information on the store.                                                               |
| <code>HDFStore.keys()</code>                                 | Return a (potentially unordered) list of the keys corresponding to the objects stored in the HDFStore. |
| <code>HDFStore.groups()</code>                               | return a list of all the top-level nodes (that are not themselves a pandas storage object)             |
| <code>HDFStore.walk([where])</code>                          | Walk the pytables group hierarchy for pandas objects                                                   |

#### 35.1.7.1 pandas.read\_hdf

`pandas.read_hdf(path_or_buf, key=None, mode='r', **kwargs)`

Read from the store, close it if we opened it.

Retrieve pandas object stored in file, optionally based on where criteria

#### Parameters

**path\_or\_buf** [string, buffer or path object] Path to the file to open, or an open `pandas.HDFStore` object. Supports any object implementing the `__fspath__` protocol. This includes `pathlib.Path` and `py.path.local.LocalPath` objects.

New in version 0.19.0: support for `pathlib`, `py.path`.

New in version 0.21.0: support for `__fspath__` protocol.

**key** [object, optional] The group identifier in the store. Can be omitted if the HDF file contains a single pandas object.

**mode** [{ 'r', 'r+', 'a' }, optional] Mode to use when opening the file. Ignored if `path_or_buf` is a `pandas.HDFStore`. Default is 'r'.

**where** [list, optional] A list of Term (or convertible) objects.

**start** [int, optional] Row number to start selection.

**stop** [int, optional] Row number to stop selection.

**columns** [list, optional] A list of columns names to return.

**iterator** [bool, optional] Return an iterator object.

**chunksize** [int, optional] Number of rows to include in an iteration when using an iterator.

**errors** [str, default 'strict'] Specifies how encoding and decoding errors are to be handled. See the errors argument for `open()` for a full list of options.

**\*\*kwargs** Additional keyword arguments passed to HDFStore.

#### Returns

**item** [object] The selected object. Return type depends on the object stored.

See also:

**pandas.DataFrame.to\_hdf** Write a HDF file from a DataFrame.

**pandas.HDFStore** Low-level access to HDF files.

#### Examples

```
>>> df = pd.DataFrame([[1, 1.0, 'a']], columns=['x', 'y', 'z'])
>>> df.to_hdf('./store.h5', 'data')
>>> reread = pd.read_hdf('./store.h5')
```

### 35.1.7.2 pandas.HDFStore.put

**HDFStore.put** (*key, value, format=None, append=False, \*\*kwargs*)  
Store object in HDFStore

#### Parameters

**key** [object]

**value** [{Series, DataFrame, Panel}]

**format** ['fixed(f)|table(t)', default is 'fixed']

**fixed(f)** [Fixed format] Fast writing/reading. Not-appendable, nor searchable

**table(t)** [Table format] Write as a PyTables Table structure which may perform worse but allow more flexible operations like searching / selecting subsets of the data

**append** [boolean, default False] This will force Table format, append the input data to the existing.

**data\_columns** [list of columns to create as data columns, or True to] use all columns. See [here](#)  
# noqa

**encoding** [default None, provide an encoding for strings]

**dropna** [boolean, default False, do not write an ALL nan row to] the store settable by the option 'io.hdf.dropna\_table'

### 35.1.7.3 pandas.HDFStore.append

`HDFStore.append` (*key*, *value*, *format=None*, *append=True*, *columns=None*, *dropna=None*, *\*\*kwargs*)  
Append to Table in file. Node must already exist and be Table format.

#### Parameters

**key** [object]

**value** [{Series, DataFrame, Panel}]

**format** ['table' is the default]

**table(t)** [table format] Write as a PyTables Table structure which may perform worse but allow more flexible operations like searching / selecting subsets of the data

**append** [boolean, default True, append the input data to the] existing

**data\_columns** [list of columns, or True, default None] List of columns to create as indexed data columns for on-disk queries, or True to use all columns. By default only the axes of the object are indexed. See [here](#).

**min\_itemsize** [dict of columns that specify minimum string sizes]

**nan\_rep** [string to use as string nan representation]

**chunksize** [size to chunk the writing]

**expectedrows** [expected TOTAL row size of this table]

**encoding** [default None, provide an encoding for strings]

**dropna** [boolean, default False, do not write an ALL nan row to] the store settable by the option 'io.hdf.dropna\_table'

#### Notes

Does *not* check if data being appended overlaps with existing data in the table, so be careful

### 35.1.7.4 pandas.HDFStore.get

`HDFStore.get` (*key*)  
Retrieve pandas object stored in file

#### Parameters

**key** [object]

#### Returns

**obj** [same type as object stored in file]

### 35.1.7.5 pandas.HDFStore.select

`HDFStore.select` (*key*, *where=None*, *start=None*, *stop=None*, *columns=None*, *iterator=False*, *chunksize=None*, *auto\_close=False*, *\*\*kwargs*)  
Retrieve pandas object stored in file, optionally based on where criteria

#### Parameters

**key** [object]

**where** [list of Term (or convertible) objects, optional]  
**start** [integer (defaults to None), row number to start selection]  
**stop** [integer (defaults to None), row number to stop selection]  
**columns** [a list of columns that if not None, will limit the return] columns  
**iterator** [boolean, return an iterator, default False]  
**chunksize** [nrows to include in iteration, return an iterator]  
**auto\_close** [boolean, should automatically close the store when] finished, default is False

#### Returns

The selected object

### 35.1.7.6 pandas.HDFStore.info

`HDFStore.info()`

Print detailed information on the store.

New in version 0.21.0.

### 35.1.7.7 pandas.HDFStore.keys

`HDFStore.keys()`

Return a (potentially unordered) list of the keys corresponding to the objects stored in the HDFStore. These are ABSOLUTE path-names (e.g. have the leading '/')

### 35.1.7.8 pandas.HDFStore.groups

`HDFStore.groups()`

return a list of all the top-level nodes (that are not themselves a pandas storage object)

### 35.1.7.9 pandas.HDFStore.walk

`HDFStore.walk(where='/')`

Walk the pytables group hierarchy for pandas objects

This generator will yield the group path, subgroups and pandas object names for each group. Any non-pandas PyTables objects that are not a group will be ignored.

The *where* group itself is listed first (preorder), then each of its child groups (following an alphanumerical order) is also traversed, following the same procedure.

New in version 0.24.0.

#### Parameters

**where** [str, optional] Group where to start walking. If not supplied, the root group is used.

#### Yields

**path** [str] Full path to a group (without trailing '/')

**groups** [list of str] names of the groups contained in *path*

**leaves** [list of str] names of the pandas objects contained in *path*

## 35.1.8 Feather

---

|                                                         |                                                 |
|---------------------------------------------------------|-------------------------------------------------|
| <code>read_feather(path[, columns, use_threads])</code> | Load a feather-format object from the file path |
|---------------------------------------------------------|-------------------------------------------------|

---

### 35.1.8.1 pandas.read\_feather

`pandas.read_feather(path, columns=None, use_threads=True)`

Load a feather-format object from the file path

#### Parameters

**path** [string file path, or file-like object]

**columns** [sequence, default None] If not provided, all columns are read

**nthreads** [int, default 1]

Number of CPU threads to use when reading to pandas.DataFrame

**use\_threads** [bool, default True]

Whether to parallelize reading using multiple threads

#### Returns

type of object stored in file

## 35.1.9 Parquet

---

|                                                    |                                                                  |
|----------------------------------------------------|------------------------------------------------------------------|
| <code>read_parquet(path[, engine, columns])</code> | Load a parquet object from the file path, returning a DataFrame. |
|----------------------------------------------------|------------------------------------------------------------------|

---

### 35.1.9.1 pandas.read\_parquet

`pandas.read_parquet(path, engine='auto', columns=None, **kwargs)`

Load a parquet object from the file path, returning a DataFrame.

#### Parameters

**path** [string] File path

**columns** [list, default=None] If not None, only these columns will be read from the file.

**engine** [{ 'auto', 'pyarrow', 'fastparquet' }, default 'auto'] Parquet library to use. If 'auto', then the option `io.parquet.engine` is used. The default `io.parquet.engine` behavior is to try 'pyarrow', falling back to 'fastparquet' if 'pyarrow' is unavailable.

**kwargs are passed to the engine**

#### Returns

DataFrame

## 35.1.10 SAS

---

|                                                          |                                                                 |
|----------------------------------------------------------|-----------------------------------------------------------------|
| <code>read_sas(filepath_or_buffer[, format, ...])</code> | Read SAS files stored as either XPORT or SAS7BDAT format files. |
|----------------------------------------------------------|-----------------------------------------------------------------|

---

### 35.1.10.1 pandas.read\_sas

`pandas.read_sas(filepath_or_buffer, format=None, index=None, encoding=None, chunksize=None, iterator=False)`

Read SAS files stored as either XPORT or SAS7BDAT format files.

#### Parameters

- filepath\_or\_buffer** [string or file-like object] Path to the SAS file.
- format** [string { 'xport', 'sas7bdat' } or None] If None, file format is inferred from file extension. If 'xport' or 'sas7bdat', uses the corresponding format.
- index** [identifier of index column, defaults to None] Identifier of column that should be used as index of the DataFrame.
- encoding** [string, default is None] Encoding for text data. If None, text data are stored as raw bytes.
- chunksize** [int] Read file *chunksize* lines at a time, returns iterator.
- iterator** [bool, defaults to False] If True, returns an iterator for reading the file incrementally.

#### Returns

**DataFrame if iterator=False and chunksize=None, else SAS7BDATReader or XportReader**

## 35.1.11 SQL

---

|                                                             |                                                    |
|-------------------------------------------------------------|----------------------------------------------------|
| <code>read_sql_table(table_name, con[, schema, ...])</code> | Read SQL database table into a DataFrame.          |
| <code>read_sql_query(sql, con[, index_col, ...])</code>     | Read SQL query into a DataFrame.                   |
| <code>read_sql(sql, con[, index_col, ...])</code>           | Read SQL query or database table into a DataFrame. |

---

### 35.1.11.1 pandas.read\_sql\_table

`pandas.read_sql_table(table_name, con, schema=None, index_col=None, coerce_float=True, parse_dates=None, columns=None, chunksize=None)`

Read SQL database table into a DataFrame.

Given a table name and a SQLAlchemy connectable, returns a DataFrame. This function does not support DBAPI connections.

#### Parameters

- table\_name** [string] Name of SQL table in database.
- con** [SQLAlchemy connectable (or database string URI)] SQLite DBAPI connection mode not supported.
- schema** [string, default None] Name of SQL schema in database to query (if database flavor supports this). Uses default schema if None (default).
- index\_col** [string or list of strings, optional, default: None] Column(s) to set as index(MultiIndex).

**coerce\_float** [boolean, default True] Attempts to convert values of non-string, non-numeric objects (like decimal.Decimal) to floating point. Can result in loss of Precision.

**parse\_dates** [list or dict, default: None]

- List of column names to parse as dates.
- Dict of {column\_name: format string} where format string is strftime compatible in case of parsing string times or is one of (D, s, ns, ms, us) in case of parsing integer timestamps.
- Dict of {column\_name: arg dict}, where the arg dict corresponds to the keyword arguments of `pandas.to_datetime()` Especially useful with databases without native Datetime support, such as SQLite.

**columns** [list, default: None] List of column names to select from SQL table

**chunksize** [int, default None] If specified, returns an iterator where *chunksize* is the number of rows to include in each chunk.

#### Returns

**DataFrame**

See also:

**read\_sql\_query** Read SQL query into a DataFrame.

`read_sql`

#### Notes

Any datetime values with time zone information will be converted to UTC.

#### 35.1.11.2 pandas.read\_sql\_query

`pandas.read_sql_query(sql, con, index_col=None, coerce_float=True, params=None, parse_dates=None, chunksize=None)`

Read SQL query into a DataFrame.

Returns a DataFrame corresponding to the result set of the query string. Optionally provide an *index\_col* parameter to use one of the columns as the index, otherwise default integer index will be used.

#### Parameters

**sql** [string SQL query or SQLAlchemy Selectable (select or text object)] SQL query to be executed.

**con** [SQLAlchemy connectable(engine/connection), database string URI,] or sqlite3 DBAPI2 connection Using SQLAlchemy makes it possible to use any DB supported by that library. If a DBAPI2 object, only sqlite3 is supported.

**index\_col** [string or list of strings, optional, default: None] Column(s) to set as index(MultiIndex).

**coerce\_float** [boolean, default True] Attempts to convert values of non-string, non-numeric objects (like decimal.Decimal) to floating point. Useful for SQL result sets.

**params** [list, tuple or dict, optional, default: None] List of parameters to pass to execute method. The syntax used to pass parameters is database driver dependent. Check your database driver documentation for which of the five syntax styles, described in PEP 249's paramstyle, is supported. Eg. for psycopg2, uses `%(name)s` so use `params={'name': 'value'}`

**parse\_dates** [list or dict, default: None]

- List of column names to parse as dates.
- Dict of {column\_name: format string} where format string is strftime compatible in case of parsing string times, or is one of (D, s, ns, ms, us) in case of parsing integer timestamps.
- Dict of {column\_name: arg dict}, where the arg dict corresponds to the keyword arguments of `pandas.to_datetime()` Especially useful with databases without native Datetime support, such as SQLite.

**chunksize** [int, default None] If specified, return an iterator where *chunksize* is the number of rows to include in each chunk.

#### Returns

**DataFrame**

See also:

**read\_sql\_table** Read SQL database table into a DataFrame.

*read\_sql*

#### Notes

Any datetime values with time zone information parsed via the *parse\_dates* parameter will be converted to UTC.

### 35.1.11.3 pandas.read\_sql

`pandas.read_sql(sql, con, index_col=None, coerce_float=True, params=None, parse_dates=None, columns=None, chunksize=None)`  
Read SQL query or database table into a DataFrame.

This function is a convenience wrapper around `read_sql_table` and `read_sql_query` (for backward compatibility). It will delegate to the specific function depending on the provided input. A SQL query will be routed to `read_sql_query`, while a database table name will be routed to `read_sql_table`. Note that the delegated function might have more specific notes about their functionality not listed here.

#### Parameters

**sql** [string or SQLAlchemy Selectable (select or text object)] SQL query to be executed or a table name.

**con** [SQLAlchemy connectable (engine/connection) or database string URI] or DBAPI2 connection (fallback mode)

Using SQLAlchemy makes it possible to use any DB supported by that library. If a DBAPI2 object, only sqlite3 is supported.

**index\_col** [string or list of strings, optional, default: None] Column(s) to set as index(MultiIndex).

**coerce\_float** [boolean, default True] Attempts to convert values of non-string, non-numeric objects (like decimal.Decimal) to floating point, useful for SQL result sets.

**params** [list, tuple or dict, optional, default: None] List of parameters to pass to execute method. The syntax used to pass parameters is database driver dependent. Check your database driver documentation for which of the five syntax styles, described in PEP 249's paramstyle, is supported. Eg. for psycopg2, uses %(name)s so use params={'name' : 'value'}

**parse\_dates** [list or dict, default: None]

- List of column names to parse as dates.
- Dict of {column\_name: format\_string} where format string is strftime compatible in case of parsing string times, or is one of (D, s, ns, ms, us) in case of parsing integer timestamps.
- Dict of {column\_name: arg dict}, where the arg dict corresponds to the keyword arguments of `pandas.to_datetime()` Especially useful with databases without native Datetime support, such as SQLite.

**columns** [list, default: None] List of column names to select from SQL table (only used when reading a table).

**chunksize** [int, default None] If specified, return an iterator where *chunksize* is the number of rows to include in each chunk.

#### Returns

**DataFrame**

See also:

**`read_sql_table`** Read SQL database table into a DataFrame.

**`read_sql_query`** Read SQL query into a DataFrame.

### 35.1.12 Google BigQuery

---

|                                                            |                                 |
|------------------------------------------------------------|---------------------------------|
| <code>read_gbq(query[, project_id, index_col, ...])</code> | Load data from Google BigQuery. |
|------------------------------------------------------------|---------------------------------|

---

#### 35.1.12.1 pandas.read\_gbq

`pandas.read_gbq(query, project_id=None, index_col=None, col_order=None, reauth=False, auth_local_webserver=False, dialect=None, location=None, configuration=None, credentials=None, private_key=None, verbose=None)`

Load data from Google BigQuery.

This function requires the [pandas-gbq package](#).

See the [How to authenticate with Google BigQuery](#) guide for authentication instructions.

#### Parameters

**query** [str] SQL-Like Query to return data values.

**project\_id** [str, optional] Google BigQuery Account project ID. Optional when available from the environment.

**index\_col** [str, optional] Name of result column to use for index in results DataFrame.

**col\_order** [list(str), optional] List of BigQuery column names in the desired order for results DataFrame.

**reauth** [boolean, default False] Force Google BigQuery to re-authenticate the user. This is useful if multiple accounts are used.

**auth\_local\_webserver** [boolean, default False] Use the [local webserver flow](#) instead of the [console flow](#) when getting user credentials.

*New in version 0.2.0 of pandas-gbq.*

**dialect** [str, default 'legacy'] Note: The default value is changing to 'standard' in a future version.

SQL syntax dialect to use. Value can be one of:

'**legacy**' Use BigQuery's legacy SQL dialect. For more information see [BigQuery Legacy SQL Reference](#).

'**standard**' Use BigQuery's standard SQL, which is compliant with the SQL 2011 standard. For more information see [BigQuery Standard SQL Reference](#).

Changed in version 0.24.0.

**location** [str, optional] Location where the query job should run. See the [BigQuery locations documentation](#) for a list of available locations. The location must match that of any datasets used in the query.

*New in version 0.5.0 of pandas-gbq.*

**configuration** [dict, optional] Query config parameters for job processing. For example:

```
configuration = {'query': {'useQueryCache': False}}
```

For more information see [BigQuery REST API Reference](#).

**credentials** [google.auth.credentials.Credentials, optional] Credentials for accessing Google APIs. Use this parameter to override default credentials, such as to use Compute Engine `google.auth.compute_engine.Credentials` or Service Account `google.oauth2.service_account.Credentials` directly.

*New in version 0.8.0 of pandas-gbq.*

New in version 0.24.0.

**private\_key** [str, deprecated] Deprecated in pandas-gbq version 0.8.0. Use the `credentials` parameter and `google.oauth2.service_account.Credentials.from_service_account_info()` or `google.oauth2.service_account.Credentials.from_service_account_file()` instead.

Service account private key in JSON format. Can be file path or string contents. This is useful for remote server authentication (eg. Jupyter/IPython notebook on remote host).

**verbose** [None, deprecated] Deprecated in pandas-gbq version 0.4.0. Use the [logging module](#) to adjust verbosity instead.

## Returns

**df: DataFrame** DataFrame representing results of query.

See also:

[`pandas\_gbq.read\_gbq`](#) This function in the pandas-gbq library.

[`pandas.DataFrame.to\_gbq`](#) Write a DataFrame to Google BigQuery.

### 35.1.13 STATA

---

|                                                    |                                 |
|----------------------------------------------------|---------------------------------|
| <code>read_stata(filepath_or_buffer[, ...])</code> | Read Stata file into DataFrame. |
|----------------------------------------------------|---------------------------------|

---

#### 35.1.13.1 pandas.read\_stata

`pandas.read_stata(filepath_or_buffer, convert_dates=True, convert_categoricals=True, encoding=None, index_col=None, convert_missing=False, preserve_dtypes=True, columns=None, order_categoricals=True, chunksize=None, iterator=False)`

Read Stata file into DataFrame.

##### Parameters

**filepath\_or\_buffer** [string or file-like object] Path to .dta file or object implementing a binary read() functions.

**convert\_dates** [boolean, defaults to True] Convert date variables to DataFrame time values.

**convert\_categoricals** [boolean, defaults to True] Read value labels and convert columns to Categorical/Factor variables.

**encoding** [string, None or encoding] Encoding used to parse the files. None defaults to latin-1.

**index\_col** [string, optional, default: None] Column to set as index.

**convert\_missing** [boolean, defaults to False] Flag indicating whether to convert missing values to their Stata representations. If False, missing values are replaced with nan. If True, columns containing missing values are returned with object data types and missing values are represented by StataMissingValue objects.

**preserve\_dtypes** [boolean, defaults to True] Preserve Stata datatypes. If False, numeric data are upcast to pandas default types for foreign data (float64 or int64).

**columns** [list or None] Columns to retain. Columns will be returned in the given order. None returns all columns.

**order\_categoricals** [boolean, defaults to True] Flag indicating whether converted categorical data are ordered.

**chunksize** [int, default None] Return StataReader object for iterations, returns chunks with given number of lines.

**iterator** [boolean, default False] Return StataReader object.

##### Returns

**DataFrame or StataReader**

See also:

**pandas.io.stata.StataReader** Low-level reader for Stata data files.

**pandas.DataFrame.to\_stata** Export Stata data files.

##### Examples

Read a Stata dta file:

```
>>> df = pd.read_stata('filename.dta')
```

Read a Stata dta file in 10,000 line chunks:

```
>>> itr = pd.read_stata('filename.dta', chunksize=10000)
>>> for chunk in itr:
...     do_something(chunk)
```

| <code>StataWriter.write_file()</code>      |                                                                                                       |

### 35.1.13.2 pandas.io.stata.StataReader.data

`StataReader.data(**kwargs)`

Reads observations from Stata file, converting them into a dataframe

Deprecated since version This: is a legacy method. Use *read* in new code.

#### Parameters

**convert\_dates** [boolean, defaults to True] Convert date variables to DataFrame time values.

**convert\_categoricals** [boolean, defaults to True] Read value labels and convert columns to Categorical/Factor variables.

**index\_col** [string, optional, default: None] Column to set as index.

**convert\_missing** [boolean, defaults to False] Flag indicating whether to convert missing values to their Stata representations. If False, missing values are replaced with nan. If True, columns containing missing values are returned with object data types and missing values are represented by StataMissingValue objects.

**preserve\_dtypes** [boolean, defaults to True] Preserve Stata datatypes. If False, numeric data are upcast to pandas default types for foreign data (float64 or int64).

**columns** [list or None] Columns to retain. Columns will be returned in the given order. None returns all columns.

**order\_categoricals** [boolean, defaults to True] Flag indicating whether converted categorical data are ordered.

#### Returns

**DataFrame**

### 35.1.13.3 pandas.io.stata.StataReader.data\_label

`StataReader.data_label()`

Returns data label of Stata file

### 35.1.13.4 pandas.io.stata.StataReader.value\_labels

`StataReader.value_labels()`

Returns a dict, associating each variable name a dict, associating each value its corresponding label

### 35.1.13.5 pandas.io.stata.StataReader.variable\_labels

`StataReader.variable_labels()`

Returns variable labels as a dict, associating each variable name with corresponding label

### 35.1.13.6 pandas.io.stata.StataWriter.write\_file

`StataWriter.write_file()`

{{ header }}

## 35.2 General functions

### 35.2.1 Data manipulations

|                                                                |                                                                                                    |
|----------------------------------------------------------------|----------------------------------------------------------------------------------------------------|
| <code>melt(frame[, id_vars, value_vars, var_name, ...])</code> | Unpivots a DataFrame from wide format to long format, optionally leaving identifier variables set. |
| <code>pivot(data[, index, columns, values])</code>             | Return reshaped DataFrame organized by given index / column values.                                |
| <code>pivot_table(data[, values, index, columns, ...])</code>  | Create a spreadsheet-style pivot table as a DataFrame.                                             |
| <code>crosstab(index, columns[, values, rownames, ...])</code> | Compute a simple cross-tabulation of two (or more) factors.                                        |
| <code>cut(x, bins[, right, labels, retbins, ...])</code>       | Bin values into discrete intervals.                                                                |
| <code>qcut(x, q[, labels, retbins, precision, ...])</code>     | Quantile-based discretization function.                                                            |
| <code>merge(left, right[, how, on, left_on, ...])</code>       | Merge DataFrame or named Series objects with a database-style join.                                |
| <code>merge_ordered(left, right[, on, left_on, ...])</code>    | Perform merge with optional filling/interpolation designed for ordered data like time series data. |
| <code>merge_asof(left, right[, on, left_on, ...])</code>       | Perform an asof merge.                                                                             |
| <code>concat(objs[, axis, join, join_axes, ...])</code>        | Concatenate pandas objects along a particular axis with optional set logic along the other axes.   |
| <code>get_dummies(data[, prefix, prefix_sep, ...])</code>      | Convert categorical variable into dummy/indicator variables                                        |
| <code>factorize(values[, sort, order, ...])</code>             | Encode the object as an enumerated type or categorical variable.                                   |
| <code>unique(values)</code>                                    | Hash table-based unique.                                                                           |
| <code>wide_to_long(df, stubnames, i, j[, sep, suffix])</code>  | Wide panel to long format.                                                                         |

#### 35.2.1.1 pandas.melt

`pandas.melt(frame, id_vars=None, value_vars=None, var_name=None, value_name='value', col_level=None)`

Unpivots a DataFrame from wide format to long format, optionally leaving identifier variables set.

This function is useful to massage a DataFrame into a format where one or more columns are identifier variables (*id\_vars*), while all other columns, considered measured variables (*value\_vars*), are “unpivoted” to the row axis, leaving just two non-identifier columns, ‘variable’ and ‘value’.

#### Parameters

**frame** [DataFrame]

**id\_vars** [tuple, list, or ndarray, optional] Column(s) to use as identifier variables.

**value\_vars** [tuple, list, or ndarray, optional] Column(s) to unpivot. If not specified, uses all columns that are not set as *id\_vars*.

**var\_name** [scalar] Name to use for the ‘variable’ column. If None it uses `frame.columns.name` or ‘variable’.

**value\_name** [scalar, default ‘value’] Name to use for the ‘value’ column.

**col\_level** [int or string, optional] If columns are a MultiIndex then use this level to melt.

See also:

`DataFrame.melt`, `pivot_table`, `DataFrame.pivot`

## Examples

```
>>> df = pd.DataFrame({'A': {0: 'a', 1: 'b', 2: 'c'},
...                    'B': {0: 1, 1: 3, 2: 5},
...                    'C': {0: 2, 1: 4, 2: 6}})
>>> df
   A  B  C
0  a  1  2
1  b  3  4
2  c  5  6
```

```
>>> pd.melt(df, id_vars=['A'], value_vars=['B'])
   A variable  value
0  a         B      1
1  b         B      3
2  c         B      5
```

```
>>> pd.melt(df, id_vars=['A'], value_vars=['B', 'C'])
   A variable  value
0  a         B      1
1  b         B      3
2  c         B      5
3  a         C      2
4  b         C      4
5  c         C      6
```

The names of ‘variable’ and ‘value’ columns can be customized:

```
>>> pd.melt(df, id_vars=['A'], value_vars=['B'],
...         var_name='myVarname', value_name='myValname')
   A myVarname  myValname
0  a         B          1
1  b         B          3
2  c         B          5
```

If you have multi-index columns:

```
>>> df.columns = [list('ABC'), list('DEF')]
>>> df
   A  B  C
   D  E  F
0  a  1  2
```

(continues on next page)

(continued from previous page)

```
1  b  3  4
2  c  5  6
```

```
>>> pd.melt(df, col_level=0, id_vars=['A'], value_vars=['B'])
   A variable  value
0  a         B      1
1  b         B      3
2  c         B      5
```

```
>>> pd.melt(df, id_vars=['A', 'D'], value_vars=[('B', 'E')])
   (A, D) variable_0 variable_1  value
0      a         B         E      1
1      b         B         E      3
2      c         B         E      5
```

### 35.2.1.2 pandas.pivot

`pandas.pivot` (*data*, *index=None*, *columns=None*, *values=None*)

Return reshaped DataFrame organized by given index / column values.

Reshape data (produce a “pivot” table) based on column values. Uses unique values from specified *index* / *columns* to form axes of the resulting DataFrame. This function does not support data aggregation, multiple values will result in a MultiIndex in the columns. See the *User Guide* for more on reshaping.

#### Parameters

**data** [DataFrame]

**index** [string or object, optional] Column to use to make new frame’s index. If None, uses existing index.

**columns** [string or object] Column to use to make new frame’s columns.

**values** [string, object or a list of the previous, optional] Column(s) to use for populating new frame’s values. If not specified, all remaining columns will be used and the result will have hierarchically indexed columns.

Changed in version 0.23.0: Also accept list of column names.

#### Returns

**DataFrame** Returns reshaped DataFrame.

#### Raises

**ValueError:** When there are any *index*, *columns* combinations with multiple values.  
*DataFrame.pivot\_table* when you need to aggregate.

See also:

**DataFrame.pivot\_table** Generalization of pivot that can handle duplicate values for one index/column pair.

**DataFrame.unstack** Pivot based on the index values instead of a column.

#### Notes

For finer-tuned control, see hierarchical indexing documentation along with the related *stack/unstack* methods.

## Examples

```
>>> df = pd.DataFrame({'foo': ['one', 'one', 'one', 'two', 'two',
...                             'two'],
...                    'bar': ['A', 'B', 'C', 'A', 'B', 'C'],
...                    'baz': [1, 2, 3, 4, 5, 6],
...                    'zoo': ['x', 'y', 'z', 'q', 'w', 't']})
>>> df
   foo  bar  baz  zoo
0  one   A    1    x
1  one   B    2    y
2  one   C    3    z
3  two   A    4    q
4  two   B    5    w
5  two   C    6    t
```

```
>>> df.pivot(index='foo', columns='bar', values='baz')
bar A    B    C
foo
one 1    2    3
two 4    5    6
```

```
>>> df.pivot(index='foo', columns='bar')['baz']
bar A    B    C
foo
one 1    2    3
two 4    5    6
```

```
>>> df.pivot(index='foo', columns='bar', values=['baz', 'zoo'])
      baz      zoo
bar  A  B  C  A  B  C
foo
one   1  2  3  x  y  z
two   4  5  6  q  w  t
```

A `ValueError` is raised if there are any duplicates.

```
>>> df = pd.DataFrame({"foo": ['one', 'one', 'two', 'two'],
...                    "bar": ['A', 'A', 'B', 'C'],
...                    "baz": [1, 2, 3, 4]})
>>> df
   foo bar  baz
0  one  A    1
1  one  A    2
2  two  B    3
3  two  C    4
```

Notice that the first two rows are the same for our *index* and *columns* arguments.

```
>>> df.pivot(index='foo', columns='bar', values='baz')
Traceback (most recent call last):
...
ValueError: Index contains duplicate entries, cannot reshape
```

### 35.2.1.3 pandas.pivot\_table

`pandas.pivot_table(data, values=None, index=None, columns=None, aggfunc='mean', fill_value=None, margins=False, dropna=True, margins_name='All')`

Create a spreadsheet-style pivot table as a DataFrame. The levels in the pivot table will be stored in MultiIndex objects (hierarchical indexes) on the index and columns of the result DataFrame.

#### Parameters

**data** [DataFrame]

**values** [column to aggregate, optional]

**index** [column, Grouper, array, or list of the previous] If an array is passed, it must be the same length as the data. The list can contain any of the other types (except list). Keys to group by on the pivot table index. If an array is passed, it is being used as the same manner as column values.

**columns** [column, Grouper, array, or list of the previous] If an array is passed, it must be the same length as the data. The list can contain any of the other types (except list). Keys to group by on the pivot table column. If an array is passed, it is being used as the same manner as column values.

**aggfunc** [function, list of functions, dict, default numpy.mean] If list of functions passed, the resulting pivot table will have hierarchical columns whose top level are the function names (inferred from the function objects themselves) If dict is passed, the key is column to aggregate and value is function or list of functions

**fill\_value** [scalar, default None] Value to replace missing values with

**margins** [boolean, default False] Add all row / columns (e.g. for subtotal / grand totals)

**dropna** [boolean, default True] Do not include columns whose entries are all NaN

**margins\_name** [string, default 'All'] Name of the row / column that will contain the totals when margins is True.

#### Returns

**table** [DataFrame]

See also:

**DataFrame.pivot** Pivot without aggregation that can handle non-numeric data.

#### Examples

```
>>> df = pd.DataFrame({"A": ["foo", "foo", "foo", "foo", "foo",
...                           "bar", "bar", "bar", "bar"],
...                    "B": ["one", "one", "one", "two", "two",
...                           "one", "one", "two", "two"],
...                    "C": ["small", "large", "large", "small",
...                           "small", "large", "small", "small",
...                           "large"],
...                    "D": [1, 2, 2, 3, 3, 4, 5, 6, 7],
...                    "E": [2, 4, 5, 5, 6, 6, 8, 9, 9]})
>>> df
   A  B  C  D  E
0  foo one small  1  2
1  foo one large  2  4
```

(continues on next page)

(continued from previous page)

```

2  foo  one  large  2  5
3  foo  two  small  3  5
4  foo  two  small  3  6
5  bar  one  large  4  6
6  bar  one  small  5  8
7  bar  two  small  6  9
8  bar  two  large  7  9

```

This first example aggregates values by taking the sum.

```

>>> table = pivot_table(df, values='D', index=['A', 'B'],
...                      columns=['C'], aggfunc=np.sum)
>>> table
C      large  small
A  B
bar one      4      5
    two      7      6
foo one      4      1
    two    NaN      6

```

We can also fill missing values using the *fill\_value* parameter.

```

>>> table = pivot_table(df, values='D', index=['A', 'B'],
...                      columns=['C'], aggfunc=np.sum, fill_value=0)
>>> table
C      large  small
A  B
bar one      4      5
    two      7      6
foo one      4      1
    two      0      6

```

The next example aggregates by taking the mean across multiple columns.

```

>>> table = pivot_table(df, values=['D', 'E'], index=['A', 'C'],
...                      aggfunc={'D': np.mean,
...                               'E': np.mean})
>>> table
      D      E
      mean  mean
A  C
bar large  5.500000  7.500000
    small  5.500000  8.500000
foo large  2.000000  4.500000
    small  2.333333  4.333333

```

We can also calculate multiple types of aggregations for any given value column.

```

>>> table = pivot_table(df, values=['D', 'E'], index=['A', 'C'],
...                      aggfunc={'D': np.mean,
...                               'E': [min, max, np.mean]})
>>> table
      D      E
      mean max  mean min
A  C
bar large  5.500000  9  7.500000  6

```

(continues on next page)

(continued from previous page)

|     |       |          |   |          |   |
|-----|-------|----------|---|----------|---|
|     | small | 5.500000 | 9 | 8.500000 | 8 |
| foo | large | 2.000000 | 5 | 4.500000 | 4 |
|     | small | 2.333333 | 6 | 4.333333 | 2 |

### 35.2.1.4 pandas.crosstab

`pandas.crosstab` (*index, columns, values=None, rownames=None, colnames=None, aggfunc=None, margins=False, margins\_name='All', dropna=True, normalize=False*)

Compute a simple cross-tabulation of two (or more) factors. By default computes a frequency table of the factors unless an array of values and an aggregation function are passed

#### Parameters

**index** [array-like, Series, or list of arrays/Series] Values to group by in the rows

**columns** [array-like, Series, or list of arrays/Series] Values to group by in the columns

**values** [array-like, optional] Array of values to aggregate according to the factors. Requires *aggfunc* be specified.

**rownames** [sequence, default None] If passed, must match number of row arrays passed

**colnames** [sequence, default None] If passed, must match number of column arrays passed

**aggfunc** [function, optional] If specified, requires *values* be specified as well

**margins** [boolean, default False] Add row/column margins (subtotals)

**margins\_name** [string, default 'All'] Name of the row / column that will contain the totals when margins is True.

New in version 0.21.0.

**dropna** [boolean, default True] Do not include columns whose entries are all NaN

**normalize** [boolean, {'all', 'index', 'columns'}, or {0,1}, default False] Normalize by dividing all values by the sum of values.

- If passed 'all' or *True*, will normalize over all values.
- If passed 'index' will normalize over each row.
- If passed 'columns' will normalize over each column.
- If margins is *True*, will also normalize margin values.

New in version 0.18.1.

#### Returns

**crosstab** [DataFrame]

#### Notes

Any Series passed will have their name attributes used unless row or column names for the cross-tabulation are specified.

Any input passed containing Categorical data will have **all** of its categories included in the cross-tabulation, even if the actual data does not contain any instances of a particular category.

In the event that there aren't overlapping indexes an empty DataFrame will be returned.

## Examples

```
>>> a = np.array(["foo", "foo", "foo", "foo", "bar", "bar",
...              "bar", "bar", "foo", "foo", "foo"], dtype=object)
>>> b = np.array(["one", "one", "one", "two", "one", "one",
...              "one", "two", "two", "two", "one"], dtype=object)
>>> c = np.array(["dull", "dull", "shiny", "dull", "dull", "shiny",
...              "shiny", "dull", "shiny", "shiny", "shiny"],
...              dtype=object)
```

```
>>> pd.crosstab(a, [b, c], rownames=['a'], colnames=['b', 'c'])
... # doctest: +NORMALIZE_WHITESPACE
b   one      two
c   dull shiny dull shiny
a
bar    1      2    1      0
foo    2      2    1      2
```

```
>>> foo = pd.Categorical(['a', 'b'], categories=['a', 'b', 'c'])
>>> bar = pd.Categorical(['d', 'e'], categories=['d', 'e', 'f'])
>>> crosstab(foo, bar) # 'c' and 'f' are not represented in the data,
                       # and will not be shown in the output because
                       # dropna is True by default. Set 'dropna=False'
                       # to preserve categories with no data

... # doctest: +SKIP
col_0  d  e
row_0
a      1  0
b      0  1
```

```
>>> crosstab(foo, bar, dropna=False) # 'c' and 'f' are not represented
                                     # in the data, but they still will be counted
                                     # and shown in the output

... # doctest: +SKIP
col_0  d  e  f
row_0
a      1  0  0
b      0  1  0
c      0  0  0
```

### 35.2.1.5 pandas.cut

`pandas.cut` (*x*, *bins*, *right=True*, *labels=None*, *rebins=False*, *precision=3*, *include\_lowest=False*, *duplicates='raise'*)

Bin values into discrete intervals.

Use *cut* when you need to segment and sort data values into bins. This function is also useful for going from a continuous variable to a categorical variable. For example, *cut* could convert ages to groups of age ranges. Supports binning into an equal number of bins, or a pre-specified array of bins.

#### Parameters

**x** [array-like] The input array to be binned. Must be 1-dimensional.

**bins** [int, sequence of scalars, or pandas.IntervalIndex] The criteria to bin by.

- **int** : Defines the number of equal-width bins in the range of *x*. The range of *x* is extended by .1% on each side to include the minimum and maximum values of *x*.
- **sequence of scalars** : Defines the bin edges allowing for non-uniform width. No extension of the range of *x* is done.
- **IntervalIndex** : Defines the exact bins to be used. Note that IntervalIndex for *bins* must be non-overlapping.

**right** [bool, default True] Indicates whether *bins* includes the rightmost edge or not. If `right == True` (the default), then the *bins* [1, 2, 3, 4] indicate (1,2], (2,3], (3,4]. This argument is ignored when *bins* is an IntervalIndex.

**labels** [array or bool, optional] Specifies the labels for the returned bins. Must be the same length as the resulting bins. If False, returns only integer indicators of the bins. This affects the type of the output container (see below). This argument is ignored when *bins* is an IntervalIndex.

**retbins** [bool, default False] Whether to return the bins or not. Useful when bins is provided as a scalar.

**precision** [int, default 3] The precision at which to store and display the bins labels.

**include\_lowest** [bool, default False] Whether the first interval should be left-inclusive or not.

**duplicates** [{default 'raise', 'drop'}, optional] If bin edges are not unique, raise ValueError or drop non-uniques.

New in version 0.23.0.

### Returns

**out** [pandas.Categorical, Series, or ndarray] An array-like object representing the respective bin for each value of *x*. The type depends on the value of *labels*.

- **True (default)** : returns a Series for Series *x* or a pandas.Categorical for all other inputs. The values stored within are Interval dtype.
- **sequence of scalars** : returns a Series for Series *x* or a pandas.Categorical for all other inputs. The values stored within are whatever the type in the sequence is.
- **False** : returns an ndarray of integers.

**bins** [numpy.ndarray or IntervalIndex.] The computed or specified bins. Only returned when *retbins=True*. For scalar or sequence *bins*, this is an ndarray with the computed bins. If set *duplicates=drop*, *bins* will drop non-unique bin. For an IntervalIndex *bins*, this is equal to *bins*.

### See also:

**qcut** Discretize variable into equal-sized buckets based on rank or based on sample quantiles.

**pandas.Categorical** Array type for storing data that come from a fixed set of values.

**Series** One-dimensional array with axis labels (including time series).

**pandas.IntervalIndex** Immutable Index implementing an ordered, sliceable set.

### Notes

Any NA values will be NA in the result. Out of bounds values will be NA in the resulting Series or pandas.Categorical object.

## Examples

Discretize into three equal-sized bins.

```
>>> pd.cut(np.array([1, 7, 5, 4, 6, 3]), 3)
... # doctest: +ELLIPSIS
[(0.994, 3.0], (5.0, 7.0], (3.0, 5.0], (3.0, 5.0], (5.0, 7.0], ...
Categories (3, interval[float64]): [(0.994, 3.0] < (3.0, 5.0] ...
```

```
>>> pd.cut(np.array([1, 7, 5, 4, 6, 3]), 3, retbins=True)
... # doctest: +ELLIPSIS
[(0.994, 3.0], (5.0, 7.0], (3.0, 5.0], (3.0, 5.0], (5.0, 7.0], ...
Categories (3, interval[float64]): [(0.994, 3.0] < (3.0, 5.0] ...
array([0.994, 3.    , 5.    , 7.    ])
```

Discovers the same bins, but assign them specific labels. Notice that the returned Categorical's categories are *labels* and is ordered.

```
>>> pd.cut(np.array([1, 7, 5, 4, 6, 3]),
...         3, labels=["bad", "medium", "good"])
[bad, good, medium, medium, good, bad]
Categories (3, object): [bad < medium < good]
```

`labels=False` implies you just want the bins back.

```
>>> pd.cut([0, 1, 1, 2], bins=4, labels=False)
array([0, 1, 1, 3])
```

Passing a Series as an input returns a Series with categorical dtype:

```
>>> s = pd.Series(np.array([2, 4, 6, 8, 10]),
...               index=['a', 'b', 'c', 'd', 'e'])
>>> pd.cut(s, 3)
... # doctest: +ELLIPSIS
a    (1.992, 4.667]
b    (1.992, 4.667]
c    (4.667, 7.333]
d    (7.333, 10.0]
e    (7.333, 10.0]
dtype: category
Categories (3, interval[float64]): [(1.992, 4.667] < (4.667, ...
```

Passing a Series as an input returns a Series with mapping value. It is used to map numerically to intervals based on bins.

```
>>> s = pd.Series(np.array([2, 4, 6, 8, 10]),
...               index=['a', 'b', 'c', 'd', 'e'])
>>> pd.cut(s, [0, 2, 4, 6, 8, 10], labels=False, retbins=True, right=False)
... # doctest: +ELLIPSIS
(a    0.0
 b    1.0
 c    2.0
 d    3.0
 e    4.0
 dtype: float64, array([0, 2, 4, 6, 8]))
```

Use `drop` optional when bins is not unique

```
>>> pd.cut(s, [0, 2, 4, 6, 10, 10], labels=False, retbins=True,
...         right=False, duplicates='drop')
... # doctest: +ELLIPSIS
(a    0.0
 b    1.0
 c    2.0
 d    3.0
 e    3.0
 dtype: float64, array([0, 2, 4, 6, 8]))
```

Passing an IntervalIndex for *bins* results in those categories exactly. Notice that values not covered by the IntervalIndex are set to NaN. 0 is to the left of the first bin (which is closed on the right), and 1.5 falls between two bins.

```
>>> bins = pd.IntervalIndex.from_tuples([(0, 1), (2, 3), (4, 5)])
>>> pd.cut([0, 0.5, 1.5, 2.5, 4.5], bins)
[NaN, (0, 1], NaN, (2, 3], (4, 5]]
Categories (3, interval[int64]): [(0, 1] < (2, 3] < (4, 5]]
```

### 35.2.1.6 pandas.qcut

`pandas.qcut(x, q, labels=None, retbins=False, precision=3, duplicates='raise')`

Quantile-based discretization function. Discretize variable into equal-sized buckets based on rank or based on sample quantiles. For example 1000 values for 10 quantiles would produce a Categorical object indicating quantile membership for each data point.

#### Parameters

**x** [1d ndarray or Series]

**q** [integer or array of quantiles] Number of quantiles. 10 for deciles, 4 for quartiles, etc. Alternately array of quantiles, e.g. [0, .25, .5, .75, 1.] for quartiles

**labels** [array or boolean, default None] Used as labels for the resulting bins. Must be of the same length as the resulting bins. If False, return only integer indicators of the bins.

**retbins** [bool, optional] Whether to return the (bins, labels) or not. Can be useful if bins is given as a scalar.

**precision** [int, optional] The precision at which to store and display the bins labels

**duplicates** [{default 'raise', 'drop'}, optional] If bin edges are not unique, raise ValueError or drop non-uniques.

New in version 0.20.0.

#### Returns

**out** [Categorical or Series or array of integers if labels is False] The return type (Categorical or Series) depends on the input: a Series of type category if input is a Series else Categorical. Bins are represented as categories when categorical data is returned.

**bins** [ndarray of floats] Returned only if *retbins* is True.

#### Notes

Out of bounds values will be NA in the resulting Categorical object

## Examples

```
>>> pd.qcut(range(5), 4)
... # doctest: +ELLIPSIS
[(-0.001, 1.0], (-0.001, 1.0], (1.0, 2.0], (2.0, 3.0], (3.0, 4.0]]
Categories (4, interval[float64]): [(-0.001, 1.0] < (1.0, 2.0] ...
```

```
>>> pd.qcut(range(5), 3, labels=["good", "medium", "bad"])
... # doctest: +SKIP
[good, good, medium, bad, bad]
Categories (3, object): [good < medium < bad]
```

```
>>> pd.qcut(range(5), 4, labels=False)
array([0, 0, 1, 2, 3])
```

### 35.2.1.7 pandas.merge

`pandas.merge(left, right, how='inner', on=None, left_on=None, right_on=None, left_index=False, right_index=False, sort=False, suffixes=('_x', '_y'), copy=True, indicator=False, validate=None)`

Merge DataFrame or named Series objects with a database-style join.

The join is done on columns or indexes. If joining columns on columns, the DataFrame indexes *will be ignored*. Otherwise if joining indexes on indexes or indexes on a column or columns, the index will be passed on.

#### Parameters

**left** [DataFrame]

**right** [DataFrame or named Series] Object to merge with.

**how** [{ 'left', 'right', 'outer', 'inner' }, default 'inner'] Type of merge to be performed.

- left: use only keys from left frame, similar to a SQL left outer join; preserve key order.
- right: use only keys from right frame, similar to a SQL right outer join; preserve key order.
- outer: use union of keys from both frames, similar to a SQL full outer join; sort keys lexicographically.
- inner: use intersection of keys from both frames, similar to a SQL inner join; preserve the order of the left keys.

**on** [label or list] Column or index level names to join on. These must be found in both DataFrames. If *on* is None and not merging on indexes then this defaults to the intersection of the columns in both DataFrames.

**left\_on** [label or list, or array-like] Column or index level names to join on in the left DataFrame. Can also be an array or list of arrays of the length of the left DataFrame. These arrays are treated as if they are columns.

**right\_on** [label or list, or array-like] Column or index level names to join on in the right DataFrame. Can also be an array or list of arrays of the length of the right DataFrame. These arrays are treated as if they are columns.

**left\_index** [bool, default False] Use the index from the left DataFrame as the join key(s). If it is a MultiIndex, the number of keys in the other DataFrame (either the index or a number of columns) must match the number of levels.

**right\_index** [bool, default False] Use the index from the right DataFrame as the join key. Same caveats as left\_index.

**sort** [bool, default False] Sort the join keys lexicographically in the result DataFrame. If False, the order of the join keys depends on the join type (how keyword).

**suffixes** [tuple of (str, str), default ('\_x', '\_y')] Suffix to apply to overlapping column names in the left and right side, respectively. To raise an exception on overlapping columns use (False, False).

**copy** [bool, default True] If False, avoid copy if possible.

**indicator** [bool or str, default False] If True, adds a column to output DataFrame called “\_merge” with information on the source of each row. If string, column with information on source of each row will be added to output DataFrame, and column will be named value of string. Information column is Categorical-type and takes on a value of “left\_only” for observations whose merge key only appears in ‘left’ DataFrame, “right\_only” for observations whose merge key only appears in ‘right’ DataFrame, and “both” if the observation’s merge key is found in both.

**validate** [str, optional] If specified, checks if merge is of specified type.

- “one\_to\_one” or “1:1”: check if merge keys are unique in both left and right datasets.
- “one\_to\_many” or “1:m”: check if merge keys are unique in left dataset.
- “many\_to\_one” or “m:1”: check if merge keys are unique in right dataset.
- “many\_to\_many” or “m:m”: allowed, but does not result in checks.

New in version 0.21.0.

## Returns

**DataFrame** A DataFrame of the two merged objects.

See also:

**merge\_ordered** Merge with optional filling/interpolation.

**merge\_asof** Merge on nearest keys.

**DataFrame.join** Similar method using indices.

## Notes

Support for specifying index levels as the *on*, *left\_on*, and *right\_on* parameters was added in version 0.23.0  
Support for merging named Series objects was added in version 0.24.0

## Examples

```
>>> df1 = pd.DataFrame({'lkey': ['foo', 'bar', 'baz', 'foo'],
...                     'value': [1, 2, 3, 5]})
>>> df2 = pd.DataFrame({'rkey': ['foo', 'bar', 'baz', 'foo'],
...                     'value': [5, 6, 7, 8]})
>>> df1
   lkey  value
0   foo      1
1   bar      2
2   baz      3
```

(continues on next page)

(continued from previous page)

```

3   foo      5
>>> df2
   rkey value
0   foo      5
1   bar      6
2   baz      7
3   foo      8

```

Merge df1 and df2 on the lkey and rkey columns. The value columns have the default suffixes, \_x and \_y, appended.

```

>>> df1.merge(df2, left_on='lkey', right_on='rkey')
   lkey  value_x rkey  value_y
0   foo         1   foo         5
1   foo         1   foo         8
2   foo         5   foo         5
3   foo         5   foo         8
4   bar         2   bar         6
5   baz         3   baz         7

```

Merge DataFrames df1 and df2 with specified left and right suffixes appended to any overlapping columns.

```

>>> df1.merge(df2, left_on='lkey', right_on='rkey',
...           suffixes=('_left', '_right'))
   lkey  value_left rkey  value_right
0   foo         1   foo         5
1   foo         1   foo         8
2   foo         5   foo         5
3   foo         5   foo         8
4   bar         2   bar         6
5   baz         3   baz         7

```

Merge DataFrames df1 and df2, but raise an exception if the DataFrames have any overlapping columns.

```

>>> df1.merge(df2, left_on='lkey', right_on='rkey', suffixes=(False, False))
Traceback (most recent call last):
...
ValueError: columns overlap but no suffix specified:
Index(['value'], dtype='object')

```

### 35.2.1.8 pandas.merge\_ordered

`pandas.merge_ordered(left, right, on=None, left_on=None, right_on=None, left_by=None, right_by=None, fill_method=None, suffixes=('_x', '_y'), how='outer')`

Perform merge with optional filling/interpolation designed for ordered data like time series data. Optionally perform group-wise merge (see examples)

#### Parameters

**left** [DataFrame]

**right** [DataFrame]

**on** [label or list] Field names to join on. Must be found in both DataFrames.

**left\_on** [label or list, or array-like] Field names to join on in left DataFrame. Can be a vector or list of vectors of the length of the DataFrame to use a particular vector as the join key

instead of columns

**right\_on** [label or list, or array-like] Field names to join on in right DataFrame or vector/list of vectors per left\_on docs

**left\_by** [column name or list of column names] Group left DataFrame by group columns and merge piece by piece with right DataFrame

**right\_by** [column name or list of column names] Group right DataFrame by group columns and merge piece by piece with left DataFrame

**fill\_method** [{ 'ffill', None }, default None] Interpolation method for data

**suffixes** [2-length sequence (tuple, list, ...)] Suffix to apply to overlapping column names in the left and right side, respectively

**how** [{ 'left', 'right', 'outer', 'inner' }, default 'outer']

- left: use only keys from left frame (SQL: left outer join)
- right: use only keys from right frame (SQL: right outer join)
- outer: use union of keys from both frames (SQL: full outer join)
- inner: use intersection of keys from both frames (SQL: inner join)

New in version 0.19.0.

### Returns

**merged** [DataFrame] The output type will be the same as 'left', if it is a subclass of DataFrame.

### See also:

*merge, merge\_asof*

### Examples

```
>>> A
   key  lvalue group
0    a      1     a
1    c      2     a
2    e      3     a
3    a      1     b
4    c      2     b
5    e      3     b

>>> B
   key  rvalue
0    b      1
1    c      2
2    d      3
```

```
>>> merge_ordered(A, B, fill_method='ffill', left_by='group')
   group key  lvalue  rvalue
0     a  a      1     NaN
1     a  b      1     1.0
2     a  c      2     2.0
3     a  d      2     3.0
4     a  e      3     3.0
5     b  a      1     NaN
6     b  b      1     1.0
7     b  c      2     2.0
8     b  d      2     3.0
9     b  e      3     3.0
```

### 35.2.1.9 pandas.merge\_asof

`pandas.merge_asof` (*left*, *right*, *on=None*, *left\_on=None*, *right\_on=None*, *left\_index=False*, *right\_index=False*, *by=None*, *left\_by=None*, *right\_by=None*, *suffixes=('\_x', '\_y')*, *tolerance=None*, *allow\_exact\_matches=True*, *direction='backward'*)

Perform an asof merge. This is similar to a left-join except that we match on nearest key rather than equal keys.

Both DataFrames must be sorted by the key.

For each row in the left DataFrame:

- A “backward” search selects the last row in the right DataFrame whose ‘on’ key is less than or equal to the left’s key.
- A “forward” search selects the first row in the right DataFrame whose ‘on’ key is greater than or equal to the left’s key.
- A “nearest” search selects the row in the right DataFrame whose ‘on’ key is closest in absolute distance to the left’s key.

The default is “backward” and is compatible in versions below 0.20.0. The direction parameter was added in version 0.20.0 and introduces “forward” and “nearest”.

Optionally match on equivalent keys with ‘by’ before searching with ‘on’.

New in version 0.19.0.

#### Parameters

**left** [DataFrame]

**right** [DataFrame]

**on** [label] Field name to join on. Must be found in both DataFrames. The data MUST be ordered. Furthermore this must be a numeric column, such as datetimelike, integer, or float. On or left\_on/right\_on must be given.

**left\_on** [label] Field name to join on in left DataFrame.

**right\_on** [label] Field name to join on in right DataFrame.

**left\_index** [boolean] Use the index of the left DataFrame as the join key.

New in version 0.19.2.

**right\_index** [boolean] Use the index of the right DataFrame as the join key.

New in version 0.19.2.

**by** [column name or list of column names] Match on these columns before performing merge operation.

**left\_by** [column name] Field names to match on in the left DataFrame.

New in version 0.19.2.

**right\_by** [column name] Field names to match on in the right DataFrame.

New in version 0.19.2.

**suffixes** [2-length sequence (tuple, list, ...)] Suffix to apply to overlapping column names in the left and right side, respectively.

**tolerance** [integer or Timedelta, optional, default None] Select asof tolerance within this range; must be compatible with the merge index.

**allow\_exact\_matches** [boolean, default True]

- If True, allow matching with the same ‘on’ value (i.e. less-than-or-equal-to / greater-than-or-equal-to)
- If False, don’t match the same ‘on’ value (i.e., strictly less-than / strictly greater-than)

**direction** [‘backward’ (default), ‘forward’, or ‘nearest’] Whether to search for prior, subsequent, or closest matches.

New in version 0.20.0.

### Returns

**merged** [DataFrame]

### See also:

*merge, merge\_ordered*

### Examples

```
>>> left = pd.DataFrame({'a': [1, 5, 10], 'left_val': ['a', 'b', 'c']})
>>> left
   a left_val
0  1         a
1  5         b
2 10         c
```

```
>>> right = pd.DataFrame({'a': [1, 2, 3, 6, 7],
...                        'right_val': [1, 2, 3, 6, 7]})
>>> right
   a right_val
0  1          1
1  2          2
2  3          3
3  6          6
4  7          7
```

```
>>> pd.merge_asof(left, right, on='a')
   a left_val right_val
0  1         a         1
1  5         b         3
2 10         c         7
```

```
>>> pd.merge_asof(left, right, on='a', allow_exact_matches=False)
   a left_val right_val
0  1         a      NaN
1  5         b      3.0
2 10         c      7.0
```

```
>>> pd.merge_asof(left, right, on='a', direction='forward')
   a left_val right_val
0  1         a      1.0
1  5         b      6.0
2 10         c      NaN
```

```
>>> pd.merge_asof(left, right, on='a', direction='nearest')
   a left_val right_val
```

(continues on next page)

(continued from previous page)

|   |    |   |   |
|---|----|---|---|
| 0 | 1  | a | 1 |
| 1 | 5  | b | 6 |
| 2 | 10 | c | 7 |

We can use indexed DataFrames as well.

```
>>> left = pd.DataFrame({'left_val': ['a', 'b', 'c']}, index=[1, 5, 10])
>>> left
   left_val
1         a
5         b
10        c
```

```
>>> right = pd.DataFrame({'right_val': [1, 2, 3, 6, 7]},
...                       index=[1, 2, 3, 6, 7])
>>> right
   right_val
1          1
2          2
3          3
6          6
7          7
```

```
>>> pd.merge_asof(left, right, left_index=True, right_index=True)
   left_val right_val
1         a         1
5         b         3
10        c         7
```

Here is a real-world times-series example

```
>>> quotes
      time ticker  bid  ask
0 2016-05-25 13:30:00.023  GOOG  720.50  720.93
1 2016-05-25 13:30:00.023  MSFT   51.95   51.96

### 35.2.1.10 pandas.concat

`pandas.concat` (*objs*, *axis=0*, *join='outer'*, *join\_axes=None*, *ignore\_index=False*, *keys=None*, *levels=None*, *names=None*, *verify\_integrity=False*, *sort=None*, *copy=True*)

Concatenate pandas objects along a particular axis with optional set logic along the other axes.

Can also add a layer of hierarchical indexing on the concatenation axis, which may be useful if the labels are the same (or overlapping) on the passed axis number.

#### Parameters

**objs** [a sequence or mapping of Series, DataFrame, or Panel objects] If a dict is passed, the sorted keys will be used as the *keys* argument, unless it is passed, in which case the values will be selected (see below). Any None objects will be dropped silently unless they are all None in which case a ValueError will be raised

**axis** [{0/'index', 1/'columns'}, default 0] The axis to concatenate along

**join** [{ 'inner', 'outer' }, default 'outer'] How to handle indexes on other axis(es)

**join\_axes** [list of Index objects] Specific indexes to use for the other n - 1 axes instead of performing inner/outer set logic

**ignore\_index** [boolean, default False] If True, do not use the index values along the concatenation axis. The resulting axis will be labeled 0, ..., n - 1. This is useful if you are concatenating objects where the concatenation axis does not have meaningful indexing information. Note the index values on the other axes are still respected in the join.

**keys** [sequence, default None] If multiple levels passed, should contain tuples. Construct hierarchical index using the passed keys as the outermost level

**levels** [list of sequences, default None] Specific levels (unique values) to use for constructing a MultiIndex. Otherwise they will be inferred from the keys

**names** [list, default None] Names for the levels in the resulting hierarchical index

**verify\_integrity** [boolean, default False] Check whether the new concatenated axis contains duplicates. This can be very expensive relative to the actual data concatenation

**sort** [boolean, default None] Sort non-concatenation axis if it is not already aligned when *join* is 'outer'. The current default of sorting is deprecated and will change to not-sorting in a future version of pandas.

Explicitly pass `sort=True` to silence the warning and sort. Explicitly pass `sort=False` to silence the warning and not sort.

This has no effect when `join='inner'`, which already preserves the order of the non-concatenation axis.

New in version 0.23.0.

**copy** [boolean, default True] If False, do not copy data unnecessarily

### Returns

**concatenated** [object, type of objs] When concatenating all *Series* along the index (`axis=0`), a *Series* is returned. When `objs` contains at least one *DataFrame*, a *DataFrame* is returned. When concatenating along the columns (`axis=1`), a *DataFrame* is returned.

### See also:

*Series.append*, *DataFrame.append*, *DataFrame.join*, *DataFrame.merge*

### Notes

The keys, levels, and names arguments are all optional.

A walkthrough of how this method fits in with other tools for combining pandas objects can be found [here](#).

### Examples

Combine two *Series*.

```
>>> s1 = pd.Series(['a', 'b'])
>>> s2 = pd.Series(['c', 'd'])
>>> pd.concat([s1, s2])
0    a
1    b
0    c
1    d
dtype: object
```

Clear the existing index and reset it in the result by setting the `ignore_index` option to True.

```
>>> pd.concat([s1, s2], ignore_index=True)
0    a
1    b
2    c
3    d
dtype: object
```

Add a hierarchical index at the outermost level of the data with the `keys` option.

```
>>> pd.concat([s1, s2], keys=['s1', 's2',])
s1  0    a
    1    b
s2  0    c
    1    d
dtype: object
```

Label the index keys you create with the `names` option.

```
>>> pd.concat([s1, s2], keys=['s1', 's2'],
...           names=['Series name', 'Row ID'])
Series name  Row ID
s1           0      a
            1      b
s2           0      c
            1      d
dtype: object
```

Combine two `DataFrame` objects with identical columns.

```
>>> df1 = pd.DataFrame([[ 'a', 1], [ 'b', 2]],
...                    columns=[ 'letter', 'number'])
>>> df1
  letter  number
0     a       1
1     b       2
>>> df2 = pd.DataFrame([[ 'c', 3], [ 'd', 4]],
...                    columns=[ 'letter', 'number'])
>>> df2
  letter  number
0     c       3
1     d       4
>>> pd.concat([df1, df2])
  letter  number
0     a       1
1     b       2
0     c       3
1     d       4
```

Combine `DataFrame` objects with overlapping columns and return everything. Columns outside the intersection will be filled with `NaN` values.

```
>>> df3 = pd.DataFrame([[ 'c', 3, 'cat'], [ 'd', 4, 'dog']],
...                    columns=[ 'letter', 'number', 'animal'])
>>> df3
  letter  number animal
0     c       3    cat
1     d       4    dog
```

(continues on next page)

(continued from previous page)

```
>>> pd.concat([df1, df3], sort=False)
  letter  number animal
0      a        1   NaN
1      b        2   NaN
0      c        3   cat
1      d        4   dog
```

Combine DataFrame objects with overlapping columns and return only those that are shared by passing `inner` to the `join` keyword argument.

```
>>> pd.concat([df1, df3], join="inner")
  letter  number
0      a        1
1      b        2
0      c        3
1      d        4
```

Combine DataFrame objects horizontally along the x axis by passing in `axis=1`.

```
>>> df4 = pd.DataFrame(['bird', 'polly'], ['monkey', 'george'],
...                     columns=['animal', 'name'])
>>> pd.concat([df1, df4], axis=1)
  letter  number  animal  name
0      a        1   bird  polly
1      b        2  monkey george
```

Prevent the result from including duplicate index values with the `verify_integrity` option.

```
>>> df5 = pd.DataFrame([1], index=['a'])
>>> df5
0
a  1
>>> df6 = pd.DataFrame([2], index=['a'])
>>> df6
0
a  2
>>> pd.concat([df5, df6], verify_integrity=True)
Traceback (most recent call last):
...
ValueError: Indexes have overlapping values: ['a']
```

### 35.2.1.11 pandas.get\_dummies

`pandas.get_dummies` (*data*, *prefix=None*, *prefix\_sep='\_'*, *dummy\_na=False*, *columns=None*, *sparse=False*, *drop\_first=False*, *dtype=None*)

Convert categorical variable into dummy/indicator variables

#### Parameters

**data** [array-like, Series, or DataFrame]

**prefix** [string, list of strings, or dict of strings, default None] String to append DataFrame column names. Pass a list with length equal to the number of columns when calling `get_dummies` on a DataFrame. Alternatively, *prefix* can be a dictionary mapping column names to prefixes.

**prefix\_sep** [string, default '\_'] If appending prefix, separator/delimiter to use. Or pass a list or dictionary as with *prefix*.

**dummy\_na** [bool, default False] Add a column to indicate NaNs, if False NaNs are ignored.

**columns** [list-like, default None] Column names in the DataFrame to be encoded. If *columns* is None then all the columns with *object* or *category* dtype will be converted.

**sparse** [bool, default False] Whether the dummy-encoded columns should be backed by a *SparseArray* (True) or a regular NumPy array (False).

**drop\_first** [bool, default False] Whether to get k-1 dummies out of k categorical levels by removing the first level.

New in version 0.18.0.

**dtype** [dtype, default np.uint8] Data type for new columns. Only a single dtype is allowed.

New in version 0.23.0.

### Returns

**dummies** [DataFrame]

### See also:

*Series.str.get\_dummies*

### Examples

```
>>> s = pd.Series(list('abca'))
```

```
>>> pd.get_dummies(s)
   a  b  c
0  1  0  0
1  0  1  0
2  0  0  1
3  1  0  0
```

```
>>> s1 = ['a', 'b', np.nan]
```

```
>>> pd.get_dummies(s1)
   a  b
0  1  0
1  0  1
2  0  0
```

```
>>> pd.get_dummies(s1, dummy_na=True)
   a  b  NaN
0  1  0    0
1  0  1    0
2  0  0    1
```

```
>>> df = pd.DataFrame({'A': ['a', 'b', 'a'], 'B': ['b', 'a', 'c'],
...                    'C': [1, 2, 3]})
```

```
>>> pd.get_dummies(df, prefix=['col1', 'col2'])
   C  col1_a  col1_b  col2_a  col2_b  col2_c
0  1         1         0         0         1         0
1  2         0         1         1         0         0
2  3         1         0         0         0         1
```

```
>>> pd.get_dummies(pd.Series(list('abcaa'))
   a  b  c
0  1  0  0
1  0  1  0
2  0  0  1
3  1  0  0
4  1  0  0
```

```
>>> pd.get_dummies(pd.Series(list('abcaa')), drop_first=True)
   b  c
0  0  0
1  1  0
2  0  1
3  0  0
4  0  0
```

```
>>> pd.get_dummies(pd.Series(list('abc')), dtype=float)
   a  b  c
0  1.0  0.0  0.0
1  0.0  1.0  0.0
2  0.0  0.0  1.0
```

### 35.2.1.12 pandas.factorize

pandas.**factorize** (*values*, *sort=False*, *order=None*, *na\_sentinel=-1*, *size\_hint=None*)

Encode the object as an enumerated type or categorical variable.

This method is useful for obtaining a numeric representation of an array when all that matters is identifying distinct values. *factorize* is available as both a top-level function *pandas.factorize()*, and as a method *Series.factorize()* and *Index.factorize()*.

#### Parameters

- values** [sequence] A 1-D sequence. Sequences that aren't pandas objects are coerced to ndarrays before factorization.
- sort** [bool, default False] Sort *uniques* and shuffle *labels* to maintain the relationship.
- order** Deprecated since version 0.23.0: This parameter has no effect and is deprecated.
- na\_sentinel** [int, default -1] Value to mark “not found”.
- size\_hint** [int, optional] Hint to the hashtable sizer.

#### Returns

- labels** [ndarray] An integer ndarray that's an indexer into *uniques*. *uniques.take(labels)* will have the same values as *values*.
- uniques** [ndarray, Index, or Categorical] The unique valid values. When *values* is Categorical, *uniques* is a Categorical. When *values* is some other pandas object, an *Index* is returned. Otherwise, a 1-D ndarray is returned.

---

**Note:** Even if there's a missing value in *values*, *uniques* will *not* contain an entry for it.

---

See also:

**cut** Discretize continuous-valued array.

**unique** Find the unique value in an array.

## Examples

These examples all show `factorize` as a top-level method like `pd.factorize(values)`. The results are identical for methods like `Series.factorize()`.

```
>>> labels, uniques = pd.factorize(['b', 'b', 'a', 'c', 'b'])
>>> labels
array([0, 0, 1, 2, 0])
>>> uniques
array(['b', 'a', 'c'], dtype=object)
```

With `sort=True`, the *uniques* will be sorted, and *labels* will be shuffled so that the relationship is the maintained.

```
>>> labels, uniques = pd.factorize(['b', 'b', 'a', 'c', 'b'], sort=True)
>>> labels
array([1, 1, 0, 2, 1])
>>> uniques
array(['a', 'b', 'c'], dtype=object)
```

Missing values are indicated in *labels* with *na\_sentinel* (-1 by default). Note that missing values are never included in *uniques*.

```
>>> labels, uniques = pd.factorize(['b', None, 'a', 'c', 'b'])
>>> labels
array([ 0, -1,  1,  2,  0])
>>> uniques
array(['b', 'a', 'c'], dtype=object)
```

Thus far, we've only factorized lists (which are internally coerced to NumPy arrays). When factorizing pandas objects, the type of *uniques* will differ. For Categoricals, a *Categorical* is returned.

```
>>> cat = pd.Categorical(['a', 'a', 'c'], categories=['a', 'b', 'c'])
>>> labels, uniques = pd.factorize(cat)
>>> labels
array([0, 0, 1])
>>> uniques
[a, c]
Categories (3, object): [a, b, c]
```

Notice that 'b' is in `uniques.categories`, despite not being present in `cat.values`.

For all other pandas objects, an Index of the appropriate type is returned.

```
>>> cat = pd.Series(['a', 'a', 'c'])
>>> labels, uniques = pd.factorize(cat)
>>> labels
```

(continues on next page)

(continued from previous page)

```
array([0, 0, 1])
>>> uniques
Index(['a', 'c'], dtype='object')
```

### 35.2.1.13 pandas.unique

pandas.**unique** (*values*)

Hash table-based unique. Uniques are returned in order of appearance. This does NOT sort.

Significantly faster than numpy.unique. Includes NA values.

#### Parameters

**values** [1d array-like]

#### Returns

**unique values.**

- If the input is an Index, the return is an Index
- If the input is a Categorical dtype, the return is a Categorical
- If the input is a Series/ndarray, the return will be an ndarray

See also:

*pandas.Index.unique, pandas.Series.unique*

#### Examples

```
>>> pd.unique(pd.Series([2, 1, 3, 3]))
array([2, 1, 3])
```

```
>>> pd.unique(pd.Series([2] + [1] * 5))
array([2, 1])
```

```
>>> pd.unique(pd.Series([pd.Timestamp('20160101'),
...                      pd.Timestamp('20160101')]))
array(['2016-01-01T00:00:00.000000000', dtype='datetime64[ns]')
```

```
>>> pd.unique(pd.Series([pd.Timestamp('20160101', tz='US/Eastern'),
...                      pd.Timestamp('20160101', tz='US/Eastern')]))
array([Timestamp('2016-01-01 00:00:00-0500', tz='US/Eastern')],
      dtype=object)
```

```
>>> pd.unique(pd.Index([pd.Timestamp('20160101', tz='US/Eastern'),
...                     pd.Timestamp('20160101', tz='US/Eastern')]))
DatetimeIndex(['2016-01-01 00:00:00-05:00'],
...           dtype='datetime64[ns, US/Eastern]', freq=None)
```

```
>>> pd.unique(list('baabc'))
array(['b', 'a', 'c'], dtype=object)
```

An unordered Categorical will return categories in the order of appearance.

```
>>> pd.unique(pd.Series(pd.Categorical(list('baabc'))))
[b, a, c]
Categories (3, object): [b, a, c]
```

```
>>> pd.unique(pd.Series(pd.Categorical(list('baabc'),
...                                   categories=list('abc'))))
[b, a, c]
Categories (3, object): [b, a, c]
```

An ordered Categorical preserves the category ordering.

```
>>> pd.unique(pd.Series(pd.Categorical(list('baabc'),
...                                   categories=list('abc'),
...                                   ordered=True)))
[b, a, c]
Categories (3, object): [a < b < c]
```

An array of tuples

```
>>> pd.unique([('a', 'b'), ('b', 'a'), ('a', 'c'), ('b', 'a')])
array([('a', 'b'), ('b', 'a'), ('a', 'c')], dtype=object)
```

### 35.2.1.14 pandas.wide\_to\_long

`pandas.wide_to_long(df, stubnames, i, j, sep=",", suffix="\d+")`

Wide panel to long format. Less flexible but more user-friendly than melt.

With stubnames ['A', 'B'], this function expects to find one or more group of columns with format A-suffix1, A-suffix2,..., B-suffix1, B-suffix2,... You specify what you want to call this suffix in the resulting long format with *j* (for example *j*='year')

Each row of these wide variables are assumed to be uniquely identified by *i* (can be a single column name or a list of column names)

All remaining variables in the data frame are left intact.

#### Parameters

**df** [DataFrame] The wide-format DataFrame

**stubnames** [str or list-like] The stub name(s). The wide format variables are assumed to start with the stub names.

**i** [str or list-like] Column(s) to use as id variable(s)

**j** [str] The name of the sub-observation variable. What you wish to name your suffix in the long format.

**sep** [str, default "-"] A character indicating the separation of the variable names in the wide format, to be stripped from the names in the long format. For example, if your column names are A-suffix1, A-suffix2, you can strip the hyphen by specifying *sep*='\_'

New in version 0.20.0.

**suffix** [str, default '\d+'] A regular expression capturing the wanted suffixes. '\d+' captures numeric suffixes. Suffixes with no numbers could be specified with the negated character class '\D+'. You can also further disambiguate suffixes, for example, if your wide variables are of the form A-one, B-two,..., and you have an unrelated column A-rating, you can ignore the last one by specifying *suffix*='(!?one|two)'

New in version 0.20.0.

Changed in version 0.23.0: When all suffixes are numeric, they are cast to int64/float64.

### Returns

**DataFrame** A DataFrame that contains each stub name as a variable, with new index (i, j)

### Notes

All extra variables are left untouched. This simply uses *pandas.melt* under the hood, but is hard-coded to “do the right thing” in a typical case.

### Examples

```
>>> np.random.seed(123)
>>> df = pd.DataFrame({"A1970" : {0 : "a", 1 : "b", 2 : "c"},
...                    "A1980" : {0 : "d", 1 : "e", 2 : "f"},
...                    "B1970" : {0 : 2.5, 1 : 1.2, 2 : .7},
...                    "B1980" : {0 : 3.2, 1 : 1.3, 2 : .1},
...                    "X"      : dict(zip(range(3), np.random.randn(3)))
...                    })
>>> df["id"] = df.index
>>> df
   A1970 A1980  B1970  B1980         X  id
0      a      d    2.5    3.2 -1.085631  0
1      b      e    1.2    1.3  0.997345  1
2      c      f    0.7    0.1  0.282978  2
>>> pd.wide_to_long(df, ["A", "B"], i="id", j="year")
... # doctest: +NORMALIZE_WHITESPACE
      X  A      B
id year
0  1970 -1.085631  a  2.5
1  1970  0.997345  b  1.2
2  1970  0.282978  c  0.7
0  1980 -1.085631  d  3.2
1  1980  0.997345  e  1.3
2  1980  0.282978  f  0.1
```

### With multiple id columns

```
>>> df = pd.DataFrame({
...     'famid': [1, 1, 1, 2, 2, 2, 3, 3, 3],
...     'birth': [1, 2, 3, 1, 2, 3, 1, 2, 3],
...     'ht1': [2.8, 2.9, 2.2, 2, 1.8, 1.9, 2.2, 2.3, 2.1],
...     'ht2': [3.4, 3.8, 2.9, 3.2, 2.8, 2.4, 3.3, 3.4, 2.9]
... })
>>> df
   birth  famid  ht1  ht2
0      1      1  2.8  3.4
1      2      1  2.9  3.8
2      3      1  2.2  2.9
3      1      2  2.0  3.2
4      2      2  1.8  2.8
5      3      2  1.9  2.4
6      1      3  2.2  3.3
```

(continues on next page)

(continued from previous page)

```

7      2      3  2.3  3.4
8      3      3  2.1  2.9
>>> l = pd.wide_to_long(df, stubnames='ht', i=['famid', 'birth'], j='age')
>>> l
... # doctest: +NORMALIZE_WHITESPACE
      ht
famid birth age
1      1      1  2.8
      2      2  3.4
      2      1  2.9
      2      2  3.8
      3      1  2.2
      2      2  2.9
2      1      1  2.0
      2      2  3.2
      2      1  1.8
      2      2  2.8
      3      1  1.9
      2      2  2.4
3      1      1  2.2
      2      2  3.3
      2      1  2.3
      2      2  3.4
      3      1  2.1
      2      2  2.9

```

Going from long back to wide just takes some creative use of *unstack*

```

>>> w = l.unstack()
>>> w.columns = w.columns.map('{0[0]}{0[1]}'.format)
>>> w.reset_index()
      famid  birth  ht1  ht2
0         1      1  2.8  3.4
1         1      2  2.9  3.8
2         1      3  2.2  2.9
3         2      1  2.0  3.2
4         2      2  1.8  2.8
5         2      3  1.9  2.4
6         3      1  2.2  3.3
7         3      2  2.3  3.4
8         3      3  2.1  2.9

```

Less wildy column names are also handled

```

>>> np.random.seed(0)
>>> df = pd.DataFrame({'A(quarterly)-2010': np.random.rand(3),
...                   'A(quarterly)-2011': np.random.rand(3),
...                   'B(quarterly)-2010': np.random.rand(3),
...                   'B(quarterly)-2011': np.random.rand(3),
...                   'X' : np.random.randint(3, size=3)})
>>> df['id'] = df.index
>>> df # doctest: +NORMALIZE_WHITESPACE, +ELLIPSIS
      A(quarterly)-2010  A(quarterly)-2011  B(quarterly)-2010  ...
0         0.548814         0.544883         0.437587  ...
1         0.715189         0.423655         0.891773  ...
2         0.602763         0.645894         0.963663  ...
X      id

```

(continues on next page)

(continued from previous page)

```
0 0 0
1 1 1
2 1 2
```

```
>>> pd.wide_to_long(df, ['A(quarterly)', 'B(quarterly)'], i='id',
...                  j='year', sep='-')
... # doctest: +NORMALIZE_WHITESPACE
      X  A(quarterly)  B(quarterly)
id year
0  2010  0          0.548814      0.437587
1  2010  1          0.715189      0.891773
2  2010  1          0.602763      0.963663
0  2011  0          0.544883      0.383442
1  2011  1          0.423655      0.791725
2  2011  1          0.645894      0.528895
```

If we have many columns, we could also use a regex to find our stubnames and pass that list on to `wide_to_long`

```
>>> stubnames = sorted(
...     set([match[0] for match in df.columns.str.findall(
...         r'[A-B]\(.*\)').values if match != [] ]))
... )
>>> list(stubnames)
['A(quarterly)', 'B(quarterly)']
```

All of the above examples have integers as suffixes. It is possible to have non-integers as suffixes.

```
>>> df = pd.DataFrame({
...     'famid': [1, 1, 1, 2, 2, 2, 3, 3, 3],
...     'birth': [1, 2, 3, 1, 2, 3, 1, 2, 3],
...     'ht_one': [2.8, 2.9, 2.2, 2, 1.8, 1.9, 2.2, 2.3, 2.1],
...     'ht_two': [3.4, 3.8, 2.9, 3.2, 2.8, 2.4, 3.3, 3.4, 2.9]
... })
>>> df
   birth  famid  ht_one  ht_two
0      1      1     2.8     3.4
1      2      1     2.9     3.8
2      3      1     2.2     2.9
3      1      2     2.0     3.2
4      2      2     1.8     2.8
5      3      2     1.9     2.4
6      1      3     2.2     3.3
7      2      3     2.3     3.4
8      3      3     2.1     2.9
```

```
>>> l = pd.wide_to_long(df, stubnames='ht', i=['famid', 'birth'], j='age',
...                      sep='_', suffix='\w')
>>> l
... # doctest: +NORMALIZE_WHITESPACE
      ht
famid birth age
1      1     one 2.8
      2     two 3.4
      2     one 2.9
      3     two 3.8
      3     one 2.2
```

### 35.2.2 Top-level missing data

|                      |                                                     |
|----------------------|-----------------------------------------------------|
| <i>isna</i> (obj)    | Detect missing values for an array-like object.     |
| <i>isnull</i> (obj)  | Detect missing values for an array-like object.     |
| <i>notna</i> (obj)   | Detect non-missing values for an array-like object. |
| <i>notnull</i> (obj) | Detect non-missing values for an array-like object. |

#### 35.2.2.1 pandas.isna

pandas.**isna** (obj)

Detect missing values for an array-like object.

This function takes a scalar or array-like object and indicates whether values are missing (NaN in numeric arrays, None or NaN in object arrays, NaT in datetimelike).

##### Parameters

**obj** [scalar or array-like] Object to check for null or missing values.

##### Returns

**bool or array-like of bool** For scalar input, returns a scalar boolean. For array input, returns an array of boolean indicating whether each corresponding element is missing.

See also:

**notna** Boolean inverse of pandas.isna.

**Series.isna** Detect missing values in a Series.

**DataFrame.isna** Detect missing values in a DataFrame.

**Index.isna** Detect missing values in an Index.

#### Examples

Scalar arguments (including strings) result in a scalar boolean.

```
>>> pd.isna('dog')
False
```

```
>>> pd.isna(np.nan)
True
```

ndarrays result in an ndarray of booleans.

```
>>> array = np.array([[1, np.nan, 3], [4, 5, np.nan]])
>>> array
array([[ 1., nan,  3.],
       [ 4.,  5., nan]])
>>> pd.isna(array)
array([[False,  True, False],
       [False, False,  True]])
```

For indexes, an ndarray of booleans is returned.

```
>>> index = pd.DatetimeIndex(["2017-07-05", "2017-07-06", None,
...                           "2017-07-08"])
>>> index
DatetimeIndex(['2017-07-05', '2017-07-06', 'NaT', '2017-07-08'],
              dtype='datetime64[ns]', freq=None)
>>> pd.isna(index)
array([False, False,  True, False])
```

For Series and DataFrame, the same type is returned, containing booleans.

```
>>> df = pd.DataFrame([['ant', 'bee', 'cat'], ['dog', None, 'fly']])
>>> df
   0    1    2
0  ant  bee  cat
1  dog None  fly
>>> pd.isna(df)
   0    1    2
0  False False False
1  False  True False
```

```
>>> pd.isna(df[1])
0    False
1     True
Name: 1, dtype: bool
```

### 35.2.2.2 pandas.isnull

`pandas.isnull(obj)`

Detect missing values for an array-like object.

This function takes a scalar or array-like object and indicates whether values are missing (NaN in numeric arrays, None or NaT in object arrays, NaT in datetimelike).

#### Parameters

**obj** [scalar or array-like] Object to check for null or missing values.

#### Returns

**bool or array-like of bool** For scalar input, returns a scalar boolean. For array input, returns an array of boolean indicating whether each corresponding element is missing.

See also:

**notna** Boolean inverse of pandas.isna.

**Series.isna** Detect missing values in a Series.

**DataFrame.isna** Detect missing values in a DataFrame.

**Index.isna** Detect missing values in an Index.

## Examples

Scalar arguments (including strings) result in a scalar boolean.

```
>>> pd.isna('dog')
False
```

```
>>> pd.isna(np.nan)
True
```

ndarrays result in an ndarray of booleans.

```
>>> array = np.array([[1, np.nan, 3], [4, 5, np.nan]])
>>> array
array([[ 1., nan,  3.],
       [ 4.,  5., nan]])
>>> pd.isna(array)
array([[False,  True, False],
       [False, False,  True]])
```

For indexes, an ndarray of booleans is returned.

```
>>> index = pd.DatetimeIndex(["2017-07-05", "2017-07-06", None,
...                           "2017-07-08"])
>>> index
DatetimeIndex(['2017-07-05', '2017-07-06', 'NaT', '2017-07-08'],
              dtype='datetime64[ns]', freq=None)
>>> pd.isna(index)
array([False, False,  True, False])
```

For Series and DataFrame, the same type is returned, containing booleans.

```
>>> df = pd.DataFrame(['ant', 'bee', 'cat'], ['dog', None, 'fly'])
>>> df
   0    1    2
0 ant  bee cat
1 dog None fly
>>> pd.isna(df)
   0    1    2
0 False False False
1 False  True False
```

```
>>> pd.isna(df[1])
0    False
1     True
Name: 1, dtype: bool
```

### 35.2.2.3 pandas.notna

pandas.**notna** (*obj*)

Detect non-missing values for an array-like object.

This function takes a scalar or array-like object and indicates whether values are valid (not missing, which is NaN in numeric arrays, None or NaT in object arrays, NaT in datetimelike).

#### Parameters

**obj** [array-like or object value] Object to check for *not* null or *non*-missing values.

#### Returns

**bool or array-like of bool** For scalar input, returns a scalar boolean. For array input, returns an array of boolean indicating whether each corresponding element is valid.

See also:

**isna** Boolean inverse of pandas.notna.

**Series.notna** Detect valid values in a Series.

**DataFrame.notna** Detect valid values in a DataFrame.

**Index.notna** Detect valid values in an Index.

### Examples

Scalar arguments (including strings) result in a scalar boolean.

```
>>> pd.notna('dog')
True
```

```
>>> pd.notna(np.nan)
False
```

ndarrays result in an ndarray of booleans.

```
>>> array = np.array([[1, np.nan, 3], [4, 5, np.nan]])
>>> array
array([[ 1., nan,  3.],
       [ 4.,  5., nan]])
>>> pd.notna(array)
array([[ True, False,  True],
       [ True,  True, False]])
```

For indexes, an ndarray of booleans is returned.

```
>>> index = pd.DatetimeIndex(["2017-07-05", "2017-07-06", None,
...                           "2017-07-08"])
>>> index
DatetimeIndex(['2017-07-05', '2017-07-06', 'NaT', '2017-07-08'],
              dtype='datetime64[ns]', freq=None)
>>> pd.notna(index)
array([ True,  True, False,  True])
```

For Series and DataFrame, the same type is returned, containing booleans.

```
>>> df = pd.DataFrame(['ant', 'bee', 'cat'], ['dog', None, 'fly'])
>>> df
   0    1    2
0  ant  bee  cat
1  dog None fly
>>> pd.notna(df)
   0    1    2
0  True  True  True
1  True False  True
```

```
>>> pd.notna(df[1])
0    True
1   False
Name: 1, dtype: bool
```

### 35.2.2.4 pandas.notnull

pandas.**notnull** (*obj*)

Detect non-missing values for an array-like object.

This function takes a scalar or array-like object and indicates whether values are valid (not missing, which is NaN in numeric arrays, None or NaN in object arrays, NaT in datetimelike).

#### Parameters

**obj** [array-like or object value] Object to check for *not* null or *non*-missing values.

#### Returns

**bool or array-like of bool** For scalar input, returns a scalar boolean. For array input, returns an array of boolean indicating whether each corresponding element is valid.

**See also:**

**isna** Boolean inverse of pandas.notna.

**Series.notna** Detect valid values in a Series.

**DataFrame.notna** Detect valid values in a DataFrame.

**Index.notna** Detect valid values in an Index.

### Examples

Scalar arguments (including strings) result in a scalar boolean.

```
>>> pd.notna('dog')
True
```

```
>>> pd.notna(np.nan)
False
```

ndarrays result in an ndarray of booleans.

```
>>> array = np.array([[1, np.nan, 3], [4, 5, np.nan]])
>>> array
array([[ 1., nan,  3.],
       [ 4.,  5., nan]])
>>> pd.notna(array)
array([[ True, False,  True],
       [ True,  True, False]])
```

For indexes, an ndarray of booleans is returned.

```
>>> index = pd.DatetimeIndex(["2017-07-05", "2017-07-06", None,
...                           "2017-07-08"])
>>> index
DatetimeIndex(['2017-07-05', '2017-07-06', 'NaT', '2017-07-08'],
              dtype='datetime64[ns]', freq=None)
>>> pd.notna(index)
array([ True,  True, False,  True])
```

For Series and DataFrame, the same type is returned, containing booleans.

```
>>> df = pd.DataFrame(['ant', 'bee', 'cat'], ['dog', None, 'fly'])
>>> df
   0    1    2
0 ant  bee cat
1 dog None fly
>>> pd.notna(df)
   0    1    2
0 True True True
1 True False True
```

```
>>> pd.notna(df[1])
0    True
1   False
Name: 1, dtype: bool
```

### 35.2.3 Top-level conversions

`to_numeric(arg[, errors, downcast])`

Convert argument to a numeric type.

#### 35.2.3.1 pandas.to\_numeric

`pandas.to_numeric(arg, errors='raise', downcast=None)`

Convert argument to a numeric type.

The default return dtype is *float64* or *int64* depending on the data supplied. Use the *downcast* parameter to obtain other dtypes.

##### Parameters

**arg** [list, tuple, 1-d array, or Series]

**errors** [{‘ignore’, ‘raise’, ‘coerce’}, default ‘raise’]

- If ‘raise’, then invalid parsing will raise an exception
- If ‘coerce’, then invalid parsing will be set as NaN

- If 'ignore', then invalid parsing will return the input

**downcast** [{ 'integer', 'signed', 'unsigned', 'float' }, default None] If not None, and if the data has been successfully cast to a numerical dtype (or if the data was numeric to begin with), downcast that resulting data to the smallest numerical dtype possible according to the following rules:

- 'integer' or 'signed': smallest signed int dtype (min.: np.int8)
- 'unsigned': smallest unsigned int dtype (min.: np.uint8)
- 'float': smallest float dtype (min.: np.float32)

As this behaviour is separate from the core conversion to numeric values, any errors raised during the downcasting will be surfaced regardless of the value of the 'errors' input.

In addition, downcasting will only occur if the size of the resulting data's dtype is strictly larger than the dtype it is to be cast to, so if none of the dtypes checked satisfy that specification, no downcasting will be performed on the data.

New in version 0.19.0.

### Returns

**ret** [numeric if parsing succeeded.] Return type depends on input. Series if Series, otherwise ndarray

See also:

**pandas.DataFrame.astype** Cast argument to a specified dtype.

**pandas.to\_datetime** Convert argument to datetime.

**pandas.to\_timedelta** Convert argument to timedelta.

**numpy.ndarray.astype** Cast a numpy array to a specified type.

### Examples

Take separate series and convert to numeric, coercing when told to

```
>>> s = pd.Series(['1.0', '2', -3])
>>> pd.to_numeric(s)
0    1.0
1    2.0
2   -3.0
dtype: float64
>>> pd.to_numeric(s, downcast='float')
0    1.0
1    2.0
2   -3.0
dtype: float32
>>> pd.to_numeric(s, downcast='signed')
0     1
1     2
2    -3
dtype: int8
>>> s = pd.Series(['apple', '1.0', '2', -3])
>>> pd.to_numeric(s, errors='ignore')
0    apple
1     1.0
```

(continues on next page)

(continued from previous page)

```

2      2
3     -3
dtype: object
>>> pd.to_numeric(s, errors='coerce')
0      NaN
1      1.0
2      2.0
3     -3.0
dtype: float64

```

### 35.2.4 Top-level dealing with datetimelike

|                                                                |                                                                                    |
|----------------------------------------------------------------|------------------------------------------------------------------------------------|
| <code>to_datetime(arg[, errors, dayfirst, ...])</code>         | Convert argument to datetime.                                                      |
| <code>to_timedelta(arg[, unit, box, errors])</code>            | Convert argument to timedelta.                                                     |
| <code>date_range([start, end, periods, freq, tz, ...])</code>  | Return a fixed frequency DatetimeIndex.                                            |
| <code>bdate_range([start, end, periods, freq, tz, ...])</code> | Return a fixed frequency DatetimeIndex, with business day as the default frequency |
| <code>period_range([start, end, periods, freq, name])</code>   | Return a fixed frequency PeriodIndex, with day (calendar) as the default frequency |
| <code>timedelta_range([start, end, periods, freq, ...])</code> | Return a fixed frequency TimedeltaIndex, with day as the default frequency         |
| <code>infer_freq(index[, warn])</code>                         | Infer the most likely frequency given the input index.                             |

#### 35.2.4.1 pandas.to\_datetime

`pandas.to_datetime` (*arg*, *errors*='raise', *dayfirst*=False, *yearfirst*=False, *utc*=None, *box*=True, *format*=None, *exact*=True, *unit*=None, *infer\_datetime\_format*=False, *origin*='unix', *cache*=False)

Convert argument to datetime.

##### Parameters

**arg** [integer, float, string, datetime, list, tuple, 1-d array, Series] New in version 0.18.1: or DataFrame/dict-like

**errors** [{ 'ignore', 'raise', 'coerce' }, default 'raise']

- If 'raise', then invalid parsing will raise an exception
- If 'coerce', then invalid parsing will be set as NaT
- If 'ignore', then invalid parsing will return the input

**dayfirst** [boolean, default False] Specify a date parse order if *arg* is str or its list-likes. If True, parses dates with the day first, eg 10/11/12 is parsed as 2012-11-10. Warning: *dayfirst*=True is not strict, but will prefer to parse with day first (this is a known bug, based on dateutil behavior).

**yearfirst** [boolean, default False] Specify a date parse order if *arg* is str or its list-likes.

- If True parses dates with the year first, eg 10/11/12 is parsed as 2010-11-12.
- If both *dayfirst* and *yearfirst* are True, *yearfirst* is preceded (same as dateutil).

Warning: *yearfirst*=True is not strict, but will prefer to parse with year first (this is a known bug, based on dateutil behavior).

New in version 0.16.1.

**utc** [boolean, default None] Return UTC DatetimeIndex if True (converting any tz-aware datetime.datetime objects as well).

**box** [boolean, default True]

- If True returns a DatetimeIndex or Index-like object
- If False returns ndarray of values.

**format** [string, default None] strftime to parse time, eg “%d/%m/%Y”, note that “%f” will parse all the way up to nanoseconds.

**exact** [boolean, True by default]

- If True, require an exact format match.
- If False, allow the format to match anywhere in the target string.

**unit** [string, default ‘ns’] unit of the arg (D,s,ms,us,ns) denote the unit, which is an integer or float number. This will be based off the origin. Example, with unit=‘ms’ and origin=‘unix’ (the default), this would calculate the number of milliseconds to the unix epoch start.

**infer\_datetime\_format** [boolean, default False] If True and no *format* is given, attempt to infer the format of the datetime strings, and if it can be inferred, switch to a faster method of parsing them. In some cases this can increase the parsing speed by ~5-10x.

**origin** [scalar, default is ‘unix’] Define the reference date. The numeric values would be parsed as number of units (defined by *unit*) since this reference date.

- If ‘unix’ (or POSIX) time; origin is set to 1970-01-01.
- If ‘julian’, unit must be ‘D’, and origin is set to beginning of Julian Calendar. Julian day number 0 is assigned to the day starting at noon on January 1, 4713 BC.
- If Timestamp convertible, origin is set to Timestamp identified by origin.

New in version 0.20.0.

**cache** [boolean, default False] If True, use a cache of unique, converted dates to apply the datetime conversion. May produce significant speed-up when parsing duplicate date strings, especially ones with timezone offsets.

New in version 0.23.0.

## Returns

**ret** [datetime if parsing succeeded.] Return type depends on input:

- list-like: DatetimeIndex
- Series: Series of datetime64 dtype
- scalar: Timestamp

In case when it is not possible to return designated types (e.g. when any element of input is before Timestamp.min or after Timestamp.max) return will have datetime.datetime type (or corresponding array/Series).

See also:

**pandas.DataFrame.astype** Cast argument to a specified dtype.

**pandas.to\_timedelta** Convert argument to timedelta.

## Examples

Assembling a datetime from multiple columns of a DataFrame. The keys can be common abbreviations like ['year', 'month', 'day', 'minute', 'second', 'ms', 'us', 'ns']) or plurals of the same

```
>>> df = pd.DataFrame({'year': [2015, 2016],
                        'month': [2, 3],
                        'day': [4, 5]})
>>> pd.to_datetime(df)
0    2015-02-04
1    2016-03-05
dtype: datetime64[ns]
```

If a date does not meet the [timestamp limitations](#), passing errors='ignore' will return the original input instead of raising any exception.

Passing errors='coerce' will force an out-of-bounds date to NaT, in addition to forcing non-dates (or non-parseable dates) to NaT.

```
>>> pd.to_datetime('13000101', format='%Y%m%d', errors='ignore')
datetime.datetime(1300, 1, 1, 0, 0)
>>> pd.to_datetime('13000101', format='%Y%m%d', errors='coerce')
NaT
```

Passing infer\_datetime\_format=True can often-times speedup a parsing if its not an ISO8601 format exactly, but in a regular format.

```
>>> s = pd.Series(['3/11/2000', '3/12/2000', '3/13/2000']*1000)
```

```
>>> s.head()
0    3/11/2000
1    3/12/2000
2    3/13/2000
3    3/11/2000
4    3/12/2000
dtype: object
```

```
>>> %timeit pd.to_datetime(s,infer_datetime_format=True)
100 loops, best of 3: 10.4 ms per loop
```

```
>>> %timeit pd.to_datetime(s,infer_datetime_format=False)
1 loop, best of 3: 471 ms per loop
```

Using a unix epoch time

```
>>> pd.to_datetime(1490195805, unit='s')
Timestamp('2017-03-22 15:16:45')
>>> pd.to_datetime(1490195805433502912, unit='ns')
Timestamp('2017-03-22 15:16:45.433502912')
```

**Warning:** For float arg, precision rounding might happen. To prevent unexpected behavior use a fixed-width exact type.

Using a non-unix epoch origin

```
>>> pd.to_datetime([1, 2, 3], unit='D',
                    origin=pd.Timestamp('1960-01-01'))
0    1960-01-02
1    1960-01-03
2    1960-01-04
```

### 35.2.4.2 pandas.to\_timedelta

pandas.**to\_timedelta** (*arg*, *unit*='ns', *box*=True, *errors*='raise')

Convert argument to timedelta.

Timedeltas are absolute differences in times, expressed in difference units (e.g. days, hours, minutes, seconds). This method converts an argument from a recognized timedelta format / value into a Timedelta type.

#### Parameters

**arg** [str, timedelta, list-like or Series] The data to be converted to timedelta.

**unit** [str, default 'ns'] Denotes the unit of the arg. Possible values: ('Y', 'M', 'W', 'D', 'days', 'day', 'hours', 'hour', 'hr', 'h', 'm', 'minute', 'min', 'minutes', 'T', 'S', 'seconds', 'sec', 'second', 'ms', 'milliseconds', 'millisecond', 'milli', 'millis', 'L', 'us', 'microseconds', 'microsecond', 'micro', 'micros', 'U', 'ns', 'nanoseconds', 'nano', 'nanos', 'nanosecond', 'N').

**box** [bool, default True]

- If True returns a Timedelta/TimedeltaIndex of the results.
- If False returns a numpy.timedelta64 or numpy.darray of values of dtype timedelta64[ns].

**errors** [{ 'ignore', 'raise', 'coerce' }, default 'raise']

- If 'raise', then invalid parsing will raise an exception.
- If 'coerce', then invalid parsing will be set as NaT.
- If 'ignore', then invalid parsing will return the input.

#### Returns

**timedelta64 or numpy.array of timedelta64** Output type returned if parsing succeeded.

See also:

**DataFrame.astype** Cast argument to a specified dtype.

**to\_datetime** Convert argument to datetime.

### Examples

Parsing a single string to a Timedelta:

```
>>> pd.to_timedelta('1 days 06:05:01.00003')
Timedelta('1 days 06:05:01.000030')
>>> pd.to_timedelta('15.5us')
Timedelta('0 days 00:00:00.000015')
```

Parsing a list or array of strings:

```
>>> pd.to_timedelta(['1 days 06:05:01.00003', '15.5us', 'nan'])
TimedeltaIndex(['1 days 06:05:01.000030', '0 days 00:00:00.000015', NaT],
               dtype='timedelta64[ns]', freq=None)
```

Converting numbers by specifying the *unit* keyword argument:

```
>>> pd.to_timedelta(np.arange(5), unit='s')
TimedeltaIndex(['00:00:00', '00:00:01', '00:00:02',
               '00:00:03', '00:00:04'],
               dtype='timedelta64[ns]', freq=None)
>>> pd.to_timedelta(np.arange(5), unit='d')
TimedeltaIndex(['0 days', '1 days', '2 days', '3 days', '4 days'],
               dtype='timedelta64[ns]', freq=None)
```

Returning an ndarray by using the ‘box’ keyword argument:

```
>>> pd.to_timedelta(np.arange(5), box=False)
array([0, 1, 2, 3, 4], dtype='timedelta64[ns]')
```

### 35.2.4.3 pandas.date\_range

`pandas.date_range` (*start=None, end=None, periods=None, freq=None, tz=None, normalize=False, name=None, closed=None, \*\*kwargs*)

Return a fixed frequency DatetimeIndex.

#### Parameters

**start** [str or datetime-like, optional] Left bound for generating dates.

**end** [str or datetime-like, optional] Right bound for generating dates.

**periods** [integer, optional] Number of periods to generate.

**freq** [str or DateOffset, default ‘D’] Frequency strings can have multiples, e.g. ‘5H’. See *here* for a list of frequency aliases.

**tz** [str or tzinfo, optional] Time zone name for returning localized DatetimeIndex, for example ‘Asia/Hong\_Kong’. By default, the resulting DatetimeIndex is timezone-naive.

**normalize** [bool, default False] Normalize start/end dates to midnight before generating date range.

**name** [str, default None] Name of the resulting DatetimeIndex.

**closed** [{None, ‘left’, ‘right’}, optional] Make the interval closed with respect to the given frequency to the ‘left’, ‘right’, or both sides (None, the default).

**\*\*kwargs** For compatibility. Has no effect on the result.

#### Returns

**rng** [DatetimeIndex]

See also:

**pandas.DatetimeIndex** An immutable container for datetimes.

**pandas.timedelta\_range** Return a fixed frequency TimedeltaIndex.

**pandas.period\_range** Return a fixed frequency PeriodIndex.

**pandas.interval\_range** Return a fixed frequency IntervalIndex.

## Notes

Of the four parameters `start`, `end`, `periods`, and `freq`, exactly three must be specified. If `freq` is omitted, the resulting `DatetimeIndex` will have periods linearly spaced elements between `start` and `end` (closed on both sides).

To learn more about the frequency strings, please see [this link](#).

## Examples

### Specifying the values

The next four examples generate the same `DatetimeIndex`, but vary the combination of `start`, `end` and `periods`.

Specify `start` and `end`, with the default daily frequency.

```
>>> pd.date_range(start='1/1/2018', end='1/08/2018')
DatetimeIndex(['2018-01-01', '2018-01-02', '2018-01-03', '2018-01-04',
              '2018-01-05', '2018-01-06', '2018-01-07', '2018-01-08'],
              dtype='datetime64[ns]', freq='D')
```

Specify `start` and `periods`, the number of periods (days).

```
>>> pd.date_range(start='1/1/2018', periods=8)
DatetimeIndex(['2018-01-01', '2018-01-02', '2018-01-03', '2018-01-04',
              '2018-01-05', '2018-01-06', '2018-01-07', '2018-01-08'],
              dtype='datetime64[ns]', freq='D')
```

Specify `end` and `periods`, the number of periods (days).

```
>>> pd.date_range(end='1/1/2018', periods=8)
DatetimeIndex(['2017-12-25', '2017-12-26', '2017-12-27', '2017-12-28',
              '2017-12-29', '2017-12-30', '2017-12-31', '2018-01-01'],
              dtype='datetime64[ns]', freq='D')
```

Specify `start`, `end`, and `periods`; the frequency is generated automatically (linearly spaced).

```
>>> pd.date_range(start='2018-04-24', end='2018-04-27', periods=3)
DatetimeIndex(['2018-04-24 00:00:00', '2018-04-25 12:00:00',
              '2018-04-27 00:00:00'],
              dtype='datetime64[ns]', freq=None)
```

### Other Parameters

Changed the `freq` (frequency) to 'M' (month end frequency).

```
>>> pd.date_range(start='1/1/2018', periods=5, freq='M')
DatetimeIndex(['2018-01-31', '2018-02-28', '2018-03-31', '2018-04-30',
              '2018-05-31'],
              dtype='datetime64[ns]', freq='M')
```

Multiples are allowed

```
>>> pd.date_range(start='1/1/2018', periods=5, freq='3M')
DatetimeIndex(['2018-01-31', '2018-04-30', '2018-07-31', '2018-10-31',
              '2019-01-31'],
              dtype='datetime64[ns]', freq='3M')
```

*freq* can also be specified as an Offset object.

```
>>> pd.date_range(start='1/1/2018', periods=5, freq=pd.offsets.MonthEnd(3))
DatetimeIndex(['2018-01-31', '2018-04-30', '2018-07-31', '2018-10-31',
              '2019-01-31'],
              dtype='datetime64[ns]', freq='3M')
```

Specify *tz* to set the timezone.

```
>>> pd.date_range(start='1/1/2018', periods=5, tz='Asia/Tokyo')
DatetimeIndex(['2018-01-01 00:00:00+09:00', '2018-01-02 00:00:00+09:00',
              '2018-01-03 00:00:00+09:00', '2018-01-04 00:00:00+09:00',
              '2018-01-05 00:00:00+09:00'],
              dtype='datetime64[ns, Asia/Tokyo]', freq='D')
```

*closed* controls whether to include *start* and *end* that are on the boundary. The default includes boundary points on either end.

```
>>> pd.date_range(start='2017-01-01', end='2017-01-04', closed=None)
DatetimeIndex(['2017-01-01', '2017-01-02', '2017-01-03', '2017-01-04'],
              dtype='datetime64[ns]', freq='D')
```

Use *closed='left'* to exclude *end* if it falls on the boundary.

```
>>> pd.date_range(start='2017-01-01', end='2017-01-04', closed='left')
DatetimeIndex(['2017-01-01', '2017-01-02', '2017-01-03'],
              dtype='datetime64[ns]', freq='D')
```

Use *closed='right'* to exclude *start* if it falls on the boundary.

```
>>> pd.date_range(start='2017-01-01', end='2017-01-04', closed='right')
DatetimeIndex(['2017-01-02', '2017-01-03', '2017-01-04'],
              dtype='datetime64[ns]', freq='D')
```

#### 35.2.4.4 pandas.bdate\_range

`pandas.bdate_range` (*start=None, end=None, periods=None, freq='B', tz=None, normalize=True, name=None, weekmask=None, holidays=None, closed=None, \*\*kwargs*)

Return a fixed frequency DatetimeIndex, with business day as the default frequency

##### Parameters

**start** [string or datetime-like, default None] Left bound for generating dates.

**end** [string or datetime-like, default None] Right bound for generating dates.

**periods** [integer, default None] Number of periods to generate.

**freq** [string or DateOffset, default 'B' (business daily)] Frequency strings can have multiples, e.g. '5H'.

**tz** [string or None] Time zone name for returning localized DatetimeIndex, for example Asia/Beijing.

**normalize** [bool, default False] Normalize start/end dates to midnight before generating date range.

**name** [string, default None] Name of the resulting DatetimeIndex.

**weekmask** [string or None, default None] Weekmask of valid business days, passed to `numpy.busdaycalendar`, only used when custom frequency strings are passed. The default value None is equivalent to 'Mon Tue Wed Thu Fri'.

New in version 0.21.0.

**holidays** [list-like or None, default None] Dates to exclude from the set of valid business days, passed to `numpy.busdaycalendar`, only used when custom frequency strings are passed.

New in version 0.21.0.

**closed** [string, default None] Make the interval closed with respect to the given frequency to the 'left', 'right', or both sides (None).

**\*\*kwargs** For compatibility. Has no effect on the result.

#### Returns

**DatetimeIndex**

#### Notes

Of the four parameters: `start`, `end`, `periods`, and `freq`, exactly three must be specified. Specifying `freq` is a requirement for `bdate_range`. Use `date_range` if specifying `freq` is not desired.

To learn more about the frequency strings, please see [this link](#).

#### Examples

Note how the two weekend days are skipped in the result.

```
>>> pd.bdate_range(start='1/1/2018', end='1/08/2018')
DatetimeIndex(['2018-01-01', '2018-01-02', '2018-01-03', '2018-01-04',
               '2018-01-05', '2018-01-08'],
              dtype='datetime64[ns]', freq='B')
```

### 35.2.4.5 pandas.period\_range

`pandas.period_range` (*start=None, end=None, periods=None, freq=None, name=None*)

Return a fixed frequency PeriodIndex, with day (calendar) as the default frequency

#### Parameters

**start** [string or period-like, default None] Left bound for generating periods

**end** [string or period-like, default None] Right bound for generating periods

**periods** [integer, default None] Number of periods to generate

**freq** [string or DateOffset, optional] Frequency alias. By default the freq is taken from `start` or `end` if those are Period objects. Otherwise, the default is "D" for daily frequency.

**name** [string, default None] Name of the resulting PeriodIndex

#### Returns

**prng** [PeriodIndex]

## Notes

Of the three parameters: `start`, `end`, and `periods`, exactly two must be specified.

To learn more about the frequency strings, please see [this link](#).

## Examples

```
>>> pd.period_range(start='2017-01-01', end='2018-01-01', freq='M')
PeriodIndex(['2017-01', '2017-02', '2017-03', '2017-04', '2017-05',
            '2017-06', '2017-06', '2017-07', '2017-08', '2017-09',
            '2017-10', '2017-11', '2017-12', '2018-01'],
            dtype='period[M]', freq='M')
```

If `start` or `end` are `Period` objects, they will be used as anchor endpoints for a `PeriodIndex` with frequency matching that of the `period_range` constructor.

```
>>> pd.period_range(start=pd.Period('2017Q1', freq='Q'),
...                 end=pd.Period('2017Q2', freq='Q'), freq='M')
PeriodIndex(['2017-03', '2017-04', '2017-05', '2017-06'],
            dtype='period[M]', freq='M')
```

### 35.2.4.6 pandas.timedelta\_range

`pandas.timedelta_range` (*start=None, end=None, periods=None, freq=None, name=None, closed=None*)

Return a fixed frequency `TimedeltaIndex`, with day as the default frequency

#### Parameters

- start** [string or timedelta-like, default None] Left bound for generating timesteps
- end** [string or timedelta-like, default None] Right bound for generating timesteps
- periods** [integer, default None] Number of periods to generate
- freq** [string or DateOffset, default 'D'] Frequency strings can have multiples, e.g. '5H'
- name** [string, default None] Name of the resulting `TimedeltaIndex`
- closed** [string, default None] Make the interval closed with respect to the given frequency to the 'left', 'right', or both sides (None)

#### Returns

**rng** [`TimedeltaIndex`]

## Notes

Of the four parameters `start`, `end`, `periods`, and `freq`, exactly three must be specified. If `freq` is omitted, the resulting `TimedeltaIndex` will have periods linearly spaced elements between `start` and `end` (closed on both sides).

To learn more about the frequency strings, please see [this link](#).

## Examples

```
>>> pd.timedelta_range(start='1 day', periods=4)
TimedeltaIndex(['1 days', '2 days', '3 days', '4 days'],
                dtype='timedelta64[ns]', freq='D')
```

The `closed` parameter specifies which endpoint is included. The default behavior is to include both endpoints.

```
>>> pd.timedelta_range(start='1 day', periods=4, closed='right')
TimedeltaIndex(['2 days', '3 days', '4 days'],
                dtype='timedelta64[ns]', freq='D')
```

The `freq` parameter specifies the frequency of the `TimedeltaIndex`. Only fixed frequencies can be passed, non-fixed frequencies such as 'M' (month end) will raise.

```
>>> pd.timedelta_range(start='1 day', end='2 days', freq='6H')
TimedeltaIndex(['1 days 00:00:00', '1 days 06:00:00', '1 days 12:00:00',
                '1 days 18:00:00', '2 days 00:00:00'],
                dtype='timedelta64[ns]', freq='6H')
```

Specify start, end, and periods; the frequency is generated automatically (linearly spaced).

```
>>> pd.timedelta_range(start='1 day', end='5 days', periods=4)
TimedeltaIndex(['1 days 00:00:00', '2 days 08:00:00', '3 days 16:00:00',
                '5 days 00:00:00'],
                dtype='timedelta64[ns]', freq=None)
```

### 35.2.4.7 pandas.infer\_freq

`pandas.infer_freq(index, warn=True)`

Infer the most likely frequency given the input index. If the frequency is uncertain, a warning will be printed.

#### Parameters

**index** [DatetimeIndex or TimedeltaIndex] if passed a Series will use the values of the series (NOT THE INDEX)

**warn** [boolean, default True]

#### Returns

**freq** [string or None] None if no discernible frequency `TypeError` if the index is not datetime-like `ValueError` if there are less than three values.

## 35.2.5 Top-level dealing with intervals

---

`interval_range([start, end, periods, freq, ...])`      Return a fixed frequency `IntervalIndex`

---

### 35.2.5.1 pandas.interval\_range

`pandas.interval_range(start=None, end=None, periods=None, freq=None, name=None, closed='right')`

Return a fixed frequency `IntervalIndex`

#### Parameters

**start** [numeric or datetime-like, default None] Left bound for generating intervals

**end** [numeric or datetime-like, default None] Right bound for generating intervals

**periods** [integer, default None] Number of periods to generate

**freq** [numeric, string, or DateOffset, default None] The length of each interval. Must be consistent with the type of start and end, e.g. 2 for numeric, or '5H' for datetime-like. Default is 1 for numeric and 'D' for datetime-like.

**name** [string, default None] Name of the resulting IntervalIndex

**closed** [{ 'left', 'right', 'both', 'neither' }, default 'right'] Whether the intervals are closed on the left-side, right-side, both or neither.

**Returns**

**rng** [IntervalIndex]

**See also:**

**IntervalIndex** An Index of intervals that are all closed on the same side.

**Notes**

Of the four parameters `start`, `end`, `periods`, and `freq`, exactly three must be specified. If `freq` is omitted, the resulting `IntervalIndex` will have periods linearly spaced elements between `start` and `end`, inclusively.

To learn more about datetime-like frequency strings, please see [this link](#).

**Examples**

Numeric start and end is supported.

```
>>> pd.interval_range(start=0, end=5)
IntervalIndex([(0, 1], (1, 2], (2, 3], (3, 4], (4, 5]]
              closed='right', dtype='interval[int64]')
```

Additionally, datetime-like input is also supported.

```
>>> pd.interval_range(start=pd.Timestamp('2017-01-01'),
                      end=pd.Timestamp('2017-01-04'))
IntervalIndex([(2017-01-01, 2017-01-02], (2017-01-02, 2017-01-03],
              (2017-01-03, 2017-01-04]]
              closed='right', dtype='interval[datetime64[ns]]')
```

The `freq` parameter specifies the frequency between the left and right endpoints of the individual intervals within the `IntervalIndex`. For numeric start and end, the frequency must also be numeric.

```
>>> pd.interval_range(start=0, periods=4, freq=1.5)
IntervalIndex([(0.0, 1.5], (1.5, 3.0], (3.0, 4.5], (4.5, 6.0]]
              closed='right', dtype='interval[float64]')
```

Similarly, for datetime-like start and end, the frequency must be convertible to a `DateOffset`.

```
>>> pd.interval_range(start=pd.Timestamp('2017-01-01'),
                      periods=3, freq='MS')
IntervalIndex([(2017-01-01, 2017-02-01], (2017-02-01, 2017-03-01],
              (2017-03-01, 2017-04-01]]
              closed='right', dtype='interval[datetime64[ns]]')
```

Specify start, end, and periods; the frequency is generated automatically (linearly spaced).

```
>>> pd.interval_range(start=0, end=6, periods=4)
IntervalIndex([(0.0, 1.5], (1.5, 3.0], (3.0, 4.5], (4.5, 6.0]]
              closed='right',
              dtype='interval[float64]')
```

The `closed` parameter specifies which endpoints of the individual intervals within the `IntervalIndex` are closed.

```
>>> pd.interval_range(end=5, periods=4, closed='both')
IntervalIndex([[1, 2], [2, 3], [3, 4], [4, 5]]
              closed='both', dtype='interval[int64]')
```

## 35.2.6 Top-level evaluation

`eval(expr[, parser, engine, truediv, ...])`

Evaluate a Python expression as a string using various backends.

---

### 35.2.6.1 pandas.eval

`pandas.eval(expr, parser='pandas', engine=None, truediv=True, local_dict=None, global_dict=None, resolvers=(), level=0, target=None, inplace=False)`  
Evaluate a Python expression as a string using various backends.

The following arithmetic operations are supported: `+`, `-`, `*`, `/`, `**`, `%`, `//` (python engine only) along with the following boolean operations: `|` (or), `&` (and), and `~` (not). Additionally, the 'pandas' parser allows the use of `and`, `or`, and `not` with the same semantics as the corresponding bitwise operators. *Series* and *DataFrame* objects are supported and behave as they would with plain ol' Python evaluation.

#### Parameters

**expr** [str or unicode] The expression to evaluate. This string cannot contain any Python *statements*, only Python *expressions*.

**parser** [string, default 'pandas', {'pandas', 'python'}] The parser to use to construct the syntax tree from the expression. The default of 'pandas' parses code slightly different than standard Python. Alternatively, you can parse an expression using the 'python' parser to retain strict Python semantics. See the *enhancing performance* documentation for more details.

**engine** [string or None, default 'numexpr', {'python', 'numexpr'}] The engine used to evaluate the expression. Supported engines are

- `None` : tries to use `numexpr`, falls back to `python`
- **'numexpr'** : This default engine evaluates pandas objects using `numexpr` for large speed ups in complex expressions with large frames.

- **'python'**: Performs operations as if you had `eval`'d in top level python. This engine is generally not that useful.

More backends may be available in the future.

**truediv** [bool, optional] Whether to use true division, like in Python  $\geq 3$

**local\_dict** [dict or None, optional] A dictionary of local variables, taken from `locals()` by default.

**global\_dict** [dict or None, optional] A dictionary of global variables, taken from `globals()` by default.

**resolvers** [list of dict-like or None, optional] A list of objects implementing the `__getitem__` special method that you can use to inject an additional collection of namespaces to use for variable lookup. For example, this is used in the `query()` method to inject the `DataFrame.index` and `DataFrame.columns` variables that refer to their respective `DataFrame` instance attributes.

**level** [int, optional] The number of prior stack frames to traverse and add to the current scope. Most users will **not** need to change this parameter.

**target** [object, optional, default None] This is the target object for assignment. It is used when there is variable assignment in the expression. If so, then *target* must support item assignment with string keys, and if a copy is being returned, it must also support `.copy()`.

**inplace** [bool, default False] If *target* is provided, and the expression mutates *target*, whether to modify *target* inplace. Otherwise, return a copy of *target* with the mutation.

#### Returns

**ndarray, numeric scalar, DataFrame, Series**

#### Raises

**ValueError** There are many instances where such an error can be raised:

- *target=None*, but the expression is multiline.
- The expression is multiline, but not all them have item assignment. An example of such an arrangement is this:

```
a = b + 1 a + 2
```

Here, there are expressions on different lines, making it multiline, but the last line has no variable assigned to the output of `a + 2`.

- *inplace=True*, but the expression is missing item assignment.
- Item assignment is provided, but the *target* does not support string item assignment.
- Item assignment is provided and *inplace=False*, but the *target* does not support the `.copy()` method

#### See also:

`pandas.DataFrame.query`, `pandas.DataFrame.eval`

#### Notes

The `dtype` of any objects involved in an arithmetic `%` operation are recursively cast to `float64`.

See the *enhancing performance* documentation for more details.

## 35.2.7 Hashing

|                                                               |                                                              |
|---------------------------------------------------------------|--------------------------------------------------------------|
| <code>util.hash_array(vals[, encoding, hash_key, ...])</code> | Given a 1d array, return an array of deterministic integers. |
| <code>util.hash_pandas_object(obj[, index, ...])</code>       | Return a data hash of the Index/Series/DataFrame             |

---

### 35.2.7.1 pandas.util.hash\_array

`pandas.util.hash_array(vals, encoding='utf8', hash_key=None, categorize=True)`

Given a 1d array, return an array of deterministic integers.

New in version 0.19.2.

#### Parameters

**vals** [ndarray, Categorical]

**encoding** [string, default 'utf8'] encoding for data & key when strings

**hash\_key** [string key to encode, default to `_default_hash_key`]

**categorize** [bool, default True] Whether to first categorize object arrays before hashing. This is more efficient when the array contains duplicate values.

New in version 0.20.0.

#### Returns

1d uint64 numpy array of hash values, same length as the vals

### 35.2.7.2 pandas.util.hash\_pandas\_object

`pandas.util.hash_pandas_object(obj, index=True, encoding='utf8', hash_key=None, categorize=True)`

Return a data hash of the Index/Series/DataFrame

New in version 0.19.2.

#### Parameters

**index** [boolean, default True] include the index in the hash (if Series/DataFrame)

**encoding** [string, default 'utf8'] encoding for data & key when strings

**hash\_key** [string key to encode, default to `_default_hash_key`]

**categorize** [bool, default True] Whether to first categorize object arrays before hashing. This is more efficient when the array contains duplicate values.

New in version 0.20.0.

#### Returns

Series of uint64, same length as the object

## 35.2.8 Testing

|                                 |
|---------------------------------|
| <code>test([extra_args])</code> |
|---------------------------------|

---

35.2.8.1 pandas.test

pandas.test (extra\_args=None)  
{ { header } }

35.3 Series

35.3.1 Constructor

|                                               |                                                                   |
|-----------------------------------------------|-------------------------------------------------------------------|
| Series([data, index, dtype, name, copy, ...]) | One-dimensional ndarray with axis labels (including time series). |
|-----------------------------------------------|-------------------------------------------------------------------|

35.3.1.1 pandas.Series

**class** pandas.Series (data=None, index=None, dtype=None, name=None, copy=False, fast-path=False)  
One-dimensional ndarray with axis labels (including time series).

Labels need not be unique but must be a hashable type. The object supports both integer- and label-based indexing and provides a host of methods for performing operations involving the index. Statistical methods from ndarray have been overridden to automatically exclude missing data (currently represented as NaN).

Operations between Series (+, -, /, \*) align values based on their associated index values– they need not be the same length. The result index will be the sorted union of the two indexes.

Parameters

- data** [array-like, Iterable, dict, or scalar value] Contains data stored in Series.  
Changed in version 0.23.0: If data is a dict, argument order is maintained for Python 3.6 and later.
- index** [array-like or Index (1d)] Values must be hashable and have the same length as data. Non-unique index values are allowed. Will default to RangeIndex (0, 1, 2, ..., n) if not provided. If both a dict and index sequence are used, the index will override the keys found in the dict.
- dtype** [str, numpy.dtype, or ExtensionDtype, optional] dtype for the output Series. If not specified, this will be inferred from data. See the user guide for more usages.
- copy** [bool, default False] Copy input data.

Attributes

|          |                                                                        |
|----------|------------------------------------------------------------------------|
| T        | Return the transpose, which is by definition self.                     |
| array    | The ExtensionArray of the data backing this Series or Index.           |
| asobject | Return object Series which contains boxed values.                      |
| at       | Access a single value for a row/column label pair.                     |
| axes     | Return a list of the row axis labels.                                  |
| base     | Return the base object if the memory of the underlying data is shared. |

Continued on next page

Table 26 – continued from previous page

|                                |                                                                                 |
|--------------------------------|---------------------------------------------------------------------------------|
| <i>blocks</i>                  | (DEPRECATED) Internal property, property synonym for <code>as_blocks()</code> . |
| <i>data</i>                    | Return the data pointer of the underlying data.                                 |
| <i>dtype</i>                   | Return the dtype object of the underlying data.                                 |
| <i>dtypes</i>                  | Return the dtype object of the underlying data.                                 |
| <i>flags</i>                   |                                                                                 |
| <i>ftype</i>                   | Return if the data is sparsedense.                                              |
| <i>ftypes</i>                  | Return if the data is sparsedense.                                              |
| <i>hasnans</i>                 | Return if I have any nans; enables various perf speedups.                       |
| <i>iat</i>                     | Access a single value for a row/column pair by integer position.                |
| <i>iloc</i>                    | Purely integer-location based indexing for selection by position.               |
| <i>imag</i>                    | Return imag value of vector.                                                    |
| <i>index</i>                   | The index (axis labels) of the Series.                                          |
| <i>is_copy</i>                 | Return the copy.                                                                |
| <i>is_monotonic</i>            | Return boolean if values in the object are monotonic_increasing.                |
| <i>is_monotonic_decreasing</i> | Return boolean if values in the object are monotonic_decreasing.                |
| <i>is_monotonic_increasing</i> | Return boolean if values in the object are monotonic_increasing.                |
| <i>is_unique</i>               | Return boolean if values in the object are unique.                              |
| <i>itemsizes</i>               | Return the size of the dtype of the item of the underlying data.                |
| <i>ix</i>                      | A primarily label-location based indexer, with integer position fallback.       |
| <i>loc</i>                     | Access a group of rows and columns by label(s) or a boolean array.              |
| <i>name</i>                    | Return name of the Series.                                                      |
| <i>nbytes</i>                  | Return the number of bytes in the underlying data.                              |
| <i>ndim</i>                    | Number of dimensions of the underlying data, by definition 1.                   |
| <i>real</i>                    | Return the real value of vector.                                                |
| <i>shape</i>                   | Return a tuple of the shape of the underlying data.                             |
| <i>size</i>                    | Return the number of elements in the underlying data.                           |
| <i>strides</i>                 | Return the strides of the underlying data.                                      |
| <i>values</i>                  | Return Series as ndarray or ndarray-like depending on the dtype.                |

## **pandas.Series.T**

### **Series.T**

Return the transpose, which is by definition self.

## **pandas.Series.array**

### **Series.array**

The ExtensionArray of the data backing this Series or Index.

New in version 0.24.0.

### Returns

**array** [ExtensionArray] An ExtensionArray of the values stored within. For extension types, this is the actual array. For NumPy native types, this is a thin (no copy) wrapper around `numpy.ndarray`.

`.array` differs `.values` which may require converting the data to a different form.

### See also:

**`Index.to_numpy`** Similar method that always returns a NumPy array.

**`Series.to_numpy`** Similar method that always returns a NumPy array.

### Notes

This table lays out the different array types for each extension dtype within pandas.

| dtype              | array type    |
|--------------------|---------------|
| category           | Categorical   |
| period             | PeriodArray   |
| interval           | IntervalArray |
| IntegerNA          | IntegerArray  |
| datetime64[ns, tz] | DatetimeArray |

For any 3rd-party extension types, the array type will be an ExtensionArray.

For all remaining dtypes `.array` will be a `arrays.NumpyExtensionArray` wrapping the actual ndarray stored within. If you absolutely need a NumPy array (possibly with copying / coercing data), then use `Series.to_numpy()` instead.

### Examples

For regular NumPy types like int, and float, a PandasArray is returned.

```
>>> pd.Series([1, 2, 3]).array
<PandasArray>
[1, 2, 3]
Length: 3, dtype: int64
```

For extension types, like Categorical, the actual ExtensionArray is returned

```
>>> ser = pd.Series(pd.Categorical(['a', 'b', 'a']))
>>> ser.array
[a, b, a]
Categories (2, object): [a, b]
```

## pandas.Series.asobject

### `Series.asobject`

Return object Series which contains boxed values.

Deprecated since version 0.23.0: Use `astype(object)` instead.

*this is an internal non-public method*

## pandas.Series.at

### Series.at

Access a single value for a row/column label pair.

Similar to `loc`, in that both provide label-based lookups. Use `at` if you only need to get or set a single value in a DataFrame or Series.

#### Raises

**KeyError** When label does not exist in DataFrame

#### See also:

**DataFrame.iat** Access a single value for a row/column pair by integer position.

**DataFrame.loc** Access a group of rows and columns by label(s).

**Series.at** Access a single value using a label.

## Examples

```
>>> df = pd.DataFrame([[0, 2, 3], [0, 4, 1], [10, 20, 30]],
...                    index=[4, 5, 6], columns=['A', 'B', 'C'])
>>> df
   A  B  C
4  0  2  3
5  0  4  1
6 10 20 30
```

Get value at specified row/column pair

```
>>> df.at[4, 'B']
2
```

Set value at specified row/column pair

```
>>> df.at[4, 'B'] = 10
>>> df.at[4, 'B']
10
```

Get value within a Series

```
>>> df.loc[5].at['B']
4
```

## pandas.Series.axes

### Series.axes

Return a list of the row axis labels.

### **pandas.Series.base**

#### **Series.base**

Return the base object if the memory of the underlying data is shared.

### **pandas.Series.blocks**

#### **Series.blocks**

Internal property, property synonym for `as_blocks()`.

Deprecated since version 0.21.0.

### **pandas.Series.data**

#### **Series.data**

Return the data pointer of the underlying data.

### **pandas.Series.dtype**

#### **Series.dtype**

Return the dtype object of the underlying data.

### **pandas.Series.dtypes**

#### **Series.dtypes**

Return the dtype object of the underlying data.

### **pandas.Series.flags**

#### **Series.flags**

### **pandas.Series.ftype**

#### **Series.ftype**

Return if the data is sparse/dense.

### **pandas.Series.ftypes**

#### **Series.ftypes**

Return if the data is sparse/dense.

### **pandas.Series.hasnans**

#### **Series.hasnans**

Return if I have any nans; enables various perf speedups.

## pandas.Series.iat

### Series.iat

Access a single value for a row/column pair by integer position.

Similar to `iloc`, in that both provide integer-based lookups. Use `iat` if you only need to get or set a single value in a DataFrame or Series.

#### Raises

**IndexError** When integer position is out of bounds

#### See also:

**DataFrame.at** Access a single value for a row/column label pair.

**DataFrame.loc** Access a group of rows and columns by label(s).

**DataFrame.iloc** Access a group of rows and columns by integer position(s).

## Examples

```
>>> df = pd.DataFrame([[0, 2, 3], [0, 4, 1], [10, 20, 30]],
...                    columns=['A', 'B', 'C'])
>>> df
   A  B  C
0  0  2  3
1  0  4  1
2 10 20 30
```

Get value at specified row/column pair

```
>>> df.iat[1, 2]
1
```

Set value at specified row/column pair

```
>>> df.iat[1, 2] = 10
>>> df.iat[1, 2]
10
```

Get value within a series

```
>>> df.loc[0].iat[1]
2
```

## pandas.Series.iloc

### Series.iloc

Purely integer-location based indexing for selection by position.

`.iloc[]` is primarily integer position based (from 0 to `length-1` of the axis), but may also be used with a boolean array.

Allowed inputs are:

- An integer, e.g. 5.

- A list or array of integers, e.g. `[4, 3, 0]`.
- A slice object with ints, e.g. `1:7`.
- A boolean array.
- A callable function with one argument (the calling Series, DataFrame or Panel) and that returns valid output for indexing (one of the above). This is useful in method chains, when you don't have a reference to the calling object, but would like to base your selection on some value.

`.iloc` will raise `IndexError` if a requested indexer is out-of-bounds, except *slice* indexers which allow out-of-bounds indexing (this conforms with python/numpy *slice* semantics).

See more at [ref:Selection by Position <indexing.integer>](#).

**See also:**

**DataFrame.iat** Fast integer location scalar accessor.

**DataFrame.loc** Purely label-location based indexer for selection by label.

**Series.iloc** Purely integer-location based indexing for selection by position.

## Examples

```
>>> mydict = [{'a': 1, 'b': 2, 'c': 3, 'd': 4},
...           {'a': 100, 'b': 200, 'c': 300, 'd': 400},
...           {'a': 1000, 'b': 2000, 'c': 3000, 'd': 4000}]
>>> df = pd.DataFrame(mydict)
>>> df
```

|   | a    | b    | c    | d    |
|---|------|------|------|------|
| 0 | 1    | 2    | 3    | 4    |
| 1 | 100  | 200  | 300  | 400  |
| 2 | 1000 | 2000 | 3000 | 4000 |

### Indexing just the rows

With a scalar integer.

```
>>> type(df.iloc[0])
<class 'pandas.core.series.Series'>
>>> df.iloc[0]
a    1
b    2
c    3
d    4
Name: 0, dtype: int64
```

With a list of integers.

```
>>> df.iloc[[0]]
   a  b  c  d
0  1  2  3  4
>>> type(df.iloc[[0]])
<class 'pandas.core.frame.DataFrame'>
```

```
>>> df.iloc[[0, 1]]
   a  b  c  d
```

(continues on next page)

(continued from previous page)

|   |     |     |     |     |
|---|-----|-----|-----|-----|
| 0 | 1   | 2   | 3   | 4   |
| 1 | 100 | 200 | 300 | 400 |

With a *slice* object.

```
>>> df.iloc[:3]
```

|   | a    | b    | c    | d    |
|---|------|------|------|------|
| 0 | 1    | 2    | 3    | 4    |
| 1 | 100  | 200  | 300  | 400  |
| 2 | 1000 | 2000 | 3000 | 4000 |

With a boolean mask the same length as the index.

```
>>> df.iloc[[True, False, True]]
```

|   | a    | b    | c    | d    |
|---|------|------|------|------|
| 0 | 1    | 2    | 3    | 4    |
| 2 | 1000 | 2000 | 3000 | 4000 |

With a callable, useful in method chains. The *x* passed to the *lambda* is the DataFrame being sliced. This selects the rows whose index label even.

```
>>> df.iloc[lambda x: x.index % 2 == 0]
```

|   | a    | b    | c    | d    |
|---|------|------|------|------|
| 0 | 1    | 2    | 3    | 4    |
| 2 | 1000 | 2000 | 3000 | 4000 |

### Indexing both axes

You can mix the indexer types for the index and columns. Use *:* to select the entire axis.

With scalar integers.

```
>>> df.iloc[0, 1]
```

2

With lists of integers.

```
>>> df.iloc[[0, 2], [1, 3]]
```

|   | b    | d    |
|---|------|------|
| 0 | 2    | 4    |
| 2 | 2000 | 4000 |

With *slice* objects.

```
>>> df.iloc[1:3, 0:3]
```

|   | a    | b    | c    |
|---|------|------|------|
| 1 | 100  | 200  | 300  |
| 2 | 1000 | 2000 | 3000 |

With a boolean array whose length matches the columns.

```
>>> df.iloc[:, [True, False, True, False]]
```

|   | a    | c    |
|---|------|------|
| 0 | 1    | 3    |
| 1 | 100  | 300  |
| 2 | 1000 | 3000 |

With a callable function that expects the Series or DataFrame.

```
>>> df.iloc[:, lambda df: [0, 2]]
   a    c
0   1    3
1  100  300
2 1000 3000
```

### **pandas.Series.imag**

**Series.imag**

Return imag value of vector.

### **pandas.Series.index**

**Series.index**

The index (axis labels) of the Series.

### **pandas.Series.is\_copy**

**Series.is\_copy**

Return the copy.

### **pandas.Series.is\_monotonic**

**Series.is\_monotonic**

Return boolean if values in the object are monotonic\_increasing.

New in version 0.19.0.

**Returns**

**is\_monotonic** [boolean]

### **pandas.Series.is\_monotonic\_decreasing**

**Series.is\_monotonic\_decreasing**

Return boolean if values in the object are monotonic\_decreasing.

New in version 0.19.0.

**Returns**

**is\_monotonic\_decreasing** [boolean]

### **pandas.Series.is\_monotonic\_increasing**

**Series.is\_monotonic\_increasing**

Return boolean if values in the object are monotonic\_increasing.

New in version 0.19.0.

**Returns**

`is_monotonic` [boolean]

### `pandas.Series.is_unique`

`Series.is_unique`

Return boolean if values in the object are unique.

#### Returns

`is_unique` [boolean]

### `pandas.Series.itemsize`

`Series.itemsize`

Return the size of the dtype of the item of the underlying data.

### `pandas.Series.ix`

`Series.ix`

A primarily label-location based indexer, with integer position fallback.

Warning: Starting in 0.20.0, the `.ix` indexer is deprecated, in favor of the more strict `.iloc` and `.loc` indexers.

`.ix[]` supports mixed integer and label based access. It is primarily label based, but will fall back to integer positional access unless the corresponding axis is of integer type.

`.ix` is the most general indexer and will support any of the inputs in `.loc` and `.iloc`. `.ix` also supports floating point label schemes. `.ix` is exceptionally useful when dealing with mixed positional and label based hierarchical indexes.

However, when an axis is integer based, **ONLY** label based access and not positional access is supported. Thus, in such cases, it's usually better to be explicit and use `.iloc` or `.loc`.

See more at *Advanced Indexing*.

### `pandas.Series.loc`

`Series.loc`

Access a group of rows and columns by label(s) or a boolean array.

`.loc[]` is primarily label based, but may also be used with a boolean array.

Allowed inputs are:

- A single label, e.g. 5 or 'a', (note that 5 is interpreted as a *label* of the index, and **never** as an integer position along the index).
- A list or array of labels, e.g. ['a', 'b', 'c'].
- A slice object with labels, e.g. 'a':'f'.

**Warning:** Note that contrary to usual python slices, **both** the start and the stop are included

- A boolean array of the same length as the axis being sliced, e.g. [True, False, True].

- A callable function with one argument (the calling Series, DataFrame or Panel) and that returns valid output for indexing (one of the above)

See more at *Selection by Label*

#### Raises

**KeyError:** when any items are not found

See also:

**DataFrame.at** Access a single value for a row/column label pair.

**DataFrame.iloc** Access group of rows and columns by integer position(s).

**DataFrame.xs** Returns a cross-section (row(s) or column(s)) from the Series/DataFrame.

**Series.loc** Access group of values using labels.

## Examples

### Getting values

```
>>> df = pd.DataFrame([[1, 2], [4, 5], [7, 8]],
...                    index=['cobra', 'viper', 'sidewinder'],
...                    columns=['max_speed', 'shield'])
>>> df
```

|            | max_speed | shield |
|------------|-----------|--------|
| cobra      | 1         | 2      |
| viper      | 4         | 5      |
| sidewinder | 7         | 8      |

Single label. Note this returns the row as a Series.

```
>>> df.loc['viper']
max_speed    4
shield       5
Name: viper, dtype: int64
```
