The validator function is responsible for validating options given in `CREATE` and `ALTER` commands for its foreign data wrapper, as well as foreign servers, user mappings, and foreign tables using the wrapper. The validator function must be registered as taking two arguments, a text array containing the options to be validated, and an OID representing the type of object the options are associated with. The latter corresponds to the OID of the system catalog the object would be stored in, one of:

- `AttributeRelationId`
- `ForeignDataWrapperRelationId`
- `ForeignServerRelationId`
- `ForeignTableRelationId`
- `UserMappingRelationId`

If no validator function is supplied, options are not checked at object creation time or object alteration time.

58.2. Foreign Data Wrapper Callback Routines

The FDW handler function returns a palloc'd `FdwRoutine` struct containing pointers to the callback functions described below. The scan-related functions are required, the rest are optional.

The `FdwRoutine` struct type is declared in [src/include/foreign/fdwapi.h](#), which see for additional details.

58.2.1. FDW Routines for Scanning Foreign Tables

```
void
GetForeignRelSize(PlannerInfo *root,
                  RelOptInfo *baserel,
                  Oid foreigntableid);
```

Obtain relation size estimates for a foreign table. This is called at the beginning of planning for a query that scans a foreign table. `root` is the planner's global information about the query; `baserel` is the planner's information about this table; and `foreigntableid`

is the `pg_class` OID of the foreign table. (`foreigntableid` could be obtained from the planner data structures, but it's passed explicitly to save effort.)

This function should update `baserel->rows` to be the expected number of rows returned by the table scan, after accounting for the filtering done by the restriction quals. The initial value of `baserel->rows` is just a constant default estimate, which should be replaced if at all possible. The function may also choose to update `baserel->width` if it can compute a better estimate of the average result row width. (The initial value is based on column data types and on column average-width values measured by the last `ANALYZE`.) Also, this function may update `baserel->tuples` if it can compute a better estimate of the foreign table's total row count. (The initial value is from `pg_class.rel tuples` which represents the total row count seen by the last `ANALYZE`; it will be `-1` if no `ANALYZE` has been done on this foreign table.)

See [Section 58.4](#) for additional information.

```
void
GetForeignPaths(PlannerInfo *root,
                RelOptInfo *baserel,
                Oid foreigntableid);
```

Create possible access paths for a scan on a foreign table. This is called during query planning. The parameters are the same as for `GetForeignRelSize`, which has already been called.

This function must generate at least one access path (`ForeignPath` node) for a scan on the foreign table and must call `add_path` to add each such path to `baserel->pathlist`. It's recommended to use `create_foreignscan_path` to build the `ForeignPath` nodes. The function can generate multiple access paths, e.g., a path which has valid `pathkeys` to represent a pre-sorted result. Each access path must contain cost estimates, and can contain any FDW-private information that is needed to identify the specific scan method intended.

See [Section 58.4](#) for additional information.

```
ForeignScan *
GetForeignPlan(PlannerInfo *root,
               RelOptInfo *baserel,
               Oid foreigntableid,
               ForeignPath *best_path,
               List *tlist,
               List *scan_clauses,
               Plan *outer_plan);
```

Create a `ForeignScan` plan node from the selected foreign access path. This is called at the end of query planning. The parameters are as for `GetForeignRelSize`, plus the selected `ForeignPath` (previously produced by `GetForeignPaths`, `GetForeignJoinPaths`, or `GetForeignUpperPaths`), the target list to be emitted by the plan node, the restriction clauses to be enforced by the plan node, and the outer subplan of the `ForeignScan`, which is used for rechecks performed by `RecheckForeignScan`. (If the path is for a join rather than a base relation, `foreigntableid` is `InvalidOid`.)

This function must create and return a `ForeignScan` plan node; it's recommended to use `make_foreignscan` to build the `ForeignScan` node.

See [Section 58.4](#) for additional information.

```
void
BeginForeignScan(ForeignScanState *node,
                 int eflags);
```

Begin executing a foreign scan. This is called during executor startup. It should perform any initialization needed before the scan can start, but not start executing the actual scan (that should be done upon the first call to `IterateForeignScan`). The `ForeignScanState` node has already been created, but its `fdw_state` field is still `NULL`. Information about the table to scan is accessible through the `ForeignScanState` node (in particular, from the underlying `ForeignScan` plan node, which contains any FDW-private information provided by `GetForeignPlan`). `eflags` contains flag bits describing the executor's operating mode for this plan node.

Note that when `(eflags & EXEC_FLAG_EXPLAIN_ONLY)` is true, this function should not perform any externally-visible actions; it should only do the minimum required to make the node state valid for `ExplainForeignScan` and `EndForeignScan`.

```
TupleTableSlot *  
IterateForeignScan(ForeignScanState *node);
```

Fetch one row from the foreign source, returning it in a tuple table slot (the node's `ScanTupleSlot` should be used for this purpose). Return `NULL` if no more rows are available. The tuple table slot infrastructure allows either a physical or virtual tuple to be returned; in most cases the latter choice is preferable from a performance standpoint. Note that this is called in a short-lived memory context that will be reset between invocations. Create a memory context in `BeginForeignScan` if you need longer-lived storage, or use the `es_query_cxt` of the node's `EState`.

The rows returned must match the `fdw_scan_tlist` target list if one was supplied, otherwise they must match the row type of the foreign table being scanned. If you choose to optimize away fetching columns that are not needed, you should insert nulls in those column positions, or else generate a `fdw_scan_tlist` list with those columns omitted.

Note that Postgres Pro's executor doesn't care whether the rows returned violate any constraints that were defined on the foreign table — but the planner does care, and may optimize queries incorrectly if there are rows visible in the foreign table that do not satisfy a declared constraint. If a constraint is violated when the user has declared that the constraint should hold true, it may be appropriate to raise an error (just as you would need to do in the case of a data type mismatch).

```
void  
ReScanForeignScan(ForeignScanState *node);
```

Restart the scan from the beginning. Note that any parameters the scan depends on may have changed value, so the new scan does not necessarily return exactly the same rows.

```
void  
EndForeignScan(ForeignScanState *node);
```

End the scan and release resources. It is normally not important to release palloc'd memory, but for example open files and connections to remote servers should be cleaned up.

58.2.2. FDW Routines for Scanning Foreign Joins

If an FDW supports performing foreign joins remotely (rather than by fetching both tables' data and doing the join locally), it should provide this callback function:

```
void  
GetForeignJoinPaths(PlannerInfo *root,  
                   RelOptInfo *joinrel,  
                   RelOptInfo *outerrel,  
                   RelOptInfo *innerrel,  
                   JoinType jointype,  
                   JoinPathExtraData *extra);
```

Create possible access paths for a join of two (or more) foreign tables that all belong to the same foreign server. This optional function is called during query planning. As with `GetForeignPaths`, this function should generate `ForeignPath` path(s) for the supplied `joinrel` (use `create_foreign_join_path` to build them), and call `add_path` to add these paths to the set of paths considered for the join. But unlike `GetForeignPaths`, it is not necessary that this function succeed in creating at least one path, since paths involving local joining are always possible.

Note that this function will be invoked repeatedly for the same join relation, with different combinations of inner and outer relations; it is the responsibility of the FDW to minimize duplicated work.

Note also that the set of join clauses to apply to the join, which is passed as `extra->restrictlist`, varies depending on the combination of inner and outer relations. A `ForeignPath` path generated for the `joinrel` must contain the set of join clauses it uses, which will be used by the planner to convert the `ForeignPath` path into a plan, if it is selected by the planner as the best path for the `joinrel`.

If a `ForeignPath` path is chosen for the join, it will represent the entire join process; paths generated for the component tables and subsidiary joins will not be used. Subsequent processing of the join path proceeds much as it does for a path scanning a single foreign table. One difference is that the `scanrelid` of the resulting `ForeignScan` plan node should be set to zero, since there is no single relation that it represents; instead, the `fs_relids` field of the `ForeignScan` node represents the set of relations that

were joined. (The latter field is set up automatically by the core planner code, and need not be filled by the FDW.) Another difference is that, because the column list for a remote join cannot be found from the system catalogs, the FDW must fill `fdw_scan_tlist` with an appropriate list of `TargetEntry` nodes, representing the set of columns it will supply at run time in the tuples it returns.

Note

Beginning with Postgres Pro 16, `fs_relids` includes the rangetable indexes of outer joins, if any were involved in this join. The new field `fs_base_relids` includes only base relation indexes, and thus mimics `fs_relids`'s old semantics.

See [Section 58.4](#) for additional information.

58.2.3. FDW Routines for Planning Post-Scan/Join Processing

If an FDW supports performing remote post-scan/join processing, such as remote aggregation, it should provide this callback function:

```
void
GetForeignUpperPaths(PlannerInfo *root,
                     UpperRelationKind stage,
                     RelOptInfo *input_rel,
                     RelOptInfo *output_rel,
                     void *extra);
```

Create possible access paths for *upper relation* processing, which is the planner's term for all post-scan/join query processing, such as aggregation, window functions, sorting, and table updates. This optional function is called during query planning. Currently, it is called only if all base relation(s) involved in the query belong to the same FDW. This function should generate `ForeignPath` path(s) for any post-scan/join processing that the FDW knows how to perform remotely (use `create_foreign_upper_path` to build them), and call `add_path` to add these paths to the indicated upper relation. As with `GetForeignJoinPaths`, it is not necessary that this function succeed in creating any paths, since paths involving local processing are always possible.

The `stage` parameter identifies which post-scan/join step is currently being considered. `output_rel` is the upper relation that should receive paths representing computation of this step, and `input_rel` is the relation representing the input to this step. The `extra` parameter provides additional details, currently, it is set only for `UPPERREL_PARTIAL_GROUP_AGG` or `UPPERREL_GROUP_AGG`, in which case it points to a `GroupPathExtraData` structure; or for `UPPERREL_FINAL`, in which case it points to a `FinalPathExtraData` structure. (Note that `ForeignPath` paths added to `output_rel` would typically not have any direct dependency on paths of the `input_rel`, since their processing is expected to be done externally. However, examining paths previously generated for the previous processing step can be useful to avoid redundant planning work.)

See [Section 58.4](#) for additional information.

58.2.4. FDW Routines for Updating Foreign Tables

If an FDW supports writable foreign tables, it should provide some or all of the following callback functions depending on the needs and capabilities of the FDW:

```
void
AddForeignUpdateTargets(PlannerInfo *root,
                       Index rtindex,
                       RangeTblEntry *target_rte,
                       Relation target_relation);
```

`UPDATE` and `DELETE` operations are performed against rows previously fetched by the table-scanning functions. The FDW may need extra information, such as a row ID or the values of primary-key columns, to ensure that it can identify the exact row to update or delete. To support that, this function can add extra hidden, or “junk”, target columns to the list of columns that are to be retrieved from the foreign table during an `UPDATE` or `DELETE`.

To do that, construct a `Var` representing an extra value you need, and pass it to `add_row_identity_var`, along with a name for the junk column. (You can do this more than once if several columns are needed.) You must choose a distinct junk column name for each different `Var` you need, except that `Vars` that are identical except for the `varno` field can and should share a column name.

The core system uses the junk column names `tableoid` for a table's `tableoid` column, `ctid` or `ctidN` for `ctid`, `wholerow` for a whole-row `Var` marked with `vartype = RECORD`, and `wholerowN` for a whole-row `Var` with `vartype` equal to the table's declared row type. Re-use these names when you can (the planner will combine duplicate requests for identical junk columns). If you need another kind of junk column besides these, it might be wise to choose a name prefixed with your extension name, to avoid conflicts against other FDWs.

If the `AddForeignUpdateTargets` pointer is set to `NULL`, no extra target expressions are added. (This will make it impossible to implement `DELETE` operations, though `UPDATE` may still be feasible if the FDW relies on an unchanging primary key to identify rows.)

```
List *
PlanForeignModify(PlannerInfo *root,
                  ModifyTable *plan,
                  Index resultRelation,
                  int subplan_index);
```

Perform any additional planning actions needed for an insert, update, or delete on a foreign table. This function generates the FDW-private information that will be attached to the `ModifyTable` plan node that performs the update action. This private information must have the form of a `List`, and will be delivered to `BeginForeignModify` during the execution stage.

`root` is the planner's global information about the query. `plan` is the `ModifyTable` plan node, which is complete except for the `fdwPrivLists` field. `resultRelation` identifies the target foreign table by its range table index. `subplan_index` identifies which target of the `ModifyTable` plan node this is, counting from zero; use this if you want to index into per-target-relation substructures of the plan node.

See [Section 58.4](#) for additional information.

If the `PlanForeignModify` pointer is set to `NULL`, no additional plan-time actions are taken, and the `fdw_private` list delivered to `BeginForeignModify` will be `NIL`.

```
void
BeginForeignModify(ModifyTableState *mtstate,
                  ResultRelInfo *rinfo,
                  List *fdw_private,
                  int subplan_index,
                  int eflags);
```

Begin executing a foreign table modification operation. This routine is called during executor startup. It should perform any initialization needed prior to the actual table modifications. Subsequently, `ExecForeignInsert`/`ExecForeignBatchInsert`, `ExecForeignUpdate` or `ExecForeignDelete` will be called for tuple(s) to be inserted, updated, or deleted.

`mtstate` is the overall state of the `ModifyTable` plan node being executed; global data about the plan and execution state is available via this structure. `rinfo` is the `ResultRelInfo` struct describing the target foreign table. (The `ri_FdwState` field of `ResultRelInfo` is available for the FDW to store any private state it needs for this operation.) `fdw_private` contains the private data generated by `PlanForeignModify`, if any. `subplan_index` identifies which target of the `ModifyTable` plan node this is. `eflags` contains flag bits describing the executor's operating mode for this plan node.

Note that when `(eflags & EXEC_FLAG_EXPLAIN_ONLY)` is true, this function should not perform any externally-visible actions; it should only do the minimum required to make the node state valid for `ExplainForeignModify` and `EndForeignModify`.

If the `BeginForeignModify` pointer is set to `NULL`, no action is taken during executor startup.

```
TupleTableSlot *
ExecForeignInsert(EState *estate,
                  ResultRelInfo *rinfo,
                  TupleTableSlot *slot,
                  TupleTableSlot *planSlot);
```

Insert one tuple into the foreign table. `estate` is global execution state for the query. `rinfo` is the `ResultRelInfo` struct describing the target foreign table. `slot` contains the tuple to be inserted; it will match the row-type definition of the foreign table.

`planSlot` contains the tuple that was generated by the `ModifyTable` plan node's subplan; it differs from `slot` in possibly containing additional “junk” columns. (The `planSlot` is typically of little interest for `INSERT` cases, but is provided for completeness.)

The return value is either a slot containing the data that was actually inserted (this might differ from the data supplied, for example as a result of trigger actions), or `NULL` if no row was actually inserted (again, typically as a result of triggers). The passed-in `slot` can be re-used for this purpose.

The data in the returned slot is used only if the `INSERT` statement has a `RETURNING` clause or involves a view `WITH CHECK OPTION`; or if the foreign table has an `AFTER ROW` trigger. Triggers require all columns, but the FDW could choose to optimize away returning some or all columns depending on the contents of the `RETURNING` clause or `WITH CHECK OPTION` constraints. Regardless, some slot must be returned to indicate success, or the query's reported row count will be wrong.

If the `ExecForeignInsert` pointer is set to `NULL`, attempts to insert into the foreign table will fail with an error message.

Note that this function is also called when inserting routed tuples into a foreign-table partition or executing `COPY FROM` on a foreign table, in which case it is called in a different way than it is in the `INSERT` case. See the callback functions described below that allow the FDW to support that.

```
TupleTableSlot **
ExecForeignBatchInsert(EState *estate,
                      ResultRelInfo *rinfo,
                      TupleTableSlot **slots,
                      TupleTableSlot **planSlots,
                      int *numSlots);
```

Insert multiple tuples in bulk into the foreign table. The parameters are the same for `ExecForeignInsert` except `slots` and `planSlots` contain multiple tuples and `*numSlots` specifies the number of tuples in those arrays.

The return value is an array of slots containing the data that was actually inserted (this might differ from the data supplied, for example as a result of trigger actions.) The passed-in `slots` can be re-used for this purpose. The number of successfully inserted tuples is returned in `*numSlots`.

The data in the returned slot is used only if the `INSERT` statement involves a view `WITH CHECK OPTION`; or if the foreign table has an `AFTER ROW` trigger. Triggers require all columns, but the FDW could choose to optimize away returning some or all columns depending on the contents of the `WITH CHECK OPTION` constraints.

If the `ExecForeignBatchInsert` or `GetForeignModifyBatchSize` pointer is set to `NULL`, attempts to insert into the foreign table will use `ExecForeignInsert`. This function is not used if the `INSERT` has the `RETURNING` clause.

Note that this function is also called when inserting routed tuples into a foreign-table partition or executing `COPY FROM` on a foreign table, in which case it is called in a different way than it is in the `INSERT` case. See the callback functions described below that allow the FDW to support that.

```
int
GetForeignModifyBatchSize(ResultRelInfo *rinfo);
```

Report the maximum number of tuples that a single `ExecForeignBatchInsert` call can handle for the specified foreign table. The executor passes at most the given number of tuples to `ExecForeignBatchInsert`. `rinfo` is the `ResultRelInfo` struct describing the target foreign table. The FDW is expected to provide a foreign server and/or foreign table option for the user to set this value, or some hard-coded value.

If the `ExecForeignBatchInsert` or `GetForeignModifyBatchSize` pointer is set to `NULL`, attempts to insert into the foreign table will use `ExecForeignInsert`.

```
TupleTableSlot *
ExecForeignUpdate(EState *estate,
                 ResultRelInfo *rinfo,
                 TupleTableSlot *slot,
                 TupleTableSlot *planSlot);
```

Update one tuple in the foreign table. `estate` is global execution state for the query. `rinfo` is the `ResultRelInfo` struct describing the target foreign table. `slot` contains the new data for the tuple; it will match the row-type definition of the foreign table.

`planSlot` contains the tuple that was generated by the `ModifyTable` plan node's subplan. Unlike `slot`, this tuple contains only the new values for columns changed by the query, so do not rely on attribute numbers of the foreign table to index into `planSlot`. Also, `planSlot` typically contains additional “junk” columns. In particular, any junk columns that were requested by `AddForeignUpdateTargets` will be available from this slot.

The return value is either a slot containing the row as it was actually updated (this might differ from the data supplied, for example as a result of trigger actions), or `NULL` if no row was actually updated (again, typically as a result of triggers). The passed-in `slot` can be re-used for this purpose.

The data in the returned slot is used only if the `UPDATE` statement has a `RETURNING` clause or involves a view `WITH CHECK OPTION`; or if the foreign table has an `AFTER ROW` trigger. Triggers require all columns, but the FDW could choose to optimize away returning some or all columns depending on the contents of the `RETURNING` clause or `WITH CHECK OPTION` constraints. Regardless, some slot must be returned to indicate success, or the query's reported row count will be wrong.

If the `ExecForeignUpdate` pointer is set to `NULL`, attempts to update the foreign table will fail with an error message.

```
TupleTableSlot *
ExecForeignDelete(EState *estate,
                  ResultRelInfo *rinfo,
                  TupleTableSlot *slot,
                  TupleTableSlot *planSlot);
```

Delete one tuple from the foreign table. `estate` is global execution state for the query. `rinfo` is the `ResultRelInfo` struct describing the target foreign table. `slot` contains nothing useful upon call, but can be used to hold the returned tuple. `planSlot` contains the tuple that was generated by the `ModifyTable` plan node's subplan; in particular, it will carry any junk columns that were requested by `AddForeignUpdateTargets`. The junk column(s) must be used to identify the tuple to be deleted.

The return value is either a slot containing the row that was deleted, or `NULL` if no row was deleted (typically as a result of triggers). The passed-in `slot` can be used to hold the tuple to be returned.

The data in the returned slot is used only if the `DELETE` query has a `RETURNING` clause or the foreign table has an `AFTER ROW` trigger. Triggers require all columns, but the FDW could choose to optimize away returning some or all columns depending on the contents of the `RETURNING` clause. Regardless, some slot must be returned to indicate success, or the query's reported row count will be wrong.

If the `ExecForeignDelete` pointer is set to `NULL`, attempts to delete from the foreign table will fail with an error message.

```
void
EndForeignModify(EState *estate,
                 ResultRelInfo *rinfo);
```

End the table update and release resources. It is normally not important to release palloc'd memory, but for example open files and connections to remote servers should be cleaned up.

If the `EndForeignModify` pointer is set to `NULL`, no action is taken during executor shutdown.

Tuples inserted into a partitioned table by `INSERT` or `COPY FROM` are routed to partitions. If an FDW supports routable foreign-table partitions, it should also provide the following callback functions. These functions are also called when `COPY FROM` is executed on a foreign table.

```
void
BeginForeignInsert(ModifyTableState *mtstate,
                  ResultRelInfo *rinfo);
```

Begin executing an insert operation on a foreign table. This routine is called right before the first tuple is inserted into the foreign table in both cases when it is the partition chosen for tuple routing and the target specified in a `COPY FROM` command. It should perform any initialization needed prior to the actual insertion. Subsequently, `ExecForeignInsert` or `ExecForeignBatchInsert` will be called for tuple(s) to be inserted into the foreign table.

`mtstate` is the overall state of the `ModifyTable` plan node being executed; global data about the plan and execution state is available via this structure. `rinfo` is the `ResultRelInfo` struct describing the target foreign table. (The `ri_FdwState` field of `ResultRelInfo` is available for the FDW to store any private state it needs for this operation.)

When this is called by a `COPY FROM` command, the plan-related global data in `mtstate` is not provided and the `planSlot` parameter of `ExecForeignInsert` subsequently called for each inserted tuple is `NULL`, whether the foreign table is the partition chosen for tuple routing or the target specified in the command.

If the `BeginForeignInsert` pointer is set to `NULL`, no action is taken for the initialization.

Note that if the FDW does not support routable foreign-table partitions and/or executing `COPY FROM` on foreign tables, this function or `ExecForeignInsert/ExecForeignBatchInsert` subsequently called must throw error as needed.

```
void
EndForeignInsert(EState *estate,
                 ResultRelInfo *rinfo);
```

End the insert operation and release resources. It is normally not important to release `palloc'd` memory, but for example open files and connections to remote servers should be cleaned up.

If the `EndForeignInsert` pointer is set to `NULL`, no action is taken for the termination.

```
int
IsForeignRelUpdatable(Relation rel);
```

Report which update operations the specified foreign table supports. The return value should be a bit mask of rule event numbers indicating which operations are supported by the foreign table, using the `CmdType` enumeration; that is, $(1 \ll \text{CMD\_UPDATE}) = 4$ for `UPDATE`, $(1 \ll \text{CMD\_INSERT}) = 8$ for `INSERT`, and $(1 \ll \text{CMD\_DELETE}) = 16$ for `DELETE`.

If the `IsForeignRelUpdatable` pointer is set to `NULL`, foreign tables are assumed to be insertable, updatable, or deletable if the FDW provides `ExecForeignInsert`, `ExecForeignUpdate`, or `ExecForeignDelete` respectively. This function is only needed if the FDW supports some tables that are updatable and some that are not. (Even then, it's permissible to throw an error in the execution routine instead of checking in this function. However, this function is used to determine updatability for display in the `information_schema` views.)

Some inserts, updates, and deletes to foreign tables can be optimized by implementing an alternative set of interfaces. The ordinary interfaces for inserts, updates, and deletes fetch rows from the remote server and then modify those rows one at a time. In some cases, this row-by-row approach is necessary, but it can be inefficient. If it is possible for the foreign server to determine which rows should be modified without actually retrieving them, and if there are no local structures which would affect the operation (row-level local triggers, stored generated columns, or `WITH CHECK OPTION` constraints from parent views), then it is possible to arrange things so that the entire operation is performed on the remote server. The interfaces described below make this possible.

```
bool
PlanDirectModify(PlannerInfo *root,
                 ModifyTable *plan,
                 Index resultRelation,
                 int subplan_index);
```

Decide whether it is safe to execute a direct modification on the remote server. If so, return `true` after performing planning actions needed for that. Otherwise, return `false`. This optional function is called during query planning. If this function succeeds, `BeginDirectModify`, `IterateDirectModify` and `EndDirectModify` will be called at the execution stage, instead. Otherwise, the table modification will be executed using the table-updating functions described above. The parameters are the same as for `PlanForeignModify`.

To execute the direct modification on the remote server, this function must rewrite the target subplan with a `ForeignScan` plan node that executes the direct modification on the remote server. The `operation` and `resultRelation` fields of the `ForeignScan` must be set appropriately. `operation` must be set to the `CmdType` enumeration corresponding to the statement kind (that is, `CMD_UPDATE` for `UPDATE`, `CMD_INSERT` for `INSERT`, and `CMD_DELETE` for `DELETE`), and the `resultRelation` argument must be copied to the `resultRelation` field.

See [Section 58.4](#) for additional information.

If the `PlanDirectModify` pointer is set to `NULL`, no attempts to execute a direct modification on the remote server are taken.

```
void
BeginDirectModify(ForeignScanState *node,
```

```
int eflags);
```

Prepare to execute a direct modification on the remote server. This is called during executor startup. It should perform any initialization needed prior to the direct modification (that should be done upon the first call to `IterateDirectModify`). The `ForeignScanState` node has already been created, but its `fdw_state` field is still `NULL`. Information about the table to modify is accessible through the `ForeignScanState` node (in particular, from the underlying `ForeignScan` plan node, which contains any FDW-private information provided by `PlanDirectModify`). `eflags` contains flag bits describing the executor's operating mode for this plan node.

Note that when `(eflags & EXEC_FLAG_EXPLAIN_ONLY)` is true, this function should not perform any externally-visible actions; it should only do the minimum required to make the node state valid for `ExplainDirectModify` and `EndDirectModify`.

If the `BeginDirectModify` pointer is set to `NULL`, no attempts to execute a direct modification on the remote server are taken.

```
TupleTableSlot *
IterateDirectModify(ForeignScanState *node);
```

When the `INSERT`, `UPDATE` or `DELETE` query doesn't have a `RETURNING` clause, just return `NULL` after a direct modification on the remote server. When the query has the clause, fetch one result containing the data needed for the `RETURNING` calculation, returning it in a tuple table slot (the node's `ScanTupleSlot` should be used for this purpose). The data that was actually inserted, updated or deleted must be stored in `node->resultRelInfo->ri_projectReturning->pi_exprContext->ecxt_scantuple`. Return `NULL` if no more rows are available. Note that this is called in a short-lived memory context that will be reset between invocations. Create a memory context in `BeginDirectModify` if you need longer-lived storage, or use the `es_query_cxt` of the node's `EState`.

The rows returned must match the `fdw_scan_tlist` target list if one was supplied, otherwise they must match the row type of the foreign table being updated. If you choose to optimize away fetching columns that are not needed for the `RETURNING` calculation, you should insert nulls in those column positions, or else generate a `fdw_scan_tlist` list with those columns omitted.

Whether the query has the clause or not, the query's reported row count must be incremented by the FDW itself. When the query doesn't have the clause, the FDW must also increment the row count for the `ForeignScanState` node in the `EXPLAIN ANALYZE` case.

If the `IterateDirectModify` pointer is set to `NULL`, no attempts to execute a direct modification on the remote server are taken.

```
void
EndDirectModify(ForeignScanState *node);
```

Clean up following a direct modification on the remote server. It is normally not important to release palloc'd memory, but for example open files and connections to the remote server should be cleaned up.

If the `EndDirectModify` pointer is set to `NULL`, no attempts to execute a direct modification on the remote server are taken.

58.2.5. FDW Routines for TRUNCATE

```
void
ExecForeignTruncate(List *rels,
                    DropBehavior behavior,
                    bool restart_seqs);
```

Truncate foreign tables. This function is called when `TRUNCATE` is executed on a foreign table. `rels` is a list of `Relation` data structures of foreign tables to truncate.

`behavior` is either `DROP_RESTRICT` or `DROP_CASCADE` indicating that the `RESTRICT` or `CASCADE` option was requested in the original `TRUNCATE` command, respectively.

If `restart_seqs` is true, the original `TRUNCATE` command requested the `RESTART IDENTITY` behavior, otherwise the `CONTINUE IDENTITY` behavior was requested.

Note that the `ONLY` options specified in the original `TRUNCATE` command are not passed to `ExecForeignTruncate`. This behavior is similar to the callback functions of `SELECT`, `UPDATE` and `DELETE` on a foreign table.

`ExecForeignTruncate` is invoked once per foreign server for which foreign tables are to be truncated. This means that all foreign tables included in `rels` must belong to the same server.

If the `ExecForeignTruncate` pointer is set to `NULL`, attempts to truncate foreign tables will fail with an error message.

58.2.6. FDW Routines for Row Locking

If an FDW wishes to support *late row locking* (as described in [Section 58.5](#)), it must provide the following callback functions:

```
RowMarkType
GetForeignRowMarkType(RangeTblEntry *rte,
                      LockClauseStrength strength);
```

Report which row-marking option to use for a foreign table. `rte` is the `RangeTblEntry` node for the table and `strength` describes the lock strength requested by the relevant `FOR UPDATE/SHARE` clause, if any. The result must be a member of the `RowMarkType` enum type.

This function is called during query planning for each foreign table that appears in an `UPDATE`, `DELETE`, or `SELECT FOR UPDATE/SHARE` query and is not the target of `UPDATE` or `DELETE`.

If the `GetForeignRowMarkType` pointer is set to `NULL`, the `ROW_MARK_COPY` option is always used. (This implies that `RefetchForeignRow` will never be called, so it need not be provided either.)

See [Section 58.5](#) for more information.

```
void
RefetchForeignRow(EState *estate,
                  ExecRowMark *erm,
                  Datum rowid,
                  TupleTableSlot *slot,
                  bool *updated);
```

Re-fetch one tuple slot from the foreign table, after locking it if required. `estate` is global execution state for the query. `erm` is the `ExecRowMark` struct describing the target foreign table and the row lock type (if any) to acquire. `rowid` identifies the tuple to be fetched. `slot` contains nothing useful upon call, but can be used to hold the returned tuple. `updated` is an output parameter.

This function should store the tuple into the provided slot, or clear it if the row lock couldn't be obtained. The row lock type to acquire is defined by `erm->markType`, which is the value previously returned by `GetForeignRowMarkType`. (`ROW_MARK_REFERENCE` means to just re-fetch the tuple without acquiring any lock, and `ROW_MARK_COPY` will never be seen by this routine.)

In addition, `*updated` should be set to `true` if what was fetched was an updated version of the tuple rather than the same version previously obtained. (If the FDW cannot be sure about this, always returning `true` is recommended.)

Note that by default, failure to acquire a row lock should result in raising an error; returning with an empty slot is only appropriate if the `SKIP LOCKED` option is specified by `erm->waitPolicy`.

The `rowid` is the `ctid` value previously read for the row to be re-fetched. Although the `rowid` value is passed as a `Datum`, it can currently only be a `tid`. The function API is chosen in hopes that it may be possible to allow other data types for row IDs in future.

If the `RefetchForeignRow` pointer is set to `NULL`, attempts to re-fetch rows will fail with an error message.

See [Section 58.5](#) for more information.

```
bool
RecheckForeignScan(ForeignScanState *node,
                  TupleTableSlot *slot);
```

Recheck that a previously-returned tuple still matches the relevant scan and join qualifiers, and possibly provide a modified version of the tuple. For foreign data wrappers which do not perform join pushdown, it will typically be more convenient to set this to `NULL` and instead set `fdw_recheck_qual` appropriately. When outer joins are pushed down, however, it isn't sufficient to reapply the checks relevant to all the base tables to the result tuple, even if all needed attributes are present, because failure to match some qualifier might result in some attributes going to `NULL`, rather than in no tuple being returned. `RecheckForeignScan`

can recheck qualifiers and return true if they are still satisfied and false otherwise, but it can also store a replacement tuple into the supplied slot.

To implement join pushdown, a foreign data wrapper will typically construct an alternative local join plan which is used only for rechecks; this will become the outer subplan of the `ForeignScan`. When a recheck is required, this subplan can be executed and the resulting tuple can be stored in the slot. This plan need not be efficient since no base table will return more than one row; for example, it may implement all joins as nested loops. The function `GetExistingLocalJoinPath` may be used to search existing paths for a suitable local join path, which can be used as the alternative local join plan. `GetExistingLocalJoinPath` searches for an unparameterized path in the path list of the specified join relation. (If it does not find such a path, it returns NULL, in which case a foreign data wrapper may build the local path by itself or may choose not to create access paths for that join.)

58.2.7. FDW Routines for EXPLAIN

```
void
ExplainForeignScan(ForeignScanState *node,
                   ExplainState *es);
```

Print additional EXPLAIN output for a foreign table scan. This function can call `ExplainPropertyText` and related functions to add fields to the EXPLAIN output. The flag fields in `es` can be used to determine what to print, and the state of the `ForeignScanState` node can be inspected to provide run-time statistics in the EXPLAIN ANALYZE case.

If the `ExplainForeignScan` pointer is set to NULL, no additional information is printed during EXPLAIN.

```
void
ExplainForeignModify(ModifyTableState *mtstate,
                    ResultRelInfo *rinfo,
                    List *fdw_private,
                    int subplan_index,
                    struct ExplainState *es);
```

Print additional EXPLAIN output for a foreign table update. This function can call `ExplainPropertyText` and related functions to add fields to the EXPLAIN output. The flag fields in `es` can be used to determine what to print, and the state of the `ModifyTableState` node can be inspected to provide run-time statistics in the EXPLAIN ANALYZE case. The first four arguments are the same as for `BeginForeignModify`.

If the `ExplainForeignModify` pointer is set to NULL, no additional information is printed during EXPLAIN.

```
void
ExplainDirectModify(ForeignScanState *node,
                   ExplainState *es);
```

Print additional EXPLAIN output for a direct modification on the remote server. This function can call `ExplainPropertyText` and related functions to add fields to the EXPLAIN output. The flag fields in `es` can be used to determine what to print, and the state of the `ForeignScanState` node can be inspected to provide run-time statistics in the EXPLAIN ANALYZE case.

If the `ExplainDirectModify` pointer is set to NULL, no additional information is printed during EXPLAIN.

58.2.8. FDW Routines for ANALYZE

```
bool
AnalyzeForeignTable(Relation relation,
                   AcquireSampleRowsFunc *func,
                   BlockNumber *totalpages);
```

This function is called when [ANALYZE](#) is executed on a foreign table. If the FDW can collect statistics for this foreign table, it should return true, and provide a pointer to a function that will collect sample rows from the table in `func`, plus the estimated size of the table in pages in `totalpages`. Otherwise, return false.

If the FDW does not support collecting statistics for any tables, the `AnalyzeForeignTable` pointer can be set to NULL.

If provided, the sample collection function must have the signature

```
int
```

```
AcquireSampleRowsFunc(Relation relation,
                      int elevel,
                      HeapTuple *rows,
                      int targrows,
                      double *totalrows,
                      double *totaldeadrows);
```

A random sample of up to *targrows* rows should be collected from the table and stored into the caller-provided *rows* array. The actual number of rows collected must be returned. In addition, store estimates of the total numbers of live and dead rows in the table into the output parameters *totalrows* and *totaldeadrows*. (Set *totaldeadrows* to zero if the FDW does not have any concept of dead rows.)

58.2.9. FDW Routines for `IMPORT FOREIGN SCHEMA`

```
List *
ImportForeignSchema(ImportForeignSchemaStmt *stmt, Oid serverOid);
```

Obtain a list of foreign table creation commands. This function is called when executing `IMPORT FOREIGN SCHEMA`, and is passed the parse tree for that statement, as well as the OID of the foreign server to use. It should return a list of C strings, each of which must contain a `CREATE FOREIGN TABLE` command. These strings will be parsed and executed by the core server.

Within the `ImportForeignSchemaStmt` struct, `remote_schema` is the name of the remote schema from which tables are to be imported. `list_type` identifies how to filter table names: `FDW_IMPORT_SCHEMA_ALL` means that all tables in the remote schema should be imported (in this case `table_list` is empty), `FDW_IMPORT_SCHEMA_LIMIT_TO` means to include only tables listed in `table_list`, and `FDW_IMPORT_SCHEMA_EXCEPT` means to exclude the tables listed in `table_list`. `options` is a list of options used for the import process. The meanings of the options are up to the FDW. For example, an FDW could use an option to define whether the `NOT NULL` attributes of columns should be imported. These options need not have anything to do with those supported by the FDW as database object options.

The FDW may ignore the `local_schema` field of the `ImportForeignSchemaStmt`, because the core server will automatically insert that name into the parsed `CREATE FOREIGN TABLE` commands.

The FDW does not have to concern itself with implementing the filtering specified by `list_type` and `table_list`, either, as the core server will automatically skip any returned commands for tables excluded according to those options. However, it's often useful to avoid the work of creating commands for excluded tables in the first place. The function `IsImportableForeignTable()` may be useful to test whether a given foreign-table name will pass the filter.

If the FDW does not support importing table definitions, the `ImportForeignSchema` pointer can be set to `NULL`.

58.2.10. FDW Routines for Parallel Execution

A `ForeignScan` node can, optionally, support parallel execution. A parallel `ForeignScan` will be executed in multiple processes and must return each row exactly once across all cooperating processes. To do this, processes can coordinate through fixed-size chunks of dynamic shared memory. This shared memory is not guaranteed to be mapped at the same address in every process, so it must not contain pointers. The following functions are all optional, but most are required if parallel execution is to be supported.

```
bool
IsForeignScanParallelSafe(PlannerInfo *root, RelOptInfo *rel,
                          RangeTblEntry *rte);
```

Test whether a scan can be performed within a parallel worker. This function will only be called when the planner believes that a parallel plan might be possible, and should return true if it is safe for that scan to run within a parallel worker. This will generally not be the case if the remote data source has transaction semantics, unless the worker's connection to the data can somehow be made to share the same transaction context as the leader.

If this function is not defined, it is assumed that the scan must take place within the parallel leader. Note that returning true does not mean that the scan itself can be done in parallel, only that the scan can be performed within a parallel worker. Therefore, it can be useful to define this method even when parallel execution is not supported.

```
Size
EstimatedDSMForeignScan(ForeignScanState *node, ParallelContext *pcxt);
```

Estimate the amount of dynamic shared memory that will be required for parallel operation. This may be higher than the amount that will actually be used, but it must not be lower. The return value is in bytes. This function is optional, and can be omitted if not needed; but if it is omitted, the next three functions must be omitted as well, because no shared memory will be allocated for the FDW's use.

```
void  
InitializeDSMForeignScan(ForeignScanState *node, ParallelContext *pcxt,  
                        void *coordinate);
```

Initialize the dynamic shared memory that will be required for parallel operation. `coordinate` points to a shared memory area of size equal to the return value of `EstimatedDSMForeignScan`. This function is optional, and can be omitted if not needed.

```
void  
ReInitializeDSMForeignScan(ForeignScanState *node, ParallelContext *pcxt,  
                          void *coordinate);
```

Re-initialize the dynamic shared memory required for parallel operation when the foreign-scan plan node is about to be re-scanned. This function is optional, and can be omitted if not needed. Recommended practice is that this function reset only shared state, while the `ReScanForeignScan` function resets only local state. Currently, this function will be called before `ReScanForeignScan`, but it's best not to rely on that ordering.

```
void  
InitializeWorkerForeignScan(ForeignScanState *node, shm_toc *toc,  
                          void *coordinate);
```

Initialize a parallel worker's local state based on the shared state set up by the leader during `InitializeDSMForeignScan`. This function is optional, and can be omitted if not needed.

```
void  
ShutdownForeignScan(ForeignScanState *node);
```

Release resources when it is anticipated the node will not be executed to completion. This is not called in all cases; sometimes, `EndForeignScan` may be called without this function having been called first. Since the DSM segment used by parallel query is destroyed just after this callback is invoked, foreign data wrappers that wish to take some action before the DSM segment goes away should implement this method.

58.2.11. FDW Routines for Asynchronous Execution

A `ForeignScan` node can, optionally, support asynchronous execution. The following functions are all optional, but are all required if asynchronous execution is to be supported.

```
bool  
IsForeignPathAsyncCapable(ForeignPath *path);
```

Test whether a given `ForeignPath` path can scan the underlying foreign relation asynchronously. This function will only be called at the end of query planning when the given path is a direct child of an `AppendPath` path and when the planner believes that asynchronous execution improves performance, and should return true if the given path is able to scan the foreign relation asynchronously.

If this function is not defined, it is assumed that the given path scans the foreign relation using `IterateForeignScan`. (This implies that the callback functions described below will never be called, so they need not be provided either.)

```
void  
ForeignAsyncRequest(AsyncRequest *areq);
```

Produce one tuple asynchronously from the `ForeignScan` node. `areq` is the `AsyncRequest` struct describing the `ForeignScan` node and the parent `Append` node that requested the tuple from it. This function should store the tuple into the slot specified by `areq->result`, and set `areq->request_complete` to true; or if it needs to wait on an event external to the core server such as network I/O, and cannot produce any tuple immediately, set the flag to false, and set `areq->callback_pending` to true for the `ForeignScan` node to get a callback from the callback functions described below. If no more tuples are available, set the slot to NULL or an empty slot, and the `areq->request_complete` flag to true. It's recommended to use `ExecAsyncRequestDone` or `ExecAsyncRequestPending` to set the output parameters in the `areq`.

```
void
```

```
ForeignAsyncConfigureWait(AsyncRequest *areq);
```

Configure a file descriptor event for which the `ForeignScan` node wishes to wait. This function will only be called when the `ForeignScan` node has the `areq->callback_pending` flag set, and should add the event to the `as_eventset` of the parent `Append` node described by the `areq`. When the file descriptor event occurs, `ForeignAsyncNotify` will be called.

```
void  
ForeignAsyncNotify(AsyncRequest *areq);
```

Process a relevant event that has occurred, then produce one tuple asynchronously from the `ForeignScan` node. This function should set the output parameters in the `areq` in the same way as `ForeignAsyncRequest`.

58.2.12. FDW Routines for Reparameterization of Paths

```
List *  
ReparameterizeForeignPathByChild(PlannerInfo *root, List *fdw_private,  
                                RelOptInfo *child_rel);
```

This function is called while converting a path parameterized by the top-most parent of the given child relation `child_rel` to be parameterized by the child relation. The function is used to reparameterize any paths or translate any expression nodes saved in the given `fdw_private` member of a `ForeignPath`. The callback may use `reparameterize_path_by_child`, `adjust_appendrel_attrs` or `adjust_appendrel_attrs_multilevel` as required.

58.3. Foreign Data Wrapper Helper Functions

Several helper functions are exported from the core server so that authors of foreign data wrappers can get easy access to attributes of FDW-related objects, such as FDW options. To use any of these functions, you need to include the header file [foreign/foreign.h](#) in your source file. That header also defines the struct types that are returned by these functions.

```
ForeignDataWrapper *  
GetForeignDataWrapperExtended(Oid fdwid, bits16 flags);
```

This function returns a `ForeignDataWrapper` object for the foreign-data wrapper with the given OID. A `ForeignDataWrapper` object contains properties of the FDW (see [foreign/foreign.h](#) for details). `flags` is a bitwise-or'd bit mask indicating an extra set of options. It can take the value `FDW_MISSING_OK`, in which case a `NULL` result is returned to the caller instead of an error for an undefined object.

```
ForeignDataWrapper *  
GetForeignDataWrapper(Oid fdwid);
```

This function returns a `ForeignDataWrapper` object for the foreign-data wrapper with the given OID. A `ForeignDataWrapper` object contains properties of the FDW (see [foreign/foreign.h](#) for details).

```
ForeignServer *  
GetForeignServerExtended(Oid serverid, bits16 flags);
```

This function returns a `ForeignServer` object for the foreign server with the given OID. A `ForeignServer` object contains properties of the server (see [foreign/foreign.h](#) for details). `flags` is a bitwise-or'd bit mask indicating an extra set of options. It can take the value `FSV_MISSING_OK`, in which case a `NULL` result is returned to the caller instead of an error for an undefined object.

```
ForeignServer *  
GetForeignServer(Oid serverid);
```

This function returns a `ForeignServer` object for the foreign server with the given OID. A `ForeignServer` object contains properties of the server (see [foreign/foreign.h](#) for details).

```
UserMapping *  
GetUserMapping(Oid userid, Oid serverid);
```

This function returns a `UserMapping` object for the user mapping of the given role on the given server. (If there is no mapping for the specific user, it will return the mapping for `PUBLIC`, or throw error if there is none.) A `UserMapping` object contains properties of the user mapping (see [foreign/foreign.h](#) for details).

```
ForeignTable *  
GetForeignTable(Oid relid);
```

This function returns a `ForeignTable` object for the foreign table with the given OID. A `ForeignTable` object contains properties of the foreign table (see `foreign/foreign.h` for details).

```
List *  
GetForeignColumnOptions(Oid relid, AttrNumber attnum);
```

This function returns the per-column FDW options for the column with the given foreign table OID and attribute number, in the form of a list of `DefElem`. NIL is returned if the column has no options.

Some object types have name-based lookup functions in addition to the OID-based ones:

```
ForeignDataWrapper *  
GetForeignDataWrapperByName(const char *name, bool missing_ok);
```

This function returns a `ForeignDataWrapper` object for the foreign-data wrapper with the given name. If the wrapper is not found, return NULL if `missing_ok` is true, otherwise raise an error.

```
ForeignServer *  
GetForeignServerByName(const char *name, bool missing_ok);
```

This function returns a `ForeignServer` object for the foreign server with the given name. If the server is not found, return NULL if `missing_ok` is true, otherwise raise an error.

58.4. Foreign Data Wrapper Query Planning

The FDW callback functions `GetForeignRelSize`, `GetForeignPaths`, `GetForeignPlan`, `PlanForeignModify`, `GetForeignJoinPaths`, `GetForeignUpperPaths`, and `PlanDirectModify` must fit into the workings of the Postgres Pro planner. Here are some notes about what they must do.

The information in `root` and `baserel` can be used to reduce the amount of information that has to be fetched from the foreign table (and therefore reduce the cost). `baserel->baserestrictinfo` is particularly interesting, as it contains restriction quals (`WHERE` clauses) that should be used to filter the rows to be fetched. (The FDW itself is not required to enforce these quals, as the core executor can check them instead.) `baserel->reltarget->exprs` can be used to determine which columns need to be fetched; but note that it only lists columns that have to be emitted by the `ForeignScan` plan node, not columns that are used in qual evaluation but not output by the query.

Various private fields are available for the FDW planning functions to keep information in. Generally, whatever you store in FDW private fields should be `palloc'd`, so that it will be reclaimed at the end of planning.

`baserel->fdw_private` is a `void` pointer that is available for FDW planning functions to store information relevant to the particular foreign table. The core planner does not touch it except to initialize it to NULL when the `RelOptInfo` node is created. It is useful for passing information forward from `GetForeignRelSize` to `GetForeignPaths` and/or `GetForeignPlan`, thereby avoiding recalculation.

`GetForeignPaths` can identify the meaning of different access paths by storing private information in the `fdw_private` field of `ForeignPath` nodes. `fdw_private` is declared as a `List` pointer, but could actually contain anything since the core planner does not touch it. However, best practice is to use a representation that's dumpable by `nodeToString`, for use with debugging support available in the backend.

`GetForeignPlan` can examine the `fdw_private` field of the selected `ForeignPath` node, and can generate `fdw_exprs` and `fdw_private` lists to be placed in the `ForeignScan` plan node, where they will be available at execution time. Both of these lists must be represented in a form that `copyObject` knows how to copy. The `fdw_private` list has no other restrictions and is not interpreted by the core backend in any way. The `fdw_exprs` list, if not NIL, is expected to contain expression trees that are intended to be executed at run time. These trees will undergo post-processing by the planner to make them fully executable.

In `GetForeignPlan`, generally the passed-in target list can be copied into the plan node as-is. The passed `scan_clauses` list contains the same clauses as `baserel->baserestrictinfo`, but may be re-ordered for better execution efficiency. In simple cases the FDW can just strip `RestrictInfo` nodes from the `scan_clauses` list (using `extract_actual_clauses`) and put all the clauses into the plan node's qual list, which means that all the clauses will be checked by the executor at run time. More

complex FDWs may be able to check some of the clauses internally, in which case those clauses can be removed from the plan node's qual list so that the executor doesn't waste time rechecking them.

As an example, the FDW might identify some restriction clauses of the form *foreign_variable = sub_expression*, which it determines can be executed on the remote server given the locally-evaluated value of the *sub_expression*. The actual identification of such a clause should happen during `GetForeignPaths`, since it would affect the cost estimate for the path. The path's `fdw_private` field would probably include a pointer to the identified clause's `RestrictInfo` node. Then `GetForeignPlan` would remove that clause from `scan_clauses`, but add the *sub_expression* to `fdw_exprs` to ensure that it gets massaged into executable form. It would probably also put control information into the plan node's `fdw_private` field to tell the execution functions what to do at run time. The query transmitted to the remote server would involve something like `WHERE foreign_variable = $1`, with the parameter value obtained at run time from evaluation of the `fdw_exprs` expression tree.

Any clauses removed from the plan node's qual list must instead be added to `fdw_recheck_quals` or rechecked by `RecheckForeignScan` in order to ensure correct behavior at the `READ COMMITTED` isolation level. When a concurrent update occurs for some other table involved in the query, the executor may need to verify that all of the original quals are still satisfied for the tuple, possibly against a different set of parameter values. Using `fdw_recheck_quals` is typically easier than implementing checks inside `RecheckForeignScan`, but this method will be insufficient when outer joins have been pushed down, since the join tuples in that case might have some fields go to `NULL` without rejecting the tuple entirely.

Another `ForeignScan` field that can be filled by FDWs is `fdw_scan_tlist`, which describes the tuples returned by the FDW for this plan node. For simple foreign table scans this can be set to `NIL`, implying that the returned tuples have the row type declared for the foreign table. A non-`NIL` value must be a target list (list of `TargetEntry`s) containing `Vars` and/or expressions representing the returned columns. This might be used, for example, to show that the FDW has omitted some columns that it noticed won't be needed for the query. Also, if the FDW can compute expressions used by the query more cheaply than can be done locally, it could add those expressions to `fdw_scan_tlist`. Note that join plans (created from paths made by `GetForeignJoinPaths`) must always supply `fdw_scan_tlist` to describe the set of columns they will return.

The FDW should always construct at least one path that depends only on the table's restriction clauses. In join queries, it might also choose to construct path(s) that depend on join clauses, for example *foreign_variable = local_variable*. Such clauses will not be found in `baserel->baserestrictinfo` but must be sought in the relation's join lists. A path using such a clause is called a “parameterized path”. It must identify the other relations used in the selected join clause(s) with a suitable value of `param_info`; use `get_baserel_parampathinfo` to compute that value. In `GetForeignPlan`, the *local_variable* portion of the join clause would be added to `fdw_exprs`, and then at run time the case works the same as for an ordinary restriction clause.

If an FDW supports remote joins, `GetForeignJoinPaths` should produce `ForeignPaths` for potential remote joins in much the same way as `GetForeignPaths` works for base tables. Information about the intended join can be passed forward to `GetForeignPlan` in the same ways described above. However, `baserestrictinfo` is not relevant for join relations; instead, the relevant join clauses for a particular join are passed to `GetForeignJoinPaths` as a separate parameter (`extra->restrictlist`).

An FDW might additionally support direct execution of some plan actions that are above the level of scans and joins, such as grouping or aggregation. To offer such options, the FDW should generate paths and insert them into the appropriate *upper relation*. For example, a path representing remote aggregation should be inserted into the `UPPERREL_GROUP_AGG` relation, using `add_path`. This path will be compared on a cost basis with local aggregation performed by reading a simple scan path for the foreign relation (note that such a path must also be supplied, else there will be an error at plan time). If the remote-aggregation path wins, which it usually would, it will be converted into a plan in the usual way, by calling `GetForeignPlan`. The recommended place to generate such paths is in the `GetForeignUpperPaths` callback function, which is called for each upper relation (i.e., each post-scan/join processing step), if all the base relations of the query come from the same FDW.

`PlanForeignModify` and the other callbacks described in [Section 58.2.4](#) are designed around the assumption that the foreign relation will be scanned in the usual way and then individual row updates will be driven by a local `ModifyTable` plan node. This approach is necessary for the general case where an update requires reading local tables as well as foreign tables. However, if the operation could be executed entirely by the foreign server, the FDW could generate a path representing that and insert it into the `UPPERREL_FINAL` upper relation, where it would compete against the `ModifyTable` approach. This approach could also be used to implement remote `SELECT FOR UPDATE`, rather than using the row locking callbacks described in [Section 58.2.6](#). Keep in mind that a path inserted into `UPPERREL_FINAL` is responsible for implementing *all* behavior of the query.

When planning an `UPDATE` or `DELETE`, `PlanForeignModify` and `PlanDirectModify` can look up the `RelOptInfo` struct for the foreign table and make use of the `baserel->fdw_private` data previously created by the scan-planning functions.

However, in `INSERT` the target table is not scanned so there is no `RelOptInfo` for it. The `List` returned by `PlanForeignModify` has the same restrictions as the `fdw_private` list of a `ForeignScan` plan node, that is it must contain only structures that `copyObject` knows how to copy.

`INSERT` with an `ON CONFLICT` clause does not support specifying the conflict target, as unique constraints or exclusion constraints on remote tables are not locally known. This in turn implies that `ON CONFLICT DO UPDATE` is not supported, since the specification is mandatory there.

58.5. Row Locking in Foreign Data Wrappers

If an FDW's underlying storage mechanism has a concept of locking individual rows to prevent concurrent updates of those rows, it is usually worthwhile for the FDW to perform row-level locking with as close an approximation as practical to the semantics used in ordinary Postgres Pro tables. There are multiple considerations involved in this.

One key decision to be made is whether to perform *early locking* or *late locking*. In early locking, a row is locked when it is first retrieved from the underlying store, while in late locking, the row is locked only when it is known that it needs to be locked. (The difference arises because some rows may be discarded by locally-checked restriction or join conditions.) Early locking is much simpler and avoids extra round trips to a remote store, but it can cause locking of rows that need not have been locked, resulting in reduced concurrency or even unexpected deadlocks. Also, late locking is only possible if the row to be locked can be uniquely re-identified later. Preferably the row identifier should identify a specific version of the row, as Postgres Pro TIDs do.

By default, Postgres Pro ignores locking considerations when interfacing to FDWs, but an FDW can perform early locking without any explicit support from the core code. The API functions described in [Section 58.2.6](#), which were added in Postgres Pro 9.5, allow an FDW to use late locking if it wishes.

An additional consideration is that in `READ COMMITTED` isolation mode, Postgres Pro may need to re-check restriction and join conditions against an updated version of some target tuple. Rechecking join conditions requires re-obtaining copies of the non-target rows that were previously joined to the target tuple. When working with standard Postgres Pro tables, this is done by including the TIDs of the non-target tables in the column list projected through the join, and then re-fetching non-target rows when required. This approach keeps the join data set compact, but it requires inexpensive re-fetch capability, as well as a TID that can uniquely identify the row version to be re-fetched. By default, therefore, the approach used with foreign tables is to include a copy of the entire row fetched from a foreign table in the column list projected through the join. This puts no special demands on the FDW but can result in reduced performance of merge and hash joins. An FDW that is capable of meeting the re-fetch requirements can choose to do it the first way.

For an `UPDATE` or `DELETE` on a foreign table, it is recommended that the `ForeignScan` operation on the target table perform early locking on the rows that it fetches, perhaps via the equivalent of `SELECT FOR UPDATE`. An FDW can detect whether a table is an `UPDATE/DELETE` target at plan time by comparing its `relid` to `root->parse->resultRelation`, or at execution time by using `ExecRelationIsTargetRelation()`. An alternative possibility is to perform late locking within the `ExecForeignUpdate` or `ExecForeignDelete` callback, but no special support is provided for this.

For foreign tables that are specified to be locked by a `SELECT FOR UPDATE/SHARE` command, the `ForeignScan` operation can again perform early locking by fetching tuples with the equivalent of `SELECT FOR UPDATE/SHARE`. To perform late locking instead, provide the callback functions defined in [Section 58.2.6](#). In `GetForeignRowMarkType`, select rowmark option `ROW_MARK_EXCLUSIVE`, `ROW_MARK_NOKEYEXCLUSIVE`, `ROW_MARK_SHARE`, or `ROW_MARK_KEYSHARE` depending on the requested lock strength. (The core code will act the same regardless of which of these four options you choose.) Elsewhere, you can detect whether a foreign table was specified to be locked by this type of command by using `get_plan_rowmark` at plan time, or `ExecFindRowMark` at execution time; you must check not only whether a non-null rowmark struct is returned, but that its `strength` field is not `LCS_NONE`.

Lastly, for foreign tables that are used in an `UPDATE`, `DELETE` or `SELECT FOR UPDATE/SHARE` command but are not specified to be row-locked, you can override the default choice to copy entire rows by having `GetForeignRowMarkType` select option `ROW_MARK_REFERENCE` when it sees lock strength `LCS_NONE`. This will cause `RefetchForeignRow` to be called with that value for `markType`; it should then re-fetch the row without acquiring any new lock. (If you have a `GetForeignRowMarkType` function but don't wish to re-fetch unlocked rows, select option `ROW_MARK_COPY` for `LCS_NONE`.)

Chapter 59. Writing a Table Sampling Method

Postgres Pro's implementation of the TABLESAMPLE clause supports custom table sampling methods, in addition to the BERNOLLI and SYSTEM methods that are required by the SQL standard. The sampling method determines which rows of the table will be selected when the TABLESAMPLE clause is used.

At the SQL level, a table sampling method is represented by a single SQL function, typically implemented in C, having the signature `method_name(internal) RETURNS tsm_handler`

The name of the function is the same method name appearing in the TABLESAMPLE clause. The `internal` argument is a dummy (always having value zero) that simply serves to prevent this function from being called directly from an SQL command. The result of the function must be a palloc'd struct of type `TsmRoutine`, which contains pointers to support functions for the sampling method. These support functions are plain C functions and are not visible or callable at the SQL level. The support functions are described in [Section 59.1](#).

In addition to function pointers, the `TsmRoutine` struct must provide these additional fields:

`List *parameterTypes`

This is an OID list containing the data type OIDs of the parameter(s) that will be accepted by the TABLESAMPLE clause when this sampling method is used. For example, for the built-in methods, this list contains a single item with value `FLOAT4OID`, which represents the sampling percentage. Custom sampling methods can have more or different parameters.

`bool repeatable_across_queries`

If `true`, the sampling method can deliver identical samples across successive queries, if the same parameters and `REPEATABLE` seed value are supplied each time and the table contents have not changed. When this is `false`, the `REPEATABLE` clause is not accepted for use with the sampling method.

`bool repeatable_across_scans`

If `true`, the sampling method can deliver identical samples across successive scans in the same query (assuming unchanging parameters, seed value, and snapshot). When this is `false`, the planner will not select plans that would require scanning the sampled table more than once, since that might result in inconsistent query output.

The table sampling methods included in the standard distribution are good references when trying to write your own. Look into the `contrib` subdirectory for add-on methods.

59.1. Sampling Method Support Functions

The TSM handler function returns a palloc'd `TsmRoutine` struct containing pointers to the support functions described below. Most of the functions are required, but some are optional, and those pointers can be `NULL`.

```
void
SampleScanGetSampleSize (PlannerInfo *root,
                        RelOptInfo *baserel,
                        List *paramexprs,
                        BlockNumber *pages,
                        double *tuples);
```

This function is called during planning. It must estimate the number of relation pages that will be read during a sample scan, and the number of tuples that will be selected by the scan. (For example, these might be determined by estimating the sampling fraction, and then multiplying the `baserel->pages` and `baserel->tuples` numbers by that, being sure to round the results to integral values.) The `paramexprs` list holds the expression(s) that are parameters to the TABLESAMPLE clause. It is recommended to use `estimate_expression_value()` to try to reduce these expressions to constants, if their values are needed for estimation purposes; but the function must provide size estimates even if they cannot be reduced, and it should not fail even if the values appear invalid (remember that they're only estimates of what the run-time values will be). The `pages` and `tuples` parameters are outputs.

```
void
InitSampleScan (SampleScanState *node,
```

```
int eflags);
```

Initialize for execution of a `SampleScan` plan node. This is called during executor startup. It should perform any initialization needed before processing can start. The `SampleScanState` node has already been created, but its `tsm_state` field is `NULL`. The `InitSampleScan` function can `malloc` whatever internal state data is needed by the sampling method, and store a pointer to it in `node->tsm_state`. Information about the table to scan is accessible through other fields of the `SampleScanState` node (but note that the `node->ss.ss_currentScanDesc` scan descriptor is not set up yet). `eflags` contains flag bits describing the executor's operating mode for this plan node.

When `(eflags & EXEC_FLAG_EXPLAIN_ONLY)` is true, the scan will not actually be performed, so this function should only do the minimum required to make the node state valid for `EXPLAIN` and `EndSampleScan`.

This function can be omitted (set the pointer to `NULL`), in which case `BeginSampleScan` must perform all initialization needed by the sampling method.

```
void
BeginSampleScan (SampleScanState *node,
                 Datum *params,
                 int nparams,
                 uint32 seed);
```

Begin execution of a sampling scan. This is called just before the first attempt to fetch a tuple, and may be called again if the scan needs to be restarted. Information about the table to scan is accessible through fields of the `SampleScanState` node (but note that the `node->ss.ss_currentScanDesc` scan descriptor is not set up yet). The `params` array, of length `nparams`, contains the values of the parameters supplied in the `TABLESAMPLE` clause. These will have the number and types specified in the sampling method's `parameterTypes` list, and have been checked to not be null. `seed` contains a seed to use for any random numbers generated within the sampling method; it is either a hash derived from the `REPEATABLE` value if one was given, or the result of `random()` if not.

This function may adjust the fields `node->use_bulkread` and `node->use_pagemode`. If `node->use_bulkread` is `true`, which it is by default, the scan will use a buffer access strategy that encourages recycling buffers after use. It might be reasonable to set this to `false` if the scan will visit only a small fraction of the table's pages. If `node->use_pagemode` is `true`, which it is by default, the scan will perform visibility checking in a single pass for all tuples on each visited page. It might be reasonable to set this to `false` if the scan will select only a small fraction of the tuples on each visited page. That will result in fewer tuple visibility checks being performed, though each one will be more expensive because it will require more locking.

If the sampling method is marked `repeatable_across_scans`, it must be able to select the same set of tuples during a rescan as it did originally, that is a fresh call of `BeginSampleScan` must lead to selecting the same tuples as before (if the `TABLESAMPLE` parameters and seed don't change).

```
BlockNumber
NextSampleBlock (SampleScanState *node, BlockNumber nblocks);
```

Returns the block number of the next page to be scanned, or `InvalidBlockNumber` if no pages remain to be scanned.

This function can be omitted (set the pointer to `NULL`), in which case the core code will perform a sequential scan of the entire relation. Such a scan can use synchronized scanning, so that the sampling method cannot assume that the relation pages are visited in the same order on each scan.

```
OffsetNumber
NextSampleTuple (SampleScanState *node,
                 BlockNumber blockno,
                 OffsetNumber maxoffset);
```

Returns the offset number of the next tuple to be sampled on the specified page, or `InvalidOffsetNumber` if no tuples remain to be sampled. `maxoffset` is the largest offset number in use on the page.

Note

`NextSampleTuple` is not explicitly told which of the offset numbers in the range `1 .. maxoffset` actually contain valid tuples. This is not normally a problem since the core code ignores requests to sample missing or invisible tuples; that

should not result in any bias in the sample. However, if necessary, the function can use `node->doneTuples` to examine how many of the tuples it returned were valid and visible.

Note

`NextSampleTuple` must *not* assume that `blockno` is the same page number returned by the most recent `NextSampleBlock` call. It was returned by some previous `NextSampleBlock` call, but the core code is allowed to call `NextSampleBlock` in advance of actually scanning pages, so as to support prefetching. It is OK to assume that once sampling of a given page begins, successive `NextSampleTuple` calls all refer to the same page until `InvalidOffsetNumber` is returned.

```
void  
EndSampleScan (SampleScanState *node);
```

End the scan and release resources. It is normally not important to release `palloc'd` memory, but any externally-visible resources should be cleaned up. This function can be omitted (set the pointer to `NULL`) in the common case where no such resources exist.

Chapter 60. Writing a Custom Scan Provider

Postgres Pro supports a set of experimental facilities which are intended to allow extension modules to add new scan types to the system. Unlike a [foreign data wrapper](#), which is only responsible for knowing how to scan its own foreign tables, a custom scan provider can provide an alternative method of scanning any relation in the system. Typically, the motivation for writing a custom scan provider will be to allow the use of some optimization not supported by the core system, such as caching or some form of hardware acceleration. This chapter outlines how to write a new custom scan provider.

Implementing a new type of custom scan is a three-step process. First, during planning, it is necessary to generate access paths representing a scan using the proposed strategy. Second, if one of those access paths is selected by the planner as the optimal strategy for scanning a particular relation, the access path must be converted to a plan. Finally, it must be possible to execute the plan and generate the same results that would have been generated for any other access path targeting the same relation.

60.1. Creating Custom Scan Paths

A custom scan provider will typically add paths for a base relation by setting the following hook, which is called after the core code has generated all the access paths it can for the relation (except for Gather and Gather Merge paths, which are made after this call so that they can use partial paths added by the hook):

```
typedef void (*set_rel_pathlist_hook_type) (PlannerInfo *root,
                                           RelOptInfo *rel,
                                           Index rti,
                                           RangeTblEntry *rte);

extern PGDLLIMPORT set_rel_pathlist_hook_type set_rel_pathlist_hook;
```

Although this hook function can be used to examine, modify, or remove paths generated by the core system, a custom scan provider will typically confine itself to generating `CustomPath` objects and adding them to `rel` using `add_path`, or `add_partial_path` if they are partial paths. The custom scan provider is responsible for initializing the `CustomPath` object, which is declared like this:

```
typedef struct CustomPath
{
    Path      path;
    uint32    flags;
    List      *custom_paths;
    List      *custom_restrictinfo;
    List      *custom_private;
    const CustomPathMethods *methods;
} CustomPath;
```

`path` must be initialized as for any other path, including the row-count estimate, start and total cost, and sort ordering provided by this path. `flags` is a bit mask, which specifies whether the scan provider can support certain optional capabilities. `flags` should include `CUSTOMPATH_SUPPORT_BACKWARD_SCAN` if the custom path can support a backward scan, `CUSTOMPATH_SUPPORT_MARK_RESTORE` if it can support mark and restore, and `CUSTOMPATH_SUPPORT_PROJECTION` if it can perform projections. (If `CUSTOMPATH_SUPPORT_PROJECTION` is not set, the scan node will only be asked to produce Vars of the scanned relation; while if that flag is set, the scan node must be able to evaluate scalar expressions over these Vars.) An optional `custom_paths` is a list of `Path` nodes used by this custom-path node; these will be transformed into `Plan` nodes by planner. As described below, custom paths can be created for join relations as well. In such a case, `custom_restrictinfo` should be used to store the set of join clauses to apply to the join the custom path replaces. Otherwise it should be `NIL`. `custom_private` can be used to store the custom path's private data. Private data should be stored in a form that can be handled by `nodeToString`, so that debugging routines that attempt to print the custom path will work as designed. `methods` must point to a (usually statically allocated) object implementing the required custom path methods, which are further detailed below.

A custom scan provider can also provide join paths. Just as for base relations, such a path must produce the same output as would normally be produced by the join it replaces. To do this, the join provider should set the following hook, and then within the hook function, create `CustomPath` path(s) for the join relation.

```
typedef void (*set_join_pathlist_hook_type) (PlannerInfo *root,
                                              RelOptInfo *joinrel,
                                              RelOptInfo *outerrel,
```

```

                                RelOptInfo *innerrel,
                                JoinType jointype,
                                JoinPathExtraData *extra);
extern PGDLLIMPORT set_join_pathlist_hook_type set_join_pathlist_hook;

```

This hook will be invoked repeatedly for the same join relation, with different combinations of inner and outer relations; it is the responsibility of the hook to minimize duplicated work.

Note also that the set of join clauses to apply to the join, which is passed as `extra->restrictlist`, varies depending on the combination of inner and outer relations. A `CustomPath` path generated for the `joinrel` must contain the set of join clauses it uses, which will be used by the planner to convert the `CustomPath` path into a plan, if it is selected by the planner as the best path for the `joinrel`.

60.1.1. Custom Scan Path Callbacks

```

Plan *(*PlanCustomPath) (PlannerInfo *root,
                          RelOptInfo *rel,
                          CustomPath *best_path,
                          List *tlist,
                          List *clauses,
                          List *custom_plans);

```

Convert a custom path to a finished plan. The return value will generally be a `CustomScan` object, which the callback must allocate and initialize. See [Section 60.2](#) for more details.

```

List *(*ReparameterizeCustomPathByChild) (PlannerInfo *root,
                                           List *custom_private,
                                           RelOptInfo *child_rel);

```

This callback is called while converting a path parameterized by the top-most parent of the given child relation `child_rel` to be parameterized by the child relation. The callback is used to reparameterize any paths or translate any expression nodes saved in the given `custom_private` member of a `CustomPath`. The callback may use `reparameterize_path_by_child`, `adjust_appendrel_attrs` or `adjust_appendrel_attrs_multilevel` as required.

60.2. Creating Custom Scan Plans

A custom scan is represented in a finished plan tree using the following structure:

```

typedef struct CustomScan
{
    Scan      scan;
    uint32    flags;
    List      *custom_plans;
    List      *custom_exprs;
    List      *custom_private;
    List      *custom_scan_tlist;
    Bitmapset *custom_relids;
    const CustomScanMethods *methods;
} CustomScan;

```

`scan` must be initialized as for any other scan, including estimated costs, target lists, qualifications, and so on. `flags` is a bit mask with the same meaning as in `CustomPath`. `custom_plans` can be used to store child `Plan` nodes. `custom_exprs` should be used to store expression trees that will need to be fixed up by `setrefs.c` and `subselect.c`, while `custom_private` should be used to store other private data that is only used by the custom scan provider itself. `custom_scan_tlist` can be `NIL` when scanning a base relation, indicating that the custom scan returns scan tuples that match the base relation's row type. Otherwise it is a target list describing the actual scan tuples. `custom_scan_tlist` must be provided for joins, and could be provided for scans if the custom scan provider can compute some non-Var expressions. `custom_relids` is set by the core code to the set of relations (range table indexes) that this scan node handles; except when this scan is replacing a join, it will have only one member. `methods` must point to a (usually statically allocated) object implementing the required custom scan methods, which are further detailed below.

When a `CustomScan` scans a single relation, `scan.scanrelid` must be the range table index of the table to be scanned. When it replaces a join, `scan.scanrelid` should be zero.

Plan trees must be able to be duplicated using `copyObject`, so all the data stored within the “custom” fields must consist of nodes that that function can handle. Furthermore, custom scan providers cannot substitute a larger structure that embeds a `CustomScan` for the structure itself, as would be possible for a `CustomPath` or `CustomScanState`.

60.2.1. Custom Scan Plan Callbacks

```
Node *(*CreateCustomScanState) (CustomScan *cscan);
```

Allocate a `CustomScanState` for this `CustomScan`. The actual allocation will often be larger than required for an ordinary `CustomScanState`, because many providers will wish to embed that as the first field of a larger structure. The value returned must have the node tag and `methods` set appropriately, but other fields should be left as zeroes at this stage; after `ExecInitCustomScan` performs basic initialization, the `BeginCustomScan` callback will be invoked to give the custom scan provider a chance to do whatever else is needed.

60.3. Executing Custom Scans

When a `CustomScan` is executed, its execution state is represented by a `CustomScanState`, which is declared as follows:

```
typedef struct CustomScanState
{
    ScanState ss;
    uint32    flags;
    const CustomExecMethods *methods;
} CustomScanState;
```

`ss` is initialized as for any other scan state, except that if the scan is for a join rather than a base relation, `ss.ss_currentRelation` is left `NULL`. `flags` is a bit mask with the same meaning as in `CustomPath` and `CustomScan`. `methods` must point to a (usually statically allocated) object implementing the required custom scan state methods, which are further detailed below. Typically, a `CustomScanState`, which need not support `copyObject`, will actually be a larger structure embedding the above as its first member.

60.3.1. Custom Scan Execution Callbacks

```
void (*BeginCustomScan) (CustomScanState *node,
                        Estate *estate,
                        int eflags);
```

Complete initialization of the supplied `CustomScanState`. Standard fields have been initialized by `ExecInitCustomScan`, but any private fields should be initialized here.

```
TupleTableSlot *(*ExecCustomScan) (CustomScanState *node);
```

Fetch the next scan tuple. If any tuples remain, it should fill `ps_ResultTupleSlot` with the next tuple in the current scan direction, and then return the tuple slot. If not, `NULL` or an empty slot should be returned.

```
void (*EndCustomScan) (CustomScanState *node);
```

Clean up any private data associated with the `CustomScanState`. This method is required, but it does not need to do anything if there is no associated data or it will be cleaned up automatically.

```
void (*ReScanCustomScan) (CustomScanState *node);
```

Rewind the current scan to the beginning and prepare to rescan the relation.

```
void (*MarkPosCustomScan) (CustomScanState *node);
```

Save the current scan position so that it can subsequently be restored by the `RestrPosCustomScan` callback. This callback is optional, and need only be supplied if the `CUSTOMPATH_SUPPORT_MARK_RESTORE` flag is set.

```
void (*RestrPosCustomScan) (CustomScanState *node);
```

Restore the previous scan position as saved by the `MarkPosCustomScan` callback. This callback is optional, and need only be supplied if the `CUSTOMPATH_SUPPORT_MARK_RESTORE` flag is set.

```
Size (*EstimatedDSMCustomScan) (CustomScanState *node,  
                                ParallelContext *pcxt);
```

Estimate the amount of dynamic shared memory that will be required for parallel operation. This may be higher than the amount that will actually be used, but it must not be lower. The return value is in bytes. This callback is optional, and need only be supplied if this custom scan provider supports parallel execution.

```
void (*InitializedDSMCustomScan) (CustomScanState *node,  
                                ParallelContext *pcxt,  
                                void *coordinate);
```

Initialize the dynamic shared memory that will be required for parallel operation. `coordinate` points to a shared memory area of size equal to the return value of `EstimatedDSMCustomScan`. This callback is optional, and need only be supplied if this custom scan provider supports parallel execution.

```
void (*ReInitializedDSMCustomScan) (CustomScanState *node,  
                                   ParallelContext *pcxt,  
                                   void *coordinate);
```

Re-initialize the dynamic shared memory required for parallel operation when the custom-scan plan node is about to be re-scanned. This callback is optional, and need only be supplied if this custom scan provider supports parallel execution. Recommended practice is that this callback reset only shared state, while the `ReScanCustomScan` callback resets only local state. Currently, this callback will be called before `ReScanCustomScan`, but it's best not to rely on that ordering.

```
void (*InitializeWorkerCustomScan) (CustomScanState *node,  
                                   shm_toc *toc,  
                                   void *coordinate);
```

Initialize a parallel worker's local state based on the shared state set up by the leader during `InitializedDSMCustomScan`. This callback is optional, and need only be supplied if this custom scan provider supports parallel execution.

```
void (*ShutdownCustomScan) (CustomScanState *node);
```

Release resources when it is anticipated the node will not be executed to completion. This is not called in all cases; sometimes, `EndCustomScan` may be called without this function having been called first. Since the DSM segment used by parallel query is destroyed just after this callback is invoked, custom scan providers that wish to take some action before the DSM segment goes away should implement this method.

```
void (*ExplainCustomScan) (CustomScanState *node,  
                           List *ancestors,  
                           ExplainState *es);
```

Output additional information for `EXPLAIN` of a custom-scan plan node. This callback is optional. Common data stored in the `ScanState`, such as the target list and scan relation, will be shown even without this callback, but the callback allows the display of additional, private state.

Chapter 61. Genetic Query Optimizer

Author

Written by Martin Utesch (<utesch@aut.tu-freiberg.de>) for the Institute of Automatic Control at the University of Mining and Technology in Freiberg, Germany.

61.1. Query Handling as a Complex Optimization Problem

Among all relational operators the most difficult one to process and optimize is the *join*. The number of possible query plans grows exponentially with the number of joins in the query. Further optimization effort is caused by the support of a variety of *join methods* (e.g., nested loop, hash join, merge join in Postgres Pro) to process individual joins and a diversity of *indexes* (e.g., B-tree, hash, GiST and GIN in Postgres Pro) as access paths for relations.

The normal Postgres Pro query optimizer performs a *near-exhaustive search* over the space of alternative strategies. This algorithm, first introduced in IBM's System R database, produces a near-optimal join order, but can take an enormous amount of time and memory space when the number of joins in the query grows large. This makes the ordinary Postgres Pro query optimizer inappropriate for queries that join a large number of tables.

The Institute of Automatic Control at the University of Mining and Technology, in Freiberg, Germany, encountered some problems when it wanted to use PostgreSQL as the backend for a decision support knowledge based system for the maintenance of an electrical power grid. The DBMS needed to handle large join queries for the inference machine of the knowledge based system. The number of joins in these queries made using the normal query optimizer infeasible.

In the following we describe the implementation of a *genetic algorithm* to solve the join ordering problem in a manner that is efficient for queries involving large numbers of joins.

61.2. Genetic Algorithms

The genetic algorithm (GA) is a heuristic optimization method which operates through randomized search. The set of possible solutions for the optimization problem is considered as a *population of individuals*. The degree of adaptation of an individual to its environment is specified by its *fitness*.

The coordinates of an individual in the search space are represented by *chromosomes*, in essence a set of character strings. A *gene* is a subsection of a chromosome which encodes the value of a single parameter being optimized. Typical encodings for a gene could be *binary* or *integer*.

Through simulation of the evolutionary operations *recombination*, *mutation*, and *selection* new generations of search points are found that show a higher average fitness than their ancestors. [Figure 61.1](#) illustrates these steps.

Figure 61.1. Structure of a Genetic Algorithm

According to the comp.ai.genetic FAQ it cannot be stressed too strongly that a GA is not a pure random search for a solution to a problem. A GA uses stochastic processes, but the result is distinctly non-random (better than random).

61.3. Genetic Query Optimization (GEQO) in Postgres Pro

The GEQO module approaches the query optimization problem as though it were the well-known traveling salesman problem (TSP). Possible query plans are encoded as integer strings. Each string represents the join order from one relation of the query to the next. For example, the join tree

```

  /\
 /\ 2
 /\ 3

```

4 1

is encoded by the integer string '4-1-3-2', which means, first join relation '4' and '1', then '3', and then '2', where 1, 2, 3, 4 are relation IDs within the Postgres Pro optimizer.

Specific characteristics of the GEQO implementation in Postgres Pro are:

- Usage of a *steady state* GA (replacement of the least fit individuals in a population, not whole-generational replacement) allows fast convergence towards improved query plans. This is essential for query handling with reasonable time;
- Usage of *edge recombination crossover* which is especially suited to keep edge losses low for the solution of the TSP by means of a GA;
- Mutation as genetic operator is deprecated so that no repair mechanisms are needed to generate legal TSP tours.

Parts of the GEQO module are adapted from D. Whitley's Genitor algorithm.

The GEQO module allows the Postgres Pro query optimizer to support large join queries effectively through non-exhaustive search.

61.3.1. Generating Possible Plans with GEQO

The GEQO planning process uses the standard planner code to generate plans for scans of individual relations. Then join plans are developed using the genetic approach. As shown above, each candidate join plan is represented by a sequence in which to join the base relations. In the initial stage, the GEQO code simply generates some possible join sequences at random. For each join sequence considered, the standard planner code is invoked to estimate the cost of performing the query using that join sequence. (For each step of the join sequence, all three possible join strategies are considered; and all the initially-determined relation scan plans are available. The estimated cost is the cheapest of these possibilities.) Join sequences with lower estimated cost are considered “more fit” than those with higher cost. The genetic algorithm discards the least fit candidates. Then new candidates are generated by combining genes of more-fit candidates — that is, by using randomly-chosen portions of known low-cost join sequences to create new sequences for consideration. This process is repeated until a preset number of join sequences have been considered; then the best one found at any time during the search is used to generate the finished plan.

This process is inherently nondeterministic, because of the randomized choices made during both the initial population selection and subsequent “mutation” of the best candidates. To avoid surprising changes of the selected plan, each run of the GEQO algorithm restarts its random number generator with the current `geqo_seed` parameter setting. As long as `geqo_seed` and the other GEQO parameters are kept fixed, the same plan will be generated for a given query (and other planner inputs such as statistics). To experiment with different search paths, try changing `geqo_seed`.

61.3.2. Future Implementation Tasks for PostgreSQL GEQO

Work is still needed to improve the genetic algorithm parameter settings. We have to find a compromise for the parameter settings to satisfy two competing demands:

- Optimality of the query plan
- Computing time

In the current implementation, the fitness of each candidate join sequence is estimated by running the standard planner's join selection and cost estimation code from scratch. To the extent that different candidates use similar sub-sequences of joins, a great deal of work will be repeated. This could be made significantly faster by retaining cost estimates for sub-joins. The problem is to avoid expending unreasonable amounts of memory on retaining that state.

At a more basic level, it is not clear that solving query optimization with a GA algorithm designed for TSP is appropriate. In the TSP case, the cost associated with any substring (partial tour) is independent of the rest of the tour, but this is certainly not true for query optimization. Thus it is questionable whether edge recombination crossover is the most effective mutation procedure.

Chapter 62. Table Access Method Interface Definition

This chapter explains the interface between the core Postgres Pro system and *table access methods*, which manage the storage for tables. The core system knows little about these access methods beyond what is specified here, so it is possible to develop entirely new access method types by writing add-on code.

Each table access method is described by a row in the `pg_am` system catalog. The `pg_am` entry specifies a name and a *handler function* for the table access method. These entries can be created and deleted using the `CREATE ACCESS METHOD` and `DROP ACCESS METHOD` SQL commands.

A table access method handler function must be declared to accept a single argument of type `internal` and to return the pseudo-type `table_am_handler`. The argument is a dummy value that simply serves to prevent handler functions from being called directly from SQL commands. The result of the function must be a pointer to a struct of type `TableAmRoutine`, which contains everything that the core code needs to know to make use of the table access method. The return value needs to be of server lifetime, which is typically achieved by defining it as a `static const` variable in global scope. The `TableAmRoutine` struct, also called the access method's *API struct*, defines the behavior of the access method using callbacks. These callbacks are pointers to plain C functions and are not visible or callable at the SQL level. All the callbacks and their behavior is defined in the `TableAmRoutine` structure (with comments inside the struct defining the requirements for callbacks). Most callbacks have wrapper functions, which are documented from the point of view of a user (rather than an implementor) of the table access method. For details, please refer to the `src/include/access/tableam.h` file.

To implement an access method, an implementor will typically need to implement an AM-specific type of tuple table slot (see `src/include/executor/tuptable.h`), which allows code outside the access method to hold references to tuples of the AM, and to access the columns of the tuple.

Currently, the way an AM actually stores data is fairly unconstrained. For example, it's possible, but not required, to use postgres' shared buffer cache. In case it is used, it likely makes sense to use Postgres Pro's standard page layout as described in [Section 66.6](#).

One fairly large constraint of the table access method API is that, currently, if the AM wants to support modifications and/or indexes, it is necessary for each tuple to have a tuple identifier (TID) consisting of a block number and an item number (see also [Section 66.6](#)). It is not strictly necessary that the sub-parts of TIDs have the same meaning they e.g., have for `heap`, but if bitmap scan support is desired (it is optional), the block number needs to provide locality.

For crash safety, an AM can use postgres' `WAL`, or a custom implementation. If `WAL` is chosen, either [Generic WAL Records](#) can be used, or a [Custom WAL Resource Manager](#) can be implemented.

To implement transactional support in a manner that allows different table access methods be accessed within a single transaction, it likely is necessary to closely integrate with the machinery in `src/backend/access/transam/xlog.c`.

Chapter 63. Index Access Method Interface Definition

This chapter defines the interface between the core Postgres Pro system and *index access methods*, which manage individual index types. The core system knows nothing about indexes beyond what is specified here, so it is possible to develop entirely new index types by writing add-on code.

All indexes in Postgres Pro are what are known technically as *secondary indexes*; that is, the index is physically separate from the table file that it describes. Each index is stored as its own physical *relation* and so is described by an entry in the `pg_class` catalog. The contents of an index are entirely under the control of its index access method. In practice, all index access methods divide indexes into standard-size pages so that they can use the regular storage manager and buffer manager to access the index contents. (All the existing index access methods furthermore use the standard page layout described in [Section 66.6](#), and most use the same format for index tuple headers; but these decisions are not forced on an access method.)

An index is effectively a mapping from some data key values to *tuple identifiers*, or TIDs, of row versions (tuples) in the index's parent table. A TID consists of a block number and an item number within that block (see [Section 66.6](#)). This is sufficient information to fetch a particular row version from the table. Indexes are not directly aware that under MVCC, there might be multiple extant versions of the same logical row; to an index, each tuple is an independent object that needs its own index entry. Thus, an update of a row always creates all-new index entries for the row, even if the key values did not change. ([HOT tuples](#) are an exception to this statement; but indexes do not deal with those, either.) Index entries for dead tuples are reclaimed (by vacuuming) when the dead tuples themselves are reclaimed.

63.1. Basic API Structure for Indexes

Each index access method is described by a row in the `pg_am` system catalog. The `pg_am` entry specifies a name and a *handler function* for the index access method. These entries can be created and deleted using the [CREATE ACCESS METHOD](#) and [DROP ACCESS METHOD](#) SQL commands.

An index access method handler function must be declared to accept a single argument of type `internal` and to return the pseudo-type `index_am_handler`. The argument is a dummy value that simply serves to prevent handler functions from being called directly from SQL commands. The result of the function must be a palloc'd struct of type `IndexAmRoutine`, which contains everything that the core code needs to know to make use of the index access method. The `IndexAmRoutine` struct, also called the access method's *API struct*, includes fields specifying assorted fixed properties of the access method, such as whether it can support multicolumn indexes. More importantly, it contains pointers to support functions for the access method, which do all of the real work to access indexes. These support functions are plain C functions and are not visible or callable at the SQL level. The support functions are described in [Section 63.2](#).

The structure `IndexAmRoutine` is defined thus:

```
typedef struct IndexAmRoutine
{
    NodeTag      type;

    /*
     * Total number of strategies (operators) by which we can traverse/search
     * this AM. Zero if AM does not have a fixed set of strategy assignments.
     */
    uint16       amstrategies;
    /* total number of support functions that this AM uses */
    uint16       amsupport;
    /* opclass options support function number or 0 */
    uint16       amoptsprocnum;
    /* does AM support ORDER BY indexed column's value? */
    bool         amcanorder;
    /* does AM support ORDER BY result of an operator on indexed column? */
    bool         amcanorderbyop;
    /*
     * Does AM support only one ORDER BY operator on first indexed column?
     * amcanorderbyop is implied.
     */
    bool         amorderbyopfirstcol;
}
```

```
/* does AM support backward scanning? */
bool        amcanbackward;
/* does AM support UNIQUE indexes? */
bool        amcanunique;
/* does AM support multi-column indexes? */
bool        amcanmulticol;
/* does AM require scans to have a constraint on the first index column? */
bool        amoptionalkey;
/* does AM handle ScalarArrayOpExpr quals? */
bool        amsearcharray;
/* does AM handle IS NULL/IS NOT NULL quals? */
bool        amsearchnulls;
/* can index storage data type differ from column data type? */
bool        amstorage;
/* can an index of this type be clustered on? */
bool        amclusterable;
/* does AM handle predicate locks? */
bool        ampredlocks;
/* does AM support parallel scan? */
bool        amcanparallel;
/* does AM support parallel build? */
bool        amcanbuildparallel;
/* does AM support columns included with clause INCLUDE? */
bool        amcaninclude;
/* does AM use maintenance_work_mem? */
bool        amusemaintenanceworkmem;
/* does AM summarize tuples, with at least all tuples in the block
 * summarized in one summary */
bool        amsummarizing;
/* OR of parallel vacuum flags */
uint8       amparallelvacuumoptions;
/* type of data stored in index, or InvalidOid if variable */
Oid         amkeytype;

/* interface functions */
ambuild_function ambuild;
ambuildempty_function ambuildempty;
amininsert_function amininsert;
amininsertcleanup_function amininsertcleanup; /* can be NULL */
ambulkdelete_function ambulkdelete;
amvacuumcleanup_function amvacuumcleanup;
amcanreturn_function amcanreturn; /* can be NULL */
amcostestimate_function amcostestimate;
amoptions_function amoptions;
amproperty_function amproperty; /* can be NULL */
ambuildphasename_function ambuildphasename; /* can be NULL */

amrescan_function amrescan;
amgettupple_function amgettupple; /* can be NULL */
amgetbitmap_function amgetbitmap; /* can be NULL */
amendscan_function amendscan;
ammarkpos_function ammarkpos; /* can be NULL */
amrestrpos_function amrestrpos; /* can be NULL */

/* interface functions to support parallel index scans */
amestimateparallelscan_function amestimateparallelscan; /* can be NULL */
```

```

    aminitparallelsan_function aminitparallelsan;    /* can be NULL */
    amparallelrescan_function amparallelrescan;    /* can be NULL */
} IndexAmRoutine;

```

To be useful, an index access method must also have one or more *operator families* and *operator classes* defined in [pg_opfamily](#), [pg_opclass](#), [pg_amop](#), and [pg_amproc](#). These entries allow the planner to determine what kinds of query qualifications can be used with indexes of this access method. Operator families and classes are described in [Section 39.16](#), which is prerequisite material for reading this chapter.

An individual index is defined by a [pg_class](#) entry that describes it as a physical relation, plus a [pg_index](#) entry that shows the logical content of the index — that is, the set of index columns it has and the semantics of those columns, as captured by the associated operator classes. The index columns (key values) can be either simple columns of the underlying table or expressions over the table rows. The index access method normally has no interest in where the index key values come from (it is always handed precomputed key values) but it will be very interested in the operator class information in [pg_index](#). Both of these catalog entries can be accessed as part of the [Relation](#) data structure that is passed to all operations on the index.

Some of the flag fields of [IndexAmRoutine](#) have nonobvious implications. The requirements of [amcanunique](#) are discussed in [Section 63.5](#). The [amcanmulticol](#) flag asserts that the access method supports multi-key-column indexes, while [amoptionalkey](#) asserts that it allows scans where no indexable restriction clause is given for the first index column. When [amcanmulticol](#) is false, [amoptionalkey](#) essentially says whether the access method supports full-index scans without any restriction clause. Access methods that support multiple index columns *must* support scans that omit restrictions on any or all of the columns after the first; however they are permitted to require some restriction to appear for the first index column, and this is signaled by setting [amoptionalkey](#) false. One reason that an index AM might set [amoptionalkey](#) false is if it doesn't index null values. Since most indexable operators are strict and hence cannot return true for null inputs, it is at first sight attractive to not store index entries for null values: they could never be returned by an index scan anyway. However, this argument fails when an index scan has no restriction clause for a given index column. In practice this means that indexes that have [amoptionalkey](#) true must index nulls, since the planner might decide to use such an index with no scan keys at all. A related restriction is that an index access method that supports multiple index columns *must* support indexing null values in columns after the first, because the planner will assume the index can be used for queries that do not restrict these columns. For example, consider an index on (a,b) and a query with `WHERE a = 4`. The system will assume the index can be used to scan for rows with `a = 4`, which is wrong if the index omits rows where `b` is null. It is, however, OK to omit rows where the first indexed column is null. An index access method that does index nulls may also set [amsearchnulls](#), indicating that it supports `IS NULL` and `IS NOT NULL` clauses as search conditions.

The [amcaninclude](#) flag indicates whether the access method supports “included” columns, that is it can store (without processing) additional columns beyond the key column(s). The requirements of the preceding paragraph apply only to the key columns. In particular, the combination of [amcanmulticol=false](#) and [amcaninclude=true](#) is sensible: it means that there can only be one key column, but there can also be included column(s). Also, included columns must be allowed to be null, independently of [amoptionalkey](#).

The [amsummarizing](#) flag indicates whether the access method summarizes the indexed tuples, with summarizing granularity of at least per block. Access methods that do not point to individual tuples, but to block ranges (like BRIN), may allow the HOT optimization to continue. This does not apply to attributes referenced in index predicates, an update of such an attribute always disables HOT.

63.2. Index Access Method Functions

The index construction and maintenance functions that an index access method must provide in [IndexAmRoutine](#) are:

```

IndexBuildResult *
ambuild (Relation heapRelation,
         Relation indexRelation,
         IndexInfo *indexInfo);

```

Build a new index. The index relation has been physically created, but is empty. It must be filled in with whatever fixed data the access method requires, plus entries for all tuples already existing in the table. Ordinarily the `ambuild` function will call `table_index_build_scan()` to scan the table for existing tuples and compute the keys that need to be inserted into the index. The function must return a palloc'd struct containing statistics about the new index. The [amcanbuildparallel](#) flag indicates whether the access method supports parallel index builds. When set to `true`, the system will attempt to allocate parallel workers for the build. Access methods supporting only non-parallel index builds should leave this flag set to `false`.

```
void  
ambuildempty (Relation indexRelation);
```

Build an empty index, and write it to the initialization fork (INIT_FORKNUM) of the given relation. This method is called only for unlogged indexes; the empty index written to the initialization fork will be copied over the main relation fork on each server restart.

```
bool  
amininsert (Relation indexRelation,  
            Datum *values,  
            bool *isnull,  
            ItemPointer heap_tid,  
            Relation heapRelation,  
            IndexUniqueCheck checkUnique,  
            bool indexUnchanged,  
            IndexInfo *indexInfo);
```

Insert a new tuple into an existing index. The `values` and `isnull` arrays give the key values to be indexed, and `heap_tid` is the TID to be indexed. If the access method supports unique indexes (its `amcanunique` flag is true) then `checkUnique` indicates the type of uniqueness check to perform. This varies depending on whether the unique constraint is deferrable; see [Section 63.5](#) for details. Normally the access method only needs the `heapRelation` parameter when performing uniqueness checking (since then it will have to look into the heap to verify tuple liveness).

The `indexUnchanged` Boolean value gives a hint about the nature of the tuple to be indexed. When it is true, the tuple is a duplicate of some existing tuple in the index. The new tuple is a logically unchanged successor MVCC tuple version. This happens when an `UPDATE` takes place that does not modify any columns covered by the index, but nevertheless requires a new version in the index. The index AM may use this hint to decide to apply bottom-up index deletion in parts of the index where many versions of the same logical row accumulate. Note that updating a non-key column or a column that only appears in a partial index predicate does not affect the value of `indexUnchanged`. The core code determines each tuple's `indexUnchanged` value using a low overhead approach that allows both false positives and false negatives. Index AMs must not treat `indexUnchanged` as an authoritative source of information about tuple visibility or versioning.

The function's Boolean result value is significant only when `checkUnique` is `UNIQUE_CHECK_PARTIAL`. In this case a true result means the new entry is known unique, whereas false means it might be non-unique (and a deferred uniqueness check must be scheduled). For other cases a constant false result is recommended.

Some indexes might not index all tuples. If the tuple is not to be indexed, `amininsert` should just return without doing anything.

If the index AM wishes to cache data across successive index insertions within an SQL statement, it can allocate space in `indexInfo->ii_Context` and store a pointer to the data in `indexInfo->ii_AmCache` (which will be NULL initially). If resources other than memory have to be released after index insertions, `amininsertcleanup` may be provided, which will be called before the memory is released.

```
void  
amininsertcleanup (Relation indexRelation,  
                  IndexInfo *indexInfo);
```

Clean up state that was maintained across successive inserts in `indexInfo->ii_AmCache`. This is useful if the data requires additional cleanup steps (e.g., releasing pinned buffers), and simply releasing the memory is not sufficient.

```
IndexBulkDeleteResult *  
ambulkdelete (IndexVacuumInfo *info,  
              IndexBulkDeleteResult *stats,  
              IndexBulkDeleteCallback callback,  
              void *callback_state);
```

Delete tuple(s) from the index. This is a “bulk delete” operation that is intended to be implemented by scanning the whole index and checking each entry to see if it should be deleted. The passed-in `callback` function must be called, in the style `callback(TID, callback_state)` returns `bool`, to determine whether any particular index entry, as identified by its referenced TID, is to be deleted. Must return either NULL or a palloc'd struct containing statistics about the effects of the deletion operation. It is OK to return NULL if no information needs to be passed on to `amvacuumcleanup`.

Because of limited `maintenance_work_mem`, `ambulkdelete` might need to be called more than once when many tuples are to be deleted. The `stats` argument is the result of the previous call for this index (it is `NULL` for the first call within a `VACUUM` operation). This allows the AM to accumulate statistics across the whole operation. Typically, `ambulkdelete` will modify and return the same struct if the passed `stats` is not null.

```
IndexBulkDeleteResult *
amvacuumcleanup (IndexVacuumInfo *info,
                 IndexBulkDeleteResult *stats);
```

Clean up after a `VACUUM` operation (zero or more `ambulkdelete` calls). This does not have to do anything beyond returning index statistics, but it might perform bulk cleanup such as reclaiming empty index pages. `stats` is whatever the last `ambulkdelete` call returned, or `NULL` if `ambulkdelete` was not called because no tuples needed to be deleted. If the result is not `NULL` it must be a palloc'd struct. The statistics it contains will be used to update `pg_class`, and will be reported by `VACUUM` if `VERBOSE` is given. It is OK to return `NULL` if the index was not changed at all during the `VACUUM` operation, but otherwise correct stats should be returned.

`amvacuumcleanup` will also be called at completion of an `ANALYZE` operation. In this case `stats` is always `NULL` and any return value will be ignored. This case can be distinguished by checking `info->analyze_only`. It is recommended that the access method do nothing except post-insert cleanup in such a call, and that only in an autovacuum worker process.

```
bool
amcanreturn (Relation indexRelation, int attno);
```

Check whether the index can support *index-only scans* on the given column, by returning the column's original indexed value. The attribute number is 1-based, i.e., the first column's `attno` is 1. Returns true if supported, else false. This function should always return true for included columns (if those are supported), since there's little point in an included column that can't be retrieved. If the access method does not support index-only scans at all, the `amcanreturn` field in its `IndexAmRoutine` struct can be set to `NULL`.

```
void
amcostestimate (PlannerInfo *root,
               IndexPath *path,
               double loop_count,
               Cost *indexStartupCost,
               Cost *indexTotalCost,
               Selectivity *indexSelectivity,
               double *indexCorrelation,
               double *indexPages);
```

Estimate the costs of an index scan. This function is described fully in [Section 63.6](#), below.

```
bytea *
amoptions (ArrayType *reloptions,
          bool validate);
```

Parse and validate the reloptions array for an index. This is called only when a non-null reloptions array exists for the index. *reloptions* is a `text` array containing entries of the form *name=value*. The function should construct a `bytea` value, which will be copied into the `rd_options` field of the index's relcache entry. The data contents of the `bytea` value are open for the access method to define; most of the standard access methods use struct `StdRdOptions`. When *validate* is true, the function should report a suitable error message if any of the options are unrecognized or have invalid values; when *validate* is false, invalid entries should be silently ignored. (*validate* is false when loading options already stored in `pg_catalog`; an invalid entry could only be found if the access method has changed its rules for options, and in that case ignoring obsolete entries is appropriate.) It is OK to return `NULL` if default behavior is wanted.

```
bool
amproperty (Oid index_oid, int attno,
            IndexAMProperty prop, const char *propname,
            bool *res, bool *isnull);
```

The `amproperty` method allows index access methods to override the default behavior of `pg_index_column_has_property` and related functions. If the access method does not have any special behavior for index property inquiries, the `amproperty` field in its `IndexAmRoutine` struct can be set to `NULL`. Otherwise, the `amproperty` method will be called with *index_oid* and *attno* both zero for `pg_indexam_has_property` calls, or with *index_oid* valid and *attno* zero for `pg_in-`

`dex_has_property` calls, or with `index_oid` valid and `attno` greater than zero for `pg_index_column_has_property` calls. `prop` is an enum value identifying the property being tested, while `propname` is the original property name string. If the core code does not recognize the property name then `prop` is `AMPROP_UNKNOWN`. Access methods can define custom property names by checking `propname` for a match (use `pg_strcasecmp` to match, for consistency with the core code); for names known to the core code, it's better to inspect `prop`. If the `amproperty` method returns `true` then it has determined the property test result: it must set `*res` to the Boolean value to return, or set `*isnull` to `true` to return a `NULL`. (Both of the referenced variables are initialized to `false` before the call.) If the `amproperty` method returns `false` then the core code will proceed with its normal logic for determining the property test result.

Access methods that support ordering operators should implement `AMPROP_DISTANCE_ORDERABLE` property testing, as the core code does not know how to do that and will return `NULL`. It may also be advantageous to implement `AMPROP_RETURNABLE` testing, if that can be done more cheaply than by opening the index and calling `amcanreturn`, which is the core code's default behavior. The default behavior should be satisfactory for all other standard properties.

```
char *
ambuildphasename (int64 phasenum);
```

Return the textual name of the given build phase number. The phase numbers are those reported during an index build via the `pg_stat_progress_update_param` interface. The phase names are then exposed in the `pg_stat_progress_create_index` view.

```
bool
amvalidate (Oid opclassoid);
```

Validate the catalog entries for the specified operator class, so far as the access method can reasonably do that. For example, this might include testing that all required support functions are provided. The `amvalidate` function must return `false` if the `opclass` is invalid. Problems should be reported with `ereport` messages, typically at `INFO` level.

```
void
amadjustmembers (Oid opfamilyoid,
                 Oid opclassoid,
                 List *operators,
                 List *functions);
```

Validate proposed new operator and function members of an operator family, so far as the access method can reasonably do that, and set their dependency types if the default is not satisfactory. This is called during `CREATE OPERATOR CLASS` and during `ALTER OPERATOR FAMILY ADD`; in the latter case `opclassoid` is `InvalidOid`. The `List` arguments are lists of `OpFamilyMember` structs. Tests done by this function will typically be a subset of those performed by `amvalidate`, since `amadjustmembers` cannot assume that it is seeing a complete set of members. For example, it would be reasonable to check the signature of a support function, but not to check whether all required support functions are provided. Any problems can be reported by throwing an error. The dependency-related fields of the `OpFamilyMember` structs are initialized by the core code to create hard dependencies on the `opclass` if this is `CREATE OPERATOR CLASS`, or soft dependencies on the `opfamily` if this is `ALTER OPERATOR FAMILY ADD`. `amadjustmembers` can adjust these fields if some other behavior is more appropriate. For example, `GIN`, `GiST`, and `SP-GiST` always set operator members to have soft dependencies on the `opfamily`, since the connection between an operator and an `opclass` is relatively weak in these index types; so it is reasonable to allow operator members to be added and removed freely. Optional support functions are typically also given soft dependencies, so that they can be removed if necessary.

The purpose of an index, of course, is to support scans for tuples matching an indexable `WHERE` condition, often called a *qualifier* or *scan key*. The semantics of index scanning are described more fully in [Section 63.3](#), below. An index access method can support “plain” index scans, “bitmap” index scans, or both. The scan-related functions that an index access method must or may provide are:

```
IndexScanDesc
ambeginscan (Relation indexRelation,
             int nkeys,
             int norderbys);
```

Prepare for an index scan. The `nkeys` and `norderbys` parameters indicate the number of quals and ordering operators that will be used in the scan; these may be useful for space allocation purposes. Note that the actual values of the scan keys aren't provided yet. The result must be a palloc'd struct. For implementation reasons the index access method *must* create this struct by calling `RelationGetIndexScan()`. In most cases `ambeginscan` does little beyond making that call and perhaps acquiring locks; the interesting parts of index-scan startup are in `amrescan`.

```
void  
amrescan (IndexScanDesc scan,  
          ScanKey keys,  
          int nkeys,  
          ScanKey orderbys,  
          int norderbys);
```

Start or restart an index scan, possibly with new scan keys. (To restart using previously-passed keys, NULL is passed for `keys` and/or `orderbys`.) Note that it is not allowed for the number of keys or order-by operators to be larger than what was passed to `ambeginscan`. In practice the restart feature is used when a new outer tuple is selected by a nested-loop join and so a new key comparison value is needed, but the scan key structure remains the same.

```
bool  
amgettupletuple (IndexScanDesc scan,  
                 ScanDirection direction);
```

Fetch the next tuple in the given scan, moving in the given direction (forward or backward in the index). Returns true if a tuple was obtained, false if no matching tuples remain. In the true case the tuple TID is stored into the `scan` structure. Note that “success” means only that the index contains an entry that matches the scan keys, not that the tuple necessarily still exists in the heap or will pass the caller's snapshot test. On success, `amgettupletuple` must also set `scan->xs_recheck` to true or false. False means it is certain that the index entry matches the scan keys. True means this is not certain, and the conditions represented by the scan keys must be rechecked against the heap tuple after fetching it. This provision supports “lossy” index operators. Note that rechecking will extend only to the scan conditions; a partial index predicate (if any) is never rechecked by `amgettupletuple` callers.

If the index supports [index-only scans](#) (i.e., `amcanreturn` returns true for any of its columns), then on success the AM must also check `scan->xs_want_itup`, and if that is true it must return the originally indexed data for the index entry. Columns for which `amcanreturn` returns false can be returned as nulls. The data can be returned in the form of an `IndexTuple` pointer stored at `scan->xs_itup`, with tuple descriptor `scan->xs_itupdesc`; or in the form of a `HeapTuple` pointer stored at `scan->xs_hitup`, with tuple descriptor `scan->xs_hitupdesc`. (The latter format should be used when reconstructing data that might possibly not fit into an `IndexTuple`.) In either case, management of the data referenced by the pointer is the access method's responsibility. The data must remain good at least until the next `amgettupletuple`, `amrescan`, or `amendscan` call for the scan.

The `amgettupletuple` function need only be provided if the access method supports “plain” index scans. If it doesn't, the `amgettupletuple` field in its `IndexAmRoutine` struct must be set to NULL.

```
int64  
amgetbitmap (IndexScanDesc scan,  
            TIDBitmap *tbm);
```

Fetch all tuples in the given scan and add them to the caller-supplied `TIDBitmap` (that is, OR the set of tuple IDs into whatever set is already in the bitmap). The number of tuples fetched is returned (this might be just an approximate count, for instance some AMs do not detect duplicates). While inserting tuple IDs into the bitmap, `amgetbitmap` can indicate that rechecking of the scan conditions is required for specific tuple IDs. This is analogous to the `xs_recheck` output parameter of `amgettupletuple`. Note: in the current implementation, support for this feature is conflated with support for lossy storage of the bitmap itself, and therefore callers recheck both the scan conditions and the partial index predicate (if any) for recheckable tuples. That might not always be true, however. `amgetbitmap` and `amgettupletuple` cannot be used in the same index scan; there are other restrictions too when using `amgetbitmap`, as explained in [Section 63.3](#).

The `amgetbitmap` function need only be provided if the access method supports “bitmap” index scans. If it doesn't, the `amgetbitmap` field in its `IndexAmRoutine` struct must be set to NULL.

```
void  
amendscan (IndexScanDesc scan);
```

End a scan and release resources. The `scan` struct itself should not be freed, but any locks or pins taken internally by the access method must be released, as well as any other memory allocated by `ambeginscan` and other scan-related functions.

```
void  
ammarkpos (IndexScanDesc scan);
```

Mark current scan position. The access method need only support one remembered scan position per scan.

The `ammarkpos` function need only be provided if the access method supports ordered scans. If it doesn't, the `ammarkpos` field in its `IndexAmRoutine` struct may be set to `NULL`.

```
void  
amrestrpos (IndexScanDesc scan);
```

Restore the scan to the most recently marked position.

The `amrestrpos` function need only be provided if the access method supports ordered scans. If it doesn't, the `amrestrpos` field in its `IndexAmRoutine` struct may be set to `NULL`.

In addition to supporting ordinary index scans, some types of index may wish to support *parallel index scans*, which allow multiple backends to cooperate in performing an index scan. The index access method should arrange things so that each cooperating process returns a subset of the tuples that would be performed by an ordinary, non-parallel index scan, but in such a way that the union of those subsets is equal to the set of tuples that would be returned by an ordinary, non-parallel index scan. Furthermore, while there need not be any global ordering of tuples returned by a parallel scan, the ordering of that subset of tuples returned within each cooperating backend must match the requested ordering. The following functions may be implemented to support parallel index scans:

```
Size  
amestimateparallelsan (int nkeys,  
                      int norderbys);
```

Estimate and return the number of bytes of dynamic shared memory which the access method will be needed to perform a parallel scan. (This number is in addition to, not in lieu of, the amount of space needed for AM-independent data in `ParallelIndexScanDescData`.)

The `nkeys` and `norderbys` parameters indicate the number of quals and ordering operators that will be used in the scan; the same values will be passed to `amrescan`. Note that the actual values of the scan keys aren't provided yet.

It is not necessary to implement this function for access methods which do not support parallel scans or for which the number of additional bytes of storage required is zero.

```
void  
aminitparallelsan (void *target);
```

This function will be called to initialize dynamic shared memory at the beginning of a parallel scan. *target* will point to at least the number of bytes previously returned by `amestimateparallelsan`, and this function may use that amount of space to store whatever data it wishes.

It is not necessary to implement this function for access methods which do not support parallel scans or in cases where the shared memory space required needs no initialization.

```
void  
amparallelrescan (IndexScanDesc scan);
```

This function, if implemented, will be called when a parallel index scan must be restarted. It should reset any shared state set up by `aminitparallelsan` such that the scan will be restarted from the beginning.

63.3. Index Scanning

In an index scan, the index access method is responsible for regurgitating the TIDs of all the tuples it has been told about that match the *scan keys*. The access method is *not* involved in actually fetching those tuples from the index's parent table, nor in determining whether they pass the scan's visibility test or other conditions.

A scan key is the internal representation of a `WHERE` clause of the form *index_key operator constant*, where the index key is one of the columns of the index and the operator is one of the members of the operator family associated with that index column. An index scan has zero or more scan keys, which are implicitly ANDed — the returned tuples are expected to satisfy all the indicated conditions.

The access method can report that the index is *lossy*, or requires rechecks, for a particular query. This implies that the index scan will return all the entries that pass the scan key, plus possibly additional entries that do not. The core system's index-scan machinery

will then apply the index conditions again to the heap tuple to verify whether or not it really should be selected. If the `recheck` option is not specified, the index scan must return exactly the set of matching entries.

Note that it is entirely up to the access method to ensure that it correctly finds all and only the entries passing all the given scan keys. Also, the core system will simply hand off all the `WHERE` clauses that match the index keys and operator families, without any semantic analysis to determine whether they are redundant or contradictory. As an example, given `WHERE x > 4 AND x > 14` where `x` is a b-tree indexed column, it is left to the b-tree `amrescan` function to realize that the first scan key is redundant and can be discarded. The extent of preprocessing needed during `amrescan` will depend on the extent to which the index access method needs to reduce the scan keys to a “normalized” form.

Some access methods return index entries in a well-defined order, others do not. There are actually two different ways that an access method can support sorted output:

- Access methods that always return entries in the natural ordering of their data (such as btree) should set `amcanorder` to true. Currently, such access methods must use btree-compatible strategy numbers for their equality and ordering operators.
- Access methods that support ordering operators should set `amcanorderbyop` to true. This indicates that the index is capable of returning entries in an order satisfying `ORDER BY index_key operator constant`. Scan modifiers of that form can be passed to `amrescan` as described previously. If the access method supports only one `ORDER BY` operator on the first indexed column, then it should set `amorderbyopfirstcol` to true.

The `amgettup` function has a `direction` argument, which can be either `ForwardScanDirection` (the normal case) or `BackwardScanDirection`. If the first call after `amrescan` specifies `BackwardScanDirection`, then the set of matching index entries is to be scanned back-to-front rather than in the normal front-to-back direction, so `amgettup` must return the last matching tuple in the index, rather than the first one as it normally would. (This will only occur for access methods that set `amcanorder` to true.) After the first call, `amgettup` must be prepared to advance the scan in either direction from the most recently returned entry. (But if `amcanbackward` is false, all subsequent calls will have the same direction as the first one.)

Access methods that support ordered scans must support “marking” a position in a scan and later returning to the marked position. The same position might be restored multiple times. However, only one position need be remembered per scan; a new `ammarkpos` call overrides the previously marked position. An access method that does not support ordered scans need not provide `ammarkpos` and `amrestpos` functions in `IndexAmRoutine`; set those pointers to `NULL` instead.

Both the scan position and the mark position (if any) must be maintained consistently in the face of concurrent insertions or deletions in the index. It is OK if a freshly-inserted entry is not returned by a scan that would have found the entry if it had existed when the scan started, or for the scan to return such an entry upon rescanning or backing up even though it had not been returned the first time through. Similarly, a concurrent delete might or might not be reflected in the results of a scan. What is important is that insertions or deletions not cause the scan to miss or multiply return entries that were not themselves being inserted or deleted.

If the index stores the original indexed data values (and not some lossy representation of them), it is useful to support [index-only scans](#), in which the index returns the actual data not just the TID of the heap tuple. This will only avoid I/O if the visibility map shows that the TID is on an all-visible page; else the heap tuple must be visited anyway to check MVCC visibility. But that is no concern of the access method's.

Instead of using `amgettup`, an index scan can be done with `amgetbitmap` to fetch all tuples in one call. This can be noticeably more efficient than `amgettup` because it allows avoiding lock/unlock cycles within the access method. In principle `amgetbitmap` should have the same effects as repeated `amgettup` calls, but we impose several restrictions to simplify matters. First of all, `amgetbitmap` returns all tuples at once and marking or restoring scan positions isn't supported. Secondly, the tuples are returned in a bitmap which doesn't have any specific ordering, which is why `amgetbitmap` doesn't take a `direction` argument. (Ordering operators will never be supplied for such a scan, either.) Also, there is no provision for index-only scans with `amgetbitmap`, since there is no way to return the contents of index tuples. Finally, `amgetbitmap` does not guarantee any locking of the returned tuples, with implications spelled out in [Section 63.4](#).

Note that it is permitted for an access method to implement only `amgetbitmap` and not `amgettup`, or vice versa, if its internal implementation is unsuited to one API or the other.

63.4. Index Locking Considerations

Index access methods must handle concurrent updates of the index by multiple processes. The core Postgres Pro system obtains `AccessShareLock` on the index during an index scan, and `RowExclusiveLock` when updating the index (including plain

VACUUM). Since these lock types do not conflict, the access method is responsible for handling any fine-grained locking it might need. An ACCESS EXCLUSIVE lock on the index as a whole will be taken only during index creation, destruction, or REINDEX (SHARE UPDATE EXCLUSIVE is taken instead with CONCURRENTLY).

Building an index type that supports concurrent updates usually requires extensive and subtle analysis of the required behavior.

Aside from the index's own internal consistency requirements, concurrent updates create issues about consistency between the parent table (the *heap*) and the index. Because Postgres Pro separates accesses and updates of the heap from those of the index, there are windows in which the index might be inconsistent with the heap. We handle this problem with the following rules:

- A new heap entry is made before making its index entries. (Therefore a concurrent index scan is likely to fail to see the heap entry. This is okay because the index reader would be uninterested in an uncommitted row anyway. But see [Section 63.5.](#))
- When a heap entry is to be deleted (by VACUUM), all its index entries must be removed first.
- An index scan must maintain a pin on the index page holding the item last returned by `amgettuple`, and `ambulkdelete` cannot delete entries from pages that are pinned by other backends. The need for this rule is explained below.

Without the third rule, it is possible for an index reader to see an index entry just before it is removed by VACUUM, and then to arrive at the corresponding heap entry after that was removed by VACUUM. This creates no serious problems if that item number is still unused when the reader reaches it, since an empty item slot will be ignored by `heap_fetch()`. But what if a third backend has already re-used the item slot for something else? When using an MVCC-compliant snapshot, there is no problem because the new occupant of the slot is certain to be too new to pass the snapshot test. However, with a non-MVCC-compliant snapshot (such as `SnapshotAny`), it would be possible to accept and return a row that does not in fact match the scan keys. We could defend against this scenario by requiring the scan keys to be rechecked against the heap row in all cases, but that is too expensive. Instead, we use a pin on an index page as a proxy to indicate that the reader might still be “in flight” from the index entry to the matching heap entry. Making `ambulkdelete` block on such a pin ensures that VACUUM cannot delete the heap entry before the reader is done with it. This solution costs little in run time, and adds blocking overhead only in the rare cases where there actually is a conflict.

This solution requires that index scans be “synchronous”: we have to fetch each heap tuple immediately after scanning the corresponding index entry. This is expensive for a number of reasons. An “asynchronous” scan in which we collect many TIDs from the index, and only visit the heap tuples sometime later, requires much less index locking overhead and can allow a more efficient heap access pattern. Per the above analysis, we must use the synchronous approach for non-MVCC-compliant snapshots, but an asynchronous scan is workable for a query using an MVCC snapshot.

In an `amgetbitmap` index scan, the access method does not keep an index pin on any of the returned tuples. Therefore it is only safe to use such scans with MVCC-compliant snapshots.

When the `ampredlocks` flag is not set, any scan using that index access method within a serializable transaction will acquire a nonblocking predicate lock on the full index. This will generate a read-write conflict with the insert of any tuple into that index by a concurrent serializable transaction. If certain patterns of read-write conflicts are detected among a set of concurrent serializable transactions, one of those transactions may be canceled to protect data integrity. When the flag is set, it indicates that the index access method implements finer-grained predicate locking, which will tend to reduce the frequency of such transaction cancellations.

63.5. Index Uniqueness Checks

Postgres Pro enforces SQL uniqueness constraints using *unique indexes*, which are indexes that disallow multiple entries with identical keys. An access method that supports this feature sets `amcanunique` true. (At present, only b-tree supports it.) Columns listed in the `INCLUDE` clause are not considered when enforcing uniqueness.

Because of MVCC, it is always necessary to allow duplicate entries to exist physically in an index: the entries might refer to successive versions of a single logical row. The behavior we actually want to enforce is that no MVCC snapshot could include two rows with equal index keys. This breaks down into the following cases that must be checked when inserting a new row into a unique index:

- If a conflicting valid row has been deleted by the current transaction, it's okay. (In particular, since an UPDATE always deletes the old row version before inserting the new version, this will allow an UPDATE on a row without changing the key.)
- If a conflicting row has been inserted by an as-yet-uncommitted transaction, the would-be inserter must wait to see if that transaction commits. If it rolls back then there is no conflict. If it commits without deleting the conflicting row again, there is a uniqueness violation. (In practice we just wait for the other transaction to end and then redo the visibility check in toto.)
- Similarly, if a conflicting valid row has been deleted by an as-yet-uncommitted transaction, the would-be inserter must wait for that transaction to commit or abort, and then repeat the test.

Furthermore, immediately before reporting a uniqueness violation according to the above rules, the access method must recheck the liveness of the row being inserted. If it is committed dead then no violation should be reported. (This case cannot occur during the ordinary scenario of inserting a row that's just been created by the current transaction. It can happen during `CREATE UNIQUE INDEX CONCURRENTLY`, however.)

We require the index access method to apply these tests itself, which means that it must reach into the heap to check the commit status of any row that is shown to have a duplicate key according to the index contents. This is without a doubt ugly and non-modular, but it saves redundant work: if we did a separate probe then the index lookup for a conflicting row would be essentially repeated while finding the place to insert the new row's index entry. What's more, there is no obvious way to avoid race conditions unless the conflict check is an integral part of insertion of the new index entry.

If the unique constraint is deferrable, there is additional complexity: we need to be able to insert an index entry for a new row, but defer any uniqueness-violation error until end of statement or even later. To avoid unnecessary repeat searches of the index, the index access method should do a preliminary uniqueness check during the initial insertion. If this shows that there is definitely no conflicting live tuple, we are done. Otherwise, we schedule a recheck to occur when it is time to enforce the constraint. If, at the time of the recheck, both the inserted tuple and some other tuple with the same key are live, then the error must be reported. (Note that for this purpose, “live” actually means “any tuple in the index entry's HOT chain is live”.) To implement this, the `aminsert` function is passed a `checkUnique` parameter having one of the following values:

- `UNIQUE_CHECK_NO` indicates that no uniqueness checking should be done (this is not a unique index).
- `UNIQUE_CHECK_YES` indicates that this is a non-deferrable unique index, and the uniqueness check must be done immediately, as described above.
- `UNIQUE_CHECK_PARTIAL` indicates that the unique constraint is deferrable. Postgres Pro will use this mode to insert each row's index entry. The access method must allow duplicate entries into the index, and report any potential duplicates by returning false from `aminsert`. For each row for which false is returned, a deferred recheck will be scheduled.

The access method must identify any rows which might violate the unique constraint, but it is not an error for it to report false positives. This allows the check to be done without waiting for other transactions to finish; conflicts reported here are not treated as errors and will be rechecked later, by which time they may no longer be conflicts.

- `UNIQUE_CHECK_EXISTING` indicates that this is a deferred recheck of a row that was reported as a potential uniqueness violation. Although this is implemented by calling `aminsert`, the access method must *not* insert a new index entry in this case. The index entry is already present. Rather, the access method must check to see if there is another live index entry. If so, and if the target row is also still live, report error.

It is recommended that in a `UNIQUE_CHECK_EXISTING` call, the access method further verify that the target row actually does have an existing entry in the index, and report error if not. This is a good idea because the index tuple values passed to `aminsert` will have been recomputed. If the index definition involves functions that are not really immutable, we might be checking the wrong area of the index. Checking that the target row is found in the recheck verifies that we are scanning for the same tuple values as were used in the original insertion.

63.6. Index Cost Estimation Functions

The `amcostestimate` function is given information describing a possible index scan, including lists of `WHERE` and `ORDER BY` clauses that have been determined to be usable with the index. It must return estimates of the cost of accessing the index and the selectivity of the `WHERE` clauses (that is, the fraction of parent-table rows that will be retrieved during the index scan). For simple cases, nearly all the work of the cost estimator can be done by calling standard routines in the optimizer; the point of having an `amcostestimate` function is to allow index access methods to provide index-type-specific knowledge, in case it is possible to improve on the standard estimates.

Each `amcostestimate` function must have the signature:

```
void
amcostestimate (PlannerInfo *root,
                IndexPath *path,
                double loop_count,
                Cost *indexStartupCost,
                Cost *indexTotalCost,
                Selectivity *indexSelectivity,
                double *indexCorrelation,
```

```
double *indexPages);
```

The first three parameters are inputs:

root

The planner's information about the query being processed.

path

The index access path being considered. All fields except cost and selectivity values are valid.

loop_count

The number of repetitions of the index scan that should be factored into the cost estimates. This will typically be greater than one when considering a parameterized scan for use in the inside of a nestloop join. Note that the cost estimates should still be for just one scan; a larger *loop_count* means that it may be appropriate to allow for some caching effects across multiple scans.

The last five parameters are pass-by-reference outputs:

**indexStartupCost*

Set to cost of index start-up processing

**indexTotalCost*

Set to total cost of index processing

**indexSelectivity*

Set to index selectivity

**indexCorrelation*

Set to correlation coefficient between index scan order and underlying table's order

**indexPages*

Set to number of index leaf pages

Note that cost estimate functions must be written in C, not in SQL or any available procedural language, because they must access internal data structures of the planner/optimizer.

The index access costs should be computed using the parameters: a sequential disk block fetch has cost *seq_page_cost*, a non-sequential fetch has cost *random_page_cost*, and the cost of processing one index row should usually be taken as *cpu_index_tuple_cost*. In addition, an appropriate multiple of *cpu_operator_cost* should be charged for any comparison operators invoked during index processing (especially evaluation of the *indexquals* themselves).

The “start-up cost” is the part of the total scan cost that must be expended before we can begin to fetch the first row. For most indexes this can be taken as zero, but an index type with a high start-up cost might want to set it nonzero.

The *indexSelectivity* should be set to the estimated fraction of the parent table rows that will be retrieved during the index scan. In the case of a lossy query, this will typically be higher than the fraction of rows that actually pass the given qual conditions.

The *indexCorrelation* should be set to the correlation (ranging between -1.0 and 1.0) between the index order and the table order. This is used to adjust the estimate for the cost of fetching rows from the parent table.

The *indexPages* should be set to the number of leaf pages. This is used to estimate the number of workers for parallel index scan.

When *loop_count* is greater than one, the returned numbers should be averages expected for any one scan of the index.

Cost Estimation

A typical cost estimator will proceed as follows:

1. Estimate and return the fraction of parent-table rows that will be visited based on the given qual conditions. In the absence of any index-type-specific knowledge, use the standard optimizer function *clauselist_selectivity()*:

```
*indexSelectivity = clauselist_selectivity(root, path->indexquals,  
                                           path->indexinfo->rel->relid,  
                                           JOIN_INNER, NULL);
```

2. Estimate the number of index rows that will be visited during the scan. For many index types this is the same as *indexSelectivity* times the number of rows in the index, but it might be more. (Note that the index's size in pages and rows is available from the `path->indexinfo` struct.)
3. Estimate the number of index pages that will be retrieved during the scan. This might be just *indexSelectivity* times the index's size in pages.
4. Compute the index access cost. A generic estimator might do this:

```
/*  
 * Our generic assumption is that the index pages will be read  
 * sequentially, so they cost seq_page_cost each, not random_page_cost.  
 * Also, we charge for evaluation of the indexquals at each index row.  
 * All the costs are assumed to be paid incrementally during the scan.  
 */  
cost_qual_eval(&index_qual_cost, path->indexquals, root);  
*indexStartupCost = index_qual_cost.startup;  
*indexTotalCost = seq_page_cost * numIndexPages +  
    (cpu_index_tuple_cost + index_qual_cost.per_tuple) * numIndexTuples;
```

However, the above does not account for amortization of index reads across repeated index scans.

5. Estimate the index correlation. For a simple ordered index on a single field, this can be retrieved from `pg_statistic`. If the correlation is not known, the conservative estimate is zero (no correlation).

Chapter 64. Write Ahead Logging for Extensions

Certain extensions, principally extensions that implement custom access methods, may need to perform write-ahead logging in order to ensure crash-safety. Postgres Pro provides two ways for extensions to achieve this goal.

First, extensions can choose to use [generic WAL](#), a special type of WAL record which describes changes to pages in a generic way. This method is simple to implement and does not require that an extension library be loaded in order to apply the records. However, generic WAL records will be ignored when performing logical decoding.

Second, extensions can choose to use a [custom resource manager](#). This method is more flexible, supports logical decoding, and can sometimes generate much smaller write-ahead log records than would be possible with generic WAL. However, it is more complex for an extension to implement.

64.1. Generic WAL Records

Although all built-in WAL-logged modules have their own types of WAL records, there is also a generic WAL record type, which describes changes to pages in a generic way.

Note

Generic WAL records are ignored during [Logical Decoding](#). If logical decoding is required for your extension, consider a Custom WAL Resource Manager.

The API for constructing generic WAL records is defined in `access/generic_xlog.h` and implemented in `access/transam/generic_xlog.c`.

To perform a WAL-logged data update using the generic WAL record facility, follow these steps:

1. `state = GenericXLogStart(relation)` — start construction of a generic WAL record for the given relation.
2. `page = GenericXLogRegisterBuffer(state, buffer, flags)` — register a buffer to be modified within the current generic WAL record. This function returns a pointer to a temporary copy of the buffer's page, where modifications should be made. (Do not modify the buffer's contents directly.) The third argument is a bit mask of flags applicable to the operation. Currently the only such flag is `GENERIC_XLOG_FULL_IMAGE`, which indicates that a full-page image rather than a delta update should be included in the WAL record. Typically this flag would be set if the page is new or has been rewritten completely. `GenericXLogRegisterBuffer` can be repeated if the WAL-logged action needs to modify multiple pages.
3. Apply modifications to the page images obtained in the previous step.
4. `GenericXLogFinish(state)` — apply the changes to the buffers and emit the generic WAL record.

WAL record construction can be canceled between any of the above steps by calling `GenericXLogAbort(state)`. This will discard all changes to the page image copies.

Please note the following points when using the generic WAL record facility:

- No direct modifications of buffers are allowed! All modifications must be done in copies acquired from `GenericXLogRegisterBuffer()`. In other words, code that makes generic WAL records should never call `BufferGetPage()` for itself. However, it remains the caller's responsibility to pin/unpin and lock/unlock the buffers at appropriate times. Exclusive lock must be held on each target buffer from before `GenericXLogRegisterBuffer()` until after `GenericXLogFinish()`.
- Registrations of buffers (step 2) and modifications of page images (step 3) can be mixed freely, i.e., both steps may be repeated in any sequence. Keep in mind that buffers should be registered in the same order in which locks are to be obtained on them during replay.
- The maximum number of buffers that can be registered for a generic WAL record is `MAX_GENERIC_XLOG_PAGES`. An error will be thrown if this limit is exceeded.
- Generic WAL assumes that the pages to be modified have standard layout, and in particular that there is no useful data between `pd_lower` and `pd_upper`.

- Since you are modifying copies of buffer pages, `GenericXLogStart()` does not start a critical section. Thus, you can safely do memory allocation, error throwing, etc. between `GenericXLogStart()` and `GenericXLogFinish()`. The only actual critical section is present inside `GenericXLogFinish()`. There is no need to worry about calling `GenericXLogAbort()` during an error exit, either.
- `GenericXLogFinish()` takes care of marking buffers dirty and setting their LSNs. You do not need to do this explicitly.
- For unlogged relations, everything works the same except that no actual WAL record is emitted. Thus, you typically do not need to do any explicit checks for unlogged relations.
- The generic WAL redo function will acquire exclusive locks to buffers in the same order as they were registered. After redoing all changes, the locks will be released in the same order.
- If `GENERIC_XLOG_FULL_IMAGE` is not specified for a registered buffer, the generic WAL record contains a delta between the old and the new page images. This delta is based on byte-by-byte comparison. This is not very compact for the case of moving data within a page, and might be improved in the future.

64.2. Custom WAL Resource Managers

This section explains the interface between the core Postgres Pro system and custom WAL resource managers, which enable extensions to integrate directly with the [WAL](#).

An extension, especially a [Table Access Method](#) or [Index Access Method](#), may need to use WAL for recovery, replication, and/or [Logical Decoding](#).

To create a new custom WAL resource manager, first define an `RmgrData` structure with implementations for the resource manager methods.

```
/*
 * Method table for resource managers.
 *
 * This struct must be kept in sync with the PG_RMGR definition in
 * rmgr.c.
 *
 * rm_identify must return a name for the record based on xl_info (without
 * reference to the rmid). For example, XLOG_BTREE_VACUUM would be named
 * "VACUUM". rm_desc can then be called to obtain additional detail for the
 * record, if available (e.g. the last block).
 *
 * rm_mask takes as input a page modified by the resource manager and masks
 * out bits that shouldn't be flagged by wal_consistency_checking.
 *
 * RmgrTable[] is indexed by RmgrId values (see rmgrlist.h). If rm_name is
 * NULL, the corresponding RmgrTable entry is considered invalid.
 */
typedef struct RmgrData
{
    const char *rm_name;
    void (*rm_redo) (XLogReaderState *record);
    void (*rm_desc) (StringInfo buf, XLogReaderState *record);
    const char *(*rm_identify) (uint8 info);
    void (*rm_startup) (void);
    void (*rm_cleanup) (void);
    void (*rm_mask) (char *pagedata, BlockNumber blkno);
    void (*rm_decode) (struct LogicalDecodingContext *ctx,
                      struct XLogRecordBuffer *buf);
} RmgrData;
```

Then, register your new resource manager.

```
/*
 * Register a new custom WAL resource manager.
```

```
*  
* Resource manager IDs must be globally unique across all extensions. Refer  
* to https://wiki.postgresql.org/wiki/CustomWALResourceManagers to reserve a  
* unique RmgrId for your extension, to avoid conflicts with other extension  
* developers. During development, use RM_EXPERIMENTAL_ID to avoid needlessly  
* reserving a new ID.  
*/
```

```
extern void RegisterCustomRmgr(RmgrId rmid, const RmgrData *rmgr);
```

RegisterCustomRmgr must be called from the extension module's `_PG_init` function. While developing a new extension, use `RM_EXPERIMENTAL_ID` for *rmid*. When you are ready to release the extension to users, reserve a new resource manager ID at the [Custom WAL Resource Manager](#) page.

Place the extension module implementing the custom resource manager in [shared_preload_libraries](#) so that it will be loaded early during Postgres Pro startup.

Note

The extension must remain in `shared_preload_libraries` as long as any custom WAL records may exist in the system. Otherwise Postgres Pro will not be able to apply or decode the custom WAL records, which may prevent the server from starting.

Chapter 65. Built-in Index Access Methods

65.1. B-Tree Indexes

65.1.1. Introduction

Postgres Pro includes an implementation of the standard btree (multi-way balanced tree) index data structure. Any data type that can be sorted into a well-defined linear order can be indexed by a btree index. The only limitation is that an index entry cannot exceed approximately one-third of a page (after TOAST compression, if applicable).

Because each btree operator class imposes a sort order on its data type, btree operator classes (or, really, operator families) have come to be used as Postgres Pro's general representation and understanding of sorting semantics. Therefore, they've acquired some features that go beyond what would be needed just to support btree indexes, and parts of the system that are quite distant from the btree AM make use of them.

65.1.2. Behavior of B-Tree Operator Classes

As shown in [Table 39.3](#), a btree operator class must provide five comparison operators, `<`, `<=`, `=`, `>=` and `>`. One might expect that `<>` should also be part of the operator class, but it is not, because it would almost never be useful to use a `<>` WHERE clause in an index search. (For some purposes, the planner treats `<>` as associated with a btree operator class; but it finds that operator via the `=` operator's negator link, rather than from `pg_amop`.)

When several data types share near-identical sorting semantics, their operator classes can be grouped into an operator family. Doing so is advantageous because it allows the planner to make deductions about cross-type comparisons. Each operator class within the family should contain the single-type operators (and associated support functions) for its input data type, while cross-type comparison operators and support functions are “loose” in the family. It is recommendable that a complete set of cross-type operators be included in the family, thus ensuring that the planner can represent any comparison conditions that it deduces from transitivity.

There are some basic assumptions that a btree operator family must satisfy:

- An `=` operator must be an equivalence relation; that is, for all non-null values *A*, *B*, *C* of the data type:
 - *A* = *A* is true (*reflexive law*)
 - if *A* = *B*, then *B* = *A* (*symmetric law*)
 - if *A* = *B* and *B* = *C*, then *A* = *C* (*transitive law*)
- A `<` operator must be a strong ordering relation; that is, for all non-null values *A*, *B*, *C*:
 - *A* < *A* is false (*irreflexive law*)
 - if *A* < *B* and *B* < *C*, then *A* < *C* (*transitive law*)
- Furthermore, the ordering is total; that is, for all non-null values *A*, *B*:
 - exactly one of *A* < *B*, *A* = *B*, and *B* < *A* is true (*trichotomy law*)

(The trichotomy law justifies the definition of the comparison support function, of course.)

The other three operators are defined in terms of `=` and `<` in the obvious way, and must act consistently with them.

For an operator family supporting multiple data types, the above laws must hold when *A*, *B*, *C* are taken from any data types in the family. The transitive laws are the trickiest to ensure, as in cross-type situations they represent statements that the behaviors of two or three different operators are consistent. As an example, it would not work to put `float8` and `numeric` into the same operator family, at least not with the current semantics that `numeric` values are converted to `float8` for comparison to a `float8`. Because of the limited accuracy of `float8`, this means there are distinct `numeric` values that will compare equal to the same `float8` value, and thus the transitive law would fail.

Another requirement for a multiple-data-type family is that any implicit or binary-coercion casts that are defined between data types included in the operator family must not change the associated sort ordering.

It should be fairly clear why a btree index requires these laws to hold within a single data type: without them there is no ordering to arrange the keys with. Also, index searches using a comparison key of a different data type require comparisons to behave sanely

across two data types. The extensions to three or more data types within a family are not strictly required by the btree index mechanism itself, but the planner relies on them for optimization purposes.

To implement the distance ordered (nearest-neighbor) search, we only need to define a distance operator (usually called $\lt\rightarrow$) with the corresponding operator family for distance comparison in the index's operator class. These operators must satisfy the following assumptions for all non-null values A , B , C of the datatype:

- $A \lt\rightarrow B = B \lt\rightarrow A$ (*symmetric law*)
- if $A = B$, then $A \lt\rightarrow C = B \lt\rightarrow C$ (*distance equivalence*)
- if $(A \leq B \text{ and } B \leq C)$ or $(A \geq B \text{ and } B \geq C)$, then $A \lt\rightarrow B \leq A \lt\rightarrow C$ (*monotonicity*)

65.1.3. B-Tree Support Functions

As shown in [Table 39.9](#), btree defines one required and four optional support functions. The five user-defined methods are:

order

For each combination of data types that a btree operator family provides comparison operators for, it must provide a comparison support function, registered in `pg_amproc` with support function number 1 and `amproclefttype/amprocrighttype` equal to the left and right data types for the comparison (i.e., the same data types that the matching operators are registered with in `pg_amop`). The comparison function must take two non-null values A and B and return an `int32` value that is < 0 , 0 , or > 0 when $A < B$, $A = B$, or $A > B$, respectively. A null result is disallowed: all values of the data type must be comparable.

If the compared values are of a collatable data type, the appropriate collation OID will be passed to the comparison support function, using the standard `PG_GET_COLLATION( )` mechanism.

sortsupport

Optionally, a btree operator family may provide *sort support* function(s), registered under support function number 2. These functions allow implementing comparisons for sorting purposes in a more efficient way than naively calling the comparison support function. The APIs involved in this are defined in [src/include/utils/sortsupport.h](#).

in_range

Optionally, a btree operator family may provide *in_range* support function(s), registered under support function number 3. These are not used during btree index operations; rather, they extend the semantics of the operator family so that it can support window clauses containing the `RANGE offset PRECEDING` and `RANGE offset FOLLOWING` frame bound types (see [Section 4.2.8](#)). Fundamentally, the extra information provided is how to add or subtract an *offset* value in a way that is compatible with the family's data ordering.

An *in_range* function must have the signature

```
in_range(val type1, base type1, offset type2, sub bool, less bool)
returns bool
```

val and *base* must be of the same type, which is one of the types supported by the operator family (i.e., a type for which it provides an ordering). However, *offset* could be of a different type, which might be one otherwise unsupported by the family. An example is that the built-in `time_ops` family provides an *in_range* function that has *offset* of type `interval`. A family can provide *in_range* functions for any of its supported types and one or more *offset* types. Each *in_range* function should be entered in `pg_amproc` with `amproclefttype` equal to *type1* and `amprocrighttype` equal to *type2*.

The essential semantics of an *in_range* function depend on the two Boolean flag parameters. It should add or subtract *base* and *offset*, then compare *val* to the result, as follows:

- if *!sub* and *!less*, return $val \geq (base + offset)$
- if *!sub* and *less*, return $val \leq (base + offset)$
- if *sub* and *!less*, return $val \geq (base - offset)$
- if *sub* and *less*, return $val \leq (base - offset)$

Before doing so, the function should check the sign of *offset*: if it is less than zero, raise error `ERRCODE_INVALID_PRECEDING_OR_FOLLOWING_SIZE` (22013) with error text like “invalid preceding or following size in window function”. (This is required by the SQL standard, although nonstandard operator families might perhaps choose to ignore this restriction, since

there seems to be little semantic necessity for it.) This requirement is delegated to the `in_range` function so that the core code needn't understand what “less than zero” means for a particular data type.

An additional expectation is that `in_range` functions should, if practical, avoid throwing an error if $base + offset$ or $base - offset$ would overflow. The correct comparison result can be determined even if that value would be out of the data type's range. Note that if the data type includes concepts such as “infinity” or “NaN”, extra care may be needed to ensure that `in_range`'s results agree with the normal sort order of the operator family.

The results of the `in_range` function must be consistent with the sort ordering imposed by the operator family. To be precise, given any fixed values of *offset* and *sub*, then:

- If `in_range` with *less* = true is true for some *val1* and *base*, it must be true for every $val2 \leq val1$ with the same *base*.
- If `in_range` with *less* = true is false for some *val1* and *base*, it must be false for every $val2 \geq val1$ with the same *base*.
- If `in_range` with *less* = true is true for some *val* and *base1*, it must be true for every $base2 \geq base1$ with the same *val*.
- If `in_range` with *less* = true is false for some *val* and *base1*, it must be false for every $base2 \leq base1$ with the same *val*.

Analogous statements with inverted conditions hold when *less* = false.

If the type being ordered (*type1*) is collatable, the appropriate collation OID will be passed to the `in_range` function, using the standard `PG_GET_COLLATION()` mechanism.

`in_range` functions need not handle NULL inputs, and typically will be marked strict.

equalimage

Optionally, a btree operator family may provide `equalimage` (“equality implies image equality”) support functions, registered under support function number 4. These functions allow the core code to determine when it is safe to apply the btree deduplication optimization. Currently, `equalimage` functions are only called when building or rebuilding an index.

An `equalimage` function must have the signature

`equalimage(opcintype oid) returns bool`

The return value is static information about an operator class and collation. Returning `true` indicates that the `order` function for the operator class is guaranteed to only return 0 (“arguments are equal”) when its *A* and *B* arguments are also interchangeable without any loss of semantic information. Not registering an `equalimage` function or returning `false` indicates that this condition cannot be assumed to hold.

The *opcintype* argument is the `pg_type.oid` of the data type that the operator class indexes. This is a convenience that allows reuse of the same underlying `equalimage` function across operator classes. If *opcintype* is a collatable data type, the appropriate collation OID will be passed to the `equalimage` function, using the standard `PG_GET_COLLATION()` mechanism.

As far as the operator class is concerned, returning `true` indicates that deduplication is safe (or safe for the collation whose OID was passed to its `equalimage` function). However, the core code will only deem deduplication safe for an index when every indexed column uses an operator class that registers an `equalimage` function, and each function actually returns `true` when called.

Image equality is *almost* the same condition as simple bitwise equality. There is one subtle difference: When indexing a varlena data type, the on-disk representation of two image equal datums may not be bitwise equal due to inconsistent application of TOAST compression on input. Formally, when an operator class's `equalimage` function returns `true`, it is safe to assume that the `datum_image_eq()` C function will always agree with the operator class's `order` function (provided that the same collation OID is passed to both the `equalimage` and `order` functions).

The core code is fundamentally unable to deduce anything about the “equality implies image equality” status of an operator class within a multiple-data-type family based on details from other operator classes in the same family. Also, it is not sensible for an operator family to register a cross-type `equalimage` function, and attempting to do so will result in an error. This is because “equality implies image equality” status does not just depend on sorting/equality semantics, which are more or less defined at the operator family level. In general, the semantics that one particular data type implements must be considered separately.

The convention followed by the operator classes included with the core Postgres Pro distribution is to register a stock, generic `equalimage` function. Most operator classes register `btequalimage()`, which indicates that deduplication is safe unconditionally. Operator classes for collatable data types such as `text` register `btvarstrequalimage()`, which indicates that deduplication is safe with deterministic collations. Best practice for third-party extensions is to register their own custom function to retain control.

options

Optionally, a B-tree operator family may provide `options` (“operator class specific options”) support functions, registered under support function number 5. These functions define a set of user-visible parameters that control operator class behavior.

An `options` support function must have the signature

```
options(relopts local_relopts *) returns void
```

The function is passed a pointer to a `local_relopts` struct, which needs to be filled with a set of operator class specific options. The options can be accessed from other support functions using the `PG_HAS_OPCLASS_OPTIONS()` and `PG_GET_OPCLASS_OPTIONS()` macros.

Currently, no B-Tree operator class has an `options` support function. B-tree doesn't allow flexible representation of keys like GiST, SP-GiST, GIN and BRIN do. So, `options` probably doesn't have much application in the current B-tree index access method. Nevertheless, this support function was added to B-tree for uniformity, and will probably find uses during further evolution of B-tree in Postgres Pro.

65.1.4. Implementation

This section covers B-Tree index implementation details that may be of use to advanced users.

65.1.4.1. B-Tree Structure

Postgres Pro B-Tree indexes are multi-level tree structures, where each level of the tree can be used as a doubly-linked list of pages. A single metapage is stored in a fixed position at the start of the first segment file of the index. All other pages are either leaf pages or internal pages. Leaf pages are the pages on the lowest level of the tree. All other levels consist of internal pages. Each leaf page contains tuples that point to table rows. Each internal page contains tuples that point to the next level down in the tree. Typically, over 99% of all pages are leaf pages. Both internal pages and leaf pages use the standard page format described in [Section 66.6](#).

New leaf pages are added to a B-Tree index when an existing leaf page cannot fit an incoming tuple. A *page split* operation makes room for items that originally belonged on the overflowing page by moving a portion of the items to a new page. Page splits must also insert a new *downlink* to the new page in the parent page, which may cause the parent to split in turn. Page splits “cascade upwards” in a recursive fashion. When the root page finally cannot fit a new downlink, a *root page split* operation takes place. This adds a new level to the tree structure by creating a new root page that is one level above the original root page.

65.1.4.2. Bottom-up Index Deletion

B-Tree indexes are not directly aware that under MVCC, there might be multiple extant versions of the same logical table row; to an index, each tuple is an independent object that needs its own index entry. “Version churn” tuples may sometimes accumulate and adversely affect query latency and throughput. This typically occurs with `UPDATE`-heavy workloads where most individual updates cannot apply the [HOT optimization](#). Changing the value of only one column covered by one index during an `UPDATE` *always* necessitates a new set of index tuples — one for *each and every* index on the table. Note in particular that this includes indexes that were not “logically modified” by the `UPDATE`. All indexes will need a successor physical index tuple that points to the latest version in the table. Each new tuple within each index will generally need to coexist with the original “updated” tuple for a short period of time (typically until shortly after the `UPDATE` transaction commits).

B-Tree indexes incrementally delete version churn index tuples by performing *bottom-up index deletion* passes. Each deletion pass is triggered in reaction to an anticipated “version churn page split”. This only happens with indexes that are not logically modified by `UPDATE` statements, where concentrated build up of obsolete versions in particular pages would occur otherwise. A page split will usually be avoided, though it's possible that certain implementation-level heuristics will fail to identify and delete even one garbage index tuple (in which case a page split or deduplication pass resolves the issue of an incoming new tuple not fitting on a leaf page). The worst-case number of versions that any index scan must traverse (for any single logical row) is an important contributor to overall system responsiveness and throughput. A bottom-up index deletion pass targets suspected garbage tuples in a single leaf page based on *qualitative* distinctions involving logical rows and versions. This contrasts with the “top-down” index cleanup performed by autovacuum workers, which is triggered when certain *quantitative* table-level thresholds are exceeded (see [Section 24.1.6](#)).

Note

Not all deletion operations that are performed within B-Tree indexes are bottom-up deletion operations. There is a distinct category of index tuple deletion: *simple index tuple deletion*. This is a deferred maintenance operation that deletes index tuples that are known to be safe to delete (those whose item identifier's `LP_DEAD` bit is already set). Like bottom-up index deletion, simple index deletion takes place at the point that a page split is anticipated as a way of avoiding the split.

Simple deletion is opportunistic in the sense that it can only take place when recent index scans set the `LP_DEAD` bits of affected items in passing. Prior to Postgres Pro 14, the only category of B-Tree deletion was simple deletion. The main differences between it and bottom-up deletion are that only the former is opportunistically driven by the activity of passing index scans, while only the latter specifically targets version churn from `UPDATE`s that do not logically modify indexed columns.

Bottom-up index deletion performs the vast majority of all garbage index tuple cleanup for particular indexes with certain workloads. This is expected with any B-Tree index that is subject to significant version churn from `UPDATE`s that rarely or never logically modify the columns that the index covers. The average and worst-case number of versions per logical row can be kept low purely through targeted incremental deletion passes. It's quite possible that the on-disk size of certain indexes will never increase by even one single page/block despite *constant* version churn from `UPDATE`s. Even then, an exhaustive “clean sweep” by a `VACUUM` operation (typically run in an autovacuum worker process) will eventually be required as a part of *collective* cleanup of the table and each of its indexes.

Unlike `VACUUM`, bottom-up index deletion does not provide any strong guarantees about how old the oldest garbage index tuple may be. No index can be permitted to retain “floating garbage” index tuples that became dead prior to a conservative cutoff point shared by the table and all of its indexes collectively. This fundamental table-level invariant makes it safe to recycle table TIDs. This is how it is possible for distinct logical rows to reuse the same table TID over time (though this can never happen with two logical rows whose lifetimes span the same `VACUUM` cycle).

65.1.4.3. Deduplication

A duplicate is a leaf page tuple (a tuple that points to a table row) where *all* indexed key columns have values that match corresponding column values from at least one other leaf page tuple in the same index. Duplicate tuples are quite common in practice. B-Tree indexes can use a special, space-efficient representation for duplicates when an optional technique is enabled: *deduplication*.

Deduplication works by periodically merging groups of duplicate tuples together, forming a single *posting list* tuple for each group. The column key value(s) only appear once in this representation. This is followed by a sorted array of TIDs that point to rows in the table. This significantly reduces the storage size of indexes where each value (or each distinct combination of column values) appears several times on average. The latency of queries can be reduced significantly. Overall query throughput may increase significantly. The overhead of routine index vacuuming may also be reduced significantly.

Note

B-Tree deduplication is just as effective with “duplicates” that contain a `NULL` value, even though `NULL` values are never equal to each other according to the `=` member of any B-Tree operator class. As far as any part of the implementation that understands the on-disk B-Tree structure is concerned, `NULL` is just another value from the domain of indexed values.

The deduplication process occurs lazily, when a new item is inserted that cannot fit on an existing leaf page, though only when index tuple deletion could not free sufficient space for the new item (typically deletion is briefly considered and then skipped over). Unlike GIN posting list tuples, B-Tree posting list tuples do not need to expand every time a new duplicate is inserted; they are merely an alternative physical representation of the original logical contents of the leaf page. This design prioritizes consistent performance with mixed read-write workloads. Most client applications will at least see a moderate performance benefit from using deduplication. Deduplication is enabled by default.

`CREATE INDEX` and `REINDEX` apply deduplication to create posting list tuples, though the strategy they use is slightly different. Each group of duplicate ordinary tuples encountered in the sorted input taken from the table is merged into a posting list tuple *before* being added to the current pending leaf page. Individual posting list tuples are packed with as many TIDs as possible. Leaf pages are written out in the usual way, without any separate deduplication pass. This strategy is well-suited to `CREATE INDEX` and `REINDEX` because they are once-off batch operations.

Write-heavy workloads that don't benefit from deduplication due to having few or no duplicate values in indexes will incur a small, fixed performance penalty (unless deduplication is explicitly disabled). The `deduplicate_items` storage parameter can be used to disable deduplication within individual indexes. There is never any performance penalty with read-only workloads, since reading posting list tuples is at least as efficient as reading the standard tuple representation. Disabling deduplication isn't usually helpful.

It is sometimes possible for unique indexes (as well as unique constraints) to use deduplication. This allows leaf pages to temporarily “absorb” extra version churn duplicates. Deduplication in unique indexes augments bottom-up index deletion, especially in cases where a long-running transaction holds a snapshot that blocks garbage collection. The goal is to buy time for the bottom-up index deletion strategy to become effective again. Delaying page splits until a single long-running transaction naturally goes away can allow a bottom-up deletion pass to succeed where an earlier deletion pass failed.

Tip

A special heuristic is applied to determine whether a deduplication pass in a unique index should take place. It can often skip straight to splitting a leaf page, avoiding a performance penalty from wasting cycles on unhelpful deduplication passes. If you're concerned about the overhead of deduplication, consider setting `deduplicate_items = off` selectively. Leaving deduplication enabled in unique indexes has little downside.

Deduplication cannot be used in all cases due to implementation-level restrictions. Deduplication safety is determined when `CREATE INDEX` or `REINDEX` is run.

Note that deduplication is deemed unsafe and cannot be used in the following cases involving semantically significant differences among equal datums:

- `text`, `varchar`, and `char` cannot use deduplication when a *nondeterministic* collation is used. Case and accent differences must be preserved among equal datums.
- `numeric` cannot use deduplication. Numeric display scale must be preserved among equal datums.
- `jsonb` cannot use deduplication, since the `jsonb` B-Tree operator class uses `numeric` internally.
- `float4` and `float8` cannot use deduplication. These types have distinct representations for `-0` and `0`, which are nevertheless considered equal. This difference must be preserved.

There is one further implementation-level restriction that may be lifted in a future version of Postgres Pro:

- Container types (such as composite types, arrays, or range types) cannot use deduplication.

There is one further implementation-level restriction that applies regardless of the operator class or collation used:

- `INCLUDE` indexes can never use deduplication.

65.2. GiST Indexes

65.2.1. Introduction

GiST stands for Generalized Search Tree. It is a balanced, tree-structured access method, that acts as a base template in which to implement arbitrary indexing schemes. B-trees, R-trees and many other indexing schemes can be implemented in GiST.

One advantage of GiST is that it allows the development of custom data types with the appropriate access methods, by an expert in the domain of the data type, rather than a database expert.

Some of the information here is derived from the University of California at Berkeley's GiST Indexing Project [web site](#) and Marcel Kornacker's thesis, *Access Methods for Next-Generation Database Systems*. The GiST implementation in Postgres Pro is primarily maintained by Teodor Sigaev and Oleg Bartunov, and there is more information on their [web site](#).

65.2.2. Built-in Operator Classes

The core Postgres Pro distribution includes the GiST operator classes shown in [Table 65.1](#). (Some of the optional modules described in [Appendix F](#) provide additional GiST operator classes.)

Table 65.1. Built-in GiST Operator Classes

Name	Indexable Operators	Ordering Operators
box_ops	<< (box, box)	<-> (box, point)
	&< (box, box)	
	&& (box, box)	
	&> (box, box)	
	>> (box, box)	
	~= (box, box)	
	@> (box, box)	
	<@ (box, box)	
	&< (box, box)	
	<< (box, box)	
	>> (box, box)	
	&> (box, box)	
circle_ops	<< (circle, circle)	<-> (circle, point)
	&< (circle, circle)	
	&> (circle, circle)	
	>> (circle, circle)	
	<@ (circle, circle)	
	@> (circle, circle)	
	~= (circle, circle)	
	&& (circle, circle)	
	>> (circle, circle)	
	<< (circle, circle)	
	&< (circle, circle)	
	&> (circle, circle)	
inet_ops	<< (inet, inet)	
	<<= (inet, inet)	
	>> (inet, inet)	
	>>= (inet, inet)	
	= (inet, inet)	
	<> (inet, inet)	
	< (inet, inet)	
	<= (inet, inet)	
	> (inet, inet)	
	>= (inet, inet)	
	&& (inet, inet)	
multirange_ops	= (anymultirange, anymultirange)	
	&& (anymultirange, anymultirange)	
	&& (anymultirange, anyrange)	
	@> (anymultirange, anyelement)	
	@> (anymultirange, anymultirange)	

Name	Indexable Operators	Ordering Operators
	@> (anymultirange, anyrange) <@ (anymultirange, anymultirange) <@ (anymultirange, anyrange) << (anymultirange, anymultirange) << (anymultirange, anyrange) >> (anymultirange, anymultirange) >> (anymultirange, anyrange) &< (anymultirange, anymultirange) &< (anymultirange, anyrange) &> (anymultirange, anymultirange) &> (anymultirange, anyrange) - - (anymultirange, anymultirange) - - (anymultirange, anyrange)	
point_ops	>> (point, point) << (point, point) >> (point, point) << (point, point) ~ = (point, point) <@ (point, box) <@ (point, polygon) <@ (point, circle)	<-> (point, point)
poly_ops	<< (polygon, polygon) &< (polygon, polygon) &> (polygon, polygon) >> (polygon, polygon) <@ (polygon, polygon) @> (polygon, polygon) ~ = (polygon, polygon) && (polygon, polygon) << (polygon, polygon) &< (polygon, polygon) &> (polygon, polygon) >> (polygon, polygon)	<-> (polygon, point)
range_ops	= (anyrange, anyrange) && (anyrange, anyrange) && (anyrange, anymultirange) @> (anyrange, anyelement) @> (anyrange, anyrange) @> (anyrange, anymultirange) <@ (anyrange, anyrange) <@ (anyrange, anymultirange)	

Name	Indexable Operators	Ordering Operators
	<< (anyrange, anyrange)	
	<< (anyrange, anymultirange)	
	>> (anyrange, anyrange)	
	>> (anyrange, anymultirange)	
	&< (anyrange, anyrange)	
	&< (anyrange, anymultirange)	
	&> (anyrange, anyrange)	
	&> (anyrange, anymultirange)	
	- - (anyrange, anyrange)	
	- - (anyrange, anymultirange)	
tsquery_ops	<@ (tsquery, tsquery)	
	@> (tsquery, tsquery)	
tsvector_ops	@@ (tsvector, tsquery)	

For historical reasons, the `inet_ops` operator class is not the default class for types `inet` and `cidr`. To use it, mention the class name in `CREATE INDEX`, for example

```
CREATE INDEX ON my_table USING GIST (my_inet_column inet_ops);
```

65.2.3. Extensibility

Traditionally, implementing a new index access method meant a lot of difficult work. It was necessary to understand the inner workings of the database, such as the lock manager and Write-Ahead Log. The GiST interface has a high level of abstraction, requiring the access method implementer only to implement the semantics of the data type being accessed. The GiST layer itself takes care of concurrency, logging and searching the tree structure.

This extensibility should not be confused with the extensibility of the other standard search trees in terms of the data they can handle. For example, Postgres Pro supports extensible B-trees and hash indexes. That means that you can use Postgres Pro to build a B-tree or hash over any data type you want. But B-trees only support range predicates (`<`, `=`, `>`), and hash indexes only support equality queries.

So if you index, say, an image collection with a Postgres Pro B-tree, you can only issue queries such as “is imagex equal to imagey”, “is imagex less than imagey” and “is imagex greater than imagey”. Depending on how you define “equals”, “less than” and “greater than” in this context, this could be useful. However, by using a GiST based index, you could create ways to ask domain-specific questions, perhaps “find all images of horses” or “find all over-exposed images”.

All it takes to get a GiST access method up and running is to implement several user-defined methods, which define the behavior of keys in the tree. Of course these methods have to be pretty fancy to support fancy queries, but for all the standard queries (B-trees, R-trees, etc.) they're relatively straightforward. In short, GiST combines extensibility along with generality, code reuse, and a clean interface.

There are five methods that an index operator class for GiST must provide, and six that are optional. Correctness of the index is ensured by proper implementation of the `same`, `consistent` and `union` methods, while efficiency (size and speed) of the index will depend on the `penalty` and `picksplit` methods. Two optional methods are `compress` and `decompress`, which allow an index to have internal tree data of a different type than the data it indexes. The leaves are to be of the indexed data type, while the other tree nodes can be of any C struct (but you still have to follow Postgres Pro data type rules here, see about `varlena` for variable sized data). If the tree's internal data type exists at the SQL level, the `STORAGE` option of the `CREATE OPERATOR CLASS` command can be used. The optional eighth method is `distance`, which is needed if the operator class wishes to support ordered scans (nearest-neighbor searches). The optional ninth method `fetch` is needed if the operator class wishes to support index-only scans, except when the `compress` method is omitted. The optional tenth method `options` is needed if the operator class has user-specified parameters. The optional eleventh method `sortsupport` is used to speed up building a GiST index.

`consistent`

Given an index entry `p` and a query value `q`, this function determines whether the index entry is “consistent” with the query; that is, could the predicate “`indexed_column indexable_operator q`” be true for any row represented by the index

entry? For a leaf index entry this is equivalent to testing the indexable condition, while for an internal tree node this determines whether it is necessary to scan the subtree of the index represented by the tree node. When the result is `true`, a `recheck` flag must also be returned. This indicates whether the predicate is certainly true or only possibly true. If `recheck = false` then the index has tested the predicate condition exactly, whereas if `recheck = true` the row is only a candidate match. In that case the system will automatically evaluate the *indexable_operator* against the actual row value to see if it is really a match. This convention allows GiST to support both lossless and lossy index structures.

The SQL declaration of the function must look like this:

```
CREATE OR REPLACE FUNCTION my_consistent(internal, data_type, smallint, oid,
    internal)
RETURNS bool
AS 'MODULE_PATHNAME'
LANGUAGE C STRICT;
```

And the matching code in the C module could then follow this skeleton:

```
PG_FUNCTION_INFO_V1(my_consistent);
```

```
Datum
```

```
my_consistent(PG_FUNCTION_ARGS)
```

```
{
    GISTENTRY *entry = (GISTENTRY *) PG_GETARG_POINTER(0);
    data_type *query = PG_GETARG_DATA_TYPE_P(1);
    StrategyNumber strategy = (StrategyNumber) PG_GETARG_UINT16(2);
    /* Oid subtype = PG_GETARG_OID(3); */
    bool *recheck = (bool *) PG_GETARG_POINTER(4);
    data_type *key = DatumGetDataType(entry->key);
    bool retval;

    /*
     * determine return value as a function of strategy, key and query.
     *
     * Use GIST_LEAF(entry) to know where you're called in the index tree,
     * which comes handy when supporting the = operator for example (you could
     * check for non empty union() in non-leaf nodes and equality in leaf
     * nodes).
     */

    *recheck = true;          /* or false if check is exact */

    PG_RETURN_BOOL(retval);
}
```

Here, `key` is an element in the index and `query` the value being looked up in the index. The `StrategyNumber` parameter indicates which operator of your operator class is being applied — it matches one of the operator numbers in the `CREATE OPERATOR CLASS` command.

Depending on which operators you have included in the class, the data type of `query` could vary with the operator, since it will be whatever type is on the right-hand side of the operator, which might be different from the indexed data type appearing on the left-hand side. (The above code skeleton assumes that only one type is possible; if not, fetching the `query` argument value would have to depend on the operator.) It is recommended that the SQL declaration of the `consistent` function use the opclass's indexed data type for the `query` argument, even though the actual type might be something else depending on the operator.

union

This method consolidates information in the tree. Given a set of entries, this function generates a new index entry that represents all the given entries.

The SQL declaration of the function must look like this:

```
CREATE OR REPLACE FUNCTION my_union(internal, internal)
```

```
RETURNS storage_type
AS 'MODULE_PATHNAME'
LANGUAGE C STRICT;
```

And the matching code in the C module could then follow this skeleton:

```
PG_FUNCTION_INFO_V1(my_union);
```

```
Datum
my_union(PG_FUNCTION_ARGS)
{
    GistEntryVector *entryvec = (GistEntryVector *) PG_GETARG_POINTER(0);
    GISTENTRY *ent = entryvec->vector;
    data_type *out,
               *tmp,
               *old;
    int numranges,
        i = 0;

    numranges = entryvec->n;
    tmp = DatumGetDataTypes(ent[0].key);
    out = tmp;

    if (numranges == 1)
    {
        out = data_type_deep_copy(tmp);

        PG_RETURN_DATA_TYPE_P(out);
    }

    for (i = 1; i < numranges; i++)
    {
        old = out;
        tmp = DatumGetDataTypes(ent[i].key);
        out = my_union_implementation(out, tmp);
    }

    PG_RETURN_DATA_TYPE_P(out);
}
```

As you can see, in this skeleton we're dealing with a data type where `union(X, Y, Z) = union(union(X, Y), Z)`. It's easy enough to support data types where this is not the case, by implementing the proper union algorithm in this GiST support method.

The result of the `union` function must be a value of the index's storage type, whatever that is (it might or might not be different from the indexed column's type). The `union` function should return a pointer to newly `palloc()`ed memory. You can't just return the input value as-is, even if there is no type change.

As shown above, the `union` function's first `internal` argument is actually a `GistEntryVector` pointer. The second argument is a pointer to an integer variable, which can be ignored. (It used to be required that the `union` function store the size of its result value into that variable, but this is no longer necessary.)

compress

Converts a data item into a format suitable for physical storage in an index page. If the `compress` method is omitted, data items are stored in the index without modification.

The SQL declaration of the function must look like this:

```
CREATE OR REPLACE FUNCTION my_compress(internal)
RETURNS internal
AS 'MODULE_PATHNAME'
```

```
LANGUAGE C STRICT;
```

And the matching code in the C module could then follow this skeleton:

```
PG_FUNCTION_INFO_V1(my_compress);
```

```
Datum
```

```
my_compress(PG_FUNCTION_ARGS)
```

```
{
    GISTENTRY *entry = (GISTENTRY *) PG_GETARG_POINTER(0);
    GISTENTRY *retval;

    if (entry->leafkey)
    {
        /* replace entry->key with a compressed version */
        compressed_data_type *compressed_data =
        palloc(sizeof(compressed_data_type));

        /* fill *compressed_data from entry->key ... */

        retval = palloc(sizeof(GISTENTRY));
        gistentryinit(*retval, PointerGetDatum(compressed_data),
                      entry->rel, entry->page, entry->offset, FALSE);
    }
    else
    {
        /* typically we needn't do anything with non-leaf entries */
        retval = entry;
    }

    PG_RETURN_POINTER(retval);
}
```

You have to adapt *compressed_data_type* to the specific type you're converting to in order to compress your leaf nodes, of course.

decompress

Converts the stored representation of a data item into a format that can be manipulated by the other GiST methods in the operator class. If the `decompress` method is omitted, it is assumed that the other GiST methods can work directly on the stored data format. (`decompress` is not necessarily the reverse of the `compress` method; in particular, if `compress` is lossy then it's impossible for `decompress` to exactly reconstruct the original data. `decompress` is not necessarily equivalent to `fetch`, either, since the other GiST methods might not require full reconstruction of the data.)

The SQL declaration of the function must look like this:

```
CREATE OR REPLACE FUNCTION my_decompress(internal)
RETURNS internal
AS 'MODULE_PATHNAME'
LANGUAGE C STRICT;
```

And the matching code in the C module could then follow this skeleton:

```
PG_FUNCTION_INFO_V1(my_decompress);
```

```
Datum
```

```
my_decompress(PG_FUNCTION_ARGS)
```

```
{
    PG_RETURN_POINTER(PG_GETARG_POINTER(0));
}
```

The above skeleton is suitable for the case where no decompression is needed. (But, of course, omitting the method altogether is even easier, and is recommended in such cases.)

penalty

Returns a value indicating the “cost” of inserting the new entry into a particular branch of the tree. Items will be inserted down the path of least `penalty` in the tree. Values returned by `penalty` should be non-negative. If a negative value is returned, it will be treated as zero.

The SQL declaration of the function must look like this:

```
CREATE OR REPLACE FUNCTION my_penalty(internal, internal, internal)
RETURNS internal
AS 'MODULE_PATHNAME'
LANGUAGE C STRICT; -- in some cases penalty functions need not be strict
```

And the matching code in the C module could then follow this skeleton:

```
PG_FUNCTION_INFO_V1(my_penalty);
```

Datum

```
my_penalty(PG_FUNCTION_ARGS)
```

```
{
    GISTENTRY *origentry = (GISTENTRY *) PG_GETARG_POINTER(0);
    GISTENTRY *newentry = (GISTENTRY *) PG_GETARG_POINTER(1);
    float *penalty = (float *) PG_GETARG_POINTER(2);
    data_type *orig = DatumGetDataType(origentry->key);
    data_type *new = DatumGetDataType(newentry->key);

    *penalty = my_penalty_implementation(orig, new);
    PG_RETURN_POINTER(penalty);
}
```

For historical reasons, the `penalty` function doesn't just return a `float` result; instead it has to store the value at the location indicated by the third argument. The return value per se is ignored, though it's conventional to pass back the address of that argument.

The `penalty` function is crucial to good performance of the index. It'll get used at insertion time to determine which branch to follow when choosing where to add the new entry in the tree. At query time, the more balanced the index, the quicker the lookup.

picksplit

When an index page split is necessary, this function decides which entries on the page are to stay on the old page, and which are to move to the new page.

The SQL declaration of the function must look like this:

```
CREATE OR REPLACE FUNCTION my_picksplit(internal, internal)
RETURNS internal
AS 'MODULE_PATHNAME'
LANGUAGE C STRICT;
```

And the matching code in the C module could then follow this skeleton:

```
PG_FUNCTION_INFO_V1(my_picksplit);
```

Datum

```
my_picksplit(PG_FUNCTION_ARGS)
```

```
{
    GistEntryVector *entryvec = (GistEntryVector *) PG_GETARG_POINTER(0);
    GIST_SPLITVEC *v = (GIST_SPLITVEC *) PG_GETARG_POINTER(1);
    OffsetNumber maxoff = entryvec->n - 1;
    GISTENTRY *ent = entryvec->vector;
    int i,
        nbytes;
    OffsetNumber *left,
        *right;
    data_type *tmp_union;
```

```
data_type *unionL;
data_type *unionR;
GISTENTRY **raw_entryvec;

maxoff = entryvec->n - 1;
nbytes = (maxoff + 1) * sizeof(OffsetNumber);

v->spl_left = (OffsetNumber *) palloc(nbytes);
left = v->spl_left;
v->spl_nleft = 0;

v->spl_right = (OffsetNumber *) palloc(nbytes);
right = v->spl_right;
v->spl_nright = 0;

unionL = NULL;
unionR = NULL;

/* Initialize the raw entry vector. */
raw_entryvec = (GISTENTRY **) malloc(entryvec->n * sizeof(void *));
for (i = FirstOffsetNumber; i <= maxoff; i = OffsetNumberNext(i))
    raw_entryvec[i] = &(entryvec->vector[i]);

for (i = FirstOffsetNumber; i <= maxoff; i = OffsetNumberNext(i))
{
    int          real_index = raw_entryvec[i] - entryvec->vector;

    tmp_union = DatumGetDataType(entryvec->vector[real_index].key);
    Assert(tmp_union != NULL);

    /*
     * Choose where to put the index entries and update unionL and unionR
     * accordingly. Append the entries to either v->spl_left or
     * v->spl_right, and care about the counters.
     */

    if (my_choice_is_left(unionL, curl, unionR, curr))
    {
        if (unionL == NULL)
            unionL = tmp_union;
        else
            unionL = my_union_implementation(unionL, tmp_union);

        *left = real_index;
        ++left;
        ++(v->spl_nleft);
    }
    else
    {
        /*
         * Same on the right
         */
    }
}

v->spl_ldatum = DataTypeGetDatum(unionL);
v->spl_rdatum = DataTypeGetDatum(unionR);
PG_RETURN_POINTER(v);
```

```
}
```

Notice that the `picksplit` function's result is delivered by modifying the passed-in `v` structure. The return value per se is ignored, though it's conventional to pass back the address of `v`.

Like `penalty`, the `picksplit` function is crucial to good performance of the index. Designing suitable `penalty` and `picksplit` implementations is where the challenge of implementing well-performing GiST indexes lies.

`same`

Returns true if two index entries are identical, false otherwise. (An “index entry” is a value of the index's storage type, not necessarily the original indexed column's type.)

The SQL declaration of the function must look like this:

```
CREATE OR REPLACE FUNCTION my_same(storage_type, storage_type, internal)
RETURNS internal
AS 'MODULE_PATHNAME'
LANGUAGE C STRICT;
```

And the matching code in the C module could then follow this skeleton:

```
PG_FUNCTION_INFO_V1(my_same);
```

Datum

```
my_same(PG_FUNCTION_ARGS)
{
    prefix_range *v1 = PG_GETARG_PREFIX_RANGE_P(0);
    prefix_range *v2 = PG_GETARG_PREFIX_RANGE_P(1);
    bool          *result = (bool *) PG_GETARG_POINTER(2);

    *result = my_eq(v1, v2);
    PG_RETURN_POINTER(result);
}
```

For historical reasons, the `same` function doesn't just return a Boolean result; instead it has to store the flag at the location indicated by the third argument. The return value per se is ignored, though it's conventional to pass back the address of that argument.

`distance`

Given an index entry `p` and a query value `q`, this function determines the index entry's “distance” from the query value. This function must be supplied if the operator class contains any ordering operators. A query using the ordering operator will be implemented by returning index entries with the smallest “distance” values first, so the results must be consistent with the operator's semantics. For a leaf index entry the result just represents the distance to the index entry; for an internal tree node, the result must be the smallest distance that any child entry could have.

The SQL declaration of the function must look like this:

```
CREATE OR REPLACE FUNCTION my_distance(internal, data_type, smallint, oid, internal)
RETURNS float8
AS 'MODULE_PATHNAME'
LANGUAGE C STRICT;
```

And the matching code in the C module could then follow this skeleton:

```
PG_FUNCTION_INFO_V1(my_distance);
```

Datum

```
my_distance(PG_FUNCTION_ARGS)
{
    GISTENTRY *entry = (GISTENTRY *) PG_GETARG_POINTER(0);
    data_type *query = PG_GETARG_DATA_TYPE_P(1);
    StrategyNumber strategy = (StrategyNumber) PG_GETARG_UINT16(2);
    /* Oid subtype = PG_GETARG_OID(3); */
    /* bool *recheck = (bool *) PG_GETARG_POINTER(4); */
}
```

```
data_type  *key = DatumGetDataType(entry->key);
double     retval;

/*
 * determine return value as a function of strategy, key and query.
 */

PG_RETURN_FLOAT8(retval);
}
```

The arguments to the `distance` function are identical to the arguments of the `consistent` function.

Some approximation is allowed when determining the distance, so long as the result is never greater than the entry's actual distance. Thus, for example, distance to a bounding box is usually sufficient in geometric applications. For an internal tree node, the distance returned must not be greater than the distance to any of the child nodes. If the returned distance is not exact, the function must set `*recheck` to true. (This is not necessary for internal tree nodes; for them, the calculation is always assumed to be inexact.) In this case the executor will calculate the accurate distance after fetching the tuple from the heap, and reorder the tuples if necessary.

If the distance function returns `*recheck = true` for any leaf node, the original ordering operator's return type must be `float8` or `float4`, and the distance function's result values must be comparable to those of the original ordering operator, since the executor will sort using both distance function results and recalculated ordering-operator results. Otherwise, the distance function's result values can be any finite `float8` values, so long as the relative order of the result values matches the order returned by the ordering operator. (Infinity and minus infinity are used internally to handle cases such as nulls, so it is not recommended that distance functions return these values.)

fetch

Converts the compressed index representation of a data item into the original data type, for index-only scans. The returned data must be an exact, non-lossy copy of the originally indexed value.

The SQL declaration of the function must look like this:

```
CREATE OR REPLACE FUNCTION my_fetch(internal)
RETURNS internal
AS 'MODULE_PATHNAME'
LANGUAGE C STRICT;
```

The argument is a pointer to a `GISTENTRY` struct. On entry, its `key` field contains a non-NULL leaf datum in compressed form. The return value is another `GISTENTRY` struct, whose `key` field contains the same datum in its original, uncompressed form. If the opclass's compress function does nothing for leaf entries, the `fetch` method can return the argument as-is. Or, if the opclass does not have a compress function, the `fetch` method can be omitted as well, since it would necessarily be a no-op.

The matching code in the C module could then follow this skeleton:

```
PG_FUNCTION_INFO_V1(my_fetch);

Datum
my_fetch(PG_FUNCTION_ARGS)
{
    GISTENTRY *entry = (GISTENTRY *) PG_GETARG_POINTER(0);
    input_data_type *in = DatumGetPointer(entry->key);
    fetched_data_type *fetched_data;
    GISTENTRY *retval;

    retval = palloc(sizeof(GISTENTRY));
    fetched_data = palloc(sizeof(fetched_data_type));

    /*
     * Convert 'fetched_data' into the a Datum of the original datatype.
     */

    /* fill *retval from fetched_data. */
}
```

```
gistentryinit(*retval, PointerGetDatum(converted_datum),
              entry->rel, entry->page, entry->offset, FALSE);

PG_RETURN_POINTER(retval);
}
```

If the compress method is lossy for leaf entries, the operator class cannot support index-only scans, and must not define a `fetch` function.

options

Allows definition of user-visible parameters that control operator class behavior.

The SQL declaration of the function must look like this:

```
CREATE OR REPLACE FUNCTION my_options(internal)
RETURNS void
AS 'MODULE_PATHNAME'
LANGUAGE C STRICT;
```

The function is passed a pointer to a `local_relopts` struct, which needs to be filled with a set of operator class specific options. The options can be accessed from other support functions using the `PG_HAS_OPCLASS_OPTIONS()` and `PG_GET_OPCLASS_OPTIONS()` macros.

An example implementation of `my_options()` and parameters use from other support functions are given below:

```
typedef enum MyEnumType
{
    MY_ENUM_ON,
    MY_ENUM_OFF,
    MY_ENUM_AUTO
} MyEnumType;

typedef struct
{
    int32    vl_len_; /* varlena header (do not touch directly!) */
    int      int_param; /* integer parameter */
    double   real_param; /* real parameter */
    MyEnumType enum_param; /* enum parameter */
    int      str_param; /* string parameter */
} MyOptionsStruct;

```

    * Normally, when opclass contains 'options' method, then options are always
    * passed to support functions. However, if you add 'options' method to
    * existing opclass, previously defined indexes have no options, so the
    * check is required.
    */
if (PG_HAS_OPCLASS_OPTIONS())
{
    MyOptionsStruct *options = (MyOptionsStruct *) PG_GET_OPCLASS_OPTIONS();

    int_param = options->int_param;
    real_param = options->real_param;
    enum_param = options->enum_param;
    str_param = GET_STRING_RELOPTION(options, str_param);
}

/* the rest implementation of support function */
}
```

Since the representation of the key in GiST is flexible, it may depend on user-specified parameters. For instance, the length of key signature may be specified. See `gtsvector_options()` for example.

sortsupport

Returns a comparator function to sort data in a way that preserves locality. It is used by `CREATE INDEX` and `REINDEX` commands. The quality of the created index depends on how well the sort order determined by the comparator function preserves locality of the inputs.

The `sortsupport` method is optional. If it is not provided, `CREATE INDEX` builds the index by inserting each tuple to the tree using the `penalty` and `picksplit` functions, which is much slower.

The SQL declaration of the function must look like this:

```
CREATE OR REPLACE FUNCTION my_sortsupport(internal)
RETURNS void
AS 'MODULE_PATHNAME'
LANGUAGE C STRICT;
```

The argument is a pointer to a `SortSupport` struct. At a minimum, the function must fill in its comparator field. The comparator takes three arguments: two `Datums` to compare, and a pointer to the `SortSupport` struct. The `Datums` are the two indexed values in the format that they are stored in the index; that is, in the format returned by the `compress` method. The full API is defined in [src/include/utils/sortsupport.h](#).

The matching code in the C module could then follow this skeleton:

```
PG_FUNCTION_INFO_V1(my_sortsupport);

static int
my_fastcmp(Datum x, Datum y, SortSupport ssup)
{
    /* establish order between x and y by computing some sorting value z */

    int z1 = ComputeSpatialCode(x);
    int z2 = ComputeSpatialCode(y);

    return z1 == z2 ? 0 : z1 > z2 ? 1 : -1;
}

Datum
my_sortsupport(PG_FUNCTION_ARGS)
{
```

```
SortSupport ssup = (SortSupport) PG_GETARG_POINTER(0);

ssup->comparator = my_fastcmp;
PG_RETURN_VOID();
}
```

All the GiST support methods are normally called in short-lived memory contexts; that is, `CurrentMemoryContext` will get reset after each tuple is processed. It is therefore not very important to worry about pfree'ing everything you palloc. However, in some cases it's useful for a support method to cache data across repeated calls. To do that, allocate the longer-lived data in `fcinfo->flinfo->fn_mcxt`, and keep a pointer to it in `fcinfo->flinfo->fn_extra`. Such data will survive for the life of the index operation (e.g., a single GiST index scan, index build, or index tuple insertion). Be careful to pfree the previous value when replacing a `fn_extra` value, or the leak will accumulate for the duration of the operation.

65.2.4. Implementation

65.2.4.1. GiST Index Build Methods

The simplest way to build a GiST index is just to insert all the entries, one by one. This tends to be slow for large indexes, because if the index tuples are scattered across the index and the index is large enough to not fit in cache, a lot of random I/O will be needed. Postgres Pro supports two alternative methods for initial build of a GiST index: *sorted* and *buffered* modes.

The sorted method is only available if each of the opclasses used by the index provides a `sortsupport` function, as described in [Section 65.2.3](#). If they do, this method is usually the best, so it is used by default.

The buffered method works by not inserting tuples directly into the index right away. It can dramatically reduce the amount of random I/O needed for non-ordered data sets. For well-ordered data sets the benefit is smaller or non-existent, because only a small number of pages receive new tuples at a time, and those pages fit in cache even if the index as a whole does not.

The buffered method needs to call the `penalty` function more often than the simple method does, which consumes some extra CPU resources. Also, the buffers need temporary disk space, up to the size of the resulting index. Buffering can also influence the quality of the resulting index, in both positive and negative directions. That influence depends on various factors, like the distribution of the input data and the operator class implementation.

If sorting is not possible, then by default a GiST index build switches to the buffering method when the index size reaches [effective_cache_size](#). Buffering can be manually forced or prevented by the `buffering` parameter to the `CREATE INDEX` command. The default behavior is good for most cases, but turning buffering off might speed up the build somewhat if the input data is ordered.

65.2.5. Examples

The Postgres Pro core system currently provides text search support (indexing for `tsvector` and `tsquery`) as well as R-Tree equivalent functionality for some of the built-in geometric data types. The following `contrib` modules also contain GiST operator classes:

`btree_gist`

B-tree equivalent functionality for several data types

`cube`

Indexing for multidimensional cubes

`hstore`

Module for storing (key, value) pairs

`intarray`

RD-Tree for one-dimensional array of int4 values

`ltree`

Indexing for tree-like structures

`pg_trgm`

Text similarity using trigram matching

seg

Indexing for “float ranges”

65.3. SP-GiST Indexes

65.3.1. Introduction

SP-GiST is an abbreviation for space-partitioned GiST. SP-GiST supports partitioned search trees, which facilitate development of a wide range of different non-balanced data structures, such as quad-trees, k-d trees, and radix trees (tries). The common feature of these structures is that they repeatedly divide the search space into partitions that need not be of equal size. Searches that are well matched to the partitioning rule can be very fast.

These popular data structures were originally developed for in-memory usage. In main memory, they are usually designed as a set of dynamically allocated nodes linked by pointers. This is not suitable for direct storing on disk, since these chains of pointers can be rather long which would require too many disk accesses. In contrast, disk-based data structures should have a high fanout to minimize I/O. The challenge addressed by SP-GiST is to map search tree nodes to disk pages in such a way that a search need access only a few disk pages, even if it traverses many nodes.

Like GiST, SP-GiST is meant to allow the development of custom data types with the appropriate access methods, by an expert in the domain of the data type, rather than a database expert.

Some of the information here is derived from Purdue University's SP-GiST Indexing Project [web site](#). The SP-GiST implementation in Postgres Pro is primarily maintained by Teodor Sigaev and Oleg Bartunov, and there is more information on their [web site](#).

65.3.2. Built-in Operator Classes

The core Postgres Pro distribution includes the SP-GiST operator classes shown in [Table 65.2](#).

Table 65.2. Built-in SP-GiST Operator Classes

Name	Indexable Operators	Ordering Operators
box_ops	<< (box, box)	<-> (box, point)
	&< (box, box)	
	&> (box, box)	
	>> (box, box)	
	<@ (box, box)	
	@> (box, box)	
	~= (box, box)	
	&& (box, box)	
	<< (box, box)	
	&< (box, box)	
	&> (box, box)	
	>> (box, box)	
inet_ops	<< (inet, inet)	
	<<= (inet, inet)	
	>> (inet, inet)	
	>>= (inet, inet)	
	= (inet, inet)	
	<> (inet, inet)	
	< (inet, inet)	
	<= (inet, inet)	
	> (inet, inet)	

Name	Indexable Operators	Ordering Operators
	>= (inet, inet)	
	&& (inet, inet)	
kd_point_ops	>> (point, point)	<-> (point, point)
	<< (point, point)	
	>> (point, point)	
	<< (point, point)	
	~= (point, point)	
	<@ (point, box)	
poly_ops	<< (polygon, polygon)	<-> (polygon, point)
	&< (polygon, polygon)	
	&> (polygon, polygon)	
	>> (polygon, polygon)	
	<@ (polygon, polygon)	
	@> (polygon, polygon)	
	~= (polygon, polygon)	
	&& (polygon, polygon)	
	<< (polygon, polygon)	
	&< (polygon, polygon)	
	>> (polygon, polygon)	
	&> (polygon, polygon)	
quad_point_ops	>> (point, point)	<-> (point, point)
	<< (point, point)	
	>> (point, point)	
	<< (point, point)	
	~= (point, point)	
	<@ (point, box)	
range_ops	= (anyrange, anyrange)	
	&& (anyrange, anyrange)	
	@> (anyrange, anyelement)	
	@> (anyrange, anyrange)	
	<@ (anyrange, anyrange)	
	<< (anyrange, anyrange)	
	>> (anyrange, anyrange)	
	&< (anyrange, anyrange)	
	&> (anyrange, anyrange)	
	- - (anyrange, anyrange)	
text_ops	= (text, text)	
	< (text, text)	
	<= (text, text)	
	> (text, text)	
	>= (text, text)	

Name	Indexable Operators	Ordering Operators
	~<~ (text, text)	
	~<=~ (text, text)	
	~>=~ (text, text)	
	~>~ (text, text)	
	^@ (text, text)	

Of the two operator classes for type `point`, `quad_point_ops` is the default. `kd_point_ops` supports the same operators but uses a different index data structure that may offer better performance in some applications.

The `quad_point_ops`, `kd_point_ops` and `poly_ops` operator classes support the `<->` ordering operator, which enables the k-nearest neighbor (k - NN) search over indexed point or polygon data sets.

65.3.3. Extensibility

SP-GiST offers an interface with a high level of abstraction, requiring the access method developer to implement only methods specific to a given data type. The SP-GiST core is responsible for efficient disk mapping and searching the tree structure. It also takes care of concurrency and logging considerations.

Leaf tuples of an SP-GiST tree usually contain values of the same data type as the indexed column, although it is also possible for them to contain lossy representations of the indexed column. Leaf tuples stored at the root level will directly represent the original indexed data value, but leaf tuples at lower levels might contain only a partial value, such as a suffix. In that case the operator class support functions must be able to reconstruct the original value using information accumulated from the inner tuples that are passed through to reach the leaf level.

When an SP-GiST index is created with `INCLUDE` columns, the values of those columns are also stored in leaf tuples. The `INCLUDE` columns are of no concern to the SP-GiST operator class, so they are not discussed further here.

Inner tuples are more complex, since they are branching points in the search tree. Each inner tuple contains a set of one or more *nodes*, which represent groups of similar leaf values. A node contains a downlink that leads either to another, lower-level inner tuple, or to a short list of leaf tuples that all lie on the same index page. Each node normally has a *label* that describes it; for example, in a radix tree the node label could be the next character of the string value. (Alternatively, an operator class can omit the node labels, if it works with a fixed set of nodes for all inner tuples; see [Section 65.3.4.2](#).) Optionally, an inner tuple can have a *prefix* value that describes all its members. In a radix tree this could be the common prefix of the represented strings. The prefix value is not necessarily really a prefix, but can be any data needed by the operator class; for example, in a quad-tree it can store the central point that the four quadrants are measured with respect to. A quad-tree inner tuple would then also contain four nodes corresponding to the quadrants around this central point.

Some tree algorithms require knowledge of level (or depth) of the current tuple, so the SP-GiST core provides the possibility for operator classes to manage level counting while descending the tree. There is also support for incrementally reconstructing the represented value when that is needed, and for passing down additional data (called *traverse values*) during a tree descent.

Note

The SP-GiST core code takes care of null entries. Although SP-GiST indexes do store entries for nulls in indexed columns, this is hidden from the index operator class code: no null index entries or search conditions will ever be passed to the operator class methods. (It is assumed that SP-GiST operators are strict and so cannot succeed for null values.) Null values are therefore not discussed further here.

There are five user-defined methods that an index operator class for SP-GiST must provide, and two are optional. All five mandatory methods follow the convention of accepting two `internal` arguments, the first of which is a pointer to a C struct containing input values for the support method, while the second argument is a pointer to a C struct where output values must be placed. Four of the mandatory methods just return `void`, since all their results appear in the output struct; but `leaf_consistent` returns a `boolean` result. The methods must not modify any fields of their input structs. In all cases, the output struct is initialized to zeroes before calling the user-defined method. The optional sixth method `compress` accepts a `datum` to be indexed as the only argument and returns a value suitable for physical storage in a leaf tuple. The optional seventh method `options` accepts an `internal` pointer to a C struct, where opclass-specific parameters should be placed, and returns `void`.

The five mandatory user-defined methods are:

config

Returns static information about the index implementation, including the data type OIDs of the prefix and node label data types.

The SQL declaration of the function must look like this:

```
CREATE FUNCTION my_config(internal, internal) RETURNS void ...
```

The first argument is a pointer to a `spgConfigIn` C struct, containing input data for the function. The second argument is a pointer to a `spgConfigOut` C struct, which the function must fill with result data.

```
typedef struct spgConfigIn
{
    Oid          attType;          /* Data type to be indexed */
} spgConfigIn;

typedef struct spgConfigOut
{
    Oid          prefixType;       /* Data type of inner-tuple prefixes */
    Oid          labelType;        /* Data type of inner-tuple node labels */
    Oid          leafType;         /* Data type of leaf-tuple values */
    bool         canReturnData;    /* Opclass can reconstruct original data */
    bool         longValuesOK;     /* Opclass can cope with values > 1 page */
} spgConfigOut;
```

`attType` is passed in order to support polymorphic index operator classes; for ordinary fixed-data-type operator classes, it will always have the same value and so can be ignored.

For operator classes that do not use prefixes, `prefixType` can be set to `VOIDOID`. Likewise, for operator classes that do not use node labels, `labelType` can be set to `VOIDOID`. `canReturnData` should be set true if the operator class is capable of reconstructing the originally-supplied index value. `longValuesOK` should be set true only when the `attType` is of variable length and the operator class is capable of segmenting long values by repeated suffixing (see [Section 65.3.4.1](#)).

`leafType` should match the index storage type defined by the operator class's `opkeytype` catalog entry. (Note that `opkeytype` can be zero, implying the storage type is the same as the operator class's input type, which is the most common situation.) For reasons of backward compatibility, the `config` method can set `leafType` to some other value, and that value will be used; but this is deprecated since the index contents are then incorrectly identified in the catalogs. Also, it's permissible to leave `leafType` uninitialized (zero); that is interpreted as meaning the index storage type derived from `opkeytype`.

When `attType` and `leafType` are different, the optional method `compress` must be provided. Method `compress` is responsible for transformation of datums to be indexed from `attType` to `leafType`.

choose

Chooses a method for inserting a new value into an inner tuple.

The SQL declaration of the function must look like this:

```
CREATE FUNCTION my_choose(internal, internal) RETURNS void ...
```

The first argument is a pointer to a `spgChooseIn` C struct, containing input data for the function. The second argument is a pointer to a `spgChooseOut` C struct, which the function must fill with result data.

```
typedef struct spgChooseIn
{
    Datum        datum;           /* original datum to be indexed */
    Datum        leafDatum;       /* current datum to be stored at leaf */
    int          level;           /* current level (counting from zero) */

    /* Data from current inner tuple */
    bool         allTheSame;      /* tuple is marked all-the-same? */
    bool         hasPrefix;       /* tuple has a prefix? */
    Datum        prefixDatum;     /* if so, the prefix value */
}
```

```

    int          nNodes;          /* number of nodes in the inner tuple */
    Datum        *nodeLabels;     /* node label values (NULL if none) */
} spgChooseIn;

typedef enum spgChooseResultType
{
    spgMatchNode = 1,             /* descend into existing node */
    spgAddNode,                   /* add a node to the inner tuple */
    spgSplitTuple                 /* split inner tuple (change its prefix) */
} spgChooseResultType;

typedef struct spgChooseOut
{
    spgChooseResultType resultType; /* action code, see above */
    union
    {
        struct /* results for spgMatchNode */
        {
            int      nodeN;        /* descend to this node (index from 0) */
            int      levelAdd;     /* increment level by this much */
            Datum     restDatum;    /* new leaf datum */
        } matchNode;
        struct /* results for spgAddNode */
        {
            Datum     nodeLabel;    /* new node's label */
            int        nodeN;       /* where to insert it (index from 0) */
        } addNode;
        struct /* results for spgSplitTuple */
        {
            /* Info to form new upper-level inner tuple with one child tuple */
            bool      prefixHasPrefix; /* tuple should have a prefix? */
            Datum     prefixPrefixDatum; /* if so, its value */
            int        prefixNNodes;    /* number of nodes */
            Datum     *prefixNodeLabels; /* their labels (or NULL for
                                         * no labels) */
            int        childNodeN;     /* which node gets child tuple */

            /* Info to form new lower-level inner tuple with all old nodes */
            bool      postfixHasPrefix; /* tuple should have a prefix? */
            Datum     postfixPrefixDatum; /* if so, its value */
        } splitTuple;
    } result;
} spgChooseOut;

```

`datum` is the original datum of `spgConfigIn.attType` type that was to be inserted into the index. `leafDatum` is a value of `spgConfigOut.leafType` type, which is initially a result of method `compress` applied to `datum` when method `compress` is provided, or the same value as `datum` otherwise. `leafDatum` can change at lower levels of the tree if the `choose` or `picksplit` methods change it. When the insertion search reaches a leaf page, the current value of `leafDatum` is what will be stored in the newly created leaf tuple. `level` is the current inner tuple's level, starting at zero for the root level. `allTheSame` is true if the current inner tuple is marked as containing multiple equivalent nodes (see [Section 65.3.4.3](#)). `hasPrefix` is true if the current inner tuple contains a prefix; if so, `prefixDatum` is its value. `nNodes` is the number of child nodes contained in the inner tuple, and `nodeLabels` is an array of their label values, or NULL if there are no labels.

The `choose` function can determine either that the new value matches one of the existing child nodes, or that a new child node must be added, or that the new value is inconsistent with the tuple prefix and so the inner tuple must be split to create a less restrictive prefix.

If the new value matches one of the existing child nodes, set `resultType` to `spgMatchNode`. Set `nodeN` to the index (from zero) of that node in the node array. Set `levelAdd` to the increment in `level` caused by descending through that node, or

leave it as zero if the operator class does not use levels. Set `restDatum` to equal `leafDatum` if the operator class does not modify datums from one level to the next, or otherwise set it to the modified value to be used as `leafDatum` at the next level.

If a new child node must be added, set `resultType` to `spgAddNode`. Set `nodeLabel` to the label to be used for the new node, and set `nodeN` to the index (from zero) at which to insert the node in the node array. After the node has been added, the `choose` function will be called again with the modified inner tuple; that call should result in an `spgMatchNode` result.

If the new value is inconsistent with the tuple prefix, set `resultType` to `spgSplitTuple`. This action moves all the existing nodes into a new lower-level inner tuple, and replaces the existing inner tuple with a tuple having a single downlink pointing to the new lower-level inner tuple. Set `prefixHasPrefix` to indicate whether the new upper tuple should have a prefix, and if so set `prefixPrefixDatum` to the prefix value. This new prefix value must be sufficiently less restrictive than the original to accept the new value to be indexed. Set `prefixNNodes` to the number of nodes needed in the new tuple, and set `prefixNodeLabels` to a palloc'd array holding their labels, or to NULL if node labels are not required. Note that the total size of the new upper tuple must be no more than the total size of the tuple it is replacing; this constrains the lengths of the new prefix and new labels. Set `childNodeN` to the index (from zero) of the node that will downlink to the new lower-level inner tuple. Set `postfixHasPrefix` to indicate whether the new lower-level inner tuple should have a prefix, and if so set `postfixPrefixDatum` to the prefix value. The combination of these two prefixes and the downlink node's label (if any) must have the same meaning as the original prefix, because there is no opportunity to alter the node labels that are moved to the new lower-level tuple, nor to change any child index entries. After the node has been split, the `choose` function will be called again with the replacement inner tuple. That call may return an `spgAddNode` result, if no suitable node was created by the `spgSplitTuple` action. Eventually `choose` must return `spgMatchNode` to allow the insertion to descend to the next level.

picksplit

Decides how to create a new inner tuple over a set of leaf tuples.

The SQL declaration of the function must look like this:

```
CREATE FUNCTION my_picksplit(internal, internal) RETURNS void ...
```

The first argument is a pointer to a `spgPickSplitIn` C struct, containing input data for the function. The second argument is a pointer to a `spgPickSplitOut` C struct, which the function must fill with result data.

```
typedef struct spgPickSplitIn
{
    int          nTuples;          /* number of leaf tuples */
    Datum        *datums;          /* their datums (array of length nTuples) */
    int          level;           /* current level (counting from zero) */
} spgPickSplitIn;

typedef struct spgPickSplitOut
{
    bool         hasPrefix;        /* new inner tuple should have a prefix? */
    Datum        prefixDatum;      /* if so, its value */

    int          nNodes;          /* number of nodes for new inner tuple */
    Datum        *nodeLabels;      /* their labels (or NULL for no labels) */

    int          *mapTuplesToNodes; /* node index for each leaf tuple */
    Datum        *leafTupleDatums; /* datum to store in each new leaf tuple */
} spgPickSplitOut;
```

`nTuples` is the number of leaf tuples provided. `datums` is an array of their datum values of `spgConfigOut.leafType` type. `level` is the current level that all the leaf tuples share, which will become the level of the new inner tuple.

Set `hasPrefix` to indicate whether the new inner tuple should have a prefix, and if so set `prefixDatum` to the prefix value. Set `nNodes` to indicate the number of nodes that the new inner tuple will contain, and set `nodeLabels` to an array of their label values, or to NULL if node labels are not required. Set `mapTuplesToNodes` to an array that gives the index (from zero) of the node that each leaf tuple should be assigned to. Set `leafTupleDatums` to an array of the values to be stored in the new leaf tuples (these will be the same as the input `datums` if the operator class does not modify datums from one level to the next). Note that the `picksplit` function is responsible for palloc'ing the `nodeLabels`, `mapTuplesToNodes` and `leafTupleDatums` arrays.

If more than one leaf tuple is supplied, it is expected that the `picksplit` function will classify them into more than one node; otherwise it is not possible to split the leaf tuples across multiple pages, which is the ultimate purpose of this operation. Therefore, if the `picksplit` function ends up placing all the leaf tuples in the same node, the core SP-GiST code will override that decision and generate an inner tuple in which the leaf tuples are assigned at random to several identically-labeled nodes. Such a tuple is marked `allTheSame` to signify that this has happened. The `choose` and `inner_consistent` functions must take suitable care with such inner tuples. See [Section 65.3.4.3](#) for more information.

`picksplit` can be applied to a single leaf tuple only in the case that the `config` function set `longValuesOK` to true and a larger-than-a-page input value has been supplied. In this case the point of the operation is to strip off a prefix and produce a new, shorter leaf datum value. The call will be repeated until a leaf datum short enough to fit on a page has been produced. See [Section 65.3.4.1](#) for more information.

`inner_consistent`

Returns set of nodes (branches) to follow during tree search.

The SQL declaration of the function must look like this:

```
CREATE FUNCTION my_inner_consistent(internal, internal) RETURNS void ...
```

The first argument is a pointer to a `spgInnerConsistentIn` C struct, containing input data for the function. The second argument is a pointer to a `spgInnerConsistentOut` C struct, which the function must fill with result data.

```
typedef struct spgInnerConsistentIn
{
    ScanKey      scankeys;          /* array of operators and comparison values */
    ScanKey      orderbys;          /* array of ordering operators and comparison
                                     * values */
    int          nkeys;             /* length of scankeys array */
    int          norderbys;         /* length of orderbys array */

    Datum        reconstructedValue; /* value reconstructed at parent */
    void         *traversalValue;    /* opclass-specific traverse value */
    MemoryContext traversalMemoryContext; /* put new traverse values here */
    int          level;             /* current level (counting from zero) */
    bool         returnData;        /* original data must be returned? */

    /* Data from current inner tuple */
    bool         allTheSame;        /* tuple is marked all-the-same? */
    bool         hasPrefix;         /* tuple has a prefix? */
    Datum        prefixDatum;       /* if so, the prefix value */
    int          nNodes;            /* number of nodes in the inner tuple */
    Datum        *nodeLabels;       /* node label values (NULL if none) */
} spgInnerConsistentIn;

typedef struct spgInnerConsistentOut
{
    int          nNodes;            /* number of child nodes to be visited */
    int          *nodeNumbers;      /* their indexes in the node array */
    int          *levelAdds;        /* increment level by this much for each */
    Datum        *reconstructedValues; /* associated reconstructed values */
    void         **traversalValues; /* opclass-specific traverse values */
    double       **distances;       /* associated distances */
} spgInnerConsistentOut;
```

The array `scankeys`, of length `nkeys`, describes the index search condition(s). These conditions are combined with AND — only index entries that satisfy all of them are interesting. (Note that `nkeys = 0` implies that all index entries satisfy the query.) Usually the consistent function only cares about the `sk_strategy` and `sk_argument` fields of each array entry, which respectively give the indexable operator and comparison value. In particular it is not necessary to check `sk_flags` to see if the comparison value is NULL, because the SP-GiST core code will filter out such conditions. The array `orderbys`, of length `norderbys`, describes ordering operators (if any) in the same manner. `reconstructedValue` is the value reconstructed for the parent tuple; it is (`Datum`) 0 at the root level or if the `inner_consistent` function did not provide a value at the

parent level. `traversalValue` is a pointer to any traverse data passed down from the previous call of `inner_consistent` on the parent index tuple, or NULL at the root level. `traversalMemoryContext` is the memory context in which to store output traverse values (see below). `level` is the current inner tuple's level, starting at zero for the root level. `returnData` is true if reconstructed data is required for this query; this will only be so if the `config` function asserted `canReturnData`. `allTheSame` is true if the current inner tuple is marked “all-the-same”; in this case all the nodes have the same label (if any) and so either all or none of them match the query (see [Section 65.3.4.3](#)). `hasPrefix` is true if the current inner tuple contains a prefix; if so, `prefixDatum` is its value. `nNodes` is the number of child nodes contained in the inner tuple, and `nodeLabels` is an array of their label values, or NULL if the nodes do not have labels.

`nNodes` must be set to the number of child nodes that need to be visited by the search, and `nodeNumbers` must be set to an array of their indexes. If the operator class keeps track of levels, set `levelAdds` to an array of the level increments required when descending to each node to be visited. (Often these increments will be the same for all the nodes, but that's not necessarily so, so an array is used.) If value reconstruction is needed, set `reconstructedValues` to an array of the values reconstructed for each child node to be visited; otherwise, leave `reconstructedValues` as NULL. The reconstructed values are assumed to be of type `spgConfigOut.leafType`. (However, since the core system will do nothing with them except possibly copy them, it is sufficient for them to have the same `typlen` and `typbyval` properties as `leafType`.) If ordered search is performed, set `distances` to an array of distance values according to `orderbys` array (nodes with lowest distances will be processed first). Leave it NULL otherwise. If it is desired to pass down additional out-of-band information (“traverse values”) to lower levels of the tree search, set `traversalValues` to an array of the appropriate traverse values, one for each child node to be visited; otherwise, leave `traversalValues` as NULL. Note that the `inner_consistent` function is responsible for `palloc`'ing the `nodeNumbers`, `levelAdds`, `distances`, `reconstructedValues`, and `traversalValues` arrays in the current memory context. However, any output traverse values pointed to by the `traversalValues` array should be allocated in `traversalMemoryContext`. Each traverse value must be a single `palloc`'d chunk.

leaf_consistent

Returns true if a leaf tuple satisfies a query.

The SQL declaration of the function must look like this:

```
CREATE FUNCTION my_leaf_consistent(internal, internal) RETURNS bool ...
```

The first argument is a pointer to a `spgLeafConsistentIn` C struct, containing input data for the function. The second argument is a pointer to a `spgLeafConsistentOut` C struct, which the function must fill with result data.

```
typedef struct spgLeafConsistentIn
{
    ScanKey      scankeys;          /* array of operators and comparison values */
    ScanKey      orderbys;          /* array of ordering operators and comparison
                                   * values */
    int          nkeys;             /* length of scankeys array */
    int          norderbys;         /* length of orderbys array */

    Datum        reconstructedValue; /* value reconstructed at parent */
    void         *traversalValue;    /* opclass-specific traverse value */
    int          level;             /* current level (counting from zero) */
    bool         returnData;        /* original data must be returned? */

    Datum        leafDatum;         /* datum in leaf tuple */
} spgLeafConsistentIn;

typedef struct spgLeafConsistentOut
{
    Datum        leafValue;         /* reconstructed original data, if any */
    bool         recheck;           /* set true if operator must be rechecked */
    bool         recheckDistances; /* set true if distances must be rechecked */
    double       *distances;        /* associated distances */
} spgLeafConsistentOut;
```

The array `scankeys`, of length `nkeys`, describes the index search condition(s). These conditions are combined with AND — only index entries that satisfy all of them satisfy the query. (Note that `nkeys = 0` implies that all index entries satisfy the query.) Usually the consistent function only cares about the `sk_strategy` and `sk_argument` fields of each array entry, which

respectively give the indexable operator and comparison value. In particular it is not necessary to check `sk_flags` to see if the comparison value is `NULL`, because the SP-GiST core code will filter out such conditions. The array `orderbys`, of length `norderbys`, describes the ordering operators in the same manner. `reconstructedValue` is the value reconstructed for the parent tuple; it is (`Datum`) `0` at the root level or if the `inner_consistent` function did not provide a value at the parent level. `traversalValue` is a pointer to any traverse data passed down from the previous call of `inner_consistent` on the parent index tuple, or `NULL` at the root level. `level` is the current leaf tuple's level, starting at zero for the root level. `returnData` is `true` if reconstructed data is required for this query; this will only be so if the `config` function asserted `canReturnData`. `leafDatum` is the key value of `spgConfigOut.leafType` stored in the current leaf tuple.

The function must return `true` if the leaf tuple matches the query, or `false` if not. In the `true` case, if `returnData` is `true` then `leafValue` must be set to the value (of type `spgConfigIn.attType`) originally supplied to be indexed for this leaf tuple. Also, `recheck` may be set to `true` if the match is uncertain and so the operator(s) must be re-applied to the actual heap tuple to verify the match. If ordered search is performed, set `distances` to an array of distance values according to `orderbys` array. Leave it `NULL` otherwise. If at least one of returned distances is not exact, set `recheckDistances` to `true`. In this case, the executor will calculate the exact distances after fetching the tuple from the heap, and will reorder the tuples if needed.

The optional user-defined methods are:

`Datum compress(Datum in)`

Converts a data item into a format suitable for physical storage in a leaf tuple of the index. It accepts a value of type `spgConfigIn.attType` and returns a value of type `spgConfigOut.leafType`. The output value must not contain an out-of-line TOAST pointer.

Note: the `compress` method is only applied to values to be stored. The consistent methods receive query scankeys unchanged, without transformation using `compress`.

`options`

Defines a set of user-visible parameters that control operator class behavior.

The SQL declaration of the function must look like this:

```
CREATE OR REPLACE FUNCTION my_options(internal)
RETURNS void
AS 'MODULE_PATHNAME'
LANGUAGE C STRICT;
```

The function is passed a pointer to a `local_relopts` struct, which needs to be filled with a set of operator class specific options. The options can be accessed from other support functions using the `PG_HAS_OPCLASS_OPTIONS()` and `PG_GET_OPCLASS_OPTIONS()` macros.

Since the representation of the key in SP-GiST is flexible, it may depend on user-specified parameters.

All the SP-GiST support methods are normally called in a short-lived memory context; that is, `CurrentMemoryContext` will be reset after processing of each tuple. It is therefore not very important to worry about pfree'ing everything you palloc. (The `config` method is an exception: it should try to avoid leaking memory. But usually the `config` method need do nothing but assign constants into the passed parameter struct.)

If the indexed column is of a collatable data type, the index collation will be passed to all the support methods, using the standard `PG_GET_COLLATION()` mechanism.

65.3.4. Implementation

This section covers implementation details and other tricks that are useful for implementers of SP-GiST operator classes to know.

65.3.4.1. SP-GiST Limits

Individual leaf tuples and inner tuples must fit on a single index page (8kB by default). Therefore, when indexing values of variable-length data types, long values can only be supported by methods such as radix trees, in which each level of the tree includes a prefix that is short enough to fit on a page, and the final leaf level includes a suffix also short enough to fit on a page. The operator class should set `longValuesOK` to `true` only if it is prepared to arrange for this to happen. Otherwise, the SP-GiST core will reject any request to index a value that is too large to fit on an index page.

Likewise, it is the operator class's responsibility that inner tuples do not grow too large to fit on an index page; this limits the number of child nodes that can be used in one inner tuple, as well as the maximum size of a prefix value.

Another limitation is that when an inner tuple's node points to a set of leaf tuples, those tuples must all be in the same index page. (This is a design decision to reduce seeking and save space in the links that chain such tuples together.) If the set of leaf tuples grows too large for a page, a split is performed and an intermediate inner tuple is inserted. For this to fix the problem, the new inner tuple *must* divide the set of leaf values into more than one node group. If the operator class's `picksplit` function fails to do that, the SP-GiST core resorts to extraordinary measures described in [Section 65.3.4.3](#).

When `longValuesOK` is true, it is expected that successive levels of the SP-GiST tree will absorb more and more information into the prefixes and node labels of the inner tuples, making the required leaf datum smaller and smaller, so that eventually it will fit on a page. To prevent bugs in operator classes from causing infinite insertion loops, the SP-GiST core will raise an error if the leaf datum does not become any smaller within ten cycles of `choose` method calls.

65.3.4.2. SP-GiST Without Node Labels

Some tree algorithms use a fixed set of nodes for each inner tuple; for example, in a quad-tree there are always exactly four nodes corresponding to the four quadrants around the inner tuple's centroid point. In such a case the code typically works with the nodes by number, and there is no need for explicit node labels. To suppress node labels (and thereby save some space), the `picksplit` function can return NULL for the `nodeLabels` array, and likewise the `choose` function can return NULL for the `prefixNodeLabels` array during a `spgSplitTuple` action. This will in turn result in `nodeLabels` being NULL during subsequent calls to `choose` and `inner_consistent`. In principle, node labels could be used for some inner tuples and omitted for others in the same index.

When working with an inner tuple having unlabeled nodes, it is an error for `choose` to return `spgAddNode`, since the set of nodes is supposed to be fixed in such cases.

65.3.4.3. “All-the-Same” Inner Tuples

The SP-GiST core can override the results of the operator class's `picksplit` function when `picksplit` fails to divide the supplied leaf values into at least two node categories. When this happens, the new inner tuple is created with multiple nodes that each have the same label (if any) that `picksplit` gave to the one node it did use, and the leaf values are divided at random among these equivalent nodes. The `allTheSame` flag is set on the inner tuple to warn the `choose` and `inner_consistent` functions that the tuple does not have the node set that they might otherwise expect.

When dealing with an `allTheSame` tuple, a `choose` result of `spgMatchNode` is interpreted to mean that the new value can be assigned to any of the equivalent nodes; the core code will ignore the supplied `nodeN` value and descend into one of the nodes at random (so as to keep the tree balanced). It is an error for `choose` to return `spgAddNode`, since that would make the nodes not all equivalent; the `spgSplitTuple` action must be used if the value to be inserted doesn't match the existing nodes.

When dealing with an `allTheSame` tuple, the `inner_consistent` function should return either all or none of the nodes as targets for continuing the index search, since they are all equivalent. This may or may not require any special-case code, depending on how much the `inner_consistent` function normally assumes about the meaning of the nodes.

65.4. GIN Indexes

65.4.1. Introduction

GIN stands for Generalized Inverted Index. GIN is designed for handling cases where the items to be indexed are composite values, and the queries to be handled by the index need to search for element values that appear within the composite items. For example, the items could be documents, and the queries could be searches for documents containing specific words.

We use the word *item* to refer to a composite value that is to be indexed, and the word *key* to refer to an element value. GIN always stores and searches for keys, not item values per se.

A GIN index stores a set of (key, posting list) pairs, where a *posting list* is a set of row IDs in which the key occurs. The same row ID can appear in multiple posting lists, since an item can contain more than one key. Each key value is stored only once, so a GIN index is very compact for cases where the same key appears many times.

GIN is generalized in the sense that the GIN access method code does not need to know the specific operations that it accelerates. Instead, it uses custom strategies defined for particular data types. The strategy defines how keys are extracted from indexed items and query conditions, and how to determine whether a row that contains some of the key values in a query actually satisfies the query.

One advantage of GIN is that it allows the development of custom data types with the appropriate access methods, by an expert in the domain of the data type, rather than a database expert. This is much the same advantage as using GiST.

The GIN implementation in Postgres Pro is primarily maintained by Teodor Sigaev and Oleg Bartunov. There is more information about GIN on their [website](#).

65.4.2. Built-in Operator Classes

The core Postgres Pro distribution includes the GIN operator classes shown in [Table 65.3](#). (Some of the optional modules described in [Appendix F](#) provide additional GIN operator classes.)

Table 65.3. Built-in GIN Operator Classes

Name	Indexable Operators
array_ops	&& (anyarray, anyarray)
	@> (anyarray, anyarray)
	<@ (anyarray, anyarray)
	= (anyarray, anyarray)
jsonb_ops	@> (jsonb, jsonb)
	@? (jsonb, jsonpath)
	@@ (jsonb, jsonpath)
	? (jsonb, text)
	? (jsonb, text[])
	?& (jsonb, text[])
jsonb_path_ops	@> (jsonb, jsonb)
	@? (jsonb, jsonpath)
	@@ (jsonb, jsonpath)
tsvector_ops	@@ (tsvector, tsquery)

Of the two operator classes for type `jsonb`, `jsonb_ops` is the default. `jsonb_path_ops` supports fewer operators but offers better performance for those operators. See [Section 8.14.4](#) for details.

65.4.3. Extensibility

The GIN interface has a high level of abstraction, requiring the access method implementer only to implement the semantics of the data type being accessed. The GIN layer itself takes care of concurrency, logging and searching the tree structure.

All it takes to get a GIN access method working is to implement a few user-defined methods, which define the behavior of keys in the tree and the relationships between keys, indexed items, and indexable queries. In short, GIN combines extensibility with generality, code reuse, and a clean interface.

There are two methods that an operator class for GIN must provide:

`Datum *extractValue(Datum itemValue, int32 *nkeys, bool **nullFlags)`

Returns a palloc'd array of keys given an item to be indexed. The number of returned keys must be stored into `*nkeys`. If any of the keys can be null, also palloc an array of `*nkeys` `bool` fields, store its address at `*nullFlags`, and set these null flags as needed. `*nullFlags` can be left `NULL` (its initial value) if all keys are non-null. The return value can be `NULL` if the item contains no keys.

`Datum *extractQuery(Datum query, int32 *nkeys, StrategyNumber n, bool **pmatch, Pointer **extra_data, bool **nullFlags, int32 *searchMode)`

Returns a palloc'd array of keys given a value to be queried; that is, `query` is the value on the right-hand side of an indexable operator whose left-hand side is the indexed column. `n` is the strategy number of the operator within the operator class (see [Section 39.16.2](#)). Often, `extractQuery` will need to consult `n` to determine the data type of `query` and the method it should use to extract key values. The number of returned keys must be stored into `*nkeys`. If any of the keys can be null, also palloc

an array of `*nkeys` `bool` fields, store its address at `*nullFlags`, and set these null flags as needed. `*nullFlags` can be left `NULL` (its initial value) if all keys are non-null. The return value can be `NULL` if the query contains no keys.

`searchMode` is an output argument that allows `extractQuery` to specify details about how the search will be done. If `*searchMode` is set to `GIN_SEARCH_MODE_DEFAULT` (which is the value it is initialized to before call), only items that match at least one of the returned keys are considered candidate matches. If `*searchMode` is set to `GIN_SEARCH_MODE_INCLUDE_EMPTY`, then in addition to items containing at least one matching key, items that contain no keys at all are considered candidate matches. (This mode is useful for implementing is-subset-of operators, for example.) If `*searchMode` is set to `GIN_SEARCH_MODE_ALL`, then all non-null items in the index are considered candidate matches, whether they match any of the returned keys or not. (This mode is much slower than the other two choices, since it requires scanning essentially the entire index, but it may be necessary to implement corner cases correctly. An operator that needs this mode in most cases is probably not a good candidate for a GIN operator class.) The symbols to use for setting this mode are defined in `access/gin.h`.

`pmatch` is an output argument for use when partial match is supported. To use it, `extractQuery` must allocate an array of `*nkeys` `bool`s and store its address at `*pmatch`. Each element of the array should be set to true if the corresponding key requires partial match, false if not. If `*pmatch` is set to `NULL` then GIN assumes partial match is not required. The variable is initialized to `NULL` before call, so this argument can simply be ignored by operator classes that do not support partial match.

`extra_data` is an output argument that allows `extractQuery` to pass additional data to the `consistent` and `comparePartial` methods. To use it, `extractQuery` must allocate an array of `*nkeys` pointers and store its address at `*extra_data`, then store whatever it wants to into the individual pointers. The variable is initialized to `NULL` before call, so this argument can simply be ignored by operator classes that do not require extra data. If `*extra_data` is set, the whole array is passed to the `consistent` method, and the appropriate element to the `comparePartial` method.

An operator class must also provide a function to check if an indexed item matches the query. It comes in two flavors, a Boolean `consistent` function, and a ternary `triConsistent` function. `triConsistent` covers the functionality of both, so providing `triConsistent` alone is sufficient. However, if the Boolean variant is significantly cheaper to calculate, it can be advantageous to provide both. If only the Boolean variant is provided, some optimizations that depend on refuting index items before fetching all the keys are disabled.

```
bool consistent(bool check[], StrategyNumber n, Datum query, int32 nkeys, Pointer extra_data[], bool *recheck, Datum queryKeys[], bool nullFlags[])
```

Returns true if an indexed item satisfies the query operator with strategy number `n` (or might satisfy it, if the recheck indication is returned). This function does not have direct access to the indexed item's value, since GIN does not store items explicitly. Rather, what is available is knowledge about which key values extracted from the query appear in a given indexed item. The `check` array has length `nkeys`, which is the same as the number of keys previously returned by `extractQuery` for this query datum. Each element of the `check` array is true if the indexed item contains the corresponding query key, i.e., if (`check[i] == true`) the `i`-th key of the `extractQuery` result array is present in the indexed item. The original query datum is passed in case the `consistent` method needs to consult it, and so are the `queryKeys[]` and `nullFlags[]` arrays previously returned by `extractQuery`. `extra_data` is the extra-data array returned by `extractQuery`, or `NULL` if none.

When `extractQuery` returns a null key in `queryKeys[]`, the corresponding `check[]` element is true if the indexed item contains a null key; that is, the semantics of `check[]` are like `IS NOT DISTINCT FROM`. The `consistent` function can examine the corresponding `nullFlags[]` element if it needs to tell the difference between a regular value match and a null match.

On success, `*recheck` should be set to true if the heap tuple needs to be rechecked against the query operator, or false if the index test is exact. That is, a false return value guarantees that the heap tuple does not match the query; a true return value with `*recheck` set to false guarantees that the heap tuple does match the query; and a true return value with `*recheck` set to true means that the heap tuple might match the query, so it needs to be fetched and rechecked by evaluating the query operator directly against the originally indexed item.

```
GinTernaryValue triConsistent(GinTernaryValue check[], StrategyNumber n, Datum query, int32 nkeys, Pointer extra_data[], Datum queryKeys[], bool nullFlags[])
```

`triConsistent` is similar to `consistent`, but instead of Booleans in the `check` vector, there are three possible values for each key: `GIN_TRUE`, `GIN_FALSE` and `GIN_MAYBE`. `GIN_FALSE` and `GIN_TRUE` have the same meaning as regular Boolean values, while `GIN_MAYBE` means that the presence of that key is not known. When `GIN_MAYBE` values are present, the function should only return `GIN_TRUE` if the item certainly matches whether or not the index item contains the corresponding query keys. Likewise, the function must return `GIN_FALSE` only if the item certainly does not match, whether or not it contains

the `GIN_MAYBE` keys. If the result depends on the `GIN_MAYBE` entries, i.e., the match cannot be confirmed or refuted based on the known query keys, the function must return `GIN_MAYBE`.

When there are no `GIN_MAYBE` values in the `check` vector, a `GIN_MAYBE` return value is the equivalent of setting the `recheck` flag in the Boolean `consistent` function.

In addition, GIN must have a way to sort the key values stored in the index. The operator class can define the sort ordering by specifying a comparison method:

```
int compare(Datum a, Datum b)
```

Compares two keys (not indexed items!) and returns an integer less than zero, zero, or greater than zero, indicating whether the first key is less than, equal to, or greater than the second. Null keys are never passed to this function.

Alternatively, if the operator class does not provide a `compare` method, GIN will look up the default btree operator class for the index key data type, and use its comparison function. It is recommended to specify the comparison function in a GIN operator class that is meant for just one data type, as looking up the btree operator class costs a few cycles. However, polymorphic GIN operator classes (such as `array_ops`) typically cannot specify a single comparison function.

An operator class for GIN can optionally supply the following methods:

```
int comparePartial(Datum partial_key, Datum key, StrategyNumber n, Pointer extra_data)
```

Compare a partial-match query key to an index key. Returns an integer whose sign indicates the result: less than zero means the index key does not match the query, but the index scan should continue; zero means that the index key does match the query; greater than zero indicates that the index scan should stop because no more matches are possible. The strategy number `n` of the operator that generated the partial match query is provided, in case its semantics are needed to determine when to end the scan. Also, `extra_data` is the corresponding element of the extra-data array made by `extractQuery`, or `NULL` if none. Null keys are never passed to this function.

```
void options(local_relopts *relopts)
```

Defines a set of user-visible parameters that control operator class behavior.

The `options` function is passed a pointer to a `local_relopts` struct, which needs to be filled with a set of operator class specific options. The options can be accessed from other support functions using the `PG_HAS_OPCLASS_OPTIONS()` and `PG_GET_OPCLASS_OPTIONS()` macros.

Since both key extraction of indexed values and representation of the key in GIN are flexible, they may depend on user-specified parameters.

To support “partial match” queries, an operator class must provide the `comparePartial` method, and its `extractQuery` method must set the `pmatch` parameter when a partial-match query is encountered. See [Section 65.4.4.2](#) for details.

The actual data types of the various `Datum` values mentioned above vary depending on the operator class. The item values passed to `extractValue` are always of the operator class's input type, and all key values must be of the class's `STORAGE` type. The type of the `query` argument passed to `extractQuery`, `consistent` and `triConsistent` is whatever is the right-hand input type of the class member operator identified by the strategy number. This need not be the same as the indexed type, so long as key values of the correct type can be extracted from it. However, it is recommended that the SQL declarations of these three support functions use the opclass's indexed data type for the `query` argument, even though the actual type might be something else depending on the operator.

65.4.4. Implementation

Internally, a GIN index contains a B-tree index constructed over keys, where each key is an element of one or more indexed items (a member of an array, for example) and where each tuple in a leaf page contains either a pointer to a B-tree of heap pointers (a “posting tree”), or a simple list of heap pointers (a “posting list”) when the list is small enough to fit into a single index tuple along with the key value. [Figure 65.1](#) illustrates these components of a GIN index.

As of PostgreSQL 9.1, null key values can be included in the index. Also, placeholder nulls are included in the index for indexed items that are null or contain no keys according to `extractValue`. This allows searches that should find empty items to do so.

Multicolumn GIN indexes are implemented by building a single B-tree over composite values (column number, key value). The key values for different columns can be of different types.

Figure 65.1. GIN Internals

65.4.4.1. GIN Fast Update Technique

Updating a GIN index tends to be slow because of the intrinsic nature of inverted indexes: inserting or updating one heap row can cause many inserts into the index (one for each key extracted from the indexed item). GIN is capable of postponing much of this work by inserting new tuples into a temporary, unsorted list of pending entries. When the table is vacuumed or autoanalyzed, or when `gin_clean_pending_list` function is called, or if the pending list becomes larger than `gin_pending_list_limit`, the entries are moved to the main GIN data structure using the same bulk insert techniques used during initial index creation. This greatly improves GIN index update speed, even counting the additional vacuum overhead. Moreover the overhead work can be done by a background process instead of in foreground query processing.

The main disadvantage of this approach is that searches must scan the list of pending entries in addition to searching the regular index, and so a large list of pending entries will slow searches significantly. Another disadvantage is that, while most updates are fast, an update that causes the pending list to become “too large” will incur an immediate cleanup cycle and thus be much slower than other updates. Proper use of autovacuum can minimize both of these problems.

If consistent response time is more important than update speed, use of pending entries can be disabled by turning off the `fastupdate` storage parameter for a GIN index. See [CREATE INDEX](#) for details.

65.4.4.2. Partial Match Algorithm

GIN can support “partial match” queries, in which the query does not determine an exact match for one or more keys, but the possible matches fall within a reasonably narrow range of key values (within the key sorting order determined by the `compare` support method). The `extractQuery` method, instead of returning a key value to be matched exactly, returns a key value that is the lower bound of the range to be searched, and sets the `pmatch` flag true. The key range is then scanned using the `comparePartial` method. `comparePartial` must return zero for a matching index key, less than zero for a non-match that is still within the range to be searched, or greater than zero if the index key is past the range that could match.

65.4.5. GIN Tips and Tricks

Create vs. insert

Insertion into a GIN index can be slow due to the likelihood of many keys being inserted for each item. So, for bulk insertions into a table it is advisable to drop the GIN index and recreate it after finishing bulk insertion.

When `fastupdate` is enabled for GIN (see [Section 65.4.4.1](#) for details), the penalty is less than when it is not. But for very large updates it may still be best to drop and recreate the index.

`maintenance_work_mem`

Build time for a GIN index is very sensitive to the `maintenance_work_mem` setting; it doesn't pay to skimp on work memory during index creation.

`gin_pending_list_limit`

During a series of insertions into an existing GIN index that has `fastupdate` enabled, the system will clean up the pending-entry list whenever the list grows larger than `gin_pending_list_limit`. To avoid fluctuations in observed response time, it's desirable to have pending-list cleanup occur in the background (i.e., via autovacuum). Foreground cleanup operations can be avoided by increasing `gin_pending_list_limit` or making autovacuum more aggressive. However, enlarging the threshold of the cleanup operation means that if a foreground cleanup does occur, it will take even longer.

`gin_pending_list_limit` can be overridden for individual GIN indexes by changing storage parameters, which allows each GIN index to have its own cleanup threshold. For example, it's possible to increase the threshold only for the GIN index which can be updated heavily, and decrease it otherwise.

`gin_fuzzy_search_limit`

The primary goal of developing GIN indexes was to create support for highly scalable full-text search in Postgres Pro, and there are often situations when a full-text search returns a very large set of results. Moreover, this often happens when the query contains very frequent words, so that the large result set is not even useful. Since reading many tuples from the disk and sorting them could take a lot of time, this is unacceptable for production. (Note that the index search itself is very fast.)

To facilitate controlled execution of such queries, GIN has a configurable soft upper limit on the number of rows returned: the `gin_fuzzy_search_limit` configuration parameter. It is set to 0 (meaning no limit) by default. If a non-zero limit is set, then the returned set is a subset of the whole result set, chosen at random.

“Soft” means that the actual number of returned results could differ somewhat from the specified limit, depending on the query and the quality of the system's random number generator.

From experience, values in the thousands (e.g., 5000 — 20000) work well.

65.4.6. Limitations

GIN assumes that indexable operators are strict. This means that `extractValue` will not be called at all on a null item value (instead, a placeholder index entry is created automatically), and `extractQuery` will not be called on a null query value either (instead, the query is presumed to be unsatisfiable). Note however that null key values contained within a non-null composite item or query value are supported.

65.4.7. Examples

The core Postgres Pro distribution includes the GIN operator classes previously shown in [Table 65.3](#). The following `contrib` modules also contain GIN operator classes:

`btree_gin`

B-tree equivalent functionality for several data types

`hstore`

Module for storing (key, value) pairs

`intarray`

Enhanced support for `int[]`

`pg_trgm`

Text similarity using trigram matching

65.5. BRIN Indexes

65.5.1. Introduction

BRIN stands for Block Range Index. BRIN is designed for handling very large tables in which certain columns have some natural correlation with their physical location within the table.

BRIN works in terms of *block ranges* (or “page ranges”). A block range is a group of pages that are physically adjacent in the table; for each block range, some summary info is stored by the index. For example, a table storing a store's sale orders might have a date column on which each order was placed, and most of the time the entries for earlier orders will appear earlier in the table as well; a table storing a ZIP code column might have all codes for a city grouped together naturally.

BRIN indexes can satisfy queries via regular bitmap index scans, and will return all tuples in all pages within each range if the summary info stored by the index is *consistent* with the query conditions. The query executor is in charge of rechecking these tuples and discarding those that do not match the query conditions — in other words, these indexes are lossy. Because a BRIN index is very small, scanning the index adds little overhead compared to a sequential scan, but may avoid scanning large parts of the table that are known not to contain matching tuples.

The specific data that a BRIN index will store, as well as the specific queries that the index will be able to satisfy, depend on the operator class selected for each column of the index. Data types having a linear sort order can have operator classes that store the minimum and maximum value within each block range, for instance; geometrical types might store the bounding box for all the objects in the block range.

The size of the block range is determined at index creation time by the `pages_per_range` storage parameter. The number of index entries will be equal to the size of the relation in pages divided by the selected value for `pages_per_range`. Therefore, the smaller the number, the larger the index becomes (because of the need to store more index entries), but at the same time the summary data stored can be more precise and more data blocks can be skipped during an index scan.

65.5.1.1. Index Maintenance

At the time of creation, all existing heap pages are scanned and a summary index tuple is created for each range, including the possibly-incomplete range at the end. As new pages are filled with data, page ranges that are already summarized will cause the summary information to be updated with data from the new tuples. When a new page is created that does not fall within the last summarized range, the range that the new page belongs to does not automatically acquire a summary tuple; those tuples remain unsummarized until a summarization run is invoked later, creating the initial summary for that range.

There are several ways to trigger the initial summarization of a page range. If the table is vacuumed, either manually or by [autovacuum](#), all existing unsummarized page ranges are summarized. Also, if the index's `autosummarize` parameter is enabled, which it isn't by default, whenever autovacuum runs in that database, summarization will occur for all unsummarized page ranges that have been filled, regardless of whether the table itself is processed by autovacuum; see below.

Lastly, the following functions can be used (while these functions run, `search_path` is temporarily changed to `pg_catalog`, `pg_temp`):

`brin_summarize_new_values(regclass)` which summarizes all unsummarized ranges;
`brin_summarize_range(regclass, bigint)` which summarizes only the range containing the given page, if it is unsummarized.

When autosummarization is enabled, a request is sent to `autovacuum` to execute a targeted summarization for a block range when an insertion is detected for the first item of the first page of the next block range, to be fulfilled the next time an autovacuum worker finishes running in the same database. If the request queue is full, the request is not recorded and a message is sent to the server log:

```
LOG:  request for BRIN range summarization for index "brin_wi_idx" page 128 was not
recorded
```

When this happens, the range will remain unsummarized until the next regular vacuum run on the table, or one of the functions mentioned above are invoked.

Conversely, a range can be de-summarized using the `brin_desummarize_range(regclass, bigint)` function, which is useful when the index tuple is no longer a very good representation because the existing values have changed. See [Section 9.28.8](#) for details.

65.5.2. Built-in Operator Classes

The core Postgres Pro distribution includes the BRIN operator classes shown in [Table 65.4](#).

The *minmax* operator classes store the minimum and the maximum values appearing in the indexed column within the range. The *inclusion* operator classes store a value which includes the values in the indexed column within the range. The *bloom* operator classes

build a Bloom filter for all values in the range. The *minmax-multi* operator classes store multiple minimum and maximum values, representing values appearing in the indexed column within the range.

65.5.2.1. Operator Class Parameters

Some of the built-in operator classes allow specifying parameters affecting behavior of the operator class. Each operator class has its own set of allowed parameters. Only the `bloom` and `minmax-multi` operator classes allow specifying parameters:

`bloom` operator classes accept these parameters:

`n_distinct_per_range`

Defines the estimated number of distinct non-null values in the block range, used by BRIN bloom indexes for sizing of the Bloom filter. It behaves similarly to `n_distinct` option for [ALTER TABLE](#). When set to a positive value, each block range is assumed to contain this number of distinct non-null values. When set to a negative value, which must be greater than or equal to -1, the number of distinct non-null values is assumed to grow linearly with the maximum possible number of tuples in the block range (about 290 rows per block). The default value is `-0.1`, and the minimum number of distinct non-null values is 16.

`false_positive_rate`

Defines the desired false positive rate used by BRIN bloom indexes for sizing of the Bloom filter. The values must be between 0.0001 and 0.25. The default value is 0.01, which is 1% false positive rate.

`minmax-multi` operator classes accept these parameters:

`values_per_range`

Defines the maximum number of values stored by BRIN minmax indexes to summarize a block range. Each value may represent either a point, or a boundary of an interval. Values must be between 8 and 256, and the default value is 32.

65.5.3. Extensibility

The BRIN interface has a high level of abstraction, requiring the access method implementer only to implement the semantics of the data type being accessed. The BRIN layer itself takes care of concurrency, logging and searching the index structure.

All it takes to get a BRIN access method working is to implement a few user-defined methods, which define the behavior of summary values stored in the index and the way they interact with scan keys. In short, BRIN combines extensibility with generality, code reuse, and a clean interface.

There are four methods that an operator class for BRIN must provide:

`BrinOpcInfo *opcInfo(Oid type_oid)`

Returns internal information about the indexed columns' summary data. The return value must point to a palloc'd `BrinOpcInfo`, which has this definition:

```
typedef struct BrinOpcInfo
{
    /* Number of columns stored in an index column of this opclass */
    uint16      oi_nstored;

    /* Opaque pointer for the opclass' private use */
    void        *oi_opaque;

    /* Type cache entries of the stored columns */
    TypeCacheEntry *oi_tpcache[FLEXIBLE_ARRAY_MEMBER];
} BrinOpcInfo;
```

`BrinOpcInfo.oi_opaque` can be used by the operator class routines to pass information between support functions during an index scan.

`bool consistent(BrinDesc *bdesc, BrinValues *column, ScanKey *keys, int nkeys)`

Returns whether all the `ScanKey` entries are consistent with the given indexed values for a range. The attribute number to use is passed as part of the scan key. Multiple scan keys for the same attribute may be passed at once; the number of entries is determined by the `nkeys` parameter.

```
bool consistent(BrinDesc *bdesc, BrinValues *column, ScanKey key)
```

Returns whether the ScanKey is consistent with the given indexed values for a range. The attribute number to use is passed as part of the scan key. This is an older backward-compatible variant of the consistent function.

```
bool addValue(BrinDesc *bdesc, BrinValues *column, Datum newval, bool isnull)
```

Given an index tuple and an indexed value, modifies the indicated attribute of the tuple so that it additionally represents the new value. If any modification was done to the tuple, `true` is returned.

```
bool unionTuples(BrinDesc *bdesc, BrinValues *a, BrinValues *b)
```

Consolidates two index tuples. Given two index tuples, modifies the indicated attribute of the first of them so that it represents both tuples. The second tuple is not modified.

An operator class for BRIN can optionally specify the following method:

```
void options(local_relopts *relopts)
```

Defines a set of user-visible parameters that control operator class behavior.

The `options` function is passed a pointer to a `local_relopts` struct, which needs to be filled with a set of operator class specific options. The options can be accessed from other support functions using the `PG_HAS_OPCLASS_OPTIONS()` and `PG_GET_OPCLASS_OPTIONS()` macros.

Since both key extraction of indexed values and representation of the key in BRIN are flexible, they may depend on user-specified parameters.

The core distribution includes support for four types of operator classes: minmax, minmax-multi, inclusion and bloom. Operator class definitions using them are shipped for in-core data types as appropriate. Additional operator classes can be defined by the user for other data types using equivalent definitions, without having to write any source code; appropriate catalog entries being declared is enough. Note that assumptions about the semantics of operator strategies are embedded in the support functions' source code.

Operator classes that implement completely different semantics are also possible, provided implementations of the four main support functions described above are written. Note that backwards compatibility across major releases is not guaranteed: for example, additional support functions might be required in later releases.

To write an operator class for a data type that implements a totally ordered set, it is possible to use the minmax support functions alongside the corresponding operators, as shown in [Table 65.5](#). All operator class members (functions and operators) are mandatory.

Table 65.5. Function and Support Numbers for Minmax Operator Classes

Operator class member	Object
Support Function 1	internal function <code>brin_minmax_opcinfo()</code>
Support Function 2	internal function <code>brin_minmax_add_value()</code>
Support Function 3	internal function <code>brin_minmax_consistent()</code>
Support Function 4	internal function <code>brin_minmax_union()</code>
Operator Strategy 1	operator less-than
Operator Strategy 2	operator less-than-or-equal-to
Operator Strategy 3	operator equal-to
Operator Strategy 4	operator greater-than-or-equal-to
Operator Strategy 5	operator greater-than

To write an operator class for a complex data type which has values included within another type, it's possible to use the inclusion support functions alongside the corresponding operators, as shown in [Table 65.6](#). It requires only a single additional function, which can be written in any language. More functions can be defined for additional functionality. All operators are optional. Some operators require other operators, as shown as dependencies on the table.

Table 65.6. Function and Support Numbers for Inclusion Operator Classes

Operator class member	Object	Dependency
Support Function 1	internal function <code>brin_inclusion_opcinfo()</code>	
Support Function 2	internal function <code>brin_inclusion_add_value()</code>	
Support Function 3	internal function <code>brin_inclusion_consistent()</code>	
Support Function 4	internal function <code>brin_inclusion_union()</code>	
Support Function 11	function to merge two elements	
Support Function 12	optional function to check whether two elements are mergeable	
Support Function 13	optional function to check if an element is contained within another	
Support Function 14	optional function to check whether an element is empty	
Operator Strategy 1	operator left-of	Operator Strategy 4
Operator Strategy 2	operator does-not-extend-to-the-right-of	Operator Strategy 5
Operator Strategy 3	operator overlaps	
Operator Strategy 4	operator does-not-extend-to-the-left-of	Operator Strategy 1
Operator Strategy 5	operator right-of	Operator Strategy 2
Operator Strategy 6, 18	operator same-as-or-equal-to	Operator Strategy 7
Operator Strategy 7, 16, 24, 25	operator contains-or-equal-to	
Operator Strategy 8, 26, 27	operator is-contained-by-or-equal-to	Operator Strategy 3
Operator Strategy 9	operator does-not-extend-above	Operator Strategy 11
Operator Strategy 10	operator is-below	Operator Strategy 12
Operator Strategy 11	operator is-above	Operator Strategy 9
Operator Strategy 12	operator does-not-extend-below	Operator Strategy 10
Operator Strategy 20	operator less-than	Operator Strategy 5
Operator Strategy 21	operator less-than-or-equal-to	Operator Strategy 5
Operator Strategy 22	operator greater-than	Operator Strategy 1
Operator Strategy 23	operator greater-than-or-equal-to	Operator Strategy 1

Support function numbers 1 through 10 are reserved for the BRIN internal functions, so the SQL level functions start with number 11. Support function number 11 is the main function required to build the index. It should accept two arguments with the same data type as the operator class, and return the union of them. The inclusion operator class can store union values with different data types if it is defined with the `STORAGE` parameter. The return value of the union function should match the `STORAGE` data type.

Support function numbers 12 and 14 are provided to support irregularities of built-in data types. Function number 12 is used to support network addresses from different families which are not mergeable. Function number 14 is used to support empty ranges. Function number 13 is an optional but recommended one, which allows the new value to be checked before it is passed to the union function. As the BRIN framework can shortcut some operations when the union is not changed, using this function can improve index performance.

To write an operator class for a data type that implements only an equality operator and supports hashing, it is possible to use the bloom support procedures alongside the corresponding operators, as shown in [Table 65.7](#). All operator class members (procedures and operators) are mandatory.

Table 65.7. Procedure and Support Numbers for Bloom Operator Classes

Operator class member	Object
Support Procedure 1	internal function <code>brin_bloom_opcinfo()</code>
Support Procedure 2	internal function <code>brin_bloom_add_value()</code>

Operator class member	Object
Support Procedure 3	internal function <code>brin_bloom_consistent()</code>
Support Procedure 4	internal function <code>brin_bloom_union()</code>
Support Procedure 5	internal function <code>brin_bloom_options()</code>
Support Procedure 11	function to compute hash of an element
Operator Strategy 1	operator equal-to

Support procedure numbers 1-10 are reserved for the BRIN internal functions, so the SQL level functions start with number 11. Support function number 11 is the main function required to build the index. It should accept one argument with the same data type as the operator class, and return a hash of the value.

The minmax-multi operator class is also intended for data types implementing a totally ordered set, and may be seen as a simple extension of the minmax operator class. While minmax operator class summarizes values from each block range into a single contiguous interval, minmax-multi allows summarization into multiple smaller intervals to improve handling of outlier values. It is possible to use the minmax-multi support procedures alongside the corresponding operators, as shown in [Table 65.8](#). All operator class members (procedures and operators) are mandatory.

Table 65.8. Procedure and Support Numbers for minmax-multi Operator Classes

Operator class member	Object
Support Procedure 1	internal function <code>brin_minmax_multi_opcinfo()</code>
Support Procedure 2	internal function <code>brin_minmax_multi_add_value()</code>
Support Procedure 3	internal function <code>brin_minmax_multi_consistent()</code>
Support Procedure 4	internal function <code>brin_minmax_multi_union()</code>
Support Procedure 5	internal function <code>brin_minmax_multi_options()</code>
Support Procedure 11	function to compute distance between two values (length of a range)
Operator Strategy 1	operator less-than
Operator Strategy 2	operator less-than-or-equal-to
Operator Strategy 3	operator equal-to
Operator Strategy 4	operator greater-than-or-equal-to
Operator Strategy 5	operator greater-than

Both minmax and inclusion operator classes support cross-data-type operators, though with these the dependencies become more complicated. The minmax operator class requires a full set of operators to be defined with both arguments having the same data type. It allows additional data types to be supported by defining extra sets of operators. Inclusion operator class operator strategies are dependent on another operator strategy as shown in [Table 65.6](#), or the same operator strategy as themselves. They require the dependency operator to be defined with the `STORAGE` data type as the left-hand-side argument and the other supported data type to be the right-hand-side argument of the supported operator. See `float4_minmax_ops` as an example of minmax, and `box_inclusion_ops` as an example of inclusion.

65.6. Hash Indexes

65.6.1. Overview

Postgres Pro includes an implementation of persistent on-disk hash indexes, which are fully crash recoverable. Any data type can be indexed by a hash index, including data types that do not have a well-defined linear ordering. Hash indexes store only the hash value of the data being indexed, thus there are no restrictions on the size of the data column being indexed.

Hash indexes support only single-column indexes and do not allow uniqueness checking.

Hash indexes support only the `=` operator, so `WHERE` clauses that specify range operations will not be able to take advantage of hash indexes.

Each hash index tuple stores just the 4-byte hash value, not the actual column value. As a result, hash indexes may be much smaller than B-trees when indexing longer data items such as UUIDs, URLs, etc. The absence of the column value also makes all hash index scans lossy. Hash indexes may take part in bitmap index scans and backward scans.

Hash indexes are best optimized for SELECT and UPDATE-heavy workloads that use equality scans on larger tables. In a B-tree index, searches must descend through the tree until the leaf page is found. In tables with millions of rows, this descent can increase access time to data. The equivalent of a leaf page in a hash index is referred to as a bucket page. In contrast, a hash index allows accessing the bucket pages directly, thereby potentially reducing index access time in larger tables. This reduction in "logical I/O" becomes even more pronounced on indexes/data larger than shared_buffers/RAM.

Hash indexes have been designed to cope with uneven distributions of hash values. Direct access to the bucket pages works well if the hash values are evenly distributed. When inserts mean that the bucket page becomes full, additional overflow pages are chained to that specific bucket page, locally expanding the storage for index tuples that match that hash value. When scanning a hash bucket during queries, we need to scan through all of the overflow pages. Thus an unbalanced hash index might actually be worse than a B-tree in terms of number of block accesses required, for some data.

As a result of the overflow cases, we can say that hash indexes are most suitable for unique, nearly unique data or data with a low number of rows per hash bucket. One possible way to avoid problems is to exclude highly non-unique values from the index using a partial index condition, but this may not be suitable in many cases.

Like B-Trees, hash indexes perform simple index tuple deletion. This is a deferred maintenance operation that deletes index tuples that are known to be safe to delete (those whose item identifier's LP_DEAD bit is already set). If an insert finds no space is available on a page we try to avoid creating a new overflow page by attempting to remove dead index tuples. Removal cannot occur if the page is pinned at that time. Deletion of dead index pointers also occurs during VACUUM.

If it can, VACUUM will also try to squeeze the index tuples onto as few overflow pages as possible, minimizing the overflow chain. If an overflow page becomes empty, overflow pages can be recycled for reuse in other buckets, though we never return them to the operating system. There is currently no provision to shrink a hash index, other than by rebuilding it with REINDEX. There is no provision for reducing the number of buckets, either.

Hash indexes may expand the number of bucket pages as the number of rows indexed grows. The hash key-to-bucket-number mapping is chosen so that the index can be incrementally expanded. When a new bucket is to be added to the index, exactly one existing bucket will need to be "split", with some of its tuples being transferred to the new bucket according to the updated key-to-bucket-number mapping.

The expansion occurs in the foreground, which could increase execution time for user inserts. Thus, hash indexes may not be suitable for tables with rapidly increasing number of rows.

65.6.2. Implementation

There are four kinds of pages in a hash index: the meta page (page zero), which contains statically allocated control information; primary bucket pages; overflow pages; and bitmap pages, which keep track of overflow pages that have been freed and are available for re-use. For addressing purposes, bitmap pages are regarded as a subset of the overflow pages.

Both scanning the index and inserting tuples require locating the bucket where a given tuple ought to be located. To do this, we need the bucket count, highmask, and lowmask from the metapage; however, it's undesirable for performance reasons to have to have to lock and pin the metapage for every such operation. Instead, we retain a cached copy of the metapage in each backend's relcache entry. This will produce the correct bucket mapping as long as the target bucket hasn't been split since the last cache refresh.

Primary bucket pages and overflow pages are allocated independently since any given index might need more or fewer overflow pages relative to its number of buckets. The hash code uses an interesting set of addressing rules to support a variable number of overflow pages while not having to move primary bucket pages around after they are created.

Each row in the table indexed is represented by a single index tuple in the hash index. Hash index tuples are stored in bucket pages, and if they exist, overflow pages. We speed up searches by keeping the index entries in any one index page sorted by hash code, thus allowing binary search to be used within an index page. Note however that there is **no** assumption about the relative ordering of hash codes across different index pages of a bucket.

The bucket splitting algorithms to expand the hash index are too complex to be worthy of mention here. The split algorithm is crash safe and can be restarted if not completed successfully.

Chapter 66. Database Physical Storage

This chapter provides an overview of the physical storage format used by Postgres Pro databases.

66.1. Database File Layout

This section describes the storage format at the level of files and directories.

Traditionally, the configuration and data files used by a database cluster are stored together within the cluster's data directory, commonly referred to as PGDATA (after the name of the environment variable that can be used to define it). A common location for PGDATA is `/var/lib/pgpro/ent-17/data`. Multiple clusters, managed by different server instances, can exist on the same machine.

The PGDATA directory contains several subdirectories and control files, as shown in [Table 66.1](#). In addition to these required items, the cluster configuration files `postgresql.conf`, `pg_hba.conf`, and `pg_ident.conf` are traditionally stored in PGDATA, although it is possible to place them elsewhere.

Table 66.1. Contents of PGDATA

Item	Description
PG_VERSION	A file containing the major version number of Postgres Pro
base	Subdirectory containing per-database subdirectories
current_logfiles	File recording the log file(s) currently written to by the logging collector
global	Subdirectory containing cluster-wide tables, such as <code>pg_database</code>
pg_commit_ts	Subdirectory containing transaction commit timestamp data
pg_dynshmem	Subdirectory containing files used by the dynamic shared memory subsystem
pg_logical	Subdirectory containing status data for logical decoding
pg_multixact	Subdirectory containing multitransaction status data (used for shared row locks)
pg_notify	Subdirectory containing LISTEN/NOTIFY status data
pg_replslot	Subdirectory containing replication slot data
pg_serial	Subdirectory containing information about committed serializable transactions
pg_snapshots	Subdirectory containing exported snapshots
pg_stat	Subdirectory containing permanent files for the statistics subsystem
pg_stat_tmp	Subdirectory containing temporary files for the statistics subsystem
pg_subtrans	Subdirectory containing subtransaction status data
pg_tblspc	Subdirectory containing symbolic links to tablespaces
pg_twophase	Subdirectory containing state files for prepared transactions
pg_wal	Subdirectory containing WAL (Write Ahead Log) files
pg_xact	Subdirectory containing transaction commit status data
postgresql.auto.conf	A file used for storing configuration parameters that are set by <code>ALTER SYSTEM</code>
postmaster.opts	A file recording the command-line options the server was last started with

Item	Description
<code>postmaster.pid</code>	A lock file recording the current postmaster process ID (PID), cluster data directory path, postmaster start timestamp, port number, Unix-domain socket directory path (could be empty), first valid <code>listen_address</code> (IP address or <code>*</code> , or empty if not listening on TCP), and shared memory segment ID (this file is not present after server shutdown)

For each database in the cluster there is a subdirectory within `PGDATA/base`, named after the database's OID in `pg_database`. This subdirectory is the default location for the database's files; in particular, its system catalogs are stored there.

Note that the following sections describe the behavior of the builtin [heap table access method](#), and the builtin [index access methods](#). Due to the extensible nature of Postgres Pro, other access methods might work differently.

Each table and index is stored in a separate file. For ordinary relations, these files are named after the table or index's *filenode* number, which can be found in `pg_class.relfilenode`. But for temporary relations, the file name is of the form `tBBB_FFF`, where *BBB* is the process number of the backend which created the file, and *FFF* is the filenode number. In either case, in addition to the main file (a/k/a main fork), each table and index has a *free space map* (see [Section 66.3](#)), which stores information about free space available in the relation. The free space map is stored in a file named with the filenode number plus the suffix `_fsm`. Tables also have a *visibility map*, stored in a fork with the suffix `_vm`, to track which pages are known to have no dead tuples. The visibility map is described further in [Section 66.4](#). Unlogged tables and indexes have a third fork, known as the initialization fork, which is stored in a fork with the suffix `_init` (see [Section 66.5](#)).

Caution

Note that while a table's filenode often matches its OID, this is *not* necessarily the case; some operations, like `TRUNCATE`, `REINDEX`, `CLUSTER` and some forms of `ALTER TABLE`, can change the filenode while preserving the OID. Avoid assuming that filenode and table OID are the same. Also, for certain system catalogs including `pg_class` itself, `pg_class.relfilenode` contains zero. The actual filenode number of these catalogs is stored in a lower-level data structure, and can be obtained using the `pg_relation_filenode()` function.

When a table or index exceeds 1 GB, it is divided into gigabyte-sized *segments*. The first segment's file name is the same as the filenode; subsequent segments are named `filenode.1`, `filenode.2`, etc. This arrangement avoids problems on platforms that have file size limitations. (Actually, 1 GB is just the default segment size. The segment size can be adjusted using the configuration option `-with-segsize` when building Postgres Pro.) In principle, free space map and visibility map forks could require multiple segments as well, though this is unlikely to happen in practice.

A table that has columns with potentially large entries will have an associated *TOAST* table, which is used for out-of-line storage of field values that are too large to keep in the table rows proper. `pg_class.reltoastrelid` links from a table to its TOAST table, if any. See [Section 66.2](#) for more information.

The contents of tables and indexes are discussed further in [Section 66.6](#).

Tablespaces make the scenario more complicated. Each user-defined tablespace has a symbolic link inside the `PGDATA/pg_tblspc` directory, which points to the physical tablespace directory (i.e., the location specified in the tablespace's `CREATE TABLESPACE` command). This symbolic link is named after the tablespace's OID. Inside the physical tablespace directory there is a subdirectory with a name that depends on the Postgres Pro server version, such as `PG_9.0_201008051`. (The reason for using this subdirectory is so that successive versions of the database can use the same `CREATE TABLESPACE` location value without conflicts.) Within the version-specific subdirectory, there is a subdirectory for each database that has elements in the tablespace, named after the database's OID. Tables and indexes are stored within that directory, using the filenode naming scheme. The `pg_default` tablespace is not accessed through `pg_tblspc`, but corresponds to `PGDATA/base`. Similarly, the `pg_global` tablespace is not accessed through `pg_tblspc`, but corresponds to `PGDATA/global`.

The `pg_relation_filepath()` function shows the entire path (relative to `PGDATA`) of any relation. It is often useful as a substitute for remembering many of the above rules. But keep in mind that this function just gives the name of the first segment of the main fork of the relation — you may need to append a segment number and/or `_fsm`, `_vm`, or `_init` to find all the files associated with the relation.

Temporary files (for operations such as sorting more data than can fit in memory) are created within `PGDATA/base/pgsql_tmp`, or within a `pgsql_tmp` subdirectory of a tablespace directory if a tablespace other than `pg_default` is specified for them. The name of a temporary file has the form `pgsql_tmpPPP.NNN`, where *PPP* is the PID of the owning backend and *NNN* distinguishes different temporary files of that backend.

66.2. TOAST

This section provides an overview of TOAST (The Oversized-Attribute Storage Technique).

Postgres Pro uses a fixed page size (commonly 8 kB), and does not allow tuples to span multiple pages. Therefore, it is not possible to store very large field values directly. To overcome this limitation, large field values are compressed and/or broken up into multiple physical rows. This happens transparently to the user, with only small impact on most of the backend code. The technique is affectionately known as TOAST (or “the best thing since sliced bread”). The TOAST infrastructure is also used to improve handling of large data values in-memory.

Only certain data types support TOAST — there is no need to impose the overhead on data types that cannot produce large field values. To support TOAST, a data type must have a variable-length (*varlena*) representation, in which, ordinarily, the first four-byte word of any stored value contains the total length of the value in bytes (including itself). TOAST does not constrain the rest of the data type's representation. The special representations collectively called *TOASTed values* work by modifying or reinterpreting this initial length word. Therefore, the C-level functions supporting a TOAST-able data type must be careful about how they handle potentially TOASTed input values: an input might not actually consist of a four-byte length word and contents until after it's been *detoasted*. (This is normally done by invoking `PG_DETOAST_DATUM` before doing anything with an input value, but in some cases more efficient approaches are possible. See [Section 39.13.1](#) for more detail.)

TOAST usurps two bits of the varlena length word (the high-order bits on big-endian machines, the low-order bits on little-endian machines), thereby limiting the logical size of any value of a TOAST-able data type to 1 GB (2^{30} - 1 bytes). When both bits are zero, the value is an ordinary un-TOASTed value of the data type, and the remaining bits of the length word give the total datum size (including length word) in bytes. When the highest-order or lowest-order bit is set, the value has only a single-byte header instead of the normal four-byte header, and the remaining bits of that byte give the total datum size (including length byte) in bytes. This alternative supports space-efficient storage of values shorter than 127 bytes, while still allowing the data type to grow to 1 GB at need. Values with single-byte headers aren't aligned on any particular boundary, whereas values with four-byte headers are aligned on at least a four-byte boundary; this omission of alignment padding provides additional space savings that is significant compared to short values. As a special case, if the remaining bits of a single-byte header are all zero (which would be impossible for a self-inclusive length), the value is a pointer to out-of-line data, with several possible alternatives as described below. The type and size of such a *TOAST pointer* are determined by a code stored in the second byte of the datum. Lastly, when the highest-order or lowest-order bit is clear but the adjacent bit is set, the content of the datum has been compressed and must be decompressed before use. In this case the remaining bits of the four-byte length word give the total size of the compressed datum, not the original data. Note that compression is also possible for out-of-line data but the varlena header does not tell whether it has occurred — the content of the TOAST pointer tells that, instead.

The compression technique used for either in-line or out-of-line compressed data can be selected for each column by setting the `COMPRESSION` column option in `CREATE TABLE` or `ALTER TABLE`. The default for columns with no explicit setting is to consult the `default_toast_compression` parameter at the time data is inserted.

As mentioned, there are multiple types of TOAST pointer datums. The oldest and most common type is a pointer to out-of-line data stored in a *TOAST table* that is separate from, but associated with, the table containing the TOAST pointer datum itself. These *on-disk* pointer datums are created by the TOAST management code when a tuple to be stored on disk is too large to be stored as-is. Further details appear in [Section 66.2.1](#). Alternatively, a TOAST pointer datum can contain a pointer to out-of-line data that appears elsewhere in memory. Such datums are necessarily short-lived, and will never appear on-disk, but they are very useful for avoiding copying and redundant processing of large data values. Further details appear in [Section 66.2.2](#).

66.2.1. Out-of-Line, On-Disk TOAST Storage

If any of the columns of a table are TOAST-able, the table will have an associated TOAST table, whose OID is stored in the table's `pg_class.reltoastrelid` entry. On-disk TOASTed values are kept in the TOAST table, as described in more detail below.

Out-of-line values are divided (after compression if used) into chunks of at most `TOAST_MAX_CHUNK_SIZE` bytes (by default this value is chosen so that four chunk rows will fit on a page, making it about 2000 bytes). Each chunk is stored as a separate row in the TOAST table belonging to the owning table. Every TOAST table has the columns `chunk_id` (an OID identifying the particular TOASTed value), `chunk_seq` (a sequence number for the chunk within its value), and `chunk_data` (the actual data of the chunk).

A unique index on `chunk_id` and `chunk_seq` provides fast retrieval of the values. A pointer datum representing an out-of-line on-disk TOASTed value therefore needs to store the OID of the TOAST table in which to look and the OID of the specific value (its `chunk_id`). For convenience, pointer datums also store the logical datum size (original uncompressed data length), physical stored size (different if compression was applied), and the compression method used, if any. Allowing for the varlena header bytes, the total size of an on-disk TOAST pointer datum is therefore 18 bytes regardless of the actual size of the represented value.

The TOAST management code is triggered only when a row value to be stored in a table is wider than `TOAST_TUPLE_THRESHOLD` bytes (normally 2 kB). The TOAST code will compress and/or move field values out-of-line until the row value is shorter than `TOAST_TUPLE_TARGET` bytes (also normally 2 kB, adjustable) or no more gains can be had. During an UPDATE operation, values of unchanged fields are normally preserved as-is; so an UPDATE of a row with out-of-line values incurs no TOAST costs if none of the out-of-line values change.

The TOAST management code recognizes four different strategies for storing TOAST-able columns on disk:

- **PLAIN** prevents either compression or out-of-line storage. This is the only possible strategy for columns of non-TOAST-able data types.
- **EXTENDED** allows both compression and out-of-line storage. This is the default for most TOAST-able data types. Compression will be attempted first, then out-of-line storage if the row is still too big.
- **EXTERNAL** allows out-of-line storage but not compression. Use of **EXTERNAL** will make substring operations on wide `text` and `bytea` columns faster (at the penalty of increased storage space) because these operations are optimized to fetch only the required parts of the out-of-line value when it is not compressed.
- **MAIN** allows compression but not out-of-line storage. (Actually, out-of-line storage will still be performed for such columns, but only as a last resort when there is no other way to make the row small enough to fit on a page.)

Each TOAST-able data type specifies a default strategy for columns of that data type, but the strategy for a given table column can be altered with `ALTER TABLE ... SET STORAGE`.

`TOAST_TUPLE_TARGET` can be adjusted for each table using `ALTER TABLE ... SET (toast_tuple_target = N)`

This scheme has a number of advantages compared to a more straightforward approach such as allowing row values to span pages. Assuming that queries are usually qualified by comparisons against relatively small key values, most of the work of the executor will be done using the main row entry. The big values of TOASTed attributes will only be pulled out (if selected at all) at the time the result set is sent to the client. Thus, the main table is much smaller and more of its rows fit in the shared buffer cache than would be the case without any out-of-line storage. Sort sets shrink also, and sorts will more often be done entirely in memory. A little test showed that a table containing typical HTML pages and their URLs was stored in about half of the raw data size including the TOAST table, and that the main table contained only about 10% of the entire data (the URLs and some small HTML pages). There was no run time difference compared to an un-TOASTed comparison table, in which all the HTML pages were cut down to 7 kB to fit.

66.2.2. Out-of-Line, In-Memory TOAST Storage

TOAST pointers can point to data that is not on disk, but is elsewhere in the memory of the current server process. Such pointers obviously cannot be long-lived, but they are nonetheless useful. There are currently two sub-cases: pointers to *indirect* data and pointers to *expanded* data.

Indirect TOAST pointers simply point at a non-indirect varlena value stored somewhere in memory. This case was originally created merely as a proof of concept, but it is currently used during logical decoding to avoid possibly having to create physical tuples exceeding 1 GB (as pulling all out-of-line field values into the tuple might do). The case is of limited use since the creator of the pointer datum is entirely responsible that the referenced data survives for as long as the pointer could exist, and there is no infrastructure to help with this.

Expanded TOAST pointers are useful for complex data types whose on-disk representation is not especially suited for computational purposes. As an example, the standard varlena representation of a Postgres Pro array includes dimensionality information, a nulls bitmap if there are any null elements, then the values of all the elements in order. When the element type itself is variable-length, the only way to find the *N*'th element is to scan through all the preceding elements. This representation is appropriate for on-disk storage because of its compactness, but for computations with the array it's much nicer to have an “expanded” or “deconstructed” representation in which all the element starting locations have been identified. The TOAST pointer mechanism supports this need by allowing a pass-by-reference Datum to point to either a standard varlena value (the on-disk representation) or a TOAST pointer that points to an expanded representation somewhere in memory. The details of this expanded representation are up to the data type, though it must have a standard header and meet the other API requirements given in `src/include/utils/expandeddatum.h`. C-level functions working with the data type can choose to handle either representation. Functions that do not know about

the expanded representation, but simply apply `PG_DETOAST_DATUM` to their inputs, will automatically receive the traditional varlena representation; so support for an expanded representation can be introduced incrementally, one function at a time.

TOAST pointers to expanded values are further broken down into *read-write* and *read-only* pointers. The pointed-to representation is the same either way, but a function that receives a read-write pointer is allowed to modify the referenced value in-place, whereas one that receives a read-only pointer must not; it must first create a copy if it wants to make a modified version of the value. This distinction and some associated conventions make it possible to avoid unnecessary copying of expanded values during query execution.

For all types of in-memory TOAST pointer, the TOAST management code ensures that no such pointer datum can accidentally get stored on disk. In-memory TOAST pointers are automatically expanded to normal in-line varlena values before storage — and then possibly converted to on-disk TOAST pointers, if the containing tuple would otherwise be too big.

66.2.3. Pluggable TOAST

TOAST is a part of Postgres Pro core. TOAST is not extensible, has the same strategy for all data types and is not effective for structured data (JSON) or data that requires a special workflow (*bytea*).

Experimental pluggable TOAST provides an open API allowing you to develop and plug in custom TOAST implementations for table columns and data types in addition to the default one. These implementations are called TOASTers. A TOASTER can process TOASTed data using the knowledge about the internal data structure and workflow.

TOASTers can use any storage, advanced compression, encryption and other functionalities internally, without being aware of the table access method that calls the TOASTER.

The pluggable TOAST consists of the core, that is, the TOAST API, and custom TOASTers plugged in to Postgres Pro with this API.

This API does not possess any logic regarding the TOAST functionality, it is just a wraparound that allows registering, calling and dropping plugged TOASTers.

To enable using custom TOAST implementations, the TOAST API defines a new `Custom` type of TOAST pointer in addition to `External` and `Extended` (corresponding to `EXTERNAL` and `EXTENDED` TOAST-able column storing strategies).

Currently the pluggable TOAST has several limitations:

- Custom TOASTers must only be assigned to a column with the `EXTERNAL` storing strategy.
- Currently the pluggable TOAST does not support logical replication. A custom TOAST pointer is skipped by the logical replication engine and is not replicated. This is because support of custom pointers requires heavy modifications in the Postgres Pro core (the logical replication engine) and even architecture changes as now custom pointers allow updating TOASTed values, while default pointers do not.
- Custom TOASTers are not restored from dumps and require manual actions for restoring. The TOASTER extension is not restored from dump, thus the data processed with it are not available. Another point is that the same TOASTER extension has different IDs in different systems, so restoring a TOASTed value from dump would require determining the TOASTER used for processing data.
- When a custom TOASTER is assigned to a table column, in all the transactions after the TOASTER assignment, data being stored in the TOAST tables is processed with the TOASTER assigned to the column.
- When a custom TOASTER is assigned to a table column, old data values are left as-is and are not re-TOASTed although while being updated, an old data value is TOASTed with the assigned TOASTER because of the workflow of the default TOAST mechanics.
- If the TOASTER is somehow dropped, the data TOASTed with it will not be accessible with any standard techniques and is considered to be lost. To protect TOASTed values, the API creates some dependencies in the system (`PG_DEPEND` table):
 - When the TOASTER is added to a system, a TOASTER-extension dependency is created.
 - When the TOASTER is assigned to a column, a TOASTER-relation dependency is created.
 - When the TOASTER is unassigned from a column, the TOASTER-relation dependency is deleted.
 - When the TOASTER is dropped from a system, the TOASTER-extension dependency is deleted.

Custom TOASTers are added as extensions implementing some mandatory functions. Pluggable TOAST provides a set of SQL functions to control custom TOASTers. These functions are called with SQL `SELECT` command:

`add_toaster(toaster_name text, toaster_handler_func text) → integer`

Plug in a new TOASTer (added before as an extension). This function also creates a dependency in `PG_DEPEND` for the TOASTer OID to its extension OID, which is used to protect the TOASTer from being dropped when dropping the TOASTer extension.

Arguments:

- *toaster_name* — TOASTer name to be stored in `PG_TOASTER`. Must be unique.
- *toaster_handler_func* — TOASTer handler function name (automatically added as a `regproc` when the TOASTer extension is installed).

Returns OID assigned to the new TOASTer.

`set_toaster(toaster_name text, tab_name text, col_name text) → integer`

Assign a TOASTer to a table column. This function also creates a dependency in `PG_DEPEND` for the TOASTer OID to the relation OID. This dependency is used to protect TOASTed data by restricting dropping the TOASTer that is assigned to a column.

Arguments:

- *toaster_name* — name of the TOASTer assigned to a table column.
- *tab_name* — table name.
- *col_name* — column name.

Returns OID of the TOASTer assigned to the column.

`reset_toaster(tab_name text, col_name text) → integer`

Reset the TOAST mechanism to a default one for a table column. This function drops the TOASTer-relation dependency, which allows dropping the TOASTer later, when all dependencies are dropped.

Arguments:

- *tab_name* — table name.
- *col_name* — table column name.

Returns always 0.

`drop_toaster(toaster_name text)`

Drop a TOASTer from the system. Only unused TOASTers, which do not have any data TOASTed with them can be dropped. Dropping is protected by the dependencies created by `add_toaster` and `set_toaster` functions. If a dependency still exists, the TOASTer would not be dropped. If the TOASTer was dropped successfully, the extension with its implementation can be dropped by the `DROP EXTENSION` command.

Arguments:

- *toaster_name* — name of the TOASTer to be dropped.

Returns the TOASTer OID on success or 0 if the TOASTer is used.

`get_toaster(tab_name text, col_name text) → integer`

Get the OID of the TOASTer assigned to a table column.

Arguments:

- *tab_name* — table name.
- *col_name* — table column name.

Returns the OID of the TOASTer assigned to a column or 0 if none.

The following example illustrates the use of the pluggable TOAST API:

```
CREATE EXTENSION toastapi;

CREATE EXTENSION bytea_toaster;

SELECT add_toaster('bytea_toaster');

CREATE TABLE test_bytea_append (id int, a bytea);

ALTER TABLE test_bytea_append ALTER a SET STORAGE external;

SELECT set_toaster('bytea_toaster', 'test_bytea_append', 'a');
       test_set_toaster
-----
(1 row)

...

SELECT get_toaster('test_bytea_append', 'a') AS bytea_toaster_oid;
       get_toaster
-----
          16348
(1 row)

SELECT pgpro_toast.reset_toaster('test_bytea_append', 'a');
       reset_toaster
-----
              0
(1 row)

DROP TABLE test_bytea_append;
SELECT pgpro_toast.drop_toaster('bytea_toaster');
       drop_toaster
-----
          16348
(1 row)

DROP EXTENSION bytea_toaster;
```

66.3. Free Space Map

Each heap and index relation, except for hash indexes, has a Free Space Map (FSM) to keep track of available space in the relation. It's stored alongside the main relation data in a separate relation fork, named after the filenode number of the relation, plus a `_fsm` suffix. For example, if the filenode of a relation is 12345, the FSM is stored in a file called `12345_fsm`, in the same directory as the main relation file.

The Free Space Map is organized as a tree of FSM pages. The bottom level FSM pages store the free space available on each heap (or index) page, using one byte to represent each such page. The upper levels aggregate information from the lower levels.

Within each FSM page is a binary tree, stored in an array with one byte per node. Each leaf node represents a heap page, or a lower level FSM page. In each non-leaf node, the higher of its children's values is stored. The maximum value in the leaf nodes is therefore stored at the root.

The [pg_freespacemap](#) module can be used to examine the information stored in free space maps.

66.4. Visibility Map

Each heap relation has a Visibility Map (VM) to keep track of which pages contain only tuples that are known to be visible to all active transactions; it also keeps track of which pages contain only frozen tuples. It's stored alongside the main relation data in a separate relation fork, named after the filenode number of the relation, plus a `_vm` suffix. For example, if the filenode of a relation is 12345, the VM is stored in a file called `12345_vm`, in the same directory as the main relation file. Note that indexes do not have VMs.

The visibility map stores two bits per heap page. The first bit, if set, indicates that the page is all-visible, or in other words that the page does not contain any tuples that need to be vacuumed. This information can also be used by [index-only scans](#) to answer queries using only the index tuple. The second bit, if set, means that all tuples on the page have been frozen.

The map is conservative in the sense that we make sure that whenever a bit is set, we know the condition is true, but if a bit is not set, it might or might not be true. Visibility map bits are only set by vacuum, but are cleared by any data-modifying operations on a page.

The `pg_visibility` module can be used to examine the information stored in the visibility map.

66.5. The Initialization Fork

Each unlogged table, and each index on an unlogged table, has an initialization fork. The initialization fork is an empty table or index of the appropriate type. When an unlogged table must be reset to empty due to a crash, the initialization fork is copied over the main fork, and any other forks are erased (they will be recreated automatically as needed).

66.6. Database Page Layout

This section provides an overview of the page format used within Postgres Pro tables and indexes.¹ Sequences and TOAST tables are formatted just like a regular table.

In the following explanation, a *byte* is assumed to contain 8 bits. In addition, the term *item* refers to an individual data value that is stored on a page. In a table, an item is a row; in an index, an item is an index entry.

Every table and index is stored as an array of *pages* of a fixed size (usually 8 kB, although a different page size can be selected when compiling the server). In a table, all the pages are logically equivalent, so a particular item (row) can be stored in any page. In indexes, the first page is generally reserved as a *metapage* holding control information, and there can be different types of pages within the index, depending on the index access method.

[Table 66.2](#) shows the overall layout of a page. There are five parts to each page.

Table 66.2. Overall Page Layout

Item	Description
PageHeaderData	24 bytes long. Contains general information about the page, including free space pointers.
ItemIdData	Array of item identifiers pointing to the actual items. Each entry is an (offset,length) pair. 4 bytes per item.
Free space	The unallocated space. New item identifiers are allocated from the start of this area, new items from the end.
Items	The actual items themselves.
Special space	Index access method specific data. Different methods store different data. Additionally, this space is used to store information about 64-bit transaction IDs.

The first 20 bytes of each page consists of a page header (`PageHeaderData`). Its format is detailed in [Table 66.3](#). The first field tracks the most recent WAL entry related to this page. The second field contains the page checksum if [data checksums](#) are enabled. Next is a 2-byte field containing flag bits. This is followed by three 2-byte integer fields (`pd_lower`, `pd_upper`, and `pd_special`). These contain byte offsets from the page start to the start of unallocated space, to the end of unallocated space, and to the start of the special space. The next 2 bytes of the page header, `pd_pagesize_version`, store both the page size and a version indicator. Beginning with PostgreSQL 8.3 the version number is 4; PostgreSQL 8.1 and 8.2 used version number 3; PostgreSQL 8.0 used version number 2; PostgreSQL 7.3 and 7.4 used version number 1; prior releases used version number 0. (The

¹ Actually, use of this page format is not required for either table or index access methods. The heap table access method always uses this format. All the existing index methods also use the basic format, but the data kept on index metapages usually doesn't follow the item layout rules.

basic page layout and header format has not changed in most of these versions, but the layout of heap row headers has.) The page size is basically only present as a cross-check; there is no support for having more than one page size in an installation.

Table 66.3. PageHeaderData Layout

Field	Type	Length	Description
pd_lsn	PageXLogRecPtr	8 bytes	LSN: next byte after last byte of WAL record for last change to this page
pd_checksum	uint16	2 bytes	Page checksum
pd_flags	uint16	2 bytes	Flag bits
pd_lower	LocationIndex	2 bytes	Offset to start of free space
pd_upper	LocationIndex	2 bytes	Offset to end of free space
pd_special	LocationIndex	2 bytes	Offset to start of special space
pd_pagesize_version	uint16	2 bytes	Page size and layout version number information

Following the page header are item identifiers (`ItemIdData`), each requiring four bytes. An item identifier contains a byte-offset to the start of an item, its length in bytes, and a few attribute bits which affect its interpretation. New item identifiers are allocated as needed from the beginning of the unallocated space. The number of item identifiers present can be determined by looking at `pd_lower`, which is increased to allocate a new identifier. Because an item identifier is never moved until it is freed, its index can be used on a long-term basis to reference an item, even when the item itself is moved around on the page to compact free space. In fact, every pointer to an item (`ItemPointer`, also known as `CTID`) created by Postgres Pro consists of a page number and the index of an item identifier.

The items themselves are stored in space allocated backwards from the end of unallocated space. The exact structure varies depending on what the table is to contain. Tables and sequences both use a structure named `HeapTupleHeaderData`, described below.

The final section is the “special section” which can contain anything the access method wishes to store. For example, b-tree indexes store links to the page's left and right siblings, as well as some other data relevant to the index structure. Ordinary tables and sequences store the `HeapPageSpecialData` structure in this section. Its format is specified in [Table 66.4](#).

[Figure 66.1](#) illustrates how these parts are laid out in a page.

Figure 66.1. Page Layout

66.6.1. Table Row Layout

`HeapPageSpecialData` is a 24-byte structure. The first two 8-byte fields contain the base (i.e., an offset) for short (4-byte) transaction IDs in this page. The next field is a hint that shows whether pruning the page is likely to be profitable: it tracks the oldest un-pruned XMAX on the page. The last field is a magic number identifying the type of the page (`0x1010` for ordinary tables and `0x1717` for sequences).

Table 66.4. HeapPageSpecialData Layout

Field	Type	Length	Description
pd_xid_base	TransactionId	8 bytes	Base for short 4-byte transaction IDs in this page
pd_multi_base	TransactionId	8 bytes	Base for short 4-byte multixact IDs in this page
pd_prune_xid	ShortTransactionId	4 bytes	Oldest unpruned XMAX on page, or zero if none
pd_magic	uint32	4 bytes	Magic number identifying the type of this page

All table rows are structured in the same way. There is a fixed-size header (occupying 40 bytes on most machines), followed by an optional null bitmap, an optional object ID field, and the user data. The header is detailed in [Table 66.5](#). The actual user data (columns of the row) begins at the offset indicated by `t_hoff`, which must always be a multiple of the `MAXALIGN` distance for the platform. The null bitmap is only present if the `HEAP_HASNULL` bit is set in `t_infomask`. If it is present it begins just after the fixed header and occupies enough bytes to have one bit per data column (that is, the number of bits that equals the attribute count in `t_infomask2`). In this list of bits, a 1 bit indicates not-null, a 0 bit is a null. When the bitmap is not present, all columns are assumed not-null. The object ID is only present if the `HEAP_HASOID_OLD` bit is set in `t_infomask`. If present, it appears just before the `t_hoff` boundary. Any padding needed to make `t_hoff` a `MAXALIGN` multiple will appear between the null bitmap and the object ID. (This in turn ensures that the object ID is suitably aligned.)

Table 66.5. HeapTupleHeaderData Layout

Field	Type	Length	Description
t_xmin	ShortTransactionId	4 bytes	insert XID stamp
t_xmax	ShortTransactionId	4 bytes	delete XID stamp
t_cid	CommandId	4 bytes	insert and/or delete CID stamp (overlays with <code>t_xvac</code>)
t_xvac	ShortTransactionId	4 bytes	XID for VACUUM operation moving a row version
t_ctid	ItemPointerData	6 bytes	current TID of this or newer row version
t_infomask2	uint16	2 bytes	number of attributes, plus various flag bits
t_infomask	uint16	2 bytes	various flag bits
t_hoff	uint8	1 byte	offset to user data

Interpreting the actual data can only be done with information obtained from other tables, mostly `pg_attribute`. The key values needed to identify field locations are `attlen` and `attalign`. There is no way to directly get a particular attribute, except when there are only fixed width fields and no null values. All this trickery is wrapped up in the functions `heap_getattr`, `fastgetattr` and `heap_getsysattr`.

To read the data you need to examine each attribute in turn. First check whether the field is NULL according to the null bitmap. If it is, go to the next. Then make sure you have the right alignment. If the field is a fixed width field, then all the bytes are simply placed. If it's a variable length field (`attlen = -1`) then it's a bit more complicated. All variable-length data types share the common header structure `struct varlena`, which includes the total length of the stored value and some flag bits. Depending on the flags, the data can be either inline or in a TOAST table; it might be compressed, too (see [Section 66.2](#)).

66.7. Heap-Only Tuples (HOT)

To allow for high concurrency, Postgres Pro uses [multiversion concurrency control](#) (MVCC) to store rows. However, MVCC has some downsides for update queries. Specifically, updates require new versions of rows to be added to tables. This can also require new index entries for each updated row, and removal of old versions of rows and their index entries can be expensive.

To help reduce the overhead of updates, Postgres Pro has an optimization called heap-only tuples (HOT). This optimization is possible when:

- The update does not modify any columns referenced by the table's indexes, not including summarizing indexes. The only summarizing index method in the core Postgres Pro distribution is [BRIN](#).
- There is sufficient free space on the page containing the old row for the updated row.

In such cases, heap-only tuples provide two optimizations:

- New index entries are not needed to represent updated rows, however, summary indexes may still need to be updated.
- When a row is updated multiple times, row versions other than the oldest and the newest can be completely removed during normal operation, including `SELECT`s, instead of requiring periodic vacuum operations. (Indexes always refer to the [page item identifier](#) of the original row version. The tuple data associated with that row version is removed, and its item identifier is converted to a redirect that points to the oldest version that may still be visible to some concurrent transaction. Intermediate row versions that are no longer visible to anyone are completely removed, and the associated page item identifiers are made available for reuse.)

You can increase the likelihood of sufficient page space for HOT updates by decreasing a table's [fillfactor](#). If you don't, HOT updates will still happen because new rows will naturally migrate to new pages and existing pages with sufficient free space for new row versions. The system view [pg_stat_all_tables](#) allows monitoring of the occurrence of HOT and non-HOT updates.

Chapter 67. Transaction Processing

This chapter provides an overview of the internals of Postgres Pro's transaction management system. The word transaction is often abbreviated as *xact*.

67.1. Transactions and Identifiers

Transactions can be created explicitly using `BEGIN` or `START TRANSACTION` and ended using `COMMIT` or `ROLLBACK`. SQL statements outside of explicit transactions automatically use single-statement transactions.

Every transaction is identified by a unique `VirtualTransactionId` (also called `virtualXID` or `vxid`), which is comprised of a backend's process number (or `procNumber`) and a sequentially-assigned number local to each backend, known as `localXID`. For example, the virtual transaction ID 4/12532 has a `procNumber` of 4 and a `localXID` of 12532.

Non-virtual `TransactionIds` (or `xid`), e.g., 278394, are assigned sequentially to transactions from a global counter used by all databases within the Postgres Pro cluster. This assignment happens when a transaction first writes to the database. This means lower-numbered `xids` started writing before higher-numbered `xids`. Note that the order in which transactions perform their first database write might be different from the order in which the transactions started, particularly if the transaction started with statements that only performed database reads.

In Postgres Pro Enterprise, the internal transaction ID type `xid` is 64 bits wide to prevent [transaction ID wraparound](#). Each tuple header contains two XIDs, so extending them would lead to high overhead. For that reason, when saved on disk on-tuple XIDs are 32-bit, but each page special area contains an offset, called *base XID*. When a tuple is read into memory, the base XID is added to its 32-bit XIDs, and both XIDs in the tuple become full 64 bits wide so the tuple becomes the so-called in-memory tuple. Full 64-bit XIDs acquired after adding the base XID are used in comparison and other arithmetic operations. In some contexts, `xid8` is also used. The functions in [Table 9.82](#) return `xid8` values. Xids are used as the basis for Postgres Pro's [MVCC](#) concurrency mechanism and streaming replication.

When a top-level transaction with a (non-virtual) `xid` commits, it is marked as committed in the `pg_xact` directory. Additional information is recorded in the `pg_commit_ts` directory if [track_commit_timestamp](#) is enabled.

In addition to `vxid` and `xid`, prepared transactions are also assigned Global Transaction Identifiers (GID). GIDs are string literals up to 200 bytes long, which must be unique amongst other currently prepared transactions. The mapping of GID to `xid` is shown in [pg_prepared_xacts](#).

67.2. Transactions and Locking

The transaction IDs of currently executing transactions are shown in [pg_locks](#) in columns `virtualxid` and `transactionid`. Read-only transactions will have `virtualxids` but NULL `transactionids`, while both columns will be set in read-write transactions.

Some lock types wait on `virtualxid`, while other types wait on `transactionid`. Row-level read and write locks are recorded directly in the locked rows and can be inspected using the [pgrowlocks](#) extension. Row-level read locks might also require the assignment of multixact IDs (`mxid`; see [Section 24.1.5.1](#)).

67.3. Subtransactions

Subtransactions are started inside transactions, allowing large transactions to be broken into smaller units. Subtransactions can commit or abort without affecting their parent transactions, allowing parent transactions to continue. This allows errors to be handled more easily, which is a common application development pattern. The word subtransaction is often abbreviated as *subxact*.

Subtransactions can be started explicitly using the `SAVEPOINT` command, but can also be started in other ways, such as PL/pgSQL's `EXCEPTION` clause. PL/Python and PL/Tcl also support explicit subtransactions. Subtransactions can also be started from other subtransactions. The top-level transaction and its child subtransactions form a hierarchy or tree, which is why we refer to the main transaction as the top-level transaction.

If a subtransaction is assigned a non-virtual transaction ID, its transaction ID is referred to as a “subxid”. In Postgres Pro Enterprise, subxids are 64 bits wide. Read-only subtransactions are not assigned subxids, but once they attempt to write, they will be assigned

one. This also causes all of a subxid's parents, up to and including the top-level transaction, to be assigned non-virtual transaction ids. We ensure that a parent xid is always lower than any of its child subxids.

The immediate parent xid of each subxid is recorded in the `pg_subtrans` directory. No entry is made for top-level xids since they do not have a parent, nor is an entry made for read-only subtransactions.

When a subtransaction commits, all of its committed child subtransactions with subxids will also be considered subcommitted in that transaction. When a subtransaction aborts, all of its child subtransactions will also be considered aborted.

When a top-level transaction with an xid commits, all of its subcommitted child subtransactions are also persistently recorded as committed in the `pg_xact` subdirectory. If the top-level transaction aborts, all its subtransactions are also aborted, even if they were subcommitted.

The more subtransactions each transaction keeps open (not rolled back or released), the greater the transaction management overhead. Up to 64 open subxids are cached in shared memory for each backend; after that point, the storage I/O overhead increases significantly due to additional lookups of subxid entries in `pg_subtrans`.

67.4. Two-Phase Transactions

Postgres Pro supports a two-phase commit (2PC) protocol that allows multiple distributed systems to work together in a transactional manner. The commands are `PREPARE TRANSACTION`, `COMMIT PREPARED` and `ROLLBACK PREPARED`. Two-phase transactions are intended for use by external transaction management systems. Postgres Pro follows the features and model proposed by the X/Open XA standard, but does not implement some less often used aspects.

When the user executes `PREPARE TRANSACTION`, the only possible next commands are `COMMIT PREPARED` or `ROLLBACK PREPARED`. In general, this prepared state is intended to be of very short duration, but external availability issues might mean transactions stay in this state for an extended interval. Short-lived prepared transactions are stored only in shared memory and WAL. Transactions that span checkpoints are recorded in the `pg_twophase` directory. Transactions that are currently prepared can be inspected using [pg_prepared_xacts](#).

Chapter 68. How the Planner Uses Statistics

This chapter builds on the material covered in [Section 14.1](#) and [Section 14.2](#) to show some additional details about how the planner uses the system statistics to estimate the number of rows each part of a query might return. This is a significant part of the planning process, providing much of the raw material for cost calculation.

The intent of this chapter is not to document the code in detail, but to present an overview of how it works. This will perhaps ease the learning curve for someone who subsequently wishes to read the code.

68.1. Row Estimation Examples

The examples shown below use tables in the Postgres Pro regression test database. Note also that since `ANALYZE` uses random sampling while producing statistics, the results will change slightly after any new `ANALYZE`.

Let's start with a very simple query:

```
EXPLAIN SELECT * FROM tenk1;
```

QUERY PLAN

```
-----  
Seq Scan on tenk1 (cost=0.00..458.00 rows=10000 width=244)
```

How the planner determines the cardinality of `tenk1` is covered in [Section 14.2](#), but is repeated here for completeness. The number of pages and rows is looked up in `pg_class`:

```
SELECT relpages, reltuples FROM pg_class WHERE relname = 'tenk1';
```

```
relpages | reltuples  
-----+-----  
    358 |    10000
```

These numbers are current as of the last `VACUUM` or `ANALYZE` on the table. The planner then fetches the actual current number of pages in the table (this is a cheap operation, not requiring a table scan). If that is different from `relpages` then `reltuples` is scaled accordingly to arrive at a current number-of-rows estimate. In the example above, the value of `relpages` is up-to-date so the rows estimate is the same as `reltuples`.

Let's move on to an example with a range condition in its `WHERE` clause:

```
EXPLAIN SELECT * FROM tenk1 WHERE unique1 < 1000;
```

QUERY PLAN

```
-----  
Bitmap Heap Scan on tenk1 (cost=24.06..394.64 rows=1007 width=244)  
  Recheck Cond: (unique1 < 1000)  
    -> Bitmap Index Scan on tenk1_unique1 (cost=0.00..23.80 rows=1007 width=0)  
        Index Cond: (unique1 < 1000)
```

The planner examines the `WHERE` clause condition and looks up the selectivity function for the operator `<` in `pg_operator`. This is held in the column `oprrest`, and the entry in this case is `scalarltsel`. The `scalarltsel` function retrieves the histogram for `unique1` from `pg_statistic`. For manual queries it is more convenient to look in the simpler `pg_stats` view:

```
SELECT histogram_bounds FROM pg_stats  
WHERE tablename='tenk1' AND attname='unique1';
```

histogram_bounds

```
-----  
{0, 993, 1997, 3050, 4040, 5036, 5957, 7057, 8029, 9016, 9995}
```

Next the fraction of the histogram occupied by “< 1000” is worked out. This is the selectivity. The histogram divides the range into equal frequency buckets, so all we have to do is locate the bucket that our value is in and count *part* of it and *all* of the ones before. The value 1000 is clearly in the second bucket (993–1997). Assuming a linear distribution of values inside each bucket, we can calculate the selectivity as:

```
selectivity = (1 + (1000 - bucket[2].min)/(bucket[2].max - bucket[2].min))/num_buckets
             = (1 + (1000 - 993)/(1997 - 993))/10
             = 0.100697
```

that is, one whole bucket plus a linear fraction of the second, divided by the number of buckets. The estimated number of rows can now be calculated as the product of the selectivity and the cardinality of `tenk1`:

```
rows = rel_cardinality * selectivity
      = 10000 * 0.100697
      = 1007 (rounding off)
```

Next let's consider an example with an equality condition in its `WHERE` clause:

```
EXPLAIN SELECT * FROM tenk1 WHERE stringu1 = 'CRAAAA';
```

QUERY PLAN

```
-----
Seq Scan on tenk1 (cost=0.00..483.00 rows=30 width=244)
  Filter: (stringu1 = 'CRAAAA'::name)
```

Again the planner examines the `WHERE` clause condition and looks up the selectivity function for `=`, which is `eqsel`. For equality estimation the histogram is not useful; instead the list of *most common values* (MCVs) is used to determine the selectivity. Let's have a look at the MCVs, with some additional columns that will be useful later:

```
SELECT null_frac, n_distinct, most_common_vals, most_common_freqs FROM pg_stats
WHERE tablename='tenk1' AND attname='stringu1';
```

```
null_frac      | 0
n_distinct     | 676
most_common_vals | {EJAAAA, BBAAAA, CRAAAA, FCAAAA, FEAAAA, GSAAAA,
JOAAAA, MCAAAA, NAAAAA, WGAAAA}
most_common_freqs | {0.00333333, 0.003, 0.003, 0.003, 0.003, 0.003, 0.003, 0.003, 0.003}
```

Since `CRAAAA` appears in the list of MCVs, the selectivity is merely the corresponding entry in the list of most common frequencies (MCFs):

```
selectivity = mcf[3]
             = 0.003
```

As before, the estimated number of rows is just the product of this with the cardinality of `tenk1`:

```
rows = 10000 * 0.003
      = 30
```

Now consider the same query, but with a constant that is not in the MCV list:

```
EXPLAIN SELECT * FROM tenk1 WHERE stringu1 = 'xxx';
```

QUERY PLAN

```
-----
Seq Scan on tenk1 (cost=0.00..483.00 rows=15 width=244)
  Filter: (stringu1 = 'xxx'::name)
```

This is quite a different problem: how to estimate the selectivity when the value is *not* in the MCV list. The approach is to use the fact that the value is not in the list, combined with the knowledge of the frequencies for all of the MCVs:

```
selectivity = (1 - sum(mcv_freqs))/(num_distinct - num_mcv)
             = (1 - (0.00333333 + 0.003 + 0.003 + 0.003 + 0.003 + 0.003 +
0.003 + 0.003 + 0.003 + 0.003))/(676 - 10)
             = 0.0014559
```

That is, add up all the frequencies for the MCVs and subtract them from one, then divide by the number of *other* distinct values. This amounts to assuming that the fraction of the column that is not any of the MCVs is evenly distributed among all the other distinct values. Notice that there are no null values so we don't have to worry about those (otherwise we'd subtract the null fraction from the numerator as well). The estimated number of rows is then calculated as usual:

```
rows = 10000 * 0.0014559
      = 15   (rounding off)
```

The previous example with `unique1 < 1000` was an oversimplification of what `scalarltsel` really does; now that we have seen an example of the use of MCVs, we can fill in some more detail. The example was correct as far as it went, because since `unique1` is a unique column it has no MCVs (obviously, no value is any more common than any other value). For a non-unique column, there will normally be both a histogram and an MCV list, and *the histogram does not include the portion of the column population represented by the MCVs*. We do things this way because it allows more precise estimation. In this situation `scalarltsel` directly applies the condition (e.g., “< 1000”) to each value of the MCV list, and adds up the frequencies of the MCVs for which the condition is true. This gives an exact estimate of the selectivity within the portion of the table that is MCVs. The histogram is then used in the same way as above to estimate the selectivity in the portion of the table that is not MCVs, and then the two numbers are combined to estimate the overall selectivity. For example, consider

```
EXPLAIN SELECT * FROM tenk1 WHERE stringu1 < 'IAAAAA';
```

QUERY PLAN

```
-----
Seq Scan on tenk1  (cost=0.00..483.00 rows=3077 width=244)
  Filter: (stringu1 < 'IAAAAA'::name)
```

We already saw the MCV information for `stringu1`, and here is its histogram:

```
SELECT histogram_bounds FROM pg_stats
WHERE tablename='tenk1' AND attname='stringu1';
```

histogram_bounds

```
-----
{AAAAAA, CQAAAA, FRAAAA, IBAAAA, KRAAAA, NFAAAA, PSAAAA, SGAAAA, VAAAAA, XLAAAA, ZZAAAA}
```

Checking the MCV list, we find that the condition `stringu1 < 'IAAAAA'` is satisfied by the first six entries and not the last four, so the selectivity within the MCV part of the population is

```
selectivity = sum(relevant mvfs)
             = 0.00333333 + 0.003 + 0.003 + 0.003 + 0.003 + 0.003
             = 0.01833333
```

Summing all the MCFs also tells us that the total fraction of the population represented by MCVs is 0.03033333, and therefore the fraction represented by the histogram is 0.96966667 (again, there are no nulls, else we'd have to exclude them here). We can see that the value `IAAAAA` falls nearly at the end of the third histogram bucket. Using some rather cheesy assumptions about the frequency of different characters, the planner arrives at the estimate 0.298387 for the portion of the histogram population that is less than `IAAAAA`. We then combine the estimates for the MCV and non-MCV populations:

```
selectivity = mcv_selectivity + histogram_selectivity * histogram_fraction
             = 0.01833333 + 0.298387 * 0.96966667
             = 0.307669
```

```
rows      = 10000 * 0.307669
          = 3077   (rounding off)
```

In this particular example, the correction from the MCV list is fairly small, because the column distribution is actually quite flat (the statistics showing these particular values as being more common than others are mostly due to sampling error). In a more typical case where some values are significantly more common than others, this complicated process gives a useful improvement in accuracy because the selectivity for the most common values is found exactly.

Now let's consider a case with more than one condition in the `WHERE` clause:

```
EXPLAIN SELECT * FROM tenk1 WHERE unique1 < 1000 AND stringu1 = 'xxx';
```

QUERY PLAN

```
-----
Bitmap Heap Scan on tenk1  (cost=23.80..396.91 rows=1 width=244)
  Recheck Cond: (unique1 < 1000)
  Filter: (stringu1 = 'xxx'::name)
```

```
-> Bitmap Index Scan on tenk1_unique1 (cost=0.00..23.80 rows=1007 width=0)
    Index Cond: (unique1 < 1000)
```

The planner assumes that the two conditions are independent, so that the individual selectivities of the clauses can be multiplied together:

```
selectivity = selectivity(unique1 < 1000) * selectivity(stringu1 = 'xxx')
              = 0.100697 * 0.0014559
              = 0.0001466
```

```
rows        = 10000 * 0.0001466
              = 1 (rounding off)
```

Notice that the number of rows estimated to be returned from the bitmap index scan reflects only the condition used with the index; this is important since it affects the cost estimate for the subsequent heap fetches.

Finally we will examine a query that involves a join:

```
EXPLAIN SELECT * FROM tenk1 t1, tenk2 t2
WHERE t1.unique1 < 50 AND t1.unique2 = t2.unique2;
```

QUERY PLAN

```
-----
Nested Loop (cost=4.64..456.23 rows=50 width=488)
-> Bitmap Heap Scan on tenk1 t1 (cost=4.64..142.17 rows=50 width=244)
    Recheck Cond: (unique1 < 50)
-> Bitmap Index Scan on tenk1_unique1 (cost=0.00..4.63 rows=50 width=0)
    Index Cond: (unique1 < 50)
-> Index Scan using tenk2_unique2 on tenk2 t2 (cost=0.00..6.27 rows=1 width=244)
    Index Cond: (unique2 = t1.unique2)
```

The restriction on `tenk1`, `unique1 < 50`, is evaluated before the nested-loop join. This is handled analogously to the previous range example. This time the value 50 falls into the first bucket of the `unique1` histogram:

```
selectivity = (0 + (50 - bucket[1].min)/(bucket[1].max - bucket[1].min))/num_buckets
              = (0 + (50 - 0)/(993 - 0))/10
              = 0.005035
```

```
rows        = 10000 * 0.005035
              = 50 (rounding off)
```

The restriction for the join is `t2.unique2 = t1.unique2`. The operator is just our familiar `=`, however the selectivity function is obtained from the `oprjoin` column of `pg_operator`, and is `eqjoinsel`. `eqjoinsel` looks up the statistical information for both `tenk2` and `tenk1`:

```
SELECT tablename, null_frac, n_distinct, most_common_vals FROM pg_stats
WHERE tablename IN ('tenk1', 'tenk2') AND attname='unique2';
```

tablename	null_frac	n_distinct	most_common_vals
tenk1	0	-1	
tenk2	0	-1	

In this case there is no MCV information for `unique2` and all the values appear to be unique (`n_distinct = -1`), so we use an algorithm that relies on the row count estimates for both relations (`num_rows`, not shown, but "tenk") together with the column null fractions (zero for both):

```
selectivity = (1 - null_frac1) * (1 - null_frac2) / max(num_rows1, num_rows2)
              = (1 - 0) * (1 - 0) / max(10000, 10000)
              = 0.0001
```

This is, subtract the null fraction from one for each of the relations, and divide by the row count of the larger relation (this value does get scaled in the non-unique case). The number of rows that the join is likely to emit is calculated as the cardinality of the Cartesian product of the two inputs, multiplied by the selectivity:

```

rows = (outer_cardinality * inner_cardinality) * selectivity
      = (50 * 10000) * 0.0001
      = 50

```

Had there been MCV lists for the two columns, `eqjoinsel` would have used direct comparison of the MCV lists to determine the join selectivity within the part of the column populations represented by the MCVs. The estimate for the remainder of the populations follows the same approach shown here.

Notice that we showed `inner_cardinality` as 10000, that is, the unmodified size of `tenk2`. It might appear from inspection of the `EXPLAIN` output that the estimate of join rows comes from $50 * 1$, that is, the number of outer rows times the estimated number of rows obtained by each inner index scan on `tenk2`. But this is not the case: the join relation size is estimated before any particular join plan has been considered. If everything is working well then the two ways of estimating the join size will produce about the same answer, but due to round-off error and other factors they sometimes diverge significantly.

68.2. Multivariate Statistics Examples

68.2.1. Functional Dependencies

Multivariate correlation can be demonstrated with a very simple data set — a table with two columns, both containing the same values:

```

CREATE TABLE t (a INT, b INT);
INSERT INTO t SELECT i % 100, i % 100 FROM generate_series(1, 10000) s(i);
ANALYZE t;

```

As explained in [Section 14.2](#), the planner can determine cardinality of `t` using the number of pages and rows obtained from `pg_class`:

```
SELECT relpages, reltuples FROM pg_class WHERE relname = 't';
```

```

relpages | reltuples
-----+-----
      45 |      10000

```

The data distribution is very simple; there are only 100 distinct values in each column, uniformly distributed.

The following example shows the result of estimating a `WHERE` condition on the `a` column:

```
EXPLAIN (ANALYZE, TIMING OFF) SELECT * FROM t WHERE a = 1;
               QUERY PLAN
```

```

-----
Seq Scan on t  (cost=0.00..170.00 rows=100 width=8) (actual rows=100 loops=1)
  Filter: (a = 1)
  Rows Removed by Filter: 9900

```

The planner examines the condition and determines the selectivity of this clause to be 1%. By comparing this estimate and the actual number of rows, we see that the estimate is very accurate (in fact exact, as the table is very small). Changing the `WHERE` condition to use the `b` column, an identical plan is generated. But observe what happens if we apply the same condition on both columns, combining them with `AND`:

```
EXPLAIN (ANALYZE, TIMING OFF) SELECT * FROM t WHERE a = 1 AND b = 1;
               QUERY PLAN
```

```

-----
Seq Scan on t  (cost=0.00..195.00 rows=1 width=8) (actual rows=100 loops=1)
  Filter: ((a = 1) AND (b = 1))
  Rows Removed by Filter: 9900

```

The planner estimates the selectivity for each condition individually, arriving at the same 1% estimates as above. Then it assumes that the conditions are independent, and so it multiplies their selectivities, producing a final selectivity estimate of just 0.01%. This is a significant underestimate, as the actual number of rows matching the conditions (100) is two orders of magnitude higher.

This problem can be fixed by creating a statistics object that directs `ANALYZE` to calculate functional-dependency multivariate statistics on the two columns:

```
CREATE STATISTICS stts (dependencies) ON a, b FROM t;
ANALYZE t;
EXPLAIN (ANALYZE, TIMING OFF) SELECT * FROM t WHERE a = 1 AND b = 1;
                                QUERY PLAN
```

```
-----
Seq Scan on t  (cost=0.00..195.00 rows=100 width=8) (actual rows=100 loops=1)
  Filter: ((a = 1) AND (b = 1))
  Rows Removed by Filter: 9900
```

68.2.2. Multivariate N-Distinct Counts

A similar problem occurs with estimation of the cardinality of sets of multiple columns, such as the number of groups that would be generated by a `GROUP BY` clause. When `GROUP BY` lists a single column, the n-distinct estimate (which is visible as the estimated number of rows returned by the HashAggregate node) is very accurate:

```
EXPLAIN (ANALYZE, TIMING OFF) SELECT COUNT(*) FROM t GROUP BY a;
                                QUERY PLAN
```

```
-----
HashAggregate  (cost=195.00..196.00 rows=100 width=12) (actual rows=100 loops=1)
  Group Key: a
    -> Seq Scan on t  (cost=0.00..145.00 rows=10000 width=4) (actual rows=10000
  loops=1)
```

But without multivariate statistics, the estimate for the number of groups in a query with two columns in `GROUP BY`, as in the following example, is off by an order of magnitude:

```
EXPLAIN (ANALYZE, TIMING OFF) SELECT COUNT(*) FROM t GROUP BY a, b;
                                QUERY PLAN
```

```
-----
HashAggregate  (cost=220.00..230.00 rows=1000 width=16) (actual rows=100 loops=1)
  Group Key: a, b
    -> Seq Scan on t  (cost=0.00..145.00 rows=10000 width=8) (actual rows=10000
  loops=1)
```

By redefining the statistics object to include n-distinct counts for the two columns, the estimate is much improved:

```
DROP STATISTICS stts;
CREATE STATISTICS stts (dependencies, ndistinct) ON a, b FROM t;
ANALYZE t;
EXPLAIN (ANALYZE, TIMING OFF) SELECT COUNT(*) FROM t GROUP BY a, b;
                                QUERY PLAN
```

```
-----
HashAggregate  (cost=220.00..221.00 rows=100 width=16) (actual rows=100 loops=1)
  Group Key: a, b
    -> Seq Scan on t  (cost=0.00..145.00 rows=10000 width=8) (actual rows=10000
  loops=1)
```

68.2.3. MCV Lists

As explained in [Section 68.2.1](#), functional dependencies are very cheap and efficient type of statistics, but their main limitation is their global nature (only tracking dependencies at the column level, not between individual column values).

This section introduces multivariate variant of MCV (most-common values) lists, a straightforward extension of the per-column statistics described in [Section 68.1](#). These statistics address the limitation by storing individual values, but it is naturally more expensive, both in terms of building the statistics in `ANALYZE`, storage and planning time.

Let's look at the query from [Section 68.2.1](#) again, but this time with a MCV list created on the same set of columns (be sure to drop the functional dependencies, to make sure the planner uses the newly created statistics).

```
DROP STATISTICS stts;
CREATE STATISTICS stts2 (mcv) ON a, b FROM t;
ANALYZE t;
EXPLAIN (ANALYZE, TIMING OFF) SELECT * FROM t WHERE a = 1 AND b = 1;
                                QUERY PLAN
```

```
-----
Seq Scan on t  (cost=0.00..195.00 rows=100 width=8) (actual rows=100 loops=1)
  Filter: ((a = 1) AND (b = 1))
  Rows Removed by Filter: 9900
```

The estimate is as accurate as with the functional dependencies, mostly thanks to the table being fairly small and having a simple distribution with a low number of distinct values. Before looking at the second query, which was not handled by functional dependencies particularly well, let's inspect the MCV list a bit.

Inspecting the MCV list is possible using `pg_mcv_list_items` set-returning function.

```
SELECT m.* FROM pg_statistic_ext join pg_statistic_ext_data on (oid = stxoid),
       pg_mcv_list_items(stxmcv) m WHERE stxname = 'stts2';
```

index	values	nulls	frequency	base_frequency
0	{0, 0}	{f, f}	0.01	0.0001
1	{1, 1}	{f, f}	0.01	0.0001
...				
49	{49, 49}	{f, f}	0.01	0.0001
50	{50, 50}	{f, f}	0.01	0.0001
...				
97	{97, 97}	{f, f}	0.01	0.0001
98	{98, 98}	{f, f}	0.01	0.0001
99	{99, 99}	{f, f}	0.01	0.0001

(100 rows)

This confirms there are 100 distinct combinations in the two columns, and all of them are about equally likely (1% frequency for each one). The base frequency is the frequency computed from per-column statistics, as if there were no multi-column statistics. Had there been any null values in either of the columns, this would be identified in the `nulls` column.

When estimating the selectivity, the planner applies all the conditions on items in the MCV list, and then sums the frequencies of the matching ones.

Compared to functional dependencies, MCV lists have two major advantages. Firstly, the list stores actual values, making it possible to decide which combinations are compatible.

```
EXPLAIN (ANALYZE, TIMING OFF) SELECT * FROM t WHERE a = 1 AND b = 10;
                                QUERY PLAN
```

```
-----
Seq Scan on t  (cost=0.00..195.00 rows=1 width=8) (actual rows=0 loops=1)
  Filter: ((a = 1) AND (b = 10))
  Rows Removed by Filter: 10000
```

Secondly, MCV lists handle a wider range of clause types, not just equality clauses like functional dependencies. For example, consider the following range query for the same table:

```
EXPLAIN (ANALYZE, TIMING OFF) SELECT * FROM t WHERE a <= 49 AND b > 49;
                                QUERY PLAN
```

```
-----
Seq Scan on t  (cost=0.00..195.00 rows=1 width=8) (actual rows=0 loops=1)
  Filter: ((a <= 49) AND (b > 49))
  Rows Removed by Filter: 10000
```

68.3. Planner Statistics and Security

Access to the table `pg_statistic` is restricted to superusers, so that ordinary users cannot learn about the contents of the tables of other users from it. Some selectivity estimation functions will use a user-provided operator (either the operator appearing in the

query or a related operator) to analyze the stored statistics. For example, in order to determine whether a stored most common value is applicable, the selectivity estimator will have to run the appropriate `=` operator to compare the constant in the query to the stored value. Thus the data in `pg_statistic` is potentially passed to user-defined operators. An appropriately crafted operator can intentionally leak the passed operands (for example, by logging them or writing them to a different table), or accidentally leak them by showing their values in error messages, in either case possibly exposing data from `pg_statistic` to a user who should not be able to see it.

In order to prevent this, the following applies to all built-in selectivity estimation functions. When planning a query, in order to be able to use stored statistics, the current user must either have `SELECT` privilege on the table or the involved columns, or the operator used must be `LEAKPROOF` (more accurately, the function that the operator is based on). If not, then the selectivity estimator will behave as if no statistics are available, and the planner will proceed with default or fall-back assumptions.

If a user does not have the required privilege on the table or columns, then in many cases the query will ultimately receive a permission-denied error, in which case this mechanism is invisible in practice. But if the user is reading from a security-barrier view, then the planner might wish to check the statistics of an underlying table that is otherwise inaccessible to the user. In that case, the operator should be leak-proof or the statistics will not be used. There is no direct feedback about that, except that the plan might be suboptimal. If one suspects that this is the case, one could try running the query as a more privileged user, to see if a different plan results.

This restriction applies only to cases where the planner would need to execute a user-defined operator on one or more values from `pg_statistic`. Thus the planner is permitted to use generic statistical information, such as the fraction of null values or the number of distinct values in a column, regardless of access privileges.

Selectivity estimation functions contained in third-party extensions that potentially operate on statistics with user-defined operators should follow the same security rules.

Chapter 69. Adaptive Query Execution

Adaptive query execution (AQE) enables reoptimizing a query, if during the execution some trigger indicates that it is non-optimal, so a more optimal plan should be looked for.

AQE is disabled by default and can be enabled with the configuration parameter [aqe_enable](#).

AQE currently has the following limitations:

- Cursors are not supported.
- `SELECT` statements are only supported except `SELECT FOR UPDATE` and `SELECT FOR SHARE`.
- Statements with volatile functions are not supported.

69.1. How It Works

If an [AQE trigger](#) fires during query execution, the partially executed query is paused, and AQE attempts to reoptimize it. Information about the query statement, node cardinalities of non-parameterized nodes and parameterized nodes with actual cardinalities larger than predicted is used to choose a new plan and is stored for further reoptimizations. Then the query is rerun using the new plan. AQE triggers may be disabled for future reoptimizations of the same query in the following situations:

- No new information was gathered during execution. In this case, the output of `EXPLAIN ANALYZE` includes the text: `AQE Deactivation Reason: no new learning data`.
- The newly generated plan matches a plan that was already tried. In this case, the output of `EXPLAIN ANALYZE` includes the text: `AQE Deactivation Reason: repeated plan`.
- The maximum number of reruns, set by the [aqe_max_reruns](#) configuration parameter, was reached. In this case, the output of `EXPLAIN ANALYZE` includes the text: `AQE Deactivation Reason: rerun limit reached`.
- An extension, such as [pgpro_multiplan](#), disabled further reoptimizations. In this case, the output of `EXPLAIN ANALYZE` includes the text: `AQE Deactivation Reason: external deactivation`.

In such cases, the query execution continues without interruption.

If an AQE trigger is activated, a query that meets the trigger condition is executed in an implicitly created subtransaction. In case of rerunning, this helps in cleaning up after the previous execution and releasing system resources, such as memory or disk space.

69.1.1. AQE Triggers

The following triggers can interrupt a query and launch AQE:

- Query execution time: the trigger fires when the query runs longer than the value of the [aqe_sql_execution_time_trigger](#) configuration parameter.
- Number of processed node tuples: the trigger fires when this number exceeds the number normally expected by the planner, which is multiplied by the value of the [aqe_rows_underestimation_rate_trigger](#) configuration parameter.
- Backend memory consumption: the trigger fires when memory consumption of a backend exceeds the value of the [aqe_backend_memory_used_trigger](#) configuration parameter and the number of processed node tuples trigger fired.
- Manual trigger: the trigger fires when the user calls [replan_signal](#) from another session. Unlike other triggers, this trigger cannot be deactivated.

69.1.2. Viewing AQE Details

If [aqe_show_details](#) is on, information related to AQE is included in the `EXPLAIN ANALYZE` output. The `SUMMARY` section additionally includes the following characteristics:

- `AQE Active` — whether AQE was active by the end of the query execution.
- `Table Entries` — number of tables in the query, including subqueries.
- `Controlled Statements` — number of statements that were reoptimized during execution of the query.

- **AQE Reruns** — total number of the query reruns.
- **Total Time Elapsed** — total time of the query execution including the time of all reruns. This property is only displayed if the query was reoptimized and rerun at least once.
- **Final Run Planning Time** — planning time during last AQE reoptimization. This property is only displayed if the query was reoptimized and rerun at least once.
- **AQE Deactivation Reason** — what caused AQE to be disabled. Possible values are self-explanatory: `rerun limit reached`, `repeated plan`, `no new learning data`, or `external deactivation`. Displayed only if AQE was not active by the end of the query execution.

For each plan node, the following characteristics are included:

- **NodeSign** — a 64-bit signature (hash) of the node that uniquely identifies the node of the query plan. Not all nodes are signed, but only those where errors of the optimizer estimation model can cause errors in searching the optimal query plan.
- **Cardinality** — cardinality of the plan node achieved in previous executions of the query. Only available with the `VERBOSE` parameter.
- **Groups Number** — number of groups computed for this plan node from previous executions of the query. Only available with the `VERBOSE` parameter.

69.1.3. Integration with `pgpro_multiplan`

AQE can work in conjunction with the `pgpro_multiplan` extension providing the following features:

- [real-time plan management](#), that is, automatic addition of plans produced by AQE to a list of allowed plans used by `pgpro_multiplan`
- the ability to override and adjust [trigger values for individual queries](#)
- [collecting AQE statistics](#) for all statements considered feasible for reoptimization

69.1.4. Example

Example 69.1. Using AQE

The following example illustrates AQE:

```
DROP TABLE IF EXISTS aqe_test;
CREATE TABLE aqe_test WITH (autovacuum_enabled=off) AS
SELECT x as x, x as y, x as z from generate_series(1, 100000) as x;
INSERT INTO aqe_test SELECT 1, x, x FROM generate_series(1, 1000000) as x;

CREATE INDEX ON aqe_test(x);
CREATE INDEX ON aqe_test(y);
ANALYZE;

-- AQE is disabled
SET aqe_enable = false;
EXPLAIN ANALYZE
SELECT FROM aqe_test t1, aqe_test t2, aqe_test t3

Chapter 70. Backup Manifest Format

The backup manifest generated by [pg_basebackup](#) is primarily intended to permit the backup to be verified using [pg_verifybackup](#). However, it is also possible for other tools to read the backup manifest file and use the information contained therein for their own purposes. To that end, this chapter describes the format of the backup manifest file.

A backup manifest is a JSON document encoded as UTF-8. (Although in general JSON documents are required to be Unicode, Postgres Pro permits the `json` and `jsonb` data types to be used with any supported server encoding. There is no similar exception for backup manifests.) The JSON document is always an object; the keys that are present in this object are described in the next section.

70.1. Backup Manifest Top-level Object

The backup manifest JSON document contains the following keys.

PostgreSQL-Backup-Manifest-Version

The associated value is an integer. Beginning in Postgres Pro 17, it is 2; in older versions, it is 1.

System-Identifier

The database system identifier of the Postgres Pro instance where the backup was taken. This field is present only when `PostgreSQL-Backup-Manifest-Version` is 2.

Files

The associated value is always a list of objects, each describing one file that is present in the backup. No entries are present in this list for the WAL files that are needed in order to use the backup, or for the backup manifest itself. The structure of each object in the list is described in [Section 70.2](#).

WAL-Ranges

The associated value is always a list of objects, each describing a range of WAL records that must be readable from a particular timeline in order to make use of the backup. The structure of these objects is further described in [Section 70.3](#).

Manifest-Checksum

This key is always present on the last line of the backup manifest file. The associated value is a SHA256 checksum of all the preceding lines. We use a fixed checksum method here to make it possible for clients to do incremental parsing of the manifest. While a SHA256 checksum is significantly more expensive than a CRC32C checksum, the manifest should normally be small enough that the extra computation won't matter very much.

70.2. Backup Manifest File Object

The object which describes a single file contains either a `Path` key or an `Encoded-Path` key. Normally, the `Path` key will be present. The associated string value is the path of the file relative to the root of the backup directory. Files located in a user-defined tablespace will have paths whose first two components are `pg_tblspc` and the OID of the tablespace. If the path is not a string that is legal in UTF-8, or if the user requests that encoded paths be used for all files, then the `Encoded-Path` key will be present instead. This stores the same data, but it is encoded as a string of hexadecimal digits. Each pair of hexadecimal digits in the string represents a single octet.

The following two keys are always present:

Size

The expected size of this file, as an integer.

Last-Modified

The last modification time of the file as reported by the server at the time of the backup. Unlike the other fields stored in the backup, this field is not used by [pg_verifybackup](#). It is included only for informational purposes.

If the backup was taken with file checksums enabled, the following keys will be present:

Checksum-Algorithm

The checksum algorithm used to compute a checksum for this file. Currently, this will be the same for every file in the backup manifest, but this may change in future releases. At present, the supported checksum algorithms are `CRC32C`, `SHA224`, `SHA256`, `SHA384`, and `SHA512`.

Checksum

The checksum computed for this file, stored as a series of hexadecimal characters, two for each byte of the checksum.

70.3. Backup Manifest WAL Range Object

The object which describes a WAL range always has three keys:

Timeline

The timeline for this range of WAL records, as an integer.

Start-LSN

The LSN at which replay must begin on the indicated timeline in order to make use of this backup. The LSN is stored in the format normally used by Postgres Pro; that is, it is a string consisting of two strings of hexadecimal characters, each with a length of between 1 and 8, separated by a slash.

End-LSN

The earliest LSN at which replay on the indicated timeline may end when making use of this backup. This is stored in the same format as `Start-LSN`.

Ordinarily, there will be only a single WAL range. However, if a backup is taken from a standby which switches timelines during the backup due to an upstream promotion, it is possible for multiple ranges to be present, each with a different timeline. There will never be multiple WAL ranges present for the same timeline.

Part VIII. Appendixes

Appendix A. Postgres Pro Error Codes

All messages emitted by the Postgres Pro server are assigned five-character error codes that follow the SQL standard's conventions for “SQLSTATE” codes. Applications that need to know which error condition has occurred should usually test the error code, rather than looking at the textual error message. The error codes are less likely to change across Postgres Pro releases, and also are not subject to change due to localization of error messages. Note that some, but not all, of the error codes produced by Postgres Pro are defined by the SQL standard; some additional error codes for conditions not defined by the standard have been invented or borrowed from other databases.

According to the standard, the first two characters of an error code denote a class of errors, while the last three characters indicate a specific condition within that class. Thus, an application that does not recognize the specific error code might still be able to infer what to do from the error class.

[Table A.1](#) lists all the error codes defined in Postgres Pro Enterprise 17.7.1. (Some are not actually used at present, but are defined by the SQL standard.) The error classes are also shown. For each error class there is a “standard” error code having the last three characters 000. This code is used only for error conditions that fall within the class but do not have any more-specific code assigned.

The symbol shown in the column “Condition Name” is the condition name to use in PL/pgSQL. Condition names can be written in either upper or lower case. (Note that PL/pgSQL does not recognize warning, as opposed to error, condition names; those are classes 00, 01, and 02.)

For some types of errors, the server reports the name of a database object (a table, table column, data type, or constraint) associated with the error; for example, the name of the unique constraint that caused a `unique_violation` error. Such names are supplied in separate fields of the error report message so that applications need not try to extract them from the possibly-localized human-readable text of the message. As of PostgreSQL 9.3, complete coverage for this feature exists only for errors in SQLSTATE class 23 (integrity constraint violation), but this is likely to be expanded in future.

Table A.1. Postgres Pro Error Codes

Error Code	Condition Name
Class 00 — Successful Completion	
00000	successful_completion
Class 01 — Warning	
01000	warning
0100C	dynamic_result_sets_returned
01008	implicit_zero_bit_padding
01003	null_value_eliminated_in_set_function
01007	privilege_not_granted
01006	privilege_not_revoked
01004	string_data_right_truncation
01P01	deprecated_feature
Class 02 — No Data (this is also a warning class per the SQL standard)	
02000	no_data
02001	no_additional_dynamic_result_sets_returned
Class 03 — SQL Statement Not Yet Complete	
03000	sql_statement_not_yet_complete
Class 08 — Connection Exception	
08000	connection_exception
08003	connection_does_not_exist
08006	connection_failure
08001	sqlclient_unable_to_establish_sqlconnection

Error Code	Condition Name
08004	sqlserver_rejected_establishment_of_sqlconnection
08007	transaction_resolution_unknown
08P01	protocol_violation
Class 09 — Triggered Action Exception	
09000	triggered_action_exception
Class 0A — Feature Not Supported	
0A000	feature_not_supported
Class 0B — Invalid Transaction Initiation	
0B000	invalid_transaction_initiation
Class 0F — Locator Exception	
0F000	locator_exception
0F001	invalid_locator_specification
Class 0L — Invalid Grantor	
0L000	invalid_grantor
0LP01	invalid_grant_operation
Class 0P — Invalid Role Specification	
0P000	invalid_role_specification
Class 0Z — Diagnostics Exception	
0Z000	diagnostics_exception
0Z002	stacked_diagnostics_accessed_without_active_handler
Class 20 — Case Not Found	
20000	case_not_found
Class 21 — Cardinality Violation	
21000	cardinality_violation
Class 22 — Data Exception	
22000	data_exception
2202E	array_subscript_error
22021	character_not_in_repertoire
22008	datetime_field_overflow
22012	division_by_zero
22005	error_in_assignment
2200B	escape_character_conflict
22022	indicator_overflow
22015	interval_field_overflow
2201E	invalid_argument_for_logarithm
22014	invalid_argument_for_ntile_function
22016	invalid_argument_for_nth_value_function
2201F	invalid_argument_for_power_function
2201G	invalid_argument_for_width_bucket_function
22018	invalid_character_value_for_cast
22007	invalid_datetime_format

Error Code	Condition Name
22019	invalid_escape_character
2200D	invalid_escape_octet
22025	invalid_escape_sequence
22P06	nonstandard_use_of_escape_character
22010	invalid_indicator_parameter_value
22023	invalid_parameter_value
22013	invalid_preceding_or_following_size

Appendix B. Date/Time Support

Postgres Pro uses an internal heuristic parser for all date/time input support. Dates and times are input as strings, and are broken up into distinct fields with a preliminary determination of what kind of information can be in the field. Each field is interpreted and either assigned a numeric value, ignored, or rejected. The parser contains internal lookup tables for all textual fields, including months, days of the week, and time zones.

This appendix includes information on the content of these lookup tables and describes the steps used by the parser to decode dates and times.

B.1. Date/Time Input Interpretation

Date/time input strings are decoded using the following procedure.

1. Break the input string into tokens and categorize each token as a string, time, time zone, or number.
 - a. If the numeric token contains a colon (:), this is a time string. Include all subsequent digits and colons.
 - b. If the numeric token contains a dash (-), slash (/), or two or more dots (.), this is a date string which might have a text month. If a date token has already been seen, it is instead interpreted as a time zone name (e.g., `America/New_York`).
 - c. If the token is numeric only, then it is either a single field or an ISO 8601 concatenated date (e.g., `19990113` for January 13, 1999) or time (e.g., `141516` for 14:15:16).
 - d. If the token starts with a plus (+) or minus (-), then it is either a numeric time zone or a special field.
2. If the token is an alphabetic string, match up with possible strings:
 - a. See if the token matches any known time zone abbreviation. These abbreviations are supplied by the configuration file described in [Section B.4](#).
 - b. If not found, search an internal table to match the token as either a special string (e.g., `today`), day (e.g., `Thursday`), month (e.g., `January`), or noise word (e.g., `at`, `on`).
 - c. If still not found, throw an error.
3. When the token is a number or number field:
 - a. If there are eight or six digits, and if no other date fields have been previously read, then interpret as a “concatenated date” (e.g., `19990118` or `990118`). The interpretation is `YYYYMMDD` or `YYMMDD`.
 - b. If the token is three digits and a year has already been read, then interpret as day of year.
 - c. If four or six digits and a year has already been read, then interpret as a time (`HHMM` or `HHMMSS`).
 - d. If three or more digits and no date fields have yet been found, interpret as a year (this forces `yy-mm-dd` ordering of the remaining date fields).
 - e. Otherwise the date field ordering is assumed to follow the `DateStyle` setting: `mm-dd-yy`, `dd-mm-yy`, or `yy-mm-dd`. Throw an error if a month or day field is found to be out of range.
4. If BC has been specified, negate the year and add one for internal storage. (There is no year zero in the Gregorian calendar, so numerically 1 BC becomes year zero.)
5. If BC was not specified, and if the year field was two digits in length, then adjust the year to four digits. If the field is less than 70, then add 2000, otherwise add 1900.

Tip

Gregorian years AD 1–99 can be entered by using 4 digits with leading zeros (e.g., `0099` is AD 99).

B.2. Handling of Invalid or Ambiguous Timestamps

Ordinarily, if a date/time string is syntactically valid but contains out-of-range field values, an error will be thrown. For example, input specifying the 31st of February will be rejected.

During a daylight-savings-time transition, it is possible for a seemingly valid timestamp string to represent a nonexistent or ambiguous timestamp. Such cases are not rejected; the ambiguity is resolved by determining which UTC offset to apply. For example, supposing that the [TimeZone](#) parameter is set to `America/New_York`, consider

```
=> SELECT '2018-03-11 02:30'::timestampz;
       timestampz
-----
2018-03-11 03:30:00-04
(1 row)
```

Because that day was a spring-forward transition date in that time zone, there was no civil time instant 2:30AM; clocks jumped forward from 2AM EST to 3AM EDT. Postgres Pro interprets the given time as if it were standard time (UTC-5), which then renders as 3:30AM EDT (UTC-4).

Conversely, consider the behavior during a fall-back transition:

```
=> SELECT '2018-11-04 01:30'::timestampz;
       timestampz
-----
2018-11-04 01:30:00-05
(1 row)
```

On that date, there were two possible interpretations of 1:30AM; there was 1:30AM EDT, and then an hour later after clocks jumped back from 2AM EDT to 1AM EST, there was 1:30AM EST. Again, Postgres Pro interprets the given time as if it were standard time (UTC-5). We can force the other interpretation by specifying daylight-savings time:

```
=> SELECT '2018-11-04 01:30 EDT'::timestampz;
       timestampz
-----
2018-11-04 01:30:00-04
(1 row)
```

The precise rule that is applied in such cases is that an invalid timestamp that appears to fall within a jump-forward daylight savings transition is assigned the UTC offset that prevailed in the time zone just before the transition, while an ambiguous timestamp that could fall on either side of a jump-back transition is assigned the UTC offset that prevailed just after the transition. In most time zones this is equivalent to saying that “the standard-time interpretation is preferred when in doubt”.

In all cases, the UTC offset associated with a timestamp can be specified explicitly, using either a numeric UTC offset or a time zone abbreviation that corresponds to a fixed UTC offset. The rule just given applies only when it is necessary to infer a UTC offset for a time zone in which the offset varies.

B.3. Date/Time Key Words

[Table B.1](#) shows the tokens that are recognized as names of months.

Table B.1. Month Names

Month	Abbreviations
January	Jan
February	Feb
March	Mar
April	Apr
May	
June	Jun

Month	Abbreviations
July	Jul
August	Aug
September	Sep, Sept
October	Oct
November	Nov
December	Dec

Table B.2 shows the tokens that are recognized as names of days of the week.

Table B.2. Day of the Week Names

Day	Abbreviations
Sunday	Sun
Monday	Mon
Tuesday	Tue, Tues
Wednesday	Wed, Weds
Thursday	Thu, Thur, Thurs
Friday	Fri
Saturday	Sat

Table B.3 shows the tokens that serve various modifier purposes.

Table B.3. Date/Time Field Modifiers

Identifier	Description
AM	Time is before 12:00
AT	Ignored
JULIAN, JD, J	Next field is Julian Date
ON	Ignored
PM	Time is on or after 12:00
T	Next field is time

B.4. Date/Time Configuration Files

Since timezone abbreviations are not well standardized, Postgres Pro provides a means to customize the set of abbreviations accepted by the server. The `timezone_abbreviations` run-time parameter determines the active set of abbreviations. While this parameter can be altered by any database user, the possible values for it are under the control of the database administrator — they are in fact names of configuration files stored in `.../share/timezonesets/` of the installation directory. By adding or altering files in that directory, the administrator can set local policy for timezone abbreviations.

`timezone_abbreviations` can be set to any file name found in `.../share/timezonesets/`, if the file's name is entirely alphabetic. (The prohibition against non-alphabetic characters in `timezone_abbreviations` prevents reading files outside the intended directory, as well as reading editor backup files and other extraneous files.)

A timezone abbreviation file can contain blank lines and comments beginning with `#`. Non-comment lines must have one of these formats:

```
zone_abbreviation offset
zone_abbreviation offset D
zone_abbreviation time_zone_name
@INCLUDE file_name
@OVERRIDE
```

A *zone_abbreviation* is just the abbreviation being defined. An *offset* is an integer giving the equivalent offset in seconds from UTC, positive being east from Greenwich and negative being west. For example, -18000 would be five hours west of Greenwich, or North American east coast standard time. *D* indicates that the zone name represents local daylight-savings time rather than standard time.

Alternatively, a *time_zone_name* can be given, referencing a zone name defined in the IANA timezone database. The zone's definition is consulted to see whether the abbreviation is or has been in use in that zone, and if so, the appropriate meaning is used — that is, the meaning that was currently in use at the timestamp whose value is being determined, or the meaning in use immediately before that if it wasn't current at that time, or the oldest meaning if it was used only after that time. This behavior is essential for dealing with abbreviations whose meaning has historically varied. It is also allowed to define an abbreviation in terms of a zone name in which that abbreviation does not appear; then using the abbreviation is just equivalent to writing out the zone name.

Tip

Using a simple integer *offset* is preferred when defining an abbreviation whose offset from UTC has never changed, as such abbreviations are much cheaper to process than those that require consulting a time zone definition.

The **@INCLUDE** syntax allows inclusion of another file in the `.../share/timezonesets/` directory. Inclusion can be nested, to a limited depth.

The **@OVERRIDE** syntax indicates that subsequent entries in the file can override previous entries (typically, entries obtained from included files). Without this, conflicting definitions of the same timezone abbreviation are considered an error.

In an unmodified installation, the file **Default** contains all the non-conflicting time zone abbreviations for most of the world. Additional files **Australia** and **India** are provided for those regions: these files first include the **Default** file and then add or modify abbreviations as needed.

For reference purposes, a standard installation also contains files **Africa.txt**, **America.txt**, etc., containing information about every time zone abbreviation known to be in use according to the IANA timezone database. The zone name definitions found in these files can be copied and pasted into a custom configuration file as needed. Note that these files cannot be directly referenced as `timezone_abbreviations` settings, because of the dot embedded in their names.

Note

If an error occurs while reading the time zone abbreviation set, no new value is applied and the old set is kept. If the error occurs while starting the database, startup fails.

Caution

Time zone abbreviations defined in the configuration file override non-timezone meanings built into Postgres Pro. For example, the **Australia** configuration file defines SAT (for South Australian Standard Time). When this file is active, SAT will not be recognized as an abbreviation for Saturday.

Caution

If you modify files in `.../share/timezonesets/`, it is up to you to make backups — a normal database dump will not include this directory.

B.5. POSIX Time Zone Specifications

Postgres Pro can accept time zone specifications that are written according to the POSIX standard's rules for the TZ environment variable. POSIX time zone specifications are inadequate to deal with the complexity of real-world time zone history, but there are sometimes reasons to use them.

A POSIX time zone specification has the form

STD offset [DST [dstoffset] [, rule]]

(For readability, we show spaces between the fields, but spaces should not be used in practice.) The fields are:

- *STD* is the zone abbreviation to be used for standard time.
- *offset* is the zone's standard-time offset from UTC.
- *DST* is the zone abbreviation to be used for daylight-savings time. If this field and the following ones are omitted, the zone uses a fixed UTC offset with no daylight-savings rule.
- *dstoffset* is the daylight-savings offset from UTC. This field is typically omitted, since it defaults to one hour less than the standard-time *offset*, which is usually the right thing.
- *rule* defines the rule for when daylight savings is in effect, as described below.

In this syntax, a zone abbreviation can be a string of letters, such as `EST`, or an arbitrary string surrounded by angle brackets, such as `<UTC-05>`. Note that the zone abbreviations given here are only used for output, and even then only in some timestamp output formats. The zone abbreviations recognized in timestamp input are determined as explained in [Section B.4](#).

The offset fields specify the hours, and optionally minutes and seconds, difference from UTC. They have the format *hh[:mm[:ss]]* optionally with a leading sign (+ or -). The positive sign is used for zones west of Greenwich. (Note that this is the opposite of the ISO-8601 sign convention used elsewhere in Postgres Pro.) *hh* can have one or two digits; *mm* and *ss* (if used) must have two.

The daylight-savings transition *rule* has the format

dstdate [/ dsttime] , stddate [/ stdtime]

(As before, spaces should not be included in practice.) The *dstdate* and *dsttime* fields define when daylight-savings time starts, while *stddate* and *stdtime* define when standard time starts. (In some cases, notably in zones south of the equator, the former might be later in the year than the latter.) The date fields have one of these formats:

n

A plain integer denotes a day of the year, counting from zero to 364, or to 365 in leap years.

Jn

In this form, *n* counts from 1 to 365, and February 29 is not counted even if it is present. (Thus, a transition occurring on February 29 could not be specified this way. However, days after February have the same numbers whether it's a leap year or not, so that this form is usually more useful than the plain-integer form for transitions on fixed dates.)

Mm.n.d

This form specifies a transition that always happens during the same month and on the same day of the week. *m* identifies the month, from 1 to 12. *n* specifies the *n*'th occurrence of the weekday identified by *d*. *n* is a number between 1 and 4, or 5 meaning the last occurrence of that weekday in the month (which could be the fourth or the fifth). *d* is a number between 0 and 6, with 0 indicating Sunday. For example, `M3.2.0` means “the second Sunday in March”.

Note

The M format is sufficient to describe many common daylight-savings transition laws. But note that none of these variants can deal with daylight-savings law changes, so in practice the historical data stored for named time zones (in the IANA time zone database) is necessary to interpret past time stamps correctly.

The time fields in a transition rule have the same format as the offset fields described previously, except that they cannot contain signs. They define the current local time at which the change to the other time occurs. If omitted, they default to `02:00:00`.

If a daylight-savings abbreviation is given but the transition *rule* field is omitted, the fallback behavior is to use the rule `M3.2.0, M11.1.0`, which corresponds to USA practice as of 2020 (that is, spring forward on the second Sunday of March, fall back on the first Sunday of November, both transitions occurring at 2AM prevailing time). Note that this rule does not give correct USA transition dates for years before 2007.

As an example, `CET-1CEST,M3.5.0,M10.5.0/3` describes the current (as of 2020) timekeeping practice in Paris. This specification says that standard time has the abbreviation `CET` and is one hour ahead (east) of UTC; daylight savings time has the abbreviation `CEST` and is implicitly two hours ahead of UTC; daylight savings time begins on the last Sunday in March at 2AM CET and ends on the last Sunday in October at 3AM CEST.

The four timezone names `EST5EDT`, `CST6CDT`, `MST7MDT`, and `PST8PDT` look like they are POSIX zone specifications. However, they actually are treated as named time zones because (for historical reasons) there are files by those names in the IANA time zone database. The practical implication of this is that these zone names will produce valid historical USA daylight-savings transitions, even when a plain POSIX specification would not.

One should be wary that it is easy to misspell a POSIX-style time zone specification, since there is no check on the reasonableness of the zone abbreviation(s). For example, `SET TIMEZONE TO FOOBAR0` will work, leaving the system effectively using a rather peculiar abbreviation for UTC.

B.6. History of Units

The SQL standard states that “Within the definition of a ‘datetime literal’, the ‘datetime values’ are constrained by the natural rules for dates and times according to the Gregorian calendar”. Postgres Pro follows the SQL standard's lead by counting dates exclusively in the Gregorian calendar, even for years before that calendar was in use. This rule is known as the *proleptic Gregorian calendar*.

The Julian calendar was introduced by Julius Caesar in 45 BC. It was in common use in the Western world until the year 1582, when countries started changing to the Gregorian calendar. In the Julian calendar, the tropical year is approximated as $365 \frac{1}{4}$ days = 365.25 days. This gives an error of about 1 day in 128 years.

The accumulating calendar error prompted Pope Gregory XIII to reform the calendar in accordance with instructions from the Council of Trent. In the Gregorian calendar, the tropical year is approximated as $365 + 97 / 400$ days = 365.2425 days. Thus it takes approximately 3300 years for the tropical year to shift one day with respect to the Gregorian calendar.

The approximation $365+97/400$ is achieved by having 97 leap years every 400 years, using the following rules:

Every year divisible by 4 is a leap year.

However, every year divisible by 100 is not a leap year.

However, every year divisible by 400 is a leap year after all.

So, 1700, 1800, 1900, 2100, and 2200 are not leap years. But 1600, 2000, and 2400 are leap years. By contrast, in the older Julian calendar all years divisible by 4 are leap years.

The papal bull of February 1582 decreed that 10 days should be dropped from October 1582 so that 15 October should follow immediately after 4 October. This was observed in Italy, Poland, Portugal, and Spain. Other Catholic countries followed shortly after, but Protestant countries were reluctant to change, and the Greek Orthodox countries didn't change until the start of the 20th century. The reform was observed by Great Britain and its dominions (including what is now the USA) in 1752. Thus 2 September 1752 was followed by 14 September 1752. This is why Unix systems that have the `cal` program produce the following:

```
$ cal 9 1752
   September 1752
 S  M Tu  W Th  F  S
      1  2 14 15 16
17 18 19 20 21 22 23
24 25 26 27 28 29 30
```

But, of course, this calendar is only valid for Great Britain and dominions, not other places. Since it would be difficult and confusing to try to track the actual calendars that were in use in various places at various times, Postgres Pro does not try, but rather follows the Gregorian calendar rules for all dates, even though this method is not historically accurate.

Different calendars have been developed in various parts of the world, many predating the Gregorian system. For example, the beginnings of the Chinese calendar can be traced back to the 14th century BC. Legend has it that the Emperor Huangdi invented that calendar in 2637 BC. The People's Republic of China uses the Gregorian calendar for civil purposes. The Chinese calendar is used for determining festivals.

B.7. Julian Dates

In the Julian Date system, each day has a sequential number, starting from JD 0 (which is sometimes called *the* Julian Date). JD 0 corresponds to 1 January 4713 BC in the Julian calendar, or 24 November 4714 BC in the Gregorian calendar. Julian Date counting is most often used by astronomers for labeling their nightly observations, and therefore a date runs from noon UTC to the next noon UTC, rather than from midnight to midnight: JD 0 designates the 24 hours from noon UTC on 24 November 4714 BC to noon UTC on 25 November 4714 BC.

This definition does, however, provide a way to obtain the astronomical definition when you need it: do the arithmetic in time zone UTC+12. For example,

```

      extract
-----
2459388.9583333333333333333333
(1 row)

```

[illegible]

```
=> SELECT extract(julian from date '2021-06-23');
extract
-----
2459389
(1 row)
```

Appendix C. SQL Key Words

[Table C.1](#) lists all tokens that are key words in the SQL standard and in Postgres Pro Enterprise 17.7.1. Background information can be found in [Section 4.1.1](#). (For space reasons, only the latest two versions of the SQL standard, and SQL-92 for historical comparison, are included. The differences between those and the other intermediate standard versions are small.)

SQL distinguishes between *reserved* and *non-reserved* key words. According to the standard, reserved key words are the only real key words; they are never allowed as identifiers. Non-reserved key words only have a special meaning in particular contexts and can be used as identifiers in other contexts. Most non-reserved key words are actually the names of built-in tables and functions specified by SQL. The concept of non-reserved key words essentially only exists to declare that some predefined meaning is attached to a word in some contexts.

In the Postgres Pro parser, life is a bit more complicated. There are several different classes of tokens ranging from those that can never be used as an identifier to those that have absolutely no special status in the parser, but are considered ordinary identifiers. (The latter is usually the case for functions specified by SQL.) Even reserved key words are not completely reserved in Postgres Pro, but can be used as column labels (for example, `SELECT 55 AS CHECK`, even though `CHECK` is a reserved key word).

In [Table C.1](#) in the column for Postgres Pro we classify as “non-reserved” those key words that are explicitly known to the parser but are allowed as column or table names. Some key words that are otherwise non-reserved cannot be used as function or data type names and are marked accordingly. (Most of these words represent built-in functions or data types with special syntax. The function or type is still available but it cannot be redefined by the user.) Labeled “reserved” are those tokens that are not allowed as column or table names. Some reserved key words are allowable as names for functions or data types; this is also shown in the table. If not so marked, a reserved key word is only allowed as a column label. A blank entry in this column means that the word is treated as an ordinary identifier by Postgres Pro.

Furthermore, while most key words can be used as “bare” column labels without writing `AS` before them (as described in [Section 7.3.2](#)), there are a few that require a leading `AS` to avoid ambiguity. These are marked in the table as “requires AS”.

As a general rule, if you get spurious parser errors for commands that use any of the listed key words as an identifier, you should try quoting the identifier to see if the problem goes away.

It is important to understand before studying [Table C.1](#) that the fact that a key word is not reserved in Postgres Pro does not mean that the feature related to the word is not implemented. Conversely, the presence of a key word does not indicate the existence of a feature.

Appendix D. SQL Conformance

This section attempts to outline to what extent Postgres Pro conforms to the current SQL standard. The following information is not a full statement of conformance, but it presents the main topics in as much detail as is both reasonable and useful for users.

The formal name of the SQL standard is ISO/IEC 9075 “Database Language SQL”. A revised version of the standard is released from time to time; the most recent update appearing in 2023. The 2023 version is referred to as ISO/IEC 9075:2023, or simply as SQL:2023. The versions prior to that were SQL:2016, SQL:2011, SQL:2008, SQL:2006, SQL:2003, SQL:1999, and SQL-92. Each version replaces the previous one, so claims of conformance to earlier versions have no official merit. Postgres Pro development aims for conformance with the latest official version of the standard where such conformance does not contradict traditional features or common sense. Many of the features required by the SQL standard are supported, though sometimes with slightly differing syntax or function. Further moves towards conformance can be expected over time.

SQL-92 defined three feature sets for conformance: Entry, Intermediate, and Full. Most database management systems claiming SQL standard conformance were conforming at only the Entry level, since the entire set of features in the Intermediate and Full levels was either too voluminous or in conflict with legacy behaviors.

Starting with SQL:1999, the SQL standard defines a large set of individual features rather than the ineffectively broad three levels found in SQL-92. A large subset of these features represents the “Core” features, which every conforming SQL implementation must supply. The rest of the features are purely optional.

The standard is split into a number of parts, each also known by a shorthand name:

- ISO/IEC 9075-1 Framework (SQL/Framework)
- ISO/IEC 9075-2 Foundation (SQL/Foundation)
- ISO/IEC 9075-3 Call Level Interface (SQL/CLI)
- ISO/IEC 9075-4 Persistent Stored Modules (SQL/PSM)
- ISO/IEC 9075-9 Management of External Data (SQL/MED)
- ISO/IEC 9075-10 Object Language Bindings (SQL/OLB)
- ISO/IEC 9075-11 Information and Definition Schemas (SQL/Schemata)
- ISO/IEC 9075-13 Routines and Types using the Java Language (SQL/JRT)
- ISO/IEC 9075-14 XML-related specifications (SQL/XML)
- ISO/IEC 9075-15 Multi-dimensional arrays (SQL/MDA)
- ISO/IEC 9075-16 Property Graph Queries (SQL/PGQ)

Note that some part numbers are not (or no longer) used.

The Postgres Pro core covers parts 1, 2, 9, 11, and 14. Part 3 is covered by the ODBC driver, and part 13 is covered by the PL/Java plug-in, but exact conformance is currently not being verified for these components. There are currently no implementations of parts 4, 10, 15, and 16 for Postgres Pro.

Postgres Pro supports most of the major features of SQL:2023. Out of 177 mandatory features required for full Core conformance, Postgres Pro conforms to at least 170. In addition, there is a long list of supported optional features. It might be worth noting that at the time of writing, no current version of any database management system claims full conformance to Core SQL:2023.

In the following two sections, we provide a list of those features that Postgres Pro supports, followed by a list of the features defined in SQL:2023 which are not yet supported in Postgres Pro. Both of these lists are approximate: There might be minor details that are

nonconforming for a feature that is listed as supported, and large parts of an unsupported feature might in fact be implemented. The main body of the documentation always contains the most accurate information about what does and does not work.

Note

Feature codes containing a hyphen are subfeatures. Therefore, if a particular subfeature is not supported, the main feature is listed as unsupported even if some other subfeatures are supported.

D.1. Supported Features

Identifier	Core?	Description	Comment
B012		Embedded C	
B021		Direct SQL	
B128		Routine language SQL	
E011	Core	Numeric data types	
E011-01	Core	INTEGER and SMALLINT data types	
E011-02	Core	REAL, DOUBLE PRECISION, and FLOAT data types	
E011-03	Core	DECIMAL and NUMERIC data types	
E011-04	Core	Arithmetic operators	
E011-05	Core	Numeric comparison	
E011-06	Core	Implicit casting among the numeric data types	
E021	Core	Character data types	
E021-01	Core	CHARACTER data type	
E021-02	Core	CHARACTER VARYING data type	
E021-03	Core	Character literals	
E021-04	Core	CHARACTER_LENGTH function	trims trailing spaces from CHARACTER values before counting
E021-05	Core	OCTET_LENGTH function	
E021-06	Core	SUBSTRING function	
E021-07	Core	Character concatenation	
E021-08	Core	UPPER and LOWER functions	
E021-09	Core	TRIM function	
E021-10	Core	Implicit casting among the character string types	
E021-11	Core	POSITION function	
E021-12	Core	Character comparison	
E031	Core	Identifiers	
E031-01	Core	Delimited identifiers	
E031-02	Core	Lower case identifiers	
E031-03	Core	Trailing underscore	
E051	Core	Basic query specification	
E051-01	Core	SELECT DISTINCT	
E051-02	Core	GROUP BY clause	
E051-04	Core	GROUP BY can contain columns not in <select list>	

Identifier	Core?	Description	Comment
E051-05	Core	Select list items can be renamed	
E051-06	Core	HAVING clause	
E051-07	Core	Qualified * in select list	
E051-08	Core	Correlation names in the FROM clause	
E051-09	Core	Rename columns in the FROM clause	
E061	Core	Basic predicates and search conditions	
E061-01	Core	Comparison predicate	
E061-02	Core	BETWEEN predicate	
E061-03	Core	IN predicate with list of values	
E061-04	Core	LIKE predicate	
E061-05	Core	LIKE predicate ESCAPE clause	
E061-06	Core	NULL predicate	
E061-07	Core	Quantified comparison predicate	
E061-08	Core	EXISTS predicate	
E061-09	Core	Subqueries in comparison predicate	
E061-11	Core	Subqueries in IN predicate	
E061-12	Core	Subqueries in quantified comparison predicate	
E061-13	Core	Correlated subqueries	
E061-14	Core	Search condition	
E071	Core	Basic query expressions	
E071-01	Core	UNION DISTINCT table operator	
E071-02	Core	UNION ALL table operator	
E071-03	Core	EXCEPT DISTINCT table operator	
E071-05	Core	Columns combined via table operators need not have exactly the same data type	
E071-06	Core	Table operators in subqueries	
E081	Core	Basic Privileges	
E081-01	Core	SELECT privilege	
E081-02	Core	DELETE privilege	
E081-03	Core	INSERT privilege at the table level	
E081-04	Core	UPDATE privilege at the table level	
E081-05	Core	UPDATE privilege at the column level	
E081-06	Core	REFERENCES privilege at the table level	
E081-07	Core	REFERENCES privilege at the column level	
E081-08	Core	WITH GRANT OPTION	
E081-09	Core	USAGE privilege	
E081-10	Core	EXECUTE privilege	
E091	Core	Set functions	
E091-01	Core	AVG	
E091-02	Core	COUNT	
E091-03	Core	MAX	

Identifier	Core?	Description	Comment
E091-04	Core	MIN	
E091-05	Core	SUM	
E091-06	Core	ALL quantifier	
E091-07	Core	DISTINCT quantifier	
E101	Core	Basic data manipulation	
E101-01	Core	INSERT statement	
E101-03	Core	Searched UPDATE statement	
E101-04	Core	Searched DELETE statement	
E111	Core	Single row SELECT statement	
E121	Core	Basic cursor support	
E121-01	Core	DECLARE CURSOR	
E121-02	Core	ORDER BY columns need not be in select list	
E121-03	Core	Value expressions in ORDER BY clause	
E121-04	Core	OPEN statement	
E121-06	Core	Positioned UPDATE statement	
E121-07	Core	Positioned DELETE statement	
E121-08	Core	CLOSE statement	
E121-10	Core	FETCH statement implicit NEXT	
E121-17	Core	WITH HOLD cursors	
E131	Core	Null value support (nulls in lieu of values)	
E141	Core	Basic integrity constraints	
E141-01	Core	NOT NULL constraints	
E141-02	Core	UNIQUE constraints of NOT NULL columns	
E141-03	Core	PRIMARY KEY constraints	
E141-04	Core	Basic FOREIGN KEY constraint with the NO ACTION default for both referential delete action and referential update action	
E141-06	Core	CHECK constraints	
E141-07	Core	Column defaults	
E141-08	Core	NOT NULL inferred on PRIMARY KEY	
E141-10	Core	Names in a foreign key can be specified in any order	
E151	Core	Transaction support	
E151-01	Core	COMMIT statement	
E151-02	Core	ROLLBACK statement	
E152	Core	Basic SET TRANSACTION statement	
E152-01	Core	SET TRANSACTION statement: ISOLATION LEVEL SERIALIZABLE clause	
E152-02	Core	SET TRANSACTION statement: READ ONLY and READ WRITE clauses	
E153	Core	Updatable queries with subqueries	
E161	Core	SQL comments using leading double minus	
E171	Core	SQLSTATE support	
E182	Core	Host language binding	

Identifier	Core?	Description	Comment
F021	Core	Basic information schema

T878		SQL/JSON item method: timestamp precision	
T879		JSON in equality operations	with jsonb
T880		JSON in grouping operations	with jsonb
X010		XML type	
X011		Arrays of XML type	
X014		Attributes of XML type	
X016		Persistent XML values	
X020		XMLConcat	
X031		XMLElement	
X032		XMLForest	
X034		XMLAgg	
X035		XMLAgg: ORDER BY option	
X036		XMLComment	
X037		XMLPI	
X038		XMLText	supported except for RETURNING
X040		Basic table mapping	
X041		Basic table mapping: null absent	
X042		Basic table mapping: null as nil	
X043		Basic table mapping: table as forest	
X044		Basic table mapping: table as element	
X045		Basic table mapping: with target namespace	
X046		Basic table mapping: data mapping	
X047		Basic table mapping: metadata mapping	

Identifier	Core?	Description	Comment
X048		Basic table mapping: base64 encoding of binary strings	
X049		Basic table mapping: hex encoding of binary strings	
X050		Advanced table mapping	
X051		Advanced table mapping: null absent	
X052		Advanced table mapping: null as nil	
X053		Advanced table mapping: table as forest	
X054		Advanced table mapping: table as element	
X055		Advanced table mapping: with target namespace	
X056		Advanced table mapping: data mapping

X058		Advanced table mapping: base64 encoding of binary strings	
X059		Advanced table mapping: hex encoding of binary strings	
X060		XMLParse: character string input and CONTENT option	
X061		XMLParse: character string input and DOCUMENT option	
X069		XMLSerialize: INDENT	
X070		XMLSerialize: character string serialization and CONTENT option	
X071		XMLSerialize: character string serialization and DOCUMENT option	
X072		XMLSerialize: character string serialization	
X090		XML document predicate	
X120		XML parameters in SQL routines	
X121		XML parameters in external routines	
X221		XML passing mechanism BY VALUE	
X301		XMLTable: derived column list option	
X302		XMLTable: ordinality column option	
X303		XMLTable: column default option	
X304		XMLTable: passing a context item	must be XML DOCUMENT
X400		Name and identifier mapping	
X410		Alter column data type: XML type	

D.2. Unsupported Features

The following features defined in SQL:2023 are not implemented in this release of Postgres Pro. In a few cases, equivalent functionality is available.

Identifier	Core?	Description	Comment
B011		Embedded Ada	
B013		Embedded COBOL	
B014		Embedded Fortran	
B015		Embedded MUMPS	
B016		Embedded Pascal	
B017		Embedded PL/I	
B030		Enhanced dynamic SQL	
B031		Basic dynamic SQL	

Identifier	Core?	Description	Comment
B032		Extended dynamic SQL	
B033		Untyped SQL-invoked function arguments	
B034		Dynamic specification of cursor attributes	
B035		Non-extended descriptor names	
B036		Describe input statement	
B041		Extensions to embedded SQL exception declarations	
B051		Enhanced execution rights	
B111		Module language Ada	
B112		Module language C	
B113		Module language COBOL	
B114		Module language Fortran	
B115		Module language MUMPS	
B116		Module language Pascal	
B117		Module language PL/I	
B121		Routine language Ada	
B122		Routine language C	
B123		Routine language COBOL	
B124		Routine language Fortran	
B125		Routine language MUMPS	
B126		Routine language Pascal	
B127		Routine language PL/I	
B200		Polymorphic table functions	
B201		More than one PTF generic table parameter	
B202		PTF copartitioning	
B203		More than one copartition specification	
B204		PRUNE WHEN EMPTY	
B205		Pass-through columns	
B206		PTF descriptor parameters	
B207		Cross products of partitionings	
B208		PTF component procedure interface	
B209		PTF extended names	
B211		Module language Ada: VARCHAR and NUMERIC support	
B221		Routine language Ada: VARCHAR and NUMERIC support	
F054		TIMESTAMP in DATE type precedence list	
F120		Get diagnostics statement	
F121		Basic diagnostics management	
F122		Enhanced diagnostics management	
F123		All diagnostics	
F124		SET TRANSACTION statement: DIAGNOSTICS SIZE clause	
F263		Comma-separated predicates in simple CASE expression	
F291		UNIQUE predicate	

Identifier	Core?	Description	Comment
F301		CORRESPONDING in query expressions

X300		XMLTable	XPath 1.0 only
X305		XMLTable: initializing an XQuery variable	

D.3. XML Limits and Conformance to SQL/XML

Significant revisions to the XML-related specifications in ISO/IEC 9075-14 (SQL/XML) were introduced with SQL:2006. Postgres Pro's implementation of the XML data type and related functions largely follows the earlier 2003 edition, with some borrowing from later editions. In particular:

- Where the current standard provides a family of XML data types to hold “document” or “content” in untyped or XML Schema-typed variants, and a type XML (SEQUENCE) to hold arbitrary pieces of XML content, Postgres Pro provides the single `xml` type, which can hold “document” or “content”. There is no equivalent of the standard's “sequence” type.
- Postgres Pro provides two functions introduced in SQL:2006, but in variants that use the XPath 1.0 language, rather than XML Query as specified for them in the standard.
- Postgres Pro does not support the `RETURNING CONTENT` or `RETURNING SEQUENCE` clauses, functions which are defined to have these in the specification are implicitly returning content.

This section presents some of the resulting differences you may encounter.

D.3.1. Queries Are Restricted to XPath 1.0

The Postgres Pro-specific functions `xpath()` and `xpath_exists()` query XML documents using the XPath language. Postgres Pro also provides XPath-only variants of the standard functions `XMLEXISTS` and `XMLTABLE`, which officially use the XQuery language. For all of these functions, Postgres Pro relies on the libxml2 library, which provides only XPath 1.0.

There is a strong connection between the XQuery language and XPath versions 2.0 and later: any expression that is syntactically valid and executes successfully in both produces the same result (with a minor exception for expressions containing numeric character references or predefined entity references, which XQuery replaces with the corresponding character while XPath leaves them alone). But there is no such connection between these languages and XPath 1.0; it was an earlier language and differs in many respects.

There are two categories of limitation to keep in mind: the restriction from XQuery to XPath for the functions specified in the SQL standard, and the restriction of XPath to version 1.0 for both the standard and the Postgres Pro-specific functions.

D.3.1.1. Restriction of XQuery to XPath

Features of XQuery beyond those of XPath include:

- XQuery expressions can construct and return new XML nodes, in addition to all possible XPath values. XPath can create and return values of the atomic types (numbers, strings, and so on) but can only return XML nodes that were already present in documents supplied as input to the expression.
- XQuery has control constructs for iteration, sorting, and grouping.
- XQuery allows declaration and use of local functions.

Recent XPath versions begin to offer capabilities overlapping with these (such as functional-style `for-each` and `sort`, anonymous functions, and `parse-xml` to create a node from a string), but such features were not available before XPath 3.0.

D.3.1.2. Restriction of XPath to 1.0

For developers familiar with XQuery and XPath 2.0 or later, XPath 1.0 presents a number of differences to contend with:

- The fundamental type of an XQuery/XPath expression, the **sequence**, which can contain XML nodes, atomic values, or both, does not exist in XPath 1.0. A 1.0 expression can only produce a node-set (containing zero or more XML nodes), or a single atomic value.
- Unlike an XQuery/XPath sequence, which can contain any desired items in any desired order, an XPath 1.0 node-set has no guaranteed order and, like any set, does not allow multiple appearances of the same item.

Note

The libxml2 library does seem to always return node-sets to Postgres Pro with their members in the same relative order they had in the input document. Its documentation does not commit to this behavior, and an XPath 1.0 expression cannot control it.

- While XQuery/XPath provides all of the types defined in XML Schema and many operators and functions over those types, XPath 1.0 has only node-sets and the three atomic types `boolean`, `double`, and `string`.
- XPath 1.0 has no conditional operator. An XQuery/XPath expression such as `if ( hat ) then hat/@size else "no hat"` has no XPath 1.0 equivalent.
- XPath 1.0 has no ordering comparison operator for strings. Both `"cat" < "dog"` and `"cat" > "dog"` are false, because each is a numeric comparison of two NaNs. In contrast, `=` and `!=` do compare the strings as strings.
- XPath 1.0 blurs the distinction between *value comparisons* and *general comparisons* as XQuery/XPath define them. Both `sale/@hatsize = 7` and `sale/@customer = "alice"` are existentially quantified comparisons, true if there is any `sale` with the given value for the attribute, but `sale/@taxable = false()` is a value comparison to the *effective boolean value* of a whole node-set. It is true only if no `sale` has a `taxable` attribute at all.
- In the XQuery/XPath data model, a *document node* can have either document form (i.e., exactly one top-level element, with only comments and processing instructions outside of it) or content form (with those constraints relaxed). Its equivalent in XPath 1.0, the *root node*, can only be in document form. This is part of the reason an `xml` value passed as the context item to any Postgres Pro XPath-based function must be in document form.

The differences highlighted here are not all of them. In XQuery and the 2.0 and later versions of XPath, there is an XPath 1.0 compatibility mode, and the W3C lists of [function library changes](#) and [language changes](#) applied in that mode offer a more complete (but still not exhaustive) account of the differences. The compatibility mode cannot make the later languages exactly equivalent to XPath 1.0.

D.3.1.3. Mappings between SQL and XML Data Types and Values

In SQL:2006 and later, both directions of conversion between standard SQL data types and the XML Schema types are specified precisely. However, the rules are expressed using the types and semantics of XQuery/XPath, and have no direct application to the different data model of XPath 1.0.

When Postgres Pro maps SQL data values to XML (as in `xml element`), or XML to SQL (as in the output columns of `xml table`), except for a few cases treated specially, Postgres Pro simply assumes that the XML data type's XPath 1.0 string form will be valid as the text-input form of the SQL datatype, and conversely. This rule has the virtue of simplicity while producing, for many data types, results similar to the mappings specified in the standard.

Where interoperability with other systems is a concern, for some data types, it may be necessary to use data type formatting functions (such as those in [Section 9.8](#)) explicitly to produce the standard mappings.

D.3.2. Incidental Limits of the Implementation

This section concerns limits that are not inherent in the libxml2 library, but apply to the current implementation in Postgres Pro.

D.3.2.1. Only BY VALUE Passing Mechanism Is Supported

The SQL standard defines two *passing mechanisms* that apply when passing an XML argument from SQL to an XML function or receiving a result: `BY REF`, in which a particular XML value retains its node identity, and `BY VALUE`, in which the content of the XML is passed but node identity is not preserved. A mechanism can be specified before a list of parameters, as the default mechanism for all of them, or after any parameter, to override the default.

To illustrate the difference, if *x* is an XML value, these two queries in an SQL:2006 environment would produce true and false, respectively:

```
SELECT XMLQUERY('$a is $b' PASSING BY REF x AS a, x AS b NULL ON EMPTY);  
SELECT XMLQUERY('$a is $b' PASSING BY VALUE x AS a, x AS b NULL ON EMPTY);
```

Postgres Pro will accept `BY VALUE` or `BY REF` in an `XMLEXISTS` or `XMLTABLE` construct, but it ignores them. The `xml` data type holds a character-string serialized representation, so there is no node identity to preserve, and passing is always effectively `BY VALUE`.

D.3.2.2. Cannot Pass Named Parameters to Queries

The XPath-based functions support passing one parameter to serve as the XPath expression's context item, but do not support passing additional values to be available to the expression as named parameters.

D.3.2.3. No XML (SEQUENCE) Type

The Postgres Pro `xml` data type can only hold a value in `DOCUMENT` or `CONTENT` form. An XQuery/XPath expression context item must be a single XML node or atomic value, but XPath 1.0 further restricts it to be only an XML node, and has no node type allowing `CONTENT`. The upshot is that a well-formed `DOCUMENT` is the only form of XML value that Postgres Pro can supply as an XPath context item.

Appendix E. Release Notes

The release notes contain the significant changes in each Postgres Pro Enterprise release, with major features and migration issues listed at the top. The release notes do not contain changes that affect only a few users or changes that are internal and therefore not user-visible. For example, the optimizer is improved in almost every release, but the improvements are usually observed by users as simply faster queries.

E.1. Postgres Pro Enterprise 17.7.1

Release Date: 2025-12-23

E.1.1. Overview

This release is based on PostgreSQL 17.7 and Postgres Pro Enterprise 17.6.1. All changes inherited from PostgreSQL 17.7 are listed in [PostgreSQL 17.7 Release Notes](#). As compared with Postgres Pro Enterprise 17.6.1, this version also provides the following changes:

- Improved the search mechanism for matching `mchar` and `mvarchar` strings using the `LIKE` operator. Optimized case-insensitive comparison results in significant speed increase. This may be useful for 1C.
- Improved performance of [getting information on crashes of a backend](#) by optimizing utility functions and commands.
- Improved performance in cases where [resource prioritization](#) is disabled.
- Implemented password masking in the server log by default to protect sensitive data from being revealed.
- Added the [enable_sorted_merge_join](#) configuration parameter that enables or disables the query planner's use of merge joins in plans with sorting.
- Added the [max_wal_segments_prealloc](#) configuration parameter, which enables the background writer to create WAL segments in advance during its main operation cycle, reducing the load on backend processes. The parameter sets the maximum number of such segments.
- Added details, like information about internal signal handlers, to `crash_info` output files.
- Limited the maximum number of assigned transaction IDs to 2^{63} . Now a warning is also shown when a threshold of 10 million XIDs is reached. Once the maximum number of XIDs is reached, new transactions cannot be started, but read-only queries continue to work.
- Implemented the following enhancements and bug fixes for [CFS](#):
 - Added the [cfs_compression](#) configuration parameter that allows you to temporary disable CFS compression. It speeds up the migration of large compressed tables.
 - Fixed an issue with [CFS](#) failing to compress relation files where OID exceeds `INT32_MAX`. The issue occurred when moving an existing table to a CFS tablespace.
- Fixed an issue with the vacuum process, which could wait indefinitely to freeze a page due to the [BufferPin](#) wait event. The issue could occur in case there was a buffer that was constantly used by backends.
- Fixed a bug that caused incorrect calculation of the internal [vacuum_freeze_min_age](#) threshold, which should equal half of the [autovacuum_freeze_max_age](#) value. Previously, this bug could cause internal miscalculation of autovacuum parameters and, consequently, unnecessary vacuum runs.
- Fixed an issue where the limit set by the [max_backend_memory](#) configuration parameter was not taken into account for the “bump” memory context when allocating memory for a backend.
- Added new values of the `PGPRO_TUNE` environment variable used by `initdb`.
- Added the [auto_dump](#) extension, which collects data for long-running and problematic queries and creates files with all information to reproduce them for troubleshooting.
- Added the [ldap2pg](#) utility that automates the creation, update, and removal of Postgres Pro roles and users from an enterprise directory.
- Added the [pg_trgm_mchar](#) extension, which allows fast trigram-based search for similar `mchar` and `mvarchar` strings. This extension also provides support of GIN indexes for `mchar` and `mvarchar` types. This may be useful for 1C.
- Added the [pgpro_planner](#) extension that provides query transformations and optimizations to produce efficient query execution plans and improve performance.

- Added the [pgpro_cpumeter](#) extension, which provides access to a new CPU usage monitoring system function. This `pgpro_cpumeter` function continuously collects and records information about CPU cores used by Postgres Pro server processes.
- Upgraded [apache_age](#) to version 1.5.2.
- Upgraded [aqo](#) to provide the following enhancements and bug fixes:
 - Improved the mechanism of [aqo](#) learning on subqueries.
 - Fixed an issue where the [aqo_cleanup](#) function did not remove data in the basic mode.
- Upgraded the [BiHA](#) solution to provide the following optimizations and bug fixes:
 - Fixed an issue where the leader was lost after non-incremental upgrade of a BiHA cluster from Postgres Pro Enterprise 17.4 or lower to 17.6.
 - Fixed a bug that occurred when the MIN value of the [synchronous_standby_names](#) configuration parameter was higher than 0 and the current number of standbys was higher than the `num_sync` value. This could cause hanging of transactions in case of replication hanging.
 - Fixed a bug where [biha.add_to_ssn](#), [biha.remove_from_ssn](#), and [biha.set_ssn](#) functions modified the list of synchronous standbys of the [synchronous_standby_names](#) parameter on the leader node only.
 - Fixed a bug where `bihactl init --convert` failed when executed in a Postgres Pro Enterprise instance with configured `pg_proaudit`.
 - Fixed an issue of multiple error messages caused by large heartbeats that might not fit into the shared memory buffer. The issue was solved by decreasing the size of heartbeats written to WAL.
 - Fixed memory leaks caused by incorrect error handling.
 - Fixed redundant memory allocation checks.
- Upgraded [multimaster](#) to provide the following bug fixes:
 - Fixed an issue where multimaster returned an error when executing read-write transactions containing queries to [postgres_fdw](#) foreign tables. The root cause was that `postgres_fdw` does not support two-phase commit transactions used by multimaster. To fix the issue, the [postgres_fdw.read_only_transactions](#) configuration parameter was implemented. When set to `ON`, it enables read-only queries to foreign tables in read-write transactions, which allows seamless operation of multimaster and `postgres_fdw`.
 - Fixed an issue of potential transaction commit latency caused by an error in the exchange logic for messages containing information about transaction application on nodes.
- Upgraded [orafce](#) to version 4.16.3.
- Upgraded [pageinspect](#) to fix an issue with the [page_header](#) function, which returned incorrect information for double xmax and some index pages. Specifically, the sequence of columns was confused and the `prune_xid` value was returned in the `xid_base` column. Now the information is returned correctly.
- Upgraded [pg_filedump](#) to version 18.0.
- Upgraded [pg_hint_plan](#) to version 1.7.1 to provide the following enhancements and bug fixes:
 - Implemented the ability to re-read hint strings if hints were added outside the standard planner. This functionality is required to provide interoperability with the [pgpro_multiplan](#) extension when working with plans that are based on hint sets.
 - Fixed an issue in `pg_hint_plan` that could result in an infinite loop while processing queries with dollar-quoted strings.
- Upgraded `pg_portal_modify` to version 0.3.6.
- Upgraded [pg_proaudit](#) to provide the following enhancements and bug fixes:
 - Added support for logging of the following event types: `ANALYZE`, `DISCARD ALL`, `DISCARD PLANS`, `DISCARD SEQUENCES`, `DISCARD TEMP` (for temporary tables), `CHECKPOINT`, `FETCH`, and `MOVE`.
 - Added the new event class `MISC`. This class allows logging of all events (including those mentioned above) not related to other event classes.

- Added a [new method](#) for logging security events. Events in CEF format can now be logged not only in a separate file but also in syslog.
- Added a new event log field: application name. **AUTHENTICATE** events now contain the name of the initiating application alongside the connection parameters.
- Fixed an issue with `pg_proaudit` failing to log security events in a CEF file.
- Fixed an issue with `pg_proaudit` failing to log events for the **INSERT** command following **CREATE** within anonymous code blocks (the **DO** command) and stored procedures/functions.
- Fixed an issue with `pg_proaudit` overloading a CPU core due to failed log rotation.
- Upgraded [pg_probackup](#) to version 2.8.11 Enterprise, which provides the following new features, optimizations, and bug fixes:
 - Added support for Postgres Pro Enterprise 18.
 - Added support for Transparent Data Encryption (TDE). The version output of `pg_probackup` now displays a TDE support indicator.
 - Made the host from which a backup was taken to be saved in `backup.control` and displayed in the `show` command output.
 - Improved the behavior during restore from read-only media, including more informative warning messages.
 - For `archive-push` and `archive-get` operations in the remote mode, made **SIGQUIT** signals to be ignored to prevent core dumps of helper programs when the server stops.
 - Added validation to ensure consistency between the port number in `PGDATA` and the `--pgport` option. Also added the `--force` flag to perform backups even when these values mismatch.
 - Fixed handling of external tablespaces during incremental restore. When using the `--force` flag, the tablespace contents are no longer overwritten.
 - Fixed a problem with the `backup` command holding the replication slot after successful completion.
 - Fixed the identifier conflict for the `--wal-tree` option by adding a uniqueness test.
 - Fixed the order of displaying the calculated and expected checksum values in the warning message.
- Upgraded [pg_repack](#) to version 1.5.3.
- Upgraded [pgpro_autopart](#) to version 1.1 to fix an issue with the `ap_enable_automatic_partition_creation` function, which failed if the table column name matched an [SQL key word](#). This version also provides interoperability with [pg-pro_gbtrees](#).
- Upgraded [pgpro_bindump](#) to fix compression level validation. Previously, `pgpro_bindump` enforced the same compression-level range regardless of the selected algorithm.
- Upgraded [pgpro_controldata](#) to version 18.1.0.
- Upgraded [pgpro_datactl](#) to version 1.2.
- Upgraded [pgpro_gbtrees](#) to include fixes that ensured compatibility of global indexes with logical replication and the `pgpro_autopart` extension.
- Upgraded [pgpro_multiplan](#) to version 1.4, which provides the following enhancements and bug fixes:
 - Implemented the ability to store [global prepared statements](#) and use them in multiple sessions within a single server.
 - Improved the stability of the `auto_approve_plans` mode for real-time query replanning with the enabled `pgpro_multiplan.auto_capturing` parameter.
 - Added the new `pgpro_multiplan_remove_template` function that removes the specified `template` plan from the permanent `pgpro_multiplan` storage.
 - Added the new `pgpro_multiplan_template_hintset_update` function that replaces the generated hint set for the `template` plan with the specified set of custom hints.
 - Improved messages for errors that can occur when registering queries and freezing query plans.

- Changed the logic of specifying values of the [pgpro_multiplan.wildcards](#) parameter. Now this parameter accepts a single regular expression rather than a comma-separated list of multiple expressions.
- Fixed an issue where the `template` plan was not identified and applied if constants in the corresponding query were changed.
- Fixed an issue in `pgpro_multiplan` that could cause a server crash when the same query was executed repeatedly due to incorrect handling of the `sample_string` value.
- Upgraded [pgpro_pwr](#) to version 4.12, which provides optimizations and bug fixes. Notable changes are as follows:
 - Improved `take_sample` time tracking.
 - Added support of [pgpro_stats](#) 1.10.
 - Added a possibility to exclude server connection strings from dumps.
 - Added statistics on restartpoints to the reports when it is available.
- Upgraded [pgpro_queue](#) to version 1.3 to provide the following enhancements:
 - Added new [functions for exchange management](#) and [procedures for message publishing](#) to support efficient message distribution based on the publish-subscribe model.
 - Added new procedures for queue access management: [reset_queue_access](#), [grant_queue_access](#), and [revoke_queue_access](#). Queue management procedures can now be used only by a superuser who created the `pgpro_queue` extension, while the `grant_queue_access` and `revoke_queue_access` procedures are also available to the queue owner.
- Upgraded [pgpro_result_cache](#) to version 1.1.1 to provide the following enhancements and bug fixes:
 - Implemented [automatic cache invalidation](#) at the cluster level using WAL files. It can be enabled using the [pgpro_result_cache.consistent](#) and [pgpro_result_cache.wal](#) parameters.
 - Added a possibility to set the [pgpro_result_cache.max_memory_size](#) parameter at runtime using the `ALTER SYSTEM` command.
 - Added support for the new [no_result_cache](#) hint that allows excluding specific queries from caching.
 - Added two optional `limit` and `offset` arguments to the [result_cache](#) hint. These arguments allow you to restrict the number of rows returned from cached result sets and skip certain rows before returning.
 - Fixed an issue that could occur in [pgpro_result_cache](#) when caching a large number of simple queries by changing the algorithm for storing cached results.
 - Fixed a segmentation fault that could occur when reloading the configuration file after the [pgpro_result_cache.consistent](#) parameter was set to `on`.
- Upgraded [pgpro_scheduler](#) to fix an issue with incorrectly recording timestamp values in the service table associated with the `get_log` function. Now missing data is properly recorded when a `NULL` value is specified.
- Upgraded [pgpro_stats](#) to version 1.10 to provide the following enhancements and bug fixes:
 - Added new statistics to `pgpro_stats_statements` and `pgpro_stats_totals` views. These statistics were added to `pg_stats_statements` in Postgres Pro 18. Related functions are updated accordingly.
 - Added the new `pgpro_stats_statements_filtered` function to filter statistics similar to those provided in the `pgpro_stats_statements` view by one or several fields: `userid`, `dbid`, `queryid`, and `planid`. Calling this function is faster than querying the `pgpro_stats_statements` view with appropriate values of these fields.
 - Improved the behavior of [pgpro_stats](#) similarly to [pg_stat_statements](#). The changes are:
 - Allow the parameterization of `SET` values. This reduces the bloat caused by `SET` statements with differing constants.
 - Allow the parameterization of constant lists.
 - Fixed an issue that could occur when in `pgpro_stats` custom metrics were changed on the fly. Now any change to custom metrics requires a server restart.
- Upgraded [pgpro_tde](#) to version 1.4 to provide the following enhancements and bug fixes:

- Provided interoperability with the [Compressed File System](#) (CFS) feature. `pgpro_tde` can now encrypt compressed data blocks. Note, however, that `pg_rewind` cannot be currently used for tablespaces that are both encrypted and compressed.
- Optimized WAL records processing to improve performance.
- Upgraded `pgpro-orautl` to version 2.1.
- Upgraded `pgvector` to version 0.8.1.
- Upgraded `pldebugger` to version 1.1.6.
- Upgraded `pljava` to version 1.6.10.
- Upgraded `plpgsql_check` to version 2.8.5.
- Upgraded [proxima](#) to provide the following features, enhancements, and bug fixes:
 - Implemented the [weighted-round-robin](#) algorithm of workload distribution, as well as the `proxima.load_balancer_node_weight` configuration parameter to set node weights.
 - Implemented the [least-connections](#) algorithm of workload distribution.
 - Implemented integration of [proxima](#) and `pgpro_multiplan` to avoid establishing the dynamic dedicated session for queries with prepared statements. For more information, refer to [Integration with pgpro_multiplan for Prepared Statements](#).
 - Added the `pg_backend_set_config` function to the list of objects and functions that make proxima automatically establish the dynamic dedicated session. To view the full list, refer to [Dynamic Dedicated Session](#).
 - Implemented code optimization and fixed potential issues of the dynamic dedicated session functionality.
 - Implemented a range of internal fixes and optimizations to improve performance and reliability of the proxima extension.
 - Fixed a bug where the dynamic dedicated session established by the `SET TRANSACTION` command could not be terminated.
 - Fixed an issue where proxima would hang causing high CPU usage and disk overflow. The hanging occurred when attempting to connect to a follower in a BiHA cluster where nodes had different port numbers set for the `proxima.port` configuration parameter. Currently, the hanging was fixed, however, the `proxima.port` value must be identical on all nodes for normal operation of the BiHA cluster.
- Upgraded [rum](#) to fix a bug with the module upgrade that was caused by an incorrect variable specified in its makefile.
- Upgraded `tds_fdw` to version 2.0.5.
- Upgraded `utl_mail` to fix an issue with incorrect processing of some email address formats. Now, a number of common formats, including `root@localhost`, are processed correctly.
- Disabled [online_analyze](#). This module is not recommended for use with modern versions of 1C. However, it can be enabled if needed.

E.1.2. Migration to Version 17.7.1

If you are upgrading from a Postgres Pro Enterprise release based on the same PostgreSQL major version, it is enough to install the new version into your current installation directory.

ABI versions may change between minor releases of Postgres Pro. If this is the case, and you see the `ABI mismatch` error when trying to run your extension, make sure to install a new version of the extension supplied with a new release of Postgres Pro, or recompile your third-party extension to be able to use it with the current version of Postgres Pro.

Important

- To upgrade your [BiHA cluster](#) from Postgres Pro Enterprise 17.6 or earlier to Postgres Pro Enterprise 17.7, see the [migration instructions for BiHA](#).
- When using `pgpro_multiplan` together with proxima in a multi-node cluster, to upgrade to Postgres Pro Enterprise 17.7, consider [migration recommendations](#) for proxima.

To upgrade Postgres Pro Enterprise from version 16.X to version 17.X together with the [citus](#) extension of version 13.0, see the [upgrade instructions](#).

To migrate from PostgreSQL, as well as Postgres Pro Standard or Postgres Pro Enterprise based on a previous PostgreSQL major version, see the [migration instructions for version 17](#).

E.2. Postgres Pro Enterprise 17.6.1

Release Date: 2025-10-17

E.2.1. Overview

This release is based on PostgreSQL 17.6 and Postgres Pro Enterprise 17.5.1. All changes inherited from PostgreSQL 17.6 are listed in [PostgreSQL 17.6 Release Notes](#). As compared with Postgres Pro Enterprise 17.5.1, this version also provides the following changes:

- Added the [num_xloginsert_locks](#) configuration parameter, which specifies the number of insertion locks on concurrent write-ahead logging. This parameter is used to improve the efficiency of writing write-ahead logs.
- Added the [share_lock_fk](#) storage parameter that enables or disables acquisition of a single SHARE lock on the table during foreign key constraint checks.
- Added a possibility for the optimizer to use memoize nodes for parameterized ANTI JOINS when the [enable_extra_transformations](#) parameter is set to ON.
- Implemented the following enhancements and bug fixes for [Adaptive Query Execution](#):
 - Implemented a set of optimizations to improve query planning and execution time. In particular, time spent executing each plan node is no longer measured when the query execution time trigger is disabled, which has a significant impact on query performance.
 - Fixed an issue with logging the duration of completed statements with the extended query protocol when the [log_duration](#) parameter was enabled.
- Improved performance by introducing a more efficient synchronization primitive instead of previously used spinlocks for a shared invalidation message queue, which allows avoiding a bottleneck. This may be useful for 1C.
- Improved performance by suppressing catalog cache invalidation messages for DDL operations on temporary tables and for analyzing these tables. This is useful for 1C.
- Improved performance by avoiding invalidation of the `pg_internal.init` file when analyzing catalog tables, particularly when statistics for these tables change frequently. This may be useful for 1C.
- Improved performance by reducing the number of lock requests for the `pg_attribute` and `pg_statistic` tables for queries with a large number of relations that are not present in the system cache. This may be useful for some usage scenarios with 1C.
- Improved performance of non-transactional truncate operations on temporary tables and [fast truncate](#) operations. This is useful for 1C.
- Improved performance by adding a possibility to skip locking for indexes on temporary relations, which can be enabled using the [skip_temp_rel_lock](#) parameter. This is useful for 1C.
- Improved truncation performance for temporary relations. Previously, truncating a temporary relation required scanning the entire local buffer pool once per relation fork to invalidate buffers. Now the buffer pool is scanned only once for all forks. This is useful for 1C.
- Improved the efficiency of parallel processing of table indexes in a parallel mode by refactoring the [parallel autovacuum](#) code.
- Updated [CREATE DATABASE](#), `createdb`, and `initdb` to display an information message when the value of [lc_collate](#) is used as the default for `icu_locale` or `--icu-locale`.
- Optimized the behavior when working with the [COALESCE](#) function. Now this function is replaced with one of its arguments if all other arguments were evaluated to null. This allows improving the selectivity of query clauses and producing better execution plans.
- Introduced the following changes to the implementation of [crash_info](#):

- Added the [crash_info_timer](#), [crash_info_timer_interval](#), and [crash_info_query_threshold](#) configuration parameters that allow profiling long queries in `crash_info` output files.
- Extended the diagnostic information that the [crash_info_dump](#) configuration parameter can specify to write in case of a backend crash. By default, now the general information on the signal is dumped and for Linux x64, also the information on the processor state and bytes near RIP (return instruction pointer). All this ensures better diagnostics, in particular, in case of SIGILL (illegal instruction) signals. The way of dumping stack files in case of crashes has also been changed for Linux x64. Besides, `memory_context` has been removed from the default list of sources to be dumped in order to avoid failures that could occur when writing the diagnostic information.
- Implemented the following enhancements and bug fixes for CFS:
 - Improved compressed tablespace operations on s390/s390x architectures.
 - Improved the compression ratio estimation for tables using the `cfs_estimate(relation)` function. Note that `cfs_estimate(relation)` should be used only *after a checkpoint* to avoid incorrect estimations.
 - Disabled truncation for compressed relations during vacuum operations.
 - Removed encryption support for CFS, including the `cfs_encryption` configuration parameter.
- Fixed an issue with [autonomous transactions](#), which caused a failure to release resources, leading to accumulation of cached plan references.
- Fixed page image inconsistency during heap insert on an empty page. Previously, this could result in incorrect page contents on standby servers.
- Fixed an issue with page conversion from 32-bit to 64-bit format after migration to Postgres Pro Enterprise using `pg_upgrade`. When a page was converted only in memory, without writing it to disk, and autovacuum removed corresponding `pg_xact` segments at the same time, transaction status in tuples was lost, leading to errors on access.
- Fixed a possible race condition in the `walreceiver` process.
- Fixed an issue in LISTEN/NOTIFY queue handling, which caused failure to obtain transaction status. Previously, `VACUUM FREEZE` could advance `datfrozenxid` too far forward.
- Fixed an issue where the planner could choose non-optimal execution plans for queries that use the `LIKE` operator with the `mchar` data type.
- Fixed a memory leak in the [enable_temp_memory_catalog](#) implementation.
- Fixed replication issues caused by incorrect WAL horizon advancement. Previously, if transaction freeze was initiated when calculating the page base for 64-bit XIDs rather than by `VACUUM`, an incorrect horizon value was written to WAL. This could result in invalidation of logical replication slots or replication lag on physical standbys.
- Fixed a possible segmentation fault, which could occur when handling an error during global index creation.
- Added support for Debian 13, Red Hat Enterprise Linux 10, Rocky Linux 10, Oracle Linux 10, and AlmaLinux 10.
- Ended support for Ubuntu 20.04.
- Added the [wal2json](#) extension for logical decoding that converts database changes from the write-ahead log (WAL) into JSON format.
- Upgraded [aqo](#) to provide the following enhancements and bugfixes:
 - Added the `tmpoids` field to the [aqo_data](#) view and the `tmpoids` parameter to the [aqo_data_update](#) function to support queries that involve temporary tables along with persistent tables.
 - Fixed the race condition when calling the [aqo_cleanup](#) function from different sessions.
 - Fixed an issue where aqo learning data was not saved for queries that use materialization.
 - Fixed an issue with learning on early terminated nodes. Now for these nodes, if the number of actual rows exceeds the number of predicted rows, aqo learns but with the minimum `reliability` value. Otherwise, learning on these nodes is disabled.
- Upgraded [auto_explain](#) to move the planning time of a query in the output to a separate line under the planner tree, as in the EXPLAIN output. With the former location of the planning time in the output, [pgbadger](#) could not recognize the information on a query and therefore did not include it in the report.

- Upgraded the [BiHA](#) solution to version 1.6 to provide the following features, optimizations, and bug fixes:
 - Implemented the ability to use SSL certificates for user authentication. For more information about SSL authentication configuration and other available authentication methods, see [User Authentication Configuration](#).
 - Implemented the `STATUS_CHANGED` callback that is called on every node whenever values in the fields of the `biha.status_v` view change (except `since_last_hb`).
 - Implemented a set of functions to manage quorum-based synchronous replication in a BiHA cluster: `biha.add_to_ssn`, `biha.get_ssn`, `biha.remove_from_ssn`, and `biha.set_ssn`. For more information, see [Managing Replication](#).
 - Implemented the ability to force the `pg_rewrite` process in a BiHA cluster when required, for example, for partial database recovery, emergency repairs when standard rewind fails, or for recovery of specific WAL ranges. You can execute force run of `pg_rewrite` by specifying both `--force` and `--start` options. The `--force` option overrides failed safety check to allow `pg_rewrite` execution. The `--start=LSN[, TLI]` option specifies the exact WAL location (*LSN*) and an optional timeline ID (*TLI*) that defaults to the current timeline of the target node if omitted. If these options are specified, `pg_rewrite` replays WAL using the checkpoint preceding the specified WAL location instead of the last common checkpoint.
 - Implemented the WAL trimming functionality that helps to avoid running `pg_rewrite` to synchronize cluster nodes after failover when WAL divergence is caused only by redundant heartbeat records. The WAL trimming algorithm finds the last common point in WALs of the diverged node and the new leader, verifies that all subsequent records are only heartbeats, and automatically deletes redundant heartbeat records from the diverged node so it can resume replication. You can manage the WAL trimming functionality by means of the new `biha.autowaltrim` configuration parameter. For more information, see [Automatic Cluster Synchronization after Failover](#).
 - Improved the `LEADER_CHANGE_STARTED` callback functionality. Previously, the callback could fail on the old leader after you set the new leader by `biha.set_leader`, as the old leader immediately restarts. Currently, the callback is delayed and then called on the old leader right after its restart. For more information, see the `LEADER_CHANGE_STARTED` description in the [Callback Types](#) table.
 - Improved the mechanism of managing [relaxed synchronous replication](#) in a BiHA cluster. Previously, it was required that you set the `--sync-standbys-min` option of `bihactl init` when initializing the cluster to be able to relax synchronous replication restrictions later. Currently, you can enable, modify, or disable relaxed synchronous replication at any time using the `biha.set_sync_standbys_min` function. The `biha.sync_standbys_min` parameter was deleted as redundant.
 - Fixed a bug where the `biha.port` value greater than or equal to 32768 caused the server to loop.
- Ensured compatibility with [citux](#) version 13.0.4.1.
- Fixed an issue where [fasttrun](#) could fail to fully truncate temporary tables if the cached segment count was smaller than the actual number of file segments on disk, leaving disk space occupied even though the table appeared empty.
- Upgraded [multimaster](#) to provide the following enhancements and bug fixes:
 - Improved the ability of the node to return to normal operation after catchup by accelerating the transaction filter building process at the start of `walreceiver`.
 - Fixed a bug that caused recovery hanging and potential data desynchronization when adding a new node.
 - Fixed unexpected errors in execution of DDL commands that were caused by incorrect processing of catalog cache invalidation messages.
- Implemented the ability to configure LDAP authentication for [pgbouncer](#) by means of [PAM](#) (Pluggable Authentication Modules). For more information, see [LDAP Authentication Configuration for pgbouncer](#).
- Updated the [pg_freespace](#) module to include the `pg_freespace_relation_logical_blocks` function for computing the disk space used by relation forks. This function works with both compressed and uncompressed tables.
- Fixed a memory allocation issue in [pg_prewarm](#), which could previously produce errors like “invalid memory alloc request size” when `shared_buffers` was set to a huge value.
- Upgraded [pg_proaudit](#) to provide the following enhancements:
 - Added support for CEF format for event log files.
 - Adjusted `pg_proaudit` output. `xid` and `vxid` fields are no longer displayed if they are zero.

- Upgraded [pg_probackup](#) to version 2.8.10 Enterprise, which provides the following new features, optimizations, and bug fixes:
 - Added the `--wal-tree` option for the `add-instance` command to store archived WAL files in a tree-like structure. This improves WAL operation performance with large volumes of logs.
 - Added the `postgres-edition` field to the `show` command output in the JSON format to display DBMS edition information.
 - Improved the `--dry-run` option operation during tablespace recovery. The operation estimation and plan output are now more precise.
 - Fixed an issue related to the retention window calculation. The time value is now taken from the host where `pg_probackup` is running. The retention window is now calculated correctly even with the timezone differences between the servers.
 - Fixed a problem with the `archive-get` command operation. The `pbk_prefetch` directory is now created with correct access rights, inheriting permissions from PGDATA.
 - Fixed false failure of the `checkdb` command in the remote mode during concurrent TRUNCATE operations or table drops on standby nodes.
- Fixed the following issues in the [pgpro_bindump](#) module:
 - Fixed potential [pg_probackup3](#) failure caused by temporary tables during backup validation using the `pgpro_bindump` module in the PRO mode.
 - Fixed a memory leak in [pg_probackup3](#) using the `pgpro_bindump` module for PTRACK operations.
 - Fixed an issue that could cause infinite looping in [pg_probackup3](#) when using the `pgpro_bindump` module.
 - Fixed an issue with multi-timeline backup in the PTRACK mode in [pg_probackup3](#) using the `pgpro_bindump` module in the PRO mode.
- Updated the [pgpro_datactl](#) utility to include the following new features:
 - Added the `repack` command for changing the compression algorithm and/or compression level of CFS files.
 - Added the `ground` command for replacing corrupted blocks with zeros to prevent potential operation failures.
 - Added the `stat` command to monitor tablespace statistics.
- Upgraded [pgpro_gbtrees](#) to accelerate VACUUM, scan, and uniqueness check for global indexes. To this end, fetching a tuple with a dirty snapshot was replaced with the use of the visibility map when searching values by the primary key, and the order of performing VACUUM for a partitioned table was changed: VACUUM is first performed for partitions with their primary keys and then for global indexes.
- Upgraded [pgpro_multiplan](#) to version 1.3, which provides the following enhancements, changes, and bug fixes:
 - Added the new [pgpro_multiplan.mode](#) parameter that allows you to enable or disable the extension, the use of available plan types, as well as statistics collection.
 - Added the new [pgpro_multiplan.aqe_mode](#) parameter that allows you to enable or disable AQE-related features.
 - Added the `baseline` value for the `plan_type` field of the [pgpro_multiplan_storage](#) view to identify allowed plans.
 - Renamed the following entities:
 - `pgpro_multiplan_fs_counter` view to [pgpro_multiplan_stats](#)
 - `usage_numb` field of the `pgpro_multiplan_stats` view to `counter`
 - `pgpro_multiplan_fs_counter()` function to [pgpro_multiplan_stats\(\)](#)
 - `pgpro_multiplan.fs_ctr_max` parameter to [pgpro_multiplan.max_stats](#)
 - Updated the `set_aqe_trigger` function, which now accepts the query text string when setting individual AQE trigger values for a query. The parameterized version of the query text is displayed in the `aqe_triggers` view.
 - Changed the default behavior of statistics collection. Now statistics are not gathered unless you enable this feature using the `pgpro_multiplan.mode` parameter.

- Changed the default behavior of the `set_aqe_trigger()` function. Now this function does not work unless you enable individual AQE trigger values using the `pgpro_multiplan.aqe_mode` parameter.
- Removed the `pgpro_multiplan.enable` parameter that is no longer required. Instead, use the `pgpro_multiplan.mode` parameter.
- Removed the `pgpro_multiplan.aqe_plans_auto_approve` and `pgpro_multiplan.aqe_collect_stats` parameters. Instead, use the `pgpro_multiplan.aqe_mode` parameter.
- Added the `sample_string` field to the `pgpro_multiplan_storage` view to store a non-parameterized query for which a plan was frozen or added to a set of allowed plans.
- Added the `planid` field to the `pgpro_multiplan_captured_queries` and `pgpro_multiplan_stats` views. This field specifies the plan ID compatible with the `pgpro_stats` extension and allows you to get extended statistics by joining information from the `pgpro_multiplan_stats` and `pgpro_stats_statements` views.
- Added the `pgpro_multiplan_remove_baseline` function that removes the specified plan from a set of allowed plans.
- Fixed an issue with `pgpro_multiplan` failing to register queries involving the `INTERVAL 'const'` notation.
- Fixed an issue where `plan_hash` was not calculated when adding plans for queries with custom hints to a set of allowed plans (baseline). Now such plans can be added to a baseline with correct `plan_hash` values.
- Fixed a segmentation fault, which occurred on attempts to access the `aqe_triggers` view or call the `aqe_triggers_reset` function with disabled `pgpro_multiplan`. Now all functionality related to AQE triggers works regardless of whether `pgpro_multiplan` is enabled.
- Upgraded `pgpro_pwr` to version 4.10, which completely redesigns the report and supports PostgreSQL 18.
- Upgraded the `pgpro_queue` extension to version 1.2 and provided the following enhancements and bug fixes:
 - Fixed an issue with processing too long queue names when using `CREATE_QUEUE`.
 - Corrected returned types for message reading functions.
 - Fixed an issue, which could cause data modification attempts on replicas after restart.
- Upgraded `pgpro_result_cache` to version 1.1, which provides the following enhancements:
 - Implemented automatic invalidation of cached result sets that can be enabled using the new `pgpro_result_cache.consistent` parameter.
 - Added two new `configuration parameters` that will be useful for debugging purposes.
- Upgraded `pgpro_rp` to version 1.4 to support upgrade from older major versions and to add new views. These views are reserved to be implemented in future releases. Until then, using them will return an error.
- Upgraded `pgpro_scheduler` to version 2.12, which provides the following bug fixes and improvements:
 - Added two `schedule.clean_at_jobs_done cleanup functions` with the same name but different argument types. These functions delete records from the `schedule.at_jobs_done` table that are older either than a specified interval or a specified timestamp.
 - Provided the ability to change the next start time for a cron job that has `next_time_statement` by updating `cron`, `date`, `dates`, or `rule` using the `set_job_attributes()` function.
- Upgraded `pgpro_sfile` to add the `sf_import` and `sf_export` server functions for import and export of `sfile` objects, respectively, as well as their client-side analogs.
- Upgraded `pgpro_stats` to provide the following enhancements and bug fixes:
 - Implemented the ability to track utility commands by their `query_id`, as it is done in `pg_stat_statements`. Previously, utility commands were tracked based on strict comparison of their textual query strings, and therefore could not be properly normalized.
 - Fixed a segmentation fault that could occur when defining custom metrics. The error originated from a memory allocation issue, which was fixed.
- Added the Transparent Data Encryption (TDE) feature, which enables page level encryption in Postgres Pro Enterprise with the `pgpro_tde` extension. Note that tablespaces cannot be both encrypted and `compressed`.

- Fixed an issue with incorrect configuration parameter values specified when using the `1c.tune` preset of the `pgpro_tune` utility.
- Upgraded the `pgpro_usage` extension to fix an issue with usage statistics, which could be unexpectedly lost after a crash. Now the statistics file is preserved at startup and updated regularly at checkpoints.
- Upgraded `pg_query_state` to version 1.2 to add the `pg_progress_bar` and `pg_progress_bar_visual` functions that allow monitoring the current progress of query execution.
- Added the `--enable-large-mem-buffers` option to the `pg_restore` to allow restoring a database that does not contain large `bytea` values and records with several `text` values as a non-superuser.
- Improved the `pg_waldump` utility behavior when used with a segment containing an unfinished WAL record. Previously, if an unfinished WAL record was found, the utility displayed a misleading log message about an invalid page header. Now, the log message clearly informs about an unfinished WAL record found providing the beginning LSN of the record, as well as the lost part LSN.
- Upgraded `plpgsql_check` to version 2.8.2 for all operating systems, except for AlterOS 7.5 and SLES 12, which continue using the previous version.
- Fixed an issue in `postgres_fdw`, which could cause `UPDATE` and `DELETE` queries with a `RETURNING` clause to fail with “out of memory for query result” errors. Now `RETURNING` results are processed in batches, with the buffer size for each batch controlled by the `fetch_size` option.
- Upgraded `proxima` to provide the following enhancements and bugfixes:
 - Implemented the monitoring functionality that allows tracking the `proxima` state in a BiHA cluster. For more information, see [Section F.73.1.4](#).
 - Improved the distribution strategy for read-only workloads on the Proxy-to-Follower port. Previously, read-only transactions within one session were distributed across cluster replicas according to the [selected algorithm](#). Currently, `proxima` attaches a client session to a certain cluster replica to ensure that all transactions within this particular session are executed on the same replica.
 - Improved `proxima` troubleshooting capabilities by adding code location to the log file for messages of the `error` log level.
 - Fixed a bug where `proxima` was unable to process or break a client connection query in case of unexpected memory shortage that could cause hanging on the client side.
 - Fixed a bug where `proxima` could not release some Postgres Pro backend processes when disabled or enabled using the `proxima.enabled` configuration parameter that led to a growing number of idle backend processes and memory leaks.
 - Fixed a bug that caused a referee node to fail when added to a BiHA cluster with `proxima` enabled. The main symptom was the connection loss in `pg_basebackup` followed by the error message: “error: could not initiate base backup: server closed the connection unexpectedly”.
 - Fixed an issue with incorrect termination of the system thread in `proxima`.
 - Fixed a bug that caused termination of the `proxima` process after restart of the BiHA cluster.
 - Fixed an issue with incorrect `proxima` startup order after restarting a node in a BiHA cluster.
 - Fixed memory leak in `libev` caused by unoptimized resource allocation.
 - Fixed a bug where log messages about modification of `proxima` configuration parameters were duplicated by other processes.
- Upgraded `rum` to provide the following bugfixes:
 - Fixed a segmentation fault caused by invalid memory access when a buffer pointer was used after the underlying buffer was modified by another thread.
 - Fixed an index scan infinite loop when using multiple `ORDER BY` clauses.
- Upgraded `utl_http` to version 2.0, which provides the following improvements:
 - Added the support for TLS and MD5.

- Improved the error message for setting invalid `OPT_SSL_VERIFYHOST`.
- The built-in analytical platform and `pgpro_duckdb` are no longer included. This functionality will be covered by the upcoming Postgres Pro AXE product.

E.2.2. Migration to Version 17.6.1

If you are upgrading from a Postgres Pro Enterprise release based on the same PostgreSQL major version, it is enough to install the new version into your current installation directory.

ABI versions may change between minor releases of Postgres Pro. If this is the case, and you see the `ABI mismatch` error when trying to run your extension, make sure to install a new version of the extension supplied with a new release of Postgres Pro, or recompile your third-party extension to be able to use it with the current version of Postgres Pro.

Important

- Direct migration of a [BiHA cluster](#) from version 17.4 or earlier to version 17.6 is not supported. You must first upgrade your cluster to version 17.5 and then upgrade to version 17.6.

To upgrade your BiHA cluster from Postgres Pro Enterprise 17.5 to Postgres Pro Enterprise 17.6, see the [migration instructions for BiHA](#).

- To upgrade Postgres Pro Enterprise from version 16.X to version 17.X together with the [citus](#) extension of version 13.0, see the [upgrade instructions](#).

To migrate from PostgreSQL, as well as Postgres Pro Standard or Postgres Pro Enterprise based on a previous PostgreSQL major version, see the [migration instructions for version 17](#).

E.3. Postgres Pro Enterprise 17.5.1

Release Date: 2025-06-19

E.3.1. Overview

This release is based on PostgreSQL 17.5 and Postgres Pro Enterprise 17.4.1. All changes inherited from PostgreSQL 17.5 are listed in [PostgreSQL 17.5 Release Notes](#). As compared with Postgres Pro Enterprise 17.4.1, this version also provides the following changes:

- Added the [background freezer](#) feature that vacuums modified and non-locked data pages of permanent tables stored in RAM. Background freezer is managed using new specific [configuration parameters](#). This feature is useful for 1C.
- Changed lock logic to reduce CPU consumption significantly in case of startup recovery on physical replicas used as a source for logical replication with many downstreams. Walsenders no longer slow down WAL application as a more efficient synchronization primitive has replaced the previously used spinlock.
- Added the experimental feature that enables the [parallel query execution](#) mechanism for queries that involve at least one temporary table. It can be enabled using the new [enable_parallel_temptables](#) configuration parameter. This feature cannot be used in production for now. Also, added the new [write_page_cost](#) configuration parameter that allows estimating the cost of flushing temporary table pages to disk. It will only work if `enable_parallel_temptables` is enabled. These parameters are useful for 1C.
- Added the new [planner_upper_limit_estimation](#) configuration parameter that enables the query planner to overestimate the expected number of rows in statements that contain a comparison to an unknown constant. This feature is useful for 1C.
- Added the experimental feature that allows using an in-memory system catalog for temporary tables, and can be enabled using the new [enable_temp_memory_catalog](#) configuration parameter. This feature cannot be used in production for now. This feature is useful for 1C.
- Added a possibility for the autovacuum daemon to process indexes of a table in a parallel mode. The [parallel_autovacuum_workers](#) storage parameter of a table controls whether it should be processed in parallel and defines the number of additional parallel autovacuum workers that can be launched for table processing. The number of autovacuum workers per cluster

that can be used for parallel table processing is limited by the [autovacuum_max_workers](#) configuration parameter. Parallel autovacuum is currently in an experimental phase and is intended for testing purposes only. Do not deploy it in production environments. This feature is useful for 1C.

- Implemented the following enhancements and bug fixes for [Adaptive Query Execution](#):
 - Added a possibility to trigger the reoptimization through the adaptive query execution (AQE) for a query that is currently run in the specified session. The replanning request is sent by the [replan_signal](#) function.
 - Hid the confusing “early terminated” notice in `EXPLAIN VERBOSE` unless `aqe_enable` was on and AQE was active.
 - Fixed an issue with [AQE](#) failing to optimize queries with subqueries.
- Added the [enable_any_to_lateral_transformation](#) configuration parameter that allows enabling or disabling transformation of ANY subqueries into LATERAL joins.
- Implemented performance optimization when working with table metadata, which allows obtaining information about attributes using the system cache instead of direct reading from the system catalog.
- Introduced the following changes to the implementation of [crash_info](#):
 - Added handling of SIGILL signals to `crash_info` processing.
 - Added details, like process start time and query text at planning, to `crash_info` output files.
 - Fixed incorrect function names in the first 2-3 lines of `crash_info` backtrace stacks.
 - Fixed possible data truncation at the end of SQL query dump files. Previously, a buffer overflow during SQL query dumping could result in incomplete writes, causing truncated data at the end of files produced by `crash_info`.
 - Fixed handling of crash information signals (sent using the kill command) by backends. Previously, the first signal would flush `crash_info` information to the log, but the process would continue running without producing a core dump, even if configured, and only the second signal would terminate the backend and generate the core dump as expected.
- Restricted superuser actions with temporary relations of other sessions. Superusers can now only use the [DROP TABLE](#) command with such relations. If the [skip_temp_rel_lock](#) configuration parameter is set to ON, even dropping such relations is not allowed. This feature is useful for 1C.
- Fixed an issue when the checkpointer process could get stuck, repeatedly throwing “invalid memory alloc request size” errors. This could occur when using a huge `shared_buffers` setting, causing checkpointer memory allocation requests to exceed the allowed limit.
- Fixed high CPU consumption on a standby instance with enabled cascading logical replication. Now wake-ups of walsender processes are sent after applying a group of WAL records rather than each individual record in case of high stream of changes from the upstream instance.
- Fixed an issue with the planner erroneously clearing partition information when there was a global index on a partitioned table and `enable_partitionwise_join` was enabled. As a result, the join was replaced with an empty result, even when data was available. This led to queries silently returning no rows.
- Fixed incorrect tuple scanning. Previously, in some cases XIDs were compared using modulo-2³² arithmetic instead of modulo-2⁶⁴.
- Fixed an issue with possible duplication of entries in global indexes built by `CREATE INDEX` or `REINDEX`. This could cause incorrect query results (duplicate rows).
- Fixed the following issues for [CFS](#):
 - Fixed compatibility of CFS with the `ALTER TABLESPACE . . . SET/RESET` commands.
 - Fixed an issue with memory allocation within a critical section in the implementation of `VACUUM ANALYZE` for compressed tables.
- Fixed the following bugs related to [autonomous transactions](#):
 - Fixed a segmentation fault, which could occur when using [postgres_fdw](#) with autonomous transactions.
 - Fixed loss of temporary tables from parent transaction on autonomous transaction rollback.

- Fixed an issue with empty `xact_start` columns in the `pg_stat_activity` view for backends executing autonomous transactions.
- Fixed an issue with missing statistics about vacuuming when multiple index vacuum workers are used.
- Fixed misuse of spinlocks in the automatic page repair worker.
- Added support for MosOS 15.
- Added the [daterange_inclusive](#) extension, which allows you to include the upper bound of a time range in output.
- Added the [pg_probackup3](#) solution for backup and recovery of Postgres Pro database clusters. Refer to the [pg_probackup3 release notes](#) for more details. You can get the exact repositories and commands for supported Linux distributions from the Postgres Pro support team.
- Added the [pgpro_bindump](#) module to manage backup and restore operations. This module implements specialized replication commands for an extended replication protocol, has its own format for archiving files, and does not require SSH connection. It is provided in the `postgrespro-ent-17-contrib` package and designed specifically for use with the [pg_probackup3](#) utility.
- Added the [pgpro_datactl](#) utility to manage Postgres Pro data files, which includes a module for unpacking and analyzing CFS files.
- Added `pgpro_duckdb` — a Postgres Pro extension that embeds DuckDB columnar-vectorized analytics engine and features into Postgres Pro. The `pgpro_duckdb` is the key component of the built-in analytical platform — a Postgres Pro solution designed to operate with OLAP workloads within a Postgres Pro instance. The `pgpro_duckdb` extension is currently in an experimental phase.
- Added the [pgpro_result_cache](#) extension to save query results for reuse.
- Added the new [pgpro_tune](#) utility for automatic tuning of Postgres Pro configuration parameters.
- Upgraded [aqo](#) to version 3.1, which provides the following enhancements and bug fixes:
 - Enabled aggregation of the knowledge base for queries that only differ in table names. The so-called *basic hash*, which is the same for such queries, is now used as the feature space identifier.
 - Fixed an issue, which could lead to a standby crash with SIGABRT if the standby had a different `aqo` version than the primary.
- Upgraded the [BiHA](#) solution to version 1.5 to provide the following features, optimizations, and bug fixes:
 - Implemented the ability to manage the [proxima](#) extension in the existing BiHA cluster. You can now enable and disable `proxima` by calling the new [biha.enable_proxima](#) and [biha.disable_proxima](#) functions, as well as check the extension status by means of the new [biha.proxima_status](#) configuration parameter. For more information, see [Managing proxima](#).
 - Implemented the ability to use the `--enable-proxima` option with the `bihactl add` command. This enables `proxima` on a follower node converted from a standby node when you convert your existing primary-standby cluster into a BiHA cluster.
 - Added the [biha.set_sync_standbys](#) function that allows configuring quorum-based synchronous replication in the existing asynchronous BiHA cluster. You can also use the function to change the number of quorum-based synchronous standbys. For more information, see [Enabling Quorum-Based Synchronous Replication](#).
 - Improved the process of the `biha_replication_user` password verification during BiHA cluster initialization. If you have preliminarily specified the password in the [password file](#), `bihactl` now gets the password automatically. If you have not specified the password in the password file, you are now prompted to enter the password twice to avoid misspelling.
 - Changed the connection database from `postgres` to `biha_db` for the automatic rewind functionality. This helps to avoid automatic rewind errors in cases when the connection string for the `postgres` database is not present in the [password file](#).
 - Added the `LEADER_CHANGE_STARTED` callback type that is called on all nodes when the leader is not available and the quorum is ready to start elections or when you set the leader by the [biha.set_leader](#) function. You can use this callback to fence the old leader. For more information about the new callback, see [Callback Types](#).
 - Added the `--referee-with-postgres-db` option of the `bihactl add` command that allows to copy the `postgres` database to the referee node. For more information, see [The postgres Database on the Referee](#).
 - Changed the behavior of nodes in the `NODE_ERROR` state during elections. Such nodes can no longer participate in voting.

- Expanded the list of cluster parameters returned by the `biha.config` function. The function now also returns the `mode` column displaying the `operation mode` of the node: `regular`, `referee`, or `referee_with_wal`.
- Fixed an issue with multiple “waiting for WAL to become available at...” log messages on the referee node in the `referee` mode.
- Fixed a bug that caused a segmentation fault when calling `biha.set_*` functions in a single-node (leader only) BiHA cluster.
- Fixed an issue of decreasing the `max_wal_senders` parameter in a single-node (leader only) BiHA cluster. For more information about decreasing `max_wal_senders` and some other Postgres Pro configuration parameters, see [Decreasing Postgres Pro Parameter Values](#).
- Fixed a bug where nodes attempted to check the `biha.sync_standbys_min` value when updating configuration of the asynchronous BiHA cluster.
- Fixed a bug that allowed to set an empty password for `biha_replication_user` when executing the `init` command.
- Fixed a bug where the old leader in the `CSTATE_FORMING` state could ignore progressing elections and start as the leader together with the new leader. Now, the old leader does not start as the leader if it detects a node in the `CANDIDATE` state.
- Fixed a bug that caused unexpected cluster behavior when the `biha.sync_standbys_min` value was set outside the valid range by the `biha.set_sync_standbys_min` function. BiHA now does not allow to modify the `biha.sync_standbys_min` parameter if the new value is higher than the number of quorum-based synchronous nodes of the `synchronous_standby_names` parameter.
- Upgraded `dbms_lob` to version 1.3 to fix incorrect handling of the `amount` in `write`. If `buffer` is longer, it writes exactly `amount` bytes (for BLOB) or characters (for CLOB).
- Upgraded the `pg_hint_plan` module to ignore hints of the new `pgpro_result_cache` extension.
- Added a new `PGPRO_TUNE` environment variable to `initdb`, which specifies whether to use `pgpro_tune` without modifying command-line options directly.
- Upgraded `multimaster` to version 1.3.0, which provides the following enhancements and bug fixes:
 - Improved the way nodes delete old synchronization points. Previously, every node deleted only a part of the synchronization point table and replicated changes to other nodes. This could cause synchronization issues and inability to delete old synchronization points. Now, every node deletes all synchronization points and does not replicate changes to other nodes.
 - Fixed potential node hanging during catchup when attempting to process aborted DDL transactions in a cluster of three or more nodes.
- Upgraded `oracle_fdw` to provide the following enhancements and bug fixes:
 - Increased line size for `EXPLAIN` output as some Oracle catalog queries have long filter conditions. The line size was increased to the value of 3000.
 - Fixed a crash with column options on non-existing columns. If the Oracle table has fewer columns than the Postgres Pro and one of these extra columns has a column option set, `oracle_fdw` would write past the end of an array, leading to memory corruption and crashes. Now options for such columns are ignored.
- Fixed an issue with updating `pageinspect`. In rare cases, depending on the sequence of previous updates, upgrading the database cluster and then attempting to update the `pageinspect` extension using `ALTER EXTENSION pageinspect UPDATE TO` could result in an error. To avoid such issues, it is strongly recommended to drop and recreate the extension using `DROP EXTENSION` followed by `CREATE EXTENSION` after upgrading the cluster. Since `pageinspect` does not create dependent objects, this approach is safe.
- Upgraded `pg_proaudit` to provide the following enhancements and bug fixes:
 - Added new object types: `CATALOG RELATION` and `CATALOG FUNCTION`.
 - Added new event fields: `UUID`, `XID`, and `VXID`. Now it is possible to identify an event by its `UUID` and transaction IDs (if applicable).
 - The behavior of the `pg_proaudit.log_catalog_access` configuration parameter was corrected to reflect the new logic of logging for system catalog objects.

- Changed the logic of handling disconnection events. Now these events are associated with the corresponding authentication events, so the disconnection events will be logged even in the case when the rule is removed after authentication, but before disconnect.
- Fixed an issue where the `DISCONNECT` event type was not logged for a user who was a member of the role that was set in the logging rule.
- Fixed the bug that caused a log entry to be written to an incorrect log file when log file rotation was configured.
- Fixed an issue with `pg_proaudit` failing to log schema creation events.
- Corrected the behavior of the `logger` process when deleting a role from a parallel session configured by the rule.
- Upgraded `pg_probackup` to version 2.8.9 Enterprise, which provides the following new features, optimizations, and bug fixes:
 - Added the `maintain` command to resolve issues that can occur during a forced backup termination.
 - Added the `--lock-lifetime` option that sets the timeout for locks. This option is useful for computational environments with a slow network.
 - Stabilized retaining the initial permissions for directories when running the `init` command.
 - Stabilized the `checkdb` command on a remote host.
 - Improved the stability of the point-in-time recovery (PITR) with validation.
 - Fixed the “SignatureDoesNotMatch” error that could occur when connecting to the VK Cloud S3 storage.
 - Fixed an incorrect behavior that could occur when launching the wait for a WAL streaming thread in the ARCHIVE WAL delivery mode.
- Upgraded `pgpro_bfile` to version 1.3 to add the new `bfile_md5()` function that calculates a 16-byte MD5 hash for the specified `bfile` object.
- Upgraded `pgpro_ilm` to version 2.0 which provides the following enhancements and bug fixes:
 - Implemented only one-direction moving of relations to new tablespaces. Now if according to the rules, a relation was moved to the first tablespace after a short period of time and then moved somewhere else after a longer period of time, a subsequent modification of this relation no longer causes moving it to the first tablespace after the period of time defined in the rule.
 - Enabled moving tables and its indexes to tablespaces that differ from each other.
 - Prohibited moving partitioned tables and indexes on partitioned tables to other tablespaces. This allows you to avoid undesirable creation of child tables in the new tablespace.
- Upgraded `pgpro_multiplan` to version 1.2, which provides the following enhancements and bug fixes:
 - Added the `set_aqe_trigger()` function that allows you to override global `AQE trigger values` for individual queries. All individual trigger values are stored in the new `aqe_triggers` view. The new `pgpro_multiplan.aqe_max_items` parameter specifies the maximum number of items in this view.
 - Added the new `pgpro_multiplan.aqe_collect_stats` parameter that enables `pgpro_multiplan` to collect statistics for all statements considered feasible for `AQE` reoptimization. All statistics values are stored in the new `aqe_stats` view. The new `pgpro_multiplan.aqe_max_stats` parameter specifies the maximum number of collected statistics values.
 - Added the `pgpro_multiplan.aqe_plans_auto_approve` parameter that enables `pgpro_multiplan` to add plans produced by `AQE` to the list of allowed plans automatically.
 - Implemented the ability to back up frozen plans and then restore them into the current database using the `pgpro_multiplan.restore()` function. You can now transfer frozen plans between databases or even server instances.
 - Fixed a `PANIC`-level failure in `pgpro_multiplan`, which could occur if the standby had a different `pgpro_multiplan` version than the primary.
 - Fixed an issue, which could cause errors like “unrecognized node type” when working with stored procedures and functions.
 - Fixed empty hint string generation in `pgpro_multiplan`, which caused `pg_hint_plan` to report a syntax error.

- Upgraded [pgpro_pwr](#) to version 4.9, which mainly provides optimizations and bug fixes. Notable changes are as follows:
 - Added support for [pgpro_stats](#) 1.9.
 - Added a possibility to define the mode of collecting relation sizes globally through the `pgpro_pwr.relsizes_collect_mode` extension parameter or for a server through the `set_server_size_sampling` function parameter.
 - Enabled fine-tuning the server statistics collection by calling the `set_server_setting` function. It allows you to define which statistics should be collected.
 - Added a preview of storage parameters for tables and indexes in the “Schema object statistics” report section.
- Upgraded [pgpro_rp](#) to version 1.3 to prevent related dump/restore failures. Previously, creating the `pgpro_rp` extension before restoring a dump could lead to a unique constraint violation during restoration of `pgpro_rp`.
- Upgraded [pgpro_queue](#) to support message queueing management for [subtransactions](#) and [autonomous transactions](#).
- Upgraded [pgpro_scheduler](#) to version 2.11.2 to fix an issue where repeated jobs could be executed at additional time if days of the week were set using the `crontab` format. `pgpro_scheduler` now checks all job time settings and runs jobs at the specified time.
- Upgraded [pgpro_sfile](#) to version 1.5, which provides the following bug fixes and improvements:
 - Added the variant of the `sf_find` function that searches an `sfile` object by an ID of the `bigint` type and to implement the type cast `bigint::sfile`.
 - Fixed an issue in `pgpro_sfile`, which could cause errors like “tuple concurrently updated” during `DELETE` or `TRUNCATE` operations.
- Upgraded [pgpro_stats](#) to version 1.9, which provides the following bug fixes and improvements:
 - Enhanced session tracing to provide more information. Specifically, the new `time_info` filter attribute controls inclusion of additional information in the session-tracing output, and the `pgpro_stats.trace_query_text_size` configuration parameter can limit the size of the query in the session-tracing output.
 - Aligned the names of the `explain_*` filter attributes of the session tracer with the names of session-tracing configuration parameters.
 - Changed the format of the statistics dump file and the corresponding save/load routines.
 - Implemented turning off the session tracer functionality when no session-tracing filters are specified.
 - Prohibited inclusion of both [pgpro_stats](#) and [pg_stat_statements](#) in the list of `shared_preload_libraries`. If both are included, the database server will not start.
- Upgraded [pgpro_usage](#) to provide the following enhancements and bug fixes:
 - Added tracking of direct DML operations on individual partitions in `pg_stat_all_tables_per_user`.
 - Fixed incrementing the `SELECT` counter for `UPDATE` and `DELETE` on partition tables. Only `UPDATE/DELETE` counters are incremented now.
 - Fixed incorrect statistics update for referenced tables in `pgpro_usage` during `INSERT` on table columns with `REFERENCES` operations.
 - Fixed `pgpro_usage` to log `SELECT FOR UPDATE` and `SELECT FOR KEY SHARE` events as `SELECT`, rather than `UPDATE`.
- Upgraded the [proxima](#) extension to provide the following features, optimizations, and bug fixes:
 - Added the [proxima.enabled](#) configuration parameter to temporarily disable and enable `proxima`.
 - Added the [proxima.is_dedicated](#) configuration parameter to verify whether the current session is dedicated.
 - Added the ability to distribute read-only workloads across cluster replicas using the new [Proxy-to-Follower](#) port. For more information about workload distribution, see [Workload Distribution](#) and [Section F.73.3.4](#).
 - Improved the processing logic of node configuration modification. The `proxima` extension now terminates connections only to those nodes, which configuration was modified. For example, adding and removing nodes no longer terminates all connections. Previously, all connections to all cluster nodes were terminated in case of any node configuration modifica-

tion. For BiHA clusters, this improvement is only partially implemented, so some events in a BiHA cluster may still lead to termination of all connections.

- Implemented a number of internal fixes and optimizations to improve performance and reliability of the proxima extension.
- Upgraded the [pg_wait_sampling](#) extension to provide the following bug fixes:
 - Fixed an issue where GUC variables could be overridden when using parallel workers.
 - Fixed an issue with malformed samples caused by a race condition when `pg_wait_sampling.sample_cpu` is disabled.
- Removed the `--tune` option from `pg-setup`. Use the new [pgpro_tune](#) utility instead.
- Deprecated the experimental vops extension.

E.3.2. Migration to Version 17.5.1

If you are upgrading from a Postgres Pro Enterprise release based on the same PostgreSQL major version, it is enough to install the new version into your current installation directory.

ABI versions may change between minor releases of Postgres Pro. If this is the case, and you see the `ABI mismatch` error when trying to run your extension, make sure to install a new version of the extension supplied with a new release of Postgres Pro, or recompile your third-party extension to be able to use it with the current version of Postgres Pro.

Important

To upgrade your [BiHA cluster](#) from Postgres Pro Enterprise 17.4 or earlier to Postgres Pro Enterprise 17.5, see [migration instructions for BiHA](#).

To migrate from PostgreSQL, as well as Postgres Pro Standard or Postgres Pro Enterprise based on a previous PostgreSQL major version, see the [migration instructions for version 17](#).

E.4. Postgres Pro Enterprise 17.4.1

Release Date: 2025-03-13

E.4.1. Overview

This release is based on PostgreSQL 17.4 and Postgres Pro Enterprise 17.2.2. All changes inherited from PostgreSQL 17.4 are listed in [PostgreSQL 17.4 Release Notes](#). As compared with Postgres Pro Enterprise 17.2.2, this version also provides the following changes:

- Added details, like current working directory, the PGDATA directory, etc., to `crash_info` output files.
- Added the increased security requirements for the [CREATE PROFILE](#) command. Now the `PASSWORD_REQUIRE_COMPLEX` parameter requires characters from three different groups. Also, all characters of languages without case distinction (Hindi, Chinese, etc.) in the UTF-8 encoding are considered lowercase.
- Added the [skip_temp_rel_lock](#) configuration parameter, which allows you to skip locking for temporary relations.
- Implemented the following enhancements and bug fixes for [CFS](#):
 - Changed the default value for the [cfs_gc_threshold](#) configuration parameter from 50 to 30 percent.
 - Fixed an issue with [CFS](#) garbage collector being blocked by the backup process. If backup took ran too long, this could lead to write locks, preventing writes to compressed tablespaces. Now both processes lock only specific data files briefly, avoiding mutual blocking.
 - Fixed an issue with missing compression settings for tablespaces on standby servers by adding a new WAL record type. Previously, standby servers did not receive such compression settings because `ALTER TABLESPACE ... SET (compression=true)` was not logged in WAL.
 - Fixed the [cfs_start_gc](#) function to reject invalid values of the `n_workers` argument.
 - Fixed an issue where [CFS](#) garbage collector launcher failed to start and to launch garbage collector worker processes on standby servers.

- Fixed an issue with upgrading Postgres Pro Standard to Postgres Pro Enterprise using [pg_upgrade](#), which could fail if the old cluster had an epoch greater than 1 with an error like “could not open file”.
- Fixed an issue with handling *.cfm.bck files by [pg_upgrade](#).
- Fixed the [pg_upgrade - -check](#) option to correctly check that pg_upgrade is run on a standby. Previously, it would fail with errors like “cannot assign TransactionIds during recovery”.
- Fixed a segmentation fault caused by foreign data wrapper invalidation during [autonomous transactions](#) if an autonomous transaction reset global variables while registered callback functions remained active. Now callback functions check for global variables and invalidation data is preserved for parent transactions.
- Fixed an issue that caused the server to crash with PANIC instead of returning an appropriate error when deleting tuples from a page where the difference between the minimum transaction ID and the current transaction ID exceeded 2^{31} .
- Fixed [pg_multixact](#) bloating by introducing “soft” limits that trigger [autovacuum](#) earlier.
- Fixed an issue where [crash_info](#) could fail to write diagnostic files when handling a stack overflow. Previously, the signal handler ran on the same stack that had overflowed, which could prevent it from executing due to lack of available stack space. Now the handler runs on an alternate signal stack.
- Fixed an issue where roles without explicitly set VALID UNTIL attribute and associated with a profile that had [PASSWORD_GRACE_TIME](#) set to 0 and [PASSWORD_LIFE_TIME](#) set to UNLIMITED incorrectly received password expiration warnings. Now they are correctly considered valid indefinitely.
- Fixed a bug that caused problems with starting followers added after execution of ALTER SYSTEM on the initialized leader.
- Upgraded the [apache_age](#) extension to version 1.5.1.
- Upgraded the [BiHA](#) solution to provide the following features, optimizations, and bug fixes:
 - Implemented the ability to decrease the [max_connections](#) configuration parameter in a [BiHA cluster](#) without turning off the biha extension. You can now decrease the parameter value on the leader node and restart the node for the changes to take effect. Previously, the [max_connections](#) value could only be decreased if you temporarily remove the biha extension from [shared_preload_libraries](#).
 - Implemented [- -enable-proxima](#) — a [bihactl init](#) option that allows to [enable proxima](#) when creating a BiHA cluster.
 - Fixed a bug that caused the [biha-background-worker](#) process reboot when removing a replication slot.
 - Fixed a bug that caused problems with conversion of a cluster with the set [shared_preload_libraries](#) variable in the [postgresql.auto.conf](#) file into a BiHA cluster.
 - Fixed a bug that caused problems with conversion of a synchronous cluster into a BiHA cluster. Resetting the [synchronous_standby_names](#) parameter before conversion of a synchronous cluster is no longer required.
- Optimized [fasttrun](#) to skip unnecessary truncate operations on empty temporary relations.
- Fixed an issue with upgrading [pageinspect](#) in some corner cases to 1.10.1 or higher.
- Upgraded the [pgpro_multiplan](#) extension version 1.1, which provides the following bug fixes:
 - Fixed an issue with query execution when a plan was approved while [pgpro_multiplan.auto_capturing](#) was enabled, and then the query was executed with a different plan and [pgpro_multiplan.auto_capturing](#) was disabled. The issue could manifest itself in errors like “cache lookup failed for type”.
 - Fixed an issue with [pgpro_multiplan](#) failing to identify registered query with the parameter used in several places in this query, which prevented plan freezing for such queries.
- Upgraded [pgbadger](#) to version 13.0.
- Upgraded [pgbouncer](#) to version 1.24.0.
- Upgraded [pg_hint_plan](#) to version 1.7.0.3.
- Upgraded [pg_portal_modify](#) to version 0.3.5.
- Upgraded [pgpro_anonymizer](#) to version 1.3.2.
- Upgraded [pg_proaudit](#) to provide the following enhancements:
 - Added a new event field: session user name. Now an event contains the information about both [session_user](#) and [current_user](#) attributes of an SQL session.

- Added support for new event classes: `ALL_DDL_NONTEMP` and `ALL_DML_NONTEMP`. The scope of these classes is limited to the objects that are not contained in `pg_temp_nnn` temporary schemas.
- Fixed logging of `SELECT FOR UPDATE` and `SELECT FOR KEY SHARE` events as `SELECT`, rather than `UPDATE`.
- Upgraded `pg_probackup` to version 2.8.7 Enterprise, which provides the following optimizations and bug fixes:
 - Reduced the log level for “checking WAL file name” messages that are issued when the `show` with the `--archive` option is executed from `INFO` to `VERBOSE`.
 - Updated the `add-instance` command logic to make the `-D` option that specifies the path to the catalog mandatory. `add-instance` no longer relies on the `PGDATA` environment variable for the catalog location, but requires explicitly specifying the path to the catalog as the command option.
 - Improved the garbage collection mechanism in CFS used when a backup copy is created. File-system level locks resolve an issue with the concurrent access to files from compressed tablespaces during copying to a backup and during the defragmentation.
 - Fixed an issue of the multi-threaded file copying technique that prevents repeated copying of one file. This issue could previously stop the backup creation under high load on the server.
- Added the `pgpro_gbtree` extension that enables creation and use of a global index on a partitioned table. The global index is created for one or several columns of a partitioned table and does not include the partition key. It allows you to perform index scan without iterating through all the partitions.
- Upgraded `pgpro_queue` to version 1.1, where the no-longer-required `pgpro_queue.launcher_database` parameter is removed. Now when trying to specify this parameter, a corresponding warning will be displayed.
- Upgraded `pgpro_scheduler` to version 2.11.1 to fix a segmentation fault, which could occur when `pgpro_scheduler` did not terminate its processes when the associated extension or schema was dropped. Now it terminates with an error instead of crashing.
- Upgraded `pgpro_sf` to add a check for the value of the `a_sf_index` argument of the `sf_write` function to be greater than zero.
- Upgraded `pgpro_stats` to provide the following bug fixes and improvements:
 - Changed the format of the statistics dump file and the corresponding save/load routines.
 - Aligned the names of the `explain_*` filter attributes of the session tracer with the names of session-tracing configuration parameters.
 - Implemented turning off the session tracer functionality when no session-tracing filters are specified.
- Fixed an issue with `pgpro_usage` recording earlier timestamps. Previously, the last usage time of a privilege was recorded based on transaction start time, which could cause the timestamp to move backward if a long-running transaction accessed a table late, while a shorter concurrent transaction accessed it earlier.
- Upgraded the `proxima` extension to provide the following features, optimizations, and bug fixes:
 - Implemented `proxima.p2p_ssl_enabled`, `proxima.p2p_auth_methods`, and `proxima.ssl_trusted_certs_dir` configuration parameters to manage SSL communication and authentication between cluster nodes.
 - Extended the list of SQL functions that enable `proxima` to automatically establish the `dynamic dedicated session` when they are present in a query. The new functions are `set_config()` and `setseed()`.
 - Disabled launching `proxima` on a referee node of a `BiHA cluster` as this could cause authorization issues.
 - Fixed an issue where `BiHA` node IDs were not displayed in the `proxima` process.
 - Fixed a bug where `proxima` did not consider Postgres Pro `listen_addresses` values when starting local backends.
- Upgraded the `rum` module to update an error message for an error that can occur in the case when a `SELECT` query uses `ORDER BY`.

E.4.2. Migration to Version 17.4.1

If you are upgrading from a Postgres Pro Enterprise release based on the same PostgreSQL major version, it is enough to install the new version into your current installation directory.

ABI versions may change between minor releases of Postgres Pro. If this is the case, and you see the `ABI mismatch` error when trying to run your extension, make sure to install a new version of the extension supplied with a new release of Postgres Pro, or recompile your third-party extension to be able to use it with the current version of Postgres Pro.

Important

To upgrade your [BiHA cluster](#) from Postgres Pro Enterprise 17.2 to Postgres Pro Enterprise 17.4, see [migration instructions for BiHA](#).

To migrate from PostgreSQL, as well as Postgres Pro Standard or Postgres Pro Enterprise based on a previous PostgreSQL major version, see the [migration instructions for version 17](#).

E.5. Postgres Pro Enterprise 17.2.2

Release Date: 2025-01-21

E.5.1. Overview

This release is based on Postgres Pro Enterprise 17.2.1 and provides the following changes:

- Fixed an issue where temporary tables could fail to grow when their size exceeded a segment boundary, which could manifest itself in “could not open file” errors.
- Upgraded [aqo](#) to introduce the `auto` mode, which behaves like the `learn` mode but prevents memory overflow by implementing the least recently used (LRU) cache mechanism.
- Improved the `bihactl init --convert` command to skip the creation of objects required for [BiHA cluster](#) operation if these objects already exist in the database. Previously, the conversion would fail in such cases.
- Fixed a bug that caused the [biha.nodes](#) function to return an empty row for the node where it was called on.
- Upgraded [mamonsu](#) to version 3.5.11 to provide support for [pgpro_stats](#) version 1.8.
- Upgraded [pgpro_multiplan](#) to version 1.1, which provides the following new features:
 - Introduced `plan_hash`, which is the internal plan identifier of a frozen plan.
 - Added support for `template` plans and the [wildcards](#) feature. Now the `pgpro_multiplan` extension can create a template plan, which can be applied to the queries with table names matching the POSIX regular expressions in the `pgpro_multiplan.wildcards` configuration parameter.
- Upgraded [pgpro_stats](#) to version 1.8.1, which provides the following improvements and fixes:
 - Implemented an optimization that lowers the locking time in some cases when copying metrics from the local memory to the shared memory.
 - Fixed an issue that could occur during session tracing and cause errors “could not write file “pg_stat/pgpro_stats_filter-s.trace.tmp””: No such file or directory”. Concurrent writing from different sessions to a trace file is fixed now, so processes can write to the trace file in parallel without collisions.
 - Fixed an issue that could occur when a custom scan was used, which could cause an incorrect state of the query plan and could result in an error when `pgpro_stats` was involved.

E.5.2. Migration to Version 17.2.2

If you are upgrading from a Postgres Pro Enterprise release based on the same PostgreSQL major version, it is enough to install the new version into your current installation directory.

To migrate from PostgreSQL, as well as Postgres Pro Standard or Postgres Pro Enterprise based on a previous PostgreSQL major version, see the [migration instructions for version 17](#).

E.6. Postgres Pro Enterprise 17.2.1

Release Date: 2024-12-27

E.6.1. Overview

This release is based on PostgreSQL 17.2 and includes all the new features introduced in PostgreSQL 17, as well as bug fixes implemented in PostgreSQL 17.2 update. For the detailed description, see [PostgreSQL 17](#), and [PostgreSQL 17.2 Release Notes](#).

For the list of extension modules and utilities specific to Postgres Pro Enterprise, as well as the main user-visible core changes over vanilla PostgreSQL, see [Section 2](#). As compared to Postgres Pro Enterprise 16.6.1, the following differences are worth mentioning:

- Added the [SPLIT PARTITION](#) and [MERGE PARTITIONS](#) subcommands to the `ALTER TABLE` command. The subcommands split a single partition into several partitions and merge several partitions into one, respectively, hence improving partitioned table management.
- Added the [pg_backend_get_config_value](#) function that allows you to request the current value of a parameter for the backend with the specified PID.
- Added the [enable_extra_transformations](#) configuration parameter, which enables additional query-tree transformations.
- Optimized [CFS](#) operation: enhanced the reliability of the garbage collector, introduced automatic restart mechanisms to ensure that CFS worker processes are relaunched in the event of a failure.
- Renamed the real-time query replanning functionality to [adaptive query execution \(AQE\)](#).
- Inherited the PostgreSQL implementation of [SLRU](#) cache size configuration. The corresponding `slru_buffers_size_scale` configuration parameter is removed now. Use the following parameters instead: [commit_timestamp_buffers](#), [multixact_member_buffers](#), [multixact_offset_buffers](#), [notify_buffers](#), [serializable_buffers](#), [subtransaction_buffers](#), and [transaction_buffers](#).
- Added the [pgpro_autopart](#) extension that allows dynamic partition creation by using triggers on the partitioned table view.
- Added the [pgpro_ilm](#) extension that enables moving rarely used relations to a lower-cost storage. This feature is similar to Oracle's information lifecycle management (ILM). Only moving of regular tables and partitions of partitioned tables is currently supported.
- Added the [pgpro_multiplan](#) extension, which includes the full functionality of the `sr_plan` extension as well as new features, such as `plan_hash` of the frozen plan for further usage. The `sr_plan` extension was removed from Postgres Pro Enterprise.
- Added the [pgpro_queue](#) extension for message queueing management directly within the database.
- Added the [pgpro_usage](#) extension that provides per-user statistics on accessing relations and calling functions, including a view that shows which privileges are unused and functions that return the date and time of the last access to tables.
- Implemented the [proxima](#) extension that combines functionality of a proxy server and a connection pooler.
- Upgraded the [apache_age](#) extension to support Postgres Pro 17. In particular, added an error message to clarify that, in prepared statements, using a property filter as a parameter in a `MATCH` clause is only supported with the `agtype` containment operator (`@>`), and not with access method operators.
- Upgraded [aqo](#) to version 3.0, which provides the following major changes and enhancements:
 - Introduced the sandbox mode, which allows working in an isolated environment without touching the main aqo knowledge base. This mode can be turned on either on a primary or a standby node by setting [aqo.sandbox](#) to on.
 - Introduced a learning mechanism where aqo adjusts the planner's row estimates with its own predictions. It can be turned on by enabling [aqo.delta_rows](#).
- Improved the [BiHA callbacks](#) functionality:
 - Added the `NODE_ADDED`, `NODE_REMOVED`, and `LEADER_STATE_IS_RW` callback types.
 - Updated the `TERM_CHANGED` type.
 - Added the `biha_callbacks_user` user role as the default user for callback execution.
- Upgraded [mamonsu](#) to version 3.5.10.
- Upgraded [multimaster](#) to add the ability to specify the catchup mode for reconnected nodes using the [multimaster.catchup_algorithm](#) configuration parameter. Supported the `parallel` catchup mode, in which non-conflicting replicated transactions are applied in parallel.
- Added support for `COPY` to the [online_analyze](#) module.
- Upgraded [pg_hint_plan](#) to version 1.7.0, where the format of hint table changed to require the unique `query_id` instead of the parameterized query text.
- Upgraded [pg_probackup](#) to version 2.8.6 Enterprise.

- Upgraded [pgpro_pwr](#) to version 4.8, which provides new features and bug fixes. Notable changes are as follows:
 - Added tracking of extension versions installed in the cluster through a new report section.
 - Added a possibility to hide data for certain databases in the report. To this end, a new parameter that accepts an array of databases to be excluded was added to report generation functions.
- Upgraded [pg_variables](#). The `DISCARD ALL` command now discards all packages and variables in `pg_variables`. You can use the extension with [proxima](#) via the [forced dynamic dedicated session](#).
- Deprecated the `pgpro_version`, `pgpro_edition`, and `pgpro_build` functions, which will be removed in future releases. Use the [pgpro_version](#), [pgpro_edition](#), and [pgpro_build](#) configuration parameters instead.
- Removed the ability to create constructs using `JSON_EXISTS()` with the `RETURNING` clause, which in earlier versions allowed the function to return values of any type. This syntax is not supported by the SQL/JSON standard, which states that the `JSON_EXISTS()` predicate should only return `TRUE`, `FALSE`, or `UNKNOWN`.
- Removed the deprecated built-in connection pooler. It's recommended to use the new [proxima](#) extension instead.
- Removed the deprecated `pg_pathman` extension.
- Ended support for AlterOS 7, ALT 8.2 SP, ALT 9, Debian 10, SLES 12.

E.6.2. Migration to Version 17

You can migrate to Postgres Pro Enterprise 17 from the same or a previous version of PostgreSQL (that is supported by the upgrade method chosen) or Postgres Pro Standard/Postgres Pro Standard Certified and from a previous version of Postgres Pro Enterprise/Postgres Pro Enterprise Certified. The same holds for migration to Postgres Pro Enterprise Certified 17. See [Section 18.6](#) for the methods to upgrade your database cluster. Consult the Postgres Pro Enterprise support team if you experience issues during migration. Backward migration is not supported. Note that migration from Postgres Pro Enterprise to Postgres Pro Enterprise Certified of the same major version (or vice versa) is an update between Postgres Pro compatible versions (see [Section 18.6](#) for more details).

To migrate from PostgreSQL, Postgres Pro Standard, or Postgres Pro Enterprise release based on a previous PostgreSQL major version, make sure to install its latest available minor version and then perform a dump/restore using [pg_dumpall](#) or use the [pg_upgrade](#) utility.

If you choose to run `pg_upgrade`, make sure to initialize the new database cluster with compatible parameters. In particular, pay attention to the [checksum](#) settings in the cluster you are migrating from. If `pg_upgrade` creates any SQL files in its current directory, run these files to complete the upgrade.

For the instructions on migrating your [BiHA cluster](#) to version 17, see [migration instructions for BiHA](#).

When migrating from PostgreSQL or Postgres Pro Standard, make sure to pay special attention to implementation specifics of [64-bit transaction IDs](#). If you have used explicit casts to 32-bit integers when handling transaction IDs, you have to replace them with casts to `bigint` since 64-bit transaction IDs are of the `bigint` type.

Note

To avoid conflicts, do not use the `postgrespro-ent-17` package to install the new Postgres Pro binaries. Use the individual packages instead. In this case, server autostart needs to be enabled manually, if required. For details on the available packages and installation instructions, see [Chapter 17](#).

For other upgrade requirements imposed by vanilla PostgreSQL, see [Section E.14](#).

E.7. Release 17.7

Release date: 2025-11-13

This release contains a variety of fixes from 17.6. For information about new features in major release 17, see [Section E.14](#).

E.7.1. Migration to Version 17.7

A dump/restore is not required for those running 17.X.

However, if you are upgrading from a version earlier than 17.6, see [Section E.8](#).

E.7.2. Changes

- Check for `CREATE` privileges on the schema in `CREATE STATISTICS` (Jelte Fennema-Nio)

This omission allowed table owners to create statistics in any schema, potentially leading to unexpected naming conflicts.

The PostgreSQL Project thanks Jelte Fennema-Nio for reporting this problem. (CVE-2025-12817)

- Avoid integer overflow in allocation-size calculations within `libpq` (Jacob Champion)

Several places in `libpq` were not sufficiently careful about computing the required size of a memory allocation. Sufficiently large inputs could cause integer overflow, resulting in an undersized buffer, which would then lead to writing past the end of the buffer.

The PostgreSQL Project thanks Aleksey Solovev of Positive Technologies for reporting this problem. (CVE-2025-12818)

- Prevent “unrecognized node type” errors when a SQL/JSON function such as `JSON_VALUE` has a `DEFAULT` clause containing a `COLLATE` expression (Jian He)
- Correctly treat JSON constructor expressions, such as `JSON_OBJECT ( )`, as non-strict (Tender Wang, Richard Guo)

In some cases these expressions can yield a non-null result despite having one or more null inputs, making them non-strict. The planner incorrectly classified them as strict and could perform incorrect query transformations as a result.

- Further fix processing of character classes within `SIMILAR TO` regular expressions (Laurenz Albe)

The previous fix for translating `SIMILAR TO` pattern matching expressions to POSIX-style regular expressions broke a corner case that formerly worked: if there is an escape character right after the opening bracket and then a closing bracket right after the escape sequence (for example `[\w]`), the closing bracket was no longer seen as terminating the character class.

- Fix parsing of aggregate functions whose arguments contain a sub-select with a `FROM` reference to a CTE outside the aggregate function (Tom Lane)

Such a CTE reference must act like a outer-level column reference when determining the aggregate’s semantic level; but it was not being accounted for, leading to obscure planner or executor errors.

- Fix “no relation entry for relid” errors in corner cases while estimating SubPlan costs (Richard Guo)
- Avoid unlikely use-after-free in planner’s expansion of partitioned tables (Bernd Reib)

There was a hazard only when the last live partition was concurrently dropped.

- Remove faulty assertion in btree index cleanup (Peter Geoghegan)
- Fix possible infinite loop in GIN index scans with multiple scan conditions (Tom Lane)

GIN can handle scan conditions that can reject non-matching entries but are not useful for searching for relevant entries, for example a `tsquery` clause like `!term`. But such a condition must not be first in the array of scan conditions. The code failed to ensure that in all cases, with the result that a query having a mix of such conditions with normal conditions might work or not depending on the order in which the conditions were given in the query.

- Ensure that GIN index scans can be canceled (Tom Lane)

Some code paths were capable of running for a long time without checking for interrupts.

- Ensure that BRIN autosummarization provides a snapshot for index expressions that need one (Álvaro Herrera)

Previously, autosummarization would fail for such indexes, and then leave placeholder index tuples behind, causing the index to bloat over time.

- Fix integer-overflow hazard in BRIN index scans when the table contains close to 2^{32} pages (Sunil S)

This oversight could result in an infinite loop or scanning of unneeded table pages.

- Fix incorrect zero-extension of stored values in JIT-generated tuple deforming code (David Rowley)

When not using JIT, the equivalent code does sign-extension not zero-extension, leading to a different Datum representation of small integer data types. This inconsistency was masked in most cases, but it is known to lead to “could not find memoization table entry” errors when using Memoize plan nodes, and there might be other symptoms.

- Fix incorrect logic for caching result-relation information for triggers (David Rowley, Amit Langote)

In cases where partitions' column sets aren't physically identical to their parent partitioned tables' column sets, this oversight could lead to crashes.

- Add missing EvalPlanQual rechecks for TID Scan and TID Range Scan plan nodes (Sophie Alpert, David Rowley)

This omission led to possibly not rechecking a condition on `ctid` during concurrent-update situations, causing the update's behavior to vary depending on which plan type had been selected.

- Fix EvalPlanQual handling of foreign or custom joins that do not have an alternative local-join plan prepared for EPQ (Masahiko Sawada, Etsuro Fujita)

In such cases the foreign or custom access method should be invoked normally, but that did not happen, typically leading to a crash.

- Avoid duplicating hash partition constraints during `DETACH CONCURRENTLY` (Haiyang Li)

`ALTER TABLE DETACH PARTITION CONCURRENTLY` was written to add a copy of the partitioning constraint to the now-detached partition. This was misguided, partially because non-concurrent `DETACH` doesn't do that, but mostly because in the case of hash partitioning the constraint expression contains references to the parent table's OID. That causes problems during dump/restore, or if the parent table is dropped after `DETACH`. In v19 and later, we'll no longer create any such copied constraints at all. In released branches, to minimize the risk of unforeseen consequences, only skip adding a copied constraint if it is for hash partitioning.

- Disallow generated columns in partition keys (Jian He, Ashutosh Bapat)

This was already not allowed, but the check missed some cases, such as where the column reference is implicit in a whole-row reference.

- Disallow generated columns in `COPY . . . FROM . . . WHERE` clauses (Peter Eisentraut, Jian He)

Previously, incorrect behavior or an obscure error message resulted from attempting to reference such a column, since generated columns have not yet been computed at the point where `WHERE` filtering is done.

- Avoid potential use-after-free in parallel vacuum (Kevin Oommen Anish)

This bug seems to have no consequences in standard builds, but it's theoretically a hazard.

- Fix visibility checking for statistics objects in `pg_temp` (Noah Misch)

A statistics object located in a temporary schema cannot be named without schema qualification, but `pg_statistics_obj_is_visible()` missed that memo and could return “true” regardless. In turn, functions such as `pg_describe_object()` could fail to schema-qualify the object's name as expected.

- Fix `pg_event_trigger_dropped_objects()`'s reporting of temporary status (Antoine Violin, Tom Lane)

If a dropped column default, trigger, or RLS policy belongs to a temporary table, report it with `is_temporary` true.

- Fix memory leakage in hashed subplans (Haiyang Li)

Any memory consumed by the hash functions used for hashing tuples constituted a query-lifespan memory leak. One way that could happen is if the values being hashed require de-toasting.

- Avoid leaking `SMgrRelation` objects in the startup process (Jingtang Zhang)

In a long-running standby server, the hashtable holding these objects could bloat substantially, because there was no mechanism for freeing no-longer-interesting entries.

- Fix minor memory leak during WAL replay of database creation (Nathan Bossart)
- Fix corruption of the shared statistics table after out-of-memory failures (Mikhail Kot)

Previously, an out-of-memory failure partway through creating a new hash table entry left a broken entry behind, potentially causing errors in other sessions later.

- Fix concurrent update issue in **MERGE** (Yugo Nagata)

When executing a **MERGE UPDATE** action, if there is more than one concurrent update of the target row, the lock-and-retry code would sometimes incorrectly identify the latest version of the target tuple, leading to incorrect results.

- Add missing replica identity checks in **MERGE** and **INSERT . . . ON CONFLICT DO UPDATE** (Zhijie Hou)

If **MERGE** may require update or delete actions, and the target table publishes updates or deletes, insist that it have a **REPLICA IDENTITY** defined. Failing to require this can silently break replication. Likewise, **INSERT** with an **UPDATE** option must require **REPLICA IDENTITY** if the target table publishes either inserts or updates.

- Avoid deadlock during **DROP SUBSCRIPTION** when publisher is on the same server as subscriber (Dilip Kumar)
- Fix incorrect reporting of replication lag in `pg_stat_replication` view (Fujii Masao)

If any standby server's replay LSN stopped advancing, the `write_lag` and `flush_lag` columns would eventually stop updating.

- Avoid duplicative log messages about invalid `primary_slot_name` settings (Fujii Masao)
- Avoid failures when `synchronized_standby_slots` references nonexistent replication slots (Shlok Kyal)
- Remove the unfinished slot state file after failing to write a replication slot's state to disk (Michael Paquier)

Previously, a failure such as out-of-disk-space resulted in leaving a temporary `state.tmp` file behind. That's problematic because it would block all subsequent attempts to write the state, requiring manual intervention to clean up.

- Fix mishandling of lock timeout signals in parallel apply workers for logical replication (Hayato Kuroda)

The same signal number was being used for both worker shutdown and lock timeout, leading to confusion.

- Avoid unwanted WAL receiver shutdown when switching from streaming to archive WAL source (Xuneng Zhou)

During a timeline change, a standby server's WAL receiver should remain alive, waiting for a new WAL streaming start point. Instead it was repeatedly shutting down and immediately getting restarted, which could confuse status monitoring code.

- Avoid failures in logical replication due to chance collisions of file numbers between regular and temporary tables (Vignesh C)

This low-probability problem manifested as transient errors like “unexpected duplicate for tablespace X, relfilenode Y”. `contrib/autoprewarm` was also affected. A side-effect of the fix is that the SQL function `pg_filenode_relation()` will now ignore temporary tables.

- Fix use-after-free issue in the relation synchronization cache maintained by the `pgoutput` logical decoding plugin (Vignesh C, Masahiko Sawada)

An error during logical decoding could result in crashes in subsequent logical decoding attempts in the same session. The case is only reachable when `pgoutput` is invoked via SQL functions.

- Avoid unnecessary invalidation of logical replication slots (Bertrand Drouvot)
- Avoid assertion failure when trying to release a replication slot in single-user mode (Hayato Kuroda)
- Fix incorrect printing of messages about failures in checking whether the user has Windows administrator privilege (Bryan Green)

This code would have crashed or at least printed garbage. No such cases have been reported though, indicating that failure of these system calls is extremely rare.

- Avoid startup failure on macOS and BSD platforms when there is a collision with a pre-existing semaphore set (Tom Lane)

If the pre-existing set has fewer semaphores than we asked for, these platforms return `EINVAL` not `EEXIST` as our code expected, resulting in failure to start the database.

- Avoid crash when attempting to test PostgreSQL with certain libsanitizer options (Emmanuel Sibi, Jacob Champion)
- Fix false memory-context-checking warnings in debug builds on 64-bit Windows (David Rowley)
- Correctly handle `GROUP BY DISTINCT` in PL/pgSQL assignment statements (Tom Lane)

The parser failed to record the `DISTINCT` option in this context, so that the command would act as if it were plain `GROUP BY`.

- Avoid leaking memory when handling a SQL error within PL/Python (Tom Lane)

This fixes a session-lifespan memory leak introduced in our previous minor releases.

- Fix libpq's trace output of characters with the high bit set (Ran Benita)

On platforms where `char` is considered signed, the output included unsightly `\xfffff` decoration.

- Fix libpq's handling of socket-related errors on Windows within its GSSAPI logic (Ning Wu, Tom Lane)

The code for encrypting/decrypting transmitted data using GSSAPI did not correctly recognize error conditions on the connection socket, since Windows reports those differently than other platforms. This led to failure to make such connections on Windows.

- Fix dumping of non-inherited not-null constraints on inherited table columns (Dilip Kumar)

`pg_dump` failed to preserve such constraints when dumping from a pre-v18 server.

- In `pg_dump`, dump security labels on subscriptions and event triggers (Jian He, Fujii Masao)

Labels on these types of objects were previously missed.

- Fix `pg_dump`'s sorting of default ACLs and foreign key constraints (Kirill Reshke, Álvaro Herrera)

Ensure consistent ordering of these database object types, as was already done for other object types.

- In `pg_dump`, label comments for separately-dumped domain constraints with the proper dependency (Noah Misch)

This error could lead to parallel `pg_restore` attempting to create the comment before the constraint itself has been restored.

- In `pg_restore`, skip comments and security labels for publications and subscriptions that are not being restored (Jian He, Fujii Masao)

Do not emit `COMMENT` or `SECURITY LABEL` commands for these objects when `--no-publications` or `--no-subscriptions` is specified.

- Fix assorted errors in the data compression logic in `pg_dump` and `pg_restore` (Daniel Gustafsson, Tom Lane)

Error checking was missing or incorrect in several places, and there were also portability issues that would manifest on big-endian hardware. These problems had been missed because this code is only used to read compressed TOC files within directory-format dumps. `pg_dump` never produces such a dump; the case can be reached only by manually compressing the TOC file after the fact, which is a supported thing to do but very uncommon.

- Fix `pgbench` to error out cleanly if a `COPY` operation is started (Anthonin Bonnefoy)

`pgbench` doesn't intend to support this case, but previously it went into an infinite loop.

- Fix `pgbench`'s reporting of multiple errors (Yugo Nagata)

In cases where two successive `PQgetResult` calls both fail, `pgbench` might report the wrong error message.

- In `pgbench`, fix faulty assertion about errors in pipeline mode (Yugo Nagata)

- Fix per-file memory leakage in `pg_combinebackup` (Tom Lane)

- Ensure that `contrib/pg_buffercache` functions can be canceled (Satyanarayana Narlapuram, Yuhang Qiu)

Some code paths were capable of running for a long time without checking for interrupts.

- Fix `contrib/pg_prewarm`'s privilege checks for indexes (Ayush Vatsa, Nathan Bossart)

`pg_prewarm()` requires `SELECT` privilege on relations to be prewarmed. However, since indexes have no SQL privileges of their own, this resulted in non-superusers being unable to prewarm indexes. Instead, check for `SELECT` privilege on the index's table.

- Make `contrib/pgstattuple` more robust about empty or invalid index pages (Nitin Motiani)

Count all-zero pages as free space, and ignore pages that are invalid according to a check of the page's special-space size. The code for btree indexes already counted all-zero pages as free, but the hash and gist code would error out, which has been found to be much less user-friendly. Similarly, make all three cases agree on ignoring corrupted pages rather than throwing errors.

- Harden our read and write barrier macros to satisfy Clang (Thomas Munro)

We supposed that `__atomic_thread_fence()` is a sufficient barrier to prevent the C compiler from re-ordering memory accesses around it, but it appears that that's not true for Clang, allowing it to generate incorrect code for at least RISC-V, MIPS, and LoongArch machines. Add explicit compiler barriers to fix that.

- Fix building with LLVM version 21 and later (Holger Hoffstätte)
- When building with meson, apply the same special optimization flags for `numeric.c` and `checksum.c` as the makefile build does (Nathan Bossart, Jeff Davis)

Use `-ftree-vectorize` for both files, as well as `-funroll-loops` for `checksum.c`, to match what the makefiles have long done.

- Fix PGXS build infrastructure to support building NLS po files for extensions (Ryo Matsumura)

E.8. Release 17.6

Release date: 2025-08-14

This release contains a variety of fixes from 17.5. For information about new features in major release 17, see [Section E.14](#).

E.8.1. Migration to Version 17.6

A dump/restore is not required for those running 17.X.

However, if you have any BRIN `numeric_minmax_multi_ops` indexes, it is advisable to reindex them after updating. See the fourth changelog entry below.

Also, if you are upgrading from a version earlier than 17.5, see [Section E.9](#).

E.8.2. Changes

- Tighten security checks in planner estimation functions (Dean Rasheed)

The fix for CVE-2017-7484, plus followup fixes, intended to prevent leaky functions from being applied to statistics data for columns that the calling user does not have permission to read. Two gaps in that protection have been found. One gap applies to partitioning and inheritance hierarchies where RLS policies on the tables should restrict access to statistics data, but did not.

The other gap applies to cases where the query accesses a table via a view, and the view owner has permissions to read the underlying table but the calling user does not have permissions on the view. The view owner's permissions satisfied the security checks, and the leaky function would get applied to the underlying table's statistics before we check the calling user's permissions on the view. This has been fixed by making security checks on views occur at the start of planning. That might cause permissions failures to occur earlier than before.

The PostgreSQL Project thanks Dean Rasheed for reporting this problem. (CVE-2025-8713)

- Prevent `pg_dump` scripts from being used to attack the user running the restore (Nathan Bossart)

Since dump/restore operations typically involve running SQL commands as superuser, the target database installation must trust the source server. However, it does not follow that the operating system user who executes `psql` to perform the restore should have to trust the source server. The risk here is that an attacker who has gained superuser-level control over the source

server might be able to cause it to emit text that would be interpreted as psql meta-commands. That would provide shell-level access to the restoring user's own account, independently of access to the target database.

To provide a positive guarantee that this can't happen, extend psql with a `\restrict` command that prevents execution of further meta-commands, and teach `pg_dump` to issue that before any data coming from the source server.

The PostgreSQL Project thanks Martin Rakhmanov, Matthieu Denais, and RyotaK for reporting this problem. (CVE-2025-8714)

- Convert newlines to spaces in names included in comments in `pg_dump` output (Noah Misch)

Object names containing newlines offered the ability to inject arbitrary SQL commands into the output script. (Without the preceding fix, injection of psql meta-commands would also be possible this way.) CVE-2012-0868 fixed this class of problem at the time, but later work reintroduced several cases.

The PostgreSQL Project thanks Noah Misch for reporting this problem. (CVE-2025-8715)

- Fix incorrect distance calculation in BRIN `numeric_minmax_multi_ops` support function (Peter Eisentraut, Tom Lane)

The results were sometimes wrong on 64-bit platforms, and wildly wrong on 32-bit platforms. This did not produce obvious failures because the logic is only used to choose how to merge values into ranges; at worst the index would become inefficient and bloated. Nonetheless it's recommended to reindex any BRIN indexes that use the `numeric_minmax_multi_ops` operator class.

- Avoid regression in the size of XML input that we will accept (Michael Paquier, Erik Wienhold)

Our workaround for a bug in early 2.13.x releases of libxml2 made use of a code path that rejects text chunks exceeding 10MB, whereas the previous coding did not. Those early releases are presumably extinct in the wild by now, so revert to the previous coding.

- Fix MERGE problems with concurrent updates (Dean Rasheed)

If a MERGE inside a CTE attempts an update or delete on a table with `BEFORE ROW` triggers, and a concurrent `UPDATE` or `DELETE` changes the target row, the MERGE command would fail (crashing in the case of an update action, and potentially executing the wrong action in the case of a delete action).

- Fix MERGE into a plain-inheritance parent table (Dean Rasheed)

Insertions into such a target table could crash or produce incorrect query results due to failing to handle `WITH CHECK OPTION` and `RETURNING` actions.

- Allow tables with statement-level triggers to become partitions or inheritance children (Etsuro Fujita)

We do not allow partitions or inheritance child tables to have row-level triggers with transition tables, because an operation on the whole inheritance tree would need to maintain a separate transition table for each such child table. But that problem does not apply for statement-level triggers, because only the parent's statement-level triggers will be fired. The code that checks whether an existing table can become a partition or inheritance child nonetheless rejected both kinds of trigger.

- Disallow collecting transition tuples from child foreign tables (Etsuro Fujita)

We do not support triggers with transition tables on foreign tables. However, the case of a partition or inheritance child that is a foreign table was overlooked. If the parent has such a trigger, incorrect transition tuples were collected from the foreign child. Instead throw an error, reporting that the case is not supported.

- Allow resetting unknown custom parameters with reserved prefixes (Nathan Bossart)

Previously, if a parameter setting had been stored using `ALTER DATABASE/ROLE/SYSTEM`, the stored setting could not be removed if the parameter was unknown but had a reserved prefix. This case could arise if an extension used to have a parameter, but that parameter had been removed in an upgrade.

- Fix a potential deadlock during `ALTER SUBSCRIPTION ... DROP PUBLICATION` (Ajin Cherian)

Ensure that server processes acquire catalog locks in a consistent order during replication origin drops.

- Shorten the race condition window for creating indexes with conflicting names (Tom Lane)

When choosing an auto-generated name for an index, avoid conflicting with not-yet-committed `pg_class` rows as well as fully-valid ones. This avoids possibly choosing the same name as some concurrent `CREATE INDEX` did, when that command is still in process of filling its index, or is done but is part of a not-yet-committed transaction. There's still a window for trouble, but it's only as long as the time needed to validate a new index's parameters and insert its `pg_class` row.

- Prevent usage of incorrect `VACUUM` options in some cases where multiple tables are vacuumed in a single command (Nathan Bossart, Michael Paquier)

The `TRUNCATE` and `INDEX_CLEANUP` options of one table could be applied to others.

- Ensure that the table's free-space map is updated in a timely way when vacuuming a table that has no indexes (Masahiko Sawada)

A previous optimization caused FSM vacuuming to sometimes be skipped for such tables.

- Fix processing of character classes within `SIMILAR TO` regular expressions (Laurenz Albe)

The code that translates `SIMILAR TO` pattern matching expressions to POSIX-style regular expressions did not consider that square brackets can be nested. For example, in a pattern like `[[:alpha:]]%_`, the code treated the `%` and `_` characters as metacharacters when they should be literals.

- When deparsing queries, always add parentheses around the expression in `FETCH FIRST expression ROWS WITH TIES` clauses (Heikki Linnakangas)

This avoids some cases where the deparsed result wasn't syntactically valid.

- Limit the checkpoint process's fsync request queue size (Alexander Korotkov, Xuneng Zhou)

With very large `shared_buffers` settings, it was possible for the checkpoint to attempt to allocate more than 1GB for fsync requests, leading to failure and an infinite loop. Clamp the queue size to prevent this scenario.

- Avoid infinite wait in logical decoding when reading a partially-written WAL record (Vignesh C)

If the server crashes after writing the first part of a WAL record that would span multiple pages, subsequent logical decoding of the WAL stream would wait for data to arrive on the next WAL page. That might never happen if the server is now idle.

- Fix inconsistent spelling of LWLock names for `MultiXactOffsetSLRU` and `MultiXactMemberSLRU` (Bertrand Drouvot)

This resulted in different wait-event names being displayed in `pg_wait_events` and `pg_stat_activity`, potentially breaking monitoring queries that join those views.

- Fix inconsistent quoting of role names in ACL strings (Tom Lane)

The previous quoting rule was locale-sensitive, which could lead to portability problems when transferring `aclitem` values across installations. (`pg_dump` does not do that, but other tools might.) To ensure consistency, always quote non-ASCII characters in `aclitem` output; but to preserve backward compatibility, never require that they be quoted during `aclitem` input.

- Reject equal signs (=) in the names of relation options and foreign-data options (Tom Lane)

There's no evident use-case for option names like this, and allowing them creates ambiguity in the stored representation.

- Fix potentially-incorrect decompression of LZ4-compressed archive data (Mikhail Gribkov)

This error seems to manifest only with not-very-compressible input data, which may explain why it escaped detection.

- Avoid a rare scenario where a btree index scan could mark the wrong index entries as dead (Peter Geoghegan)
- Avoid re-distributing cache invalidation messages from other transactions during logical replication (vignesh C)

Our previous round of minor releases included a bug fix to ensure that replication receiver processes would respond to cross-process cache invalidation messages, preventing them from using stale catalog data while performing replication updates. However, the fix unintentionally made them also redistribute those messages again, leading to an exponential increase in the number of invalidation messages, which would often end in a memory allocation failure. Fix by not redistributing received messages.

- Avoid unexpected server shutdown when replication slot synchronization is misconfigured (Fujii Masao)

The postmaster process would report an error (and then stop) if `sync_replication_slots` was set to `true` while `wal_level` was less than `logical`. The desired behavior is just that slot synchronization should be disabled, so reduce this error message's level to avoid postmaster shutdown.

- Avoid premature removal of old WAL during checkpoints (Vitaly Davydov)

If a replication slot's restart point is advanced while a checkpoint is in progress, no-longer-needed WAL segments could get removed too soon, leading to recovery failure if the database crashes immediately afterwards. Fix by keeping them for one additional checkpoint cycle.

- Never move a replication slot's confirmed-flush position backwards (Shveta Malik)

In some cases a replication client could acknowledge an LSN that's past what it has stored persistently, and then perhaps send an older LSN after a restart. We consider this not-a-bug so long as the client did not have anything it needed to do for the WAL between the two points. However, we should not re-send that WAL for fear of data duplication, so make sure we always believe the latest confirmed LSN for a given slot.

- Prevent excessive delays before launching new logical replication workers (Tom Lane)

In some cases the logical replication launcher could sleep considerably longer than the configured `wal_retrieve_retry_interval` before launching a new worker.

- Fix use-after-free during logical replication of `INSERT . . . ON CONFLICT` (Ethan Mertz, Michael Paquier)

This could result in incorrect progress reporting, or with very bad luck it could result in a crash of the WAL sender process.

- Allow waiting for a transaction on a standby server to be interrupted (Kevin K Biju)

Creation of a replication slot on a standby server may require waiting for some active transaction(s) to finish on the primary and then be replayed on the standby. Since that could be an indefinite wait, it's desirable to allow the operation to be cancelled, but there was no check for query cancel in the loop.

- Do not let cascading logical WAL senders try to send data that's beyond what has been replayed on their standby server (Alexey Makhmutov)

This avoids a situation where such WAL senders could get stuck at standby server shutdown, waiting for replay work that will not happen because the server's startup process is already shut down.

- Fix per-relation memory leakage in autovacuum (Tom Lane)
- Fix session-lifespan memory leaks in `XMLSERIALIZE( . . . INDENT )` (Dmitry Kovalenko, Tom Lane)
- Fix possible crash after out-of-memory when allocating large chunks with the “bump” allocator (Tom Lane)
- Fix some places that might try to fetch toasted fields of system catalogs without any snapshot (Nathan Bossart)

This could result in an assertion failure or “cannot fetch toast data without an active snapshot” error.

- Avoid assertion failure during cross-table constraint updates (Tom Lane, Jian He)
- Remove faulty assertion that a command tag must have been determined by the end of `PortalRunMulti()` (Álvaro Herrera)

This failed in edge cases such as an empty prepared statement.

- Fix assertion failure in `XMLTABLE` parsing (Richard Guo)
- Restore the ability to run PL/pgSQL expressions in parallel (Dipesh Dhameliya)

PL/pgSQL's notion of an “expression” is very broad, encompassing any SQL `SELECT` query that returns a single column and no more than one row. So there are cases, for example evaluation of an aggregate function, where the query involves significant work and it'd be useful to run it with parallel workers. This used to be possible, but a previous bug fix unintentionally disabled it.

- Fix edge-case resource leaks in PL/Python error reporting (Tom Lane)

An out-of-memory failure while reporting an error from Python could result in failure to drop reference counts on Python objects, leading to session-lifespan memory leakage.

- Fix libpq's `PQcancelCreate()` function for the case where the server's address was specified using `hostaddr` (Sergei Kornilov)

libpq would crash if the resulting cancel object was actually used.

- Fix libpq's `PQport()` function to never return NULL unless the passed connection is NULL (Daniele Varrazzo)

This is the documented behavior, but recent libpq versions would return NULL in some cases where the user had not provided a port specification. Revert to our historical behavior of returning an empty string in such cases. (v18 and later will return the compiled-in default port number, typically "5432", instead.)

- Avoid failure when GSSAPI authentication requires packets larger than 16kB (Jacob Champion, Tom Lane)

Larger authentication packets are needed for Active Directory users who belong to many AD groups. This limitation manifested in connection failures with unintelligible error messages, typically "GSSAPI context establishment error: The routine must be called again to complete its function: Unknown error".

- Fix timing-dependent failures in SSL and GSSAPI data transmission (Tom Lane)

When using SSL or GSSAPI encryption in non-blocking mode, libpq sometimes failed with "SSL error: bad length" or "GSSAPI caller failed to retransmit all data needing to be retried".

- Avoid null-pointer dereference during connection lookup in ecpg applications (Aleksander Alekseev)

The case could occur only if the application has some connections that are named and some that are not.

- Improve psql's tab completion for `COPY` and `\copy` options (Atsushi Torikoshi)

The same completions were offered for both `COPY FROM` and `COPY TO`, although some options are only valid for one case or the other. Distinguish these cases to provide more accurate suggestions.

- Avoid assertion failure in `pgbench` when multiple pipeline sync messages are received (Fujii Masao)
- Fix duplicate transaction replay when initializing a subscription with `pg_createsubscriber` (Shlok Kyal)

It was possible for the last transaction processed during subscriber recovery to be sent again once normal replication begins.

- Ensure that `pg_dump` dumps comments on not-null constraints on domain types (Jian He, Álvaro Herrera)
- Ensure that `pg_dump` dumps comments on domain constraints in a valid order (Jian He)

In some cases the comment command could appear before creation of the constraint.

- Ensure stable sort ordering in `pg_dump` for all types of database objects (Noah Misch, Andreas Karlsson)

`pg_dump` sorts objects by their logical names before performing dependency-driven reordering. This sort did not account for the full unique key identifying certain object types such as rules and constraints, and thus it could produce dissimilar sort orders for logically-identical databases. That made it difficult to compare databases by diff'ing `pg_dump` output, so improve the logic to ensure stable sort ordering in all cases.

- Fix incorrect parsing of object types in `pg_dump` filter files (Fujii Masao)

Treat keywords as extending to the next whitespace, rather than stopping at the first non-alphanumeric character as before. This makes no difference for valid keywords, but it allows some error cases to be recognized properly. For example, `table-data` will now be rejected, whereas previously it was misinterpreted as `table`.

- `pg_restore` failed to restore large objects (BLOBs) from directory-format dumps made by `pg_dump` versions before PostgreSQL v12 (Pavel Stehule)
- In `pg_upgrade`, check for inconsistent inherited not-null constraints (Ali Akbar)

PostgreSQL versions before 18 allow an inherited column not-null constraint to be dropped. However, this results in a schema that cannot be restored, leading to failure in `pg_upgrade`. Detect such cases during `pg_upgrade`'s preflight checks to allow users to fix them before initiating the upgrade.

- Don't require that the target installation have `max_slot_wal_keep_size` set to its default during `pg_upgrade` (Dilip Kumar)
- Avoid assertion failure if `track_commit_timestamp` is enabled during `initdb` (Hayato Kuroda, Andy Fan)
- Fix `pg_waldump` to show information about dropped statistics in `PREPARE TRANSACTION` WAL records (Daniil Davydov)
- Avoid possible leak of the open connection during `contrib/dblink` connection establishment (Tom Lane)

In the rare scenario where we hit out-of-memory while inserting the new connection object into `dblink`'s hashtable, the open connection would be leaked until end of session, leaving an idle session sitting on the remote server.

- Make `contrib/pg_prewarm` cope with very large `shared_buffers` settings (Daria Shanina)

Autoprewarm failed with a memory allocation error if `shared_buffers` was larger than about 50 million buffers (400GB).

- Prevent assertion failure in `contrib/pg_prewarm` (Masahiro Ikeda)

Applying `pg_prewarm()` to a relation lacking storage (such as a view) caused an assertion failure, although there was no ill effect in non-assert builds. Add an error check to reject that case.

- In `contrib/pg_stat_statements`, avoid leaving gaps in the set of parameter numbers used in a normalized query (Sami Imseih)
- Fix memory leakage in `contrib/postgres_fdw`'s `DirectModify` methods (Tom Lane)

The `PGresult` holding the results of the remote modify command would be leaked for the rest of the session if the query fails between invocations of the `DirectModify` methods, which could happen when there's `RETURNING` data to process.

- Ensure that directories listed in `configure's --with-includes` and `--with-libraries` options are searched before system-supplied directories (Tom Lane)

A common reason for using these options is to allow a user-built version of some library to override the system-supplied version. However, that failed to work in some environments because of careless ordering of switches in the commands issued by the `makefiles`.

- Fix `configure's` checks for `__cpuid()` and `__cpuidex()` (Lukas Fittl, Michael Paquier)

`configure` failed to detect these Windows-specific functions, so that they would not be used, leading to slower-than-necessary CRC computations since the availability of hardware instructions could not be verified. The practical impact of this error was limited, because production builds for Windows typically do not use the `Autoconf` toolchain.

- Fix build failure with `--with-pam` option on Solaris-based platforms (Tom Lane)

Solaris is inconsistent with other Unix platforms about the API for PAM authentication. This manifested as an “inconsistent pointer” compiler warning, which we never did anything about. But as of GCC 14 it's an error not warning by default, so fix it.

- Make our code portable to GNU Hurd (Michael Banck, Christoph Berg, Samuel Thibault)

Fix assumptions about `IOV_MAX` and `O_RDONLY` that don't hold on Hurd.

- Make our usage of `memset_s()` conform strictly to the C11 standard (Tom Lane)

This avoids compile failures on some platforms.

- Silence compatibility warning when using Meson to build with MSVC (Peter Eisentraut)
- Prevent uninitialized-value compiler warnings in JSONB comparison code (Tom Lane)
- Avoid deprecation warnings when building with libxml2 2.14 and later (Michael Paquier)
- Avoid problems when compiling `pg_locale.h` under C++ (John Naylor)

PostgreSQL header files generally need to be wrapped in `extern "C" { ... }` in order to be included in extensions written in C++. This failed for `pg_locale.h` because of its use of `libc` headers, but we can work around that by suppressing C++-only declarations in those headers. C++ extensions that want to use `libc`'s C++ APIs can do so by including the `libc` headers ahead of `pg_locale.h`.

E.9. Release 17.5

Release date: 2025-05-08

This release contains a variety of fixes from 17.4. For information about new features in major release 17, see [Section E.14](#).

E.9.1. Migration to Version 17.5

A dump/restore is not required for those running 17.X.

However, if you have any self-referential foreign key constraints on partitioned tables, it may be necessary to recreate those constraints to ensure that they are being enforced correctly. See the second changelog entry below.

Also, if you have any BRIN bloom indexes, it may be advisable to reindex them after updating. See the third changelog entry below.

Also, if you are upgrading from a version earlier than 17.1, see [Section E.13](#).

E.9.2. Changes

- Avoid one-byte buffer overread when examining invalidly-encoded strings that are claimed to be in GB18030 encoding (Noah Misch, Andres Freund)

While unlikely, a SIGSEGV crash could occur if an incomplete multibyte character appeared at the end of memory. This was possible both in the server and in libpq-using applications. (CVE-2025-4207)

- Handle self-referential foreign keys on partitioned tables correctly (Álvaro Herrera)

Creating or attaching partitions failed to make the required catalog entries for a foreign-key constraint, if the table referenced by the constraint was the same partitioned table. This resulted in failure to enforce the constraint fully.

To fix this, you should drop and recreate any self-referential foreign keys on partitioned tables, if partitions have been created or attached since the constraint was created. Bear in mind that violating rows might already be present, in which case recreating the constraint will fail, and you'll need to fix up those rows before trying again.

- Avoid data loss when merging compressed BRIN summaries in `brin_bloom_union()` (Tomas Vondra)

The code failed to account for decompression results not being identical to the input objects, which would result in failure to add some of the data to the merged summary, leading to missed rows in index searches.

This mistake was present back to v14 where BRIN bloom indexes were introduced, but this code path was only rarely reached then. It's substantially more likely to be hit in v17 because parallel index builds now use the code.

- Fix unexpected “attribute has wrong type” errors in UPDATE, DELETE, and MERGE queries that use whole-row table references to views or functions in FROM (Tom Lane)
- Fix MERGE into a partitioned table with DO NOTHING actions (Tender Wang)

Some cases failed with “unknown action in MERGE WHEN clause” errors.

- Prevent failure in INSERT commands when the table has a GENERATED column of a domain data type and the domain's constraints disallow null values (Jian He)

Constraint failure was reported even if the generation expression produced a perfectly okay result.

- Correctly process references to outer CTE names that appear within a WITH clause attached to an INSERT/UPDATE/DELETE/MERGE command that's inside WITH (Tom Lane)

The parser failed to detect disallowed recursion cases, nor did it account for such references when sorting CTEs into a usable order.

- Fix misprocessing of casts within the keys of JSON constructor expressions (Amit Langote)
- Don't try to parallelize `array_agg()` when the argument is of an anonymous record type (Richard Guo, Tom Lane)

The protocol for communicating with parallel workers doesn't support identifying the concrete record type that a worker is returning.

- Fix `ARRAY(subquery)` and `ARRAY[expression, ...]` constructs to produce sane results when the input is of type `int2vector` or `oidvector` (Tom Lane)

This patch restores the behavior that existed before PostgreSQL 9.5: the result is of type `int2vector[]` or `oidvector[]`.

- Fix possible erroneous reports of invalid affixes while parsing Ispell dictionaries (Jacob Brazeal)
- Fix `ALTER TABLE ADD COLUMN` to correctly handle the case of a domain type that has a default (Jian He, Tom Lane, Tender Wang)

If a domain type has a default, adding a column of that type (without any explicit `DEFAULT` clause) failed to install the domain's default value in existing rows, instead leaving the new column null.

- Repair misbehavior when there are duplicate column names in a foreign key constraint's `ON DELETE SET DEFAULT` or `SET NULL` action (Tom Lane)
- Improve the error message for disallowed attempts to alter the properties of a foreign key constraint (Álvaro Herrera)
- Avoid error when resetting the `relhassubclass` flag of a temporary table that's marked `ON COMMIT DELETE ROWS` (Noah Misch)
- Add missing deparsing of the `INDENT` option of `XMLSERIALIZE( )` (Jim Jones)

Previously, views or rules using `XMLSERIALIZE(... INDENT)` were dumped without the `INDENT` clause, causing incorrect results after restore.

- Avoid premature evaluation of the arguments of an aggregate function that has both `FILTER` and `ORDER BY` (or `DISTINCT`) options (David Rowley)

If there is `ORDER BY` or `DISTINCT`, we consider pre-sorting the aggregate input values rather than doing the sort within the Agg plan node. But this is problematic if the aggregate inputs include expressions that could fail (for example, a division where some of the input divisors could be zero) and there is a `FILTER` clause that's meant to prevent such failures. Pre-sorting would push the expression evaluations to before the `FILTER` test, allowing the failures to happen anyway. Avoid this by not pre-sorting if there's a `FILTER` and the input expressions are anything more complex than a simple Var or Const.

- Fix erroneous deductions from column `NOT NULL` constraints in the presence of outer joins (Richard Guo)

In some cases the planner would discard an `IS NOT NULL` query condition, even though the condition applies after an outer join and thus is not redundant.

- Avoid incorrect optimizations based on `IS [NOT] NULL` tests that are applied to composite values (Bruce Momjian)
- Fix planner's failure to identify more than one hashable `ScalarArrayOpExpr` subexpression within a top-level expression (David Geier)

This resulted in unnecessarily-inefficient execution of any additional subexpressions that could have been processed with a hash table (that is, `IN`, `NOT IN`, or `= ANY` clauses with all-constant right-hand sides).

- Fix incorrect table size estimate with low fill factor (Tomas Vondra)

When the planner estimates the number of rows in a never-yet-analyzed table, it uses the table's `fillfactor` setting in the estimation, but it neglected to clamp the result to at least one row per page. A low `fillfactor` could thus result in an unreasonably small estimate.

- Disable “skip fetch” optimization in bitmap heap scan (Matthias van de Meent)

It turns out that this optimization can result in returning dead tuples when a concurrent vacuum marks a page all-visible.

- Fix performance issues in GIN index search startup when there are many search keys (Tom Lane, Vinod Sridharan)

An indexable clause with many keys (for example, `jsonbcol ?| array[...]` with tens of thousands of array elements) took $O(N^2)$ time to start up, and was uncancelable for that interval too.

- Detect missing support procedures in a BRIN index operator class, and report an error instead of crashing (Álvaro Herrera)
- Respond to interrupts (such as query cancel) while waiting for asynchronous subplans of an Append plan node (Heikki Lin-nakangas)

Previously, nothing would happen until one of the subplans becomes ready.

- Report the I/O statistics of active WAL senders more frequently (Bertrand Drouvot)

Previously, the `pg_stat_io` view failed to accumulate I/O performed by a WAL sender until that process exited. Now such I/O will be reported after at most one second's delay.

- Fix race condition in handling of `synchronous_standby_names` immediately after startup (Melnikov Maksim, Michael Paquier)

For a short period after system startup, backends might fail to wait for synchronous commit even though `synchronous_standby_names` is enabled.

- Cope with possible intra-query changes of `io_combine_limit` (Thomas Munro)
- Avoid infinite loop if `scram_iterations` is set to `INT_MAX` (Kevin K Biju)
- Avoid possible crashes due to double transformation of `json_array()`'s subquery (Tom Lane)
- Fix `pg_strtof()` to not crash with null endptr (Alexander Lakhin, Tom Lane)
- Fix crash after out-of-memory in certain GUC assignments (Daniel Gustafsson)
- Avoid crash when a Snowball stemmer encounters an out-of-memory condition (Maksim Korotkov)
- Fix over-enthusiastic freeing of `SpecialJoinInfo` structs during planning (Richard Guo)

This led to crashes during planning if partitionwise joining is enabled.

- Disallow copying of invalidated replication slots (Shlok Kyal)

This prevents trouble when the invalid slot points to WAL that's already been removed.

- Disallow restoring logical replication slots on standby servers that are not in hot-standby mode (Masahiko Sawada)

This prevents a scenario where the slot could remain valid after promotion even if `wal_level` is too low.

- Prevent over-advancement of catalog xmin in “fast forward” mode of logical decoding (Zhijie Hou)

This mistake could allow deleted catalog entries to be vacuumed away even though they were still potentially needed by the WAL-reading process.

- Avoid data loss when DDL operations that don't take a strong lock affect tables that are being logically replicated (Shlok Kyal, Hayato Kuroda)

The catalog changes caused by the DDL command were not reflected into WAL-decoding processes, allowing them to decode subsequent changes using stale catalog data, probably resulting in data corruption.

- Prevent incorrect reset of replication origin when an apply worker encounters an error but the error is caught and does not result in worker exit (Hayato Kuroda)

This mistake could allow duplicate data to be applied.

- Fix crash in logical replication if the subscriber's partitioned table has a BRIN index (Tom Lane)
- Avoid duplicate snapshot creation in logical replication index lookups (Heikki Linnakangas)
- Improve detection of mixed-origin subscriptions (Hou Zhijie, Shlok Kyal)

Subscription creation gives a warning if a subscribed-to table is also being followed through other publications, since that could cause duplicate data to be received. This change improves that logic to also detect cases where a partition parent or child table is the one being followed through another publication.

- Fix wrong checkpoint details in error message about incorrect recovery timeline choice (David Steele)

If the requested recovery timeline is not reachable, the reported checkpoint and timeline should be the values read from the `backup_label`, if there is one. This message previously reported values from the control file, which is correct when recovering from the control file without a `backup_label`, but not when there is a `backup_label`.

- Fix order of operations in `smgropen()` (Andres Freund)

Ensure that the `SMgrRelation` object is fully initialized before calling the `smgr_open` callback, so that it can be cleaned up properly if the callback fails.

- Remove incorrect assertion in `pgstat_report_stat()` (Michael Paquier)
- Fix overly-strict assertion in `gistFindCorrectParent()` (Heikki Linnakangas)
- Avoid assertion failure in parallel vacuum when `maintenance_work_mem` has a very small value (Masahiko Sawada)
- Fix rare assertion failure in standby servers when the primary is restarted (Heikki Linnakangas)
- In PL/pgSQL, avoid “unexpected plan node type” error when a scrollable cursor is defined on a simple `SELECT expression` query (Andrei Lepikhov)
- Don't try to drop individual index partitions in `pg_dump's -clean` mode (Jian He)

The server rejects such `DROP` commands. That has no real consequences, since the partitions will go away anyway in the subsequent `DROPs` of either their parent tables or their partitioned index. However, the error reported for the attempted drop causes problems when restoring in `--single-transaction` mode.

- In `pg_dumpall`, avoid emitting invalid role `GRANT` commands if `pg_auth_members` contains invalid role OIDs (Tom Lane)

Instead, print a warning and skip the entry. This copes better with catalog corruption that has been seen to occur in back branches as a result of race conditions between `GRANT` and `DROP ROLE`.

- In `pg_amcheck` and `pg_upgrade`, use the correct function to free allocations made by `libpq` (Michael Paquier, Ranier Vilela)

These oversights could result in crashes in certain Windows build configurations, such as a debug build of `libpq` used by a non-debug build of the calling application.

- Fix `reindexdb's` scheduling of parallel reindex operations (Alexander Korotkov)

The original coding failed to achieve the expected amount of parallelism.

- Avoid crashing with corrupt input data in `contrib/pageinspect's heap_page_items()` (Dmitry Kovalenko)
- Prevent assertion failure in `contrib/pg_freespacemap's pg_freespacemap()` (Tender Wang)

Applying `pg_freespacemap()` to a relation lacking storage (such as a view) caused an assertion failure, although there was no ill effect in non-assert builds. Add an error check to reject that case.

- In `contrib/postgres_fdw`, avoid pulling up restriction conditions from subqueries (Alexander Pyhalov)

This fix prevents rare cases of “unexpected expression in subquery output” errors.

- Fix build failure when an old version of `libpq-fe.h` is present in system include directories (Tom Lane)
- Fix build failure on macOS 15.4 (Tom Lane, Peter Eisentraut)

This macOS update broke our configuration probe for `strchrnul()`.

- Fix `valgrind` labeling of per-buffer data of read streams (Thomas Munro)

This affects no core code in released versions of PostgreSQL, but an extension using the per-buffer data feature might have encountered spurious failures when being tested under `valgrind`.

- Avoid `valgrind` complaints about string hashing code (John Naylor)
- Update time zone data files to `tzdata` release 2025b for DST law changes in Chile, plus historical corrections for Iran (Tom Lane)

There is a new time zone `America/Coyhaique` for Chile's Aysén Region, to account for it changing to UTC-03 year-round and thus diverging from `America/Santiago`.

E.10. Release 17.4

Release date: 2025-02-20

This release contains a few fixes from 17.3. For information about new features in major release 17, see [Section E.14](#).

E.10.1. Migration to Version 17.4

A dump/restore is not required for those running 17.X.

However, if you are upgrading from a version earlier than 17.1, see [Section E.13](#).

E.10.2. Changes

- Improve behavior of `libpq's` quoting functions (Andres Freund, Tom Lane)

The changes made for CVE-2025-1094 had one serious oversight: `PQescapeLiteral()` and `PQescapeIdentifier()` failed to honor their string length parameter, instead always reading to the input string's trailing null. This resulted in including unwanted text in the output, if the caller intended to truncate the string via the length parameter. With very bad luck it could cause a crash due to reading off the end of memory.

In addition, modify all these quoting functions so that when invalid encoding is detected, an invalid sequence is substituted for just the first byte of the presumed character, not all of it. This reduces the risk of problems if a calling application performs additional processing on the quoted string.

- Fix small memory leak in `pg_createsubscriber` (Ranier Vilela)
- Fix meson build system to correctly detect availability of the `bsd_auth.h` system header (Nazir Bilal Yavuz)

E.11. Release 17.3

Release date: 2025-02-13

This release contains a variety of fixes from 17.2. For information about new features in major release 17, see [Section E.14](#).

E.11.1. Migration to Version 17.3

A dump/restore is not required for those running 17.X.

However, if you are upgrading from a version earlier than 17.1, see [Section E.13](#).

E.11.2. Changes

- Harden `PQescapeString` and allied functions against invalidly-encoded input strings (Andres Freund, Noah Misch)

Data-quoting functions supplied by `libpq` now fully check the encoding validity of their input. If invalid characters are detected, they report an error if possible. For the ones that lack an error return convention, the output string is adjusted to ensure that the server will report invalid encoding and no intervening processing will be fooled by bytes that might happen to match single quote, backslash, etc.

The purpose of this change is to guard against SQL-injection attacks that are possible if one of these functions is used to quote crafted input. There is no hazard when the resulting string is sent directly to a PostgreSQL server (which would check its encoding anyway), but there is a risk when it is passed through `psql` or other client-side code. Historically such code has not carefully vetted encoding, and in many cases it's not clear what it should do if it did detect such a problem.

This fix is effective only if the data-quoting function, the server, and any intermediate processing agree on the character encoding that's being used. Applications that insert untrusted input into SQL commands should take special care to ensure that that's true.

Applications and drivers that quote untrusted input without using these `libpq` functions may be at risk of similar problems. They should first confirm the data is valid in the encoding expected by the server.

The PostgreSQL Project thanks Stephen Fewer for reporting this problem. (CVE-2025-1094)

- Restore auto-truncation of database and user names appearing in connection requests (Nathan Bossart)

This reverts a v17 change that proved to cause trouble for some users. Over-length names should be truncated in an encoding-aware fashion, but for now just return to the former behavior of blind truncation at `NAMEDATALEN - 1` bytes.

- Exclude parallel workers from connection privilege checks and limits (Tom Lane)

Do not check `data lowconn`, `rolcanlogin`, and `ACL_CONNECT` privileges when starting a parallel worker, instead assuming that it's enough for the leader process to have passed similar checks originally. This avoids, for example, unexpected failures of parallelized queries when the leader is running as a role that lacks login privilege. In the same vein, enforce `ReservedConnections`, `datconnlimit`, and `rolconnlimit` limits only against regular backends, and count only regular backends while checking if the limits were already reached. Those limits are meant to prevent excessive consumption of process slots for regular backends --- but parallel workers and other special processes have their own pools of process slots with their own limit checks.

- Drop “Lock” suffix from LWLock wait event names (Bertrand Drouvot)

Refactoring unintentionally caused the `pg_stat_activity` view to show lock-related wait event names with a “Lock” suffix, which among other things broke joining it to `pg_wait_events`.

- Fix possible failure to return all matching tuples for a btree index scan with a `ScalarArrayOp (= ANY)` condition (Peter Geoghegan)
- Fix possible re-use of stale results in window aggregates (David Rowley)

A window aggregate with a “run condition” optimization and a pass-by-reference result type might incorrectly return the result from the previous partition instead of performing a fresh calculation.

- Keep `TransactionXmin` in sync with `MyProc->xmin` (Heikki Linnakangas)

This oversight could permit a process to try to access data that had already been vacuumed away. One known consequence is transient “could not access status of transaction” errors.

- Fix race condition that could cause failure to add a newly-inserted catalog entry to a catalog cache list (Heikki Linnakangas)

This could result, for example, in failure to use a newly-created function within an existing session.

- Prevent possible catalog corruption when a system catalog is vacuumed concurrently with an update (Noah Misch)
- Fix data corruption when relation truncation fails (Thomas Munro)

The filesystem calls needed to perform relation truncation could fail, leaving inconsistent state on disk (for example, effectively reviving deleted data). We can't really prevent that, but we can recover by dint of making such failures into PANICs, so that consistency is restored by replaying from WAL up to just before the attempted truncation. This isn't a hugely desirable behavior, but such failures are rare enough that it seems an acceptable solution.

- Prevent checkpoints from starting during relation truncation (Robert Haas)

This avoids a race condition wherein the modified file might not get `fsync`'d before completing the checkpoint, creating a risk of data corruption if the operating system crashes soon after.

- Avoid possibly losing an update of `pg_database.datfrozenxid` when `VACUUM` runs concurrently with a `REASSIGN OWNED` that changes that database's owner (Kirill Reshke)
- Fix incorrect `tg_updatedcols` values passed to `AFTER UPDATE` triggers (Tom Lane)

In some cases the `tg_updatedcols` bitmap could describe the set of columns updated by an earlier command in the same transaction, fooling the trigger into doing the wrong thing.

Also, prevent memory bloat caused by making too many copies of the `tg_updatedcols` bitmap.

- Fix detach of a partition that has its own foreign-key constraint referencing a partitioned table (Amul Sul)

In common cases, foreign keys are defined on a partitioned table's top level; but if instead one is defined on a partition and references a partitioned table, and the referencing partition is detached, the relevant `pg_constraint` entries were updated incorrectly. This led to errors like “could not find ON INSERT check triggers of foreign key constraint”.

- Fix `pg_get_constraintdef`'s support for `NOT NULL` constraints on domains (Álvaro Herrera)
- Fix mis-processing of `to_timestamp`'s `FFn` format codes (Tom Lane)

An integer format code immediately preceding `FFn` would consume all available digits, leaving none for `FFn`.

- When deparsing a `PASSING` clause in a SQL/JSON query function, ensure that variable names are double-quoted when necessary (Dean Rasheed)
- When deparsing an `XMLTABLE()` expression, ensure that XML namespace names are double-quoted when necessary (Dean Rasheed)
- Include the `ldapscheme` option in `pg_hba_file_rules()` output (Laurenz Albe)
- Fix planning of pre-sorted `UNION` operations for cases where the input column datatypes don't all match (David Rowley)

This error could lead to sorting data with the wrong sort operator, with consequences ranging from no visible problem to core dumps.

- Don't merge `UNION` operations if their column collations aren't consistent (Tom Lane)

Previously we ignored collations when deciding if it's safe to merge `UNION` steps into a single N-way `UNION` operation. This was arguably valid before the introduction of nondeterministic collations, but it's not anymore, since the collation in use can affect the definition of uniqueness.

- Prevent “wrong varnullingrels” planner errors after pulling up a subquery that's underneath an outer join (Tom Lane)
- Ignore nulling-relation marker bits when looking up statistics (Richard Guo)

This oversight could lead to failure to use relevant statistics about expressions, or to “corrupt MVNDistinct entry” errors.

- Fix missed expression processing for partition pruning steps (Tom Lane)

This oversight could lead to “unrecognized node type” errors, and perhaps other problems, in queries accessing partitioned tables.

- Give the slotsync worker process its own process slot (Tom Lane, Hou Zhijie)

This was overlooked in the addition of the slotsync worker, with the result that its process slot effectively came out of the pool meant for regular backend processes. This could result in failure to launch the worker, or to subsequent failures of connection requests that should have succeeded according to the configured settings, if the number of regular backend processes approached `max_connections`.

- Allow dshash tables to grow past 1GB (Matthias van de Meent)

This avoids errors like “invalid DSA memory alloc request size”. The case can occur for example in transactions that process several million tables.

- Avoid possible integer overflow in `bringetbitmap()` (James Hunter, Evgeniy Gorbanyov)

Since the result is only used for statistical purposes, the effects of this error were mostly cosmetic.

- Correct miscalculation of SLRU bank numbers (Yura Sokolov)

This error led to using a smaller number of banks than intended, causing more contention but no functional misbehavior.

- Ensure that an already-set process latch doesn't prevent the postmaster from noticing socket events (Thomas Munro)

An extremely heavy workload of backends launching workers and workers exiting could prevent the postmaster from responding to incoming client connections in a timely fashion.

- Prevent streaming standby servers from looping infinitely when reading a WAL record that crosses pages (Kyotaro Horiguchi, Alexander Kukushkin)

This would happen when the record's continuation is on a page that needs to be read from a different WAL source.

- Fix unintended promotion of FATAL errors to PANIC during early process startup (Noah Misch)

This fixes some unlikely cases that would result in “PANIC: proc_exit() called in child process”.

- Fix cases where an operator family member operator or support procedure could become a dangling reference (Tom Lane)

In some cases a data type could be dropped while references to its OID still remain in `pg_amop` or `pg_amproc`. While that caused no immediate issues, an attempt to drop the owning operator family would fail, and `pg_dump` would produce bogus output when dumping the operator family. This fix causes creation and modification of operator families/classes to add needed

dependency entries so that dropping a data type will also drop any dependent operator family elements. That does not help vulnerable pre-existing operator families, though, so a band-aid has also been added to `DROP OPERATOR FAMILY` to prevent failure when dropping a family that has dangling members.

- Fix multiple memory leaks in logical decoding output (Vignesh C, Masahiko Sawada, Boyu Yang)
- Fix small memory leak when updating the `application_name` or `cluster_name` settings (Tofig Aliev)
- Avoid crash when a background process tries to check a new value of `synchronized_standby_slots` (Álvaro Herrera)
- Avoid integer overflow while testing `wal_skip_threshold` condition (Tom Lane)

A transaction that created a very large relation could mistakenly decide to ensure durability by copying the relation into WAL instead of fsync'ing it, thereby negating the point of `wal_skip_threshold`. (This only matters when `wal_level` is set to `minimal`, else a WAL copy is required anyway.)

- Fix unsafe order of operations during cache lookups (Noah Misch)

The only known consequence was a usually-harmless “you don't own a lock of type ExclusiveLock” warning during `GRANT TABLESPACE`.

- Avoid potential use-after-free in parallel vacuum (Vallimaharajan G, John Naylor)

This bug seems to have no consequences in standard builds, but it's theoretically a hazard.

- Fix possible “failed to resolve name” failures when using JIT on older ARM platforms (Thomas Munro)

This could occur as a consequence of inconsistency about the default setting of `-moutline-atomics` between gcc and clang. At least Debian and Ubuntu are known to ship gcc and clang compilers that target armv8-a but differ on the use of outline atomics by default.

- Fix assertion failure in `WITH RECURSIVE . . . UNION` queries (David Rowley)
- Avoid assertion failure in rule deparsing if a set operation leaf query contains set operations (Man Zeng, Tom Lane)
- Avoid edge-case assertion failure in parallel query startup (Tom Lane)
- Fix assertion failure at shutdown when writing out the statistics file (Michael Paquier)
- Avoid valgrind complaints about string hashing code (John Naylor)
- In `NULLIF ( )`, avoid passing a read-write expanded object pointer to the data type's equality function (Tom Lane)

The equality function could modify or delete the object if it's given a read-write pointer, which would be bad if we decide to return it as the `NULLIF ( )` result. There is probably no problem with any built-in equality function, but it's easy to demonstrate a failure with one coded in PL/pgSQL.

- Ensure that expression preprocessing is applied to a default null value in `INSERT` (Tom Lane)

If the target column is of a domain type, the planner must insert a coerce-to-domain step not just a null constant, and this expression missed going through some required processing steps. There is no known consequence with domains based on core data types, but in theory an error could occur with domains based on extension types.

- Avoid data loss when starting a bulk write on a relation fork that already contains data (Matthias van de Meent)

Any pre-existing data was overwritten with zeroes. This is not an issue for core PostgreSQL, which never does that. Some extensions would like to, however.

- Avoid crash if a server process tried to iterate over a shared radix tree that it didn't create (Masahiko Sawada)

There is no code in core PostgreSQL that does this, but an extension might wish to.

- Repair memory leaks in PL/Python (Mat Arye, Tom Lane)

Repeated use of `PLyPlan.execute` or `plpy.cursor` resulted in memory leakage for the duration of the calling PL/Python function.

- Fix PL/Tcl to compile with Tcl 9 (Peter Eisentraut)
- In the `ecpg` preprocessor, fix possible misprocessing of cursors that reference out-of-scope variables (Tom Lane)

- In `ecpg`, fix compile-time warnings about unsupported use of `COPY . . . FROM STDIN` (Ryo Kanbayashi)

Previously, the intended warning was not issued due to a typo.

- Fix `psql` to safely handle file path names that are encoded in SJIS (Tom Lane)

Some two-byte characters in SJIS have a second byte that is equal to ASCII backslash (`\`). These characters were corrupted by path name normalization, preventing access to files whose names include such characters.

- Add `psql` tab completion for `COPY (MERGE INTO)` (Jian He)
- Fix use of wrong version of `pqsignal()` in `pgbench` and `psql` (Fujii Masao, Tom Lane)

This error could lead to misbehavior when using the `-T` option in `pgbench` or the `\watch` command in `psql`, due to interrupted system calls not being resumed as expected.

- Fix misexecution of some nested `\if` constructs in `pgbench` (Michail Nikolaev)

An `\if` command appearing within a false (not-being-executed) `\if` branch was incorrectly treated the same as `\elif`.

- In `pgbench`, fix possible misdisplay of progress messages during table initialization (Yushi Ogiwara, Tatsuo Ishii, Fujii Masao)
- Make `pg_controldata` more robust against corrupted `pg_control` files (Ilyasov Ian, Anton Voloshin)

Since `pg_controldata` will attempt to print the contents of `pg_control` even if the CRC check fails, it must take care not to misbehave for invalid field values. This patch fixes some issues triggered by invalid timestamps and apparently-negative WAL segment sizes.

- Fix possible crash in `pg_dump` with identity sequences attached to tables that are extension members (Tom Lane)
- Fix memory leak in `pg_restore` with `zstd`-compressed data (Tom Lane)

The leak was per-decompression-operation, so would be most noticeable with a dump containing many tables or large objects.

- Fix `pg_basebackup` to correctly handle `pg_wal.tar` files exceeding 2GB on Windows (Davinder Singh, Thomas Munro)
- Use SQL-standard function bodies in the declarations of `contrib/earthdistance`'s SQL-language functions (Tom Lane, Ronan Dunklau)

This change allows their references to `contrib/cube` to be resolved during extension creation, reducing the risk of search-path-based failures and possible attacks.

In particular, this restores their usability in contexts like generated columns, for which PostgreSQL v17 restricts the search path on security grounds. We have received reports of databases failing to be upgraded to v17 because of that. This patch has been included in v16 to provide a workaround: updating the `earthdistance` extension to this version beforehand should allow an upgrade to succeed.

- Detect version mismatch between `contrib/pageinspect`'s SQL declarations and the underlying shared library (Tomas Vondra)

Previously, such a mismatch could result in a crash while calling `brin_page_items()`. Instead throw an error recommending updating the extension.

- When trying to cancel a remote query in `contrib/postgres_fdw`, re-issue the cancel request a few times if it didn't seem to do anything (Tom Lane)

This fixes a race condition where we might try to cancel a just-sent query before the remote server has started to process it, so that the initial cancel request is ignored.

- Update configuration probes that determine the compiler switches needed to access ARM CRC instructions (Tom Lane)

On ARM platforms where the baseline CPU target lacks CRC instructions, we need to supply a `-march` switch to persuade the compiler to compile such instructions. Recent versions of `gcc` reject the value we were trying, leading to silently falling back to software CRC.

- Fix meson build system to support old OpenSSL libraries on Windows (Darek Slusarczyk)

Add support for the legacy library names `ssleay32` and `libeay32`.

- In Windows builds using meson, ensure all libcommon and libpgport functions are exported (Vladlen Popolitov, Heikki Lin-nakangas)

This fixes “unresolved external symbol” build errors for extensions.

- Fix meson configuration process to correctly detect OSSP's `uuid.h` header file under MSVC (Andrew Dunstan)
- When building with meson, install `pgevent` in `pkglibdir` not `bindir` (Peter Eisentraut)

This matches the behavior of the make-based build system and the old MSVC build system.

- When building with meson, install `sepgsql.sql` under `share/contrib/` not `share/extension/` (Peter Eisentraut)
- This matches what the make-based build system does.
- Update time zone data files to tzdata release 2025a for DST law changes in Paraguay, plus historical corrections for the Philip-pines (Tom Lane)

E.12. Release 17.2

Release date: 2024-11-21

This release contains a few fixes from 17.1. For information about new features in major release 17, see [Section E.14](#).

E.12.1. Migration to Version 17.2

A dump/restore is not required for those running 17.X.

However, if you are upgrading from a version earlier than 17.1, see [Section E.13](#).

E.12.2. Changes

- Repair ABI break for extensions that work with struct `ResultRelInfo` (Tom Lane)

Last week's minor releases unintentionally broke binary compatibility with timescaledb and several other extensions. Restore the affected structure to its previous size, so that such extensions need not be rebuilt.

- Restore functionality of `ALTER {ROLE|DATABASE} SET role` (Tom Lane, Noah Misch)

The fix for CVE-2024-10978 accidentally caused settings for `role` to not be applied if they come from non-interactive sources, including previous `ALTER {ROLE|DATABASE}` commands and the `PGOPTIONS` environment variable.

- Fix cases where a logical replication slot's `restart_lsn` could go backwards (Masahiko Sawada)

Previously, restarting logical replication could sometimes cause the slot's restart point to be recomputed as an older value than had previously been advertised in `pg_replication_slots`. This is bad, since for example WAL files might have been removed on the basis of the later `restart_lsn` value, in which case replication would fail to restart.

- Avoid deleting still-needed WAL files during `pg_rewrite` (Polina Bungina, Alexander Kukushkin)

Previously, in unlucky cases, it was possible for `pg_rewrite` to remove important WAL files from the rewound demoted pri-mary. In particular this happens if those files have been marked for archival (i.e., their `.ready` files were created) but not yet archived. Then the newly promoted node no longer has such files because of them having been recycled, but likely they are needed for recovery in the demoted node. If `pg_rewrite` removes them, recovery is not possible anymore.

- Fix race conditions associated with dropping shared statistics entries (Kyotaro Horiguchi, Michael Paquier)

These bugs could lead to loss of statistics data, assertion failures, or “can only drop stats once” errors.

- Count index scans in `contrib/bloom` indexes in the statistics views, such as the `pg_stat_user_indexes.idx_scan` counter (Masahiro Ikeda)
- Fix crash when checking to see if an index's opclass options have changed (Alexander Korotkov)

Some forms of `ALTER TABLE` would fail if the table has an index with non-default operator class options.

- Avoid assertion failure caused by disconnected NFA sub-graphs in regular expression parsing (Tom Lane)

This bug does not appear to have any visible consequences in non-assert builds.

E.13. Release 17.1

Release date: 2024-11-14

This release contains a variety of fixes from 17.0. For information about new features in major release 17, see [Section E.14](#).

E.13.1. Migration to Version 17.1

A dump/restore is not required for those running 17.X.

However, if you have ever detached a partition from a partitioned table that has a foreign-key reference to another partitioned table, and not dropped the former partition, then you may have catalog and/or data corruption to repair, as detailed in the fifth changelog entry below.

Also, in the uncommon case that a database's `LC_CTYPE` setting is `C` while its `LC_COLLATE` setting is some other locale, indexes on textual columns should be reindexed, as described in the sixth changelog entry below.

E.13.2. Changes

- Ensure cached plans are marked as dependent on the calling role when RLS applies to a non-top-level table reference (Nathan Bossart)

If a CTE, subquery, sublink, security invoker view, or coercion projection in a query references a table with row-level security policies, we neglected to mark the resulting plan as potentially dependent on which role is executing it. This could lead to later query executions in the same session using the wrong plan, and then returning or hiding rows that should have been hidden or returned instead.

The PostgreSQL Project thanks Wolfgang Walther for reporting this problem. (CVE-2024-10976)

- Make libpq discard error messages received during SSL or GSS protocol negotiation (Jacob Champion)

An error message received before encryption negotiation is completed might have been injected by a man-in-the-middle, rather than being real server output. Reporting it opens the door to various security hazards; for example, the message might spoof a query result that a careless user could mistake for correct output. The best answer seems to be to discard such data and rely only on libpq's own report of the connection failure.

The PostgreSQL Project thanks Jacob Champion for reporting this problem. (CVE-2024-10977)

- Fix unintended interactions between `SET SESSION AUTHORIZATION` and `SET ROLE` (Tom Lane)

The SQL standard mandates that `SET SESSION AUTHORIZATION` have a side-effect of doing `SET ROLE NONE`. Our implementation of that was flawed, creating more interaction between the two settings than intended. Notably, rolling back a transaction that had done `SET SESSION AUTHORIZATION` would revert `ROLE` to `NONE` even if that had not been the previous state, so that the effective user ID might now be different from what it had been before the transaction. Transiently setting `session_authorization` in a function `SET` clause had a similar effect. A related bug was that if a parallel worker inspected `current_setting('role')`, it saw `none` even when it should see something else.

The PostgreSQL Project thanks Tom Lane for reporting this problem. (CVE-2024-10978)

- Prevent trusted PL/Perl code from changing environment variables (Andrew Dunstan, Noah Misch)

The ability to manipulate process environment variables such as `PATH` gives an attacker opportunities to execute arbitrary code. Therefore, “trusted” PLs must not offer the ability to do that. To fix `plperl`, replace `%ENV` with a tied hash that rejects any modification attempt with a warning. Untrusted `plperl` retains the ability to change the environment.

The PostgreSQL Project thanks Coby Abrams for reporting this problem. (CVE-2024-10979)

- Fix updates of catalog state for foreign-key constraints when attaching or detaching table partitions (Jehan-Guillaume de Rorthais, Tender Wang, Álvaro Herrera)

If the referenced table is partitioned, then different catalog entries are needed for a referencing table that is stand-alone versus one that is a partition. `ATTACH/DETACH PARTITION` commands failed to perform this conversion correctly. In particular, after `DETACH` the now stand-alone table would be missing foreign-key enforcement triggers, which could result in the table later containing rows that fail the foreign-key constraint. A subsequent `re-ATTACH` could fail with surprising errors, too.

The way to fix this is to do `ALTER TABLE DROP CONSTRAINT` on the now stand-alone table for each faulty constraint, and then re-add the constraint. If re-adding the constraint fails, then some erroneous data has crept in. You will need to manually re-establish consistency between the referencing and referenced tables, then re-add the constraint.

This query can be used to identify broken constraints and construct the commands needed to recreate them:

```
SELECT conrelid::pg_catalog.regclass AS "constrained table",
       conname AS constraint,
       confrelid::pg_catalog.regclass AS "references",
       pg_catalog.format('ALTER TABLE %s DROP CONSTRAINT %I;',
                          conrelid::pg_catalog.regclass, conname) AS "drop",
       pg_catalog.format('ALTER TABLE %s ADD CONSTRAINT %I %s;',
                          conrelid::pg_catalog.regclass, conname,
                          pg_catalog.pg_get_constraintdef(oid)) AS "add"
FROM pg_catalog.pg_constraint c
WHERE contype = 'f' AND conparentid = 0 AND
      (SELECT count(*) FROM pg_catalog.pg_constraint c2
       WHERE c2.conparentid = c.oid) <>
      ((SELECT count(*) FROM pg_catalog.pg_inherits i
        WHERE (i.inhparent = c.conrelid OR i.inhparent = c.confrelid) AND
              EXISTS (SELECT 1 FROM pg_catalog.pg_partitioned_table
                      WHERE partrelid = i.inhparent)) +
       CASE WHEN pg_catalog.pg_partition_root(conrelid) = confrelid THEN
         (SELECT count(*) FROM pg_catalog.pg_partition_tree(confrelid)
          WHERE level = 1)
       ELSE 0 END);
```

Since it is possible that one or more of the `ADD CONSTRAINT` steps will fail, you should save the query's output in a file and then attempt to perform each step.

- Fix test for C locale when `LC_COLLATE` is different from `LC_CTYPE` (Jeff Davis)

When using `libc` as the default collation provider, the test to see if C locale is in use for collation accidentally checked `LC_CTYPE` not `LC_COLLATE`. This has no impact in the typical case where those settings are the same, nor if both are not C (nor its alias `POSIX`). However, if `LC_CTYPE` is C while `LC_COLLATE` is some other locale, wrong query answers could ensue, and corruption of indexes on strings was possible. Users of databases with such settings should reindex affected indexes after installing this update. The converse case with `LC_COLLATE` being C while `LC_CTYPE` is some other locale would cause performance degradation, but no actual errors.

- Don't use partitionwise joins or grouping if the query's collation for the key column doesn't match the partition key's collation (Jian He, Webbo Han)

Such plans could produce incorrect results.

- Avoid planner failure after converting an `IS NULL` test on a `NOT NULL` column to constant `FALSE` (Richard Guo)

This bug typically led to errors such as “variable not found in subplan target lists”.

- Avoid possible planner crash while inlining a SQL function whose arguments contain certain array-related constructs (Tom Lane, Nathan Bossart)
- Fix possible wrong answers or “wrong varnullingrels” planner errors for `MERGE . . . WHEN NOT MATCHED BY SOURCE` actions (Dean Rasheed)
- Fix possible “could not find pathkey item to sort” error when the output of a `UNION ALL` member query needs to be sorted, and the sort column is an expression (Andrei Lepikhov, Tom Lane)
- Fix edge case in B-tree `ScalarArrayOp` index scans (Peter Geoghegan)

When a scrollable cursor with a plan of this kind was backed up to its starting point and then run forward again, wrong answers were possible.

- Fix assertion failure or confusing error message for `COPY (query) TO . . .`, when the *query* is rewritten by a `DO INSTEAD NOTIFY` rule (Tender Wang, Tom Lane)
- Fix validation of `COPY`'s `FORCE_NOT_NULL` and `FORCE_NULL` options (Joel Jacobson)

Some incorrect usages are now rejected as they should be.

- Fix server crash when a `json_objectagg()` call contains a volatile function (Amit Langote)
- Fix detection of skewed data during parallel hash join (Thomas Munro)

After repartitioning the inner side of a hash join because one partition has accumulated too many tuples, we check to see if all the partition's tuples went into the same child partition, which suggests that they all have the same hash value and further repartitioning cannot improve matters. This check malfunctioned in some cases, allowing repeated futile repartitioning which would eventually end in a resource-exhaustion error.

- Avoid crash when `ALTER DATABASE SET` is used to set a server parameter that requires search-path-based lookup, such as `default_text_search_config` (Jeff Davis)
- Avoid repeated lookups of opclasses and collations while creating a new index on a partitioned table (Tom Lane)

This was problematic mainly because some of the lookups would be done with a restricted `search_path`, leading to unexpected failures if the `CREATE INDEX` command referenced objects outside `pg_catalog`.

This fix also prevents comments on the parent partitioned index from being copied to child indexes.

- Add missing dependency from a partitioned table to a non-built-in access method specified in `CREATE TABLE . . . USING` (Michael Paquier)

Dropping the access method should be blocked when a table exists that depends on it, but it was not, allowing subsequent odd behavior. Note that this fix only prevents problems for partitioned tables created after this update.

- Disallow locale names containing non-ASCII characters (Thomas Munro)

This is only an issue on Windows, as such locale names are not used elsewhere. They are problematic because it's quite unclear what encoding such names are represented in (since the locale itself defines the encoding to use). In recent PostgreSQL releases, an abort in the Windows runtime library could occur because of confusion about that.

Anyone who encounters the new error message should either create a new duplicated locale with an ASCII-only name using Windows Locale Builder, or consider using BCP 47-compliant locale names like `tr-TR`.

- Fix race condition in committing a serializable transaction (Heikki Linnakangas)

Mis-processing of a recently committed transaction could lead to an assertion failure or a “could not access status of transaction” error.

- Fix race condition in `COMMIT PREPARED` that resulted in orphaned 2PC files (wuchengwen)

A concurrent `PREPARE TRANSACTION` could cause `COMMIT PREPARED` to not remove the on-disk two-phase state file for the completed transaction. There was no immediate ill effect, but a subsequent crash-and-recovery could fail with “could not access status of transaction”, requiring manual removal of the orphaned file to restore service.

- Avoid invalid memory accesses after skipping an invalid toast index during `VACUUM FULL` (Tender Wang)

A list tracking yet-to-be-rebuilt indexes was not properly updated in this code path, risking assertion failures or crashes later on.

- Fix ways in which an “in place” catalog update could be lost (Noah Misch)

Normal row updates write a new version of the row to preserve rollback-ability of the transaction. However, certain system catalog updates are intentionally non-transactional and are done with an in-place update of the row. These patches fix race conditions that could cause the effects of an in-place update to be lost. As an example, it was possible to forget having set `pg_class.relhasindex` to true, preventing updates of the new index and thus causing index corruption.

- Reset catalog caches at end of recovery (Noah Misch)

This prevents scenarios wherein an in-place catalog update could be lost due to using stale data from a catalog cache.

- Avoid using parallel query while holding off interrupts (Francesco Degraffi, Noah Misch, Tom Lane)

This situation cannot arise normally, but it can be reached with test scenarios such as using a SQL-language function as B-tree support (which would be far too slow for production usage). If it did occur it would result in an indefinite wait.

- Ignore not-yet-defined Portals in the `pg_cursors` view (Tom Lane)

It is possible for user-defined code that inspects this view to be called while a new cursor is being set up, and if that happens a null pointer dereference would ensue. Avoid the problem by defining the view to exclude incompletely-set-up cursors.

- Avoid “unexpected table_index_fetch_tuple call during logical decoding” error while decoding a transaction involving insertion of a column default value (Takeshi Ideriha, Hou Zhijie)

- Reduce memory consumption of logical decoding (Masahiko Sawada)

Use a smaller default block size to store tuple data received during logical replication. This reduces memory wastage, which has been reported to be severe while processing long-running transactions, even leading to out-of-memory failures.

- Fix behavior of stable functions called from a `CALL` statement's argument list, when the `CALL` is within a PL/pgSQL `EXCEPTION` block (Tom Lane)

As with a similar fix in our previous quarterly releases, this case allowed such functions to be passed the wrong snapshot, causing them to see stale values of rows modified since the start of the outer transaction.

- Parse libpq's `keepalives` connection option in the same way as other integer-valued options (Yuto Sasaki)

The coding used here rejected trailing whitespace in the option value, unlike other cases. This turns out to be problematic in `ecpg`'s usage, for example.

- In `ecpglib`, fix out-of-bounds read when parsing incorrect datetime input (Bruce Momjian, Pavel Nekrasov)

It was possible to try to read the location just before the start of a constant array. Real-world consequences seem minimal, though.

- Fix `psql`'s describe commands to again work with pre-9.4 servers (Tom Lane)

Commands involving display of an ACL (permissions) column failed with very old PostgreSQL servers, due to use of a function not present in those versions.

- Avoid hanging if an interval less than 1ms is specified in `psql`'s `\watch` command (Andrey Borodin, Michael Paquier)

Instead, treat this the same as an interval of zero (no wait between executions).

- Fix failure to find replication password in `~/ .pgpass` (Tom Lane)

`pg_basebackup` and `pg_receivewal` failed to match an entry in `~/ .pgpass` that had `replication` in the database name field, if no `-d` or `--dbname` switch was supplied. This resulted in an unexpected prompt for password.

- In `pg_combinebackup`, throw an error if an incremental backup file is present in a directory that is supposed to contain a full backup (Robert Haas)

- In `pg_combinebackup`, don't construct filenames containing double slashes (Robert Haas)

This caused no functional problems, but the duplicate slashes were visible in error messages, which could create confusion.

- Avoid trying to reindex temporary tables and indexes in `vacuumdb` and in `parallel reindexdb` (VaibhaveS, Michael Paquier, Fujii Masao, Nathan Bossart)

Reindexing other sessions' temporary tables cannot work, but the check to skip them was missing in some code paths, leading to unwanted failures.

- Fix incorrect LLVM-generated code on ARM64 platforms (Thomas Munro, Anthonin Bonnefoy)

When using JIT compilation on ARM platforms, the generated code could not support relocation distances exceeding 32 bits, allowing unlucky placement of generated code to cause server crashes on large-memory systems.

- Fix a few places that assumed that process start time (represented as a `time_t`) will fit into a `long` value (Max Johnson, Nathan Bossart)

On platforms where `long` is 32 bits (notably Windows), this coding would fail after Y2038. Most of the failures appear only cosmetic, but notably `pg_ctl start` would hang.

- Update time zone data files to tzdata release 2024b (Tom Lane)

This tzdata release changes the old System-V-compatibility zone names to duplicate the corresponding geographic zones; for example `PST8PDT` is now an alias for `America/Los_Angeles`. The main visible consequence is that for timestamps before the introduction of standardized time zones, the zone is considered to represent local mean solar time for the named location. For example, in `PST8PDT`, `timestampz` input such as `1801-01-01 00:00` would previously have been rendered as `1801-01-01 00:00:00-08`, but now it is rendered as `1801-01-01 00:00:00-07:52:58`.

Also, historical corrections for Mexico, Mongolia, and Portugal. Notably, `Asia/Choibalsan` is now an alias for `Asia/Ulaanbaatar` rather than being a separate zone, mainly because the differences between those zones were found to be based on untrustworthy data.

E.14. Release 17

Release date: 2024-09-26

E.14.1. Overview

PostgreSQL 17 contains many new features and enhancements, including:

- New memory management system for `VACUUM`, which reduces memory consumption and can improve overall vacuuming performance.
- New SQL/JSON capabilities, including constructors, identity functions, and the `JSON_TABLE()` function, which converts JSON data into a table representation.
- Various query performance improvements, including for sequential reads using streaming I/O, write throughput under high concurrency, and searches over multiple values in a `btree` index.
- Logical replication enhancements, including:
 - Failover control
 - `pg_createsubscriber`, a utility that creates logical replicas from physical standbys
 - `pg_upgrade` now preserves logical replication slots on publishers and full subscription state on subscribers. This will allow upgrades to future major versions to continue logical replication without requiring copy to resynchronize.
- New client-side connection option, `sslnegotiation=direct`, that performs a direct TLS handshake to avoid a round-trip negotiation.
- `pg_basebackup` now supports incremental backup.
- `COPY` adds a new option, `ON_ERROR ignore`, that allows a copy operation to continue in the event of an error.

The above items and other new features of PostgreSQL 17 are explained in more detail in the sections below.

E.14.2. Migration to Version 17

A dump/restore using `pg_dumpall` or use of `pg_upgrade` or logical replication is required for those wishing to migrate data from any previous release. See [Section 18.6](#) for general information on migrating to new major releases.

Version 17 contains a number of changes that may affect compatibility with previous releases. Observe the following incompatibilities:

- Change functions to use a safe `search_path` during maintenance operations (Jeff Davis)

This prevents maintenance operations (`ANALYZE`, `CLUSTER`, `CREATE INDEX`, `CREATE MATERIALIZED VIEW`, `REFRESH MATERIALIZED VIEW`, `REINDEX`, or `VACUUM`) from performing unsafe access. Functions used by expression indexes and materialized views that need to reference non-default schemas must specify a search path during function creation.

- Restrict `ago` to only appear at the end in `interval` values (Joseph Koshakow)

Also, prevent empty interval units from appearing multiple times.

- Remove server variable `old_snapshot_threshold` (Thomas Munro)

This variable allowed vacuum to remove rows that potentially could be still visible to running transactions, causing "snapshot too old" errors later if accessed. This feature might be re-added to PostgreSQL later if an improved implementation is found.

- Change `SET SESSION AUTHORIZATION` handling of the initial session user's superuser status (Joseph Koshakow)

The new behavior is based on the session user's superuser status at the time the `SET SESSION AUTHORIZATION` command is issued, rather than their superuser status at connection time.

- Remove feature which simulated per-database users (Nathan Bossart)

The feature, `db_user_namespace`, was rarely used.

- Remove `adminpack` contrib extension (Daniel Gustafsson)

This was used by now end-of-life `pgAdmin III`.

- Remove `wal_sync_method` value `fsync_writethrough` on Windows (Thomas Munro)

This value was the same as `fsync` on Windows.

- Change file boundary handling of two WAL file name functions (Kyotaro Horiguchi, Andres Freund, Bruce Momjian)

The functions `pg_walfile_name()` and `pg_walfile_name_offset()` used to report the previous LSN segment number when the LSN was on a file segment boundary; it now returns the current LSN segment.

- Remove server variable `trace_recovery_messages` since it is no longer needed (Bharath Rupireddy)

- Remove `information schema` column `element_types.domain_default` (Peter Eisentraut)

- Change `pgrowlocks` lock mode output labels (Bruce Momjian)

- Remove `buffers_backend` and `buffers_backend_fsync` from `pg_stat_bgwriter` (Bharath Rupireddy)

These fields are considered redundant to similar columns in `pg_stat_io`.

- Rename I/O block read/write timing statistics columns of `pg_stat_statements` (Nazir Bilal Yavuz)

This renames `blk_read_time` to `shared_blk_read_time`, and `blk_write_time` to `shared_blk_write_time`.

- Change `pg_attribute.attstattarget` and `pg_statistic_ext.stxstattarget` to represent the default statistics target as `NULL` (Peter Eisentraut)

- Rename `pg_collation.colliculocale` to `colllocale` and `pg_database.daticulocale` to `datlocale` (Jeff Davis)

- Rename `pg_stat_progress_vacuum` column `max_dead_tuples` to `max_dead_tuple_bytes`, rename `num_dead_tuples` to `num_dead_item_ids`, and add `dead_tuple_bytes` (Masahiko Sawada)

- Rename SLRU columns in system view `pg_stat_slru` (Alvaro Herrera)

The column names accepted by `pg_stat_reset_slru()` are also changed.

E.14.3. Changes

Below you will find a detailed account of the changes between PostgreSQL 17 and the previous major release.

E.14.3.1. Server

E.14.3.1.1. Optimizer

- Allow the optimizer to improve CTE plans by considering the statistics and sort order of columns referenced in earlier row output clauses (Jian Guo, Richard Guo, Tom Lane)
- Improve optimization of `IS NOT NULL` and `IS NULL` query restrictions (David Rowley, Richard Guo, Andy Fan)

Remove `IS NOT NULL` restrictions from queries on `NOT NULL` columns and eliminate scans on `NOT NULL` columns if `IS NULL` is specified.

- Allow partition pruning on boolean columns on `IS [NOT] UNKNOWN` conditionals (David Rowley)
- Improve optimization of range values when using containment operators `<@` and `@>` (Kim Johan Andersson, Jian He)
- Allow correlated `IN` subqueries to be transformed into joins (Andy Fan, Tom Lane)
- Improve optimization of the `LIMIT` clause on partitioned tables, inheritance parents, and `UNION ALL` queries (Andy Fan, David Rowley)
- Allow query nodes to be run in parallel in more cases (Tom Lane)
- Allow `GROUP BY` columns to be internally ordered to match `ORDER BY` (Andrei Lepikhov, Teodor Sigaev)

This can be disabled using server variable [enable_group_by_reordering](#).

- Allow `UNION` (without `ALL`) to use MergeAppend (David Rowley)
- Fix MergeAppend plans to more accurately compute the number of rows that need to be sorted (Alexander Kuzmenkov)
- Allow [GiST](#) and [SP-GiST](#) indexes to be part of incremental sorts (Miroslav Bendik)

This is particularly useful for `ORDER BY` clauses where the first column has a GiST and SP-GiST index, and other columns do not.

- Add columns to [pg_stats](#) to report range-type histogram information (Egor Rogov, Soumyadeep Chakraborty)

E.14.3.1.2. Indexes

- Allow [btree](#) indexes to more efficiently find a set of values, such as those supplied by `IN` clauses using constants (Peter Geoghegan, Matthias van de Meent)
- Allow [BRIN](#) indexes to be created using parallel workers (Tomas Vondra, Matthias van de Meent)

E.14.3.1.3. General Performance

- Allow vacuum to more efficiently remove and freeze tuples (Melanie Plageman, Heikki Linnakangas)

WAL traffic caused by vacuum is also more compact.

- Allow vacuum to more efficiently store tuple references (Masahiko Sawada, John Naylor)

Additionally, vacuum is no longer silently limited to one gigabyte of memory when [maintenance_work_mem](#) or [autovacuum_work_mem](#) are higher.

- Optimize vacuuming of relations with no indexes (Melanie Plageman)
- Increase default [vacuum_buffer_usage_limit](#) to 2MB (Thomas Munro)
- Improve performance when checking roles with many memberships (Nathan Bossart)
- Improve performance of heavily-contended WAL writes (Bharath Rupireddy)
- Improve performance when transferring large blocks of data to a client (Melih Mutlu)
- Allow the grouping of file system reads with the new system variable [io_combine_limit](#) (Thomas Munro, Andres Freund, Melanie Plageman, Nazir Bilal Yavuz)

E.14.3.1.4. Monitoring

- Create system view [pg_stat_checkpoint](#) (Bharath Rupireddy, Anton A. Melnikov, Alexander Korotkov)

Relevant columns have been removed from [pg_stat_bgwriter](#) and added to this new system view.

- Improve control over resetting statistics (Atsushi Torikoshi, Bharath Rupireddy)

Allow `pg_stat_reset_shared()` (with no arguments) and `pg_stat_reset_shared(NULL)` to reset all shared statistics. Allow `pg_stat_reset_shared('slru')` and `pg_stat_reset_slru()` (with no arguments) to reset SLRU statistics, which was already possible with `pg_stat_reset_slru(NULL)`.

- Add log messages related to WAL recovery from backups (Andres Freund)
- Add `log_connections` log line for `trust` connections (Jacob Champion)
- Add log message to report walsender acquisition and release of replication slots (Bharath Rupireddy)

This is enabled by the server variable `log_replication_commands`.

- Add system view `pg_wait_events` that reports wait event types (Bertrand Drouvot)

This is useful for adding descriptions to wait events reported in `pg_stat_activity`.

- Add `wait events` for checkpoint delays (Thomas Munro)
- Allow vacuum to report the progress of index processing (Sami Imseih)

This appears in system view `pg_stat_progress_vacuum` columns `indexes_total` and `indexes_processed`.

E.14.3.1.5. Privileges

- Allow granting the right to perform maintenance operations (Nathan Bossart)

The permission can be granted on a per-table basis using the `MAINTAIN` privilege and on a per-role basis via the `pg_maintain` predefined role. Permitted operations are `VACUUM`, `ANALYZE`, `REINDEX`, `REFRESH MATERIALIZED VIEW`, `CLUSTER`, and `LOCK TABLE`.

- Allow roles with `pg_monitor` membership to execute `pg_current_logfile()` (Pavlo Golub, Nathan Bossart)

E.14.3.1.6. Server Configuration

- Add system variable `allow_alter_system` to disallow `ALTER SYSTEM` (Jelte Fennema-Nio, Gabriele Bartolini)
- Allow `ALTER SYSTEM` to set unrecognized custom server variables (Tom Lane)

This is also possible with `GRANT ON PARAMETER`.

- Add server variable `transaction_timeout` to restrict the duration of transactions (Andrey Borodin, Japin Li, Junwang Zhao, Alexander Korotkov)
- Add a builtin platform-independent collation provider (Jeff Davis)

This supports `C` and `C.UTF-8` collations.

- Add server variable `huge_pages_status` to report the use of huge pages by Postgres (Justin Pryzby)

This is useful when `huge_pages` is set to `try`.

- Add server variable to disable event triggers (Daniel Gustafsson)

The setting, `event_triggers`, allows for the temporary disabling of event triggers for debugging.

- Allow the `SLRU` cache sizes to be configured (Andrey Borodin, Dilip Kumar, Alvaro Herrera)

The new server variables are `commit_timestamp_buffers`, `multixact_member_buffers`, `multixact_offset_buffers`, `notify_buffers`, `serializable_buffers`, `subtransaction_buffers`, and `transaction_buffers`. `commit_timestamp_buffers`, `transaction_buffers`, and `subtransaction_buffers` scale up automatically with `shared_buffers`.

E.14.3.1.7. Streaming Replication and Recovery

- Add support for incremental file system backup (Robert Haas, Jakub Wartak, Tomas Vondra)

Incremental backups can be created using `pg_basebackup`'s new `--incremental` option. The new application `pg_combine-backup` allows manipulation of base and incremental file system backups.

- Allow the creation of WAL summarization files (Robert Haas, Nathan Bossart, Hubert Depesz Lubaczewski)

These files record the block numbers that have changed within an [LSN](#) range and are useful for incremental file system backups. This is controlled by the server variables [summarize_wal](#) and [wal_summary_keep_time](#), and introspected with [pg_available_wal_summaries\(\)](#), [pg_wal_summary_contents\(\)](#), and [pg_get_wal_summarizer_state\(\)](#).

- Add the system identifier to file system [backup manifest](#) files (Amul Sul)

This helps detect invalid WAL usage.

- Allow connection string value `dbname` to be written when [pg_basebackup](#) writes connection information to `postgresql.auto.conf` (Vignesh C, Hayato Kuroda)
- Add column [pg_replication_slots.invalidation_reason](#) to report the reason for invalid slots (Shveta Malik, Bharath Rupireddy)
- Add column [pg_replication_slots.inactive_since](#) to report slot inactivity duration (Bharath Rupireddy)
- Add function [pg_sync_replication_slots\(\)](#) to synchronize logical replication slots (Hou Zhijie, Shveta Malik, Ajin Cherian, Peter Eisentraut)
- Add the `failover` property to the [replication protocol](#) (Hou Zhijie, Shveta Malik)

E.14.3.1.8. Logical Replication

- Add application [pg_createsubscriber](#) to create a logical replica from a physical standby server (Euler Taveira)
- Have [pg_upgrade](#) migrate valid logical slots and subscriptions (Hayato Kuroda, Hou Zhijie, Vignesh C, Julien Rouhaud, Shlok Kyal)

This allows logical replication to continue quickly after the upgrade. This only works for old PostgreSQL clusters that are version 17 or later.

- Enable the failover of [logical slots](#) (Hou Zhijie, Shveta Malik, Ajin Cherian)

This is controlled by an optional fifth argument to [pg_create_logical_replication_slot\(\)](#).

- Add server variable [sync_replication_slots](#) to enable failover logical slot synchronization (Shveta Malik, Hou Zhijie, Peter Smith)
- Add logical replication failover control to [CREATE/ALTER SUBSCRIPTION](#) (Shveta Malik, Hou Zhijie, Ajin Cherian)
- Allow the application of logical replication changes to use [hash](#) indexes on the subscriber (Hayato Kuroda)

Previously only [btree](#) indexes could be used for this purpose.

- Improve [logical decoding](#) performance in cases where there are many subtransactions (Masahiko Sawada)
- Restart apply workers if subscription owner's superuser privileges are revoked (Vignesh C)

This forces reauthentication.

- Add `flush` option to [pg_logical_emit_message\(\)](#) (Michael Paquier)

This makes the message durable.

- Allow specification of physical standbys that must be synchronized before they are visible to subscribers (Hou Zhijie, Shveta Malik)

The new server variable is [synchronized_standby_slots](#).

- Add worker type column to [pg_stat_subscription](#) (Peter Smith)

E.14.3.2. Utility Commands

- Add new [COPY](#) option `ON_ERROR ignore` to discard error rows (Damir Belyalov, Atsushi Torikoshi, Alex Shulgin, Jian He, Yugo Nagata)

The default behavior is `ON_ERROR stop`.

- Add new `COPY` option `LOG_VERBOSITY` which reports `COPY FROM` ignored error rows (Bharath Rupireddy)
- Allow `COPY FROM` to report the number of skipped rows during processing (Atsushi Torikoshi)

This appears in system view column `pg_stat_progress_copy.tuples_skipped`.

- In `COPY FROM`, allow easy specification that all columns should be forced null or not null (Zhang Mingli)
- Allow partitioned tables to have identity columns (Ashutosh Bapat)
- Allow [exclusion constraints](#) on partitioned tables (Paul A. Jungwirth)

As long as exclusion constraints compare partition key columns for equality, other columns can use exclusion constraint-specific comparisons.

- Add clearer `ALTER TABLE` method to set a column to the default statistics target (Peter Eisentraut)

The new syntax is `ALTER TABLE ... SET STATISTICS DEFAULT`; using `SET STATISTICS -1` is still supported.

- Allow `ALTER TABLE` to change a column's generation expression (Amul Sul)

The syntax is `ALTER TABLE ... ALTER COLUMN ... SET EXPRESSION`.

- Allow specification of [table access methods](#) on partitioned tables (Justin Pryzby, Soumyadeep Chakraborty, Michael Paquier)
- Add `DEFAULT` setting for `ALTER TABLE ... SET ACCESS METHOD` (Michael Paquier)
- Add support for [event triggers](#) that fire at connection time (Konstantin Knizhnik, Mikhail Gribkov)
- Add event trigger support for `REINDEX` (Garrett Thornburg, Jian He)
- Allow parenthesized syntax for `CLUSTER` options if a table name is not specified (Nathan Bossart)

E.14.3.2.1. [EXPLAIN](#)

- Allow `EXPLAIN` to report optimizer memory usage (Ashutosh Bapat)

The option is called `MEMORY`.

- Add `EXPLAIN` option `SERIALIZE` to report the cost of converting data for network transmission (Stepan Rutz, Matthias van de Meent)
- Add local I/O block read/write timing statistics to `EXPLAIN`'s `BUFFERS` output (Nazir Bilal Yavuz)
- Improve `EXPLAIN`'s display of SubPlan nodes and output parameters (Tom Lane, Dean Rasheed)
- Add JIT `deform_counter` details to `EXPLAIN` (Dmitry Dolgov)

E.14.3.3. Data Types

- Allow the `interval` data type to support `+/-infinity` values (Joseph Koshakow, Jian He, Ashutosh Bapat)
- Allow the use of an [ENUM](#) added via `ALTER TYPE` if the type was created in the same transaction (Tom Lane)

This was previously disallowed.

E.14.3.4. [MERGE](#)

- Allow `MERGE` to modify updatable views (Dean Rasheed)
- Add `WHEN NOT MATCHED BY SOURCE` to `MERGE` (Dean Rasheed)

`WHEN NOT MATCHED` on target rows was already supported.

- Allow `MERGE` to use the `RETURNING` clause (Dean Rasheed)

The new `RETURNING` function `merge_action()` reports on the DML that generated the row.

E.14.3.5. Functions

- Add function `JSON_TABLE()` to convert `JSON` data to a table representation (Nikita Glukhov, Teodor Sigaev, Oleg Bartunov, Alexander Korotkov, Andrew Dunstan, Amit Langote, Jian He)

This function can be used in the `FROM` clause of `SELECT` queries as a tuple source.

- Add SQL/JSON constructor functions `JSON()`, `JSON_SCALAR()`, and `JSON_SERIALIZE()` (Nikita Glukhov, Teodor Sigaev, Oleg Bartunov, Alexander Korotkov, Andrew Dunstan, Amit Langote)
- Add SQL/JSON query functions `JSON_EXISTS()`, `JSON_QUERY()`, and `JSON_VALUE()` (Nikita Glukhov, Teodor Sigaev, Oleg Bartunov, Alexander Korotkov, Andrew Dunstan, Amit Langote, Peter Eisentraut, Jian He)
- Add `jsonpath` methods to convert JSON values to other JSON data types (Jeevan Chalke)

The `jsonpath` methods are `.bigint()`, `.boolean()`, `.date()`, `.decimal([precision [, scale]])`, `.integer()`, `.number()`, `.string()`, `.time()`, `.time_tz()`, `.timestamp()`, and `.timestamp_tz()`.

- Add `to_timestamp()` time zone format specifiers (Tom Lane)

TZ accepts time zone abbreviations or numeric offsets, while OF accepts only numeric offsets.

- Allow the session `time zone` to be specified by `AT LOCAL` (Vik Fearing)

This is useful when converting adding and removing time zones from time stamps values, rather than specifying the literal session time zone.

- Add functions `uuid_extract_timestamp()` and `uuid_extract_version()` to return UUID information (Andrey Borodin)
- Add functions to generate random numbers in a specified range (Dean Rasheed)

The functions are `random(min, max)` and they take values of type `integer`, `bigint`, and `numeric`.

- Add functions to convert integers to binary and octal strings (Eric Radman, Nathan Bossart)

The functions are `to_bin()` and `to_oct()`.

- Add Unicode informational functions (Jeff Davis)

Function `unicode_version()` returns the Unicode version, `icu_unicode_version()` returns the ICU version, and `unicode_assigned()` returns if the characters are assigned Unicode codepoints.

- Add function `xmltext()` to convert text to a single XML text node (Jim Jones)
- Add function `to_regtypemod()` to return the type modifier of a type specification (David Wheeler, Erik Wienhold)
- Add `pg_basetype()` function to return a domain's base type (Steve Chavez)
- Add function `pg_column_toast_chunk_id()` to return a value's `TOAST` identifier (Yugo Nagata)

This returns `NULL` if the value is not stored in `TOAST`.

E.14.3.6. PL/pgSQL

- Allow `plpgsql %TYPE` and `%ROWTYPE` specifications to represent arrays of non-array types (Quan Zongliang, Pavel Stehule)
- Allow `plpgsql %TYPE` specification to reference composite column (Tom Lane)

E.14.3.7. libpq

- Add `libpq` function to change role passwords (Joe Conway)

The new function, `PQchangePassword()`, hashes the new password before sending it to the server.

- Add `libpq` functions to close portals and prepared statements (Jelte Fennema-Nio)

The functions are `PQclosePrepared()`, `PQclosePortal()`, `PQsendClosePrepared()`, and `PQsendClosePortal()`.

- Add `libpq` API which allows for blocking and non-blocking `cancel requests`, with encryption if already in use (Jelte Fennema-Nio)

Previously only blocking, unencrypted cancel requests were supported.

- Add libpq function `PQsocketPoll()` to allow polling of network sockets (Tristan Partin, Tom Lane)
- Add libpq function `PQsendPipelineSync()` to send a pipeline synchronization point (Anton Kirilov)

This is similar to `PQpipelineSync()` but it does not flush to the server unless the size threshold of the output buffer is reached.

- Add libpq function `PQsetChunkedRowsMode()` to allow retrieval of results in chunks (Daniel Vérité)
- Allow TLS connections without requiring a network round-trip negotiation (Greg Stark, Heikki Linnakangas, Peter Eisentraut, Michael Paquier, Daniel Gustafsson)

This is enabled with the client-side option `sslnegotiation=direct`, requires ALPN, and only works on PostgreSQL 17 and later servers.

- Improve psql display of default and empty privileges (Erik Wienhold, Laurenz Albe)

Command `\dp` now displays `(none)` for empty privileges; default still displays as empty.

- Have backslash commands honor `\pset null` (Erik Wienhold, Laurenz Albe)

Previously `\pset null` was ignored.

- Allow psql's `\watch` to stop after a minimum number of rows returned (Greg Sabino Mullane)

The parameter is `min_rows`.

- Allow psql connection attempts to be canceled with control-C (Tristan Partin)
- Allow psql to honor `FETCH_COUNT` for non-`SELECT` queries (Daniel Vérité)
- Improve psql tab completion (Dagfinn Ilmari Mannsåker, Gilles Darold, Christoph Heiss, Steve Chavez, Vignesh C, Pavel Borisov, Jian He)

E.14.3.9. Server Applications

- Add application `pg_walsummary` to dump WAL summary files (Robert Haas)
- Allow `pg_dump`'s large objects to be restorable in batches (Tom Lane)

This allows the restoration of many large objects to avoid transaction limits and to be restored in parallel.

- Add `pg_dump` option `--exclude-extension` (Ayush Vatsa)
- Allow `pg_dump`, `pg_dumpall`, and `pg_restore` to specify include/exclude objects in a file (Pavel Stehule, Daniel Gustafsson)

The option is called `--filter`.

- Add the `--sync-method` parameter to several client applications (Justin Pryzby, Nathan Bossart)

The applications are `initdb`, `pg_basebackup`, `pg_checksums`, `pg_dump`, `pg_rewind`, and `pg_upgrade`.

- Add `pg_restore` option `--transaction-size` to allow object restores in transaction batches (Tom Lane)

This allows the performance benefits of transaction batches without the problems of excessively large transaction blocks.

- Change `pgbench` debug mode option from `-d` to `--debug` (Greg Sabino Mullane)

Option `-d` is now used for the database name, and the new `--dbname` option can be used as well.

- Add `pgbench` option `--exit-on-abort` to exit after any client aborts (Yugo Nagata)
- Add `pgbench` command `\syncpipeline` to allow sending of sync messages (Anthonin Bonnefoy)
- Allow `pg_archivecleanup` to remove backup history files (Atsushi Torikoshi)

The option is `--clean-backup-history`.

- Add some long options to `pg_archivecleanup` (Atsushi Torikoshi)

The long options are `--debug`, `--dry-run`, and `--strip-extension`.

- Allow `pg_basebackup` and `pg_receivewal` to use dbname in their connection specification (Jelte Fennema-Nio)

This is useful for connection poolers that are sensitive to the database name.

- Add `pg_upgrade` option `--copy-file-range` (Thomas Munro)

This is supported on Linux and FreeBSD.

- Allow `reindexdb` `--index` to process indexes from different tables in parallel (Maxim Orlov, Svetlana Derevyanko, Alexander Korotkov)
- Allow `reindexdb`, `vacuumdb`, and `clusterdb` to process objects in all databases matching a pattern (Nathan Bossart)

The new option `--all` controls this behavior.

E.14.3.10. Source Code

- Remove support for OpenSSL 1.0.1 (Michael Paquier)
- Allow tests to pass in OpenSSL FIPS mode (Peter Eisentraut)
- Use CPU AVX-512 instructions for bit counting (Paul Amonson, Nathan Bossart, Ants Aasma)
- Require LLVM version 10 or later (Thomas Munro)
- Use native CRC instructions on 64-bit LoongArch CPUs (Xudong Yang)
- Remove AIX support (Heikki Linnakangas)
- Remove the Microsoft Visual Studio-specific PostgreSQL build option (Michael Paquier)

Meson is now the only available method for Visual Studio builds.

- Remove configure option `--disable-thread-safety` (Thomas Munro, Heikki Linnakangas)

We now assume all supported platforms have sufficient thread support.

- Remove configure option `--with-CC` (Heikki Linnakangas)

Setting the `CC` environment variable is now the only supported method for specifying the compiler.

- User-defined data type receive functions will no longer receive their data null-terminated (David Rowley)
- Add incremental JSON parser for use with huge JSON documents (Andrew Dunstan)
- Convert top-level README file to Markdown (Nathan Bossart)
- Remove no longer needed top-level INSTALL file (Tom Lane)
- Remove make's `distprep` option (Peter Eisentraut)
- Add make support for Android shared libraries (Peter Eisentraut)
- Add backend support for injection points (Michael Paquier)

This is used for server debugging and they must be enabled at server compile time.

- Add dynamic shared memory registry (Nathan Bossart)

This allows shared libraries which are not initialized at startup to coordinate dynamic shared memory access.

- Fix `emit_log_hook` to use the same time value as other log records for the same query (Kambam Vinay, Michael Paquier)
- Improve documentation for using `jsonpath` for predicate checks (David Wheeler)

E.14.3.11. Additional Modules

- Allow joins with non-join qualifications to be pushed down to foreign servers and custom scans (Richard Guo, Etsuro Fujita)

Foreign data wrappers and custom scans will need to be modified to handle these cases.

- Allow pushdown of EXISTS and IN subqueries to [postgres_fdw](#) foreign servers (Alexander Pyhalov)
- Increase the default foreign data wrapper tuple cost (David Rowley, Umair Shahid)

This value is used by the optimizer.

- Allow [dblink](#) database operations to be interrupted (Noah Misch)
- Allow the creation of hash indexes on [ltree](#) columns (Tommy Pavlicek)

This also enables hash join and hash aggregation on [ltree](#) columns.

- Allow [unaccent](#) character translation rules to contain whitespace and quotes (Michael Paquier)

The syntax for the `unaccent.rules` file has changed.

- Allow [amcheck](#) to check for unique constraint violations using new option `--checkunique` (Anastasia Lubennikova, Pavel Borisov, Maxim Orlov)
- Allow [ciphertext](#) tests to pass in OpenSSL FIPS mode (Peter Eisentraut)
- Allow [pgcrypto](#) tests to pass in OpenSSL FIPS mode (Peter Eisentraut)
- Remove some unused [SPI](#) macros (Bharath Rupireddy)
- Allow [ALTER OPERATOR](#) to set more optimization attributes (Tommy Pavlicek)

This is useful for extensions.

- Allow extensions to define [custom wait events](#) (Masahiro Ikeda)

Custom wait events have been added to [postgres_fdw](#) and [dblink](#).

- Add [pg_buffercache](#) function `pg_buffercache_evict()` to allow shared buffer eviction (Palak Chaturvedi, Thomas Munro)

This is useful for testing.

E.14.3.11.1. [pg_stat_statements](#)

- Replace [CALL](#) parameters in `pg_stat_statements` with placeholders (Sami Imseih)
- Replace savepoint names stored in `pg_stat_statements` with placeholders (Greg Sabino Mullane)

This greatly reduces the number of entries needed to record [SAVEPOINT](#), [RELEASE SAVEPOINT](#), and [ROLLBACK TO SAVEPOINT](#) commands.

- Replace the two-phase commit GIDs stored in `pg_stat_statements` with placeholders (Michael Paquier)

This greatly reduces the number of entries needed to record [PREPARE TRANSACTION](#), [COMMIT PREPARED](#), and [ROLLBACK PREPARED](#).

- Track [DEALLOCATE](#) in `pg_stat_statements` (Dagfinn Ilmari Mannsåker, Michael Paquier)

[DEALLOCATE](#) names are stored in `pg_stat_statements` as placeholders.

- Add local I/O block read/write timing statistics columns of `pg_stat_statements` (Nazir Bilal Yavuz)

The new columns are `local_blk_read_time` and `local_blk_write_time`.

- Add JIT deform_counter details to `pg_stat_statements` (Dmitry Dolgov)
- Add optional fourth argument (`minmax_only`) to `pg_stat_statements_reset()` to allow for the resetting of only min/max statistics (Andrei Zubkov)

This argument defaults to `false`.

- Add `pg_stat_statements` columns `stats_since` and `minmax_stats_since` to track entry creation time and last min/max reset time (Andrei Zubkov)

E.14.4. Acknowledgments

The following individuals (in alphabetical order) have contributed to this release as patch authors, committers, reviewers, testers, or reporters of issues.

E.15. Prior Releases

Release notes for prior versions can be found online. At the time of Postgres Pro Enterprise 17 release, these prior versions were supported:

- Postgres Pro Enterprise 16: <https://postgrespro.com/docs/enterprise/16/release.html>
- Postgres Pro Enterprise 15: <https://postgrespro.com/docs/enterprise/15/release.html>
- Postgres Pro Enterprise 14: <https://postgrespro.com/docs/enterprise/14/release.html>
- Postgres Pro Enterprise 13: <https://postgrespro.com/docs/enterprise/13/release.html>
- Postgres Pro Enterprise 12: <https://postgrespro.com/docs/enterprise/12/release.html>

Appendix F. Additional Supplied Modules and Extensions Shipped in postgrespro-ent-17-contrib

This appendix, [Appendix G](#), [Appendix H](#), and [Appendix I](#) contain information on the optional components available in the Postgres Pro Enterprise distribution. These include porting tools, analysis utilities, and plug-in features that are not part of the core Postgres Pro system. They are separate mainly because they address a limited audience or are too experimental to be part of the main source tree. This does not preclude their usefulness.

This appendix, [Appendix G](#), [Appendix H](#) cover the extensions and other server plug-in modules. [Appendix I](#) covers the utility programs.

Many components supply new user-defined functions, operators, or types, packaged as *extensions*. To make use of one of these extensions, after you have installed the code you need to register the new SQL objects in the database system. This is done by executing a [CREATE EXTENSION](#) command. In a fresh database, you can simply do

```
CREATE EXTENSION extension_name;
```

This command registers the new SQL objects in the current database only, so you need to run it in every database in which you want the extension's facilities to be available. Alternatively, run it in database `template1` so that the extension will be copied into subsequently-created databases by default.

For all extensions, the `CREATE EXTENSION` command must be run by a database superuser, unless the extension is considered “trusted”. Trusted extensions can be run by any user who has `CREATE` privilege on the current database. Extensions that are trusted are identified as such in the sections that follow. Generally, trusted extensions are ones that cannot provide access to outside-the-database functionality.

The following extensions are trusted in a default installation:

btree_gin	fuzzystrmatch	ltree	tcn
btree_gist	hstore	pgcrypto	tsm_system_rows
citext	intarray	pg_trgm	tsm_system_time
cube	isn	seg	unaccent
dict_int	lo	tablefunc	uuid-oss

Many extensions allow you to install their objects in a schema of your choice. To do that, add `SCHEMA schema_name` to the `CREATE EXTENSION` command. By default, the objects will be placed in your current creation target schema, which in turn defaults to `public`.

Note, however, that some of these components are not “extensions” in this sense, but are loaded into the server in some other way, for instance by way of [shared_preload_libraries](#). See the documentation of each component for details.

This appendix contains modules and extensions that are made available in Postgres Pro Enterprise as a separate subpackage `postgrespro-ent-17-contrib`. Note that the `toastapi` extension to add custom TOASTers is also available in `postgrespro-ent-17-contrib` (see [Section 66.2.3](#) for details).

F.1. amcheck — tools to verify table and index consistency

The `amcheck` module provides functions that allow you to verify the logical consistency of the structure of relations.

The B-Tree checking functions verify various *invariants* in the structure of the representation of particular relations. The correctness of the access method functions behind index scans and other important operations relies on these invariants always holding. For example, certain functions verify, among other things, that all B-Tree pages have items in “logical” order (e.g., for B-Tree indexes on `text`, index tuples should be in collated lexical order). If that particular invariant somehow fails to hold, we can expect binary searches on the affected page to incorrectly guide index scans, resulting in wrong answers to SQL queries. If the structure appears to be valid, no error is raised. While these checking functions are run, the `search_path` is temporarily changed to `pg_catalog`, `pg_temp`.

Verification is performed using the same procedures as those used by index scans themselves, which may be user-defined operator class code. For example, B-Tree index verification relies on comparisons made with one or more B-Tree support function 1 routines. See [Section 39.16.3](#) for details of operator class support functions.

Unlike the B-Tree checking functions which report corruption by raising errors, the heap checking function `verify_heapam` checks a table and attempts to return a set of rows, one row per corruption detected. Despite this, if facilities that `verify_heapam` relies upon are themselves corrupted, the function may be unable to continue and may instead raise an error.

Permission to execute `amcheck` functions may be granted to non-superusers, but before granting such permissions careful consideration should be given to data security and privacy concerns. Although the corruption reports generated by these functions do not focus on the contents of the corrupted data so much as on the structure of that data and the nature of the corruptions found, an attacker who gains permission to execute these functions, particularly if the attacker can also induce corruption, might be able to infer something of the data itself from such messages.

Note

Using `amcheck 1.1.1` is not recommended as the `bt_index_parent_check` function works incorrectly in that version.

F.1.1. Functions

`bt_index_check(index regclass, heapallindexed boolean, checkunique boolean)` returns void

`bt_index_check` tests that its target, a B-Tree index, respects a variety of invariants. Example usage:

```
test=# SELECT bt_index_check(index => c.oid, heapallindexed => i.indisunique),
        c.relname,
        c.relpages
```

```
FROM pg_index i
JOIN pg_opclass op ON i.indclass[0] = op.oid
JOIN pg_am am ON op.opcmethod = am.oid
JOIN pg_class c ON i.indexrelid = c.oid
JOIN pg_namespace n ON c.relnamespace = n.oid
WHERE am.amname = 'btree' AND n.nspname = 'pg_catalog'
-- Don't check temp tables, which may be from another session:
AND c.relpersistence != 't'
-- Function may throw an error when this is omitted:
AND c.relkind = 'i' AND i.indisready AND i.indisvalid
ORDER BY c.relpages DESC LIMIT 10;
```

bt_index_check	relname	relpages
	pg_depend_reference_index	43
	pg_depend_depender_index	40
	pg_proc_proname_args_nsp_index	31
	pg_description_o_c_o_index	21
	pg_attribute_relid_attnam_index	14
	pg_proc_oid_index	10
	pg_attribute_relid_attnum_index	9

Additional Supplied Modules and
Extensions Shipped in `post-
grespro-ent-17-contrib`

<code>pg_amproc_fam_proc_index</code>	5
<code>pg_amop_opr_fam_index</code>	5
<code>pg_amop_fam_strat_index</code>	5

(10 rows)

This example shows a session that performs verification of the 10 largest catalog indexes in the database “test”. Verification of the presence of heap tuples as index tuples is requested for the subset that are unique indexes. Since no error is raised, all indexes tested appear to be logically consistent. Naturally, this query could easily be changed to call `bt_index_check` for every index in the database where verification is supported.

`bt_index_check` acquires an `AccessShareLock` on the target index and the heap relation it belongs to. This lock mode is the same lock mode acquired on relations by simple `SELECT` statements. `bt_index_check` does not verify invariants that span child/parent relationships, but will verify the presence of all heap tuples as index tuples within the index when *heapallindexed* is true. When *checkunique* is true `bt_index_check` will check that no more than one among duplicate entries in unique index is visible. When a routine, lightweight test for corruption is required in a live production environment, using `bt_index_check` often provides the best trade-off between thoroughness of verification and limiting the impact on application performance and availability.

`bt_index_parent_check(index regclass, heapallindexed boolean, rootdescend boolean, checkunique boolean)` returns void

`bt_index_parent_check` tests that its target, a B-Tree index, respects a variety of invariants. Optionally, when the *heapallindexed* argument is true, the function verifies the presence of all heap tuples that should be found within the index. When *checkunique* is true `bt_index_parent_check` will check that no more than one among duplicate entries in unique index is visible. When the optional *rootdescend* argument is true, verification re-finds tuples on the leaf level by performing a new search from the root page for each tuple. The checks that can be performed by `bt_index_parent_check` are a superset of the checks that can be performed by `bt_index_check`. `bt_index_parent_check` can be thought of as a more thorough variant of `bt_index_check`: unlike `bt_index_check`, `bt_index_parent_check` also checks invariants that span parent/child relationships, including checking that there are no missing downlinks in the index structure. `bt_index_parent_check` follows the general convention of raising an error if it finds a logical inconsistency or other problem.

A `ShareLock` is required on the target index by `bt_index_parent_check` (a `ShareLock` is also acquired on the heap relation). These locks prevent concurrent data modification from `INSERT`, `UPDATE`, and `DELETE` commands. The locks also prevent the underlying relation from being concurrently processed by `VACUUM`, as well as all other utility commands. Note that the function holds locks only while running, not for the entire transaction.

`bt_index_parent_check`'s additional verification is more likely to detect various pathological cases. These cases may involve an incorrectly implemented B-Tree operator class used by the index that is checked, or, hypothetically, undiscovered bugs in the underlying B-Tree index access method code. Note that `bt_index_parent_check` cannot be used when hot standby mode is enabled (i.e., on read-only physical replicas), unlike `bt_index_check`.

Tip

`bt_index_check` and `bt_index_parent_check` both output log messages about the verification process at `DEBUG1` and `DEBUG2` severity levels. These messages provide detailed information about the verification process that may be of interest to PostgreSQL developers. Advanced users may also find this information helpful, since it provides additional context should verification actually detect an inconsistency. Running:

```
SET client_min_messages = DEBUG1;
```

in an interactive psql session before running a verification query will display messages about the progress of verification with a manageable level of detail.

`verify_heapam(relation regclass, on_error_stop boolean, check_toast boolean, skip_text, startblock bigint, endblock bigint, blkno OUT bigint, offnum OUT integer, attnum OUT integer, msg OUT text)` returns setof record

Checks a table, sequence, or materialized view for structural corruption, where pages in the relation contain data that is invalidly formatted, and for logical corruption, where pages are structurally valid but inconsistent with the rest of the database cluster.

The following optional arguments are recognized:

on_error_stop

If true, corruption checking stops at the end of the first block in which any corruptions are found.

Defaults to false.

check_toast

If true, toasted values are checked against the target relation's TOAST table.

This option is known to be slow. Also, if the toast table or its index is corrupt, checking it against toast values could conceivably crash the server, although in many cases this would just produce an error.

Defaults to false.

skip

If not `none`, corruption checking skips blocks that are marked as all-visible or all-frozen, as specified. Valid options are `all-visible`, `all-frozen` and `none`.

Defaults to `none`.

startblock

If specified, corruption checking begins at the specified block, skipping all previous blocks. It is an error to specify a *startblock* outside the range of blocks in the target table.

By default, checking begins at the first block.

endblock

If specified, corruption checking ends at the specified block, skipping all remaining blocks. It is an error to specify an *endblock* outside the range of blocks in the target table.

By default, all blocks are checked.

For each corruption detected, `verify_heapam` returns a row with the following columns:

blkno

The number of the block containing the corrupt page.

offnum

The OffsetNumber of the corrupt tuple.

attnum

The attribute number of the corrupt column in the tuple, if the corruption is specific to a column and not the tuple as a whole.

msg

A message describing the problem detected.

F.1.2. Optional *heapallindexed* Verification

When the *heapallindexed* argument to B-Tree verification functions is `true`, an additional phase of verification is performed against the table associated with the target index relation. This consists of a “dummy” `CREATE INDEX` operation, which checks for the presence of all hypothetical new index tuples against a temporary, in-memory summarizing structure (this is built when needed during the basic first phase of verification). The summarizing structure “fingerprints” every tuple found within the target index. The high level principle behind *heapallindexed* verification is that a new index that is equivalent to the existing, target index must only have entries that can be found in the existing structure.

The additional *heapallindexed* phase adds significant overhead: verification will typically take several times longer. However, there is no change to the relation-level locks acquired when *heapallindexed* verification is performed.

The summarizing structure is bound in size by `maintenance_work_mem`. In order to ensure that there is no more than a 2% probability of failure to detect an inconsistency for each heap tuple that should be represented in the index, approximately 2 bytes of memory are needed per tuple. As less memory is made available per tuple, the probability of missing an inconsistency slowly increases. This approach limits the overhead of verification significantly, while only slightly reducing the probability of detecting a problem, especially for installations where verification is treated as a routine maintenance task. Any single absent or malformed tuple has a new opportunity to be detected with each new verification attempt.

F.1.3. Using `amcheck` Effectively

`amcheck` can be effective at detecting various types of failure modes that [data checksums](#) will fail to catch. These include:

- Structural inconsistencies caused by incorrect operator class implementations.

This includes issues caused by the comparison rules of operating system collations changing. Comparisons of datums of a collatable type like `text` must be immutable (just as all comparisons used for B-Tree index scans must be immutable), which implies that operating system collation rules must never change. Though rare, updates to operating system collation rules can cause these issues. More commonly, an inconsistency in the collation order between a primary server and a standby server is implicated, possibly because the *major* operating system version in use is inconsistent. Such inconsistencies will generally only arise on standby servers, and so can generally only be detected on standby servers.

If a problem like this arises, it may not affect each individual index that is ordered using an affected collation, simply because *indexed* values might happen to have the same absolute ordering regardless of the behavioral inconsistency. See [Section 23.1](#) and [Section 23.2](#) for further details about how Postgres Pro uses operating system locales and collations.

- Structural inconsistencies between indexes and the heap relations that are indexed (when *heapallindexed* verification is performed).

There is no cross-checking of indexes against their heap relation during normal operation. Symptoms of heap corruption can be subtle.

- Corruption caused by hypothetical undiscovered bugs in the underlying Postgres Pro access method code, sort code, or transaction management code.

Automatic verification of the structural integrity of indexes plays a role in the general testing of new or proposed Postgres Pro features that could plausibly allow a logical inconsistency to be introduced. Verification of table structure and associated visibility and transaction status information plays a similar role. One obvious testing strategy is to call `amcheck` functions continuously when running the standard regression tests.

- File system or storage subsystem faults where checksums happen to simply not be enabled.

Note that `amcheck` examines a page as represented in some shared memory buffer at the time of verification if there is only a shared buffer hit when accessing the block. Consequently, `amcheck` does not necessarily examine data read from the file system at the time of verification. Note that when checksums are enabled, `amcheck` may raise an error due to a checksum failure when a corrupt block is read into a buffer.

- Corruption caused by faulty RAM, or the broader memory subsystem.

Postgres Pro does not protect against correctable memory errors and it is assumed you will operate using RAM that uses industry standard Error Correcting Codes (ECC) or better protection. However, ECC memory is typically only immune to single-bit errors, and should not be assumed to provide *absolute* protection against failures that result in memory corruption.

When *heapallindexed* verification is performed, there is generally a greatly increased chance of detecting single-bit errors, since strict binary equality is tested, and the indexed attributes within the heap are tested.

Structural corruption can happen due to faulty storage hardware, or relation files being overwritten or modified by unrelated software. This kind of corruption can also be detected with [data page checksums](#).

Relation pages which are correctly formatted, internally consistent, and correct relative to their own internal checksums may still contain logical corruption. As such, this kind of corruption cannot be detected with checksums. Examples include toasted values in

the main table which lack a corresponding entry in the toast table, and tuples in the main table with a Transaction ID that is older than the oldest valid Transaction ID in the database or cluster.

Multiple causes of logical corruption have been observed in production systems, including bugs in the PostgreSQL server software, faulty and ill-conceived backup and restore tools, and user error.

Corrupt relations are most concerning in live production environments, precisely the same environments where high risk activities are least welcome. For this reason, `verify_heapam` has been designed to diagnose corruption without undue risk. It cannot guard against all causes of backend crashes, as even executing the calling query could be unsafe on a badly corrupted system. Access to [catalog tables](#) is performed and could be problematic if the catalogs themselves are corrupted.

In general, `amcheck` can only prove the presence of corruption; it cannot prove its absence.

F.1.4. Repairing Corruption

No error concerning corruption raised by `amcheck` should ever be a false positive. `amcheck` raises errors in the event of conditions that, by definition, should never happen, and so careful analysis of `amcheck` errors is often required.

There is no general method of repairing problems that `amcheck` detects. An explanation for the root cause of an invariant violation should be sought. [pageinspect](#) may play a useful role in diagnosing corruption that `amcheck` detects. A `REINDEX` may not be effective in repairing corruption.

F.2. aqo — cost-based query optimization

The aqo module is a Postgres Pro Enterprise extension for cost-based query optimization. Using machine learning methods, more precisely, a modification of the k-NN algorithm, aqo improves cardinality estimation, which can optimize execution plans and, consequently, speed up query execution.

F.2.1. Description

The aqo module can collect statistics on all the executed queries, excluding the queries that access system relations. The collected statistics is classified by query class. If the queries differ in their constants only, they belong to the same class. For each query class, aqo stores the cardinality quality, planning time, execution time, and execution statistics for machine learning. Based on this data, aqo builds a new query plan and uses it for the next query of the same class. aqo test runs have shown significant performance improvements for complex queries.

aqo saves all the learning data (`aqo_data`), queries (`aqo_query_texts`), query settings (`aqo_queries`), and query execution statistics (`aqo_query_stat`) to files. When aqo starts, it loads this data to shared memory. You can access aqo data through functions and views.

When `aqo.advanced` is on, and aqo is run in the `intelligent` or `learn` mode, a unique hash value, which is computed from the query tree, is assigned to each query class to identify it and separate the collected statistics. If `aqo.advanced` is off, the statistics for all untracked query classes is stored in a common query class with hash 0.

Each query class has an associated separate space, called *feature space*, in which the statistics for this query class is collected. This feature space is identified by a hash value (`fs`), called a *basic hash*, which is the same for queries that only differ in table names, so the learning data is aggregated for such queries. Each feature space has associated *feature subspaces*, where the information about selectivity and cardinality for each query plan node is collected. Each subspace is also identified by a hash value (`fss`).

Query-specific optimization settings are stored in the `aqo_queries` view.

F.2.1.1. Limitations

aqo currently has the following limitations:

- Query optimization using the aqo module is not supported on standby.
- Query optimization with aqo does not work with queries that only have temporary objects.
- Query optimization with aqo does not work for queries that contain `IMMUTABLE` functions.
- aqo does not collect statistics on replicas because replicas are read-only. However, aqo may use query execution statistics from the primary if the replica is physical.
- `learn` and `intelligent` modes are not supposed to work for a whole cluster with queries having a dynamically generated structure because these modes store all query class IDs, which are different for all queries in such a workload. Dynamically generated constants are supported, however.

F.2.2. Installation and Setup

The aqo extension is included into Postgres Pro Enterprise. Once you have Postgres Pro Enterprise installed, complete the following steps to enable aqo:

1. Add aqo to the `shared_preload_libraries` parameter in the `postgresql.conf` file:

```
shared_preload_libraries = 'aqo'
```

The aqo library must be preloaded at the server startup, since adaptive query optimization needs to be enabled per cluster.

2. Create the aqo extension using the following query:

```
CREATE EXTENSION aqo;
```

Once the extension is created, you can start optimizing queries.

To disable aqo in the current database, run:

```
DROP EXTENSION aqo;
```

To disable aqo at the cluster level, run:

```
ALTER SYSTEM SET aqo.enable = off;
```

```
SELECT pg_reload_conf();
```

To remove all the aqo data including the collected statistics, call `aqo_reset()`: to remove the data from the current database, run:

```
SELECT aqo_reset();
```

to remove all the data from the aqo storage, run:

```
SELECT aqo_reset(NULL);
```

If you do not want aqo to be loaded at the server restart, remove the line

```
shared_preload_libraries = 'aqo'
```

from the `postgresql.conf` file.

Important

For smooth physical replication transferring aqo data from the primary to a replica, ensure that the same aqo versions are installed on both. You can have different aqo versions installed, but in this case, set `aqo.wal_rw` to `Off` on both and anticipate no replication.

F.2.2.1. Configuration

aqo behavior mainly depends on the `aqo.enable`, `aqo.mode` and `aqo.advanced` configuration parameters. Their default values allow you to start learning in the `aqo basic mode` once you just set `aqo.enable` to `on`.

To dynamically change any of these parameters, for example, `mode`, in your current session, run the following command:

```
SET aqo.mode = 'mode';
```

where *mode* is the name of the operation mode to use.

F.2.3. Usage

F.2.3.1. Using aqo in a Basic Mode

By default, `aqo.advanced` is off. This sets a recommended, basic, mode, where statistics is collected for plan nodes (identified by `fss`), and the collected machine learning data is used to correct the cardinality error for all queries whose plan contains a certain plan node. Once you set `aqo.enable` to `on`, aqo starts learning. Execute queries that you need to optimize several times until the plan is good enough and change `aqo.mode` to `frozen`. To apply the machine learning data at the level of the server instance, run the following command:

```
ALTER SYSTEM SET aqo.mode = frozen;
ALTER SYSTEM SET aqo.enable = on;
SELECT pg_reload_conf();
```

The machine learning data will be applied not only to the queries on which aqo learned, but to all the queries whose plan contains the nodes for which the statistics was collected. For the machine learning data not affect other queries, set `aqo.advanced` to `on` and collect statistics for individual queries. See [Section F.2.3.2](#) for details.

F.2.3.2. Choosing the Operation Mode for Advanced Query Optimization

If you often run queries of the same class, for example, your application limits the number of possible query classes, you can enable `aqo.advanced` and use the `intelligent` mode to improve planning for these queries. In this mode, aqo analyzes each query execution and stores statistics. Statistics on queries of different classes is stored separately. If performance is not improved after 50 iterations, the aqo extension falls back to the default query planner.

Note

You can view the current query plan using the standard Postgres Pro `EXPLAIN` command with the `ANALYZE` option. For details, see the [Section 14.1](#).

Since the `intelligent` mode tries to learn separately for different query classes, aqo may fail to provide performance improvements if queries in the workload are of multiple different classes or if the classes of the queries in the workload are constantly changing. For such workloads, reset the aqo extension to the `controlled` mode, or try to turn off `aqo.advanced`.

When `aqo.advanced` is on, in the `controlled` mode, aqo does not collect statistics for new query classes, so they will not be optimized, but for known query classes, aqo will continue collecting statistics and using optimized planning algorithms. So use the `controlled` mode only after aqo learned in the `learn` or `intelligent` mode.

After aqo has already learned, `controlled` is the mode recommended for production use. To make aqo run in this mode on your whole production cluster, run

```
ALTER SYSTEM SET aqo.mode = 'controlled';  
SELECT pg_reload_conf();
```

When `aqo.advanced` is on, the `learn` mode collects statistics from all the executed queries and updates the data for query classes. This mode is similar to the `intelligent` mode, except that it does not provide intelligent tuning. This mode is not recommended to be used permanently for a whole cluster because it tries aqo optimizations for every query class, even for those that do not need it, and this may lead to an unnecessary computational overhead and cause performance degradation.

Use the `learn` mode with `aqo.advanced` turned off to handle workloads with dynamically generated query structures. Overall performance improvement is not guaranteed. As this mode lacks intelligent tuning, the performance for some queries may even decrease, but this mode is good for a dynamic workload and consumes less memory than the `intelligent` mode.

When `aqo.advanced` is on, in the `auto` mode, aqo behaves like in the `learn` mode, but the `auto` mode prevents the memory overflow by implementing the least recently used (LRU) cache mechanism. This mechanism ensures that the [aqo.dsm_size_max](#) and the [aqo.fss_max_items](#) limits are not exceeded when incoming queries are saved. When the `aqo_query_texts_update` function is called in this mode, aqo does not save query texts and does not free the dynamic shared memory used.

For data that may change significantly between queries, enabling the `aqo.delta_rows` parameter may be useful. With this setting, aqo makes predictions based on the planner's row count estimates. For example, if data is deleted from a table, the planner estimates fewer rows than before. aqo can then use this updated information to predict a lower row count without requiring additional learning steps.

If you want to reduce the impact of aqo on query planning and execution, you can use it in the `frozen` mode. In this mode, aqo only reads the collected statistics, but does not collect any new data.

F.2.3.3. Fine-Tuning aqo

You must have superuser rights to access aqo views and configure advanced query settings.

You can view all the processed query classes and their corresponding hash values in the [aqo_query_texts](#) view:

```
SELECT * FROM aqo_query_texts;
```

To find out the class, that is, hash, of a query and aqo mode, enable [aqo.show_hash](#) (boolean) and [aqo.show_details](#) (boolean) environment variables and execute the query. The output will contain something like this:

```
...  
Planning Time: 23.538 ms  
...  
Execution Time: 249813.875 ms  
...  
Using aqo: true  
AQO mode: LEARN  
AQO advanced: OFF  
...  
Query hash: -2439501042637610315
```

Each query class has its own optimization settings. These settings are shown in the [aqo_queries](#) view:

```
SELECT * FROM aqo_queries;
```

You can manually change these settings to adjust the optimization for a particular query class. For example:

-- Add a new query class to the `aqo_queries` view:

```
SET aqo.enable='on';
SET aqo.advanced='on';
SET aqo.mode='intelligent';
SELECT * FROM a, b WHERE a.id=b.id;
SET aqo.mode='controlled';
```

-- Disable `auto_tuning`, enable both `learn_aqo` and `use_aqo`
-- for this query class:

```
SELECT count(*) FROM aqo_queries,
  LATERAL aqo_queries_update(fs, NULL, true, true, false)
WHERE fs = (SELECT fs FROM aqo_query_texts
WHERE query_text LIKE 'SELECT * FROM a, b WHERE a.id=b.id;');
```

-- Run `EXPLAIN ANALYZE` while the plan changes:

```
EXPLAIN ANALYZE SELECT * FROM a, b WHERE a.id=b.id;
EXPLAIN ANALYZE SELECT * FROM a, b WHERE a.id=b.id;
```

-- Disable learning to stop statistics collection
-- and use the optimized plan:

```
SELECT count(*) FROM aqo_queries,
  LATERAL aqo_queries_update(fs, NULL, false, true, false)
WHERE fs = (SELECT fs FROM aqo_query_texts
WHERE query_text LIKE 'SELECT * FROM a, b WHERE a.id=b.id;');
```

To stop intelligent tuning for a particular query class, disable the `auto_tuning` setting:

```
SELECT count(*) FROM aqo_queries,
  LATERAL aqo_queries_update(fs, NULL, NULL, NULL, false)
WHERE fs = 'hash';
```

where *hash* is the hash value for this query class. As a result, `aqo` disables automatic change of the `learn_aqo` and `use_aqo` settings.

To disable further learning for a particular query class, use the following command:

```
SELECT count(*) FROM aqo_queries,
  LATERAL aqo_queries_update(fs, NULL, false, NULL, false)
WHERE fs = 'hash';
```

where *hash* is the hash value for this query class.

To fully disable `aqo` for all queries and use the default Postgres Pro query planner, run:

```
SELECT count(*) FROM aqo_queries,
  LATERAL aqo_disable_class(fs, NULL)
WHERE fs <> 0;
```

To disable `aqo` for all queries temporarily in the current session or for the whole cluster, but not remove or change the collected statistics and settings, turn off [aqo.enable](#):

```
SET aqo.enable = 'off';
```

or

```
ALTER SYSTEM SET aqo.enable = 'off'
```

F.2.3.4. Sandbox Mode

You can experiment with aqo without touching its main knowledge base. To do this, execute the command

```
SET aqo.sandbox = ON;
```

This turns on the *sandbox mode*, which means that aqo will work in the isolated environment. However, if you turn on `aqo.sandbox` in different SQL sessions, they will use the same data.

Data obtained in the sandbox mode does not get replicated. But the sandbox mode can be used on a standby. Moreover, the only way to train aqo on a standby is turning on the sandbox mode when the replication is turned on, that is, `aqo.wal_rw` is true. Without the sandbox mode, aqo will work on the standby as if `aqo.mode = FROZEN`, that is, it will be able to use the existing knowledge base, but not update or extend it.

F.2.4. Reference

F.2.4.1. Configuration Parameters

`aqo.enable` (boolean)

Defines the state of aqo. If set to `off` aqo does not work except when `aqo.force_collect_stat = on`.

Default: `off`.

`aqo.mode` (text)

Sets the aqo operation mode. Defines how aqo handles new queries. Possible values:

- `intelligent` — saves new queries with `auto_tuning` enabled. See the description of the `aqo_queries` view for more details. May disable aqo for a query in the case of average performance reduction. Only works in this way if `aqo.advanced = on`, otherwise, this mode works exactly like `learn`.
- `learn` — collects statistics on all the executed queries, learns and makes predictions based on these statistics.
- `controlled` — only learns and makes predictions for known queries.
- `frozen` — makes predictions for known queries, but does not learn from any queries.
- `auto` — behaves like `learn` but prevents memory overflow by implementing the LRU cache mechanism.

Default: `learn`.

`aqo.advanced` (boolean)

Enables the advanced learning routine, which saves separate learning statistics for each query class. Also allows fine-tuning the `use_aqo` and `learn_aqo` settings in the `aqo_queries` view. Fine-tuned query settings in the `aqo_query` view continue to work if `aqo.advanced` is disabled.

Default: `off`.

`aqo.force_collect_stat` (boolean)

Collects statistics on query executions in all aqo modes and even if `aqo.enable` is `off`.

Default: `off`.

`aqo.show_details` (boolean)

Adds some details to `EXPLAIN` output of a query, such as the prediction or feature-subspace hash, and shows some additional aqo-specific on-screen information.

Default: `on`.

`aqo.show_hash` (boolean)

Shows a hash value that uniquely identifies the class of queries or class of plan nodes. aqo uses the native query ID to identify a query class for consistency with other extensions, such as `pg_stat_statements`. So, the query ID can be taken from the `Query hash` field in `EXPLAIN ANALYZE` output of a query.

Default: `on`.

`aqo.join_threshold` (integer)

Ignores queries that contain smaller number of joins, which means that statistics for such queries is not collected.

Default: 0 (no queries are ignored).

`aqo.learn_statement_timeout` (boolean)

Learns on a plan interrupted by the statement timeout.

Default: `off`.

`aqo.statement_timeout` (integer)

Defines the initial value of the *smart statement timeout*, in milliseconds, which is needed to limit the execution time when manually training aqo on special queries with a poor cardinality forecast. aqo can dynamically change the value of the smart statement timeout during this training. When the cardinality estimation error on nodes exceeds 0.1, the value of `aqo.statement_timeout` is automatically incremented exponentially, but remains not greater than `statement_timeout`.

Default: 0.

`aqo.wide_search` (boolean)

Enables searching neighbors with the same feature subspace among different query classes. Only has an effect if `aqo.advanced` = `on`.

Default: `off`.

`aqo.min_neighbors_for_predicting` (integer)

Defines how many samples collected in previous executions of the query will be used to predict the cardinality next time. If there are fewer of them, aqo will not make any prediction. A too large value may affect performance, but a too small value may reduce the prediction quality.

Default: 3.

`aqo.predict_with_few_neighbors` (boolean)

Enables aqo to make predictions with fewer neighbors than specified by `aqo.min_neighbors_for_predicting`. When set to `off`, then aqo learns, but does not make predictions until the execution count for the query with different constants reaches 3 (default for `aqo.min_neighbors_for_predicting`).

Default: `on`.

`aqo.fs_max_items` (integer)

Defines the maximum number of feature spaces that aqo can operate with. When this number is exceeded, learning on new query classes will no longer occur, and they will not appear in the views accordingly. This parameter can only be set at server start.

Default: 10000.

`aqo.fss_max_items` (integer)

Defines the maximum number of feature subspaces that aqo can operate with. When this number is exceeded, the selectivity and cardinality for new query plan nodes will no longer be collected, and new feature subspaces will not appear in the `aqo_data` view accordingly. This parameter can only be set at server start.

Default: 100000.

`aqo.querytext_max_size` (integer)

Defines the maximum size of the query in the `aqo_query_texts` view. This parameter can only be set at server start.

Default: 1000.

`aqo.dsm_size_max` (integer)

Defines the maximum size of dynamic shared memory, in MB, that aqo can allocate to store learning data and query texts. If set to a number that is less than the size of the saved aqo data, the server will not start. This parameter can only be set at server start.

Default: 100.

`aqo.wal_rw` (boolean)

Enables physical replication and allows complete aqo data recovery after failure. When set to `off` on the primary, no data is transferred from it to a replica. When set to `off` on a replica, any data transferred from the primary is ignored. With this value, when the server fails, data can only be restored as of the last checkpoint. This parameter can only be set at server start.

Default: on.

`aqo.sandbox` (boolean)

Enables reserving a separate memory area in shared memory to be used by a primary or standby node, which allows collecting and using statistics with the data in this memory area. If enabled on the primary, the extension uses the separate shared memory area that is not replicated to the standby. Changing the value of this parameter resets the aqo cache. Only superusers can change this setting.

Default: off.

`aqo.delta_rows` (boolean)

Enables a learning mechanism where aqo adjusts the planner's row count estimates with its own predictions. If disabled, aqo uses its own predictions.

Default: off.

F.2.4.2. Views

F.2.4.2.1. `aqo_query_texts`

The `aqo_query_texts` view classifies all the query classes processed by aqo. For each query class, the view shows the text of the first analyzed query of this class.

Table F.1. `aqo_query_texts` View

Column Name	Description
<code>queryid</code>	The unique identifier of the query.
<code>dbid</code>	The identifier of the database.
<code>fs</code>	The identifier of the feature space.
<code>query_text</code>	Text of the first analyzed query of the given class. The query text length is limited by aqo.querytext_max_size .

F.2.4.2.2. `aqo_queries`

The `aqo_queries` view shows optimization settings for different query classes. One query executed in two different databases is stored twice although the `fs` is the same.

Table F.2. `aqo_queries` View

Setting	Description
<code>fs</code>	The identifier of the feature space.
<code>dbid</code>	The identifier of the database in which the query was executed.
<code>learn_aqo</code>	Shows whether statistics collection for this query class is enabled.
<code>use_aqo</code>	Shows whether the aqo cardinality prediction for the next execution of this query class is enabled.

Setting	Description
<code>auto_tuning</code>	Shows whether aqo can dynamically change <code>use_aqo</code> and <code>learn_aqo</code> settings for this query class. By default, set to <code>true</code> for new queries if <code>aqo.advanced</code> is on and <code>aqo.mode = intelligent</code>. When <code>auto_tuning</code> is on, if for several successive executions of a query for which <code>use_aqo</code> is off, the cardinality error remains sufficiently small and stable, aqo turns on <code>use_aqo</code>. For queries with <code>learn_aqo=true</code> (it is so for new queries), several first executions are done both using aqo and without it. The faster the query is executed compared to the execution with the standard planner, the more likely aqo will be used for the next query execution. If after a certain number of executions the execution time with aqo appears to be worse than with the standard planner, aqo will never be used for this query class: <code>auto_tuning</code>, <code>use_aqo</code> and <code>learn_aqo</code> are set to <code>off</code>.
<code>smart_timeout</code>	The value of the smart statement timeout for this query class. The initial value of the smart statement timeout for any query is defined by the <code>statement_timeout</code> configuration parameter.
<code>count_increase_timeout</code>	Shows how many times the smart statement timeout increased for this query class.

F.2.4.2.3. `aqo_data`

The `aqo_data` view shows machine learning data for cardinality estimation refinement. The number of rows is limited by `aqo.fss_max_items`. To discard all the collected statistics for a particular query class, you can delete all rows from `aqo_data` with the corresponding `fs`.

Table F.3. `aqo_data` View

Data	Description
<code>fs</code>	The identifier (hash) of the feature space.
<code>fss</code>	The identifier (hash) of the feature subspace.
<code>dbid</code>	The identifier of the database.
<code>delta_rows</code>	If true, aqo makes predictions based on the planner's estimates, otherwise <code>false</code> .
<code>nfeatures</code>	Feature-subspace size for the query plan node.
<code>features</code>	Logarithm of the selectivity which the cardinality prediction is based on.
<code>targets</code>	Cardinality logarithm for the query plan node.
<code>reliability</code>	Confidence level of the learning statistics. Equals: • 1 (default) — indicates data obtained after normal execution of a query • 0.1 — indicates data obtained from a partially executed node (not needed as unreliable) • 0.9 — indicates data obtained from a finished node, but from a partially executed statement
<code>oids</code>	List of IDs of tables that were involved in the prediction for this node.
<code>tmpoids</code>	List of IDs of temporary tables that were involved in the prediction for this node.

F.2.4.2.4. `aqo_query_stat`

The `aqo_query_stat` view shows statistics on query execution, by query class. `aqo` uses this data when `auto_tuning` is enabled for a particular query class.

Table F.4. `aqo_query_stat` View

Data	Description
<code>fs</code>	The identifier of the feature space.
<code>dbid</code>	The identifier of the database.
<code>execution_time_with_aqo</code>	Array of execution times for queries run with <code>aqo</code> enabled.
<code>execution_time_without_aqo</code>	Array of execution times for queries run with <code>aqo</code> disabled.
<code>planning_time_with_aqo</code>	Array of planning times for queries run with <code>aqo</code> enabled.
<code>planning_time_without_aqo</code>	Array of planning times for queries run with <code>aqo</code> disabled.
<code>cardinality_error_with_aqo</code>	Array of cardinality estimation errors in the selected query plans with <code>aqo</code> enabled.
<code>cardinality_error_without_aqo</code>	Array of cardinality estimation errors in the selected query plans with <code>aqo</code> disabled.
<code>executions_with_aqo</code>	Number of queries run with <code>aqo</code> enabled.
<code>executions_without_aqo</code>	Number of queries run with <code>aqo</code> disabled.

F.2.4.3. Functions

`aqo` adds several functions to Postgres Pro catalog.

F.2.4.3.1. Storage Management Functions

Important

Functions `aqo_queries_update`, `aqo_query_texts_update`, `aqo_query_stat_update`, `aqo_data_update` and `aqo_data_delete` modify data files underlying `aqo` views. Therefore, call these functions only if you understand the logic of adaptive query optimization.

`aqo_cleanup()` → `setof integer`

Removes data related to query classes that are linked (may be partially) with removed relations. Returns the number of removed feature spaces (classes) and feature subspaces. Insensitive to removing other objects.

`aqo_enable_class(fs bigint, dbid oid)` → `void`

Sets `learn_aqo`, `use_aqo` and `auto_tuning` (only in the `intelligent` mode) to true for the query class with the specified `fs` and `dbid`. You can set `dbid` to NULL instead of the ID of the current database.

`aqo_disable_class(fs bigint, dbid oid)` → `void`

Sets `learn_aqo`, `use_aqo` and `auto_tuning` to false for the query class with the specified `fs` and `dbid`. You can set `dbid` to NULL instead of the ID of the current database.

`aqo_drop_class(fs bigint, dbid oid)` → `integer`

Removes all data related to the specified query class and database from the `aqo` storage. You can set `dbid` to NULL instead of the ID of the current database. Returns the number of records removed from the `aqo` storage.

`aqo_reset(dbid oid)` → `bigint`

Removes records from the specified database: machine learning data, query texts, statistics and query class preferences. If `dbid` is omitted, removes the data from the current database. If `dbid` is NULL, removes all records from the `aqo` storage. Returns the number of records removed.

`aqo_queries_update(fs bigint, dbid oid, learn_aqo boolean, use_aqo boolean, auto_tuning boolean)`
`→ boolean`

Updates or inserts a record in a data file underlying the [aqo_queries](#) view for the specified *fs* and *dbid*. You can set *dbid* to NULL instead of the ID of the current database. NULL values for parameters being set mean leave them as is. Note that records with a zero value of *fs* or *dbid* cannot be updated. Returns `false` in case of error, `true` otherwise.

`aqo_query_texts_update(fs bigint, dbid oid, query_text text) → boolean`

Updates or inserts a record in a data file underlying the [aqo_query_texts](#) view for the specified *fs* and *dbid*. You can set *dbid* to NULL instead of the ID of the current database. Note that records with a zero value of *fs* or *dbid* cannot be updated. Returns `false` in case of error, `true` otherwise.

`aqo_query_stat_update(fs bigint, dbid oid, execution_time_with_aqo double precision[], execution_time_without_aqo double precision[], planning_time_with_aqo double precision[], planning_time_without_aqo double precision[], cardinality_error_with_aqo double precision[], cardinality_error_without_aqo double precision[], executions_with_aqo bigint[], executions_without_aqo bigint[]) → boolean`

Updates or inserts a record in a data file underlying the [aqo_query_stat](#) view for the specified *fs* and *dbid*. You cannot update a record for a common feature space, i.e., for *fs* or *dbid* equal to zero. You can set *dbid* to NULL instead of the ID of the current database. Returns `false` in case of error, `true` otherwise.

`aqo_data_update(fs bigint, fss integer, dbid oid, delta_rows boolean, nfeatures integer, features double precision[][], targets double precision[], reliability double precision[], oids oid[], tmpoids oid[]) → boolean`

Updates or inserts a record in a data file underlying the [aqo_data](#) view for the specified *fs*, *fss* and *dbid*. You can set *dbid* to NULL instead of the ID of the current database. If you set *delta_rows* to NULL, the value of `aqo.delta_rows` is used. Returns `false` in case of error, `true` otherwise.

`aqo_data_delete(fs bigint, fss integer, dbid oid, delta_rows boolean) → boolean`

Removes a record from a data file underlying the [aqo_data](#) view for the specified *fs*, *fss* and *dbid*. You can set *dbid* to NULL instead of the ID of the current database. If you omit *delta_rows* or set it to NULL, the value of `aqo.delta_rows` is used. Returns `false` in case of error, `true` otherwise.

F.2.4.3.2. Memory Management Functions

`aqo_memory_usage() → setof record`

Shows allocated and used sizes of aqo memory contexts and hash tables. Returns a table:

`name`

Short description of the memory context or hash table

`allocated_size`

Total size of the allocated memory

`used_size`

Size of the currently used memory

F.2.4.3.3. Functions for Analytics

`aqo_cardinality_error(controlled boolean) → setof record`

Shows the cardinality error for the last execution of queries. If *controlled* is true, shows queries executed with aqo enabled. If *controlled* is false, shows queries that were executed with aqo disabled, but that have collected aqo statistics. Returns a table:

`num`

Sequential number

`dbid`

The identifier of the database

`fs`

The identifier of the feature space. Can be zero or the basic hash.

`error`

aqo error calculated on query plan nodes

`nexecs`

Number of executions of queries associated with this `fs`

`aqo_execution_time` (*controlled* boolean) → setof record

Shows the execution time for queries. If *controlled* is true, shows the execution time of the last execution with aqo enabled. If *controlled* is false, returns the average execution time for all logged executions with aqo disabled. Execution time without aqo can be collected when `aqo.mode = intelligent` or `aqo.force_collect_stat = on`. Returns a table:

`num`

Sequential number

`dbid`

The identifier of the database

`fs`

The identifier of the feature space. Can be zero or the basic hash.

`exec_time`

If *controlled* = true, last query execution time with aqo, otherwise, average execution time for all executions without aqo

`nexecs`

Number of executions of queries associated with this `fs`

F.2.5. Examples

Example F.1. Learning on a Query (Basic Mode)

Consider optimization of a query using aqo.

When the query is executed for the first time, it is missing in tables underlying aqo views. So there is no data for predicting with aqo for each plan node, and “AQO not used” lines appear in the EXPLAIN output:

```
demo=# EXPLAIN (ANALYZE, SUMMARY OFF, TIMING OFF)
SELECT bp.*
FROM ticket_flights tf
JOIN flights f ON f.flight_id = tf.flight_id
JOIN boarding_passes bp ON bp.ticket_no = tf.ticket_no AND bp.flight_id = tf.flight_id
WHERE f.scheduled_departure > '2017-08-15 15:00:00+00';
```

Query hash: 402936317627943257
JOINS: 2
(23 rows)

```

If there is no information on a certain node in the [aqo_data](#) view, aqo will add the appropriate record there for future learning and predictions except for nodes with fss=0 in the EXPLAIN output. As each of features and targets in the aqo_data view is a logarithm to base e, to get the actual value, raise e to this power. For example: exp(7.703007682479236):

```

demo=# select * from aqo_data;
 fs |          fss          | dbid | delta_rows | nfeatures |          features          |
-----+-----+-----+-----+-----+-----+-----
 0 | 1362775811343989307 | 16429 | f          |           | {14.454357295615447} | {1} |
 0 | -6410966714754547713 | 16429 | f          |           | {14.674314116080508} | {1} |
 0 | -1289471166524579716 | 16429 | f          |           | {9.701371368413994} | {1} |
 0 | 8598194613120045129 | 16429 | f          |           | {-13.492416828684513, -1.3775704575284085} | {1} |
 0 | -7651474063207585780 | 16429 | f          |           | {-11.092306109090387, -1.3775704575284085} | {1} |
(5 rows)

```

When the query is executed for the second time, aqo recognizes the query and makes a prediction. Pay attention to the cardinality predicted by aqo and the value of aqo error ("error=0%").

```

demo=# EXPLAIN (ANALYZE, SUMMARY OFF, TIMING OFF)
SELECT bp.*
FROM ticket_flights tf
JOIN flights f ON f.flight_id = tf.flight_id
JOIN boarding_passes bp ON bp.ticket_no = tf.ticket_no AND bp.flight_id = tf.flight_id
WHERE f.scheduled_departure > '2017-08-15 15:00:00+00';

```

```

However, instead of recalculating features and targets, aqo added new values of selectivity and cardinality for this query to aqo_data:

```

demo=# select * from aqo_data;
 fs |          fss          | dbid | delta_rows | nfeatures |          targets
      |          features      |      |            |           |
      | reliability |      |            | tmpoids
-----+-----+-----+-----+-----+-----
+-----+-----+-----+-----+-----+-----+
+-----+-----+-----+-----+-----+-----+
+-----+-----+-----+-----+-----+-----+
0 | 1362775811343989307 | 16429 | f          |           | 0 | {14.454357295615447}
      | {1}          | {16452} |           |           |
0 | -6410966714754547713 | 16429 | f          |           | 0 | {14.674314116080508}
      | {1}          | {16479} |           |           |
0 | -1289471166524579716 | 16429 | f          |           | 1 | {{-1.3775704575284085},
{-1.2287385463463019}}
{9.701371368413994, 9.854297308345357} | {1,1} | {16458} |
0 | 8598194613120045129 | 16429 | f          |           | 2 |
{{-13.492416828684513, -1.3775704575284085}, {-13.492416828684513, -1.2287385463463019}}
| {7.703007682479236, 11.620855676130656} | {1,1} | {16479,16458,16452} |
0 | -7651474063207585780 | 16429 | f          |           | 2 |
{{-11.092306109090387, -1.3775704575284085}, {-11.092306109090387, -1.2287385463463019}}
| {13.056768298305919, 13.266354624518149} | {1,1} | {16479,16458} |
(5 rows)

```

Now the prediction has a small error of about 3%, which can be explained by a calculation error:

```

demo=# EXPLAIN (ANALYZE, SUMMARY OFF, TIMING OFF)
SELECT bp.*
FROM ticket_flights tf
JOIN flights f ON f.flight_id = tf.flight_id
JOIN boarding_passes bp ON bp.ticket_no = tf.ticket_no AND bp.flight_id = tf.flight_id
WHERE f.scheduled_departure > '2017-08-10 15:00:00+00';

```

```

Example F.2. Using the `aqo_query_stat` View

The `aqo_query_stats` view shows statistics on the query planning time, query execution time and cardinality error. Based on this data you can make a decision whether to use aqo predictions for different query classes.

Let's query the `aqo_query_stats` view:

```

demo=# SELECT * FROM aqo_query_stat \gx
-[ RECORD 1 ]-----+-----
fs                  | 7809046947949890015
dbid                | 16429
execution_time_with_aqo | {1.039218233,0.925258453,0.831166925,0.779602353}
execution_time_without_aqo | {1.022052611,0.936486619}
planning_time_with_aqo | {0.003305339,0.002129048,0.002538877,0.002142972}
planning_time_without_aqo | {0.000767553,0.000711208}
cardinality_error_with_aqo | {0.4854215265638894,0,1.1711726076352047,0.007732205169478082}
cardinality_error_without_aqo | {0.4854215265638894,1.571562511977072}
executions_with_aqo | 4
executions_without_aqo | 2

```

The retrieved data is for the query from [Example F.1](#), which was executed once without aqo for each of the parameters `f.scheduled_departure > '2017-08-10 15:00:00+00'` and `f.scheduled_departure > '2017-08-15 15:00:00+00'` and twice with aqo for each of these parameters. It is clear that with aqo, the cardinality error decreases to 0.0077, while the minimum cardinality error without aqo is 0.4854. Besides, the execution time with aqo is lower than without it. So the conclusion is that aqo learns well on this query, and the prediction can be used for this query class.

Example F.3. Using aqo in the Advanced Mode

The advanced mode allows a more flexible control over aqo. When this mode is activated, that is,

```
demo=# SET aqo.advanced = on;
```

aqo will collect the machine learning data separately for each query executed. For example:

```

demo=# EXPLAIN (ANALYZE, SUMMARY OFF, TIMING OFF)
SELECT bp.*
FROM ticket_flights tf
JOIN flights f ON f.flight_id = tf.flight_id
JOIN boarding_passes bp ON bp.ticket_no = tf.ticket_no AND bp.flight_id = tf.flight_id
WHERE f.scheduled_departure > '2017-08-15 15:00:00+00';

```

QUERY PLAN

```

Hash Join (cost=63796.33..140286.73 rows=477728 width=25) (actual rows=2215 loops=1)
  AQO not used, fss=8598194613120045129

{16479, 16458, 16452} |
402936317627943257 | -7651474063207585780 | 16429 | f          | 2 |
{{-11.092306109090387, -1.3775704575284085}} | {13.056768298305919} | {1}   |
{16479, 16458} |

```

(5 rows)

We can make a few settings individually for this query. These are values of `learn_aqo`, `use_aqo` and `auto_tuning` in the `aqo_queries` view:

```
demo=# SELECT * FROM aqo_queries;
      fs      | dbid | learn_aqo | use_aqo | auto_tuning | smart_timeout |
count_increase_timeout
-----+-----+-----+-----+-----+-----+-----
402936317627943257 | 16429 | t         | t         | f           |              0 |
0
0 | 0 | f         | f         | f           |              0 |
0
```

(2 rows)

Let's set `use_aqo` to false:

```
demo=# SELECT aqo_queries_update(402936317627943257, NULL, NULL, false, NULL);
aqo_queries_update
```

t

(1 row)

Now we change a constant in the query:

```
demo=# EXPLAIN (ANALYZE, SUMMARY OFF, TIMING OFF)
SELECT bp.*
FROM ticket_flights tf
JOIN flights f ON f.flight_id = tf.flight_id
JOIN boarding_passes bp ON bp.ticket_no = tf.ticket_no AND bp.flight_id = tf.flight_id
WHERE f.scheduled_departure > '2017-08-10 15:00:00+00';
```

QUERY PLAN

```

    reliability, oids, tmpoids)
FROM aqo_data_sandbox WHERE fs = 0;
DROP TABLE aqo_data_sandbox;
```

F.2.6. Author

Oleg Ivanov

F.3. auth_delay — pause on authentication failure

`auth_delay` causes the server to pause briefly before reporting authentication failure, to make brute-force attacks on database passwords more difficult. Note that it does nothing to prevent denial-of-service attacks, and may even exacerbate them, since processes that are waiting before reporting authentication failure will still consume connection slots.

In order to function, this module must be loaded via [shared_preload_libraries](#) in `postgresql.conf`.

F.3.1. Configuration Parameters

`auth_delay.milliseconds` (integer)

The number of milliseconds to wait before reporting an authentication failure. The default is 0.

These parameters must be set in `postgresql.conf`. Typical usage might be:

```
# postgresql.conf
shared_preload_libraries = 'auth_delay'

auth_delay.milliseconds = '500'
```

F.3.2. Author

KaiGai Kohei <kaigai@ak.jp.nec.com>

F.4. auto_dump — get data and reproduce problematic queries

The `auto_dump` module is a Postgres Pro extension that is designed to collect data on long-running and problematic queries and to further reproduce these problems for troubleshooting.

To simplify reproducing problematic queries, this extension generates a dump file containing the following entities:

1. `CREATE TABLE` statements for both temporary and permanent tables referenced in the query.
2. `INSERT/COPY` statements to populate the tables with data available during the original problematic query execution.
3. The original problematic SQL query along with its execution plan, which can be generated by `EXPLAIN`, `EXPLAIN ANALYZE`, or both.

F.4.1. Installation and Configuration

The `auto_dump` extension is included into Postgres Pro Enterprise. Once you have Postgres Pro Enterprise installed, complete the following steps to enable `auto_dump`:

1. Add `auto_dump` to the [shared_preload_libraries](#) parameter in the `postgresql.conf` file:

```
shared_preload_libraries = 'auto_dump'
```

2. As `auto_dump` is disabled by default, enable it:

```
auto_dump.enable = on
```

Before using the extension, set other [required configuration parameters](#) and restart the database server for the changes to take effect.

F.4.2. Configuration Parameters

The `auto_dump` extension provides the following configuration parameters for managing automatic query dumping parameters.

F.4.2.1. General Configuration Parameters

`auto_dump.enable` (boolean)

Enables the extension. This parameter is disabled by default.

`auto_dump.output_directory` (string)

Specifies the file system path to the directory where table dump files are saved. This is a mandatory parameter. The operating system user the service run as must have read-write permissions for this directory.

F.4.2.2. Trigger Condition Control Parameters

The following configuration parameters control the conditions that trigger automatic query dumps.

`auto_dump.dump_on_query_string` (string)

Specifies a case-insensitive fragment of an SQL query. If this fragment appears anywhere in a query, the query is dumped. The default is an empty string (`' '`), which means that no query is dumped.

`auto_dump.dump_on_cancel` (boolean)

Controls whether a dump is triggered for queries that are canceled by the DBMS, for example, by the `pg_cancel_backend` function or due to a lock timeout.

Note that `auto_dump.dump_on_cancel` does not trigger dumps for sessions terminated due to [idle_in_transaction_session_timeout](#), [idle_session_timeout](#), or [transaction_timeout](#).

This parameter is disabled by default.

`auto_dump.dump_on_bad_plan` (boolean)

Analyzes the expected and actual row counts for all queries. It uses two thresholds to identify problematic queries: [auto_dump.bad_plan_count_threshold](#) and [auto_dump.bad_plan_percent_threshold](#). An automatic dump is triggered for a query only when the difference in row counts exceeds both thresholds simultaneously.

This parameter is disabled by default.

`auto_dump.bad_plan_count_threshold` (integer)

Defines a trigger condition for automatic dumps based on the absolute difference between the expected and actual row counts.

All nodes of the execution plan are analyzed. The condition is considered satisfied if the difference between the expected and actual row counts exceeds this parameter value.

If the value is set to 0, the condition is always considered satisfied. The default value is 1000000.

`auto_dump.bad_plan_percent_threshold` (integer)

Defines a trigger condition for automatic dumps based on the percentage difference between the expected and actual row counts. The possible value is an integer between 0 and 100 (default).

All nodes of the execution plan are analyzed. For each node, the percentage difference between expected and actual row counts is checked. The condition is considered satisfied if this difference exceeds this parameter value.

If this value is set to 0, the condition is always considered satisfied.

`auto_dump.dump_on_time` (boolean)

Saves a dump for a query if its execution time exceeds the [auto_dump.timeout](#) value. This parameter is disabled by default.

`auto_dump.timeout` (integer)

Specifies the timeout value for [auto_dump.dump_on_time](#) in milliseconds. Possible values are integers greater than or equal to 0 (default). If the value is set to 0, every query is dumped.

If multiple trigger condition control parameters are specified, they are processed in the following order:

1. `auto_dump.dump_on_cancel`
2. `auto_dump.dump_on_query_string`
3. `auto_dump.dump_on_bad_plan`
4. `auto_dump.dump_on_time`

F.4.2.3. Dump Content Control Parameters

The following configuration parameters control the scope and content of automatic dumps.

`auto_dump.dump_temporary_tables` (boolean)

Writes session temporary tables used by the current query to the dump. This parameter is disabled by default.

`auto_dump.dump_persistent_tables` (boolean)

Writes all persistent tables used by the current query to the dump. This parameter is disabled by default.

`auto_dump.dump_all_temp_tables` (boolean)

Writes all session temporary tables, including those used by the current query, to the dump. This parameter is disabled by default.

`auto_dump.dump_data` (boolean)

Writes the table content to the dump. When disabled, the SQL query only includes table creation commands without populating them with data. This parameter is disabled by default.

Enable this parameter together with [auto_dump.dump_temporary_tables](#) or [auto_dump.dump_persistent_tables](#) to create an SQL file with table contents.

`auto_dump.dump_indexes` (boolean)

Writes index creation commands for tables to the dump. This parameter is disabled by default.

`auto_dump.dump_copy_data` (boolean)

Specifies the method for dumping table data.

If enabled, dumps table data using the `COPY TO` command. As a result, a separate TXT file for each table is created, which is referenced by a `COPY . . . FROM` statement in the dump file.

If disabled, dumps table data as `INSERT` statements in the dump file containing all table values.

This parameter is disabled by default.

`auto_dump.dump_query` (boolean)

Writes the SQL query for which the dump is created to the dump. This parameter is disabled by default.

`auto_dump.dump_create` (boolean)

Writes SQL commands for creating the tables being dumped to the dump. This parameter is disabled by default.

`auto_dump.dump_plan` (boolean)

Writes the execution plan of the current SQL query to the dump. This parameter is disabled by default.

F.4.3. Limitations and Considerations

Use `auto_dump` with caution. This extension is designed as a debugging tool and cannot be used for continuous monitoring. Thus, it is not recommended to configure `auto_dump` to dump every query.

`auto_dump` operation can cause conflicts, particularly when dumping temporary tables or data. Consider the following possible issues:

- The `auto_dump` extension is incompatible with the `PREPARE TRANSACTION` command when working with temporary tables. A check for operations on temporary objects occurs earlier than the check for enabled prepared transactions, so an error occurs even if `max_prepared_transactions` is correctly configured.
- When `auto_dump.dump_all_temp_tables` is enabled, `auto_dump` cannot access temporary namespaces from autonomous transactions. A corresponding error message is raised in this case.
- The performance statistics can also be affected. When `auto_dump.dump_data` is enabled, the extension reads table data to generate dumps and thus artificially inflates the number of sequential scans, which leads to inaccurate statistics.

F.5. `auto_explain` — log execution plans of slow queries

The `auto_explain` module provides a means for logging execution plans of slow statements automatically, without having to run `EXPLAIN` by hand. This is especially helpful for tracking down un-optimized queries in large applications.

The module provides no SQL-accessible functions. To use it, simply load it into the server. You can load it into an individual session:

```
LOAD 'auto_explain';
```

(You must be superuser to do that.) More typical usage is to preload it into some or all sessions by including `auto_explain` in `session_preload_libraries` or `shared_preload_libraries` in `postgresql.conf`. Then you can track unexpectedly slow queries no matter when they happen. Of course there is a price in overhead for that.

F.5.1. Configuration Parameters

There are several configuration parameters that control the behavior of `auto_explain`. Note that the default behavior is to do nothing, so you must set at least `auto_explain.log_min_duration` if you want any results.

`auto_explain.log_min_duration`(integer)

`auto_explain.log_min_duration` is the minimum statement execution time, in milliseconds, that will cause the statement's plan to be logged. Setting this to 0 logs all plans. -1 (the default) disables logging of plans. For example, if you set it to 250ms then all statements that run 250ms or longer will be logged. Only superusers can change this setting.

`auto_explain.log_parameter_max_length`(integer)

`auto_explain.log_parameter_max_length` controls the logging of query parameter values. A value of -1 (the default) logs the parameter values in full. 0 disables logging of parameter values. A value greater than zero truncates each parameter value to that many bytes. Only superusers can change this setting.

`auto_explain.log_analyze`(boolean)

`auto_explain.log_analyze` causes `EXPLAIN ANALYZE` output, rather than just `EXPLAIN` output, to be printed when an execution plan is logged. This parameter is off by default. Only superusers can change this setting.

Note

When this parameter is on, per-plan-node timing occurs for all statements executed, whether or not they run long enough to actually get logged. This can have an extremely negative impact on performance. Turning off `auto_explain.log_timing` ameliorates the performance cost, at the price of obtaining less information.

`auto_explain.log_buffers`(boolean)

`auto_explain.log_buffers` controls whether buffer usage statistics are printed when an execution plan is logged; it's equivalent to the `BUFFERS` option of `EXPLAIN`. This parameter has no effect unless `auto_explain.log_analyze` is enabled. This parameter is off by default. Only superusers can change this setting.

`auto_explain.log_wal`(boolean)

`auto_explain.log_wal` controls whether WAL usage statistics are printed when an execution plan is logged; it's equivalent to the `WAL` option of `EXPLAIN`. This parameter has no effect unless `auto_explain.log_analyze` is enabled. This parameter is off by default. Only superusers can change this setting.

`auto_explain.log_timing`(boolean)

`auto_explain.log_timing` controls whether per-node timing information is printed when an execution plan is logged; it's equivalent to the `TIMING` option of `EXPLAIN`. The overhead of repeatedly reading the system clock can slow down queries significantly on some systems, so it may be useful to set this parameter to off when only actual row counts, and not exact times, are needed. This parameter has no effect unless `auto_explain.log_analyze` is enabled. This parameter is on by default. Only superusers can change this setting.

`auto_explain.log_triggers` (boolean)

`auto_explain.log_triggers` causes trigger execution statistics to be included when an execution plan is logged. This parameter has no effect unless `auto_explain.log_analyze` is enabled. This parameter is off by default. Only superusers can change this setting.

`auto_explain.log_verbose` (boolean)

`auto_explain.log_verbose` controls whether verbose details are printed when an execution plan is logged; it's equivalent to the `VERBOSE` option of `EXPLAIN`. This parameter is off by default. Only superusers can change this setting.

`auto_explain.log_settings` (boolean)

`auto_explain.log_settings` controls whether information about modified configuration options is printed when an execution plan is logged. Only options affecting query planning with value different from the built-in default value are included in the output. This parameter is off by default. Only superusers can change this setting.

`auto_explain.log_format` (enum)

`auto_explain.log_format` selects the `EXPLAIN` output format to be used. The allowed values are `text`, `xml`, `json`, and `yaml`. The default is `text`. Only superusers can change this setting.

`auto_explain.log_level` (enum)

`auto_explain.log_level` selects the log level at which `auto_explain` will log the query plan. Valid values are `DEBUG5`, `DEBUG4`, `DEBUG3`, `DEBUG2`, `DEBUG1`, `INFO`, `NOTICE`, `WARNING`, and `LOG`. The default is `LOG`. Only superusers can change this setting.

`auto_explain.log_nested_statements` (boolean)

`auto_explain.log_nested_statements` causes nested statements (statements executed inside a function) to be considered for logging. When it is off, only top-level query plans are logged. This parameter is off by default. Only superusers can change this setting.

`auto_explain.sample_rate` (real)

`auto_explain.sample_rate` causes `auto_explain` to only explain a fraction of the statements in each session. The default is 1, meaning explain all the queries. In case of nested statements, either all will be explained or none. Only superusers can change this setting.

In ordinary usage, these parameters are set in `postgresql.conf`, although superusers can alter them on-the-fly within their own sessions. Typical usage might be:

```
# postgresql.conf
session_preload_libraries = 'auto_explain'

auto_explain.log_min_duration = '3s'
```

F.5.2. Example

```
postgres=# LOAD 'auto_explain';
postgres=# SET auto_explain.log_min_duration = 0;
postgres=# SET auto_explain.log_analyze = true;
postgres=# SELECT count(*)
           FROM pg_class, pg_index
           WHERE oid = indrelid AND indisunique;
```

This might produce log output such as:

```
LOG:  duration: 0.196 ms plan:
      Query Text: SELECT count(*)
                  FROM pg_class, pg_index
                  WHERE oid = indrelid AND indisunique;
```

```
Aggregate (cost=16.79..16.80 rows=1 width=0) (actual time=3.626..3.627 rows=1
loops=1)
-> Hash Join (cost=4.17..16.55 rows=92 width=0) (actual time=3.349..3.594 rows=92
loops=1)
    Hash Cond: (pg_class.oid = pg_index.indrelid)
    -> Seq Scan on pg_class (cost=0.00..9.55 rows=255 width=4) (actual
time=0.016..0.140 rows=255 loops=1)
    -> Hash (cost=3.02..3.02 rows=92 width=4) (actual time=3.238..3.238 rows=92
loops=1)
        Buckets: 1024 Batches: 1 Memory Usage: 4kB
        -> Seq Scan on pg_index (cost=0.00..3.02 rows=92 width=4) (actual
time=0.008..3.187 rows=92 loops=1)
            Filter: indisunique
Planning Time: 0.548 ms
```

Note that Postgres Pro added a new field to the output to show planning time.

Postgres Professional, Moscow, Russia

F.6. `basebackup_to_shell` — example "shell" `pg_basebackup` module

`basebackup_to_shell` adds a custom `basebackup` target called `shell`. This makes it possible to run `pg_basebackup --target=shell` or, depending on how this module is configured, `pg_basebackup --target=shell:DETAIL_STRING`, and cause a server command chosen by the server administrator to be executed for each tar archive generated by the backup process. The command will receive the contents of the archive via standard input.

This module is primarily intended as an example of how to create a new backup targets via an extension module, but in some scenarios it may be useful for its own sake. In order to function, this module must be loaded via [shared_preload_libraries](#) or [local_preload_libraries](#).

F.6.1. Configuration Parameters

`basebackup_to_shell.command(string)`

The command which the server should execute for each archive generated by the backup process. If `%f` occurs in the command string, it will be replaced by the name of the archive (e.g. `base.tar`). If `%d` occurs in the command string, it will be replaced by the target detail provided by the user. A target detail is required if `%d` is used in the command string, and prohibited otherwise. For security reasons, it may contain only alphanumeric characters. If `%%` occurs in the command string, it will be replaced by a single `%`. If `%` occurs in the command string followed by any other character or at the end of the string, an error occurs.

`basebackup_to_shell.required_role(string)`

The role required in order to make use of the `shell` backup target. If this is not set, any replication user may make use of the `shell` backup target.

F.6.2. Author

Robert Haas <rhaas@postgresql.org>

F.7. `basic_archive` — an example WAL archive module

`basic_archive` is an example of an archive module. This module copies completed WAL segment files to the specified directory. This may not be especially useful, but it can serve as a starting point for developing your own archive module. For more information about archive modules, see [Chapter 52](#).

In order to function, this module must be loaded via [archive_library](#), and [archive_mode](#) must be enabled.

F.7.1. Configuration Parameters

`basic_archive.archive_directory` (string)

The directory where the server should copy WAL segment files. This directory must already exist. The default is an empty string, which effectively halts WAL archiving, but if [archive_mode](#) is enabled, the server will accumulate WAL segment files in the expectation that a value will soon be provided.

These parameters must be set in `postgresql.conf`. Typical usage might be:

```
# postgresql.conf
archive_mode = 'on'
archive_library = 'basic_archive'
basic_archive.archive_directory = '/path/to/archive/directory'
```

F.7.2. Notes

Server crashes may leave temporary files with the prefix `archtemp` in the archive directory. It is recommended to delete such files before restarting the server after a crash. It is safe to remove such files while the server is running as long as they are unrelated to any archiving still in progress, but users should use extra caution when doing so.

Nathan Bossart

F.8. biha — built-in high-availability cluster

biha is a Postgres Pro extension that allows managing a BiHA cluster — a cluster with physical replication and built-in failover, high availability, and automatic node failure recovery. For more information about the BiHA solution and using the biha extension, see [Built-in High Availability \(BiHA\)](#).

F.9. bloom — bloom filter index access method

`bloom` provides an index access method based on *Bloom filters*.

A Bloom filter is a space-efficient data structure that is used to test whether an element is a member of a set. In the case of an index access method, it allows fast exclusion of non-matching tuples via signatures whose size is determined at index creation.

A signature is a lossy representation of the indexed attribute(s), and as such is prone to reporting false positives; that is, it may be reported that an element is in the set, when it is not. So index search results must always be rechecked using the actual attribute values from the heap entry. Larger signatures reduce the odds of a false positive and thus reduce the number of useless heap visits, but of course also make the index larger and hence slower to scan.

This type of index is most useful when a table has many attributes and queries test arbitrary combinations of them. A traditional btree index is faster than a bloom index, but it can require many btree indexes to support all possible queries where one needs only a single bloom index. Note however that bloom indexes only support equality queries, whereas btree indexes can also perform inequality and range searches.

F.9.1. Parameters

A `bloom` index accepts the following parameters in its `WITH` clause:

`length`

Length of each signature (index entry) in bits. It is rounded up to the nearest multiple of 16. The default is 80 bits and the maximum is 4096.

`col1 – col32`

Number of bits generated for each index column. Each parameter's name refers to the number of the index column that it controls. The default is 2 bits and the maximum is 4095. Parameters for index columns not actually used are ignored.

F.9.2. Examples

This is an example of creating a bloom index:

```
CREATE INDEX bloomidx ON tbloom USING bloom (i1,i2,i3)
  WITH (length=80, col1=2, col2=2, col3=4);
```

The index is created with a signature length of 80 bits, with attributes `i1` and `i2` mapped to 2 bits, and attribute `i3` mapped to 4 bits. We could have omitted the `length`, `col1`, and `col2` specifications since those have the default values.

Here is a more complete example of bloom index definition and usage, as well as a comparison with equivalent btree indexes. The bloom index is considerably smaller than the btree index, and can perform better.

```
=# CREATE TABLE tbloom AS
SELECT
  (random() * 1000000)::int as i1,
  (random() * 1000000)::int as i2,
  (random() * 1000000)::int as i3,
  (random() * 1000000)::int as i4,
  (random() * 1000000)::int as i5,
  (random() * 1000000)::int as i6
FROM
  generate_series(1,10000000);
SELECT 10000000
```

A sequential scan over this large table takes a long time:

```
=# EXPLAIN ANALYZE SELECT * FROM tbloom WHERE i2 = 898732 AND i5 = 123451;
      QUERY PLAN
```

```
-----
-----
```

```
Seq Scan on tbloom (cost=0.00..213744.00 rows=250 width=24) (actual
time=357.059..357.059 rows=0 loops=1)
  Filter: ((i2 = 898732) AND (i5 = 123451))
  Rows Removed by Filter: 10000000
Planning Time: 0.346 ms
Execution Time: 357.076 ms
(5 rows)
```

Even with the btree index defined the result will still be a sequential scan:

```
=# CREATE INDEX btreeidx ON tbloom (i1, i2, i3, i4, i5, i6);
CREATE INDEX
=# SELECT pg_size_pretty(pg_relation_size('btreeidx'));
pg_size_pretty
-----
386 MB
(1 row)
=# EXPLAIN ANALYZE SELECT * FROM tbloom WHERE i2 = 898732 AND i5 = 123451;
               QUERY PLAN
-----
Seq Scan on tbloom (cost=0.00..213744.00 rows=2 width=24) (actual
time=351.016..351.017 rows=0 loops=1)
  Filter: ((i2 = 898732) AND (i5 = 123451))
  Rows Removed by Filter: 10000000
Planning Time: 0.138 ms
Execution Time: 351.035 ms
(5 rows)
```

Having the bloom index defined on the table is better than btree in handling this type of search:

```
=# CREATE INDEX bloomidx ON tbloom USING bloom (i1, i2, i3, i4, i5, i6);
CREATE INDEX
=# SELECT pg_size_pretty(pg_relation_size('bloomidx'));
pg_size_pretty
-----
153 MB
(1 row)
=# EXPLAIN ANALYZE SELECT * FROM tbloom WHERE i2 = 898732 AND i5 = 123451;
               QUERY PLAN
-----
Bitmap Heap Scan on tbloom (cost=1792.00..1799.69 rows=2 width=24) (actual
time=22.605..22.606 rows=0 loops=1)
  Recheck Cond: ((i2 = 898732) AND (i5 = 123451))
  Rows Removed by Index Recheck: 2300
  Heap Blocks: exact=2256
-> Bitmap Index Scan on bloomidx (cost=0.00..178436.00 rows=1 width=0) (actual
time=20.005..20.005 rows=2300 loops=1)
  Index Cond: ((i2 = 898732) AND (i5 = 123451))
Planning Time: 0.099 ms
Execution Time: 22.632 ms
(8 rows)
```

Now, the main problem with the btree search is that btree is inefficient when the search conditions do not constrain the leading index column(s). A better strategy for btree is to create a separate index on each column. Then the planner will choose something like this:

```
=# CREATE INDEX btreeidx1 ON tbloom (i1);
CREATE INDEX
=# CREATE INDEX btreeidx2 ON tbloom (i2);
```

```
CREATE INDEX
=# CREATE INDEX btreeidx3 ON tbloom (i3);
CREATE INDEX
=# CREATE INDEX btreeidx4 ON tbloom (i4);
CREATE INDEX
=# CREATE INDEX btreeidx5 ON tbloom (i5);
CREATE INDEX
=# CREATE INDEX btreeidx6 ON tbloom (i6);
CREATE INDEX
=# EXPLAIN ANALYZE SELECT * FROM tbloom WHERE i2 = 898732 AND i5 = 123451;
                                QUERY PLAN
-----
Bitmap Heap Scan on tbloom  (cost=9.29..13.30 rows=1 width=24) (actual
time=0.032..0.033 rows=0 loops=1)
  Recheck Cond: ((i5 = 123451) AND (i2 = 898732))
    -> BitmapAnd  (cost=9.29..9.29 rows=1 width=0) (actual time=0.047..0.047 rows=0
loops=1)
      -> Bitmap Index Scan on btreeidx5  (cost=0.00..4.52 rows=11 width=0) (actual
time=0.026..0.026 rows=7 loops=1)
        Index Cond: (i5 = 123451)
      -> Bitmap Index Scan on btreeidx2  (cost=0.00..4.52 rows=11 width=0) (actual
time=0.007..0.007 rows=8 loops=1)
        Index Cond: (i2 = 898732)
Planning Time: 0.264 ms
Execution Time: 0.047 ms
(9 rows)
```

Although this query runs much faster than with either of the single indexes, we pay a penalty in index size. Each of the single-column btree indexes occupies 88.5 MB, so the total space needed is 531 MB, over three times the space used by the bloom index.

F.9.3. Operator Class Interface

An operator class for bloom indexes requires only a hash function for the indexed data type and an equality operator for searching. This example shows the operator class definition for the `text` data type:

```
CREATE OPERATOR CLASS text_ops
DEFAULT FOR TYPE text USING bloom AS
    OPERATOR      1      =(text, text),
    FUNCTION      1      hashtext(text);
```

F.9.4. Limitations

- Only operator classes for `int4` and `text` are included with the module.
- Only the `=` operator is supported for search. But it is possible to add support for arrays with union and intersection operations in the future.
- `bloom` access method doesn't support `UNIQUE` indexes.
- `bloom` access method doesn't support searching for `NULL` values.

Oleg Bartunov <obartunov@postgrespro.ru>, Postgres Professional, Moscow, Russia

F.10. btree_gin — GIN operator classes with B-tree behavior

`btree_gin` provides GIN operator classes that implement B-tree equivalent behavior for the data types `int2`, `int4`, `int8`, `float4`, `float8`, `timestamp with time zone`, `timestamp without time zone`, `time with time zone`, `time without time zone`, `date`, `interval`, `oid`, `money`, `"char"`, `varchar`, `text`, `bytea`, `bit`, `varbit`, `macaddr`, `macaddr8`, `inet`, `cidr`, `uuid`, `name`, `bool`, `bpchar`, and all enum types.

In general, these operator classes will not outperform the equivalent standard B-tree index methods, and they lack one major feature of the standard B-tree code: the ability to enforce uniqueness. However, they are useful for GIN testing and as a base for developing other GIN operator classes. Also, for queries that test both a GIN-indexable column and a B-tree-indexable column, it might be more efficient to create a multicolumn GIN index that uses one of these operator classes than to create two separate indexes that would have to be combined via bitmap ANDing.

This module is considered “trusted”, that is, it can be installed by non-superusers who have `CREATE` privilege on the current database.

F.10.1. Example Usage

```
CREATE TABLE test (a int4);
-- create index
CREATE INDEX testidx ON test USING GIN (a);
-- query
SELECT * FROM test WHERE a < 10;
```

F.10.2. Authors

Teodor Sigaev (<teodor@stack.net>) and Oleg Bartunov (<oleg@sai.msu.su>). See <http://www.sai.msu.su/~megeera/oddmuse/index.cgi/Gin> for additional information.

F.11. btree_gist — GiST operator classes with B-tree behavior

`btree_gist` provides GiST index operator classes that implement B-tree equivalent behavior for the data types `int2`, `int4`, `int8`, `float4`, `float8`, `numeric`, `timestamp with time zone`, `timestamp without time zone`, `time with time zone`, `time without time zone`, `date`, `interval`, `oid`, `money`, `char`, `varchar`, `text`, `bytea`, `bit`, `varbit`, `macaddr`, `macaddr8`, `inet`, `cidr`, `uuid`, `bool` and all enum types.

In general, these operator classes will not outperform the equivalent standard B-tree index methods, and they lack one major feature of the standard B-tree code: the ability to enforce uniqueness. However, they provide some other features that are not available with a B-tree index, as described below. Also, these operator classes are useful when a multicolumn GiST index is needed, wherein some of the columns are of data types that are only indexable with GiST but other columns are just simple data types. Lastly, these operator classes are useful for GiST testing and as a base for developing other GiST operator classes.

In addition to the typical B-tree search operators, `btree_gist` also provides index support for `<>` (“not equals”). This may be useful in combination with an [exclusion constraint](#), as described below.

Also, for data types for which there is a natural distance metric, `btree_gist` defines a distance operator `<->`, and provides GiST index support for nearest-neighbor searches using this operator. Distance operators are provided for `int2`, `int4`, `int8`, `float4`, `float8`, `timestamp with time zone`, `timestamp without time zone`, `time without time zone`, `date`, `interval`, `oid`, and `money`.

This module is considered “trusted”, that is, it can be installed by non-superusers who have `CREATE` privilege on the current database.

F.11.1. Example Usage

Simple example using `btree_gist` instead of `btree`:

```
CREATE TABLE test (a int4);
-- create index
CREATE INDEX testidx ON test USING GIST (a);
-- query
SELECT * FROM test WHERE a < 10;
-- nearest-neighbor search: find the ten entries closest to "42"
SELECT *, a <-> 42 AS dist FROM test ORDER BY a <-> 42 LIMIT 10;
```

Use an [exclusion constraint](#) to enforce the rule that a cage at a zoo can contain only one kind of animal:

```
=> CREATE TABLE zoo (
    cage    INTEGER,
    animal  TEXT,
    EXCLUDE USING GIST (cage WITH =, animal WITH <>)
);

=> INSERT INTO zoo VALUES(123, 'zebra');
INSERT 0 1
=> INSERT INTO zoo VALUES(123, 'zebra');
INSERT 0 1
=> INSERT INTO zoo VALUES(123, 'lion');
ERROR:  conflicting key value violates exclusion constraint "zoo_cage_animal_excl"
DETAIL:  Key (cage, animal)=(123, lion) conflicts with existing key (cage,
        animal)=(123, zebra).
=> INSERT INTO zoo VALUES(124, 'lion');
INSERT 0 1
```

F.11.2. Upgrade notes for version 1.6

In version 1.6 `btree_gist` switched to using in-core distance operators, and its own implementations were removed. References to these operators in `btree_gist` opclasses will be updated automatically during the extension upgrade, but if the user has created objects referencing these operators or functions, then these objects must be dropped manually before updating the extension.

F.11.3. Authors

Teodor Sigaev (<teodor@stack.net>), Oleg Bartunov (<oleg@sai.msu.su>), Janko Richter (<jankorichter@yahoo.de>), and Paul Jungwirth (<pj@illuminatedcomputing.com>). See <http://www.sai.msu.su/~megeera/postgres/gist/> for additional information.

F.12. citext — a case-insensitive character string type

The `citext` module provides a case-insensitive character string type, `citext`. Essentially, it internally calls `lower` when comparing values. Otherwise, it behaves almost exactly like `text`.

Tip

Consider using *nondeterministic collations* (see [Section 23.2.2.4](#)) instead of this module. They can be used for case-insensitive comparisons, accent-insensitive comparisons, and other combinations, and they handle more Unicode special cases correctly.

This module is considered “trusted”, that is, it can be installed by non-superusers who have `CREATE` privilege on the current database.

F.12.1. Rationale

The standard approach to doing case-insensitive matches in Postgres Pro has been to use the `lower` function when comparing values, for example

```
SELECT * FROM tab WHERE lower(col) = LOWER(?);
```

This works reasonably well, but has a number of drawbacks:

- It makes your SQL statements verbose, and you always have to remember to use `lower` on both the column and the query value.
- It won't use an index, unless you create a functional index using `lower`.
- If you declare a column as `UNIQUE` or `PRIMARY KEY`, the implicitly generated index is case-sensitive. So it's useless for case-insensitive searches, and it won't enforce uniqueness case-insensitively.

The `citext` data type allows you to eliminate calls to `lower` in SQL queries, and allows a primary key to be case-insensitive. `citext` is locale-aware, just like `text`, which means that the matching of upper case and lower case characters is dependent on the rules of the database's `LC_CTYPE` setting. Again, this behavior is identical to the use of `lower` in queries. But because it's done transparently by the data type, you don't have to remember to do anything special in your queries.

F.12.2. How to Use It

Here's a simple example of usage:

```
CREATE TABLE users (  
    nick CITEXT PRIMARY KEY,  
    pass TEXT NOT NULL  
);  
  
INSERT INTO users VALUES ( 'larry', sha256(random()::text::bytea) );  
INSERT INTO users VALUES ( 'Tom', sha256(random()::text::bytea) );  
INSERT INTO users VALUES ( 'Damian', sha256(random()::text::bytea) );  
INSERT INTO users VALUES ( 'NEAL', sha256(random()::text::bytea) );  
INSERT INTO users VALUES ( 'Bjørn', sha256(random()::text::bytea) );  
  
SELECT * FROM users WHERE nick = 'Larry';
```

The `SELECT` statement will return one tuple, even though the `nick` column was set to `larry` and the query was for `Larry`.

F.12.3. String Comparison Behavior

`citext` performs comparisons by converting each string to lower case (as though `lower` were called) and then comparing the results normally. Thus, for example, two strings are considered equal if `lower` would produce identical results for them.

In order to emulate a case-insensitive collation as closely as possible, there are `citext`-specific versions of a number of string-processing operators and functions. So, for example, the regular expression operators `~` and `~*` exhibit the same behavior when

applied to `citext`: they both match case-insensitively. The same is true for `!~` and `!~*`, as well as for the `LIKE` operators `~~` and `~~*`, and `!~~` and `!~~*`. If you'd like to match case-sensitively, you can cast the operator's arguments to `text`.

Similarly, all of the following functions perform matching case-insensitively if their arguments are `citext`:

- `regexp_match()`
- `regexp_matches()`
- `regexp_replace()`
- `regexp_split_to_array()`
- `regexp_split_to_table()`
- `replace()`
- `split_part()`
- `strpos()`
- `translate()`

For the `regexp` functions, if you want to match case-sensitively, you can specify the “`c`” flag to force a case-sensitive match. Otherwise, you must cast to `text` before using one of these functions if you want case-sensitive behavior.

F.12.4. Limitations

- `citext`'s case-folding behavior depends on the `LC_CTYPE` setting of your database. How it compares values is therefore determined when the database is created. It is not truly case-insensitive in the terms defined by the Unicode standard. Effectively, what this means is that, as long as you're happy with your collation, you should be happy with `citext`'s comparisons. But if you have data in different languages stored in your database, users of one language may find their query results are not as expected if the collation is for another language.
- As of PostgreSQL 9.1, you can attach a `COLLATE` specification to `citext` columns or data values. Currently, `citext` operators will honor a non-default `COLLATE` specification while comparing case-folded strings, but the initial folding to lower case is always done according to the database's `LC_CTYPE` setting (that is, as though `COLLATE "default"` were given). This may be changed in a future release so that both steps follow the input `COLLATE` specification.
- `citext` is not as efficient as `text` because the operator functions and the B-tree comparison functions must make copies of the data and convert it to lower case for comparisons. Also, only `text` can support B-Tree deduplication. However, `citext` is slightly more efficient than using `lower` to get case-insensitive matching.
- `citext` doesn't help much if you need data to compare case-sensitively in some contexts and case-insensitively in other contexts. The standard answer is to use the `text` type and manually use the `lower` function when you need to compare case-insensitively; this works all right if case-insensitive comparison is needed only infrequently. If you need case-insensitive behavior most of the time and case-sensitive infrequently, consider storing the data as `citext` and explicitly casting the column to `text` when you want case-sensitive comparison. In either situation, you will need two indexes if you want both types of searches to be fast.
- The schema containing the `citext` operators must be in the current `search_path` (typically `public`); if it is not, the normal case-sensitive `text` operators will be invoked instead.
- The approach of lower-casing strings for comparison does not handle some Unicode special cases correctly, for example when one upper-case letter has two lower-case letter equivalents. Unicode distinguishes between *case mapping* and *case folding* for this reason. Use nondeterministic collations instead of `citext` to handle that correctly.

F.12.5. Author

David E. Wheeler <david@kineticcode.com>

Inspired by the original `citext` module by Donald Fraser.

F.13. cube — a multi-dimensional cube data type

This module implements a data type `cube` for representing multidimensional cubes.

This module is considered “trusted”, that is, it can be installed by non-superusers who have `CREATE` privilege on the current database.

F.13.1. Syntax

Table F.5 shows the valid external representations for the `cube` type. x , y , etc. denote floating-point numbers.

Table F.5. Cube External Representations

External Syntax	Meaning
x	A one-dimensional point (or, zero-length one-dimensional interval)
(x)	Same as above
$x_1, x_2, \dots, x_n$	A point in n -dimensional space, represented internally as a zero-volume cube
$(x_1, x_2, \dots, x_n)$	Same as above
$(x), (y)$	A one-dimensional interval starting at x and ending at y or vice versa; the order does not matter
$[(x), (y)]$	Same as above
$(x_1, \dots, x_n), (y_1, \dots, y_n)$	An n -dimensional cube represented by a pair of its diagonally opposite corners
$[(x_1, \dots, x_n), (y_1, \dots, y_n)]$	Same as above

It does not matter which order the opposite corners of a cube are entered in. The `cube` functions automatically swap values if needed to create a uniform “lower left — upper right” internal representation. When the corners coincide, `cube` stores only one corner along with an “is point” flag to avoid wasting space.

White space is ignored on input, so $[(x), (y)]$ is the same as $[(x), (y)]$.

F.13.2. Precision

Values are stored internally as 64-bit floating point numbers. This means that numbers with more than about 16 significant digits will be truncated.

F.13.3. Usage

Table F.6 shows the specialized operators provided for type `cube`.

Table F.6. Cube Operators

Operator	Description
<code>cube && cube</code>	<code>boolean</code> Do the cubes overlap?
<code>cube @> cube</code>	<code>boolean</code> Does the first cube contain the second?
<code>cube <@ cube</code>	<code>boolean</code> Is the first cube contained in the second?
<code>cube -> integer</code>	<code>float8</code> Extracts the n -th coordinate of the cube (counting from 1).
<code>cube ~> integer</code>	<code>float8</code>

Operator	Description
	Extracts the n -th coordinate of the cube, counting in the following way: $n = 2 * k - 1$ means lower bound of k -th dimension, $n = 2 * k$ means upper bound of k -th dimension. Negative n denotes the inverse value of the corresponding positive coordinate. This operator is designed for KNN-GiST support.
<code>cube <-> cube → float8</code>	Computes the Euclidean distance between the two cubes.
<code>cube <#> cube → float8</code>	Computes the taxicab (L-1 metric) distance between the two cubes.
<code>cube <=> cube → float8</code>	Computes the Chebyshev (L-inf metric) distance between the two cubes.

In addition to the above operators, the usual comparison operators shown in [Table 9.1](#) are available for type `cube`. These operators first compare the first coordinates, and if those are equal, compare the second coordinates, etc. They exist mainly to support the b-tree index operator class for `cube`, which can be useful for example if you would like a `UNIQUE` constraint on a `cube` column. Otherwise, this ordering is not of much practical use.

The `cube` module also provides a GiST index operator class for `cube` values. A `cube` GiST index can be used to search for values using the `=`, `&&`, `@>`, and `<@` operators in `WHERE` clauses.

In addition, a `cube` GiST index can be used to find nearest neighbors using the metric operators `<->`, `<#>`, and `<=>` in `ORDER BY` clauses. For example, the nearest neighbor of the 3-D point (0.5, 0.5, 0.5) could be found efficiently with:

```
SELECT c FROM test ORDER BY c <-> cube(array[0.5,0.5,0.5]) LIMIT 1;
```

The `~>` operator can also be used in this way to efficiently retrieve the first few values sorted by a selected coordinate. For example, to get the first few cubes ordered by the first coordinate (lower left corner) ascending one could use the following query:

```
SELECT c FROM test ORDER BY c ~> 1 LIMIT 5;
```

And to get 2-D cubes ordered by the first coordinate of the upper right corner descending:

```
SELECT c FROM test ORDER BY c ~> 3 DESC LIMIT 5;
```

[Table F.7](#) shows the available functions.

Table F.7. Cube Functions

Function	Description	Example(s)
<code>cube (float8) → cube</code>	Makes a one dimensional cube with both coordinates the same.	<code>cube(1) → (1)</code>
<code>cube (float8, float8) → cube</code>	Makes a one dimensional cube.	<code>cube(1, 2) → (1), (2)</code>
<code>cube (float8[]) → cube</code>	Makes a zero-volume cube using the coordinates defined by the array.	<code>cube(ARRAY[1,2,3]) → (1, 2, 3)</code>
<code>cube (float8[], float8[]) → cube</code>	Makes a cube with upper right and lower left coordinates as defined by the two arrays, which must be of the same length.	<code>cube(ARRAY[1,2], ARRAY[3,4]) → (1, 2), (3, 4)</code>
<code>cube (cube, float8) → cube</code>		

Function	Description Example(s)
	Makes a new cube by adding a dimension on to an existing cube, with the same values for both endpoints of the new coordinate. This is useful for building cubes piece by piece from calculated values. <code>cube(' (1,2), (3,4)'::cube, 5) → (1, 2, 5), (3, 4, 5)</code>
<code>cube(cube, float8, float8) → cube</code>	Makes a new cube by adding a dimension on to an existing cube. This is useful for building cubes piece by piece from calculated values. <code>cube(' (1,2), (3,4)'::cube, 5, 6) → (1, 2, 5), (3, 4, 6)</code>
<code>cube_dim(cube) → integer</code>	Returns the number of dimensions of the cube. <code>cube_dim(' (1,2), (3,4)') → 2</code>
<code>cube_ll_coord(cube, integer) → float8</code>	Returns the n -th coordinate value for the lower left corner of the cube. <code>cube_ll_coord(' (1,2), (3,4)', 2) → 2</code>
<code>cube_ur_coord(cube, integer) → float8</code>	Returns the n -th coordinate value for the upper right corner of the cube. <code>cube_ur_coord(' (1,2), (3,4)', 2) → 4</code>
<code>cube_is_point(cube) → boolean</code>	Returns true if the cube is a point, that is, the two defining corners are the same. <code>cube_is_point(cube(1,1)) → t</code>
<code>cube_distance(cube, cube) → float8</code>	Returns the distance between two cubes. If both cubes are points, this is the normal distance function. <code>cube_distance(' (1,2)', ' (3,4)') → 2.8284271247461903</code>
<code>cube_subset(cube, integer[]) → cube</code>	Makes a new cube from an existing cube, using a list of dimension indexes from an array. Can be used to extract the endpoints of a single dimension, or to drop dimensions, or to reorder them as desired. <code>cube_subset(cube(' (1,3,5), (6,7,8)'), ARRAY[2]) → (3), (7)</code> <code>cube_subset(cube(' (1,3,5), (6,7,8)'), ARRAY[3,2,1,1]) → (5, 3, 1, 1), (8, 7, 6, 6)</code>
<code>cube_union(cube, cube) → cube</code>	Produces the union of two cubes. <code>cube_union(' (1,2)', ' (3,4)') → (1, 2), (3, 4)</code>
<code>cube_inter(cube, cube) → cube</code>	Produces the intersection of two cubes. <code>cube_inter(' (1,2)', ' (3,4)') → (3, 4), (1, 2)</code>
<code>cube_enlarge(c cube, r double, n integer) → cube</code>	Increases the size of the cube by the specified radius r in at least n dimensions. If the radius is negative the cube is shrunk instead. All defined dimensions are changed by the radius r . Lower-left coordinates are decreased by r and upper-right coordinates are increased by r . If a lower-left coordinate is increased to more than the corresponding upper-right coordinate (this can only happen when $r < 0$) then both coordinates are set to their average. If n is greater than the number of defined dimensions and the cube is being enlarged ($r > 0$), then extra dimensions are added to make n altogether; 0 is used as the initial value for the extra coordinates. This function is useful for creating bounding boxes around a point for searching for nearby points. <code>cube_enlarge(' (1,2), (3,4)', 0.5, 3) → (0.5, 1.5, -0.5), (3.5, 4.5, 0.5)</code>

F.13.4. Defaults

This union:

```
select cube_union('(0,5,2),(2,3,1)', '0');
cube_union
-----
(0, 0, 0),(2, 5, 2)
(1 row)
```

does not contradict common sense, neither does the intersection:

```
select cube_inter('(0,-1),(1,1)', '(-2),(2)');
cube_inter
-----
(0, 0),(1, 0)
(1 row)
```

In all binary operations on differently-dimensioned cubes, the lower-dimensional one is assumed to be a Cartesian projection, i. e., having zeroes in place of coordinates omitted in the string representation. The above examples are equivalent to:

```
cube_union('(0,5,2),(2,3,1)', '(0,0,0),(0,0,0)');
cube_inter('(0,-1),(1,1)', '(-2,0),(2,0)');
```

The following containment predicate uses the point syntax, while in fact the second argument is internally represented by a box. This syntax makes it unnecessary to define a separate point type and functions for (box,point) predicates.

```
select cube_contains('(0,0),(1,1)', '0.5,0.5');
cube_contains
-----
t
(1 row)
```

F.13.5. Notes

For examples of usage, see the regression test `sql/cube.sql`.

To make it harder for people to break things, there is a limit of 100 on the number of dimensions of cubes. This is set in `cubedata.h` if you need something bigger.

F.13.6. Credits

Original author: Gene Selkov, Jr. <selkovjr@mcs.anl.gov>, Mathematics and Computer Science Division, Argonne National Laboratory.

My thanks are primarily to Prof. Joe Hellerstein (<https://dsf.berkeley.edu/jmh/>) for elucidating the gist of the GiST (<http://gist.cs.berkeley.edu/>), and to his former student Andy Dong for his example written for Illustra. I am also grateful to all Postgres developers, present and past, for enabling myself to create my own world and live undisturbed in it. And I would like to acknowledge my gratitude to Argonne Lab and to the U.S. Department of Energy for the years of faithful support of my database research.

Minor updates to this package were made by Bruno Wolff III <bruno@wolff.to> in August/September of 2002. These include changing the precision from single precision to double precision and adding some new functions.

Additional updates were made by Joshua Reich <josh@root.net> in July 2006. These include `cube(float8[], float8[])` and cleaning up the code to use the V1 call protocol instead of the deprecated V0 protocol.

F.14. daterange_inclusive — upper bound-inclusive daterange

`daterange_inclusive` is an extension to the built-in `daterange` range type. By default, `daterange` excludes the upper bound of the range — `[ )`, whereas `daterange_inclusive` does not — `[ ]`. Other than the covered range bound, there are no other differences between `daterange` and `daterange_inclusive`.

This module is considered “trusted”, that is, it can be installed by non-superusers who have `CREATE` privilege on the current database.

F.14.1. Rationale

At times, it is more convenient to output date ranges with inclusive upper bounds. For example, it may apply to employees' absences. If an employee is absent from January 1, 2025, to January 10, 2025, using the `daterange` range type will prevent the database from outputting this date range in its entirety. In such cases, you would need to manually subtract one day from the output. The `daterange_inclusive` extension addresses this issue.

F.14.2. Example Usage

```
CREATE EXTENSION daterange_inclusive;
SELECT daterange( '[2024-01-01,2024-06-01]' );
       daterange
-----
[2024-01-01,2024-06-02)

SELECT daterange_inclusive( '[2024-01-01,2024-06-01]' );
       daterange_inclusive
-----
[2024-01-01,2024-06-01]
```

F.15. `dbcopies_decoding` — 1C module for updating database copies

`dbcopies_decoding` is a 1C module for updating database copies. It is implemented as a logical replication plug-in and provided in `postgrespro-ent-17-contrib`. For the module to work properly, `wal_level` must be set to `logical`. For more information about this module contact 1C support.

F.16. dblink — connect to other Postgres Pro databases

`dblink` is a module that supports connections to other Postgres Pro databases from within a database session.

`dblink` can report the following wait events under the wait event type `Extension`.

`DbLinkConnect`

Waiting to establish a connection to a remote server.

`DbLinkGetConnect`

Waiting to establish a connection to a remote server when it could not be found in the list of already-opened connections.

`DbLinkGetResult`

Waiting to receive the results of a query from a remote server.

See also [postgres_fdw](#), which provides roughly the same functionality using a more modern and standards-compliant infrastructure.

dblink_connect

`dblink_connect` — opens a persistent connection to a remote database

Synopsis

```
dblink_connect(text connstr) returns text
dblink_connect(text connname, text connstr) returns text
```

Description

`dblink_connect()` establishes a connection to a remote Postgres Pro database. The server and database to be contacted are identified through a standard libpq connection string. Optionally, a name can be assigned to the connection. Multiple named connections can be open at once, but only one unnamed connection is permitted at a time. The connection will persist until closed or until the database session is ended.

The connection string may also be the name of an existing foreign server. It is recommended to use the foreign-data wrapper `dblink_fdw` when defining the foreign server. See the example below, as well as [CREATE SERVER](#) and [CREATE USER MAPPING](#).

Arguments

connname

The name to use for this connection; if omitted, an unnamed connection is opened, replacing any existing unnamed connection.

connstr

libpq-style connection info string, for example `hostaddr=127.0.0.1 port=5432 dbname=mydb user=postgres password=mypasswd options=-csearch_path=`. For details see [Section 35.1.1](#). Alternatively, the name of a foreign server.

Return Value

Returns status, which is always OK (since any error causes the function to throw an error instead of returning).

Notes

If untrusted users have access to a database that has not adopted a [secure schema usage pattern](#), begin each session by removing publicly-writable schemas from `search_path`. One could, for example, add `options=-csearch_path=` to *connstr*. This consideration is not specific to `dblink`; it applies to every interface for executing arbitrary SQL commands.

Only superusers may use `dblink_connect` to create non-password-authenticated and non-GSSAPI-authenticated connections. If non-superusers need this capability, use `dblink_connect_u` instead.

It is unwise to choose connection names that contain equal signs, as this opens a risk of confusion with connection info strings in other `dblink` functions.

Examples

```
SELECT dblink_connect('dbname=postgres options=-csearch_path=');
 dblink_connect
-----
 OK
(1 row)

SELECT dblink_connect('myconn', 'dbname=postgres options=-csearch_path=');
 dblink_connect
-----
 OK
(1 row)
```

```
-- FOREIGN DATA WRAPPER functionality
-- Note: local connection must require password authentication for this to work
-- properly
--      Otherwise, you will receive the following error from dblink_connect():
--      ERROR: password is required
--      DETAIL: Non-superuser cannot connect if the server does not request a
--      password.
--      HINT: Target server's authentication method must be changed.

CREATE SERVER fdtest FOREIGN DATA WRAPPER dblink_fdw OPTIONS (hostaddr '127.0.0.1',
  dbname 'contrib_regression');

CREATE USER regress_dblink_user WITH PASSWORD 'secret';
CREATE USER MAPPING FOR regress_dblink_user SERVER fdtest OPTIONS (user
  'regress_dblink_user', password 'secret');
GRANT USAGE ON FOREIGN SERVER fdtest TO regress_dblink_user;
GRANT SELECT ON TABLE foo TO regress_dblink_user;

\set ORIGINAL_USER :USER
\c - regress_dblink_user
SELECT dblink_connect('myconn', 'fdtest');
  dblink_connect
-----
OK
(1 row)

SELECT * FROM dblink('myconn', 'SELECT * FROM foo') AS t(a int, b text, c text[]);
 a | b |          c
-----+-----+-----
 0 | a | {a0,b0,c0}
 1 | b | {a1,b1,c1}
 2 | c | {a2,b2,c2}
 3 | d | {a3,b3,c3}
 4 | e | {a4,b4,c4}
 5 | f | {a5,b5,c5}
 6 | g | {a6,b6,c6}
 7 | h | {a7,b7,c7}
 8 | i | {a8,b8,c8}
 9 | j | {a9,b9,c9}
10 | k | {a10,b10,c10}
(11 rows)

\c - :ORIGINAL_USER
REVOKE USAGE ON FOREIGN SERVER fdtest FROM regress_dblink_user;
REVOKE SELECT ON TABLE foo FROM regress_dblink_user;
DROP USER MAPPING FOR regress_dblink_user SERVER fdtest;
DROP USER regress_dblink_user;
DROP SERVER fdtest;
```

dblink_connect_u

`dblink_connect_u` — opens a persistent connection to a remote database, insecurely

Synopsis

```
dblink_connect_u(text connstr) returns text  
dblink_connect_u(text connname, text connstr) returns text
```

Description

`dblink_connect_u()` is identical to `dblink_connect()`, except that it will allow non-superusers to connect using any authentication method.

If the remote server selects an authentication method that does not involve a password, then impersonation and subsequent escalation of privileges can occur, because the session will appear to have originated from the user as which the local Postgres Pro server runs. Also, even if the remote server does demand a password, it is possible for the password to be supplied from the server environment, such as a `~/ .pgpass` file belonging to the server's user. This opens not only a risk of impersonation, but the possibility of exposing a password to an untrustworthy remote server. Therefore, `dblink_connect_u()` is initially installed with all privileges revoked from `PUBLIC`, making it un-callable except by superusers. In some situations it may be appropriate to grant `EXECUTE` permission for `dblink_connect_u()` to specific users who are considered trustworthy, but this should be done with care. It is also recommended that any `~/ .pgpass` file belonging to the server's user *not* contain any records specifying a wildcard host name.

For further details see `dblink_connect()`.

dblink_disconnect

`dblink_disconnect` — closes a persistent connection to a remote database

Synopsis

```
dblink_disconnect() returns text
dblink_disconnect(text connname) returns text
```

Description

`dblink_disconnect()` closes a connection previously opened by `dblink_connect()`. The form with no arguments closes an unnamed connection.

Arguments

connname

The name of a named connection to be closed.

Return Value

Returns status, which is always OK (since any error causes the function to throw an error instead of returning).

Examples

```
SELECT dblink_disconnect();
 dblink_disconnect
-----
      OK
(1 row)

SELECT dblink_disconnect('myconn');
 dblink_disconnect
-----
      OK
(1 row)
```

dblink

`dblink` — executes a query in a remote database

Synopsis

```
dblink(text connname, text sql [, bool fail_on_error]) returns setof record
dblink(text connstr, text sql [, bool fail_on_error]) returns setof record
dblink(text sql [, bool fail_on_error]) returns setof record
```

Description

`dblink` executes a query (usually a `SELECT`, but it can be any SQL statement that returns rows) in a remote database.

When two `text` arguments are given, the first one is first looked up as a persistent connection's name; if found, the command is executed on that connection. If not found, the first argument is treated as a connection info string as for `dblink_connect`, and the indicated connection is made just for the duration of this command.

Arguments

connname

Name of the connection to use; omit this parameter to use the unnamed connection.

connstr

A connection info string, as previously described for `dblink_connect`.

sql

The SQL query that you wish to execute in the remote database, for example `select * from foo`.

fail_on_error

If true (the default when omitted) then an error thrown on the remote side of the connection causes an error to also be thrown locally. If false, the remote error is locally reported as a `NOTICE`, and the function returns no rows.

Return Value

The function returns the row(s) produced by the query. Since `dblink` can be used with any query, it is declared to return `record`, rather than specifying any particular set of columns. This means that you must specify the expected set of columns in the calling query — otherwise Postgres Pro would not know what to expect. Here is an example:

```
SELECT *
FROM dblink('dbname=mydb options=-csearch_path=',
            'select proname, prosrc from pg_proc')
AS t1(proname name, prosrc text)
WHERE proname LIKE 'bytea%';
```

The “alias” part of the `FROM` clause must specify the column names and types that the function will return. (Specifying column names in an alias is actually standard SQL syntax, but specifying column types is a Postgres Pro extension.) This allows the system to understand what `*` should expand to, and what `proname` in the `WHERE` clause refers to, in advance of trying to execute the function. At run time, an error will be thrown if the actual query result from the remote database does not have the same number of columns shown in the `FROM` clause. The column names need not match, however, and `dblink` does not insist on exact type matches either. It will succeed so long as the returned data strings are valid input for the column type declared in the `FROM` clause.

Notes

A convenient way to use `dblink` with predetermined queries is to create a view. This allows the column type information to be buried in the view, instead of having to spell it out in every query. For example,

```
CREATE VIEW myremote_pg_proc AS
SELECT *
```

```
FROM dblink('dbname=postgres options=-csearch_path=',
            'select proname, prosrc from pg_proc')
AS t1(proname name, prosrc text);
```

```
SELECT * FROM myremote_pg_proc WHERE proname LIKE 'bytea%';
```

Examples

```
SELECT * FROM dblink('dbname=postgres options=-csearch_path=',
                    'select proname, prosrc from pg_proc')
AS t1(proname name, prosrc text) WHERE proname LIKE 'bytea%';
```

proname	prosrc
byteacat	byteacat
byteaeq	byteaeq
bytealt	bytealt
byteale	byteale
byteagt	byteagt
byteage	byteage
byteane	byteane
byteacmp	byteacmp
bytealike	bytealike
byteanlike	byteanlike
byteain	byteain
byteaout	byteaout

```
(12 rows)
```

```
SELECT dblink_connect('dbname=postgres options=-csearch_path=');
dblink_connect
-----
OK
(1 row)
```

```
SELECT * FROM dblink('select proname, prosrc from pg_proc')
AS t1(proname name, prosrc text) WHERE proname LIKE 'bytea%';
```

proname	prosrc
byteacat	byteacat
byteaeq	byteaeq
bytealt	bytealt
byteale	byteale
byteagt	byteagt
byteage	byteage
byteane	byteane
byteacmp	byteacmp
bytealike	bytealike
byteanlike	byteanlike
byteain	byteain
byteaout	byteaout

```
SELECT dblink_connect('myconn', 'dbname=regression options=-csearch_path=');
dblink_connect
-----
OK
(1 row)
```

```
SELECT * FROM dblink('myconn', 'select proname, prosrc from pg_proc')
AS t1(proname name, prosrc text) WHERE proname LIKE 'bytea%';
```

dblink_exec

`dblink_exec` — executes a command in a remote database

Synopsis

```
dblink_exec(text connname, text sql [, bool fail_on_error]) returns text
dblink_exec(text connstr, text sql [, bool fail_on_error]) returns text
dblink_exec(text sql [, bool fail_on_error]) returns text
```

Description

`dblink_exec` executes a command (that is, any SQL statement that doesn't return rows) in a remote database.

When two `text` arguments are given, the first one is first looked up as a persistent connection's name; if found, the command is executed on that connection. If not found, the first argument is treated as a connection info string as for `dblink_connect`, and the indicated connection is made just for the duration of this command.

Arguments

connname

Name of the connection to use; omit this parameter to use the unnamed connection.

connstr

A connection info string, as previously described for `dblink_connect`.

sql

The SQL command that you wish to execute in the remote database, for example `insert into foo values(0, 'a', '{"a0","b0","c0"}')`.

fail_on_error

If true (the default when omitted) then an error thrown on the remote side of the connection causes an error to also be thrown locally. If false, the remote error is locally reported as a NOTICE, and the function's return value is set to `ERROR`.

Return Value

Returns status, either the command's status string or `ERROR`.

Examples

```
SELECT dblink_connect('dbname=dblink_test_standby');
dblink_connect
-----
OK
(1 row)

SELECT dblink_exec('insert into foo values(21, ''z'', ''{"a0","b0","c0"}'');');
dblink_exec
-----
INSERT 943366 1
(1 row)

SELECT dblink_connect('myconn', 'dbname=regression');
dblink_connect
-----
OK
(1 row)
```

```
SELECT dblink_exec('myconn', 'insert into foo values(21, ''z'',  
''{"a0","b0","c0"}'');');  
dblink_exec
```

```
-----
```

```
INSERT 6432584 1
```

```
(1 row)
```

```
SELECT dblink_exec('myconn', 'insert into pg_class values (''foo''),false);
```

```
NOTICE:  sql error
```

```
DETAIL:  ERROR:  null value in column "relnamespace" violates not-null constraint
```

```
dblink_exec
```

```
-----
```

```
ERROR
```

```
(1 row)
```

dblink_open

`dblink_open` — opens a cursor in a remote database

Synopsis

```
dblink_open(text cursorname, text sql [, bool fail_on_error]) returns text
dblink_open(text connname, text cursorname, text sql [, bool fail_on_error]) returns
text
```

Description

`dblink_open()` opens a cursor in a remote database. The cursor can subsequently be manipulated with `dblink_fetch()` and `dblink_close()`.

Arguments

connname

Name of the connection to use; omit this parameter to use the unnamed connection.

cursorname

The name to assign to this cursor.

sql

The `SELECT` statement that you wish to execute in the remote database, for example `select * from pg_class`.

fail_on_error

If true (the default when omitted) then an error thrown on the remote side of the connection causes an error to also be thrown locally. If false, the remote error is locally reported as a `NOTICE`, and the function's return value is set to `ERROR`.

Return Value

Returns status, either `OK` or `ERROR`.

Notes

Since a cursor can only persist within a transaction, `dblink_open` starts an explicit transaction block (`BEGIN`) on the remote side, if the remote side was not already within a transaction. This transaction will be closed again when the matching `dblink_close` is executed. Note that if you use `dblink_exec` to change data between `dblink_open` and `dblink_close`, and then an error occurs or you use `dblink_disconnect` before `dblink_close`, your change *will be lost* because the transaction will be aborted.

Examples

```
SELECT dblink_connect('dbname=postgres options=-csearch_path=');
 dblink_connect
-----
 OK
(1 row)

SELECT dblink_open('foo', 'select proname, prosrc from pg_proc');
 dblink_open
-----
 OK
(1 row)
```

dblink_fetch

`dblink_fetch` — returns rows from an open cursor in a remote database

Synopsis

```
dblink_fetch(text cursorname, int howmany [, bool fail_on_error]) returns setof record
dblink_fetch(text connname, text cursorname, int howmany [, bool fail_on_error])
returns setof record
```

Description

`dblink_fetch` fetches rows from a cursor previously established by `dblink_open`.

Arguments

connname

Name of the connection to use; omit this parameter to use the unnamed connection.

cursorname

The name of the cursor to fetch from.

howmany

The maximum number of rows to retrieve. The next *howmany* rows are fetched, starting at the current cursor position, moving forward. Once the cursor has reached its end, no more rows are produced.

fail_on_error

If true (the default when omitted) then an error thrown on the remote side of the connection causes an error to also be thrown locally. If false, the remote error is locally reported as a NOTICE, and the function returns no rows.

Return Value

The function returns the row(s) fetched from the cursor. To use this function, you will need to specify the expected set of columns, as previously discussed for `dblink`.

Notes

On a mismatch between the number of return columns specified in the **FROM** clause, and the actual number of columns returned by the remote cursor, an error will be thrown. In this event, the remote cursor is still advanced by as many rows as it would have been if the error had not occurred. The same is true for any other error occurring in the local query after the remote **FETCH** has been done.

Examples

```
SELECT dblink_connect('dbname=postgres options=-csearch_path=');
```

```
dblink_connect
-----
OK
(1 row)
```

```
SELECT dblink_open('foo', 'select proname, prosrc from pg_proc where proname like
''bytea%'');
dblink_open
```

```
-----
OK
(1 row)
```

```
SELECT * FROM dblink_fetch('foo', 5) AS (funcname name, source text);
funcname | source
```

```
-----+-----
byteacat | byteacat
byteacmp | byteacmp
byteaeq  | byteaeq
byteage  | byteage
byteagt  | byteagt
(5 rows)
```

```
SELECT * FROM dblink_fetch('foo', 5) AS (funcname name, source text);
funcname | source
```

```
-----+-----
byteain  | byteain
byteale  | byteale
bytealike| bytealike
bytealt  | bytealt
byteane  | byteane
(5 rows)
```

```
SELECT * FROM dblink_fetch('foo', 5) AS (funcname name, source text);
funcname | source
```

```
-----+-----
byteanlike | byteanlike
byteaout   | byteaout
(2 rows)
```

```
SELECT * FROM dblink_fetch('foo', 5) AS (funcname name, source text);
funcname | source
```

```
-----+-----
(0 rows)
```

dblink_close

`dblink_close` — closes a cursor in a remote database

Synopsis

```
dblink_close(text cursorname [, bool fail_on_error]) returns text
dblink_close(text connname, text cursorname [, bool fail_on_error]) returns text
```

Description

`dblink_close` closes a cursor previously opened with `dblink_open`.

Arguments

connname

Name of the connection to use; omit this parameter to use the unnamed connection.

cursorname

The name of the cursor to close.

fail_on_error

If true (the default when omitted) then an error thrown on the remote side of the connection causes an error to also be thrown locally. If false, the remote error is locally reported as a NOTICE, and the function's return value is set to **ERROR**.

Return Value

Returns status, either OK or ERROR.

Notes

If `dblink_open` started an explicit transaction block, and this is the last remaining open cursor in this connection, `dblink_close` will issue the matching COMMIT.

Examples

```
SELECT dblink_connect('dbname=postgres options=-csearch_path=');
 dblink_connect
-----
 OK
(1 row)

SELECT dblink_open('foo', 'select proname, prosrc from pg_proc');
 dblink_open
-----
 OK
(1 row)

SELECT dblink_close('foo');
 dblink_close
-----
 OK
(1 row)
```

dblink_get_connections

`dblink_get_connections` — returns the names of all open named `dblink` connections

Synopsis

`dblink_get_connections()` returns `text[]`

Description

`dblink_get_connections` returns an array of the names of all open named `dblink` connections.

Return Value

Returns a text array of connection names, or `NULL` if none.

Examples

```
SELECT dblink_get_connections();
```

dblink_error_message

`dblink_error_message` — gets last error message on the named connection

Synopsis

`dblink_error_message(text connname)` returns text

Description

`dblink_error_message` fetches the most recent remote error message for a given connection.

Arguments

connname

Name of the connection to use.

Return Value

Returns last error message, or OK if there has been no error in this connection.

Notes

When asynchronous queries are initiated by `dblink_send_query`, the error message associated with the connection might not get updated until the server's response message is consumed. This typically means that `dblink_is_busy` or `dblink_get_result` should be called prior to `dblink_error_message`, so that any error generated by the asynchronous query will be visible.

Examples

```
SELECT dblink_error_message('dtest1');
```

dblink_send_query

`dblink_send_query` — sends an async query to a remote database

Synopsis

`dblink_send_query(text connname, text sql)` returns `int`

Description

`dblink_send_query` sends a query to be executed asynchronously, that is, without immediately waiting for the result. There must not be an async query already in progress on the connection.

After successfully dispatching an async query, completion status can be checked with `dblink_is_busy`, and the results are ultimately collected with `dblink_get_result`. It is also possible to attempt to cancel an active async query using `dblink_cancel_query`.

Arguments

connname

Name of the connection to use.

sql

The SQL statement that you wish to execute in the remote database, for example `select * from pg_class`.

Return Value

Returns 1 if the query was successfully dispatched, 0 otherwise.

Examples

```
SELECT dblink_send_query('dtest1', 'SELECT * FROM foo WHERE f1 < 3');
```

dblink_is_busy

`dblink_is_busy` — checks if connection is busy with an async query

Synopsis

```
dblink_is_busy(text connname) returns int
```

Description

`dblink_is_busy` tests whether an async query is in progress.

Arguments

connname

Name of the connection to check.

Return Value

Returns 1 if connection is busy, 0 if it is not busy. If this function returns 0, it is guaranteed that `dblink_get_result` will not block.

Examples

```
SELECT dblink_is_busy('dtest1');
```

`dblink_get_notify`

`dblink_get_notify` — retrieve async notifications on a connection

Synopsis

```
dblink_get_notify() returns setof (notify_name text, be_pid int, extra text)
dblink_get_notify(text connname) returns setof (notify_name text, be_pid int, extra
text)
```

Description

`dblink_get_notify` retrieves notifications on either the unnamed connection, or on a named connection if specified. To receive notifications via `dblink`, `LISTEN` must first be issued, using `dblink_exec`. For details see [LISTEN](#) and [NOTIFY](#).

Arguments

connname

The name of a named connection to get notifications on.

Return Value

Returns `setof (notify_name text, be_pid int, extra text)`, or an empty set if none.

Examples

```
SELECT dblink_exec('LISTEN virtual');
dblink_exec
-----
LISTEN
(1 row)
```

```
SELECT * FROM dblink_get_notify();
 notify_name | be_pid | extra
-----+-----+-----
(0 rows)
```

```
NOTIFY virtual;
NOTIFY
```

```
SELECT * FROM dblink_get_notify();
 notify_name | be_pid | extra
-----+-----+-----
virtual      |    1229 |
(1 row)
```

dblink_get_result

`dblink_get_result` — gets an async query result

Synopsis

`dblink_get_result(text connname [, bool fail_on_error])` returns setof record

Description

`dblink_get_result` collects the results of an asynchronous query previously sent with `dblink_send_query`. If the query is not already completed, `dblink_get_result` will wait until it is.

Arguments

connname

Name of the connection to use.

fail_on_error

If true (the default when omitted) then an error thrown on the remote side of the connection causes an error to also be thrown locally. If false, the remote error is locally reported as a NOTICE, and the function returns no rows.

Return Value

For an async query (that is, an SQL statement returning rows), the function returns the row(s) produced by the query. To use this function, you will need to specify the expected set of columns, as previously discussed for `dblink`.

For an async command (that is, an SQL statement not returning rows), the function returns a single row with a single text column containing the command's status string. It is still necessary to specify that the result will have a single text column in the calling FROM clause.

Notes

This function *must* be called if `dblink_send_query` returned 1. It must be called once for each query sent, and one additional time to obtain an empty set result, before the connection can be used again.

When using `dblink_send_query` and `dblink_get_result`, `dblink` fetches the entire remote query result before returning any of it to the local query processor. If the query returns a large number of rows, this can result in transient memory bloat in the local session. It may be better to open such a query as a cursor with `dblink_open` and then fetch a manageable number of rows at a time. Alternatively, use plain `dblink()`, which avoids memory bloat by spooling large result sets to disk.

Examples

```
contrib_regression=# SELECT dblink_connect('dtest1', 'dbname=contrib_regression');
 dblink_connect
-----
      OK
(1 row)

contrib_regression=# SELECT * FROM
contrib_regression-# dblink_send_query('dtest1', 'select * from foo where f1 < 3') AS
 t1;
 t1
----
  1
(1 row)

contrib_regression=# SELECT * FROM dblink_get_result('dtest1') AS t1(f1 int, f2 text,
 f3 text[]);
```

f1	f2	f3
0	a	{a0,b0,c0}
1	b	{a1,b1,c1}
2	c	{a2,b2,c2}

(3 rows)

```
contrib_regression=# SELECT * FROM dblink_get_result('dtest1') AS t1(f1 int, f2 text,
f3 text[]);
f1 | f2 | f3
----+-----+-----
(0 rows)
```

```
contrib_regression=# SELECT * FROM
contrib_regression-# dblink_send_query('dtest1', 'select * from foo where f1 < 3;
select * from foo where f1 > 6') AS t1;
t1
----
1
(1 row)
```

f1	f2	f3
0	a	{a0,b0,c0}
1	b	{a1,b1,c1}
2	c	{a2,b2,c2}

(3 rows)

f1	f2	f3
7	h	{a7,b7,c7}
8	i	{a8,b8,c8}
9	j	{a9,b9,c9}
10	k	{a10,b10,c10}

(4 rows)

```
contrib_regression=# SELECT * FROM dblink_get_result('dtest1') AS t1(f1 int, f2 text,
f3 text[]);
f1 | f2 | f3
----+-----+-----
(0 rows)
```

dblink_cancel_query

`dblink_cancel_query` — cancels any active query on the named connection

Synopsis

`dblink_cancel_query(text connname)` returns text

Description

`dblink_cancel_query` attempts to cancel any query that is in progress on the named connection. Note that this is not certain to succeed (since, for example, the remote query might already have finished). A cancel request simply improves the odds that the query will fail soon. You must still complete the normal query protocol, for example by calling `dblink_get_result`.

Arguments

connname

Name of the connection to use.

Return Value

Returns OK if the cancel request has been sent, or the text of an error message on failure.

Examples

```
SELECT dblink_cancel_query('dtest1');
```

`dblink_get_pkey`

`dblink_get_pkey` — returns the positions and field names of a relation's primary key fields

Synopsis

`dblink_get_pkey(text relname)` returns `setof dblink_pkey_results`

Description

`dblink_get_pkey` provides information about the primary key of a relation in the local database. This is sometimes useful in generating queries to be sent to remote databases.

Arguments

relname

Name of a local relation, for example `foo` or `myschema.mytab`. Include double quotes if the name is mixed-case or contains special characters, for example `"FooBar"`; without quotes, the string will be folded to lower case.

Return Value

Returns one row for each primary key field, or no rows if the relation has no primary key. The result row type is defined as

```
CREATE TYPE dblink_pkey_results AS (position int, colname text);
```

The `position` column simply runs from 1 to *N*; it is the number of the field within the primary key, not the number within the table's columns.

Examples

```
CREATE TABLE foobar (  
    f1 int,  
    f2 int,  
    f3 int,  
    PRIMARY KEY (f1, f2, f3)  
);  
CREATE TABLE  
  
SELECT * FROM dblink_get_pkey('foobar');  
 position | colname  
-----+-----  
         1 | f1  
         2 | f2  
         3 | f3  
(3 rows)
```

dblink_build_sql_insert

`dblink_build_sql_insert` — builds an `INSERT` statement using a local tuple, replacing the primary key field values with alternative supplied values

Synopsis

```
dblink_build_sql_insert(text relname,  
                        int2vector primary_key_attnums,  
                        integer num_primary_key_atts,  
                        text[] src_pk_att_vals_array,  
                        text[] tgt_pk_att_vals_array) returns text
```

Description

`dblink_build_sql_insert` can be useful in doing selective replication of a local table to a remote database. It selects a row from the local table based on primary key, and then builds an SQL `INSERT` command that will duplicate that row, but with the primary key values replaced by the values in the last argument. (To make an exact copy of the row, just specify the same values for the last two arguments.)

Arguments

relname

Name of a local relation, for example `foo` or `myschema.mytab`. Include double quotes if the name is mixed-case or contains special characters, for example `"FooBar"`; without quotes, the string will be folded to lower case.

primary_key_attnums

Attribute numbers (1-based) of the primary key fields, for example `1 2`.

num_primary_key_atts

The number of primary key fields.

src_pk_att_vals_array

Values of the primary key fields to be used to look up the local tuple. Each field is represented in text form. An error is thrown if there is no local row with these primary key values.

tgt_pk_att_vals_array

Values of the primary key fields to be placed in the resulting `INSERT` command. Each field is represented in text form.

Return Value

Returns the requested SQL statement as text.

Notes

As of PostgreSQL 9.0, the attribute numbers in *primary_key_attnums* are interpreted as logical column numbers, corresponding to the column's position in `SELECT * FROM relname`. Previous versions interpreted the numbers as physical column positions. There is a difference if any column(s) to the left of the indicated column have been dropped during the lifetime of the table.

Examples

```
SELECT dblink_build_sql_insert('foo', '1 2', 2, '{"1", "a"}', '{"1", "b' 'a"}');  
      dblink_build_sql_insert  
-----  
INSERT INTO foo(f1,f2,f3) VALUES('1','b' 'a','1')  
(1 row)
```

dblink_build_sql_delete

`dblink_build_sql_delete` — builds a DELETE statement using supplied values for primary key field values

Synopsis

```
dblink_build_sql_delete(text relname,  
                        int2vector primary_key_attnums,  
                        integer num_primary_key_atts,  
                        text[] tgt_pk_att_vals_array) returns text
```

Description

`dblink_build_sql_delete` can be useful in doing selective replication of a local table to a remote database. It builds an SQL DELETE command that will delete the row with the given primary key values.

Arguments

relname

Name of a local relation, for example `foo` or `myschema.mytab`. Include double quotes if the name is mixed-case or contains special characters, for example `"FooBar"`; without quotes, the string will be folded to lower case.

primary_key_attnums

Attribute numbers (1-based) of the primary key fields, for example `1 2`.

num_primary_key_atts

The number of primary key fields.

tgt_pk_att_vals_array

Values of the primary key fields to be used in the resulting DELETE command. Each field is represented in text form.

Return Value

Returns the requested SQL statement as text.

Notes

As of PostgreSQL 9.0, the attribute numbers in *primary_key_attnums* are interpreted as logical column numbers, corresponding to the column's position in `SELECT * FROM relname`. Previous versions interpreted the numbers as physical column positions. There is a difference if any column(s) to the left of the indicated column have been dropped during the lifetime of the table.

Examples

```
SELECT dblink_build_sql_delete('"MyFoo"', '1 2', 2, '{"1", "b"}');  
       dblink_build_sql_delete  
-----  
DELETE FROM "MyFoo" WHERE f1='1' AND f2='b'  
(1 row)
```

dblink_build_sql_update

`dblink_build_sql_update` — builds an UPDATE statement using a local tuple, replacing the primary key field values with alternative supplied values

Synopsis

```
dblink_build_sql_update(text relname,  
                        int2vector primary_key_attnums,  
                        integer num_primary_key_atts,  
                        text[] src_pk_att_vals_array,  
                        text[] tgt_pk_att_vals_array) returns text
```

Description

`dblink_build_sql_update` can be useful in doing selective replication of a local table to a remote database. It selects a row from the local table based on primary key, and then builds an SQL UPDATE command that will duplicate that row, but with the primary key values replaced by the values in the last argument. (To make an exact copy of the row, just specify the same values for the last two arguments.) The UPDATE command always assigns all fields of the row — the main difference between this and `dblink_build_sql_insert` is that it's assumed that the target row already exists in the remote table.

Arguments

relname

Name of a local relation, for example `foo` or `myschema.mytab`. Include double quotes if the name is mixed-case or contains special characters, for example `"FooBar"`; without quotes, the string will be folded to lower case.

primary_key_attnums

Attribute numbers (1-based) of the primary key fields, for example `1 2`.

num_primary_key_atts

The number of primary key fields.

src_pk_att_vals_array

Values of the primary key fields to be used to look up the local tuple. Each field is represented in text form. An error is thrown if there is no local row with these primary key values.

tgt_pk_att_vals_array

Values of the primary key fields to be placed in the resulting UPDATE command. Each field is represented in text form.

Return Value

Returns the requested SQL statement as text.

Notes

As of PostgreSQL 9.0, the attribute numbers in *primary_key_attnums* are interpreted as logical column numbers, corresponding to the column's position in `SELECT * FROM relname`. Previous versions interpreted the numbers as physical column positions. There is a difference if any column(s) to the left of the indicated column have been dropped during the lifetime of the table.

Examples

```
SELECT dblink_build_sql_update('foo', '1 2', 2, '{"1", "a"}', '{"1", "b"}');  
      dblink_build_sql_update  
-----  
UPDATE foo SET f1='1', f2='b', f3='1' WHERE f1='1' AND f2='b'  
(1 row)
```

F.17. `dbms_lob` — operate on large objects

`dbms_lob` is a Postgres Pro extension that allows operating on LOBs: `BLOB`, `CLOB`, `BFILE`, and temporary LOBs. The extension can be used to access and manipulate specific parts of a LOB or complete LOBs. The functionality provided by this module overlaps substantially with the functionality of Oracle's `DBMS_LOB` package.

Note

Note that the `dbms_lob` extension depends on both `pgpro_bfile` and `pgpro_sfile`. You must install these extensions before creating `dbms_lob`, or you can install all dependencies automatically with:

```
CREATE EXTENSION dbms_lob CASCADE;
```

F.17.1. Installation

The `dbms_lob` extension is a built-in extension included into Postgres Pro Enterprise. To enable `dbms_lob`, create the extension using the following query:

```
CREATE EXTENSION dbms_lob;
```

F.17.2. Data Types

The `dbms_lob` extension works with several data types:

- The `bfile` type is provided by [pgpro_bfile](#).

```
CREATE TYPE BFILE AS (  
    dir_id int,  
    file_name text  
);
```

Table F.8. `bfile` Parameters

Parameter	Description
<code>dir_id</code>	The ID of the directory where the <code>bfile</code> is stored.
<code>file_name</code>	The name of the file to read the <code>bfile</code> from.

- The `blob` type stores binary data and has the same interface as Oracle's `BLOB`. It is provided by [pgpro_sfile](#).

```
CREATE TYPE dbms_lob.blob AS (  
    temp_data bytea,  
    mime text,  
    sf @extschema:pgpro_sfile@sfile  
);
```

Table F.9. `blob` Parameters

Parameter	Description
<code>sf</code>	<code>sfile</code> object on disk, which contains <code>BLOB</code> .
<code>temp_data</code>	Temporary <code>BLOB</code> data stored in memory.
<code>mime</code>	Auxiliary data defining the type of data stored in <code>BLOB</code> .

- The `clob` type is the equivalent of Oracle's `CLOB` and `NCLOB`. Only the UTF-8 encoding is supported.

```
CREATE TYPE CLOB AS (  
    t text,
```

```

    istemp bool,
    mime    text
);

```

Table F.10. clob Parameters

Parameter	Description
<code>t</code>	<code>text</code> object on disk, which stores data.
<code>istemp</code>	Defines if the object is temporary.
<code>mime</code>	Auxiliary data defining the type of data stored in CLOB.

F.17.3. Utility Functions

`bfilename(dirname text, filename text)` returns `bfile`

Creates a `bfile` object associated with a physical file in the file system. Here *dirname* is the name of the directory object created with `bfile_directory_create()` where the file *filename* is located.

`empty_blob()` returns `blob`

Creates an empty `blob` object, which contains an `sfile` without data. It can be populated with data using write functions.

`empty_clob()` returns `clob`

Creates an empty `clob` object, which contains an empty string. It can be populated with data using write functions.

`to_blob(b bytea)` returns `blob`

`to_blob(f bfile, mime_type text)` returns `blob`

Converts a `bytea` object to a `blob`. If the original file is `bfile`, the `mime` data type can be specified.

`to_clob(t text)` returns `clob`

`to_clob(t varchar)` returns `clob`

`to_clob(b bfile, int csid, mime text)` returns `clob`

Converts text objects to `clob` objects. If the original file is `bfile`, its data is read and converted into `clob`. Only the UTF-8 encoding is supported.

`to_raw(b blob)` returns `clob`

`to_raw(b bfile)` returns `clob`

Copies the data from a `blob` or `bfile` file into a `bytea`. Only the first GB of data is processed.

F.17.4. dbms_lob Functions and Procedures

F.17.4.1. Opening and Closing LOBs

`open(file_loc IN OUT bfile, open_mode IN int)`

`open(lob_loc IN OUT blob, open_mode IN int)`

`open(lob_loc IN OUT clob, open_mode IN int)`

`open(bfile)` opens a `bfile` object. The *open_mode* parameter specifies if the file is to be open in read/write or read-only mode. For `bfile`, only read-only mode is supported (0). The functions `open(blob)` and `open(clob)` do nothing and exist only for syntax compatibility.

`isopen(file_loc IN bfile)`

`isopen(lob_loc IN blob)`

`isopen(lob_loc IN clob)`

`isopen(bfile)` checks if a `bfile` object is open. Returns 1 if the LOB is open, otherwise 0. The functions `isopen(blob)` and `isopen(clob)` always return 1 and exist only for syntax compatibility.

```
close(file_loc IN OUT bfile)  
close(lob_loc IN OUT blob)  
close(lob_loc IN OUT clob)
```

`close(bfile)` checks if a `bfile` object is open, and if it is, closes it. The functions `close(blob)` and `close(clob)` do nothing and exist only for syntax compatibility.

```
createtemporary(lob_loc IN OUT blob, cache IN bool, dur IN int default 10)  
createtemporary(lob_loc IN OUT clob, cache IN bool, dur IN int default 10)
```

Creates a temporary LOB, with `blob` data stored as `bytea` and `clob` data stored as `text`.

```
freetemporary(lob_loc IN OUT blob)  
freetemporary(lob_loc IN OUT clob)
```

Releases resources associated with the temporary LOB.

F.17.4.2. Reading LOBs

```
getlength(file_loc IN bfile)  
getlength(lob_loc IN blob)  
getlength(lob_loc IN clob)
```

Returns the length of a `blob` or `bfile` in bytes or a `clob` in characters.

```
read(file_loc IN bfile, amount IN OUT int, offset IN int, buffer OUT bytea)  
read(lob_loc IN blob, amount IN OUT int, offset IN int, buffer OUT bytea)  
read(lob_loc IN clob, amount IN OUT int, offset IN int, buffer OUT text)
```

Reads a piece of a LOB, and writes the specified amount of bytes (`blob/bfile`) or characters (`clob`) into the *buffer* parameter, starting from an absolute *offset* from the beginning of the LOB. Note that *offset* 1 should be specified to read from the beginning.

```
get_storage_limit(lob_loc IN blob)  
get_storage_limit(lob_loc IN clob)
```

Returns the LOB storage limit for the specified LOB.

```
substr(file_loc IN bfile, amount IN int, offset IN int)  
substr(lob_loc IN blob, amount IN int, offset IN int)  
substr(lob_loc IN clob, amount IN int, offset IN int)
```

Returns *amount* of bytes (`blob/bfile`) or characters (`clob`) of a LOB, starting from an absolute *offset* from the beginning of the LOB.

```
instr(file_loc IN bfile, pattern IN int, offset IN bigint default 1, nth IN bigint  
default 1)  
instr(lob_loc IN blob, pattern IN int, offset IN bigint default 1, nth IN bigint default 1)  
instr(lob_loc IN clob, pattern IN int, offset IN bigint default 1, nth IN bigint default 1)
```

Returns the matching position of the *nth* occurrence of the *pattern* in the LOB, starting from the specified *offset*. Returns 0 if the *pattern* is not found. Only the first GB of data is searched.

F.17.4.3. Updating LOBs

```
write(lob_loc IN OUT blob, amount IN int, offset IN bigint, buffer IN bytea)  
write(lob_loc IN OUT clob, amount IN int, offset IN int, buffer IN text)
```

Writes a specified *amount* of data into the internal LOB, starting from the absolute *offset* from the beginning of the LOB. The data is taken from the *buffer*. If the specified *offset* exceeds the current size of the LOB, the value is padded with zero bytes (for `blob`) or spaces (for `clob`).

If *buffer* is longer than *amount*, only the specified number of bytes (for `blob`) or characters (for `clob`) is written. This ensures that exactly *amount* of data is written into the internal LOB.

```
writeappend(lob_loc IN OUT blob, amount IN int, buffer IN bytea)  
writeappend(lob_loc IN OUT clob, amount IN int, buffer IN text)
```

Writes a specified *amount* of data to the end of an internal LOB. The data is written from the *buffer* parameter.

```
erase(lob_loc IN OUT blob, amount IN OUT int, offset IN bigint default 1)  
erase(lob_loc IN OUT clob, amount IN OUT int, offset IN int default 1)
```

Erases an entire internal LOB or part of an internal LOB. When data is erased from the middle of a LOB, zero-byte fillers (temporary blob) or spaces (clob) are written. Non-temporary blob objects can only be deleted as a whole.

```
trim(lob_loc IN OUT blob, newlen IN bigint)  
trim(lob_loc IN OUT clob, newlen IN int)
```

Trims the value of the internal LOB to the length you specify in the *newlen* parameter. Specify the length in bytes for temporary blob, and specify the length in characters for clob. For non-temporary blob, works only if the new length is 0, which means erasing the object.

F.17.4.4. Operations with Multiple LOBs

```
compare(lob_1 IN bfile, lob_2 IN bfile, amount IN bigint, offset_1 IN bigint default 1,  
offset_2 IN bigint default 1) returns int  
compare(lob_1 IN blob, lob_2 IN blob, amount IN int default 1024*1024*1024-8, offset_1  
IN bigint default 1, offset_2 IN bigint default 1) returns int  
compare(lob_1 IN clob, lob_2 IN clob, amount IN int default (1024*1024*1024-8)/2, offset_1  
IN int default 1, offset_2 IN int default 1) returns int
```

Compares two entire LOBs or parts of two LOBs. You can only compare LOBs of the same datatype. For bfile and blob, binary comparison is performed. For clob, files are compared according to the current database collation.

```
append(lob_1 IN OUT blob, lob_2 IN blob)  
append(lob_1 IN OUT clob, lob_2 IN clob)
```

Appends the contents of a source internal LOB to a destination LOB. It appends the complete source LOB.

```
copy(dest_lob IN OUT blob, src_lob IN blob, amount IN bigint, dest_offset IN bigint  
default 1, src_offset IN bigint default 1) returns int  
copy(dest_lob IN OUT clob, src_lob IN clob, amount IN int, dest_offset IN int default  
1, src_offset IN int default 1) returns int
```

Copies all, or a part of, a source internal LOB to a destination internal LOB. You can specify the offsets for both the source and destination LOBs, and the number of bytes or characters to copy.

```
converttoblob(dest_lob IN OUT blob, src_clob IN clob, amount IN int, dest_offset IN OUT  
bigint, src_offset IN OUT int, blob_csid IN int, lang_context IN OUT int, warning OUT int)
```

Reads character data from a source clob, converts the character data to the specified character set, writes the converted data to a destination blob in binary format, and returns the new offsets. Only the UTF-8 encoding is supported.

```
converttoclob(dest_lob IN OUT clob, src_blob IN blob, amount IN int, dest_offset IN OUT  
int, src_offset IN OUT bigint, blob_csid IN int, lang_context IN OUT int, warning OUT int)
```

Reads binary data from a source blob, converts it into UTF-8 encoding, and writes the converted character data to a destination clob.

F.17.4.5. Legacy API

```
fileexists(file_loc IN bfile) returns int
```

Finds out if a specified bfile locator points to a file that actually exists on the server file system. Implemented as [bfile_fileexists](#).

```
fileopen(file_loc IN OUT bfile, open_mode IN int) returns int
```

Opens the specified bfile for read-only access. Implemented as [bfile_open](#).

`fileisopen(file_loc IN bfile) returns int`

Finds out whether the specified `bfile` was opened.

`loadfromfile(dest_lob IN OUT blob, src_bfile IN bfile, amount IN int default 1024*1024*1024-8, dest_offset IN bigint default 1, src_offset IN bigint default 1)`

Converts data from the specified `bfile` to `blob`.

`fileclose(file_loc IN OUT bfile)`

Closes the previously opened `bfile`. Implemented as `bfile_close`.

`filecloseall()`

Closes all `bfile` files opened in the session. Implemented as `bfile_close_all`.

`filegetname(file_loc IN bfile, dir_alias OUT text, filename OUT text)`

Determines the directory object and filename. This function only indicates the directory object name and filename assigned to the locator, not if the physical file or directory actually exists. Implemented as `bfile_directory_get_alias_by_id`.

F.17.4.6. Other Operations

`loadblobfromfile(dest_lob IN OUT blob, src_bfile IN bfile, amount IN int default 1024*1024*1024-8, dest_offset IN bigint default 1, src_offset IN bigint default 1) returns int`

Synonym for `loadfromfile()`.

`loadclobfromfile(dest_lob IN OUT clob, src_bfile IN bfile, amount IN int, dest_offset IN OUT int, src_offset IN OUT bigint, bfile_csid IN int, lang_context IN OUT int, warning OUT int)`

Loads data from a `bfile` to an internal `clob`.

`setcontenttype(lob_loc IN OUT blob, contenttype IN text)`

`setcontenttype(lob_loc IN OUT clob, contenttype IN text)`

Sets the content type string associated with the LOB.

`getcontenttype(lob_loc IN blob) returns text`

`getcontenttype(lob_loc IN clob) returns text`

Returns the content type string associated with the LOB.

`getchunksize(lob_loc IN blob) returns text`

`getchunksize(lob_loc IN clob) returns text`

Returns the amount of space used in the LOB chunk to store the LOB value.

F.17.5. Example

```
DO
$$
DECLARE
  cur_clob  dbms_lob.clob;
  buffer    text;
  amount    int := 3000;
BEGIN
  cur_clob := dbms_lob.empty_clob();
  cur_clob.t := 'just some sample text';
  raise notice 'clob length: %', dbms_lob.getlength(cur_clob);
  call dbms_lob.read(cur_clob, amount, 1, buffer);
  raise notice 'all clob read: %', buffer;
```

```
amount := 6;
call dbms_lob.read(cur_clob, amount, 4, buffer);
raise notice 'clob read from 4 position for 6 symbols: %', buffer;
raise notice 'storage limit: %', dbms_lob.get_storage_limit(cur_clob);
raise notice 'clob substr from 6 position for 8 symbols: %',
dbms_lob.substr(cur_clob, 8, 6);
raise notice 'third postion of letter s in clob: %', dbms_lob.instr(cur_clob, 's', 1,
3);

call dbms_lob.write(cur_clob, 6, 4, 'foobar');
raise notice 'new clob contents: %', cur_clob.t;
call dbms_lob.write(cur_clob, 3, 25, 'baz');
raise notice 'new clob contents: %', cur_clob.t;

call dbms_lob.writeappend(cur_clob, 4, 'test');
raise notice 'new clob contents: %', cur_clob.t;

amount := 3;
call dbms_lob.erase(cur_clob, amount, 2);
raise notice 'amount of symbols deleted: %', amount;
raise notice 'new clob contents: %', cur_clob.t;
call dbms_lob.erase(cur_clob, amount, 30);
raise notice 'amount of symbols deleted: %', amount;
raise notice 'new clob contents: %', cur_clob.t;

call dbms_lob.trim_(cur_clob, 22);
raise notice 'new clob contents: %', cur_clob.t;
END;
$$;
--output
NOTICE: clob length: 21
NOTICE: all clob read: just some sample text
NOTICE: clob read from 4 position for 6 symbols: t some
NOTICE: storage limit: 536870908
NOTICE: clob substr from 6 position for 8 symbols: some sam
NOTICE: third postion of letter s in clob: 11

NOTICE: amount of symbols deleted: 2
NOTICE: new clob contents: j  oobar sample text    bazte
NOTICE: new clob contents: j  oobar sample text
```

F.18. `dict_int` — example full-text search dictionary for integers

`dict_int` is an example of an add-on dictionary template for full-text search. The motivation for this example dictionary is to control the indexing of integers (signed and unsigned), allowing such numbers to be indexed while preventing excessive growth in the number of unique words, which greatly affects the performance of searching.

This module is considered “trusted”, that is, it can be installed by non-superusers who have `CREATE` privilege on the current database.

F.18.1. Configuration

The dictionary accepts three options:

- The `maxlen` parameter specifies the maximum number of digits allowed in an integer word. The default value is 6.
- The `rejectlong` parameter specifies whether an overlength integer should be truncated or ignored. If `rejectlong` is `false` (the default), the dictionary returns the first `maxlen` digits of the integer. If `rejectlong` is `true`, the dictionary treats an overlength integer as a stop word, so that it will not be indexed. Note that this also means that such an integer cannot be searched for.
- The `absval` parameter specifies whether leading “+” or “-” signs should be removed from integer words. The default is `false`. When `true`, the sign is removed before `maxlen` is applied.

F.18.2. Usage

Installing the `dict_int` extension creates a text search template `intdict_template` and a dictionary `intdict` based on it, with the default parameters. You can alter the parameters, for example

```
mydb# ALTER TEXT SEARCH DICTIONARY intdict (MAXLEN = 4, REJECTLONG = true);  
ALTER TEXT SEARCH DICTIONARY
```

or create new dictionaries based on the template.

To test the dictionary, you can try

```
mydb# select ts_lexize('intdict', '12345678');  
ts_lexize  
-----  
{123456}
```

but real-world usage will involve including it in a text search configuration as described in [Chapter 12](#). That might look like this:

```
ALTER TEXT SEARCH CONFIGURATION english  
    ALTER MAPPING FOR int, uint WITH intdict;
```

F.19. `dict_xsyn` — example synonym full-text search dictionary

`dict_xsyn` (Extended Synonym Dictionary) is an example of an add-on dictionary template for full-text search. This dictionary type replaces words with groups of their synonyms, and so makes it possible to search for a word using any of its synonyms.

F.19.1. Configuration

A `dict_xsyn` dictionary accepts the following options:

- `matchorig` controls whether the original word is accepted by the dictionary. Default is `true`.
- `matchsynonyms` controls whether the synonyms are accepted by the dictionary. Default is `false`.
- `keeporig` controls whether the original word is included in the dictionary's output. Default is `true`.
- `keepsynonyms` controls whether the synonyms are included in the dictionary's output. Default is `true`.
- `rules` is the base name of the file containing the list of synonyms. This file must be stored in `$SHAREDIR/tsearch_data/` (where `$SHAREDIR` means the Postgres Pro installation's shared-data directory). Its name must end in `.rules` (which is not to be included in the `rules` parameter).

The rules file has the following format:

- Each line represents a group of synonyms for a single word, which is given first on the line. Synonyms are separated by white-space, thus:

`word syn1 syn2 syn3`
- The sharp (`#`) sign is a comment delimiter. It may appear at any position in a line. The rest of the line will be skipped.

Look at `xsyn_sample.rules`, which is installed in `$SHAREDIR/tsearch_data/`, for an example.

F.19.2. Usage

Installing the `dict_xsyn` extension creates a text search template `xsyn_template` and a dictionary `xsyn` based on it, with default parameters. You can alter the parameters, for example

```
mydb# ALTER TEXT SEARCH DICTIONARY xsyn (RULES='my_rules', KEEPORIG=false);
ALTER TEXT SEARCH DICTIONARY
```

or create new dictionaries based on the template.

To test the dictionary, you can try

```
mydb=# SELECT ts_lexize('xsyn', 'word');
       ts_lexize
-----
{syn1,syn2,syn3}
```

```
mydb# ALTER TEXT SEARCH DICTIONARY xsyn (RULES='my_rules', KEEPORIG=true);
ALTER TEXT SEARCH DICTIONARY
```

```
mydb=# SELECT ts_lexize('xsyn', 'word');
       ts_lexize
-----
{word,syn1,syn2,syn3}
```

```
mydb# ALTER TEXT SEARCH DICTIONARY xsyn (RULES='my_rules', KEEPORIG=false,
MATCHSYNONYMS=true);
ALTER TEXT SEARCH DICTIONARY
```

```
mydb=# SELECT ts_lexize('xsyn', 'syn1');
       ts_lexize
-----
{syn1,syn2,syn3}
```

```
mydb# ALTER TEXT SEARCH DICTIONARY xsyn (RULES='my_rules', KEEPORIG=true,  
      MATCHORIG=false, KEEPSYNONYMS=false);  
ALTER TEXT SEARCH DICTIONARY
```

```
mydb=# SELECT ts_lexize('xsyn', 'syn1');  
          ts_lexize
```

```
-----  
{word}
```

Real-world usage will involve including it in a text search configuration as described in [Chapter 12](#). That might look like this:

```
ALTER TEXT SEARCH CONFIGURATION english  
      ALTER MAPPING FOR word, asciiword WITH xsyn, english_stem;
```

F.20. `dump_stat` — functions to backup and recover the `pg_statistic` table

The `dump_stat` module provides functions that allow you to backup and recover the contents of the `pg_statistic` table. When performing a dump/restore, you can use `dump_stat` to migrate the original statistics to the new server instead of running the `ANALYZE` command for the whole database cluster, which can significantly reduce downtime for large databases. The `dump_statistic` function generates `INSERT` statements which can later be applied to a compatible database. To successfully restore statistical data, you must install the extension on both the original and the recipient servers since these statements rely on the provided `dump_stat` functions.

Note that the definition of the `pg_statistic` table might change occasionally, which means that generated dump might be incompatible with future releases of Postgres Pro.

F.20.1. Installation

The `dump_stat` extension is included into Postgres Pro. Once you have Postgres Pro installed, you must execute the `CREATE EXTENSION` command to enable `dump_stat`, as follows:

```
CREATE EXTENSION dump_stat;
```

F.20.2. Functions

`anyarray_to_text(array anyarray)` returns text

Returns the given array as text.

`dump_statistic()` returns setof text

`dump_statistic` dumps the contents of the `pg_statistic` system catalog. It produces an `INSERT` statement per each tuple of the `pg_statistic`, excluding the ones that contain statistical data for tables in the `information_schema` and `pg_catalog` schemas.

The `INSERT` statement takes form of

```
WITH upsert as (  
  UPDATE pg_catalog.pg_statistic SET column_name = expression [, ...]  
  WHERE starelid = t_relname::regclass  
    AND to_attnum(t_relname, staattnum) = t_attnum  
    AND to_atttype(t_relname, staattnum) = t_atttype  
    AND stainherit = t_stainherit  
  RETURNING *)
```

```
ins as (  
  SELECT expression [, ...]  
  WHERE NOT EXISTS (SELECT * FROM upsert)  
    AND to_attnum(t_relname, t_attnum) IS NOT NULL  
    AND to_atttype(t_relname, t_attnum) = t_atttype)  
INSERT INTO pg_catalog.pg_statistic SELECT * FROM ins;
```

where *expression* can be one of:

```
array_in(array_text, type_name::regtype::oid, -1)  
value::type_name
```

To save the produced statements, redirect the `psql` output into a file using standard `psql` options. For details on the available `psql` options, see [psql](#). Meta-commands starting with a backslash are not supported.

For example, to save statistics for the *dbname* database into a `dump_stat.sql` file, run:

```
$ psql -XAtq -c "SELECT dump_statistic()" dbname > dump_stat.sql
```

`dump_statistic(schema_name text)` returns setof text

`dump_statistic` dumps the contents of the `pg_statistic` system catalog. It produces an `INSERT` statement per each tuple of the `pg_statistic` that relates to some table in the `schema_name` schema.

`dump_statistic(schema_name text, table_name text)` returns `setof text`

`dump_statistic` dumps the contents of the `pg_statistic` system catalog. It produces an `INSERT` statement per each tuple of the `pg_statistic` that relates to the specified `schema_name.table_name` table.

`dump_statistic(relation regclass)` returns `setof text`

`dump_statistic` dumps the contents of the `pg_statistic` system catalog. It produces an `INSERT` statement per each tuple of the `pg_statistic` that contains statistical data for the specified `relation`.

`to_schema_qualified_operator(opid oid)` returns `text`

Fetches the schema-qualified operator name by operator id `opid`. For example:

```
test=# SELECT to_schema_qualified_operator('+(int,int)::regoperator');
           to_schema_qualified_operator
-----
pg_catalog.+(pg_catalog.int4, pg_catalog.int4)
(1 row)
```

`to_schema_qualified_type(typid oid)` returns `text`

Fetches the schema-qualified type name by type id `typid`.

`to_schema_qualified_relation(relid oid)` returns `text`

Fetches the schema-qualified relation name by relation id `relid`.

`anyarray_elemtype(arr anyarray)` returns `oid`

Returns the element type of the given array as `oid`. For example:

```
test=# SELECT anyarray_elemtype(array_in('{1,2,3}', 'int'::regtype, -1));
           anyarray_elemtype
-----
                23
(1 row)
```

`to_attname(relation regclass, colnum int2)` returns `text`

Given a relation name `relation` and a column number `colnum`, returns the column name as `text`.

`to_attnum(relation regclass, col text)` returns `int2`

Given a relation name `relation` and a column name `col`, returns the column number as `int2`.

`to_atttype(relation regclass, col text)` returns `text`

Given a relation name `relation` and a column name `col`, returns the schema-qualified column type as `text`.

`to_atttype(relation regclass, colnum int2)` returns `text`

Given a relation name `relation` and a column number `colnum`, returns the schema-qualified column type as `text`.

`to_namespace(nsp text)` returns `oid`

`to_namespace` duplicates the behavior of the cast to the `regnamespace` type, which is not present in the PostgreSQL 9.4 release (and prior releases). This function returns the `oid` of the given schema.

`get_namespace(relation oid)` returns `oid`

`get_namespace` returns the schema of the given relation as `oid`.

F.21. earthdistance — calculate great-circle distances

The `earthdistance` module provides two different approaches to calculating great circle distances on the surface of the Earth. The one described first depends on the `cube` module. The second one is based on the built-in `point` data type, using longitude and latitude for the coordinates.

In this module, the Earth is assumed to be perfectly spherical. (If that's too inaccurate for you, you might want to look at the [PostGIS](#) project.)

The `cube` module must be installed before `earthdistance` can be installed (although you can use the `CASCADE` option of `CREATE EXTENSION` to install both in one command).

Caution

It is strongly recommended that `earthdistance` and `cube` be installed in the same schema, and that that schema be one for which `CREATE` privilege has not been and will not be granted to any untrusted users. Otherwise there are installation-time security hazards if `earthdistance`'s schema contains objects defined by a hostile user. Furthermore, when using `earthdistance`'s functions after installation, the entire search path should contain only trusted schemas.

F.21.1. Cube-Based Earth Distances

Data is stored in cubes that are points (both corners are the same) using 3 coordinates representing the x, y, and z distance from the center of the Earth. A [domain](#) `earth` over type `cube` is provided, which includes constraint checks that the value meets these restrictions and is reasonably close to the actual surface of the Earth.

The radius of the Earth is obtained from the `earth()` function. It is given in meters. But by changing this one function you can change the module to use some other units, or to use a different value of the radius that you feel is more appropriate.

This package has applications to astronomical databases as well. Astronomers will probably want to change `earth()` to return a radius of $180/\pi$ so that distances are in degrees.

Functions are provided to support input in latitude and longitude (in degrees), to support output of latitude and longitude, to calculate the great circle distance between two points and to easily specify a bounding box usable for index searches.

The provided functions are shown in [Table F.11](#).

Table F.11. Cube-Based Earthdistance Functions

Function	Description
<code>earth() → float8</code>	Returns the assumed radius of the Earth.
<code>sec_to_gc (float8) → float8</code>	Converts the normal straight line (secant) distance between two points on the surface of the Earth to the great circle distance between them.
<code>gc_to_sec (float8) → float8</code>	Converts the great circle distance between two points on the surface of the Earth to the normal straight line (secant) distance between them.
<code>ll_to_earth (float8, float8) → earth</code>	Returns the location of a point on the surface of the Earth given its latitude (argument 1) and longitude (argument 2) in degrees.
<code>latitude (earth) → float8</code>	Returns the latitude in degrees of a point on the surface of the Earth.
<code>longitude (earth) → float8</code>	

Function	Description
	Returns the longitude in degrees of a point on the surface of the Earth.
<code>earth_distance (earth, earth) → float8</code>	Returns the great circle distance between two points on the surface of the Earth.
<code>earth_box (earth, float8) → cube</code>	Returns a box suitable for an indexed search using the <code>cube @></code> operator for points within a given great circle distance of a location. Some points in this box are further than the specified great circle distance from the location, so a second check using <code>earth_distance</code> should be included in the query.

F.21.2. Point-Based Earth Distances

The second part of the module relies on representing Earth locations as values of type `point`, in which the first component is taken to represent longitude in degrees, and the second component is taken to represent latitude in degrees. Points are taken as (longitude, latitude) and not vice versa because longitude is closer to the intuitive idea of x-axis and latitude to y-axis.

A single operator is provided, shown in [Table F.12](#).

Table F.12. Point-Based Earthdistance Operators

Operator	Description
<code>point <@> point → float8</code>	Computes the distance in statute miles between two points on the Earth's surface.

Note that unlike the `cube`-based part of the module, units are hardwired here: changing the `earth()` function will not affect the results of this operator.

One disadvantage of the longitude/latitude representation is that you need to be careful about the edge conditions near the poles and near +/- 180 degrees of longitude. The `cube`-based representation avoids these discontinuities.

F.22. fasttrun — a transaction unsafe function to truncate temporary tables

The `fasttrun` module provides transaction unsafe function to truncate temporary tables without growing `pg_class` size.

This module is required for 1C Enterprise support.

Fast truncate operation is not transactional, so its results cannot be rolled back and become immediately visible in all sessions regardless of isolation level.

F.22.1. Function

There is a function call example:

```
select fasttruncate('TABLE_NAME');
```

F.22.2. Test example

For tests you can use this example:

```
create or replace function f() returns void as $$
begin
  for i in 1..1000
  loop
    PERFORM fasttruncate('tt1');
  end loop;
end;
$$ language plpgsql;
```

Teodor Sigaev <teodor@sigaev.ru>

F.23. `file_fdw` — access data files in the server's file system

The `file_fdw` module provides the foreign-data wrapper `file_fdw`, which can be used to access data files in the server's file system, or to execute programs on the server and read their output. The data file or program output must be in a format that can be read by `COPY FROM`; see [COPY](#) for details. Access to data files is currently read-only.

A foreign table created using this wrapper can have the following options:

`filename`

Specifies the file to be read. Relative paths are relative to the data directory. Either `filename` or `program` must be specified, but not both.

`program`

Specifies the command to be executed. The standard output of this command will be read as though `COPY FROM PROGRAM` were used. Either `program` or `filename` must be specified, but not both.

`format`

Specifies the data format, the same as `COPY`'s `FORMAT` option.

`header`

Specifies whether the data has a header line, the same as `COPY`'s `HEADER` option.

`delimiter`

Specifies the data delimiter character, the same as `COPY`'s `DELIMITER` option.

`quote`

Specifies the data quote character, the same as `COPY`'s `QUOTE` option.

`escape`

Specifies the data escape character, the same as `COPY`'s `ESCAPE` option.

`null`

Specifies the data null string, the same as `COPY`'s `NULL` option.

`encoding`

Specifies the data encoding, the same as `COPY`'s `ENCODING` option.

Note that while `COPY` allows options such as `HEADER` to be specified without a corresponding value, the foreign table option syntax requires a value to be present in all cases. To activate `COPY` options typically written without a value, you can pass the value `TRUE`, since all such options are Booleans.

A column of a foreign table created using this wrapper can have the following options:

`force_not_null`

This is a Boolean option. If true, it specifies that values of the column should not be matched against the null string (that is, the table-level `null` option). This has the same effect as listing the column in `COPY`'s `FORCE_NOT_NULL` option.

`force_null`

This is a Boolean option. If true, it specifies that values of the column which match the null string are returned as `NULL` even if the value is quoted. Without this option, only unquoted values matching the null string are returned as `NULL`. This has the same effect as listing the column in `COPY`'s `FORCE_NULL` option.

`COPY`'s `FORCE_QUOTE` option is currently not supported by `file_fdw`.

These options can only be specified for a foreign table or its columns, not in the options of the `file_fdw` foreign-data wrapper, nor in the options of a server or user mapping using the wrapper.

Changing table-level options requires being a superuser or having the privileges of the role `pg_read_server_files` (to use a filename) or the role `pg_execute_server_program` (to use a program), for security reasons: only certain users should be able to control which file is read or which program is run. In principle regular users could be allowed to change the other options, but that's not supported at present.

When specifying the `program` option, keep in mind that the option string is executed by the shell. If you need to pass any arguments to the command that come from an untrusted source, you must be careful to strip or escape any characters that might have special meaning to the shell. For security reasons, it is best to use a fixed command string, or at least avoid passing any user input in it.

For a foreign table using `file_fdw`, `EXPLAIN` shows the name of the file to be read or program to be run. For a file, unless `COSTS OFF` is specified, the file size (in bytes) is shown as well.

Example F.5. Create a Foreign Table for Postgres Pro CSV Logs

One of the obvious uses for `file_fdw` is to make the Postgres Pro activity log available as a table for querying. To do this, first you must be [logging to a CSV file](#), which here we will call `pglog.csv`. First, install `file_fdw` as an extension:

```
CREATE EXTENSION file_fdw;
```

Then create a foreign server:

```
CREATE SERVER pglog FOREIGN DATA WRAPPER file_fdw;
```

Now you are ready to create the foreign data table. Using the `CREATE FOREIGN TABLE` command, you will need to define the columns for the table, the CSV file name, and its format:

```
CREATE FOREIGN TABLE pglog (  
    log_time timestamp(3) with time zone,  
    user_name text,  
    database_name text,  
    process_id integer,  
    connection_from text,  
    session_id text,  
    session_line_num bigint,  
    command_tag text,  
    session_start_time timestamp with time zone,  
    virtual_transaction_id text,  
    transaction_id bigint,  
    error_severity text,  
    sql_state_code text,  
    message text,  
    detail text,  
    hint text,  
    internal_query text,  
    internal_query_pos integer,  
    context text,  
    query text,  
    query_pos integer,  
    location text,  
    application_name text,  
    backend_type text,  
    leader_pid integer,  
    query_id bigint  
) SERVER pglog  
OPTIONS ( filename 'log/pglog.csv', format 'csv' );
```

That's it — now you can query your log directly. In production, of course, you would need to define some way to deal with log rotation.

Example F.6. Create a Foreign Table with an Option on a Column

To set the `force_null` option for a column, use the `OPTIONS` keyword.

```
CREATE FOREIGN TABLE films (  
  code char(5) NOT NULL,  
  title text NOT NULL,  
  rating text OPTIONS (force_null 'true')  
) SERVER film_server  
OPTIONS ( filename 'films/db.csv', format 'csv' );
```

F.24. fulleq — an additional equivalence operator for compatibility with Microsoft SQL Server

The `fulleq` module provides additional equivalence operator for compatibility with Microsoft SQL Server.

This module is required for 1C Enterprise support.

F.24.1. Overview

The Postgres Pro equivalence operator is defined to return NULL when both operands are NULLs. However, the Microsoft SQL Servers family traditionally defines other semantic for equivalence operator, where operator returns TRUE in the case of both nulled operands. This module provides such operator with MS SQL semantic.

F.24.2. Operator `fulleq`

The `==` operator is defined for the following data types:

- `bool`
- `bytea`
- `char`
- `name`
- `int2`
- `int4`
- `int8`
- `int2vector`
- `text`
- `oid`
- `xid`
- `cid`
- `oidvector`
- `float4`
- `float8`
- `abstime`
- `reltime`
- `macaddr`
- `inet`
- `cidr`
- `varchar`
- `date`
- `time`
- `timestamp`
- `timestampz`
- `interval`
- `timetz`

F.24.3. Authors

Teodor Sigaev <teodor@sigaev.ru>

F.25. fuzzystmatch — determine string similarities and distance

The `fuzzystmatch` module provides several functions to determine similarities and distance between strings.

Caution

At present, the `soundex`, `metaphone`, `dmetaphone`, and `dmetaphone_alt` functions do not work well with multibyte encodings (such as UTF-8). Use `daitch_mokotoff` or `levenshtein` with such data.

This module is considered “trusted”, that is, it can be installed by non-superusers who have `CREATE` privilege on the current database.

F.25.1. Soundex

The Soundex system is a method of matching similar-sounding names by converting them to the same code. It was initially used by the United States Census in 1880, 1900, and 1910. Note that Soundex is not very useful for non-English names.

The `fuzzystmatch` module provides two functions for working with Soundex codes:

`soundex(text)` returns `text`
`difference(text, text)` returns `int`

The `soundex` function converts a string to its Soundex code. The `difference` function converts two strings to their Soundex codes and then reports the number of matching code positions. Since Soundex codes have four characters, the result ranges from zero to four, with zero being no match and four being an exact match. (Thus, the function is misnamed — `similarity` would have been a better name.)

Here are some usage examples:

```
SELECT soundex('hello world!');

SELECT soundex('Anne'), soundex('Ann'), difference('Anne', 'Ann');
SELECT soundex('Anne'), soundex('Andrew'), difference('Anne', 'Andrew');
SELECT soundex('Anne'), soundex('Margaret'), difference('Anne', 'Margaret');

CREATE TABLE s (nm text);

INSERT INTO s VALUES ('john');
INSERT INTO s VALUES ('joan');
INSERT INTO s VALUES ('wobbly');
INSERT INTO s VALUES ('jack');

SELECT * FROM s WHERE soundex(nm) = soundex('john');

SELECT * FROM s WHERE difference(s.nm, 'john') > 2;
```

F.25.2. Daitch-Mokotoff Soundex

Like the original Soundex system, Daitch-Mokotoff Soundex matches similar-sounding names by converting them to the same code. However, Daitch-Mokotoff Soundex is significantly more useful for non-English names than the original system. Major improvements over the original system include:

- The code is based on the first six meaningful letters rather than four.
- A letter or combination of letters maps into ten possible codes rather than seven.
- Where two consecutive letters have a single sound, they are coded as a single number.
- When a letter or combination of letters may have different sounds, multiple codes are emitted to cover all possibilities.

This function generates the Daitch-Mokotoff soundex codes for its input:

`daitch_mokotoff(source text)` returns `text[]`

The result may contain one or more codes depending on how many plausible pronunciations there are, so it is represented as an array.

Since a Daitch-Mokotoff soundex code consists of only 6 digits, *source* should be preferably a single word or name.

Here are some examples:

```
SELECT daitch_mokotoff('George');
       daitch_mokotoff
-----
{595000}

SELECT daitch_mokotoff('John');
       daitch_mokotoff
-----
{160000,460000}

SELECT daitch_mokotoff('Bierschbach');
               daitch_mokotoff
-----
{794575,794574,794750,794740,745750,745740,747500,747400}

SELECT daitch_mokotoff('Schwartzenegger');
       daitch_mokotoff
-----
{479465}
```

For matching of single names, returned text arrays can be matched directly using the `&&` operator: any overlap can be considered a match. A GIN index may be used for efficiency, see [Section 65.4](#) and this example:

```
CREATE TABLE s (nm text);
CREATE INDEX ix_s_dm ON s USING gin (daitch_mokotoff(nm)) WITH (fastupdate = off);

INSERT INTO s (nm) VALUES
    ('Schwartzenegger'),
    ('John'),
    ('James'),
    ('Steinman'),
    ('Steinmetz');

SELECT * FROM s WHERE daitch_mokotoff(nm) && daitch_mokotoff('Swartzenegger');
SELECT * FROM s WHERE daitch_mokotoff(nm) && daitch_mokotoff('Jane');
SELECT * FROM s WHERE daitch_mokotoff(nm) && daitch_mokotoff('Jens');
```

For indexing and matching of any number of names in any order, Full Text Search features can be used. See [Chapter 12](#) and this example:

```
CREATE FUNCTION soundex_tsvector(v_name text) RETURNS tsvector
BEGIN ATOMIC
    SELECT to_tsvector('simple',
                      string_agg(array_to_string(daitch_mokotoff(n), ' '), ' '))
    FROM regexp_split_to_table(v_name, '\s+') AS n;
END;

CREATE FUNCTION soundex_tsquery(v_name text) RETURNS tsquery
BEGIN ATOMIC
    SELECT string_agg('(' || array_to_string(daitch_mokotoff(n), '|') || ')',
                      '&')::tsquery
    FROM regexp_split_to_table(v_name, '\s+') AS n;
END;
```

```
CREATE TABLE s (nm text);
CREATE INDEX ix_s_txt ON s USING gin (soundex_tsvector(nm)) WITH (fastupdate = off);

INSERT INTO s (nm) VALUES
    ('John Doe'),
    ('Jane Roe'),
    ('Public John Q.'),
    ('George Best'),
    ('John Yamson');

SELECT * FROM s WHERE soundex_tsvector(nm) @@ soundex_tsquery('john');
SELECT * FROM s WHERE soundex_tsvector(nm) @@ soundex_tsquery('jane doe');
SELECT * FROM s WHERE soundex_tsvector(nm) @@ soundex_tsquery('john public');
SELECT * FROM s WHERE soundex_tsvector(nm) @@ soundex_tsquery('besst, giorgio');
SELECT * FROM s WHERE soundex_tsvector(nm) @@ soundex_tsquery('Jameson John');
```

If it is desired to avoid recalculation of soundex codes during index rechecks, an index on a separate column can be used instead of an index on an expression. A stored generated column can be used for this; see [Section 5.4](#).

F.25.3. Levenshtein

This function calculates the Levenshtein distance between two strings:

```
levenshtein(source text, target text, ins_cost int, del_cost int, sub_cost int) returns
int
levenshtein(source text, target text) returns int
levenshtein_less_equal(source text, target text, ins_cost int, del_cost int, sub_cost
int, max_d int) returns int
levenshtein_less_equal(source text, target text, max_d int) returns int
```

Both `source` and `target` can be any non-null string, with a maximum of 255 characters. The cost parameters specify how much to charge for a character insertion, deletion, or substitution, respectively. You can omit the cost parameters, as in the second version of the function; in that case they all default to 1.

`levenshtein_less_equal` is an accelerated version of the Levenshtein function for use when only small distances are of interest. If the actual distance is less than or equal to `max_d`, then `levenshtein_less_equal` returns the correct distance; otherwise it returns some value greater than `max_d`. If `max_d` is negative then the behavior is the same as `levenshtein`.

Examples:

```
test=# SELECT levenshtein('GUMBO', 'GAMBOL');
 levenshtein
-----
          2
(1 row)

test=# SELECT levenshtein('GUMBO', 'GAMBOL', 2, 1, 1);
 levenshtein
-----
          3
(1 row)

test=# SELECT levenshtein_less_equal('extensive', 'exhaustive', 2);
 levenshtein_less_equal
-----
          3
(1 row)

test=# SELECT levenshtein_less_equal('extensive', 'exhaustive', 4);
 levenshtein_less_equal
```

```
-----  
4  
(1 row)
```

F.25.4. Metaphone

Metaphone, like Soundex, is based on the idea of constructing a representative code for an input string. Two strings are then deemed similar if they have the same codes.

This function calculates the metaphone code of an input string:

`metaphone(source text, max_output_length int)` returns text

`source` has to be a non-null string with a maximum of 255 characters. `max_output_length` sets the maximum length of the output metaphone code; if longer, the output is truncated to this length.

Example:

```
test=# SELECT metaphone('GUMBO', 4);  
metaphone  
-----  
KM  
(1 row)
```

F.25.5. Double Metaphone

The Double Metaphone system computes two “sounds like” strings for a given input string — a “primary” and an “alternate”. In most cases they are the same, but for non-English names especially they can be a bit different, depending on pronunciation. These functions compute the primary and alternate codes:

`dmetaphone(source text)` returns text

`dmetaphone_alt(source text)` returns text

There is no length limit on the input strings.

Example:

```
test=# SELECT dmetaphone('gumbo');  
dmetaphone  
-----  
KMP  
(1 row)
```

F.26. hstore — hstore key/value datatype

This module implements the `hstore` data type for storing sets of key/value pairs within a single Postgres Pro value. This can be useful in various scenarios, such as rows with many attributes that are rarely examined, or semi-structured data. Keys and values are simply text strings.

This module is considered “trusted”, that is, it can be installed by non-superusers who have `CREATE` privilege on the current database.

F.26.1. hstore External Representation

The text representation of an `hstore`, used for input and output, includes zero or more *key => value* pairs separated by commas. Some examples:

```
k => v
foo => bar, baz => whatever
"1-a" => "anything at all"
```

The order of the pairs is not significant (and may not be reproduced on output). Whitespace between pairs or around the `=>` sign is ignored. Double-quote keys and values that include whitespace, commas, `=`s or `>`s. To include a double quote or a backslash in a key or value, escape it with a backslash.

Each key in an `hstore` is unique. If you declare an `hstore` with duplicate keys, only one will be stored in the `hstore` and there is no guarantee as to which will be kept:

```
SELECT 'a=>1,a=>2'::hstore;
 hstore
-----
"a"=>"1"
```

A value (but not a key) can be an SQL `NULL`. For example:

```
key => NULL
```

The `NULL` keyword is case-insensitive. Double-quote the `NULL` to treat it as the ordinary string “`NULL`”.

Note

Keep in mind that the `hstore` text format, when used for input, applies *before* any required quoting or escaping. If you are passing an `hstore` literal via a parameter, then no additional processing is needed. But if you're passing it as a quoted literal constant, then any single-quote characters and (depending on the setting of the `standard_conforming_strings` configuration parameter) backslash characters need to be escaped correctly. See [Section 4.1.2.1](#) for more on the handling of string constants.

On output, double quotes always surround keys and values, even when it's not strictly necessary.

F.26.2. hstore Operators and Functions

The operators provided by the `hstore` module are shown in [Table F.13](#), the functions in [Table F.14](#).

Table F.13. hstore Operators

Operator	Description Example(s)
<code>hstore -> text → text</code>	Returns value associated with given key, or <code>NULL</code> if not present. <code>'a=>x, b=>y'::hstore -> 'a' → x</code>
<code>hstore -> text[] → text[]</code>	Returns values associated with given keys, or <code>NULL</code> if not present. <code>'a=>x, b=>y, c=>z'::hstore -> ARRAY['c', 'a'] → {"z", "x"}</code>
<code>hstore hstore → hstore</code>	

Operator	Description	Example(s)
	Concatenates two hstores.	'a=>b, c=>d'::hstore 'c=>x, d=>q'::hstore → "a"=>"b", "c"=>"x", "d"=>"q"
hstore ? text → boolean	Does hstore contain key?	'a=>1'::hstore ? 'a' → t
hstore ?& text[] → boolean	Does hstore contain all the specified keys?	'a=>1,b=>2'::hstore ?& ARRAY['a','b'] → t
hstore ? text[] → boolean	Does hstore contain any of the specified keys?	'a=>1,b=>2'::hstore ? ARRAY['b','c'] → t
hstore @> hstore → boolean	Does left operand contain right?	'a=>b, b=>1, c=>NULL'::hstore @> 'b=>1' → t
hstore <@ hstore → boolean	Is left operand contained in right?	'a=>c'::hstore <@ 'a=>b, b=>1, c=>NULL' → f
hstore - text → hstore	Deletes key from left operand.	'a=>1, b=>2, c=>3'::hstore - 'b'::text → "a"=>"1", "c"=>"3"
hstore - text[] → hstore	Deletes keys from left operand.	'a=>1, b=>2, c=>3'::hstore - ARRAY['a','b'] → "c"=>"3"
hstore - hstore → hstore	Deletes pairs from left operand that match pairs in the right operand.	'a=>1, b=>2, c=>3'::hstore - 'a=>4, b=>2'::hstore → "a"=>"1", "c"=>"3"
anyelement #=> hstore → anyelement	Replaces fields in the left operand (which must be a composite type) with matching values from hstore.	ROW(1,3) #=> 'f1=>11'::hstore → (11,3)
%% hstore → text[]	Converts hstore to an array of alternating keys and values.	%% 'a=>foo, b=>bar'::hstore → {a,foo,b,bar}
%# hstore → text[]	Converts hstore to a two-dimensional key/value array.	%# 'a=>foo, b=>bar'::hstore → {{a,foo},{b,bar}}

Table F.14. hstore Functions

Function	Description	Example(s)
hstore (record) → hstore	Constructs an hstore from a record or row.	

Function	Description	Example(s)
		<code>hstore(ROW(1,2)) → "f1"=>"1", "f2"=>"2"</code>
<code>hstore(text[]) → hstore</code>	Constructs an <code>hstore</code> from an array, which may be either a key/value array, or a two-dimensional array.	<code>hstore(ARRAY['a','1','b','2']) → "a"=>"1", "b"=>"2"</code> <code>hstore(ARRAY[['c','3'],['d','4']]) → "c"=>"3", "d"=>"4"</code>
<code>hstore(text[],text[]) → hstore</code>	Constructs an <code>hstore</code> from separate key and value arrays.	<code>hstore(ARRAY['a','b'], ARRAY['1','2']) → "a"=>"1", "b"=>"2"</code>
<code>hstore(text,text) → hstore</code>	Makes a single-item <code>hstore</code> .	<code>hstore('a','b') → "a"=>"b"</code>
<code>akeys(hstore) → text[]</code>	Extracts an <code>hstore</code> 's keys as an array.	<code>akeys('a=>1,b=>2') → {a,b}</code>
<code>skeys(hstore) → setof text</code>	Extracts an <code>hstore</code> 's keys as a set.	<code>skeys('a=>1,b=>2') →</code> <code>a</code> <code>b</code>
<code>avals(hstore) → text[]</code>	Extracts an <code>hstore</code> 's values as an array.	<code>avals('a=>1,b=>2') → {1,2}</code>
<code>svals(hstore) → setof text</code>	Extracts an <code>hstore</code> 's values as a set.	<code>svals('a=>1,b=>2') →</code> <code>1</code> <code>2</code>
<code>hstore_to_array(hstore) → text[]</code>	Extracts an <code>hstore</code> 's keys and values as an array of alternating keys and values.	<code>hstore_to_array('a=>1,b=>2') → {a,1,b,2}</code>
<code>hstore_to_matrix(hstore) → text[]</code>	Extracts an <code>hstore</code> 's keys and values as a two-dimensional array.	<code>hstore_to_matrix('a=>1,b=>2') → {{a,1},{b,2}}</code>
<code>hstore_to_json(hstore) → json</code>	Converts an <code>hstore</code> to a <code>json</code> value, converting all non-null values to JSON strings. This function is used implicitly when an <code>hstore</code> value is cast to <code>json</code> .	<code>hstore_to_json('a key=>1, b=>t, c=>null, d=>12345, e=>012345, f=>1.234, g=>2.345e+4') → {"a key": "1", "b": "t", "c": null, "d": "12345", "e": "012345", "f": "1.234", "g": "2.345e+4"}</code>
<code>hstore_to_jsonb(hstore) → jsonb</code>	Converts an <code>hstore</code> to a <code>jsonb</code> value, converting all non-null values to JSON strings.	

Function	Description Example(s)						
	This function is used implicitly when an <code>hstore</code> value is cast to <code>jsonb</code>. <pre>hstore_to_jsonb('"a key"=>1, b=>t, c=>null, d=>12345, e=>012345, f=>1.234, g=>2.345e+4') → {"a key": "1", "b": "t", "c": null, "d": "12345", "e": "012345", "f": "1.234", "g": "2.345e+4"}</pre>						
<code>hstore_to_json_loose(hstore) → json</code>	Converts an <code>hstore</code> to a <code>json</code> value, but attempts to distinguish numerical and Boolean values so they are unquoted in the JSON. <pre>hstore_to_json_loose('"a key"=>1, b=>t, c=>null, d=>12345, e=>012345, f=>1.234, g=>2.345e+4') → {"a key": 1, "b": true, "c": null, "d": 12345, "e": "012345", "f": 1.234, "g": 2.345e+4}</pre>						
<code>hstore_to_jsonb_loose(hstore) → jsonb</code>	Converts an <code>hstore</code> to a <code>jsonb</code> value, but attempts to distinguish numerical and Boolean values so they are unquoted in the JSON. <pre>hstore_to_jsonb_loose('"a key"=>1, b=>t, c=>null, d=>12345, e=>012345, f=>1.234, g=>2.345e+4') → {"a key": 1, "b": true, "c": null, "d": 12345, "e": "012345", "f": 1.234, "g": 2.345e+4}</pre>						
<code>slice(hstore, text[]) → hstore</code>	Extracts a subset of an <code>hstore</code> containing only the specified keys. <pre>slice('a=>1,b=>2,c=>3':hstore, ARRAY['b', 'c', 'x']) → "b"=>"2", "c"=>"3"</pre>						
<code>each(hstore) → setof record(key text, value text)</code>	Extracts an <code>hstore</code>'s keys and values as a set of records. <pre>select * from each('a=>1,b=>2') →</pre> <table> <thead> <tr> <th>key</th><th>value</th></tr> </thead> <tbody> <tr> <td>a</td><td>1</td></tr> <tr> <td>b</td><td>2</td></tr> </tbody> </table>	key	value	a	1	b	2
key	value						
a	1						
b	2						
<code>exist(hstore, text) → boolean</code>	Does <code>hstore</code> contain key? <pre>exist('a=>1', 'a') → t</pre>						
<code>defined(hstore, text) → boolean</code>	Does <code>hstore</code> contain a non-NULL value for key? <pre>defined('a=>NULL', 'a') → f</pre>						
<code>delete(hstore, text) → hstore</code>	Deletes pair with matching key. <pre>delete('a=>1,b=>2', 'b') → "a"=>"1"</pre>						
<code>delete(hstore, text[]) → hstore</code>	Deletes pairs with matching keys. <pre>delete('a=>1,b=>2,c=>3', ARRAY['a', 'b']) → "c"=>"3"</pre>						
<code>delete(hstore, hstore) → hstore</code>	Deletes pairs matching those in the second argument. <pre>delete('a=>1,b=>2', 'a=>4,b=>2':hstore) → "a"=>"1"</pre>						
<code>populate_record(anyelement, hstore) → anyelement</code>	Replaces fields in the left operand (which must be a composite type) with matching values from <code>hstore</code>.						

Function	Description	Example(s)
		<code>populate_record(ROW(1,2), 'f1=>42'::hstore) → (42,2)</code>

In addition to these operators and functions, values of the `hstore` type can be subscripted, allowing them to act like associative arrays. Only a single subscript of type `text` can be specified; it is interpreted as a key and the corresponding value is fetched or stored. For example,

```
CREATE TABLE mytable (h hstore);
INSERT INTO mytable VALUES ('a=>b, c=>d');
SELECT h['a'] FROM mytable;
  h
---
  b
(1 row)
```

```
UPDATE mytable SET h['c'] = 'new';
SELECT h FROM mytable;
      h
-----
"a"=>"b", "c"=>"new"
(1 row)
```

A subscripted fetch returns `NULL` if the subscript is `NULL` or that key does not exist in the `hstore`. (Thus, a subscripted fetch is not greatly different from the `->` operator.) A subscripted update fails if the subscript is `NULL`; otherwise, it replaces the value for that key, adding an entry to the `hstore` if the key does not already exist.

F.26.3. Indexes

`hstore` has GiST and GIN index support for the `@>`, `?`, `?&` and `?|` operators. For example:

```
CREATE INDEX hidx ON testhstore USING GIST (h);

CREATE INDEX hidx ON testhstore USING GIN (h);
```

`gist_hstore_ops` GiST opclass approximates a set of key/value pairs as a bitmap signature. Its optional integer parameter `siglen` determines the signature length in bytes. The default length is 16 bytes. Valid values of signature length are between 1 and 2024 bytes. Longer signatures lead to a more precise search (scanning a smaller fraction of the index and fewer heap pages), at the cost of a larger index.

Example of creating such an index with a signature length of 32 bytes:

```
CREATE INDEX hidx ON testhstore USING GIST (h gist_hstore_ops(siglen=32));
```

`hstore` also supports `btree` or `hash` indexes for the `=` operator. This allows `hstore` columns to be declared `UNIQUE`, or to be used in `GROUP BY`, `ORDER BY` or `DISTINCT` expressions. The sort ordering for `hstore` values is not particularly useful, but these indexes may be useful for equivalence lookups. Create indexes for `=` comparisons as follows:

```
CREATE INDEX hidx ON testhstore USING BTREE (h);

CREATE INDEX hidx ON testhstore USING HASH (h);
```

F.26.4. Examples

Add a key, or update an existing key with a new value:

```
UPDATE tab SET h['c'] = '3';
```

Another way to do the same thing is:

```
UPDATE tab SET h = h || hstore('c', '3');
```

If multiple keys are to be added or changed in one operation, the concatenation approach is more efficient than subscripting:

```
UPDATE tab SET h = h || hstore(array['q', 'w'], array['11', '12']);
```

Delete a key:

```
UPDATE tab SET h = delete(h, 'k1');
```

Convert a record to an `hstore`:

```
CREATE TABLE test (col1 integer, col2 text, col3 text);
INSERT INTO test VALUES (123, 'foo', 'bar');
```

```
SELECT hstore(t) FROM test AS t;
           hstore
-----
"col1"=>"123", "col2"=>"foo", "col3"=>"bar"
(1 row)
```

Convert an `hstore` to a predefined record type:

```
CREATE TABLE test (col1 integer, col2 text, col3 text);

SELECT * FROM populate_record(null::test,
                               '"col1"=>"456", "col2"=>"zzz"');
 col1 | col2 | col3
-----+-----+-----
  456 | zzz  |
(1 row)
```

Modify an existing record using the values from an `hstore`:

```
CREATE TABLE test (col1 integer, col2 text, col3 text);
INSERT INTO test VALUES (123, 'foo', 'bar');

SELECT (r).* FROM (SELECT t #= '"col3"=>"baz"' AS r FROM test t) s;
 col1 | col2 | col3
-----+-----+-----
  123 | foo  | baz
(1 row)
```

F.26.5. Statistics

The `hstore` type, because of its intrinsic liberality, could contain a lot of different keys. Checking for valid keys is the task of the application. The following examples demonstrate several techniques for checking keys and obtaining statistics.

Simple example:

```
SELECT * FROM each('aaa=>bq, b=>NULL, ""=>1');
```

Using a table:

```
CREATE TABLE stat AS SELECT (each(h)).key, (each(h)).value FROM testhstore;
```

Online statistics:

```
SELECT key, count(*) FROM
  (SELECT (each(h)).key FROM testhstore) AS stat
GROUP BY key
ORDER BY count DESC, key;
   key   | count
-----+-----
line     |    883
query    |    207
```

<code>pos</code>		203
<code>node</code>		202
<code>space</code>		197
<code>status</code>		195
<code>public</code>		194
<code>title</code>		190
<code>org</code>		189
.....		

F.26.6. Compatibility

As of PostgreSQL 9.0, `hstore` uses a different internal representation than previous versions. This presents no obstacle for dump/restore upgrades since the text representation (used in the dump) is unchanged.

In the event of a binary upgrade, upward compatibility is maintained by having the new code recognize old-format data. This will entail a slight performance penalty when processing data that has not yet been modified by the new code. It is possible to force an upgrade of all values in a table column by doing an `UPDATE` statement as follows:

```
UPDATE tablename SET hstorecol = hstorecol || '';
```

Another way to do it is:

```
ALTER TABLE tablename ALTER hstorecol TYPE hstore USING hstorecol || '';
```

The `ALTER TABLE` method requires an `ACCESS EXCLUSIVE` lock on the table, but does not result in bloating the table with old row versions.

F.26.7. Transforms

Additional extensions are available that implement transforms for the `hstore` type for the languages PL/Perl and PL/Python. The extensions for PL/Perl are called `hstore_plperl` and `hstore_plperl_u`, for trusted and untrusted PL/Perl. If you install these transforms and specify them when creating a function, `hstore` values are mapped to Perl hashes. The extension for PL/Python is called `hstore_plpython3u`. If you use it, `hstore` values are mapped to Python dictionaries.

Caution

It is strongly recommended that the transform extensions be installed in the same schema as `hstore`. Otherwise there are installation-time security hazards if a transform extension's schema contains objects defined by a hostile user.

F.26.8. Authors

Oleg Bartunov <oleg@sai.msu.su>, Moscow, Moscow University, Russia

Teodor Sigaev <teodor@sigaev.ru>, Moscow, Delta-Soft Ltd., Russia

Additional enhancements by Andrew Gierth <andrew@tao11.riddles.org.uk>, United Kingdom

F.27. Hunspell Dictionaries Modules

These modules provide Hunspell dictionaries for various languages. Upon installation of the module into database using CREATE EXTENSION command, text search dictionary and configuration objects in the public schema appear.

Table F.15. Modules

Language	Extension name	Dictionary name	Configuration name
American English	hunspell_en_us	english_hunspell	english_hunspell
Dutch	hunspell_nl_nl	dutch_hunspell	dutch_hunspell
French	hunspell_fr	french_hunspell	french_hunspell
Russian	hunspell_ru_ru	russian_hunspell	russian_hunspell

F.27.1. Examples

Text search objects will be created after installation of a dictionary module. We can test created configuration:

```
SELECT * FROM ts_debug('english_hunspell', 'abilities');
  alias | description | token | dictionaries |
  dictionary | lexemes
-----+-----+-----+-----+-----
+-----+-----+-----+-----+-----
asciword | Word, all ASCII | abilities | {english_hunspell,english_stem} |
english_hunspell | {ability}
(1 row)
```

Or you can create your own text search configuration. For example, with the created dictionaries and with the Snowball dictionary you can create mixed russian-english configuration:

```
CREATE TEXT SEARCH CONFIGURATION russian_en (
  COPY = simple
);

ALTER TEXT SEARCH CONFIGURATION russian_en
  ALTER MAPPING FOR asciword, asciihword, hword_asciipart
  WITH english_hunspell, english_stem;

ALTER TEXT SEARCH CONFIGURATION russian_en
  ALTER MAPPING FOR word, hword, hword_part
  WITH russian_hunspell, russian_stem;
```

You can create mixed dictionaries only for languages with different alphabets. If languages have similar alphabets then Postgres Pro can not decide which dictionary should be used.

A text search configuration which is created with a dictionary module is ready to use. For example, in this text you can search some words:

```
SELECT to_tsvector('english_hunspell', 'The blue whale is the largest animal');
      to_tsvector
-----
'animal':7 'blue':2 'large':6 'whale':3
(1 row)
```

Search query might looks like this:

```
SELECT to_tsvector('english_hunspell', 'The blue whale is the largest animal')
  @@ to_tsquery('english_hunspell', 'large & whale');
?column?
-----
t
```

(1 row)

With this configurations you can search a text using GIN or GIST indexes. For example, there is a table with GIN index:

```
CREATE TABLE table1 (t varchar);
INSERT INTO table1 VALUES ('The blue whale is the largest animal');
CREATE INDEX t_idx ON table1 USING GIN (to_tsvector('english_hunspell', "t"));
```

For this table you can execute the following query:

```
SELECT * FROM table1 where to_tsvector('english_hunspell', t)
    @@ to_tsquery('english_hunspell', 'blue & animal');
      t
```

```
-----
The blue whale is the largest animal
(1 row)
```

F.28. hypopg — support for hypothetical indexes

F.28.1. Description

hypopg is a Postgres Pro extension, adding support for *hypothetical indexes*.

A hypothetical, or virtual, index is an index that does not really exist, and therefore does not cost CPU, disk, or any resource to create. They are useful to find out whether specific indexes can increase the performance for problematic queries, since you can discover if Postgres Pro will use these indexes or not without having to spend resources to create them.

F.28.2. Installation

The hypopg extension is provided with Postgres Pro as a separate pre-built package `hypopg-ent-16` (for the detailed installation instructions, see [Chapter 17](#)). Once you have Postgres Pro installed, create the hypopg extension:

```
CREATE EXTENSION hypopg;
```

hypopg is now available. You can check easily if the extension is present using `psql`:

```
\dx
      List of installed extensions
  Name | Version | Schema | Description
-----+-----+-----+-----
hypopg | 1.4.1   | public | Hypothetical indexes for Postgres Pro
plpgsql | 1.0     | pg_catalog | PL/pgSQL procedural language
(2 rows)
```

As you can see, hypopg is installed.

F.28.3. Functions

hypopg is useful if you want to check if some index would help one or multiple queries. Therefore, you should already know what are the queries you need to optimize, and ideas on which indexes you want to try.

Also, the hypothetical indexes that hypopg will create are not stored in any catalog, but in your connection private memory. Therefore, it won't bloat any table and won't impact any concurrent connection.

Moreover, since the hypothetical indexes don't really exist, hypopg makes sure they will only be using a simple `EXPLAIN` statement (without the `ANALYZE` option).

The following access methods are supported:

- `btree`
- `brin`
- `hash`
- `bloom` (requires the [bloom](#) extension to be installed)

Note

Using hypopg requires some knowledge on the [EXPLAIN](#) command.

F.28.3.1. Create a Hypothetical Index

```
hypopg_create_index()
```

For clarity, let's see how it works with a very simple test case:

```
CREATE TABLE hypo (id integer, val text) ;
INSERT INTO hypo SELECT i, 'line ' || i FROM generate_series(1, 100000) i ;
VACUUM ANALYZE hypo ;
```

This table doesn't have any index. Let's assume we want to check if an index would help a simple query. First, let's see how it behaves:

```
EXPLAIN SELECT val FROM hypo WHERE id = 1;
               QUERY PLAN
-----
Seq Scan on hypo  (cost=0.00..1791.00 rows=1 width=14)
  Filter: (id = 1)
(2 rows)
```

A plain sequential scan is used, since no index exists on the table. A simple btree index on the `id` column should help this query. Let's check with `hypopg`. The function `hypopg_create_index()` will accept any standard `CREATE INDEX` statement(s) (any other statement passed to this function will be ignored), and create a hypothetical index for each:

```
SELECT * FROM hypopg_create_index('CREATE INDEX ON hypo (id)') ;
 indexrelid |      indexname
-----+-----
      18284 | <18284>btree_hypo_id
(1 row)
```

The function returns two columns:

- the object identifier of the hypothetical index
- the generated hypothetical index name

We can run the `EXPLAIN` again to see if Postgres Pro would use this index:

```
EXPLAIN SELECT val FROM hypo WHERE id = 1;
               QUERY PLAN
-----
Index Scan using <18284>btree_hypo_id on hypo  (cost=0.04..8.06 rows=1 width=10)
  Index Cond: (id = 1)
(2 rows)
```

Yes, Postgres Pro would use such an index. Just to be sure, let's check that the hypothetical index won't be used to actually run the query:

```
EXPLAIN ANALYZE SELECT val FROM hypo WHERE id = 1;
               QUERY PLAN
-----
Seq Scan on hypo  (cost=0.00..1791.00 rows=1 width=10) (actual time=0.046..46.390
rows=1 loops=1)
  Filter: (id = 1)
  Rows Removed by Filter: 99999
Planning time: 0.160 ms
Execution time: 46.460 ms
(5 rows)
```

That's all you need to create hypothetical indexes and see if Postgres Pro would use such indexes.

F.28.3.2. Manipulate Hypothetical Indexes

The `hypopg_list_indexes` view lists all hypothetical indexes that have been created.

```
SELECT * FROM hypopg_list_indexes ;
 indexrelid |      index_name      | schema_name | table_name | am_name
-----+-----+-----+-----+-----
      18284 | <18284>btree_hypo_id | public      | hypo       | btree
(1 row)

hypopg()
```

`hypopg()` lists all hypothetical indexes that have been created with the same format as `pg_index`.

```
SELECT * FROM hypopg() ;
      indexname      | indexrelid | indrelid | innatts | indisunique | indkey |
      indcollation   | indclass  | indooption | indexprs | indpred     | amid
-----+-----+-----+-----+-----+-----+-----
<18284>btree_hypo_id |      13543 |      18122 |        1 | f           | 1      | 0
      | 1978      | <NULL>      | <NULL>      | <NULL>      | 403
(1 row)
```

`hypopg_get_indexdef(oid)`

`hypopg_get_indexdef(oid)` lists the `CREATE INDEX` statements that would recreate a stored hypothetical index.

```
SELECT index_name, hypopg_get_indexdef(indexrelid) FROM hypopg_list_indexes ;
      index_name      |      hypopg_get_indexdef
-----+-----
<18284>btree_hypo_id | CREATE INDEX ON public.hypo USING btree (id)
(1 row)
```

`hypopg_relation_size(oid)`

`hypopg_relation_size(oid)` estimates how big a hypothetical index would be:

```
SELECT index_name, pg_size_pretty(hypopg_relation_size(indexrelid))
FROM hypopg_list_indexes ;
      index_name      | pg_size_pretty
-----+-----
<18284>btree_hypo_id | 2544 kB
(1 row)
```

`hypopg_drop_index(oid)`

`hypopg_drop_index(oid)` removes the given hypothetical index.

`hypopg_reset()`

`hypopg_reset()` removes all hypothetical indexes.

F.28.3.3. Hypothetically Hide Existing Indexes

`hypopg_hide_index(oid)`

You can hide both existing and hypothetical indexes hypothetically. If you want to test it as described in the documentation, you should first use `hypopg_reset()` to clear the effects of any other hypothetical indexes.

As a simple case, let's consider two indexes:

```
SELECT hypopg_reset();
CREATE INDEX ON hypo(id);
CREATE INDEX ON hypo(id, val);
EXPLAIN SELECT * FROM hypo WHERE id = 1;
          QUERY PLAN
```

```
-----+-----
Index Only Scan using hypo_id_val_idx on hypo (cost=0.29..8.30 rows=1 width=13)
Index Cond: (id = 1)
(2 rows)
```

The query plan is using the `hypo_id_val_idx` index now.

`hypopg_hide_index(oid)` allows you to hide an index in the `EXPLAIN` output by using its OID. It returns true if the index was successfully hidden, and false otherwise.

```
SELECT hypopg_hide_index('hypo_id_val_idx'::REGCLASS);
hypopg_hide_index
```

```
-----
t
(1 row)
```

```
EXPLAIN SELECT * FROM hypo WHERE id = 1;
          QUERY PLAN
```

```
-----
Index Scan using hypo_id_idx on hypo  (cost=0.29..8.30 rows=1 width=13)
Index Cond: (id = 1)
(2 rows)
```

As an example, let's assume that the query plan is currently using the `hypo_id_val_idx` index. To continue testing, use the `hypopg_hide_index(oid)` function to hide another index.

```
SELECT hypopg_hide_index('hypo_id_idx'::REGCLASS);
 hypopg_hide_index
```

```
-----
t
(1 row)
```

```
EXPLAIN SELECT * FROM hypo WHERE id = 1;
          QUERY PLAN
```

```
-----
Seq Scan on hypo  (cost=0.00..180.00 rows=1 width=13)
Filter: (id = 1)
(2 rows)
```

`hypopg_unhide_index(oid)`

`hypopg_unhide_index(oid)` restores a previously hidden index in the `EXPLAIN` output by using its OID. It returns true if the index was successfully restored, and false otherwise.

```
SELECT hypopg_unhide_index('hypo_id_idx'::regclass);
 hypopg_unhide_index
```

```
-----
t
(1 row)
```

```
EXPLAIN SELECT * FROM hypo WHERE id = 1;
          QUERY PLAN
```

```
-----
Index Scan using hypo_id_idx on hypo  (cost=0.29..8.30 rows=1 width=13)
Index Cond: (id = 1)
(2 rows)
```

`hypopg_unhide_all_index(oid)`

`hypopg_unhide_all_index()` restores all hidden indexes and returns void.

`hypopg_hidden_indexes()`

`hypopg_hidden_indexes()` returns a list of OIDs for all hidden indexes.

```
SELECT * FROM hypopg_hidden_indexes();
 indexid
```

```
-----
526604
(1 rows)
```

The `hypopg_hidden_indexes` view returns a formatted list of all hidden indexes.

```
SELECT * FROM hypopg_hidden_indexes;
```

indexrelid	index_name	schema_name	table_name	am_name	is_hypo
526604	hypo_id_val_idx	public	hypo	btree	f

(1 rows)

Note

Hypothetical indexes can be hidden as well.

```
SELECT hypopg_create_index('CREATE INDEX ON hypo(id)');
hypopg_create_index
```

```
-----
(12659,<12659>btree_hypo_id)
(1 row)
```

```
EXPLAIN SELECT * FROM hypo WHERE id = 1;
               QUERY PLAN
```

```
-----
Index Scan using "<12659>btree_hypo_id" on hypo  (cost=0.04..8.05 rows=1 width=13)
Index Cond: (id = 1)
(2 rows)
```

Now that the hypothetical index is being used, we can try hiding it to see the change:

```
SELECT hypopg_hide_index(12659);
hypopg_hide_index
```

```
-----
t
(1 row)
```

```
EXPLAIN SELECT * FROM hypo WHERE id = 1;
               QUERY PLAN
```

```
-----
Index Scan using hypo_id_idx on hypo  (cost=0.29..8.30 rows=1 width=13)
Index Cond: (id = 1)
(2 rows)
```

```
SELECT * FROM hypopg_hidden_indexes;
```

indexrelid	index_name	schema_name	table_name	am_name	is_hypo
12659	<12659>btree_hypo_id	public	hypo	btree	t
526604	hypo_id_val_idx	public	hypo	btree	f

(2 rows)

Note

If a hypothetical index has been hidden, it will be automatically unhidden when it is deleted using `hypopg_drop_index(oid)` or `hypopg_reset()`.

```
SELECT hypopg_drop_index(12659);
```

```
SELECT * FROM hypopg_hidden_indexes;
```

indexrelid	index_name	schema_name	table_name	am_name	is_hypo
526604	hypo_id_val_idx	public	hypo	btree	f

(2 rows)

F.28.4. GUC Parameters

The following configuration parameters (GUCs) are available, and can be changed interactively:

`hypopg.enabled`

Defaults to `on`. Use this parameter to globally enable or disable `hypopg`. When `hypopg` is disabled, no hypothetical index will be used, but the defined hypothetical indexes won't be removed.

`hypopg.use_real_oids`

Defaults to `off`. By default, `hypopg` won't use "real" object identifiers, but instead borrow ones from the $\sim 14000 / 16384$ (respectively the lowest unused OID less than `FirstNormalObjectId` and `FirstNormalObjectId`) range, which are reserved by Postgres Pro for future usage in future releases. This doesn't cause any problem, as the free range is dynamically computed the first time a connection uses `hypopg`, and has the advantage to work on a standby server. But the drawback is that you can't have more than approximately 2500 hypothetical indexes at the same time, and creating a new hypothetical index will become very slow once more than the maximum number of objects has been created until `hypopg_reset()` is called.

If those drawbacks are problematic, you can enable this parameter. `hypopg` will then ask for a real object identifier, which will need to obtain more locks and won't work on a standby, but will allow using the full range of object identifiers.

Note that switching this parameter doesn't require resetting the entries, both can coexist at the same time.

F.29. `in_memory` — store data in shared memory using tables implemented via FDW

The `in_memory` extension enables you to store data in Postgres Pro shared memory using in-memory tables implemented via foreign data wrappers (FDW).

Note

This extension cannot be used together with prepared transactions.

In-memory tables are *index-organized* — table rows are stored in leaf pages of the B-tree index defined on the primary key for the table. This solution offers the following benefits:

- Fast random access on the primary key. This can result in significant performance benefits when working with data that requires a very high read and write access rate, especially on multi-core systems.
- Effective space usage. There is no primary key duplication as all data is stored directly in the index.

In-memory tables support transactions, including savepoints. However, the data in such tables is stored only while the server is running. Once the server is shut down, all in-memory data gets truncated. When using in-memory tables, you should also take into account the following restrictions:

- Persistence, WAL, and data replication are currently not supported for in-memory tables.
- Secondary indexes are not supported.
- Isolation levels are supported up to `REPEATABLE READ`. `SERIALIZABLE` isolation level is not supported. `REPEATABLE READ` level is used instead.
- In-memory tables do not support TOAST or any other mechanism for storing big tuples. Since the in-memory page size is 1 kB, and the B-tree index requires at least three tuples in a page, the maximum row length is limited to 304 bytes.
- When a row is deleted from an in-memory table, the corresponding data page is not freed. See [Section F.29.2.3](#) for details.

F.29.1. Installation and Setup

To enable in-memory tables for your cluster:

1. Make sure that the `postgres_fdw` module is enabled.
2. Add the `in_memory` value to the `shared_preload_libraries` variable in the `postgresql.conf` file:
`shared_preload_libraries = 'in_memory'`
3. Create the `in_memory` extension using the following statement:

```
CREATE EXTENSION in_memory;
```

As a result, the `in_memory` foreign server is created, and a separate shared memory pool is allocated for in-memory tables, with pre-created pages for storing in-memory data. For in-memory tables, smaller locality is required for effective memory access, as compared to hard drives or SSD, so in-memory page size is 1 kB only. Once the extension is created, you can start using in-memory tables as explained in [Section F.29.2](#).

Tip

If required, you can increase the memory size allocated for in-memory tables. For details, see [Section F.29.2.6](#).

F.29.2. Usage

F.29.2.1. Creating In-Memory Tables

To add an in-memory table to your database, create a foreign table on the `in_memory` server, using the regular `CREATE FOREIGN TABLE` syntax. By default, a unique B-tree index is built upon the first column, in the ascending order. If required, you can use the `INDICES` option in the `OPTIONS` clause to define a different B-tree index structure, as follows:

```
OPTIONS ( INDICES '[ UNIQUE ] {column [ COLLATE collation ] [ASC | DESC] } [, ... ]' )
```

where *column* is the column to include into the B-tree index, and *collation* is the name of the collation to use for this column. You can specify up to eight arbitrary columns separated by commas, with sorting options defined for each of these columns (COLLATE, ASC/DESC). The `UNIQUE` declares the created index unique, reiterating the default behavior.

All columns to be used in the B-tree index must be of a type for which the default B-tree operator class is available. For details on operator classes, see [Section 11.10](#).

Examples

Create an in-memory table `blog_views` to store statistics on blog views based on blog post IDs, with the unique B-tree index built upon the first column, in the ascending order:

```
CREATE FOREIGN TABLE blog_views
(
    id int8 NOT NULL,
    author text,
    views bigint NOT NULL
) SERVER in_memory
OPTIONS (INDICES 'UNIQUE (id)');
```

Define the B-tree index on the `id` and `author` columns, with the `author` values sorted in the ascending order using `"ru_RU"` collation:

```
CREATE FOREIGN TABLE blog_views
(
    id int8 NOT NULL,
    author text,
    views bigint NOT NULL
) SERVER in_memory
OPTIONS (INDICES '(id, author COLLATE "ru_RU" ASC)');
```

F.29.2.2. Running Queries on In-Memory Tables

Once an in-memory table is created, you can run all the main DML operations on this table: `SELECT`, `INSERT`, `UPDATE`, `DELETE`.

If you use the primary key as the scan qualifier when running queries, a key lookup or range scan is performed. Otherwise, a full index scan is required.

Examples

Fill the `blog_views` table with initial zero values for initial ten blog posts:

```
postgres=# INSERT INTO blog_views (SELECT id, 0 FROM generate_series(1, 10) AS id);
```

Increment the view count for a couple of posts and display the result:

```
postgres=# UPDATE blog_views SET views = views + 1 WHERE id = 1;
UPDATE 1
postgres=# UPDATE blog_views SET views = views + 1 WHERE id = 1;
UPDATE 2
postgres=# UPDATE blog_views SET views = views + 1 WHERE id = 2;
UPDATE 1
postgres=# SELECT * FROM blog_views WHERE id = 1 OR id = 2;
 id | views
-----+-----
  1 |    2
  2 |    1
(2 rows)
```

Check planning and execution costs for a query that only requires a primary key lookup:

```
postgres=# EXPLAIN ANALYZE SELECT * FROM blog_views WHERE id = 1;
```

QUERY PLAN

```
-----
Foreign Scan on blog_views (cost=0.02..0.03 rows=1 width=16)
(actual time=0.013..0.014 rows=1 loops=1)
  Pk conds: (id = 1)
Planning time: 0.060 ms
Execution time: 0.035 ms
(4 rows)
```

Check the costs of calculating the sum of all views, which requires a full index scan:

```
postgres=# EXPLAIN ANALYZE SELECT SUM(views) FROM blog_views;
               QUERY PLAN
```

```
-----
Aggregate (cost=1.62..1.63 rows=1 width=32)
(actual time=0.323..0.323 rows=1 loops=1)
Foreign Scan on blog_views (cost=0.02..1.30 rows=128 width=8)
(actual time=0.005..0.168 rows=1000 loops=1)
Planning time: 0.113 ms
Execution time: 0.353 ms
(4 rows)
```

F.29.2.3. Deleting In-Memory Data

When a row is deleted from an in-memory table, data pages are not freed. To free the pages occupied by in-memory tables, you can:

- Delete the table using the `DROP FOREIGN TABLE` command.
- Truncate the table using the `TRUNCATE` command.

`RESTART IDENTITY`, `CONTINUE IDENTITY`, `CASCADE`, and `RESTRICT` options of the `TRUNCATE` command are not supported by in-memory tables.

F.29.2.4. Writing Data to In-Memory Tables on Hot Standby

In some cases, it can be useful to perform write operations on hot standby servers. For example, suppose you need to collect statistics on queries run on hot standby. Since in-memory tables are writable, you can use them for such purposes.

To set up in-memory tables for write queries on standby, create the required in-memory tables on the primary server as explained in [Section F.29.2.1](#). Once the replication is complete, you can start writing data to these tables on hot standby.

Important

If the hot standby server is restarted, all the data stored in its in-memory tables gets truncated. You can continue writing data to the same in-memory tables, but all the previously stored data will be lost.

F.29.2.5. Getting Statistics on In-Memory Tables

To get statistics on in-memory pages available in your cluster, run the `in_memory_page_stats` function, which returns the number of all used and free in-memory pages, as well as the total number of pages allocated for in-memory tables. For example:

```
postgres=# SELECT * FROM in_memory.in_memory_page_stats();
 busy_pages | free_pages | all_pages
-----+-----+-----
          576 |          7616 |          8192
(1 row)
```

F.29.2.6. Fine-Tuning Memory Settings

F.29.2.6.1. Increasing Shared Memory Pool for In-Memory Tables

In-memory tables are stored in a separate shared memory segment. Its size is defined by the `in_memory.shared_pool_size` parameter. By default, this memory segment is limited to 8 MB.

If the data to be stored in in-memory tables exceeds the size of the allocated memory segment, the following error occurs:

ERROR: failed to get a new page: shared pool size is exceeded

To avoid such issues, you can increase the `in_memory.shared_pool_size` value, or limit the size of the stored data. Changing the shared pool size requires a server restart.

F.29.2.6.2. Managing the Undo Log

To enable multi-version concurrency control (MVCC), the `in_memory` module uses the *undo log* — a shared-memory ring buffer that stores the previous versions of data entries and pages. The size of the undo log is defined by the `in_memory.undo_size` parameter and is limited to 1 MB by default. If a buffer overflow occurs before a transaction is complete, the following error is returned:

ERROR: failed to add undo record: undo size is exceeded

To avoid this issue, you can increase the `in_memory.undo_size` value, or split the transactions into smaller ones.

If the required version of the entry or page has already been overwritten in the undo log when it is accessed for read, the following error occurs:

ERROR: snapshot is outdated

In this case, you can:

- Increase the `in_memory.undo_size` value. Changing this parameter requires a server restart.
- Ensure that the undo log is not truncated while the snapshot is in use. To achieve this, you can use the `READ COMMITTED` isolation level, or split a complex query into several smaller ones.

F.29.3. Reference

F.29.3.1. Configuration Variables

`in_memory.shared_pool_size` (integer)

Defines the size of the shared memory segment allocated for in-memory tables.

Default: 8MB

`in_memory.undo_size` (integer)

Defines the size of the undo log.

Default: 1MB

F.29.3.2. Functions

`in_memory.in_memory_page_stats()`

Displays statistics on pages of in-memory tables:

- `busy_pages` — in-memory pages containing any data.
- `free_pages` — empty in-memory pages. This number includes all the initially allocated pages to which no data has been written yet, as well as the pages from which all data has been deleted.
- `all_pages` — the total number of in-memory pages allocated on this server.

F.29.4. Authors

Postgres Professional, Moscow, Russia

F.30. intagg — integer aggregator and enumerator

The `intagg` module provides an integer aggregator and an enumerator. `intagg` is now obsolete, because there are built-in functions that provide a superset of its capabilities. However, the module is still provided as a compatibility wrapper around the built-in functions.

F.30.1. Functions

The aggregator is an aggregate function `int_array_aggregate(integer)` that produces an integer array containing exactly the integers it is fed. This is a wrapper around `array_agg`, which does the same thing for any array type.

The enumerator is a function `int_array_enum(integer[])` that returns `setof integer`. It is essentially the reverse operation of the aggregator: given an array of integers, expand it into a set of rows. This is a wrapper around `unnest`, which does the same thing for any array type.

F.30.2. Sample Uses

Many database systems have the notion of a many to many table. Such a table usually sits between two indexed tables, for example:

```
CREATE TABLE left_table (id INT PRIMARY KEY, ...);
CREATE TABLE right_table (id INT PRIMARY KEY, ...);
CREATE TABLE many_to_many(id_left INT REFERENCES left_table,
                           id_right INT REFERENCES right_table);
```

It is typically used like this:

```
SELECT right_table.*
FROM right_table JOIN many_to_many ON (right_table.id = many_to_many.id_right)
WHERE many_to_many.id_left = item;
```

This will return all the items in the right hand table for an entry in the left hand table. This is a very common construct in SQL.

Now, this methodology can be cumbersome with a very large number of entries in the `many_to_many` table. Often, a join like this would result in an index scan and a fetch for each right hand entry in the table for a particular left hand entry. If you have a very dynamic system, there is not much you can do. However, if you have some data which is fairly static, you can create a summary table with the aggregator.

```
CREATE TABLE summary AS
  SELECT id_left, int_array_aggregate(id_right) AS rights
  FROM many_to_many
  GROUP BY id_left;
```

This will create a table with one row per left item, and an array of right items. Now this is pretty useless without some way of using the array; that's why there is an array enumerator. You can do

```
SELECT id_left, int_array_enum(rights) FROM summary WHERE id_left = item;
```

The above query using `int_array_enum` produces the same results as

```
SELECT id_left, id_right FROM many_to_many WHERE id_left = item;
```

The difference is that the query against the summary table has to get only one row from the table, whereas the direct query against `many_to_many` must index scan and fetch a row for each entry.

On one system, an `EXPLAIN` showed a query with a cost of 8488 was reduced to a cost of 329. The original query was a join involving the `many_to_many` table, which was replaced by:

```
SELECT id_right, count(id_right) FROM
  ( SELECT id_left, int_array_enum(rights) AS id_right
    FROM summary
    JOIN (SELECT id FROM left_table
          WHERE id = item) AS lefts
    ON (summary.id_left = lefts.id)
  ) AS list
```

Additional Supplied Modules and
Extensions Shipped in post-
grespro-ent-17-contrib

```
GROUP BY id_right  
ORDER BY count DESC;
```

F.31. intarray — manipulate arrays of integers

The `intarray` module provides a number of useful functions and operators for manipulating null-free arrays of integers. There is also support for indexed searches using some of the operators.

All of these operations will throw an error if a supplied array contains any `NULL` elements.

Many of these operations are only sensible for one-dimensional arrays. Although they will accept input arrays of more dimensions, the data is treated as though it were a linear array in storage order.

This module is considered “trusted”, that is, it can be installed by non-superusers who have `CREATE` privilege on the current database.

F.31.1. intarray Functions and Operators

The functions provided by the `intarray` module are shown in [Table F.16](#), the operators in [Table F.17](#).

Table F.16. intarray Functions

Function Description Example(s)
<code>icount (integer[]) → integer</code> Returns the number of elements in the array. <code>icount('{1,2,3}'::integer[]) → 3</code>
<code>sort (integer[], dir text) → integer[]</code> Sorts the array in either ascending or descending order. <i>dir</i> must be <code>asc</code> or <code>desc</code> . <code>sort('{1,3,2}'::integer[], 'desc') → {3,2,1}</code>
<code>sort (integer[]) → integer[]</code> <code>sort_asc (integer[]) → integer[]</code> Sorts in ascending order. <code>sort(array[11,77,44]) → {11,44,77}</code>
<code>sort_desc (integer[]) → integer[]</code> Sorts in descending order. <code>sort_desc(array[11,77,44]) → {77,44,11}</code>
<code>uniq (integer[]) → integer[]</code> Removes adjacent duplicates. Often used with <code>sort</code> to remove all duplicates. <code>uniq('{1,2,2,3,1,1}'::integer[]) → {1,2,3,1}</code> <code>uniq(sort('{1,2,3,2,1}'::integer[])) → {1,2,3}</code>
<code>idx (integer[], item integer) → integer</code> Returns index of the first array element matching <i>item</i> , or 0 if no match. <code>idx(array[11,22,33,22,11], 22) → 2</code>
<code>subarray (integer[], start integer, len integer) → integer[]</code> Extracts the portion of the array starting at position <i>start</i> , with <i>len</i> elements. <code>subarray('{1,2,3,2,1}'::integer[], 2, 3) → {2,3,2}</code>
<code>subarray (integer[], start integer) → integer[]</code> Extracts the portion of the array starting at position <i>start</i> . <code>subarray('{1,2,3,2,1}'::integer[], 2) → {2,3,2,1}</code>
<code>intset (integer) → integer[]</code> Makes a single-element array. <code>intset(42) → {42}</code>

Table F.17. `intarray` Operators

Operator	Description
<code>integer[] && integer[] → boolean</code>	Do arrays overlap (have at least one element in common)?
<code>integer[] @> integer[] → boolean</code>	Does left array contain right array?
<code>integer[] <@ integer[] → boolean</code>	Is left array contained in right array?
<code># integer[] → integer</code>	Returns the number of elements in the array.
<code>integer[] # integer → integer</code>	Returns index of the first array element matching the right argument, or 0 if no match. (Same as <code>idx</code> function.)
<code>integer[] + integer → integer[]</code>	Adds element to end of array.
<code>integer[] + integer[] → integer[]</code>	Concatenates the arrays.
<code>integer[] - integer → integer[]</code>	Removes entries matching the right argument from the array.
<code>integer[] - integer[] → integer[]</code>	Removes elements of the right array from the left array.
<code>integer[] integer → integer[]</code>	Computes the union of the arguments.
<code>integer[] integer[] → integer[]</code>	Computes the union of the arguments.
<code>integer[] & integer[] → integer[]</code>	Computes the intersection of the arguments.
<code>integer[] @@ query_int → boolean</code>	Does array satisfy query? (see below)
<code>query_int ~~ integer[] → boolean</code>	Does array satisfy query? (commutator of @@)

The operators `&&`, `@>` and `<@` are equivalent to Postgres Pro's built-in operators of the same names, except that they work only on integer arrays that do not contain nulls, while the built-in operators work for any array type. This restriction makes them faster than the built-in operators in many cases.

The `@@` and `~~` operators test whether an array satisfies a *query*, which is expressed as a value of a specialized data type `query_int`. A *query* consists of integer values that are checked against the elements of the array, possibly combined using the operators `&` (AND), `|` (OR), and `!` (NOT). Parentheses can be used as needed. For example, the query `1&(2|3)` matches arrays that contain 1 and also contain either 2 or 3.

F.31.2. Index Support

`intarray` provides index support for the `&&`, `@>`, and `@@` operators, as well as regular array equality.

Two parameterized GiST index operator classes are provided: `gist__int_ops` (used by default) is suitable for small- to medium-size data sets, while `gist__intbig_ops` uses a larger signature and is more suitable for indexing large data sets (i.e., columns containing a large number of distinct array values). The implementation uses an RD-tree data structure with built-in lossy compression.

`gist__int_ops` approximates an integer set as an array of integer ranges. Its optional integer parameter `numranges` determines the maximum number of ranges in one index key. The default value of `numranges` is 100. Valid values are between 1 and 253. Using larger arrays as GiST index keys leads to a more precise search (scanning a smaller fraction of the index and fewer heap pages), at the cost of a larger index.

`gist__intbig_ops` approximates an integer set as a bitmap signature. Its optional integer parameter `siglen` determines the signature length in bytes. The default signature length is 16 bytes. Valid values of signature length are between 1 and 2024 bytes. Longer signatures lead to a more precise search (scanning a smaller fraction of the index and fewer heap pages), at the cost of a larger index.

There is also a non-default GIN operator class `gin__int_ops`, which supports these operators as well as `<@`.

The choice between GiST and GIN indexing depends on the relative performance characteristics of GiST and GIN, which are discussed elsewhere.

F.31.3. Example

```
-- a message can be in one or more "sections"
CREATE TABLE message (mid INT PRIMARY KEY, sections INT[], ...);

-- create specialized index with signature length of 32 bytes
CREATE INDEX message_rdtree_idx ON message USING GIST (sections gist__intbig_ops
(siglen = 32));

-- select messages in section 1 OR 2 - OVERLAP operator
SELECT message.mid FROM message WHERE message.sections && '{1,2}';

-- select messages in sections 1 AND 2 - CONTAINS operator
SELECT message.mid FROM message WHERE message.sections @> '{1,2}';

-- the same, using QUERY operator
SELECT message.mid FROM message WHERE message.sections @@ '1&2'::query_int;
```

F.31.4. Authors

All work was done by Teodor Sigaev (<teodor@sigaev.ru>) and Oleg Bartunov (<oleg@sai.msu.su>). See <http://www.sai.msu.su/~megeera/postgres/gist/> for additional information. Andrey Oktyabrski did a great work on adding new functions and operations.

F.32. isn — data types for international standard numbers (ISBN, EAN, UPC, etc.)

The `isn` module provides data types for the following international product numbering standards: EAN13, UPC, ISBN (books), ISMN (music), and ISSN (serials). Numbers are validated on input according to a hard-coded list of prefixes; this list of prefixes is also used to hyphenate numbers on output. Since new prefixes are assigned from time to time, the list of prefixes may be out of date. It is hoped that a future version of this module will obtain the prefix list from one or more tables that can be easily updated by users as needed; however, at present, the list can only be updated by modifying the source code and recompiling. Alternatively, prefix validation and hyphenation support may be dropped from a future version of this module.

This module is considered “trusted”, that is, it can be installed by non-superusers who have `CREATE` privilege on the current database.

F.32.1. Data Types

Table F.18 shows the data types provided by the `isn` module.

Table F.18. isn Data Types

Data Type	Description
EAN13	European Article Numbers, always displayed in the EAN13 display format
ISBN13	International Standard Book Numbers to be displayed in the new EAN13 display format
ISMN13	International Standard Music Numbers to be displayed in the new EAN13 display format
ISSN13	International Standard Serial Numbers to be displayed in the new EAN13 display format
ISBN	International Standard Book Numbers to be displayed in the old short display format
ISMN	International Standard Music Numbers to be displayed in the old short display format
ISSN	International Standard Serial Numbers to be displayed in the old short display format
UPC	Universal Product Codes

Some notes:

1. ISBN13, ISMN13, ISSN13 numbers are all EAN13 numbers.
2. EAN13 numbers aren't always ISBN13, ISMN13 or ISSN13 (some are).
3. Some ISBN13 numbers can be displayed as ISBN.
4. Some ISMN13 numbers can be displayed as ISMN.
5. Some ISSN13 numbers can be displayed as ISSN.
6. UPC numbers are a subset of the EAN13 numbers (they are basically EAN13 without the first 0 digit).
7. All UPC, ISBN, ISMN and ISSN numbers can be represented as EAN13 numbers.

Internally, all these types use the same representation (a 64-bit integer), and all are interchangeable. Multiple types are provided to control display formatting and to permit tighter validity checking of input that is supposed to denote one particular type of number.

The `ISBN`, `ISMN`, and `ISSN` types will display the short version of the number (ISxN 10) whenever it's possible, and will show ISxN 13 format for numbers that do not fit in the short version. The `EAN13`, `ISBN13`, `ISMN13` and `ISSN13` types will always display the long version of the ISxN (EAN13).

F.32.2. Casts

The `isn` module provides the following pairs of type casts:

- `ISBN13 <=> EAN13`
- `ISMN13 <=> EAN13`

- `ISSN13 <=> EAN13`
- `ISBN <=> EAN13`
- `ISMN <=> EAN13`
- `ISSN <=> EAN13`
- `UPC <=> EAN13`
- `ISBN <=> ISBN13`
- `ISMN <=> ISMN13`
- `ISSN <=> ISSN13`

When casting from `EAN13` to another type, there is a run-time check that the value is within the domain of the other type, and an error is thrown if not. The other casts are simply relabelings that will always succeed.

F.32.3. Functions and Operators

The `isn` module provides the standard comparison operators, plus B-tree and hash indexing support for all these data types. In addition there are several specialized functions; shown in [Table F.19](#). In this table, `isn` means any one of the module's data types.

Table F.19. `isn` Functions

Function	Description
<code>isn_weak (boolean) → boolean</code>	Sets the weak input mode, and returns new setting.
<code>isn_weak () → boolean</code>	Returns the current status of the weak mode.
<code>make_valid (isn) → isn</code>	Validates an invalid number (clears the invalid flag).
<code>is_valid (isn) → boolean</code>	Checks for the presence of the invalid flag.

Weak mode is used to be able to insert invalid data into a table. Invalid means the check digit is wrong, not that there are missing numbers.

Why would you want to use the weak mode? Well, it could be that you have a huge collection of ISBN numbers, and that there are so many of them that for weird reasons some have the wrong check digit (perhaps the numbers were scanned from a printed list and the OCR got the numbers wrong, perhaps the numbers were manually captured... who knows). Anyway, the point is you might want to clean the mess up, but you still want to be able to have all the numbers in your database and maybe use an external tool to locate the invalid numbers in the database so you can verify the information and validate it more easily; so for example you'd want to select all the invalid numbers in the table.

When you insert invalid numbers in a table using the weak mode, the number will be inserted with the corrected check digit, but it will be displayed with an exclamation mark (!) at the end, for example `0-11-000322-5!`. This invalid marker can be checked with the `is_valid` function and cleared with the `make_valid` function.

You can also force the insertion of invalid numbers even when not in the weak mode, by appending the `!` character at the end of the number.

Another special feature is that during input, you can write `?` in place of the check digit, and the correct check digit will be inserted automatically.

F.32.4. Examples

```
--Using the types directly:
SELECT isbn('978-0-393-04002-9');
SELECT isbn13('0901690546');
```

```
SELECT issn('1436-4522');

--Casting types:
-- note that you can only cast from ean13 to another type when the
-- number would be valid in the realm of the target type;
-- thus, the following will NOT work: select isbn(ean13('0220356483481'));
-- but these will:
SELECT upc(ean13('0220356483481'));
SELECT ean13(upc('220356483481'));

--Create a table with a single column to hold ISBN numbers:
CREATE TABLE test (id isbn);
INSERT INTO test VALUES('9780393040029');

--Automatically calculate check digits (observe the '?'):
INSERT INTO test VALUES('220500896?');
INSERT INTO test VALUES('978055215372?');

SELECT issn('3251231?');
SELECT ismn('979047213542?');

--Using the weak mode:
SELECT isn_weak(true);
INSERT INTO test VALUES('978-0-11-000533-4');
INSERT INTO test VALUES('9780141219307');
INSERT INTO test VALUES('2-205-00876-X');
SELECT isn_weak(false);

SELECT id FROM test WHERE NOT is_valid(id);
UPDATE test SET id = make_valid(id) WHERE id = '2-205-00876-X!';

SELECT * FROM test;

SELECT isbn13(id) FROM test;
```

F.32.5. Bibliography

The information to implement this module was collected from several sites, including:

- <https://www.isbn-international.org/>
- <https://www.issn.org/>
- <https://www.ismn-international.org/>
- <https://www.wikipedia.org/>

The prefixes used for hyphenation were also compiled from:

- <https://www.gs1.org/standards/id-keys>
- https://en.wikipedia.org/wiki/List_of_ISBN_identifier_groups
- <https://www.isbn-international.org/content/isbn-users-manual/29>
- https://en.wikipedia.org/wiki/International_Standard_Music_Number
- <https://www.ismn-international.org/ranges/tools>

Care was taken during the creation of the algorithms and they were meticulously verified against the suggested algorithms in the official ISBN, ISMN, ISSN User Manuals.

F.32.6. Author

Germán Méndez Bravo (Kronuz), 2004–2006

This module was inspired by Garrett A. Wollman's `isbn_issn` code.

F.33. jquery — a language to query jsonb data type

jQuery is a language to query jsonb data type. Its primary goal is to provide an additional functionality for jsonb, such as a simple and effective way for search in nested objects and arrays, as well as additional comparison operators with index support.

jQuery is implemented by means of a jquery data type (similar to tsquery) and the @@ match operator for jsonb.

F.33.1. Installation

Postgres Pro Enterprise distribution includes jquery as a contrib module. Once you complete Postgres Pro Enterprise installation, create the jquery extension, as follows:

```
CREATE EXTENSION jquery;
```

F.33.2. JSON query language

jQuery extension contains jquery datatype which represents whole JSON query as a single value (like tsquery does for fulltext search). The query is an expression on JSON-document values.

Simple expression is specified as *path binary_operator value* or *path unary_operator*. See the following examples.

- `x = "abc"` - value of key "x" is equal to "abc";
- `$ @> [4, 5, "zzz"]` - the JSON document is an array containing values 4, 5 and "zzz";
- `"abc xyz" >= 10` - value of key "abc xyz" is greater than or equal to 10;
- `volume IS NUMERIC` - type of key "volume" is numeric.
- `$ = true` - the whole JSON document is just a true.
- `similar_ids.@@ > 5` - `similar_ids` is an array or object of length greater than 5;
- `similar_product_ids.# = "0684824396"` - array `similar_product_ids` contains string "0684824396".
- `*.color = "red"` - there is object somewhere which key "color" has value "red".
- `foo = *` - key "foo" exists in object.

Path selects set of JSON values to be checked using given operators. In the simplest case, path is just a key name. In general, path is key names and placeholders combined by dot signs. Path can use the following placeholders:

- `#` - any index of array;
- `#N` - Nth index of array;
- `%` - any key of object;
- `*` - any sequence of array indexes and object keys;
- `@@` - length of array or object, could be only used as last component of path;
- `$` - the whole JSON document as single value, could be only the whole path.

Expression is true when operator is true against at least one value selected by path.

Key names could be given either with or without double quotes. Key names without double quotes shouldn't contain spaces, start with number, or concur with jquery keyword.

The supported binary operators are:

- Equality operator: `=`;
- Numeric comparison operators: `>`, `>=`, `<`, `<=`;
- Search in the list of scalar values using `IN` operator;
- Array comparison operators: `&&` (overlap), `@>` (contains), `<@` (contained in).
- Filtering operator: `~~`. Taking jsonb data as the left operand and a jquery expression as the right operand, this operator checks that jsonb data contains any entries that satisfy the condition provided in a jquery expression and returns an array of such entries, if any.

The supported unary operators are:

- Check for existence operator: `= *`;
- Check for type operators: `IS ARRAY`, `IS NUMERIC`, `IS OBJECT`, `IS STRING` and `IS BOOLEAN`.

Expressions could be complex. Complex expression is a set of expressions combined by logical operators (`AND`, `OR`, `NOT`) and grouped using parentheses.

Examples of complex expressions are given below.

- `a = 1 AND (b = 2 OR c = 3) AND NOT d = 1`
- `x.% = true OR x.# = true`

Prefix expressions are expressions given in the form `path (subexpression)`. In this case `path` selects JSON values to be checked using given `subexpression`. Check results are aggregated in the same way as in simple expressions.

- `$(a = 1 AND b = 2)` - an array contains an element where the `a` key is 2 and the `b` key is 2
- `$( $ >= 10 AND $ <= 20 )` - an object contains a key with a value between 10 and 20

Path also could contain the following special placeholders with "every" semantics:

- `#:` - every index of array;
- `%:` - every key of object;
- `*` - every sequence of array indexes and object keys.

Consider the following example.

```
%.#:( $ >= 0 AND $ <= 1 )
```

This example could be read as follows: there is at least one key for which the value is an array of numerics between 0 and 1.

We can rewrite this example in the following form with extra parentheses.

```
%(#:( $ >= 0 AND $ <= 1 ))
```

The first placeholder `%` checks that expression in parentheses is true for at least one value in object. The second placeholder `#:` checks that the value is an array and all its elements satisfy expressions in parentheses.

We can rewrite this example without `#:` placeholder as follows.

```
%(NOT #(NOT ( $ >= 0 AND $ <= 1 )) AND $ IS ARRAY)
```

In this example we transform assertion that every element of array satisfies some condition to assertion that there is no one element which doesn't satisfy the same condition.

Some examples of using paths are given below.

- `numbers.#: IS NUMERIC` - every element of "numbers" array is numeric.
- `*:($ IS OBJECT OR $ IS BOOLEAN)` - JSON is a structure of nested objects with booleans as leaf values.
- `#:.$:( $ >= 0 AND $ <= 1 )` - each element of array is object containing only numeric values between 0 and 1.
- `documents.#:.% = *` - "documents" is an array of objects containing at least one key.
- `%.#:( $ IS STRING)` - JSON object contains at least one array of strings.
- `%.% = true` - at least one array element is an object that contains at least one "true" value.

Usage of path operators and parentheses needs some explanation. When same path operators are used multiple times they may refer to different values while you can refer to the same value multiple times by using parentheses and `$` operator. See the following examples.

- `# < 10 AND # > 20` - there is an element less than 10 and another element greater than 20.
- `$( $ < 10 AND $ > 20 )` - there is an element that is both less than 10 and greater than 20 (impossible).
- `$( $ >= 10 AND $ <= 20 )` - there is an element between 10 and 20.
- `# >= 10 AND # <= 20` - there is an element greater than or equal to 10 and another element less than or equal to 20. The query can be satisfied by an array with no elements between 10 and 20, for instance `[0,30]`.

Same rules apply when you search inside objects and branchy structures.

Type checking operators and "every" placeholders are useful for document schema validation. JQuery matching operator `@@` is immutable and can be used in CHECK constraint. See the following example.

```
CREATE TABLE js (  
    id serial,  
    data jsonb,
```

```
CHECK (data @@ '
    name IS STRING AND
    similar_ids.#: IS NUMERIC AND
    points.#:(x IS NUMERIC AND y IS NUMERIC)')::jsquery));
```

In this example check constraint validates that in "data" jsonb column: value of "name" key is string, value of "similar_ids" key is array of numerics, value of "points" key is array of objects which contain numeric values in "x" and "y" keys.

See our [pgconf.eu presentation](https://pgconf.eu/presentation) for more examples.

F.33.3. GIN indexes

JsQuery extension contains two operator classes (opclasses) for GIN which provide different kinds of query optimization.

- `jsonb_path_value_ops`
- `jsonb_value_path_ops`

In each of two GIN opclasses jsonb documents are decomposed into entries. Each entry is associated with a particular value and its path. Difference between opclasses is in the entry representation, comparison, and usage for search optimization.

For example, jsonb document `{"a": [{"b": "xyz", "c": true}, 10], "d": {"e": [7, false]}}` would be decomposed into the following entries:

- `"a".#."b"."xyz"`
- `"a".#."c".true`
- `"a".#.10`
- `"d"."e".#.7`
- `"d"."e".#.false`

Since JsQuery doesn't support search in a particular array index, we consider all array elements to be equivalent. Thus, each array element is marked with the same # sign in the path.

Major problem in the entries representation is its size. In the given example key "a" is presented three times. In the large branchy documents with long keys size of naive entries representation becomes unreasonable. Both opclasses address this issue but in a slightly different way.

F.33.3.1. `jsonb_path_value_ops`

`jsonb_path_value_ops` represents entry as pair of path hash and value. The following pseudocode illustrates it.

```
(hash(path_item_1.path_item_2. ... .path_item_n); value)
```

In comparison of entries path hash is the higher part of entry and value is its lower part. This determines the features of this opclass. Since path is hashed and it is higher part of entry we need to know the full path to the value in order to use it for search. However, once path is specified we can use both exact and range searches very efficiently.

F.33.3.2. `jsonb_value_path_ops`

`jsonb_value_path_ops` represents entry as pair of value and bloom filter of path.

```
(value; bloom(path_item_1) | bloom(path_item_2) | ... | bloom(path_item_n))
```

In comparison of entries value is the higher part of entry and bloom filter of path is its lower part. This determines the features of this opclass. Since value is the higher part of entry we can perform only exact value search efficiently. Range value search is possible as well but we would have to filter all the different paths where matching values occur. Bloom filter over path items allows index usage for conditions containing % and * in their paths.

F.33.3.3. Query optimization

JsQuery opclasses perform complex query optimization. Thus it's valuable for developer or administrator to see the result of such optimization. Unfortunately, opclasses aren't allowed to do any custom output to the EXPLAIN. That's why JsQuery provides the following functions which allows to see how particular opclass optimizes given query.

- `gin_debug_query_path_value(jsquery)` - for `jsonb_path_value_ops`

- `gin_debug_query_value_path(jsquery)` - for `jsonb_value_path_ops`

Result of these functions is a textual representation of query tree which leaves are GIN search entries. The following examples show different results of query optimization by different opclasses.

```
# SELECT gin_debug_query_path_value('x = 1 AND (*.y = 1 OR y = 2)');
gin_debug_query_path_value
-----
x = 1 , entry 0          +

# SELECT gin_debug_query_value_path('x = 1 AND (*.y = 1 OR y = 2)');
gin_debug_query_value_path
-----
AND                      +
  x = 1 , entry 0        +
  OR                      +
    *.y = 1 , entry 1    +
    y = 2 , entry 2      +
```

Unfortunately, `jsonb` has no statistics yet. That's why JsQuery optimizer has to do imperative decision while selecting conditions to be evaluated using index. This decision is made by assumption that some condition types are less selective than others. Optimizer divides conditions into the following selectivity class (listed by descending of selectivity).

1. Equality ($x = c$)
2. Range ($c1 < x < c2$)
3. Inequality ($x > c$)
4. Is (x is type)
5. Any ($x = *$)

Optimizer evades index evaluation of less selective conditions when possible. For example, in the `x = 1 AND y > 0` query `x = 1` is assumed to be more selective than `y > 0`. That's why index isn't used for evaluation of `y > 0`.

```
# SELECT gin_debug_query_path_value('x = 1 AND y > 0');
gin_debug_query_path_value
-----
x = 1 , entry 0          +
```

With lack of statistics decisions made by optimizer can be inaccurate. That's why JsQuery supports hints. Comments `/*-- index */` and `/*-- noindex */` placed in the conditions force optimizer to use and not to use index correspondingly.

```
SELECT gin_debug_query_path_value('x = 1 AND y /*-- index */ > 0');
gin_debug_query_path_value
-----
AND                      +
  x = 1 , entry 0        +
  y > 0 , entry 1        +

SELECT gin_debug_query_path_value('x /*-- noindex */ = 1 AND y > 0');
gin_debug_query_path_value
-----
y > 0 , entry 0          +
```

F.34. lo — manage large objects

The `lo` module provides support for managing Large Objects (also called LOs or BLOBs). This includes a data type `lo` and a trigger `lo_manage`.

This module is considered “trusted”, that is, it can be installed by non-superusers who have `CREATE` privilege on the current database.

F.34.1. Rationale

One of the problems with the JDBC driver (and this affects the ODBC driver also), is that the specification assumes that references to BLOBs (Binary Large Objects) are stored within a table, and if that entry is changed, the associated BLOB is deleted from the database.

As Postgres Pro stands, this doesn't occur. Large objects are treated as objects in their own right; a table entry can reference a large object by OID, but there can be multiple table entries referencing the same large object OID, so the system doesn't delete the large object just because you change or remove one such entry.

Now this is fine for Postgres Pro-specific applications, but standard code using JDBC or ODBC won't delete the objects, resulting in orphan objects — objects that are not referenced by anything, and simply occupy disk space.

The `lo` module allows fixing this by attaching a trigger to tables that contain LO reference columns. The trigger essentially just does a `lo_unlink` whenever you delete or modify a value referencing a large object. When you use this trigger, you are assuming that there is only one database reference to any large object that is referenced in a trigger-controlled column!

The module also provides a data type `lo`, which is really just a [domain](#) over the `oid` type. This is useful for differentiating database columns that hold large object references from those that are OIDs of other things. You don't have to use the `lo` type to use the trigger, but it may be convenient to use it to keep track of which columns in your database represent large objects that you are managing with the trigger. It is also rumored that the ODBC driver gets confused if you don't use `lo` for BLOB columns.

F.34.2. How to Use It

Here's a simple example of usage:

```
CREATE TABLE image (title text, raster lo);

CREATE TRIGGER t_raster BEFORE UPDATE OR DELETE ON image
    FOR EACH ROW EXECUTE FUNCTION lo_manage(raster);
```

For each column that will contain unique references to large objects, create a `BEFORE UPDATE OR DELETE` trigger, and give the column name as the sole trigger argument. You can also restrict the trigger to only execute on updates to the column by using `BEFORE UPDATE OF column_name`. If you need multiple `lo` columns in the same table, create a separate trigger for each one, remembering to give a different name to each trigger on the same table.

F.34.3. Limitations

- Dropping a table will still orphan any objects it contains, as the trigger is not executed. You can avoid this by preceding the `DROP TABLE` with `DELETE FROM table`.

`TRUNCATE` has the same hazard.

If you already have, or suspect you have, orphaned large objects, see the [vacuumlo](#) module to help you clean them up. It's a good idea to run `vacuumlo` occasionally as a back-stop to the `lo_manage` trigger.

- Some frontends may create their own tables, and will not create the associated trigger(s). Also, users may not remember (or know) to create the triggers.

F.35. ltree — hierarchical tree-like data type

This module implements a data type `ltree` for representing labels of data stored in a hierarchical tree-like structure. Extensive facilities for searching through label trees are provided.

This module is considered “trusted”, that is, it can be installed by non-superusers who have `CREATE` privilege on the current database.

F.35.1. Definitions

A *label* is a sequence of alphanumeric characters, underscores, and hyphens. Valid alphanumeric character ranges are dependent on the database locale. For example, in C locale, the characters A-Za-z0-9_- are allowed. Labels must be no more than 1000 characters long.

Examples: 42, Personal_Services

A *label path* is a sequence of zero or more labels separated by dots, for example L1.L2.L3, representing a path from the root of a hierarchical tree to a particular node. The length of a label path cannot exceed 65535 labels.

Example: Top.Countries.Europe.Russia

The `ltree` module provides several data types:

- `ltree` stores a label path.
- `lquery` represents a regular-expression-like pattern for matching `ltree` values. A simple word matches that label within a path. A star symbol (`*`) matches zero or more labels. These can be joined with dots to form a pattern that must match the whole label path. For example:

<code>foo</code>	<i>Match the exact label path foo</i>
<code>*.foo.*</code>	<i>Match any label path containing the label foo</i>
<code>*.foo</code>	<i>Match any label path whose last label is foo</i>

Both star symbols and simple words can be quantified to restrict how many labels they can match:

<code>{n}</code>	<i>Match exactly n labels</i>
<code>{n,}</code>	<i>Match at least n labels</i>
<code>{n,m}</code>	<i>Match at least n but not more than m labels</i>
<code>{,m}</code>	<i>Match at most m labels – same as <code>{0,m}</code></i>
<code>foo{n,m}</code>	<i>Match at least n but not more than m occurrences of foo</i>
<code>foo{,}</code>	<i>Match any number of occurrences of foo, including zero</i>

In the absence of any explicit quantifier, the default for a star symbol is to match any number of labels (that is, `{,}`) while the default for a non-star item is to match exactly once (that is, `{1}`).

There are several modifiers that can be put at the end of a non-star `lquery` item to make it match more than just the exact match:

<code>@</code>	<i>Match case-insensitively, for example <code>a@</code> matches <code>A</code></i>
<code>*</code>	<i>Match any label with this prefix, for example <code>foo*</code> matches <code>foobar</code></i>
<code>%</code>	<i>Match initial underscore-separated words</i>

The behavior of `%` is a bit complicated. It tries to match words rather than the entire label. For example `foo_bar%` matches `foo_bar_baz` but not `foo_barbaz`. If combined with `*`, prefix matching applies to each word separately, for example `foo_bar%*` matches `foo1_bar2_baz` but not `foo1_br2_baz`.

Also, you can write several possibly-modified non-star items separated with `|` (OR) to match any of those items, and you can put `!` (NOT) at the start of a non-star group to match any label that doesn't match any of the alternatives. A quantifier, if any, goes at the end of the group; it means some number of matches for the group as a whole (that is, some number of labels matching or not matching any of the alternatives).

Here's an annotated example of `lquery`:

`Top.*{0,2}.sport*@.!football|tennis{1,}.Russ*|Spain`

a. b. c. d. e.

This query will match any label path that:

- a. begins with the label `Top`
 - b. and next has zero to two labels before
 - c. a label beginning with the case-insensitive prefix `sport`
 - d. then has one or more labels, none of which match `football` nor `tennis`
 - e. and then ends with a label beginning with `Russ` or exactly matching `Spain`.
- `ltxquery` represents a full-text-search-like pattern for matching `ltree` values. An `ltxquery` value contains words, possibly with the modifiers `@`, `*`, `%` at the end; the modifiers have the same meanings as in `lquery`. Words can be combined with `&` (AND), `|` (OR), `!` (NOT), and parentheses. The key difference from `lquery` is that `ltxquery` matches words without regard to their position in the label path.

Here's an example `ltxquery`:

`Europe & Russia*@ & !Transportation`

This will match paths that contain the label `Europe` and any label beginning with `Russia` (case-insensitive), but not paths containing the label `Transportation`. The location of these words within the path is not important. Also, when `%` is used, the word can be matched to any underscore-separated word within a label, regardless of position.

Note: `ltxquery` allows whitespace between symbols, but `ltree` and `lquery` do not.

F.35.2. Operators and Functions

Type `ltree` has the usual comparison operators `=`, `<>`, `<`, `>`, `<=`, `>=`. Comparison sorts in the order of a tree traversal, with the children of a node sorted by label text. In addition, the specialized operators shown in [Table F.20](#) are available.

Table F.20. `ltree` Operators

Operator Description
<code>ltree @> ltree → boolean</code> Is left argument an ancestor of right (or equal)?
<code>ltree <@ ltree → boolean</code> Is left argument a descendant of right (or equal)?
<code>ltree ~ lquery → boolean</code> <code>lquery ~ ltree → boolean</code> Does <code>ltree</code> match <code>lquery</code> ?
<code>ltree ? lquery[] → boolean</code> <code>lquery[] ? ltree → boolean</code> Does <code>ltree</code> match any <code>lquery</code> in array?
<code>ltree @ ltxquery → boolean</code> <code>ltxquery @ ltree → boolean</code> Does <code>ltree</code> match <code>ltxquery</code> ?
<code>ltree ltree → ltree</code> Concatenates <code>ltree</code> paths.
<code>ltree text → ltree</code> <code>text ltree → ltree</code> Converts text to <code>ltree</code> and concatenates.
<code>ltree[] @> ltree → boolean</code>

Operator	Description
<code>ltree <@ ltree[] → boolean</code> Does array contain an ancestor of <code>ltree</code> ?	
<code>ltree[] <@ ltree → boolean</code> <code>ltree @> ltree[] → boolean</code> Does array contain a descendant of <code>ltree</code> ?	
<code>ltree[] ~ lquery → boolean</code> <code>lquery ~ ltree[] → boolean</code> Does array contain any path matching <code>lquery</code> ?	
<code>ltree[] ? lquery[] → boolean</code> <code>lquery[] ? ltree[] → boolean</code> Does <code>ltree</code> array contain any path matching any <code>lquery</code> ?	
<code>ltree[] @ ltxtquery → boolean</code> <code>ltxtquery @ ltree[] → boolean</code> Does array contain any path matching <code>ltxtquery</code> ?	
<code>ltree[] ?@> ltree → ltree</code> Returns first array entry that is an ancestor of <code>ltree</code> , or NULL if none.	
<code>ltree[] ?<@ ltree → ltree</code> Returns first array entry that is a descendant of <code>ltree</code> , or NULL if none.	
<code>ltree[] ?~ lquery → ltree</code> Returns first array entry that matches <code>lquery</code> , or NULL if none.	
<code>ltree[] ?@ ltxtquery → ltree</code> Returns first array entry that matches <code>ltxtquery</code> , or NULL if none.	

The operators `<@`, `@>`, `@` and `~` have analogues `^<@`, `^@>`, `^@`, `^~`, which are the same except they do not use indexes. These are useful only for testing purposes.

The available functions are shown in [Table F.21](#).

Table F.21. `ltree` Functions

Function	Description	Example(s)
<code>subltree (ltree, start integer, end integer) → ltree</code> Returns subpath of <code>ltree</code> from position <code>start</code> to position <code>end-1</code> (counting from 0). <code>subltree('Top.Child1.Child2', 1, 2) → Child1</code>		
<code>subpath (ltree, offset integer, len integer) → ltree</code> Returns subpath of <code>ltree</code> starting at position <code>offset</code> , with length <code>len</code> . If <code>offset</code> is negative, subpath starts that far from the end of the path. If <code>len</code> is negative, leaves that many labels off the end of the path. <code>subpath('Top.Child1.Child2', 0, 2) → Top.Child1</code>		
<code>subpath (ltree, offset integer) → ltree</code> Returns subpath of <code>ltree</code> starting at position <code>offset</code> , extending to end of path. If <code>offset</code> is negative, subpath starts that far from the end of the path. <code>subpath('Top.Child1.Child2', 1) → Child1.Child2</code>		
<code>nlevel (ltree) → integer</code>		

Function	Description	Example(s)
	Returns number of labels in path.	<code>nlevel('Top.Child1.Child2') → 3</code>
<code>index(a ltree, b ltree) → integer</code>	Returns position of first occurrence of <i>b</i> in <i>a</i> , or -1 if not found.	<code>index('0.1.2.3.5.4.5.6.8.5.6.8', '5.6') → 6</code>
<code>index(a ltree, b ltree, offset integer) → integer</code>	Returns position of first occurrence of <i>b</i> in <i>a</i> , or -1 if not found. The search starts at position <i>offset</i> ; negative <i>offset</i> means start <i>-offset</i> labels from the end of the path.	<code>index('0.1.2.3.5.4.5.6.8.5.6.8', '5.6', -4) → 9</code>
<code>text2ltree(text) → ltree</code>	Casts <i>text</i> to <i>ltree</i> .	
<code>ltree2text(ltree) → text</code>	Casts <i>ltree</i> to <i>text</i> .	
<code>lca(ltree[, ltree[, ...]]) → ltree</code>	Computes longest common ancestor of paths (up to 8 arguments are supported).	<code>lca('1.2.3', '1.2.3.4.5.6') → 1.2</code>
<code>lca(ltree[]) → ltree</code>	Computes longest common ancestor of paths in array.	<code>lca(array['1.2.3'::ltree, '1.2.3.4']) → 1.2</code>

F.35.3. Indexes

ltree supports several types of indexes that can speed up the indicated operators:

- B-tree index over *ltree*: `<`, `<=`, `=`, `>=`, `>`
- Hash index over *ltree*: `=`
- GiST index over *ltree* (`gist_ltree_ops` opclass): `<`, `<=`, `=`, `>=`, `>`, `@>`, `<@`, `@`, `~`, `?`

`gist_ltree_ops` GiST opclass approximates a set of path labels as a bitmap signature. Its optional integer parameter `siglen` determines the signature length in bytes. The default signature length is 8 bytes. The length must be a positive multiple of `int` alignment (4 bytes on most machines) up to 2024. Longer signatures lead to a more precise search (scanning a smaller fraction of the index and fewer heap pages), at the cost of a larger index.

Example of creating such an index with the default signature length of 8 bytes:

```
CREATE INDEX path_gist_idx ON test USING GIST (path);
```

Example of creating such an index with a signature length of 100 bytes:

```
CREATE INDEX path_gist_idx ON test USING GIST (path gist_ltree_ops(siglen=100));
```

- GiST index over *ltree[]* (`gist__ltree_ops` opclass): `ltree[] <@ ltree, ltree @> ltree[], @, ~, ?`

`gist__ltree_ops` GiST opclass works similarly to `gist_ltree_ops` and also takes signature length as a parameter. The default value of `siglen` in `gist__ltree_ops` is 28 bytes.

Example of creating such an index with the default signature length of 28 bytes:

```
CREATE INDEX path_gist_idx ON test USING GIST (array_path);
```

Example of creating such an index with a signature length of 100 bytes:

```
CREATE INDEX path_gist_idx ON test USING GIST (array_path
gist__ltree_ops(siglen=100));
```

Note: This index type is lossy.

F.35.4. Example

This example uses the following data (also available in file contrib/ltree/ltreetest.sql in the source distribution):

```
CREATE TABLE test (path ltree);
INSERT INTO test VALUES ('Top');
INSERT INTO test VALUES ('Top.Science');
INSERT INTO test VALUES ('Top.Science.Astronomy');
INSERT INTO test VALUES ('Top.Science.Astronomy.Astrophysics');
INSERT INTO test VALUES ('Top.Science.Astronomy.Cosmology');
INSERT INTO test VALUES ('Top.Hobbies');
INSERT INTO test VALUES ('Top.Hobbies.Amateurs_Astronomy');
INSERT INTO test VALUES ('Top.Collections');
INSERT INTO test VALUES ('Top.Collections.Pictures');
INSERT INTO test VALUES ('Top.Collections.Pictures.Astronomy');
INSERT INTO test VALUES ('Top.Collections.Pictures.Astronomy.Stars');
INSERT INTO test VALUES ('Top.Collections.Pictures.Astronomy.Galaxies');
INSERT INTO test VALUES ('Top.Collections.Pictures.Astronomy.Astronauts');
CREATE INDEX path_gist_idx ON test USING GIST (path);
CREATE INDEX path_idx ON test USING BTREE (path);
CREATE INDEX path_hash_idx ON test USING HASH (path);
```

Now, we have a table test populated with data describing the hierarchy shown below:

We can do inheritance:

```
ltreetest=> SELECT path FROM test WHERE path <@ 'Top.Science';
           path
-----
Top.Science
Top.Science.Astronomy
Top.Science.Astronomy.Astrophysics
Top.Science.Astronomy.Cosmology
(4 rows)
```

Here are some examples of path matching:

```
ltreetest=> SELECT path FROM test WHERE path ~ '*.Astronomy.*';
           path
-----
Top.Science.Astronomy
Top.Science.Astronomy.Astrophysics
Top.Science.Astronomy.Cosmology
Top.Collections.Pictures.Astronomy
Top.Collections.Pictures.Astronomy.Stars
Top.Collections.Pictures.Astronomy.Galaxies
```

```
Top.Collections.Pictures.Astronomy.Astronauts
(7 rows)
```

```
ltreetest=> SELECT path FROM test WHERE path ~ '.*!pictures@.Astronomy.*';
           path
```

```
-----
Top.Science.Astronomy
Top.Science.Astronomy.Astrophysics
Top.Science.Astronomy.Cosmology
(3 rows)
```

Here are some examples of full text search:

```
ltreetest=> SELECT path FROM test WHERE path @ 'Astro*% & !pictures@';
           path
```

```
-----
Top.Science.Astronomy
Top.Science.Astronomy.Astrophysics
Top.Science.Astronomy.Cosmology
Top.Hobbies.Amateurs_Astronomy
(4 rows)
```

```
ltreetest=> SELECT path FROM test WHERE path @ 'Astro* & !pictures@';
           path
```

```
-----
Top.Science.Astronomy
Top.Science.Astronomy.Astrophysics
Top.Science.Astronomy.Cosmology
(3 rows)
```

Path construction using functions:

```
ltreetest=> SELECT subpath(path,0,2)||'Space'||subpath(path,2) FROM test WHERE path <@
           'Top.Science.Astronomy';
           ?column?
```

```
-----
Top.Science.Space.Astronomy
Top.Science.Space.Astronomy.Astrophysics
Top.Science.Space.Astronomy.Cosmology
(3 rows)
```

We could simplify this by creating an SQL function that inserts a label at a specified position in a path:

```
CREATE FUNCTION ins_label(ltree, int, text) RETURNS ltree
AS 'select subpath($1,0,$2) || $3 || subpath($1,$2);'
LANGUAGE SQL IMMUTABLE;
```

```
ltreetest=> SELECT ins_label(path,2,'Space') FROM test WHERE path <@
           'Top.Science.Astronomy';
           ins_label
```

```
-----
Top.Science.Space.Astronomy
Top.Science.Space.Astronomy.Astrophysics
Top.Science.Space.Astronomy.Cosmology
(3 rows)
```

F.35.5. Transforms

The `ltree_plpython3u` extension implements transforms for the `ltree` type for PL/Python. If installed and specified when creating a function, `ltree` values are mapped to Python lists. (The reverse is currently not supported, however.)

Caution

It is strongly recommended that the transform extension be installed in the same schema as `ltree`. Otherwise there are installation-time security hazards if a transform extension's schema contains objects defined by a hostile user.

F.35.6. Authors

All work was done by Teodor Sigaev (<teodor@stack.net>) and Oleg Bartunov (<oleg@sai.msu.su>). See <http://www.sai.msu.su/~megeera/postgres/gist/> for additional information. Authors would like to thank Eugeny Rodichev for helpful discussions. Comments and bug reports are welcome.

F.36. mchar — additional data types for compatibility with Microsoft SQL Server

The `mchar` module provides additional data types for compatibility with Microsoft SQL Server (MS SQL).

F.36.1. Overview

This module has been designed to improve 1C Enterprise support, most popular Russian CRM and ERP system.

It implements types `MCHAR` and `MVARCHAR`, which are bug-to-bug compatible with MS SQL `CHAR` and `VARCHAR` respectively. Additionally, these types use the ICU library for comparison and case conversion, so their behavior is identical across different operating systems.

Postgres Pro also includes [citext](#) extension which provides types similar to `MCHAR`. But this extension doesn't emulate MS-SQL behavior concerning end-of-value whitespace.

Differences from Postgres Pro standard `CHAR` and `VARCHAR` are:

- Case insensitive comparison
- Handling of the whitespace at the end of string
- These types are always stored as two-byte unicode value regardless of database encoding.

F.36.2. Additional types

- `mchar` — analog of the MS SQL `char` type
- `mvarchar` — analog of the MS SQL `varchar` type

For how to prevent type resolution issues associated with [pg_dump/pg_restore](#) or [pg_upgrade](#) for operators that use custom types, refer to [Section 10.2.1](#).

F.36.3. MCHAR and MVARCHAR features

- Defines `length(str)` function
- Defines `substr(str, pos[, length])` function
- Defines `||` operator, which would be applied to concatenate any (`mchar` and `mvarchar`) arguments
- Defines set of operators: `<`, `<=`, `=`, `>=`, `>` for case-insensitive comparison (ICU)
- Defines set of operators: `&<`, `&<=`, `&=`, `&>=`, `&>` to case-sensitive comparison (ICU)
- Implicit cast between `mchar` and `mvarchar` types
- B-tree and Hash-index support
- The `LIKE [ESCAPE]` operator support
- The `SIMILAR TO [ESCAPE]` operator support
- The `~` operator (POSIX regexp) support
- Index support for the *LIKE* operator

F.36.4. Authors

Teodor Sigaev <teodor@sigaev.ru>

F.37. multimaster — synchronous cluster to provide OLTP scalability and high availability

`multimaster` is a Postgres Pro Enterprise extension with a set of patches that turns Postgres Pro Enterprise into a synchronous shared-nothing cluster to provide Online Transaction Processing (OLTP) scalability for read transactions and high availability with automatic disaster recovery.

As compared to a standard PostgreSQL primary-standby cluster, a cluster configured with the `multimaster` extension offers the following benefits:

- Fault tolerance and automatic node recovery
- Synchronous logical replication and DDL replication
- Read scalability
- Working with temporary tables on each cluster node (with limitations)
- Upgrading minor releases of Postgres Pro Enterprise seamlessly for multimaster cluster clients

Important

Before deploying `multimaster` on production systems, make sure to take its replication restrictions into account. For details, see [Section F.37.1](#).

The `multimaster` extension replicates your database to all nodes of the cluster and allows write transactions on each node. Write transactions are synchronously replicated to all nodes, which increases commit latency. Read-only transactions and queries are executed locally, without any measurable overhead.

To ensure high availability and fault tolerance of the cluster, `multimaster` determines each transaction outcome through Paxos consensus algorithm, uses custom recovery protocol and heartbeats for failure discovery. A multi-master cluster of N nodes can continue working while the majority of the nodes are alive and reachable by other nodes. To be configured with `multimaster`, the cluster must include at least three nodes. Since the data on all cluster nodes is the same, you do not typically need more than five cluster nodes. There is also a special 2+1 (referee) mode in which 2 nodes hold data and an additional one called *referee* only participates in voting. Compared to traditional three nodes setup, this is cheaper (referee resources demands are low) but availability is decreased. For details, see [Section F.37.3.3](#).

When a failed node is reconnected to the cluster, `multimaster` automatically fast-forwards the node to the actual state based on the Write-Ahead Log (WAL) data in the corresponding replication slot. If a node was excluded from the cluster, you can [add it back using pg_basebackup](#).

To learn more about the `multimaster` internals, see [Section F.37.2](#).

F.37.1. Limitations

The `multimaster` extension takes care of the database replication in a fully automated way. You can perform write transactions on any node and work with temporary tables on each cluster node simultaneously. However, make sure to take the following replication restrictions into account:

- Microsoft Windows operating system is not supported.
- 1C solutions are not supported.
- When used with [postgres_fdw](#), queries to foreign tables in read-write transactions are not supported. However, you can enable support of read-only queries to foreign tables in read-write transactions by setting the value of the [postgres_fdw.read_only_transactions](#) configuration parameter to `on`.
- `multimaster` can replicate only one database in a cluster. If it is required to replicate the contents of several databases, you can either transfer all data into different schemas within a single database or create a separate cluster for each database and set up `multimaster` for each cluster.

- [Large objects](#) are not supported. Although creating large objects is allowed, `multimaster` cannot replicate such objects, and their OIDs may conflict on different nodes, so their use is not recommended.
- Since `multimaster` is based on [logical replication and Paxos over three-phase commit protocol](#), its operation is highly affected by network latency. It is not recommended to set up a `multimaster` cluster with geographically distributed nodes.
- Using tables without primary keys can have negative impact on performance. In some cases, it can even lead to inability to restore a cluster node, so you should avoid replicating such tables with `multimaster`.
- Unlike in vanilla PostgreSQL, `read committed` isolation level can cause serialization failures on a multi-master cluster (with an SQLSTATE code '40001') if there are conflicting transactions from different nodes, so the application must be ready to retry transactions. *Serializable* isolation level works only with respect to local transactions on the current node.
- Sequence generation. To avoid conflicts between unique identifiers on different nodes, `multimaster` modifies the default behavior of sequence generators. By default, ID generation on each node is started with this node number and is incremented by the number of nodes. For example, in a three-node cluster, 1, 4, and 7 IDs are allocated to the objects written onto the first node, while 2, 5, and 8 IDs are reserved for the second node. If you change the number of nodes in the cluster, the incrementation interval for new IDs is adjusted accordingly. Thus, the generated sequence values are not monotonic. If it is critical to get a monotonically increasing sequence cluster-wide, you can set the `multimaster.monotonic_sequences` to `true`.
- Commit latency. In the current implementation of logical replication, `multimaster` sends data to subscriber nodes only after the local commit, so you have to wait for transaction processing twice: first on the local node, and then on all the other nodes simultaneously. In the case of a heavy-write transaction, this may result in a noticeable delay.
- Logical replication does not guarantee that a system object OID is the same on all cluster nodes, so OIDs for the same object may differ between `multimaster` cluster nodes. If your driver or application relies on OIDs, make sure that their use is restricted to connections to one and the same node to avoid errors. For example, the `Npgsql` driver may not work correctly with `multimaster` if the `NpgsqlConnection.GlobalTypeMapper` method tries using OIDs in connections to different cluster nodes.
- A `multimaster` cluster node cannot function as a logical replication subscriber. While a `multimaster` node can function as a publisher, the subscription cannot automatically switch to another node if the node fails.
- Replicated non-conflicting transactions are applied on the receiving nodes in parallel, so such transactions may become visible on different nodes in different order.
- `REINDEX CONCURRENTLY`, `CREATE TABLESPACE`, and `DROP TABLESPACE` are not replicated to other nodes.
- `CREATE INDEX CONCURRENTLY` is not supported.
- `COMMIT AND CHAIN` feature is not supported.
- `CREATE [TEMP] TABLE AS` is not supported with queries that contain explicit use of variables or arguments of functions or procedures (if the command is executed in the context of a function or procedure), and other context-sensitive objects. It is not recommended to use `CREATE TABLE AS` with the `WITH DATA` clause (data copy) in a query that uses temporary tables as it may cause the new table data synchronization issues across cluster nodes.
- `multimaster` does not support an [in-memory system catalog for temporary tables](#).

F.37.2. Architecture

F.37.2.1. Replication

Since each server in a multi-master cluster can accept writes, any server can abort a transaction because of a concurrent update — in the same way as it happens on a single server between different backends. To ensure high availability and data consistency on all cluster nodes, `multimaster` uses [logical replication](#) and the three-phase commit protocol with transaction outcome determined by [Paxos consensus algorithm](#).

When Postgres Pro Enterprise loads the `multimaster` shared library, `multimaster` sets up a logical replication producer and consumer for each node, and hooks into the transaction commit pipeline. The typical data replication workflow consists of the following phases:

1. **PREPARE phase.** `multimaster` captures and implicitly transforms each `COMMIT` statement to a `PREPARE` statement. All the nodes that get the transaction via the replication protocol (*the cohort nodes*) send their vote for approving or declining the transaction to the backend process on the initiating node. This ensures that all the cohort can accept the transaction, and no write conflicts occur. For details on `PREPARE` transactions support in PostgreSQL, see the [PREPARE TRANSACTION](#) topic.

2. **PRECOMMIT** phase. If all the cohort nodes approve the transaction, the backend process sends a **PRECOMMIT** message to all the cohort nodes to express an intention to commit the transaction. The cohort nodes respond to the backend with the **PRECOMMITTED** message. In case of a failure, all the nodes can use this information to complete the transaction using a quorum-based voting procedure.
3. **COMMIT** phase. If **PRECOMMIT** is successful, the transaction is committed to all nodes.

If a node crashes or gets disconnected from the cluster between the **PREPARE** and **COMMIT** phases, the **PRECOMMIT** phase ensures that the survived nodes have enough information to complete the prepared transaction. The **PRECOMMITTED** messages help avoid the situation when the crashed node has already committed or aborted the transaction, but has not notified other nodes about the transaction status. In a two-phase commit (2PC), such a transaction would block resources (hold locks) until the recovery of the crashed node. Otherwise, data inconsistencies can appear in the database when the failed node is recovered, for example, if the failed node committed the transaction, but the survived node aborted it.

To complete the transaction, the backend must receive a response from the majority of the nodes. For example, for a cluster of $2N+1$ nodes, at least $N+1$ responses are required. Thus, **multimaster** ensures that your cluster is available for reads and writes while the majority of the nodes are connected, and no data inconsistencies occur in case of a node or connection failure.

F.37.2.2. Failure Detection and Recovery

Since **multimaster** allows writes to each node, it has to wait for responses about transaction acknowledgment from all the other nodes. Without special actions in case of a node failure, each commit would have to wait until the failed node recovery. To deal with such situations, **multimaster** periodically sends heartbeats to check the node state and the connectivity between nodes. When several heartbeats to the node are lost in a row, this node is kicked out of the cluster to allow writes to the remaining alive nodes. You can configure the heartbeat frequency and the response timeout in the `multimaster.heartbeat_send_timeout` and `multimaster.heartbeat_recv_timeout` parameters, respectively.

For example, suppose a five-node multi-master cluster experienced a network failure that split the network into two isolated subnets, with two and three cluster nodes. Based on heartbeats propagation information, **multimaster** will continue accepting writes at each node in the bigger partition, and deny all writes in the smaller one. Thus, a cluster consisting of $2N+1$ nodes can tolerate N node failures and stay alive if any $N+1$ nodes are alive and connected to each other. You can also set up a two nodes cluster plus a lightweight referee node that does not hold the data, but acts as a tie-breaker during symmetric node partitioning. For details, see [Section F.37.3.3](#).

In case of a partial network split when different nodes have different connectivity, **multimaster** finds a fully connected subset of nodes and disconnects nodes outside of this subset. For example, in a three-node cluster, if node A can access both B and C, but node B cannot access node C, **multimaster** isolates node C to ensure that both A and B can work.

To preserve order of transactions on different nodes and thus data integrity, the decision to exclude or add back node(s) must be taken coherently. Generations which represent a subset of currently supposedly live nodes serve this purpose. Technically, generation is a pair $\langle n, \text{members} \rangle$ where n is unique number and *members* is subset of configured nodes. A node always lives in some generation and switches to the one with higher number as soon as it learns about its existence; generation numbers act as logical clocks/terms/epochs here. Each transaction is stamped during commit with current generation of the node it is being executed on. The transaction can be proposed to be committed only after it has been **PREPARED** on all its generation members. This allows to design the recovery protocol so that order of conflicting committed transactions is the same on all nodes. Node resides in generation in one of three states (can be shown with `mtm.status()`):

1. **ONLINE**: node is member of the generation and making transactions normally;
2. **RECOVERY**: node is member of the generation, but it must apply in recovery mode transactions from previous generations to become **ONLINE**;
3. **DEAD**: node will never be **ONLINE** in this generation;

For alive nodes, there is no way to distinguish between a failed node that stopped serving requests and a network-partitioned node that can be accessed by database users, but is unreachable for other nodes. If during commit of writing transaction some of current generation members are disconnected, transaction is rolled back according to generation rules. To avoid futile work, connectivity is also checked during transaction start; if you try to access an isolated node, **multimaster** returns an error message indicating the current status of the node. Thus, to prevent stale reads read-only queries are also forbidden. If you would like to continue using a disconnected node outside of the cluster in the standalone mode, you have to uninstall the **multimaster** extension on this node, as explained in [Section F.37.4.5](#).

Each node maintains a data structure that keeps the information about the state of all nodes in relation to this node. You can get this data by calling the `mtm.status()` and the `mtm.nodes()` functions.

When a failed node connects back to the cluster, `multimaster` starts automatic recovery:

1. The reconnected node selects a cluster node, which is **ONLINE** in the highest generation, referred to as the *donor* node, and starts catching up with the current state of the cluster based on the Write-Ahead Log (WAL).
2. When the node is caught up, it ballots for including itself in the next generation. Once generation is elected, commit of new transactions will start waiting for apply on the joining node.
3. When the rest of transactions till the switch to the new generation is applied, the reconnected node is promoted to the **onLine** state and included into the replication scheme.

The correctness of recovery protocol was verified with TLA+ model checker. You can find the model (and more detailed description) at [doc/specs](#) directory of the source code.

Automatic recovery requires presence of all WAL files generated after node failure. If a node is down for a long time and storing more WALs is unacceptable, you may have to exclude this node from the cluster and manually restore it from one of the working nodes using `pg_basebackup`. For details, see [Section F.37.4.3](#).

F.37.2.3. Multimaster Background Workers

`mtm-monitor`

Starts all other workers for a database managed with multimaster. This is the first worker loaded during multimaster boot. Each multimaster node has a single `mtm-monitor` worker. When a new node is added, `mtm-monitor` starts `mtm-logrep-receiver` and `mtm-dmq-receiver` workers to enable replication to this node. If a node is dropped, `mtm-monitor` stops `mtm-logrep-receiver` and `mtm-dmq-receiver` workers that have been serving the dropped node. Each `mtm-monitor` controls workers on its own node only.

`mtm-logrep-receiver`

Receives logical replication stream from a given peer node. During normal operation, `mtm-logrep-receiver` sends replicated transactions to the pool of dynamic workers (see [mtm-logrep-receiver-dynworker](#)). During catchup, depending on the value of the [multimaster.catchup_algorithm](#) configuration parameter, `mtm-logrep-receiver` applies replicated transactions on the reconnected node or sends them to the pool of dynamic workers. The number of `mtm-logrep-receiver` workers on each node corresponds to the number of peer nodes available.

`mtm-dmq-receiver`

Receives acknowledgment for transactions sent to peers and checks for heartbeat timeouts. The number of `mtm-logrep-receiver` workers on each node corresponds to the number of peer nodes available.

`mtm-dmq-sender`

Collects acknowledgment for transactions applied on the current node and sends them to the corresponding [mtm-dmq-receiver](#) on the peer node. There is a single worker per Postgres Pro Enterprise instance.

`mtm-logrep-receiver-dynworker`

Dynamic pool worker for a given [mtm-logrep-receiver](#). Applies replicated transactions received during normal operation or catchup. You can use the [multimaster.max_workers](#) configuration parameter to specify the maximum number of dynamic workers.

`mtm-resolver`

Performs Paxos to resolve unfinished transactions. This worker is only active during recovery or when connection with other nodes was lost. There is a single worker per Postgres Pro Enterprise instance.

`mtm-campaigner`

Ballots for new generations to exclude some node(s) or add myself. There is a single worker per Postgres Pro Enterprise instance.

`mtm-replier`

Responds to requests of [mtm-campaigner](#) and [mtm-resolver](#).

F.37.3. Installation and Setup

To use `multimaster`, you need to install Postgres Pro Enterprise on all nodes of your cluster. Postgres Pro Enterprise includes all the required dependencies and extensions.

F.37.3.1. Setting up a Multi-Master Cluster

Suppose you are setting up a cluster of three nodes, with `node1`, `node2`, and `node3` host names. After installing Postgres Pro Enterprise on all nodes, you need to initialize data directory on each node, as explained in [Section 18.2](#). If you would like to set up a multi-master cluster for an already existing `mydb` database, you can load data from `mydb` to one of the nodes once the cluster is initialized, or you can load data to all new nodes before cluster initialization using any convenient mechanism, such as `pg_basebackup` or `pg_dump`.

Once the data directory is set up, complete the following steps on each cluster node:

1. Modify the `postgresql.conf` configuration file, as follows:

- Add `multimaster` to the `shared_preload_libraries` variable:

```
shared_preload_libraries = 'multimaster'
```

Tip

If the `shared_preload_libraries` variable is already defined in `postgresql.auto.conf`, you will need to modify its value using the `ALTER SYSTEM` command. For details, see [Section 19.1.2](#). Note that in a multi-master cluster, the `ALTER SYSTEM` command only affects the configuration of the node from which it was run.

- Set up Postgres Pro Enterprise parameters related to replication:

```
wal_level = logical
max_connections = 100
max_prepared_transactions = 300 # max_connections * N
max_wal_senders = 10           # at least N
max_replication_slots = 10     # at least 2N
wal_sender_timeout = 0
```

where N is the number of nodes in your cluster.

You must change the replication level to `logical` as `multimaster` relies on logical replication. For a cluster of N nodes, enable at least N WAL sender processes and replication slots. Since `multimaster` implicitly adds a `PREPARE` phase to each `COMMIT` transaction, make sure to set the number of prepared transactions to $N * \text{max\_connections}$. `wal_sender_timeout` should be disabled as `multimaster` uses its custom logic for failure detection.

- Make sure you have enough background workers allocated for each node:

```
max_worker_processes = 250 # (N - 1) * (multimaster.max_workers + 1) + 5
```

For example, for a three-node cluster with `multimaster.max_workers = 100`, `multimaster` may need up to 207 background workers at peak times: five always-on workers (monitor, resolver, dmq-sender, campaigner, replier), one wal-receiver per each peer node and up to 200 replication dynamic workers. When setting this parameter, remember that other modules may also use background workers at the same time.

- Depending on your network environment and usage patterns, you may want to tune other `multimaster` parameters. For details, see [Section F.37.3.2](#).

2. Start Postgres Pro Enterprise on all nodes.

3. Create database `mydb` and user `mtmuser` on each node:

```
CREATE USER mtmuser WITH SUPERUSER PASSWORD 'mtmuserpassword';
CREATE DATABASE mydb OWNER mtmuser;
```

If you are using password-based authentication, you may want to create a [password file](#).

You can omit this step if you already have a database you are going to replicate, but you are recommended to create a separate superuser for multi-master replication. The examples below assume that you are going to replicate the `mydb` database on behalf of `mtmuser`.

4. Allow replication of the `mydb` database to each cluster node on behalf of `mtmuser`, as explained in [Section 20.1](#). Make sure to use the [authentication method](#) that satisfies your security requirements. For example, `pg_hba.conf` might have the following lines on `node1`:

```
host replication mtmuser node2 md5
host mydb mtmuser node2 md5
host replication mtmuser node3 md5
host mydb mtmuser node3 md5
```

5. Connect to any node on behalf of the `mtmuser` database user, create the `multimaster` extension in the `mydb` database and run `mtm.init_cluster()`, specifying the connection string to the current node as the first argument and an array of connection strings to the other nodes as the second argument.

For example, if you would like to connect to `node1`, run:

```
CREATE EXTENSION multimaster;
SELECT mtm.init_cluster('dbname=mydb user=mtmuser host=node1',
'{"dbname=mydb user=mtmuser host=node2", "dbname=mydb user=mtmuser host=node3"}');
```

6. To ensure that `multimaster` is enabled, you can run the `mtm.status()` and `mtm.nodes()` functions:

```
SELECT * FROM mtm.status();
SELECT * FROM mtm.nodes();
```

If `status` is equal to `online` and all nodes are present in the `mtm.nodes` output, your cluster is successfully configured and ready to use.

Tip

If you have any data that must be present on one of the nodes only, you can exclude a particular table from replication, as follows:

```
SELECT mtm.make_table_local('table_name')
```

F.37.3.2. Tuning Configuration Parameters

While you can use `multimaster` in the default configuration, you may want to tune several parameters for faster failure detection or more reliable automatic recovery.

F.37.3.2.1. Setting Timeout for Failure Detection

To check availability of the peer nodes, `multimaster` periodically sends heartbeat packets to all nodes. You can define the timeout for failure detection with the following variables:

- The `multimaster.heartbeat_send_timeout` variable defines the time interval between the heartbeats. By default, this variable is set to 200ms.
- The `multimaster.heartbeat_recv_timeout` variable sets the timeout for the response. If no heartbeats are received during this time, the node is assumed to be disconnected and is excluded from the cluster. By default, this variable is set to 2000ms.

It's a good idea to set `multimaster.heartbeat_send_timeout` based on typical ping latencies between the nodes. Small `recv/send` ratio decreases the time of failure detection, but increases the probability of false-positive failure detection. When setting this parameter, take into account the typical packet loss ratio between your cluster nodes.

F.37.3.3. 2+1 Mode: Setting up a Standalone Referee Node

By default, `multimaster` uses a majority-based algorithm to determine whether the cluster nodes have a quorum: a cluster can only continue working if the majority of its nodes are alive and can access each other. Majority-based approach is pointless for

two nodes cluster: if one of them fails, another one becomes inaccessible. There is a special 2+1 or referee mode which trades less hardware resources by decreasing availability: two nodes hold full copy of data, and separate referee node participates only in voting, acting as a tie-breaker.

If one node goes down, another one requests referee grant (elects referee-approved generation with single node). Once the grant is received, it continues to work normally. If offline node gets up, it recovers and elects full generation containing both nodes, essentially removing the grant - this allows the node to get it in its turn later. While the grant is issued, it can't be given to another node until full generation is elected and excluded node recovers. This ensures data loss doesn't happen by the price of availability: in this setup two nodes (one normal and one referee) can be alive but cluster might be still unavailable if the referee winner is down, which is impossible with classic three nodes configuration.

The referee node does not store any cluster data, so it is not resource-intensive and can be configured on virtually any system with Postgres Pro Enterprise installed.

To avoid split-brain problems, you must have only a single referee in your cluster.

To set up a referee for your cluster:

1. Install Postgres Pro Enterprise on the node you are going to make a referee and create the `referee` extension:

```
CREATE EXTENSION referee;
```

2. Make sure the `pg_hba.conf` file allows access to the referee node.
3. Set up the nodes that will hold cluster data following the instructions in [Section F.37.3.1](#).
4. On all data nodes, specify the referee connection string in the `postgresql.conf` file:

```
multimaster.referee_connstring = connstring
```

where *connstring* holds [libpq options](#) required to access the referee.

The first subset of nodes that gets connected to the referee wins the voting and starts working. The other nodes have to go through the recovery process to catch up with them and join the cluster. Under heavy load, the recovery can take unpredictably long, so it is recommended to wait for all data nodes going online before switching on the load when setting up a new cluster. Once all the nodes get online, the referee discards the voting result, and all data nodes start operating together.

In case of any failure, the voting mechanism is triggered again. At this time, all nodes appear to be offline for a short period of time to allow the referee to choose a new winner, so you can see the following error message when trying to access the cluster: `[multimaster] node is not online: current status is "disabled"`.

F.37.4. Multi-Master Cluster Administration

- [Monitoring the Cluster Status](#)
- [Accessing Disabled Nodes](#)
- [Adding New Nodes to the Cluster](#)
- [Removing Nodes from the Cluster](#)
- [Checking Data Consistency Across Cluster Nodes](#)
- [Delayed Transaction Commits](#)

F.37.4.1. Monitoring Cluster Status

`multimaster` provides several functions to check the current cluster state.

To check node-specific information, use `mtm.status()`:

```
SELECT * FROM mtm.status();
```

To get the list of all nodes in the cluster together with their status, use `mtm.nodes()`:

```
SELECT * FROM mtm.nodes();
```

For details on all the returned information, see [Section F.37.5.2](#).

F.37.4.2. Accessing Disabled Nodes

If a cluster node is disabled, any attempt to read or write data on this node raises an error by default. If you need to access the data on a disabled node, you can override this behavior at connection time by setting the `application_name` parameter to `mtm_admin`. In this case, you can run read and write queries on this node without multimaster supervision.

F.37.4.3. Adding New Nodes to the Cluster

Note

You must add nodes one by one. Avoid adding several nodes in parallel as this could cause errors.

With the `multimaster` extension, you can add or drop cluster nodes. Before adding node, stop the load and ensure (with `mtm.status()`) that all nodes are `online`. When adding a new node, you need to load all the data to this node using `pg_basebackup` from any cluster node, and then start this node.

Suppose we have a working cluster of three nodes, with `node1`, `node2`, and `node3` host names. To add `node4`, follow these steps:

1. Figure out the required connection string to access the new node. For example, for the database `mydb`, user `mtmuser`, and the new node `node4`, the connection string can be `"dbname=mydb user=mtmuser host=node4"`.
2. In `psql` connected to any alive node, run:

```
SELECT mtm.add_node('dbname=mydb user=mtmuser host=node4');
```

This command changes the cluster configuration on all nodes and creates replication slots for the new node. It also returns `node_id` of the new node, which will be required to complete the setup.

3. Go to the new node and clone all the data from one of the alive nodes to this node:

```
pg_basebackup -D datadir -h node1 -U mtmuser -c fast -v
```

`pg_basebackup` copies the entire data directory from `node1`, together with configuration settings, and prints the last LSN replayed from WAL, such as `'0/12D357F0'`. This value will be required to complete the setup.

4. Configure the new node to boot with `recovery_target=immediate` to prevent redo past the point where replication will begin. Add to `postgresql.conf`:

```
restore_command = 'false'  
recovery_target = 'immediate'  
recovery_target_action = 'promote'
```

And create `recovery.signal` file in the data directory.

5. Start Postgres Pro Enterprise on the new node.
6. In `psql` connected to the node used to take the base backup, run:

```
SELECT mtm.join_node(4, '0/12D357F0');
```

where 4 is the `node_id` returned by the `mtm.add_node()` function call and `'0/12D357F0'` is the LSN value returned by `pg_basebackup`.

F.37.4.4. Removing Nodes from the Cluster

Before removing node, stop the load and ensure (with `mtm.status()`) that all nodes (except the ones to be dropped) are `online`. Shut down the nodes you are going to remove. To remove the node from the cluster:

1. Run the `mtm.nodes()` function to learn the ID of the node to be removed:

```
SELECT * FROM mtm.nodes();
```

2. Run the `mtm.drop_node()` function with this node ID as a parameter:

```
SELECT mtm.drop_node(3);
```

This will delete replication slots for node 3 on all cluster nodes and stop replication to this node.

If you would like to return the node to the cluster later, you will have to add it as a new node, as explained in [Section F.37.4.3](#).

F.37.4.5. Uninstalling the multimaster Extension

If you would like to continue using the node that has been removed from the cluster in the standalone mode, you have to drop the `multimaster` extension on this node and clean up all `multimaster`-related subscriptions and uncommitted transactions to ensure that the node is no longer associated with the cluster.

1. Remove `multimaster` from [shared_preload_libraries](#) and restart Postgres Pro Enterprise.
2. Delete the `multimaster` extension and publication:

```
DROP EXTENSION multimaster;  
DROP PUBLICATION multimaster;
```

3. Review the list of existing subscriptions using the `\dRs` command and delete each subscription that starts with the `mtm_sub_` prefix:

```
\dRs  
DROP SUBSCRIPTION mtm_sub_subscription_name;
```

4. Review the list of existing replication slots and delete each slot that starts with the `mtm_` prefix:

```
SELECT * FROM pg_replication_slots;  
SELECT pg_drop_replication_slot('mtm_slot_name');
```

5. Review the list of existing replication origins and delete each origin that starts with the `mtm_` prefix:

```
SELECT * FROM pg_replication_origin;  
SELECT pg_replication_origin_drop('mtm_origin_name');
```

6. Review the list of prepared transaction left, if any:

```
SELECT * FROM pg_prepared_xacts;
```

You have to commit or abort these transactions by running `ABORT PREPARED transaction_id` or `COMMIT PREPARED transaction_id`, respectively.

Once all these steps are complete, you can start using the node in the standalone mode, if required.

F.37.4.6. Checking Data Consistency Across Cluster Nodes

You can check that the data is the same on all cluster nodes using the `mtm.check_query(query_text)` function.

As a parameter, this function takes the text of a query you would like to run for data comparison. When you call this function, it takes a consistent snapshot of data on each cluster node and runs this query against the captured snapshots. The query results are compared between pairs of nodes. If there are no differences, this function returns `true`. Otherwise, it reports the first detected difference in a warning and returns `false`.

To avoid false-positive results, always use the `ORDER BY` clause in your test query. For example, suppose you would like to check that the data in a `my_table` is the same on all cluster nodes. Compare the results of the following queries:

```
postgres=# SELECT mtm.check_query('SELECT * FROM my_table ORDER BY id');  
check_query
```

```
-----
```

```
t  
(1 row)
```

```
postgres=# SELECT mtm.check_query('SELECT * FROM my_table');  
WARNING: mismatch in column 'b' of row 0: 256 on node0, 255 on node1  
check_query
```

```
-----
```

```
f
(1 row)
```

Even though the data is the same, the second query reports an issue because the order of the returned data differs between cluster nodes.

F.37.4.7. Delayed Transaction Commits

When a lagging node is catching up to the donor node and cannot apply changes as quickly, you can slow down transaction execution on the donor node using the `multimaster.tx_delay_on_slow_catchup` configuration parameter. To do this, set this parameter to `on` in the `postgresql.conf` configuration file on the donor node, but not on the lagging peer node. If you edit the file on a running server, you will need to signal the postmaster to make it re-read the file (see [Chapter 19](#) for details). If necessary, you can also specify the maximum possible delay for transaction execution in the optional `multimaster.max_tx_delay_on_slow_catchup` parameter (in milliseconds). A value of `0` means that no maximum delay is set. Currently, delays can range from 1 ms to approximately 4 seconds. Values outside the allowed range will be truncated towards the nearest valid value.

By default, this feature is disabled.

F.37.5. Reference

F.37.5.1. Configuration Parameters

`multimaster.heartbeat_recv_timeout`

Timeout, in milliseconds. If no heartbeat message is received from the node within this timeframe, the node is excluded from the cluster.

Default: 2000 ms

`multimaster.heartbeat_send_timeout`

Time interval between heartbeat messages, in milliseconds. An arbiter process broadcasts heartbeat messages to all nodes to detect connection problems.

Default: 200 ms

`multimaster.max_workers`

The maximum number of `walreceiver` workers per peer node.

Important

This parameter should be used with caution. If the number of simultaneous transactions in the whole cluster is bigger than the provided value, it can lead to undetected deadlocks.

Default: 100

`multimaster.monotonic_sequences`

Defines the sequence generation mode for unique identifiers. This variable can take the following values:

- `false` (default) — ID generation on each node is started with this node number and is incremented by the number of nodes. For example, in a three-node cluster, 1, 4, and 7 IDs are allocated to the objects written onto the first node, while 2, 5, and 8 IDs are reserved for the second node. If you change the number of nodes in the cluster, the incrementation interval for new IDs is adjusted accordingly.
- `true` — the generated sequence increases monotonically cluster-wide. ID generation on each node is started with this node number and is incremented by the number of nodes, but the values are omitted if they are smaller than the already generated IDs on another node. For example, in a three-node cluster, if 1, 4 and 7 IDs are already allocated to the objects on the first node, 2 and 5 IDs will be omitted on the second node. In this case, the first ID on the second node is 8. Thus, the next generated ID is always higher than the previous one, regardless of the cluster node.

Default: `false`

`multimaster.referee_connstring`

Connection string to access the referee node. You must set this parameter on all cluster nodes if the referee is set up.

`multimaster.remote_functions`

Provides a comma-separated list of function names that should be executed remotely on all multimaster nodes instead of replicating the result of their work.

`multimaster.trans_spill_threshold`

The maximal size of transaction, in kB. When this threshold is reached, the transaction is written to the disk.

Default: 100MB

`multimaster.break_connection`

Break connection with clients connected to the node if this node disconnects from the cluster. If this variable is set to `false`, the client stays connected to the node but receives an error that the node is disabled.

Default: `false`

`multimaster.connect_timeout`

Maximum time to wait while connecting, in seconds. Zero, negative, or not specified means wait indefinitely. The minimum allowed timeout is 2 seconds, therefore a value of 1 is interpreted as 2.

Default: 0

`multimaster.ignore_tables_without_pk`

Do not replicate tables without primary key. When `false`, such tables are replicated.

Default: `false`

`multimaster.syncpoint_interval`

Amount of WAL generated between synchronization points.

Default: 10 MB

`multimaster.binary_basetypes`

Send data of built-in types in binary format.

Default: `true`

`multimaster.wait_peer_commits`

Wait until all peers commit the transaction before the command returns a success indication to the client.

Default: `true`

`multimaster.deadlock_prevention`

Manage prevention of transaction deadlocks that can occur when the same tuple is updated or deleted on different nodes simultaneously. If set to `off`, deadlock prevention is disabled.

If set to `simple`, the conflicting transactions are rejected. This setting may be used in any setup.

If set to `smart`, a specific algorithm is used to provide best resource availability by selectively committing or rejecting transactions. This is recommended for a setup of [two nodes and a referee](#). In three node setups, deadlocks are still possible. If there are more than four nodes, all conflicting transactions are rejected, just as with `simple`.

Default: `off`

`multimaster.tx_delay_on_slow_catchup`

Enable delay of transaction commits on the donor node when peer nodes are catching up to this node. This parameter should only be set on the donor node.

Default: `off`

`multimaster.max_tx_delay_on_slow_catchup`

If `multimaster.tx_delay_on_slow_catchup` is enabled, this parameter specifies maximum transaction execution delay, in milliseconds. Possible values are integers greater than 0, but it allows values only up to 4 seconds.

Default: 0

`multimaster.enable_async_3pc_on_catchup`

Enables asynchronous commit operations (`PREPARE`, `PRECOMMIT`, and `COMMIT PREPARED`) on a lagging node syncing with the donor node. This significantly accelerates the catchup process. Data integrity is maintained using the synchronization point mechanism: during catchup, the system periodically creates synchronization points when all preceding transactions are safely written to disk. This way, even if the lagging node is restarted, no transaction data is lost.

Default: `true`

`multimaster.catchup_algorithm`

Catchup mode for reconnected nodes. It determines how replicated transactions are applied on the reconnected node that is catching up. This configuration parameter can take one of the following values:

- `sequential` — `mtm-logrep-receiver` applies replicated transactions sequentially in the order they are received.
- `parallel` — `mtm-logrep-receiver` sends replicated transactions to the pool of dynamic workers (see [mtm-logrep-receiver-dynworker](#)). Dynamic workers apply non-conflicting transactions in parallel and conflicting transactions sequentially in the receiving order, similar to the `sequential` catchup mode. You can use the [multimaster.parallel_catchup_workers](#) configuration parameter to specify the maximum number of dynamic workers that can apply replicated transactions in this catchup mode.

Default: `sequential`

`multimaster.parallel_catchup_workers`

The maximum number of dynamic workers that can apply replicated transactions on the reconnected node in the `parallel` catchup mode. The value of this configuration parameter cannot be greater than that of the [multimaster.max_workers](#) configuration parameter. You can use the [multimaster.catchup_algorithm](#) configuration parameter to specify the catchup mode for reconnected nodes.

Default: 8

F.37.5.2. Functions

`mtm.init_cluster(my_conninfo text, peers_conninfo text[])`

Initializes cluster configuration on all nodes. It connects the current node to all nodes listed in `peers_conninfo` and creates the multimaster extension, replications slots, and replication origins on each node. Run this function once all the nodes are running and can accept connections.

Arguments:

- `my_conninfo` — connection string to the node on which you are running this function. Peer nodes use this string to connect back to this node.
- `peers_conninfo` — an array of connection strings to all the other nodes to be added to the cluster.

`mtm.add_node(connstr text)`

Adds a new node to the cluster. This function should be called before loading data to this node using `pg_basebackup`. `mtm.add_node` creates the required replication slots for a new node, so you can add a node while the cluster is under load.

Arguments:

- *connstr* — connection string for the new node. For example, for the database `mydb`, user `mtmuser`, and the new node `node4`, the connection string is `"dbname=mydb user=mtmuser host=node4"`.

`mtm.join_node(node_id int, backup_end_lsn pg_lsn)`

Completes the cluster setup after adding a new node. This function should be called after the added node has been started.

Arguments:

- *node_id* — ID of the node to add to the cluster. It corresponds to the value in the `id` column returned by `mtm.nodes()`.

backup_end_lsn — the last LSN of the base backup copied to the new node. This LSN will be used as the starting point for data replication once the node joins the cluster.

`mtm.drop_node(node_id integer)`

Excludes a node from the cluster.

If you would like to continue using this node outside of the cluster in the standalone mode, you have to uninstall the `multi-master` extension from this node, as explained in [Section F.37.4.5](#).

Arguments:

- *node_id* — ID of the node being dropped. It corresponds to the value in the `id` column returned by `mtm.nodes()`.

`mtm.alter_sequences()`

Fixes unique identifiers on all cluster nodes. This may be required after restoring all nodes from a single base backup.

`mtm.status()`

Shows the status of the `multimaster` extension on the current node. Returns a tuple of the following values:

- *my_node_id*, `int` — ID of this node.
- *status*, `text` — status of the node. Possible values are: `online`, `recovery`, `catchup`, `disabled` (need to recover, but not yet clear from whom), `isolated` (online in current generation, but some members are disconnected).
- *connected*, `int[]` — array of peer IDs connected to this node.
- *gen_num*, `int8` — current generation number.
- *gen_members*, `int[]` — array of current generation members node IDs.
- *gen_members_online*, `int[]` — array of current generation members node IDs which are `online` in it.
- *gen_configured*, `int[]` — array of node IDs configured in current generation.

`mtm.nodes()`

Shows the information on all nodes in the cluster. Returns a tuple of the following values:

- *id*, `integer` — node ID.
- *conninfo*, `text` — connection string to this node.
- *is_self*, `boolean` — is it me?
- *enabled*, `boolean` — is this node online in current generation?
- *connected*, `boolean` — shows whether the node is connected to our node.
- *sender_pid*, `integer` — WAL sender process ID.

- `receiver_pid`, integer — WAL receiver process ID.
- `n_workers`, text — number of started dynamic apply workers from this node.
- `receiver_mode`, text — in which mode receiver from this node works. Possible values are: `disabled`, `recovery`, `normal`.

`mtm.make_table_local(relation regclass)`

Stops replication for the specified table.

Arguments:

- `relation` — the table you would like to exclude from the replication scheme.

`mtm.check_query(query_text text)`

Checks data consistency across cluster nodes. This function takes a snapshot of the current state of each node, runs the specified query against these snapshots, and compares the results. If the results are different between any two nodes, displays a warning with the first found issue and returns `false`. Otherwise, returns `true`.

Arguments:

- `query_text` — the query you would like to run on all nodes for data comparison. To avoid false-positive results, always use the `ORDER BY` clause in the test query.

`mtm.get_snapshots()`

Takes a snapshot of data on each cluster node and returns the snapshot ID. The snapshots remain available until the `mtm.free_snapshots()` is called, or the current session is terminated. This function is used by the [mtm.check_query\(query_text\)](#), there is no need to call it manually.

`mtm.free_snapshots()`

Removes data snapshots taken by the `mtm.get_snapshots()` function. This function is used by the [mtm.check_query\(query_text\)](#), there is no need to call it manually.

F.37.6. Compatibility

F.37.6.1. Local and Global DDL Statements

By default, any DDL statement is executed on all cluster nodes, except the following statements that can only act locally on a given node:

- `ALTER SYSTEM`
- `CREATE DATABASE`
- `DROP DATABASE`
- `REINDEX`
- `CHECKPOINT`
- `CLUSTER`
- `LOAD`
- `LISTEN`
- `CHECKPOINT`
- `NOTIFY`

F.37.7. Authors

Postgres Professional, Moscow, Russia.

F.37.7.1. Credits

The replication mechanism is based on logical decoding and an earlier version of the `pglogical` extension provided for community by the 2ndQuadrant team.

The Paxos consensus algorithm is described at:

- Leslie Lamport. [*The Part-Time Parliament*](#)

Parallel replication and recovery mechanism is similar to the one described in:

- Odorico M. Mendizabal, et al. [*Checkpointing in Parallel State-Machine Replication*](#).

F.38. online_analyze — update statistics after INSERT, UPDATE, DELETE, SELECT INTO, or COPY operations

The `online_analyze` module provides a set of features that immediately update statistics after `INSERT`, `UPDATE`, `DELETE`, `SELECT INTO`, or `COPY` operations for the affected tables.

Note

This extension cannot be used together with autonomous transactions.

Note

It is not recommended to use this module with modern versions of 1C.

However, you can enable `online_analyze` if background updates do not provide the desired result or if the optimizer frequently fails to estimate the row count.

The instruction below is relevant only if you decide to use the module.

F.38.1. Module Loading

To use `online_analyze` module, load the shared library:

```
LOAD 'online_analyze';
```

F.38.2. Module Configuration

You can configure `online_analyze` using the following custom variables (default values are shown):

- `online_analyze.enable = on`

Enables `online_analyze`.

- `online_analyze.verbose = on`

Executes `ANALYZE VERBOSE`.

Note

Since `verbose` is a reserved SQL key word, this parameter has to be double-quoted when used in SQL queries. For example:

```
ALTER SYSTEM SET "online_analyze.verbose" = 'off';
```

- `online_analyze.scale_factor = 0.1`

Fraction of table size to start online analysis (similar to [autovacuum_analyze_scale_factor](#)).

- `online_analyze.threshold = 50`

Minimum number of row updates before starting online analysis (similar to [autovacuum_analyze_threshold](#)).

- `online_analyze.min_interval = 10000`

Minimum time interval between `ANALYZE` calls per table, in milliseconds.

- `online_analyze.table_type = "all"`

Type(s) of tables for online analysis. Possible values are: `all`, `persistent`, `temporary`, `none`.

- `online_analyze.exclude_tables = ''`

List of tables to exclude from online analysis.

- `online_analyze.include_tables = ''`

List of tables to include in online analysis (`online_analyze.include_tables` overrides `online_analyze.exclude_tables`).

- `online_analyze.local_tracking = off`

Enables per-backend tracking for temporary tables by `online_analyze`. When this variable is set to `off`, `online_analyze` uses the default system statistics for temporary tables.

- `online_analyze.lower_limit = 0`

Minimum number of rows in a table required to trigger `online_analyze`.

- `online_analyze.capacity_threshold = 100000`

Maximum number of temporary tables to store in local cache.

F.38.3. Authors

Teodor Sigaev <teodor@sigaev.ru>

F.39. pageinspect — low-level inspection of database pages

The `pageinspect` module provides functions that allow you to inspect the contents of database pages at a low level, which is useful for debugging purposes. All of these functions may be used only by superusers.

F.39.1. General Functions

`get_raw_page(relname text, fork text, blkno bigint)` returns `bytea`

`get_raw_page` reads the specified block of the named relation and returns a copy as a `bytea` value. This allows a single time-consistent copy of the block to be obtained. *fork* should be 'main' for the main data fork, 'fsm' for the [free space map](#), 'vm' for the [visibility map](#), or 'init' for the initialization fork.

`get_raw_page(relname text, blkno bigint)` returns `bytea`

A shorthand version of `get_raw_page`, for reading from the main fork. Equivalent to `get_raw_page(relname, 'main', blkno)`

`page_header(page bytea)` returns `record`

`page_header` shows fields that are common to all Postgres Pro heap and index pages.

A page image obtained with `get_raw_page` should be passed as argument. For example:

```
test=# SELECT * FROM page_header(get_raw_page('pg_class', 0));
   lsn      | checksum | flags | lower | upper | special | pagesize | version |
   xid_base | multi_base | prune_xid
-----+-----+-----+-----+-----+-----+-----+-----+
0/1605260 |      6885 |    1 |   204 |  7480 |      8168 |      8192 |      254 |
   0       |         0 |     0
```

The returned columns correspond to the fields in the `PageHeaderData` struct.

The `checksum` field is the checksum stored in the page, which might be incorrect if the page is somehow corrupted. If data checksums are not enabled for this instance, then the value stored is meaningless.

`page_checksum(page bytea, blkno bigint)` returns `smallint`

`page_checksum` computes the checksum for the page, as if it was located at the given block.

A page image obtained with `get_raw_page` should be passed as argument. For example:

```
test=# SELECT page_checksum(get_raw_page('pg_class', 0), 0);
 page_checksum
-----
      13443
```

Note that the checksum depends on the block number, so matching block numbers should be passed (except when doing esoteric debugging).

The checksum computed with this function can be compared with the `checksum` result field of the function `page_header`. If data checksums are enabled for this instance, then the two values should be equal.

`fsm_page_contents(page bytea)` returns `text`

`fsm_page_contents` shows the internal node structure of an FSM page. For example:

```
test=# SELECT fsm_page_contents(get_raw_page('pg_class', 'fsm', 0));
```

The output is a multiline string, with one line per node in the binary tree within the page. Only those nodes that are not zero are printed. The so-called "next" pointer, which points to the next slot to be returned from the page, is also printed.

F.39.2. Heap Functions

`heap_page_items(page bytea)` returns setof record

`heap_page_items` shows all line pointers on a heap page. For those line pointers that are in use, tuple headers as well as tuple raw data are also shown. All tuples are shown, whether or not the tuples were visible to an MVCC snapshot at the time the raw page was copied.

A heap page image obtained with `get_raw_page` should be passed as argument. For example:

```
test=# SELECT * FROM heap_page_items(get_raw_page('pg_class', 0));
```

The `heap_tuple_infomask_flags` function can be used to unpack the flag bits of `t_infomask` and `t_infomask2` for heap tuples.

`tuple_data_split(rel_oid oid, t_data bytea, t_infomask integer, t_infomask2 integer, t_bits text [, do_detoast bool])` returns bytea[]

`tuple_data_split` splits tuple data into attributes in the same way as backend internals.

```
test=# SELECT tuple_data_split('pg_class'::regclass, t_data, t_infomask,
    t_infomask2, t_bits) FROM heap_page_items(get_raw_page('pg_class', 0));
```

This function should be called with the same arguments as the return attributes of `heap_page_items`.

If `do_detoast` is true, attributes will be detoasted as needed. Default value is false.

`heap_page_item_attrs(page bytea, rel_oid regclass [, do_detoast bool])` returns setof record

`heap_page_item_attrs` is equivalent to `heap_page_items` except that it returns tuple raw data as an array of attributes that can optionally be detoasted by `do_detoast` which is false by default.

A heap page image obtained with `get_raw_page` should be passed as argument. For example:

```
test=# SELECT * FROM heap_page_item_attrs(get_raw_page('pg_class', 0),
    'pg_class'::regclass);
```

`heap_tuple_infomask_flags(t_infomask integer, t_infomask2 integer)` returns record

`heap_tuple_infomask_flags` decodes the `t_infomask` and `t_infomask2` returned by `heap_page_items` into a human-readable set of arrays made of flag names, with one column for all the flags and one column for combined flags. For example:

```
test=# SELECT t_ctid, raw_flags, combined_flags
    FROM heap_page_items(get_raw_page('pg_class', 0)),
    LATERAL heap_tuple_infomask_flags(t_infomask, t_infomask2)
    WHERE t_infomask IS NOT NULL OR t_infomask2 IS NOT NULL;
```

This function should be called with the same arguments as the return attributes of `heap_page_items`.

Combined flags are displayed for source-level macros that take into account the value of more than one raw bit, such as `HEAP_XMIN_FROZEN`.

F.39.3. B-Tree Functions

`bt_metap(relname text)` returns record

`bt_metap` returns information about a B-tree index's metapage. For example:

```
test=# SELECT * FROM bt_metap('pg_cast_oid_index');
-[ RECORD 1 ]-----+-----
magic          | 340322
version        | 4
root           | 1
level          | 0
fastroot       | 1
```

<code>fastlevel</code>	0
<code>last_cleanup_num_delpages</code>	0
<code>last_cleanup_num_tuples</code>	230
<code>allequalimage</code>	f

`bt_page_stats(relname text, blkno bigint)` returns record

`bt_page_stats` returns summary information about a data page of a B-tree index. For example:

```
test=# SELECT * FROM bt_page_stats('pg_cast_oid_index', 1);
-[ RECORD 1 ]-+-----
blkno         | 1
type          | l
live_items    | 224
dead_items    | 0
avg_item_size | 16
page_size     | 8192
free_size     | 3668
btpo_prev     | 0
btpo_next     | 0
btpo_level    | 0
btpo_flags    | 3
```

`bt_multi_page_stats(relname text, blkno bigint, blk_count bigint)` returns setof record

`bt_multi_page_stats` returns the same information as `bt_page_stats`, but does so for each page of the range of pages beginning at *blkno* and extending for *blk_count* pages. If *blk_count* is negative, all pages from *blkno* to the end of the index are reported on. For example:

```
test=# SELECT * FROM bt_multi_page_stats('pg_proc_oid_index', 5, 2);
-[ RECORD 1 ]-+-----
blkno         | 5
type          | l
live_items    | 367
dead_items    | 0
avg_item_size | 16
page_size     | 8192
free_size     | 808
btpo_prev     | 4
btpo_next     | 6
btpo_level    | 0
btpo_flags    | 1
-[ RECORD 2 ]-+-----
blkno         | 6
type          | l
live_items    | 367
dead_items    | 0
avg_item_size | 16
page_size     | 8192
free_size     | 808
btpo_prev     | 5
btpo_next     | 7
btpo_level    | 0
btpo_flags    | 1
```

`bt_page_items(relname text, blkno bigint)` returns setof record

`bt_page_items` returns detailed information about all of the items on a B-tree index page. For example:

```
test=# SELECT itemoffset, ctid, itemlen, nulls, vars, data, dead, htid, tids[0:2] AS
       some_tids
       FROM bt_page_items('tenk2_hundred', 5);
```

Additional Supplied Modules and
Extensions Shipped in post-
grespro-ent-17-contrib

itemoffset htid	ctid some_tids	itemlen	nulls	vars	data	dead

(13 rows)

This is a B-tree leaf page. All tuples that point to the table happen to be posting list tuples (all of which store a total of 100 6 byte TIDs). There is also a “high key” tuple at `itemoffset` number 1. `ctid` is used to store encoded information about each tuple in this example, though leaf page tuples often store a heap TID directly in the `ctid` field instead. `tids` is the list of TIDs stored as a posting list.

In an internal page (not shown), the block number part of `ctid` is a “downlink”, which is a block number of another page in the index itself. The offset part (the second number) of `ctid` stores encoded information about the tuple, such as the number of columns present (suffix truncation may have removed unneeded suffix columns). Truncated columns are treated as having the value “minus infinity”.

`htid` shows a heap TID for the tuple, regardless of the underlying tuple representation. This value may match `ctid`, or may be decoded from the alternative representations used by posting list tuples and tuples from internal pages. Tuples in internal pages usually have the implementation level heap TID column truncated away, which is represented as a NULL `htid` value.

Note that the first item on any non-rightmost page (any page with a non-zero value in the `btpo_next` field) is the page's “high key”, meaning its `data` serves as an upper bound on all items appearing on the page, while its `ctid` field does not point to another block. Also, on internal pages, the first real data item (the first item that is not a high key) reliably has every column truncated away, leaving no actual value in its `data` field. Such an item does have a valid downlink in its `ctid` field, however.

For more details about the structure of B-tree indexes, see [Section 65.1.4.1](#). For more details about deduplication and posting lists, see [Section 65.1.4.3](#).

`bt_page_items(page bytea)` returns `setof record`

It is also possible to pass a page to `bt_page_items` as a `bytea` value. A page image obtained with `get_raw_page` should be passed as argument. So the last example could also be rewritten like this:

```
test=# SELECT itemoffset, ctid, itemlen, nulls, vars, data, dead, htid, tids[0:2] AS
some_tids
```

FROM bt_page_items(get_raw_page('tenk2_hundred', 5));									
itemoffset	ctid	itemlen	nulls	vars	data				dead
htid	some_tids								
+-----+-----+-----+-----+-----+-----+-----+-----+-----+-----									
	1	(16,1)		16	f		f		30 00 00 00 00 00 00 00

(0,27)	{ "(0,27)", "(1,13)" }			616	f		f		2f 00 00 00 00 00 00 00
(4,17)	{ "(4,17)", "(4,21)" }								
(13 rows)									

All the other details are the same as explained in the previous item.

F.39.4. BRIN Functions

`brin_page_type`(page bytea) returns text

`brin_page_type` returns the page type of the given BRIN index page, or throws an error if the page is not a valid BRIN page. For example:

```
test=# SELECT brin_page_type(get_raw_page('brinidx', 0));
brin_page_type
-----
meta
```

`brin_metapage_info`(page bytea) returns record

`brin_metapage_info` returns assorted information about a BRIN index metapage. For example:

```
test=# SELECT * FROM brin_metapage_info(get_raw_page('brinidx', 0));
 magic | version | pagesperpage | lastrevmappage
-----+-----+-----+-----
0xA8109CFA | 1 | 4 | 2
```

`brin_revmap_data`(page bytea) returns setof tid

`brin_revmap_data` returns the list of tuple identifiers in a BRIN index range map page. For example:

```
test=# SELECT * FROM brin_revmap_data(get_raw_page('brinidx', 2)) LIMIT 5;
pages
```

```
-----
(6,137)
(6,138)
(6,139)
(6,140)
(6,141)
```

brin_page_items(page bytea, index oid) returns setof record

brin_page_items returns the data stored in the BRIN data page. For example:

```
test=# SELECT * FROM brin_page_items(get_raw_page('brinidx', 5),
                                     'brinidx')
      ORDER BY blknum, attnum LIMIT 6;
 itemoffset | blknum | attnum | allnulls | hasnulls | placeholder | empty | value
-----+-----+-----+-----+-----+-----+-----+-----
+-----+
      137 |      0 |      1 | t         | f         | f           | f      |
      137 |      0 |      2 | f         | f         | f           | f      | {1 ..
88}
      138 |      4 |      1 | t         | f         | f           | f      |
      138 |      4 |      2 | f         | f         | f           | f      | {89 ..
176}
      139 |      8 |      1 | t         | f         | f           | f      |
      139 |      8 |      2 | f         | f         | f           | f      | {177 ..
264}
```

The returned columns correspond to the fields in the BrinMemTuple and BrinValues structs.

F.39.5. GIN Functions

gin_metapage_info(page bytea) returns record

gin_metapage_info returns information about a GIN index metapage. For example:

```
test=# SELECT * FROM gin_metapage_info(get_raw_page('gin_index', 0));
-[ RECORD 1 ]-----+-----
pending_head      | 4294967295
pending_tail      | 4294967295
tail_free_size    | 0
n_pending_pages   | 0
n_pending_tuples  | 0
n_total_pages     | 7
n_entry_pages     | 6
n_data_pages      | 0
n_entries         | 693
version           | 2
```

gin_page_opaque_info(page bytea) returns record

gin_page_opaque_info returns information about a GIN index opaque area, like the page type. For example:

```
test=# SELECT * FROM gin_page_opaque_info(get_raw_page('gin_index', 2));
 rightlink | maxoff | flags
-----+-----+-----
          5 |      0 | {data, leaf, compressed}
(1 row)
```

gin_leafpage_items(page bytea) returns setof record

gin_leafpage_items returns information about the data stored in a compressed GIN leaf page. For example:

```
test=# SELECT first_tid, nbytes, tids[0:5] AS some_tids
      FROM gin_leafpage_items(get_raw_page('gin_test_idx', 2));
```

first_tid	nbytes	some_tids
(8,41)	244	{"(8,41)","(8,43)","(8,44)","(8,45)","(8,46)"}
(10,45)	248	{"(10,45)","(10,46)","(10,47)","(10,48)","(10,49)"}
(12,52)	248	{"(12,52)","(12,53)","(12,54)","(12,55)","(12,56)"}
(14,59)	320	{"(14,59)","(14,60)","(14,61)","(14,62)","(14,63)"}
(167,16)	376	{"(167,16)","(167,17)","(167,18)","(167,19)","(167,20)"}
(170,30)	376	{"(170,30)","(170,31)","(170,32)","(170,33)","(170,34)"}
(173,44)	197	{"(173,44)","(173,45)","(173,46)","(173,47)","(173,48)"}

(7 rows)

F.39.6. GiST Functions

`gist_page_opaque_info(page bytea)` returns record

`gist_page_opaque_info` returns information from a GiST index page's opaque area, such as the NSN, rightlink and page type. For example:

```
test=# SELECT * FROM gist_page_opaque_info(get_raw_page('test_gist_idx', 2));
 lsn | nsn | rightlink | flags
-----+-----+-----+-----
 0/1 | 0/0 |          1 | {leaf}
(1 row)
```

`gist_page_items(page bytea, index_oid regclass)` returns setof record

`gist_page_items` returns information about the data stored in a page of a GiST index. For example:

```
test=# SELECT * FROM gist_page_items(get_raw_page('test_gist_idx', 0),
 'test_gist_idx');
 itemoffset |   ctid   | itemlen | dead |          keys
-----+-----+-----+-----+-----
          1 | (1,65535) |      40 | f    | (p)=("(185,185),(1,1)")
          2 | (2,65535) |      40 | f    | (p)=("(370,370),(186,186)")
          3 | (3,65535) |      40 | f    | (p)=("(555,555),(371,371)")
          4 | (4,65535) |      40 | f    | (p)=("(740,740),(556,556)")
          5 | (5,65535) |      40 | f    | (p)=("(870,870),(741,741)")
          6 | (6,65535) |      40 | f    | (p)=("(1000,1000),(871,871)")
(6 rows)
```

`gist_page_items_bytea(page bytea)` returns setof record

Same as `gist_page_items`, but returns the key data as a raw `bytea` blob. Since it does not attempt to decode the key, it does not need to know which index is involved. For example:

```
test=# SELECT * FROM gist_page_items_bytea(get_raw_page('test_gist_idx', 0));
 itemoffset |   ctid   | itemlen | dead |          key_data
-----+-----+-----+-----+-----
          1 | (1,65535) |      40 | f    | \x000000100ffff2800000000000000c064400000000000c064400000000000f03f00000000000f03f
          2 | (2,65535) |      40 | f    | \x000000200ffff280000000000000c074400000000000c074400000000000e06440000000000e06440
          3 | (3,65535) |      40 | f    | \x000000300ffff280000000000000207f400000000000207f400000000000d07440000000000d07440
          4 | (4,65535) |      40 | f    | \x000000400ffff280000000000000c084400000000000c084400000000000307f400000000000307f40
          5 | (5,65535) |      40 | f    | \x000000500ffff280000000000000f089400000000000f089400000000000c88440000000000c88440

(7 rows)

```

F.39.7. Hash Functions

hash_page_type(page bytea) returns text

hash_page_type returns page type of the given HASH index page. For example:

```

test=# SELECT hash_page_type(get_raw_page('con_hash_index', 0));
 hash_page_type
-----
metapage

```

hash_page_stats(page bytea) returns setof record

hash_page_stats returns information about a bucket or overflow page of a HASH index. For example:

```

test=# SELECT * FROM hash_page_stats(get_raw_page('con_hash_index', 1));
-[ RECORD 1 ]-----+-----
live_items          | 407
dead_items          | 0
page_size           | 8192
free_size           | 8
hasho_prevblkno     | 4096
hasho_nextblkno     | 8474
hasho_bucket        | 0
hasho_flag           | 66
hasho_page_id       | 65408

```

hash_page_items(page bytea) returns setof record

hash_page_items returns information about the data stored in a bucket or overflow page of a HASH index page. For example:

```

test=# SELECT * FROM hash_page_items(get_raw_page('con_hash_index', 1)) LIMIT 5;
 itemoffset | ctid      | data
-----+-----+-----
1 | (899,77) | 1053474816
2 | (897,29) | 1053474816
3 | (894,207) | 1053474816
4 | (892,159) | 1053474816
5 | (890,111) | 1053474816

```

hash_bitmap_info(index oid, blkno bigint) returns record

hash_bitmap_info shows the status of a bit in the bitmap page for a particular overflow page of HASH index. For example:

```

test=# SELECT * FROM hash_bitmap_info('con_hash_index', 2052);
 bitmapblkno | bitmapbit | bitstatus
-----+-----+-----
65 | 3 | t

```

hash_metapage_info(page bytea) returns record

hash_metapage_info returns information stored in the meta page of a HASH index. For example:

```

test=# SELECT magic, version, ntuples, ffactor, bsize, bmsize, bmshift,
test=#       maxbucket, highmask, lowmask, ovflpoint, firstfree, nmaps, procid,
test=#       regexp_replace(spares::text, '(\,0)*}', '{}') as spares,
test=#       regexp_replace(mapp::text, '(\,0)*}', '{}') as mapp
test=# FROM hash_metapage_info(get_raw_page('con_hash_index', 0));
-[ RECORD 1 ]-----+-----

```

F.40. passwordcheck — verify password strength

The `passwordcheck` module checks users' passwords whenever they are set with [CREATE ROLE](#) or [ALTER ROLE](#) (it doesn't work, if a non-default profile is assigned to the user). If a password is considered too weak, it will be rejected and the command will terminate with an error.

To enable this module, add `'$libdir/passwordcheck'` to [shared_preload_libraries](#) in `postgresql.conf`, then restart the server.

Caution

To prevent unencrypted passwords from being sent across the network, written to the server log or otherwise stolen by a database administrator, Postgres Pro allows the user to supply pre-encrypted passwords. Many client programs make use of this functionality and encrypt the password before sending it to the server.

This limits the usefulness of the `passwordcheck` module, because in that case it can only try to guess the password. For this reason, `passwordcheck` is not recommended if your security requirements are high. It is more secure to use an external authentication method such as GSSAPI (see [Chapter 20](#)) than to rely on passwords within the database.

F.41. `pg_buffercache` — inspect Postgres Pro buffer cache state

The `pg_buffercache` module provides a means for examining what's happening in the shared buffer cache in real time. It also offers a low-level way to evict data from it, for testing purposes.

This module provides the `pg_buffercache_pages()` function (wrapped in the `pg_buffercache` view), the `pg_buffercache_summary()` function, the `pg_buffercache_usage_counts()` function and the `pg_buffercache_evict()` function.

The `pg_buffercache_pages()` function returns a set of records, each row describing the state of one shared buffer entry. The `pg_buffercache` view wraps the function for convenient use.

The `pg_buffercache_summary()` function returns a single row summarizing the state of the shared buffer cache.

The `pg_buffercache_usage_counts()` function returns a set of records, each row describing the number of buffers with a given usage count.

By default, use of the above functions is restricted to superusers and roles with privileges of the `pg_monitor` role. Access may be granted to others using `GRANT`.

The `pg_buffercache_evict()` function allows a block to be evicted from the buffer pool given a buffer identifier. Use of this function is restricted to superusers only.

F.41.1. The `pg_buffercache` View

The definitions of the columns exposed by the view are shown in [Table F.22](#).

Table F.22. `pg_buffercache` Columns

Column Type Description
<code>bufferid</code> integer ID, in the range 1.. <code>shared_buffers</code>
<code>relfilenode</code> oid (references pg_class.relfilenode) Filenode number of the relation
<code>reltablespace</code> oid (references pg_tablespace.oid) Tablespace OID of the relation
<code>reldatabase</code> oid (references pg_database.oid) Database OID of the relation
<code>relforknumber</code> smallint Fork number within the relation
<code>relblocknumber</code> bigint Page number within the relation
<code>isdirty</code> boolean Is the page dirty?
<code>usagecount</code> smallint Clock-sweep access count
<code>pinning_backends</code> integer Number of backends pinning this buffer

There is one row for each buffer in the shared cache. Unused buffers are shown with all fields null except `bufferid`. Shared system catalogs are shown as belonging to database zero.

Because the cache is shared by all the databases, there will normally be pages from relations not belonging to the current database. This means that there may not be matching join rows in `pg_class` for some rows, or that there could even be incorrect joins. If you are trying to join against `pg_class`, it's a good idea to restrict the join to rows having `reldatabase` equal to the current database's OID or zero.

Since buffer manager locks are not taken to copy the buffer state data that the view will display, accessing `pg_buffercache` view has less impact on normal buffer activity but it doesn't provide a consistent set of results across all buffers. However, we ensure that the information of each buffer is self-consistent.

F.41.2. The `pg_buffercache_summary()` Function

The definitions of the columns exposed by the function are shown in [Table F.23](#).

Table F.23. `pg_buffercache_summary()` Output Columns

Column Type Description
<code>buffers_used</code> int4 Number of used shared buffers
<code>buffers_unused</code> int4 Number of unused shared buffers
<code>buffers_dirty</code> int4 Number of dirty shared buffers
<code>buffers_pinned</code> int4 Number of pinned shared buffers
<code>usagecount_avg</code> float8 Average usage count of used shared buffers

The `pg_buffercache_summary()` function returns a single row summarizing the state of all shared buffers. Similar and more detailed information is provided by the `pg_buffercache` view, but `pg_buffercache_summary()` is significantly cheaper.

Like the `pg_buffercache` view, `pg_buffercache_summary()` does not acquire buffer manager locks. Therefore concurrent activity can lead to minor inaccuracies in the result.

F.41.3. The `pg_buffercache_usage_counts()` Function

The definitions of the columns exposed by the function are shown in [Table F.24](#).

Table F.24. `pg_buffercache_usage_counts()` Output Columns

Column Type Description
<code>usage_count</code> int4 A possible buffer usage count
<code>buffers</code> int4 Number of buffers with the usage count
<code>dirty</code> int4 Number of dirty buffers with the usage count
<code>pinned</code> int4 Number of pinned buffers with the usage count

The `pg_buffercache_usage_counts()` function returns a set of rows summarizing the states of all shared buffers, aggregated over the possible usage count values. Similar and more detailed information is provided by the `pg_buffercache` view, but `pg_buffercache_usage_counts()` is significantly cheaper.

Like the `pg_buffercache` view, `pg_buffercache_usage_counts()` does not acquire buffer manager locks. Therefore concurrent activity can lead to minor inaccuracies in the result.

F.41.4. The `pg_buffercache_evict()` Function

The `pg_buffercache_evict()` function takes a buffer identifier, as shown in the `bufferid` column of the `pg_buffercache` view. It returns true on success, and false if the buffer wasn't valid, if it couldn't be evicted because it was pinned, or if it

became dirty again after an attempt to write it out. The result is immediately out of date upon return, as the buffer might become valid again at any time due to concurrent activity. The function is intended for developer testing only.

F.41.5. Sample Output

```
regression=# SELECT n.nspname, c.relname, count(*) AS buffers
              FROM pg_buffercache b JOIN pg_class c
              ON b.relfilenode = pg_relation_filenode(c.oid) AND
                 b.reldatabase IN (0, (SELECT oid FROM pg_database
                                     WHERE datname = current_database()))
              JOIN pg_namespace n ON n.oid = c.relnamespace
              GROUP BY n.nspname, c.relname
              ORDER BY 3 DESC
              LIMIT 10;
```

nspname	relname	buffers
public	delete_test_table	593

F.41.6. Authors

Mark Kirkwood <markir@paradise.net.nz>

Design suggestions: Neil Conway <neilc@samurai.com>

Debugging advice: Tom Lane <tgl@sss.pgh.pa.us>

F.42. pgcrypto — cryptographic functions

The `pgcrypto` module provides cryptographic functions for Postgres Pro.

This module is considered “trusted”, that is, it can be installed by non-superusers who have `CREATE` privilege on the current database.

`pgcrypto` requires OpenSSL and won't be installed if OpenSSL support was not selected when Postgres Pro was built.

F.42.1. General Hashing Functions

F.42.1.1. `digest()`

`digest(data text, type text)` returns `bytea`
`digest(data bytea, type text)` returns `bytea`

Computes a binary hash of the given *data*. *type* is the algorithm to use. Standard algorithms are `md5`, `sha1`, `sha224`, `sha256`, `sha384` and `sha512`. Moreover, any digest algorithm OpenSSL supports is automatically picked up.

If you want the digest as a hexadecimal string, use `encode()` on the result. For example:

```
CREATE OR REPLACE FUNCTION sha1(bytea) returns text AS $$  
    SELECT encode(digest($1, 'sha1'), 'hex')  
$$ LANGUAGE SQL STRICT IMMUTABLE;
```

F.42.1.2. `hmac()`

`hmac(data text, key text, type text)` returns `bytea`
`hmac(data bytea, key bytea, type text)` returns `bytea`

Calculates hashed MAC for *data* with key *key*. *type* is the same as in `digest()`.

This is similar to `digest()` but the hash can only be recalculated knowing the key. This prevents the scenario of someone altering data and also changing the hash to match.

If the key is larger than the hash block size it will first be hashed and the result will be used as key.

F.42.2. Password Hashing Functions

The functions `crypt()` and `gen_salt()` are specifically designed for hashing passwords. `crypt()` does the hashing and `gen_salt()` prepares algorithm parameters for it.

The algorithms in `crypt()` differ from the usual MD5 or SHA1 hashing algorithms in the following respects:

1. They are slow. As the amount of data is so small, this is the only way to make brute-forcing passwords hard.
2. They use a random value, called the *salt*, so that users having the same password will have different encrypted passwords. This is also an additional defense against reversing the algorithm.
3. They include the algorithm type in the result, so passwords hashed with different algorithms can co-exist.
4. Some of them are adaptive — that means when computers get faster, you can tune the algorithm to be slower, without introducing incompatibility with existing passwords.

[Table F.25](#) lists the algorithms supported by the `crypt()` function.

Table F.25. Supported Algorithms for `crypt()`

Algorithm	Max Password Length	Adaptive?	Salt Bits	Output Length	Description
bf	72	yes	128	60	Blowfish-based, variant 2a
md5	unlimited	no	48	34	MD5-based crypt
xdes	8	yes	24	20	Extended DES

Algorithm	Max Password Length	Adaptive?	Salt Bits	Output Length	Description
des	8	no	12	13	Original UNIX crypt

F.42.2.1. `crypt()`

`crypt(password text, salt text)` returns `text`

Calculates a `crypt(3)`-style hash of *password*. When storing a new password, you need to use `gen_salt()` to generate a new *salt* value. To check a password, pass the stored hash value as *salt*, and test whether the result matches the stored value.

Example of setting a new password:

```
UPDATE ... SET pswhash = crypt('new password', gen_salt('md5'));
```

Example of authentication:

```
SELECT (pswhash = crypt('entered password', pswhash)) AS pswmatch FROM ... ;
```

This returns `true` if the entered password is correct.

F.42.2.2. `gen_salt()`

`gen_salt(type text [, iter_count integer])` returns `text`

Generates a new random salt string for use in `crypt()`. The salt string also tells `crypt()` which algorithm to use.

The *type* parameter specifies the hashing algorithm. The accepted types are: `des`, `xdes`, `md5` and `bf`.

The *iter_count* parameter lets the user specify the iteration count, for algorithms that have one. The higher the count, the more time it takes to hash the password and therefore the more time to break it. Although with too high a count the time to calculate a hash may be several years — which is somewhat impractical. If the *iter_count* parameter is omitted, the default iteration count is used. Allowed values for *iter_count* depend on the algorithm and are shown in [Table F.26](#).

Table F.26. Iteration Counts for `crypt()`

Algorithm	Default	Min	Max
xdes	725	1	16777215
bf	6	4	31

For `xdes` there is an additional limitation that the iteration count must be an odd number.

To pick an appropriate iteration count, consider that the original DES crypt was designed to have the speed of 4 hashes per second on the hardware of that time. Slower than 4 hashes per second would probably dampen usability. Faster than 100 hashes per second is probably too fast.

[Table F.27](#) gives an overview of the relative slowness of different hashing algorithms. The table shows how much time it would take to try all combinations of characters in an 8-character password, assuming that the password contains either only lower case letters, or upper- and lower-case letters and numbers. In the `crypt-bf` entries, the number after a slash is the *iter_count* parameter of `gen_salt`.

Table F.27. Hash Algorithm Speeds

Algorithm	Hashes/sec	For [a-z]	For [A-Za-z0-9]	Duration relative to md5 hash
crypt-bf/8	1792	4 years	3927 years	100k
crypt-bf/7	3648	2 years	1929 years	50k
crypt-bf/6	7168	1 year	982 years	25k
crypt-bf/5	13504	188 days	521 years	12.5k

Additional Supplied Modules and
Extensions Shipped in `post-grespro-ent-17-contrib`

Algorithm	Hashes/sec	For [a-z]	For [A-Za-z0-9]	Duration relative to md5 hash
<code>crypt-md5</code>	171584	15 days	41 years	1k
<code>crypt-des</code>	23221568	157.5 minutes	108 days	7
<code>sha1</code>	37774272	90 minutes	68 days	4
<code>md5 (hash)</code>	150085504	22.5 minutes	17 days	1

Notes:

- The machine used is an Intel Mobile Core i3.
- `crypt-des` and `crypt-md5` algorithm numbers are taken from John the Ripper v1.6.38 -test output.
- `md5 hash` numbers are from mdcrack 1.2.
- `sha1` numbers are from lcrack-20031130-beta.
- `crypt-bf` numbers are taken using a simple program that loops over 1000 8-character passwords. That way the speed with different numbers of iterations can be shown. For reference: `john -test` shows 13506 loops/sec for `crypt-bf/5`. (The very small difference in results is in accordance with the fact that the `crypt-bf` implementation in `pgcrypto` is the same one used in John the Ripper.)

Note that “try all combinations” is not a realistic exercise. Usually password cracking is done with the help of dictionaries, which contain both regular words and various mutations of them. So, even somewhat word-like passwords could be cracked much faster than the above numbers suggest, while a 6-character non-word-like password may escape cracking. Or not.

F.42.3. PGP Encryption Functions

The functions here implement the encryption part of the OpenPGP ([RFC 4880](#)) standard. Supported are both symmetric-key and public-key encryption.

An encrypted PGP message consists of 2 parts, or *packets*:

- Packet containing a session key — either symmetric-key or public-key encrypted.
- Packet containing data encrypted with the session key.

When encrypting with a symmetric key (i.e., a password):

1. The given password is hashed using a String2Key (S2K) algorithm. This is rather similar to `crypt()` algorithms — purposefully slow and with random salt — but it produces a full-length binary key.
2. If a separate session key is requested, a new random key will be generated. Otherwise the S2K key will be used directly as the session key.
3. If the S2K key is to be used directly, then only S2K settings will be put into the session key packet. Otherwise the session key will be encrypted with the S2K key and put into the session key packet.

When encrypting with a public key:

1. A new random session key is generated.
2. It is encrypted using the public key and put into the session key packet.

In either case the data to be encrypted is processed as follows:

1. Optional data-manipulation: compression, conversion to UTF-8, and/or conversion of line-endings.
2. The data is prefixed with a block of random bytes. This is equivalent to using a random IV.
3. A SHA1 hash of the random prefix and data is appended.
4. All this is encrypted with the session key and placed in the data packet.

F.42.3.1. `pgp_sym_encrypt()`

`pgp_sym_encrypt(data text, psw text [, options text ])` returns `bytea`
`pgp_sym_encrypt_bytea(data bytea, psw text [, options text ])` returns `bytea`

Encrypt *data* with a symmetric PGP key *psw*. The *options* parameter can contain option settings, as described below.

F.42.3.2. `pgp_sym_decrypt()`

`pgp_sym_decrypt(msg bytea, psw text [, options text ])` returns `text`
`pgp_sym_decrypt_bytea(msg bytea, psw text [, options text ])` returns `bytea`

Decrypt a symmetric-key-encrypted PGP message.

Decrypting `bytea` data with `pgp_sym_decrypt` is disallowed. This is to avoid outputting invalid character data. Decrypting originally textual data with `pgp_sym_decrypt_bytea` is fine.

The *options* parameter can contain option settings, as described below.

F.42.3.3. `pgp_pub_encrypt()`

`pgp_pub_encrypt(data text, key bytea [, options text ])` returns `bytea`
`pgp_pub_encrypt_bytea(data bytea, key bytea [, options text ])` returns `bytea`

Encrypt *data* with a public PGP key *key*. Giving this function a secret key will produce an error.

The *options* parameter can contain option settings, as described below.

F.42.3.4. `pgp_pub_decrypt()`

`pgp_pub_decrypt(msg bytea, key bytea [, psw text [, options text ]])` returns `text`
`pgp_pub_decrypt_bytea(msg bytea, key bytea [, psw text [, options text ]])` returns `bytea`

Decrypt a public-key-encrypted message. *key* must be the secret key corresponding to the public key that was used to encrypt. If the secret key is password-protected, you must give the password in *psw*. If there is no password, but you want to specify options, you need to give an empty password.

Decrypting `bytea` data with `pgp_pub_decrypt` is disallowed. This is to avoid outputting invalid character data. Decrypting originally textual data with `pgp_pub_decrypt_bytea` is fine.

The *options* parameter can contain option settings, as described below.

F.42.3.5. `pgp_key_id()`

`pgp_key_id(bytea)` returns `text`

`pgp_key_id` extracts the key ID of a PGP public or secret key. Or it gives the key ID that was used for encrypting the data, if given an encrypted message.

It can return 2 special key IDs:

- `SYMKEY`

The message is encrypted with a symmetric key.

- `ANYKEY`

The message is public-key encrypted, but the key ID has been removed. That means you will need to try all your secret keys on it to see which one decrypts it. `pgcrypto` itself does not produce such messages.

Note that different keys may have the same ID. This is rare but a normal event. The client application should then try to decrypt with each one, to see which fits — like handling `ANYKEY`.

F.42.3.6. `armor()`, `dearmor()`

`armor(data bytea [, keys text[], values text[] ])` returns `text`
`dearmor(data text)` returns `bytea`

These functions wrap/unwrap binary data into PGP ASCII-armor format, which is basically Base64 with CRC and additional formatting.

If the *keys* and *values* arrays are specified, an *armor header* is added to the armored format for each key/value pair. Both arrays must be single-dimensional, and they must be of the same length. The keys and values cannot contain any non-ASCII characters.

F.42.3.7. `pgp_armor_headers`

`pgp_armor_headers(data text, key out text, value out text)` returns `setof record`

`pgp_armor_headers()` extracts the armor headers from *data*. The return value is a set of rows with two columns, key and value. If the keys or values contain any non-ASCII characters, they are treated as UTF-8.

F.42.3.8. Options for PGP Functions

Options are named to be similar to GnuPG. An option's value should be given after an equal sign; separate options from each other with commas. For example:

```
pgp_sym_encrypt(data, psw, 'compress-algo=1, cipher-algo=aes256')
```

All of the options except `convert-crlf` apply only to encrypt functions. Decrypt functions get the parameters from the PGP data.

The most interesting options are probably `compress-algo` and `unicode-mode`. The rest should have reasonable defaults.

F.42.3.8.1. `cipher-algo`

Which cipher algorithm to use.

Values: `bf`, `aes128`, `aes192`, `aes256`, `3des`, `cast5`

Default: `aes128`

Applies to: `pgp_sym_encrypt`, `pgp_pub_encrypt`

F.42.3.8.2. `compress-algo`

Which compression algorithm to use. Only available if Postgres Pro was built with `zlib`.

Values:

0 - no compression

1 - ZIP compression

2 - ZLIB compression (= ZIP plus meta-data and block CRCs)

Default: 0

Applies to: `pgp_sym_encrypt`, `pgp_pub_encrypt`

F.42.3.8.3. `compress-level`

How much to compress. Higher levels compress smaller but are slower. 0 disables compression.

Values: 0, 1-9

Default: 6

Applies to: `pgp_sym_encrypt`, `pgp_pub_encrypt`

F.42.3.8.4. `convert-crlf`

Whether to convert `\n` into `\r\n` when encrypting and `\r\n` to `\n` when decrypting. RFC 4880 specifies that text data should be stored using `\r\n` line-feeds. Use this to get fully RFC-compliant behavior.

Values: 0, 1

Default: 0

Applies to: `pgp_sym_encrypt`, `pgp_pub_encrypt`, `pgp_sym_decrypt`, `pgp_pub_decrypt`

F.42.3.8.5. `disable-mdc`

Do not protect data with SHA-1. The only good reason to use this option is to achieve compatibility with ancient PGP products, predating the addition of SHA-1 protected packets to RFC 4880. Recent `gnupg.org` and `pgp.com` software supports it fine.

Values: 0, 1

Default: 0

Applies to: `pgp_sym_encrypt`, `pgp_pub_encrypt`

F.42.3.8.6. sess-key

Use separate session key. Public-key encryption always uses a separate session key; this option is for symmetric-key encryption, which by default uses the S2K key directly.

Values: 0, 1

Default: 0

Applies to: `pgp_sym_encrypt`

F.42.3.8.7. s2k-mode

Which S2K algorithm to use.

Values:

0 - Without salt. Dangerous!

1 - With salt but with fixed iteration count.

3 - Variable iteration count.

Default: 3

Applies to: `pgp_sym_encrypt`

F.42.3.8.8. s2k-count

The number of iterations of the S2K algorithm to use. It must be a value between 1024 and 65011712, inclusive.

Default: A random value between 65536 and 253952

Applies to: `pgp_sym_encrypt`, only with `s2k-mode=3`

F.42.3.8.9. s2k-digest-algo

Which digest algorithm to use in S2K calculation.

Values: `md5`, `sha1`

Default: `sha1`

Applies to: `pgp_sym_encrypt`

F.42.3.8.10. s2k-cipher-algo

Which cipher to use for encrypting separate session key.

Values: `bf`, `aes`, `aes128`, `aes192`, `aes256`

Default: `use cipher-algo`

Applies to: `pgp_sym_encrypt`

F.42.3.8.11. unicode-mode

Whether to convert textual data from database internal encoding to UTF-8 and back. If your database already is UTF-8, no conversion will be done, but the message will be tagged as UTF-8. Without this option it will not be.

Values: 0, 1

Default: 0

Applies to: `pgp_sym_encrypt`, `pgp_pub_encrypt`

F.42.3.9. Generating PGP Keys with GnuPG

To generate a new key:

```
gpg --gen-key
```

The preferred key type is “DSA and Elgamal”.

For RSA encryption you must create either DSA or RSA sign-only key as master and then add an RSA encryption subkey with `gpg --edit-key`.

To list keys:

```
gpg --list-secret-keys
```

To export a public key in ASCII-armor format:

```
gpg -a --export KEYID > public.key
```

To export a secret key in ASCII-armor format:

```
gpg -a --export-secret-keys KEYID > secret.key
```

You need to use `dearmor()` on these keys before giving them to the PGP functions. Or if you can handle binary data, you can drop `-a` from the command.

For more details see `man gpg`, *The GNU Privacy Handbook* and other documentation on <https://www.gnupg.org/>.

F.42.3.10. Limitations of PGP Code

- No support for signing. That also means that it is not checked whether the encryption subkey belongs to the master key.
- No support for encryption key as master key. As such practice is generally discouraged, this should not be a problem.
- No support for several subkeys. This may seem like a problem, as this is common practice. On the other hand, you should not use your regular GPG/PGP keys with `pgcrypto`, but create new ones, as the usage scenario is rather different.

F.42.4. Raw Encryption Functions

These functions only run a cipher over data; they don't have any advanced features of PGP encryption. Therefore they have some major problems:

1. They use user key directly as cipher key.
2. They don't provide any integrity checking, to see if the encrypted data was modified.
3. They expect that users manage all encryption parameters themselves, even IV.
4. They don't handle text.

So, with the introduction of PGP encryption, usage of raw encryption functions is discouraged.

`encrypt(data bytea, key bytea, type text)` returns `bytea`

`decrypt(data bytea, key bytea, type text)` returns `bytea`

`encrypt_iv(data bytea, key bytea, iv bytea, type text)` returns `bytea`

`decrypt_iv(data bytea, key bytea, iv bytea, type text)` returns `bytea`

Encrypt/decrypt data using the cipher method specified by *type*. The syntax of the *type* string is:

```
algorithm [ - mode ] [ /pad: padding ]
```

where *algorithm* is one of:

- `bf` — Blowfish
- `aes` — AES (Rijndael-128, -192 or -256)

and *mode* is one of:

- `cbc` — next block depends on previous (default)
- `ecb` — each block is encrypted separately (for testing only)

and *padding* is one of:

- `pkcs` — data may be any length (default)
- `none` — data must be multiple of cipher block size

So, for example, these are equivalent:

```
encrypt(data, 'fooz', 'bf')  
encrypt(data, 'fooz', 'bf-cbc/pad:pkcs')
```

In `encrypt_iv` and `decrypt_iv`, the `iv` parameter is the initial value for the CBC mode; it is ignored for ECB. It is clipped or padded with zeroes if not exactly block size. It defaults to all zeroes in the functions without this parameter.

F.42.5. Random-Data Functions

`gen_random_bytes(count integer)` returns `bytea`

Returns *count* cryptographically strong random bytes. At most 1024 bytes can be extracted at a time. This is to avoid draining the randomness generator pool.

`gen_random_uuid()` returns `uuid`

Returns a version 4 (random) UUID. (Obsolete, this function internally calls the [core function](#) of the same name.)

F.42.6. Notes

F.42.6.1. Configuration

`pgcrypto` configures itself according to the findings of the main Postgres Pro `configure` script. The options that affect it are `--with-zlib` and `--with-ssl=openssl`.

When compiled with `zlib`, PGP encryption functions are able to compress data before encrypting.

`pgcrypto` requires `OpenSSL`. Otherwise, it will not be built or installed.

When compiled against `OpenSSL 3.0.0` and later versions, the legacy provider must be activated in the `openssl.cnf` configuration file in order to use older ciphers like DES or Blowfish.

F.42.6.2. NULL Handling

As is standard in SQL, all functions return `NULL`, if any of the arguments are `NULL`. This may create security risks on careless usage.

F.42.6.3. Security Limitations

All `pgcrypto` functions run inside the database server. That means that all the data and passwords move between `pgcrypto` and client applications in clear text. Thus you must:

1. Connect locally or use SSL connections.
2. Trust both system and database administrator.

If you cannot, then better do crypto inside client application.

The implementation does not resist [side-channel attacks](#). For example, the time required for a `pgcrypto` decryption function to complete varies among ciphertexts of a given size.

F.42.7. Author

Marko Kreen <markokr@gmail.com>

`pgcrypto` uses code from the following sources:

Algorithm	Author	Source origin
DES crypt	David Burren and others	FreeBSD libcrypt
MD5 crypt	Poul-Henning Kamp	FreeBSD libcrypt
Blowfish crypt	Solar Designer	www.openwall.com

F.43. `pg_freespacemap` — examine the free space map

The `pg_freespacemap` module provides a means for examining the [free space map](#) (FSM). It provides a function called `pg_freespace`, or two overloaded functions, to be precise. The functions show the value recorded in the free space map for a given page, or for all pages in the relation.

By default use is restricted to superusers and roles with privileges of the `pg_stat_scan_tables` role. Access may be granted to others using `GRANT`.

F.43.1. Functions

`pg_freespace(rel regclass IN, blkno bigint IN)` returns `int2`

Returns the amount of free space on the page of the relation, specified by `blkno`, according to the FSM.

`pg_freespace(rel regclass IN, blkno OUT bigint, avail OUT int2)`

Displays the amount of free space on each page of the relation, according to the FSM. A set of (`blkno bigint`, `avail int2`) tuples is returned, one tuple for each page in the relation.

`pg_freespace_relation_logical_blocks(relation regclass [, fork text ])` returns `bigint`

Computes the disk space used by one fork of the specified relation in blocks (pages). Use the `fork` parameter to specify which fork to examine. Possible values:

- `main` returns the size of the main data fork of the relation.
- `fsm` returns the size of the Free Space Map (see [Section 66.3](#)) associated with the relation.
- `vm` returns the size of the Visibility Map (see [Section 66.4](#)) associated with the relation.

Note

The `init` value will always return 0, as the `init` fork is not associated with the disk.

If `fork` is omitted, the function will return the size of the main data fork of the relation.

This function returns correct results independent of whether the table is compressed or not.

The values stored in the free space map are not exact. They're rounded to precision of 1/256th of `BLCKSZ` (32 bytes with default `BLCKSZ`), and they're not kept fully up-to-date as tuples are inserted and updated.

For indexes, what is tracked is entirely-unused pages, rather than free space within pages. Therefore, the values are not meaningful, just whether a page is in-use or empty.

F.43.2. Sample Output

```
postgres=# SELECT * FROM pg_freespace('foo');
```

blkno	avail
0	0
1	0
2	0
3	32
4	704

F.44. pgpro_application_info — port applications using DBMS_APPLICATION_INFO package

pgpro_application_info is an extension designed to help developers who port applications using the DBMS_APPLICATION_INFO package from Oracle to Postgres Pro. It can also be used by database administrators as an additional source of data when analyzing performance and by developers when debugging.

pgpro_application_info creates procedures and functions that an application can use to report its status, performed actions, and action progress. The database administrator can access this information through specific views.

The typical sequence of client actions reporting to pgpro_application_info will look like this (in the example, a librarian wants to count all the words “the” in the library):

1. Once the client makes a connection to the database, it registers itself as the **Librarian** and runs the scanner application, which, in its turn, registers itself as the **Book Scanner** module and indicates that it is currently attempting to perform **Book Scanning** to find all occurrences of the word “the” in 18042 books, having completed 0 scans as of now.
2. Having scanned a few books, the application updates the information to reflect its progress.
3. When the scanning is completed, the application registers this fact and sets its current action as **Idle** (or **NULL**).

F.44.1. Installation

The pgpro_application_info extension is a built-in extension included into Postgres Pro Enterprise. To enable pgpro_application_info, do the following:

1. Add the library name to the shared_preload_libraries variable in the postgresql.conf file:

```
shared_preload_libraries = 'pgpro_application_info'
```
2. Reload the database server for the changes to take effect.

Note

To verify that the library was installed correctly, you can run the following command:

```
SHOW shared_preload_libraries;
```

3. Create the extension using the following query:

```
CREATE EXTENSION pgpro_application_info;
```

F.44.2. Usage

pgpro_application_info handles the following main data classes:

- **Application Data**: current module name, performed action, and client description. The database administrator can access the information about active clients and their actions via the [V_SESSION](#) view.
- **Information about Long Operations**: textual descriptions and comments, operation progress report and optionally the link to the database object in question. The database administrator can access the information about long operations via the [V_SESSION_LONGOPS](#) view, which in addition to the data sent by the client contains operation start and latest update time-stamps, as well as the estimated time remaining.

Note

Note that in Oracle's DBMS_APPLICATION_INFO textual parameters supplied by the user have various maximum length up to 64 bytes, but for convenience in pgpro_application_info all of them have the same maximum length of 64 bytes. Exceeding information is truncated.

F.44.2.1. Application Data

To set application information, `pgpro_application_info` provides the following procedures:

```
CREATE PROCEDURE DBMS_APPLICATION_INFO.SET_CLIENT_INFO(client_info TEXT)
```

Sets the client information. This is typically the client name or a more complex description, but strictly speaking, it can be any text provided by the user.

```
CREATE PROCEDURE DBMS_APPLICATION_INFO.SET_ACTION(action_name TEXT)
```

Sets the name of the executed action in the current module.

```
CREATE PROCEDURE DBMS_APPLICATION_INFO.SET_MODULE(module_name TEXT, action_name TEXT DE-  
FAULT NULL)
```

Sets the name of the current module (program) and action. When the program terminates, call this procedure with the name of the next module if there is one, or `NULL` otherwise.

```
CREATE PROCEDURE DBMS_APPLICATION_INFO.READ_CLIENT_INFO(OUT client_info TEXT)
```

Returns the client information previously set by `SET_CLIENT_INFO` in the current session.

```
CREATE PROCEDURE DBMS_APPLICATION_INFO.READ_MODULE(OUT module_name TEXT, OUT action_name  
TEXT)
```

Returns the module information previously set by `SET_MODULE` and action information set by `SET_MODULE` or `SET_ACTION` in the current session.

F.44.2.1.1. The `V_SESSION` View

The `V_SESSION` view provides the information about all the active sessions reported via `pgpro_application_info` procedures, the connected clients, modules, and current actions. The view contains one row for each distinct session. When a session reports its information for the first time, the corresponding view entry is created. Each row exists during the corresponding session lifetime so the view is empty after server restart. The columns of the view are shown in [Table F.28](#). For ease of use, Postgres Pro also provides an equivalent view called `V$SESSION`, familiar to Oracle users, which contains the same information. Note, however, that better compatibility with Oracle provided by this alternative is a deviation from the SQL standard and, consequently, makes the code less portable.

```
CREATE FUNCTION DBMS_APPLICATION_INFO.READ_V_SESSION(  
    OUT SID INTEGER,  
    OUT DBNAME TEXT,  
    OUT MODULE TEXT,  
    OUT ACTION TEXT,  
    OUT CLIENT_INFO TEXT  
)  
CREATE VIEW V_SESSION AS SELECT * FROM DBMS_APPLICATION_INFO.READ_V_SESSION();
```

Table F.28. `V_SESSION` Columns

Name	Description
<code>SID</code>	Session ID, PID
<code>DBNAME</code>	Name of the database the session is connected to. If you want to view the entries only for the current database, add the following condition to the query: <code>WHERE DBNAME=current_database()</code> .
<code>MODULE</code>	Name of the module executed by the session that was previously set by <code>SET_MODULE</code> .
<code>ACTION</code>	Name of the action executed by the session that was previously set by <code>SET_MODULE</code> or <code>SET_ACTION</code> .
<code>CLIENT_INFO</code>	Information about the client associated with the session that was previously set by <code>SET_CLIENT_INFO</code> .

F.44.2.2. Information about Long Operations

```
CREATE PROCEDURE DBMS_APPLICATION_INFO.SET_SESSION_LONGOPS(  
    INOUT RINDEX INTEGER,  
    INOUT SLNO INTEGER,  
    OP_NAME TEXT DEFAULT NULL,  
    TARGET OID DEFAULT 0,  
    CONTEXT INTEGER DEFAULT 0,  
    SOFAR DOUBLE PRECISION DEFAULT 0,  
    TOTALWORK DOUBLE PRECISION DEFAULT 0,  
    TARGET_DESC TEXT DEFAULT 'unknown target',  
    UNITS TEXT DEFAULT NULL  
)
```

The `SET_SESSION_LONGOPS` procedure creates a new row (or updates the existing one) in the `V_SESSION_LONGOPS` view. Each row contains information about a single long operation (typically longer than 6 seconds): its description, the accessed objects, and the estimated time remaining.

- **RINDEX**: A token which represents the row in the `V_SESSION_LONGOPS` view. To start a new row, set this to the result of the `DBMS_APPLICATION_INFO.SET_SESSION_LONGOPS_NOHINT()` function. When you call `SET_SESSION_LONGOPS` to update the existing row, set this to the returned value from the prior call.
- **SLNO**: Internal information saved between calls. To start a new row, set this to `NULL`. When you call `SET_SESSION_LONGOPS` to update the existing row, set this to the returned value from the prior call.
- **OP_NAME**: Short description of the performed operation, usually its name.
- **TARGET**: OID of the object that is being worked on during the long-running operation.
- **CONTEXT**: Any number the user wants to store.
- **SOFAR**: Any number the user wants to store. This is typically the amount of work which has been done so far.
- **TOTALWORK**: Any number the user wants to store. This is typically the amount of work to be done.
- **TARGET_DESC**: The description of the object that is being worked on during the long-running operation (**TARGET**).
- **UNITS**: The units in which **SOFAR** and **TOTALWORK** are represented.

SOFAR and **TOTALWORK** values are used to calculate the estimated time remaining in the `V_SESSION_LONGOPS` view, but valid values are any numbers so if they are inconsistent (for example, both values are negative, or **TOTALWORK**=0), the estimated time remaining will not be calculated.

F.44.2.2.1. The `V_SESSION_LONGOPS` View

The `V_SESSION_LONGOPS` view provides the information about long operations previously passed by `SET_SESSION_LONGOPS`. The view contains one row for each distinct long operation. Each row exists until it is rewritten or the server is shut down. The view is empty after server restart. The columns of the view are shown in [Table F.29](#). For ease of use, Postgres Pro also provides an equivalent view called `V$SESSION_LONGOPS`, familiar to Oracle users, which contains the same information. Also, the `P_TIMESTAMP` column was renamed `TIMESTAMP` in this view. Note, however, that better compatibility with Oracle provided by these alternatives is a deviation from the SQL standard and, consequently, makes the code less portable.

```
CREATE FUNCTION DBMS_APPLICATION_INFO.READ_V_SESSION_LONGOPS(  
    OUT SID INTEGER,  
    OUT SERIAL_N INTEGER,  
    OUT DBNAME TEXT,  
    OUT OPNAME TEXT,  
    OUT TARGET OID,  
    OUT TARGET_DESC TEXT,  
    OUT SOFAR DOUBLE PRECISION,  
    OUT TOTALWORK DOUBLE PRECISION,  
    OUT UNITS TEXT,  
    OUT START_TIME TIMESTAMP,  
    OUT LAST_UPDATE_TIME TIMESTAMP,  
    OUT P_TIMESTAMP TIMESTAMP,  
    OUT TIME_REMAINING INTEGER,  
    OUT ELAPSED_SECONDS INTEGER,
```

```

OUT CONTEXT INTEGER,
OUT MESSAGE TEXT,
OUT USERNAME TEXT
)
CREATE VIEW V_SESSION_LONGOPS AS SELECT * FROM
DBMS_APPLICATION_INFO.READ_V_SESSION_LONGOPS( );

```

Table F.29. V_SESSION_LONGOPS Columns

Name	Description
SID	ID of the session processing the long-running operation.
SERIAL_N	Synonym for SID. Added for Oracle-compatibility reasons.
DBNAME	Name of the database the session is connected to. If you want to view the rows only for the current database, add the following condition to the query: WHERE DBNAME=current_database().
OPNAME	Short description of the performed operation, usually its name.
TARGET	OID of the object that is being worked on during the long-running operation.
TARGET_DESC	The description of the object that is being worked on during the long-running operation (TARGET).
SOFAR	The amount of work which has been done so far in units specified in UNITS.
TOTALWORK	The amount of work to be done in units specified in UNITS.
UNITS	The units in which SOFAR and TOTALWORK are represented.
START_TIME	Operation start time (or the time the row was created).
LAST_UPDATE_TIME	Last row update time.
P_TIMESTAMP	Synonym for LAST_UPDATE_TIME. Added for Oracle-compatibility reasons. For convenience, you can use another parameter name by adding an alias. For example, to create a TIMESTAMP alias, add SELECT P_TIMESTAMP AS TIMESTAMP to the view definition.
TIME_REMAINING	Estimate of time remaining for the operation to complete (in seconds). Calculated based on SOFAR and TOTALWORK values. The estimated time remaining will not be calculated, if these values are inconsistent, SOFAR=0, or LAST_UPDATE_TIME is the same as START_TIME.
ELAPSED_SECONDS	Number of elapsed seconds from the operation start (row creation).
CONTEXT	The number set by the user as the context.
MESSAGE	Statistics summary message about the operation progress.
USERNAME	Name of the user performing the operation.

F.44.3. Example

In our simple example, the application represents a lazy boy counting crows:

```

DO $$
DECLARE
    rindex integer := DBMS_APPLICATION_INFO.SET_SESSION_LONGOPS_NOHINT( );
    slno integer := NULL;
    total_crows integer := 146;
BEGIN

```

Additional Supplied Modules and
Extensions Shipped in post-
grespro-ent-17-contrib

```

F.45. `pgpro_bfile` — a composite type to access an external file

The `pgpro_bfile` extension introduces a composite type `bfile` that implements an Oracle-like technique to access an external file.

F.45.1. Data Structures

The `bfile` type contains two fields:

- `dir_id` — the directory identifier in the `bfile_directories` table
- `file_name` — the name of the external file

Information on directories is stored in the `bfile_directories` table, which has the following columns:

- `dir_id` — a unique directory identifier of the `int32` type.
- `dir_alias` — a unique directory alias.
- `dir_path` — path to the directory.

Although having two unique identifiers `dir_id` and `dir_alias` is excessive, `dir_id` is best for storing in `bfile` because it requires less storage and ensures faster search, while working with `dir_alias` is more convenient for a user migrating from Oracle, especially to better understand command semantics.

Information on directory access rights is stored in the `bfile_directory_roles` table, which has the following columns:

- `dr_dir_id` — a directory identifier of the `int32` type, that is, an external reference to the `dir_id` column in the `bfile_directories` table.
- `dr_role_id` — ID of a user/role that has access rights on the directory.
- `dr_rights` — a bit array of access rights on the directory (1 means read access, 2 means write access). Choice of a bit array assumes that a need to grant new access rights can arise, such as a need in a separate delete right.

F.45.2. Functions

Functions to work with directories and to manage directory access rights are implemented in PL/PgSQL, while functions to work with `bfile` values are implemented in C for better performance.

Table F.30. Functions for Working with Directories

Function	Description
<code>bfile_directory_create (a_dir_alias text, a_dir_path text) returns (int)</code>	Creates a directory for the given alias and path and returns the ID of the created directory. Superuser privileges are required to call this function.
<code>bfile_directory_delete (a_dir_alias text) returns (void)</code>	Deletes the directory with the given alias. Superuser privileges are required to call this function.
<code>bfile_directory_rename (a_dir_alias text, a_new_dir_alias text) returns (void)</code>	Changes the alias of the directory. Superuser privileges are required to call this function.
<code>bfile_directory_set_path (a_dir_alias text, a_dir_path text) returns (void)</code>	Changes the path to the directory with the given alias. Superuser privileges are required to call this function.
<code>bfile_directory_get_path_by_alias (a_dir_alias text) returns (text)</code>	Returns the path to the directory with the given alias.
<code>bfile_directory_get_path_by_id (a_dir_id int) returns (text)</code>	Returns the path to the directory with the given ID.
<code>bfile_directory_get_alias_by_id (a_dir_id int) returns (text)</code>	Returns the alias of the directory with the given ID.
<code>bfile_directory_get_id_by_alias (a_dir_alias text) returns (int)</code>	Returns the ID of the directory with the given alias.

Table F.31. Functions for Granting and Revoking Directory Access Rights

Function	Description
<code>bfile_grant_directory (a_dir_alias text, a_role_name text, a_access_mask int)</code>	returns (void) Grants access rights on the <i>a_dir_alias</i> directory to the <i>a_role_name</i> user/role. <i>a_access_mask</i> specifies the access to grant (1 — read, 2 — write, 3 — read and write). Superuser privileges are required to call this function.
<code>bfile_revoke_directory (a_dir_alias text, a_role_name text, a_access_mask int)</code>	returns (void) Revokes access rights on the <i>a_dir_alias</i> directory from the <i>a_role_name</i> user/role. <i>a_access_mask</i> specifies the access to revoke (1 — read, 2 — write, 3 — read and write). Superuser privileges are required to call this function.
<code>bfile_cleanup_directory_roles ()</code>	returns (void) Removes information on directory access rights of deleted users/roles from the <i>bfile_directory_roles</i> table. Superuser privileges are required to call this function.

Table F.32. Functions for Working with bfile Values

Function	Description
<code>bfile_make (a_dir_alias text, a_file_name text)</code>	returns (bfile) Returns the <i>bfile</i> structure for the given directory alias and filename.
<code>bfile_make_dir_id (a_dir_id int, a_file_name text)</code>	returns (bfile) Returns the <i>bfile</i> structure for the given directory ID and filename.
<code>bfile_open (a_bfile bfile[, a_access_mask int])</code>	returns (int) Opens the file for the given <i>a_bfile</i> and returns its descriptor. <i>a_access_mask</i> specifies the file access mode (1 — read, 2 — write, 3 — read and write), the default is 1.
<code>bfile_close (a_handler int)</code>	returns (void) Closes the file for the given descriptor returned by the <i>bfile_open</i> function.
<code>bfile_close_all ()</code>	returns (int) Closes all the files that were opened earlier by the <i>bfile_open</i> function. Returns the number of closed files.
<code>bfile_length (a_handler int)</code>	returns (bigint) Returns the size of the open file with the given descriptor.
<code>bfile_read (a_handler int[, a_offset bigint, a_length bigint])</code>	returns (bytea) From the open file with the descriptor <i>a_handler</i> , reads <i>a_length</i> bytes at the <i>a_offset</i> offset from the beginning of file and returns the bytes read. By default, <i>a_length</i> is -1, which specifies reading to the end of file, and <i>a_offset</i> is 0, which specifies reading from the beginning of file.
<code>bfile_write (a_handler int, a_buffer bytea[, a_offset bigint])</code>	returns (void) Writes the given buffer <i>a_buffer</i> to the open file having the given descriptor <i>a_handler</i> at the given <i>a_offset</i> offset from the beginning of file. By default, <i>a_offset</i> is -1, which means writing from the end of file.
<code>bfile_fileexists (a_bfile bfile)</code>	returns (boolean) Returns <i>true</i> if the file corresponding to <i>a_bfile</i> can be used. The function checks that the file opens without errors.
<code>bfile_length_direct (a_bfile bfile)</code>	returns (bigint) Returns the file size for the given <i>a_bfile</i> .
<code>bfile_read_direct (a_bfile bfile[, a_offset bigint, a_length bigint])</code>	returns (bytea) For the given <i>a_bfile</i> , reads <i>a_length</i> bytes at the <i>a_offset</i> offset from the beginning of file and returns the bytes read. By default, <i>a_length</i> is -1, which means reading to the end of file, and <i>a_offset</i> is 0, which means reading from the beginning of file.
<code>bfile_write_direct (a_bfile bfile, a_buffer bytea)</code>	returns (void) For the given <i>a_bfile</i> , writes the given buffer <i>a_buffer</i> to a new file. Write access to the <i>a_bfile</i> directory is required.

Function	Description
<code>bfile_delete (a_bfile bfile)</code>	returns (void) Deletes the file for the given <i>a_bfile</i> . Write access to the <i>a_bfile</i> directory is required.
<code>bfile_compare (a_bfile_1 bfile, a_bfile_2 bfile[, a_amount bigint, a_offset_1 bigint, a_offset_2 bigint])</code>	returns (int) When <i>a_amount</i> , <i>a_offset_1</i> and <i>a_offset_2</i> are not specified, if the sizes of <i>a_bfile_1</i> and <i>a_bfile_2</i> files are different, returns -1 if the size of <i>a_bfile_1</i> is less than the size of <i>a_bfile_2</i> and 1 otherwise. If the files have equal sizes, the function performs byte-wise comparison of the file data and returns 0 if the comparison shows equal data, -1 if the data in <i>a_bfile_1</i> is less than in <i>a_bfile_2</i> and 1 if the data in <i>a_bfile_1</i> is greater than in <i>a_bfile_2</i> . <i>a_amount</i> specifies the number of bytes in the given <i>bfile</i> values to compare, while <i>a_offset_1</i> and <i>a_offset_2</i> specify the offsets to start the comparison at.
<code>bfile_md5 (a_bfile bfile)</code>	returns (text) Calculates an MD5 hash for the specified <i>bfile</i> object and returns the result as a 16-byte value in text form.

F.45.3. Example

The following example illustrates usage of the `bfile` type.

We will run a script on the server file system. But first, let's create a directory to store `bfile` data:

```
mkdir "/tmp/bfiles"
```

Now we will use `psql` to run the script below:

```
-- Create the pgpro_bfile extension:
CREATE EXTENSION pgpro_bfile;

-- Create a directory in the database to store bfile:
SELECT bfile_directory_create('BFILE_DATA', '/tmp/bfiles');

-- Create the file bfile.data on the file system and add there the value of
'0123456789':
SELECT bfile_write_direct(bfile_make('BFILE_DATA', 'bfile.data'), '0123456789');

-- Create the table bfile and add there one record referencing that file:
CREATE TABLE bfile_table(id int, bf bfile);
INSERT INTO bfile_table VALUES (1, bfile_make('BFILE_DATA', 'bfile.data'));

-- Create a user to run the script:
CREATE USER bf_test_user;

-- Grant bf_test_user with read-write access to BFILE_DATA:
SELECT bfile_grant_directory('BFILE_DATA', 'bf_test_user', 3);

-- Grant bf_test_user with rights on bfile_table:
GRANT ALL ON bfile_table TO bf_test_user;

-- Register as bf_test_user:
SET SESSION AUTHORIZATION bf_test_user;

DO $$
DECLARE
    v_bfile bfile;
    v_buffer bytea;
    v_length bigint;
    v_handler int;
BEGIN
    -- Open the file for reading and writing:
```

```
SELECT bfile_open(bf, 3) INTO v_handler FROM bfile_table WHERE id = 1;

-- This character string will be written to end of file:
PERFORM bfile_write(v_handler, '_suffix');
-- This character string will be written from the position 0 and replace '0123456':
PERFORM bfile_write(v_handler, 'prefix_', 0);

-- Read the character string from file to a buffer and print out its length and
contents:
v_buffer = bfile_read(v_handler);
RAISE NOTICE 'Buffer length: %', length(v_buffer);
RAISE NOTICE 'Buffer content: %', encode(v_buffer, 'escape');

-- Get and print out the file size:
v_length = bfile_length(v_handler);
RAISE NOTICE 'BFILE length: %', v_length;

-- Close bfile:
PERFORM bfile_close(v_handler);
END $$;

-- Check the contents of the table:
SELECT encode(b, 'escape'), length(b) from (SELECT bfile_read_direct(bf) b FROM
bfile_table) x;

-- Delete the table, user and pgpro_bfile extension:
RESET SESSION AUTHORIZATION;
DROP TABLE bfile_table;
DROP USER bf_test_user;
DROP EXTENSION pgpro_bfile;
```

The script produces the following output:

```
CREATE EXTENSION
bfile_directory_create
-----
1
(1 row)

bfile_write_direct
-----
(1 row)

CREATE TABLE
INSERT 0 1
CREATE ROLE
bfile_grant_directory
-----
(1 row)

GRANT
SET
NOTICE: Buffer length: 17
NOTICE: Buffer content: prefix_789_suffix
NOTICE: BFILE length: 17
DO
      encode      | length
```

```
-----+-----  
prefix_789_suffix |      17  
(1 row)
```

```
RESET  
DROP TABLE  
DROP ROLE  
DROP EXTENSION
```

F.46. `pg_proaudit` — enables detailed logging of various security events

The `pg_proaudit` extension enables detailed logging of various security events.

`pg_proaudit` works in parallel with the standard PostgreSQL logging solutions (logging collector) and does not depend on them. Security event log of the `pg_proaudit` extension is stored separately from the server log. At the Postgres Pro Enterprise startup, `pg_proaudit` launches a special background process to log security events.

Logging rules are stored in the `pg_proaudit.conf` configuration file located in the cluster data directory (PGDATA). It is a text file that can be edited directly using operating system facilities. To modify the file using SQL, you can use several `pg_proaudit` functions. The `pg_proaudit_settings` view displays the current `pg_proaudit` rules, even if they have not been saved into the `pg_proaudit.conf` file yet.

All the logged events belong to the following classes:

- DDL commands for creating, changing, and deleting DBMS objects (databases, tablespaces, schemas, tables, views, sequences, languages, functions)
- access control commands for database objects (GRANT, REVOKE)
- DML commands for access to database objects (INSERT, UPDATE, DELETE, SELECT, TRUNCATE for tables and/or views, EXECUTE for functions)
- database authentication/disconnection events
- all commands executed by a particular user

Security events can be logged both in the centralized logging solution of the operating system (syslog) and in the standard file-system files. Event logs can be written both into the syslog and into the files simultaneously. For clear identification, all `pg_proaudit` records in the syslog are marked with `AUDIT`. Event log files can be written in the CEF (Common Event Format) and CSV (Comma-Separated Values) formats. Each event is logged on a separate line that contains the following fields:

- date and time of the event
- current user name
- database name
- server process ID (PID)
- severity level: `INFO` or `ERROR`
- serial number of the command in a session
- subcommand number in complex commands (`CREATE TABLE ... AS SELECT ...`)
- operator name
- object type
- object name
- operator execution results: `SUCCESS` or `FAILURE`
- additional information like error message in case of `FAILURE` or connection parameters and the application name for the `AUTHENTICATE` event; unfinished authentication attempts are marked as [EOF. No credentials provided]
- text of the SQL command
- parameters of the command (for example, for `PREPARE`)
- session user name
- unique ID of the event (in the `UUIDv7` format)
- transaction ID (XID)
- virtual transaction ID (VXID)

An event contains the information about both `session_user` and `current_user` of the session. Therefore, it will be possible to identify the user, even if they execute the `SET ROLE` command to change user identifier.

The XID and VXID values can be zero if an event does not relate to a transaction (e. g. the `DISCONNECT` event).

You can define a directory to store security log files and set up log file rotation. `pg_proaudit` can switch to a new log file either after the specified time interval, or when the specified size of the log file is exceeded. This enables you to define a workflow for cleaning up security event logs.

Postgres Pro user with the `SUPERUSER` attribute should grant access to the `pg_proaudit` extension and security event log files only to the user with the information security administrator role.

F.46.1. Installing the `pg_proaudit` Extension

The `pg_proaudit` extension is a built-in extension included into Postgres Pro Enterprise. To enable `pg_proaudit`, complete the following steps:

1. Add `pg_proaudit` to the `shared_preload_libraries` variable in the `postgresql.conf` file:

```
shared_preload_libraries = 'pg_proaudit'
```

2. Restart the database server for the changes to take effect. To verify that the `pg_proaudit` library was installed correctly, you can run the following command:

```
SHOW shared_preload_libraries;
```

3. In each database for which you are going to log security events, create the `pg_proaudit` extension using the following query:

```
CREATE EXTENSION pg_proaudit;
```

The `pg_proaudit` extension adds several functions for managing the `pg_proaudit.conf` file, the `pg_proaudit_settings` view that displays the current `pg_proaudit` rules and event triggers.

F.46.2. Uninstalling the `pg_proaudit` Extension

To properly uninstall `pg_proaudit`, complete the following steps:

1. Delete the `pg_proaudit` extension using the following query:

```
DROP EXTENSION pg_proaudit;
```

2. Remove `pg_proaudit` from the `shared_preload_libraries` variable in the `postgresql.conf` file.

Skip this step if you have several databases in the cluster and you want to remove the extension only for one of them. In this case, it is recommended to remove logging rules related to the corresponding database prior to uninstalling the extension.

F.46.3. Functions to Configure Security Event Logging

To configure security event logging, `pg_proaudit` provides an SQL interface that consists of several functions and the `pg_proaudit_settings` view.

```
pg_proaudit_set_rule(db_name text, event_type text, object_type text, object_name text,  
    role_name text, comment text)
```

Creates the logging rule with the specified parameters. When the `pg_proaudit_set_rule()` function completes, security event logging starts immediately, but the `pg_proaudit.conf` file is not updated. To save the changes in the `pg_proaudit.conf` file, call the `pg_proaudit_save()` function.

Arguments:

- ***db_name*** — name of the database for which the logging rule is established. An empty string or `NULL` specified in this argument means that events are logged for all databases where the `pg_proaudit` extension is created. When set to [current_database\(\)](#), events for the current database are logged.
- ***event_type*** — type of the event that needs to be logged, including SQL operator names, as well as `AUTHENTICATE` and `DISCONNECT` events. When set to `ALL`, as well as when an empty string or `NULL` is specified, enables logging for all events available for the specified object type. For example, for the `TABLE` object type, the `ALL` keyword enables logging for commands `SELECT`, `INSERT`, `UPDATE`, `DELETE`, `TRUNCATE`, `COPY`, as well as `CREATE`, `ALTER`, `DROP`. You can also set up logging of event classes by specifying the following values: `ALL_DDL`, `ALL_DDL_NONTEMP`, `ALL_DML`, `ALL_DML_NONTEMP`, `ALL_MOD`, `ALL_PROC`, `ALL_ROLE`, and `MISC`. For the full list of possible *event_type* values, see [Section F.46.5](#).
- ***object_type*** — type of the object for which security events need to be logged. When set to `ALL`, as well as when an empty string or the `NULL` is specified, enables logging of events for all object types. For example, specify `FOREIGN TABLE` object type for the `SELECT` event to log all attempts to access foreign tables. Use `NULL` if *event_type* is set to `AUTHENTI`-

CATE, DISCONNECT, SET, or RESET, and the ROLE value for all events that reference user actions, such as CREATE USER or DROP USER. The following object types are supported: COMPOSITE TYPE, DATABASE, EVENT TRIGGER, FUNCTION, INDEX, PREPARED STATEMENT, ROLE, SEQUENCE, SCHEMA, TABLE, FOREIGN TABLE, TOAST TABLE, TABLESPACE, VIEW, MATERIALIZED VIEW, CATALOG RELATION, and CATALOG FUNCTION.

Note

To log security events for system catalog objects, it is required to enable the `pg_proaudit.log_catalog_access` configuration parameter. Otherwise, these events will not be logged, even if the CATALOG RELATION, CATALOG FUNCTION, or ALL object type is specified in the rule.

- *object_name* — name of the object for which the logging rule is established. When an empty string or NULL is specified, enables logging of events for all object names.
- *role_name* — name of the role for which the logging rule is established. If specified, allows logging the actions caused by the user who has the privileges of the role. This means that at least one of the user session attributes, `session_user` or `current_user`, should either be equal to the `role_name`, or be directly or indirectly a member of this role. When an empty string or NULL is specified, enables logging of actions caused by any user. When set to `current_role`, the logging rule is established for the user current role.
- *comment* — comment to describe the created logging rule. This argument does not affect the rule execution and is not reflected in the log.

`pg_proaudit_remove_rule(db_name text, event_type text, object_type text, object_name text, role_name text)`

Removes the specific logging rule with the set parameters. To save the changes in the `pg_proaudit.conf` file, call the `pg_proaudit_save()` function.

Note

If the rule that you want to remove is configured to log the DISCONNECT event type, then disconnect events may still be logged after the rule is removed. For additional information, see [Section F.46.3.1](#).

Arguments:

- *db_name* — name of the database for which the logging rule needs to be removed.
- *event_type* — type of the event for which the logging rule needs to be removed. For the full list of possible *event_type* values, see [Section F.46.5](#).
- *object_type* — type of the object for which the logging rule needs to be removed.
- *object_name* — name of the object for which the logging rule needs to be removed.
- *role_name* — name of the role for which the logging rule needs to be removed.

`pg_proaudit_show()`

Returns logged events in a table view. This function is used by the `pg_proaudit_settings` view.

`pg_proaudit_reload()`

Reads logging configuration from the `pg_proaudit.conf` file. You must call this function if the `pg_proaudit.conf` file was modified manually using the operating system facilities.

`pg_proaudit_reset()`

Removes all logging rules. To save information about the canceled logging in the `pg_proaudit.conf` file, call the `pg_proaudit_save()` function.

`pg_proaudit_save()`

Saves logging rules from memory into the `pg_proaudit.conf` file. The `pg_proaudit.conf` file is located in the cluster data directory (PGDATA). You cannot change the `pg_proaudit.conf` file location.

F.46.3.1. Handling Database Disconnection Events

When a logging rule is configured for `DISCONNECT` event type, and a user authenticates in a database, then the `pg_proaudit` extension checks whether the corresponding disconnection event satisfies the rule and must be logged.

If the event must be logged, then the removal of the logging rule has no effect on the event. This event will be logged no matter if the logging rule exists at the moment of disconnect.

Consider the following example:

1. An administrator configures the following logging rule:

```
SELECT pg_proaudit_set_rule ('postgres', 'DISCONNECT', null, null, null, 'Any  
disconnect from the postgres DB');
```

2. A user connects to the `postgres` database and goes through authentication.

For the rule in effect, a corresponding disconnection event will be logged later.

3. The administrator removes the logging rule, while the user is still connected to the database:

```
SELECT pg_proaudit_remove_rule('postgres', 'DISCONNECT', null, null, null);
```

4. The user disconnects from the database.

The corresponding disconnection event is logged despite the removal of the logging rule.

F.46.3.2. Handling Object Names

Comparison of string representations of names for database, user, role and other objects is case-insensitive even if the object name in the database is enclosed in quotes. These string representations are stored as lower-case strings.

Strings representing object names need to be passed to functions `pg_proaudit_set_rule` and `pg_proaudit_remove_rule` as regular strings: a single quote needs repeating, and other characters are passed as is, without escaping or wrapping.

For example, rules for tables `table1` and `"TABLE1"` will be the same, and their names can be passed in upper-case or lower-case characters. The same holds for roles. As for databases, before creating a rule, `pg_proaudit` checks whether this database actually exists, and this check is case-sensitive.

The following examples illustrate creation of "weird" object names and specifying correct audit rules for them.

```
create table "TABLE"123();  
SELECT pg_proaudit_set_rule(current_database(), null, null, 'public.Table'123',  
    null, 'tst cmnt');  
  
create table "table"123();  
SELECT pg_proaudit_set_rule(null, null, null, 'public.table"123', null);  
  
create schema "(BIG!) Schema";  
create table "(BIG!) Schema"."My Tab.le"();  
SELECT pg_proaudit_set_rule(null, null, null, '(BIG!) Schema.My Tab.le', null);  
  
create role "Some '@#$$' person" with login;  
SELECT pg_proaudit_set_rule(null, 'authenticate', null, null, 'Some '@#$$' person');  
  
create role "Some '@#$$' person" with superuser;  
\c - "Some '@#$$' person"  
SELECT pg_proaudit_set_rule(null, 'disconnect', null, null, current_user);  
  
create database " D B 1";  
SELECT pg_proaudit_set_rule(' D B 1', 'authenticate', null, null, null);  
  
create database " D b 2";  
\c " D b 2"
```

```
create extension pg_proaudit;  
SELECT pg_proaudit_set_rule(current_database(), 'disconnect', null, null, null);
```

F.46.4. pg_proaudit_settings View

This view displays the current `pg_proaudit` rules, even if they have not been saved into the `pg_proaudit.conf` file yet. The `pg_proaudit_settings` view consists of the following columns:

- *db_name* (text) — name of the database for which to log security events.
- *event_type* (text) — event type to log.
- *object_type* (text) — type of the object for which security events are to be logged.
- *object_name* (text) — name of the object for which security events are to be logged.
- *role_name* (text) — the role on behalf of which logged actions are performed.
- *comment* (text) — comment to describe the created logging rule.

F.46.5. Security Events

You can configure the `pg_proaudit` extension to log classes of security events and specific events by specifying the respective value in the *event_type* argument of the `pg_proaudit_set_rule()` function.

The following classes of security events are supported:

- **ALL_DDL**: CREATE, ALTER, DROP for any database object except stored procedures and functions.
- **ALL_DDL_NONTEMP**: same as **ALL_DDL** but the scope is limited to the objects that are not contained in `pg_temp_nnn` temporary schemas.
- **ALL_DML**: SELECT, INSERT, UPDATE, DELETE, TRUNCATE for any table type; EXECUTE for functions and stored procedures.
- **ALL_DML_NONTEMP**: same as **ALL_DML** but the scope is limited to the objects that are not contained in `pg_temp_nnn` temporary schemas.
- **ALL_MOD**: INSERT, UPDATE, DELETE, TRUNCATE for any table type.
- **ALL_PROC**: CREATE, ALTER, DROP for any function and stored procedure.
- **ALL_ROLE**: CREATE, ALTER, DROP for USER, ROLE, GROUP, PROFILE, as well as execution of the GRANT command.
- **MISC**: all events not related to any of the other classes mentioned above.

The following specific security events are supported:

- ANALYZE
- AUTHENTICATE
- DISCONNECT
- ALTER AGGREGATE
- ALTER COLLATION
- ALTER CONVERSION
- ALTER DATABASE
- ALTER DEFAULT PRIVILEGES
- ALTER DOMAIN
- ALTER EVENT TRIGGER
- ALTER EXTENSION
- ALTER FOREIGN DATA WRAPPER
- ALTER FOREIGN TABLE
- ALTER FUNCTION
- ALTER INDEX
- ALTER LANGUAGE
- ALTER LARGE OBJECT
- ALTER MATERIALIZED VIEW
- ALTER OPERATOR
- ALTER OPERATOR CLASS
- ALTER OPERATOR FAMILY
- ALTER POLICY
- ALTER PROFILE

- ALTER ROLE, ALTER USER, ALTER GROUP
- ALTER RULE
- ALTER SCHEMA
- ALTER SEQUENCE
- ALTER SERVER
- ALTER SYSTEM
- ALTER TABLE
- ALTER TABLESPACE
- ALTER TEXT SEARCH CONFIGURATION
- ALTER TEXT SEARCH DICTIONARY
- ALTER TEXT SEARCH PARSER
- ALTER TEXT SEARCH TEMPLATE
- ALTER TRIGGER
- ALTER TYPE
- ALTER USER MAPPING
- ALTER VIEW
- CHECKPOINT
- CLUSTER
- COMMENT
- COPY
- CREATE ACCESS METHOD
- CREATE AGGREGATE
- CREATE CAST
- CREATE COLLATION
- CREATE CONVERSION
- CREATE DATABASE
- CREATE DOMAIN
- CREATE EVENT TRIGGER
- CREATE EXTENSION
- CREATE FOREIGN DATA WRAPPER
- CREATE FOREIGN TABLE
- CREATE FUNCTION
- CREATE INDEX
- CREATE LANGUAGE
- CREATE MATERIALIZED VIEW
- CREATE OPERATOR
- CREATE OPERATOR CLASS
- CREATE OPERATOR FAMILY
- CREATE POLICY
- CREATE PROFILE
- CREATE ROLE, CREATE USER, CREATE GROUP
- CREATE RULE
- CREATE SCHEMA
- CREATE SEQUENCE
- CREATE SERVER
- CREATE TABLE, CREATE TABLE AS, SELECT INTO
- CREATE TABLESPACE
- CREATE TEXT SEARCH CONFIGURATION
- CREATE TEXT SEARCH DICTIONARY
- CREATE TEXT SEARCH PARSER
- CREATE TEXT SEARCH TEMPLATE
- CREATE TRANSFORM
- CREATE TRIGGER
- CREATE TYPE
- CREATE USER MAPPING
- CREATE VIEW
- DEALLOCATE
- DELETE

- DISCARD ALL
- DISCARD PLANS
- DISCARD SEQUENCES
- DISCARD TEMP
- DO
- DROP ACCESS METHOD
- DROP AGGREGATE
- DROP CAST
- DROP COLLATION
- DROP CONVERSION
- DROP DATABASE
- DROP DOMAIN
- DROP EVENT TRIGGER
- DROP EXTENSION
- DROP FOREIGN DATA WRAPPER
- DROP FOREIGN TABLE
- DROP FUNCTION
- DROP INDEX
- DROP LANGUAGE
- DROP MATERIALIZED VIEW
- DROP OPERATOR
- DROP OPERATOR CLASS
- DROP OPERATOR FAMILY
- DROP OWNED
- DROP POLICY
- DROP PROFILE
- DROP ROLE, DROP USER, DROP GROUP
- DROP RULE
- DROP SCHEMA
- DROP SEQUENCE
- DROP SERVER
- DROP TABLE
- DROP TABLESPACE
- DROP TEXT SEARCH CONFIGURATION
- DROP TEXT SEARCH DICTIONARY
- DROP TEXT SEARCH PARSER
- DROP TEXT SEARCH TEMPLATE
- DROP TRANSFORM
- DROP TRIGGER
- DROP TYPE
- DROP USER MAPPING
- DROP VIEW
- EXECUTE
- FETCH
- GRANT
- INSERT
- MOVE
- PREPARE
- REASSIGN OWNED
- REFRESH MATERIALIZED VIEW
- REINDEX
- RESET
- REVOKE
- SECURITY LABEL
- SELECT
- SET
- UPDATE
- TRUNCATE TABLE

- `VACUUM`

F.46.6. Security Event Log Configuration Parameters

The `pg_proaudit` extension provides several configuration parameters for managing security event log files. These parameters can be set in the `postgresql.conf` configuration file, or with the help of the `ALTER SYSTEM` command. For the changes to take effect, call the `pg_reload_conf()` function or restart the database server. For additional configuration, the `syslog_ident` and `syslog_facility` configuration parameters can be used.

`pg_proaudit.log_destination` (string)

Defines the method for logging security events. Possible values are:

- `csvlog` — log security events in a CSV file.
- `ceflog` — log security events in a CEF file. CEF is an open text-based format designed for log records. It contains a standard header and a variable extension formatted as key-value pairs.
- `syslog` — log security events in syslog.
- `cefsyslog` — log security events in the CEF format in syslog.

You can specify one or more values separated by commas. Note, however, that `syslog` and `cefsyslog` are mutually exclusive. If both are specified, `cefsyslog` takes precedence and `syslog` is ignored.

Default: `csvlog`

`pg_proaudit.log_catalog_access` (boolean)

Specifies whether to log access to system catalog objects in the `pg_catalog` schema.

When set to `off`, no events will be logged, even if there are rules for the `CATALOG RELATION`, `CATALOG FUNCTION`, or `ALL` object types.

It is not recommended to set the parameter to `on`, if you do not plan to log events for system catalog objects. Doing otherwise may impact Postgres Pro performance, even if there are no rules for the aforementioned object types.

Default: `off`

`pg_proaudit.log_command_text` (boolean)

Specifies whether to log the SQL command text for security events.

Default: `on`

`pg_proaudit.log_directory` (string)

Specifies the path to the directory that stores CSV and CEF log files. This can be an absolute path or a relative path to the cluster data directory (PGDATA). This parameter is used if the `csvlog` or `ceflog` value is specified in the `pg_proaudit.log_destination` parameter.

Default: `pg_proaudit`

`pg_proaudit.log_filename` (string)

Defines the filenames of the created security event log files. The filename template can contain %-escapes, similar to the ones listed in the `strftime` specification of the Open Group (<http://pubs.opengroup.org/onlinepubs/009695399/functions/strftime.html>). This parameter is used if the `csvlog` or `ceflog` value is specified in the `pg_proaudit.log_destination` parameter.

Default: `postgresql-%Y-%m-%d_%H%M%S.log`

`pg_proaudit.log_rotation_size` (integer)

Sets the maximum size of a log file, in kilobytes. When this size is achieved, `pg_proaudit` creates a new file for logging security events. If set to `0`, disables size-based creation of new log files. This parameter is used if the `csvlog` or `ceflog` value is specified in the `pg_proaudit.log_destination` parameter.

Default: 10MB

`pg_proaudit.log_rotation_age` (integer)

Sets the maximum lifetime of a log file, in minutes. After this timeframe is elapsed, `pg_proaudit` creates a new file for logging security events. If set to 0, disables time-based creation of new log files. This parameter is used if the `csvlog` or `ceflog` value is specified in the `pg_proaudit.log_destination` parameter.

Default: 1 day

`pg_proaudit.log_truncate_on_rotation` (boolean)

Specifies whether to truncate log files when logging is switched to an existing log file. If set to `off`, `pg_proaudit` appends new log entries to the end of the file. This parameter is used if the `csvlog` or `ceflog` value is specified in the `pg_proaudit.log_destination` parameter.

Default: `off`

`pg_proaudit.max_rules_count` (integer)

Specifies the maximum number of rules allowed. For the parameter changes to take effect, the database server must be restarted.

Default: 500

F.46.7. Viewing Security Event Log

Security event log files are text files that can be viewed by the operating system facilities. To access log files using SQL, you can use the `file_fdw` extension — a foreign data wrapper for accessing files on the database server. To use this method, complete the following steps:

1. Install the `file_fdw` and create an external server:

```
CREATE EXTENSION file_fdw;  
CREATE SERVER pg_proauditlog FOREIGN DATA WRAPPER file_fdw;
```

2. Create a foreign table, specifying the columns and the absolute path to the log file. The actual log file location is determined by the `pg_proaudit.log_directory` and `pg_proaudit.log_filename` parameters.

```
CREATE FOREIGN TABLE pg_proaudit_log  
    ( log_time timestamp(3) with time zone,  
      current_usr_name text,  
      database_name text,  
      session_pid text,  
      error_severity text,  
      session_line_num bigint,  
      session_line_subcommand_num bigint,  
      event_type text,  
      object_type text,  
      object_name text,  
      status text,  
      error_message text,  
      query_text text,  
      query_args text,  
      session_usr_name text,  
      uuid text,  
      xid text,  
      vxid text )
```

```
SERVER pg_proauditlog  
OPTIONS (filename 'absolute_file_path_to_log_file.csv', FORMAT 'csv' );
```

Make sure that the `pg_proaudit.log_destination` parameter contains the `csvlog` value, which enables writing security event logs to CSV files.

F.46.8. Examples

As an example, let's set up logging for the following security events:

- authentications/disconnections to the `postgres` database
- all actions of the user if at least one of the user session attributes, `session_user` or `current_user`, is either explicitly set to the `postgres` role, or is directly or indirectly a member of this role
- creating, updating, and deleting any tables
- all operations on the `app_table` table that belongs to the `public` schema

All events must be logged in the CSV format and stored for a week. It is required to set up SQL access to the security event log. To complete the scenario, do the following:

In `psql`, check that the preliminary setup of the `pg_proaudit` extension is complete in the `postgres` database:

```
SHOW shared_preload_libraries;
shared_preload_libraries
-----
pg_proaudit

\dx pg_proaudit
           List of installed extensions
  Name      | Version | Schema | Description
-----+-----+-----+-----
pg_proaudit | 2.0     | public | provides auditing functionality
```

Add the following lines to the `postgresql.conf` configuration file:

```
pg_proaudit.log_destination = 'csvlog'
pg_proaudit.log_directory = 'audit'
pg_proaudit.log_filename = 'audit-%u.csv'
pg_proaudit.log_rotation_age = 1440
pg_proaudit.log_rotation_size = 0
pg_proaudit.log_truncate_on_rotation = on
pg_proaudit.log_command_text = on
```

For the changes to take effect, run the following query:

```
SELECT pg_reload_conf();
```

Check that the following parameters are set as expected:

```
SHOW pg_proaudit.log_destination;
SHOW pg_proaudit.log_directory;
SHOW pg_proaudit.log_filename;
SHOW pg_proaudit.log_rotation_age;
SHOW pg_proaudit.log_rotation_size;
SHOW pg_proaudit.log_truncate_on_rotation;
SHOW pg_proaudit.log_command_text;
```

Suppose your `PGDATA` environment variable points to the cluster data directory. Since the `pg_proaudit.log_directory` defines a relative path to the log files, they will be located in the `$PGDATA/audit` directory. Let's create an empty file for each day of the week and make them available to their owner only:

```
touch $PGDATA/audit/audit-1.csv
touch $PGDATA/audit/audit-2.csv
touch $PGDATA/audit/audit-3.csv
touch $PGDATA/audit/audit-4.csv
touch $PGDATA/audit/audit-5.csv
touch $PGDATA/audit/audit-6.csv
touch $PGDATA/audit/audit-7.csv
chmod 600 $PGDATA/audit/audit-*.csv
```

Create a table for reading log entries:

```
CREATE TABLE pg_proaudit_log (  
    log_time timestamp(3) with time zone,  
    current_usr_name text,  
    database_name text,  
    session_pid text,  
    error_severity text,  
    session_line_num bigint,  
    session_line_subcommand_num bigint,  
    event_type text,  
    object_type text,  
    object_name text,  
    status text,  
    error_message text,  
    query_text text,  
    query_args text,  
    session_usr_name text,  
    uuid text,  
    xid text,  
    vxid text  
);
```

Install the file_fdw extension and create an external server:

```
CREATE EXTENSION file_fdw;  
CREATE SERVER pg_proauditlog FOREIGN DATA WRAPPER file_fdw;
```

Now let's create seven child foreign tables for the pg_proaudit_log table, for each day of the week:

```
CREATE FOREIGN TABLE pg_proaudit_log_1 () INHERITS (pg_proaudit_log) SERVER  
pg_proauditlog  
    OPTIONS (filename '/path_to_PGDATA/audit/audit-1.csv', FORMAT 'csv');  
CREATE FOREIGN TABLE pg_proaudit_log_2 () INHERITS (pg_proaudit_log) SERVER  
pg_proauditlog  
    OPTIONS (filename '/path_to_PGDATA/audit/audit-2.csv', FORMAT 'csv');  
CREATE FOREIGN TABLE pg_proaudit_log_3 () INHERITS (pg_proaudit_log) SERVER  
pg_proauditlog  
    OPTIONS (filename '/path_to_PGDATA/audit/audit-3.csv', FORMAT 'csv');  
CREATE FOREIGN TABLE pg_proaudit_log_4 () INHERITS (pg_proaudit_log) SERVER  
pg_proauditlog  
    OPTIONS (filename '/path_to_PGDATA/audit/audit-4.csv', FORMAT 'csv');  
CREATE FOREIGN TABLE pg_proaudit_log_5 () INHERITS (pg_proaudit_log) SERVER  
pg_proauditlog  
    OPTIONS (filename '/path_to_PGDATA/audit/audit-5.csv', FORMAT 'csv');  
CREATE FOREIGN TABLE pg_proaudit_log_6 () INHERITS (pg_proaudit_log) SERVER  
pg_proauditlog  
    OPTIONS (filename '/path_to_PGDATA/audit/audit-6.csv', FORMAT 'csv');  
CREATE FOREIGN TABLE pg_proaudit_log_7 () INHERITS (pg_proaudit_log) SERVER  
pg_proauditlog  
    OPTIONS (filename '/path_to_PGDATA/audit/audit-7.csv', FORMAT 'csv');
```

To set up logging for the required security events, connect to the postgres database and execute the following commands:

```
SELECT pg_proaudit_set_rule (current_database(), 'AUTHENTICATE', null, null, null, 'Any  
authentication in the current DB');  
SELECT pg_proaudit_set_rule (current_database(), 'DISCONNECT', null, null, null, 'Any  
disconnect from the current DB');  
SELECT pg_proaudit_set_rule (current_database(), 'ALL', 'TABLE', null, null, 'Any  
operations with any table in the current DB');
```

```
SELECT pg_proaudit_set_rule (current_database(), 'ALL', null, null, 'postgres', 'Any
operation by "postgres" user in the current DB');
```

Create the app_table table and enable logging for all operations on this table:

```
CREATE TABLE app_table (id int, name text);
SELECT pg_proaudit_set_rule (current_database(), 'ALL', null, 'public.app_table',
null);
```

Check that event logging is configured as expected:

```
SELECT * FROM pg_proaudit_settings;
db_name | event_type | object_type | object_name | role_name |
comment
-----+-----+-----+-----+-----+
postgres | authenticate | ALL | | | Any
authentication in the current DB
postgres | disconnect | ALL | | | Any disconnect
from the current DB
postgres | ALL | table | | | Any operations
with any table in the current DB
postgres | ALL | ALL | | postgres | Any operation
by "postgres" user in the current DB
postgres | ALL | ALL | public.app_table | |
(5 rows)
```

Save these logging rules into the pg_proaudit.conf file, so that they are not lost after the server restart:

```
SELECT pg_proaudit_save();
```

Let's run several queries on the app_table table:

```
INSERT INTO app_table VALUES (1, 'first');
SELECT * FROM app_table;
```

Check the log entries for the app_table table:

```
SELECT to_char(log_time, 'DD.MM.YY HH24:MI:SS') AS when, current_usr_name,
session_pid, event_type, query_text, session_usr_name
FROM pg_proaudit_log
WHERE object_name = 'public.app_table';
when | current_usr_name | session_pid | event_type |
query_text | session_usr_name
-----+-----+-----+-----+
27.09.23 12:44:27 | postgres | 2010 | CREATE TABLE | CREATE TABLE
app_table (id int, name text); | postgres
27.09.23 12:45:55 | postgres | 2010 | INSERT | INSERT INTO
app_table VALUES (1, 'first'); | postgres
27.09.23 12:46:00 | postgres | 2010 | SELECT | SELECT * FROM
app_table; | postgres
(3 rows)
```

We have set up a weekly rotation of log files, with the log file switched once a day. It means that queries to the pg_proaudit_log table will return only those security events that have happened in the latest week. Older events will be automatically removed at log file rotation. To define additional access constraints for specific log entries, you can create separate views based on queries to the pg_proaudit_log table and grant read rights to such views using built-in Postgres Pro access control methods.

F.47. `pgpro_autopart` — dynamic partition creation

The `pgpro_autopart` extension enables dynamic creation of partitions, that is automatic partitioning when data is added or modified in a table. The fastest way to create partitions is to do it manually or on schedule using a scheduler. However, for some tasks the speed of adding data does not matter much. For such tasks, `pgpro_autopart` implements automatic partitioning using triggers on a view of a partitioned table.

F.47.1. Installation

The `pgpro_autopart` extension is included in Postgres Pro. To enable `pgpro_autopart`, create the extension using the following query:

```
CREATE EXTENSION pgpro_autopart;
```

F.47.2. Usage

The `pgpro_autopart` extension uses the [ap_enable_automatic_partition_creation](#) function for automatic partitioning.

Note

Note that the extension works only with newly created tables. It cannot be used with existing partitioned tables, since it cannot track partitions previously created by users.

First, this function adds the `real_` prefix to the specified table name. Then, it creates a view with the original table name and adds the `INSTEAD OF INSERT/UPDATE` triggers to it.

Note

Note that the database administrator should grant privileges on the view created by the `ap_enable_automatic_partition_creation` function manually. It is expected that these privileges are the same as on the parent table.

These triggers work as follows:

- **INSTEAD OF INSERT:** When an entry is inserted into the view, `pgpro_autopart` searches for a partition for this entry. If the partition is not found, it is created. Then this entry is inserted into the partitioned table.
- **INSTEAD OF UPDATE:** When an entry is updated in the view, `pgpro_autopart` searches for a partition for this entry. If the partition is not found, it is created. Then this entry is updated in the partitioned table.

Note

The `INSERT` or `UPDATE` statement must contain a value for a partitioning key.

When using a sequence as the key value, it is required to explicitly set the value using `nextval()` because it can not be omitted. Otherwise, the `INSERT` or `UPDATE` operation will fail.

Currently, only tables with partitioning by range (`BY RANGE`) are supported, having one column of the `date`, `timestamp`, `timestampz`, `smallint`, `int`, or `bigint` type as a key.

When creating partitions for a partitioning key of `date/timestamp` types, valid values of the interval are `year`, `quarter`, `month`, and `day`. That is, a new partition is created for each new year, quarter, month or day.

Names for new partitions follow a strict format: a partitioned table name is followed by a suffix indicating the interval for which the partition is created. For example, for the following interval types table names will be as follows:

`day`

`real_t_day_2024_05_13` for the `real_t_day` table

`month`

`real_t_month_2024_05` for the `real_t_month` table

`quarter`

`real_t_quarter_2024_2` for the `real_t_quarter` table

`year`

`real_t_year_2025` for the `real_t_year` table

`int`

`real_t_int_120_130` for the `real_t_int` table

`bigint`

`"real_t_bigint_-60_-50"` for the `real_t_bigint` table

The `INSTEAD OF INSERT/UPDATE` triggers check the presence of a partition for *each* inserted or updated entry, and it can slow down the performance.

Since the original partitioned table is renamed, you should use its name with the `real_` prefix to work directly with the table.

Important

Remember that the maximum length for the table name in Postgres Pro is 63 bytes. When `pgpro_autopart` creates a partition, it automatically adds up to 29 bytes (prefix `real_`, two underscores, symbols of borders) to the table name for the `int` type and up to 51 bytes for the `bigint` type of the partition key. It is the user's responsibility to choose appropriate table names to avoid errors.

F.47.3. `ap_tables_view` View

Tables with enabled automatic partitioning are shown in the `ap_tables_view` view. Here is an example of the data in the view.

```
SELECT * FROM ap_tables_view;
 apt_relname | apt_relschema | apt_mode
-----+-----
+-----+-----
 t_month1    | user_schema   | automatic partition creation with using triggers on VIEW
 (C-implementation)
 t_bigint1   | user_schema   | automatic partition creation with using triggers on VIEW
 (C-implementation)
(2 rows)
```

F.47.4. Functions

`ap_enable_automatic_partition_creation(a_relname text[, a_relschema text], a_interval text)` returns void

This function is used for tables with a partitioning key of the `date`, `timestamp`, or `timestampz` type. It renames the partitioned table `a_relname` (of the `a_relschema` schema) by adding the `real_` prefix. The function then creates a view with the same name as the original table and adds the `INSTEAD OF INSERT/UPDATE` triggers to it. These triggers create a new partition when needed. The limits of the partition are determined by the defined `a_interval` (year, quarter, month, day).

```
ap_enable_automatic_partition_creation(a_relname text[, a_relschema text], a_interval
smallint, a_firstval smallint) returns void
ap_enable_automatic_partition_creation(a_relname text[, a_relschema text], a_interval
int, a_firstval int) returns void
ap_enable_automatic_partition_creation(a_relname text[, a_relschema text], a_interval
bigint, a_firstval bigint) returns void
```

These functions are used for tables with a partitioning key of the `smallint`, `int`, or `bigint` type. They rename the partitioned table `a_relname` (of the `a_relschema` schema) by adding the `real_` prefix. The function then creates a view with the same

name as the original table and the `INSTEAD OF INSERT/UPDATE` triggers for it. These triggers create a new partition when needed. The limits of the partition are determined by the original `a_firstval` value, from which the intervals are counted, and the `a_interval` value defining the interval length.

`ap_disable_automatic_partition_creation(a_relname text[, a_relschema text])` returns `void`

The function removes the triggers created by the `ap_enable_automatic_partition_creation` function for the view of the defined partitioned table `a_relname` (of the `a_relschema` schema). It also deletes the view and renames the partitioned table, removing the `real_` prefix from its name.

F.47.5. Example

This example illustrates the usage of `pgpro_autopart` with the partitioning key of the `bigint` type.

Create the extension.

```
CREATE EXTENSION pgpro_autopart;
```

Create the table partitioned `BY RANGE` with one-column key of the `bigint` type.

```
CREATE TABLE t_bigint (b bigint, i int) PARTITION BY RANGE (b);
```

Use the extension to rename the `t_bigint` table into `real_t_bigint`, create the `t_bigint` view for this table, and then create the `INSTEAD OF INSERT/UPDATE` triggers. Note that the initial value for creating partitions is 100, and partitions are created at intervals of 10 in both directions.

```
SELECT ap_enable_automatic_partition_creation('t_bigint', 10, 100);
ap_enable_automatic_partition_creation
```

```
-----
(1 row)
```

Insert two entries into the table. The `real_t_bigint_110_120` partition will be created automatically after the first entry.

```
INSERT INTO t_bigint VALUES (111, 1);
NOTICE: New partition "public"."real_t_bigint_110_120" created
INSERT 0 1
INSERT INTO t_bigint VALUES (114, 2);
INSERT 0 1
```

Change the key field for one of the entries. This will automatically create the `real_t_bigint_-60_-50` partition.

```
UPDATE t_bigint SET b = -55 WHERE b = 114 RETURNING *;
NOTICE: New partition "public"."real_t_bigint_-60_-50" created
 b | i
----+---
-55 | 2
(1 row)
UPDATE 1
```

Check partitions of the `real_t_bigint` table. There should be two of them.

```
SELECT
  c.oid::pg_catalog.regclass AS "name",
  pg_catalog.pg_get_expr(c.relpartbound, c.oid) AS "condition"
FROM
  pg_catalog.pg_class c,
  pg_catalog.pg_inherits i
WHERE
  c.oid = i.inhrelid AND i.inhparent = 'real_t_bigint'::regclass;
      name                | condition
-----+-----
real_t_bigint_110_120    | FOR VALUES FROM ('110') TO ('120')
"real_t_bigint_-60_-50" | FOR VALUES FROM ('-60') TO ('-50')
```

(2 rows)

Check the data in the `real_t_bigint` table and its partitions. The table should contain two entries:

```
SELECT * FROM real_t_bigint;
  b | i
-----+---
-55 | 2
111 | 1
(2 rows)
```

There should be one entry in the `real_t_bigint_110_120` partition:

```
SELECT * FROM real_t_bigint_110_120;
  b | i
-----+---
111 | 1
(1 row)
```

And also there should be one entry in the `real_t_bigint_-60_-50` partition.

```
SELECT * FROM "real_t_bigint_-60_-50";
  b | i
-----+---
-55 | 2
(1 row)
```

Disable triggers, drop the view, and rename the `real_t_bigint` table into `t_bigint`.

```
SELECT ap_disable_automatic_partition_creation('t_bigint');
ap_disable_automatic_partition_creation
-----
(1 row)
```

Drop the table and the extension.

```
DROP TABLE t_bigint;
DROP TABLE
DROP EXTENSION pgpro_autopart;
DROP EXTENSION
```

F.48. pgpro_bindump — a replication protocol module for backup and restore

`pgpro_bindump` is a plugin designed to implement additional commands for the Postgres Pro replication protocol, specifically for use with the [pg_probackup3](#) utility. `pgpro_bindump` offers the following benefits:

- Simplified communication: `pgpro_bindump` does not require the SSH protocol and associated configurations to connect to a database server.
- Integrated WAL transfer: WAL files are transferred together with data files, reducing the risk of data loss during backups.
- Optimized storage: Files are not copied as they are, but are archived using the `pg_probackup3` own format, CBOR (RFC 8949 Concise Binary Object Representation), which enhances the storage efficiency.

F.48.1. Architecture

Here are some key points of how `pgpro_bindump` works:

- A dedicated backend process is created to handle connections from external applications. You can use the `pg_probackup3` utility or a custom application to send requests to this backend.
- Multiple connections can be established for the same application if needed.
- Since the `pgpro_bindump` plugin has direct access to the database files, it does not require any additional permissions.
- `pgpro_bindump` uses the [libpgprobackup](#) library, along with its built-in encoder module, to send data to the application.
- The `walsender_plugin_libraries` configuration parameter simplifies the process of adding and utilizing new replication commands, including custom ones.

F.48.2. Limitations and Requirements

`pgpro_bindump` currently has the following limitations and requirements:

- `libpgprobackup.so` and `libpb3_encoder.so` are required for `pgpro_bindump` operation.

F.48.3. Installation and Setup

The `pgpro_bindump` plugin is included in Postgres Pro as part of the `postgrespro-ent-17-contrib` package (for the installation instructions, see [Chapter 17](#)). Once you complete Postgres Pro installation, follow the steps below.

1. Specify the following parameters in the `postgresql.conf` file:

```
shared_preload_libraries = 'pgpro_bindump'  
wal_level = 'replica' # or 'logical'  
walsender_plugin_libraries = 'pgpro_bindump'
```

2. Restart the Postgres Pro instance.

Note

Since `pgpro_bindump` is a plugin and not an extension, the `CREATE EXTENSION` command is not needed.

F.48.4. Replication Commands

The `pgpro_bindump` plugin implements the following replication commands:

- `just-noop` — a do-nothing command.
- `start_backup` — starts the backup process.
- `copy_files` — copies files in the CBOR format.

- `stop_backup` — stops the backup process.

The backup process runs in the *PRO mode* — an advanced backup data source mode that incorporates all available optimizations and enhancements, including the proprietary replication protocol and specialized replication commands.

To send commands from a user application to `pgpro_bindump` and to receive the output data from `pgpro_bindump` by the application, use `libpq`.

Note

An established connection to a running Postgres Pro server is required.

F.48.4.1. `start_backup`

```
start_backup LABEL label, INCR_MODE incr_mode, START_LSN start_lsn,  
TRANSFER_MODE transfer_mode,  
[TRANSFER_BUFFER_SIZE buffer_size]
```

Starts the backup process. Sends the following data to the application:

- `start_lsn` — LSN at the start of the backup.
- `start_tli` — the timeline ID at the start of the backup.
- `min_xid` — the minimal transaction ID at the start of the backup.
- `min_multixact` — the minimal `multixact` ID at the start of the backup.
- `tablespace_list` — a list of tablespaces included in the backup.
- `database_list` — a list of databases included in the backup.

LABEL *label*

The name of the backup.

INCR_MODE *incr_mode*

The type of incremental backup. Possible values: `PTRACK`, `DELTA`.

START_LSN *start_lsn*

An `XLogRecPtr` value representing LSN at the start of the backup.

TRANSFER_MODE *transfer_mode*

The method to be used for sending data from a server to an application. Possible values:

- `raw` — unpacked data is sent in random blocks of arbitrary size.
- `packed` — packed data is sent in blocks of 128 KB with a common header.

`packed` is the default value.

TRANSFER_BUFFER_SIZE *buffer_size*

A numeric value representing the buffer size. The preset (unchanged) value is 131072 (128 KB).

F.48.4.2. `copy_files`

```
copy_files VERIFY_CHECKSUMS [TRUE | FALSE], COMPRESS_ALG compress_alg,  
COMPRESS_LVL compress_lvl, TRANSFER_MODE transfer_mode,  
[INCR_MODE incr_mode], [START_LSN start_lsn], [TRANSFER_BUFFER_SIZE buffer_size],  
[WORKER_INFO number_of_workers:worker_id]
```

Forwards blocks of data files and WAL files packaged in the CBOR format.

VERIFY_CHECKSUMS

A boolean value (`true` or `false`) indicating whether to verify checksums.

COMPRESS_ALG *compress_alg*

The compression algorithm to be used. Possible values: `zlib`, `zstd`, `lz4`, `none`.

COMPRESS_LVL *compress_lvl*

The compression level. Possible values: 1, 2, 3, 4, 5.

TRANSFER_MODE *transfer_mode*

The method to be used for sending data from a server to an application. Possible values:

- `raw` — unpacked data is sent in random blocks of arbitrary size.
- `packed` — packed data is sent in blocks of 128 KB with a common header.

`packed` is the default value.

INCR_MODE *incr_mode*

The type of incremental backup. Possible values: `PTRACK`, `DELTA`.

START_LSN *start_lsn*

An `XLogRecPtr` value representing LSN at the start of the backup.

TRANSFER_BUFFER_SIZE *buffer_size*

A numeric value representing the buffer size. The preset (unchanged) value is 131072 (128 KB).

WORKER_INFO *number_of_workers:worker_id*

The number of workers and the worker ID.

F.48.4.3. **stop_backup**

`stop_backup` STREAM [`TRUE` | `FALSE`], COMPRESS_ALG *compress_alg*,
COMPRESS_LVL *compress_lvl*,
[EXTERNALS *externals*] [TRANSFER_BUFFER_SIZE *buffer_size*], [TRANSFER_MODE *transfer_mode*]

Completes the copy process and closes the existing connection. Sends the following data to the application:

- `stop_lsn` — LSN at the end of the backup.
- `stop_tli` — the timeline ID at the end of the backup.
- The `backup.control` file.
- A set of WAL files (only if WAL streaming is enabled).

STREAM

A boolean value (`true` or `false`) indicating whether WAL streaming is enabled.

COMPRESS_ALG *compress_alg*

The compression algorithm to be used. Possible values: `zlib`, `zstd`, `lz4`, `none`.

COMPRESS_LVL *compress_lvl*

The compression level. Possible values: 1, 2, 3, 4, 5.

EXTERNALS *externals*

A list of external directories.

`TRANSFER_BUFFER_SIZE` *buffer_size*

A numeric value representing the buffer size. The preset (unchanged) value is 131072 (128 KB).

`TRANSFER_MODE` *transfer_mode*

The method to be used for sending data from a server to an application. Possible values:

- `raw` — unpacked data is sent in random blocks of arbitrary size.
- `packed` — packed data is sent in blocks of 128 KB with a common header.

`packed` is the default value.

F.48.5. Authors

Postgres Professional, Moscow, Russia.

F.49. pgpro_cpumeter — a CPU usage monitoring system function

pgpro_cpumeter is an extension providing access to a new CPU usage monitoring system function. This pgpro_cpumeter function continuously collects and records information about CPU cores used by Postgres Pro server processes.

F.49.1. Installation

The pgpro_cpumeter extension is a built-in extension included into Postgres Pro Enterprise. To enable pgpro_cpumeter, use the following query:

```
CREATE EXTENSION pgpro_cpumeter;
```

F.49.2. pgpro_cpumeter function

The pgpro_cpumeter provides the following system function:

pgpro_cpumeter(OUT start_time timestampz, OUT end_time timestampz, OUT user_time int, OUT system_time int, OUT cpus_allowed int, OUT cpus_online int, OUT arch text, OUT machine_id text, OUT system_identifier bigint) returns setof record

Returns the collected statistics on CPU usage in the following output columns:

start_time

The start time of the measurement period. This value is inclusive ([start_time, end_time)). It matches the end_time of the previous measurement record.

end_time

The end time of the measurement period, indicating when the collected information is recorded to the disk. This value is exclusive ([start_time, end_time)). It becomes the start_time of the subsequent measurement period.

user_time

The user CPU time, which is the total CPU time in seconds spent by all Postgres Pro processes in user mode.

system_time

The system CPU time, which is the total CPU time in seconds spent by all Postgres Pro processes in system (kernel) mode.

cpus_allowed

The number of logical CPU cores available to Postgres Pro processes. This value may be limited, for example, by the taskset tool and is typically less than or equal to cpus_online.

cpus_online

The number of logical CPU cores currently active and available to the operating system. This value may be less than the total number of physical cores in the system, for example, if some cores are disabled.

arch

The processor architecture. This value remains constant for the entire database cluster.

machine_id

The unique identifier of the host stored in the /etc/machine-id file. This value may change if the PGDATA directory is moved to a different server.

system_identifier

The system identifier of the database cluster. This value remains constant for the cluster lifetime, changing only in very limited and exceptional circumstances.

F.49.3. Limitations and Considerations

When using pgpro_cpumeter, consider the following issues:

- The collected statistics are recorded every 10 minutes. This interval cannot be changed.

However, statistics are also recorded at the server shutdown. In this case, the last measurement period may be less than 10 minutes.

At the next server start, `start_time` will not match `end_time` of the previous period. The `start_time` value for the first record will be equal to the server start time.

- If the server crashes, the collected statistics for the most recent measurement period (up to 10 minutes) are lost.

F.49.4. Example

The example below illustrates how to use `pgpro_cpumeter` and its expected output.

```
postgres=# CREATE EXTENSION pgpro_cpumeter;
CREATE EXTENSION
```

```
postgres=# SELECT * FROM pgpro_cpumeter() ORDER BY start_time ASC LIMIT 5;
      start_time      |      end_time      | user_time |
system_time | cpus_allowed | cpus_online | arch |      machine_id      |
system_identifier

F.50. `pg_prewarm` — preload relation data into buffer caches

The `pg_prewarm` module provides a convenient way to load relation data into either the operating system buffer cache or the Postgres Pro buffer cache. Prewarming can be performed manually using the `pg_prewarm` function, or can be performed automatically by including `pg_prewarm` in [shared_preload_libraries](#). In the latter case, the system will run a background worker which periodically records the contents of shared buffers in a file called `autoprewarm.blocks` and will, using 2 background workers, reload those same blocks after a restart.

F.50.1. Functions

```
pg_prewarm(regclass, mode text default 'buffer', fork text default 'main',  
           first_block int8 default null,  
           last_block int8 default null) RETURNS int8
```

The first argument is the relation to be prewarmed. The second argument is the prewarming method to be used, as further discussed below; the third is the relation fork to be prewarmed, usually `main`. The fourth argument is the first block number to prewarm (`NULL` is accepted as a synonym for zero). The fifth argument is the last block number to prewarm (`NULL` means prewarm through the last block in the relation). The return value is the number of blocks prewarmed.

There are three available prewarming methods. `prefetch` issues asynchronous prefetch requests to the operating system, if this is supported, or throws an error otherwise. `read` reads the requested range of blocks; unlike `prefetch`, this is synchronous and supported on all platforms and builds, but may be slower. `buffer` reads the requested range of blocks into the database buffer cache.

Note that with any of these methods, attempting to prewarm more blocks than can be cached — by the OS when using `prefetch` or `read`, or by Postgres Pro when using `buffer` — will likely result in lower-numbered blocks being evicted as higher numbered blocks are read in. Prewarmed data also enjoys no special protection from cache evictions, so it is possible that other system activity may evict the newly prewarmed blocks shortly after they are read; conversely, prewarming may also evict other data from cache. For these reasons, prewarming is typically most useful at startup, when caches are largely empty.

```
autoprewarm_start_worker() RETURNS void
```

Launch the main autoprewarm worker. This will normally happen automatically, but is useful if automatic prewarm was not configured at server startup time and you wish to start up the worker at a later time.

```
autoprewarm_dump_now() RETURNS int8
```

Update `autoprewarm.blocks` immediately. This may be useful if the autoprewarm worker is not running but you anticipate running it after the next restart. The return value is the number of records written to `autoprewarm.blocks`.

F.50.2. Configuration Parameters

```
pg_prewarm.autoprewarm (boolean)
```

Controls whether the server should run the autoprewarm worker. This is on by default. This parameter can only be set at server start.

```
pg_prewarm.autoprewarm_interval (integer)
```

This is the interval between updates to `autoprewarm.blocks`. The default is 300 seconds. If set to 0, the file will not be dumped at regular intervals, but only when the server is shut down.

These parameters must be set in `postgresql.conf`. Typical usage might be:

```
# postgresql.conf  
shared_preload_libraries = 'pg_prewarm'  
  
pg_prewarm.autoprewarm = true  
pg_prewarm.autoprewarm_interval = 300s
```

F.50.3. Author

Robert Haas <rhaas@postgresql.org>

F.51. pgpro_gbtrees — global index on a partitioned table

The `pgpro_gbtrees` extension enables creation and use of a global index on a partitioned table.

A *global index* is an index that is created for one or several columns of a partitioned table and does not include the partition key. At the physical level, a global index on a partitioned table contains data related to the indexed columns for all the partitions, which means that the global index allows you to perform index scan without iterating through all the partitions.

A global index provides the following benefits:

- It enables a much faster search of rows of the partitioned table by a condition on the indexed columns. The search appears to be faster because the global index is not partitioned, and therefore, there is no need to perform index scans of individual partitions.
- It lifts a Postgres Pro restriction that does not allow creation of a unique index for columns that do not contain the partition key.

F.51.1. Global Index Operation

These are a few details of how a global index works:

- A global index is created for a user-defined set of columns, and the primary key columns of the partitioned table are automatically added to the global index as **INCLUDE** columns.
- An index scan with a global index is performed in two steps:
 1. The value is searched for in the global index.
 2. The value of the primary key in **INCLUDE** index columns is used to search for the partition and for the value in this partition.
- A global index is not rebuilt for delete and **DETACH PARTITION** operations. So it is OK that a global index contains some outdated data, which can be cleaned up with **VACUUM**.
- A global index is not partitioned. Therefore, the data size limitation of 32 TB holds for it. It is assumed that the global index fits these 32 TB as it contains only part of data of the partitioned table (this assumption may, however, appear not to be true in some circumstances).

F.51.2. Limitations

Creation of global indexes has the following limitations:

- The partitioned table for which a global index is created must have a primary key.
- As for any index on a partitioned table, the **CONCURRENTLY** option cannot be used.
- Expressions used instead of column names and predicates in the **WHERE** clause are not currently supported.
- Specifying non-key columns (in the **INCLUDE** clause) is not supported. The **CREATE INDEX** command issues a warning if such columns are specified and ignores them.

Usage of global indexes has the following limitations:

- A global index, like a standard b-tree index, is not suitable for columns that contain few unique values. An example of an unsuitable column is the *gender* column with two values *M* and *F*. In addition to a high overhead of the pure index, for the global index, when a new value is added, a hash sum of the value gets locked. With few possible values, modifying transactions are likely to block one another, that is, hang on this lock.
- As a global index does not store information on row versions, a need in garbage collection for this index is not so important as for normal indexes. Therefore, **autovacuum** is not currently supported.
- External links to the global index on a partitioned table from other tables are not currently supported.
- It is forbidden to add a partitioned table with a global index, as a partition, to another partitioned table.
- If a partitioned table has a global index, deleting its primary key is not allowed. Delete the global index first.
- The **CLUSTER** command for global indexes is not currently supported.

- The `ON CONFLICT` clause is not currently applicable to unique global indexes.

F.51.3. Installation

The `pgpro_gbtree` extension is included in Postgres Pro Enterprise. To enable `pgpro_gbtree`, create the extension using the following query:

```
CREATE EXTENSION pgpro_gbtree;
```

F.51.4. Usage

F.51.4.1. Creating and Removing Global Indexes

To create a global index, execute the `CREATE INDEX` command specifying the `gbtree` access method from the `pgpro_gbtree` extension. The following command creates a global index for the `t_int` table:

```
CREATE INDEX t_int_v ON t_int USING gbtree (v);
```

To remove a global index, execute the `DROP INDEX` command. For example:

```
DROP INDEX t_int_v;
```

F.51.4.2. Using Global indexes in Queries

It is not possible to implement a usual Postgres Pro behavior for a global index as in the standard implementation, an entire partitioned table, on which the global index is created, is not regarded as a node when the query plan is built. Plans get linked to partitions, and then the best scan method is chosen for each partition, such as `SeqScan`, `IndexOnlyScan`, `IndexScan`, and so on. For the Postgres Pro planner, a partitioned table only provides the list of partitions and is not considered a planning object. A global index can be used if the partitioned table becomes a planning object. And this only happens under the following conditions:

- The query does not contain a condition on the partition key that excludes at least one partition. It is assumed that the search by a condition on the partition key in a query is more efficient than the the global index.
- The query contains a condition on columns of the global index.

F.51.5. Example

The following example illustrates usage of a global index.

```
-- Creating the pgpro_gbtree extension
CREATE EXTENSION pgpro_gbtree;

-- Creating a partitioned table with three partitions
CREATE TABLE t_int (i int PRIMARY KEY, v int, x int) PARTITION BY RANGE (i);
CREATE TABLE t_int_1 PARTITION OF t_int FOR VALUES FROM (0) TO (100);
CREATE TABLE t_int_2 PARTITION OF t_int FOR VALUES FROM (100) TO (200);
CREATE TABLE t_int_3 PARTITION OF t_int FOR VALUES FROM (200) TO (300);

-- Creating a global index for the v column
CREATE INDEX t_int_v ON t_int USING gbtree (v);

-- Creating a normal index for the x column
CREATE INDEX t_int_x ON t_int (x);

-- Query plan for a condition on the column with the global index
EXPLAIN SELECT * FROM t_int WHERE v > 100;

-- Query plan for a condition on the column with the normal index
EXPLAIN SELECT * FROM t_int WHERE x > 100;
```

The example produces the following output:

```
CREATE EXTENSION
CREATE TABLE
```

```
CREATE TABLE
CREATE TABLE
CREATE TABLE
CREATE INDEX
CREATE INDEX
```

QUERY PLAN

```
-----
Index Scan using t_int_v on t_int  (cost=0.12..8.14 rows=0 width=0)
  Index Cond: (v > 100)
(2 rows)
```

QUERY PLAN

```
-----
Append (cost=9.42..93.97 rows=2040 width=12)
-> Bitmap Heap Scan on t_int_1 (cost=9.42..27.92 rows=680 width=12)
    Recheck Cond: (x > 100)
    -> Bitmap Index Scan on t_int_1_x_idx (cost=0.00..9.25 rows=680 width=0)
        Index Cond: (x > 100)
-> Bitmap Heap Scan on t_int_2 (cost=9.42..27.92 rows=680 width=12)
    Recheck Cond: (x > 100)
    -> Bitmap Index Scan on t_int_2_x_idx (cost=0.00..9.25 rows=680 width=0)
        Index Cond: (x > 100)
-> Bitmap Heap Scan on t_int_3 (cost=9.42..27.92 rows=680 width=12)
    Recheck Cond: (x > 100)
    -> Bitmap Index Scan on t_int_3_x_idx (cost=0.00..9.25 rows=680 width=0)
        Index Cond: (x > 100)
(13 rows)
```

The result of this example shows that with the global index, the index scan is performed for the entire partitioned table, while with the normal index, the index scan is performed for each partition individually, and this search can be slow when the number of partitions is high.

F.52. `pgpro_ilm` — enables moving rarely used relations to a lower-cost storage

The `pgpro_ilm` extension solves the problem similar to Oracle's information lifecycle management (ILM), which analyzes usage frequency of data in a database and performs certain actions with rarely used tables, for example, moves tables to a lower-cost and slower storage.

`pgpro_ilm` allows you to define rules for moving tables. A rule can have the `NO_MODIFICATION` or `NO_ACCESS` type. A `NO_MODIFICATION` rule defines an action to perform on the table if it was not modified (by `UPDATE`, `INSERT`, `DELETE`, or `TRUNCATE` commands), but could be read (by `SELECT`) for a certain period of time. A `NO_ACCESS` rule defines an action to perform on the table if none of the above commands was executed on this table for a certain period of time. `pgpro_ilm` provides functions to manage the rules and apply them.

`pgpro_ilm` gets per-user statistics on when tables were last accessed from [pgpro_usage](#) functions and views. For the ILM purposes, maintenance operations with tables, such as taking regular backups, archiving, etc., should not be taken into account. These operations are performed by particular users, e.g., `postgres`, and such users must be excluded when checking whether `pgpro_ilm` rules apply. `pgpro_ilm` provides functions to manage the user exclusion list.

F.52.1. Limitations

The current version of `pgpro_ilm` has the following limitations:

- The only action supported is moving the relation to another tablespace.
- Regular tables, indexes, and partitions of partitioned tables are only supported.

F.52.2. Installation

`pgpro_ilm` is a built-in extension included in Postgres Pro Enterprise. To enable `pgpro_ilm`, create the extension using the following query:

```
CREATE EXTENSION pgpro_ilm;
```

For `pgpro_ilm` to work, make sure that the `pgpro_usage` extension is installed, as explained in [Section F.57.1](#).

F.52.3. Functions

To configure moving tables to a lower-cost storage, `pgpro_ilm` provides an SQL interface that consists of several functions.

F.52.3.1. Rule Management Functions

The following functions manage `pgpro_ilm` rules:

`add_rule( iv_object_name text, iv_rule_type text, iv_period interval, iv_action text, iv_parameter text )` returns void

Adds a new rule.

Arguments:

- *iv_object_name* — name of the relation. Can be qualified or not. If the name is unqualified, the schema will be determined automatically by following a search path (as explained in [Section 5.10.4](#)) when saving the rule to an internal table.
- *iv_rule_type* — type of the rule: `NO_ACCESS` or `NO_MODIFICATION`.
- *iv_period* — period after which the rule gets activated.
- *iv_action* — action to perform. Possible value: `ALTER_TS` — move the relation to another tablespace.
- *iv_parameter* — action parameter. Possible value is the tablespace where to move the table.

`remove_rule( iv_object_name text, iv_rule_type text, iv_period interval, iv_action text )` returns void

Removes a rule or rules.

Arguments:

- *iv_object_name* — name of the relation. Can be qualified or not. If the name is unqualified, the schema will be determined automatically by following a search path (as explained in [Section 5.10.4](#)) when searching the rule to remove.
- *iv_rule_type* — type of the rule: `NO_ACCESS` or `NO_MODIFICATION`. `NULL` value removes rules with any rule type.
- *iv_period* — period after which the rule gets activated. `NULL` value removes rules with any value of the period.
- *iv_action* — action to perform. Possible value: `ALTER_TS` — move the relation to another tablespace. `NULL` value removes rules with any action.

`get_rules( [iv_object_name text] )` returns table

Returns the list of all rules if called without the parameter or the list of rules that apply to the specified relation. For tables that are partitions of partitioned tables, this list also includes rules that apply to them indirectly, through the rules that apply to different-level parent tables. The list is returned in a table of the following format:

Column	Type	Description
<code>nspname</code>	<code>name</code>	Name of the schema that a relation is in
<code>relname</code>	<code>name</code>	Name of the relation
<code>relkind</code>	<code>char</code>	The value defined in the <code>relkind</code> column of the pg_class catalog corresponding to this relation.
<code>rule_type</code>	<code>char</code>	Type of a rule: <code>NO_ACCESS</code> or <code>NO_MODIFICATION</code>
<code>period</code>	<code>interval</code>	Period after which the rule gets activated
<code>action</code>	<code>text</code>	Action to perform
<code>parameter</code>	<code>text</code>	Action parameter

Arguments:

- *iv_object_name* — name of the relation. Can be qualified or not. If the name is unqualified, the schema will be determined automatically by following a search path (as explained in [Section 5.10.4](#)).

F.52.3.2. Exclusion-List Management Functions

The following functions manage the list of users to be excluded when checking `pgpro_ilm` rules:

`set_exclude_users( iv_exclude_access name[], iv_exclude_modification name[] )` returns `void`

Resets the user exclusion list and creates a new one.

Arguments:

- *iv_exclude_access* — array of names of users to exclude when checking `NO_ACCESS` rules.
- *iv_exclude_modification* — array of names of users to exclude when checking `NO_MODIFICATION` rules.

`get_exclude_users()` returns table

Returns the user exclusion list in a table of the following format:

Column	Type	Description
<code>user_name</code>	<code>name</code>	

Column Type	Description
	Name of a user.
<code>exclude_access bool</code>	Whether to exclude this user from checking <code>NO_ACCESS</code> rules.
<code>exclude_modification bool</code>	Whether to exclude this user from checking <code>NO_MODIFICATION</code> rules.

F.52.3.3. Rule Processing Functions

The following functions check whether `pgpro_ilm` rules apply to relations and perform the needed action with the relations to which the rules apply. These functions apply no rules to partitioned tables and indexes on partitioned tables. For regular tables, the functions check the rules in the descending order of the period after which the rule gets activated. For partitions of partitioned tables, rules are checked for parent partitions from the lowest level of the partitioned table hierarchy to the highest level, and on the same level, rules are checked in the descending order of the period. Once a rule that applies to a relation is found, the functions perform the appropriate action, and finish processing of this relation.

If a rule to move a relation applies to a table, it is moved together with its indexes for which no rules are explicitly defined. However, if rules are defined for an index, they are processed independently of the table.

`process_rules( iv_object_name text )` returns void

Checks whether any rule applies to a relation, performs the needed action with the relation if the rule applies to it, and exits. When this function is called for a relation more than once, `pgpro_ilm` determines whether a certain rule has already been applied and does not apply the rule again.

Arguments:

- *iv_object_name* — name of the relation. Can be qualified or not. If the name is unqualified, the schema will be determined automatically by following a search path (as explained in [Section 5.10.4](#)) when iterating through the rules.

`process_all_rules()` returns void

For each relation in the database, checks whether any rule applies to this relation, performs the needed action with the relation if the rule applies to it, and proceeds to the next relation. The function actually calls `process_rules` for all the relations in the database for which any rule exists.

F.52.4. Examples

The following example illustrates usage of `pgpro_ilm`:

Let's create and view the user exception list:

```
test=# SELECT pgpro_ilm.set_exclude_users(array['exclude_access_user'], array['Exclude
Write User']);
set_exclude_users
-----
```

(1 row)

```
test=# SELECT user_name, exclude_access, exclude_modification FROM
pgpro_ilm.get_exclude_users();
 user_name | exclude_access | exclude_modification
-----+-----+-----
exclude_access_user | t | f
Exclude Write User | f | t
(2 rows)
```

Consider a partitioned table with one partition:

```
test=# \d+ measurement
```

Partitioned table "public.measurement"

Column target	Type Description	Collation	Nullable	Default	Storage	Compression	Stats
city_id	integer		not null		plain		
logdate	date		not null		plain		
peaktemp	integer		not null		plain		
unitsales	integer				plain		

Partition key: RANGE (logdate)

Indexes:

"measurement_pkey" PRIMARY KEY, btree (city_id, logdate, peaktemp)

"measurement_city_id_idx" btree (city_id)

"measurement_logdate_idx" btree (logdate)

Partitions: measurement_y2006m03 FOR VALUES FROM ('2006-03-01') TO ('2006-04-01')

test=# \d+ measurement_y2006m03

Table "public.measurement_y2006m03"

Column target	Type Description	Collation	Nullable	Default	Storage	Compression	Stats
city_id	integer		not null		plain		
logdate	date		not null		plain		
peaktemp	integer		not null		plain		
unitsales	integer				plain		

Partition of: measurement FOR VALUES FROM ('2006-03-01') TO ('2006-04-01')

Partition constraint: ((logdate IS NOT NULL) AND (logdate >= '2006-03-01'::date) AND (logdate < '2006-04-01'::date))

Indexes:

"measurement_y2006m03_pkey" PRIMARY KEY, btree (city_id, logdate, peaktemp)

"measurement_y2006m03_city_id_idx" btree (city_id)

"measurement_y2006m03_logdate_idx" btree (logdate)

Access method: heap

Let's add a few rules:

```
test=# SELECT * from pgpro_ilm.add_rule('measurement', 'NO_ACCESS', interval '16 mons',
'ALTER_TS', 'slow_space');
add_rule
```

(1 row)

```
test=# SELECT * from pgpro_ilm.add_rule('measurement', 'NO_MODIFICATION', interval '16
mons', 'ALTER_TS', 'slow_space');
add_rule
```

(1 row)

```
test=# SELECT * from pgpro_ilm.add_rule('measurement_y2006m03', 'NO_ACCESS', interval
'14 mons', 'ALTER_TS', 'slow_space');
add_rule
-----
```

(1 row)

```
test=# SELECT * from pgpro_ilm.add_rule('measurement_y2006m03', 'NO_ACCESS', interval
'12 mons', 'ALTER_TS', 'slow_space');
add_rule
-----
```

(1 row)

Rules for the partitioned table look as follows:

```
test=# select * from pgpro_ilm.get_rules('measurement');
 nsname |   relname   |   rule_type   |   period   |   action   | parameter
-----+-----+-----+-----+-----+-----
 public | measurement | NO_ACCESS     | 1 year 4 mons | ALTER_TS | slow_space
 public | measurement | NO_MODIFICATION | 1 year 4 mons | ALTER_TS | slow_space
(2 rows)
```

Two explicitly specified NO_ACCESS rules and a NO_MODIFICATION rule inherited from the parent table apply to the partition:

```
test=# select * from pgpro_ilm.get_rules('measurement_y2006m03');
 nsname |   relname   |   rule_type   |   period   |   action   | parameter
-----+-----+-----+-----+-----+-----
 public | measurement | NO_MODIFICATION | 1 year 4 mons | ALTER_TS | slow_space
 public | measurement_y2006m03 | NO_ACCESS     | 1 year 2 mons | ALTER_TS | slow_space
 public | measurement_y2006m03 | NO_ACCESS     | 1 year      | ALTER_TS | slow_space
(3 rows)
```

Let's add one more explicit rule for the partition:

```
test=# SELECT * from pgpro_ilm.add_rule('measurement_y2006m03', 'NO_MODIFICATION',
interval '12 mons', 'ALTER_TS', 'slow_space');
add_rule
-----
```

(1 row)

Now only explicitly specified rules apply to the partition:

```
test=# select * from pgpro_ilm.get_rules('measurement_y2006m03');
 nsname |   relname   |   rule_type   |   period   |   action   | parameter
-----+-----+-----+-----+-----+-----
 public | measurement_y2006m03 | NO_ACCESS     | 1 year 2 mons | ALTER_TS | slow_space
 public | measurement_y2006m03 | NO_ACCESS     | 1 year      | ALTER_TS | slow_space
 public | measurement_y2006m03 | NO_MODIFICATION | 1 year      | ALTER_TS | slow_space
(3 rows)
```

Note that rules are not processed for partitioned tables.

```
test=# SELECT pgpro_ilm.process_rules('measurement');
NOTICE: ILM: no rules matched for 'public.measurement'
process_rules
-----
```

(1 row)

When rules are processed, indexes are moved together with the table:

```
test=# SELECT pgpro_ilm.process_rules('measurement_y2006m03');
NOTICE: ILM: found rule 'public.measurement_y2006m03' with type 'NO_ACCESS' and period
'1 year 2 mons'. Action 'ALTER_TS', parameter 'slow_space'
NOTICE: ILM: executing 'ALTER TABLE public.measurement_y2006m03 SET TABLESPACE
slow_space;'
NOTICE: ILM: executing 'ALTER INDEX public.measurement_y2006m03_pkey SET TABLESPACE
slow_space;'
NOTICE: ILM: executing 'ALTER INDEX public.measurement_y2006m03_city_id_idx SET
TABLESPACE slow_space;'
NOTICE: ILM: executing 'ALTER INDEX public.measurement_y2006m03_logdate_idx SET
TABLESPACE slow_space;'
process_rules
-----
```

(1 row)

Result:

```
test=# \d+ measurement_y2006m03
```

```

                                Table "public.measurement_y2006m03"
  Column   | Type   | Collation | Nullable | Default | Storage  | Compression | Stats
target | Description
-----+-----+-----+-----+-----+-----+-----+-----
city_id   | integer |           | not null |         | plain    |             |
|
logdate   | date    |           | not null |         | plain    |             |
|
peaktemp  | integer |           | not null |         | plain    |             |
|
unitsales | integer |           |          |         | plain    |             |
|
```

Partition of: measurement FOR VALUES FROM ('2006-03-01') TO ('2006-04-01')

Partition constraint: ((logdate IS NOT NULL) AND (logdate >= '2006-03-01'::date) AND (logdate < '2006-04-01'::date))

Indexes:

"measurement_y2006m03_pkey" PRIMARY KEY, btree (city_id, logdate, peaktemp),
tablespace "slow_space"

"measurement_y2006m03_city_id_idx" btree (city_id), tablespace "slow_space"

"measurement_y2006m03_logdate_idx" btree (logdate), tablespace "slow_space"

Tablespace: "slow_space"

Access method: heap

When the function is called again, pgpro_ilm determines whether the table has already been moved and does not move it again.

```
test=# SELECT pgpro_ilm.process_rules('measurement_y2006m03');
NOTICE: ILM: found rule 'public.measurement_y2006m03' with type 'NO_ACCESS' and period
'1 year 2 mons'. Action 'ALTER_TS', parameter 'slow_space'
NOTICE: ILM: 'public.measurement_y2006m03' is already in the 'slow_space' tablespace
process_rules
-----
```

(1 row)

Removing all types of rules for the measurement table:

```
test=# select pgpro_ilm.remove_rule('measurement', NULL, '16 month'::interval,  
    'ALTER_TS');  
remove_rule  
-----
```

(1 row)

```
test=# select * from pgpro_ilm.get_rules('measurement');  
nspname | relname | rule_type | period | action | parameter  
-----+-----+-----+-----+-----+-----  
(0 rows)
```

To process all tables, pgpro_ilm.process_all_rules() function can be called. In this example, one already moved table is found:

```
test=# call pgpro_ilm.process_all_rules();  
NOTICE: ILM: checking 'public.measurement_y2006m03'  
NOTICE: ILM: found rule 'public.measurement_y2006m03' with type 'NO_ACCESS' and period  
    '1 year 2 mons'. Action 'ALTER_TS', parameter 'slow_space'  
NOTICE: ILM: 'public.measurement_y2006m03' is already in the 'slow_space' tablespace  
CALL
```

F.53. `pgpro_queue` — message queueing management

`pgpro_queue` is a built-in Postgres Pro Enterprise extension for message queueing management. It enables reliable communication between applications using database queues.

`pgpro_queue` allows managing message queues directly within the database. With `pgpro_queue`, you can create queues, add messages to them, and process messages efficiently while ensuring data integrity and reliability. A message from the queue is processed by one of the consumers. Once a message is retrieved from the queue, it is no longer available to other consumers.

`pgpro_queue` also supports message queueing management for [subtransactions](#) and [autonomous transactions](#) even if they have multiple nested levels.

Because `pgpro_queue` provides database-integrated message queueing, standard features, such as transaction recovery, crash restart, and standby synchronization, are fully supported.

Messages in the queue are processed based on assigned priorities, allowing higher-priority messages to be handled ahead of others, even if they arrive later.

Note

The `pgpro_queue` extension can be used only for transactions running at the `READ COMMITTED` [isolation level](#).

The diagram below shows a practical example of requesting the creation of a PDF file. Rather than processing these requests directly, they can be sent to a queue, allowing for efficient handling of high volumes, improved user experience with asynchronous processing, and greater flexibility through a decoupled architecture.

Figure F.1. PDF File Creation Example

In addition to the basic message queueing management described above, `pgpro_queue` also uses exchanges to support efficient message distribution based on the publish-subscribe model. In this model, messages are first published to an exchange — a component that receives messages and then routes them to one or more queues. Routing is determined by the following elements:

- bindings: links between an exchange and a queue
- exchange type: the routing algorithm
- routing keys: message attributes that specify a destination or category

This method allows sending messages to multiple consumers at once instead of sending messages directly to specific point-to-point queues. It also allows consumers to receive messages selectively from specific queues by creating subscriptions to those queues.

F.53.1. Installation and Uninstallation

The `pgpro_queue` extension is included into Postgres Pro Enterprise. Once you have Postgres Pro Enterprise installed, complete the following steps to enable `pgpro_queue`:

1. Add `pgpro_queue` to the [shared_preload_libraries](#) parameter in the `postgresql.conf` file:

```
shared_preload_libraries = 'pgpro_queue'
```

2. Create the `pgpro_queue` extension using the following query:

```
CREATE EXTENSION pgpro_queue;
```

A set of API functions will be created in the current schema.

3. Initialize the extension:

```
SELECT queue_initialize();
```

This function creates a dedicated schema called `pgpro_queue_data` where all service objects, such as metadata tables, views, and queue-specific tables, are stored. The initialization decouples queue objects from the extension itself, ensuring proper replication and database dumps.

To remove all objects created by the extension, execute the following command (available only to superusers):

```
SELECT queue_deinitialize();
```

This function performs a cascaded delete of the `pgpro_queue_data` schema.

F.53.2. Considerations for Prepared Transactions

When using `pgpro_queue` for prepared transactions, take note the following considerations:

- If a transaction that calls the [READ_MESSAGE\(\)](#) function is prepared for a two-phase commit using `PREPARE TRANSACTION`, the corresponding message becomes locked in the queue table until you execute the `COMMIT PREPARED` or `ROLLBACK PREPARED` command. In other words, this message will be shown in the queue table but will not be available for further read operations.
- For `pgpro_queue`, the `COMMIT PREPARED` command works like the regular `COMMIT` command. If a message was read in a prepared transaction successfully, the message is removed from the queue table once the `COMMIT PREPARED` command is executed.
- Unlike the `ROLLBACK` command, the `ROLLBACK PREPARED` command does not enable retry-management logic for a message that was read in a prepared transaction. Instead, `ROLLBACK PREPARED` only unlocks the message in the queue table.

F.53.3. Reference

F.53.3.1. Configuration Parameters

`pgpro_queue.database_with_managed_retry(text)`

Specifies a comma-separated list of database names for which retry-management logic is enabled. If a database name is missing from the list, incorrectly specified, or uses an invalid delimiter, any messages unsuccessfully processed within a transaction, i.e. sent to retry on rollback, will be deleted, regardless of the queue or message parameters. Be careful when specifying this parameter because its incorrect change may cause loss of some messages from the retry queue. The default value is `postgres`. This parameter can be set either at server start or when the configuration is reloaded.

`pgpro_queue.shared_retry_list_size(integer)`

Specifies the capacity of the hash table in shared memory for the Shared Retry Pending List. This parameter essentially determines the maximum number of retry requests that user backend processes can simultaneously queue for processing by the launcher. The default value is 10000.

F.53.3.2. Functions

F.53.3.2.1. Queue Management Procedures

`pgpro_queue` provides the following procedures for queue management, which can be used only by a superuser who created the `pgpro_queue` extension.

```
CREATE PROCEDURE CREATE_QUEUE( IN queue_name name, IN queue_type char DEFAULT 'N'::char,
IN queue_dlg name DEFAULT null, IN queue_retries int DEFAULT 10, IN queue_retry_delay
int DEFAULT 30 )
```

Creates a queue in an existing queue table. The queue owner can restrict other users from accessing a queue by denying them access to the queue table at the ACL level or by using the [reset_queue_access](#) and [revoke_queue_access](#) procedures. If any parameter is not specified, its default value is applied for all new messages.

- *queue_name*: The name of the queue, which can only contain letters, digits, and underscores, and cannot exceed 54 symbols.
- *queue_type*: The type of the new queue. The valid values are: N for a normal queue (the default), and D for the dead-letter queue. (The dead-letter queue is not implemented at the moment, the parameter value is reserved for use in future releases.)
- *queue_dlg*: The existing dead-letter queue. (The dead-letter queue is not implemented at the moment, the parameter is reserved for use in future releases.)
- *queue_retries*: The maximum number of retries. The default value is 10.
- *queue_retry_delay*: The number of seconds until a message is scheduled for reprocessing after a ROLLBACK. Specify 0 to retry the message immediately.

```
CREATE PROCEDURE ALTER_QUEUE( IN queue_name name, IN new_type char DEFAULT null, IN new_dlg  
name DEFAULT null, IN new_retries int DEFAULT null, IN new_retrydelay int DEFAULT null )
```

Modifies the parameters of an existing queue. If any parameter is not specified, its default value is applied for all new messages. This change will not affect any existing messages. Only the queue owner who created the queue can change its parameters.

- *queue_name*: The name of the queue, which can only contain letters, digits, and underscores.
- *new_type*: The new type of the queue. The valid values are: N for a normal queue (the default), and D for the dead-letter queue. (The dead-letter queue is not implemented at the moment, the parameter value is reserved for use in future releases.)
- *new_dlg*: The existing dead-letter queue. (The dead-letter queue is not implemented at the moment, the parameter is reserved for use in future releases.)
- *new_retries*: The maximum number of retries.
- *new_retrydelay*: The number of seconds until a message is scheduled for reprocessing after a ROLLBACK. Specify 0 to retry the message immediately.

```
CREATE PROCEDURE DROP_QUEUE(IN queue_name name)
```

Deletes a queue with the specified name.

```
CREATE FUNCTION GET_QUEUE_TABLE(IN queue_name name)
```

Returns the OID of the queue table used for the queue.

```
CREATE PROCEDURE RESET_QUEUE_ACCESS(IN queue_name name)
```

Restricts access to a queue for all users, except the queue owner. This procedure can only be executed by the queue owner. If the superuser who created the extension is deleted, the procedure does nothing.

```
CREATE PROCEDURE GRANT_QUEUE_ACCESS( IN queue_name name, IN role_name name )
```

```
CREATE PROCEDURE GRANT_QUEUE_ACCESS( IN queue_name name, IN role_oid oid )
```

Grants access to a queue to the specified role.

- *queue_name*: The name of the queue.
- *role_name*: The name of the role.
- *role_oid*: The OID of the role.

```
CREATE PROCEDURE REVOKE_QUEUE_ACCESS( IN queue_name name, IN role_name name )
```

```
CREATE PROCEDURE REVOKE_QUEUE_ACCESS( IN queue_name name, IN role_oid oid )
```

Revokes access to a queue from the specified role.

F.53.3.2.2. Procedures for Inserting Messages

`pgpro_queue` provides the following procedures for sending messages to the queue. It is not recommended to mix XML and JSONB payloads within the same queue.

```
CREATE PROCEDURE INSERT_MESSAGE( IN q_name name, IN q_msg_body jsonb, IN q_msg_priority
int DEFAULT 0, IN q_msg_properties jsonb DEFAULT '{}'::jsonb, IN q_msg_retries int DEFAULT
null, IN q_msg_retrydelay int DEFAULT null, IN q_msg_enable_time timestamptz DEFAULT
null )
CREATE PROCEDURE INSERT_MESSAGE_XML( IN q_name name, IN q_msg_body xml, IN q_msg_priority
int DEFAULT 0, IN q_msg_properties jsonb DEFAULT '{}'::jsonb, IN q_msg_retries int DEFAULT
null, IN q_msg_retrydelay int DEFAULT null, IN q_msg_enable_time timestamptz DEFAULT
null )
```

Inserts a JSON/XML message into the queue.

- *q_name*: The name of the queue.
- *q_msg_body*: Message payload (JSONB or XML).
- *q_msg_priority*: Message priority. The lower the number, the higher the priority. The default value is 0, which means the highest priority.
- *q_msg_properties*: No properties by default.
- *q_msg_retries*: The maximum number of retries. If not specified, the default value from the queue is used.
- *q_msg_retrydelay*: The number of seconds until a message is scheduled for reprocessing after a ROLLBACK. If not specified, the default value from the queue is used.
- *q_msg_enable_time*: Time of message delay.

F.53.3.2.3. Functions for Reading Messages

`pgpro_queue` provides the following functions for reading messages from the queue.

```
CREATE FUNCTION READ_MESSAGE( IN q_name name, IN q_msg_hfilter jsonb DEFAULT null, IN
q_msg_pfilter jsonb DEFAULT null ) RETURNS jsonb
CREATE FUNCTION READ_MESSAGE_XML( IN q_name name, IN q_msg_hfilter jsonb DEFAULT null,
IN q_msg_pfilter jsonb DEFAULT null ) RETURNS xml
CREATE FUNCTION READ_MESSAGE_ANY( IN q_name name, IN q_msg_hfilter jsonb DEFAULT null,
IN q_msg_pfilter jsonb DEFAULT null ) RETURNS RECORD
```

Retrieves a message from the queue as a read operation without waiting. Returns the message payload or null if the queue is empty. On a successful read, the message is removed from the queue table.

- *q_name*: The name of the queue.
- *q_msg_hfilter*: A header filter, applied in addition to a standard filter.
- *q_msg_pfilter*: A properties filter, applied in addition to a standard filter.
- *q_jsonb*: Returned JSON body value.
- *q_xml*: Returned XML body value.

```
CREATE FUNCTION READ_MESSAGE_BY_ID( IN q_name name, IN msgid bigint ) RETURNS jsonb
CREATE FUNCTION READ_MESSAGE_BY_ID_XML( IN q_name name, IN msgid bigint ) RETURNS xml
CREATE FUNCTION READ_MESSAGE_BY_ID_ANY( IN q_name name, IN msgid bigint ) RETURNS RECORD
```

Retrieves a specific message from the queue by its ID as a read operation without waiting. Returns the message payload or null if the queue is empty. On a successful read, the message is removed from the queue table.

- *q_name*: The name of the queue.
- *msgid*: The message ID.
- *body*: Returned JSON body value.
- *body_xml*: Returned XML body value.

F.53.3.2.4. Functions for Exchange Management

`pgpro_queue` provides the following functions and procedures for managing exchanges.

CREATE FUNCTION CREATE_EXCHANGE(IN e_name name, IN e_type text)

Creates an exchange with the specified name and type. The exchange owner can restrict other users from accessing the exchange by using the [revoke_publish_access](#) procedure.

- *e_name*: The name of the exchange, which can only contain letters, digits, and underscores, and cannot exceed 63 symbols.
- *e_type*: The type of the new exchange. Possible values are:
 - `fanout` (default): Routes messages to all bound queues.
 - `direct`: Routes messages to queues based on a matching routing key.

CREATE FUNCTION DROP_EXCHANGE(IN e_name name, IN do_cascade bool)

Deletes a specified exchange.

- *e_name*: The name of the exchange.
- *do_cascade*: When set to `true`, all the bound queues are also deleted. When set to `false`, the function fails if any queues are bound to the exchange.

CREATE FUNCTION BIND_QUEUE(IN q_name name, IN e_name name, IN e_key text)

Binds a queue to an exchange. For `direct` exchanges, bindings are based on routing keys. One queue can be bound to multiple exchanges.

Note

If a queue is deleted using [DROP_QUEUE\(\)](#), it is automatically unbound from all exchanges.

- *q_name*: The name of the queue.
- *e_name*: The name of the exchange.
- *e_key*: The routing key for the binding. `NULL` (default) is used only for `fanout` exchanges.

CREATE FUNCTION UNBIND_QUEUE(IN q_name name, IN e_name name, IN e_key text)

Deletes a binding between a queue and an exchange. If a routing key is provided, only that specific key is deleted from the binding. Deleting the last key unbinds the queue.

- *q_name*: The name of the queue.
- *e_name*: The name of the exchange.
- *e_key*: The routing key to be deleted. If `NULL` (default), the queue is unbound completely.

CREATE PROCEDURE GRANT_PUBLISH_ACCESS(IN exchange_name name, IN role_name name)

Grants the `INSERT`, `UPDATE`, and `DELETE` privileges on an exchange and a binding table to the specified role.

- *exchange_name*: The name of the exchange.
- *role_name*: The name of the role.

CREATE PROCEDURE REVOKE_PUBLISH_ACCESS(IN exchange_name name, IN role_name name)

Revokes all privileges on the exchange and the binding table from the specified role.

- *exchange_name*: The name of the exchange.
- *role_name*: The name of the role.

F.53.3.2.5. Procedures for Publishing Messages to Exchanges

`pgpro_queue` provides the following procedures for publishing messages to exchanges. It is not recommended to mix XML and JSONB payloads within the same queue.

```
CREATE PROCEDURE PUBLISH_MESSAGE( IN e_name name, IN e_routing_key text, IN q_msg_body  
jsonb, IN q_msg_priority int DEFAULT 0, IN q_msg_properties jsonb DEFAULT '{} '::jsonb, IN  
q_msg_retries int DEFAULT null, IN q_msg_retrydelay int DEFAULT null, IN q_msg_enable_time  
timestampz DEFAULT null )  
CREATE PROCEDURE PUBLISH_MESSAGE_XML( IN e_name name, IN e_routing_key text, IN q_msg_body  
xml, IN q_msg_priority int DEFAULT 0, IN q_msg_properties jsonb DEFAULT '{} '::jsonb, IN  
q_msg_retries int DEFAULT null, IN q_msg_retrydelay int DEFAULT null, IN q_msg_enable_time  
timestampz DEFAULT null )
```

Publishes a JSON/XML message via an exchange.

- *e_name*: The name of the exchange.
- *e_routing_key*: The routing key.
- *q_msg_body*: Message payload (JSONB or XML).
- *q_msg_priority*: Message priority. The lower the number, the higher the priority. The default value is 0, which means the highest priority.
- *q_msg_properties*: Message properties, for example, the encoding name or the application-level routing information. No properties by default.
- *q_msg_retries*: The maximum number of retries. If not specified, the default value from the queue is used.
- *q_msg_retrydelay*: The number of seconds until a message is scheduled for reprocessing after a ROLLBACK. If not specified, the default value from the queue is used.
- *q_msg_enable_time*: Time of message delay.

F.53.4. Authors

Postgres Professional, Moscow, Russia

F.54. pgpro_rp — resource prioritization

pgpro_rp is a Postgres Pro Enterprise extension for resource prioritization.

On systems with limited resources or under heavy load, you may need to prioritize transaction execution, so that some transactions are executed more quickly than the others. For example, you may want to execute simple user queries as fast as possible, even if it delays less urgent tasks, such as complex OLAP queries that may be running at the same time. Postgres Pro Enterprise enables you to assign a *resource prioritization plan* to a particular session, which can slow it down based on the amount of CPU, I/O read, and I/O write resources this session consumes as compared to other sessions. These parameters can take weight values 1, 2, 4, and 8. The higher the value, the more resources the session can use. By default, all sessions have weight 4 for all types of resources. The resource prioritization plan contains a set of these prioritization parameters as a `jsonb` and can be assigned to any user or role.

The plan is selected during session creation using a [login event trigger](#) as follows:

- First, pgpro_rp calls the [plan selection function](#) if it has been set. Otherwise, it searches for a plan assigned to the current user.
- If no plan is assigned to the user, pgpro_rp selects the plan with the maximum sum of priorities from the plans assigned to the roles that the user is a member of.
- Finally, the priority settings of the found plan are applied.

If the plan cannot be determined, the default priority settings are applied: all priorities have the value of 4.

Note

Only superusers can manage and update plans.

F.54.1. Installation

The pgpro_rp extension is a built-in extension included into Postgres Pro Enterprise, but since pgpro_rp uses shared memory for caching user prioritization parameters, it has to be installed separately. Once you have pgpro_rp installed, complete the following steps to enable pgpro_rp:

1. Add pgpro_rp to the [shared_preload_libraries](#) parameter in the `postgresql.conf` file:

```
shared_preload_libraries = 'pgpro_rp'
```

2. Restart the Postgres Pro Enterprise instance for the changes to take effect.
3. Create the pgpro_rp extension:

```
CREATE EXTENSION pgpro_rp;
```

F.54.2. Usage

pgpro_rp extension supports the following operation modes:

- [Permanent plan mode](#)
- [Changeable plan mode](#)

F.54.2.1. Permanent Plan Mode

This operation mode is used to set up permanent resource prioritization plans for users or roles. These plans remain unchanged regardless of the time of the day, the day of the week, etc. You don't have to create and set up plan assignment groups for users or roles. In other words, only the preinstalled default group is used implicitly.

This mode includes the following steps:

- Create a set of resource prioritization plans using [pgpro_rp_create_plan](#).
- Assign created plans to users or roles using [pgpro_rp_create_role_plan](#).

The created plans can be updated or deleted if needed.

Example:

```
-- Create resource prioritization plans
SELECT pgpro_rp_create_plan('plan_2_2_2', 2, 2, 2);
SELECT pgpro_rp_create_plan('plan_8_8_8', '{ "session_cpu_weight":8,
"session_ioread_weight":8, "session_iowrite_weight":8}');

-- Assign plans to roles
SELECT pgpro_rp_create_role_plan('users', 'plan_2_2_2');
SELECT pgpro_rp_create_role_plan('admins', 'plan_8_8_8');
```

F.54.2.2. Changeable Plan Mode

This operation mode is used to set up various resource prioritization plans for users or roles that are subject to changing in accordance with the time of the day, the day of the week, etc.

This mode includes the following steps:

- Create a set of resource prioritization plans using `pgpro_rp_create_plan`.
- Create several plan assignment groups for users or roles using `pgpro_rp_create_group`.
- Add plans to plan assignment groups using `pgpro_rp_create_group_role_plan`.
- Set an active group when necessary using `pgpro_rp_set_active_group`.

Example:

```
-- Create resource prioritization plans
SELECT pgpro_rp_create_plan('plan_8_8_8', 8, 8, 8);
SELECT pgpro_rp_create_plan('plan_4_4_4', 4, 4, 4);
SELECT pgpro_rp_create_plan('plan_2_2_2', 2, 2, 2);
SELECT pgpro_rp_create_plan('plan_1_1_1', 1, 1, 1);

-- Create plan assignment groups to users or roles and add in plan assignment
groups
SELECT pgpro_rp_create_group('day_plan');
SELECT pgpro_rp_create_group_role_plan('day_plan', 'top', 'plan_4_4_4');
SELECT pgpro_rp_create_group_role_plan('day_plan', 'main', 'plan_2_2_2');
SELECT pgpro_rp_create_group_role_plan('day_plan', 'hr', 'plan_1_1_1');

SELECT pgpro_rp_create_group('night_plan');
SELECT pgpro_rp_create_group_role_plan('night_plan', 'top', 'plan_8_8_8');
SELECT pgpro_rp_create_group_role_plan('night_plan', 'main', 'plan_1_1_1');
SELECT pgpro_rp_create_group_role_plan('night_plan', 'hr', 'plan_2_2_2');

-- Set an active group
CALL pgpro_rp_set_active_group('day_plan');
```

F.54.3. The `pgpro_rp_roles_plans_view` View

All plan assignment groups along with the roles that are included in them, and the plans assigned to the roles are available via a view named `pgpro_rp_roles_plans_view`. This view contains one row for each role with an assigned plan. The columns of the view are shown in [Table F.33](#).

Table F.33. `pgpro_rp_roles_plans_view` Columns

Name	Type	Description
<code>group_name</code>	text	The name of the group

Name	Type	Description
<code>rolname</code>	<code>text</code>	The name of the user/role
<code>plan_name</code>	<code>text</code>	The plan used for the user/role

F.54.4. Functions

F.54.4.1. Plan Management Functions

The functions described in this section provide the ability to create, modify, or delete a resource prioritization plan.

`pgpro_rp_create_plan(a_plan_name text, a_plan_options jsonb)` returns `bigint`
`pgpro_rp_create_plan(a_plan_name text, a_cpu_weight int, a_ioread_weight int, a_iowrite_weight int)` returns `bigint`

Creates a plan with the given name and options or prioritization parameters and returns the ID of the created plan. Superuser privileges are required to call this function.

`pgpro_rp_rename_plan(a_plan_name_old text, a_plan_name_new text)` returns `void`

Renames the specified plan. Superuser privileges are required to call this function.

`pgpro_rp_update_plan(a_plan_name text, a_plan_options jsonb)` returns `void`

Modifies the options of the specified plan. Superuser privileges are required to call this function.

`pgpro_rp_delete_plan(a_plan_name text)` returns `void`

Deletes the specified plan. Superuser privileges are required to call this function.

`pgpro_rp_get_plan_id_by_name(a_plan_name text)` returns `bigint`

Returns the ID of the created plan by the plan name.

F.54.4.2. Plan Assignment Group Functions

The functions described in this section provide the ability to manage plan assignment groups for users or roles.

`pgpro_rp_create_group(a_group_name text)` returns `bigint`

Creates a plan assignment group and returns the ID of the created group. Superuser privileges are required to call this function.

`pgpro_rp_rename_group(a_group_name text, a_new_group_name text)` returns `void`

Renames the specified group. Superuser privileges are required to call this function.

`pgpro_rp_delete_group(a_group_name text)` returns `void`

Deletes the specified group. Superuser privileges are required to call this function.

F.54.4.3. Plan Assignment Functions

The functions described in this section provide the ability to manage plan assignment for roles.

The following functions work with an active plan assignment group specified in the `pgpro_rp_options` table:

`pgpro_rp_create_role_plan(a_role_name text, a_plan_name text)` returns `void`

Assigns the default plan to the specified role. Superuser privileges are required to call this function.

`pgpro_rp_update_role_plan(a_role_name text, a_plan_name text)` returns `void`

Changes the default plan for the specified role. Superuser privileges are required to call this function.

`pgpro_rp_delete_role_plan(a_role_name text)` returns `void`

Deletes the plan assigned to the specified role. Superuser privileges are required to call this function.

Functions to add/delete in plan assignment groups for users or roles:

`pgpro_rp_create_group_role_plan(a_group_name text, a_role_name text, a_plan_name text)`
returns void

Adds the specified plan to the specified group. Superuser privileges are required to call this function.

`pgpro_rp_delete_group_role_plan(a_group_name text, a_role_name text)` returns void

Deletes the specified plan from the specified group. Superuser privileges are required to call this function.

Other functions:

`pgpro_rp_cleanup_roles_plans()` returns void

Deletes the plans assigned to the non-existent roles from the `pgpro_rp_roles_plans` table. Superuser privileges are required to call this function.

`pgpro_rp_set_active_group(a_group_name text)` returns void

Makes the specified plan assignment group active and clears the prioritization parameter cache. Superuser privileges are required to call this function.

`pgpro_rp_get_active_group()` returns text

Returns the ID of the active group.

F.54.4.4. Plan Selection Functions

You can declare a custom function to select resource prioritization plans, which takes no arguments and returns the plan ID, to be called at the session start using the functions described below.

`pgpro_rp_set_plan_selection_function(a_func_name text)` returns void

Sets the plan selection function. If NULL is passed, the current function is reset. Superuser privileges are required to call this function.

`pgpro_rp_get_plan_selection_function()` returns text

Returns the current plan selection function.

F.54.4.5. Backend Plan Function

`pgpro_rp_backend_set_plan(a_pid int, a_plan_name text)` returns void

Searches for a plan with the given name and applies its settings to the backend with the specified PID. Superuser privileges are required to call this function.

F.54.4.6. Cache Functions

When creating any session, the prioritization parameter values from the assigned plan are applied to this session. However, searching for a plan requires certain resources (you need to read data from several tables), so the values of user prioritization parameters are cached in shared memory. If you create another session, its user will be searched in the cache, and if the user is found, the values of the prioritization parameters stored in the cache will be applied to the newly created session. Since the values in the cache may expire, the following function is provided to clear the cache:

`pgpro_rp_invalidate_cache()` returns void

Clears the cache of prioritization parameters in shared memory. Superuser privileges are required to call this function.

This function should be called in cases where user prioritization settings may change (assigning roles to users, changing the parameters of the active group/plans in use, etc.).

F.54.5. Configuration Parameters

If necessary, you can also manage priorities manually:

- Configure the time interval for collecting usage statistics for all active backends by setting the `usage_tracking_interval` parameter in the `postgresql.conf`. Avoid setting `usage_tracking_interval` to small values as frequent statistics collection can cause overhead.
- Depending on the resources you need to control, modify one or more of the following parameters for the sessions you would like to prioritize:
 - `session_cpu_weight` — CPU usage.
 - `session_ioread_weight` — I/O read throughput.
 - `session_iowrite_weight` — I/O write throughput.

Sessions with the same weight have the same priority for resource usage, so if equal weights are assigned to all sessions, performance is not affected, regardless of the weight value.

For all possible ways of modifying configuration for a particular session, see [Section 19.1](#).

F.54.6. Example

The following example demonstrates using `pgpro-rp`.

```
CREATE EXTENSION pgpro_rp;
CREATE USER test_user;
SELECT pgpro_rp_create_plan(
    'test_plan',
    '{ "session_cpu_weight":8, "session_ioread_weight":8, "session_iowrite_weight":8 }'
);
SELECT pgpro_rp_create_role_plan('test_user', 'test_plan');
```

The next time that the `test_user` user logs in, the prioritization parameters will look as follows:

```
SHOW session_cpu_weight;
 session_cpu_weight
-----
      8
(1 row)
SHOW session_ioread_weight;
 session_ioread_weight
-----
      8
(1 row)
SHOW session_iowrite_weight;
 session_iowrite_weight
-----
      8
(1 row)
```

F.55. `pgpro_scheduler` — scheduling, monitoring and managing job execution

`pgpro_scheduler` is a built-in Postgres Pro Enterprise extension for scheduling, monitoring, and managing job execution within the Postgres Pro Enterprise database. With `pgpro_scheduler`, you can:

- Set advanced schedules using `jsonb` objects or `crontab` strings.
- Dynamically calculate the next execution time for repeated jobs.
- Execute SQL commands of the job in a single transaction or in sequential transactions, if required.
- Submit jobs for immediate or delayed one-time execution in parallel with the scheduled jobs.

Unlike external scheduling daemons, `pgpro_scheduler` offers the following benefits:

- Any user can schedule jobs independently.
- Job scheduling can be managed on the fly without restarting the database.
- Scheduling is very lightweight since `pgpro_scheduler` uses background workers to schedule, monitor, and manage job execution. At the same time, `pgpro_scheduler` does not require any client connections for scheduling.
- For enhanced stability, each database has its own supervisor scheduler, with each scheduled job executed by a separate background worker.

Note

`pgpro_scheduler` waits in the suspended state on a standby server to be started when the standby is promoted to a primary server.

Note

Note that for all the executed jobs, the `pg_stat_activity` view will still show the name of the database superuser, which is used by the background worker.

F.55.1. Installation and Setup

The `pgpro_scheduler` extension is included into Postgres Pro Enterprise. Once you have Postgres Pro Enterprise installed, complete the following steps to enable `pgpro_scheduler`:

1. Add `pgpro_scheduler` to the `shared_preload_libraries` parameter in the `postgresql.conf` file:
2. Create the `pgpro_scheduler` extension using the following query:

```
shared_preload_libraries = 'pgpro_scheduler'
```

```
CREATE EXTENSION pgpro_scheduler;
```

Make sure to create the `pgpro_scheduler` extension for each database you are planning to use.

Once you complete the installation and setup, configure `pgpro_scheduler` for your database.

F.55.2. Configuration

You must have superuser rights to configure `pgpro_scheduler`.

To configure `pgpro_scheduler`, modify the following settings in the `postgresql.conf` file:

1. Specify the names of the databases for which you need to schedule jobs, in the comma-separated format:
- ```
schedule.database = 'database1,database2'
```

2. To control the workload in your system, set the maximum number of background workers that can run simultaneously on each database:

```
schedule.max_workers = 5
```

3. Optionally, set the number of background workers available for one-time job execution:

```
schedule.max_parallel_workers = 3
```

By default, two background workers for one-time jobs are available. These workers are not included into the `schedule.max_workers` number. Thus, one-time jobs can run in parallel with the scheduled jobs even if all the `schedule.max_workers` workers are busy.

4. Run `pg_reload_conf()` for the changes to take effect:

```
SELECT pg_reload_conf();
```

### Important

When setting the `schedule.max_workers` variable, make sure to leave enough workers for the rest of the system as other subsystems may also use background workers. The `schedule.max_workers` value cannot exceed the total number of workers enabled by the `max_worker_processes` Postgres Pro variable.

The `pgpro_scheduler` extension starts a separate background worker for the system, each database, and each executed job. For example, if you work with two databases and set the maximum number of workers and parallel workers to 5 and 3, respectively, `pgpro_scheduler` can use up to 19 workers at peak times: one worker is supervising the system, two workers are monitoring the two databases, and each database uses five workers for job scheduling and three workers for running one-time jobs. If all background workers are busy, the jobs will wait for the next available worker. Scheduled and one-time jobs have separate job queues.

If required, you can later change the number of workers. The running jobs will not be affected.

You can also dynamically configure `pgpro_scheduler` from the command line. In this case, you can set different number of workers for different databases:

```
ALTER SYSTEM SET schedule.database = 'database1,database2';
ALTER DATABASE database1 SET schedule.max_workers = 5;
ALTER DATABASE database2 SET schedule.max_workers = 3;
ALTER SYSTEM SET schedule.max_parallel_workers = 3;
SELECT pg_reload_conf();
```

Once `pgpro_scheduler` is configured, enable it on your system, as follows:

```
SELECT schedule.enable();
```

If this function returns `true`, `pgpro_scheduler` is ready to use, and you can start scheduling jobs as explained in [Section F.55.3.1](#) and [Section F.55.3.2](#).

### Note

If you restart the server, `pgpro_scheduler` is not automatically restarted by default. To change this behavior, you can set the `schedule.auto_enabled` parameter to `on`.

## F.55.3. Usage

### F.55.3.1. Creating Scheduled Jobs

To create and schedule a job, run the `create_job()` function that takes scheduling options as a `jsonb` object:

`schedule.create_job(options jsonb)`

In the `jsonb` object, you must specify one or more SQL commands in the `commands` key, and set the job schedule with at least one of the following keys:

- `dates` — a single date or an array of dates, in the `timestamp with time zone` format
- `cron` — a string, in the `crontab` format. A traditional five-field `crontab` format is used. The first field stands for minute, the second — for hour, the third — for day of the month, the fourth — for month, and the fifth — for day of the week.

```
minute (0 - 59)
hour (0 - 23)
day of the month (1 - 31)
month (1 - 12)
day of the week (0 - 6) (Sunday to Saturday)
#
* * * * *
```

A six-field `crontab` format can be used alongside the traditional five-field format. In this case the first field stands for second. When you use the six-field format and do not want to specify a second you have to put 0 in the first field.

Alternatively, the following keywords can be used instead of a `crontab` string to specify when the job will be started:

- `@every_second` — each second
- `@hourly` — at the beginning of each hour
- `@daily` — at the beginning of each day
- `@midnight` — at the beginning of each day
- `@weekly` — at the beginning of each week
- `@monthly` — at the beginning of each month
- `@yearly` — at the beginning of each year
- `@annually` — at the beginning of each year
- `rule` — a `jsonb` object that includes one or more of the following keys:
  - `seconds` — seconds; an array of integers in range [0, 59]
  - `minutes` — minutes; an array of integers in range [0, 59]
  - `hours` — hours; an array of integers in range [0, 23]
  - `days` — days of the month; an array of integers in range [1, 31]
  - `months` — months; an array of integers in range [1, 12]
  - `wdays` — days of the week; an array of integers in range [0, 6], where 0 is Sunday.
  - `onstart` — integer value 0 or 1. If `onstart` is set to 1, the job is executed only once when `pgpro_scheduler` is started.

You can combine `dates`, `cron`, and `rule` scheduling keys for advanced use cases.

As a result, `pgpro_scheduler` creates an active job with the specified schedule and returns the job ID.

### Tip

For simple job schedules, you can use the following shortcut syntax:

```
schedule.create_job(cron, commands)
schedule.create_job(dates, commands)
```

For details, see [schedule.create\\_job\(\)](#) function description.

If required, you can later modify one or more scheduling options with the `set_job_attribute()` or `set_job_attributes()` functions, respectively.

If all background workers are busy at the specified time, the job waits for the next available worker. By default, the job can wait forever. You can limit the maximum wait time by setting the `last_start_available` key, in the [time interval](#) format. If the timeout is reached, `pgpro_scheduler` cancels the job execution.

#### Examples:

To run the job every day at 3pm, and, additionally, on December 31, 2017 at 7pm , and on April 4, 2020 at 1pm:

```
SELECT schedule.create_job('{ "commands": "SELECT 15", "cron": "0 15 * * *", "dates":
["2017-12-31 19:00", "2020-04-04 13:00"]}');
```

To limit the wait time for job execution to 30 seconds after the scheduled time:

```
SELECT schedule.create_job('{ "commands": "SELECT pg_sleep(100)", "cron": "15 */2 * *
*", "last_start_available": "30 seconds" }');
```

#### Note

Both for scheduled and one-time jobs, you cannot manage their main transactions, namely using `COMMIT` and `ROLLBACK`. However, you can create and manage autonomous transactions.

#### F.55.3.1.1. Specifying the Time Window for Job Execution

In addition to the general schedule, you can specify the timeframe during which the scheduled job can be executed. To ensure that `pgpro_scheduler` only executes the job within the specified time window, define the `start_date` and `end_date` keys, in the `timestamp with time zone` format. You can set one of these keys only to limit the start or the end time, respectively. If you define a time window for the job, `pgpro_scheduler` will only schedule this job within this time window. If the started job is incomplete when the specified time window ends, `pgpro_scheduler` completes the job and then excludes the job from further scheduling.

#### Examples:

To start scheduling the job only after 11am on May 1, 2017:

```
SELECT schedule.create_job('{ "commands": "SELECT now()", "cron": "2 17 * * *",
"start_date": "2017-05-01 11:00" }');
```

To schedule the job in the timeframe from 11am on May 1 to 3pm on June 4, 2017:

```
SELECT schedule.create_job('{ "commands": "SELECT now()", "cron": "2 17 * * *",
"start_date": "2017-05-01 11:00", "end_date": "2017-06-04 15:00" }');
```

#### F.55.3.1.2. Running SQL Commands in Separate Transactions

The `commands` key can have values of text and array types. If you specify several SQL commands as text separated by semicolons, the whole job is executed in a single transaction. If it is critical to perform each SQL command in a separate transaction, pass the SQL commands as an array. You can modify this behavior by setting the `use_same_transaction` key to `true`. In this case, SQL commands in the array are executed in a single transaction.

#### Examples:

To run the whole job in a single transaction:

```
SELECT schedule.create_job('{ "commands": "SELECT 1; SELECT 2; SELECT 3;", "cron": "23
23 */2 * *" }');
```

To run commands in separate transactions:

```
SELECT schedule.create_job('{ "commands": ["SELECT 1", "SELECT 2", "SELECT 3"],
"cron": "23 23 */2 * *" }');
```

To run the whole job in a single transaction when passing the commands as an array:

```
SELECT schedule.create_job('{ "commands": ["SELECT 1", "SELECT 2", "SELECT 3"],
 "cron": "23 23 */2 * *", "use_same_transaction": true }');
```

#### F.55.3.1.3. Calculating the Next Start Time of the Scheduled Job

For repeated jobs, the next start time can be computed by an SQL statement specified in the `next_time_statement` key. In this case, the first job starts on schedule, while all the successive job runs occur at the computed times.

After the job run completes, `pgpro_scheduler` executes the SQL statement in the `next_time_statement` key to calculate the next start time and returns the result, in the `timestamp with time zone` type. If the return value is of a different type or an error occurs, `pgpro_scheduler` marks the job as broken and cancels any further execution. This process is repeated for each successive job run.

#### Tip

When the job run completes, `pgpro_scheduler` sets the transaction state in the `schedule.transaction_state` variable, in the `text` format. You can use this variable in your `next_time_statement` to dynamically calculate the next start time depending on the transaction state. At the time of the `next_time_statement` execution, the `schedule.transaction_state` variable must contain either `success` or `failure` state values for the main transaction. Other values may indicate an internal `pgpro_scheduler` error.

#### Examples:

To run the job first at 10:45, and then in a day after the job completes:

```
SELECT schedule.create_job('{ "commands": "SELECT random()", "cron": "45 10 * * *",
 "next_time_statement": "SELECT now() + ''1 day''::interval" }');
```

#### F.55.3.1.4. Setting Additional Conditions for Job Execution

The `pgpro_scheduler` extension enables you to define additional conditions for task execution:

- Set time limits for job execution with the `max_run_time` key. If the execution time is exceeded, `pgpro_scheduler` cancels the job.
- Define the maximum time a scheduled job can wait for execution using the `last_start_available` key. If the timeout is reached, `pgpro_scheduler` cancels the job.
- Schedule a job to be executed with the rights of another user by specifying the `run_as` key. You must have superuser rights to use this key.
- Define an SQL command to execute if the main command fails using the `onrollback` key.

#### Examples:

To limit job execution to 5 seconds:

```
SELECT schedule.create_job('{ "commands": "SELECT pg_sleep(10)", "cron": "15 */10 * *
 *", "max_run_time": "5 seconds" }');
```

To limit the wait time for job execution to 30 seconds after the scheduled time:

```
SELECT schedule.create_job('{ "commands": "SELECT pg_sleep(100)", "cron": "15 */2 * *
 *", "last_start_available": "30 seconds" }');
```

To start the job with the rights of the `robot` user:

```
SELECT schedule.create_job('{ "commands": "SELECT session_user", "cron": "5 */5 * * *",
 "run_as": "robot" }');
```

To define a fallback SQL command in case the main command fails:

```
SELECT schedule.create_job('{ "commands": "SELECT ''zzz''", "cron": "55 */12 * * *",
 "onrollback": "SELECT ''Cannot select zzz''" }');
```

### F.55.3.2. Submitting One-Time Jobs

You can submit jobs for one-time execution using the `schedule.submit_job()` function. Such jobs use a separate pool of background workers defined by the `schedule.max_parallel_workers` variable, and can run in parallel with the scheduled jobs. By default, two one-time jobs can run concurrently. If you submit more jobs, they will wait in the queue for the next available background worker.

To execute a one-time job immediately, pass SQL commands in the *query* argument. For example:

```
schedule.submit_job(query := 'select 1');
```

Instead of passing SQL query parameters directly, you can define numbered placeholders in the *query* argument, such as `$1` and `$2`, and pass an array of parameters in the *params* argument, with each array element corresponding to a placeholder. For brevity, you can omit the *query* and *params* names:

```
schedule.submit_job(query := 'select $1, $2', params := '{"text 1", "text 2"}')
```

To start a one-time job at the specified time, use the *run\_after* argument:

```
schedule.submit_job('select ''flowers''', run_after := '2017-03-08 08:00:01');
```

Alternatively, you can delay the job start until the specified jobs are complete using the *depends\_on* argument. For example, to run a job after completing the jobs with 23, 15, and 334 IDs, run:

```
schedule.submit_job('select ''well done''', depends_on := '{23, 15, 334}')
```

If required, you can repeat the job execution by passing the `schedule.resubmit()` function as part of the *query* argument. For example:

```
schedule.submit_job('select 1, schedule.resubmit(run_after := ''5'')');
```

The *run\_after* argument specifies the time interval before the job is restarted, in seconds. By default, the interval is 1 second.

The resubmitted job cannot be executed more than the number of times set in the *resubmit\_limit* argument. If this limit is reached, the job receives the `done` status, with the corresponding error message.

If you want to cancel a resubmitted job, run:

```
schedule.cancel_job(job_id bigint);
```

To monitor one-time jobs, use the [job\\_status](#) and [all\\_job\\_status](#) `pgpro_scheduler` views.

For details on all the functions available for managing one-time jobs, see [Section F.55.4.6.3](#).

### F.55.3.3. Changing and Removing Scheduled Jobs

When you create a new job with the `create_job()` function, the job becomes active and waits for execution based on the specified schedule. Using the job ID returned by the `create_job()` function, you can change the scheduling settings or remove the job from the schedule. To change the specified schedule for the jobs, use `set_job_attribute()` or `set_job_attributes()` functions:

- To modify a single property of the job, run the `set_job_attribute()` function with the job ID, the property name to change, and the new value for this property.
- To modify more than one property of the job, run the `set_job_attributes()` function instead. In this case, you can specify all the job properties at once in a `jsonb` object. For details on all the keys available for job scheduling, see the `create_job()` function description.

To temporarily exclude the job from scheduling, run the `deactivate_job()` function:

```
schedule.deactivate_job(job_id integer)
```

You can re-activate the job later by running the `activate_job()` function:

```
schedule.activate_job(job_id integer)
```

To permanently remove the job from the schedule, run the `drop_job()` function:

`schedule.drop_job(job_id integer)`

#### F.55.3.4. Monitoring Scheduled Jobs

You must have superuser rights to monitor job execution for the whole system. Otherwise, you can only monitor the jobs that you own. To monitor scheduled jobs, `pgpro_scheduler` provides multiple functions that return `cron_rec` or `cron_job` records:

- `get_job()` — retrieves information about the job.
- `get_owned_cron()` — retrieves the list of jobs owned by user.
- `get_cron()` — retrieves the list of jobs executed by user.
- `get_active_jobs()` — returns the list of jobs executed at the moment of the function call.
- `get_log()` — returns the list of all completed jobs.
- `get_user_log()` — returns list of the completed jobs executed by the specified user.
- `clean_log()` — deletes all records with information about completed jobs.

To learn more about each function, see [Section F.55.4.6](#).

#### F.55.3.5. Auditing Job Scheduling

`pgpro_scheduler` enables you to audit job scheduling to rule out human error if you observe unexpected changes in scheduled job execution.

By default, `pgpro_scheduler` does not store information on schedule changes. To enable this feature, set the [`schedule.enable\_history`](#) parameter to `true`. Once this parameter is enabled, `pgpro_scheduler` stores schedule modifications in the `schedule.cron__history` table, and logs all deleted jobs in the `schedule.cron__deleted` table. Logged history is never deleted from these tables, so a superuser can review schedule changes introduced by all users at any time.

For details on logged information, see [Section F.55.4.5](#).

#### F.55.3.6. Scheduling Jobs on a Multi-Master Cluster

Using `pgpro_scheduler`, you can manage scheduled and one-time jobs on a cluster configured with [`multimaster`](#). `pgpro_scheduler` can only manage jobs on the node on which it is installed. Thus, you must install and enable `pgpro_scheduler` on all nodes on which you would like to schedule jobs. `pgpro_scheduler` instances will manage jobs on different nodes independently, but the executed jobs will be replicated to other nodes.

Even if you are planning to schedule jobs on a single node only, it is recommended to enable `pgpro_scheduler` on several nodes. In this case, if a node with scheduled jobs fails, another `pgpro_scheduler` instance picks up these jobs. If `pgpro_scheduler` is running on more than one node, the node with the smallest node ID is selected. The naming pattern of node IDs is defined by the [`schedule.nodename`](#) GUC variable.

### F.55.4. Reference

#### F.55.4.1. GUC Variables

`schedule.enabled` (boolean)

Deprecated. Specifies whether `pgpro_scheduler` is enabled on your system.

Default: `false`.

For `pgpro_scheduler` 2.5 or higher, you can set the [`schedule.auto\_enabled`](#) parameter to control whether `pgpro_scheduler` is enabled at the server start, or use `schedule.enable()`/`schedule.disable()` functions to enable/disable `pgpro_scheduler` on demand. To check if `pgpro_scheduler` is currently running, use the `schedule.is_enabled()` function.

`schedule.auto_enabled` (boolean)

Specifies whether to enable `pgpro_scheduler` at the server start.

Default: `false`.

`schedule.database` (text)

Specifies the databases for which `pgpro_scheduler` is enabled. Database names must be separated by commas.

Default: empty string.

`schedule.database_to_connect` (text)

The database to which `pgpro_scheduler` gets connected to receive Postgres Pro Enterprise cluster metadata. The specified database cannot be dropped while `pgpro_scheduler` is running. You can change this parameter only when restarting the server.

Default: `postgres`.

`schedule.schema` (text)

Deprecated. Specifies the name of a schema where the scheduler stores its tables and functions. If you need to change the default schema, use [ALTER EXTENSION](#).

Default: `schedule`.

`schedule.nodename` (text)

Specifies the name of the cluster node on which `pgpro_scheduler` is running. Do not change or use this variable if you run a single-server cluster configuration.

On a cluster configured with `multimaster`, the node name is derived from the node ID provided by `multimaster`. For example, if the node ID is 3, the `schedule.nodename` variable is set to `mtm-node-3`. However, if you explicitly set the `schedule.nodename` variable by editing the `postgresql.conf` file or running the `ALTER` command, `pgpro_scheduler` will ignore the node ID and use the provided value instead.

Default: `primary`.

`schedule.max_workers` (integer)

Specifies the maximum number of simultaneously running scheduled jobs in one database.

Default: 2.

`schedule.max_parallel_workers` (integer)

Specifies the maximum number of parallel threads that can be used for executing one-time jobs.

Default: 2.

`schedule.transaction_state` (text)

An internal variable containing the state of the executed job. `pgpro_scheduler` uses this variable when calculating the next job start time. Possible values are:

- `success` — transaction has finished successfully.
- `failure` — transaction has failed to finish.
- `running` — transaction is in progress.
- `undefined` — transaction has not started yet.

At the time of the `next_time_statement` execution, the `schedule.transaction_state` variable must contain either `success` or `failure` state values. Other values may indicate an internal `pgpro_scheduler` error.

`schedule.enable_history` (boolean)

Log all schedule changes, including the name of the user who initiated the change and the time when this change occurred. If a new job is added, or the schedule of an existing job is modified, this information is stored in the `schedule.cron__history` table. If a job is deleted, this information is stored in the `schedule.cron__deleted` table. If you later disable the `schedule.enable_history` parameter, the history of the already recorded changes is preserved.

Default: `false`

### F.55.4.2. SQL Schema

To store its internal tables and functions, `pgpro_scheduler` uses the `schedule` SQL schema. Direct access to tables is not recommended and should not be attempted. To manage job scheduling, use the functions defined by the `pgpro_scheduler` extension.

### F.55.4.3. SQL Types

`pgpro_scheduler` defines the following types that are used by some of the `pgpro_scheduler` functions.

#### F.55.4.3.1. `cron_rec`

This type contains information about the scheduled job.

```
CREATE TYPE schedule.cron_rec AS(
 id integer, -- job ID
 node text, -- name of the node
 -- on which to execute the job
 name text, -- job name
 comments text, -- comments about the job
 rule jsonb, -- scheduling rules
 commands text[], -- SQL commands to be executed
 run_as text, -- username of the job executor
 owner text, -- username of the job owner
 start_date timestamptz, -- lower bound of the execution window;
 -- NULL if unbound
 end_date timestamptz, -- upper bound of the execution window;
 -- NULL if unbound
 use_same_transaction boolean, -- true if an array of SQL
 -- commands will be executed
 -- in a single transaction
 last_start_available interval, -- maximum wait time for
 -- the scheduled job if all
 -- allowed workers are busy
 max_run_time interval, -- maximum execution time
 onrollback text, -- SQL statement to execute
 -- if the main transaction fails
 max_instances int, -- maximum number of simultaneously
 -- running job instances
 next_time_statement text, -- SQL statement to calculate
 -- the next start time
 active boolean, -- true if job is scheduled
 -- successfully
 broken boolean -- true if job has errors in
 -- configuration that prevented
 -- its further execution
);
```

#### F.55.4.3.2. `cron_job`

This type contains information about a particular job execution.

```
CREATE TYPE schedule.cron_job AS(
 cron integer, -- job id
 node text, -- name of the node
 -- on which to execute the job
 scheduled_at timestamptz, -- scheduled execution time
 name text, -- job name
 comments text, -- comments about the job
 commands text[], -- SQL statement to be executed
 run_as text, -- username of the job executor
 owner text, -- username of the job owner
);
```

```

use_same_transaction boolean, -- true if an array of SQL
 -- commands will be executed
 -- in a single transaction
started timestampz, -- timestamp of the job execution start
last_start_available timestamp, -- maximum wait time for
 -- the scheduled job if all
 -- allowed workers are busy
finished timestampz, -- timestamp of the job
 -- execution finish
max_run_time interval, -- maximum execution time
onrollback text, -- SQL statement to execute if the main
 -- transaction fails
next_time_statement text, -- SQL statement to calculate
 -- the next start time
max_instances int, -- the number of simultaneously
 -- running job instances
status job_status_t, -- status of the task:
 -- working, done, or error
message text -- error message
);

```

#### F.55.4.3.3. `job_status_t`

Enumerated type. Can take the following values:

- `working` — the job is being executed.
- `done` — job execution is complete.
- `error` — job execution has failed.

#### F.55.4.3.4. `job_at_status_t`

Enumerated type. Can take the following values:

- `submitted` — the job is submitted into the queue, but the execution has not started yet.
- `processing` — the job is being executed.
- `done` — job execution is complete.

#### F.55.4.3.5. `timetable_job_type_t`

Enumerated type. Can take the following values:

- `periodical` — a scheduled job.
- `onetime` — a one-time job.

#### F.55.4.3.6. `timetable_job_status_t`

Enumerated type. Can take the following values:

- `inprogress` — the job is being executed.
- `done` — job execution is complete.
- `error` — job execution has failed.
- `submitted` — the job is submitted into the queue, but the execution has not started yet.

### F.55.4.4. Views

`pgpro_scheduler` provides several views for monitoring execution status of one-time jobs.

#### F.55.4.4.1. `job_status` View

Shows the status of one-time jobs belonging to the current user.

**Table F.34. `job_status` View**

| Column Name                    | Column Type                           | Description                                                                                                                                                                    |
|--------------------------------|---------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>id</code>                | <code>bigint</code>                   | Job ID.                                                                                                                                                                        |
| <code>node</code>              | <code>text</code>                     | Name of the node on which the job is being executed.                                                                                                                           |
| <code>name</code>              | <code>text</code>                     | Name of the job.                                                                                                                                                               |
| <code>comments</code>          | <code>text</code>                     | Comments about the job.                                                                                                                                                        |
| <code>run_after</code>         | <code>timestamp with time zone</code> | Timestamp after which the job execution must start.                                                                                                                            |
| <code>query</code>             | <code>text</code>                     | SQL commands executed by the job.                                                                                                                                              |
| <code>params</code>            | <code>text[]</code>                   | An array of parameters for the SQL query.                                                                                                                                      |
| <code>depends_on</code>        | <code>bigint[]</code>                 | An array of job IDs on which the job execution depends.                                                                                                                        |
| <code>run_as</code>            | <code>text</code>                     | User or role whose rights are used to execute the job.                                                                                                                         |
| <code>attempt</code>           | <code>bigint</code>                   | The number of execution attempts.                                                                                                                                              |
| <code>resubmit_limit</code>    | <code>bigint</code>                   | The maximum number of allowed job re-submissions.                                                                                                                              |
| <code>max_wait_interval</code> | <code>interval</code>                 | The maximum time interval to postpone the job execution if all background workers are busy at the scheduled moment.                                                            |
| <code>max_duration</code>      | <code>interval</code>                 | Time interval during which the job can be executed.                                                                                                                            |
| <code>submit_time</code>       | <code>timestamp with time zone</code> | Time when the job was submitted to the execution queue.                                                                                                                        |
| <code>canceled</code>          | <code>boolean</code>                  | Specifies whether the job was canceled by user.                                                                                                                                |
| <code>start_time</code>        | <code>timestamp with time zone</code> | Job execution start time.                                                                                                                                                      |
| <code>is_success</code>        | <code>boolean</code>                  | <ul style="list-style-type: none"> <li><code>true</code> — job execution completed successfully.</li> <li><code>false</code> — job execution completed with errors.</li> </ul> |
| <code>error</code>             | <code>text</code>                     | Error message.                                                                                                                                                                 |
| <code>done_time</code>         | <code>timestamp with time zone</code> | Time when the job execution completed.                                                                                                                                         |
| <code>status</code>            | <code>job_at_status_t</code>          | Job status. See the <a href="#">Section F.55.4.3.4</a> for details.                                                                                                            |

#### F.55.4.4.2. `all_job_status` View

Shows the status of all one-time jobs. You must have superuser rights to access this view.

**Table F.35. `all_job_status` View**

| Column Name       | Column Type         | Description                                          |
|-------------------|---------------------|------------------------------------------------------|
| <code>id</code>   | <code>bigint</code> | Job ID.                                              |
| <code>node</code> | <code>text</code>   | Name of the node on which the job is being executed. |
| <code>name</code> | <code>text</code>   | Name of the job.                                     |

Extensions Shipped in `post-  
grespro-ent-17-contrib`

| Column Name                    | Column Type                           | Description                                                                                                                                                                    |
|--------------------------------|---------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>comments</code>          | <code>text</code>                     | Comments about the job.                                                                                                                                                        |
| <code>run_after</code>         | <code>timestamp with time zone</code> | Timestamp after which the job execution must start.                                                                                                                            |
| <code>query</code>             | <code>text</code>                     | SQL commands executed by the job.                                                                                                                                              |
| <code>params</code>            | <code>text[]</code>                   | An array of parameters for the SQL query.                                                                                                                                      |
| <code>depends_on</code>        | <code>bigint[]</code>                 | An array of job IDs on which the job execution depends.                                                                                                                        |
| <code>run_as</code>            | <code>text</code>                     | User or role whose rights are used to execute the job.                                                                                                                         |
| <code>owner</code>             | <code>text</code>                     | The user who created the job.                                                                                                                                                  |
| <code>attempt</code>           | <code>bigint</code>                   | The number of execution attempts.                                                                                                                                              |
| <code>resubmit_limit</code>    | <code>bigint</code>                   | The maximum number of allowed job re-submissions.                                                                                                                              |
| <code>max_wait_interval</code> | <code>interval</code>                 | The maximum time interval to postpone the job execution for if all background workers are busy at the scheduled moment.                                                        |
| <code>max_duration</code>      | <code>interval</code>                 | Time interval during which the job can be executed.                                                                                                                            |
| <code>submit_time</code>       | <code>timestamp with time zone</code> | Time when the job was submitted to the execution queue.                                                                                                                        |
| <code>canceled</code>          | <code>boolean</code>                  | Specifies whether the job was canceled by user.                                                                                                                                |
| <code>start_time</code>        | <code>timestamp with time zone</code> | Job execution start time.                                                                                                                                                      |
| <code>is_success</code>        | <code>boolean</code>                  | <ul style="list-style-type: none"> <li><code>true</code> — job execution completed successfully.</li> <li><code>false</code> — job execution completed with errors.</li> </ul> |
| <code>error</code>             | <code>text</code>                     | Error message.                                                                                                                                                                 |
| <code>done_time</code>         | <code>timestamp with time zone</code> | Time when the job execution completed.                                                                                                                                         |
| <code>status</code>            | <code>job_at_status_t</code>          | Job status. See the <a href="#">Section F.55.4.3.4</a> for details.                                                                                                            |

### F.55.4.5. Audit Tables

The following tables store all schedule changes if the `schedule.enable_history` parameter is set to `true`. If you later disable the `schedule.enable_history` parameter, the history of the already recorded changes is preserved.

#### F.55.4.5.1. `schedule.cron__history` Table

Registers job scheduling changes. Whenever a new job is scheduled, or the schedule for an existing job is changed, a new row is inserted into this table to record the following information:

- All details about the scheduled job, as defined by the `cron_rec` data type. For details on the `cron_rec` type, see [Section F.55.4.3](#).
- `submitter` — name of the user who updated the schedule.
- `version_id` — a unique ID for each registered change in the schedule.
- `submit_time` — time when the schedule was updated.

#### F.55.4.5.2. `schedule.cron__deleted` Table

Registers all jobs that were removed from the schedule:

- `cron` — ID of the deleted job.
- `submitter` — name of the user who deleted the job.
- `submit_time` — time when the job was deleted.

#### F.55.4.6. Functions

`pgpro_scheduler` provides two separate sets of functions for managing scheduled and one-time jobs, as well as several common functions that can toggle `pgpro_scheduler` on and off for your database and show the current status of the extension:

- [Section F.55.4.6.1](#)
- [Section F.55.4.6.2](#)
- [Section F.55.4.6.3](#)
- [Section F.55.4.6.5](#)

### Important

With each job, you can only use the function specifically tailored for this job type.

#### F.55.4.6.1. Common Functions

These functions facilitate `pgpro_scheduler` management.

`schedule.enable()`

Enables `pgpro_scheduler` for the current Postgres Pro Enterprise instance.

Return values:

- `true` if `pgpro_scheduler` is enabled and ready to use.
- `false` if the command has failed.

`schedule.is_enabled()`

Checks whether `pgpro_scheduler` is enabled.

Return values:

- `true` if `pgpro_scheduler` is enabled and ready to use.
- `false` if `pgpro_scheduler` is not currently running.

`schedule.disable()`

Disables `pgpro_scheduler` for the current Postgres Pro Enterprise instance.

Return values:

- `true` if `pgpro_scheduler` is disabled.
- `false` if the command has failed.

`schedule.start()`

Launches `pgpro_scheduler` for the currently connected database.

Return values:

- `true` — `pgpro_scheduler` started successfully.
- `false` — if the command has failed, or `pgpro_scheduler` is already started.

## `schedule.stop()`

Stops `pgpro_scheduler` for the currently connected database.

Return values:

- `true` — `pgpro_scheduler` is stopped.
- `false` — if the command has failed, or `pgpro_scheduler` is not running.

## `schedule.status()`

Returns the status of `pgpro_scheduler` background workers:

- `pid` — process ID of the background worker. If the process ID is `NULL`, the background worker is not running.
- `database` — name of the database to which the background worker is connected.
- `type` — type of the background worker:
  - `supervisor` — distributes the scheduled jobs between the databases.
  - `database manager` distributes the scheduled jobs within the database.
  - `cron job executor` executes a scheduled job.
  - `at job executor` executes a one-time job.

## `schedule.version()`

Returns `pgpro_scheduler` version.

### F.55.4.6.2. Functions for Managing Scheduled Jobs

#### `schedule.create_job(options jsonb)`

Creates an active job and returns the job ID.

##### Alternative Syntax:

```
schedule.create_job(cron text, commands text [, node text])
schedule.create_job(cron text, commands text[] [, node text])
schedule.create_job(dates timestamp with time zone, commands text [, node text])
schedule.create_job(dates timestamp with time zone, commands text[] [, node text])
schedule.create_job(dates timestamp with time zone[], commands text [, node text])
schedule.create_job(dates timestamp with time zone[], commands text[] [, node text])
```

Arguments:

- *options* — a `jsonb` object defining all the job properties. You do not need to define other parameters if the *data* is set. All the available `jsonb` keys are listed in [Table F.36](#).

Type: `jsonb`

- *cron* — a crontab-like string defining the job schedule.

Type: `text`

- *dates* — the exact date or an array of dates for job execution.

Type: `timestamp with time zone, timestamp with time zone[]`

- *commands* — SQL statement to execute. You can pass one or more SQL commands separated by semicolons, or an array of SQL commands. When passed as an array, SQL commands are executed in separate transactions.

Type: `text, text[]`

- *node* — the name of the node on which the scheduled jobs run. Optional. You may need to specify this argument if you are scheduling jobs on a multi-master cluster.

Type: `text`

Return values:

- ID of the created job.

**Table F.36. `jsonb` Keys for Job Scheduling**

| Key                | Type                                                                  | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
|--------------------|-----------------------------------------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>cron</code>  | <code>text</code>                                                     | <p>A crontab-like string defining the job schedule. A traditional five-field or non-standard six-field (seconds in the first field) <code>crontab</code> format may be used. You can combine <code>cron</code> with <code>rule</code> and <code>dates</code> keys, but at least one of them is mandatory. Alternatively, the following keywords can be used instead of a <code>crontab</code> string to specify when the job will be started:</p> <ul style="list-style-type: none"> <li>• <code>@every_second</code> — each second</li> <li>• <code>@hourly</code> — at the beginning of each hour</li> <li>• <code>@daily</code> — at the beginning of each day</li> <li>• <code>@midnight</code> — at the beginning of each day</li> <li>• <code>@weekly</code> — at the beginning of each week</li> <li>• <code>@monthly</code> — at the beginning of each month</li> <li>• <code>@yearly</code> — at the beginning of each year</li> <li>• <code>@annually</code> — at the beginning of each year</li> </ul> |
| <code>dates</code> | <code>timestamp with time zone,<br/>timestamp with time zone[]</code> | The exact date or an array of dates when the scheduled job will be executed. You can combine <code>dates</code> with <code>rule</code> and <code>cron</code> keys, but at least one of them is mandatory.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
| <code>rule</code>  | <code>jsonb</code>                                                    | <p>A <code>jsonb</code> object defining the job schedule. Mandatory, if both <code>cron</code> and <code>dates</code> keys are undefined. The <code>rule</code> object includes one or more of the following keys:</p> <ul style="list-style-type: none"> <li>• <code>seconds</code> — seconds; an array of integers in range [0, 59]</li> <li>• <code>minutes</code> — minutes; an array of integers in range [0, 59]</li> <li>• <code>hours</code> — hours; an array of integers in range [0, 23]</li> <li>• <code>days</code> — days of the month; an array of integers in range [1, 31]</li> <li>• <code>months</code> — months; an array of integers in range [1, 12]</li> </ul>                                                                                                                                                                                                                                                                                                                             |

Additional Supplied Modules and  
Extensions Shipped in `post-  
grespro-ent-17-contrib`

| Key                               | Type                                  | Description                                                                                                                                                                                                                                                                                                                                    |
|-----------------------------------|---------------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|                                   |                                       | <ul style="list-style-type: none"> <li><code>wdays</code> — days of the week; an array of integers in range [0, 6], where 0 is Sunday.</li> <li><code>onstart</code> — integer value 0 or 1. If <code>onstart</code> is set to 1, the job is executed only once when <code>pgpro_scheduler</code> is started.</li> </ul>                       |
| <code>commands</code>             | <code>text, text[]</code>             | SQL statements to execute. You can pass one or more SQL statements separated by semicolons, or an array of SQL statements. When passed as an array, SQL statements are executed in separate transactions by default. You can change this behavior by setting the <code>use_same_transaction</code> key.                                        |
| <code>name</code>                 | <code>text</code>                     | Optional. Job name.                                                                                                                                                                                                                                                                                                                            |
| <code>node</code>                 | <code>text</code>                     | Optional. The name of the node on which the scheduled jobs run. You may need to specify this argument if you are scheduling jobs on a multi-master cluster.                                                                                                                                                                                    |
| <code>comments</code>             | <code>text</code>                     | Optional. Comments about the scheduled job.                                                                                                                                                                                                                                                                                                    |
| <code>run_as</code>               | <code>text</code>                     | Optional. The user whose rights are used to execute the job.                                                                                                                                                                                                                                                                                   |
| <code>start_date</code>           | <code>timestamp with time zone</code> | Optional. The start of the timeframe when the scheduled job can be executed. This key can be <code>NULL</code> .                                                                                                                                                                                                                               |
| <code>end_date</code>             | <code>timestamp with time zone</code> | Optional. The end of the timeframe when the scheduled job can be executed. This key can be <code>NULL</code> .                                                                                                                                                                                                                                 |
| <code>use_same_transaction</code> | <code>boolean</code>                  | Optional. If set to <code>true</code> , forces an array of SQL statements to be executed in a single transaction. Default: <code>false</code>                                                                                                                                                                                                  |
| <code>last_start_available</code> | <code>interval</code>                 | Optional. The maximum time interval to postpone the job execution for if all background workers are busy at the scheduled moment. For example, if this key is set to <code>'00:02:34'</code> , the job will wait for 2 minutes 34 seconds. If this key is <code>NULL</code> or not set, the job can wait forever. Default: <code>NULL</code> . |
| <code>max_instances</code>        | <code>integer</code>                  | Optional. The maximum number of job instances that can be executed simultaneously. Default: 1.                                                                                                                                                                                                                                                 |
| <code>max_run_time</code>         | <code>interval</code>                 | Optional. The maximum time interval during which the scheduled job can be executed. If this key is <code>NULL</code> or not set, there are no time limits. Default: <code>NULL</code> .                                                                                                                                                        |
| <code>onrollback</code>           | <code>text</code>                     | Optional. SQL statement to be executed if the main transaction fails.                                                                                                                                                                                                                                                                          |

| Key                              | Type              | Description                                                                                                                           |
|----------------------------------|-------------------|---------------------------------------------------------------------------------------------------------------------------------------|
| <code>next_time_statement</code> | <code>text</code> | Optional. SQL statement to calculate the start time for the next job execution. For details, see <a href="#">Section F.55.3.1.3</a> . |

`schedule.set_job_attributes(job_id integer, data jsonb)`

Updates properties of the existing job.

Arguments:

- `job_id` — identifier of the existing job.
- `data` — a `jsonb` object with properties to be edited. For the list of keys and their structure, see [Table F.36](#).

Return values:

- `true` — job properties were updated successfully.
- `false` — job properties were not updated.

To update the job properties, you must be the owner of the job or have superuser rights.

`schedule.set_job_attribute(job_id integer, name text, value text || anyarray)`

Updates a property of the existing job.

Arguments:

- `job_id` — identifier of the existing job.
- `name` — property name.
- `value` — property value.

See [Table F.36](#) for the list of job properties you can update. Some values are of array types. They should be passed as an array. If a value of a wrong type is passed, an exception is raised.

Return values:

- `true` — job property was updated successfully.
- `false` — job property was not updated.

To update the job properties, you must be the owner of the job or have superuser rights.

`schedule.deactivate_job(job_id integer)`

Deactivates the job and suspends its further scheduling and execution.

Arguments:

- `job_id` — identifier of the existing job.

Return values:

- `true` — the job is deactivated successfully.
- `false` — job deactivation failed.

`schedule.activate_job(job_id integer)`

Activates a job and starts its scheduling and execution.

Arguments:

- `job_id` — identifier of the existing job.

Return values:

- `true` — the job was activated successfully.
- `false` — job activation failed.

`schedule.drop_job(job_id integer)`

Deletes a job.

Arguments:

- `job_id` — identifier of the existing job.

Return values:

- `true` — the job was deleted successfully.
- `false` — job was not deleted.

`schedule.get_job(job_id integer)`

Returns information about the specified job.

Arguments:

- `job_id` — identifier of the existing job.

Return values:

- An object of type `cron_rec`.

For details on the `cron_rec` type, see [Section F.55.4.3](#).

`schedule.get_owned_cron(username text)`

Retrieves the list of jobs owned by the specified user.

Arguments:

- `username` — username, optional.

Return values:

- A set of records of type `cron_rec`. These records contain information about all jobs owned by the specified user. If the `username` is omitted, the session username is used. You must have superuser rights to retrieve jobs owned by another user.

For details on the `cron_rec` type, see [Section F.55.4.3](#).

`schedule.get_cron()`

Retrieves the list of jobs executed by the session user.

Return values:

- A set of records of type `cron_rec`. These records contain information about all jobs executed by the session user. You must have superuser rights to retrieve the jobs.

For details on the `cron_rec` type, see [Section F.55.4.3](#).

`schedule.get_active_jobs(username text)`

Returns the list of jobs currently being executed by the specified user.

Arguments:

- `username` — username, optional.

If `username` is omitted, the session username is used. You must have superuser rights to retrieve jobs executed by another user.

Return values:

- A set of records of type `cron_job`.

For details on the `cron_job` type, see [Section F.55.4.3](#).

#### `schedule.get_active_jobs()`

Returns the list of jobs being currently executed. You must have superuser rights to call this function.

Return values:

- A set of records of type `cron_job`.

For details on the `cron_job` type, see [Section F.55.4.3](#).

#### `schedule.get_log()`

Returns the list of all completed jobs. You must have superuser rights to call this function.

Return values:

- A set of records of type `cron_job`.

For details on the `cron_job` type, see [Section F.55.4.3](#).

#### `schedule.get_user_log(username text)`

Returns the list of completed jobs executed by the specified user.

Arguments:

- *username* — username, optional.

If *username* is omitted, the session username is used. You must have superuser rights to retrieve the list of jobs executed by another user.

Return values:

- A set of records of type `cron_job`.

For details on the `cron_job` type, see [Section F.55.4.3](#).

#### `schedule.clean_log()`

Deletes all records with information about the completed jobs. You must have superuser rights to call this function.

Return values:

- The number of records deleted.

#### `schedule.nodename()`

Returns the current node name.

### F.55.4.6.3. Functions for Managing One-Time Jobs

#### `schedule.submit_job(query text [options...])`

Submits a job for immediate or delayed one-time execution. By default, the job is scheduled for immediate execution and can run in parallel with other scheduled jobs. To submit a job with a delayed start, you can set the execution start time using the *run\_after* argument, or pass an array of job IDs in the *depends\_on* argument to schedule job execution right after these jobs are complete.

Arguments:

- *query* — SQL commands to execute.

Type: `text`

- *params* — an array of parameters for the SQL query that can substitute numbered placeholders in the *query* argument, such as \$1, \$2, etc. Default: `NULL`

Type: `text[]`

- *run\_after* — a timestamp after which the job execution starts. If this argument is set to `NULL`, the job is scheduled for immediate execution. You can also use the *depends\_on* argument to delay the job start. Default: `NULL`

Type: `timestamp with time zone`

- *node* — the name of the node on which to execute the job. Default: `NULL`

Type: `text`

- *max\_duration* — the maximum time interval during which the job can be executed. If this time is exceeded, the job is forced to stop. If this argument is `NULL` or not set, there are no time limits. Default: `NULL`

Type: `interval`

- *max\_wait\_interval* — the maximum time interval to postpone the job execution for if all background workers are busy at the scheduled moment. For example, if this key is set to `'00:02:34'`, the job will wait for 2 minutes 34 seconds. If this key is `NULL` or not set, the job can wait forever. Default: `NULL`

Type: `interval`

- *run\_as* — user or role whose rights are used to execute the job. If *run\_as* is set to `NULL`, the job is executed with the rights of the current user. You must have superuser rights to set this argument. Default: `NULL`

Type: `text`

- *depends\_on* — an array of job IDs. The created job starts immediately after the specified jobs complete the execution. This argument is an alternative to *run\_after*. Default: `NULL`

Type: `bigint[]`

- *name* — name of the job. Default: `NULL`

Type: `text`

- *comments* — comments about the job.

Type: `text`

- *resubmit\_limit* — maximum number of times the job can be resubmitted for execution. See the `schedule.resubmit()` function for details. Default: 100

Type: `bigint`

Return values:

- ID of the created job.

Type: `bigint`

`schedule.get_self_id()`

Returns the ID of the job, in the context of which it was called. The returned ID is of the `bigint` type. This function must be called inside the *query* of the `schedule.submit_job()` function. Otherwise, an exception is raised.

Return values:

- Job ID.

`schedule.cancel_job(job_id bigint)`

Cancels all subsequent runs of the specified job. If the job is currently being executed, it will not be interrupted, but cannot be resubmitted. You must have superuser rights or be the owner of the job to call this function.

Arguments:

- `job_id` — identifier of the job to cancel.

Return values:

- `true` if the operation completed successfully.
- `false` if the operation failed.

`schedule.resubmit(run_after interval default NULL)`

Sets the start time for the next execution of the job, without interrupting the current job run. This function must be called inside the `query` argument of the `schedule.submit_job()` function. Otherwise, an exception is raised. If this function is called several times within a single job execution, only the last function call is taken into account.

Arguments:

- `run_after` — time interval after which the job will be resubmitted for execution. If the time interval is less than a second but greater than zero, it is rounded to 1 second. Intervals longer than 1 second are rounded to integral values. If 0 is passed, the job is resubmitted immediately after execution. Default: 1 second

Type: `interval`

Return values:

- The number of seconds after which the job will be resubmitted for execution.

#### F.55.4.6.4. Cleanup Functions

When many one-time jobs are submitted, the `schedule.at_jobs_done` table may grow rapidly. To clean up this table, `pgpro_scheduler` provides the following functions with the same name but different argument types:

`schedule.clean_at_jobs_done(older_than interval, delete_failed_tasks boolean, default NULL)`

`schedule.clean_at_jobs_done(older_than timestamp with time zone, delete_failed_tasks boolean, default NULL)`

Delete all records in `schedule.at_jobs_done` that are older than either a specified timestamp or a specified interval relative to the current time.

Arguments:

- `older_than` — an interval or a timestamp for cleanup. Records older than this value will be deleted.

Type: `interval`, `timestamp with time zone`

- `delete_failed_tasks` — specifies whether to delete failed jobs. Default: `false`.

Type: `boolean`

Return values:

- The number of deleted records.

These functions can be called manually or scheduled using cron jobs in the `pgpro_scheduler` interface.

#### F.55.4.6.5. Functions for Managing Scheduled and One-Time Jobs

`schedule.timetable(start_time timestamp with time zone, end_time timestamp with time zone)`

Returns a table, which describes all the jobs, both repeated and one-time, that are scheduled to execute within the specified time interval.

**Table F.37. `schedule.timetable` Columns**

| Column Name     | Column Type         | Description                                        |
|-----------------|---------------------|----------------------------------------------------|
| <code>id</code> | <code>bigint</code> | Job ID, which is unique for the jobs of this type. |

| Column Name               | Column Type                           | Description                                                     |
|---------------------------|---------------------------------------|-----------------------------------------------------------------|
| <code>type</code>         | <code>timetable_job_type_t</code>     | Job type. See <a href="#">Section F.55.4.3.5</a> for details.   |
| <code>node</code>         | <code>text</code>                     | Name of the node on which the job is being executed.            |
| <code>name</code>         | <code>text</code>                     | Name of the job.                                                |
| <code>comments</code>     | <code>text</code>                     | Comments about the job.                                         |
| <code>commands</code>     | <code>text[]</code>                   | An array of SQL commands executed by the job.                   |
| <code>scheduled_at</code> | <code>timestamp with time zone</code> | Scheduled job execution time.                                   |
| <code>start_time</code>   | <code>timestamp with time zone</code> | Job execution start time.                                       |
| <code>done_time</code>    | <code>timestamp with time zone</code> | Time when the job execution completed.                          |
| <code>status</code>       | <code>timetable_job_status_t</code>   | Job status. See <a href="#">Section F.55.4.3.6</a> for details. |
| <code>error</code>        | <code>text</code>                     | Error message.                                                  |

## F.55.5. Authors

Postgres Professional, Moscow, Russia

## F.56. pgpro\_sfile — storage for large objects

The `pgpro_sfile` module allows storing multiple large objects. It is similar to Oracle LOBs. `pgpro_sfile` provides an engine for storing large objects in a set of tables controlled by the extension. Each object consists of chunks, or blocks. Blocks are split into pages of ~8kB size. The maximum number of objects, number of blocks and object size in bytes are limited by the size of the `bigint` type ( $2^{63} - 1$ ). A `pgpro_sfile` large object is called *sfile object*.

### F.56.1. Storage Engine

`sfile` objects are stored in tables created and controlled by `pgpro_sfile`. Regular tables only store the identifier of each `sfile` object as a reference to tables created by `pgpro_sfile`. Once an `sfile` object is created, it can be loaded, read, truncated and deleted, and these operations do not affect regular tables where it is used.

The storage engine is a set of the following storage tables:

- `SF_DESCRIPTOR` — a registry where descriptors of all `sfile` objects are stored.
- `SF_PARTITION` — a registry of storage tables (partitions). Stores information about `SF_PAGE_XX` tables.
- `SF_BLOCK` — a registry of `sfile` object blocks. Each block can include several pages of `sfile` objects.
- `SF_PAGE_XX` — tables with `sfile` object data pages.
- `SF_OPTION` — a table with `sfile` object options. Currently there is one option `TABLESPACE`, which allows setting the tablespace where `sfile` objects are stored.

All the tables, except `SF_OPTION`, are created in a special `pgpro_sfile_data` schema. The `SF_OPTION` table is created during the `pgpro_sfile` installation. `SF_DESCRIPTOR`, `SF_PARTITION`, and `SF_BLOCK` tables are created during the `pgpro_sfile` initialization, and `SF_PAGE_XX` tables are created when an `sfile` object is written to the database and are tracked in the `SF_PARTITION` registry.

Next sections describe the structure of the storage tables.

#### F.56.1.1. SF\_OPTION

The `SF_OPTION` table has the following fields:

|                        |                       |                                                                                                                                            |
|------------------------|-----------------------|--------------------------------------------------------------------------------------------------------------------------------------------|
| <code>opt_type</code>  | <code>smallint</code> | Option type: <code>GLOBAL</code> = 0, <code>TABLE</code> = 1, or <code>OBJECT</code> = 2. Currently <code>GLOBAL</code> is only supported. |
| <code>opt_name</code>  | <code>name</code>     | Unique option name.                                                                                                                        |
| <code>opt_value</code> | <code>name</code>     | Option value.                                                                                                                              |

#### F.56.1.2. SF\_DESCRIPTOR

The `SF_DESCRIPTOR` table has the following fields:

|                                |                        |                                                                                                                                         |
|--------------------------------|------------------------|-----------------------------------------------------------------------------------------------------------------------------------------|
| <code>sf_id</code>             | <code>bigint</code>    | Unique <code>sfile</code> object identifier.                                                                                            |
| <code>sf_name</code>           | <code>name</code>      | <code>sfile</code> object name.                                                                                                         |
| <code>sf_persistence</code>    | <code>smallint</code>  | Storage type of the <code>sfile</code> object: <code>RELPERSISTENCE_PERMANENT</code> ="p" or <code>RELPERSISTENCE_UNLOGGED</code> ="u". |
| <code>sf_state</code>          | <code>smallint</code>  | Set of bits that describe the <code>sfile</code> object state. For example: <code>SF_STATE_DELETED</code> =1.                           |
| <code>sys_creation_date</code> | <code>timestamp</code> | Date and time of the <code>sfile</code> object creation.                                                                                |

Additional Supplied Modules and  
Extensions Shipped in `post-  
grespro-ent-17-contrib`

|                              |                        |                                                                            |
|------------------------------|------------------------|----------------------------------------------------------------------------|
| <code>sys_update_date</code> | <code>timestamp</code> | Date and time of the last update of the <code>sfile</code> object.         |
| <code>sf_json_opts</code>    | <code>text</code>      | Options of the <code>sfile</code> object in the text or JSON format.       |
| <code>sf_type</code>         | <code>text</code>      | Manually set <code>sfile</code> object type.                               |
| <code>tbs_identity</code>    | <code>text</code>      | Name of the tablespace where the <code>sfile</code> object will be stored. |

### F.56.1.3. SF\_PARTITION

The `SF_PARTITION` table has the following fields:

|                               |                       |                                                                                                                             |
|-------------------------------|-----------------------|-----------------------------------------------------------------------------------------------------------------------------|
| <code>part_id</code>          | <code>int</code>      | Unique partition identifier.                                                                                                |
| <code>part_data_size</code>   | <code>bigint</code>   | Number of blocks that are currently stored in the partition.                                                                |
| <code>part_persistence</code> | <code>smallint</code> | Data storage type in the partition: <code>RELPERSISTENCE_PERMANENT="p"</code> or <code>RELPERSISTENCE_UNLOGGED="u"</code> . |
| <code>rel_identity</code>     | <code>text</code>     | Name of the table that stores the partition data.                                                                           |
| <code>tbs_identity</code>     | <code>text</code>     | Name of the tablespace that stores the partition data.                                                                      |

### F.56.1.4. SF\_BLOCK

The `SF_BLOCK` table has the following fields:

|                                |                        |                                                                                                                                                              |
|--------------------------------|------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>sf_id</code>             | <code>bigint</code>    | Unique <code>sfile</code> object identifier.                                                                                                                 |
| <code>block_id</code>          | <code>bigint</code>    | Unique identifier of the block in the <code>sfile</code> object. The value of the <code>a_sf_index</code> argument of <code>sf_write</code> is written here. |
| <code>part_id</code>           | <code>int</code>       | Identifier of the partition where the block data is stored.                                                                                                  |
| <code>block_size</code>        | <code>int</code>       | Block size, in bytes.                                                                                                                                        |
| <code>block_start_page</code>  | <code>int</code>       | Sequential number of the block first page, the block numbering starts at 1.                                                                                  |
| <code>block_end_page</code>    | <code>int</code>       | Sequential number of the block last page, the block numbering starts at 1.                                                                                   |
| <code>sys_creation_date</code> | <code>timestamp</code> | Date and time of the block creation .                                                                                                                        |
| <code>sys_update_date</code>   | <code>timestamp</code> | Date and time of the block last update.                                                                                                                      |

### F.56.1.5. SF\_PAGE\_XX

Each `SF_PAGE_XX` table has the following fields:

|                       |                     |                                                        |
|-----------------------|---------------------|--------------------------------------------------------|
| <code>sf_id</code>    | <code>bigint</code> | Unique <code>sfile</code> object identifier.           |
| <code>block_id</code> | <code>bigint</code> | Unique identifier of the block that includes the page. |
| <code>page_no</code>  | <code>int</code>    | Sequential number of the page in the block.            |

|                   |                    |                                                                                                                                       |
|-------------------|--------------------|---------------------------------------------------------------------------------------------------------------------------------------|
| <code>data</code> | <code>bytea</code> | The buffer to store the <code>sfile</code> object data. The maximum data size to store in the <code>data</code> buffer is 8096 bytes. |
|-------------------|--------------------|---------------------------------------------------------------------------------------------------------------------------------------|

## F.56.2. Installation

The `pgpro_sfile` extension is included in Postgres Pro Enterprise. To enable `pgpro_sfile`, create the extension using the following query:

```
CREATE EXTENSION pgpro_sfile;
```

## F.56.3. Functions

The `pgpro_sfile` functions allow performing various operations with `sfile` objects, such as creating, writing, reading, deleting and more. To access IDs of `sfile` objects, these functions use the `sfile` data type. To store object IDs, a new column of the `sfile` data type must be added to the table.

`sf_initialize()` returns `void`

Initializes the storage of `sfile` objects. The function creates the `pgpro_sfile_data` schema and then creates the needed tables and sequences in this schema. Call this function right after installation of the extension.

`sf_deinitialize()` returns `void`

Performs cascading delete of the `pgpro_sfile_data` schema. Call this function before deleting the extension to delete all the `sfile` object data. Superuser privileges are required to call this function.

`sf_create(a_sf_name text, a_sf_persistence text, a_sf_json_options text[, a_sf_tablespace text])` returns `sfile`

Creates a new `sfile` object with the name `a_sf_name` and returns the ID of the object. The object will be logged or unlogged depending on the value of `a_sf_persistence`, which must be `LOGGED` or `UNLOGGED`, and the `a_sf_json_options` argument must contain JSON with options. The `a_sf_tablespace` argument allows you to specify the tablespace where the `sfile` object will be stored, otherwise, the default tablespace is used.

This function adds a descriptor of the `sfile` object with the zero size to the `SF_DESCRIPTOR` relation. So a call to `sf_is_empty` on a newly created object returns `TRUE`, as well as `sf_is_valid`. No blocks or partitions are created by `sf_create`.

`sf_create_empty([a_sf_tablespace text])` returns `sfile`

Creates a new empty `sfile` object with an autogenerated name (`sf_gen_XX`) and empty options and returns the ID of the object. The `a_sf_tablespace` argument allows you to specify the tablespace where the `sfile` object will be stored, otherwise, the default tablespace is used.

`sf_write(a_sf sfile, a_sf_data bytea[, a_sf_index bigint])` returns `integer`

Inserts the new data block `a_sf_data` with the index specified by the `a_sf_index` argument into the `sfile` object specified by its ID `a_sf` and returns the number of bytes added. The current timestamp is used as the default index. Passing `a_sf_index`  $\leq 0$  results in an error.

This function first checks whether the `sfile` object was already written in order to figure out whether the partition table `SF_PAGE_XX` is available and has enough free space to write the block. If the partition is not available or it is the first write, all other partitions are checked and the first available is locked for writing. If no partition is available, a new one is created and added to the `SF_PARTITION` registry. Then a new block entry is initialized in `SF_BLOCK`, the block is divided into pages of ~8kB size, and these pages are written to the previously locked `SF_PAGE_XX` partition. When the block is written, the size of the data is adjusted in the `part_data_size` field of the `SF_PARTITION` table.

`sf_read(a_sf sfile[, a_offset bigint, a_length integer])` returns `bytea`

Reads the number of bytes specified by the `a_length` from the `sfile` object specified by its ID `a_sf` at the offset specified by the `a_offset` argument. Up to ~1 GB can be read due to the `varlena` limitation. The default is ~1 GB. The default offset is 0. Returns the buffer with the data read.

`sf_size(a_sf sfile)` returns `bigint`

Retrieves the `sfile` object size.

`sf_truncate(a_sf sfile)` returns `bigint`

Truncates the `sfile` object, that is, deletes all data (blocks) but leaves the object intact, and returns the new `sfile` object size, that is, 0. So a subsequent call to `sf_is_valid` for this object continues to return `TRUE`, and a call to `sf_is_empty` also returns `TRUE`.

`sf_delete(a_sf sfile)` returns `bigint`

Deletes the `sfile` object and returns the amount of data deleted. The function deletes all the blocks of data and then removes the object descriptor from `SF_DESCRIPTOR`. Since then, the object is not available, so a call to `sf_is_valid` for this object returns `FALSE`.

`sf_import(a_file text, a_sf_name text, a_sf_persistence text, a_sf_json_options text[, a_sf_tablespace text])` returns `sfile`

`sf_import(a_file text, a_sf sfile)` returns `sfile`

The two-parameter function writes the contents of the `a_file` file at the end of the existing `a_sf` `sfile` object. The function with more parameters imports the `a_file` file as a new `sfile` object with the name `a_sf_name` and returns the ID of the object. The object will be logged or unlogged depending on the value of `a_sf_persistence`, which must be `LOGGED` or `UNLOGGED`, and the `a_sf_json_options` argument must contain JSON with options. The `a_sf_tablespace` argument allows you to specify the tablespace where the `sfile` object will be stored, otherwise, the default tablespace is used.

`sf_export(a_sf sfile, a_file text)` returns `void`

Dumps the `a_sf` `sfile` object to a file named `a_file`.

`sf_describe(a_sf sfile)` returns `cstring`

Retrieves the `sfile` object descriptor data and returns it as text.

`sf_get_json_options(a_sf sfile)` returns `cstring`

Retrieves JSON with options provided when the `sfile` object was created (see `sf_create`).

`sf_find(a_sf_name text)` returns `sfile`

`sf_find(a_sf_id bigint)` returns `sfile`

Searches the `sfile` object by the specified name or by the specified unique ID of the `bigint` type and returns the `sfile` object ID. See also [Example F.8](#) for more information.

`sf_set_option(a_opt_name text, [a_opt_value text, a_opt_type text])` returns `void`

Sets the option (pgpro\_sfile setting) specified by the `a_opt_name` argument in `SF_OPTION`. The only argument values that are currently supported are `TABLESPACE` for `a_opt_name` and `GLOBAL` for `a_opt_type`. The default for `a_opt_value` is `NULL`, and the default for `a_opt_type` is `GLOBAL`. The pgpro\_sfile behavior with the `TABLESPACE` option, is to check whether the specified tablespace exists and if it does not, raise an error.

`sf_get_option(a_opt_name text)` returns `cstring`

Retrieves the option (pgpro\_sfile setting) with the specified name from `SF_OPTION`.

`sf_delete_option(a_opt_name text)` returns `void`

Deletes the option (pgpro\_sfile setting) with the specified name from `SF_OPTION`.

`sf_is_valid(a_sf sfile)` returns `bool`

Returns `TRUE` if the argument specifies a valid `sfile` object and `FALSE` otherwise.

`sf_is_empty(a_sf sfile)` returns `bool`

Returns `TRUE` if the argument specifies a valid and empty `sfile` object and `FALSE` otherwise.

`sf_is_logged(a_sf sfile)` returns `bool`

Returns `TRUE` if the argument specifies a logged (permanent) `sfile` object and `FALSE` otherwise.

`sf_trim(a_sf sfile, a_length bigint)` returns `bigint`

Trims the `sfile` object specified by the `a_sf` argument to the size specified by the `a_length` argument. The trimmed data is deleted. Returns the new object size. If the `sfile` object size is less than `a_length`, returns the actual object size.

`sf_set_type(a_sf sfile, a_type text)` returns `void`

Sets the custom type specified in the `a_type` argument to the `sfile` object specified by `a_sf`.

`sf_get_type(a_sf sfile)` returns `cstring`

Retrieves the custom object type of the specified `sfile` object as text.

`sf_md5(a_sf sfile)` returns `text`

Calculates MD5 hash for the specified `sfile` object.

## F.56.4. Client Functions

In addition to server functions for export and import of `sfile` objects, `pgpro_sfile` provides client functions for that. The differences between server-side and client-side functions for export and import are the same as described for large objects (see [Section 36.4](#)). The client functions are implemented as the following `psql` meta-commands:

`\sf_export sf_id filename`

Reads the `sfile` object specified by `sf_id` from the database, writes it to `filename`, and returns the size of the written data, in bytes.

Note that this is subtly different from the server function `sf_export`, which acts with the permissions of the user that the database server runs as and on the server's file system.

`\sf_import filename sf_id`

Stores the `filename` file into the `sfile` object specified by `sf_id` and returns the size of the stored data, in bytes.

Note that this command is subtly different from the server-side `sf_import` because it acts as the local user on the local file system, rather than the server's user and file system.

`\sf_delete sf_id`

Deletes the `sfile` object specified by `sf_id` from the database and returns the size of the deleted object.

## F.56.5. Parallel Processing

To speed up interactions with large objects, read functions `sf_read/sf_size` and write function the `sf_write` can be performed in parallel. These functions take an `AccessShareLock` lock for the `sfile` object, which does not forbid reading the object. Each of `sf_read/sf_size` functions releases this lock right after execution of the operation, while `sf_write` holds the lock up to the end of the transaction to prevent deletion/truncation/trimming of the `sfile` object before the end of the transaction. In more detail, the changes made by `sf_write` to the `SF_BLOCK` and `SF_PAGE_XX` tables are not visible to a parallel session, and if the `AccessShareLock` lock is removed before the end of the transaction, the `sfile` object can be deleted by another session, which is unaware of the rows added to `SF_BLOCK` and `SF_PAGE_XX`. As a result, the `sfile` object will be deleted while these rows will remain intact.

While writing, blocks of one object can be written from several sessions, and the block write sequence depends on the time of the `sf_write` call. To control the block write sequence, pass the `a_sf_index` argument. If it is not passed, the call timestamp is used instead, which is the default. Each call to `sf_write` takes an `AccessExclusiveLock` for partitions where blocks are written, which means that it is not permitted to write blocks in the same partition from different sessions as it is not possible to simultaneously modify the `part_data_size` field of the `SF_PARTITION` table. However, writing `sfile` object blocks from several sessions into different partitions is permitted.

`sf_trim`, `sf_truncate` and `sf_delete` functions cannot be performed in parallel as they take an `AccessExclusiveLock` for the `sfile` object.

## F.56.6. Examples

### Example F.7. Basic Usage of pgpro\_sfile

```
-- Create pgpro_sfile extension
CREATE EXTENSION pgpro_sfile;

-- Initialize sfile object storage
SELECT sf_initialize();

-- Create test table
CREATE TABLE test_sfile (id int, l sfile);

-- Create and store sfile object
INSERT INTO test_sfile VALUES (1, sf_create('sf', 'LOGGED', NULL));

-- Write data to sfile object and check data written
SELECT sf_write(t.l, '1234567890'::bytea) FROM test_sfile t WHERE id = 1;
SELECT encode(b, 'escape'), length(b) FROM (SELECT sf_read(t.l, 0, NULL) b FROM
test_sfile t WHERE id = 1) x;

-- Trim sfile object and check data
SELECT sf_trim(t.l, 5) FROM test_sfile t WHERE id = 1;
SELECT encode(b, 'escape'), length(b) FROM (SELECT sf_read(t.l, 0, NULL) b FROM
test_sfile t WHERE id = 1) x;

-- Remove table
DROP TABLE test_sfile;

-- Delete data of all sfile objects
SET client_min_messages = WARNING;
SELECT sf_deinitialize();
RESET client_min_messages;

-- Delete pgpro_sfile extension
DROP EXTENSION pgpro_sfile;
```

This example produces the following output:

```
CREATE EXTENSION
sf_initialize

```

```
(1 row)
```

```
CREATE TABLE
INSERT 0 1
sf_write

```

```
10
(1 row)
```

```
 encode | length
-----+-----
1234567890 | 10
(1 row)
```

```
sf_trim

 5
(1 row)

encode | length
-----+-----
12345 | 5
(1 row)
```

```
DROP TABLE
SET
 sf_deinitialize

(1 row)
```

#### Example F.8. Usage of Type Cast Instead of `sf_find`

```
-- Create pgpro_sfile extension
CREATE EXTENSION pgpro_sfile;

-- Initialize sfile object storage
SELECT sf_initialize();

-- Create sfile object
SELECT sf_create('test', 'LOGGED', NULL);

-- Write to sfile using sfile name
SELECT sf_write(sf_find('test'), '1234567890'::bytea);

-- Write to sfile using sfile identifier
SELECT sf_write(1::bigint::sfile, '1234567890'::bytea);
```

This example produces the following output:

```
CREATE EXTENSION
 sf_initialize

(1 row)
sf_create

 1
(1 row)
sf_write

 10
(1 row)
sf_write

 10
(1 row)
```

## F.56.7. Authors

Postgres Professional, Moscow, Russia

## F.57. pgpro\_usage — per-user statistics on relations and functions

The `pgpro_usage` extension provides per-user statistics on accessing relations and calling functions.

### Note

If the server is shut down, the statistics collected by `pgpro_usage` are stored in the `$PGDATA/pg_stat/pgpro_usage.stat` file. To retain these statistics when switching to a standby, you need to manually copy this file from the former primary or restore it from a backup.

### F.57.1. Installing the `pgpro_usage` Extension

The `pgpro_usage` extension is a built-in extension included into Postgres Pro Enterprise. To enable `pgpro_usage`, complete the following steps:

1. Add `pgpro_usage` to the `shared_preload_libraries` variable in the `postgresql.conf` file:

```
shared_preload_libraries = 'pgpro_usage'
```

2. Restart the database server for the changes to take effect. To verify that the `pgpro_usage` library was installed correctly, you can run the following command:

```
SHOW shared_preload_libraries;
```

3. Create the `pgpro_usage` extension using the following query:

```
CREATE EXTENSION pgpro_usage;
```

### F.57.2. Uninstalling the `pgpro_usage` Extension

To properly uninstall `pgpro_usage`, complete the following steps:

1. Delete the `pgpro_usage` extension using the following query:

```
DROP EXTENSION pgpro_usage;
```

2. Remove `pgpro_usage` from the `shared_preload_libraries` variable in the `postgresql.conf` file.

### F.57.3. Functions

To collect per-user statistics on accessing relations and calling functions, `pgpro_usage` provides an SQL interface that consists of several functions and views.

#### F.57.3.1. Functions to Collect Per-user Statistics on Relations

`pg_stat_get_read_req_per_user(targetoid oid, roleoid oid) → BIGINT`

Returns the number of requests from a user/role specified by `roleoid` to read a table or index specified by `targetoid`.

`pg_stat_get_insert_req_per_user(targetoid oid, roleoid oid) → BIGINT`

Returns the number of requests from a user/role specified by `roleoid` to insert data in a table specified by `targetoid`.

`pg_stat_get_update_req_per_user(targetoid oid, roleoid oid) → BIGINT`

Returns the number of requests from a user/role specified by `roleoid` to update data in a table specified by `targetoid`.

`pg_stat_get_delete_req_per_user(targetoid oid, roleoid oid) → BIGINT`

Returns the number of requests from a user/role specified by `roleoid` to delete data from a table specified by `targetoid`.

`pg_stat_get_truncate_req_per_user(targetoid oid, roleoid oid) → BIGINT`

Returns the number of requests from a user/role specified by *roleoid* to truncate a table specified by *targetoid*.

`pg_stat_get_grants_given_per_user(targetoid oid, roleoid oid) → BIGINT`

Returns the number of GRANT and REVOKE commands executed by a user/role specified by *roleoid* for the table specified by the *targetoid*.

`pg_stat_get_last_read_per_user(targetoid oid, roleoid oid) → timestamp with timezone`

Returns the date and time when a user/role specified by *roleoid* last executed SELECT from a table specified by *targetoid*.

`pg_stat_get_last_insert_per_user(targetoid oid, roleoid oid) → timestamp with timezone`

Returns the date and time when a user/role specified by *roleoid* last executed INSERT into a table specified by *targetoid*.

`pg_stat_get_last_update_per_user(targetoid oid, roleoid oid) → timestamp with timezone`

Returns the date and time when a user/role specified by *roleoid* last executed UPDATE of a table specified by *targetoid*.

`pg_stat_get_last_delete_per_user(targetoid oid, roleoid oid) → timestamp with timezone`

Returns the date and time when a user/role specified by *roleoid* last executed DELETE from a table specified by *targetoid*.

`pg_stat_get_last_truncate_per_user(targetoid oid, roleoid oid) → timestamp with timezone`

Returns the date and time when a user/role specified by *roleoid* last executed TRUNCATE of a table specified by *targetoid*.

### F.57.3.2. Functions to Collect Per-user Statistics on Functions

`pg_stat_get_func_calls_per_user(targetoid oid, roleoid oid) → BIGINT`

Returns the number of times the function specified by *targetoid* has been called by the user/role specified by *roleoid*.

`pg_stat_get_func_grants_given_per_user(targetoid oid, roleoid oid) → BIGINT`

Returns the number of GRANT and REVOKE commands executed by a user/role specified by *roleoid* for the function specified by the *targetoid*.

### F.57.3.3. Support Functions

`pgpro_usage_reset(full_reset bool default false) → void`

Resets the pgpro\_usage statistics. If *full\_reset* is true, all the statistics gets reset. If *full\_reset* is false, last-use statistics on tables remain intact.

`pgpro_usage_get_last_reset_time() → timestamp with time zone`

Time at which pgpro\_usage statistics were last reset.

## F.57.4. Views

### F.57.4.1. pg\_stat\_all\_tables\_per\_user View

The `pg_stat_all_tables_per_user` view will contain one row for each user/role and each table in the current database (including TOAST tables), showing statistics about different kinds of requests for that specific table from that user.

Table F.38. `pg_stat_all_tables_per_user` Columns

| Column Type | Description |
|-------------|-------------|
| userid oid  |             |

| Column Type        | Description                                                                   |
|--------------------|-------------------------------------------------------------------------------|
| OID                | OID of a user/role                                                            |
| username name      | Name of the user/role                                                         |
| relid oid          | OID of a table                                                                |
| nspname name       | Name of the schema that this table is in                                      |
| relname name       | Name of this table                                                            |
| n_reads bigint     | Number of requests from this user/role to read this table                     |
| n_inserts INT      | Number of requests from this user/role to insert data in this table           |
| n_updates INT      | Number of requests from this user/role to update data in this table           |
| n_deletes INT      | Number of requests from this user/role to delete data from this table         |
| n_truncates INT    | Number of requests from this user/role to truncate this table                 |
| n_grants_given INT | Number of GRANT and REVOKE commands executed by this user/role for this table |

#### F.57.4.2. `pg_stat_all_tables_last_usage` View

The `pg_stat_all_tables_last_usage` view will contain one row for each user/role and each table in the current database (including TOAST tables), showing the last date and time when that user executed different operations on that specific table.

**Table F.39. `pg_stat_all_tables_last_usage` Columns**

| Column Type                         | Description                                                          |
|-------------------------------------|----------------------------------------------------------------------|
| userid oid                          | OID of a user/role                                                   |
| username name                       | Name of the user/role                                                |
| nspname name                        | Name of the namespace                                                |
| relid oid                           | OID of a table                                                       |
| relname name                        | Name of this table                                                   |
| last_read timestamp with timezone   | Date and time when this user/role last read this table               |
| last_insert timestamp with timezone | Date and time when this user/role last inserted data into this table |
| last_update timestamp with timezone | Date and time when this user/role last updated this table            |
| last_delete timestamp with timezone | Date and time when this user/role last deleted data from this table  |

| Column Type                | Description                                                                                         |
|----------------------------|-----------------------------------------------------------------------------------------------------|
| <code>last_truncate</code> | <code>timestamp with timezone</code><br>Date and time when this user/role last truncated this table |

#### F.57.4.3. `pg_stat_all_functions_per_user` View

The `pg_stat_all_functions_per_user` view will contain one row for each user/role and each user function, stored procedure, or system function in the current database, showing statistics about function calls and grants given by that user.

**Table F.40. `pg_stat_all_functions_per_user` Columns**

| Column Type               | Description                                                                                          |
|---------------------------|------------------------------------------------------------------------------------------------------|
| <code>userid</code>       | <code>oid</code><br>OID of a user/role                                                               |
| <code>username</code>     | <code>name</code><br>Name of the user/role                                                           |
| <code>funcid</code>       | <code>oid</code><br>OID of a function                                                                |
| <code>nspname</code>      | <code>name</code><br>Name of the schema the function is in                                           |
| <code>funcname</code>     | <code>name</code><br>Name of this function                                                           |
| <code>calls</code>        | <code>INT</code><br>Number of times this function has been called by this user/role                  |
| <code>grants_given</code> | <code>INT</code><br>Number of GRANT and REVOKE commands executed by this user/role for this function |

#### F.57.4.4. `pgpro_usage_stats_privileges_usage` View

The `pgpro_usage_stats_privileges_usage` view will contain one row for each role, each privilege, and each object (table or function) for which this role has this privilege. This row will show how this privilege has been given and whether it is used.

**Table F.41. `pgpro_usage_stats_privileges_usage` Columns**

| Column Type             | Description                                                                                                                                                                          |
|-------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>username</code>   | <code>name</code><br>Name of a user                                                                                                                                                  |
| <code>access</code>     | <code>text</code><br>Type of a privilege: SELECT, INSERT, UPDATE, DELETE, or TRUNCATE for a table and EXECUTE for a function                                                         |
| <code>nspname</code>    | <code>name</code><br>Name of the schema an object (table or function) is in                                                                                                          |
| <code>targetname</code> | <code>name</code><br>Name of this object (table or function)                                                                                                                         |
| <code>provider</code>   | <code>name</code><br>Name of the role through membership in which this role got this privilege                                                                                       |

## F.57.5. Configuration Parameters

`pgpro_usage.max` (integer)

Defines the maximum number of pairs (object, user) for the statistics to store, where the object is a table or a function/procedure. Can be reduced to save the memory or increased for huge databases. If `pgpro_usage` needs to exceed this value when writing statistics, the new record is not created, and the “WARNING: max number of `pgpro_usage` records exceeded” warning is displayed.

The default value is 10000.

## F.57.6. Example

This example illustrates usage of the `pgpro_usage` extension.

First we create the extension:

```
postgres=# create extension pgpro_usage;
CREATE EXTENSION
```

Now let's try out the usage statistics. To do this, we create a user, table, and procedure and give the user access to the table:

```
postgres=# CREATE USER u1;
CREATE ROLE
postgres=# CREATE TABLE t1(val int);
CREATE TABLE
postgres=# GRANT all on t1 to u1;
GRANT
postgres=# CREATE PROCEDURE p1() AS $$ BEGIN RAISE NOTICE 'Here we are'; END; $$
LANGUAGE plpgsql;
CREATE PROCEDURE
```

Let's output all the usage statistics for all tables:

```
postgres=# SELECT * FROM pg_stat_all_tables_per_user;
userid | username | relid | nspname | relname | n_reads | n_inserts | n_updates |
n_deletes | n_truncates | n_grants_given
-----+-----+-----+-----+-----+-----+-----+-----+-----+
10 | postgres | 16445 | public | t1 | 0 | 0 | 0 |
0 | 0 | 1
(1 row)
```

Do so for all functions:

```
postgres=# SELECT * FROM pg_stat_all_functions_per_user;
userid | username | funcid | nspname | funcname | calls
| grants_given
-----+-----+-----+-----+-----+-----+
10 | postgres | 16385 | public | pgpro_usage_reset | 0
| 1
10 | postgres | 16386 | public | pgpro_usage | 0
| 1
10 | postgres | 16387 | public | pgpro_usage_full | 0
| 1
10 | postgres | 16397 | public | pg_stat_get_func_calls_per_user | 2
| 0
10 | postgres | 16398 | public | pg_stat_get_func_grants_given_per_user | 1
| 0
```

Additional Supplied Modules and  
Extensions Shipped in post-  
grespro-ent-17-contrib

|    |          |       |        |                                   |   |
|----|----------|-------|--------|-----------------------------------|---|
| 10 | postgres | 16399 | public | pg_stat_get_read_req_per_user     | 1 |
| 0  |          |       |        |                                   |   |
| 10 | postgres | 16400 | public | pg_stat_get_insert_req_per_user   | 1 |
| 0  |          |       |        |                                   |   |
| 10 | postgres | 16401 | public | pg_stat_get_update_req_per_user   | 1 |
| 0  |          |       |        |                                   |   |
| 10 | postgres | 16402 | public | pg_stat_get_delete_req_per_user   | 1 |
| 0  |          |       |        |                                   |   |
| 10 | postgres | 16403 | public | pg_stat_get_truncate_req_per_user | 1 |
| 0  |          |       |        |                                   |   |
| 10 | postgres | 16404 | public | pg_stat_get_grants_given_per_user | 1 |
| 0  |          |       |        |                                   |   |

(11 rows)

In the above output, you can only see superuser operations, who once granted access on a table and several times called the extension functions when querying the above views. The `grants_given` column is non-zero in three rows. They correspond to revoking permissions from `public` during creation of the extension. The newly created user is not included in the statistics since he did nothing.

Let's fill this gap and connect to the database as the `u1` user.

```
postgres=# \c - u1
You are now connected to database "postgres" as user "u1".
postgres=> insert into t1(val) values (1);
INSERT 0 1
postgres=> insert into t1(val) values (2);
INSERT 0 1
postgres=> select * from t1;
 val

 1
 2
(2 rows)
postgres=> call p1();
NOTICE: Here we are
CALL
```

We did two inserts in the table, queried it once, and once called the procedure. Let's switch back to the superuser and look at the statistics again:

```
postgres=> \c - postgres
You are now connected to database "postgres" as user "postgres".
postgres=# SELECT * FROM pg_stat_all_tables_per_user;
 userid | username | relid | nspname | relname | n_reads | n_inserts | n_updates | n_deletes | n_truncates | n_grants_given
-----+-----+-----+-----+-----+-----+-----+-----+-----+-----+-----
 16444 | u1 | 16445 | public | t1 | 1 | 2 | 0 | 0 | 0 | 0
 0 | | 0 | | | 0 | 0 | 0 | 0 | 0 | 0
 10 | postgres | 16445 | public | t1 | 0 | 0 | 0 | 0 | 0 | 1
 0 | | 0 | | | 0 | 0 | 0 | 0 | 0 | 1
(2 rows)
postgres=# SELECT * FROM pg_stat_all_functions_per_user;
 userid | username | funcid | nspname | funcname | calls
-----+-----+-----+-----+-----+-----
 10 | postgres | 16385 | public | pgpro_usage_reset | 0
 1 | | 1 | | | 0
 10 | postgres | 16386 | public | pgpro_usage | 0
 1 | | 1 | | | 0
```

Additional Supplied Modules and  
Extensions Shipped in post-  
grespro-ent-17-contrib

|       |          |       |        |                                        |   |
|-------|----------|-------|--------|----------------------------------------|---|
| 10    | postgres | 16387 | public | pgpro_usage_full                       | 0 |
| 10    | postgres | 16397 | public | pg_stat_get_func_calls_per_user        | 4 |
| 10    | postgres | 16398 | public | pg_stat_get_func_grants_given_per_user | 2 |
| 10    | postgres | 16399 | public | pg_stat_get_read_req_per_user          | 2 |
| 10    | postgres | 16400 | public | pg_stat_get_insert_req_per_user        | 2 |
| 10    | postgres | 16401 | public | pg_stat_get_update_req_per_user        | 2 |
| 10    | postgres | 16402 | public | pg_stat_get_delete_req_per_user        | 2 |
| 10    | postgres | 16403 | public | pg_stat_get_truncate_req_per_user      | 2 |
| 10    | postgres | 16404 | public | pg_stat_get_grants_given_per_user      | 2 |
| 16444 | u1       | 16448 | public | p1                                     | 1 |

(12 rows)

Both tables now include rows corresponding to the operations of the u1 user: two inserts and a read of the table and one execution of the procedure.

Now let's look at the last-use statistics. We will be able to see timestamps showing when the user performed the inserts and the read.

```
postgres=# select * from pg_stat_all_tables_last_usage;
userid | username | nspname | relid | relname | last_read | last_insert | last_update | last_delete | last_truncate
-----+-----+-----+-----+-----+-----+-----+-----+-----+-----
16444 | u1 | public | 16445 | t1 | 2024-11-30 01:06:24.578642+03 | 2024-11-30 01:06:17.03442+03 | | |
(1 row)
```

Let's extend this statistics with a read by a superuser:

```
postgres=# select * from t1;
val

1
2
(2 rows)

postgres=# select * from pg_stat_all_tables_last_usage;
userid | username | nspname | relid | relname | last_read | last_insert | last_update | last_delete | last_truncate
-----+-----+-----+-----+-----+-----+-----+-----+-----+-----
10 | postgres | public | 16445 | t1 | 2024-11-30 01:09:29.994188+03 | | | |
16444 | u1 | public | 16445 | t1 | 2024-11-30 01:06:24.578642+03 | 2024-11-30 01:06:17.03442+03 | | |
(2 rows)
```

Let's make sure that the last\_read timestamp gets updated:

```
postgres=# select * from t1;
val

1
```

2

```
(2 rows)
postgres=# select * from pg_stat_all_tables_last_usage;
 userid | username | nspname | relid | relname | last_read |
 last_insert | last_update | last_delete | last_truncate
-----+-----+-----+-----+-----+-----+-----
10 | postgres | public | 16445 | t1 | 2024-11-30 01:10:28.122489+03 |
16444 | u1 | public | 16445 | t1 | 2024-11-30 01:06:24.578642+03 |
2024-11-30 01:06:17.03442+03 |
(2 rows)
```

Now let's consider the statistics on unused privileges. Since there can be quite a lot of objects, users, and privileges, let's put everything related to this example in a separate schema to make it easier to filter the future result. We create a schema and a table in it, grant access on the table to a certain group role, and grant membership in this group role to a specific user:

```
postgres=# create schema shops;
CREATE SCHEMA
postgres=# create table shops.buildings();
CREATE TABLE
postgres=# create role manager;
CREATE ROLE
postgres=# grant all on schema shops to manager;
GRANT
postgres=# grant all on shops.buildings to manager;
GRANT
postgres=# create user vasya;
CREATE ROLE
postgres=# grant manager to vasya;
GRANT ROLE
```

Let's connect to the database as this user and query the table:

```
postgres=# \c - vasya
You are now connected to database "postgres" as user "vasya".
postgres=> select * from shops.buildings;
--
(0 rows)
```

Now let's switch to the superuser and look at the statistics on privileges:

```
postgres=> \c - postgres
You are now connected to database "postgres" as user "postgres".
postgres=# select * from pgpro_usage_stats_privileges_usage where username='vasya' and
 nspname='shops';
 username | access | nspname | targetname | provider | grantee | kind | used
-----+-----+-----+-----+-----+-----+-----+-----
 vasya | INSERT | shops | buildings | manager | manager | RELATION | f
 vasya | SELECT | shops | buildings | manager | manager | RELATION | t
 vasya | UPDATE | shops | buildings | manager | manager | RELATION | f
 vasya | DELETE | shops | buildings | manager | manager | RELATION | f
 vasya | TRUNCATE | shops | buildings | manager | manager | RELATION | f
(5 rows)
```

These statistics show that the user `vasya` has full access to the `shops.buildings` table, and he got all the access privileges indirectly, as a member of the `manager` role. It is also clear that among the privileges, `vasya` only used `SELECT`. Note also that the statistics on privileges do not show superuser privileges: evidently, superuser has full access.

## F.58. `pg_query_state` — a facility to know the current state of query execution on working backend

The `pg_query_state` module provides facility to know the current state of query execution on working backend.

### F.58.1. Overview

Each non-utility query statement (`SELECT/INSERT/UPDATE/DELETE`) after optimization/planning stage is translated into plan tree, which is kind of imperative representation of declarative SQL query. `EXPLAIN ANALYZE` request allows to demonstrate execution statistics gathered from each node of plan tree (full time of execution, number of rows emitted to upper nodes, etc). But this statistics is collected after execution of query. This module allows to show actual statistics of query running on external backend. At that, format of resulting output is almost identical to ordinal `EXPLAIN ANALYZE`. Thus users are able to track of query execution in progress. In fact, this module is able to explore external backend and determine its actual state. Particularly it's helpful when backend executes a heavy query or gets stuck.

### F.58.2. Use cases

Using this module there can help in the following things:

- detect a long query (along with other monitoring tools);
- supervise query execution.

### F.58.3. Installation

To install `pg_query_state`, complete the following steps:

1. Add the library name to the `shared_preload_libraries` parameter in the `postgresql.conf` file as follows:

```
shared_preload_libraries = 'pg_query_state'
```

2. Reload the database server for the changes to take effect.
3. Create the `pg_query_state` extension using the following query:

```
CREATE EXTENSION pg_query_state;
```

4. If you need to upgrade the `pg_query_state` extension, use [ALTER EXTENSION UPDATE](#).

### F.58.4. Functions

#### F.58.4.1. `pg_query_state`

```
pg_query_state (integer pid,
 verbose boolean DEFAULT FALSE,
 costs boolean DEFAULT FALSE,
 timing boolean DEFAULT FALSE,
 buffers boolean DEFAULT FALSE,
 triggers boolean DEFAULT FALSE,
 format text DEFAULT 'text')
returns TABLE (pid integer,
 frame_number integer,
 query_text text,
 plan text,
 leader_pid integer)
```

Extract current query state from backend with specified `pid`. Since parallel query can spawn multiple workers and function call causes nested subqueries so that state of execution may be viewed as stack of running queries, return value of `pg_query_state` has type `TABLE (pid integer, frame_number integer, query_text text, plan text, leader_pid integer)`. It represents tree structure consisting of leader process and its spawned workers identified by `pid`. Each worker refers to leader through `leader_pid` column. For leader process the value of this column is `null`. The state of each process is represented as stack of function calls. Each frame of that stack is specified as correspondence between `frame_number` starting from zero, `query_text` and `plan` with online statistics columns.

Thus, user can see the states of main query and queries generated from function calls for leader process and all workers spawned from it.

In process of execution some nodes of plan tree can take loops of full execution. Therefore statistics for each node consists of two parts: average statistics for previous loops just like in EXPLAIN ANALYZE output and statistics for current loop if node have not finished.

Optional arguments:

- `verbose` - use EXPLAIN VERBOSE for plan printing;
- `costs` - costs for each node;
- `timing` - print timing data for each node, if collecting of timing statistics is turned off on called side resulting output will contain WARNING message `timing statistics disabled`;
- `buffers` - print buffers usage, if collecting of buffers statistics is turned off on called side resulting output will contain WARNING message `buffers statistics disabled`;
- `triggers` - include triggers statistics in result plan trees;
- `format` - EXPLAIN format to be used for plans printing, possible values: `text`, `xml`, `json`, `yaml`.

If callable backend is not executing any query the function prints INFO message about backend's state taken from `pg_stat_activity` view if it exists there.

Calling role have to be superuser or member of the role whose backend is being called. Otherwise function prints ERROR message `permission denied`.

#### F.58.4.2. `pg_progress_bar`

`pg_progress_bar` (integer pid)  
returns FLOAT

Returns the current progress of query execution. This function extracts the state of the current query from the backend process with the specified `pid`. Then, it collects the actual and expected row counts from all plan nodes, and computes the overall progress ratio for the entire execution tree. As a result, the function returns a numeric value from 0 to 1 that means the query execution progress.

This function can be used in the Postgres Pro GUI to display the graphical progress bar indicator.

If there is no information about the current query state or it is impossible to calculate the query execution progress, the corresponding message is displayed.

This function can be called only by members of the role that owns the backend process or superusers.

#### F.58.4.3. `pg_progress_bar_visual`

`pg_progress_bar_visual` (integer pid,  
integer delay)  
returns VOID

Cyclically calculates the current progress of query execution and prints it in the text form. The function extracts the state of the current query from the backend process with the specified `pid` with the interval defined in the `delay` parameter (in seconds).

This function is a cyclic version of the `pg_progress_bar` function but returns `void`. Unlike `pg_progress_bar`, the `pg_progress_bar_visual` function can be used to track the query execution progress without using the GUI.

If there is no information about the current query state or it is impossible to calculate the query execution progress, the corresponding message is displayed.

This function can be called only by members of the role that owns the backend process or superusers.

### F.58.5. Configuration settings

There are several user-accessible GUC variables designed to toggle the whole module and the collecting of specific statistic parameters while query is running:

- `pg_query_state.enable` - disable (or enable) `pg_query_state` completely, default value is `true`
- `pg_query_state.enable_timing` - collect timing data for each node, default value is `false`
- `pg_query_state.enable_buffers` - collect buffers usage, default value is `false`

These parameters are set on called side before running any queries whose states are attempted to extract. **WARNING:** if `pg_query_state.enable_timing` is turned off the calling side cannot get time statistics, similarly for `pg_query_state.enable_buffers` parameter.

## F.58.6. Usage Examples

Set maximum number of parallel workers on `gather` node equals 2:

```
postgres=# set max_parallel_workers_per_gather = 2;
```

Assume one backend with `pid = 49265` performs a simple query:

```
postgres=# select pg_backend_pid();
pg_backend_pid

 49265
(1 row)
postgres=# select count(*) from foo join bar on foo.c1=bar.c1;
```

Other backend can extract intermediate state of execution that query:

```
postgres=# \x
postgres=# select * from pg_query_state(49265);
-[RECORD
 1]+-----
pid | 49265
frame_number | 0
query_text | select count(*) from foo join bar on foo.c1=bar.c1;
plan | Finalize Aggregate (Current loop: actual rows=0, loop number=1)
 |
 | -> Gather (Current loop: actual rows=0, loop number=1)
 |
 | Workers Planned: 2
 |
 | Workers Launched: 2
 |
 | -> Partial Aggregate (Current loop: actual rows=0, loop
number=1) |
 | -> Nested Loop (Current loop: actual rows=12, loop
number=1) |
 | Join Filter: (foo.c1 = bar.c1)
 |
 | Rows Removed by Join Filter: 5673232
 |
 | -> Parallel Seq Scan on foo (Current loop: actual
rows=12, loop number=1)
 |
 | -> Seq Scan on bar (actual rows=500000 loops=11)
 | (Current loop: actual rows=173244, loop number=12)
leader_pid | (null)
-[RECORD
 2]+-----
pid | 49324
frame_number | 0
query_text | <parallel query>
plan | Partial Aggregate (Current loop: actual rows=0, loop number=1)
 |
 | -> Nested Loop (Current loop: actual rows=10, loop number=1)
 |
 | Join Filter: (foo.c1 = bar.c1)
```

Additional Supplied Modules and  
Extensions Shipped in post-  
grespro-ent-17-contrib

```

| Rows Removed by Join Filter: 4896779
|
| +
| -> Parallel Seq Scan on foo (Current loop: actual rows=10, loop
number=1)
| +
| -> Seq Scan on bar (actual rows=500000 loops=9) (Current loop:
actual rows=396789, loop number=10)
leader_pid | 49265
-[RECORD
3]+-----
pid | 49323
frame_number | 0
query_text | <parallel query>
plan | Partial Aggregate (Current loop: actual rows=0, loop number=1)
| +
| -> Nested Loop (Current loop: actual rows=11, loop number=1)
| +
| Join Filter: (foo.c1 = bar.c1)
| +
| Rows Removed by Join Filter: 5268783
| +
| -> Parallel Seq Scan on foo (Current loop: actual rows=11, loop
number=1)
| +
| -> Seq Scan on bar (actual rows=500000 loops=10) (Current loop:
actual rows=268794, loop number=11)
leader_pid | 49265

```

In example above working backend spawns two parallel workers with pids 49324 and 49323. Their leader\_pid column's values clarify that these workers belong to the main backend. Seq Scan node has statistics on passed loops (average number of rows delivered to Nested Loop and number of passed loops are shown) and statistics on current loop. Other nodes has statistics only for current loop as this loop is first (loop number = 1).

Assume first backend executes some function:

```
postgres=# select n_join_foo_bar();
```

Other backend can get the follow output:

```

postgres=# select * from pg_query_state(49265);
-[RECORD
1]+-----
pid | 49265
frame_number | 0
query_text | select n_join_foo_bar();
plan | Result (Current loop: actual rows=0, loop number=1)
leader_pid | (null)
-[RECORD
2]+-----
pid | 49265
frame_number | 1
query_text | SELECT (select count(*) from foo join bar on foo.c1=bar.c1)
plan | Result (Current loop: actual rows=0, loop number=1)
| +
| InitPlan 1 (returns $0)
| +
| -> Aggregate (Current loop: actual rows=0, loop number=1)
| +
| -> Nested Loop (Current loop: actual rows=51, loop number=1)
| +

```

|                                            |  |                                                        |  |
|--------------------------------------------|--|--------------------------------------------------------|--|
|                                            |  | Join Filter: (foo.c1 = bar.c1)                         |  |
|                                            |  | +                                                      |  |
|                                            |  | Rows Removed by Join Filter: 51636304                  |  |
|                                            |  | +                                                      |  |
| number=1)                                  |  | -> Seq Scan on bar (Current loop: actual rows=52, loop |  |
|                                            |  | +                                                      |  |
| loop: actual rows=636355, loop number=52)+ |  | -> Materialize (actual rows=1000000 loops=51) (Current |  |
|                                            |  | -> Seq Scan on foo (Current loop: actual               |  |
| rows=1000000, loop number=1)               |  |                                                        |  |
| leader_pid                                 |  | (null)                                                 |  |

First row corresponds to function call, second - to query which is in the body of that function.

We can get result plans in different format (e.g. json):

```
postgres=# select * from pg_query_state(pid := 49265, format := 'json');
-[RECORD 1]+-----
pid | 49265
frame_number | 0
query_text | select * from n_join_foo_bar();
plan | {
 | "Plan": {
 | "Node Type": "Function Scan",
 | "Parallel Aware": false,
 | "Function Name": "n_join_foo_bar",
 | "Alias": "n_join_foo_bar",
 | "Current loop": {
 | "Actual Loop Number": 1,
 | "Actual Rows": 0
 | }
 | }
 | }
leader_pid | (null)
-[RECORD 2]+-----
pid | 49265
frame_number | 1
query_text | SELECT (select count(*) from foo join bar on foo.c1=bar.c1)
plan | {
 | "Plan": {
 | "Node Type": "Result",
 | "Parallel Aware": false,
 | "Current loop": {
 | "Actual Loop Number": 1,
 | "Actual Rows": 0
 | },
 | },
 | "Plans": [
 | {
 | "Node Type": "Aggregate",
 | "Strategy": "Plain",
 | "Partial Mode": "Simple",
 | "Parent Relationship": "InitPlan",
 | "Subplan Name": "InitPlan 1 (returns $0)",
 | "Parallel Aware": false,
 | "Current loop": {
 | "Actual Loop Number": 1,
 | "Actual Rows": 0
 | },
 | },
 |]
 | }
```

## F.58.7. Progress Bar Usage Examples

The first backend process executes the following sample query:

```
postgres=# insert into table_name select generate_series(1,10000000);
```

Another backend process can get the execution process of the query above as follows:

```
postgres=# SELECT pid FROM pg_stat_activity where query like 'insert%';
 pid

23877
(1 row)
```

```
postgres=# SELECT pg_progress_bar(23877);
 pg_progress_bar

0.6087927
(1 row)
```

To display a visual representation of the query execution progress, run the following query:

```
postgres=# SELECT pg_progress_bar_visual(23877, 1);
Progress = 0.043510
Progress = 0.085242
Progress = 0.124921
Progress = 0.168168
Progress = 0.213803
Progress = 0.250362
Progress = 0.292632
Progress = 0.331454
Progress = 0.367509
Progress = 0.407450
Progress = 0.448646
Progress = 0.488171
Progress = 0.530559
Progress = 0.565558
Progress = 0.608039
Progress = 0.645778
Progress = 0.654842
Progress = 0.699006
Progress = 0.735760
Progress = 0.787641
Progress = 0.832160
Progress = 0.871077
Progress = 0.911858
Progress = 0.956362
Progress = 0.995097
Progress = 1.000000
 pg_progress_bar_visual

1
(1 row)
```

## F.59. pgrowlocks — show a table's row locking information

The `pgrowlocks` module provides a function to show row locking information for a specified table.

By default use is restricted to superusers, roles with privileges of the `pg_stat_scan_tables` role, and users with `SELECT` permissions on the table.

### F.59.1. Overview

`pgrowlocks(text)` returns setof record

The parameter is the name of a table. The result is a set of records, with one row for each locked row within the table. The output columns are shown in [Table F.42](#).

**Table F.42. `pgrowlocks` Output Columns**

| Name                    | Type                   | Description                                                                                                                                                                                                                               |
|-------------------------|------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>locked_row</code> | <code>tid</code>       | Tuple ID (TID) of locked row                                                                                                                                                                                                              |
| <code>locker</code>     | <code>xid</code>       | Transaction ID of locker, or multixact ID if multitransaction; see <a href="#">Section 67.1</a>                                                                                                                                           |
| <code>multi</code>      | <code>boolean</code>   | True if locker is a multitransaction                                                                                                                                                                                                      |
| <code>xids</code>       | <code>xid[]</code>     | Transaction IDs of lockers (more than one if multitransaction)                                                                                                                                                                            |
| <code>modes</code>      | <code>text[]</code>    | Lock mode of lockers (more than one if multitransaction), an array of <code>For Key Share</code> , <code>For Share</code> , <code>For No Key Update</code> , <code>No Key Update</code> , <code>For Update</code> , <code>Update</code> . |
| <code>pids</code>       | <code>integer[]</code> | Process IDs of locking backends (more than one if multitransaction)                                                                                                                                                                       |

`pgrowlocks` takes `AccessShareLock` for the target table and reads each row one by one to collect the row locking information. This is not very speedy for a large table. Note that:

1. If an `ACCESS EXCLUSIVE` lock is taken on the table, `pgrowlocks` will be blocked.
2. `pgrowlocks` is not guaranteed to produce a self-consistent snapshot. It is possible that a new row lock is taken, or an old lock is freed, during its execution.

`pgrowlocks` does not show the contents of locked rows. If you want to take a look at the row contents at the same time, you could do something like this:

```
SELECT * FROM accounts AS a, pgrowlocks('accounts') AS p
WHERE p.locked_row = a.ctid;
```

Be aware however that such a query will be very inefficient.

### F.59.2. Sample Output

```
=# SELECT * FROM pgrowlocks('t1');
 locked_row | locker | multi | xids | modes | pids
-----+-----+-----+-----+-----+-----
 (0,1) | 609 | f | {609} | {"For Share"} | {3161}
 (0,2) | 609 | f | {609} | {"For Share"} | {3161}
 (0,3) | 607 | f | {607} | {"For Update"} | {3107}
 (0,4) | 607 | f | {607} | {"For Update"} | {3107}
(4 rows)
```

Tatsuo Ishii

## F.60. `pg_stat_statements` — track statistics of SQL planning and execution

The `pg_stat_statements` module provides a means for tracking planning and execution statistics of all SQL statements executed by a server.

The module must be loaded by adding `pg_stat_statements` to `shared_preload_libraries` in `postgresql.conf`, because it requires additional shared memory. This means that a server restart is needed to add or remove the module. In addition, query identifier calculation must be enabled in order for the module to be active, which is done automatically if `compute_query_id` is set to `auto` or `on`, or any third-party module that calculates query identifiers is loaded.

When `pg_stat_statements` is active, it tracks statistics across all databases of the server. To access and manipulate these statistics, the module provides views `pg_stat_statements` and `pg_stat_statements_info`, and the utility functions `pg_stat_statements_reset` and `pg_stat_statements`. These are not available globally but can be enabled for a specific database with `CREATE EXTENSION pg_stat_statements`.

### F.60.1. The `pg_stat_statements` View

The statistics gathered by the module are made available via a view named `pg_stat_statements`. This view contains one row for each distinct combination of database ID, user ID, query ID and whether it's a top-level statement or not (up to the maximum number of distinct statements that the module can track). The columns of the view are shown in [Table F.43](#).

**Table F.43. `pg_stat_statements` Columns**

| Column Type                                                         | Description                                                                                                                                                                                                                                                                                                                                     |
|---------------------------------------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>userid oid</code> (references <a href="#">pg_authid.oid</a> ) | OID of user who executed the statement                                                                                                                                                                                                                                                                                                          |
| <code>dbid oid</code> (references <a href="#">pg_database.oid</a> ) | OID of database in which the statement was executed                                                                                                                                                                                                                                                                                             |
| <code>toplevel bool</code>                                          | True if the query was executed as a top-level statement (always true if <code>pg_stat_statements.track</code> is set to <code>top</code> )                                                                                                                                                                                                      |
| <code>queryid bigint</code>                                         | Hash code to identify identical normalized queries.                                                                                                                                                                                                                                                                                             |
| <code>query text</code>                                             | Text of a representative statement                                                                                                                                                                                                                                                                                                              |
| <code>plans bigint</code>                                           | Number of times the statement was planned (if <code>pg_stat_statements.track_planning</code> is enabled, otherwise zero)                                                                                                                                                                                                                        |
| <code>total_plan_time double precision</code>                       | Total time spent planning the statement, in milliseconds (if <code>pg_stat_statements.track_planning</code> is enabled, otherwise zero)                                                                                                                                                                                                         |
| <code>min_plan_time double precision</code>                         | Minimum time spent planning the statement, in milliseconds. This field will be zero if <code>pg_stat_statements.track_planning</code> is disabled, or if the counter has been reset using the <code>pg_stat_statements_reset</code> function with the <code>minmax_only</code> parameter set to <code>true</code> and never been planned since. |
| <code>max_plan_time double precision</code>                         | Maximum time spent planning the statement, in milliseconds. This field will be zero if <code>pg_stat_statements.track_planning</code> is disabled, or if the counter has been reset using the <code>pg_stat_statements_reset</code> function with the <code>minmax_only</code> parameter set to <code>true</code> and never been planned since. |
| <code>mean_plan_time double precision</code>                        | Mean time spent planning the statement, in milliseconds (if <code>pg_stat_statements.track_planning</code> is enabled, otherwise zero)                                                                                                                                                                                                          |
| <code>stddev_plan_time double precision</code>                      |                                                                                                                                                                                                                                                                                                                                                 |

| Column Type                                         | Description                                                                                                                                                                                                                                                                       |
|-----------------------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|                                                     | Population standard deviation of time spent planning the statement, in milliseconds (if <code>pg_stat_statements.track_planning</code> is enabled, otherwise zero)                                                                                                                |
| <code>calls bigint</code>                           | Number of times the statement was executed                                                                                                                                                                                                                                        |
| <code>total_exec_time double precision</code>       | Total time spent executing the statement, in milliseconds                                                                                                                                                                                                                         |
| <code>min_exec_time double precision</code>         | Minimum time spent executing the statement, in milliseconds, this field will be zero until this statement is executed first time after reset performed by the <code>pg_stat_statements_reset</code> function with the <code>minmax_only</code> parameter set to <code>true</code> |
| <code>max_exec_time double precision</code>         | Maximum time spent executing the statement, in milliseconds, this field will be zero until this statement is executed first time after reset performed by the <code>pg_stat_statements_reset</code> function with the <code>minmax_only</code> parameter set to <code>true</code> |
| <code>mean_exec_time double precision</code>        | Mean time spent executing the statement, in milliseconds                                                                                                                                                                                                                          |
| <code>stddev_exec_time double precision</code>      | Population standard deviation of time spent executing the statement, in milliseconds                                                                                                                                                                                              |
| <code>rows bigint</code>                            | Total number of rows retrieved or affected by the statement                                                                                                                                                                                                                       |
| <code>shared_blks_hit bigint</code>                 | Total number of shared block cache hits by the statement                                                                                                                                                                                                                          |
| <code>shared_blks_read bigint</code>                | Total number of shared blocks read by the statement                                                                                                                                                                                                                               |
| <code>shared_blks_dirtied bigint</code>             | Total number of shared blocks dirtied by the statement                                                                                                                                                                                                                            |
| <code>shared_blks_written bigint</code>             | Total number of shared blocks written by the statement                                                                                                                                                                                                                            |
| <code>local_blks_hit bigint</code>                  | Total number of local block cache hits by the statement                                                                                                                                                                                                                           |
| <code>local_blks_read bigint</code>                 | Total number of local blocks read by the statement                                                                                                                                                                                                                                |
| <code>local_blks_dirtied bigint</code>              | Total number of local blocks dirtied by the statement                                                                                                                                                                                                                             |
| <code>local_blks_written bigint</code>              | Total number of local blocks written by the statement                                                                                                                                                                                                                             |
| <code>temp_blks_read bigint</code>                  | Total number of temp blocks read by the statement                                                                                                                                                                                                                                 |
| <code>temp_blks_written bigint</code>               | Total number of temp blocks written by the statement                                                                                                                                                                                                                              |
| <code>shared_blk_read_time double precision</code>  | Total time the statement spent reading shared blocks, in milliseconds (if <a href="#">track_io_timing</a> is enabled, otherwise zero)                                                                                                                                             |
| <code>shared_blk_write_time double precision</code> | Total time the statement spent writing shared blocks, in milliseconds (if <a href="#">track_io_timing</a> is enabled, otherwise zero)                                                                                                                                             |
| <code>local_blk_read_time double precision</code>   | Total time the statement spent reading local blocks, in milliseconds (if <a href="#">track_io_timing</a> is enabled, otherwise zero)                                                                                                                                              |

| <code>wal_fpi</code> bigint                              | Total number of WAL full page images generated by the statement                                                                                                                                     |
| <code>wal_bytes</code> numeric                           | Total amount of WAL generated by the statement in bytes                                                                                                                                             |
| <code>jit_functions</code> bigint                        | Total number of functions JIT-compiled by the statement                                                                                                                                             |
| <code>jit_generation_time</code> double precision        | Total time spent by the statement on generating JIT code, in milliseconds                                                                                                                           |
| <code>jit_inlining_count</code> bigint                   | Number of times functions have been inlined                                                                                                                                                         |
| <code>jit_inlining_time</code> double precision          | Total time spent by the statement on inlining functions, in milliseconds                                                                                                                            |
| <code>jit_optimization_count</code> bigint               | Number of times the statement has been optimized                                                                                                                                                    |
| <code>jit_optimization_time</code> double precision      | Total time spent by the statement on optimizing, in milliseconds                                                                                                                                    |
| <code>jit_emission_count</code> bigint                   | Number of times code has been emitted                                                                                                                                                               |
| <code>jit_emission_time</code> double precision          | Total time spent by the statement on emitting code, in milliseconds                                                                                                                                 |
| <code>jit_deform_count</code> bigint                     | Total number of tuple deform functions JIT-compiled by the statement                                                                                                                                |
| <code>jit_deform_time</code> double precision            | Total time spent by the statement on JIT-compiling tuple deform functions, in milliseconds                                                                                                          |
| <code>stats_since</code> timestamp with time zone        | Time at which statistics gathering started for this statement                                                                                                                                       |
| <code>minmax_stats_since</code> timestamp with time zone | Time at which min/max statistics gathering started for this statement (fields <code>min_plan_time</code> , <code>max_plan_time</code> , <code>min_exec_time</code> and <code>max_exec_time</code> ) |

For security reasons, only superusers and roles with privileges of the `pg_read_all_stats` role are allowed to see the SQL text and `queryid` of queries executed by other users. Other users can see the statistics, however, if the view has been installed in their database.

Plannable queries (that is, `SELECT`, `INSERT`, `UPDATE`, `DELETE`, and `MERGE`) and utility commands are combined into a single `pg_stat_statements` entry whenever they have identical query structures according to an internal hash calculation. Typically, two queries will be considered the same for this purpose if they are semantically equivalent except for the values of literal constants appearing in the query.

## Note

The following details about constant replacement and `queryid` only apply when `compute_query_id` is enabled. If you use an external module instead to compute `queryid`, you should refer to its documentation for details.

When a constant's value has been ignored for purposes of matching the query to other queries, the constant is replaced by a parameter symbol, such as `$1`, in the `pg_stat_statements` display. The rest of the query text is that of the first query that had the particular `queryid` hash value associated with the `pg_stat_statements` entry.

Queries on which normalization can be applied may be observed with constant values in `pg_stat_statements`, especially when there is a high rate of entry deallocations. To reduce the likelihood of this happening, consider increasing `pg_stat_statements.max`. The `pg_stat_statements_info` view, discussed below in [Section F.60.2](#), provides statistics about entry deallocations.

In some cases, queries with visibly different texts might get merged into a single `pg_stat_statements` entry. Normally this will happen only for semantically equivalent queries, but there is a small chance of hash collisions causing unrelated queries to be merged into one entry. (This cannot happen for queries belonging to different users or databases, however.)

Since the `queryid` hash value is computed on the post-parse-analysis representation of the queries, the opposite is also possible: queries with identical texts might appear as separate entries, if they have different meanings as a result of factors such as different `search_path` settings.

Consumers of `pg_stat_statements` may wish to use `queryid` (perhaps in combination with `dbid` and `userid`) as a more stable and reliable identifier for each entry than its query text. However, it is important to understand that there are only limited guarantees around the stability of the `queryid` hash value. Since the identifier is derived from the post-parse-analysis tree, its value is a function of, among other things, the internal object identifiers appearing in this representation. This has some counterintuitive implications. For example, `pg_stat_statements` will consider two apparently-identical queries to be distinct, if they reference a table that was dropped and recreated between the executions of the two queries. The hashing process is also sensitive to differences in machine architecture and other facets of the platform. Furthermore, it is not safe to assume that `queryid` will be stable across major versions of Postgres Pro.

Two servers participating in replication based on physical WAL replay can be expected to have identical `queryid` values for the same query. However, logical replication schemes do not promise to keep replicas identical in all relevant details, so `queryid` will not be a useful identifier for accumulating costs across a set of logical replicas. If in doubt, direct testing is recommended.

Generally, it can be assumed that `queryid` values are stable between minor version releases of Postgres Pro, providing that instances are running on the same machine architecture and the catalog metadata details match. Compatibility will only be broken between minor versions as a last resort.

The parameter symbols used to replace constants in representative query texts start from the next number after the highest `$n` parameter in the original query text, or `$1` if there was none. It's worth noting that in some cases there may be hidden parameter symbols that affect this numbering. For example, PL/pgSQL uses hidden parameter symbols to insert values of function local variables into queries, so that a PL/pgSQL statement like `SELECT i + 1 INTO j` would have representative text like `SELECT i + $2`.

The representative query texts are kept in an external disk file, and do not consume shared memory. Therefore, even very lengthy query texts can be stored successfully. However, if many long query texts are accumulated, the external file might grow unmanageably large. As a recovery method if that happens, `pg_stat_statements` may choose to discard the query texts, whereupon all existing entries in the `pg_stat_statements` view will show null `query` fields, though the statistics associated with each `queryid` are preserved. If this happens, consider reducing `pg_stat_statements.max` to prevent recurrences.

`plans` and `calls` aren't always expected to match because planning and execution statistics are updated at their respective end phase, and only for successful operations. For example, if a statement is successfully planned but fails during the execution phase, only its planning statistics will be updated. If planning is skipped because a cached plan is used, only its execution statistics will be updated.

## F.60.2. The `pg_stat_statements_info` View

The statistics of the `pg_stat_statements` module itself are tracked and made available via a view named `pg_stat_statements_info`. This view contains only a single row. The columns of the view are shown in [Table F.44](#).

**Table F.44. `pg_stat_statements_info` Columns**

| Column Type<br>Description                                                                                                                                                                                                                |
|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>dealloc bigint</code><br>Total number of times <code>pg_stat_statements</code> entries about the least-executed statements were deallocated because more distinct statements than <code>pg_stat_statements.max</code> were observed |
| <code>stats_reset timestamp with time zone</code><br>Time at which all statistics in the <code>pg_stat_statements</code> view were last reset.                                                                                            |

### F.60.3. Functions

`pg_stat_statements_reset(userid Oid, dbid Oid, queryid bigint, minmax_only boolean)` returns `timestamp with time zone`

`pg_stat_statements_reset` discards statistics gathered so far by `pg_stat_statements` corresponding to the specified `userid`, `dbid` and `queryid`. If any of the parameters are not specified, the default value `0`(invalid) is used for each of them and the statistics that match with other parameters will be reset. If no parameter is specified or all the specified parameters are `0`(invalid), it will discard all statistics. If all statistics in the `pg_stat_statements` view are discarded, it will also reset the statistics in the `pg_stat_statements_info` view. When `minmax_only` is `true` only the values of minimum and maximum planning and execution time will be reset (i.e. `min_plan_time`, `max_plan_time`, `min_exec_time` and `max_exec_time` fields). The default value for `minmax_only` parameter is `false`. Time of last min/max reset performed is shown in `minmax_stats_since` field of the `pg_stat_statements` view. This function returns the time of a reset. This time is saved to `stats_reset` field of `pg_stat_statements_info` view or to `minmax_stats_since` field of the `pg_stat_statements` view if the corresponding reset was actually performed. By default, this function can only be executed by superusers. Access may be granted to others using `GRANT`.

`pg_stat_statements(showtext boolean)` returns `setof record`

The `pg_stat_statements` view is defined in terms of a function also named `pg_stat_statements`. It is possible for clients to call the `pg_stat_statements` function directly, and by specifying `showtext := false` have query text be omitted (that is, the `OUT` argument that corresponds to the view's `query` column will return nulls). This feature is intended to support external tools that might wish to avoid the overhead of repeatedly retrieving query texts of indeterminate length. Such tools can instead cache the first query text observed for each entry themselves, since that is all `pg_stat_statements` itself does, and then retrieve query texts only as needed. Since the server stores query texts in a file, this approach may reduce physical I/O for repeated examination of the `pg_stat_statements` data.

### F.60.4. Configuration Parameters

`pg_stat_statements.max` (integer)

`pg_stat_statements.max` is the maximum number of statements tracked by the module (i.e., the maximum number of rows in the `pg_stat_statements` view). If more distinct statements than that are observed, information about the least-executed statements is discarded. The number of times such information was discarded can be seen in the `pg_stat_statements_info` view. The default value is 5000. This parameter can only be set at server start.

`pg_stat_statements.track` (enum)

`pg_stat_statements.track` controls which statements are counted by the module. Specify `top` to track top-level statements (those issued directly by clients), `all` to also track nested statements (such as statements invoked within functions), or `none` to disable statement statistics collection. The default value is `top`. Only superusers can change this setting.

`pg_stat_statements.track_utility` (boolean)

`pg_stat_statements.track_utility` controls whether utility commands are tracked by the module. Utility commands are all those other than `SELECT`, `INSERT`, `UPDATE`, `DELETE`, and `MERGE`. The default value is `on`. Only superusers can change this setting.

`pg_stat_statements.track_planning` (boolean)

`pg_stat_statements.track_planning` controls whether planning operations and duration are tracked by the module. Enabling this parameter may incur a noticeable performance penalty, especially when statements with identical query structure are executed by many concurrent connections which compete to update a small number of `pg_stat_statements` entries. The default value is `off`. Only superusers can change this setting.

`pg_stat_statements.save` (boolean)

`pg_stat_statements.save` specifies whether to save statement statistics across server shutdowns. If it is `off` then statistics are not saved at shutdown nor reloaded at server start. The default value is `on`. This parameter can only be set in the `postgresql.conf` file or on the server command line.

The module requires additional shared memory proportional to `pg_stat_statements.max`. Note that this memory is consumed whenever the module is loaded, even if `pg_stat_statements.track` is set to `none`.

These parameters must be set in `postgresql.conf`. Typical usage might be:

```
postgresql.conf
shared_preload_libraries = 'pg_stat_statements'

compute_query_id = on
pg_stat_statements.max = 10000
pg_stat_statements.track = all
```

## F.60.5. Sample Output

```
bench=# SELECT pg_stat_statements_reset();

$ pgbench -i bench
$ pgbench -c10 -t300 bench

bench=# \x

ter@2ndquadrant.com>.

## F.61. `pgstattuple` — obtain tuple-level statistics

The `pgstattuple` module provides various functions to obtain tuple-level statistics.

Because these functions return detailed page-level information, access is restricted by default. By default, only the role `pg_stat_scan_tables` has `EXECUTE` privilege. Superusers of course bypass this restriction. After the extension has been installed, users may issue `GRANT` commands to change the privileges on the functions to allow others to execute them. However, it might be preferable to add those users to the `pg_stat_scan_tables` role instead.

### F.61.1. Functions

`pgstattuple(regclass)` returns `record`

`pgstattuple` returns a relation's physical length, percentage of “dead” tuples, and other info. This may help users to determine whether vacuum is necessary or not. The argument is the target relation's name (optionally schema-qualified) or OID. For example:

```
test=> SELECT * FROM pgstattuple('pg_catalog.pg_proc');
-[RECORD 1]-----+-----
table_len | 458752
tuple_count | 1470
tuple_len | 438896
tuple_percent | 95.67
dead_tuple_count | 11
dead_tuple_len | 3157
dead_tuple_percent | 0.69
free_space | 8932
free_percent | 1.95
```

The output columns are described in [Table F.45](#).

**Table F.45. `pgstattuple` Output Columns**

| Column                          | Type                | Description                          |
|---------------------------------|---------------------|--------------------------------------|
| <code>table_len</code>          | <code>bigint</code> | Physical relation length in bytes    |
| <code>tuple_count</code>        | <code>bigint</code> | Number of live tuples                |
| <code>tuple_len</code>          | <code>bigint</code> | Total length of live tuples in bytes |
| <code>tuple_percent</code>      | <code>float8</code> | Percentage of live tuples            |
| <code>dead_tuple_count</code>   | <code>bigint</code> | Number of dead tuples                |
| <code>dead_tuple_len</code>     | <code>bigint</code> | Total length of dead tuples in bytes |
| <code>dead_tuple_percent</code> | <code>float8</code> | Percentage of dead tuples            |
| <code>free_space</code>         | <code>bigint</code> | Total free space in bytes            |
| <code>free_percent</code>       | <code>float8</code> | Percentage of free space             |

#### Note

The `table_len` will always be greater than the sum of the `tuple_len`, `dead_tuple_len` and `free_space`. The difference is accounted for by fixed page overhead, the per-page table of pointers to tuples, and padding to ensure that tuples are correctly aligned.

`pgstattuple` acquires only a read lock on the relation. So the results do not reflect an instantaneous snapshot; concurrent updates will affect them.

`pgstattuple` judges a tuple is “dead” if `HeapTupleSatisfiesDirty` returns false.

`pgstattuple(text)` returns record

This is the same as `pgstattuple(regclass)`, except that the target relation is specified as TEXT. This function is kept because of backward-compatibility so far, and will be deprecated in some future release.

`pgstatindex(regclass)` returns record

`pgstatindex` returns a record showing information about a B-tree index. For example:

```
test=> SELECT * FROM pgstatindex('pg_cast_oid_index');
-[RECORD 1]-----+-----
version | 2
tree_level | 0
index_size | 16384
root_block_no | 1
internal_pages | 0
leaf_pages | 1
empty_pages | 0
deleted_pages | 0
avg_leaf_density | 54.27
leaf_fragmentation | 0
```

The output columns are:

| Column             | Type    | Description                              |
|--------------------|---------|------------------------------------------|
| version            | integer | B-tree version number                    |
| tree_level         | integer | Tree level of the root page              |
| index_size         | bigint  | Total index size in bytes                |
| root_block_no      | bigint  | Location of root page (zero if none)     |
| internal_pages     | bigint  | Number of “internal” (upper-level) pages |
| leaf_pages         | bigint  | Number of leaf pages                     |
| empty_pages        | bigint  | Number of empty pages                    |
| deleted_pages      | bigint  | Number of deleted pages                  |
| avg_leaf_density   | float8  | Average density of leaf pages            |
| leaf_fragmentation | float8  | Leaf page fragmentation                  |

The reported `index_size` will normally correspond to one more page than is accounted for by `internal_pages` + `leaf_pages` + `empty_pages` + `deleted_pages`, because it also includes the index's metapage.

As with `pgstattuple`, the results are accumulated page-by-page, and should not be expected to represent an instantaneous snapshot of the whole index.

`pgstatindex(text)` returns record

This is the same as `pgstatindex(regclass)`, except that the target index is specified as TEXT. This function is kept because of backward-compatibility so far, and will be deprecated in some future release.

`pgstatginindex(regclass)` returns record

`pgstatginindex` returns a record showing information about a GIN index. For example:

```
test=> SELECT * FROM pgstatginindex('test_gin_index');
-[RECORD 1]--+-
version | 1
pending_pages | 0
pending_tuples | 0
```

The output columns are:

Additional Supplied Modules and  
Extensions Shipped in `post-  
grespro-ent-17-contrib`

| Column         | Type    | Description                          |
|----------------|---------|--------------------------------------|
| version        | integer | GIN version number                   |
| pending_pages  | integer | Number of pages in the pending list  |
| pending_tuples | bigint  | Number of tuples in the pending list |

`pgstathashindex(regclass)` returns record

`pgstathashindex` returns a record showing information about a HASH index. For example:

```
test=> select * from pgstathashindex('con_hash_index');
-[RECORD 1]--+-+-----
version | 4
bucket_pages | 33081
overflow_pages | 0
bitmap_pages | 1
unused_pages | 32455
live_items | 10204006
dead_items | 0
free_percent | 61.8005949100872
```

The output columns are:

| Column         | Type    | Description              |
|----------------|---------|--------------------------|
| version        | integer | HASH version number      |
| bucket_pages   | bigint  | Number of bucket pages   |
| overflow_pages | bigint  | Number of overflow pages |
| bitmap_pages   | bigint  | Number of bitmap pages   |
| unused_pages   | bigint  | Number of unused pages   |
| live_items     | bigint  | Number of live tuples    |
| dead_tuples    | bigint  | Number of dead tuples    |
| free_percent   | float   | Percentage of free space |

`pg_relpages(regclass)` returns bigint

`pg_relpages` returns the number of pages in the relation.

`pg_relpages(text)` returns bigint

This is the same as `pg_relpages(regclass)`, except that the target relation is specified as TEXT. This function is kept because of backward-compatibility so far, and will be deprecated in some future release.

`pgstattuple_approx(regclass)` returns record

`pgstattuple_approx` is a faster alternative to `pgstattuple` that returns approximate results. The argument is the target relation's name or OID. For example:

```
test=> SELECT * FROM pgstattuple_approx('pg_catalog.pg_proc'::regclass);
-[RECORD 1]-----+-----
table_len | 573440
scanned_percent | 2
approx_tuple_count | 2740
approx_tuple_len | 561210
approx_tuple_percent | 97.87
dead_tuple_count | 0
dead_tuple_len | 0
dead_tuple_percent | 0
approx_free_space | 11996
```

`approx_free_percent` | 2.09

The output columns are described in [Table F.46](#).

Whereas `pgstattuple` always performs a full-table scan and returns an exact count of live and dead tuples (and their sizes) and free space, `pgstattuple_approx` tries to avoid the full-table scan and returns exact dead tuple statistics along with an approximation of the number and size of live tuples and free space.

It does this by skipping pages that have only visible tuples according to the visibility map (if a page has the corresponding VM bit set, then it is assumed to contain no dead tuples). For such pages, it derives the free space value from the free space map, and assumes that the rest of the space on the page is taken up by live tuples.

For pages that cannot be skipped, it scans each tuple, recording its presence and size in the appropriate counters, and adding up the free space on the page. At the end, it estimates the total number of live tuples based on the number of pages and tuples scanned (in the same way that `VACUUM` estimates `pg_class.rel tuples`).

**Table F.46. `pgstattuple_approx` Output Columns**

| Column                            | Type                | Description                                      |
|-----------------------------------|---------------------|--------------------------------------------------|
| <code>table_len</code>            | <code>bigint</code> | Physical relation length in bytes (exact)        |
| <code>scanned_percent</code>      | <code>float8</code> | Percentage of table scanned                      |
| <code>approx_tuple_count</code>   | <code>bigint</code> | Number of live tuples (estimated)                |
| <code>approx_tuple_len</code>     | <code>bigint</code> | Total length of live tuples in bytes (estimated) |
| <code>approx_tuple_percent</code> | <code>float8</code> | Percentage of live tuples                        |
| <code>dead_tuple_count</code>     | <code>bigint</code> | Number of dead tuples (exact)                    |
| <code>dead_tuple_len</code>       | <code>bigint</code> | Total length of dead tuples in bytes (exact)     |
| <code>dead_tuple_percent</code>   | <code>float8</code> | Percentage of dead tuples                        |
| <code>approx_free_space</code>    | <code>bigint</code> | Total free space in bytes (estimated)            |
| <code>approx_free_percent</code>  | <code>float8</code> | Percentage of free space                         |

In the above output, the free space figures may not match the `pgstattuple` output exactly, because the free space map gives us an exact figure, but is not guaranteed to be accurate to the byte.

Tatsuo Ishii, Satoshi Nagayasu and Abhijit Menon-Sen

## F.62. pg\_surgery — perform low-level surgery on relation data

The `pg_surgery` module provides various functions to perform surgery on a damaged relation. These functions are unsafe by design and using them may corrupt (or further corrupt) your database. For example, these functions can easily be used to make a table inconsistent with its own indexes, to cause `UNIQUE` or `FOREIGN KEY` constraint violations, or even to make tuples visible which, when read, will cause a database server crash. They should be used with great caution and only as a last resort.

### F.62.1. Functions

`heap_force_kill(regclass, tid[])` returns void

`heap_force_kill` marks “used” line pointers as “dead” without examining the tuples. The intended use of this function is to forcibly remove tuples that are not otherwise accessible. For example:

```
test=> select * from t1 where ctid = '(0, 1)';
ERROR: could not access status of transaction 4007513275
DETAIL: Could not open file "pg_xact/0EED": No such file or directory.
```

```
test=# select heap_force_kill('t1'::regclass, ARRAY['(0, 1)']::tid[]);
heap_force_kill

```

```
(1 row)
```

```
test=# select * from t1 where ctid = '(0, 1)';
(0 rows)
```

`heap_force_freeze(regclass, tid[])` returns void

`heap_force_freeze` marks tuples as frozen without examining the tuple data. The intended use of this function is to make accessible tuples which are inaccessible due to corrupted visibility information, or which prevent the table from being successfully vacuumed due to corrupted visibility information. For example:

```
test=> vacuum t1;
ERROR: found xmin 507 from before relfrozenxid 515
CONTEXT: while scanning block 0 of relation "public.t1"
```

```
test=# select ctid from t1 where xmin = 507;
ctid

(0,3)
(1 row)
```

```
test=# select heap_force_freeze('t1'::regclass, ARRAY['(0, 3)']::tid[]);
heap_force_freeze

```

```
(1 row)
```

```
test=# select ctid from t1 where xmin = 2;
ctid

(0,3)
(1 row)
```

## F.63. pg\_transfer — quick transfer of tables between instances

The `pg_transfer` extension enables quick transfer of tables between Postgres Pro Enterprise instances.

It may sometimes be required to load large volumes of data into a database, for example, when consolidating data from regional servers into a central one. If your data needs to be uploaded to a server under heavy load, you can use a temporary database on another server to accumulate the data and then transfer it all at once when the main server load is minimal.

If you use `pg_dump` and `pg_restore` applications to transfer data, the load on the receiving server is usually higher than that on the sending server. Since the data is loaded using `INSERT` or `COPY` commands, it creates a significant impact on the disk subsystem. Besides, you will have to re-build indexes in the target database once all the data is loaded, which will also contribute to the server load.

To achieve a much higher load speed for read-only data, you can use the `pg_transfer` extension while doing dump/restore, which allows to copy data files directly, without using `COPY/INSERT` commands. `pg_transfer` also provides auxiliary functions for `pg_dump` and `pg_restore` to transfer tables together with pre-built indexes and collected statistics, so you can avoid extra load on the target server incurred by statistics re-collection.

### Note

Postgres Pro Enterprise configuration and the architectures of source and target servers must provide binary-compatible file formats. When restoring data, `pg_transfer` checks that source and target servers have the same alignment, page and segment sizes, etc.

### F.63.1. Installation

`pg_transfer` is included into Postgres Pro Enterprise. To enable `pg_transfer`, create its extension in your database using the following SQL command:

```
CREATE EXTENSION pg_transfer;
```

You must create `pg_transfer` extension in both source and target databases.

### F.63.2. Usage

To transfer data using the `pg_transfer` module, do the following:

#### 1. Prepare source and target systems for data transfer

Before the actual data transfer, you first need to transfer data schema to the target server:

1. In the source database, mark the table to be transferred as read-only:  

```
ALTER TABLE table_name SET CONSTANT;
```
2. Run the `VACUUM (ANALYZE)` command to remove dead tuples and refresh statistics:  

```
VACUUM (ANALYZE) table_name;
```
3. Take a logical dump of the data schema on the source server and restore it on the target server:  

```
pg_dump -Fc -t table_name --schema-only -f transfer_dir/archive.out old_database
pg_restore -d new_database --schema-only transfer_dir/archive.out
```

#### 2. Prepare TOAST identifiers for the transfer

This step is only required if the tables to be transferred have toasted values.

1. Determine TOAST identifiers (*reltoastid*) in the new database:  

```
psql new_database -c "SELECT reltoastrelid FROM pg_class WHERE
 relname='table_name';"
```
2. Using the received *reltoastid* identifiers, prepare the table for the transfer and force data flush to disk:

```
psql -d old_database -c "SELECT
pg_transfer_freeze('table_name'::regclass::oid, reltoastrelid::oid);"
```

### 3. Transfer the data to the target system

1. Copy the data into a separate directory using `pg_dump` utility:

```
pg_dump -Fc -t table_name --transfer-dir transfer_dir/ -f transfer_dir/
archive.out old_database
```

2. Restore the data in the target database:

```
pg_restore -d new_database --data-only --transfer-dir transfer_dir/ --copy-mode-
transfer transfer_dir/archive.out
```

When source and target databases are located in the same file system, the `--copy-mode-transfer` option must be specified at least once (for either `pg_dump` or `pg_restore` command) to get an independent copy of data. When restoring data on the primary server, `--generate-wal` option must be specified for `pg_restore` for changes to be replicated to a standby server.

## F.63.3. Compatibility

The `pg_transfer` extension is only supported on Linux systems.

## F.63.4. Authors

Postgres Professional, Moscow, Russia

## F.64. pg\_trgm — support for similarity of text using trigram matching

The `pg_trgm` module provides functions and operators for determining the similarity of alphanumeric text based on trigram matching, as well as index operator classes that support fast searching for similar strings.

This module is considered “trusted”, that is, it can be installed by non-superusers who have `CREATE` privilege on the current database.

### F.64.1. Trigram (or Trigraph) Concepts

A trigram is a group of three consecutive characters taken from a string. We can measure the similarity of two strings by counting the number of trigrams they share. This simple idea turns out to be very effective for measuring the similarity of words in many natural languages.

#### Note

`pg_trgm` ignores non-word characters (non-alphanumerics) when extracting trigrams from a string. Each word is considered to have two spaces prefixed and one space suffixed when determining the set of trigrams contained in the string. For example, the set of trigrams in the string “cat” is “ c”, “ ca”, “cat”, and “at ”. The set of trigrams in the string “foo|bar” is “ f”, “ fo”, “foo”, “oo ”, “ b”, “ ba”, “bar”, and “ar ”.

### F.64.2. Functions and Operators

The functions provided by the `pg_trgm` module are shown in [Table F.47](#), the operators in [Table F.48](#).

Table F.47. `pg_trgm` Functions

| Function                                               | Description                                                                                                                                                                                                                                                                                                  |
|--------------------------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>similarity(text, text) → real</code>             | Returns a number that indicates how similar the two arguments are. The range of the result is zero (indicating that the two strings are completely dissimilar) to one (indicating that the two strings are identical).                                                                                       |
| <code>show_trgm(text) → text[]</code>                  | Returns an array of all the trigrams in the given string. (In practice this is seldom useful except for debugging.)                                                                                                                                                                                          |
| <code>word_similarity(text, text) → real</code>        | Returns a number that indicates the greatest similarity between the set of trigrams in the first string and any continuous extent of an ordered set of trigrams in the second string. For details, see the explanation below.                                                                                |
| <code>strict_word_similarity(text, text) → real</code> | Same as <code>word_similarity</code> , but forces extent boundaries to match word boundaries. Since we don't have cross-word trigrams, this function actually returns greatest similarity between first string and any continuous extent of words of the second string.                                      |
| <code>show_limit() → real</code>                       | Returns the current similarity threshold used by the <code>%</code> operator. This sets the minimum similarity between two words for them to be considered similar enough to be misspellings of each other, for example. ( <i>Deprecated</i> ; instead use <code>SHOW pg_trgm.similarity_threshold</code> .) |
| <code>set_limit(real) → real</code>                    | Sets the current similarity threshold that is used by the <code>%</code> operator. The threshold must be between 0 and 1 (default is 0.3). Returns the same value passed in. ( <i>Deprecated</i> ; instead use <code>SET pg_trgm.similarity_threshold</code> .)                                              |

Consider the following example:

```
SELECT word_similarity('word', 'two words');
word_similarity
```

```

0.8
(1 row)
```

In the first string, the set of trigrams is {" w", " wo", "wor", "ord", "rd "}. In the second string, the ordered set of trigrams is {" t", " tw", "two", "wo ", " w", " wo", "wor", "ord", "rds", "ds "}. The most similar extent of an ordered set of trigrams in the second string is {" w", " wo", "wor", "ord"}, and the similarity is 0.8.

This function returns a value that can be approximately understood as the greatest similarity between the first string and any substring of the second string. However, this function does not add padding to the boundaries of the extent. Thus, the number of additional characters present in the second string is not considered, except for the mismatched word boundaries.

At the same time, `strict_word_similarity` selects an extent of words in the second string. In the example above, `strict_word_similarity` would select the extent of a single word 'words', whose set of trigrams is {" w", " wo", "wor", "ord", "rds", "ds "}.  

```
SELECT strict_word_similarity('word', 'two words'), similarity('word', 'words');
strict_word_similarity | similarity
-----+-----
0.571429 | 0.571429
(1 row)
```

Thus, the `strict_word_similarity` function is useful for finding the similarity to whole words, while `word_similarity` is more suitable for finding the similarity for parts of words.

**Table F.48. `pg_trgm` Operators**

| Operator                                        | Description                                                                                                                                                                                                                                                                                                                           |
|-------------------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>text % text → boolean</code>              | Returns <code>true</code> if its arguments have a similarity that is greater than the current similarity threshold set by <code>pg_trgm.similarity_threshold</code> .                                                                                                                                                                 |
| <code>text &lt;% text → boolean</code>          | Returns <code>true</code> if the similarity between the trigram set in the first argument and a continuous extent of an ordered trigram set in the second argument is greater than the current word similarity threshold set by <code>pg_trgm.word_similarity_threshold</code> parameter.                                             |
| <code>text %&gt; text → boolean</code>          | Commutator of the <code>&lt;%</code> operator.                                                                                                                                                                                                                                                                                        |
| <code>text &lt;&lt;% text → boolean</code>      | Returns <code>true</code> if its second argument has a continuous extent of an ordered trigram set that matches word boundaries, and its similarity to the trigram set of the first argument is greater than the current strict word similarity threshold set by the <code>pg_trgm.strict_word_similarity_threshold</code> parameter. |
| <code>text %&gt;&gt; text → boolean</code>      | Commutator of the <code>&lt;&lt;%</code> operator.                                                                                                                                                                                                                                                                                    |
| <code>text &lt;-&gt; text → real</code>         | Returns the “distance” between the arguments, that is one minus the <code>similarity()</code> value.                                                                                                                                                                                                                                  |
| <code>text &lt;&lt;-&gt; text → real</code>     | Returns the “distance” between the arguments, that is one minus the <code>word_similarity()</code> value.                                                                                                                                                                                                                             |
| <code>text &lt;-&gt;&gt; text → real</code>     | Commutator of the <code>&lt;&lt;-&gt;</code> operator.                                                                                                                                                                                                                                                                                |
| <code>text &lt;&lt;&lt;-&gt; text → real</code> | Returns the “distance” between the arguments, that is one minus the <code>strict_word_similarity()</code> value.                                                                                                                                                                                                                      |
| <code>text &lt;-&gt;&gt;&gt; text → real</code> |                                                                                                                                                                                                                                                                                                                                       |

| Operator | Description                       |
|----------|-----------------------------------|
|          | Commutator of the <<<-> operator. |

### F.64.3. GUC Parameters

`pg_trgm.similarity_threshold` (real)

Sets the current similarity threshold that is used by the % operator. The threshold must be between 0 and 1 (default is 0.3).

`pg_trgm.word_similarity_threshold` (real)

Sets the current word similarity threshold that is used by the <% and %> operators. The threshold must be between 0 and 1 (default is 0.6).

`pg_trgm.strict_word_similarity_threshold` (real)

Sets the current strict word similarity threshold that is used by the <<% and %>> operators. The threshold must be between 0 and 1 (default is 0.5).

### F.64.4. Index Support

The `pg_trgm` module provides GiST and GIN index operator classes that allow you to create an index over a text column for the purpose of very fast similarity searches. These index types support the above-described similarity operators, and additionally support trigram-based index searches for `LIKE`, `ILIKE`, `~`, `~*` and `=` queries. The similarity comparisons are case-insensitive in a default build of `pg_trgm`. Inequality operators are not supported. Note that those indexes may not be as efficient as regular B-tree indexes for equality operator.

Example:

```
CREATE TABLE test_trgm (t text);
CREATE INDEX trgm_idx ON test_trgm USING GIST (t gist_trgm_ops);
```

or

```
CREATE INDEX trgm_idx ON test_trgm USING GIN (t gin_trgm_ops);
```

`gist_trgm_ops` GiST opclass approximates a set of trigrams as a bitmap signature. Its optional integer parameter `siglen` determines the signature length in bytes. The default length is 12 bytes. Valid values of signature length are between 1 and 2024 bytes. Longer signatures lead to a more precise search (scanning a smaller fraction of the index and fewer heap pages), at the cost of a larger index.

Example of creating such an index with a signature length of 32 bytes:

```
CREATE INDEX trgm_idx ON test_trgm USING GIST (t gist_trgm_ops(siglen=32));
```

At this point, you will have an index on the `t` column that you can use for similarity searching. A typical query is

```
SELECT t, similarity(t, 'word') AS sml
FROM test_trgm
WHERE t % 'word'
ORDER BY sml DESC, t;
```

This will return all values in the text column that are sufficiently similar to *word*, sorted from best match to worst. The index will be used to make this a fast operation even over very large data sets.

A variant of the above query is

```
SELECT t, t <-> 'word' AS dist
FROM test_trgm
ORDER BY dist LIMIT 10;
```

This can be implemented quite efficiently by GiST indexes, but not by GIN indexes. It will usually beat the first formulation when only a small number of the closest matches is wanted.

Also you can use an index on the `t` column for word similarity or strict word similarity. Typical queries are:

```
SELECT t, word_similarity('word', t) AS sml
FROM test_trgm
WHERE 'word' <% t
ORDER BY sml DESC, t;
```

and

```
SELECT t, strict_word_similarity('word', t) AS sml
FROM test_trgm
WHERE 'word' <<% t
ORDER BY sml DESC, t;
```

This will return all values in the text column for which there is a continuous extent in the corresponding ordered trigram set that is sufficiently similar to the trigram set of *word*, sorted from best match to worst. The index will be used to make this a fast operation even over very large data sets.

Possible variants of the above queries are:

```
SELECT t, 'word' <<-> t AS dist
FROM test_trgm
ORDER BY dist LIMIT 10;
```

and

```
SELECT t, 'word' <<<-> t AS dist
FROM test_trgm
ORDER BY dist LIMIT 10;
```

This can be implemented quite efficiently by GiST indexes, but not by GIN indexes.

Beginning in PostgreSQL 9.1, these index types also support index searches for `LIKE` and `ILIKE`, for example

```
SELECT * FROM test_trgm WHERE t LIKE '%foo%bar';
```

The index search works by extracting trigrams from the search string and then looking these up in the index. The more trigrams in the search string, the more effective the index search is. Unlike B-tree based searches, the search string need not be left-anchored.

Beginning in PostgreSQL 9.3, these index types also support index searches for regular-expression matches (`~` and `~*` operators), for example

```
SELECT * FROM test_trgm WHERE t ~ '(foo|bar)';
```

The index search works by extracting trigrams from the regular expression and then looking these up in the index. The more trigrams that can be extracted from the regular expression, the more effective the index search is. Unlike B-tree based searches, the search string need not be left-anchored.

For both `LIKE` and regular-expression searches, keep in mind that a pattern with no extractable trigrams will degenerate to a full-index scan.

The choice between GiST and GIN indexing depends on the relative performance characteristics of GiST and GIN, which are discussed elsewhere.

## F.64.5. Text Search Integration

Trigram matching is a very useful tool when used in conjunction with a full text index. In particular it can help to recognize misspelled input words that will not be matched directly by the full text search mechanism.

The first step is to generate an auxiliary table containing all the unique words in the documents:

```
CREATE TABLE words AS SELECT word FROM
 ts_stat('SELECT to_tsvector(''simple'', bodytext) FROM documents');
```

where `documents` is a table that has a text field `bodytext` that we wish to search. The reason for using the `simple` configuration with the `to_tsvector` function, instead of using a language-specific configuration, is that we want a list of the original (unstemmed) words.

Next, create a trigram index on the word column:

```
CREATE INDEX words_idx ON words USING GIN (word gin_trgm_ops);
```

Now, a `SELECT` query similar to the previous example can be used to suggest spellings for misspelled words in user search terms. A useful extra test is to require that the selected words are also of similar length to the misspelled word.

### Note

Since the `words` table has been generated as a separate, static table, it will need to be periodically regenerated so that it remains reasonably up-to-date with the document collection. Keeping it exactly current is usually unnecessary.

## F.65. pg\_trgm\_mchar — trigram-based search for similar mchar and mvchar strings

pg\_trgm\_mchar is a Postgres Pro extension that allows fast trigram-based search for similar mchar and mvchar strings. The functionality provided by this extension overlaps substantially with the functionality of [pg\\_trgm](#): it provides equivalent [functions](#) and [operators](#) adjusted for mchar and mvchar types. However, pg\_trgm\_mchar supports only the [GIN](#) operator classes for searching these column types.

### Note

The LIKE operator supports only (mchar, mvchar) operand types. (mchar, mchar) operands are not supported.

### F.65.1. Installation

pg\_trgm\_mchar is a built-in extension included into Postgres Pro Enterprise. It depends on both pg\_trgm and [mchar](#). You must install these modules before creating pg\_trgm\_mchar, or you can install all dependencies automatically with:

```
CREATE EXTENSION pg_trgm_mchar CASCADE;
```

Alternatively, if both required modules are already installed, you can enable pg\_trgm\_mchar using the following query:

```
CREATE EXTENSION pg_trgm_mchar;
```

Since mchar and mvchar data types use the ICU library, it is also required for correct operation of the extension.

### F.65.2. Example

Since pg\_trgm\_mchar operates almost identically to pg\_trgm, for usage examples, refer to the [pg\\_trgm documentation](#).

However, there is a difference in index creation processes. The pg\_trgm\_mchar extension uses the gin\_trgm\_ops\_mvchar/gin\_trgm\_ops\_mchar operator family instead of gin\_trgm\_ops used by pg\_trgm:

```
CREATE TABLE test_trgm(t mvchar);
CREATE INDEX trgm_idx ON test_trgm USING gin (t gin_trgm_ops_mvchar);
...
CREATE TABLE test_trgm_mchar(t mchar);
CREATE INDEX trgm_mchar_idx ON test_trgm_mchar USING gin (t gin_trgm_ops_mchar);
```

In all other cases, these two modules behave identically.

## F.66. pg\_tsparser — an extension for text search

pg\_tsparser is a Postgres Pro extension for text search. This extension modifies the default text parsing strategy for words that include:

- underscores
- numbers and letters separated by the hyphen character

In addition to separate word parts returned by default, pg\_tsparser also returns the whole word.

### F.66.1. Installation and Setup

pg\_tsparser is included into the Postgres Pro distribution. To enable pg\_tsparser, once Postgres Pro is installed, create the pg\_tsparser extension for each database you are planning to use:

```
CREATE EXTENSION pg_tsparser;
```

Once pg\_tsparser is enabled, you can create your own text search configuration. In addition to pg\_tsparser, you can use any available dictionary.

For example, you can create english\_ts configuration for the English language, as follows:

```
CREATE TEXT SEARCH CONFIGURATION english_ts (
 PARSER = tsparser
);
```

```
COMMENT ON TEXT SEARCH CONFIGURATION english_ts IS 'text search configuration for
english language';
```

```
ALTER TEXT SEARCH CONFIGURATION english_ts
 ADD MAPPING FOR email, file, float, host, hword_numpart, int,
 numhword, numword, sfloat, uint, url, url_path, version
 WITH simple;
```

```
ALTER TEXT SEARCH CONFIGURATION english_ts
 ADD MAPPING FOR asciiword, asciihword, hword_asciipart,
 word, hword, hword_part
 WITH english_stem;
```

### F.66.2. Examples

The following examples illustrate the difference in search results returned by pg\_tsparser and the default parser:

```
SELECT to_tsvector('english', 'pg_trgm') as def_parser,
 to_tsvector('english_ts', 'pg_trgm') as new_parser;
def_parser | new_parser
-----+-----
'pg':1 'trgm':2 | 'pg':2 'pg_trgm':1 'trgm':3
(1 row)
```

```
SELECT to_tsvector('english', '123-abc') as def_parser,
 to_tsvector('english_ts', '123-abc') as new_parser;
def_parser | new_parser
-----+-----
'123':1 'abc':2 | '123':2 '123-abc':1 'abc':3
(1 row)
```

```
SELECT to_tsvector('english', 'rel-3.2-A') as def_parser,
 to_tsvector('english_ts', 'rel-3.2-A') as new_parser;
def_parser | new_parser
```

```
-----+-----
'-3.2':2 'rel':1 | '3.2':3 'rel':2 'rel-3.2-a':1
(1 row)
```

## F.67. `pg_variables` — functions for working with variables of various types

The `pg_variables` module provides functions for working with variables of various types. The created variables are only available in the current user session.

### F.67.1. Installation

The `pg_variables` extension is included into Postgres Pro. Once you have Postgres Pro installed, you must execute the [CREATE EXTENSION](#) command to enable `pg_variables`, as follows:

```
CREATE EXTENSION pg_variables;
```

### F.67.2. Usage

The `pg_variables` module provides several functions for creating, reading, and managing variables of scalar, record, and array types. See the following sections for function descriptions and syntax:

- [Section F.67.3.1](#) describes functions for scalar variables.
- [Section F.67.3.2](#) describes functions for collections of record variables.
- [Section F.67.3.3](#) describes functions for array variables.
- [Section F.67.3.4](#) describes functions for general collection variables.
- [Section F.67.3.5](#) describes functions for using iterators to traverse collection variables.
- [Section F.67.3.6](#) lists functions you can use to manage all variables in your current session.

For detailed usage examples, see [Section F.67.5](#).

#### Note

When using with `proxima`, before execution of the `pg_variables` commands, enable the [forced dynamic dedicated session](#) with the following command:

```
SET proxima.force_dedicated=true
```

#### F.67.2.1. Using Transactional Variables

By default, the created variables are non-transactional. Once successfully set, a variable exists for the whole session, regardless of rollbacks, if any. For example:

```
SELECT pgv_set('vars', 'int1', 101);
BEGIN;
SELECT pgv_set('vars', 'int2', 102);
ROLLBACK;
```

```
SELECT * FROM pgv_list() order by package, name;
 package | name | is_transactional
-----+-----+-----
 vars | int1 | f
 vars | int2 | f
```

If you would like to use variables that support transactions and savepoints, pass the optional `is_transactional` flag as the last parameter when creating this variable:

```
BEGIN;
SELECT pgv_set('vars', 'trans_int', 101, true);
SAVEPOINT sp1;
SELECT pgv_set('vars', 'trans_int', 102, true);
ROLLBACK TO sp1;
```

```
COMMIT;
SELECT pgv_get('vars', 'trans_int', NULL::int);
pgv_get

101
```

You must use the `is_transactional` flag every time you change the value of a transactional variable using `pgv_set()` or `pgv_insert()` functions. Otherwise, an error occurs. Other functions do not require this flag.

```
SELECT pgv_insert('pack', 'var_record', row(123::int, 'text'::text), true);

SELECT pgv_insert('pack', 'var_record', row(456::int, 'another text'::text));
ERROR: variable "var_record" already created as TRANSACTIONAL

SELECT pgv_delete('pack', 'var_record', 123::int);
```

If the `pgv_free()` or `pgv_remove()` function calls are rolled back, the affected transactional variables will be restored, unlike non-transactional variables, which are removed permanently. For example:

```
SELECT pgv_set('pack', 'var_reg', 123);
SELECT pgv_set('pack', 'var_trans', 456, true);
BEGIN;
SELECT pgv_free();
ROLLBACK;
SELECT * FROM pgv_list();
package | name | is_transactional
-----+-----+-----
pack | var_trans | t
```

## F.67.3. Functions

### F.67.3.1. Scalar Variables

The following functions support scalar variables:

| Function                                                                                             | Returns    |
|------------------------------------------------------------------------------------------------------|------------|
| <code>pgv_set(package text, name text, value anyonarray, is_transactional bool default false)</code> | void       |
| <code>pgv_get(package text, name text, var_type anyonarray, strict bool default true)</code>         | anyonarray |

To use the `pgv_get()` function, you must first create a package and a variable using the `pgv_set()` function. If the specified package or variable does not exist, an error occurs:

```
SELECT pgv_get('vars', 'int1', NULL::int);
ERROR: unrecognized package "vars"

SELECT pgv_get('vars', 'int1', NULL::int);
ERROR: unrecognized variable "int1"
```

`pgv_get()` function checks the variable type. If the specified type does not match the type of the variable, an error is raised:

```
SELECT pgv_get('vars', 'int1', NULL::text);
ERROR: variable "int1" requires "integer" value
```

### F.67.3.2. Collections of Records

The following functions support collections of record variables:

| Function                                                                                                     | Returns                     | Description                                                                                                                                                                                                                                                                                                                           |
|--------------------------------------------------------------------------------------------------------------|-----------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>pgv_insert(package text,<br/>name text, r record, is_<br/>transactional bool default<br/>false)</code> | <code>void</code>           | Inserts a record into a collection variable for the specified package. If the package or variable does not exist, it is created automatically. The first column of <code>r</code> is the primary key. If a record with the same primary key already exists or this collection variable has a different structure, an error is raised. |
| <code>pgv_update(package text,<br/>name text, r record)</code>                                               | <code>boolean</code>        | Updates a record with the corresponding primary key (the first column of <code>r</code> is the primary key). Returns <code>true</code> if the record was found. If this collection variable has a different structure, an error is raised.                                                                                            |
| <code>pgv_delete(package text,<br/>name text, value anynonar-<br/>ray)</code>                                | <code>boolean</code>        | Deletes a record with the corresponding primary key (the first column of <code>r</code> is the primary key). Returns <code>true</code> if the record was found and <code>false</code> otherwise.                                                                                                                                      |
| <code>pgv_select(package text,<br/>name text)</code>                                                         | <code>set of records</code> | Returns the collection variable records.                                                                                                                                                                                                                                                                                              |
| <code>pgv_select(package text,<br/>name text, value anynonar-<br/>ray)</code>                                | <code>record</code>         | Returns the record with the corresponding primary key (the first column of <code>r</code> is a primary key).                                                                                                                                                                                                                          |
| <code>pgv_select(package text,<br/>name text, value anyarray)</code>                                         | <code>set of records</code> | Returns the collection variable records with the corresponding primary keys (the first column of <code>r</code> is a primary key).                                                                                                                                                                                                    |

To use `pgv_update()`, `pgv_delete()` and `pgv_select()` functions, you must first create a package and a variable using the `pgv_insert()` function. The variable type and the record type must be the same; otherwise, an error occurs.

### F.67.3.3. Arrays

The following functions support array variables:

| Function                                                                                                   | Returns               |
|------------------------------------------------------------------------------------------------------------|-----------------------|
| <code>pgv_set(package text, name text, value<br/>anyarray, is_transactional bool default<br/>false)</code> | <code>void</code>     |
| <code>pgv_get(package text, name text, var_type<br/>anyarray, strict bool default true)</code>             | <code>anyarray</code> |

Usage instructions for these functions are the same as those provided in [Section F.67.3.1](#) for scalar variables.

### F.67.3.4. General Collections

The following functions support general collection variables:

| Function                                                                                                                       | Returns           | Description                                                                                                                                                                                                                                                                                                                                            |
|--------------------------------------------------------------------------------------------------------------------------------|-------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>pgv_set_elem(package text,<br/>name text, key int, value<br/>anyelement, is_transactional<br/>bool default false)</code> | <code>void</code> | Sets a value for the element with the key <code>key</code> of the collection variable <code>name</code> in the package <code>package</code> . If the package or variable does not exist, it is created automatically. Inside one collection, only keys of the same type are allowed. The <code>key</code> argument can have either <code>int</code> or |
| <code>pgv_set_elem(package text,<br/>name text, key text, value</code>                                                         |                   |                                                                                                                                                                                                                                                                                                                                                        |

| Function                                                                                                                                                                                                                                   | Returns                 | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>anyelement, is_transactional</code><br><code>bool</code> default <code>false</code> )                                                                                                                                                |                         | <code>text</code> type. If an element with the specified key already exists, its value is set to the new one. <code>is_transactional</code> shows whether the new variable is transactional and equals <code>false</code> by default. So if the variable already exists, it must be transactional/non-transactional as indicated by <code>is_transactional</code> , otherwise an error is raised. If the collection already exists and its value type does not match the type of the new value, an error is also raised.                                               |
| <code>pgv_get_elem(package text,</code><br><code>name text, key int, val_type</code><br><code>anyelement)</code><br><br><code>pgv_get_elem(package text,</code><br><code>name text, key text, val_</code><br><code>type anyelement)</code> | <code>anyelement</code> | Returns the value of the element with the key <code>key</code> of the collection variable <code>name</code> in the package <code>package</code> . If there is no element with the specified key in this collection, returns <code>NULL</code> . The <code>key</code> argument can have either <code>int</code> or <code>text</code> type. If the package or variable does not exist, an error is raised. If the specified variable is not a collection, an error is also raised. The <code>val_type</code> argument is required to properly determine the return type. |
| <code>pgv_exists_elem(package</code><br><code>text, name text, key int)</code><br><br><code>pgv_exists_elem(package</code><br><code>text, name text, key text)</code>                                                                      | <code>bool</code>       | Returns <code>true</code> if an element with the key <code>key</code> exists in the collection variable <code>name</code> in the package <code>package</code> and <code>false</code> otherwise. If the package or variable does not exist, also returns <code>false</code> . The <code>key</code> argument can have either <code>int</code> or <code>text</code> type. If the specified variable is not a collection, an error is raised.                                                                                                                              |
| <code>pgv_remove_elem(package</code><br><code>text, name text, key int)</code><br><br><code>pgv_remove_elem(package</code><br><code>text, name text, key text)</code>                                                                      | <code>void</code>       | Removes the element with the key <code>key</code> from the collection variable <code>name</code> in the package <code>package</code> . If there is no element with the specified key in this collection, does nothing. The <code>key</code> argument can have either <code>int</code> or <code>text</code> type. If the package or variable does not exist, an error is raised. If the specified variable is not a collection, an error is also raised.                                                                                                                |

### Important

Collections initialized with `pgv_set_elem()` and with `pgv_insert()` are not considered compatible.

#### F.67.3.5. Iterators

The following functions are provided to use iterators to traverse collection variables. These functions work with collections initialized with both `pgv_set_elem()` and `pgv_insert()`.

| Function                                                                             | Returns                 | Description                                                                                                                            |
|--------------------------------------------------------------------------------------|-------------------------|----------------------------------------------------------------------------------------------------------------------------------------|
| <code>pgv_first(package text, name</code><br><code>text, key_type anyelement)</code> | <code>anyelement</code> | Returns the first key from the collection variable. Collections are sorted by the key in ascending order. <code>key_type</code> is re- |

| Function                                                            | Returns                 | Description                                                                                                                                                                                                                                                                                                                                    |
|---------------------------------------------------------------------|-------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|                                                                     |                         | quired to determine the return value. If the <code>name</code> passed is the name of a non-collection variable, an error is raised.                                                                                                                                                                                                            |
| <code>pgv_last(package text, name text, key_type anyelement)</code> | <code>anyelement</code> | Returns the last key from the collection variable. Collections are sorted by the key in ascending order. <code>key_type</code> is required to determine the return value. If the <code>name</code> passed is the name of a non-collection variable, an error is raised.                                                                        |
| <code>pgv_next(package text, name text, key anyelement)</code>      | <code>anyelement</code> | Returns the next key from the collection variable. The <code>key</code> passed may not exist in the collection. Returns <code>NULL</code> if used for the last key in the collection. Collections are sorted by the key in ascending order. If the <code>name</code> passed is the name of a non-collection variable, an error is raised.      |
| <code>pgv_prior(package text, name text, key anyelement)</code>     | <code>anyelement</code> | Returns the previous key from the collection variable. The <code>key</code> passed may not exist in the collection. Returns <code>NULL</code> if used for the first key in the collection. Collections are sorted by the key in ascending order. If the <code>name</code> passed is the name of a non-collection variable, an error is raised. |
| <code>pgv_count(package text, name text)</code>                     | <code>integer</code>    | Returns the number of elements in the collection. If the <code>name</code> passed is the name of a non-collection variable, an error is raised.                                                                                                                                                                                                |

### F.67.3.6. Miscellaneous Functions

| Function                                         | Returns                                                            | Description                                                                                                                                                                                                        |
|--------------------------------------------------|--------------------------------------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>pgv_exists(package text, name text)</code> | <code>bool</code>                                                  | Returns <code>true</code> if the specified package and variable exist and <code>false</code> otherwise.                                                                                                            |
| <code>pgv_exists(package text)</code>            | <code>bool</code>                                                  | Returns <code>true</code> if the specified package exists and <code>false</code> otherwise.                                                                                                                        |
| <code>pgv_remove(package text, name text)</code> | <code>void</code>                                                  | Removes the variable with the specified name. The specified package and variable must exist; otherwise, an error is raised.                                                                                        |
| <code>pgv_remove(package text)</code>            | <code>void</code>                                                  | Removes the specified package and all the corresponding variables. The specified package must exist; otherwise, an error is raised.                                                                                |
| <code>pgv_free()</code>                          | <code>void</code>                                                  | Removes all packages and variables.                                                                                                                                                                                |
| <code>pgv_list()</code>                          | <code>table(package text, name text, is_transactional bool)</code> | Displays all the available variables and the corresponding packages, as well as whether each variable is transactional.                                                                                            |
| <code>pgv_stats()</code>                         | <code>table(package text, allocated_memory bigint)</code>          | Returns the list of assigned packages and the amount of memory used by variables, in bytes. If you are using transactional variables, this list also includes all deleted packages that still may be restored by a |

| Function | Returns | Description                                                       |
|----------|---------|-------------------------------------------------------------------|
|          |         | ROLLBACK. This function only supports Postgres Pro 9.6 or higher. |

### F.67.3.7. Deprecated Functions

#### F.67.3.7.1. Integer Variables

The following functions are deprecated. Use generic functions for [scalar variables](#) instead.

| Function                                                                                          | Returns |
|---------------------------------------------------------------------------------------------------|---------|
| <code>pgv_set_int(package text, name text, value int, is_transactional bool default false)</code> | void    |
| <code>pgv_get_int(package text, name text, strict bool default true)</code>                       | int     |

#### F.67.3.7.2. Text Variables

The following functions are deprecated. Use generic functions for [scalar variables](#) instead.

| Function                                                                                            | Returns |
|-----------------------------------------------------------------------------------------------------|---------|
| <code>pgv_set_text(package text, name text, value text, is_transactional bool default false)</code> | void    |
| <code>pgv_get_text(package text, name text, strict bool default true)</code>                        | text    |

#### F.67.3.7.3. Numeric Variables

The following functions are deprecated. Use generic functions for [scalar variables](#) instead.

| Function                                                                                                  | Returns |
|-----------------------------------------------------------------------------------------------------------|---------|
| <code>pgv_set_numeric(package text, name text, value numeric, is_transactional bool default false)</code> | void    |
| <code>pgv_get_numeric(package text, name text, strict bool default true)</code>                           | numeric |

#### F.67.3.7.4. Timestamp Variables

The following functions are deprecated. Use generic functions for [scalar variables](#) instead.

| Function                                                                                                      | Returns   |
|---------------------------------------------------------------------------------------------------------------|-----------|
| <code>pgv_set_timestamp(package text, name text, value timestamp, is_transactional bool default false)</code> | void      |
| <code>pgv_get_timestamp(package text, name text, strict bool default true)</code>                             | timestamp |

#### F.67.3.7.5. Timestamp with timezone Variables

The following functions are deprecated. Use generic functions for [scalar variables](#) instead.

| Function                                                                                                          | Returns |
|-------------------------------------------------------------------------------------------------------------------|---------|
| <code>pgv_set_timestamptz(package text, name text, value timestamptz, is_transactional bool default false)</code> | void    |

| Function                                                                            | Returns                  |
|-------------------------------------------------------------------------------------|--------------------------|
| <code>pgv_get_timestamptz(package text, name text, strict bool default true)</code> | <code>timestamptz</code> |

#### F.67.3.7.6. Date Variables

The following functions are deprecated. Use generic functions for [scalar variables](#) instead.

| Function                                                                                            | Returns           |
|-----------------------------------------------------------------------------------------------------|-------------------|
| <code>pgv_set_date(package text, name text, value date, is_transactional bool default false)</code> | <code>void</code> |
| <code>pgv_get_date(package text, name text, strict bool default true)</code>                        | <code>date</code> |

#### F.67.3.7.7. Jsonb Variables

The following functions are deprecated. Use generic functions for [scalar variables](#) instead.

| Function                                                                                              | Returns            |
|-------------------------------------------------------------------------------------------------------|--------------------|
| <code>pgv_set_jsonb(package text, name text, value jsonb, is_transactional bool default false)</code> | <code>void</code>  |
| <code>pgv_get_jsonb(package text, name text, strict bool default true)</code>                         | <code>jsonb</code> |

### F.67.4. Important Notes

#### F.67.4.1. Collations in Collections

Collections are stored in ascending order. In the case of `text` keys, you need a collation to determine the order of elements. If no collation is specified when inserting the first element of a collection, the default collation is used. Otherwise, the specified collation is used.

#### F.67.4.2. Cursors for Set-Returning Functions

All set-returning functions except `pgv_select(package, variable)` fix their return results at first `FETCH` from the cursor and are not affected by further data manipulation.

The results of `pgv_select(package, variable)` are received dynamically and are affected by transactions/changes in the collection. For `pgv_select()` called for a transactional collection, cursors look at the snapshot of the collection when the first `FETCH` was executed, but consider changes that were made in that transaction and in committed subtransactions.

### F.67.5. Examples

Define scalar variables using the `pgv_set()` function, and then return their values using the `pgv_get()` function:

```
SELECT pgv_set('vars', 'int1', 101);
SELECT pgv_set('vars', 'int2', 102);
SELECT pgv_set('vars', 'text1', 'text variable'::text);

SELECT pgv_get('vars', 'int1', NULL::int);
pgv_get

 101

SELECT pgv_get('vars', 'int2', NULL::int);
pgv_get

 102
```

```
SELECT pgv_get('vars', 'text1', NULL::text);
pgv_get

text variable
```

Let's assume we have the `tab` table and examine several examples of using record variables:

```
CREATE TABLE tab (id int, t varchar);
INSERT INTO tab VALUES (0, 'str00'), (1, 'str11');
```

You can use the following functions to work with record variables:

```
SELECT pgv_insert('vars', 'r1', tab) FROM tab;
```

```
SELECT pgv_select('vars', 'r1');
pgv_select

(1,str11)
(0,str00)
```

```
SELECT pgv_select('vars', 'r1', 1);
pgv_select

(1,str11)
```

```
SELECT pgv_select('vars', 'r1', 0);
pgv_select

(0,str00)
```

```
SELECT pgv_select('vars', 'r1', ARRAY[1, 0]);
pgv_select

(1,str11)
(0,str00)
```

```
SELECT pgv_delete('vars', 'r1', 1);
```

```
SELECT pgv_select('vars', 'r1');
pgv_select

(0,str00)
```

Consider the behavior of a transactional variable `var_text` when changed before and after savepoints:

```
SELECT pgv_set('pack', 'var_text', 'before transaction block'::text, true);
BEGIN;
SELECT pgv_set('pack', 'var_text', 'before savepoint'::text, true);
SAVEPOINT sp1;
SELECT pgv_set('pack', 'var_text', 'savepoint sp1'::text, true);
SAVEPOINT sp2;
SELECT pgv_set('pack', 'var_text', 'savepoint sp2'::text, true);
RELEASE sp2;
SELECT pgv_get('pack', 'var_text', NULL::text);
pgv_get

savepoint sp2

ROLLBACK TO sp1;
```

```
SELECT pgv_get('pack', 'var_text', NULL::text);
 pgv_get
```

```

before savepoint
```

```
ROLLBACK;
SELECT pgv_get('pack', 'var_text', NULL::text);
 pgv_get
```

```

before transaction block
```

If you create a variable after **BEGIN** or **SAVEPOINT** statements and then rollback to the previous state, the transactional variable is removed:

```
BEGIN;
SAVEPOINT sp1;
SAVEPOINT sp2;
SELECT pgv_set('pack', 'var_int', 122, true);
RELEASE SAVEPOINT sp2;
SELECT pgv_get('pack', 'var_int', NULL::int);
 pgv_get
```

```

 122
```

```
ROLLBACK TO sp1;
SELECT pgv_get('pack', 'var_int', NULL::int);
ERROR: unrecognized variable "var_int"
COMMIT;
```

List the available packages and variables:

```
SELECT * FROM pgv_list() ORDER BY package, name;
package | name | is_transactional
-----+-----+-----
pack | var_text | t
vars | int1 | f
vars | int2 | f
vars | r1 | f
vars | text1 | f
```

Get the amount of memory used by variables, in bytes:

```
SELECT * FROM pgv_stats() ORDER BY package;
package | allocated_memory
-----+-----
pack | 16384
vars | 32768
```

Delete the specified variables or packages:

```
SELECT pgv_remove('vars', 'int1');
SELECT pgv_remove('vars');
```

Delete all packages and variables:

```
SELECT pgv_free();
```

These examples show usage of collection variables and iterator functions:

```
sql
SELECT pgv_set_elem('pack', 'var', 1, 1);
SELECT pgv_set_elem('pack', 'var', 5, 5);
SELECT pgv_set_elem('pack', 'var', 10, 10);
```

```
SELECT pgv_first('pack', 'var', NULL::int);
pgv_first

 1

SELECT pgv_last('pack', 'var', NULL::int);
pgv_last

 10

SELECT pgv_next('pack', 'var', pgv_first('pack', 'var', NULL::int));
pgv_next

 5

SELECT pgv_prior('pack', 'var', pgv_last('pack', 'var', NULL::int));
pgv_prior

 5

SELECT pgv_prior('pack', 'var', pgv_first('pack', 'var', NULL::int));
pgv_prior

SELECT pgv_next('pack', 'var', pgv_last('pack', 'var', NULL::int));
pgv_prior

SELECT pgv_next('pack', 'var', 3);
pgv_next

 5

SELECT pgv_prior('pack', 'var', 3);
pgv_prior

 1

SELECT pgv_get_elem('pack', 'var', pgv_last('pack', 'var', NULL::int), NULL::int);
pgv_get_elem

 10

SELECT pgv_remove_elem('pack', 'var', pgv_last('pack', 'var', NULL::int));
pgv_remove_elem

SELECT pgv_get_elem('pack', 'var', pgv_last('pack', 'var', NULL::int), NULL::int);
pgv_get_elem

 5

(1 row)
```

These examples show how the collation affects the order of elements in a collection. They also show how to iterate over a whole collection with PL/pgSQL loops:

sql

```
SELECT pgv_set_elem('pack', 'var1', '#' COLLATE "ru_RU", '#'::text);
SELECT pgv_set_elem('pack', 'var1', '#' COLLATE "ru_RU", '#'::text);
SELECT pgv_set_elem('pack', 'var1', '#' COLLATE "ru_RU", '#'::text);
SELECT pgv_set_elem('pack', 'var1', '#' COLLATE "ru_RU", '#'::text);
SELECT pgv_set_elem('pack', 'var1', '#' COLLATE "ru_RU", '#'::text);
SELECT pgv_set_elem('pack', 'var1', '#' COLLATE "ru_RU", '#'::text);
DO
$$
DECLARE
 iter text;
BEGIN
 iter := pgv_first('pack', 'var1', NULL::text);
 WHILE iter IS NOT NULL LOOP
 RAISE NOTICE '%', pgv_get_elem('pack', 'var1', iter, NULL::text);
 iter := pgv_next('pack', 'var1', iter);
 END LOOP;
END;
$$;
NOTICE: #
NOTICE: #
NOTICE: #
NOTICE: #
NOTICE: #
NOTICE: #

SELECT pgv_set_elem('pack', 'var2', '#' COLLATE "C", '#'::text);
SELECT pgv_set_elem('pack', 'var2', '#' COLLATE "C", '#'::text);
SELECT pgv_set_elem('pack', 'var2', '#' COLLATE "C", '#'::text);
SELECT pgv_set_elem('pack', 'var2', '#' COLLATE "C", '#'::text);
SELECT pgv_set_elem('pack', 'var2', '#' COLLATE "C", '#'::text);
SELECT pgv_set_elem('pack', 'var2', '#' COLLATE "C", '#'::text);
DO
$$
DECLARE
 iter text;
BEGIN
 iter := pgv_first('pack', 'var2', NULL::text);
 WHILE iter IS NOT NULL LOOP
 RAISE NOTICE '%', pgv_get_elem('pack', 'var2', iter, NULL::text);
 iter := pgv_next('pack', 'var2', iter);
 END LOOP;
END;
$$;

## F.68. pg\_visibility — visibility map information and utilities

The `pg_visibility` module provides a means for examining the visibility map (VM) and page-level visibility information of a table. It also provides functions to check the integrity of a visibility map and to force it to be rebuilt.

Three different bits are used to store information about page-level visibility. The all-visible bit in the visibility map indicates that every tuple in the corresponding page of the relation is visible to every current and future transaction. The all-frozen bit in the visibility map indicates that every tuple in the page is frozen; that is, no future vacuum will need to modify the page until such time as a tuple is inserted, updated, deleted, or locked on that page. The page header's `PD_ALL_VISIBLE` bit has the same meaning as the all-visible bit in the visibility map, but is stored within the data page itself rather than in a separate data structure. These two bits will normally agree, but the page's all-visible bit can sometimes be set while the visibility map bit is clear after a crash recovery. The reported values can also disagree because of a change that occurs after `pg_visibility` examines the visibility map and before it examines the data page. Any event that causes data corruption can also cause these bits to disagree.

Functions that display information about `PD_ALL_VISIBLE` bits are much more costly than those that only consult the visibility map, because they must read the relation's data blocks rather than only the (much smaller) visibility map. Functions that check the relation's data blocks are similarly expensive.

### F.68.1. Functions

`pg_visibility_map(relation regclass, blkno bigint, all_visible OUT boolean, all_frozen OUT boolean)` returns record

Returns the all-visible and all-frozen bits in the visibility map for the given block of the given relation.

`pg_visibility(relation regclass, blkno bigint, all_visible OUT boolean, all_frozen OUT boolean, pd_all_visible OUT boolean)` returns record

Returns the all-visible and all-frozen bits in the visibility map for the given block of the given relation, plus the `PD_ALL_VISIBLE` bit of that block.

`pg_visibility_map(relation regclass, blkno OUT bigint, all_visible OUT boolean, all_frozen OUT boolean)` returns setof record

Returns the all-visible and all-frozen bits in the visibility map for each block of the given relation.

`pg_visibility(relation regclass, blkno OUT bigint, all_visible OUT boolean, all_frozen OUT boolean, pd_all_visible OUT boolean)` returns setof record

Returns the all-visible and all-frozen bits in the visibility map for each block of the given relation, plus the `PD_ALL_VISIBLE` bit of each block.

`pg_visibility_map_summary(relation regclass, all_visible OUT bigint, all_frozen OUT bigint)` returns record

Returns the number of all-visible pages and the number of all-frozen pages in the relation according to the visibility map.

`pg_check_frozen(relation regclass, t_ctid OUT tid)` returns setof tid

Returns the TIDs of non-frozen tuples stored in pages marked all-frozen in the visibility map. If this function returns a non-empty set of TIDs, the visibility map is corrupt.

`pg_check_visible(relation regclass, t_ctid OUT tid)` returns setof tid

Returns the TIDs of non-all-visible tuples stored in pages marked all-visible in the visibility map. If this function returns a non-empty set of TIDs, the visibility map is corrupt.

`pg_truncate_visibility_map(relation regclass)` returns void

Truncates the visibility map for the given relation. This function is useful if you believe that the visibility map for the relation is corrupt and wish to force rebuilding it. The first `VACUUM` executed on the given relation after this function is executed will scan every page in the relation and rebuild the visibility map. (Until that is done, queries will treat the visibility map as containing all zeroes.)

By default, these functions are executable only by superusers and roles with privileges of the `pg_stat_scan_tables` role, with the exception of `pg_truncate_visibility_map(relation regclass)` which can only be executed by superusers.

Robert Haas <rhaas@postgresql.org>

## F.69. pg\_wait\_sampling — collecting sampling-based statistics on wait events

pg\_wait\_sampling is a Postgres Pro extension for collecting sampling-based statistics on wait events.

Starting from the 9.6 version, Postgres Pro Enterprise provides information about the current wait events for particular processes. However, to get descriptive statistics of the server activity, you have to sample wait events multiple times. The pg\_wait\_sampling extension automates wait events sampling by launching a special background worker. With pg\_wait\_sampling enabled, you can get the following sampling-based data:

- *Waits history* — the list of wait events for recent processes, with timestamps.
- *Waits profile* — the number of wait event samples for all processes over time (per wait event type).
- Current wait events for all processes, including background workers.

Using pg\_wait\_sampling, you can troubleshoot dependencies for queries that process longer than expected. You can see what a particular process is waiting for at each moment of time, and analyze wait events statistics. For the list of possible wait events, see [Table 28.4](#).

In combination with pg\_stat\_statements, this extension can also provide per query statistics.

### See Also

[Viewing Statistics on Wait Events](#)

[Reference](#)

### F.69.1. Installation

The pg\_wait\_sampling extension is included into Postgres Pro Enterprise and requires no special prerequisites.

To enable pg\_wait\_sampling, do the following:

1. Add pg\_wait\_sampling to the shared\_preload\_libraries variable in the postgresql.conf file:

```
shared_preload_libraries = 'pg_wait_sampling'
```

#### Important

When using the pg\_wait\_sampling with the pg\_stat\_statements extension, place pg\_stat\_statements before pg\_wait\_sampling in the shared\_preload\_libraries variable. This ensures that the pg\_stat\_statements extension does not overwrite query IDs that are used by pg\_wait\_sampling.

2. Create the pg\_wait\_sampling extension using the following query:

```
CREATE EXTENSION pg_wait_sampling;
```

3. Restart the server. Since pg\_wait\_sampling requires additional shared memory and launches a background worker, you must restart the server after adding or removing pg\_wait\_sampling.

Once the extension is created, pg\_wait\_sampling starts collecting statistics on wait events for each process. Optionally, you can change the sampling frequency and configure statistics collection modes using [GUC variables](#).

If you want to stop collecting statistics, drop the pg\_wait\_sampling extension, remove the pg\_wait\_sampling from the shared\_preload\_libraries variable, and restart the server again.

### F.69.2. Usage

#### F.69.2.1. Viewing Statistics on Wait Events

When pg\_wait\_sampling is enabled, wait events are sampled each 10ms by default. You can access the collected statistics through a set of functions and views. If some of your queries appear stalled or take longer than expected, you can review all the current wait events in the pg\_wait\_sampling\_current view:

```
SELECT * FROM pg_wait_sampling_current;
```

The returned statistics covers all the active processes, including background workers. To filter the view for a single process, run `pg_wait_sampling_get_current()` function specifying the process ID:

```
SELECT * FROM pg_wait_sampling_get_current(pid);
```

To better understand the dynamics of the recent wait events, you can access the `pg_wait_sampling_history` view that provides the wait events history for the latest processes:

```
SELECT * FROM pg_wait_sampling_history;
```

The returned view displays wait samples per process, with event timestamps. Waits history is implemented as an in-memory ring buffer. By default, the history size is limited to 5000 samples. To save history for a longer period of time, you can modify the `pg_wait_sampling.history_size` variable, or connect a client application to periodically read waits history and dump it to a local storage.

To monitor wait events in your database over time, use the `pg_wait_sampling_profile` view:

```
SELECT * FROM pg_wait_sampling_profile;
```

Waits profile is stored as an in-memory hash table that accumulates samples per each process and each wait event. You can reset waits profile by calling the `pg_wait_sampling_reset_profile()` function. If you connect a client to your database that periodically dumps the wait events data and resets the profile, you can save and compare statistics of wait events intensity over time.

### Important

Since wait sampling statistics is stored in RAM, make sure to reset the waits profile from time to time to avoid memory overflow.

If you are not interested in the distribution of wait events between processes, you can set the `pg_wait_sampling.profile_pid` variable to `false`. In this case, the `pid` value for each process is set to zero, and wait samples for all the processes are stored together.

## F.69.3. Reference

### F.69.3.1. GUC Variables

The `pg_wait_sampling` extension is configured with GUC variables. They are stored in the local memory and can be changed in the `postgresql.conf` file or using the `ALTER SYSTEM` command. For the changes to take effect, reload the server configuration. You can do it, for example, by calling the `pg_reload_conf()` function or executing the `pg_ctl reload` command.

`pg_wait_sampling.history_size` (int4)

Size of in-memory ring buffer for history sampling, in the number of samples.

Default: 5000

`pg_wait_sampling.history_period` (int4)

Time interval for history sampling, in milliseconds.

Default: 10

`pg_wait_sampling.profile_period` (int4)

Time interval for waits profile sampling, in milliseconds.

Default: 10

`pg_wait_sampling.profile_pid` (bool)

Sampling mode for waits profile. If set to `true`, waits profile is collected per process. If you set `pg_wait_sampling.profile_pid` to `false`, waits profile is collected for all processes together. In this case, the `pid` value for each process is set to zero, and the corresponding row contains wait samples for all the processes.

Default: `true`

#### `pg_wait_sampling.profile_queries` (enum)

Sampling mode for the waits profile. If `pg_wait_sampling.profile_queries` is set to `none`, the `queryid` field in views will be zero. If it is set to `top`, query IDs of only the top level statements are recorded. If it is set to `all`, query IDs of nested statements are recorded. To collect the waits profile per query, ensure that the [pg\\_stat\\_statements](#) extension is configured and set `pg_wait_sampling.profile_queries` to `top`. For version 14 or higher, you can compute query IDs by configuring the `compute_query_id` parameter and set the `pg_wait_sampling.profile_queries` value to `top` or `all`. For details, see [Section 19.9.2](#).

Default: `top`

#### `pg_wait_sampling.sample_cpu` (bool)

The sampling mode that determines whether to perform sampling of on-CPU backends. If `pg_wait_sampling.sample_cpu` is set to `true`, then sampling also includes processes that are not waiting for anything. The wait event columns for such processes will have a `NULL` value.

Default: `true`

### F.69.3.2. `pg_wait_sampling` Views

#### F.69.3.2.1. `pg_wait_sampling_current` View

The `pg_wait_sampling_current` view provides the information about the current wait events for all processes, including background workers.

**Table F.49. `pg_wait_sampling_current` View**

| Column Name             | Column Type       | Description             |
|-------------------------|-------------------|-------------------------|
| <code>pid</code>        | <code>int4</code> | Process ID              |
| <code>event_type</code> | <code>text</code> | Name of wait event type |
| <code>event</code>      | <code>text</code> | Name of wait event      |
| <code>queryid</code>    | <code>int8</code> | Query ID                |

#### F.69.3.2.2. `pg_wait_sampling_history` View

The `pg_wait_sampling_history` view provides the history of wait events. This data is stored as an in-memory ring buffer.

**Table F.50. `pg_wait_sampling_history` View**

| Column Name             | Column Type             | Description             |
|-------------------------|-------------------------|-------------------------|
| <code>pid</code>        | <code>int4</code>       | Process ID              |
| <code>ts</code>         | <code>timestampz</code> | Sample timestamp        |
| <code>event_type</code> | <code>text</code>       | Name of wait event type |
| <code>event</code>      | <code>text</code>       | Name of wait event      |
| <code>queryid</code>    | <code>int8</code>       | Query ID                |

#### F.69.3.2.3. `pg_wait_sampling_profile` View

The `pg_wait_sampling_profile` view provides the profile of wait events. This data is stored as an in-memory hash table.

**Table F.51. `pg_wait_sampling_profile` View**

| Column Name             | Column Type       | Description             |
|-------------------------|-------------------|-------------------------|
| <code>pid</code>        | <code>int4</code> | Process ID              |
| <code>event_type</code> | <code>text</code> | Name of wait event type |

| Column Name | Column Type | Description        |
|-------------|-------------|--------------------|
| event       | text        | Name of wait event |
| queryid     | int8        | Query ID           |
| count       | int8        | Number of samples  |

### F.69.3.3. Functions

`pg_wait_sampling_get_current(pid int4)`

Returns the `pg_wait_sampling_current` view with the list of current wait events. If you set the *pid* argument, the view is filtered for the process with this *pid*.

Arguments:

- *pid* — Optional. The process ID for which to display the current wait events.

`pg_wait_sampling_reset_profile()`

Resets the waits profile and clears the memory.

## F.70. pg\_walinspect — low-level WAL inspection

The `pg_walinspect` module provides SQL functions that allow you to inspect the contents of write-ahead log of a running Postgres Pro database cluster at a low level, which is useful for debugging, analytical, reporting or educational purposes. It is similar to `pg_waldump`, but accessible through SQL rather than a separate utility.

All the functions of this module will provide the WAL information using the server's current timeline ID.

### Note

The `pg_walinspect` functions are often called using an LSN argument that specifies the location at which a known WAL record of interest *begins*. However, some functions, such as `pg_logical_emit_message`, return the LSN *after* the record that was just inserted.

### Tip

All of the `pg_walinspect` functions that show information about records that fall within a certain LSN range are permissive about accepting *end\_lsn* arguments that are after the server's current LSN. Using an *end\_lsn* “from the future” will not raise an error.

It may be convenient to provide the value `FFFFFFFF/FFFFFFFF` (the maximum valid `pg_lsn` value) as an *end\_lsn* argument. This is equivalent to providing an *end\_lsn* argument matching the server's current LSN.

By default, use of these functions is restricted to superusers and members of the `pg_read_server_files` role. Access may be granted by superusers to others using `GRANT`.

### F.70.1. General Functions

`pg_get_wal_record_info(in_lsn pg_lsn)` returns record

Gets WAL record information about a record that is located at or after the *in\_lsn* argument. For example:

```
postgres=# SELECT * FROM pg_get_wal_record_info('0/E419E28');
-[RECORD 1]-----+-----
start_lsn | 0/E419E28
end_lsn | 0/E419E68
prev_lsn | 0/E419D78
xid | 0
resource_manager | Heap2
record_type | VACUUM
record_length | 58
main_data_length | 2
fpi_length | 0
description | nunused: 5, unused: [1, 2, 3, 4, 5]
block_ref | blkref #0: rel 1663/16385/1249 fork main blk 364
```

If *in\_lsn* isn't at the start of a WAL record, information about the next valid WAL record is shown instead. If there is no next valid WAL record, the function raises an error.

`pg_get_wal_records_info(start_lsn pg_lsn, end_lsn pg_lsn)` returns setof record

Gets information of all the valid WAL records between *start\_lsn* and *end\_lsn*. Returns one row per WAL record. For example:

```
postgres=# SELECT * FROM pg_get_wal_records_info('0/1E913618', '0/1E913740') LIMIT
1;
-[RECORD 1]-----+-----
start_lsn | 0/1E913618
end_lsn | 0/1E913650
prev_lsn | 0/1E9135A0
```

|                  |                                                               |
|------------------|---------------------------------------------------------------|
| xid              | 0                                                             |
| resource_manager | Standby                                                       |
| record_type      | RUNNING_XACTS                                                 |
| record_length    | 50                                                            |
| main_data_length | 24                                                            |
| fpi_length       | 0                                                             |
| description      | nextXid 33775 latestCompletedXid 33774 oldestRunningXid 33775 |
| block_ref        |                                                               |

The function raises an error if `start_lsn` is not available.

`pg_get_wal_block_info(start_lsn pg_lsn, end_lsn pg_lsn, show_data boolean DEFAULT true)`  
returns setof record

Gets information about each block reference from all the valid WAL records between `start_lsn` and `end_lsn` with one or more block references. Returns one row per block reference per WAL record. For example:

```
postgres=# SELECT * FROM pg_get_wal_block_info('0/1230278', '0/12302B8');
```

```
-[RECORD 1]-----+-----
start_lsn | 0/1230278
end_lsn | 0/12302B8
prev_lsn | 0/122FD40
block_id | 0
reltablespace | 1663
reldatabase | 1
relfilenode | 2658
relforknumber | 0
relblocknumber | 11
xid | 341
resource_manager | Btree
record_type | INSERT_LEAF
record_length | 64
main_data_length | 2
block_data_length | 16
block_fpi_length | 0
block_fpi_info |
description | off: 46
block_data | \x00002a000700104026300000070696400
block_fpi_data |
```

This example involves a WAL record that only contains one block reference, but many WAL records contain several block references. Rows output by `pg_get_wal_block_info` are guaranteed to have a unique combination of `start_lsn` and `block_id` values.

Much of the information shown here matches the output that `pg_get_wal_records_info` would show, given the same arguments. However, `pg_get_wal_block_info` unnests the information from each WAL record into an expanded form by outputting one row per block reference, so certain details are tracked at the block reference level rather than at the whole-record level. This structure is useful with queries that track how individual blocks changed over time. Note that records with no block references (e.g., COMMIT WAL records) will have no rows returned, so `pg_get_wal_block_info` may actually return *fewer* rows than `pg_get_wal_records_info`.

The `reltablespace`, `reldatabase`, and `relfilenode` parameters reference [pg\\_tablespace.oid](#), [pg\\_database.oid](#), and [pg\\_class.relfilenode](#) respectively. The `relforknumber` field is the fork number within the relation for the block reference; see `common/relpath.h` for details.

### Tip

The `pg_filenode_relation` function (see [Table 9.101](#)) can help you to determine which relation was modified during original execution.

It is possible for clients to avoid the overhead of materializing block data. This may make function execution significantly faster. When `show_data` is set to `false`, `block_data` and `block_fpi_data` values are omitted (that is, the `block_data` and `block_fpi_data` OUT arguments are NULL for all rows returned). Obviously, this optimization is only feasible with queries where block data isn't truly required.

The function raises an error if `start_lsn` is not available.

`pg_get_wal_stats(start_lsn pg_lsn, end_lsn pg_lsn, per_record boolean DEFAULT false)`  
returns setof record

Gets statistics of all the valid WAL records between `start_lsn` and `end_lsn`. By default, it returns one row per *resource\_manager* type. When `per_record` is set to `true`, it returns one row per *record\_type*. For example:

```
postgres=# SELECT * FROM pg_get_wal_stats('0/1E847D00', '0/1E84F500')
 WHERE count > 0 AND
 "resource_manager/record_type" = 'Transaction'
 LIMIT 1;
```

```
-[RECORD 1]-----+-----
resource_manager/record_type | Transaction
count | 2
count_percentage | 8
record_size | 875
record_size_percentage | 41.23468426013195
fpi_size | 0
fpi_size_percentage | 0
combined_size | 875
combined_size_percentage | 2.8634072910530795
```

The function raises an error if `start_lsn` is not available.

Bharath Rupireddy <bharath.rupireddyforpostgres@gmail.com>

## F.71. plantuner — hints for the planner to disable or enable indexes for query execution

The `plantuner` module provides hints for the planner that can disable or enable indexes for query execution.

### F.71.1. Motivation

In some cases, it may be required to control the planner by providing hints that make the optimizer ignore some parts of its algorithm. There are many situations when a developer may want to temporarily disable specific index(es), without dropping them, or to instruct the planner to use a specific index.

This version of `plantuner` provides a possibility to hide the specified indexes from Postgres Pro planner, so it will not use them. For some workloads, Postgres Pro could be too pessimistic about newly created tables and assume that there are much more rows in a table than it actually has. If the `plantuner.fix_empty_table` GUC variable is set to `true`, `plantuner` sets to zero the number of pages/tuples of the table that has no blocks in a file.

### F.71.2. GUC Variables

`plantuner.disable_index` — list of indexes invisible to planner.

`plantuner.enable_index` — list of indexes visible to planner even if they are hidden by `plantuner.disable_index`.

### F.71.3. Example

To enable the module, you can either load `plantuner` shared library in a `psql` session or specify `shared_preload_libraries` option in `postgresql.conf`.

```
=# LOAD 'plantuner';
=# create table test(id int);
=# create index id_idx on test(id);
=# create index id_idx2 on test(id);
=# \d test
 Table "public.test"
 Column | Type | Modifiers
-----+-----+-----
 id | integer |
Indexes:
 "id_idx" btree (id)
 "id_idx2" btree (id)
=# explain select id from test where id=1;
 QUERY PLAN

Bitmap Heap Scan on test (cost=4.34..15.03 rows=12 width=4)
 Recheck Cond: (id = 1)
 -> Bitmap Index Scan on id_idx2 (cost=0.00..4.34 rows=12 width=0)
 Index Cond: (id = 1)
(4 rows)
=# set enable_seqscan=off;
=# set plantuner.disable_index='id_idx2';
=# explain select id from test where id=1;
 QUERY PLAN

Bitmap Heap Scan on test (cost=4.34..15.03 rows=12 width=4)
 Recheck Cond: (id = 1)
 -> Bitmap Index Scan on id_idx (cost=0.00..4.34 rows=12 width=0)
 Index Cond: (id = 1)
(4 rows)
=# set plantuner.disable_index='id_idx2,id_idx';
=# explain select id from test where id=1;
```

```

Seq Scan on test (cost=10000000000.00..10000000040.00 rows=12 width=4)
 Filter: (id = 1)
(2 rows)
=# set plantuner.enable_index='id_idx';
=# explain select id from test where id=1;
 QUERY PLAN

Bitmap Heap Scan on test (cost=4.34..15.03 rows=12 width=4)
 Recheck Cond: (id = 1)
 -> Bitmap Index Scan on id_idx (cost=0.00..4.34 rows=12 width=0)
 Index Cond: (id = 1)
(4 rows)
```

## F.72. `postgres_fdw` — access data stored in external Postgres Pro servers

The `postgres_fdw` module provides the foreign-data wrapper `postgres_fdw`, which can be used to access data stored in external Postgres Pro servers.

The functionality provided by this module overlaps substantially with the functionality of the older `dblink` module. But `postgres_fdw` provides more transparent and standards-compliant syntax for accessing remote tables, and can give better performance in many cases.

To prepare for remote access using `postgres_fdw`:

1. Install the `postgres_fdw` extension using `CREATE EXTENSION`.
2. Create a foreign server object, using `CREATE SERVER`, to represent each remote database you want to connect to. Specify connection information, except `user` and `password`, as options of the server object.
3. Create a user mapping, using `CREATE USER MAPPING`, for each database user you want to allow to access each foreign server. Specify the remote user name and password to use as `user` and `password` options of the user mapping.
4. Create a foreign table, using `CREATE FOREIGN TABLE` or `IMPORT FOREIGN SCHEMA`, for each remote table you want to access. The columns of the foreign table must match the referenced remote table. You can, however, use table and/or column names different from the remote table's, if you specify the correct remote names as options of the foreign table object.

Now you need only `SELECT` from a foreign table to access the data stored in its underlying remote table. You can also modify the remote table using `INSERT`, `UPDATE`, `DELETE`, `COPY`, or `TRUNCATE`. (Of course, the remote user you have specified in your user mapping must have privileges to do these things.)

Note that the `ONLY` option specified in `SELECT`, `UPDATE`, `DELETE` or `TRUNCATE` has no effect when accessing or modifying the remote table.

Note that `postgres_fdw` currently lacks support for `INSERT` statements with an `ON CONFLICT DO UPDATE` clause. However, the `ON CONFLICT DO NOTHING` clause is supported, provided a unique index inference specification is omitted. Note also that `postgres_fdw` supports row movement invoked by `UPDATE` statements executed on partitioned tables, but it currently does not handle the case where a remote partition chosen to insert a moved row into is also an `UPDATE` target partition that will be updated elsewhere in the same command.

It is generally recommended that the columns of a foreign table be declared with exactly the same data types, and collations if applicable, as the referenced columns of the remote table. Although `postgres_fdw` is currently rather forgiving about performing data type conversions at need, surprising semantic anomalies may arise when types or collations do not match, due to the remote server interpreting query conditions differently from the local server.

Note that a foreign table can be declared with fewer columns, or with a different column order, than its underlying remote table has. Matching of columns to the remote table is by name, not position.

### F.72.1. FDW Options of `postgres_fdw`

#### F.72.1.1. Connection Options

A foreign server using the `postgres_fdw` foreign data wrapper can have the same options that `libpq` accepts in connection strings, as described in [Section 35.1.2](#), except that these options are not allowed or have special handling:

- `user`, `password` and `sslpassword` (specify these in a user mapping instead, or use a service file)
- `client_encoding` (this is automatically set from the local server encoding)
- `application_name` - this may appear in *either or both* a connection and `postgres_fdw.application_name`. If both are present, `postgres_fdw.application_name` overrides the connection setting. Unlike `libpq`, `postgres_fdw` allows `application_name` to include “escape sequences”. See `postgres_fdw.application_name` for details.
- `fallback_application_name` (always set to `postgres_fdw`)
- `sslkey` and `sslcert` - these may appear in *either or both* a connection and a user mapping. If both are present, the user mapping setting overrides the connection setting.

Only superusers may create or modify user mappings with the `sslcert` or `sslkey` settings.

Non-superusers may connect to foreign servers using password authentication or with GSSAPI delegated credentials, so specify the `password` option for user mappings belonging to non-superusers where password authentication is required.

A superuser may override this check on a per-user-mapping basis by setting the user mapping option `password_required` `'false'`, e.g.,

```
ALTER USER MAPPING FOR some_non_superuser SERVER loopback_nopw
OPTIONS (ADD password_required 'false');
```

To prevent unprivileged users from exploiting the authentication rights of the unix user the postgres server is running as to escalate to superuser rights, only the superuser may set this option on a user mapping.

Care is required to ensure that this does not allow the mapped user the ability to connect as superuser to the mapped database per CVE-2007-3278 and CVE-2007-6601. Don't set `password_required=false` on the `public` role. Keep in mind that the mapped user can potentially use any client certificates, `.pgpass`, `.pg_service.conf` etc. in the unix home directory of the system user the postgres server runs as. They can also use any trust relationship granted by authentication modes like `peer` or `ident` authentication.

### F.72.1.2. Object Name Options

These options can be used to control the names used in SQL statements sent to the remote Postgres Pro server. These options are needed when a foreign table is created with names different from the underlying remote table's names.

`schema_name` (string)

This option, which can be specified for a foreign table, gives the schema name to use for the foreign table on the remote server. If this option is omitted, the name of the foreign table's schema is used.

`table_name` (string)

This option, which can be specified for a foreign table, gives the table name to use for the foreign table on the remote server. If this option is omitted, the foreign table's name is used.

`column_name` (string)

This option, which can be specified for a column of a foreign table, gives the column name to use for the column on the remote server. If this option is omitted, the column's name is used.

### F.72.1.3. Cost Estimation Options

`postgres_fdw` retrieves remote data by executing queries against remote servers, so ideally the estimated cost of scanning a foreign table should be whatever it costs to be done on the remote server, plus some overhead for communication. The most reliable way to get such an estimate is to ask the remote server and then add something for overhead — but for simple queries, it may not be worth the cost of an additional remote query to get a cost estimate. So `postgres_fdw` provides the following options to control how cost estimation is done:

`use_remote_estimate` (boolean)

This option, which can be specified for a foreign table or a foreign server, controls whether `postgres_fdw` issues remote `EXPLAIN` commands to obtain cost estimates. A setting for a foreign table overrides any setting for its server, but only for that table. The default is `false`.

`fdw_startup_cost` (floating point)

This option, which can be specified for a foreign server, is a floating point value that is added to the estimated startup cost of any foreign-table scan on that server. This represents the additional overhead of establishing a connection, parsing and planning the query on the remote side, etc. The default value is `100`.

`fdw_tuple_cost` (floating point)

This option, which can be specified for a foreign server, is a floating point value that is used as extra cost per-tuple for foreign-table scans on that server. This represents the additional overhead of data transfer between servers. You might increase or decrease this number to reflect higher or lower network delay to the remote server. The default value is `0.2`.

When `use_remote_estimate` is true, `postgres_fdw` obtains row count and cost estimates from the remote server and then adds `fdw_startup_cost` and `fdw_tuple_cost` to the cost estimates. When `use_remote_estimate` is false, `post-`

`gres_fdw` performs local row count and cost estimation and then adds `fdw_startup_cost` and `fdw_tuple_cost` to the cost estimates. This local estimation is unlikely to be very accurate unless local copies of the remote table's statistics are available. Running [ANALYZE](#) on the foreign table is the way to update the local statistics; this will perform a scan of the remote table and then calculate and store statistics just as though the table were local. Keeping local statistics can be a useful way to reduce per-query planning overhead for a remote table — but if the remote table is frequently updated, the local statistics will soon be obsolete.

The following option controls how such an `ANALYZE` operation behaves:

`analyze_sampling` (string)

This option, which can be specified for a foreign table or a foreign server, determines if `ANALYZE` on a foreign table samples the data on the remote side, or reads and transfers all data and performs the sampling locally. The supported values are `off`, `random`, `system`, `bernoulli` and `auto`. `off` disables remote sampling, so all data are transferred and sampled locally. `random` performs remote sampling using the `random()` function to choose returned rows, while `system` and `bernoulli` rely on the built-in `TABLESAMPLE` methods of those names. `random` works on all remote server versions, while `TABLESAMPLE` is supported only since 9.5. `auto` (the default) picks the recommended sampling method automatically; currently it means either `bernoulli` or `random` depending on the remote server version.

#### F.72.1.4. Remote Execution Options

By default, only `WHERE` clauses using built-in operators and functions will be considered for execution on the remote server. Clauses involving non-built-in functions are checked locally after rows are fetched. If such functions are available on the remote server and can be relied on to produce the same results as they do locally, performance can be improved by sending such `WHERE` clauses for remote execution. This behavior can be controlled using the following option:

`extensions` (string)

This option is a comma-separated list of names of Postgres Pro extensions that are installed, in compatible versions, on both the local and remote servers. Functions and operators that are immutable and belong to a listed extension will be considered shippable to the remote server. This option can only be specified for foreign servers, not per-table.

When using the `extensions` option, *it is the user's responsibility* that the listed extensions exist and behave identically on both the local and remote servers. Otherwise, remote queries may fail or behave unexpectedly.

`fetch_size` (integer)

This option specifies the number of rows `postgres_fdw` should get in each fetch operation. It can be specified for a foreign table or a foreign server. The option specified on a table overrides an option specified for the server. The default is `100`.

`batch_size` (integer)

This option specifies the number of rows `postgres_fdw` should insert in each insert operation. It can be specified for a foreign table or a foreign server. The option specified on a table overrides an option specified for the server. The default is `1`.

Note the actual number of rows `postgres_fdw` inserts at once depends on the number of columns and the provided `batch_size` value. The batch is executed as a single query, and the libpq protocol (which `postgres_fdw` uses to connect to a remote server) limits the number of parameters in a single query to 65535. When the number of columns \* `batch_size` exceeds the limit, the `batch_size` will be adjusted to avoid an error.

This option also applies when copying into foreign tables. In that case the actual number of rows `postgres_fdw` copies at once is determined in a similar way to the insert case, but it is limited to at most 1000 due to implementation restrictions of the `COPY` command.

#### F.72.1.5. Asynchronous Execution Options

`postgres_fdw` supports asynchronous execution, which runs multiple parts of an `Append` node concurrently rather than serially to improve performance. This execution can be controlled using the following option:

`async_capable` (boolean)

This option controls whether `postgres_fdw` allows foreign tables to be scanned concurrently for asynchronous execution. It can be specified for a foreign table or a foreign server. A table-level option overrides a server-level option. The default is `false`.

In order to ensure that the data being returned from a foreign server is consistent, `postgres_fdw` will only open one connection for a given foreign server and will run all queries against that server sequentially even if there are multiple foreign tables

involved, unless those tables are subject to different user mappings. In such a case, it may be more performant to disable this option to eliminate the overhead associated with running queries asynchronously.

Asynchronous execution is applied even when an **Append** node contains subplan(s) executed synchronously as well as subplan(s) executed asynchronously. In such a case, if the asynchronous subplans are ones processed using `postgres_fdw`, tuples from the asynchronous subplans are not returned until after at least one synchronous subplan returns all tuples, as that subplan is executed while the asynchronous subplans are waiting for the results of asynchronous queries sent to foreign servers. This behavior might change in a future release.

#### F.72.1.6. Transaction Management Options

As described in the Transaction Management section, in `postgres_fdw` transactions are managed by creating corresponding remote transactions, and subtransactions are managed by creating corresponding remote subtransactions. When multiple remote transactions are involved in the current local transaction, by default `postgres_fdw` commits or aborts those remote transactions serially when the local transaction is committed or aborted. When multiple remote subtransactions are involved in the current local subtransaction, by default `postgres_fdw` commits or aborts those remote subtransactions serially when the local subtransaction is committed or aborted. Performance can be improved with the following options:

`parallel_commit` (boolean)

This option controls whether `postgres_fdw` commits, in parallel, remote transactions opened on a foreign server in a local transaction when the local transaction is committed. This setting also applies to remote and local subtransactions. This option can only be specified for foreign servers, not per-table. The default is `false`.

`parallel_abort` (boolean)

This option controls whether `postgres_fdw` aborts, in parallel, remote transactions opened on a foreign server in a local transaction when the local transaction is aborted. This setting also applies to remote and local subtransactions. This option can only be specified for foreign servers, not per-table. The default is `false`.

If multiple foreign servers with these options enabled are involved in a local transaction, multiple remote transactions on those foreign servers are committed or aborted in parallel across those foreign servers when the local transaction is committed or aborted.

When these options are enabled, a foreign server with many remote transactions may see a negative performance impact when the local transaction is committed or aborted.

#### F.72.1.7. Updatability Options

By default all foreign tables using `postgres_fdw` are assumed to be updatable. This may be overridden using the following option:

`updatable` (boolean)

This option controls whether `postgres_fdw` allows foreign tables to be modified using `INSERT`, `UPDATE` and `DELETE` commands. It can be specified for a foreign table or a foreign server. A table-level option overrides a server-level option. The default is `true`.

Of course, if the remote table is not in fact updatable, an error would occur anyway. Use of this option primarily allows the error to be thrown locally without querying the remote server. Note however that the `information_schema` views will report a `postgres_fdw` foreign table to be updatable (or not) according to the setting of this option, without any check of the remote server.

#### F.72.1.8. Truncatability Options

By default all foreign tables using `postgres_fdw` are assumed to be truncatable. This may be overridden using the following option:

`truncatable` (boolean)

This option controls whether `postgres_fdw` allows foreign tables to be truncated using the `TRUNCATE` command. It can be specified for a foreign table or a foreign server. A table-level option overrides a server-level option. The default is `true`.

Of course, if the remote table is not in fact truncatable, an error would occur anyway. Use of this option primarily allows the error to be thrown locally without querying the remote server.

### F.72.1.9. Importing Options

`postgres_fdw` is able to import foreign table definitions using [IMPORT FOREIGN SCHEMA](#). This command creates foreign table definitions on the local server that match tables or views present on the remote server. If the remote tables to be imported have columns of user-defined data types, the local server must have compatible types of the same names.

Importing behavior can be customized with the following options (given in the `IMPORT FOREIGN SCHEMA` command):

`import_collate` (boolean)

This option controls whether column `COLLATE` options are included in the definitions of foreign tables imported from a foreign server. The default is `true`. You might need to turn this off if the remote server has a different set of collation names than the local server does, which is likely to be the case if it's running on a different operating system. If you do so, however, there is a very severe risk that the imported table columns' collations will not match the underlying data, resulting in anomalous query behavior.

Even when this parameter is set to `true`, importing columns whose collation is the remote server's default can be risky. They will be imported with `COLLATE "default"`, which will select the local server's default collation, which could be different.

`import_default` (boolean)

This option controls whether column `DEFAULT` expressions are included in the definitions of foreign tables imported from a foreign server. The default is `false`. If you enable this option, be wary of defaults that might get computed differently on the local server than they would be on the remote server; `nextval()` is a common source of problems. The `IMPORT` will fail altogether if an imported default expression uses a function or operator that does not exist locally.

`import_generated` (boolean)

This option controls whether column `GENERATED` expressions are included in the definitions of foreign tables imported from a foreign server. The default is `true`. The `IMPORT` will fail altogether if an imported generated expression uses a function or operator that does not exist locally.

`import_not_null` (boolean)

This option controls whether column `NOT NULL` constraints are included in the definitions of foreign tables imported from a foreign server. The default is `true`.

Note that constraints other than `NOT NULL` will never be imported from the remote tables. Although Postgres Pro does support check constraints on foreign tables, there is no provision for importing them automatically, because of the risk that a constraint expression could evaluate differently on the local and remote servers. Any such inconsistency in the behavior of a check constraint could lead to hard-to-detect errors in query optimization. So if you wish to import check constraints, you must do so manually, and you should verify the semantics of each one carefully. For more detail about the treatment of check constraints on foreign tables, see [CREATE FOREIGN TABLE](#).

Tables or foreign tables which are partitions of some other table are imported only when they are explicitly specified in `LIMIT TO` clause. Otherwise they are automatically excluded from [IMPORT FOREIGN SCHEMA](#). Since all data can be accessed through the partitioned table which is the root of the partitioning hierarchy, importing only partitioned tables should allow access to all the data without creating extra objects.

### F.72.1.10. Connection Management Options

By default, all connections that `postgres_fdw` establishes to foreign servers are kept open in the local session for re-use.

`keep_connections` (boolean)

This option controls whether `postgres_fdw` keeps the connections to the foreign server open so that subsequent queries can re-use them. It can only be specified for a foreign server. The default is `on`. If set to `off`, all connections to this foreign server will be discarded at the end of each transaction.

## F.72.2. Functions

`postgres_fdw_get_connections(OUT server_name text, OUT valid boolean)` returns `setof record`

This function returns the foreign server names of all the open connections that `postgres_fdw` established from the local session to the foreign servers. It also returns whether each connection is valid or not. `false` is returned if the foreign server

connection is used in the current local transaction but its foreign server or user mapping is changed or dropped (Note that server name of an invalid connection will be `NULL` if the server is dropped), and then such invalid connection will be closed at the end of that transaction. `true` is returned otherwise. If there are no open connections, no record is returned. Example usage of the function:

```
postgres=# SELECT * FROM postgres_fdw_get_connections() ORDER BY 1;
 server_name | valid
-----+-----
 loopback1 | t
 loopback2 | f
```

`postgres_fdw_disconnect(server_name text)` returns boolean

This function discards the open connections that are established by `postgres_fdw` from the local session to the foreign server with the given name. Note that there can be multiple connections to the given server using different user mappings. If the connections are used in the current local transaction, they are not disconnected and warning messages are reported. This function returns `true` if it disconnects at least one connection, otherwise `false`. If no foreign server with the given name is found, an error is reported. Example usage of the function:

```
postgres=# SELECT postgres_fdw_disconnect('loopback1');
 postgres_fdw_disconnect

 t
```

`postgres_fdw_disconnect_all()` returns boolean

This function discards all the open connections that are established by `postgres_fdw` from the local session to foreign servers. If the connections are used in the current local transaction, they are not disconnected and warning messages are reported. This function returns `true` if it disconnects at least one connection, otherwise `false`. Example usage of the function:

```
postgres=# SELECT postgres_fdw_disconnect_all();
 postgres_fdw_disconnect_all

 t
```

### F.72.3. Connection Management

`postgres_fdw` establishes a connection to a foreign server during the first query that uses a foreign table associated with the foreign server. By default this connection is kept and re-used for subsequent queries in the same session. This behavior can be controlled using `keep_connections` option for a foreign server. If multiple user identities (user mappings) are used to access the foreign server, a connection is established for each user mapping.

When changing the definition of or removing a foreign server or a user mapping, the associated connections are closed. But note that if any connections are in use in the current local transaction, they are kept until the end of the transaction. Closed connections will be re-established when they are necessary by future queries using a foreign table.

Once a connection to a foreign server has been established, it's by default kept until the local or corresponding remote session exits. To disconnect a connection explicitly, `keep_connections` option for a foreign server may be disabled, or `postgres_fdw_disconnect` and `postgres_fdw_disconnect_all` functions may be used. For example, these are useful to close connections that are no longer necessary, thereby releasing connections on the foreign server.

### F.72.4. Transaction Management

During a query that references any remote tables on a foreign server, `postgres_fdw` opens a transaction on the remote server if one is not already open corresponding to the current local transaction. The remote transaction is committed or aborted when the local transaction commits or aborts. Savepoints are similarly managed by creating corresponding remote savepoints.

The remote transaction uses `SERIALIZABLE` isolation level when the local transaction has `SERIALIZABLE` isolation level; otherwise it uses `REPEATABLE READ` isolation level. This choice ensures that if a query performs multiple table scans on the remote server, it will get snapshot-consistent results for all the scans. A consequence is that successive queries within a single transaction will see the same data from the remote server, even if concurrent updates are occurring on the remote server due to other activities. That behavior would be expected anyway if the local transaction uses `SERIALIZABLE` or `REPEATABLE READ` isolation level, but it might be surprising for a `READ COMMITTED` local transaction. A future Postgres Pro release might modify these rules.

Note that it is currently not supported by `postgres_fdw` to prepare the remote transaction for two-phase commit.

## F.72.5. Remote Query Optimization

`postgres_fdw` attempts to optimize remote queries to reduce the amount of data transferred from foreign servers. This is done by sending query `WHERE` clauses to the remote server for execution, and by not retrieving table columns that are not needed for the current query. To reduce the risk of misexecution of queries, `WHERE` clauses are not sent to the remote server unless they use only data types, operators, and functions that are built-in or belong to an extension that's listed in the foreign server's `extensions` option. Operators and functions in such clauses must be `IMMUTABLE` as well. For an `UPDATE` or `DELETE` query, `postgres_fdw` attempts to optimize the query execution by sending the whole query to the remote server if there are no query `WHERE` clauses that cannot be sent to the remote server, no local joins for the query, no row-level local `BEFORE` or `AFTER` triggers or stored generated columns on the target table, and no `CHECK OPTION` constraints from parent views. In `UPDATE`, expressions to assign to target columns must use only built-in data types, `IMMUTABLE` operators, or `IMMUTABLE` functions, to reduce the risk of misexecution of the query.

When `postgres_fdw` encounters a join between foreign tables on the same foreign server, it sends the entire join to the foreign server, unless for some reason it believes that it will be more efficient to fetch rows from each table individually, or unless the table references involved are subject to different user mappings. While sending the `JOIN` clauses, it takes the same precautions as mentioned above for the `WHERE` clauses.

The query that is actually sent to the remote server for execution can be examined using `EXPLAIN VERBOSE`.

## F.72.6. Remote Query Execution Environment

In the remote sessions opened by `postgres_fdw`, the `search_path` parameter is set to just `pg_catalog`, so that only built-in objects are visible without schema qualification. This is not an issue for queries generated by `postgres_fdw` itself, because it always supplies such qualification. However, this can pose a hazard for functions that are executed on the remote server via triggers or rules on remote tables. For example, if a remote table is actually a view, any functions used in that view will be executed with the restricted search path. It is recommended to schema-qualify all names in such functions, or else attach `SET search_path` options (see [CREATE FUNCTION](#)) to such functions to establish their expected search path environment.

`postgres_fdw` likewise establishes remote session settings for various parameters:

- `TimeZone` is set to `UTC`
- `DateStyle` is set to `ISO`
- `IntervalStyle` is set to `postgres`
- `extra_float_digits` is set to 3 for remote servers 9.0 and newer and is set to 2 for older versions

These are less likely to be problematic than `search_path`, but can be handled with function `SET` options if the need arises.

It is *not* recommended that you override this behavior by changing the session-level settings of these parameters; that is likely to cause `postgres_fdw` to malfunction.

## F.72.7. Cross-Version Compatibility

`postgres_fdw` can be used with remote servers dating back to PostgreSQL 8.3. Read-only capability is available back to 8.1. A limitation however is that `postgres_fdw` generally assumes that immutable built-in functions and operators are safe to send to the remote server for execution, if they appear in a `WHERE` clause for a foreign table. Thus, a built-in function that was added since the remote server's release might be sent to it for execution, resulting in “function does not exist” or a similar error. This type of failure can be worked around by rewriting the query, for example by embedding the foreign table reference in a sub-`SELECT` with `OFFSET 0` as an optimization fence, and placing the problematic function or operator outside the sub-`SELECT`.

## F.72.8. Wait Events

`postgres_fdw` can report the following wait events under the wait event type `Extension`:

`PostgresFdwCleanupResult`

Waiting for transaction abort on remote server.

`PostgresFdwConnect`

Waiting to establish a connection to a remote server.

## PostgresFdwGetResult

Waiting to receive the results of a query from a remote server.

## F.72.9. Configuration Parameters

`postgres_fdw.application_name` (string)

Specifies a value for `application_name` configuration parameter used when `postgres_fdw` establishes a connection to a foreign server. This overrides `application_name` option of the server object. Note that change of this parameter doesn't affect any existing connections until they are re-established.

`postgres_fdw.application_name` can be any string of any length and contain even non-ASCII characters. However when it's passed to and used as `application_name` in a foreign server, note that it will be truncated to less than `NAME-DALEN` characters. Anything other than printable ASCII characters are replaced with [C-style hexadecimal escapes](#). See [application\\_name](#) for details.

% characters begin “escape sequences” that are replaced with status information as outlined below. Unrecognized escapes are ignored. Other characters are copied straight to the application name. Note that it's not allowed to specify a plus/minus sign or a numeric literal after the % and before the option, for alignment and padding.

| Escape | Effect                                                                       |
|--------|------------------------------------------------------------------------------|
| %a     | Application name on local server                                             |
| %c     | Session ID on local server (see <a href="#">log_line_prefix</a> for details) |
| %C     | Cluster name on local server (see <a href="#">cluster_name</a> for details)  |
| %u     | User name on local server                                                    |
| %d     | Database name on local server                                                |
| %p     | Process ID of backend on local server                                        |
| %%     | Literal %                                                                    |

For example, suppose user `local_user` establishes a connection from database `local_db` to `foreign_db` as user `foreign_user`, the setting `'db=%d, user=%u'` is replaced with `'db=local_db, user=local_user'`.

`postgres_fdw.read_only_transactions` (boolean)

Enables read-only queries to foreign tables in read-write transactions. If set to `on`, all remote transactions executed by the extension are created as `READ ONLY`.

## F.72.10. Examples

Here is an example of creating a foreign table with `postgres_fdw`. First install the extension:

```
CREATE EXTENSION postgres_fdw;
```

Then create a foreign server using [CREATE SERVER](#). In this example we wish to connect to a Postgres Pro server on host `192.83.123.89` listening on port `5432`. The database to which the connection is made is named `foreign_db` on the remote server:

```
CREATE SERVER foreign_server
 FOREIGN DATA WRAPPER postgres_fdw
 OPTIONS (host '192.83.123.89', port '5432', dbname 'foreign_db');
```

A user mapping, defined with [CREATE USER MAPPING](#), is needed as well to identify the role that will be used on the remote server:

```
CREATE USER MAPPING FOR local_user
 SERVER foreign_server
 OPTIONS (user 'foreign_user', password 'password');
```

Now it is possible to create a foreign table with [CREATE FOREIGN TABLE](#). In this example we wish to access the table named `some_schema.some_table` on the remote server. The local name for it will be `foreign_table`:

```
CREATE FOREIGN TABLE foreign_table (
 id integer NOT NULL,
 data text
)
 SERVER foreign_server
 OPTIONS (schema_name 'some_schema', table_name 'some_table');
```

It's essential that the data types and other properties of the columns declared in `CREATE FOREIGN TABLE` match the actual remote table. Column names must match as well, unless you attach `column_name` options to the individual columns to show how they are named in the remote table. In many cases, use of `IMPORT FOREIGN SCHEMA` is preferable to constructing foreign table definitions manually.

## F.72.11. Author

Shigeru Hanada <shigeru.hanada@gmail.com>

## F.73. proxima — a combination of a proxy and a connection pooler

proxima is a Postgres Pro Enterprise extension that combines functionality of a proxy server and a connection pooler.

### F.73.1. Overview

The proxima extension can be used on a single-node Postgres Pro Enterprise server, in a standard Postgres Pro Enterprise primary-standby cluster or a [BiHA cluster](#). The extension offers the following features:

- *Proxy server*: proxima becomes a single connection point for client connections and redirects queries to the primary server or the BiHA cluster leader.
- *Workload distribution*: proxima can distribute read-only workloads between cluster replicas.
- *Connection pooler*: proxima manages backend processes to lower consumption of system resources and prevent performance degradation.
- *SSL support*: you can configure proxima to operate with SSL connections.
- *Monitoring*: when using proxima with BiHA, you can view a variety of metrics to track the proxima state.
- *Dynamic dedicated session*: proxima maintains a session between the client and the backend for the entire lifetime of the client connection.

#### F.73.1.1. Authentication

The proxima extension uses the same authentication rules that are listed in the `pg_hba.conf` file. The following authentication methods are supported:

- [trust](#)
- [password](#)
- [md5](#)
- [scram-sha-256](#)
- [ldap](#)

#### F.73.1.2. Workload Distribution

The proxima extension provides the following ports to process client sessions:

- The *Proxy-to-Leader (P2L)* port redirects all workloads to the primary (leader) node. The default is 4545, which can be changed using the `proxima.port` parameter. The P2L port number must be identical on all nodes of the cluster.
- The *Proxy-to-Follower (P2F)* port distributes read-only workloads across cluster replicas. The default is 4547, which can be changed using the `proxima.p2f_port` parameter.

#### Note

In a BiHA cluster, queries are redirected to the leader in the `LEADER_RW` state. However, read-only workloads sent to the P2F port can also be redirected to the leader in the `LEADER_RO` state. For more information about BiHA cluster node states, refer to [biha.status\\_v](#).

To distribute workloads across cluster nodes, configure your client application to send write workloads to the P2L port and read-only workloads to the P2F port. For more information, refer to [Section F.73.3.4](#).

#### Important

proxima attaches a client session to a certain cluster node to ensure that all transactions within this particular session are executed on the same node. If this node fails during the session, the client connection is aborted.

#### F.73.1.3. Dynamic Dedicated Session

When executing queries, a backend may keep temporary state within one session and create objects specific for this session, such as temporary tables, temporary views, etc. This information and these objects are not available for other backends. If a connection

pooler redirects a client to another backend after such an object is created, the client has no more access to the object. To avoid this issue, proxima offers the *dynamic dedicated session* functionality that allows to retain sessions between clients and specific backends during the client connection lifetime.

### Note

If you use extensions that keep their state within a session, you must manually enable the *forced dynamic dedicated session*. For more information, refer to [Section F.73.3.3](#).

The proxima extension establishes the dynamic dedicated session automatically if a query contains any of the following objects or SQL functions:

- [temporary tables](#)
- [temporary sequences](#)
- [temporary views](#)
- [prepared statements](#)
- [cursors](#)
- [notification mechanisms](#)
- [SET SESSION](#)
- [SET SESSION AUTHORIZATION](#)
- [set\\_config\(\)](#)
- [pg\\_backend\\_set\\_config\(\)](#)

### Note

When using the `pg_backend_set_config` function, the dynamic dedicated session is established for the target backend with the specified PID, rather than the one where the function is called from.

- [SET ROLE](#)
- [pg\\_advisory\\_lock](#)
- [SET SESSION CHARACTERISTICS AS TRANSACTION](#)
- [setseed\(\)](#)

The session remains dedicated until the above mentioned objects are deleted.

The `DISCARD` function deletes session objects. After executing `DISCARD ALL`, a backend exits both the dynamic dedicated session and forced dynamic dedicated session.

#### F.73.1.3.1. Integration with `pgpro_multiplan` for Prepared Statements

To avoid establishing dynamic dedicated sessions for queries with prepared statements, use the global prepared statements functionality of `pgpro_multiplan`. The `pgpro_multiplan` extension provides storing of prepared statements in shared memory making them available for all backends within a single node.

To use the global prepared statements functionality, add the `pgpro_multiplan` extension to `shared_preload_libraries` in `postgresql.conf` mutually with proxima:

```
shared_preload_libraries = 'proxima, pgpro_multiplan'
```

It is not required to execute `CREATE EXTENSION`, enable `pgpro_multiplan`, or modify any `pgpro_multiplan` configuration parameters.

### Note

Note that modification of `pgpro_multiplan` parameters related to global prepared statements impact the behavior of prepared statements in Postgres Pro Enterprise backends. You can also experience this impact when working with proxima. For example, if the `pgpro_multiplan.global_prepared_statements` parameter is set to `ON`, prepared statements are visible to all clients connected to the node.

When using `pgpro_multiplan` mutually with `proxima`, consider [migration recommendations](#).

#### F.73.1.4. Monitoring

The `proxima` extension provides the monitoring functionality with a [range of metrics](#) to track the `proxima` state. Monitoring is currently available for [BiHA clusters](#) with `proxima` enabled.

`proxima` registers the `proxima` schema in the `biha_db` database and creates there [special views](#) that are used to query metrics. For more information on viewing metrics and an example of an SQL query, refer to [Section F.73.3.5](#).

##### F.73.1.4.1. Metrics Transfer Across Cluster Nodes

To make all cluster metrics available on all nodes, every node transmits its metrics to other nodes once per second. If metrics are not received from a node within ten seconds, for example, due to connection loss or node failure, a query will not return counter values from this node.

##### F.73.1.4.2. Considerations for Queries via P2L and P2F Ports

Since metrics are queried using standard SQL, the metrics source is always the node that actually executes the query. When executing a query, consider the following:

- When connecting via the P2L port, metrics are retrieved from the cluster leader.
- When connecting via the P2F port, `proxima` may distribute consecutive metrics queries across different nodes. Due to metrics delivery latency, this may cause sequential queries showing decrease of values for integral counters.

For more information about P2L and P2F ports, refer to [Section F.73.1.2](#).

To maintain integral counter monotonicity, always take the maximum value between the current and previously observed metrics values during result processing.

### F.73.2. Considerations and Limitations

This section provides a list of considerations and limitations that must be taken into account when using `proxima`.

#### F.73.2.1. General Considerations and Limitations

- The `proxima` extension does not manage replication between cluster nodes. To provide data consistency on all nodes, either use [Built-in High Availability \(BiHA\)](#), or configure replication manually.
- IPv6 is not supported.
- Elbrus, ppc64le, and s390x CPU architectures are not supported.
- When used in a standard primary-standby cluster or a BiHA cluster, right after the launch `proxima` may log error messages about connection or synchronization faults. This behavior is normal as nodes launch at different times. The error message logging stops shortly after the launch.
- Currently, `proxima` has no mechanism to automatically establish [dynamic dedicated session](#) when you use extensions that keep their state within a session. For such cases, you must [manually enable](#) the forced dynamic dedicated session.
- [Dynamic dedicated session](#) is not established when executing `CREATE STATISTICS` in a temporary namespace.
- To enable the connection pooler to process a large number of client connections, you must set the limit of open files higher than the target number of connections:

```
sudo echo '* soft nfile {value}' >> /etc/security/limits.conf
sudo echo '* hard nfile {value}' >> /etc/security/limits.conf
ulimit -n {value}
```

For example, if the target number of client connections is 10000, set `{value}` to 11000.

#### F.73.2.2. Considerations and Limitations when Operating in a BiHA Cluster

- The `proxima` extension offers a special [operation mode](#) for a [BiHA cluster](#). When installed in the BiHA cluster, `proxima` automatically receives all required cluster configuration parameters from `biha`, such as:
  - number of cluster nodes
  - node IDs, addresses, and ports
  - node roles (leader or follower)

- You can either [install](#) proxima in the existing BiHA cluster, or [enable](#) it when setting up the cluster from scratch.
- The proxima extension does not operate on [referee](#).
- The proxima extension registers a set of [callbacks](#) to receive notifications about events in the BiHA cluster. For example, when the leader changes, proxima is notified about this event and automatically redirects traffic to the new leader. The callbacks are located in the `biha.callbacks` table of the `biha_db` database on BiHA cluster nodes. Do not delete these callbacks, as it would prevent proxima from reacting to the cluster events.
- When proxima is enabled in the BiHA cluster, cluster nodes connect to each other using the port `P2L + 1`. To ensure normal operation, the P2L port number must be identical on all nodes, and the port `P2L + 1` must be free. For more information about P2L and P2F ports, refer to [Section F.73.1.2](#).

## F.73.3. Managing proxima

This section describes how to install, configure, and use proxima.

### F.73.3.1. Installation and Configuration

The proxima extension is a built-in extension included into Postgres Pro Enterprise. To enable and configure proxima, perform the following steps:

1. Stop your Postgres Pro Enterprise server using [pg\\_ctl](#):

```
pg_ctl stop -D PGDATA_directory
```

2. Add proxima to [shared\\_preload\\_libraries](#) in [postgresql.conf](#):

```
shared_preload_libraries = 'proxima'
```

If you have a multi-node cluster, repeat this step on every node.

3. Depending on your Postgres Pro Enterprise configuration, specify the proxima configuration parameters in [postgresql.conf](#):

- For a single-node server, set the following configuration parameter:

```
proxima.cluster_mode = 'standalone'
```

- For a standard primary-standby cluster, set the following configuration parameters:

```
proxima.cluster_mode = 'guc'
proxima.cluster_config =
 'node0_id,node0_address,node0_port,node0_role;node1_id,node1_address,node1_port,node1_id'
proxima.cluster_node_id = node_id
```

For example:

```
proxima.cluster_mode = 'guc'
proxima.cluster_config = '0,192.168.0.57,4590,P;1,192.168.0.77,4590,S;'
proxima.cluster_node_id = 0
```

Ensure that the [proxima.cluster\\_config](#) values are the same on all nodes and [proxima.cluster\\_node\\_id](#) is unique for each node.

- For a BiHA cluster, set the following configuration parameter:

```
proxima.cluster_mode = 'biha'
```

When using proxima with biha, specifying cluster configuration parameters is not required as proxima receives this information directly from biha.

4. (Optional) If required, set other configuration parameters.

If you do not specify configuration parameters, proxima uses the default values. For more information about configuration parameters and their default values, refer to [Section F.73.5](#).

5. Start the node using [pg\\_ctl](#):

```
pg_ctl start -D PGDATA_directory
```

## F.73.3.2. SSL Configuration

### F.73.3.2.1. Enabling SSL

You can enable SSL both for incoming client connections and for internal communication between cluster nodes.

1. Stop the cluster nodes using `pg_ctl`.
2. Using the OpenSSL utility, generate a certificate and a private key:

```
openssl req -x509 -newkey rsa:4096 -keyout path_to_key -out path_to_certificate -
sha256 -days period_of_validity -nodes -subj "/CN=certificate_domain"
```

For example:

```
openssl req -x509 -newkey rsa:4096 -keyout ./key.pem -out ./cert.pem -sha256 -days
256 -nodes -subj "/CN=localhost"
```

3. In `postgresql.conf`, specify paths to the generated certificate and private key:

```
proxima.ssl_key = '/path/to/key.pem'
proxima.ssl_cert = '/path/to/cert.pem'
```

If you do not specify the `proxima.ssl_cert` and `proxima.ssl_key` parameters, proxima uses a certificate and a key configured for Postgres Pro in `ssl_cert_file` and `ssl_key_file`.

4. Set the following configuration parameters:

- To enable SSL for incoming connections, set the `proxima.ssl_enabled` to `on`:

```
proxima.ssl_enabled = on
```

- To enable SSL for communication between cluster nodes, set the `proxima.p2p_ssl_enabled` to `on`:

```
proxima.p2p_ssl_enabled = on
```

5. Start the nodes using `pg_ctl`.

All client connections to the proxima port or internal connections between cluster nodes are now secured with SSL.

### F.73.3.2.2. Enabling SSL Authentication for Internal Connections

Configure SSL authentication for internal connections between cluster nodes. In this procedure, you will configure SSL authentication for a two-node cluster.

1. Stop the cluster nodes using `pg_ctl`.
2. Using the OpenSSL utility, generate two public certificate and private key pairs:

```
openssl req -x509 -newkey rsa:4096 -keyout path_to_key -out path_to_certificate -
sha256 -days period_of_validity -nodes -subj "/CN=certificate_domain"
```

For example:

```
openssl req -x509 -newkey rsa:4096 -keyout ./key1.pem -out ./cert1.pem -sha256 -
days 256 -nodes -subj "/CN=localhost"
```

and

```
openssl req -x509 -newkey rsa:4096 -keyout ./key2.pem -out ./cert2.pem -sha256 -
days 256 -nodes -subj "/CN=localhost"
```

3. Create a directory and put there the generated certificates.
4. Execute the following command:

```
openssl rehash path_to_the_directory_with_certificates
```

5. Set the `proxima.p2p_auth_methods` and `proxima.ssl_trusted_certs_dir` configuration parameters as follows:

```
proxima.p2p_auth_methods = 'ssl'
proxima.ssl_trusted_certs_dir = path_to_the_directory_with_certificates
```

6. Start the nodes using `pg_ctl`.
7. Check the log to ensure that SSL authentication is successful.

The following log entries indicate that the SSL authentication method is used and that authentication has passed successfully:

```
[auth]: using SSL authentication
[auth]: authentication success
```

### F.73.3.3. Managing Dynamic Dedicated Sessions Manually

Some extensions keep their state within a session, which requires to retain the session between a client and a backend. If you use such extensions, you must manually enable the [dynamic dedicated session](#) at every connection by using the `proxima.force_dedicated` parameter.

You can manage forced dynamic dedicated sessions as follows:

- To enable the forced dynamic dedicated session, execute the following command:

```
SET proxima.force_dedicated = true;
```

- To disable the forced dynamic dedicated session, execute the following command:

```
SET proxima.force_dedicated = false;
```

- To check whether the current session is dedicated, use `proxima.is_dedicated`:

```
SHOW proxima.is_dedicated;
```

The returned `t` value means that the session is dedicated, while `f` means that it is not dedicated.

### F.73.3.4. Configuring Workload Distribution

You can configure `proxima` to distribute workloads across cluster nodes. In the example below, you will configure workload distribution for a three-node cluster with `192.168.0.1`, `192.168.0.2`, and `192.168.0.3` node addresses using the default 4545 (P2L) and 4547 (P2F) `proxima` ports.

1. Configure your client application to send write workloads to the [P2L](#) port and read-only workloads to the [P2F](#) port.

You can use the `target_session_attrs` parameter on the client side to specify the node type where the client must execute transactions and queries when connecting to the database.

For example, you can specify that queries must be executed on replicas only so within this connection the client will execute read-only queries sent to the P2F port.

2. (Optional) Specify the distribution algorithm for read-only workloads using the `proxima.load_balancer_algorithm` parameter.
3. In the connection string, list the following node addresses in accordance with the format required by your library:

```
192.168.0.1:4545
192.168.0.1:4547
192.168.0.2:4545
192.168.0.2:4547
192.168.0.3:4545
192.168.0.3:4547
```

If you use `libpq`, refer to [Section 35.1.1.3](#) for the requirements and syntax of specifying multiple addresses in a connection string.

As a result, when connected to port 4545 (P2L), write workloads are redirected to the primary (leader) node. When connected to port 4547 (P2F), read-only workloads are redirected to one of the replicas according to the selected algorithm.

### F.73.3.5. Viewing Monitoring Metrics

You can view monitoring metrics in a [BiHA cluster](#) using standard SQL queries on [metrics views](#):

- To view all cluster metrics:

```
SELECT * FROM proxima.proxima_metrics;
```

- To view all metrics of a particular node:

```
SELECT * FROM proxima.proxima_metrics WHERE node_id = node_id;
```

- To view metrics of a particular class, execute a query on a corresponding class view. For example:

```
SELECT * FROM proxima.proxima_metrics_client;
```

For more information about the monitoring functionality, refer to [Section F.73.1.4](#).

For more information about available metrics, refer to [Section F.73.6](#).

See below for the example of a query to view all metrics of the node with the 0 node ID and its output (which was cut as there are too many metrics):

```
postgres=# SELECT * FROM proxima.proxima_metrics WHERE node_id = 0;
```

| name                                     | class       | node_id | value |
|------------------------------------------|-------------|---------|-------|
| -----+-----+-----                        |             |         |       |
| thread.1.active_time_ns                  | thread-load | 0       |       |
| 12590006201                              |             |         |       |
| thread.1.purged_coroutines               | thread-load | 0       |       |
| 6                                        |             |         |       |
| thread.1.transferred_coroutines_accepted | thread-load | 0       |       |
| 2                                        |             |         |       |
| thread.1.wakeup_requests_accepted        | thread-load | 0       |       |
| 0                                        |             |         |       |
| thread.1.futex_wakeup_requests_accepted  | thread-load | 0       |       |
| 22752                                    |             |         |       |
| thread.1.active_coroutines_called        | thread-load | 0       |       |
| 72905                                    |             |         |       |
| thread.1.evruntime_once                  | thread-load | 0       |       |
| 38456                                    |             |         |       |
| thread.1.evruntime_nowait                | thread-load | 0       |       |
| 8700                                     |             |         |       |
| thread.1.scheduler.corootx_in_use        | thread-load | 0       |       |
| 19                                       |             |         |       |
| thread.1.scheduler.corootx_cached        | thread-load | 0       |       |
| 6                                        |             |         |       |
| thread.1.scheduler.cs_active             | thread-load | 0       |       |
| 1                                        |             |         |       |
| thread.1.scheduler.cs_inactive           | thread-load | 0       |       |
| 1                                        |             |         |       |
| thread.1.scheduler.cs_waiting_futex      | thread-load | 0       |       |
| 5                                        |             |         |       |
| thread.1.scheduler.cs_wakeup_futex       | thread-load | 0       |       |
| 0                                        |             |         |       |
| thread.1.scheduler.cs_waiting_io         | thread-load | 0       |       |
| 12                                       |             |         |       |
| memory.lgist-0                           | memory      | 0       |       |
| 0                                        |             |         |       |
| memory.lgist-1                           | memory      | 0       |       |
| 8                                        |             |         |       |
| memory.lgist-2                           | memory      | 0       |       |
| 15                                       |             |         |       |
| memory.lgist-3                           | memory      | 0       |       |
| 162                                      |             |         |       |

### F.73.3.6. Disabling and Enabling proxima

You can temporarily disable the proxima extension and then re-enable it using the `proxima.enabled` configuration parameter:

1. In the `postgresql.conf` file, set the `proxima.enabled` parameter as required:

- To disable proxima, set `proxima.enabled` to `off`:

```
proxima.enabled = off
```

- To enable proxima, set `proxima.enabled` to `on`:

```
proxima.enabled = on
```

2. Send the SIGHUP signal to the proxima process:

```
kill -SIGHUP proxima_pid
```

Here `proxima_pid` is the process ID of the the proxima process.

### F.73.3.7. Migration

When migrating your Postgres Pro Enterprise cluster with proxima, consider the following recommendations:

- If you upgrade the nodes of your multi-node cluster one by one from version 17.6 and lower to version 17.7 and higher, ensure that, on nodes upgraded to 17.7 and higher, the `pgpro_multiplan` extension is either not present in `shared_preload_libraries` or its `pgpro_multiplan.global_prepared_statements` parameter value is set to `off` (default).

When all nodes are upgraded, you can add `pgpro_multiplan` back to `shared_preload_libraries` and configure its parameters as required.

- Always disable proxima before you start [migrating your BiHA cluster](#). When migration is finished, re-enable proxima. You can disable and enable proxima in a BiHA cluster using the `biha.enable_proxima` function.

### F.73.3.8. Removing proxima

To stop using proxima:

1. On all nodes of the cluster, remove the extension from the `shared_preload_libraries` in `postgresql.conf`.
2. Restart the nodes using `pg_ctl`.

## F.73.4. Troubleshooting

This section contains information about typical issues that you might encounter when using proxima and the ways you can fix them.

### F.73.4.1. Database or User Not Found

The proxima extension performs authentication on a node locally and does not redirect access requests to the primary server or the leader. If a database or a user you are trying to connect to is not found, do the following:

1. Ensure that replication is configured between cluster nodes by means of the standard replication mechanism or using [BiHA](#).
2. If replication is configured and turned on, wait for some time as the data may not have reached the replica yet.

#### F.73.4.2. Failed to Connect to proxima

If you cannot connect to proxima, do the following:

1. Ensure that you use [proxima.port](#) for connection.
2. Ensure that the [pg\\_hba.conf](#) file is configured correctly.

#### F.73.4.3. Log Message: “connection cannot be established”

If you see this message from proxima in the log, do the following:

1. Ensure that all nodes are on and there are no network issues.
2. If you use the `guc cluster operation mode`, ensure that the [proxima.cluster\\_node\\_id](#) values are set up correctly for each node and match the IDs specified in [proxima.cluster\\_config](#).

#### F.73.4.4. Log Message: “failed to create cluster manager”

If you use the `guc cluster operation mode`, ensure that [proxima.cluster\\_config](#) is configured correctly:

- all required values are listed
- a set of values for each node ends with a semicolon (;)

#### F.73.4.5. Log Message: “postgres: cannot accept new connection, error: Too many open files”

Increase the maximum number of open files by means of the `ulimit -S -n` command.

#### F.73.4.6. Log Message: “router: trying to route session, last error: *error\_message*”

This log message may occur when connecting to cluster nodes.

Do the following:

- In case of a BiHA cluster, ensure that the value of the [proxima.port](#) configuration parameter (the P2L port) is the same on all nodes of your cluster. After setting identical P2L port numbers, try to reconnect.
- If different P2L port numbers are not the case, check the *error\_message* content:
  - If the message contains “failed to find leader config”, wait for the node to receive information about the primary (leader). When information is received, the connection is established.
  - If the message contains “load balancer error: are there any RO nodes in the cluster? Aborting”, ensure there are nodes in the RO state and reconnect.

### F.73.5. Configuration Parameters

#### F.73.5.1. Common Parameters

`proxima.address` (text)

Specifies the IP address of the network interface that accepts incoming connections. If set to `0.0.0.0`, the incoming connections are accepted through all network interfaces of the host. The default value is `0.0.0.0`. The value of this parameter must be the same on all nodes of the cluster.

`proxima.enabled` (boolean)

Temporarily enables and disables proxima. The available values are the following:

- `off`: temporarily stops the proxima extension.
- `on`: starts the proxima extension after it was temporarily stopped.

`proxima.force_dedicated` (boolean)

Enables and disables forced [dynamic dedicated sessions](#). The available values are the following:

- `true`: enables the forced dynamic dedicated session.
- `false`: disables the forced dynamic dedicated session.

For more information, refer to [Section F.73.3.3](#).

#### `proxima.is_dedicated` (boolean)

Allows to check whether the current session is dedicated. Returns one of the following values:

- `t`: the session is dedicated.
- `f`: the session is not dedicated.

For more information, refer to [Section F.73.3.3](#).

#### `proxima.load_balancer_algorithm` (text)

Specifies the algorithm for distributing read-only workloads between cluster replicas. The following values are supported:

- `round-robin`: workloads are distributed across replicas sequentially.
- `weighted-round-robin`: workloads are distributed across replicas sequentially, proportionally to their configured weights. If you select this algorithm, set node weights using the [proxima.load\\_balancer\\_node\\_weight](#) configuration parameter.
- `least-connections`: workloads are distributed to the replica with the lowest number of active connections.
- `random`: workloads are distributed across replicas in random order.

The default value is `round-robin`.

#### `proxima.load_balancer_node_weight` (text)

Specifies the weight of the current node for the `weighted-round-robin` algorithm set in the [proxima.load\\_balancer\\_node\\_weight](#) configuration parameter. The percentage of redirected queries to the  $k$  node is calculated based on the following formula:

$$P_k = (\text{node}_k.\text{weight} / \sum_i \text{node}_i.\text{weight}) \times 100\%$$

Only replica nodes are considered in calculation.

You can modify the parameter value without node restart by sending the SIGHUP signal.

The value can be set in the range from 1 to 10000. The default value is 100.

#### `proxima.port` (integer)

Specifies the Proxy-to-Leader (P2L) port — a TCP port where proxima accepts incoming client connections and transfers all queries to the primary (leader) node.

The value can be set in the range from 0 to 65535. The default value is 4545. The `proxima.port` number must be identical on all nodes of the cluster.

For more information about P2L and P2F ports, refer to [Section F.73.1.2](#).

#### `proxima.p2f_port` (integer)

Specifies the Proxy-to-Follower (P2F) port — a TCP port where proxima accepts incoming client connections and distribute read-only workloads between cluster replicas.

The value can be set in the range from 0 to 65535. The default value is 4547.

For more information about P2L and P2F ports, refer to [Section F.73.1.2](#).

#### `proxima.p2p_auth_methods` (text)

Specifies authentication methods for internal communication of cluster nodes. The following methods are supported:

- `trust`
- `ssl`

The default value is `trust`. You can list multiple values separated by a comma, for example:

```
proxima.p2p_auth_methods = 'trust,ssl'
```

If you list multiple methods, they are applied in descending order of priority, as follows: `ssl`, `trust`.

`proxima.p2p_ssl_enabled` (boolean)

Enables or disables SSL for internal connections between cluster nodes. The default value is `off`.

`proxima.ssl_enabled` (boolean)

Enables or disables SSL for incoming client connections on `proxima.port`. The default value is `off`. If you enable SSL without specifying `proxima.ssl_key` and `proxima.ssl_cert`, proxima will use the SSL certificate configured for Postgres Pro.

`proxima.ssl_cert` (text)

Specifies the path to the certificate that will be used for SSL connection via `proxima.port`. If not set, proxima uses the certificate specified in `ssl_cert_file`. If you set this parameter, you must also set `proxima.ssl_key`.

`proxima.ssl_key` (text)

Specifies the path to the private key file. If not set, proxima uses the key specified in `ssl_key_file`. If you set this parameter, you must also set `proxima.ssl_cert`.

`proxima.ssl_trusted_certs_dir` (text)

Specifies the path to a directory with trusted certificates when you configure SSL authentication with `proxima.p2p_auth_methods`.

`proxima.log_level` (enum)

Sets the log level for proxima messages. The following values are available: `error`, `warning`, `info`, `verbose`, `debug`. The default value is `info`.

`proxima.workers` (integer)

Sets the number of threads that are launched for processing queries by the proxima background process. The value can be set in the range from 1 to 65535. The higher the value, the more queries can be processed. The default value is 4.

### F.73.5.2. Cluster Configuration

`proxima.cluster_mode` (text)

Sets the cluster operation mode. The following modes are available:

- `standalone` mode for a single-node Postgres Pro database.
- `guc` mode for a standard Postgres Pro primary-standby cluster. The cluster configuration is set by the `proxima.cluster_config` and `proxima.cluster_node_id` parameters.
- `biha` mode for a [BiHA cluster](#). In this mode, cluster configuration is received from biha.

The default value is `standalone`. The value of this parameter must be the same on all nodes of the cluster.

`proxima.cluster_config` (text)

Sets cluster node configuration for the `guc cluster operation mode`. The value of this parameter must be the same on all nodes of the cluster. The parameters for connection and identification are specified for each node as follows:

```
'node_id,node_address,node_port,node_role'
```

where:

- `node_id` is the ID of the node specified as a value from 0 to 255. The node ID must be unique for each node of the cluster.
- `node_address` is the IP address of the node for internal connection between cluster nodes.
- `node_port` is the node port for internal connection between cluster nodes. This port must be different from `proxima.port`.
- `node_role` is the role of the node in the cluster. The available values are `P` (Primary) and `S` (Standby).

Here is an example of the `proxima.cluster_config` value for a three-node cluster:

```
'0,127.0.0.1,4090,P;1,127.0.0.1,4091,S;2,127.0.0.1,4092,S;'
```

`proxima.cluster_node_id` (integer)

Sets the unique node ID for the `guc cluster operation mode`. This parameter must not be changed once the cluster has started and until it is stopped. The node ID must be unique for each node of the cluster. The value can be set in the range from 0 to 255. The default value is 0.

The list of node IDs must always start with 0 and end with  $n-1$ , where  $n$  is the total number of nodes. For example, for a three-node cluster, the node IDs must be 0, 1, 2.

### F.73.5.3. Configuration of the Local Backend Pool

The following parameters set limits for the pool of local backends — Postgres Pro processes responsible for processing client queries.

`proxima.backend_pool_local_total_limit` (integer)

Sets the maximum number of backends that can be created on the node. The value can be set in the range from 1 to `max_connections`. The default value is 100.

`proxima.backend_pool_local_bucket_limit` (integer)

Sets the maximum number of backends that can be created within connections identified by the `user + database` binding. The value can be set in the range from 1 to the value set in `proxima.backend_pool_local_total_limit`. The default value is 100.

`proxima.backend_pool_local_overdue_interval` (float)

Sets the local backend idle time, in seconds. If a local backend is not used by clients longer than set in this parameter, the backend process will be stopped. The value can be set in the range from 1.0 to 86400.0. The default value is 10.0.

### F.73.5.4. Configuration of the Remote Backend Pool

The following parameters set limits for the pool of remote backends — logical channels that can be established through a multiplexed connection between cluster nodes to proxy queries from a standby (follower) node to the primary (leader) node. Configuring these parameters is reasonable only for multi-node clusters. The default values are optimal, and it is not recommended to change them.

`proxima.backend_pool_remote_total_limit` (integer)

Sets the maximum number of logical connection channels between cluster nodes to proxy client queries. The value can be set in the range from 1 to  $2^{32}-1$ . The default value is 100000.

`proxima.backend_pool_remote_bucket_limit` (integer)

Sets the maximum number of logical connection channels between cluster nodes to proxy client queries within connections identified by the `user + database` binding. The value can be set in the range from 1 to the value set in `proxima.backend_pool_remote_total_limit`. The default value is 1000.

`proxima.backend_pool_remote_overdue_interval` (float)

Sets the remote backend idle time, in seconds. If a remote backend is not used by clients longer than set in this parameter, the logical connection channel between cluster nodes will be closed. The value can be set in the range from 1.0 to 86400.0. The default value is 60.0.

## F.73.6. Monitoring Metrics

All proxima monitoring metrics are divided into several classes for convenient querying via [metrics views](#).

The following classes are available:

- [Thread load metrics](#)
- [Traffic metrics](#)
- [Backend pool metrics](#)
- [Client connection metrics](#)

- [RPC server metrics](#)

### F.73.6.1. Views for Monitoring Metrics

When used in a [BiHA cluster](#), proxima registers the `proxima` schema in the `biha_db` database and creates there views that are used to [query metrics](#).

The following views are available:

- `proxima.proxima_metrics` displays all cluster metrics.
- `proxima.proxima_metrics_thread_load` displays [thread load metrics](#).
- `proxima.proxima_metrics_traffic` displays [traffic metrics](#).
- `proxima.proxima_metrics_backend_pool` displays [backend pool metrics](#).
- `proxima.proxima_metrics_client` displays [client connection metrics](#).
- `proxima.proxima_metrics_rpc` displays [RPC server metrics](#).

### F.73.6.2. Thread Load Metrics

Thread load metrics display CPU utilization by proxima threads as well as metrics of the coroutine engine that proxima is based on. The number of counters that are used in this class depends on running threads.

Names of thread load metrics have the `thread.ID.counter_name`, structure, where `ID` is the internal identifier of the coroutine engine.

The following counters are available:

**Table F.52. Thread Load Counters**

| Name                                                   | Type         | Description                                                                                                                  |
|--------------------------------------------------------|--------------|------------------------------------------------------------------------------------------------------------------------------|
| <code>thread.ID.active_time_ns</code>                  | Integral     | Number of nanoseconds during which the thread executed any useful workload.                                                  |
| <code>thread.ID.purged_coroutines</code>               | Integral     | Number of coroutine contexts destructed due to prolonged inactivity.                                                         |
| <code>thread.ID.transferred_coroutines_accepted</code> | Integral     | Number of coroutine contexts transferred to this thread for execution.                                                       |
| <code>thread.ID.wakeup_requests_accepted</code>        | Integral     | Number of requests for coroutine wakeup accepted.                                                                            |
| <code>thread.ID.futex_wakeup_requests_accepted</code>  | Integral     | Number of accepted wakeup requests for a coroutine blocked on futex.                                                         |
| <code>thread.ID.active_coroutines_called</code>        | Integral     | Number of active coroutine calls. Doubling this value gives the number of coroutine context switches in the current thread.  |
| <code>thread.ID.evruntime_once</code>                  | Integral     | Number of calls to the <code>libev</code> library with thread locking to wait for events related to I/O or active timers.    |
| <code>thread.ID.evruntime_nowait</code>                | Integral     | Number of calls to the <code>libev</code> library without thread locking to wait for events related to I/O or active timers. |
| <code>thread.ID.scheduler.corocctx_in_use</code>       | Actual value | Number of coroutine contexts currently in use.                                                                               |
| <code>thread.ID.scheduler.corocctx_cached</code>       | Actual value | Number of coroutine contexts currently cached and unused, but available for quick allocation when creating new coroutines.   |

Additional Supplied Modules and  
Extensions Shipped in `post-  
grespro-ent-17-contrib`

| Name                                              | Type         | Description                                                                                                                                                      |
|---------------------------------------------------|--------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>thread.ID.scheduler.cs_active</code>        | Actual value | Number of active coroutines.                                                                                                                                     |
| <code>thread.ID.scheduler.cs_inactive</code>      | Actual value | Number of inactive coroutines.                                                                                                                                   |
| <code>thread.ID.scheduler.cs_waiting_futex</code> | Actual value | Number of coroutines waiting for futex.                                                                                                                          |
| <code>thread.ID.scheduler.cs_wakeup_futex</code>  | Actual value | Number of coroutines in the wakeup queue when locked on futex.                                                                                                   |
| <code>thread.ID.scheduler.cs_waiting_io</code>    | Actual value | Number of coroutines waiting for read or write availability on an I/O device or timer activation (for example, when locked in the <code>sleep</code> operation). |

The example of the thread load metrics query output looks as follows:

| name                                     | class       | node_id | value      |
|------------------------------------------|-------------|---------|------------|
| thread.1.active_time_ns                  | thread-load | 0       | 6319387757 |
| thread.1.purged_coroutines               | thread-load | 0       | 1          |
| thread.1.transferred_coroutines_accepted | thread-load | 0       | 2          |
| thread.1.wakeup_requests_accepted        | thread-load | 0       | 0          |
| thread.1.futex_wakeup_requests_accepted  | thread-load | 0       | 10214      |
| thread.1.active_coroutines_called        | thread-load | 0       | 32385      |
| thread.1.evruntime_once                  | thread-load | 0       | 17162      |
| thread.1.evruntime_nowait                | thread-load | 0       | 4567       |
| thread.1.scheduler.coroctx_in_use        | thread-load | 0       | 19         |
| thread.1.scheduler.coroctx_cached        | thread-load | 0       | 1          |
| thread.1.scheduler.cs_active             | thread-load | 0       | 1          |
| thread.1.scheduler.cs_inactive           | thread-load | 0       | 1          |
| thread.1.scheduler.cs_waiting_futex      | thread-load | 0       | 5          |
| thread.1.scheduler.cs_wakeup_futex       | thread-load | 0       | 0          |
| thread.1.scheduler.cs_waiting_io         | thread-load | 0       | 12         |
| thread.2.active_time_ns                  | thread-load | 0       | 974064     |
| thread.2.purged_coroutines               | thread-load | 0       | 0          |
| thread.2.transferred_coroutines_accepted | thread-load | 0       | 0          |
| thread.2.wakeup_requests_accepted        | thread-load | 0       | 0          |
| thread.2.futex_wakeup_requests_accepted  | thread-load | 0       | 6          |
| thread.2.active_coroutines_called        | thread-load | 0       | 7          |
| thread.2.evruntime_once                  | thread-load | 0       | 109        |
| thread.2.evruntime_nowait                | thread-load | 0       | 0          |
| thread.2.scheduler.coroctx_in_use        | thread-load | 0       | 1          |
| thread.2.scheduler.coroctx_cached        | thread-load | 0       | 0          |
| thread.2.scheduler.cs_active             | thread-load | 0       | 0          |
| thread.2.scheduler.cs_inactive           | thread-load | 0       | 0          |
| thread.2.scheduler.cs_waiting_futex      | thread-load | 0       | 1          |
| thread.2.scheduler.cs_wakeup_futex       | thread-load | 0       | 0          |
| thread.2.scheduler.cs_waiting_io         | thread-load | 0       | 0          |
| ...                                      |             |         |            |

### F.73.6.3. Traffic Metrics

The traffic metrics display counters of bytes and/or messages that are transferred via the communication channel, as well as the number of dropped messages and reconnections if supported by this communication channel.

Names of traffic metrics have the `traffic.CHANNEL.COUNTER` structure, where:

- `CHANNEL` is the channel, which data is displayed in the query output. The following channels are supported:

- `fe` (frontend): data transfer between all clients and proxima.
- `be` (backend): data transfer between proxima and backends of proxima.
- `rpc` (RPC, Remote Procedure Call): data transfer between proxima and other processes of the current database instance.
- `nodeID.client`: data transfer via the client connection between the current node and the node with the `ID` identifier.
- `nodeID.server`: data transfer via the server connection between the current node and the node with the `ID` identifier.
- `COUNTER` is the name of the counter.

The following counters are available:

**Table F.53. Traffic Counters**

| Name                                         | Type     | Description                                                                                                       |
|----------------------------------------------|----------|-------------------------------------------------------------------------------------------------------------------|
| <code>traffic.CHANNEL.rx_bytes</code>        | Integral | Number of bytes received via the communication channel.                                                           |
| <code>traffic.CHANNEL.tx_bytes</code>        | Integral | Number of bytes transmitted through the communication channel.                                                    |
| <code>traffic.CHANNEL.rx_msgs</code>         | Integral | Number of messages received. This counter is only present if a channel supports tracking of separate messages.    |
| <code>traffic.CHANNEL.tx_msgs</code>         | Integral | Number of messages transmitted. This counter is only present if a channel supports tracking of separate messages. |
| <code>traffic.CHANNEL.rx_msgs_dropped</code> | Integral | Number of dropped messages. This counter is only present if a channel supports message dropping.                  |
| <code>traffic.CHANNEL.reconnects</code>      | Integral | Number of reconnections after failures. This counter is only present if a channel supports reconnections.         |

The example of the traffic metrics query output looks as follows:

| name                                 | class   | node_id | value    |
|--------------------------------------|---------|---------|----------|
| traffic.fe.rx_bytes                  | traffic | 0       | 943      |
| traffic.fe.tx_bytes                  | traffic | 0       | 10632    |
| traffic.be.rx_bytes                  | traffic | 0       | 13233    |
| traffic.be.tx_bytes                  | traffic | 0       | 2099     |
| traffic.node1.client.rx_bytes        | traffic | 0       | 32       |
| traffic.node1.client.tx_bytes        | traffic | 0       | 64641815 |
| traffic.node1.client.rx_msgs         | traffic | 0       | 124      |
| traffic.node1.client.tx_msgs         | traffic | 0       | 7868     |
| traffic.node1.client.rx_msgs_dropped | traffic | 0       | 0        |
| traffic.node1.client.reconnects      | traffic | 0       | 1        |
| traffic.node2.client.rx_bytes        | traffic | 0       | 32       |
| traffic.node2.client.tx_bytes        | traffic | 0       | 64609591 |
| traffic.node2.client.rx_msgs         | traffic | 0       | 124      |
| traffic.node2.client.tx_msgs         | traffic | 0       | 7864     |
| traffic.node2.client.rx_msgs_dropped | traffic | 0       | 0        |
| traffic.node2.client.reconnects      | traffic | 0       | 1        |
| traffic.rpc.rx_bytes                 | traffic | 0       | 100      |
| traffic.rpc.tx_bytes                 | traffic | 0       | 12416    |
| traffic.rpc.rx_msgs                  | traffic | 0       | 3        |
| traffic.rpc.tx_msgs                  | traffic | 0       | 2        |
| traffic.node2.server.rx_bytes        | traffic | 0       | 56532348 |

| <code>traffic.node1.server.reconnects</code>      | <code>traffic</code> | <code>0</code> | <code>1</code>        |

#### F.73.6.4. Backend Pool Metrics

Backend pool metrics display characteristics of backend allocation requests from clients to the backend pool.

Names of backend pool metrics have the `backend_pool.SCOPE.COUNTER` structure, where:

- `SCOPE` defines the backend type: local or remote.
- `COUNTER` is the name of the counter.

The following counters are available:

**Table F.54. Backend Pool Counters**

| Name                                         | Type     | Description                                                                                                                                                                                                                                                                                                             |
|----------------------------------------------|----------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>backend_pool.SCOPE.requests</code>     | Integral | Number of backend allocation requests to the backend pool.                                                                                                                                                                                                                                                              |
| <code>backend_pool.SCOPE.creations</code>    | Integral | Number of new backends created when requested from the pool.                                                                                                                                                                                                                                                            |
| <code>backend_pool.SCOPE.destructions</code> | Integral | Number of backend destructions (closures). It may occur when a backend is evicted from the pool bucket or not in use for a long time.                                                                                                                                                                                   |
| <code>backend_pool.SCOPE.unlinks</code>      | Integral | Number of backends unbound from the pool.                                                                                                                                                                                                                                                                               |
| <code>backend_pool.SCOPE.acquisitions</code> | Integral | Number of backends allocated to clients.                                                                                                                                                                                                                                                                                |
| <code>backend_pool.SCOPE.releases</code>     | Integral | Number of backends released by clients and returned to the pool. Due to some failures a backend may be destructed by the client instead of returning to the pool. This will cause increase of the <code>backend_pool.SCOPE.unlinks</code> value, but not <code>backend_pool.SCOPE.releases</code> .                     |
| <code>backend_pool.SCOPE.steals</code>       | Integral | Number of backends "stolen" from other pool buckets. Intense growth of this value means that the system experiences high load on many different databases and/or from many different users. This indicates that the pool size is not enough for the current workload, that leads to the system performance degradation. |
| <code>backend_pool.SCOPE.errors</code>       | Integral | Number of errors occurred when requesting backends from the pool. This is a generalized counter. In some cases, errors                                                                                                                                                                                                  |

| Name                                                | Type                                                 | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
|-----------------------------------------------------|------------------------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|                                                     |                                                      | may cause termination of client connections. In other cases, an error may lead to a repeated backend request and be transparent for a client. For example, if the pool rejects to allocate a backend due to inability to create it caused by reaching the <code>max_connections</code> limit, the client will wait in a queue.                                                                                                                                                                                                                                                |
| <code>backend_pool.SCOPE.request_duration.p*</code> | Percentile (window: T = 60 seconds, C = 1000 events) | Percentiles of time between a backend request to actual backend allocation to a client. This is a cumulative counter and can have significantly different values. For example, allocation of a free backend from the pool may take microseconds, creation of a new backend — milliseconds. However, if the pool is overloaded and clients have to wait for execution of previous request to the database, this may take seconds, minutes, and even hours. In other words, this counter indicates distribution of waiting time in the pool queue before executing the request. |

The example of the backend pool metrics query output looks as follows:

| name                                                              | class        | node_id | value |
|-------------------------------------------------------------------|--------------|---------|-------|
| -----+-----+-----                                                 |              |         |       |
| backend_pool.local.requests<br>13                                 | backend-pool | 0       |       |

### F.73.6.5. Client Connection Metrics

Client connection metrics include counters of connections and their characteristics for different communication channels.

Names of client connection metrics have the `client.CHANNEL.COUNTER` structure, where:

- **CHANNEL** is the communication channel, whose data is displayed in the query output. The following channels are supported:
  - `lfe` (local frontend): clients that connect to proxima via one of the ports to execute SQL queries.
  - `lbe` (local backend): backend processes of Postgres Pro Enterprise created by proxima.
  - `rfe` (remote frontend): clients redirected to the current node from another node.
  - `rbe` (remote backend): internal communication channels created by proxima to redirect queries to a remote node.
  - `rpc` (RPC, Remote Procedure Call): data transfer between proxima and other processes of the current database instance.
- **COUNTER** is the name of the counter.

The following counters are available:

**Table F.55. Client Connection Counters**

| Name                                  | Type         | Description                                                    |
|---------------------------------------|--------------|----------------------------------------------------------------|
| <code>client.lfe.now_connected</code> | Actual value | Number of clients actually connected to the current node.      |
| <code>client.lfe.accepted</code>      | Integral     | Number of clients with successfully authenticated connections. |

Additional Supplied Modules and  
Extensions Shipped in `post-  
grespro-ent-17-contrib`

| Name                                          | Type                                                 | Description                                                                               |
|-----------------------------------------------|------------------------------------------------------|-------------------------------------------------------------------------------------------|
| <code>client.lfe.rejected</code>              | Integral                                             | Number of clients with rejected connections, mainly due to authentication errors.         |
| <code>client.lfe.disconnected</code>          | Integral                                             | Number of clients with closed connections.                                                |
| <code>client.lfe.auth_password</code>         | Integral                                             | Number of clients authenticated using the password method.                                |
| <code>client.lfe.auth_md5</code>              | Integral                                             | Number of clients authenticated using the MD5 method.                                     |
| <code>client.lfe.auth_scram_sha256</code>     | Integral                                             | Number of clients with the SCRAM-SHA-256 authentication method applied.                   |
| <code>client.lfe.auth_trust</code>            | Integral                                             | Number of clients with trusted connections according to HBA rules.                        |
| <code>client.lfe.auth_tls_accepted</code>     | Integral                                             | Number of accepted TLS connections.                                                       |
| <code>client.lfe.auth_tls_rejected</code>     | Integral                                             | Number of rejected TLS connections.                                                       |
| <code>client.lfe.auth_duration.p*</code>      | Percentile (window: T = 60 seconds, C = 1000 events) | Time distribution for client authentication procedure.                                    |
| <code>client.lbe.enter_dedicated</code>       | Integral                                             | Number of backend connections that entered the dedicated session.                         |
| <code>client.lbe.leave_dedicated</code>       | Integral                                             | Number of backend connections that left the dedicated session.                            |
| <code>client.lbe.dedicated_duration.p*</code> | Percentile (window: T = 60 seconds, C = 1000 events) | Time distribution for connections that remained in the dedicated session.                 |
| <code>client.rfe.now_connected</code>         | Actual value                                         | Actual number of clients redirected to the current node for query execution.              |
| <code>client.rfe.connected</code>             | Integral                                             | Number of clients redirected to the current node for query execution.                     |
| <code>client.rfe.disconnected</code>          | Integral                                             | Number of clients with closed connections.                                                |
| <code>client.rbe.enter_dedicated</code>       | Integral                                             | Number of backend connections that entered the dedicated session.                         |
| <code>client.rbe.leave_dedicated</code>       | Integral                                             | Number of backend connections that left the dedicated session.                            |
| <code>client.rbe.dedicated_duration.p*</code> | Percentile (window: T = 60 seconds, C = 1000 events) | Time distribution for connections that remained in the dedicated session.                 |
| <code>client.rpc.now_connected</code>         | Actual value                                         | Number of currently connected clients.                                                    |
| <code>client.rpc.accepted</code>              | Integral                                             | Number of clients with successfully accepted connections including authentication passed. |
| <code>client.rpc.rejected</code>              | Integral                                             | Number of clients with rejected connections, mainly due to authentication errors.         |
| <code>client.rpc.disconnected</code>          | Integral                                             | Number of clients with closed connections.                                                |

The example of the client connection metrics query output looks as follows:

| name                                  | class  | node_id | value |
|---------------------------------------|--------|---------|-------|
| <code>client.lfe.now_connected</code> | client | 0       | 1     |
| <code>client.lfe.accepted</code>      | client | 0       | 1     |

| <code>client.lbe.dedicated_duration.p25</code>  | <code>client</code> | <code>0</code> | <code>0</code> |
| <code>client.lbe.dedicated_duration.p50</code>  | <code>client</code> | <code>0</code> | <code>0</code> |
| <code>client.lbe.dedicated_duration.p75</code>  | <code>client</code> | <code>0</code> | <code>0</code> |
| <code>client.lbe.dedicated_duration.p95</code>  | <code>client</code> | <code>0</code> | <code>0</code> |
| <code>client.lbe.dedicated_duration.p100</code> | <code>client</code> | <code>0</code> | <code>0</code> |
| <code>client.rbe.dedicated_duration.p0</code>   | <code>client</code> | <code>0</code> | <code>0</code> |
| <code>client.rbe.dedicated_duration.p5</code>   | <code>client</code> | <code>0</code> | <code>0</code> |
| <code>client.rbe.dedicated_duration.p25</code>  | <code>client</code> | <code>0</code> | <code>0</code> |
| <code>client.rbe.dedicated_duration.p50</code>  | <code>client</code> | <code>0</code> | <code>0</code> |
| <code>client.rbe.dedicated_duration.p75</code>  | <code>client</code> | <code>0</code> | <code>0</code> |
| <code>client.rbe.dedicated_duration.p95</code>  | <code>client</code> | <code>0</code> | <code>0</code> |
| <code>client.rbe.dedicated_duration.p100</code> | <code>client</code> | <code>0</code> | <code>0</code> |

### F.73.6.6. RPC Server Metrics

The following counters are available:

**Table F.56. RPC Server Counters**

| Name                              | Type                                                 | Description                                |
|-----------------------------------|------------------------------------------------------|--------------------------------------------|
| <code>rpc.call_duration.p*</code> | Percentile (window: T = 60 seconds, C = 1000 events) | Time distribution for command execution.   |
| <code>rpc.err_not_found</code>    | Integral                                             | Number of calls to non-existent functions. |

The example of the RPC server metrics query output looks as follows:

| name                               | class            | node_id        | value                              |
|------------------------------------|------------------|----------------|------------------------------------|
| <code>rpc.call_duration.p0</code>  | <code>rpc</code> | <code>0</code> | <code>4.315190768277686e-05</code> |
| <code>rpc.call_duration.p5</code>  | <code>rpc</code> | <code>0</code> | <code>4.331642078668621e-05</code> |
| <code>rpc.call_duration.p25</code> | <code>rpc</code> | <code>0</code> | <code>6.386338595749277e-05</code> |

## F.74. ptrack — a block-level incremental backup engine for Postgres Pro

PTRACK is a block-level incremental backup engine for Postgres Pro. If PTRACK is enabled, backup tools like `pg_probackup` can use its API to get information on the changed blocks on the fly when taking incremental backups. Copying only those blocks that have changed since the previous backup can significantly speed up the creation and minimize the size of backups.

PTRACK is designed to allow false positives, but to never allow false negatives: it means that all changes within the data directory except hint bits are guaranteed to be marked in the PTRACK map file, although some unchanged blocks might be included as well.

### F.74.1. Setting up PTRACK

Once you complete Postgres Pro Enterprise installation, do the following:

1. Add `ptrack` to the `shared_preload_libraries` parameter in the `postgresql.conf` file:

```
shared_preload_libraries = 'ptrack'
```

2. Set `ptrack.map_size` parameter to a positive integer.

For optimal performance, it is recommended to set `ptrack.map_size` to  $N / 1024$ , where  $N$  is the size of the Postgres Pro cluster, in MB. If you set this parameter to a lower value, PTRACK is more likely to map several blocks together, which leads to false-positive results when tracking changed blocks and increases the incremental backup size as unchanged blocks can also be copied into the incremental backup.

Setting `ptrack.map_size` to a higher value does not affect PTRACK operation, but keep in mind that you need up to `ptrack.map_size * 3` MB of additional disk space since PTRACK uses two additional temporary files to ensure durability. It is not recommended to set this parameter to a value higher than 1024. Even for Postgres Pro clusters with  $N > 1$  TB, it makes sense to use a higher value only if the efficiency and sizes of backups are more critical than the potential overhead of maintaining a large PTRACK map.

3. Check the `wal_level` setting. When using PTRACK, it is required to set the `wal_level` parameter to `replica` or higher. Otherwise, you can lose some tracked changes if crash-recovery occurs: some commands do not write WAL at all if `wal_level` is `minimal`, and PTRACK map files are flushed to disk only at checkpoint time.
4. Restart the Postgres Pro Enterprise instance for the changes to take effect, and then create the PTRACK extension:

```
CREATE EXTENSION ptrack;
```

As a result, several PTRACK functions are created, which are required for accessing PTRACK data.

Once this setup is complete, PTRACK starts tracking all the page changes in the Postgres Pro cluster and creates a `ptrack.map` file that stores the latest LSN values for these pages.

#### Note

The `ptrack.map_size` parameter can only be set at server start. If you change this parameter, the previously created PTRACK map file is cleared, and tracking newly changed blocks starts from scratch. To avoid losing recent changes, it is recommended to retake a full backup after modifying this setting.

### F.74.2. PTRACK Configuration Parameters

`ptrack.map_size` (integer)

Specifies the size of a PTRACK map file and the amount of shared memory allocated for this file, in MB. The PTRACK map file stores the latest LSN values for all pages of the Postgres Pro cluster that have changed since PTRACK was enabled. It is not recommended to set this parameter to a value higher than 1GB. The 0 value disables PTRACK and cleans up all the related service files.

The `ptrack.map_size` parameter can only be set at server start. If you change this parameter, the previously created PTRACK map file is cleared, and tracking newly changed blocks starts from scratch. To avoid losing recent changes, it is recommended to retake a full backup after modifying this setting.

Default: 0

### F.74.3. PTRACK Functions

`ptrack_init_lsn()` returns `pg_lsn`

Returns the LSN of the last PTRACK map initialization.

`ptrack_get_pagemapset(start_lsn pg_lsn)` returns `setof record`

Returns a list of data files changed since the specified `start_lsn` with the number and bitmap of changed pages for each file.

For example:

```
postgres=# SELECT * FROM ptrack_get_pagemapset('0/185C8C0');
 path | pagecount | pagemap
-----+-----+-----
base/16384/1255 | 3 | \x00100000000050000000000000
base/16384/2674 | 3 | \x0000000090001000000000000000
base/16384/2691 | 1 | \x00004000000000000000000000
base/16384/2608 | 1 | \x00000000000000004000000000000000
base/16384/2690 | 1 | \x00040000000000000000000000
```

`ptrack_get_change_stat(start_lsn pg_lsn)` returns `record`

Returns the statistics of changes (number of files, number of changed pages and their total size in MB) since the specified `start_lsn`.

For example:

```
postgres=# SELECT * FROM ptrack_get_change_stat('0/285C8C8');
 files | pages | size, MB
-----+-----+-----
 20 | 25 | 0.19531250000000000000
```

`ptrack_version()` returns `text`

Returns PTRACK version.

## F.75. referee — manage quorum settings with an even number of nodes configured with multimaster

`referee` is a Postgres Pro Enterprise extension for managing quorum settings in clusters with an even number of nodes configured with [multimaster](#). Installed on a separate system, the `referee` extension provides a voting node to assign the quorum status to a subset of nodes if only half of the cluster nodes remain connected to each other.

If a multi-master cluster is split into equal parts, or half of the cluster nodes fail, each subset of nodes that equals half of the cluster tries to access the referee. The first subset that gets connected to the referee wins the voting and continues working, while all the other nodes are excluded from the cluster to avoid split-brain problems.

The referee node does not store any cluster data, so it is very lightweight and can be located on systems with limited resources. For details on how to set up and use a referee node with `multimaster`, see [Section F.37.3.3](#).

### F.75.1. Authors

Postgres Professional, Moscow, Russia

## F.76. rum — an access method to work with the RUM indexes

### F.76.1. Introduction

The **rum** module provides access method to work with the RUM indexes. It is based on the GIN access method code.

GIN index allows you to perform fast full-text search using `tsvector` and `tsquery` types. However, full-text search with GIN index has some performance issues because positional and other additional information is not stored.

RUM solves these issues by storing additional information in a posting tree. As compared to GIN, RUM index has the following benefits:

- Faster ranking. Ranking requires positional information. And after the index scan we do not need an additional heap scan to retrieve lexeme positions because RUM index stores them.
- Faster phrase search. This improvement is related to the previous one as phrase search also needs positional information.
- Faster ordering by timestamp. RUM index stores additional information together with lexemes, so it is not necessary to perform a heap scan.
- A possibility to perform depth-first search and therefore return first results immediately.

The drawback of RUM is that it has slower build and insert time as compared to GIN because RUM stores additional information together with keys and uses generic WAL records.

### F.76.2. Installation

`rum` is a Postgres Pro Enterprise extension and it has no special prerequisites.

Install extension as follows:

```
$ psql dbname -c "CREATE EXTENSION rum"
```

### F.76.3. Common Operators

The operators provided by the `rum` module are shown in [Table F.57](#):

**Table F.57. rum Operators**

| Operator                                   | Returns             | Description                                                                     |
|--------------------------------------------|---------------------|---------------------------------------------------------------------------------|
| <code>tsvector &lt;=&gt; tsquery</code>    | <code>float4</code> | Returns distance between <code>tsvector</code> and <code>tsquery</code> values. |
| <code>timestamp &lt;=&gt; timestamp</code> | <code>float8</code> | Returns distance between two <code>timestamp</code> values.                     |
| <code>timestamp &lt;=  timestamp</code>    | <code>float8</code> | Returns distance only for ascending <code>timestamp</code> values.              |
| <code>timestamp  =&gt; timestamp</code>    | <code>float8</code> | Returns distance only for descending <code>timestamp</code> values.             |

#### Note

`rum` introduces its own ranking function that is executed inside the `<=>` operator. It calculates the score (inverted distance) using the specified normalization method. This function is a combination of `ts_rank` and `ts_rank_cd` (see [Section 9.13](#) for details). While `ts_rank` does not support logical operators and `ts_rank_cd` works poorly with OR queries, the `rum`-specific ranking function overcomes these drawbacks.

### F.76.4. Operator Classes

The `rum` extension provides the following operator classes:

#### `rum_tsvector_ops`

Stores `tsvector` lexemes with positional information. Supports ordering by `<=>` operator and prefix search.

#### `rum_tsvector_hash_ops`

Stores hash of `tsvector` lexemes with positional information. Supports ordering by `<=>` operator, but does not support prefix search.

#### `rum_tsvector_addon_ops`

Stores `tsvector` lexemes with additional data of any type supported by RUM.

### Note

To use the `rum_tsvector_addon_ops` operator class, when creating the RUM index with `CREATE INDEX`, specify the `attach` and `to` storage parameters in the `WITH` clause.

#### `rum_tsvector_hash_addon_ops`

Stores `tsvector` lexemes with additional data of any type supported by RUM. Does not support prefix search.

#### `rum_tsquery_ops`

Stores branches of query tree in additional information.

#### `rum_anyarray_ops`

Stores `anyarray` elements with length of the array. Supports ordering by `<=>` operator.

Indexable operators: `&&` `@>` `<@` `=` `%`

#### `rum_anyarray_addon_ops`

Stores `anyarray` elements with additional data of any type supported by RUM.

#### `rum_type_ops`

Stores lexemes of the corresponding type with positional information. The `type` placeholder in the class name must be substituted by one of the following type names: `int2`, `int4`, `int8`, `float4`, `float8`, `money`, `oid`, `timestamp`, `timestampz`, `time`, `timetz`, `date`, `interval`, `macaddr`, `inet`, `cidr`, `text`, `varchar`, `char`, `bytea`, `bit`, `varbit`, `numeric`.

`rum_type_ops` supports ordering by `<=>`, `<=|`, and `|=>` operators. This operator class can be used together with `rum_tsvector_addon_ops`, `rum_tsvector_hash_addon_ops`, and `rum_anyarray_addon_ops` operator classes.

Supported indexable operators depend on the data type:

- `<` `<=` `=` `>=` `>` `<=>` `<=|` `|=>` are supported for `int2`, `int4`, `int8`, `float4`, `float8`, `money`, `oid`, `timestamp`, `timestampz`.
- `<` `<=` `=` `>=` `>` are supported for `time`, `timetz`, `date`, `interval`, `macaddr`, `inet`, `cidr`, `text`, `varchar`, `char`, `bytea`, `bit`, `varbit`, `numeric`.

### Note

The following operator classes are now deprecated: `rum_tsvector_timestamp_ops`, `rum_tsvector_timestampz_ops`, `rum_tsvector_hash_timestamp_ops`, `rum_tsvector_hash_timestampz_ops`.

## F.76.5. Examples

### F.76.5.1. `rum_tsvector_ops` Example

Let's assume we have the following table:

```
CREATE TABLE test_rum(t text, a tsvector);

CREATE TRIGGER tsvectorupdate
BEFORE UPDATE OR INSERT ON test_rum
FOR EACH ROW EXECUTE PROCEDURE tsvector_update_trigger('a', 'pg_catalog.english', 't');

INSERT INTO test_rum(t) VALUES ('The situation is most beautiful');
INSERT INTO test_rum(t) VALUES ('It is a beautiful');
INSERT INTO test_rum(t) VALUES ('It looks like a beautiful place');
```

Then we can create a new index:

```
CREATE INDEX rumidx ON test_rum USING rum (a rum_tsvector_ops);
```

And we can execute the following queries:

```
SELECT t, a <=> to_tsquery('english', 'beautiful | place') AS rank
FROM test_rum
WHERE a @@ to_tsquery('english', 'beautiful | place')
ORDER BY a <=> to_tsquery('english', 'beautiful | place');
 t | rank
-----+-----
The situation is most beautiful | 0.0303964
It is a beautiful | 0.0303964
It looks like a beautiful place | 0.0607927
(3 rows)
```

```
SELECT t, a <=> to_tsquery('english', 'place | situation') AS rank
FROM test_rum
WHERE a @@ to_tsquery('english', 'place | situation')
ORDER BY a <=> to_tsquery('english', 'place | situation');
 t | rank
-----+-----
The situation is most beautiful | 0.0303964
It looks like a beautiful place | 0.0303964
(2 rows)
```

### F.76.5.2. rum\_tsvector\_addon\_ops Example

Let's assume we have the following table:

```
CREATE TABLE tsts (id int, t tsvector, d timestamp);

\copy tsts from 'rum/data/tsts.data'

CREATE INDEX tsts_idx ON tsts USING rum (t rum_tsvector_addon_ops, d)
WITH (attach = 'd', to = 't');
```

Now we can execute the following queries:

```
EXPLAIN (costs off)
 SELECT id, d, d <=> '2016-05-16 14:21:25' FROM tsts WHERE t @@ 'wr&qh' ORDER BY d
 <=> '2016-05-16 14:21:25' LIMIT 5;
 QUERY PLAN

Limit
-> Index Scan using tsts_idx on tsts
 Index Cond: (t @@ ''wr'' & ''qh''::tsquery)
 Order By: (d <=> 'Mon May 16 14:21:25 2016'::timestamp without time zone)
(4 rows)
```

```
SELECT id, d, d <=> '2016-05-16 14:21:25' FROM tst1 WHERE t @@ 'wr&qh' ORDER BY d <=>
'2016-05-16 14:21:25' LIMIT 5;
 id | d | ?column?
-----+-----+-----
 355 | Mon May 16 14:21:22.326724 2016 | 2.673276
 354 | Mon May 16 13:21:22.326724 2016 | 3602.673276
 371 | Tue May 17 06:21:22.326724 2016 | 57597.326724
 406 | Wed May 18 17:21:22.326724 2016 | 183597.326724
 415 | Thu May 19 02:21:22.326724 2016 | 215997.326724
(5 rows)
```

### F.76.5.3. rum\_tsquery\_ops Example

Suppose we have the table:

```
CREATE TABLE query (q tsquery, tag text);

INSERT INTO query VALUES ('supernova & star', 'sn'),
 ('black', 'color'),
 ('big & bang & black & hole', 'bang'),
 ('spiral & galaxy', 'shape'),
 ('black & hole', 'color');
```

```
CREATE INDEX query_idx ON query USING rum(q);
```

We can execute the following fast query:

```
SELECT * FROM query
 WHERE to_tsvector('black holes never exists before we think about them') @@ q;
 q | tag
-----+-----
 'black' | color

### F.76.5.4. rum\_anyarray\_ops Example

Let's assume we have the following table:

```
CREATE TABLE test_array (i int2[]);

INSERT INTO test_array VALUES ('{}'), ('{0}'), ('{1,2,3,4}'), ('{1,2,3}'), ('{1,2}'),
 ('{1}');
```

```
CREATE INDEX idx_array ON test_array USING rum (i rum_anyarray_ops);
```

Now we can execute the following query using index scan:

```
SET enable_seqscan TO off;
```

```
EXPLAIN (COSTS OFF) SELECT * FROM test_array WHERE i && '{1}' ORDER BY i <=> '{1}' ASC;
 QUERY PLAN
```

```

Index Scan using idx_array on test_array
 Index Cond: (i && '{1}'::smallint[])
 Order By: (i <=> '{1}'::smallint[])
(3 rows)
```

```
SELECT * FROM test_array WHERE i && '{1}' ORDER BY i <=> '{1}' ASC;
 i

 {1}
```

`{1, 2}`  
`{1, 2, 3}`  
`{1, 2, 3, 4}`  
(4 rows)

## F.77. seg — a datatype for line segments or floating point intervals

This module implements a data type `seg` for representing line segments, or floating point intervals. `seg` can represent uncertainty in the interval endpoints, making it especially useful for representing laboratory measurements.

This module is considered “trusted”, that is, it can be installed by non-superusers who have `CREATE` privilege on the current database.

### F.77.1. Rationale

The geometry of measurements is usually more complex than that of a point in a numeric continuum. A measurement is usually a segment of that continuum with somewhat fuzzy limits. The measurements come out as intervals because of uncertainty and randomness, as well as because the value being measured may naturally be an interval indicating some condition, such as the temperature range of stability of a protein.

Using just common sense, it appears more convenient to store such data as intervals, rather than pairs of numbers. In practice, it even turns out more efficient in most applications.

Further along the line of common sense, the fuzziness of the limits suggests that the use of traditional numeric data types leads to a certain loss of information. Consider this: your instrument reads 6.50, and you input this reading into the database. What do you get when you fetch it? Watch:

```
test=> select 6.50 :: float8 as "pH";
 pH
 --
6.5
(1 row)
```

In the world of measurements, 6.50 is not the same as 6.5. It may sometimes be critically different. The experimenters usually write down (and publish) the digits they trust. 6.50 is actually a fuzzy interval contained within a bigger and even fuzzier interval, 6.5, with their center points being (probably) the only common feature they share. We definitely do not want such different data items to appear the same.

Conclusion? It is nice to have a special data type that can record the limits of an interval with arbitrarily variable precision. Variable in the sense that each data element records its own precision.

Check this out:

```
test=> select '6.25 .. 6.50'::seg as "pH";
 pH

6.25 .. 6.50
(1 row)
```

### F.77.2. Syntax

The external representation of an interval is formed using one or two floating-point numbers joined by the range operator (`..` or `...`). Alternatively, it can be specified as a center point plus or minus a deviation. Optional certainty indicators (`<`, `>` or `~`) can be stored as well. (Certainty indicators are ignored by all the built-in operators, however.) [Table F.58](#) gives an overview of allowed representations; [Table F.59](#) shows some examples.

In [Table F.58](#), `x`, `y`, and `delta` denote floating-point numbers. `x` and `y`, but not `delta`, can be preceded by a certainty indicator.

**Table F.58. seg External Representations**

|                           |                                                                |
|---------------------------|----------------------------------------------------------------|
| <code>x</code>            | Single value (zero-length interval)                            |
| <code>x .. y</code>       | Interval from <code>x</code> to <code>y</code>                 |
| <code>x (+-) delta</code> | Interval from <code>x - delta</code> to <code>x + delta</code> |
| <code>x ..</code>         | Open interval with lower bound <code>x</code>                  |
| <code>.. x</code>         | Open interval with upper bound <code>x</code>                  |

**Table F.59. Examples of Valid `seg` Input**

|                              |                                                                                                                                                                |
|------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>5.0</code>             | Creates a zero-length segment (a point, if you will)                                                                                                           |
| <code>~5.0</code>            | Creates a zero-length segment and records <code>~</code> in the data. <code>~</code> is ignored by <code>seg</code> operations, but is preserved as a comment. |
| <code>&lt;5.0</code>         | Creates a point at 5.0. <code>&lt;</code> is ignored but is preserved as a comment.                                                                            |
| <code>&gt;5.0</code>         | Creates a point at 5.0. <code>&gt;</code> is ignored but is preserved as a comment.                                                                            |
| <code>5(+ -)0.3</code>       | Creates an interval <code>4.7 . . 5.3</code> . Note that the <code>(+ -)</code> notation isn't preserved.                                                      |
| <code>50 . .</code>          | Everything that is greater than or equal to 50                                                                                                                 |
| <code>. . 0</code>           | Everything that is less than or equal to 0                                                                                                                     |
| <code>1.5e-2 . . 2E-2</code> | Creates an interval <code>0.015 . . 0.02</code>                                                                                                                |
| <code>1 . . . 2</code>       | The same as <code>1 . . . 2</code> , or <code>1 . . 2</code> , or <code>1 . 2</code> (spaces around the range operator are ignored)                            |

Because the `. . .` operator is widely used in data sources, it is allowed as an alternative spelling of the `. .` operator. Unfortunately, this creates a parsing ambiguity: it is not clear whether the upper bound in `0 . . . 23` is meant to be 23 or `0.23`. This is resolved by requiring at least one digit before the decimal point in all numbers in `seg` input.

As a sanity check, `seg` rejects intervals with the lower bound greater than the upper, for example `5 . . 2`.

### F.77.3. Precision

`seg` values are stored internally as pairs of 32-bit floating point numbers. This means that numbers with more than 7 significant digits will be truncated.

Numbers with 7 or fewer significant digits retain their original precision. That is, if your query returns 0.00, you will be sure that the trailing zeroes are not the artifacts of formatting: they reflect the precision of the original data. The number of leading zeroes does not affect precision: the value 0.0067 is considered to have just 2 significant digits.

### F.77.4. Usage

The `seg` module includes a GiST index operator class for `seg` values. The operators supported by the GiST operator class are shown in [Table F.60](#).

**Table F.60. Seg GiST Operators**

| Operator<br>Description                                                                                                                                                                     |
|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>seg &lt;&lt; seg → boolean</code><br>Is the first <code>seg</code> entirely to the left of the second? <code>[a, b] &lt;&lt; [c, d]</code> is true if <code>b &lt; c</code> .         |
| <code>seg &gt;&gt; seg → boolean</code><br>Is the first <code>seg</code> entirely to the right of the second? <code>[a, b] &gt;&gt; [c, d]</code> is true if <code>a &gt; d</code> .        |
| <code>seg &amp;&lt; seg → boolean</code><br>Does the first <code>seg</code> not extend to the right of the second? <code>[a, b] &amp;&lt; [c, d]</code> is true if <code>b &lt;= d</code> . |
| <code>seg &amp;&gt; seg → boolean</code><br>Does the first <code>seg</code> not extend to the left of the second? <code>[a, b] &amp;&gt; [c, d]</code> is true if <code>a &gt;= c</code> .  |
| <code>seg = seg → boolean</code><br>Are the two <code>segs</code> equal?                                                                                                                    |
| <code>seg &amp;&amp; seg → boolean</code><br>Do the two <code>segs</code> overlap?                                                                                                          |
| <code>seg @&gt; seg → boolean</code><br>Does the first <code>seg</code> contain the second?                                                                                                 |

| Operator                             | Description                                            |
|--------------------------------------|--------------------------------------------------------|
| <code>seg &lt;@ seg → boolean</code> | Is the first <code>seg</code> contained in the second? |

In addition to the above operators, the usual comparison operators shown in [Table 9.1](#) are available for type `seg`. These operators first compare (a) to (c), and if these are equal, compare (b) to (d). That results in reasonably good sorting in most cases, which is useful if you want to use `ORDER BY` with this type.

## F.77.5. Notes

For examples of usage, see the regression test `sql/seg.sql`.

The mechanism that converts `(+-)` to regular ranges isn't completely accurate in determining the number of significant digits for the boundaries. For example, it adds an extra digit to the lower boundary if the resulting interval includes a power of ten:

```
postgres=> select '10(+-)1'::seg as seg;
 seg

9.0 .. 11 -- should be: 9 .. 11
```

The performance of an R-tree index can largely depend on the initial order of input values. It may be very helpful to sort the input table on the `seg` column; see the script `sort-segments.pl` for an example.

## F.77.6. Credits

Original author: Gene Selkov, Jr. <[selkovjr@mcs.anl.gov](mailto:selkovjr@mcs.anl.gov)>, Mathematics and Computer Science Division, Argonne National Laboratory.

My thanks are primarily to Prof. Joe Hellerstein (<https://dsf.berkeley.edu/jmh/>) for elucidating the gist of the GiST (<http://gist.cs.berkeley.edu/>). I am also grateful to all Postgres developers, present and past, for enabling myself to create my own world and live undisturbed in it. And I would like to acknowledge my gratitude to Argonne Lab and to the U.S. Department of Energy for the years of faithful support of my database research.

## F.78. `shared_ispell` — a shared ispell dictionary

The `shared_ispell` module provides a shared ispell dictionary, i.e. a dictionary that's stored in shared segment. The traditional ispell implementation means that each session initializes and stores the dictionary on it's own, which means a lot of CPU/RAM is wasted.

This extension allocates an area in shared segment (you have to choose the size in advance) and then loads the dictionary into it when it's used for the first time.

### F.78.1. Functions

The functions provided by the `shared_ispell` module are shown in [Table F.61](#).

**Table F.61. `shared_ispell` Functions**

| Function                                   | Returns                                                                                      | Description                                                                                                                                                            |
|--------------------------------------------|----------------------------------------------------------------------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>shared_ispell_reset()</code>         | <code>void</code>                                                                            | Resets the dictionaries (e.g. so that you can reload the updated files from disk). The sessions that already use the dictionaries will be forced to reinitialize them. |
| <code>shared_ispell_mem_used()</code>      | <code>int</code>                                                                             | Returns a value of used memory of the shared segment by loaded shared dictionaries in bytes.                                                                           |
| <code>shared_ispell_mem_available()</code> | <code>int</code>                                                                             | Returns a value of available memory of the shared segment.                                                                                                             |
| <code>shared_ispell_dicts()</code>         | <code>setof(dict_name varchar, affix_name varchar, words int, affixes int, bytes int)</code> | Returns a list of dictionaries loaded in the shared segment.                                                                                                           |
| <code>shared_ispell_stoplists()</code>     | <code>setof(stop_name varchar, words int, bytes int)</code>                                  | Returns a list of stopwords loaded in the shared segment.                                                                                                              |

### F.78.2. GUC Parameters

`shared_ispell.max_size(int)`

Defines the maximum size of the shared segment. This is a hard limit, the shared segment is not extensible and you need to set it so that all the dictionaries fit into it and not much memory is wasted.

### F.78.3. Using the dictionary

The module needs to allocate space in the shared memory segment. So add this to the config file (or update the current values):

```
libraries to load
shared_preload_libraries = 'shared_ispell'

config of the shared memory
shared_ispell.max_size = 32MB
```

To find out how much memory you actually need, use a large value (e.g. 200MB) and load all the dictionaries you want to use. Then use the `shared_ispell_mem_used()` function to find out how much memory was actually used (and set the `shared_ispell.max_size` GUC variable accordingly).

Don't set it exactly to that value, leave there some free space, so that you can reload the dictionaries without changing the GUC `max_size` limit (which requires a restart of the DB). Something like 512kB should be just fine.

The extension defines a `shared_ispell` template that you may use to define custom dictionaries. E.g. you may do this:

```
CREATE TEXT SEARCH DICTIONARY english_shared (
 TEMPLATE = shared_ispell,
```

```
DictFile = en_us,
AffFile = en_us,
StopWords = english
);
```

```
CREATE TEXT SEARCH CONFIGURATION public.english_shared
 (COPY = pg_catalog.simple);
```

```
ALTER TEXT SEARCH CONFIGURATION english_shared
 ALTER MAPPING FOR asciiword, asciihword, hword_asciipart,
 word, hword, hword_part
 WITH english_shared, english_stem;
```

We can test created configuration:

```
SELECT * FROM ts_debug('english_shared', 'abilities');
 alias | description | token | dictionaries | dictionary
| lexemes
-----+-----+-----+-----+-----
+-----+-----+-----+-----+-----
asciiword | Word, all ASCII | abilities | {english_shared,english_stem} |
english_shared | {ability}
(1 row)
```

Or you can update your own text search configuration. For example, you have the `public.english` dictionary. You can update it to use the `shared_ispell` template:

```
ALTER TEXT SEARCH CONFIGURATION public.english
 ALTER MAPPING FOR asciiword, asciihword, hword_asciipart,
 word, hword, hword_part
 WITH english_shared, english_stem;
```

## F.78.4. Author

## F.79. spi — Server Programming Interface features/examples

The `spi` module provides several workable examples of using the [Server Programming Interface](#) (SPI) and triggers. While these functions are of some value in their own right, they are even more useful as examples to modify for your own purposes. The functions are general enough to be used with any table, but you have to specify table and field names (as described below) while creating a trigger.

Each of the groups of functions described below is provided as a separately-installable extension.

### F.79.1. refint — Functions for Implementing Referential Integrity

`check_primary_key()` and `check_foreign_key()` are used to check foreign key constraints. (This functionality is long since superseded by the built-in foreign key mechanism, of course, but the module is still useful as an example.)

`check_primary_key()` checks the referencing table. To use, create a `BEFORE INSERT OR UPDATE` trigger using this function on a table referencing another table. Specify as the trigger arguments: the referencing table's column name(s) which form the foreign key, the referenced table name, and the column names in the referenced table which form the primary/unique key. To handle multiple foreign keys, create a trigger for each reference.

`check_foreign_key()` checks the referenced table. To use, create a `BEFORE DELETE OR UPDATE` trigger using this function on a table referenced by other table(s). Specify as the trigger arguments: the number of referencing tables for which the function has to perform checking, the action if a referencing key is found (`cascade` — to delete the referencing row, `restrict` — to abort transaction if referencing keys exist, `setnull` — to set referencing key fields to null), the triggered table's column names which form the primary/unique key, then the referencing table name and column names (repeated for as many referencing tables as were specified by first argument). Note that the primary/unique key columns should be marked `NOT NULL` and should have a unique index.

There are examples in `refint.example`.

### F.79.2. autoinc — Functions for Autoincrementing Fields

`autoinc()` is a trigger that stores the next value of a sequence into an integer field. This has some overlap with the built-in “serial column” feature, but it is not the same: `autoinc()` will override attempts to substitute a different field value during inserts, and optionally it can be used to increment the field during updates, too.

To use, create a `BEFORE INSERT` (or optionally `BEFORE INSERT OR UPDATE`) trigger using this function. Specify two trigger arguments: the name of the integer column to be modified, and the name of the sequence object that will supply values. (Actually, you can specify any number of pairs of such names, if you'd like to update more than one autoincrementing column.)

There is an example in `autoinc.example`.

### F.79.3. insert\_username — Functions for Tracking Who Changed a Table

`insert_username()` is a trigger that stores the current user's name into a text field. This can be useful for tracking who last modified a particular row within a table.

To use, create a `BEFORE INSERT` and/or `UPDATE` trigger using this function. Specify a single trigger argument: the name of the text column to be modified.

There is an example in `insert_username.example`.

### F.79.4. moddatetime — Functions for Tracking Last Modification Time

`moddatetime()` is a trigger that stores the current time into a `timestamp` field. This can be useful for tracking the last modification time of a particular row within a table.

To use, create a `BEFORE UPDATE` trigger using this function. Specify a single trigger argument: the name of the column to be modified. The column must be of type `timestamp` or `timestamp with time zone`.

There is an example in `moddatetime.example`.

## F.80. sslinfo — obtain client SSL information

The `sslinfo` module provides information about the SSL certificate that the current client provided when connecting to Postgres Pro. The module is useless (most functions will return `NULL`) if the current connection does not use SSL.

Some of the information available through this module can also be obtained using the built-in system view `pg_stat_ssl`.

This extension won't build at all unless the installation was configured with `--with-ssl=openssl`.

### F.80.1. Functions Provided

`ssl_is_used()` returns `boolean`

Returns true if current connection to server uses SSL, and false otherwise.

`ssl_version()` returns `text`

Returns the name of the protocol used for the SSL connection (e.g., TLSv1.0, TLSv1.1, TLSv1.2 or TLSv1.3).

`ssl_cipher()` returns `text`

Returns the name of the cipher used for the SSL connection (e.g., DHE-RSA-AES256-SHA).

`ssl_client_cert_present()` returns `boolean`

Returns true if current client has presented a valid SSL client certificate to the server, and false otherwise. (The server might or might not be configured to require a client certificate.)

`ssl_client_serial()` returns `numeric`

Returns serial number of current client certificate. The combination of certificate serial number and certificate issuer is guaranteed to uniquely identify a certificate (but not its owner — the owner ought to regularly change their keys, and get new certificates from the issuer).

So, if you run your own CA and allow only certificates from this CA to be accepted by the server, the serial number is the most reliable (albeit not very mnemonic) means to identify a user.

`ssl_client_dn()` returns `text`

Returns the full subject of the current client certificate, converting character data into the current database encoding. It is assumed that if you use non-ASCII characters in the certificate names, your database is able to represent these characters, too. If your database uses the `SQL_ASCII` encoding, non-ASCII characters in the name will be represented as UTF-8 sequences.

The result looks like `/CN=Somebody /C=Some country/O=Some organization`.

`ssl_issuer_dn()` returns `text`

Returns the full issuer name of the current client certificate, converting character data into the current database encoding. Encoding conversions are handled the same as for `ssl_client_dn`.

The combination of the return value of this function with the certificate serial number uniquely identifies the certificate.

This function is really useful only if you have more than one trusted CA certificate in your server's certificate authority file, or if this CA has issued some intermediate certificate authority certificates.

`ssl_client_dn_field(fieldname text)` returns `text`

This function returns the value of the specified field in the certificate subject, or `NULL` if the field is not present. Field names are string constants that are converted into ASN1 object identifiers using the OpenSSL object database. The following values are acceptable:

`commonName` (alias `CN`)  
`surname` (alias `SN`)  
`name`  
`givenName` (alias `GN`)

countryName (alias C)  
localityName (alias L)  
stateOrProvinceName (alias ST)  
organizationName (alias O)  
organizationalUnitName (alias OU)  
title  
description  
initials  
postalCode  
streetAddress  
generationQualifier  
description  
dnQualifier  
x500UniqueIdentifier  
pseudonym  
role  
emailAddress

All of these fields are optional, except `commonName`. It depends entirely on your CA's policy which of them would be included and which wouldn't. The meaning of these fields, however, is strictly defined by the X.500 and X.509 standards, so you cannot just assign arbitrary meaning to them.

`ssl_issuer_field(fieldname text)` returns `text`

Same as `ssl_client_dn_field`, but for the certificate issuer rather than the certificate subject.

`ssl_extension_info()` returns `setof record`

Provide information about extensions of client certificate: extension name, extension value, and if it is a critical extension.

## F.81. tablefunc — functions that return tables (crosstab and others)

The `tablefunc` module includes various functions that return tables (that is, multiple rows). These functions are useful both in their own right and as examples of how to write C functions that return multiple rows.

This module is considered “trusted”, that is, it can be installed by non-superusers who have `CREATE` privilege on the current database.

### F.81.1. Functions Provided

[Table F.62](#) summarizes the functions provided by the `tablefunc` module.

**Table F.62. tablefunc Functions**

| Function                                                                                                                                                                       | Description                                                                                                                                                                                                                                                |
|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>normal_rand ( numvals integer, mean float8, stddev float8 ) → setof float8</code>                                                                                        | Produces a set of normally distributed random values.                                                                                                                                                                                                      |
| <code>crosstab ( sql text ) → setof record</code>                                                                                                                              | Produces a “pivot table” containing row names plus <i>N</i> value columns, where <i>N</i> is determined by the row type specified in the calling query.                                                                                                    |
| <code>crosstabN ( sql text ) → setof table_crosstab_N</code>                                                                                                                   | Produces a “pivot table” containing row names plus <i>N</i> value columns. <code>crosstab2</code> , <code>crosstab3</code> , and <code>crosstab4</code> are predefined, but you can create additional <code>crosstabN</code> functions as described below. |
| <code>crosstab ( source_sql text, category_sql text ) → setof record</code>                                                                                                    | Produces a “pivot table” with the value columns specified by a second query.                                                                                                                                                                               |
| <code>crosstab ( sql text, N integer ) → setof record</code>                                                                                                                   | Obsolete version of <code>crosstab(text)</code> . The parameter <i>N</i> is now ignored, since the number of value columns is always determined by the calling query.                                                                                      |
| <code>connectby ( relname text, keyid_fld text, parent_keyid_fld text [, orderby_fld text ], start_with text, max_depth integer [, branch_delim text ] ) → setof record</code> | Produces a representation of a hierarchical tree structure.                                                                                                                                                                                                |

#### F.81.1.1. normal\_rand

`normal_rand(int numvals, float8 mean, float8 stddev)` returns `setof float8`

`normal_rand` produces a set of normally distributed random values (Gaussian distribution).

*numvals* is the number of values to be returned from the function. *mean* is the mean of the normal distribution of values and *stddev* is the standard deviation of the normal distribution of values.

For example, this call requests 1000 values with a mean of 5 and a standard deviation of 3:

```
test=# SELECT * FROM normal_rand(1000, 5, 3);
normal_rand

 1.56556322244898
 9.10040991424657
 5.36957140345079
-0.369151492880995
 0.283600703686639
.
.
.
 4.82992125404908
 9.71308014517282
```

2.49639286969028  
(1000 rows)

### F.81.1.2. `crosstab(text)`

```
crosstab(text sql)
crosstab(text sql, int N)
```

The `crosstab` function is used to produce “pivot” displays, wherein data is listed across the page rather than down. For example, we might have data like

```
row1 val11
row1 val12
row1 val13
...
row2 val21
row2 val22
row2 val23
...
```

which we wish to display like

```
row1 val11 val12 val13 ...
row2 val21 val22 val23 ...
...
```

The `crosstab` function takes a text parameter that is an SQL query producing raw data formatted in the first way, and produces a table formatted in the second way.

The `sql` parameter is an SQL statement that produces the source set of data. This statement must return one `row_name` column, one `category` column, and one `value` column. `N` is an obsolete parameter, ignored if supplied (formerly this had to match the number of output value columns, but now that is determined by the calling query).

For example, the provided query might produce a set something like:

```
row_name cat value
-----+-----+-----
row1 cat1 val1
row1 cat2 val2
row1 cat3 val3
row1 cat4 val4
row2 cat1 val5
row2 cat2 val6
row2 cat3 val7
row2 cat4 val8
```

The `crosstab` function is declared to return `setof record`, so the actual names and types of the output columns must be defined in the `FROM` clause of the calling `SELECT` statement, for example:

```
SELECT * FROM crosstab('...') AS ct(row_name text, category_1 text, category_2 text);
```

This example produces a set something like:

```
 <== value columns ==>
row_name category_1 category_2
-----+-----+-----
row1 val1 val2
row2 val5 val6
```

The `FROM` clause must define the output as one `row_name` column (of the same data type as the first result column of the SQL query) followed by `N` `value` columns (all of the same data type as the third result column of the SQL query). You can set up as many output value columns as you wish. The names of the output columns are up to you.

The `crosstab` function produces one output row for each consecutive group of input rows with the same `row_name` value. It fills the output `value` columns, left to right, with the `value` fields from these rows. If there are fewer rows in a group than there are output `value` columns, the extra output columns are filled with nulls; if there are more rows, the extra input rows are skipped.

In practice the SQL query should always specify `ORDER BY 1, 2` to ensure that the input rows are properly ordered, that is, values with the same `row_name` are brought together and correctly ordered within the row. Notice that `crosstab` itself does not pay any attention to the second column of the query result; it's just there to be ordered by, to control the order in which the third-column values appear across the page.

Here is a complete example:

```
CREATE TABLE ct(id SERIAL, rowid TEXT, attribute TEXT, value TEXT);
INSERT INTO ct(rowid, attribute, value) VALUES('test1', 'att1', 'val1');
INSERT INTO ct(rowid, attribute, value) VALUES('test1', 'att2', 'val2');
INSERT INTO ct(rowid, attribute, value) VALUES('test1', 'att3', 'val3');
INSERT INTO ct(rowid, attribute, value) VALUES('test1', 'att4', 'val4');
INSERT INTO ct(rowid, attribute, value) VALUES('test2', 'att1', 'val5');
INSERT INTO ct(rowid, attribute, value) VALUES('test2', 'att2', 'val6');
INSERT INTO ct(rowid, attribute, value) VALUES('test2', 'att3', 'val7');
INSERT INTO ct(rowid, attribute, value) VALUES('test2', 'att4', 'val8');

SELECT *
FROM crosstab(
 'select rowid, attribute, value
 from ct
 where attribute = ''att2'' or attribute = ''att3''
 order by 1,2')
AS ct(row_name text, category_1 text, category_2 text, category_3 text);
```

| row_name | category_1 | category_2 | category_3 |
|----------|------------|------------|------------|
| test1    | val2       | val3       |            |
| test2    | val6       | val7       |            |

(2 rows)

You can avoid always having to write out a `FROM` clause to define the output columns, by setting up a custom `crosstab` function that has the desired output row type wired into its definition. This is described in the next section. Another possibility is to embed the required `FROM` clause in a view definition.

### Note

See also the `\crosstabview` command in `psql`, which provides functionality similar to `crosstab()`.

#### F.81.1.3. `crosstabN(text)`

`crosstabN(text sql)`

The `crosstabN` functions are examples of how to set up custom wrappers for the general `crosstab` function, so that you need not write out column names and types in the calling `SELECT` query. The `tablefunc` module includes `crosstab2`, `crosstab3`, and `crosstab4`, whose output row types are defined as

```
CREATE TYPE tablefunc_crosstab_N AS (
 row_name TEXT,
 category_1 TEXT,
 category_2 TEXT,
 .
 .
 .
 category_N TEXT
);
```

Thus, these functions can be used directly when the input query produces `row_name` and `value` columns of type `text`, and you want 2, 3, or 4 output values columns. In all other ways they behave exactly as described above for the general `crosstab` function.

For instance, the example given in the previous section would also work as

```
SELECT *
FROM crosstab3(
 'select rowid, attribute, value
 from ct
 where attribute = 'att2' or attribute = 'att3'
 order by 1,2');
```

These functions are provided mostly for illustration purposes. You can create your own return types and functions based on the underlying `crosstab()` function. There are two ways to do it:

- Create a composite type describing the desired output columns, similar to the examples in `contrib/tablefunc/tablefunc--1.0.sql`. Then define a unique function name accepting one `text` parameter and returning `setof your_type_name`, but linking to the same underlying `crosstab` C function. For example, if your source data produces row names that are `text`, and values that are `float8`, and you want 5 value columns:

```
CREATE TYPE my_crosstab_float8_5_cols AS (
 my_row_name text,
 my_category_1 float8,
 my_category_2 float8,
 my_category_3 float8,
 my_category_4 float8,
 my_category_5 float8
);

CREATE OR REPLACE FUNCTION crosstab_float8_5_cols(text)
 RETURNS setof my_crosstab_float8_5_cols
 AS '$libdir/tablefunc', 'crosstab' LANGUAGE C STABLE STRICT;
```

- Use `OUT` parameters to define the return type implicitly. The same example could also be done this way:

```
CREATE OR REPLACE FUNCTION crosstab_float8_5_cols(
 IN text,
 OUT my_row_name text,
 OUT my_category_1 float8,
 OUT my_category_2 float8,
 OUT my_category_3 float8,
 OUT my_category_4 float8,
 OUT my_category_5 float8)
 RETURNS setof record
 AS '$libdir/tablefunc', 'crosstab' LANGUAGE C STABLE STRICT;
```

#### F.81.1.4. `crosstab(text, text)`

`crosstab(text source_sql, text category_sql)`

The main limitation of the single-parameter form of `crosstab` is that it treats all values in a group alike, inserting each value into the first available column. If you want the value columns to correspond to specific categories of data, and some groups might not have data for some of the categories, that doesn't work well. The two-parameter form of `crosstab` handles this case by providing an explicit list of the categories corresponding to the output columns.

*source\_sql* is an SQL statement that produces the source set of data. This statement must return one `row_name` column, one `category` column, and one `value` column. It may also have one or more “extra” columns. The `row_name` column must be first. The `category` and `value` columns must be the last two columns, in that order. Any columns between `row_name` and `category` are treated as “extra”. The “extra” columns are expected to be the same for all rows with the same `row_name` value.

For example, *source\_sql* might produce a set something like:

```
SELECT row_name, extra_col, cat, value FROM foo ORDER BY 1;
```

| row_name | extra_col | cat  | value |
|----------|-----------|------|-------|
| row1     | extra1    | cat1 | val1  |
| row1     | extra1    | cat2 | val2  |

|      |        |      |      |
|------|--------|------|------|
| row1 | extra1 | cat4 | val4 |
| row2 | extra2 | cat1 | val5 |
| row2 | extra2 | cat2 | val6 |
| row2 | extra2 | cat3 | val7 |
| row2 | extra2 | cat4 | val8 |

`category_sql` is an SQL statement that produces the set of categories. This statement must return only one column. It must produce at least one row, or an error will be generated. Also, it must not produce duplicate values, or an error will be generated. `category_sql` might be something like:

```
SELECT DISTINCT cat FROM foo ORDER BY 1;
cat

cat1
cat2
cat3
cat4
```

The `crosstab` function is declared to return `setof record`, so the actual names and types of the output columns must be defined in the `FROM` clause of the calling `SELECT` statement, for example:

```
SELECT * FROM crosstab('...', '...')
AS ct(row_name text, extra text, cat1 text, cat2 text, cat3 text, cat4 text);
```

This will produce a result something like:

|          |        | <==  | value | columns | ==>  |
|----------|--------|------|-------|---------|------|
| row_name | extra  | cat1 | cat2  | cat3    | cat4 |
| row1     | extra1 | val1 | val2  |         | val4 |
| row2     | extra2 | val5 | val6  | val7    | val8 |

The `FROM` clause must define the proper number of output columns of the proper data types. If there are  $N$  columns in the `source_sql` query's result, the first  $N-2$  of them must match up with the first  $N-2$  output columns. The remaining output columns must have the type of the last column of the `source_sql` query's result, and there must be exactly as many of them as there are rows in the `category_sql` query's result.

The `crosstab` function produces one output row for each consecutive group of input rows with the same `row_name` value. The output `row_name` column, plus any "extra" columns, are copied from the first row of the group. The output `value` columns are filled with the `value` fields from rows having matching `category` values. If a row's `category` does not match any output of the `category_sql` query, its `value` is ignored. Output columns whose matching category is not present in any input row of the group are filled with nulls.

In practice the `source_sql` query should always specify `ORDER BY 1` to ensure that values with the same `row_name` are brought together. However, ordering of the categories within a group is not important. Also, it is essential to be sure that the order of the `category_sql` query's output matches the specified output column order.

Here are two complete examples:

```
create table sales(year int, month int, qty int);
insert into sales values(2007, 1, 1000);
insert into sales values(2007, 2, 1500);
insert into sales values(2007, 7, 500);
insert into sales values(2007, 11, 1500);
insert into sales values(2007, 12, 2000);
insert into sales values(2008, 1, 1000);
```

```
select * from crosstab(
 'select year, month, qty from sales order by 1',
 'select m from generate_series(1,12) m'
) as (
 year int,
 "Jan" int,
```

```
"Feb" int,
"Mar" int,
"Apr" int,
"May" int,
"Jun" int,
"Jul" int,
"Aug" int,
"Sep" int,
"Oct" int,
"Nov" int,
"Dec" int
);
year | Jan | Feb | Mar | Apr | May | Jun | Jul | Aug | Sep | Oct | Nov | Dec
-----+-----+-----+-----+-----+-----+-----+-----+-----+-----+-----+-----+-----
2007 | 1000 | 1500 | | | | | 500 | | | | 1500 | 2000
2008 | 1000 | | | | | | | | | | |
(2 rows)
```

```
CREATE TABLE cth(rowid text, rowdt timestamp, attribute text, val text);
INSERT INTO cth VALUES('test1','01 March 2003','temperature','42');
INSERT INTO cth VALUES('test1','01 March 2003','test_result','PASS');
INSERT INTO cth VALUES('test1','01 March 2003','volts','2.6987');
INSERT INTO cth VALUES('test2','02 March 2003','temperature','53');
INSERT INTO cth VALUES('test2','02 March 2003','test_result','FAIL');
INSERT INTO cth VALUES('test2','02 March 2003','test_startdate','01 March 2003');
INSERT INTO cth VALUES('test2','02 March 2003','volts','3.1234');
```

```
SELECT * FROM crosstab
(
 'SELECT rowid, rowdt, attribute, val FROM cth ORDER BY 1',
 'SELECT DISTINCT attribute FROM cth ORDER BY 1'
)
AS
(
 rowid text,
 rowdt timestamp,
 temperature int4,
 test_result text,
 test_startdate timestamp,
 volts float8
);
rowid | rowdt | temperature | test_result | test_startdate
| volts
-----+-----+-----+-----+-----
test1 | Sat Mar 01 00:00:00 2003 | 42 | PASS |
| 2.6987
test2 | Sun Mar 02 00:00:00 2003 | 53 | FAIL | Sat Mar 01 00:00:00
2003 | 3.1234
(2 rows)
```

You can create predefined functions to avoid having to write out the result column names and types in each query. See the examples in the previous section. The underlying C function for this form of `crosstab` is named `crosstab_hash`.

### F.81.1.5. connectby

```
connectby(text relname, text keyid_fld, text parent_keyid_fld
 [, text orderby_fld], text start_with, int max_depth
 [, text branch_delim])
```

The `connectby` function produces a display of hierarchical data that is stored in a table. The table must have a key field that uniquely identifies rows, and a parent-key field that references the parent (if any) of each row. `connectby` can display the sub-tree descending from any row.

Table F.63 explains the parameters.

**Table F.63. `connectby` Parameters**

| Parameter               | Description                                              |
|-------------------------|----------------------------------------------------------|
| <i>relname</i>          | Name of the source relation                              |
| <i>keyid_fld</i>        | Name of the key field                                    |
| <i>parent_keyid_fld</i> | Name of the parent-key field                             |
| <i>orderby_fld</i>      | Name of the field to order siblings by (optional)        |
| <i>start_with</i>       | Key value of the row to start at                         |
| <i>max_depth</i>        | Maximum depth to descend to, or zero for unlimited depth |
| <i>branch_delim</i>     | String to separate keys with in branch output (optional) |

The key and parent-key fields can be any data type, but they must be the same type. Note that the *start\_with* value must be entered as a text string, regardless of the type of the key field.

The `connectby` function is declared to return `setof record`, so the actual names and types of the output columns must be defined in the `FROM` clause of the calling `SELECT` statement, for example:

```
SELECT * FROM connectby('connectby_tree', 'keyid', 'parent_keyid', 'pos', 'row2', 0,
 '~')
 AS t(keyid text, parent_keyid text, level int, branch text, pos int);
```

The first two output columns are used for the current row's key and its parent row's key; they must match the type of the table's key field. The third output column is the depth in the tree and must be of type `integer`. If a *branch\_delim* parameter was given, the next output column is the branch display and must be of type `text`. Finally, if an *orderby\_fld* parameter was given, the last output column is a serial number, and must be of type `integer`.

The “branch” output column shows the path of keys taken to reach the current row. The keys are separated by the specified *branch\_delim* string. If no branch display is wanted, omit both the *branch\_delim* parameter and the branch column in the output column list.

If the ordering of siblings of the same parent is important, include the *orderby\_fld* parameter to specify which field to order siblings by. This field can be of any sortable data type. The output column list must include a final integer serial-number column, if and only if *orderby\_fld* is specified.

The parameters representing table and field names are copied as-is into the SQL queries that `connectby` generates internally. Therefore, include double quotes if the names are mixed-case or contain special characters. You may also need to schema-qualify the table name.

In large tables, performance will be poor unless there is an index on the parent-key field.

It is important that the *branch\_delim* string not appear in any key values, else `connectby` may incorrectly report an infinite-recursion error. Note that if *branch\_delim* is not provided, a default value of `~` is used for recursion detection purposes.

Here is an example:

```
CREATE TABLE connectby_tree(keyid text, parent_keyid text, pos int);

INSERT INTO connectby_tree VALUES('row1',NULL, 0);
INSERT INTO connectby_tree VALUES('row2','row1', 0);
INSERT INTO connectby_tree VALUES('row3','row1', 0);
INSERT INTO connectby_tree VALUES('row4','row2', 1);
INSERT INTO connectby_tree VALUES('row5','row2', 0);
INSERT INTO connectby_tree VALUES('row6','row4', 0);
INSERT INTO connectby_tree VALUES('row7','row3', 0);
INSERT INTO connectby_tree VALUES('row8','row6', 0);
```

---

```
INSERT INTO connectby_tree VALUES('row9','row5', 0);
```

```
-- with branch, without orderby_fld (order of results is not guaranteed)
SELECT * FROM connectby('connectby_tree', 'keyid', 'parent_keyid', 'row2', 0, '~')
AS t(keyid text, parent_keyid text, level int, branch text);
keyid | parent_keyid | level | branch
-----+-----+-----+-----
row2 | | 0 | row2
row4 | row2 | 1 | row2~row4
row6 | row4 | 2 | row2~row4~row6
row8 | row6 | 3 | row2~row4~row6~row8
row5 | row2 | 1 | row2~row5
row9 | row5 | 2 | row2~row5~row9
(6 rows)
```

```
-- without branch, without orderby_fld (order of results is not guaranteed)
SELECT * FROM connectby('connectby_tree', 'keyid', 'parent_keyid', 'row2', 0)
AS t(keyid text, parent_keyid text, level int);
keyid | parent_keyid | level
-----+-----+-----
row2 | | 0
row4 | row2 | 1
row6 | row4 | 2
row8 | row6 | 3
row5 | row2 | 1
row9 | row5 | 2
(6 rows)
```

```
-- with branch, with orderby_fld (notice that row5 comes before row4)
SELECT * FROM connectby('connectby_tree', 'keyid', 'parent_keyid', 'pos', 'row2', 0,
 '~')
AS t(keyid text, parent_keyid text, level int, branch text, pos int);
keyid | parent_keyid | level | branch | pos
-----+-----+-----+-----+-----
row2 | | 0 | row2 | 1
row5 | row2 | 1 | row2~row5 | 2
row9 | row5 | 2 | row2~row5~row9 | 3
row4 | row2 | 1 | row2~row4 | 4
row6 | row4 | 2 | row2~row4~row6 | 5
row8 | row6 | 3 | row2~row4~row6~row8 | 6
(6 rows)
```

```
-- without branch, with orderby_fld (notice that row5 comes before row4)
SELECT * FROM connectby('connectby_tree', 'keyid', 'parent_keyid', 'pos', 'row2', 0)
AS t(keyid text, parent_keyid text, level int, pos int);
keyid | parent_keyid | level | pos
-----+-----+-----+-----
row2 | | 0 | 1
row5 | row2 | 1 | 2
row9 | row5 | 2 | 3
row4 | row2 | 1 | 4
row6 | row4 | 2 | 5
row8 | row6 | 3 | 6
(6 rows)
```

## F.81.2. Author

Joe Conway

## F.82. tcn — a trigger function to notify listeners of changes to table content

The tcn module provides a trigger function that notifies listeners of changes to any table on which it is attached. It must be used as an AFTER trigger FOR EACH ROW.

This module is considered “trusted”, that is, it can be installed by non-superusers who have CREATE privilege on the current database.

Only one parameter may be supplied to the function in a CREATE TRIGGER statement, and that is optional. If supplied it will be used for the channel name for the notifications. If omitted tcn will be used for the channel name.

The payload of the notifications consists of the table name, a letter to indicate which type of operation was performed, and column name/value pairs for primary key columns. Each part is separated from the next by a comma. For ease of parsing using regular expressions, table and column names are always wrapped in double quotes, and data values are always wrapped in single quotes. Embedded quotes are doubled.

A brief example of using the extension follows.

```
test=# create table tcndata
test=# (
test(# a int not null,
test(# b date not null,
test(# c text,
test(# primary key (a, b)
test(#);
CREATE TABLE
test=# create trigger tcndata_tcn_trigger
test=# after insert or update or delete on tcndata
test=# for each row execute function triggered_change_notification();
CREATE TRIGGER
test=# listen tcn;
LISTEN
test=# insert into tcndata values (1, date '2012-12-22', 'one'),
test=# (1, date '2012-12-23', 'another'),
test=# (2, date '2012-12-23', 'two');
INSERT 0 3
Asynchronous notification "tcn" with payload ""tcndata",I,"a"='1',"b"='2012-12-22'"
received from server process with PID 22770.
Asynchronous notification "tcn" with payload ""tcndata",I,"a"='1',"b"='2012-12-23'"
received from server process with PID 22770.
Asynchronous notification "tcn" with payload ""tcndata",I,"a"='2',"b"='2012-12-23'"
received from server process with PID 22770.
test=# update tcndata set c = 'uno' where a = 1;
UPDATE 2
Asynchronous notification "tcn" with payload ""tcndata",U,"a"='1',"b"='2012-12-22'"
received from server process with PID 22770.
Asynchronous notification "tcn" with payload ""tcndata",U,"a"='1',"b"='2012-12-23'"
received from server process with PID 22770.
test=# delete from tcndata where a = 1 and b = date '2012-12-22';
DELETE 1
Asynchronous notification "tcn" with payload ""tcndata",D,"a"='1',"b"='2012-12-22'"
received from server process with PID 22770.
```

## F.83. test\_decoding — SQL-based test/example module for WAL logical decoding

`test_decoding` is an example of a logical decoding output plugin. It doesn't do anything especially useful, but can serve as a starting point for developing your own output plugin.

`test_decoding` receives WAL through the logical decoding mechanism and decodes it into text representations of the operations performed.

Typical output from this plugin, used over the SQL logical decoding interface, might be:

```
postgres=# SELECT * FROM pg_logical_slot_get_changes('test_slot', NULL, NULL, 'include-
xids', '0');
 location | xid | data
-----+-----+-----
 0/16D30F8 | 691 | BEGIN
 0/16D32A0 | 691 | table public.data: INSERT: id[int4]:2 data[text]:'arg'
 0/16D32A0 | 691 | table public.data: INSERT: id[int4]:3 data[text]:'demo'
 0/16D32A0 | 691 | COMMIT
 0/16D32D8 | 692 | BEGIN
 0/16D3398 | 692 | table public.data: DELETE: id[int4]:2
 0/16D3398 | 692 | table public.data: DELETE: id[int4]:3
 0/16D3398 | 692 | COMMIT
(8 rows)
```

We can also get the changes of the in-progress transaction, and the typical output might be:

```
postgres[33712]=#* SELECT * FROM pg_logical_slot_get_changes('test_slot', NULL, NULL,
'stream-changes', '1');
 lsn | xid | data
-----+-----+-----
 0/16B21F8 | 503 | opening a streamed block for transaction TXN 503
 0/16B21F8 | 503 | streaming change for TXN 503
 0/16B2300 | 503 | streaming change for TXN 503
 0/16B2408 | 503 | streaming change for TXN 503
 0/16BEBA0 | 503 | closing a streamed block for transaction TXN 503
 0/16B21F8 | 503 | opening a streamed block for transaction TXN 503
 0/16BECA8 | 503 | streaming change for TXN 503
 0/16BEDB0 | 503 | streaming change for TXN 503
 0/16BEEB8 | 503 | streaming change for TXN 503
 0/16BEBA0 | 503 | closing a streamed block for transaction TXN 503
(10 rows)
```

## F.84. tsm\_system\_rows — the SYSTEM\_ROWS sampling method for TABLESAMPLE

The `tsm_system_rows` module provides the table sampling method `SYSTEM_ROWS`, which can be used in the `TABLESAMPLE` clause of a [SELECT](#) command.

This table sampling method accepts a single integer argument that is the maximum number of rows to read. The resulting sample will always contain exactly that many rows, unless the table does not contain enough rows, in which case the whole table is selected.

Like the built-in `SYSTEM` sampling method, `SYSTEM_ROWS` performs block-level sampling, so that the sample is not completely random but may be subject to clustering effects, especially if only a small number of rows are requested.

`SYSTEM_ROWS` does not support the `REPEATABLE` clause.

This module is considered “trusted”, that is, it can be installed by non-superusers who have `CREATE` privilege on the current database.

### F.84.1. Examples

Here is an example of selecting a sample of a table with `SYSTEM_ROWS`. First install the extension:

```
CREATE EXTENSION tsm_system_rows;
```

Then you can use it in a `SELECT` command, for instance:

```
SELECT * FROM my_table TABLESAMPLE SYSTEM_ROWS(100);
```

This command will return a sample of 100 rows from the table `my_table` (unless the table does not have 100 visible rows, in which case all its rows are returned).

## F.85. `tsm_system_time` — the `SYSTEM_TIME` sampling method for `TABLESAMPLE`

The `tsm_system_time` module provides the table sampling method `SYSTEM_TIME`, which can be used in the `TABLESAMPLE` clause of a `SELECT` command.

This table sampling method accepts a single floating-point argument that is the maximum number of milliseconds to spend reading the table. This gives you direct control over how long the query takes, at the price that the size of the sample becomes hard to predict. The resulting sample will contain as many rows as could be read in the specified time, unless the whole table has been read first.

Like the built-in `SYSTEM` sampling method, `SYSTEM_TIME` performs block-level sampling, so that the sample is not completely random but may be subject to clustering effects, especially if only a small number of rows are selected.

`SYSTEM_TIME` does not support the `REPEATABLE` clause.

This module is considered “trusted”, that is, it can be installed by non-superusers who have `CREATE` privilege on the current database.

### F.85.1. Examples

Here is an example of selecting a sample of a table with `SYSTEM_TIME`. First install the extension:

```
CREATE EXTENSION tsm_system_time;
```

Then you can use it in a `SELECT` command, for instance:

```
SELECT * FROM my_table TABLESAMPLE SYSTEM_TIME(1000);
```

This command will return as large a sample of `my_table` as it can read in 1 second (1000 milliseconds). Of course, if the whole table can be read in under 1 second, all its rows will be returned.

## F.86. unaccent — a text search dictionary which removes diacritics

`unaccent` is a text search dictionary that removes accents (diacritic signs) from lexemes. It's a filtering dictionary, which means its output is always passed to the next dictionary (if any), unlike the normal behavior of dictionaries. This allows accent-insensitive processing for full text search.

The current implementation of `unaccent` cannot be used as a normalizing dictionary for the `thesaurus` dictionary.

This module is considered “trusted”, that is, it can be installed by non-superusers who have `CREATE` privilege on the current database.

### F.86.1. Configuration

An `unaccent` dictionary accepts the following options:

- `RULES` is the base name of the file containing the list of translation rules. This file must be stored in `$$SHAREDIR/tsearch_data/` (where `$$SHAREDIR` means the Postgres Pro installation's shared-data directory). Its name must end in `.rules` (which is not to be included in the `RULES` parameter).

The rules file has the following format:

- Each line represents one translation rule, consisting of a character with accent followed by a character without accent. The first is translated into the second. For example,

|   |    |
|---|----|
| À | A  |
| Á | A  |
| Â | A  |
| Ã | A  |
| Ä | A  |
| Å | A  |
| Æ | AE |

The two characters must be separated by whitespace, and any leading or trailing whitespace on a line is ignored.

- Alternatively, if only one character is given on a line, instances of that character are deleted; this is useful in languages where accents are represented by separate characters.
- Actually, each “character” can be any string not containing whitespace, so `unaccent` dictionaries could be used for other sorts of substring substitutions besides diacritic removal.
- Some characters, like numeric symbols, may require whitespaces in their translation rule. It is possible to use double quotes around the translated characters in this case. A double quote needs to be escaped with a second double quote when including one in the translated character. For example:

|   |         |
|---|---------|
| ¼ | " 1/4"  |
| ½ | " 1/2"  |
| ¾ | " 3/4"  |
| " | " "" "" |
| " | " "" "" |

- As with other Postgres Pro text search configuration files, the rules file must be stored in UTF-8 encoding. The data is automatically translated into the current database's encoding when loaded. Any lines containing untranslatable characters are silently ignored, so that rules files can contain rules that are not applicable in the current encoding.

A more complete example, which is directly useful for most European languages, can be found in `unaccent.rules`, which is installed in `$$SHAREDIR/tsearch_data/` when the `unaccent` module is installed. This rules file translates characters with accents to the same characters without accents, and it also expands ligatures into the equivalent series of simple characters (for example, `Æ` to `AE`).

### F.86.2. Usage

Installing the `unaccent` extension creates a text search template `unaccent` and a dictionary `unaccent` based on it. The `unaccent` dictionary has the default parameter setting `RULES='unaccent'`, which makes it immediately usable with the standard `unaccent.rules` file. If you wish, you can alter the parameter, for example

```
mydb=# ALTER TEXT SEARCH DICTIONARY unaccent (RULES='my_rules');
```

or create new dictionaries based on the template.

To test the dictionary, you can try:

```
mydb=# select ts_lexize('unaccent','Hôtel');
 ts_lexize

 {Hotel}
(1 row)
```

Here is an example showing how to insert the `unaccent` dictionary into a text search configuration:

```
mydb=# CREATE TEXT SEARCH CONFIGURATION fr (COPY = french);
mydb=# ALTER TEXT SEARCH CONFIGURATION fr
 ALTER MAPPING FOR hword, hword_part, word
 WITH unaccent, french_stem;
mydb=# select to_tsvector('fr','Hôtels de la Mer');
 to_tsvector

 'hotel':1 'mer':4
(1 row)

mydb=# select to_tsvector('fr','Hôtel de la Mer') @@ to_tsquery('fr','Hotels');
 ?column?

 t
(1 row)

mydb=# select ts_headline('fr','Hôtel de la Mer',to_tsquery('fr','Hotels'));
 ts_headline

 Hôtel de la Mer
(1 row)
```

### F.86.3. Functions

The `unaccent()` function removes accents (diacritic signs) from a given string. Basically, it's a wrapper around `unaccent`-type dictionaries, but it can be used outside normal text search contexts.

`unaccent([dictionary regdictionary, ] string text)` returns *text*

If the *dictionary* argument is omitted, the text search dictionary named `unaccent` and appearing in the same schema as the `unaccent()` function itself is used.

For example:

```
SELECT unaccent('unaccent', 'Hôtel');
SELECT unaccent('Hôtel');
```

## F.87. uuid-ossP — a UUID generator

The `uuid-ossP` module provides functions to generate universally unique identifiers (UUIDs) using one of several standard algorithms. There are also functions to produce certain special UUID constants. This module is only necessary for special requirements beyond what is available in core Postgres Pro. See [Section 9.14](#) for built-in ways to generate UUIDs.

This module is considered “trusted”, that is, it can be installed by non-superusers who have `CREATE` privilege on the current database.

### F.87.1. uuid-ossP Functions

[Table F.64](#) shows the functions available to generate UUIDs. The relevant standards ITU-T Rec. X.667, ISO/IEC 9834-8:2005, and [RFC 4122](#) specify four algorithms for generating UUIDs, identified by the version numbers 1, 3, 4, and 5. (There is no version 2 algorithm.) Each of these algorithms could be suitable for a different set of applications.

**Table F.64. Functions for UUID Generation**

| Function                                                         | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
|------------------------------------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>uuid_generate_v1 () → uuid</code>                          | Generates a version 1 UUID. This involves the MAC address of the computer and a time stamp. Note that UUIDs of this kind reveal the identity of the computer that created the identifier and the time at which it did so, which might make it unsuitable for certain security-sensitive applications.                                                                                                                                                                                                                                                                                                                                                     |
| <code>uuid_generate_v1mc () → uuid</code>                        | Generates a version 1 UUID, but uses a random multicast MAC address instead of the real MAC address of the computer.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
| <code>uuid_generate_v3 (namespace uuid, name text) → uuid</code> | Generates a version 3 UUID in the given namespace using the specified input name. The namespace should be one of the special constants produced by the <code>uuid_ns_* ()</code> functions shown in <a href="#">Table F.65</a> . (It could be any UUID in theory.) The name is an identifier in the selected namespace.<br>For example:<br><br><pre>SELECT uuid_generate_v3(uuid_ns_url(), 'http://www.postgresql.org');</pre><br>The name parameter will be MD5-hashed, so the cleartext cannot be derived from the generated UUID. The generation of UUIDs by this method has no random or environment-dependent element and is therefore reproducible. |
| <code>uuid_generate_v4 () → uuid</code>                          | Generates a version 4 UUID, which is derived entirely from random numbers.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
| <code>uuid_generate_v5 (namespace uuid, name text) → uuid</code> | Generates a version 5 UUID, which works like a version 3 UUID except that SHA-1 is used as a hashing method. Version 5 should be preferred over version 3 because SHA-1 is thought to be more secure than MD5.                                                                                                                                                                                                                                                                                                                                                                                                                                            |

**Table F.65. Functions Returning UUID Constants**

| Function                           | Description                                                                                                                                                              |
|------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>uuid_nil () → uuid</code>    | Returns a “nil” UUID constant, which does not occur as a real UUID.                                                                                                      |
| <code>uuid_ns_dns () → uuid</code> | Returns a constant designating the DNS namespace for UUIDs.                                                                                                              |
| <code>uuid_ns_url () → uuid</code> | Returns a constant designating the URL namespace for UUIDs.                                                                                                              |
| <code>uuid_ns_oid () → uuid</code> | Returns a constant designating the ISO object identifier (OID) namespace for UUIDs. (This pertains to ASN.1 OIDs, which are unrelated to the OIDs used in Postgres Pro.) |

| Function                            | Description                                                                           |
|-------------------------------------|---------------------------------------------------------------------------------------|
| <code>uuid_ns_x500 () → uuid</code> | Returns a constant designating the X.500 distinguished name (DN) namespace for UUIDs. |

## F.87.2. Building `uuid-oss`

Historically this module depended on the OSSP UUID library, which accounts for the module's name. While the OSSP UUID library can still be found at <http://www.ossdp.org/pkg/lib/uuid/>, it is not well maintained, and is becoming increasingly difficult to port to newer platforms. `uuid-oss` can now be built without the OSSP library on some platforms. On FreeBSD and some other BSD-derived platforms, suitable UUID creation functions are included in the core `libc` library. On Linux, macOS, and some other platforms, suitable functions are provided in the `libuuid` library, which originally came from the `e2fsprogs` project (though on modern Linux it is considered part of `util-linux-ng`). When invoking `configure`, specify `--with-uuid=bsd` to use the BSD functions, or `--with-uuid=e2fs` to use `e2fsprogs`' `libuuid`, or `--with-uuid=oss` to use the OSSP UUID library. More than one of these libraries might be available on a particular machine, so `configure` does not automatically choose one.

## F.88. vops — support for vector operations

### Important

The `vops` extension is considered deprecated. It is not recommended to use it.

The `vops` module is an experimental Postgres Pro Enterprise extension that provides support for vector operations, which allows to speed up OLAP queries with filtering and aggregation more than 10 times. Performance improvements are achieved by implementing a vertical data model that allows storing data in *tiles*, or groups of column values. Such a storage format is also called *Parquet* in some analytical databases. Reducing the overhead of unpacking tuples, vertical data model allows to speed up query execution without any radical changes in Postgres Pro planner and executor.

`vops` provides its own set of vector functions that can be used inside predicates and aggregate expressions. To avoid learning new syntax, you can use `postgres_fdw` as an abstraction layer and run regular SQL queries on vectorized data. For query types other than filtering and aggregation, `vops` can also use `postgres_fdw` to present vectorized data as a regular table with scalar column types and process this data as regular tuples. For ease of use, `vops` also provides an automated way of generating and accessing vectorized data, as explained in [Section F.88.5.5](#).

### F.88.1. Limitations

- Tile-based tables only allow `INSERT` and `APPEND` operations. Once imported, vectorized data cannot be updated.
- Vector operations are only available for filtering and aggregation. Other query types are supported via `postgres_fdw`.
- Aggregate expressions must be of the same type.
- `JOIN` operations are not supported for vector types. You have to use `postgres_fdw` to transform vectorized data back to regular tuples to run such queries.
- Since `postgres_fdw` does not support parallel query execution, you can only run parallel queries when using vector operators directly.

### F.88.2. Installation and Setup

The `vops` extension is included into Postgres Pro Enterprise. Once you have Postgres Pro Enterprise installed, complete the following steps to enable `vops`:

1. Add `vops` to the `shared_preload_libraries` parameter in the `postgresql.conf` file:

```
shared_preload_libraries = 'vops'
```

### Note

If the extension library is not added to the `shared_preload_libraries` list, it will be loaded on demand after the first function invocation of this extension. In this case, the first time you execute a vectorized query, it will not be processed correctly and can return a wrong result.

2. Restart the Postgres Pro Enterprise instance for the changes to take effect.
3. Create `vops` extension:

```
CREATE EXTENSION vops;
```

Once `vops` is enabled, you can create vectorized tables and query data using vector operations in your database.

If you would like to use regular SQL syntax for vector types, you must also enable `postgres_fdw`.

### F.88.3. Motivation

For OLTP workloads, Postgres Pro looks very competitive as compared to other mainstream databases. However, for OLAP queries, which require processing larger volumes of data, analytics-oriented database management systems can provide a much better speed. There are several main factors that limit Postgres Pro performance:

- Tuple unpacking overhead. To access column values, Postgres Pro needs to unpack the tuple. As tables can have columns of variable-length data types, to extract the N-th column, the preceding N-1 columns need to be unpacked. Thus, deforming a tuple is quite an expensive operation, especially for tables with a large number of attributes. Besides, values can be compressed or stored in another page (TOAST). In queries like Query 6 of the [TPC-H benchmark](#), deforming tuples takes about 40% of the total query execution time.
- Interpretation overhead. Postgres Pro planner and optimizer build a tree representing the query execution plan. Query executor recursively calls functions that evaluate the nodes of this tree. Some nodes may also contain switches used to select the requested action. Thus, query plan is interpreted by Postgres Pro query executor rather than directly executed. The interpreter is usually about 10 times slower than the native code. If you eliminate interpretation overhead, you can increase query speed several times, especially for queries with complex predicates that have high evaluation costs.
- Abstraction penalty. Support for abstract (user-defined) types and operations is one of the key features of Postgres Pro. However, the price of such flexibility is that each operation requires a separate function call. Instead of adding two integers directly, Postgres Pro executor invokes a function that performs addition. In this case, function call overhead is much higher than the cost the operation itself. Function call overhead is also increased because Postgres Pro requires passing parameter values through memory.
- Pull model overhead. In Postgres Pro, operators pull the operand values. This approach simplifies the implementation of operators and the executor, but has a negative impact on performance. In this model, leaf nodes that fetch a tuple from the heap or index pages have to do a lot of extra work while saving and restoring their context.
- MVCC overhead. Postgres Pro provides multi-version concurrency control, which allows multiple transactions to work with the same record in parallel without blocking each other. It is good for frequently updated data (OLTP), but for read-only or append-only data in OLAP scenarios it only adds both space overhead (about 20 extra bytes per tuple) and CPU overhead (checking visibility of each tuple).

Vector operations can address most of these issues without radical changes in the Postgres Pro executor, as explained in [Section F.88.4](#).

## F.88.4. Architecture

The `vops` extension implements a *vertical data model* for Postgres Pro. In this model, vertical columns are used as a data storing unit, with the values of the corresponding table attribute forming a vector.

The vertical data model used by `vops` has the following advantages:

- Reduces the size of fetched data: only the columns used in the query need to be fetched.
- Achieves higher compression rates: storing all values of the same attribute together makes it possible to compress them much better and faster. For example, you can use delta encoding.
- Minimizes interpretation overhead: a set of values can be processed by a single operation instead of running separate operations for each value.
- Uses CPU vector instructions (SIMD) to process data.

A traditional Postgres Pro query executor deals with a single row of data at each moment of time. For example, to evaluate an expression  $(x+y)$ , it first fetches the value of  $x$ , then fetches the value of  $y$ , performs the addition, and returns the result value to the upper node. In contrast, a vectorized executor can process multiple values within a single operation. In this case,  $x$  and  $y$  represent vectors of values instead of single scalars. The returned result is also a vector. In vector execution model, interpretation and function call overhead is divided by the vector size. The price of performing a function call is the same, but as the function processes  $N$  values instead of a single one, this overhead becomes less critical. The larger the vector, the smaller the per-row overhead.

However, performing an operation on the whole column may also turn out to be ineffective. Working with large vectors prevents efficient utilization of CPU cache levels. If the table is very large, the vector may not fit in memory at all. To avoid these issues, `vops` splits the columns into relatively small chunks, or *tiles*. The size of a tile is currently set to 64 elements. It allows to keep all operands of vector operations in cache, even for complex expressions.

The `vops` extension implements special vector types to be used instead of scalar types for table columns. The available types are listed in [Section F.88.6.1](#). To use `vops`, you have to create vectorized projections of original tables, with at least some attributes using these tile types, as explained in [Section F.88.5.1](#).

The original table can be treated as a write-optimized storage: if it has no indexes, Postgres Pro can provide a very fast insertion speed, comparable to raw disk write speed. Vectorized projection can be treated as a read-optimized storage, which is most efficient for running OLAP queries.

Once all the data is in the tile-based format, you can run vectorized queries on this data. `vops` provides a set of [vector operators](#) to work with vector types. Using these operators, you can write queries for filtering and aggregation, similar to SQL queries. For details, see [Section F.88.5.2](#).

For other query types, `vops` allows to work with vectorized data via `postgres_fdw`. You can add vectorized data to your database cluster as a foreign table and use regular SQL for running any types of queries on this data. Using the implicit type casts and post-parse ANALYZE hook, the `vops` extension either transforms the query to use vector operators for filtering and aggregation, or processes the data using scalar operators for other query types. For details, see [Section F.88.5.3](#).

## F.88.5. Usage

### F.88.5.1. Converting Data into Vectorized Format

To start using vector operations, you have to convert your data into a vectorized format, as explained below.

#### 1. Create an empty vectorized table.

To use vector operations, you need to load data into a tile-based vectorized table, which can be treated as a *projection* of the original table. It can map all columns of the original table, or include some of the most frequently used columns only. To create a vectorized table, you can use the regular [CREATE TABLE](#) syntax, but at least some of the columns must be of [vector types](#).

For example, suppose you have the following table from the TPC-H benchmark:

```
CREATE TABLE lineitem(
 l_orderkey integer,
 l_partkey integer,
 l_suppkey integer,
 l_linenummer integer,
 l_quantity double precision,
 l_extendedprice double precision,
 l_discount double precision,
 l_tax double precision,
 l_returnflag "char",
 l_linestatus "char",
 l_shipdate date,
 l_commitdate date,
 l_receiptdate date,
 l_shipinstruct char(25),
 l_shipmode char(10),
 l_comment char(44));
```

To create a vectorized projection that includes only a subset of the original columns, you can run:

```
CREATE TABLE vops_lineitem(
 l_shipdate vops_date not null,
 l_quantity vops_float8 not null,
 l_extendedprice vops_float8 not null,
 l_discount vops_float8 not null,
 l_tax vops_float8 not null,
 l_returnflag vops_char not null,
 l_linestatus vops_char not null
);
```

Alternatively, you can keep the scalar type for some of the columns. In this case, you can sort the data by these columns when loading the data. For example, let's create another vectorized projection where `l_returnflag` and `l_linestatus` fields remain scalar:

```
CREATE TABLE vops_lineitem_projection(
 l_shipdate vops_date not null,
 l_quantity vops_float8 not null,
 l_extendedprice vops_float8 not null,
```

```
l_discount vops_float8 not null,
l_tax vops_float8 not null,
l_returnflag "char" not null,
l_linestatus "char" not null
);
```

In this table, `l_returnflag` and `l_linestatus` fields are scalar, while all the other fields are of the vector types that can be used in vector operations.

## 2. Load the data into the vectorized table.

- If the data to load is already stored in your database, use the [populate\(\)](#) function to preprocess the data and unite attribute values of several rows inside a single tile. This function loads the data from the original table into its vectorized projection, using vector types instead of scalar types, as specified in the created empty table.

For example:

```
SELECT populate(destination := 'vops_lineitem'::regclass, source :=
 'lineitem'::regclass);
```

Once the table is populated, you can start running queries performing sequential scan.

Optionally, you can sort the data by one or more scalar columns when loading the data:

```
SELECT populate(destination := 'vops_lineitem_projection'::regclass, source :=
 'lineitem'::regclass, sort := 'l_returnflag,l_linestatus');
```

If you sort the original table by the scalar columns that have a lot of duplicates, **vops** can effectively collapse them and store the corresponding attribute values in tiles, which can reduce the occupied space, speed up queries, and facilitate [index creation](#) on these scalar columns.

- If your data is not yet loaded into the database and you would like to avoid having two copies of the same dataset, you can import the data into a vectorized table directly from a CSV file using the [import\(\)](#) function, bypassing creation of a regular table. For example:

```
SELECT import(destination := 'vops_lineitem'::regclass, csv_path := '/mnt/data/
lineitem.csv', separator := '|');
```

For detailed description and syntax of the `populate()` and `import()` functions, see [Section F.88.6.4](#).

Once your data is in the tile-based format, you can run queries on this data using [vector operators](#), as described in [Section F.88.5.2](#). If you create a foreign vectorized table, you can also run regular SQL queries. See [Section F.88.5.3](#) for details.

## F.88.5.2. Running Queries on Vectorized Data

**vops** implements its own vector functions and operators for working with vectorized data. See [Section F.88.6](#) for the full list of vector functions and operators and their usage specifics.

### F.88.5.2.1. Aggregating Vectorized Data

OLAP queries often aggregate large volumes of data. To enable aggregate operations for vector types, **vops** implements the following aggregate functions for vectorized data: `count`, `min`, `max`, `avg`, `var_pop`, `var_samp`, `variance`, `stddev_pop`, `stddev_samp`, `stddev`. Besides, **vops** provides the `wavg` aggregate function that calculates volume-weighted average price (VWAP).

The **vops** extension supports the following types of aggregates:

- grand aggregates calculated for the whole table
- aggregates for subsets of table rows defined by the `GROUP BY` clause

#### F.88.5.2.1.1. Calculating Grand Aggregates

To calculate grand aggregates, you can use the provided vector aggregate functions exactly like in regular SQL queries.

#### Examples:

To calculate volume-weighted average price, run the following query:

```
SELECT wavg(l_extendedprice, l_quantity) FROM vops_lineitem;
```

To calculate the company revenue for the year 1996 based on discounted prices of the shipped goods, run:

```
SELECT sum(l_extendedprice*l_discount) AS revenue
FROM vops_lineitem
WHERE filter(betwixt(l_shipdate, '1996-01-01', '1997-01-01')
 & betwixt(l_discount, 0.08, 0.1)
 & (l_quantity < 24));
```

#### F.88.5.2.1.2. Calculating Grouped Aggregates

To support grouped aggregates, `vops` provides `map()` and `reduce()` functions:

- The `map()` function collects aggregate states for all groups in a hash table. Its syntax is as follows:  

```
map(group_by_expression,
 aggregate_list, expr {,
 expr })
```
- The `reduce()` function iterates through the hash table constructed by `map` and returns the set. The `reduce` function is needed because the result of aggregation in Postgres Pro cannot be a set.

Consider the following example:

```
SELECT reduce(map(l_returnflag||l_linestatus, 'sum,sum,sum,sum,avg,avg,avg',
 l_quantity,
 l_extendedprice,
 l_extendedprice*(1-l_discount),
 l_extendedprice*(1-l_discount)*(1+l_tax),
 l_quantity,
 l_extendedprice,
 l_discount))
FROM vops_lineitem
WHERE filter(l_shipdate <= '1998-12-01'::date);
```

The concatenation operator `||` performs grouping by two columns. The `vops` extension supports grouping only by an integer type. The `map` function accepts aggregation arguments as a variadic array, so all elements of this array should have the same type. For example, you cannot calculate aggregates for `vops_float4` and `vops_int8` columns in a single operation.

An aggregate string in `map` function should contain the list of aggregate functions to call, in a comma-separated format. Standard lowercase names should be used: `count`, `sum`, `agg`, `min`, `max`. `Count` is executed for the particular column: `count(x)`. There is no need to explicitly specify `count(*)` because the number of records in each group is returned by `reduce` function in any case.

`reduce` function returns set of the `vops_aggregate` type. It contains three components: the value of the `GROUP BY` expression, the number of records in the group, and an array of floats with aggregate values. The values of all aggregates, including `count` and `min/max`, are returned as floats.

Alternatively, you can partition the vectorized table by the `GROUP BY` fields to calculate grouped aggregates. In this case, grouping keys are stored as regular scalar values, while other fields are stored inside tiles. Now Postgres Pro executor will execute `vops` aggregates for each group:

```
SELECT
 l_returnflag,
 l_linestatus,
 sum(l_quantity) as sum_qty,
 sum(l_extendedprice) AS sum_base_price,
 sum(l_extendedprice*(1-l_discount)) AS sum_disc_price,
 sum(l_extendedprice*(1-l_discount)*(1+l_tax)) AS sum_charge,
 avg(l_quantity) AS avg_qty,
 avg(l_extendedprice) AS avg_price,
 avg(l_discount) AS avg_disc,
 count(*) AS count_order
```

```
FROM
 vops_lineitem_projection
WHERE
 filter(l_shipdate <= '1998-12-01'::date)
GROUP BY
 l_returnflag,
 l_linestatus
ORDER BY
 l_returnflag,
 l_linestatus;
```

In this example, `l_returnflag` and `l_linestatus` fields of the `vops_lineitem_projection` table have the `char` type, while all the other used fields are of vector types. The query above is executed even faster than query with the `map()` and `reduce()` functions. The main problem with this approach is that you have to create a separate projection for each combination of the `GROUP BY` keys to be used in queries.

#### F.88.5.2.2. Using Vector Window Functions

The `vops` extension provides limited support for Postgres Pro window functions. It provides `mcount`, `msum`, `mmin`, `mmax`, `mavg`, and `lag` functions that correspond to the standard Postgres Pro window functions `count`, `sum`, `min`, `max`, `avg`, and `lag` functions, respectively.

Note the following important restrictions:

1. Filtering, grouping, and sorting can be done only by scalar attributes.
2. Vector window functions only support window frames specified with `ROWS BETWEEN UNBOUNDED PRECEDING AND CURRENT ROW`.

##### Examples:

```
SELECT vops_unnest(t.*)
FROM (SELECT mcount(*) over w,mcount(x) over w,msum(x) over w,mavg(x) over w,mmin(x)
over w,mmax(x) over w,x - lag(x) over w
FROM v window w
AS (rows between unbounded preceding and current row)) t;
```

#### F.88.5.2.3. Converting Results to Horizontal Format

A query from the `vops` projection returns a set of tiles. The output function of a tile type can print the tile contents. However, if you want to convert the result to the horizontal format where each tuple represents a single record, use the `vops-unnest` function. For example:

```
SELECT vops_unnest(l.*)
FROM vops_lineitem l
WHERE filter(l_shipdate >= '1998-12-01'::date);
```

#### F.88.5.3. Using Standard SQL for Vector Operations

Vector operators can efficiently execute only filtering and aggregation queries. For other query types, you have to run regular SQL queries. The `vops` extension offers the following options:

- Use the original table, if any.
- Enable a foreign data wrapper (FDW) using `postgres_fdw` to present a vectorized table to Postgres Pro as a regular table with scalar column types.

If you use `postgres_fdw` with the `vops` extension, vectorized data is not really foreign: it is stored inside the database in an alternative vectorized format. FDW allows to hide specifics of the vectorized format and provides the following opportunities for working with vectorized data:

1. Extract the data from a vectorized table and present it in the horizontal format, so that it can be processed by upper nodes in the query execution plan.
2. Push filtering and aggregation queries down to vector operations.
3. Get statistic for the underlying table by running `ANALYZE` for the foreign table. The collected statistic can be used by the query optimizer, so query execution plan should be almost the same as for regular tables.

Thus, by placing a vectorized projection under FDW, you can use standard SQL without any `vops`-specific functions to perform sequential scan and aggregation queries as if they are explicitly written for the `vops` table, and execute any other queries on this data at the same time, including `JOIN` operations, common table expressions (CTE), etc. The queries that can be efficiently executed by vector operations will be pushed by Postgres Pro query optimizer to `vops` FDW and will be executed using vector operators. For other queries, the data is fetched from vectorized tables as standard tuples. If it is determined that vector operations are required, `vops` uses a post-parse `ANALYZE` hook that replaces scalar boolean operations with vector boolean operations:

| Original Expression                    | Transformed Expression                     |
|----------------------------------------|--------------------------------------------|
| <code>NOT filter(o1)</code>            | <code>filter(vops_bool_not(o1))</code>     |
| <code>filter(o1) AND filter(o2)</code> | <code>filter(vops_bool_and(o1, o2))</code> |
| <code>filter(o1) OR filter(o2)</code>  | <code>filter(vops_bool_or(o1, o2))</code>  |

There is only one difference between standard SQL and its vectorized extension. You still have to perform explicit type cast for string literals. For example, `l_shipdate <= '1998-12-01'` will not work for the `l_shipdate` column with vector type. Postgres Pro Enterprise has two overloaded versions of the `<=` operator to choose the appropriate scalar or vector type:

- `vops_date <= vops_date`
- `vops_date <= date`

The example below shows creation of a vectorized table via `postgres_fdw` and some queries on it:

```
CREATE FOREIGN TABLE lineitem_fdw (
 l_suppkey int4 not null,
 l_orderkey int4 not null,
 l_partkey int4 not null,
 l_shipdate date not null,
 l_quantity float8 not null,
 l_extendedprice float8 not null,
 l_discount float8 not null,
 l_tax float8 not null,
 l_returnflag "char" not null,
 l_linestatus "char" not null
) SERVER vops_server OPTIONS (table_name 'vops_lineitem');
```

```
EXPLAIN SELECT
 sum(l_extendedprice*l_discount) AS revenue
FROM
 lineitem_fdw
WHERE
 l_shipdate BETWEEN '1996-01-01' AND '1997-01-01'
 AND l_discount BETWEEN 0.08 AND 0.1
 AND l_quantity < 24;
```

QUERY PLAN

```

Foreign Scan (cost=1903.26..1664020.23 rows=1 width=4)
(1 row)
```

-- Filter was pushed down to FDW

```
EXPLAIN SELECT
 n_name,
 count(*),
 sum(l_extendedprice * (1-l_discount)) AS revenue
FROM
 customer_fdw JOIN orders_fdw ON c_custkey = o_custkey
 JOIN lineitem_fdw ON l_orderkey = o_orderkey
 JOIN supplier_fdw ON l_suppkey = s_suppkey
 JOIN nation ON c_nationkey = n_nationkey
```

```
JOIN region ON n_regionkey = r_regionkey
WHERE
 c_nationkey = s_nationkey
 AND r_name = 'ASIA'
 AND o_orderdate >= '1996-01-01'
 AND o_orderdate < '1997-01-01'
GROUP BY
 n_name
ORDER BY
 revenue desc;
```

#### QUERY PLAN

```

Sort (cost=2337312.28..2337312.78 rows=200 width=48)

#### F.88.5.4. Building Indexes for Vectorized Tables

Analytic queries are usually performed on the data for which no indexes are defined. Vector operations on tiles are most effective in this case. However, you can still use indexes with vectorized data.

Since each tile represents multiple values, an index can be used only for some preliminary, non-precise filtering of data. The `vops` extension provides the following pairs of functions to obtain boundary values stored in the tile:

- `first()` and `last()` functions should be used for sorted dataset. In this case, the first and the last values in the tile are the smallest and the largest values in the tile, respectively.
- `high()` and `low()` functions should be used for unsorted data. These functions are more expensive because they need to inspect all tile values.

Using the returned values, you can construct functional indexes for vectorized data. The BRIN index seems to be the best choice:

```
CREATE INDEX low_boundary ON trades
USING brin(first(day)); -- trades table is ordered by day
CREATE INDEX high_boundary ON trades
USING brin(last(day)); -- trades table is ordered by day
```

Now you can use the created indexes in queries. However, you have to recheck the precise condition because such an index only gives an approximate result:

```
SELECT sum(price) FROM trades
WHERE first(day) >= '2015-01-01' AND last(day) <= '2016-01-01'
AND filter(betwixt(day, '2015-01-01', '2016-01-01'));
```

#### F.88.5.5. Automating Projection Usage

`vops` can automate most of the operations required to create and maintain vectorized data projections. In this case, you do not have to use `postgres_fdw`: `vops` can redirect regular SQL queries to projection tables automatically. However, these queries must satisfy the following criteria to get redirected:

- The query does not contain joins.
- The query performs aggregation of vector columns.
- All other expressions in the target list, as well as `ORDER BY` and `GROUP BY` clauses refer only to scalar columns.

To enable automatic query redirection to a vectorized projection of your data, do the following:

1. **Create a vectorized projection of the table using the `create_projection()` function.**

For example, to create a projection for the `lineitem` table shown above, similar to the `vops_lineitem`, run:

```
SELECT create_projection('auto_vops_lineitem', 'lineitem',
 array['l_shipdate', 'l_quantity', 'l_extendedprice', 'l_discount', 'l_tax'],
 array['l_returnflag', 'l_linestatus']);
```

In this example, the first two arguments specify the projection table and the original table, respectively, the first array defines all the vector columns to be included into the projection, and the second array specifies the scalar columns that will be used for grouping vectorized data into tiles.

Additionally, you can provide an optional `order_by` parameter to speed up subsequent projection refresh operations. The `order_by` values should be unique. For example, to sort all table entries by `l_shipdate`, you can create a projection table as follows:

```
SELECT create_projection('auto_vops_lineitem_ordered', 'lineitem',
 array['l_shipdate', 'l_quantity', 'l_extendedprice', 'l_discount', 'l_tax'],
 array['l_returnflag', 'l_linestatus'],
```

2. Set the `vops.auto_substitute_projections` parameter to on.

Now all queries that `vops` can redirect to the `auto_vops_lineitem` projection table will be run on the vectorized data.

Projections are not updated automatically, so once the original table gets updated, implicitly redirected queries can start returning inaccurate results. To avoid this, you have to refresh the projections before running queries on the vectorized data. For this purpose, `vops` provides the `pname_refresh()` functions, where the `pname` prefix is the name of the projection you need to refresh. For example, to refresh the `auto_vops_lineitem` projection, run:

```
SELECT auto_vops_lineitem_refresh();
```

This function calls the `populate()` method to update all the fields present in the projection. If you have specified the optional `order_by` parameter when creating the projection, only the new data will be imported from the original table, selecting only the rows with the `order_by` column value greater than the maximal value of this column in the projection. Otherwise, the whole table will be re-written. The `populate()` method also takes the grouping columns into account to efficiently group the imported data in tiles.

If you have specified the `order_by` attribute when creating a projection, `vops` also creates the following indexes:

- Two functional BRIN indexes on `first()` and `last()` functions of this attribute. Such indexes allow to efficiently select time slices. For example, if the original query contains predicates like `(l_shipdate between '01-01-2017' and '01-01-2018')`, `vops` adds the `(first(l_shipdate) >= '01-01-2017' and last(l_shipdate) >= '01-01-2018')` conjuncts when redirecting the query, so that Postgres Pro optimizer can quickly locate the affected pages using BRIN indexes.
- A BRIN index for scalar columns used for grouping. Such index allows to efficiently select groups and perform index joins.

## F.88.6. Reference

### F.88.6.1. Vector Types

The `vops` extension supports all basic Postgres Pro numeric types: 1-, 2-, 4-, 8-byte integers, as well as 4- and 8-byte floats. The `date` and `timestamp` types are using the same implementation as `int4` and `int8`, respectively. The table below illustrates the available vector types, as compared to the corresponding SQL and C types.

| SQL Type                              | C Type    | vops Vector Type      |
|---------------------------------------|-----------|-----------------------|
| bool                                  | bool      | vops_bool             |
| "char"                                | char      | vops_char             |
| date                                  | DateADT   | vops_date             |
| int2                                  | int16     | vops_int2             |
| int4                                  | int32     | vops_int4             |
| int8                                  | int64     | vops_int8             |
| float4                                | float4    | vops_float4           |
| float8                                | float8    | vops_float8           |
| timestamp                             | Timestamp | vops_timestamp        |
| char( <i>N</i> ), varchar( <i>N</i> ) | text      | vops_text( <i>N</i> ) |

#### Note

For performance reasons, using `vops_text` for single-character strings is not recommended. If you are using strings as identifiers, you can place them in a dictionary and use integer identifiers instead of the original strings.

### F.88.6.2. Vector Operators

The `vops` extension provides a set of operators for vector types.

#### F.88.6.2.1. Mathematical Operators

For mathematical operations, `vops` overloads regular SQL operators, so they can take operands of both vector and scalar types.

| Operator        | Description                                                                                                                                                                                                                                                                                             |
|-----------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>+</code>  | Addition                                                                                                                                                                                                                                                                                                |
| <code>-</code>  | Binary subtraction or unary negation                                                                                                                                                                                                                                                                    |
| <code>*</code>  | Multiplication                                                                                                                                                                                                                                                                                          |
| <code>/</code>  | Division                                                                                                                                                                                                                                                                                                |
| <code>  </code> | Concatenation. This operator is only supported for <code>char</code> , <code>int2</code> , and <code>int4</code> types. It returns an integer type of a doubled size:<br><br><code>(char    char) -&gt; int2</code><br><code>(int2    int2) -&gt; int4</code><br><code>(int4    int4) -&gt; int8</code> |

#### F.88.6.2.2. Comparison Operators

For comparison operations, `vops` overloads regular SQL operators, so they can take operands of both vector and scalar types.

| Operator              | Description            |
|-----------------------|------------------------|
| <code>=</code>        | Equals                 |
| <code>&lt;&gt;</code> | Not equals             |
| <code>&lt;</code>     | Less than              |
| <code>&lt;=</code>    | Less than or equals    |
| <code>&gt;</code>     | Greater than           |
| <code>&gt;=</code>    | Greater than or equals |

#### F.88.6.2.3. Boolean Operators

Boolean operators `AND`, `OR`, and `NOT` cannot be overloaded, so `vops` provides its own implementation of boolean operators for vector types:

| Operator           | Description |
|--------------------|-------------|
| <code>&amp;</code> | Boolean AND |
| <code> </code>     | Boolean OR  |
| <code>!</code>     | Boolean NOT |

Vector boolean operators have the following usage specifics:

- The precedence of vector boolean operators is different from `AND`, `OR`, and `NOT`, so you have to enclose the operands into parentheses. For example:  
`(x=1) | (x=2)`
- The result of vector boolean operations is `vops_bool`. Since Postgres Pro requires predicate expressions to have a regular boolean type, you have to convert the result to the `bool` type using the `filter()` function. Taking a vector boolean expression, this function calculates a `filter_mask` value that defines the result of this boolean operation for each vector element. If all mask bits are zero (the predicate is false for all vector elements), then `filter()` returns `false`, and Postgres Pro executor skips this record. Otherwise, `true` is returned, so vector operators will check the `filter_mask` value for the selected vector elements in subsequent operations.
- When using vector boolean operators, you have to use explicit cast of string constants to the required data type.

#### F.88.6.3. Comparison Functions

| Function                           | Description                                                |
|------------------------------------|------------------------------------------------------------|
| <code>bitwixt(x, low, high)</code> | Same as the <code>x BETWEEN low AND high</code> predicate. |

| Function                      | Description                                                       |
|-------------------------------|-------------------------------------------------------------------|
| <code>is_null(x)</code>       | Same as the <i>expression</i> <code>IS NULL</code> predicate.     |
| <code>is_not_null(x)</code>   | Same as the <i>expression</i> <code>IS NOT NULL</code> predicate. |
| <code>ifnull(x, subst)</code> | Same as the <code>COALESCE</code> function.                       |

#### F.88.6.4. Conversion Functions

`create_projection(projection_name text, source_table regclass, vector_columns text[], scalar_columns text[] DEFAULT null, order_by text DEFAULT null)`

Creates a projection table with specified name and attributes and updates the `vops_projections` table to include the information about this projection, so that the optimizer can automatically redirect queries from the original table to its projection. It also creates the `pname_refresh()` function that can update the projection.

Arguments:

- *projection\_name* — the name of the projection table.
- *source\_table* — the original Postgres Pro table for which to create a vectorized projection.
- *vector\_columns* — an array of column names that will be stored as `vops` tiles.
- *scalar\_columns* — an array of column names that will preserve its original scalar type. These columns will be used to group table rows into `vops` tiles. `vops` automatically builds a BRIN index over such columns.
- *order\_by* — an optional vector column that can be used to sort data in the projection table. Sorting can be useful to incrementally update the projection after the original table updates using the `pname_refresh()` function. This column should contain unique timestamp values, such as trade dates. `vops` automatically builds a functional BRIN index for `first()` and `last()` functions of this column.

Examples:

```
SELECT
 create_projection('vops_lineitem', 'lineitem', array['l_shipdate', 'l_quantity', 'l_extendeddate'],
 pname_refresh()
```

Refreshes the *pname* projection table.

Examples:

Refresh the `vops_lineitem` projection:

```
SELECT vops_lineitem_refresh();
drop_projection(projection_name text)
```

Drops the specified projection and the corresponding refresh function, as well as removes the information about this projection from the `vops_projections` table.

Examples:

Drop the `vops_lineitem` projection:

```
SELECT drop_projection(vops_lineitem);
populate(destination regclass, source regclass, predicate cstring DEFAULT null, sort
cstring DEFAULT null)
```

Copies the data from an existing table to its vectorized projection and returns the number of imported rows (`bigint`).

Arguments:

- *destination* — target table to copy the data into.

Type: `regclass`

- *source* — source table to copy the data from.

Type: `regclass`

- *predicate* — restricts the amount of imported data (optional). Using this argument, you can upload only the most recent records.

Type: `cstring`

- *sort* — sorts the source data to define the order in which the data needs to be loaded (optional).

Type: `cstring`

Examples:

```
SELECT populate(destination := 'vops_lineitem'::regclass, source :=
 'lineitem'::regclass);
```

```
SELECT populate(destination := 'vops_lineitem_projection'::regclass, source :=
 'lineitem_projection'::regclass, sort := 'l_returnflag,l_linestatus');
```

```
import(destination regclass, csv_path cstring, separator cstring DEFAULT ',', skip integer
DEFAULT 0)
```

Loads the data into a `vops` table directly from a CSV file, bypassing creation of a regular table, and returns the number of imported rows (`bigint`). Use this function to avoid storing two copies of the same dataset.

Arguments:

- *destination* — target table to copy the data into.

Type: `regclass`

- *csv\_path* — the path to the CSV file to copy the data from.

Type: `cstring`

- *separator* — specifies the field separator used in the CSV file (optional). By default, the comma is assumed to be the field separator.

Type: `cstring`

- *skip* — specifies the number of rows in the CSV header that do not need to be imported (optional).

Default: 0

Type: `cstring`

Examples:

```
SELECT import(destination := 'vops_lineitem'::regclass, csv_path := '/mnt/data/
lineitem.csv', separator := '|');
```

```
vops_unnest(anyelement)
```

Scatters records with `vops` types into records with scalar types.

### F.88.6.5. Configuration Parameters

`vops.auto_substitute_projections` (boolean)

Enables automatic query redirection to projection tables. For correct results, you have to ensure that the projection is synchronized with the original table.

Default: `off`

## **F.88.7. Authors**

Postgres Professional, Moscow, Russia

## F.89. xml2 — XPath querying and XSLT functionality

The `xml2` module provides XPath querying and XSLT functionality.

### F.89.1. Deprecation Notice

From PostgreSQL 8.3 on, there is XML-related functionality based on the SQL/XML standard in the core server. That functionality covers XML syntax checking and XPath queries, which is what this module does, and more, but the API is not at all compatible. It is planned that this module will be removed in a future version of Postgres Pro in favor of the newer standard API, so you are encouraged to try converting your applications. If you find that some of the functionality of this module is not available in an adequate form with the newer API, please explain your issue to [pgsql-hackers@lists.postgresql.org](mailto:pgsql-hackers@lists.postgresql.org) so that the deficiency can be addressed.

### F.89.2. Description of Functions

Table F.66 shows the functions provided by this module. These functions provide straightforward XML parsing and XPath queries.

**Table F.66. `xml2` Functions**

| Function                                                                                   | Description                                                                                                                                                                                                                                                                                                                                                                                |
|--------------------------------------------------------------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>xml_valid ( document text ) → boolean</code>                                         | Parses the given document and returns true if the document is well-formed XML. (Note: this is an alias for the standard Postgres Pro function <code>xml_is_well_formed()</code> . The name <code>xml_valid()</code> is technically incorrect since validity and well-formedness have different meanings in XML.)                                                                           |
| <code>xpath_string ( document text, query text ) → text</code>                             | Evaluates the XPath query on the supplied document, and casts the result to <code>text</code> .                                                                                                                                                                                                                                                                                            |
| <code>xpath_number ( document text, query text ) → real</code>                             | Evaluates the XPath query on the supplied document, and casts the result to <code>real</code> .                                                                                                                                                                                                                                                                                            |
| <code>xpath_bool ( document text, query text ) → boolean</code>                            | Evaluates the XPath query on the supplied document, and casts the result to <code>boolean</code> .                                                                                                                                                                                                                                                                                         |
| <code>xpath_nodeset ( document text, query text, toptag text, itemtag text ) → text</code> | Evaluates the query on the document and wraps the result in XML tags. If the result is multivalued, the output will look like:<br><br><pre>&lt;toptag&gt; &lt;itemtag&gt;Value 1 which could be an XML fragment&lt;/itemtag&gt; &lt;itemtag&gt;Value 2...&lt;/itemtag&gt; &lt;/toptag&gt;</pre> If either <i>toptag</i> or <i>itemtag</i> is an empty string, the relevant tag is omitted. |
| <code>xpath_nodeset ( document text, query text, itemtag text ) → text</code>              | Like <code>xpath_nodeset(document, query, toptag, itemtag)</code> but result omits <i>toptag</i> .                                                                                                                                                                                                                                                                                         |
| <code>xpath_nodeset ( document text, query text ) → text</code>                            | Like <code>xpath_nodeset(document, query, toptag, itemtag)</code> but result omits both tags.                                                                                                                                                                                                                                                                                              |
| <code>xpath_list ( document text, query text, separator text ) → text</code>               | Evaluates the query on the document and returns multiple values separated by the specified separator, for example <code>Value 1, Value 2, Value 3</code> if <i>separator</i> is <code>,</code> .                                                                                                                                                                                           |
| <code>xpath_list ( document text, query text ) → text</code>                               | This is a wrapper for the above function that uses <code>,</code> as the separator.                                                                                                                                                                                                                                                                                                        |

### F.89.3. xpath\_table

`xpath_table(text key, text document, text relation, text xpaths, text criteria)` returns setof record

`xpath_table` is a table function that evaluates a set of XPath queries on each of a set of documents and returns the results as a table. The primary key field from the original document table is returned as the first column of the result so that the result set can readily be used in joins. The parameters are described in [Table F.67](#).

**Table F.67. `xpath_table` Parameters**

| Parameter       | Description                                                                                                                                                                                                  |
|-----------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <i>key</i>      | the name of the “key” field — this is just a field to be used as the first column of the output table, i.e., it identifies the record from which each output row came (see note below about multiple values) |
| <i>document</i> | the name of the field containing the XML document                                                                                                                                                            |
| <i>relation</i> | the name of the table or view containing the documents                                                                                                                                                       |
| <i>xpaths</i>   | one or more XPath expressions, separated by                                                                                                                                                                  |
| <i>criteria</i> | the contents of the WHERE clause. This cannot be omitted, so use <code>true</code> or <code>1=1</code> if you want to process all the rows in the relation                                                   |

These parameters (except the XPath strings) are just substituted into a plain SQL SELECT statement, so you have some flexibility — the statement is

```
SELECT <key>, <document> FROM <relation> WHERE <criteria>
```

so those parameters can be *anything* valid in those particular locations. The result from this SELECT needs to return exactly two columns (which it will unless you try to list multiple fields for key or document). Beware that this simplistic approach requires that you validate any user-supplied values to avoid SQL injection attacks.

The function has to be used in a FROM expression, with an AS clause to specify the output columns; for example

```
SELECT * FROM
xpath_table('article_id',
 'article_xml',
 'articles',
 '/article/author|/article/pages|/article/title',
 'date_entered > ''2003-01-01'' ')
AS t(article_id integer, author text, page_count integer, title text);
```

The AS clause defines the names and types of the columns in the output table. The first is the “key” field and the rest correspond to the XPath queries. If there are more XPath queries than result columns, the extra queries will be ignored. If there are more result columns than XPath queries, the extra columns will be NULL.

Notice that this example defines the `page_count` result column as an integer. The function deals internally with string representations, so when you say you want an integer in the output, it will take the string representation of the XPath result and use Postgres Pro input functions to transform it into an integer (or whatever type the AS clause requests). An error will result if it can't do this — for example if the result is empty — so you may wish to just stick to `text` as the column type if you think your data has any problems.

The calling SELECT statement doesn't necessarily have to be just `SELECT *` — it can reference the output columns by name or join them to other tables. The function produces a virtual table with which you can perform any operation you wish (e.g., aggregation, joining, sorting etc.). So we could also have:

```
SELECT t.title, p.fullname, p.email
FROM xpath_table('article_id', 'article_xml', 'articles',
 '/article/title|/article/author/@id',
 'xpath_string(article_xml, '/article/@date') > ''2003-03-20'' ')
 AS t(article_id integer, title text, author_id integer),
 tblPeopleInfo AS p
WHERE t.author_id = p.person_id;
```

as a more complicated example. Of course, you could wrap all of this in a view for convenience.

### F.89.3.1. Multivalued Results

The `xpath_table` function assumes that the results of each XPath query might be multivalued, so the number of rows returned by the function may not be the same as the number of input documents. The first row returned contains the first result from each query, the second row the second result from each query. If one of the queries has fewer values than the others, null values will be returned instead.

In some cases, a user will know that a given XPath query will return only a single result (perhaps a unique document identifier) — if used alongside an XPath query returning multiple results, the single-valued result will appear only on the first row of the result. The solution to this is to use the key field as part of a join against a simpler XPath query. As an example:

```
CREATE TABLE test (
 id int PRIMARY KEY,
 xml text
);

INSERT INTO test VALUES (1, '<doc num="C1">
<line num="L1"><a>12<c>3</c></line>
<line num="L2"><a>1122<c>33</c></line>
</doc>');

INSERT INTO test VALUES (2, '<doc num="C2">
<line num="L1"><a>111222<c>333</c></line>
<line num="L2"><a>111222<c>333</c></line>
</doc>');

SELECT * FROM
 xpath_table('id','xml','test',
 '/doc/@num|/doc/line/@num|/doc/line/a|/doc/line/b|/doc/line/c',
 'true')
 AS t(id int, doc_num varchar(10), line_num varchar(10), val1 int, val2 int, val3 int)
WHERE id = 1 ORDER BY doc_num, line_num
```

| id | doc_num | line_num | val1 | val2 | val3 |
|----|---------|----------|------|------|------|
| 1  | C1      | L1       | 1    | 2    | 3    |
| 1  |         | L2       | 11   | 22   | 33   |

To get `doc_num` on every line, the solution is to use two invocations of `xpath_table` and join the results:

```
SELECT t.*,i.doc_num FROM
 xpath_table('id', 'xml', 'test',
 '/doc/line/@num|/doc/line/a|/doc/line/b|/doc/line/c',
 'true')
 AS t(id int, line_num varchar(10), val1 int, val2 int, val3 int),
 xpath_table('id', 'xml', 'test', '/doc/@num', 'true')
 AS i(id int, doc_num varchar(10))
WHERE i.id=t.id AND i.id=1
ORDER BY doc_num, line_num;
```

| id | line_num | val1 | val2 | val3 | doc_num |
|----|----------|------|------|------|---------|
| 1  | L1       | 1    | 2    | 3    | C1      |
| 1  | L2       | 11   | 22   | 33   | C1      |

(2 rows)

## F.89.4. XSLT Functions

The following functions are available if `libxslt` is installed:

### F.89.4.1. xslt\_process

`xslt_process(text document, text stylesheet, text paramlist)` returns `text`

This function applies the XSL stylesheet to the document and returns the transformed result. The `paramlist` is a list of parameter assignments to be used in the transformation, specified in the form `a=1, b=2`. Note that the parameter parsing is very simple-minded: parameter values cannot contain commas!

There is also a two-parameter version of `xslt_process` which does not pass any parameters to the transformation.

## F.89.5. Author

John Gray <jgray@azuli.co.uk>

Development of this module was sponsored by Torchbox Ltd. ([www.torchbox.com](http://www.torchbox.com)). It has the same BSD license as Postgres Pro.

# Appendix G. Postgres Pro Modules and Extensions Shipped as Individual Packages

This appendix contains Postgres Pro modules and extensions that are made available in Postgres Pro Enterprise as individual packages. These packages are listed in [Section 17.1.6.1](#), and the documentation for each module explains which package to choose to install it. [Appendix F](#) and [Appendix H](#) cover more modules and extensions included in the Postgres Pro Enterprise distribution. Note also the `pg_portal_modify` extension, which is shipped as an individual package, and the `pgpro-orautl` package, which provides packages for `utl_http`, `utl_mail`, and `utl_smtp` (see [Section 17.1.6.1](#) for details).

## G.1. pgpro\_anonymizer — mask or replace sensitive data

`pgpro_anonymizer` is an extension to mask or replace personally identifiable information (PII) or commercially sensitive data from a Postgres Pro database.

The project has a *declarative approach* of anonymization. This means you can [declare the masking rules](#) using the Data Definition Language (DDL) and specify your anonymization strategy inside the table definition itself.

Once the masking rules are defined, you can access the anonymized data in one of the following ways:

- [Anonymous dumps](#): simply export the masked data into an SQL file.
- [Static masking](#): remove the PII according to the rules.
- [Dynamic masking](#): hide PII only for the masked users.

In addition, various [functions](#) are available to implement the following masking techniques: randomization, faking, partial scrambling, shuffling, noise. You can also create a custom function.

Beyond masking, you can also use another approach called [generalization](#), which is useful for statistics and data analytics.

### G.1.1. Terms and Definitions

The following main strategies are used:

- [Dynamic masking](#) offers an altered view of the real data without modifying it. Some users may only read the masked data, others may access the authentic version.
- [Static masking](#) is the definitive action of substituting the sensitive information with uncorrelated data. Once processed, the authentic data cannot be retrieved.

The data can be altered with several techniques:

- *Deletion* simply removes data.
- [Static substitution](#) consistently replaces the data with a generic value. For instance: replacing all values of a `text` column with the value “CONFIDENTIAL”.
- [Variance](#) “shifts” dates and numeric values. For example, by applying a +/- 10% variance to a salary column, the dataset will remain meaningful.
- [Generalization](#) reduces the accuracy of the data by replacing it with a range of values. Instead of saying “Bob is 28 years old”, you can say “Bob is between 20 and 30 years old”. This is useful for analytics because the data remains true.
- [Shuffling](#) mixes values within the same columns. This method is open to being reversed if the shuffling algorithm can be deciphered.
- [Randomization](#) replaces sensitive data with *random-but-plausible* values. The goal is to avoid any identification from the data record while remaining suitable for testing, data analysis and data processing.
- [Partial scrambling](#) is similar to static substitution but leaves out some part of the data. For instance: a credit card number can be replaced by “40XX XXXX XXXX XX96”.
- [Custom rules](#) are designed to alter data following specific needs (e.g., simultaneously randomize a zipcode and a city name while keeping them coherent).

- [Pseudonymization](#) is a way to *protect* personal information by hiding it using additional information. *Encryption* and *hashing* are two examples of pseudonymization techniques. However, pseudonymized data is still linked to the original data.

## G.1.2. Anonymization Example

Suppose you want to mask last names and phone numbers:

```
SELECT * FROM people;
 id | firstname | lastname | phone
-----+-----+-----+-----
 T1 | Sarah | Connor | 0609110911
```

1. Activate the dynamic masking engine:

```
SELECT anon.start_dynamic_masking();
```

2. Declare a masked user:

```
CREATE ROLE skynet LOGIN;
SECURITY LABEL FOR anon ON ROLE skynet IS 'MASKED';
```

3. Declare the masking rules:

```
SECURITY LABEL FOR anon ON COLUMN people.lastname
IS 'MASKED WITH FUNCTION anon.fake_last_name()';

SECURITY LABEL FOR anon ON COLUMN people.phone
IS 'MASKED WITH FUNCTION anon.partial(phone,2,$$*****$$,2)';
```

4. Connect with the masked user:

```
\connect - skynet
SELECT * FROM people;
 id | firstname | lastname | phone
-----+-----+-----+-----
 T1 | Sarah | Stranahan | 06*****11
```

## G.1.3. Installation and Setup

The `pgpro_anonymizer` extension is provided with Postgres Pro Enterprise as a separate pre-built package `pgpro-anonymizer-ent-17` (for the detailed installation instructions, see [Chapter 17](#)). To enable `pgpro_anonymizer`, complete the following steps:

1. Add the library name to the `shared_preload_libraries` variable in the `postgresql.conf` file:

```
shared_preload_libraries = 'anon'
```

2. Reload the database server for the changes to take effect.

### Note

To verify that the library was installed correctly, you can run the following command:

```
SHOW shared_preload_libraries;
```

3. Create the extension using the following query:

```
CREATE EXTENSION anon CASCADE;
```

4. Initialize the extension:

```
SELECT anon.init();
```

The `init()` function imports a default dataset of random data (IBAN, names, cities, etc.). This dataset is in English and is very small (1000 values for each category).

### G.1.4. Configuration

The extension has several options that can be defined for the entire instance (in `postgresql.conf` or with `ALTER SYSTEM`).

It is also possible and often a good idea to define them at the database level like this:

```
ALTER DATABASE customers SET anon.algorithm = sha512;
```

Only a superuser can change the parameters below:

#### `anon.algorithm`

The hashing method used by pseudonymizing functions. See [pgcrypto documentation](#) for the list of available options.

See [anon.salt](#) to learn why this parameter is a very sensitive information.

Type: `text`

Default: `sha256`

Visible: only to superusers

#### `anon.maskschema`

The schema (i.e. namespace) where the dynamic masking views will be stored.

Type: `text`

Default: `mask`

Visible: to all users

#### `anon.restrict_to_trusted_schemas`

When this parameter is enabled (by default), masking rules must be defined using functions located in a limited list of namespaces. By default, only the `anon` schema is trusted.

This improves security by preventing users from declaring their custom masking filters.

This also means that the schema must be explicit inside the masking rules. For more details, see the [Write your own masks](#) section of the [Masking functions](#) chapter.

```
SECURITY LABEL FOR anon ON COLUMN people.name
IS 'MASKED WITH FUNCTION lower(people.name)';
```

The correct way to declare it would be:

```
SECURITY LABEL FOR anon ON COLUMN people.name
IS 'MASKED WITH FUNCTION pg_catalog.lower(people.name)';
```

Type: `boolean`

Default: `on`

Visible: to all users

#### `anon.salt`

The salt used by pseudonymizing functions. It is very important to define a custom salt for each database like this:

```
ALTER DATABASE foo SET anon.salt = 'This_Is_A_Very_Secret_Salt';
```

If masked users can read the salt, they can run a brute force attack to retrieve the original data based on the following elements:

- The pseudonymized data
- The hashing algorithm (see [anon.algorithm](#))
- The salt

The salt and the name of the hashing algorithm should be protected with the same level of security that the data itself. This is why the salt should be stored directly within the database with `ALTER DATABASE`.

Type: `text`

Default: (empty)

Visible: only to superusers

#### `anon.sourceschema`

The schema (i.e. namespace) where the tables are masked by the dynamic masking engine.

Change this value before starting dynamic masking.

```
ALTER DATABASE foo SET anon.sourceschema TO 'my_app';
```

Then reconnect so that the change takes effect and start the engine.

```
SELECT anon.start_dynamic_masking();
```

Type: `text`

Default: `public`

Visible: to all users

## G.1.5. Declare Masking Rules

The main idea of this extension is to offer *anonymization by design*.

The data masking rules should be written by people who develop the application because they have the best knowledge of how the data model works. Therefore, masking rules must be implemented directly inside the database schema.

This allows to mask the data directly inside the Postgres Pro instance without using an external tool, and thus limiting the exposure and the risks of data leak.

The data masking rules are declared simply by using [security labels](#):

```
CREATE TABLE player (id SERIAL, name TEXT, points INT);
```

```
INSERT INTO player VALUES
(1, 'Kareem Abdul-Jabbar', 38387),
(5, 'Michael Jordan', 32292);
```

```
SECURITY LABEL FOR anon ON COLUMN player.name
IS 'MASKED WITH FUNCTION anon.fake_last_name()';
```

```
SECURITY LABEL FOR anon ON COLUMN player.id
IS 'MASKED WITH VALUE NULL';
```

### Important

The maximum length of a masking rule is 1024 characters. If you need more, you should probably [write a dedicated masking function](#).

### Important

The masking rules are not inherited. If you have split a table into multiple partitions, you need to declare the masking rules for each partition.

#### G.1.5.1. Escaping String Literals

As you may have noticed, the masking rule definitions are placed between single quotes. Therefore, if you need to use a string inside a masking rule, use [dollar quoting](#):

```
SECURITY LABEL FOR anon ON COLUMN player.name
IS 'MASKED WITH VALUE $$CONFIDENTIAL$$';
```

#### G.1.5.2. Listing Masking Rules

To display all the masking rules declared in the current database, see `anon.pg_masking_rules`:

```
SELECT * FROM anon.pg_masking_rules;
```

#### G.1.5.3. Debugging Masking Rules

When an error occurs due to a wrong masking rule, you can get more detailed information about the problem by setting `client_min_messages` to `DEBUG` and you will get useful details.

```
postgres=# SET client_min_messages=DEBUG;
postgres=# SELECT anon.anonymize_database();

DEBUG: Anonymize table public.bar with firstname = anon.fake_first_name()
DEBUG: Anonymize table public.foo with id = NULL
ERROR: Cannot mask a "NOT NULL" column with a NULL value
HINT: If privacy_by_design is enabled, add a default value to the column
CONTEXT: PL/pgSQL function anon.anonymize_table(regclass) line 47 at RAISE
SQL function "anonymize_database" statement 1
```

#### G.1.5.4. Removing a Masking Rule

You can simply erase a masking rule like this:

```
SECURITY LABEL FOR anon ON COLUMN player.name IS NULL;
```

To remove all rules at once, you can use:

```
SELECT anon.remove_masks_for_all_columns();
```

### G.1.6. Masking Functions

The extension provides functions to implement the following main anonymization strategies:

- [Deletion](#)
- [Adding noise](#)
- [Randomization](#)
- [Faking](#)
- [Advanced faking](#)
- [Pseudonymization](#)
- [Generic hashing](#)
- [Partial scrambling](#)
- [Conditional masking](#)
- [Generalization](#)
- [Using pg\\_catalog functions](#)

- [Write Your Own Masks](#)

Depending on your data, you may need to use different strategies on different columns:

- For names and other “direct identifiers”, [faking](#) is often useful
- [Shuffling](#) is convenient for foreign keys
- [Adding noise](#) is interesting for numeric values and dates
- [Partial scrambling](#) is perfect for email addresses and phone numbers

#### G.1.6.1. Deletion

First of all, the fastest and safest way to anonymize a data is to delete it.

In many cases, the best approach to hide the content of a column is to replace all the values with a single static value.

For instance, you can replace an entire column with the word `CONFIDENTIAL` like this:

```
SECURITY LABEL FOR anon
ON COLUMN users.address
IS 'MASKED WITH VALUE $$CONFIDENTIAL$$';
```

#### G.1.6.2. Adding Noise

This is also called *Variance*. The idea is to “shift” dates and numeric values. For example, by applying a +/- 10% variance to a salary column, the dataset will remain meaningful.

```
anon.noise(noise_value anyelement, ratio double precision)
```

If *ratio* is 0.33, the return value will be the original value randomly shifted with a ratio of +/- 33%.

```
anon.dnoise(noise_value anyelement, noise_range interval)
```

If *interval* = “2 days”, the return value will be the original value randomly shifted by +/- 2 days.

#### Important

The `noise()` masking functions are vulnerable to a form of repeat attack, especially with [Dynamic Masking](#). A masked user can guess an original value by requesting its masked value multiple times and then simply use the `avg()` function to get a close approximation. In a nutshell, these functions are best fitted for [Anonymous Dumps](#) and [Static Masking](#). They should be avoided when using [Dynamic Masking](#).

#### G.1.6.3. Randomization

The extension provides a large choice of functions to generate purely random data:

##### G.1.6.3.1. Basic Random Values

```
anon.random_date()
```

Returns a date.

```
anon.random_string(n integer)
```

Returns a text value containing *n* letters.

```
anon.random_zip()
```

Returns a 5-digit code.

```
anon.random_phone(phone_prefix text)
```

Returns an 8-digit phone with *phone\_prefix* as a prefix.

#### G.1.6.3.2. Random Between

To pick any value inside between two bounds:

`random_date_between(d1 date, d2 date)`

Returns a date between *d1* and *d2*.

`random_int_between(i1 integer, i2 integer)`

Returns an integer between *i1* and *i2*.

`random_bigint_between(b1 bigint, b2 bigint)`

Returns a bigint between *b1* and *b2*.

#### Note

With these functions, the lower and upper bounds are included. For instance, `anon.random_int_between(1, 3)` returns either 1, 2 or 3.

For more advanced interval descriptions, see [Random in Range](#).

#### G.1.6.3.3. Random in Array

The `random_in` function returns an element in a given array. For example:

`anon.random_in(ARRAY[1, 2, 3])`

Returns an integer between 1 and 3.

`anon.random_in(ARRAY['red', 'green', 'blue'])`

Returns a random text value from an array of ['red', 'green', 'blue'].

#### G.1.6.3.4. Random in Enum

This function returns an element in a given variable of the ENUM type.

`anon.random_in_enum(variable_of_an_enum_type)`

Returns any value.

```
CREATE TYPE card AS ENUM ('visa', 'mastercard', 'amex');
SELECT anon.random_in_enum(NULL::CARD);
 random_in_enum

mastercard

CREATE TABLE customer (
 id INT,
 ...
 credit_card CARD
);

SECURITY LABEL FOR anon ON COLUMN customer.creditcard
IS 'MASKED WITH FUNCTION anon.random_in_enum(creditcard)'
```

#### G.1.6.3.5. Random in Range

[RANGE types](#) are a powerful way to describe an interval of values, where you can define inclusive or exclusive bounds. See [examples](#).

There is a function for each subtype of range:

```
anon.random_in_int4range('[5,6]')
```

Returns an INT of value 5.

```
anon.random_in_int8range('(6,7]')
```

Returns a BIGINT of value 7.

```
anon.random_in_numrange('[0.1,0.9]')
```

Returns a NUMERIC between 0.1 and 0.9.

```
anon.random_in_daterange('[2001-01-01, 2001-12-31]')
```

Returns a date in 2001.

```
anon.random_in_tsrage('[2022-10-01, 2022-10-31]')
```

Returns a TIMESTAMP in October 2022.

```
anon.random_in_tstzrange('[2022-10-01, 2022-10-31]')
```

Returns a TIMESTAMP WITH TIMEZONE in October 2022.

### Note

It is not possible to get a random value from a RANGE with an infinite bound. For example `anon.random_in_int4range( '[2022, )' )` returns NULL.

#### G.1.6.4. Faking

The idea of *Faking* is to replace sensitive data with *random-but-plausible* values. The goal is to avoid any identification from the data record while remaining suitable for testing, data analysis and data processing.

The following faking functions are available:

```
anon.fake_address()
```

Returns a complete postal address.

```
anon.fake_city()
```

Returns an existing city.

```
anon.fake_country()
```

Returns an existing country.

```
anon.fake_company()
```

Returns a generic company name.

```
anon.fake_email()
```

Returns a valid email address.

```
anon.fake_first_name()
```

Returns a generic first name.

```
anon.fake_iban()
```

Returns a valid IBAN.

`anon.fake_last_name()`

Returns a generic last name.

`anon.fake_postcode()`

Returns a valid zip code.

For `text` and `varchar` columns, you can use the classic *Lorem Ipsum* generator:

`anon.lorem_ipsum()`

Returns five paragraphs.

`anon.lorem_ipsum(2)`

Returns two paragraphs.

`anon.lorem_ipsum( paragraphs := 4 )`

Returns four paragraphs.

`anon.lorem_ipsum( words := 20 )`

Returns 20 words.

`anon.lorem_ipsum( characters := anon.length(table.column) )`

Returns the same number of characters as the original string.

#### G.1.6.5. Advanced Faking

Generating fake data is a complex topic. The functions provided here are limited to basic use case. For more advanced faking methods, in particular if you are looking for *localized fake data*, take a look at [PostgreSQL Faker](#), an extension based upon the well-known [Faker Python library](#).

This extension provides an advanced faking engine with localization support.

For example:

```
CREATE SCHEMA faker;
CREATE EXTENSION faker SCHEMA faker;
SELECT faker.faker('de_DE');
SELECT faker.first_name_female();
first_name_female

Mirja
```

#### G.1.6.6. Pseudonymization

Pseudonymization is similar to [Faking](#) in the sense that it generates realistic values. The main difference is that the pseudonymization is deterministic: the functions will always return the same fake value based on a seed and an optional salt.

The following pseudonymization functions are available:

`anon.pseudo_first_name(seed anyelement, salt text)`

Returns a generic first name.

`anon.pseudo_last_name(seed anyelement, salt text)`

Returns a generic last name.

`anon.pseudo_email(seed anyelement, salt text)`

Returns a valid email address.

`anon.pseudo_city(seed anyelement, salt text)`

Returns an existing city.

`anon.pseudo_country(seed anyelement, salt text)`

Returns an existing country.

`anon.pseudo_company(seed anyelement, salt text)`

Returns a generic company name.

`anon.pseudo_iban(seed anyelement, salt text)`

Returns a valid IBAN.

`anon.pseudo_siret(seed anyelement, salt text)`

Returns a valid SIRET.

The second argument (*salt*) is optional. You can call each function only with the seed like this: `anon.pseudo_city('bob')`. The salt is here to increase complexity and avoid dictionary and brute force attacks. If a specific salt is not given, the value of the *anon.salt* GUC parameter is used instead (see [Generic Hashing](#) for more details).

The seed can be any information related to the subject. For instance, we can consistently generate the same fake email address for a given person by using her login as the seed:

```
SECURITY LABEL FOR anon
ON COLUMN users.emailaddress
IS 'MASKED WITH FUNCTION anon.pseudo_email(users.login)';
```

### Note

You may want to produce unique values using a pseudonymization function. For instance, if you want to mask an `email` column that is declared as `UNIQUE`. In this case, you will need to initialize the extension with a fake dataset that is *way bigger* than the number of rows of the table. Otherwise, you may see some “collisions” happening, i.e. two different original values producing the same pseudo value.

### Important

Pseudonymization is often confused with anonymization but in fact they serve two different purposes: pseudonymization is a way to *protect* the personal information but the pseudonymized data is still “linked” to the real data.

## G.1.6.7. Generic Hashing

In theory, hashing is not a valid anonymization technique, however in practice it is sometimes necessary to generate a determinist hash of the original data.

For instance, when a pair of primary key / foreign key is a “natural key”, it may contain actual information (like a customer number containing a birth date or something similar).

Hashing such columns allows to keep referential integrity intact even for relatively unusual source data.

`anon.digest(value text, salt text, algorithm text)`

Lets you choose a salt and a hash algorithm. Supported algorithms are: md5, sha1, sha224, sha256, sha384, and sha512.

`anon.hash(value text)`

Returns a text hash of the value using a secret salt that is defined by the *anon.salt* parameter and hash algorithm that is defined by the *anon.algorithm* parameter. The default value of *anon.algorithm* is sha256 and possible values are:

md5, sha1, sha224, sha256, sha384 or sha512. The default value of `anon.salt` is an empty string. You can modify these values with:

```
ALTER DATABASE foo SET anon.salt TO 'xsfnjefnjsnfjsnf';
ALTER DATABASE foo SET anon.algorithm TO 'sha384';
```

Keep in mind that hashing is a form of [Pseudonymization](#). This means that the data can be “de-anonymized” using the hashed value and the masking function. If attackers get access to these two elements, they could re-identify some persons using **brute force** or **dictionary** attacks. Therefore, *the salt and the algorithm used to hash the data must be protected with the same level of security as the original dataset*.

In a nutshell, we recommend that you use the `anon.hash()` function rather than `anon.digest()` because the salt will not appear clearly in the masking rule.

Furthermore, in practice the hash function will return a long string of character like this:

```
SELECT anon.hash('bob');
 hash

95b6acce02c5a725a8c9abf19ab5575f99ca3d9997984181e4b3f81d96cbca4d0977d694ac490350e01d0d21363
```

For some columns, this may be too long and you may have to cut some parts of the hash in order to fit into the column. For instance, if you have a foreign key based on a phone number and the column is a `varchar(12)`, you can transform the data like this:

```
SECURITY LABEL FOR anon ON COLUMN people.phone_number
IS 'MASKED WITH FUNCTION anon.left(anon.hash(phone_number),12)';
```

```
SECURITY LABEL FOR anon ON COLUMN call_history.fk_phone_number
IS 'MASKED WITH FUNCTION anon.left(anon.hash(fk_phone_number),12)';
```

Of course, cutting the hash value to 12 characters will increase the risk of “collision” (2 different values having the same fake hash). In such case, it's up to you to evaluate this risk.

### G.1.6.8. Partial Scrambling

*Partial scrambling* leaves out some part of the data. For instance, a credit card number can be replaced by “40XX XXXX XXXX XX96”.

`anon.partial(input text, prefix int, padding text, suffix int)`

Partially replaces a given text. For example, `anon.partial('abcdefgh',1,'xxxx',3)` returns `axxxxfgh`.

`anon.partial_email(email text)`

Partially replaces a given email. For example, `anon.partial_email('daamien@gmail.com')` returns `da*****@gm*****.com`.

### G.1.6.9. Conditional Masking

In some situations, you may want to apply a masking filter only for some value or for a limited number of lines in the table.

For instance, if you want to “preserve NULL values”, that is masking only the lines that contain a value, you can use the `anon.ternary` function, which works like a `CASE WHEN x THEN y ELSE z` statement:

```
SECURITY LABEL FOR anon ON COLUMN player.score
IS 'MASKED WITH FUNCTION anon.ternary(score IS NULL,
 NULL,
 anon.random_int_between(0,100));
```

You may also want to exclude some lines within the table. Like keeping the password of some users so that they still may be able to connect to a testing deployment of your application:

```
SECURITY LABEL FOR anon ON COLUMN account.password
```

```
IS 'MASKED WITH FUNCTION anon.ternary(id > 1000, NULL::TEXT, password)';
```

### Warning

Conditional masking may create a partially deterministic "connection" between the original data and the masked data. And that connection can be used to retrieve personal information from the masked data. For instance, if NULL values are preserved for a "deceased\_date" column, it will reveal which persons are still actually alive... In a nutshell: conditional masking may often produce a dataset that is not fully anonymized and therefore would still technically contain personal information.

#### G.1.6.10. Generalization

Generalization is the principle of replacing the original value by a range containing this value. For instance, instead of saying “Paul is 42 years old”, you would say “Paul is between 40 and 50 years old”.

### Note

The generalization functions perform data type transformation. Therefore, it is not possible to use them with the dynamic masking engine. However, they are useful to create anonymized views. See example below.

Let's imagine a table containing health information:

```
SELECT * FROM patient;
```

| id | name     | zipcode | birth      | disease       |
|----|----------|---------|------------|---------------|
| 1  | Alice    | 47678   | 1979-12-29 | Heart Disease |
| 2  | Bob      | 47678   | 1959-03-22 | Heart Disease |
| 3  | Caroline | 47678   | 1988-07-22 | Heart Disease |
| 4  | David    | 47905   | 1997-03-04 | Flu           |
| 5  | Eleanor  | 47909   | 1999-12-15 | Heart Disease |
| 6  | Frank    | 47906   | 1968-07-04 | Cancer        |
| 7  | Geri     | 47605   | 1977-10-30 | Heart Disease |
| 8  | Harry    | 47673   | 1978-06-13 | Cancer        |
| 9  | Ingrid   | 47607   | 1991-12-12 | Cancer        |

We can build a view upon this table to suppress some columns ( SSN and name ) and generalize the zipcode and the birth date like this:

```
CREATE VIEW anonymized_patient AS
SELECT
 'REDACTED' AS lastname,
 anon.generalize_int4range(zipcode,100) AS zipcode,
 anon.generalize_tsrange(birth,'decade') AS birth,
 disease
FROM patient;
```

The anonymized table now looks like that:

```
SELECT * FROM anonymized_patient;
```

| lastname | zipcode       | birth                       | disease       |
|----------|---------------|-----------------------------|---------------|
| REDACTED | [47600,47700) | ["1970-01-01","1980-01-01") | Heart Disease |
| REDACTED | [47600,47700) | ["1950-01-01","1960-01-01") | Heart Disease |
| REDACTED | [47600,47700) | ["1980-01-01","1990-01-01") | Heart Disease |
| REDACTED | [47900,48000) | ["1990-01-01","2000-01-01") | Flu           |
| REDACTED | [47900,48000) | ["1990-01-01","2000-01-01") | Heart Disease |
| REDACTED | [47900,48000) | ["1960-01-01","1970-01-01") | Cancer        |
| REDACTED | [47600,47700) | ["1970-01-01","1980-01-01") | Heart Disease |

```
REDACTED | [47600,47700) | ["1970-01-01","1980-01-01") | Cancer
REDACTED | [47600,47700) | ["1990-01-01","2000-01-01") | Cancer
```

The generalized values are still useful for statistics because they remain true, but they are less accurate, and therefore reduce the risk of re-identification.

Postgres Pro offers several [range data types](#), which are perfect for dates and numeric values.

For numeric values, the following functions are available:

```
generalize_int4range(value, step)
generalize_int8range(value, step)
generalize_numrange(value, step)
```

where *value* is the data that will be generalized, and *step* is the size of each range.

### G.1.6.11. Using pg\_catalog Functions

The `pg_catalog` schema is not trusted by default. This is a security measure designed to prevent users from using sophisticated functions in masking rules (such as `pg_catalog.query_to_xml`, `pg_catalog.ts_stat` or the [system administration functions](#)) that should not be used as masking functions.

However, the extension provides bindings to some useful and safe functions from the `pg_catalog` schema for your convenience:

- `anon.concat(TEXT, TEXT)`
- `anon.concat(TEXT, TEXT, TEXT)`
- `anon.date_add(TIMESTAMP WITH TIME ZONE, INTERVAL)`
- `anon.date_part(TEXT, TIMESTAMP)`
- `anon.date_part(TEXT, INTERVAL)`
- `anon.date_subtract(TIMESTAMP WITH TIME ZONE, INTERVAL )`
- `anon.date_trunc(TEXT, TIMESTAMP)`
- `anon.date_trunc(TEXT, TIMESTAMP WITH TIME ZONE, TEXT)`
- `anon.date_trunc(TEXT, INTERVAL)`
- `anon.left(TEXT, INTEGER)`
- `anon.length(TEXT)`
- `anon.lower(TEXT)`
- `anon.make_date(INT, INT, INT )`
- `anon.make_time(INT, INT, DOUBLE PRECISION)`
- `anon.md5(TEXT)`
- `anon.random()`
- `anon.replace(TEXT, TEXT, TEXT)`
- `anon.regexp_replace(TEXT, TEXT, TEXT)`
- `anon.regexp_replace(TEXT, TEXT, TEXT, TEXT)`
- `anon.right(TEXT, INTEGER)`
- `anon.substr(TEXT, INTEGER)`
- `anon.substr(TEXT, INTEGER, INTEGER)`
- `anon.upper(TEXT)`

If you need more bindings, you can either:

- [Write your own mapping function](#) in a trusted schema.
- Set the `pg_catalog` schema as TRUSTED (not recommended).

### G.1.6.12. Write Your Own Masks

You can also use your own function as a mask. The function must either be destructive (like [Partial Scrambling](#)) or insert some randomness in the dataset (like [Faking](#)).

Especially for complex data types, you may have to write your own function. This will be a common use case if you have to hide certain parts of a JSON field.

For example:

```
CREATE TABLE company (
 business_name TEXT,
 info JSONB
)
```

The `info` field contains unstructured data like this:

```
SELECT jsonb_pretty(info) FROM company WHERE business_name = 'Soylent Green';
 jsonb_pretty

{
 "employees": [
 {
 "lastName": "Doe",
 "firstName": "John"
 },
 {
 "lastName": "Smith",
 "firstName": "Anna"
 },
 {
 "lastName": "Jones",
 "firstName": "Peter"
 }
]
}
(1 row)
```

Using the [JSON functions and operators](#), you can walk through the keys and replace the sensitive values as needed.

```
CREATE SCHEMA custom_masks;

-- This step requires superuser privilege
SECURITY LABEL FOR anon ON SCHEMA custom_masks IS 'TRUSTED';

CREATE FUNCTION custom_masks.remove_last_name(j JSONB)
RETURNS JSONB
VOLATILE
LANGUAGE SQL
AS $func$
SELECT
 json_build_object(
 'employees' ,
 array_agg(
 jsonb_set(e , '{lastName}', to_jsonb(anon.fake_last_name()))
)
)
```

```
)
)::JSONB
FROM jsonb_array_elements(j->'employees') e
$func$;
```

Then check that the function is working correctly:

```
SELECT custom_masks.remove_last_name(info) FROM company;
```

When it is okay, you can declare this function as the mask of the `info` field:

```
SECURITY LABEL FOR anon ON COLUMN company.info
IS 'MASKED WITH FUNCTION custom_masks.remove_last_name(info)';
```

And try it out:

```
SELECT anonymize_table('company');
SELECT jsonb_pretty(info) FROM company WHERE business_name = 'Soylent Green';
 jsonb_pretty

{
 "employees": [
 {
 "lastName": "Prawdzik",
 "firstName": "John"
 },
 {
 "lastName": "Baltazor",
 "firstName": "Anna"
 },
 {
 "lastName": "Taylan",
 "firstName": "Peter"
 }
]
}
(1 row)
```

This is just a quick example. As you can see, manipulating a sophisticated JSON structure with SQL is possible but it can be tricky at first. There are multiple ways of walking through the keys and updating values. You will probably have to try different approaches, depending on your real JSON data and the performance you want to reach.

## G.1.7. Static Masking

Sometimes, it is useful to transform directly the original dataset. You can do that with different methods:

- [Applying masking rules](#)
- [Shuffling a column](#)
- [Adding noise to a column](#)

These methods will destroy the original data. Use with care.

### G.1.7.1. Applying Masking Rules

You can permanently apply the [masking rules](#) of a database with `anon.anonymize_database()`.

Let's use a basic example:

```
CREATE TABLE customer (
 id SERIAL,
 full_name TEXT,
 birth DATE,
```

```

employer TEXT,
zipcode TEXT,
fk_shop INTEGER
);

INSERT INTO customer
VALUES
(911, 'Chuck Norris', '1940-03-10', 'Texas Rangers', '75001', 12),
(312, 'David Hasselhoff', '1952-07-17', 'Baywatch', '90001', 423)
;

SELECT * FROM customer;

```

| id  | full_name        | birth      | employer      | zipcode | fk_shop |
|-----|------------------|------------|---------------|---------|---------|
| 911 | Chuck Norris     | 1940-03-10 | Texas Rangers | 75001   | 12      |
| 112 | David Hasselhoff | 1952-07-17 | Baywatch      | 90001   | 423     |

1. Declare the masking rules:

```

SECURITY LABEL FOR anon ON COLUMN customer.full_name
IS 'MASKED WITH FUNCTION anon.fake_first_name() || ' ' || anon.fake_last_name()';

SECURITY LABEL FOR anon ON COLUMN customer.employer
IS 'MASKED WITH FUNCTION anon.fake_company()';

SECURITY LABEL FOR anon ON COLUMN customer.zipcode
IS 'MASKED WITH FUNCTION anon.random_zip()';

```

2. Replace authentic data in the masked columns:

```

SELECT anon.anonymize_database();

SELECT * FROM customer;

```

| id  | full_name   | birth      | employer            | zipcode | fk_shop |
|-----|-------------|------------|---------------------|---------|---------|
| 911 | Jesse Kosel | 1940-03-10 | Marigold Properties | 62172   | 12      |
| 312 | Leolin Bose | 1952-07-17 | Inventure           | 20026   | 423     |

You can also use `anonymize_table()` and `anonymize_column()` to remove data from a subset of the database:

```

SELECT anon.anonymize_table('customer');
SELECT anon.anonymize_column('customer', 'zipcode');

```

### Important

Static masking is a slow process. The principle of static masking is to update all lines of all tables containing at least one masked column. This basically means that the server will rewrite all the data on disk. Depending on the database size, the hardware and the instance configuration, it may be faster to export the anonymized data (see [Anonymous Dumps](#)) and reload it into the database.

#### G.1.7.2. Shuffling

*Shuffling* mixes values within the same columns.

```
anon.shuffle_column(shuffle_table regclass, shuffle_column name, primary_key name)
```

Rearranges all values in a given column. You need to provide the primary key of the table.

This is useful for foreign keys because referential integrity will be kept.

### Important

`shuffle_column()` is not a [masking function](#) because it works “vertically”: it will modify all the values of a column at once.

#### G.1.7.3. Adding Noise to a Column

There are also some functions that can add noise on an entire column:

```
anon.add_noise_on_numeric_column(table regclass, column text, ratio float)
```

If *ratio* = 0.33, all values of the column will be randomly shifted with a ratio of +/- 33%.

```
anon.add_noise_on_datetime_column(table regclass, column text, interval interval)
```

If *interval* = 2 days, all values of the column will be randomly shifted by +/- 2 days.

### Important

These noise functions are vulnerable to a form of repeat attack.

#### G.1.8. Dynamic Masking

You can hide some data from a role by declaring this role as a “MASKED” one. Other roles will still access the original data.

```
CREATE TABLE people (id TEXT, firstname TEXT, lastname TEXT, phone TEXT);
INSERT INTO people VALUES ('T1', 'Sarah', 'Connor', '0609110911');
SELECT * FROM people;
```

```
SELECT * FROM people;
 id | firstname | lastname | phone
-----+-----+-----+-----
 T1 | Sarah | Connor | 0609110911
(1 row)
```

1. Activate the dynamic masking engine:

```
SELECT anon.start_dynamic_masking();
```

2. Declare a masked user:

```
CREATE ROLE skynet LOGIN;
SECURITY LABEL FOR anon ON ROLE skynet
IS 'MASKED';
```

3. Declare the masking rules:

```
SECURITY LABEL FOR anon ON COLUMN people.lastname
IS 'MASKED WITH FUNCTION anon.fake_last_name()';
```

```
SECURITY LABEL FOR anon ON COLUMN people.phone
IS 'MASKED WITH FUNCTION anon.partial(phone,2,$$*****$$,2)';
```

4. Connect with the masked user:

```
\c - skynet
```

```
SELECT * FROM people;
 id | firstname | lastname | phone
-----+-----+-----+-----
 T1 | Sarah | Stranahan | 06*****11
(1 row)
```

### G.1.8.1. How to Change the Type of a Masked Column

When dynamic masking is activated, you are not allowed to change the datatype of a column if there's a mask upon it.

To modify a masked column, you need to temporarily switch off the masking engine like this:

```
BEGIN;
SELECT anon.stop_dynamic_masking();
ALTER TABLE people ALTER COLUMN phone TYPE VARCHAR(255);
SELECT anon.start_dynamic_masking();
COMMIT;
```

### G.1.8.2. How to Drop a Masked Table

The dynamic masking engine will build *masking views* upon the masked tables. This means that it is not possible to drop a masked table directly. You will get an error like this:

```
DROP TABLE people;
psql: ERROR: cannot drop table people because other objects depend on it
DETAIL: view mask.company depends on table people
```

To effectively remove the table, it is necessary to add the *CASCADE* option, so that the masking view will be dropped too:

```
DROP TABLE people CASCADE;
```

### G.1.8.3. How to Unmask a Role

Simply remove the security label like this:

```
SECURITY LABEL FOR anon ON ROLE bob IS NULL;
```

To unmask all masked roles at once, you can type:

```
SELECT anon.remove_masks_for_all_roles();
```

### G.1.8.4. Limitations

#### G.1.8.4.1. Listing the Tables

Due to how the dynamic masking engine works, when a masked role tries to display the tables in psql with the `\dt` command, then psql will not show any tables.

This is because the `search_path` of the masked role is rigged.

You can try adding explicit schema you want to search, for instance:

```
\dt *.*
\dt public.*
```

#### G.1.8.4.2. Only One Schema

The dynamic masking system only works with one schema (by default `public`). When you start the masking engine with `start_dynamic_masking()`, you can specify the schema that will be masked as follows:

```
ALTER DATABASE foo SET anon.sourceschema TO 'sales';
```

Then open a new session to the database and type:

```
SELECT start_dynamic_masking();
```

However, static masking with `anon.anonymize_column()`, `anon.anonymize_table()`, and `anon.anonymize_database()` will work fine with multiple schemas.

#### G.1.8.4.3. Performance

Dynamic Masking is known to be very slow with some queries, especially if you try to join two tables on a masked key using hashing or pseudonymization.

#### G.1.8.4.4. Graphic Tools

When you are using a masked role with a graphic interface, such as DBeaver or pgAdmin, the `data` panel may produce the following error when trying to display the content of a masked table called `foo`:

```
SQL Error [42501]: ERROR: permission denied for table foo
```

This is because most of these tools will directly query the `public.foo` table instead of being “redirected” by the masking engine toward the `mask.foo` view.

In order to view the masked data with a graphic tool, you can either:

Open the SQL query panel and type `SELECT * FROM foo`

Navigate to `Database > Schemas > mask > Views > foo`

### G.1.9. Anonymous Dumps

#### G.1.9.1. pg\_dump\_anon.sh

The `pg_dump_anon.sh` script supports most of the options of the regular `pg_dump` command. The [environment variables](#) (`PGHOST`, `PGUSER`, etc.) and the [.pgpass](#) files are also supported.

#### G.1.9.2. Example

A user named `bob` can export an anonymous dump of the `app` database like this:

```
/opt/pgpro/ent-17/bin/pg_dump_anon.sh -h localhost -U bob --password --
file=anonymous_dump.sql app
```

#### Important

The name of the database must be the last parameter.

For more details about the supported options, simply type `./pg_dump_anon.sh --help`.

#### G.1.9.3. Limitations

- The user password is asked automatically. This means you must either add the `--password` option to define it interactively or declare it in the `PGPASSWORD` variable or put it inside the [.pgpass](#) file (however on Windows, the `PGPASSFILE` variable must be specified explicitly)
- The `plain` format is the only supported format. The other formats (`custom`, `dir` and `tar`) are not supported.

### G.1.10. Generalization

#### G.1.10.1. Reducing the Accuracy of Sensitive Data

The idea of generalization is to replace data with a broader, less accurate value. For instance, instead of saying “Bob is 28 years old”, you can say “Bob is between 20 and 30 years old”. This is interesting for analytics because the data remains true while avoiding the risk of re-identification.

Generalization is a way to achieve [k-anonymity](#).

Postgres Pro can handle generalization very easily with the [range data types](#), a very powerful way to store and manipulate a set of values contained between a lower and an upper bound.

### G.1.10.2. Example

Here's a basic table containing medical data:

```
SELECT * FROM patient;
```

| ssn         | firstname | zipcode | birth      | disease       |
|-------------|-----------|---------|------------|---------------|
| 253-51-6170 | Alice     | 47012   | 1989-12-29 | Heart Disease |
| 091-20-0543 | Bob       | 42678   | 1979-03-22 | Allergy       |
| 565-94-1926 | Caroline  | 42678   | 1971-07-22 | Heart Disease |
| 510-56-7882 | Eleanor   | 47909   | 1989-12-15 | Acne          |
| 098-24-5548 | David     | 47905   | 1997-03-04 | Flu           |
| 118-49-5228 | Jean      | 47511   | 1993-09-14 | Flu           |
| 263-50-7396 | Tim       | 47900   | 1981-02-25 | Heart Disease |
| 109-99-6362 | Bernard   | 47168   | 1992-01-03 | Asthma        |
| 287-17-2794 | Sophie    | 42020   | 1972-07-14 | Asthma        |
| 409-28-2014 | Arnold    | 47000   | 1999-11-20 | Diabetes      |

(10 rows)

We want the anonymized data to remain *true* because it will be used for statistics. We can build a view upon this table to remove useless columns and generalize the indirect identifiers:

```
CREATE MATERIALIZED VIEW generalized_patient AS
SELECT
 'REDACTED'::TEXT AS firstname,
 anon.generalize_int4range(zipcode,1000) AS zipcode,
 anon.generalize_daterange(birth,'decade') AS birth,
 disease
FROM patient;
```

This will give us a less accurate view of the data:

```
SELECT * FROM generalized_patient;
```

| firstname | zipcode       | birth                   | disease       |
|-----------|---------------|-------------------------|---------------|
| REDACTED  | [47000,48000) | [1980-01-01,1990-01-01) | Heart Disease |
| REDACTED  | [42000,43000) | [1970-01-01,1980-01-01) | Allergy       |
| REDACTED  | [42000,43000) | [1970-01-01,1980-01-01) | Heart Disease |
| REDACTED  | [47000,48000) | [1980-01-01,1990-01-01) | Acne          |
| REDACTED  | [47000,48000) | [1990-01-01,2000-01-01) | Flu           |
| REDACTED  | [47000,48000) | [1990-01-01,2000-01-01) | Flu           |
| REDACTED  | [47000,48000) | [1980-01-01,1990-01-01) | Heart Disease |
| REDACTED  | [47000,48000) | [1990-01-01,2000-01-01) | Asthma        |
| REDACTED  | [42000,43000) | [1970-01-01,1980-01-01) | Asthma        |
| REDACTED  | [47000,48000) | [1990-01-01,2000-01-01) | Diabetes      |

(10 rows)

### G.1.10.3. Generalization Functions

`pgpro_anonymizer` provides generalization functions, one for each [range type](#). Generally, these functions take the original value as the first parameter, and a second parameter for the length of each step.

For numeric values:

```
anon.generalize_int4range(value integer, step integer)
```

For example, `anon.generalize_int4range(42,5)` returns the range `[40,45)`.

`anon.generalize_int8range(value integer, step integer)`

For example, `anon.generalize_int8range(12345, 1000)` returns the range `[12000, 13000)`.

`anon.generalize_numrange(value integer, step integer)`

For example, `anon.generalize_numrange(42.32378, 10)` returns the range `[40, 50)`.

For time values:

`anon.generalize_tsrange(value integer, step integer)`

For example, `anon.generalize_tsrange('1904-11-07', 'year')` returns `['1904-01-01', '1905-01-01')`.

`anon.generalize_tstzrange(value integer, step integer)`

For example, `anon.generalize_tstzrange('1904-11-07', 'week')` returns `['1904-11-07', '1904-11-14')`.

`anon.generalize_daterange(value integer, step integer)`

For example, `anon.generalize_daterange('1904-11-07', 'decade')` returns `[1900-01-01, 1910-01-01)`.

The possible steps are: microsecond, millisecond, second, minute, hour, day, week, month, year, decade, century and millennium.

#### G.1.10.4. Limitations

##### G.1.10.4.1. Singling Out and Extreme Values

*Singling Out* is the possibility to isolate an individual in a dataset by using extreme value or exceptional values.

For example:

```
SELECT * FROM employees;
```

| id   | name         | job  | salary |
|------|--------------|------|--------|
| 1578 | xkjefus3sfzd | NULL | 1498   |
| 2552 | cksnd2se5dfa | NULL | 2257   |
| 5301 | fnefckndc2xn | NULL | 45489  |
| 7114 | npodn5ltyp3d | NULL | 1821   |

In this table, we can see that a particular employee has a very high salary, very far from the average salary. Therefore this person is probably the CEO of the company.

With generalization, this is important because the size of the range (the “step”) must be wide enough to prevent the identification of one single individual.

[k-anonymity](#) is a way to assess this risk.

##### G.1.10.4.2. Generalization is Not Compatible with Dynamic Masking

By definition, with generalization the data remains true, but the column type is changed.

This means that the transformation is not transparent, and therefore it cannot be used with [dynamic masking](#).

#### G.1.10.5. k-anonymity

k-anonymity is an industry-standard term used to describe a property of an anonymized dataset. The k-anonymity principle states that within a given dataset, any anonymized individual cannot be distinguished from at least  $k - 1$  other individuals. In other words, k-anonymity might be described as a “hiding in the crowd” guarantee. A low value of  $k$  indicates there's a risk of re-identification using linkage with other data sources.

`anon.k_anonymity(id regclass)`

You can evaluate the k-anonymity factor of a table as follows:

1. Define the columns that are indirect identifiers (also known as *quasi identifiers*) like this:

```
SECURITY LABEL FOR k_anonymity ON COLUMN patient.firstname
IS 'INDIRECT IDENTIFIER';
```

```
SECURITY LABEL FOR k_anonymity ON COLUMN patient.zipcode
IS 'INDIRECT IDENTIFIER';
```

```
SECURITY LABEL FOR k_anonymity ON COLUMN patient.birth
IS 'INDIRECT IDENTIFIER';
```

2. Once the indirect identifiers are declared:

```
SELECT anon.k_anonymity('generalized_patient')
```

The higher the value, the better.

## G.1.11. Performance

Any anonymization process has a price as it will consume CPU time, RAM space and probably a lot of disk I/O. Here's a quick overview of the question depending on the strategy you are using.

In a nutshell, the anonymization performance mainly depends on the following important factors:

- The size of the database
- The number of masking rules

### G.1.11.1. Static Masking

Basically what static masking does it rewrite entirely the masked tables on disk. This may be slow depending on your environment. And during this process, the tables will be locked.

#### Note

In this case, the cost of anonymization is “paid” by all the users but it is paid *once and for all*.

### G.1.11.2. Dynamic Masking

With dynamic masking, the real data is replaced on-the-fly **every time** a masked user sends a query to the database. This means that the masking users will have slower response time than regular (unmasked) users. This is generally ok because usually masked users are not considered as important as the regular ones.

If you apply three or four rules to a table, the response time for the masked users should be approximately 20% to 30% slower than for the normal users.

As the masking rules are applied for each queries of the masked users, the dynamic masking is appropriate when you have a limited number of masked users that connect only from time to time to the database. For instance, a data analyst connecting once a week to generate a business report.

If there are multiple masked users or if a masked user is very active, you should probably export the masked data once-a-week on a secondary instance and let these users connect to this secondary instance.

#### Note

In this case, the cost of anonymization is “paid” only by the masked users.

### G.1.11.3. Anonymous Dumps

If the backup process of your database takes one hour with `pg_dump`, then anonymizing and exporting the entire database with `pg_dump_anon.sh` will probably take two hours.

#### Note

In this case, the cost of anonymization is “paid” by the user asking for the anonymous export. Other users of the database will not be affected.

### G.1.11.4. How to Speed Things Up

#### G.1.11.4.1. Prefer MASKED WITH VALUE Whenever Possible

It is always faster to replace the original data with a static value instead of calling a masking function.

#### G.1.11.4.2. Sampling

If you need to anonymize data for testing purposes, chances are that a smaller subset of your database will be enough. In that case, you can easily speed up the anonymization by downsizing the volume of data.

See [Sampling](#) for more details.

#### G.1.11.4.3. Materialized Views

Dynamic masking is not always required. In some cases, it is more efficient to build [Materialized Views](#) instead.

For instance:

```
CREATE MATERIALIZED VIEW masked_customer AS
SELECT
 id,
 anon.random_last_name() AS name,
 anon.random_date_between('1920-01-01'::DATE, now()) AS birth,
 fk_last_order,
 store_id
FROM customer;
```

## G.1.12. Security

### G.1.12.1. Permissions

Here's an overview of what users can do depending on the privilege they have:

Table G.1. Privileges

| Action                  | Superuser | Owner | Masked Role |
|-------------------------|-----------|-------|-------------|
| Create the extension    | Yes       |       |             |
| Drop the extension      | Yes       |       |             |
| Init the extension      | Yes       |       |             |
| Reset the extension     | Yes       |       |             |
| Configure the extension | Yes       |       |             |
| Put a mask upon a role  | Yes       |       |             |
| Start dynamic masking   | Yes       |       |             |
| Stop dynamic masking    | Yes       |       |             |
| Create a table          | Yes       | Yes   |             |
| Declare a masking rule  | Yes       | Yes   |             |

| Action                       | Superuser | Owner | Masked Role |
|------------------------------|-----------|-------|-------------|
| Insert, delete, update a row | Yes       | Yes   |             |
| Use static masking           | Yes       | Yes   |             |
| Select the real data         | Yes       | Yes   |             |
| Use regular dumps            | Yes       | Yes   |             |
| Use anonymous dumps          | Yes       | Yes   |             |
| Use the masking functions    | Yes       | Yes   | Yes         |
| Select the masked data       | Yes       | Yes   | Yes         |
| View the masking rules       | Yes       | Yes   | Yes         |

### G.1.12.2. Limit Masking Filters Only to Trusted Schemas

By default, database owners can only write masking rules with functions that are located in the trusted schemas which are controlled by the superusers.

Out of the box, only the `anon` schema is declared as trusted. This means that by default the functions from the `pg_catalog` cannot be used in masking rules.

For more information, see [Using `pg\_catalog` functions](#).

### G.1.12.3. Security Context of the Functions

Most of the functions of this extension are declared with the `SECURITY INVOKER` tag. This means that these functions are executed with the privileges of the user that calls them. This is an important restriction.

This extension contains another few functions declared with the tag `SECURITY DEFINER`.

## G.1.13. Sampling

If you are writing an anonymization policy for a dataset, chances are that you do not need to anonymize *the entire database*. In most cases, extracting a subset of the table is sufficient. For example, if you want to export an anonymous dumps of the data for testing purpose in a CI workflow, extracting and masking only 10% of the database might be enough.

Furthermore, anonymizing a smaller portion (that is a "sample") of the dataset will be way faster.

### G.1.13.1. Example

Let's say you have a huge amount of HTTP logs stored in a table. You want to remove the IP addresses and extract only 10% of the table:

```
CREATE TABLE http_logs (
 id integer NOT NULL,
 date_opened DATE,
 ip_address INET,
 url TEXT
);

SECURITY LABEL FOR anon ON COLUMN http_logs.ip_address
IS 'MASKED WITH VALUE NULL';

SECURITY LABEL FOR anon ON TABLE http_logs
IS 'TABLESAMPLE BERNOULLI(10)';
```

Now you can either do static masking, dynamic masking or an anonymous dumps. The mask data will represent a 10% portion of the real data.

### G.1.13.2. Syntax

The syntax is exactly the same as the [TABLESAMPLE clause](#), which can be placed at the end of a [SELECT](#) statement.

You can also define a sampling ratio at the database level, and it will be applied to all the tables that do not have their own TABLESAMPLE rule.

```
SECURITY LABEL FOR anon ON DATABASE app
IS 'TABLESAMPLE SYSTEM(33)';
```

### G.1.13.3. Maintaining Referential Integrity

#### Warning

The sampling method described above *WILL FAIL* if you have foreign keys pointing at the table you want to sample.

Extracting a subset of a database while maintaining referential integrity is tricky and it is not supported by this extension.

If you really need to keep referential integrity in an anonymized dataset, you need to do it in two steps:

1. Extract a sample with [pg\\_sample](#).
2. Anonymize the extracted sample.

There may be other sampling tools for PostgreSQL but [pg\\_sample](#) is probably the best one.

## G.2. pgpro\_datactl — manage Postgres Pro Enterprise data files

### G.2.1. Overview

The pgpro\_datactl utility provides tools for managing Postgres Pro Enterprise data files, including a module for CFS (Compressed File Storage) operations. This module offers the following functionalities:

- Retrieving metadata from compressed files, including their compression algorithm and location.
- Unpacking CFS files for further analysis.
- Repacking compressed files and changing their compression level.
- Preventing potential failures caused by corrupted files.

### G.2.2. Installation

pgpro\_datactl is provided with Postgres Pro Enterprise as a separate pre-built package `pgpro-datactl-ent-17` (for the detailed installation instructions, see [Chapter 17](#)).

### G.2.3. Commands

pgpro\_datactl supports the following commands:

- [unpack](#)
- [probe](#)
- [info](#)
- [repack](#)
- [ground](#)
- [stat](#)

#### G.2.3.1. Important Notes

Before running these commands, pay attention to the following operation specifics:

- The **repack** and **unpack** operations require the Postgres Pro Enterprise cluster to be *stopped*. This is necessary to prevent data corruption and ensure file consistency.
- When using the **--in-place** option with the **repack** command, note that:
  - The tablespace will be overwritten directly during the operation.
  - All the existing data in the target tablespace will be replaced.

### G.2.3.2. unpack

```
pgpro_datactl unpack --source=source_path --target=target_path
[--calg=compression_algorithm] [--zero-on-error] [--log-level=logging_level] [--help]
```

Unpacks CFS files.

**-s=source\_path**  
**--source=source\_path**

Specifies the path to a compressed file or directory.

#### Note

The path must be in the directory named **PG\_version\_date** that contains the **pg\_compression** file.

**-t=target\_path**  
**--target=target\_path**

Specifies the path to a directory where the unpacked files will be placed.

If the source and target directories are the same, files are unpacked with a **.dec** extension.

**-c=compression\_algorithm**  
**--calg=compression\_algorithm**

Specifies the compression algorithm used. If omitted, the **unpack** command will take this value from the **pg\_compression** file.

**--zero-on-error**

If this option is specified, any corrupted blocks are replaced with zeros, preventing the process termination or error messages.

**--log-level=logging\_level**

Sets the logging level. Possible values: **debug**, **info**, **warning**, and **error**.

Example:

```
pgpro_datactl unpack -s /path/to/archive.cfs -t /path/to/destination -c zstd
```

In this example, **unpack** extracts **archive.cfs** compressed with the **zstd** algorithm into the directory **/path/to/destination**.

### G.2.3.3. probe

```
pgpro_datactl probe --source=source_path [--log-level=logging_level] [--help]
```

Analyzes the specified file and identifies the following:

- Compression type: **zlib** or **zstd** compression algorithm.
- Fragmentation level: Analyzes the corresponding **\*.cfm** file (if available) and reports the percentage of unused storage space in the physical file.

- Whether the file belongs to CFS: Checks the presence of an associated \*.cfm file, which indicates whether the file belongs to a CFS archive.

-s=*source\_path*  
--source=*source\_path*

Specifies the path to the required file.

--log-level=*logging\_level*

Sets the logging level. Possible values: debug, info, warning, and error.

Example output:

```
Probing path: /data/sample.dat
Has cfm file: Yes
pg_compression: zstd
Actual compression: zstd
Fragmentation: 5%
```

In this example, the file is compressed with the zstd algorithm, is part of a CFS archive, and has a fragmentation level of five percent.

#### G.2.3.4. info

```
pgpro_datactl info --source=source_path [--log-level=logging_level] [--help]
```

Analyzes the file and displays the following information:

- The file physical size, virtual size, and utilized file space in bytes.
- Whether the garbage collector (GC) is active.
- Whether the \*.cfm file is present and accessible.

-s=*source\_path*  
--source=*source\_path*

Specifies the path to the required file.

--log-level=*logging\_level*

Sets the logging level. Possible values: debug, info, warning, and error.

Example output:

```
Physical size: 10485760
Virtual size: 9437184
Used size: 7864320
GC active: Yes
```

#### G.2.3.5. repack

```
pgpro_datactl repack --source=source_path --t-calg=target_compression_algorithm --
target=target_path
[--calg=compression_algorithm] [--clevel=compression_level]
[--zero-on-error] [--log-level=logging_level] [--in-place] [--help]
```

Changes the compression algorithm and/or compression level of CFS files.

Returns the following information:

- Compression algorithm ID
- Compression level
- Copy status: 1 (complete) or 0 (incomplete)

If interrupted, the process can resume from the point of failure by re-executing the command with identical compression options (both `--t-calg` and `--calg` values), leveraging per-datafile `.status` files to maintain the operation state.

`-s=source_path`  
`--source=source_path`

Specifies the path to a compressed file or directory.

### Note

The path must be in the directory named `PG_version_date` that contains the `pg_compression` file.

`--t-calg=target_compression_algorithm`

Specifies the target compression algorithm. If omitted, the files will be decompressed (unpacked).

`-t=target_path`  
`--target=target_path`

Specifies the output location for recompressed files.

`-c=compression_algorithm`  
`--calg=compression_algorithm`

Specifies the current compression algorithm. If omitted, the `repack` command will take this value from the `pg_compression` file.

`--log-level=logging_level`

Sets the logging level. Possible values: `debug`, `info`, `warning`, and `error`.

`--clevel=compression_level`

Specifies the compression level for the chosen target compression algorithm. The default value is `1`.

`--zero-on-error`

If this option is specified, any corrupted blocks are replaced with zeros, preventing the process termination or error messages.

`--in-place`

If this option is specified while `target_path` is omitted, the recompressed files will be placed in the source directory.

### Warning

Using this option will remove all the source files from the source directory, thus should be considered carefully.

#### G.2.3.6. ground

```
pgpro_datactl ground --source=source_path --block-num=block_number
[--calg=compression_algorithm] [--log-level=logging_level] [--help]
```

Replaces the specified corrupted blocks, which may appear during decompression, with zeros.

`-s=source_path`  
`--source=source_path`

Specifies the path to the required file.

`--block-num=block_number`

Specifies the number of the block that should be replaced.

`-c=compression_algorithm`  
`--calg=compression_algorithm`

Specifies the current compression algorithm. If the value does not match the CFS tablespace compression algorithm, the operation will complete with an error.

`--log-level=logging_level`

Sets the logging level. Possible values: `debug`, `info`, `warning`, and `error`.

Example:

```
pgpro_datactl ground -s /path/to/archive.cfs --block-num 4 --calg pglz
```

In this example, `ground` replaces the block number 4 with a zero and uses the `pglz` algorithm to compress it.

### G.2.3.7. stat

```
pgpro_datactl stat --source=source_path --cfs
[--log-level=logging_level] [--help]
```

Collects tablespace statistics and outputs the results as a CSV file.

This command does not modify any files (read-only operation). No locks are acquired.

`-s=source_path`  
`--source=source_path`

Specifies the path to a compressed file or directory.

#### Note

The path must be in the directory named `PG_version_date` that contains the `pg_compression` file.

`--cfs`

Specifies the tablespace type.

#### Note

Currently only the CFS type support is implemented.

`--log-level=logging_level`

Sets the logging level. Possible values: `debug`, `info`, `warning`, and `error`.

## G.2.4. pgpro\_datactl Error Codes

[Table G.2](#) displays the error code ranges defined in `pgpro_datactl`.

According to the SQL standard, the first two characters of an error code denote the class of errors, while the last three characters indicate a specific condition within that class.

**Table G.2. pgpro\_datactl Error Code Ranges**

| Error Code | Condition |
|------------|-----------|
| 00XXX      | Success   |
| 10XXX      | Warning   |

| Error Code | Condition           |
|------------|---------------------|
| 20XXX      | Command-line error  |
| 30XXX      | Database error      |
| 40XXX      | Source data error   |
| 50XXX      | Target data error   |
| 60XXX      | Filesystem/IO error |
| 70XXX      | Runtime error       |

Table G.3 lists all specific error codes and the actions that should be taken if these errors occur.

pgpro\_datactl uses the PRODCTL -XXXXX format. Warnings return a nonzero exit code but allow the utility to progress. Errors stop the current operation.

**Table G.3. pgpro\_datactl Error Codes**

| Error Code     | Message                             | Cause                                                              | Action                                                             |
|----------------|-------------------------------------|--------------------------------------------------------------------|--------------------------------------------------------------------|
| PROD-CTL-00000 | Success                             | The operation completed successfully.                              | No action required.                                                |
| PROD-CTL-10001 | File not found.                     | An optional input path is missing.                                 | Check the path. If intentional, the warning can be ignored.        |
| PROD-CTL-10002 | Failed to read file.                | A partial read, permission error, or transient IO issue occurred.  | Retry the operation. Check user permissions and disk status.       |
| PROD-CTL-10003 | Invalid parameter.                  | A noncritical argument is out of range or malformed.               | Enter a valid value, or a default value will be used to proceed.   |
| PROD-CTL-10004 | Failed to allocate memory.          | The system was low on memory during a noncritical step.            | Reduce concurrency or data size.                                   |
| PROD-CTL-10005 | Failed to create working directory. | The current or working directory could not be established.         | Check the path, permissions, and available disk space.             |
| PROD-CTL-10006 | File contains invalid content.      | An optional file failed validation.                                | Replace or skip the file.                                          |
| PROD-CTL-10007 | Failed to remove file.              | The file is locked, or permission was denied.                      | Close any handles to the file and adjust permissions.              |
| PROD-CTL-10008 | Parameter required but not set.     | An optional subtask required a value but used the default instead. | Provide the missing option to avoid the fallback behavior.         |
| PROD-CTL-20001 | Required parameter is missing.      | A mandatory command-line option is absent.                         | Supply the required option and rerun the command.                  |
| PROD-CTL-20002 | Invalid parameter.                  | A command-line option has an invalid value.                        | Enter a valid value according to the documentation.                |
| PROD-CTL-30001 | Database connection failed.         | A network, authentication, or DSN error occurred.                  | Check authentication, network connectivity, and SSL configuration. |
| PROD-CTL-30002 | Database query failed.              | An SQL error, timeout, or permission issue occurred.               | Check the SQL and logs. Fix schema or permission issues.           |
| PROD-CTL-40001 | Failed to read source file.         | An IO error occurred on input.                                     | Make sure the path exists and the user has access to it. Retry.    |
| PROD-CTL-40002 | Source file not found.              | A required input file is missing.                                  | Provide the correct file or fix the path.                          |
| PROD-CTL-40003 | Failed to construct source path.    | The root path, environment variable, or template is invalid.       | Fix the configuration and path template.                           |

| Error Code     | Message                        | Cause                                                              | Action                                                                            |
|----------------|--------------------------------|--------------------------------------------------------------------|-----------------------------------------------------------------------------------|
| PROD-CTL-40004 | File contains invalid content. | Required input failed validation, or a checksum mismatch occurred. | Replace the file or fix its format.                                               |
| PROD-CTL-50001 | Target file write failed.      | A permission, disk quota, or disk error occurred.                  | Free up disk space, fix permissions, and retry.                                   |
| PROD-CTL-50002 | Target file not found.         | The expected output path, or its parent directory is missing.      | Create the necessary directories, verify the target path.                         |
| PROD-CTL-60001 | File remove failed.            | Permission was denied, or the file is in use.                      | Release any locks on the file, adjust permissions.                                |
| PROD-CTL-60002 | Open file failed.              | The file is missing, or access was denied.                         | Make sure the file exists, check permissions.                                     |
| PROD-CTL-60003 | Open stream failed.            | A pipe, socket, or file handle was not available.                  | Validate the endpoint, check permissions.                                         |
| PROD-CTL-60004 | File write failed.             | A short write or general IO error occurred.                        | Retry. Check the disk and filesystem health.                                      |
| PROD-CTL-60005 | File fsync failed.             | Flushing data to persistent storage failed.                        | Inspect the disk, check mount options, review kernel logs ( <code>dmesg</code> ). |
| PROD-CTL-60006 | File create failed.            | The parent directory is missing, or permissions are incorrect.     | Make sure the parent directory exists, fix <code>umask</code> or permissions.     |
| PROD-CTL-60007 | File rename failed.            | The source file does not exist, or permissions are insufficient.   | Make sure the source file exists, verify permissions. Retry.                      |
| PROD-CTL-60008 | Failed to mmap file.           | A memory-mapping error occurred, or the address space is low.      | Switch to buffered IO or reduce the mapped data size.                             |
| PROD-CTL-60009 | Failed to stat file.           | The path is invalid, or permissions are insufficient.              | Check the path and user permissions.                                              |
| PROD-CTL-70001 | Memory allocation failed.      | The system ran out of memory on a critical path.                   | Reduce parallelism or increase system memory limits.                              |
| PROD-CTL-70002 | Failed to create directory.    | The parent directory is missing, or permissions are insufficient.  | Create a parent directory, check permissions.                                     |
| PROD-CTL-70003 | Failed to open directory.      | The path is not a directory, or access was denied.                 | Make sure the path is a directory with proper access.                             |

## G.3. pgpro\_multiplan — save query execution plans and prepared statements for future usage

### G.3.1. Description

The `pgpro_multiplan` extension allows you to save query execution plans and use them for subsequent executions of the same queries, thereby avoiding repeated optimization of identical queries. It can also be used to lock a specific execution plan if a plan chosen by the planner does not suit your needs for some reasons. `pgpro_multiplan` works similar to Oracle SQL Plan Management.

This extension also allows you to store global prepared statements created in different database sessions and share these statements between multiple sessions.

### G.3.2. Installation

The `pgpro_multiplan` extension is provided with Postgres Pro Enterprise as a separate pre-built package `pgpro-multiplan-ent-17` (for the detailed installation instructions, see [Chapter 17](#)). To enable `pgpro_multiplan`, complete the following steps:

1. Add the library name to the `shared_preload_libraries` variable in the `postgresql.conf` file:

```
shared_preload_libraries = 'pgpro_multiplan'
```

Note that the library names in the `shared_preload_libraries` variable must be added in the specific order, for information on compatibility of `pgpro_multiplan` with other extensions, see [Section G.3.7](#).

2. Reload the database server for the changes to take effect.

To verify that the `pgpro_multiplan` library was installed correctly, you can run the following command:

```
SHOW shared_preload_libraries;
```

3. Create the `pgpro_multiplan` extension using the following query:

```
CREATE EXTENSION pgpro_multiplan;
```

It is essential that the library is preloaded during server startup because `pgpro_multiplan` has a shared memory cache that can be initialized only during startup. The `pgpro_multiplan` extension should be created in each database where query management is required.

4. Enable the `pgpro_multiplan` extension, which is disabled by default.

To activate one or two modes related to the use of different plans and their statistics, specify the `pgpro_multiplan.mode` parameter. For more information, see [Supported Modes and Plan Types](#).

To enable the use of [global prepared statements](#), set the `pgpro_multiplan.global_prepared_statements` parameter to `ON`.

You can specify these parameters in one of the following ways:

- at server startup (in the `postgresql.conf` file) to apply them to all sessions
  - in the current session using the `SET` command
5. If you want to transfer `pgpro_multiplan` data from the primary to a standby using physical replication, set the `pgpro_multiplan.wal_rw` parameter to `ON` on both servers. In this case, ensure that the same `pgpro_multiplan` versions are installed on both primary and standby, otherwise correct replication workflow is not guaranteed.

### G.3.3. Supported Modes and Plan Types

The `pgpro_multiplan` extension supports the following plans:

- **Frozen plans:** Locked plans that are given priority when executing the corresponding queries. A query can have one frozen plan only. `pgpro_multiplan` provides the following types of frozen plans:
  - **serialized:** A serialized representation of the plan. This plan is converted into an executable plan the first time the corresponding query is matched. Serialized plans remain valid as long as the query metadata (table structures, indexes, etc.) remain unchanged. For example, if a table referenced in the frozen plan is recreated, the frozen plan becomes invalid and is ignored. Serialized plans are only valid within the current database and cannot be copied to another, as they depend on OIDs. For this reason, using serialized plans for temporary tables is impractical.
  - **hintset:** A set of hints that are formed based on the execution plan at the time of freezing. The set of hints includes optimizer environment variables differing from default values, join types, join orders, and data access methods. These hints correspond to those supported by the `pg_hint_plan` extension. To use hint-set plans, `pg_hint_plan` must be enabled. When the corresponding frozen query is matched, the hints are passed to `pg_hint_plan` to generate the executable plan. If the `pg_hint_plan` extension is not active, the hints are ignored, and the plan generated by the Postgres Pro optimizer is executed. Hint-set plans do not depend on object identifiers and remain valid when tables are recreated, fields are added, etc.
  - **template:** A special case of the `hintset` plan. These plans can be applied only to queries with table names matching the regular expression specified in the `pgpro_multiplan.wildcards` configuration parameter. The `pgpro_multiplan.wildcards` value is frozen along with the corresponding query.
- **Baselines:** Sets of allowed plans that can be used to execute queries if there are no corresponding frozen plans. Like `hintset` frozen plans, baselines rely on planner hints and require the `pg_hint_plan` extension to be enabled. If `pg_hint_plan` is not active, the hints are ignored, and the plan generated by the Postgres Pro optimizer is executed.

Use the [pgpro\\_multiplan.mode](#) configuration parameter to specify a comma-separated list of enabled modes and plan types. By default, this parameter is set to an empty string, which means that all plan modes are disabled.

### G.3.4. Frozen Plan Usage

To enable the use of frozen plans, specify the `frozen` value in the [pgpro\\_multiplan.mode](#) parameter.

To freeze a plan for future usage, perform the following steps:

1. [Register](#) the query for which you want to freeze the plan.
2. [Modify](#) the query execution plan.
3. [Freeze](#) the query execution plan.

#### G.3.4.1. Registering a Query

There are the following ways to register a query:

- Using the [pgpro\\_multiplan\\_register\\_query\(\)](#) function:

```
SELECT pgpro_multiplan_register_query(query_string, parameter_type, ...);
```

Here *query\_string* is your query with  $n$  parameters (same as in [PREPARE statement\\_name AS](#)). You can describe each parameter type with the optional *parameter\_type* argument of the function or choose not to define parameter types explicitly. In the latter case, Postgres Pro attempts to determine each parameter type from the context. This function returns the unique pair of `sql_hash` and `const_hash`. Now `pgpro_multiplan` will track executions of queries that fit the saved parameterized query template.

```
-- Create table 'a'
CREATE TABLE a AS (SELECT * FROM generate_series(1,30) AS x);
CREATE INDEX ON a(x);
ANALYZE;

-- Register the query
SELECT sql_hash, const_hash
FROM pgpro_multiplan_register_query('SELECT count(*) FROM a
WHERE x = 1 OR (x > $2 AND x < $1) OR x = $1', 'int', 'int');
 sql_hash | const_hash
-----+-----
-6037606140259443514 | 2413041345
(1 row)
```

- Using the [pgpro\\_multiplan.auto\\_tracking](#) parameter:

```
-- Set pgpro_multiplan.auto_tracking to on
SET pgpro_multiplan.auto_tracking = on;

-- Execute EXPLAIN for a non-parameterized query
EXPLAIN SELECT count(*) FROM a WHERE x = 1 OR (x > 11 AND x < 22) OR x = 22;

Custom Scan (MultiplanScan) (cost=1.60..0.00 rows=1 width=8)
 Plan is: tracked
 SQL hash: 5393873830515778388
 Const hash: 0
 Plan hash: 0
-> Aggregate (cost=1.60..1.61 rows=1 width=8)
 -> Seq Scan on a (cost=0.00..1.60 rows=2 width=0)
 Filter: ((x = $1) OR ((x > $2) AND (x < $3)) OR (x = $4))

-- Disable pgpro_multiplan.auto_tracking
```

```
SET pgpro_multiplan.auto_tracking = off;
```

All registered queries are stored in the local cache that can be accessed using the [pgpro\\_multiplan\\_local\\_cache](#) view.

### G.3.4.2. Modifying the Query Execution Plan

A query execution plan can be modified using optimizer variables, [pg\\_hint\\_plan](#) hints if the extension is enabled, or other extensions that allow changing the query plan, such as [aqo](#). For information on compatibility of `pgpro_multiplan` with other extensions, see [Section G.3.7](#).

### G.3.4.3. Freezing the Query Execution Plan

To freeze a modified query plan, use the [pgpro\\_multiplan\\_freeze](#) function. The optional *plan\_type* parameter can be set to either `serialized`, `hintset`, or `template`. The default value is `serialized`. For detailed information on types of frozen plans, see [Section G.3.3](#).

All frozen plans are stored in the [pgpro\\_multiplan\\_storage](#) view.

### G.3.4.4. Frozen Plan Example

The example below illustrates how to use frozen plans.

```
-- A plan that needs to be improved
EXPLAIN (ANALYZE, COSTS OFF, TIMING OFF)
SELECT count(*) FROM a
WHERE x = 1 OR (x > 11 AND x < 22) OR x = 22;

 QUERY PLAN

Aggregate (actual rows=1 loops=1)
 -> Seq Scan on a (actual rows=12 loops=1)
 Filter: ((x = 1) OR ((x > 11) AND (x < 22)) OR (x = 22))
 Rows Removed by Filter: 18
Planning Time: 0.179 ms
Execution Time: 0.069 ms
(6 rows)

-- Make sure that you set a required mode for pgpro_multiplan
SET pgpro_multiplan.mode = 'frozen';

-- Register the query
SELECT sql_hash, const_hash
FROM pgpro_multiplan_register_query('SELECT count(*) FROM a
WHERE x = 1 OR (x > $2 AND x < $1) OR x = $1', 'int', 'int');
 sql_hash | const_hash
-----+-----
-6037606140259443514 | 2413041345
(1 row)

-- Modify the query execution plan
-- Force index scan by disabling sequential scan
SET enable_seqscan = 'off';
EXPLAIN (ANALYZE, COSTS OFF, TIMING OFF)
SELECT count(*) FROM a
WHERE x = 1 OR (x > 11 AND x < 22) OR x = 22;

 QUERY PLAN

Custom Scan (MultiplanScan) (actual rows=1 loops=1)
 Plan is: tracked
```

```
SQL hash: -6037606140259443514
Const hash: 2413041345
Plan hash: 0
-> Aggregate (actual rows=1 loops=1)
 -> Index Only Scan using a_x_idx on a (actual rows=12 loops=1)
 Filter: ((x = 1) OR ((x > $2) AND (x < $1)) OR (x = $1))
 Rows Removed by Filter: 18
 Heap Fetches: 30
Planning Time: 0.235 ms
Execution Time: 0.099 ms
(12 rows)
```

```
-- Restore the seqscan ability
RESET enable_seqscan;
```

```
-- Freeze the query execution plan
SELECT pgpro_multiplan_freeze();
pgpro_multiplan_freeze

t
(1 row)
```

```
-- The frozen plan with indexscan is now used
EXPLAIN (ANALYZE, COSTS OFF, TIMING OFF)
SELECT count(*) FROM a
WHERE x = 1 OR (x > 11 AND x < 22) OR x = 22;
```

#### QUERY PLAN

```

Custom Scan (MultiplanScan) (actual rows=1 loops=1)
 Plan is: frozen, serialized
 SQL hash: -6037606140259443514
 Const hash: 2413041345
 Plan hash: 0
 -> Aggregate (actual rows=1 loops=1)
 -> Index Only Scan using a_x_idx on a (actual rows=12 loops=1)
 Filter: ((x = 1) OR ((x > $2) AND (x < $1)) OR (x = $1))
 Rows Removed by Filter: 18
 Heap Fetches: 30
Planning Time: 0.063 ms
Execution Time: 0.119 ms
(12 rows)
```

### G.3.5. Baseline Usage

If there is no frozen plan for a specific query, the `pgpro_multiplan` extension can use a baseline, that is, a set of allowed plans created by the standard planner. You can also enable [real-time plan management](#) that adds plans produced by [AQE](#) to the list of allowed plans automatically.

To enable the use of allowed plans, specify the `baseline` value in the `pgpro_multiplan.mode` parameter.

To add the plan created by the standard planner to the set of allowed plans, follow these steps:

- [Capture](#) the plan.
- [Approve](#) the plan.

For subsequent queries, the created plan is applied without modification if it is in the set of allowed plans. If there is no such plan, the cheapest plan from the set of allowed plans is used.

## Note

Allowed plans can be used only when [pg\\_hint\\_plan](#) extension is active. For more information, see the [Compatibility with Other Extensions](#) section. Allowed plans are not used if automatic capturing is enabled. Do not forget to disable the [pgpro\\_multiplan.auto\\_capturing](#) parameter after completing the capture.

### G.3.5.1. Capturing a Plan

The [pgpro\\_multiplan.auto\\_capturing](#) parameter allows capturing all executed queries. You can access all captured queries using the [pgpro\\_multiplan\\_captured\\_queries](#) view.

```
-- Create table 'a'
CREATE TABLE a AS SELECT x, x AS y FROM generate_series(1,1000) x;
CREATE INDEX ON a(x);
CREATE INDEX ON a(y);
ANALYZE;

-- Enable the auto_capturing parameter
SET pgpro_multiplan.mode = 'baseline'
SET pgpro_multiplan.auto_capturing = 'on';

-- Execute the query
SELECT count(*) FROM a t1, a t2 WHERE t1.x = t2.x AND t1.y <= 1000 AND t2.y > 900;
count

100
(1 row)

-- Execute it again with different constants to get a different plan
SELECT count(*) FROM a t1, a t2 WHERE t1.x = t2.x AND t1.y <= 10 AND t2.y > 900;
count

0
(1 row)

-- Now you can see the captured plans using the corresponding view
SELECT * FROM pgpro_multiplan_captured_queries \gx

dbid | 5
sql_hash | 6079808577596655075
plan_hash | -487722818968417375
queryid | -8984284243102644350
cost | 36.785
sample_string | SELECT count(*) FROM a t1, a t2 WHERE t1.x = t2.x AND t1.y <= 1000 AND
t2.y > 900;
query_string | SELECT count(*) FROM a t1, a t2 WHERE t1.x = t2.x AND t1.y <= $1 AND
t2.y > $2;
constants | 1000, 900
prep_const |
hint_str | Leading(("t1" "t2")) HashJoin("t1" "t2") IndexScan("t2" "a_y_idx")
SeqScan("t1")
explain_plan | Aggregate (cost=36.77..36.78 rows=1 width=8)
 | Output: count(*)
 | -> Hash Join (cost=11.28..36.52 rows=100 width=0)
 | Hash Cond: (t1.x = t2.x)
 | -> Seq Scan on public.a t1 (cost=0.00..20.50 rows=1000
width=4)
```

```

 Output: t1.x, t1.y

### G.3.5.2. Approving a Plan

You can approve any plan from the `pgpro_multiplan_captured_queries` view by using the `pgpro_multiplan_captured_approve()` function with the specified `dbid`, `sql_hash`, and `plan_hash` parameters.

```

-- Manually approve the plan with index scans
SELECT pgpro_multiplan_captured_approve(5, 6079808577596655075, 2719320099967191582);

```

```

pgpro_multiplan_captured_approve

t
(1 row)

```

```
-- Or approve plans selected from the captured list
SELECT pgpro_multiplan_captured_approve(dbid, sql_hash, plan_hash)
FROM pgpro_multiplan_captured_queries
WHERE query_string like '%SELECT % FROM a t1, a t2%';
```

```
pgpro_multiplan_captured_approve

t
(1 row)
```

```
-- Approved plans are automatically removed from the captured queries storage
SELECT count(*) FROM pgpro_multiplan_captured_queries;
```

```
count

0
(1 row)
```

```
-- Approved plans are shown in the pgpro_multiplan_storage view

### G.3.5.3. Allowed Plan Example

The following example illustrates the use of allowed plans.

```
-- Enable the auto_capturing parameter
SET pgpro_multiplan.mode = 'baseline'
SET pgpro_multiplan.auto_capturing = 'on';

-- Execute the query
EXPLAIN (ANALYZE, COSTS OFF, TIMING OFF)
SELECT count(*) FROM a t1, a t2 WHERE t1.x = t2.x AND t1.y <= 1000 AND t2.y > 900;
```

#### QUERY PLAN

```

Aggregate (actual rows=1 loops=1)
-> Hash Join (actual rows=100 loops=1)
 Hash Cond: (t1.x = t2.x)
 -> Seq Scan on a t1 (actual rows=1000 loops=1)
 Filter: (y <= 1000)
 -> Hash (actual rows=100 loops=1)
 Buckets: 1024 Batches: 1 Memory Usage: 12kB
 -> Index Scan using a_y_idx on a t2 (actual rows=100 loops=1)
 Index Cond: (y > 900)
Planning Time: 0.543 ms
Execution Time: 0.688 ms
(16 rows)
```

```
-- And execute it again with different constants
EXPLAIN (ANALYZE, COSTS OFF, TIMING OFF)
SELECT count(*) FROM a t1, a t2 WHERE t1.x = t2.x AND t1.y <= 10 AND t2.y > 900;
```

#### QUERY PLAN

```

Aggregate (actual rows=1 loops=1)
-> Hash Join (actual rows=0 loops=1)
 Hash Cond: (t2.x = t1.x)
 -> Index Scan using a_y_idx on a t2 (actual rows=100 loops=1)
 Index Cond: (y > 900)
 -> Hash (actual rows=10 loops=1)
 Buckets: 1024 Batches: 1 Memory Usage: 9kB
 -> Index Scan using a_y_idx on a t1 (actual rows=10 loops=1)
 Index Cond: (y <= 10)
Planning Time: 0.495 ms
Execution Time: 0.252 ms
(16 rows)
```

```
-- Disable the automatic capturing
SET pgpro_multiplan.auto_capturing = 'off';

-- Approve all captured plans
SELECT pgpro_multiplan_captured_approve(dbid, sql_hash, plan_hash)
FROM pgpro_multiplan_captured_queries;
```

```
pgpro_multiplan_captured_approve

t
t
```

(2 rows)

-- The plan does not change because it is one of the allowed ones

EXPLAIN (ANALYZE, COSTS OFF, TIMING OFF)

SELECT count(\*) FROM a t1, a t2 WHERE t1.x = t2.x AND t1.y <= 1000 AND t2.y > 900;

#### QUERY PLAN

Index Cond: (y <= \$1)

Planning Time: 2.473 ms

Execution Time: 1.859 ms

(16 rows)

## G.3.6. Frozen Plan Backups

The `pgpro_multiplan` extension allows you to create a backup of frozen plans and then restore these plans into the current database. This can be useful to transfer plans between databases or server instances.

To back up frozen plans from a specific database, use the `pgpro_multiplan_storage` view like this:

```
CREATE TABLE storage_copy AS SELECT s.*
FROM pgpro_multiplan_storage s
JOIN pg_database d ON s.dbid = d.oid
WHERE d.datname = 'db_name';
```

To restore frozen plans from a backup, call the [pgpro\\_multiplan\\_restore\(\)](#) function:

```
SELECT s.query_string, res.sql_hash IS NOT NULL AS success
FROM storage_copy s,
LATERAL pgpro_multiplan_restore(s.query_string, s.hintstr, s.paramtypes, s.plan_type)
res;
```

### Note

Plans can be restored only when the [pg\\_hint\\_plan](#) extension is active, see the [Compatibility with Other Extensions](#) section.

Plans are always restored into the current database. To restore plans into another database, connect to it first. Thus, it is recommended to create a backup with plans only from one required database as for *db\_name* in the examples in this section. If you need to transfer plans for multiple databases, create separate backups for them, connect to each target database sequentially one by one, and restore the corresponding plans from backups.

## G.3.6.1. Limitations

When you back up and restore plans, take into account the following limitations:

- Only frozen plans can be restored.
- Frozen plans of the `template` type cannot be restored. Only `serialized` and `hintset` plans are supported.
- If you back up plans from multiple databases and those databases contain different frozen plans for identical queries, only the first conflicting plan will be restored.
- Only plans for valid queries can be restored, which means that all relations used in the query must exist in the current database.

## G.3.6.2. Use Cases

This section describes how to back up and restore frozen plans in different popular scenarios.

### G.3.6.2.1. Upgrading a Server Version

Follow the steps below to save frozen plans when upgrading a server from an older version that has an incompatible data storage.

1. Back up frozen plans before upgrade.

```
CREATE TABLE storage_copy AS SELECT s.*
FROM pgpro_multiplan_storage s
JOIN pg_database d ON s.dbid = d.oid
WHERE d.datname = 'db_name';
```

2. Upgrade the server.
3. Restore frozen plans.

```
SELECT pgpro_multiplan_restore(query_string, hintstr, paramtypes, plan_type)
FROM storage_copy;
```

### G.3.6.2.2. Transferring Plans Between Server Instances

To transfer frozen plans between two servers, do the following:

1. Connect to the source server.
2. Back up frozen plans to a table.

```
CREATE TABLE storage_copy AS SELECT s.*
FROM pgpro_multiplan_storage s
JOIN pg_database d ON s.dbid = d.oid
```

```
WHERE d.datname = 'db_name';
```

3. Use the [pg\\_dump](#) utility to dump the table to a file.

```
$ pg_dump --table storage_copy -Ft postgres > storage_copy.tar
```

4. Connect to the target server and connect to the required database.

5. Move the created dump file to the target file system.

6. Use the [pg\\_restore](#) utility to restore the table with frozen plans from the dump file.

```
$ pg_restore --dbname postgres -Ft storage_copy.tar
```

7. Restore frozen plans.

```
SELECT pgpro_multiplan_restore(query_string, hintstr, paramtypes, plan_type)
FROM storage_copy;
```

```
DROP TABLE storage_copy;
```

#### G.3.6.2.3. Transferring Plans From the Sandbox to the Regular Storage

To transfer frozen plans from the sandbox to the regular storage, complete the following steps:

1. Set the [pgpro\\_multiplan.sandbox](#) parameter to ON and back up frozen plans from the sandbox.

```
SET pgpro_multiplan.sandbox = ON;
```

```
CREATE TABLE storage_copy AS SELECT s.*
FROM pgpro_multiplan_storage s
JOIN pg_database d ON s.dbid = d.oid
WHERE d.datname = 'db_name';
```

2. Set the [pgpro\\_multiplan.sandbox](#) parameter to OFF and restore frozen plans into the regular storage.

```
SET pgpro_multiplan.sandbox = OFF;
```

```
SELECT pgpro_multiplan_restore(query_string, hintstr, paramtypes, plan_type)
FROM storage_copy;
```

#### G.3.6.2.4. Transferring Plans Between Databases

To transfer frozen plans from one database to another, connect to the target database and restore plans as shown below.

```
SELECT pgpro_multiplan_restore(s.query_string, s.hintstr, s.paramtypes, s.plan_type)
FROM pgpro_multiplan_storage s JOIN pg_database d ON s.dbid = d.oid
WHERE d.datname = 'db_name';
```

Here *db\_name* is the name of the database from which you want to transfer plans.

#### G.3.6.2.5. Example of Transferring Plans

This example demonstrates how to transfer plans from one server instance to another.

```
-- Connect to the source server
```

```
psql (17.4)
```

```
Type "help" for help.
```

```
-- In this example, 1000 plans are stored in the pgpro_multiplan_storage view
```

```
postgres=# select count(*) from pgpro_multiplan_storage;
```

```
count
```

```

```

```
1000
```

```
(1 row)
```

```
-- Copy frozen plans from the postgres database to a table
postgres=# CREATE TABLE storage_copy AS SELECT s.*
FROM pgpro_multiplan_storage s
JOIN pg_database d ON s.dbid = d.oid
WHERE d.datname = 'postgres';

-- Dump the table to an archive file
$ pg_dump --table storage_copy -Ft postgres > storage_copy.tar

-- Close the connection to the source server
-- Connect to the target server
./psql postgres
psql (16.8)
Type "help" for help.

-- Create the pgpro_multiplan extension and enable it
postgres=# create extension pgpro_multiplan;
CREATE EXTENSION
SET pgpro_multiplan.mode = 'frozen';
SET

-- This server does not contain frozen plans
postgres=# select count(*) from pgpro_multiplan_storage;
 count

 0
(1 row)

-- Move the dump file with frozen plans to the target file system

-- Restore the table with frozen plans from the dump
$ pg_restore --dbname postgres -Ft storage_copy.tar

-- Restore frozen plans from the table using the pgpro_multiplan_restore function
postgres=# SELECT pgpro_multiplan_restore(query_string, hintstr, paramtypes, plan_type)
FROM storage_copy;
 pgpro_multiplan_restore

(8436876698844323073,871432885)
(8436876698844323073,573678316)
(8436876698844323073,1999378082)
(8436876698844323073,1681603536)
(8436876698844323073,3959620774)
...
(8436876698844323073,1263226437)
(8436876698844323073,4053700861)
(8436876698844323073,2418458596)
(8436876698844323073,413896030)
(1000 rows)

-- The function restores 1000 frozen plans. The result is shown as pairs of sql_hash
and const_hash
-- Frozen queries were identical and differed only in constants, so sql_hash is the
same for all plans

-- Drop the table used to restore plans
postgres=# DROP TABLE storage_copy;
DROP TABLE
```

```
-- The target server now also stores 1000 frozen plans
postgres=# select count(*) from pgpro_multiplan_storage;
count

 1000
(1 row)

-- Disable pgpro_multiplan and run the query
postgres=# SET pgpro_multiplan.mode = '';

SET
postgres=# EXPLAIN (COSTS OFF) SELECT * FROM a WHERE x > 10;
 QUERY PLAN

Seq Scan on a
 Filter: (x > 10)
(2 rows)

-- Enable pgpro_multiplan and run the same query once again
-- One of the restored plans is now used
postgres=# SET pgpro_multiplan.mode = 'frozen';
SET
postgres=# EXPLAIN (COSTS OFF) SELECT * FROM a WHERE x > 10;
 QUERY PLAN

Custom Scan (MultiplanScan)
 Plan is: frozen, serialized
 SQL hash: 8436876698844323073
 Const hash: 2295408638
 Plan hash: 0
 -> Index Scan using a_x_idx on a
 Index Cond: (x > 10)
(7 rows)
```

### G.3.7. Compatibility with Other Extensions

To ensure compatibility of `pgpro_multiplan` with other enabled extensions, specify the library names in the `shared_preload_libraries` variable in the `postgresql.conf` file in the specific order:

- [pg\\_hint\\_plan](#): `pgpro_multiplan` must be loaded after `pg_hint_plan`.  
`shared_preload_libraries = 'pg_hint_plan, pgpro_multiplan'`
- [aqo](#): `pgpro_multiplan` must be loaded before `aqo`.  
`shared_preload_libraries = 'pgpro_multiplan, aqo'`
- [pgpro\\_stats](#): `pgpro_multiplan` must be loaded after `pgpro_stats`.  
`shared_preload_libraries = 'pgpro_stats, pgpro_multiplan'`

### G.3.8. Query Identification

A query in the current database is identified by a combination of `sql_hash` and `const_hash`.

`sql_hash` is a hash generated based on the parse tree, ignoring parameters and constants. Field and table aliases are not ignored. Therefore, the same query with different aliases will have different `sql_hash` values.

`const_hash` is a hash generated based on all constants involved in the query. Constants with the same value but different types, such as `1` and `'1'`, will produce different hash values.

### G.3.9. Automatic Type Casting

pgpro\_multiplan automatically attempts to cast the types of constants involved in the query to match the parameter types of the query for which a plan is frozen or added to a set of allowed plans. If type casting is not possible, the plan is ignored.

```
SELECT sql_hash, const_hash
FROM pgpro_multiplan_register_query('SELECT count(*) FROM a
WHERE x = $1', 'int');

-- Type casting is possible
EXPLAIN SELECT count(*) FROM a WHERE x = '1';
 QUERY PLAN

Custom Scan (MultiplanScan) (cost=1.38..1.39 rows=1 width=8)
 Plan is: tracked
 SQL hash: -5166001356546372387
 Const hash: 0
 Plan hash: 0
 -> Aggregate (cost=1.38..1.39 rows=1 width=8)
 -> Seq Scan on a (cost=0.00..1.38 rows=1 width=0)
 Filter: (x = $1)

-- Type casting is possible
EXPLAIN SELECT count(*) FROM a WHERE x = 1::bigint;
 QUERY PLAN

Custom Scan (MultiplanScan) (cost=1.38..1.39 rows=1 width=8)
 Plan is: tracked
 SQL hash: -5166001356546372387
 Const hash: 0
 Plan hash: 0
 -> Aggregate (cost=1.38..1.39 rows=1 width=8)
 -> Seq Scan on a (cost=0.00..1.38 rows=1 width=0)
 Filter: (x = $1)

-- Type casting is impossible
EXPLAIN SELECT count(*) FROM a WHERE x = 111111111111;
 QUERY PLAN

Aggregate (cost=1.38..1.39 rows=1 width=8)
 -> Seq Scan on a (cost=0.00..1.38 rows=1 width=0)
 Filter: (x = '111111111111'::bigint)
```

### G.3.10. Plan Usage Statistics

To collect statistics about the usage of frozen and allowed plans, specify the `statistics` value in the `pgpro_multiplan.mode` parameter. These statistics are stored in the `pgpro_multiplan_stats` view. The `pgpro_multiplan.max_stats` parameter specifies the maximum number of collected statistics values. When this limit is reached, further statistics will be discarded. If a plan is changed, the statistics of the plan's usage are reset and recalculated using the new `plan_hash`.

For more detailed planning and execution statistics, you can use the `pgpro_stats` extension (see the [Compatibility with Other Extensions](#) section). These statistics can be accessed using the `pgpro_stats_statements` view.

You can join information from the `pgpro_multiplan_stats` and `pgpro_stats_statements` views by the `planid` field.

The following example demonstrates how to collect and view statistics. It uses the query and frozen plan from the [Frozen Plan Example](#).

```
-- Enable collecting statistics
SET pgpro_multiplan.mode = 'frozen, statistics';
```

```
-- Execute the query
SELECT count(*) FROM a
WHERE x = 1 OR (x > 11 AND x < 22) OR x = 22;
```

```
count

 12
(1 row)
```

```
-- Now you can see statistics of the plan usage
SELECT * FROM pgpro_multiplan_stats;
```

| dbid | sql_hash            | const_hash | plan_hash | planid              | counter |
|------|---------------------|------------|-----------|---------------------|---------|
| 5    | 6062491547151210914 | 2413041345 | 0         | 3549961214127427294 | 1       |

```
(1 row)
```

### G.3.11. Integration with AQE

The `pgpro_multiplan` extension can work in conjunction with adaptive query execution (AQE) providing more flexible features for managing query execution plans.

AQE attempts to reoptimize a query if a specific trigger fires during query execution indicating that it is non-optimal. To enable AQE, use the `aqe_enable` configuration parameter.

The `pgpro_multiplan.aqe_mode` configuration parameter specifies a comma-separated list of enabled AQE-related features.

#### G.3.11.1. Real-Time Plan Management

Real-time plan management adds plans produced by AQE to the list of `allowed plans` automatically.

To enable this functionality, do the following:

- Set the `aqe_enable` parameter to `on` to activate AQE.
- Specify one or more required AQE triggers using the `aqe_sql_execution_time_trigger`, `aqe_rows_underestimation_rate_trigger`, and `aqe_backend_memory_used_trigger` parameters.
- Specify the `baseline` value in the `pgpro_multiplan.mode` parameter to enable the use of allowed plans.
- Specify the `auto_approve_plans` value in the `pgpro_multiplan.aqe_mode` parameter.

The following example demonstrates how to use real-time plan management.

```
INSERT INTO a SELECT x, x AS y FROM generate_series(1001,2000) x;
```

```
-- Enable AQE and its node tuples underestimation trigger
SET aqe_enable = 'on';
SET aqe_rows_underestimation_rate_trigger = 2;
```

```
-- Configure pgpro_multiplan modes
SET pgpro_multiplan.mode = 'baseline';
SET pgpro_multiplan.aqe_mode = 'auto_approve_plans';
```

```
-- Execute a query
SELECT count(*) FROM a t1, a t2 WHERE t1.x = t2.x AND t1.y <= 2000 AND t2.y > 900;
count

 1100
(1 row)
```

```
-- The query was reoptimized by AQE according to its trigger
-- The query execution plan was saved to a baseline (a list of allowed plans)

-- Now you can see the plan using the corresponding view

### G.3.11.2. Individual Trigger Values

The `pgpro_multiplan` extension allows you to override and adjust global [AQE trigger values](#) for individual queries. Global triggers are specified in the `aqe_sql_execution_time_trigger`, `aqe_rows_underestimation_rate_trigger`, and `aqe_backend_memory_used_trigger` configuration parameters.

To use this functionality, do the following:

- Set the `aqe_enable` parameter to `ON` to activate AQE.
- Specify the `individual_triggers` value in the `pgpro_multiplan.aqe_mode` parameter.
- Call the `set_aqe_trigger` function for each query whose triggers you want to override.

All individual trigger values are shown in the `aqe_triggers` view. The `pgpro_multiplan.aqe_max_items` parameter specifies the maximum number of stored trigger values.

### G.3.11.3. AQE Statistics

`pgpro_multiplan` can collect AQE statistics for all statements considered feasible for reoptimization. These statistics are stored in shared memory until a server shutdown and are not replicated.

Perform the following steps to enable statistics collection:

- Set the `aqe_enable` parameter to `ON` to activate AQE.
- Specify the `statistics` value in the `pgpro_multiplan.aqe_mode` parameter.
- Enable query ID computation using the `compute_query_id` parameter.

All statistics values are shown in the `aqe_stats` view. The `pgpro_multiplan.aqe_max_stats` parameter specifies the maximum number of collected statistics values. Further statistics are discarded.

## G.3.12. Global Prepared Statements

By default, [prepared statements](#) are available only within the current database session. These statements can be accessed using the system `pg_prepared_statements` view. When the session ends, its prepared statements are released and cannot be used again.

The `pgpro_multiplan` extension supports global prepared statements that are shared between multiple or all sessions within the current server. To enable this functionality, set the `pgpro_multiplan.global_prepared_statements` parameter to `ON` in one of the following ways:

- at server start (in the `postgresql.conf` file) to activate the functionality for all sessions
- for individual required sessions using the `SET` command

When a prepared statement is created in such a session, it is saved to a global storage and then can be used in all active sessions in parallel. These global prepared statements can be accessed using the `pgpro_global_prepared_statements` view. When a session ends, prepared statements created in it are not removed and remain available for other sessions. But if a prepared statement is [deallocated](#) explicitly, it is removed from the global storage.

The example below demonstrates how to use global prepared statements in two sessions.

```
-- Open the first session and create a prepared statement named "p"
PREPARE p (int,int) as SELECT $1+$2 as plus;

-- Execute the created prepared statement in the same session
EXECUTE p (1,2);
plus

 3
(1 row)

-- Open the second session and try to create a prepared statement with the same name
```

```
-- The error occurs since this statement already exists
PREPARE p (int,int) as SELECT $1+$2 as plus;
ERROR: shared prepared statement "p" already exists

-- Execute the prepared statement in the second session
EXECUTE p (1,2);
plus

 3
(1 row)

-- Deallocate the prepared statement in the second session
DEALLOCATE p;

-- Try to execute this statement in the first session
-- The error occurs since this statement was released in the second session
EXECUTE p (1,2);
ERROR: prepared statement "p" does not exist
```

You can also set the [pgpro\\_multiplan.global\\_prepared\\_statements\\_allow\\_duplicate](#) parameter to `ON` to avoid errors on attempts to create prepared statements that already exist as in the example above. However, if you try to create a prepared statement with the same name but another query, the error occurs anyway.

### G.3.12.1. Considerations and Limitations

Take into account the following specifics and limitations when using global prepared statements:

- Global prepared statements are available only within a single server and cannot be shared between multiple servers in a cluster.
- The global storage contains only prepared statements created in a session after the `pgpro_multiplan.global_prepared_statements` parameter was set to `ON`. Even if a prepared statement was created earlier and is available in the local system `pg_prepared_statements` view, it is not added to the `pgpro_global_prepared_statements` view. When trying to execute such a statement, an error occurs and the statement is removed from the local storage.
- For correct execution, all relations referenced in a prepared statement must exist in all sessions. Thus, prepared statements should not rely on temporary tables or any other objects that are not supported by WAL replication.

## G.3.13. Views

### G.3.13.1. The `pgpro_multiplan_storage` View

The `pgpro_multiplan_storage` view provides detailed information about all frozen and allowed plans. The columns of the view are shown in [Table G.4](#).

**Table G.4. `pgpro_multiplan_storage` Columns**

| Name                    | Type                 | Description                                                              |
|-------------------------|----------------------|--------------------------------------------------------------------------|
| <code>dbid</code>       | <code>oid</code>     | ID of the database where the statement is executed                       |
| <code>sql_hash</code>   | <code>bigint</code>  | Internal query ID                                                        |
| <code>const_hash</code> | <code>bigint</code>  | Hash of non-parameterized constants                                      |
| <code>plan_hash</code>  | <code>bigint</code>  | Internal ID of the allowed plan, 0 for frozen plans                      |
| <code>valid</code>      | <code>boolean</code> | <code>FALSE</code> if the plan was invalidated the last time it was used |
| <code>cost</code>       | <code>float</code>   | Cost of the allowed plan, 0 for frozen plans                             |

| Name          | Type      | Description                                                                                                                                       |
|---------------|-----------|---------------------------------------------------------------------------------------------------------------------------------------------------|
| sample_string | text      | Non-parameterized query with constants for which the plan was frozen or added to a set of allowed plans                                           |
| query_string  | text      | Parameterized query for which the plan was frozen or added to a set of allowed plans                                                              |
| paramtypes    | regtype[] | Array with parameter types used in the query                                                                                                      |
| query         | text      | Internal representation of the query                                                                                                              |
| plan          | text      | Internal representation of the plan                                                                                                               |
| plan_type     | text      | Plan type. For frozen plans: <code>serialized</code> , <code>hintset</code> , or <code>template</code> . For allowed plans: <code>baseline</code> |
| hintstr       | text      | Set of hints formed based on the plan                                                                                                             |
| wildcards     | text      | Regular expression used for the <code>template</code> frozen plan, NULL for other plan types                                                      |

### G.3.13.2. The `pgpro_multiplan_local_cache` View

The `pgpro_multiplan_local_cache` view provides detailed information about registered and frozen statements in the local cache. The columns of the view are shown in [Table G.5](#).

**Table G.5. `pgpro_multiplan_local_cache` Columns**

| Name         | Type      | Description                                                                  |
|--------------|-----------|------------------------------------------------------------------------------|
| sql_hash     | bigint    | Internal query ID                                                            |
| const_hash   | bigint    | Hash of non-parameterized constants                                          |
| fs_is_frozen | boolean   | TRUE if the statement is frozen                                              |
| fs_is_valid  | boolean   | TRUE if the statement is valid                                               |
| ps_is_valid  | boolean   | TRUE if the statement should be revalidated                                  |
| query_string | text      | Query registered by the <code>pgpro_multiplan_register_query</code> function |
| query        | text      | Internal representation of the query                                         |
| paramtypes   | regtype[] | Array with parameter types used in the query                                 |
| hintstr      | text      | Set of hints formed based on the frozen plan                                 |

### G.3.13.3. The `pgpro_multiplan_captured_queries` View

The `pgpro_multiplan_captured_queries` view provides detailed information about all queries captured in sessions. The columns of the view are shown in [Table G.6](#).

**Table G.6. `pgpro_multiplan_captured_queries` Columns**

| Name     | Type   | Description                                        |
|----------|--------|----------------------------------------------------|
| dbid     | oid    | ID of the database where the statement is executed |
| sql_hash | bigint | Internal query ID                                  |

| Name          | Type   | Description                                                       |
|---------------|--------|-------------------------------------------------------------------|
| queryid       | bigint | Standard query ID                                                 |
| plan_hash     | bigint | Internal plan ID                                                  |
| planid        | bigint | Plan ID compatible with the <a href="#">pgpro_stats</a> extension |
| cost          | float  | Plan cost                                                         |
| sample_string | text   | Last used non-parameterized query with constants                  |
| query_string  | text   | Last used parameterized query                                     |
| constants     | text   | Set of constants in the query                                     |
| prep_consts   | text   | Set of constants used to EXECUTE a prepared statement             |
| hintstr       | text   | Set of hints formed based on the plan                             |
| explain_plan  | text   | Plan shown by the EXPLAIN command                                 |

#### G.3.13.4. The pgpro\_multiplan\_stats View

The `pgpro_multiplan_stats` view provides statistics about the usage of frozen and allowed plans. The columns of the view are shown in [Table G.7](#).

**Table G.7. `pgpro_multiplan_stats` Columns**

| Name      | Type   | Description                                                       |
|-----------|--------|-------------------------------------------------------------------|
| dbid      | oid    | ID of the database where the statement is executed                |
| sql_hash  | bigint | Internal query ID                                                 |
| plan_hash | bigint | Internal plan ID                                                  |
| planid    | bigint | Plan ID compatible with the <a href="#">pgpro_stats</a> extension |
| counter   | bigint | Number of times the plan was used                                 |

#### G.3.13.5. The aqe\_triggers View

The `aqe_triggers` view provides information about individual [AQE trigger](#) values. The columns of the view are shown in [Table G.8](#).

**Table G.8. `aqe_triggers` Columns**

| Name                 | Type   | Description                                                                                           |
|----------------------|--------|-------------------------------------------------------------------------------------------------------|
| dbid                 | oid    | ID of the database where the statement is executed                                                    |
| sql_hash             | bigint | Internal query ID                                                                                     |
| query_string         | text   | Parameterized query                                                                                   |
| execution_time       | int    | Value for the query execution time trigger, in milliseconds. NULL if the global trigger value is used |
| memory               | int    | Value for the backend memory consumption trigger. NULL if the global trigger value is used            |
| underestimation_rate | double | Factor for the processed number of node tuples trigger. NULL if the global trigger value is used      |

### G.3.13.6. The aqe\_stats View

The `aqe_stats` view provides cumulative statistics about [AQE](#) reoptimizations. This view stores one row per each combination of the database ID, query, and execution plan. The columns of the view are shown in [Table G.9](#).

**Table G.9. aqe\_stats Columns**

| Name                                | Type                                  | Description                                                                               |
|-------------------------------------|---------------------------------------|-------------------------------------------------------------------------------------------|
| <code>dbid</code>                   | <code>oid</code>                      | ID of the database where the statement is executed                                        |
| <code>sql_hash</code>               | <code>bigint</code>                   | Internal query ID                                                                         |
| <code>planid</code>                 | <code>bigint</code>                   | ID of the query execution plan                                                            |
| <code>query</code>                  | <code>text</code>                     | Internal representation of the query                                                      |
| <code>last_updated</code>           | <code>timestamp with time zone</code> | Timestamp of the last statistics update                                                   |
| <code>exec_num</code>               | <code>bigint</code>                   | Number of query executions                                                                |
| <code>min_attempts</code>           | <code>integer</code>                  | Minimum number of times the query was reoptimized                                         |
| <code>max_attempts</code>           | <code>integer</code>                  | Maximum number of times the query was reoptimized                                         |
| <code>total_attempts</code>         | <code>integer</code>                  | Total number of times the query was reoptimized                                           |
| <code>reason_repeated_plan</code>   | <code>bigint</code>                   | Number of times AQE was disabled because a repeated execution plan was generated          |
| <code>reason_no_data</code>         | <code>bigint</code>                   | Number of times AQE was disabled because no new information was gathered during execution |
| <code>reason_max_reruns</code>      | <code>bigint</code>                   | Number of times AQE was disabled because the maximum number of reruns was reached         |
| <code>reason_external</code>        | <code>bigint</code>                   | Number of times AQE was disabled by an extension, such as <code>pgpro_multiplan</code>    |
| <code>reruns_forced</code>          | <code>bigint</code>                   | Total number of reoptimizations caused by the manual trigger                              |
| <code>reruns_time</code>            | <code>bigint</code>                   | Total number of reoptimizations caused by the query execution time trigger                |
| <code>reruns_underestimation</code> | <code>bigint</code>                   | Total number of reoptimizations caused by the processed number of node tuples trigger     |
| <code>reruns_memory</code>          | <code>bigint</code>                   | Total number of reoptimizations caused by the backend memory trigger                      |
| <code>min_planning_time</code>      | <code>double precision</code>         | Minimum time spent planning, in milliseconds                                              |
| <code>max_planning_time</code>      | <code>double precision</code>         | Maximum time spent planning, in milliseconds                                              |
| <code>mean_planning_time</code>     | <code>double precision</code>         | Mean time spent planning, in milliseconds                                                 |
| <code>stddev_planning_time</code>   | <code>double precision</code>         | Population standard deviation of time spent planning, in milliseconds                     |
| <code>min_exec_time</code>          | <code>double precision</code>         | Minimum time spent on query execution, in milliseconds                                    |

| Name             | Type             | Description                                                                     |
|------------------|------------------|---------------------------------------------------------------------------------|
| max_exec_time    | double precision | Maximum time spent on query execution, in milliseconds                          |
| mean_exec_time   | double precision | Mean time spent on query execution, in milliseconds                             |
| stddev_exec_time | double precision | Population standard deviation of time spent on query execution, in milliseconds |

### G.3.13.7. The pgpro\_global\_prepared\_statements View

The `pgpro_global_prepared_statements` view provides detailed information about all [global prepared statements](#). The columns of the view are shown in [Table G.10](#).

**Table G.10. pgpro\_global\_prepared\_statements Columns**

| Name         | Type      | Description                                                                                                                   |
|--------------|-----------|-------------------------------------------------------------------------------------------------------------------------------|
| session_id   | bytea     | ID of the session where the prepared statement was created                                                                    |
| name         | varchar   | Name of the prepared statement                                                                                                |
| prepare_time | timestamp | Initial timestamp at which the prepared statement was created. It is not updated if the same prepared statement is re-created |
| from_sql     | bool      | <code>true</code> if the prepared statement was created using the <code>PREPARE</code> command, <code>false</code> otherwise  |
| param_num    | int4      | Number of parameters used in the prepared statement                                                                           |
| param_types  | regtype[] | Array with parameter types used in the prepared statement                                                                     |
| statement    | text      | Query used to create the prepared statement                                                                                   |

### G.3.14. Functions

Only superusers can call the functions listed below.

`pgpro_multiplan_register_query(query_string text)` returns record  
`pgpro_multiplan_register_query(query_string text, VARIADIC regtype[])` returns record

Saves the query described in the *query\_string* parameter in the local cache that can be accessed using the [pgpro\\_multiplan\\_local\\_cache](#) view. Returns the unique pair of `sql_hash` and `const_hash`.

`pgpro_multiplan_unregister_query()` returns bool

Removes the query that was registered but not frozen from the `pgpro_multiplan_local_cache` view. Returns `true` if there are no errors.

`pgpro_multiplan_freeze(plan_type text)` returns bool

Freezes the last used plan for the query and saves it to the permanent `pgpro_multiplan` storage that can be accessed using the [pgpro\\_multiplan\\_storage](#) view. The allowed values of the optional *plan\_type* argument are `serialized`, `hintset`, and `template`. `serialized` is used by default. For details about plan types, see [Supported Modes and Plan Types](#). Returns `true` if the plan was frozen successfully.

`pgpro_multiplan_unfreeze(sql_hash bigint, const_hash bigint)` returns bool

Removes the specified plan from the permanent storage but keeps the query registered in the local cache. Returns `true` if there are no errors.

`pgpro_multiplan_remove(sql_hash bigint, const_hash bigint)` returns `bool`

Removes the frozen statement with the specified `sql_hash` and `const_hash` parameters. Operates as `pgpro_multiplan_unfreeze` and `pgpro_multiplan_unregister_query` called sequentially. Returns `true` if there are no errors.

`pgpro_multiplan_reset(dbid oid)` returns `bigint`

Removes all records from the `pgpro_multiplan_storage` view for the specified database. Omit `dbid` to remove the data collected by `pgpro_multiplan` for the current database. Set `dbid` to `NULL` to reset data for all databases. Returns the number of removed records.

`pgpro_multiplan_reload_frozen_plancache()` returns `bool`

Drops all frozen plans and reloads them in the `pgpro_multiplan_storage` view. It also drops statements that have been registered but not frozen. Returns `true` if there are no errors.

`pgpro_multiplan_stats()` returns `table`

Returns statistics of the plan usage from the `pgpro_multiplan_stats` view.

`pgpro_multiplan_registered_query(sql_hash bigint, const_hash bigint)` returns `table`

Returns the registered query with the specified `sql_hash` and `const_hash` parameters even if it is not frozen, for debugging purposes only. This works if the query is registered in the current backend or frozen in the current database.

`pgpro_multiplan_captured_approve(dbid oid, sql_hash bigint, plan_hash bigint)` returns `bool`

Adds the specified plan for the captured query to a baseline (a set of allowed plans) and saves it to the `pgpro_multiplan_storage` view. Returns `true` if the plan was added successfully.

`pgpro_multiplan_remove_baseline(dbid oid, sql_hash bigint, plan_hash bigint)` returns `bool`

Removes the specified allowed plan from the permanent storage. Returns `true` if the plan was removed successfully.

`pgpro_multiplan_remove_template(dbid oid, sql_hash bigint, plan_hash bigint)` returns `bool`

Removes the specified `template` plan from the permanent storage. Returns `true` if the plan was removed successfully.

`pgpro_multiplan_set_plan_type(sql_hash bigint, const_hash bigint, plan_type text)` returns `bool`

Sets the type of the query plan for the frozen statement. The allowed values of the `plan_type` argument are `serialized`, `hintset`, and `template`. To be able to use the query plan of the `hintset` or `template` type, the `pg_hint_plan` module must be loaded. Returns `true` if the plan type was changed successfully.

`pgpro_multiplan_hintset_update(sql_hash bigint, const_hash bigint, hintset text)` returns `bool`

Replaces the generated hint set for the `hintset` frozen plan or the allowed plan with the specified set of custom hints. A string with custom hints should not be enclosed in the special comment used in `pg_hint_plan`, that is it should not start with `/*+` and end with `*/`. Returns `true` if the hint set was changed successfully.

`pgpro_multiplan_template_hintset_update(sql_hash bigint, const_hash bigint, hintset text)` returns `bool`

Replaces the generated hint set for the `template` frozen plan with the specified set of custom hints. A string with custom hints should not be enclosed in the special comment used in `pg_hint_plan`, that is it should not start with `/*+` and end with `*/`. Returns `true` if the hint set was changed successfully.

`pgpro_multiplan_captured_clean()` returns `bigint`

Removes all records from the `pgpro_multiplan_captured_queries` view. Returns the number of removed records.

`get_sql_hash(query_string text)` returns `bigint`

Returns the internal ID (`sql_hash`) for the specified query.

`set_aqe_trigger(trigger_name text, trigger_val int, query_string text)` returns bool  
`set_aqe_trigger(trigger_name text, trigger_val double precision, query_string text)` returns bool

Sets or resets the individual value of the [AQE](#) trigger for the specified query. The individual trigger value overrides the global trigger value specified in the AQE configuration parameter. For this feature to work, ensure that the `individual_triggers` value is specified in the [pgpro\\_multiplan.aqe\\_mode](#) parameter.

This function has the following arguments:

- *trigger\_name*: The trigger name. The following values are allowed:
  - *execution\_time*: The query execution time trigger. Corresponds to the [aqe\\_sql\\_execution\\_time\\_trigger](#) configuration parameter.
  - *memory*: The backend memory consumption trigger. Corresponds to the [aqe\\_backend\\_memory\\_used\\_trigger](#) configuration parameter.
  - *underestimation\_rate*: The processed number of node tuples trigger. Corresponds to the [aqe\\_rows\\_underestimation\\_rate\\_trigger](#) configuration parameter.
- *trigger\_val*: The trigger value. For *execution\_time* and *memory* triggers, specify integer values. For *underestimation\_rate*, you can define double precision values. To reset the individual trigger value, specify NULL or negative value less than -1.
- *query\_string*: The query text.

This function returns `true` if there are no errors.

`aqe_triggers_reset(dbid oid)` returns bigint

Removes all records from the `aqe_triggers` view for the specified database. To clean the `aqe_triggers` view for the current database, omit *dbid*. To remove records from this view for all databases, set *dbid* to NULL. Returns the number of removed records.

`aqe_stats_reset(dbid oid)` returns bigint

Removes all records from the `aqe_stats` view for the specified database. To clean the `aqe_stats` view for the current database, omit *dbid*. To remove records from this view for all databases, set *dbid* to NULL. Returns the number of removed records.

`pgpro_multiplan_restore(query_string text, hintstr texttext, paramtypes regtype[], plan_type text)` returns record

Restores the frozen plan for the specified query into the current database.

This function has the following arguments:

- *query\_string*: The query with *\$n* parameters (same as in [PREPARE statement\\_name AS](#)) for which to restore the frozen plan based on a set of hints.
- *hintstr*: A set of hints supported by the [pg\\_hint\\_plan](#) extension. If this argument is set to NULL or empty string, the standard plan will be used.
- *parameter\_type*: An array with parameter types used in the query. If this argument is set to NULL, parameter types should be determined automatically.
- *plan\_type*: The plan type. Allowed values are `serialized` and `hintset`. The `template` plan is not supported.

The function returns the unique pair of `sql_hash` and `const_hash` if the plan was restored successfully. Otherwise, it returns NULL.

`pgpro_global_prepared_statements_reset()` returns int

Removes all global prepared statements and returns the number of removed records.

`pgpro_global_prepared_statements_reset(session_id bytea)` returns int

Removes global prepared statements created in the specified session and returns the number of removed records.

`pgpro_global_prepared_statements_session()` returns `bytea`

Returns the ID of the current session.

`pgpro_global_prepared_statements_session(session_id bytea)`

Sets the specified ID for the current session and returns the previous ID.

### G.3.15. Configuration Parameters

`pgpro_multiplan.mode` (string)

A comma-separated list of enabled `pgpro_multiplan` modes. The following values are available:

- `frozen`: Enables the use of `serialized` and `hintset` frozen plans.
- `wildcards`: Enables the use of `template` frozen plans.
- `baseline`: Enables the use of allowed plans.
- `statistics`: Enables collecting statistics about the plan usage. These statistics are stored in the [pgpro\\_multiplan\\_stats](#) view. This value can be specified only together with one or more plan types.

```
SET pgpro_multiplan.mode = 'frozen, wildcards, baseline, statistics';
```

For details about plan types, see [Supported Modes and Plan Types](#). For more information about collecting statistics, refer to [Statistics](#).

By default, the `pgpro_multiplan.mode` parameter is set to an empty string, which means that all plan modes are disabled. Only superusers can change this setting.

`pgpro_multiplan.aqe_mode` (string)

A comma-separated list of enabled [AQE](#)-related features. The following values are available:

- `auto_approve_plans`: Enables [real-time plan management](#).
- `individual_triggers`: Enables you to specify [individual AQE trigger values](#).
- `statistics`: Enables [collecting AQE statistics](#).

```
SET pgpro_multiplan.aqe_mode = 'auto_approve_plans, individual_triggers, statistics';
```

For these features to work, ensure that AQE is enabled using the [aqe\\_enable](#) configuration parameter.

By default, the `pgpro_multiplan.aqe_mode` parameter is set to an empty string. Only superusers can change this setting.

`pgpro_multiplan.max_stats` (integer)

Sets the maximum number of statistics values that can be stored in the `pgpro_multiplan_stats` view. Further statistics will be discarded. The default value is 5000. This parameter can only be set at server start.

`pgpro_multiplan.max_items` (integer)

Sets the maximum number of entries `pgpro_multiplan` can operate with. The default value is 100. This parameter can only be set at server start.

`pgpro_multiplan.auto_tracking` (boolean)

Enables `pgpro_multiplan` to normalize and register queries executed using the `EXPLAIN` command automatically. The default value is `off`. Only superusers can change this setting.

`pgpro_multiplan.max_local_cache_size` (integer)

Sets the maximum size of local cache, in kB. The default value is zero, which means no limit. Only superusers can change this setting.

#### `pgpro_multiplan.wal_rw` (boolean)

Enables physical replication of `pgpro_multiplan` data. When set to `Off` on the primary, no data is transferred from it to a standby. When set to `Off` on a standby, any data transferred from the primary is ignored. The default value is `Off`. This parameter can only be set at server start.

#### `pgpro_multiplan.auto_capturing` (boolean)

Enables the automatic query capture in `pgpro_multiplan`. Setting this configuration parameter to `On` allows you to see the queries with constants in the text form as well as parameterized queries in the [pgpro\\_multiplan\\_captured\\_queries](#) view. Also, all plans for each query are shown. Information about executed queries is stored until the server restart. The default value is `Off`. Only superusers can change this setting.

#### `pgpro_multiplan.max_captured_items` (integer)

Sets the maximum number of queries `pgpro_multiplan` can capture. The default value is 1000. This parameter can only be set at server start.

#### `pgpro_multiplan.sandbox` (boolean)

Enables reserving a separate area in shared memory to be used by a primary or standby node, which allows testing and analyzing queries with the existing data set without affecting the node operation. If set to `On` on the standby, `pgpro_multiplan` freezes plans only on this node and stores them in the “sandbox”, an alternative plan storage. If enabled on the primary, the extension uses the separate shared memory area that is not replicated to the standby. Changing the parameter value resets the `pgpro_multiplan` cache. The default value is `Off`. Only superusers can change this setting.

#### `pgpro_multiplan.wildcards` (string)

A POSIX regular expression used for `template` plans to check matching of table names referenced in queries. The `pgpro_multiplan.wildcards` value is frozen along with the corresponding query. The default value is `.*` that means matching for any table name.

#### `pgpro_multiplan.aqe_max_items` (integer)

Sets the maximum number of stored [individual AQE trigger values](#). The default value is 100. This parameter can only be set at server start.

#### `pgpro_multiplan.aqe_max_stats` (integer)

Sets the maximum number of collected [AQE statistics values](#). Further statistics are discarded. The default value is 5000. This parameter can only be set at server start.

#### `pgpro_multiplan.global_prepared_statements` (boolean)

Enables storing and sharing [global prepared statements](#) for multiple sessions within the current server. The default value is `Off`. Only superusers can change this setting.

#### `pgpro_multiplan.global_prepared_statements_allow_duplicate` (boolean)

Enables creation of identical global prepared statements without raising errors. The default value is `Off`. Only superusers can change this setting.

## G.4. `pgpro_planner` — additional query transformations and optimizations

### G.4.1. Description

The `pgpro_planner` extension provides query transformations and optimizations that allow producing efficient query execution plans and improving performance.

These optimizations are the following:

- [transformation](#) of `x IN (VALUES (...), (...))` constructions into `x = ANY([...])` constructions
- [simplification](#) of `x + 0`, `x - 0`, `x * 1`, `x / 1`, and `x * 0` operations to `x`

- [caching](#) results of correlated subqueries using the `Memoize` nodes

By default, the extension is disabled to avoid implicit or unexpected query plan changes. You can enable it as described below. Each transformation can also be enabled or disabled separately using the corresponding [configuration parameters](#) to fit specific user needs.

## G.4.2. Installation

The `pgpro_planner` extension is provided with Postgres Pro Enterprise as a separate pre-built package `pgpro-planner-ent-17` (for the detailed installation instructions, see [Chapter 17](#)).

To enable `pgpro_planner`, do the following:

1. Load the extension in one of the following ways:

- globally for all sessions by adding the library name to the [shared\\_preload\\_libraries](#) variable in the `postgresql.conf` file

```
shared_preload_libraries = 'pgpro_planner'
```

- in the current session using the [LOAD](#) command without adding the library name to `shared_preload_libraries`

```
LOAD 'pgpro_planner';
```

2. Reload the database server for the changes to take effect.

To verify that the `pgpro_planner` library is installed correctly, you can run the following command:

```
SHOW shared_preload_libraries;
```

3. Enable the extension by setting the [pgpro\\_planner.enable](#) parameter to `on`.

```
SET pgpro_planner.enable = 'on';
```

## G.4.3. Transformation of VALUES into ANY

Typically, the standard planner processes `x IN (VALUES (...), (...))` constructions in a suboptimal way. If subqueries contain these constructions, the planner can also rewrite them to the `JOIN` clauses to avoid repeated scans. This can lead to wrong optimization decisions and inefficient query execution plans.

The `pgpro_planner` extension can transform basic `x IN (VALUES (...), (...))` constructions into `x = ANY([...])` constructions. This transformation applies to the parse tree of a query before the planner starts to create a query execution plan.

`pgpro_planner` processes queries as follows:

1. Searches for `x IN (VALUES (...), (...))` constructions in subqueries.
2. [Tries](#) to extract all values from the `VALUES` expression.
3. Builds an array from the extracted values.
4. Creates the corresponding `x = ANY([...])` construction.
5. In the parse tree, replaces the initial subquery with the corresponding scalar array operation.

This transformation allows the planner to avoid excessive `JOIN` clauses and cardinality estimation errors. For `ANY([...])` constructions, the planner can also produce query plans with any access method and hash matching strategy that are most effective in each particular case.

You can disable this transformation by setting the [pgpro\\_planner.enable\\_values\\_transformation](#) parameter to `off`, for instance, if you do not use the `VALUES` expressions.

### G.4.3.1. VALUES Transformation Example

This example demonstrates how `pgpro_planner` transformation works for the following sample query:

```
EXPLAIN (COSTS FALSE) SELECT * FROM onek
WHERE unique1 IN (VALUES(1200), (1));
```

Without this transformation, the query execution plan looks as follows:

```
Nested Loop
-> Unique
 -> Sort
 Sort Key: "*"VALUES*".column1
 -> Values Scan on "*"VALUES*"
-> Index Scan using onek_unique1 on onek
 Index Cond: (unique1 = "*"VALUES*".column1)
(7 rows)
```

For the `VALUES` expression, the planner creates the corresponding temporary table and performs value comparisons using the `Nested Loop` and `Index Cond` nodes. These decisions lead to long query execution time.

When `pgpro_planner` transforms the `VALUES` expression, the resulting plan uses the more effective `Bitmap Heap Scan` node instead of `Nested Loop`, which reduces query execution time.

```
Bitmap Heap Scan on onek
Recheck Cond: (unique1 = ANY ('{1200,1}'::integer[]))
-> Bitmap Index Scan on onek_unique1
 Index Cond: (unique1 = ANY ('{1200,1}'::integer[]))
(4 rows)
```

### G.4.3.2. VALUES Transformation Limitations

`pgpro_planner` cannot transform the `VALUES` expression in the following cases:

- The expression contains volatile functions.
- The expression contains non-constant values, for instance, `VALUES (0), (unique1)`.
- The expression contains values of complex data types, for instance, `VALUES (1,1), (20,0)`.
- The expression contains `NULL` values.
- The expression contains the `LIMIT`, `OFFSET`, or `ORDER BY` clauses.
- The expression is used in a subquery nested within another subquery.
- There is no operator for the resulting `x = ANY([...])` variable and array.

### G.4.4. Simplification of Trivial Arithmetic Operations

Even for trivial arithmetic operations, such as `x + 0`, the standard planner predicts selectivity and cardinality as it does for expressions and cannot use indexes in query execution plans.

The `pgpro_planner` extension can simplify and rewrite the following basic arithmetic operations:

- `x + 0 → x`
- `x - 0 → x`
- `x * 1 → x`
- `x / 1 → x`
- `x * 0 → x` (only if `x` is not `NULL`)

This simplification allows the planner not only to avoid unnecessary calculations, but also to reduce estimation errors, produce plans with indexes and effective access methods, and thus significantly improve performance.

You can disable this simplification by setting the `pgpro_planner.enable_simplify_trivials` parameter to `Off`, for instance, for debugging purposes.

#### G.4.4.1. Arithmetic Simplification Example

This example demonstrates how `pgpro_planner` arithmetic simplification affects execution plans for the following query:

```
SELECT * FROM t WHERE x + 0 > 900;
```

For the initial arithmetic operation, the planner produces the query execution plan with `Seq Scan` and does not use an index.

```
Seq Scan on t (cost=0.00..20.00 rows=333 width=4) (actual time=0.500..0.571
 rows=100.00 loops=1)
 Filter: ((x + 0) > 900)
 Rows Removed by Filter: 900
 Buffers: shared hit=5
Planning:
 Buffers: shared hit=14
Planning Time: 0.432 ms
Execution Time: 0.627 ms
(8 rows)
```

When `pgpro_planner` simplifies this operation, the planner creates the plan with `Index Only Scan` and performs value comparisons in `Index Cond`, which helps to reduce query execution time.

```
Index Only Scan using idx_t_x on t (cost=0.28..10.03 rows=100 width=4) (actual
 time=0.077..0.247 rows=100.00 loops=1)
 Index Cond: (x > 900)
 Heap Fetches: 100
 Index Searches: 1
 Buffers: shared hit=4
Planning Time: 0.217 ms
Execution Time: 0.319 ms
(7 rows)
```

#### G.4.4.2. Arithmetic Simplification Limitations

`pgpro_planner` has the following limitations for arithmetic simplification:

- Only the following operations are supported: `x + 0`, `x - 0`, `x * 1`, `x / 1`, and `x * 0` (if `x` is not `NULL`).
- Only the following data types for constants are supported: `int2`, `int4`, `float`, and `numeric`.
- Operations that use complex expressions to get `0` or `1`, such as `x - 100 - 100`, cannot be simplified.
- Operations that use volatile functions cannot be simplified.

#### G.4.5. Caching of Correlated Subqueries

Correlated subqueries use values from their outer queries, for instance, via the `WHERE` clause. These subqueries are executed once for each row of the outer query, so they can have major impact on performance.

The `pgpro_planner` extension can cache results of parameterized correlated subqueries by adding the `Memoize` nodes to query execution plans. This allows skipping identical scans for the same parameters and improving performance.

This functionality is enabled if the global [enable\\_memoize](#) configuration parameter and the [pgpro\\_planner.memoize\\_subplan](#) parameter of `pgpro_planner` are set to `on` (default).

`pgpro_planner` processes a query during the plan creation stage. It performs the following steps:

1. `pgpro_planner` searches for [supported](#) correlated subqueries.
2. If the [pgpro\\_planner.memoize\\_check\\_uniqueness](#) parameter is set to `on` (default), `pgpro_planner` checks uniqueness for values of columns referenced in subqueries based on statistical information. This helps to determine whether the `Memoize` node can be useful.

The `Memoize` node can be added in the following cases:

- A unique index on a column does not exist, and column values are not unique according to statistical information.
- A unique index on a column exists but a column contains `NULL` values according to statistical information.

- A multicolumn unique index exists but values of the referenced column are not unique according to statistical information.
  - Statistical information for a column is not gathered yet regardless of whether an index exists.
3. `pgpro_planner` estimates the expected cost of the resulting plan with the `Memoize` node.
  4. If the estimated cost is lower than the cost of the initial plan, `pgpro_planner` adds the `Memoize` node into the head of the corresponding subplan.

You can disable caching of correlated subqueries by setting the `pgpro_planner.memoize_subplan` parameter to `Off`, for instance, if you use correlated subqueries rarely. To disable uniqueness check for debugging purposes, set the `pgpro_planner.memoize_check_uniqueness` parameter to `Off`.

### G.4.5.1. Subquery Caching Example

This example demonstrates how caching of correlated subqueries works in different cases.

Create two sample tables named `t` and `t1` and a unique index on the `x` column of the first table.

```
CREATE TABLE t (x int, y int);
INSERT INTO t SELECT id, id%20 FROM generate_series(1,1000) id;
CREATE UNIQUE INDEX t_x_idx ON t (x);
CREATE TABLE t1 (x1 int);
INSERT INTO t1 SELECT id%2 FROM generate_series(1,1000) id;
```

Run the following query, where the subquery uses values of the correlated column named `y`. There is no unique index on this column, so the `Memoize` node is added to the query execution plan.

```
EXPLAIN (COSTS OFF)
SELECT x FROM t WHERE (t.x,t.y) = (SELECT sum(x1),1 FROM t1 WHERE x1 = t.y LIMIT 1);
 QUERY PLAN

Seq Scan on t
 Filter: (SubPlan 1)
 SubPlan 1
 -> Memoize
 Cache Key: t.y
 Cache Mode: binary
 -> Limit
 -> Aggregate
 -> Seq Scan on t1
 Filter: (x1 = t.y)

(10 rows)
```

Run another query, where the subquery uses values of the correlated column named `x`. The unique index on this column exists but statistical information is not gathered yet, so the `Memoize` node is generated.

```
EXPLAIN (COSTS OFF)
SELECT x FROM t WHERE (t.x,t.y) = (SELECT sum(x1),1 FROM t1 WHERE x1 = t.x LIMIT 1);
 QUERY PLAN

Seq Scan on t
 Filter: (SubPlan 1)
 SubPlan 1
 -> Memoize
 Cache Key: t.x
 Cache Mode: binary
 -> Limit
 -> Aggregate
 -> Seq Scan on t1
 Filter: (x1 = t.x)

(10 rows)
```

Execute the same query once again. Statistical information for the x column is now gathered, and the unique index still exists, so the Memoize node is not added to the plan.

```
EXPLAIN (COSTS OFF)
SELECT x FROM t WHERE (t.x,t.y) = (SELECT sum(x1),1 FROM t1 WHERE x1 = t.x LIMIT 1);
 QUERY PLAN

Seq Scan on t
 Filter: (x = (SubPlan 1))
 SubPlan 1
 -> Limit
 -> Aggregate
 -> Seq Scan on t1
 Filter: (x1 = t.x)

(7 rows)
```

Remove the previously created index and create a new multicolumn index on both columns named x and y.

```
CREATE UNIQUE INDEX on t(x,y);
DROP INDEX t_x_idx;
```

Run the query referencing the correlated y column. Although the multicolumn unique index now exists, values of this column are not unique according to statistical information. The Memoize node is added to the resulting plan.

```
EXPLAIN (COSTS OFF)
SELECT x FROM t WHERE (t.x,t.y) = (SELECT sum(x1),1 FROM t1 WHERE x1 = t.y LIMIT 1);
 QUERY PLAN

Seq Scan on t
 Filter: (((x = (SubPlan 1).col1) AND (y = (SubPlan 1).col2)))
 SubPlan 1
 -> Memoize
 Cache Key: t.y
 Cache Mode: binary
 -> Limit
 -> Aggregate
 -> Seq Scan on t1
 Filter: (x1 = t.y)

(10 rows)
```

Run the query referencing the correlated x column. For this case, the Memoize node is not still generated, since values of this column are unique according to statistical information.

```
EXPLAIN (COSTS OFF)
SELECT x FROM t WHERE (t.x,t.y) = (SELECT sum(x1),1 FROM t1 WHERE x1 = t.x LIMIT 1);
 QUERY PLAN

Seq Scan on t
 Filter: (((x = (SubPlan 1).col1) AND (y = (SubPlan 1).col2)))
 SubPlan 1
 -> Limit
 -> Aggregate
 -> Seq Scan on t1
 Filter: (x1 = t.x)

(7 rows)
```

#### G.4.5.2. Subquery Caching Limitations

pgpro\_planner cannot cache results of a correlated subquery in the following cases:

- A subquery uses volatile functions.

- A subquery uses non-standard operators.
- A subquery uses operands with different types without compatible hash operator classes.
- A subquery uses the `min` or `max` aggregate functions.
- A query plan tree does not contain the corresponding subplan node.
- The estimated cost of the target query plan with the `Memoize` nodes is greater than the cost of the initial plan.

## G.4.6. Configuration Parameters

`pgpro_planner.enable` (boolean)

Enables or disables the `pgpro_planner` extension. The default value is `off` to avoid implicit or unexpected query plan changes.

`pgpro_planner.enable_values_transformation` (boolean)

Enables or disables [transformation](#) of `x IN (VALUES (...), (...))` constructions into `x = ANY([...])` constructions. The default value is `on`.

`pgpro_planner.enable_simplify_trivials` (boolean)

Enables or disables [simplification of trivial arithmetic operations](#). The default value is `on`.

`pgpro_planner.memoize_subplan` (boolean)

Enables or disables [caching of correlated subqueries](#). The default value is `on`.

`pgpro_planner.memoize_check_uniqueness` (boolean)

Enables or disables the smart logic to check uniqueness of column values for [caching of correlated subqueries](#). The default value is `on`.

`pgpro_planner.force_memoize_subplan` (boolean)

Enables or disables automatic addition of the `Memoize` node for all correlated subqueries ignoring the plan cost model and uniqueness check. This parameter is designed only for debugging purposes, do not use it in production. The default value is `off`.

## G.5. pgpro\_pwr — workload reports

The `pgpro_pwr` module is designed to discover most resource-intensive activities in your database. (PWR, pronounced like "power", is an abbreviation of Postgres Pro Workload Reporting.) This extension is based on Postgres Pro's [Statistics Collector](#) views and the [pgpro\\_stats](#) or [pg\\_stat\\_statements](#) extension.

### Note

Although `pgpro_pwr` can work with the `pg_stat_statements` extension, it is recommended that you use the `pgpro_stats` extension since it provides statement plans, wait events sampling and load distribution statistics for databases, roles, client hosts and applications.

Below, use of `pgpro_stats` is assumed unless otherwise noted.

If you cannot use `pgpro_stats` for an observed database, but the [pg\\_stat\\_kcache](#) extension is available, `pgpro_pwr` can process `pg_stat_kcache` data, which also provides information about CPU resource usage of statements and filesystem load (*rusage*).

`pgpro_pwr` can obtain summary wait statistics from the [pg\\_wait\\_sampling](#) extension. When `pg_wait_sampling` is in use, `pgpro_pwr` will reset the wait sampling profile on every sample.

`pgpro_pwr` is based on cumulative statistics sampling. Each sample contains statistic increments for most active objects and queries since the time when the previous sample was taken, or more concisely, *since the previous sample*. This data is later used to generate reports.

`pgpro_pwr` provides functions to collect samples. Regular sampling allows building a report on the database workload in the past.

`pgpro_pwr` allows you to take explicit samples during batch processing, load testing, etc.

Any time a sample is taken, `pgpro_stats_statements_reset()` (see [pgpro\\_stats](#) for the function description) is called to ensure that statement statistics will not be lost when the statements count exceed `pgpro_stats.max` (see [Section G.7.7.1](#)). The report will also contain a section informing you of whether the count of captured statements in any sample reaches 90% of `pgpro_stats.max`.

`pgpro_pwr` installed on one Postgres Pro server can also collect statistics from other servers. This feature is useful for gathering workload statistics from hot standbys on the primary server. To benefit from it, make sure that all server names and connection strings are specified and that the `pgpro_pwr` server can connect to all databases on all servers.

### G.5.1. `pgpro_pwr` Architecture

The extension consists of the following parts:

- *Historical repository* is a storage for sampling data. The repository is a set of extension tables.

#### Note

Among the rest, `pgpro_pwr` tables store query texts, which can contain sensitive information. So, for security reasons, restrict access to the repository as appropriate.

- *Sample management engine* comprises functions used to [take samples](#) and maintain the repository by removing obsolete sample data.
- *Report engine* comprises functions for [generating reports](#) based on data from the historical repository.
- *Administrative functions* allow you to create and manage [servers](#) and [baselines](#).

### G.5.2. Prerequisites

The prerequisites assume that `pgpro_pwr`, which is usually installed in a *target* cluster, i.e., the cluster that you will mainly track the workload for, the extension can also collect performance data from other clusters.

#### G.5.2.1. For the `pgpro_pwr` Database

The `pgpro_pwr` extension depends on [PL/pgSQL](#) and the [dblink](#) extension.

#### G.5.2.2. For the Target Server

The target server must allow connections to all databases from the server where `pgpro_pwr` is running. To connect to the target server, provide a connection string where a particular database on this server is specified. This database is of high importance for `pgpro_pwr` since the functionality of the [pgpro\\_stats](#) or [pg\\_stat\\_statements](#) extensions will be provided through this database. Note, however, that `pgpro_pwr` will also connect to all the other databases on this server.

Optionally, for completeness of gathered statistics:

- If statement statistics are needed in reports, [pgpro\\_stats](#) must be installed and configured in the aforementioned database. The following settings may affect the completeness and accuracy of gathered statistics:

- `pgpro_stats.max`

Low setting of this parameter may cause some statement statistics to be wiped out before the sample is taken. A report will warn you if the value of `pgpro_stats.max` seems undersized.

- `pgpro_stats.track`

Avoid changing the default value of 'top' (note that the value of 'all' will affect the accuracy of %Total fields for statements-related sections of a report).

- Set the parameters of the Postgres Pro's [Statistics Collector](#) as follows:

```
track_activities = on
```

```
track_counts = on
track_io_timing = on
track_wal_io_timing = on # Since PostgreSQL 14
track_functions = all/pl
```

### G.5.3. Installation and Setup

pgpro\_pwr is provided with Postgres Pro Enterprise as a separate pre-built package `pgpro-pwr-ent-17` (for the detailed installation instructions, see [Chapter 17](#)).

#### Note

pgpro\_pwr creates a bunch of database objects, so installation in a dedicated schema is recommended.

Although the use of pgpro\_pwr with superuser privileges does not have any issues, superuser privileges are not necessary. So you can choose one of the following setup procedures depending on your configuration and security requirements or customize them to meet your needs:

#### G.5.3.1. Simple Setup

Use this setup procedure when pgpro\_pwr is to be installed on the target cluster to only track its workload as superuser.

Create a schema for the pgpro\_pwr installation and create the extension:

```
CREATE SCHEMA profile;
CREATE EXTENSION pgpro_pwr SCHEMA profile;
```

#### G.5.3.2. Complex Setup

Use this setup procedure when you intend to use pgpro\_pwr for tracking workload on one or more servers and need to follow the principle of least privilege.

##### G.5.3.2.1. In the Target Server Database

Create a user for pgpro\_pwr on the target server:

```
CREATE USER pwr_collector PASSWORD 'collector_pwd';
```

Make sure this user has permissions to connect to any database in the target cluster (by default, it is true) and that `pg_hba.conf` permits such a connection from the pgpro\_pwr database host. Also, grant `pwr_collector` with membership in the `pg_read_all_stats` role and the `EXECUTE` privilege on the following functions:

```
GRANT pg_read_all_stats TO pwr_collector;
GRANT EXECUTE ON FUNCTION pgpro_stats_statements_reset TO pwr_collector;
GRANT EXECUTE ON FUNCTION pgpro_stats_totals_reset(text,bigint) TO pwr_collector;
```

Also ensure the `SELECT` privilege on the `pgpro_stats_archiver` view:

```
GRANT SELECT ON pgpro_stats_archiver TO pwr_collector;
```

##### G.5.3.2.2. In the pgpro\_pwr Database

Create an unprivileged user:

```
CREATE USER pwr_user;
```

This user will be the owner of the extension schema and will collect samples.

Create a schema for the pgpro\_pwr installation:

```
CREATE SCHEMA profile AUTHORIZATION pwr_user;
```

Grant the `USAGE` privilege on the schema where the `dblink` extension resides:

```
GRANT USAGE ON SCHEMA public TO pwr_user;
```

Create the extension using `pwr_user` account:

```
\c - pwr_user
CREATE EXTENSION pgpro_pwr SCHEMA profile;
```

Define the connection parameters of the target server for `pgpro_pwr`. For example:

```
SELECT profile.create_server('target_server_name', 'host=192.168.1.100 dbname=postgres
port=5432');
```

The connection string provided will be used in the `dblink_connect()` call while executing the `take_sample()` function.

### Note

Connection strings are stored in a `pgpro_pwr` table in clear-text form. Make sure no other database users can access tables of the `pgpro_pwr` extension.

## G.5.3.3. Setting Up `pgpro_pwr` Roles

Up to three roles can be distinguished when `pgpro_pwr` is in operation:

- The *`pgpro_pwr` owner* role is the owner of the `pgpro_pwr` extension.
- The *collecting role* is used by `pgpro_pwr` to connect to databases and collect statistics.
- The *reporting role* is used to generate reports.

If all the actions with `pgpro_pwr` are performed by the superuser role `postgres`, you can skip most of the setup explained below.

### G.5.3.3.1. The `pgpro_pwr` Owner

This role can be used to perform all actions related to `pgpro_pwr`. This role will have access to server connection strings, which may contain passwords. You should use this role to call the `take_sample()` function. The `dblink` extension is needed for this user.

Consider an example assuming each extension in its own schema:

```
\c postgres postgres
CREATE SCHEMA dblink;
CREATE EXTENSION dblink SCHEMA dblink;
CREATE USER pwr_usr with password 'pwr_pwd';
GRANT USAGE ON SCHEMA dblink TO pwr_usr;
CREATE SCHEMA profile AUTHORIZATION pwr_usr;
\c postgres pwr_usr
CREATE EXTENSION pgpro_pwr SCHEMA profile;
```

### G.5.3.3.2. The Collecting Role

This role should be used by `pgpro_pwr` to connect to databases and collect statistics. Unprivileged users cannot open connections using `dblink` without a password, so you need to provide the password in the connection string for each server. This role should have access to all supported statistics extensions. It should also be able to perform a reset of statistics extensions.

Consider an example. If you use `pgpro_stats` to collect statistics, set up the collecting role as follows:

```
\c postgres postgres
CREATE SCHEMA pgps;
CREATE EXTENSION pgpro_stats SCHEMA pgps;
CREATE USER pwr_collector with password 'collector_pwd';
GRANT pg_read_all_stats TO pwr_collector;
GRANT USAGE ON SCHEMA pgps TO pwr_collector;
```

```
GRANT EXECUTE ON FUNCTION pgps.pgpro_stats_statements_reset TO pwr_collector;
```

If you use [pg\\_stat\\_statements](#) to collect statistics, set up the collecting role as follows:

```
\c postgres postgres
CREATE SCHEMA pgss;
CREATE SCHEMA pgsk;
CREATE SCHEMA pgws;
CREATE EXTENSION pg_stat_statements SCHEMA pgss;
CREATE EXTENSION pg_stat_kcache SCHEMA pgsk;
CREATE EXTENSION pg_wait_sampling SCHEMA pgws;
CREATE USER pwr_collector with password 'collector_pwd';
GRANT pg_read_all_stats TO pwr_collector;
GRANT USAGE ON SCHEMA pgss TO pwr_collector;
GRANT USAGE ON SCHEMA pgsk TO pwr_collector;
GRANT USAGE ON SCHEMA pgws TO pwr_collector;
GRANT EXECUTE ON FUNCTION pgss.pg_stat_statements_reset TO pwr_collector;
GRANT EXECUTE ON FUNCTION pgsk.pg_stat_kcache_reset TO pwr_collector;
GRANT EXECUTE ON FUNCTION pgws.pg_wait_sampling_reset_profile TO pwr_collector;
```

Now you should set up a connection string pointing to the database with statistics extensions installed:

```
\c postgres pwr_usr
SELECT profile.set_server_connstr('local','dbname=postgres port=5432 host=localhost
user=pwr_collector password=collector_pwd');
```

Password authentication must be configured in the `pg_hba.conf` file for the `pwr_collector` user.

Obviously, the collecting role should be properly configured on all servers observed by `pgpro_pwr`.

Now you should be able to call [take\\_sample\(\)](#) using the `pwr_usr` role:

```
\c postgres pwr_usr
SELECT * FROM take_sample();
```

And now it's time to configure the scheduler (in our example, the `crontab` command of the `postgres` user):

```
*/30 * * * * psql -U pwr_usr -d postgres -c 'SELECT profile.take_sample()' > /dev/
null 2>&1
```

Note that you can use the Postgres Pro password file to store passwords.

#### G.5.3.3.3. The Reporting Role

Any user can build a `pgpro_pwr` report. The minimal privileges needed to generate `pgpro_pwr` reports are granted to the `public` role. However a full report, with query texts, is only available to the member of the `pg_read_all_stats` role. Anyway, the reporting role cannot access server connection strings, so it cannot get the passwords of servers.

#### G.5.3.3.4. Setting Extension Parameters

In `postgresql.conf`, you can define the following `pgpro_pwr` parameters:

`pgpro_pwr.max` (integer)

Number of top objects (statements, relations, etc.) to be reported in each sorted report table. This parameter affects the size of a sample: the more objects you want to appear in your report, the more objects we need to keep in a sample. The maximum value is 100. Any larger value is lowered to 100.

The default value is 20.

`pgpro_pwr.max_sample_age` (integer)

Retention time of the sample, in days. Samples aged `pgpro_pwr.max_sample_age` days and older are automatically deleted on the next [take\\_sample\(\)](#) call.

The default value is 7 days.

#### `pgpro_pwr.max_query_length` (integer)

Maximum query length allowed in reports. All queries in a report will be truncated to `pgpro_pwr.max_query_length` characters.

The default value is 20 000 characters.

#### `pgpro_pwr.track_sample_timings` (boolean)

Enables collecting detailed timing statistics of `pgpro_pwr`'s own sampling procedures. Set this parameter to diagnose why sampling functions run slowly. Collected timing statistics will be available in the [v\\_sample\\_timings](#) view.

The default value is `off`.

#### `pgpro_pwr.statements_reset` (boolean)

Controls the `pgpro_stats/pg_stat_statements` statistics reset during taking a sample. Allows you not to reset the statistics during taking a sample due to new techniques employed. When disabled, `pgpro_pwr` will track statement evictions using the value of the `calls` field. However this method does not completely prevent statistics loss. `pg_stat_statements` v1.11 and `pgpro_stats` v1.8 contain time tracking abilities that can reduce the possible data loss. When this setting is disabled, you can temporarily enable it in a session if you want to sometimes perform a reset of `pgpro_stats/pg_stat_statements`.

The default value is `on`.

#### `pgpro_pwr.relsizes_collect_mode` (text)

Defines the mode of collecting relation sizes. Possible values:

- `off` — collection of relation sizes is based on [pg\\_class](#). Although the relation sizes collected this way are rough, their collection consumes almost no resources.
- `on` — accurate relation sizes are collected for each sample using the [pg\\_relation\\_size\(\)](#) function, which requires a lock on the table and is pretty resource intensive.
- `schedule` — accurate relation sizes are collected in the size-collection window, defined for each server.

The default value is `off`.

## G.5.4. Managing Servers

Once installed, `pgpro_pwr` creates one enabled `local` server for the current cluster. If a server is *enabled*, `pgpro_pwr` includes it in sampling when no server is explicitly specified (see [take\\_sample\(\)](#) for details). A server that is not enabled is referred to as *disabled*.

The default connection string for a local node contains only `dbname` and `port` parameters. The values of these parameters are taken from the connection used to create the extension. You can change the server connection string using the [set\\_server\\_connstr\(\)](#) function when needed.

### G.5.4.1. Server Management Functions

Use the following `pgpro_pwr` functions for server management:

```
create_server(server name, connstr text, enabled boolean DEFAULT TRUE, max_sample_age integer DEFAULT NULL description text DEFAULT NULL)
```

Creates a server definition.

Arguments:

- *server* — server name. Must be unique.
- *connstr* — connection string. Must contain all the necessary settings to connect from `pgpro_pwr` server to the target server database.
- *enabled* — set to include the server in sampling by the [take\\_sample\(\)](#) function without arguments.

- *max\_sample\_age* — retention time of the sample. Overrides the global `pgpro_pwr.max_sample_age` setting for this server.
- *description* — server description text, to be included in reports.

Here is an example of how to create a server definition:

```
SELECT profile.create_server('omega','host=192.168.1.100 dbname=postgres
port=5432');
```

`drop_server(server name)`

Drops a server and all its samples.

`set_server_description(server name description text)`

Sets a new server description.

`set_server_subsampling(server name, subsample_enabled boolean, min_query_duration interval, min_xact_duration interval, min_xact_age integer, min_idle_xact_dur interval hour to second)`

Defines subsample settings for a server.

Arguments:

- *server* — server name.
- *subsample\_enabled* — defines whether subsampling is enabled for the server, that is, whether `take_subsample()` function should actually take a subsample.
- *min\_query\_duration* — the query duration threshold.
- *min\_xact\_duration* — the transaction duration threshold.
- *min\_xact\_age* — the transaction age threshold.
- *min\_idle\_xact\_dur\_age* — the idle transaction threshold.

`enable_server(server name)`

Includes a server in sampling by the `take_sample()` function without arguments.

`disable_server(server name)`

Excludes a server from sampling by the `take_sample()` function without arguments.

`rename_server(server name, new_name name)`

Renames a server.

`set_server_max_sample_age(server name, max_sample_age integer)`

Sets the retention period for a server (in days). To reset the server retention, set the value of *max\_sample\_age* to `NULL`.

`set_server_db_exclude(server name, exclude_db name[])`

Excludes a list of databases on a server from sampling. Use when `pgpro_pwr` is unable to connect to some databases in a cluster (for example, in Amazon RDS instances).

`set_server_connstr(server name, server_connstr text)`

Sets the connection string for a server.

`set_server_setting(server name, setting text, value jsonb)`

Fine-tunes settings of the server statistics collection. `collect*` settings control which statistics should be collected, and *value* for these settings accepts boolean values, with the default equal to `true`. Available settings:

- `collect_pg_stat_statement` — collect statement statistics using `pg_stat_statements` and `pg_stat_kcache` extensions.
- `collect_pg_wait_sampling` — collect wait event statistics using the `pg_wait_sampling` extension.
- `collect_objects` — collect all the schema object statistics, that is, tables, indexes, and functions, from `pg_stat_*` views.
- `collect_relations` — collect statistics on tables and indexes from `pg_stat_*` views.
- `collect_functions` — collect statistics on user functions from the `pg_stat_user_functions` view.
- `collect_vacuum_stats` — collect the extended vacuum statistics.

`show_server_settings(server name)`

Returns the statistics collection settings for the specified server.

`show_servers()`

Displays the list of configured servers.

## G.5.5. Managing Samples

A *sample* contains the database workload statistics since the previous sample

### G.5.5.1. Sampling Functions

The following `pgpro_pwr` functions relate to sampling:

`take_sample()`

`take_sample(server name [, skip_sizes boolean])`

Takes samples.

If the parameter is omitted, the function takes a sample on each enabled server. Servers are accessed for sampling sequentially, one by one. The function returns a table with the following columns:

- `server` — server name.
- `result` — result of taking the sample. Can be `OK` if the sample was taken successfully or contain the error trace text in case of exception.
- `elapsed` — time elapsed while the sample was taken.

If called with the parameter, the function takes a sample on the specified server even if this server is disabled. Use when you need different sampling frequencies on specific servers. Returns `0` on success.

Arguments:

- `server` — server name.
- `skip_sizes` — if omitted or set to null, the size-collection policy applies; if `false`, relation sizes are collected; if `true`, the collection of relation sizes is skipped.

`take_sample_subset([sets_cnt integer, current_set integer])`

Takes a sample on each server in a subset of servers. Use to take samples on servers in parallel if you have many enabled servers. Although PL/pgSQL does not support parallel execution, you can call this function in parallel sessions. This function returns the same type as `take_sample()`. If both parameters are omitted, the function behaves like the `take_sample()` function, i.e., it takes a sample on all enabled servers one by one.

Arguments:

- `sets_cnt` — number of subsets to divide all enabled servers into.
- `current_set` — number of the subset to collect samples for. Takes values from 0 through `sets_cnt - 1`. For the specified subset, samples are collected as usual, server by server.

If a reset of statistics since the previous sample was detected, `pgpro_pwr` treats corresponding absolute values as differentials; however, the accuracy will be affected anyway.

`show_samples([server name,] [days integer])`

Returns a table with information on server samples (local server is assumed if `server` is omitted) for the last `days` days (all existing samples are assumed if omitted). This table has the following columns:

- `sample` — sample identifier.
- `sample_time` — time when this sample was taken.
- `dbstats_reset` — NULL or the statistics reset timestamp of the `pg_stat_database` view if the statistics were reset since the previous sample.
- `clustats_reset` — NULL or the statistics reset timestamp of the `pg_stat_bgwriter` view if the statistics were reset since the previous sample.
- `archstats_reset` — NULL or the statistics reset timestamp of the `pg_stat_archiver` view if the statistics were reset since the previous sample.

Sampling functions also maintain the server repository by deleting obsolete samples and baselines according to the retention policy.

### G.5.5.2. Taking Samples

To take samples for all enabled servers, call the `take_sample()` function. Usually, one or two samples per hour is sufficient. You can use a cron-like tool to schedule sampling. Here is an example for a 30-minute sampling period:

```
*/30 * * * * psql -c 'SELECT profile.take_sample()' &> /dev/null
```

However, the results of such a call are not checked for errors. In a production environment, function results can be used for monitoring. This function returns OK for all servers with successfully taken samples and shows error text for failed servers:

```
SELECT * FROM take_sample();
 server |
 | elapsed
-----+-----
+-----+-----
ok_node | OK
 | 00:00:00.48
fail_node | could not establish connection
+| 00:00:00
 | SQL statement "SELECT dblink_connect('server_connection',server_connstr)"
+|
 | PL/pgSQL function take_sample(integer) line 69 at PERFORM
+|
 | PL/pgSQL function take_sample_subset(integer,integer) line 27 at
assignment+|
 | SQL function "take_sample" statement 1
+|
 | FATAL: database "postgresno" does not exist
 |
(2 rows)
```

### G.5.5.3. Sample Retention Policy

You can define sample retention at the following levels:

#### 1. Global

The value of the `pgpro_pwr.max_sample_age` parameter in the `postgresql.conf` file defines a common retention setting, which is effective if none of other related settings are defined.

#### 2. Server

Specifying the `max_sample_age` parameter while creating a server or calling the `set_server_max_sample_age(server, max_sample_age)` function for an existing server defines the retention for the server. A server retention setting overrides `pgpro_pwr.max_sample_age` for a specific server.

### 3. Baseline

A [baseline](#) created overrides all the other retention periods for included samples.

## G.5.6. Managing the Collection of Relation Sizes

It may take considerable time to collect sizes of all relations in a database by Postgres Pro relation-size functions. Besides, those functions require `AccessExclusiveLock` on a relation. However, it may be sufficient for you to collect relation sizes on a daily basis. `pgpro_pwr` allows you to skip collecting relation sizes by defining the *size-collection policy* for servers. The policy defines:

- A daily window when the collection of relation sizes is permitted.
- A minimum gap between two samples with relation sizes collected.

When the size-collection policy is defined, sampling functions collect relation sizes only when the sample is taken in the defined window and the previous sample with sizes is older than the gap. The following function defines this policy:

`set_server_size_sampling(server name, window_start time with time zone DEFAULT NULL, window_duration interval hour to second DEFAULT NULL, sample_interval interval day to minute DEFAULT NULL, collect_mode text DEFAULT NULL)`

Defines the size-collection policy for a server.

Arguments:

- `server` — server name.
- `window_start` — start time of the size-collection window.
- `window_duration` — duration of the size-collection window.
- `sample_interval` — minimum time gap between two samples with relation sizes collected.
- `collect_mode` — when set to `off`, which is the default for new installations, relation sizes are collected from [pg\\_class](#), when set to `on`, relation sizes are collected using the [pg\\_relation\\_size\(\)](#) function, when set to `schedule`, `pgpro_pwr` collects the relation size in the size-collection window. This parameter overrides the [relsize\\_collect\\_mode](#) extension parameter. Upgrading from a previous version sets the value of this parameter to `on` or `schedule`, so the previous behavior does not change.

### Note

When you build a report between samples either of which lacks relation-size data, relation-growth sections will be based on [pg\\_class.relpages](#) data. However, you can expand the report interval bounds to the nearest samples with relation sizes collected using the *with\_growth* parameter of [report generation functions](#); this makes the growth data more accurate.

Relation sizes are needed to calculate sequentially scanned volume for tables and explicit vacuum load for indexes.

Example:

```
SELECT set_server_size_sampling('local', '23:00+03', interval '2 hour', interval '8 hour',
'schedule');
```

The `show_servers_size_sampling` function shows size collection policies for all servers:

```
postgres=# SELECT * FROM show_servers_size_sampling();
 server_name | window_start | window_end | window_duration | sample_interval |
limited_collection
-----+-----+-----+-----+-----+-----
+-----+-----+-----+-----+-----+-----
```

local | 23:00:00+03 | 01:00:00+03 | 02:00:00 | 08:00:00 | t

## G.5.7. Managing Subsamples

Some performance-related data available in Postgres Pro is not cumulative. For example, the most often used data about session states is available through the [pg\\_stat\\_activity](#) view and can only be obtained with frequent samples. However, the [take\\_sample\(\)](#) function is heavy and can take considerable amount of time. So it is not suitable for collecting session state data.

The *subsample* feature provides a new fast `take_subsample()` function. It can be used to collect relatively fast changing data. Every subsample is bound to the next regular sample and is deleted by the retention policy together with it.

The subsample feature can be used to capture the most interesting session states:

- Long running queries
- Long transactions
- Aged transactions, that is, those that hold a snapshot behind a lot of other transactions
- Transactions being in an idle state for a long time

### G.5.7.1. Subsampling Functions

The following `pgpro_pwr` functions relate to subsampling:

`take_subsample()`  
`take_subsample(server name)`

If the parameter is omitted, the function takes a subsample on each *enabled* server with subsampling enabled (see [set\\_server\\_subsampling](#) for details). Server subsamples are taken sequentially, one by one. The function returns a table with the following columns:

- `server` — server name.
- `result` — result of taking the subsample. Can be `OK` if the subsample was taken successfully or contain the error text in case of exception.
- `elapsed` — time elapsed while the subsample was taken.

This tabular return format makes it easy to control subsample creation using an SQL query.

If called with the parameter, the function takes a subsample for the specified server. Use when you need different subsampling frequencies on servers or if you want to take an explicit subsample on a specific server.

Arguments:

- `server` — server name.

#### Note

Trying to take a subsample during taking a sample fails.

`take_subsample_subset([sets_cnt integer], [current_set integer])`

Takes subsamples for a subset of enabled servers with subsampling enabled. Although subsamples should be fast enough for serial processing, subsamples can be taken in parallel, like regular samples. This function returns the same type as `take_subsample()`. If both parameters are omitted, the function behaves like the `take_subsample()` function.

Arguments:

- `sets_cnt` — number of server subsets.
- `current_set` — the subset to process. Takes values from 0 through `sets_cnt - 1`. For the specified subset, subsamples are collected as usual, server by server.

### G.5.7.2. Configuring the Subsample Feature

The following settings affect the subsample behaviour:

- `pgpro_pwr.subsample_enabled` — defines whether the `take_subsample()` function should actually take a subsample.
- `pgpro_pwr.min_query_duration` — the long running query threshold.
- `pgpro_pwr.min_xact_duration` — the long transaction threshold.
- `pgpro_pwr.min_xact_age` — the transaction age threshold.
- `pgpro_pwr.min_idle_xact_dur_age` — the idle transaction threshold.

The subsample behavior can be defined at the server level using the `set_server_subsampling` function.

The last observed session state is saved in the repository when either of the following threshold-related events happens:

- During query execution, the difference between `now()` and the `query_start` exceeds the `pgpro_pwr.min_query_duration` threshold.
- During a transaction, the difference between `now()` and the `xact_start` exceeds the `pgpro_pwr.min_xact_duration` threshold.
- During a transaction, the `age(backend_xmin)` exceeds the `pgpro_pwr.min_xact_age` threshold.
- During a transaction in a state `idle in transaction` or `idle in transaction (aborted)`, the difference between `now()` and the `state_change` exceeds the `pgpro_pwr.min_idle_xact_duration` threshold.

See [Chapter 28](#) for details of the mentioned fields. Every subsample can hold at most `pgpro_pwr.max` entries for every threshold type.

### G.5.7.3. Scheduling Subsamples

Subsamples are fast enough to take them quite often. However usually you do not need more than 2-4 subsamples per minute. Obviously the subsample frequency depends on the shortest used duration of a threshold setting.

Cron only allows one call per minute, so some effort is needed to schedule more frequent subsamples. For example, the `\watch psql` command can be used:

```
echo "select take_subsample(); \watch 15" | psql &> /dev/null
```

The psql call can be wrapped in the systemd service like this:

```
Description=pgpro_pwr subsampling unit
[Unit]

[Service]
Type=simple
ExecStart=/bin/sh -c 'echo "select take_subsample(); \watch 15" | /path/to/psql -qo /dev/null'
User=postgres
Group=postgres

[Install]
WantedBy=multi-user.target
```

## G.5.8. Managing Baselines

A *baseline* is a named sequence of samples that has its own retention setting. A baseline can be used as a sample interval in report generation functions. An undefined baseline retention means infinite retention. Use baselines to save information about the database workload for a certain time interval.

### G.5.8.1. Baseline Management Functions

Use the following `pgpro_pwr` functions for baseline management:

```
create_baseline([server name,] baseline varchar(25), start_id integer, end_id integer [,
days integer])
create_baseline([server name,] baseline varchar(25), time_range tstzrange [, days integer])
```

Creates a baseline.

Arguments:

- *server* — server name. `local` sever is assumed if omitted.
- *baseline* — baseline name. Must be unique for a server.
- *start\_id* — identifier of the first sample in the baseline.
- *end\_id* — identifier of the last sample in the baseline.
- *time\_range* — time interval for the baseline. The baseline will include all samples for the minimal interval that covers *time\_range*.
- *days* — baseline retention time, defined in integer days since `now()`. Omit or set to null for infinite retention.

```
drop_baseline([server name,] baseline varchar(25))
```

Drops a baseline. For the meaning and usage details of function arguments, see [create\\_baseline](#). Dropping a baseline does not mean dropping all its samples immediately. The baseline retention just no longer applies to them.

```
keep_baseline([server name,] baseline varchar(25) [, days integer])
```

Changes the retention of a baseline. For the meaning and usage details of function arguments, see [create\\_baseline](#). Omit the *baseline* parameter or pass null to it to change the retention of all existing baselines.

```
show_baselines([server name])
```

Displays existing baselines. Call `show_baselines` to get information about the baselines, such as names, sampling intervals and retention periods. `local` sever is assumed if the *server* parameter is omitted.

## G.5.9. Data Export and Import

Collected samples can be exported from one instance of the `pgpro_pwr` extension and then loaded into another one. This feature helps you to move server data from one instance to another or to send collected data to your support team.

### G.5.9.1. Data Export

The [export\\_data](#) function exports data to a regular table. You can use any method available to export this table from your database. For example, you can use the `\copy` meta-command of [psql](#) to obtain a single CSV file:

```
postgres=# \copy (select * from export_data()) to 'export.csv'
```

### G.5.9.2. Data Import

Since data can only be imported from a local table, first, load the data you exported. Using the `\copy` meta-command again:

```
postgres=# CREATE TABLE import (section_id bigint, row_data json);
CREATE TABLE
postgres=# \copy import from 'export.csv'
COPY 6437
```

Now you can import the data by providing the `import` table to the [import\\_data](#) function:

```
postgres=# SELECT * FROM import_data('import');
```

After successful import, you can drop the `import` table.

#### Note

If server data is imported for the first time, your local `pgpro_pwr` servers with matching names will cause a conflict during import. To avoid this, you can temporarily rename such servers or you can specify the server name prefix for import

operations. However, during import of new data for already imported servers, they are matched by system identifiers, so feel free to rename imported servers. Also keep in mind that `pgpro_pwr` sets servers being imported to the *disabled* state for `take_sample()` to bypass them.

### G.5.9.3. Export and Import Functions

Use these functions to export or import data:

```
export_data([server name, [min_sample_id integer,] [max_sample_id integer,]] [, obfuscate_queries boolean] [, hide_connstr boolean])
```

Exports collected data.

Arguments:

- *server* — server name. All configured servers are assumed if omitted.
- *min\_sample\_id*, *max\_sample\_id* — sample identifiers to bound the export (inclusive). If *min\_sample\_id* is omitted or set to null, all samples until *max\_sample\_id* sample are exported; if *max\_sample\_id* is omitted or set to null, all samples since *min\_sample\_id* sample are exported.
- *obfuscate\_queries* — exports query texts as MD5 hash and excludes server connection strings from export. Pass this argument only when you want to hide query texts.
- *hide\_connstr* — excludes server connection strings from export.

```
import_data(data regclass [, server_name_prefix text])
```

Imports previously exported data. Returns the number of actually loaded rows in `pgpro_pwr` tables.

Arguments:

- *data* is the name of the table containing import data.
- *server\_name\_prefix* specifies the server name prefix for the import operation. It can be used to avoid name conflicts.

## G.5.10. Report Generation Functions

`pgpro_pwr` reports are generated in HTML format by reporting functions. The following types of reports are available:

- *Regular reports* provide statistics on the workload for an interval.
- *Differential reports* provide statistics on the same objects for two intervals. Corresponding values are located next to each other, which makes it easy to compare the workloads.

Reporting functions take sample identifiers, baselines or time ranges to determine the intervals. For time ranges, these are the minimal intervals that cover the ranges.

### G.5.10.1. Regular Reports

Use these functions to generate regular reports:

```
get_report([server name,] start_id integer, end_id integer [, description text [, with_growth boolean [, db_exclude name[]]])
get_report([server name,] time_range tstzrange [, description text [, with_growth boolean [, db_exclude name[]]])
get_report([server name,] baseline varchar(25) [, description text [, with_growth boolean [, db_exclude name[]]])
```

Generates a regular report defined by the arguments.

Arguments:

- *server* — server name. `local` server is assumed if omitted.

- *start\_id* — identifier of the interval starting sample.
- *end\_id* — identifier of the interval ending sample.
- *baseline* — baseline name.
- *time\_range* — time range.
- *description* — short text to be included in the report as its description.
- *with\_growth* — flag requesting interval expansion to the nearest bounds with data on relation growth available. The default value is `false`.
- *db\_exclude* — the database exclusion list. Lists databases to be excluded from all report tables having the `Database` column. Use to hide some databases in the report.

```
get_report_latest([server name,])
get_report_latest([server name [, db_exclude name[]]])
```

Generates a regular report for two latest samples.

Arguments:

- *server* — server name. `local` sever is assumed if omitted.
- *db\_exclude* — the database exclusion list. Lists databases to be excluded from all report tables having the `Database` column. Use to hide some databases in the report.

### G.5.10.2. Differential Reports

Use this function to generate differential reports:

```
get_diffreport([server name,] start1_id integer, end1_id integer, start2_id integer,
end2_id integer [, description text [, with_growth boolean [, db_exclude name[]]])
get_diffreport([server name,] time_range1 tstzrange, time_range2 tstzrange [, description
text [, with_growth boolean [, db_exclude name[]]])
get_diffreport([server name,] baseline1 varchar(25), baseline2 varchar(25) [, description
text [, with_growth boolean [, db_exclude name[]]])
get_diffreport([server name,] baseline1 varchar(25), time_range2 tstzrange [, description
text [, with_growth boolean[, db_exclude name[]]])
get_diffreport([server name,] time_range1 tstzrange, baseline2 varchar(25) [, description
text [, with_growth boolean[, db_exclude name[]]])
get_diffreport([server name,] start1_id integer, end1_id integer, baseline2 varchar(25)
[, description text [, with_growth boolean[, db_exclude name[]]])
get_diffreport([server name,] baseline1 varchar(25), start2_id integer, end2_id integer
[, description text [, with_growth boolean[, db_exclude name[]]])
```

Generates a differential report for two intervals. The combinations of arguments provide possible ways to specify the two intervals.

Arguments:

- *server* — server name. `local` sever is assumed if omitted.
- *start1\_id, end1\_id* — identifiers of the starting and ending samples for the first interval.
- *start2\_id, end2\_id* — identifiers of the starting and ending samples for the second interval.
- *baseline1* — baseline name for the first interval.
- *baseline2* — baseline name for the second interval.
- *time\_range1* — time range for the first interval.
- *time\_range2* — time range for the second interval.
- *description* — short text to be included in the report as its description.

- *with\_growth* — flag requesting interval expansion to the nearest bounds with data on relation growth available. The default value is `false`.
- *db\_exclude* — the database exclusion list. Lists databases to be excluded from all report tables having the Database column. Use to hide some databases in the report.

### G.5.10.3. Report Generation Example

Generate a report for the local server and interval defined by samples:

```
psql -Aqtc "SELECT profile.get_report(480,482)" -o report_480_482.html
```

For any other server, provide its name:

```
psql -Aqtc "SELECT profile.get_report('omega',12,14)" -o report_omega_12_14.html
```

Generate a report using time ranges:

```
psql -Aqtc "SELECT profile.get_report(tstzrange('2020-05-13 11:51:35+03', '2020-05-13 11:52:18+03'))" -o report_range.html
```

Generate a relative time-range report:

```
psql -Aqtc "SELECT profile.get_report(tstzrange(now() - interval '1 day',now()))" -o report_last_day.html
```

## G.5.11. pgpro\_pwr Report Sections

Each `pgpro_pwr` report is divided into sections, described below. The number of top objects reported in each sorted report table is specified by the `pgpro_pwr.max` parameter.

Almost every item in the report can be accentuated by a single mouse click. The accentuated item will be instantly highlighted in all report sections, making it easy to find. The attributes identifying the item will appear in the bottom-right corner of the page. For example, if you click on a database name in the “Database statistics” report table, you can notice a small table with the database attributes in the bottom-right corner of the page.

When you scroll down the report, its table of contents will be available on the right side of the page. It can be hidden with a single mouse click on the “content” tag.

A substring-based filter is also available that helps limit the report contents to particular objects based on a substring. Specifically, substring-based filtering is applied to query texts.

### G.5.11.1. Server statistics

Tables in this section of a `pgpro_pwr` report are described below.

The report table “Database statistics” provides per-database statistics for the report interval. The statistics are based on the `pg_stat_database` view. [Table G.11](#) lists columns of this report table.

**Table G.11. Database statistics**

| Column            | Description                                                                                                                                                                   | Field/Calculation              |
|-------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|--------------------------------|
| Database          | Database name                                                                                                                                                                 | <code>datname</code>           |
| Commits           | Number of committed transactions                                                                                                                                              | <code>xact_commit</code>       |
| Rollbacks         | Number of rolled back transactions                                                                                                                                            | <code>xact_rollback</code>     |
| Deadlocks         | Number of deadlocks detected                                                                                                                                                  | <code>deadlocks</code>         |
| Checksum Failures | Number of data page checksum failures detected in this database. This field is only shown if any checksum failures were detected in this database during the report interval. | <code>checksum_failures</code> |

| Column                    | Description                                                                                                                                                                                   | Field/Calculation                                    |
|---------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|------------------------------------------------------|
| Checksums Last            | Time at which the last data page checksum failure was detected in this database. This field is only shown if any checksum failures were detected in this database during the report interval. | checksum_last_failure                                |
| Hit%                      | Buffer cache hit ratio, i.e., percentage of pages fetched from buffers in all pages fetched                                                                                                   |                                                      |
| Read                      | Number of disk blocks read in this database                                                                                                                                                   | blks_read                                            |
| Hit                       | Number of times disk blocks were found already in the buffer cache                                                                                                                            | blks_hit                                             |
| Ret                       | Number of returned tuples                                                                                                                                                                     | tup_returned                                         |
| Fet                       | Number of fetched tuples                                                                                                                                                                      | tup_fetched                                          |
| Ins                       | Number of inserted tuples                                                                                                                                                                     | tup_inserted                                         |
| Upd                       | Number of updated tuples                                                                                                                                                                      | tup_updated                                          |
| Del                       | Number of deleted tuples                                                                                                                                                                      | tup_deleted                                          |
| Planned Parallel workers  | Number of parallel workers planned to be launched by queries on this database                                                                                                                 |                                                      |
| Launched Parallel workers | Number of parallel workers launched by queries on this database                                                                                                                               |                                                      |
| Temp Size                 | Total amount of data written to temporary files by queries in this database                                                                                                                   | temp_bytes                                           |
| Temp Files                | Number of temporary files created by queries in this database                                                                                                                                 | temp_files                                           |
| Size                      | Database size at the time of the last sample in the report interval                                                                                                                           | pg_database_size()                                   |
| Growth                    | Database growth during the report interval                                                                                                                                                    | pg_database_size() increment between interval bounds |

The report table “Cluster I/O statistics” provides I/O statistics by object types, backend types and contexts. This table is based on the `pg_stat_io` view of the [Cumulative Statistics System](#), available since Postgres Pro 16. [Table G.12](#) lists columns of this report table. Times are provided in seconds.

**Table G.12. Cluster I/O statistics**

| Column           | Description                                                                            |
|------------------|----------------------------------------------------------------------------------------|
| Object           | Target object of an I/O operation                                                      |
| Backend          | Type of the backend that performed an I/O operation                                    |
| Context          | The context of an I/O operation                                                        |
| Reads Count      | Number of read operations                                                              |
| Reads Bytes      | Amount of data read                                                                    |
| Reads Time       | Time spent in read operations                                                          |
| Writes Count     | Number of write operations                                                             |
| Writes Bytes     | Amount of data written                                                                 |
| Writes Time      | Time spent in write operations                                                         |
| Writebacks Count | Number of blocks which the process requested the kernel write out to permanent storage |

| Column           | Description                                                                                                                                                                                                                   |
|------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Writebacks Bytes | Amount of data requested for write out to permanent storage                                                                                                                                                                   |
| Writebacks Time  | Time spent in writeback operations, including the time spent queueing write-out requests and, potentially, the time spent to write out the dirty data                                                                         |
| Extends Count    | Number of relation extend operations                                                                                                                                                                                          |
| Extends Bytes    | Amount of space used by extend operations                                                                                                                                                                                     |
| Extends Time     | Time spent in extend operations                                                                                                                                                                                               |
| Hits             | The number of times a desired block was found in a shared buffer                                                                                                                                                              |
| Evictions        | Number of times a block has been written out from a shared or local buffer in order to make it available for another use                                                                                                      |
| Reuses           | The number of times an existing buffer in a size-limited ring buffer outside of shared buffers was reused as part of an I/O operation in the <code>bulkread</code> , <code>bulkwrite</code> , or <code>vacuum contexts</code> |
| Fsyncs Count     | Number of fsync calls. These are only tracked in <code>context normal</code> .                                                                                                                                                |
| Fsyncs Time      | Time spent in fsync operations                                                                                                                                                                                                |

The report table “Cluster SLRU statistics” provides access statistics on SLRU (simple least-recently-used) caches. This table is based on the `pg_stat_slru` view of the [Cumulative Statistics System](#). [Table G.13](#) lists columns of this report table. Times are provided in seconds.

**Table G.13. Cluster SLRU statistics**

| Column    | Description                                                                                                                                                                      | Field/Calculation                              |
|-----------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|------------------------------------------------|
| Name      | Name of the SLRU                                                                                                                                                                 | <code>name</code>                              |
| Zeroed    | Number of blocks zeroed during initializations                                                                                                                                   | <code>blks_zeroed</code>                       |
| Hits      | Number of times disk blocks were found already in the SLRU, so that a read was not necessary (this only includes hits in the SLRU, not the operating system's file system cache) | <code>blks_hit</code>                          |
| Reads     | Number of disk blocks read for this SLRU                                                                                                                                         | <code>blks_read</code>                         |
| %Hit      | Number of disk block hits for this SLRU as the percentage of <code>Reads + Hits</code>                                                                                           | <code>blks_hit*100/blks_read + blks_hit</code> |
| Writes    | Number of disk blocks written for this SLRU                                                                                                                                      | <code>blks_written</code>                      |
| Checked   | Number of blocks checked for existence for this SLRU                                                                                                                             | <code>blks_exists</code>                       |
| Flushes   | Number of flushes of dirty data for this SLRU                                                                                                                                    | <code>flushes</code>                           |
| Truncates | Number of truncates for this SLRU                                                                                                                                                | <code>truncates</code>                         |

Table “Session statistics by database” is available in the report for Postgres Pro databases starting with version 14. This table is based on the `pg_stat_database` view of the [Statistics Collector](#). [Table G.14](#) lists columns of this report table. Times are provided in seconds.

**Table G.14. Session statistics by database**

| Column               | Description                                                                                                                                                                                                                              | Field/Calculation        |
|----------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|--------------------------|
| Database             | Database name                                                                                                                                                                                                                            |                          |
| Timing Total         | Time spent by database sessions in this database during the report interval (note that statistics are only updated when the state of a session changes, so if sessions have been idle for a long time, this idle time won't be included) | session_time             |
| Timing Active        | Time spent executing SQL statements in this database during the report interval (this corresponds to the states <code>active</code> and <code>fastpath function call</code> in <code>pg_stat_activity</code> )                           | active_time              |
| Timing Idle(T)       | Time spent idling while in a transaction in this database during the report interval (this corresponds to the states <code>idle in transaction</code> and <code>idle in transaction (aborted)</code> in <code>pg_stat_activity</code> )  | idle_in_transaction_time |
| Sessions Established | Total number of sessions established to this database during the report interval                                                                                                                                                         | sessions                 |
| Sessions Abandoned   | Number of database sessions to this database that were terminated because connection to the client was lost during the report interval                                                                                                   | sessions_abandoned       |
| Sessions Fatal       | Number of database sessions to this database that were terminated by fatal errors during the report interval                                                                                                                             | sessions_fatal           |
| Sessions Killed      | Number of database sessions to this database that were terminated by operator intervention during the report interval                                                                                                                    | sessions_killed          |

In Postgres Pro Enterprise databases of versions that include [pgpro\\_stats](#) version starting with 1.4, workload statistics of vacuum processes are available. The “Database vacuum statistics” report table provides per-database aggregated total vacuum statistics based on the `pgpro_stats_vacuum_tables` view. [Table G.15](#) lists columns of this report table. Times are provided in seconds.

**Table G.15. Database vacuum statistics**

| Column         | Description                                                                                                                    | Field/Calculation                      |
|----------------|--------------------------------------------------------------------------------------------------------------------------------|----------------------------------------|
| Database       | Database name                                                                                                                  |                                        |
| Blocks fetched | Total number of database blocks fetched by vacuum operations                                                                   | total_blks_read + total_blks_hit       |
| %Total         | Total number of database blocks fetched (read+hit) by vacuum operations as the percentage of all blocks fetched in the cluster | Blocks fetched * 100 / Cluster fetched |
| Blocks read    | Total number of database blocks read by vacuum operations                                                                      | total_blks_read                        |
| %Total         | Total number of database blocks read by vacuum operations as the percentage of all blocks read in the cluster                  | Blocks read * 100 / Cluster read       |

| Column            | Description                                                                                                                                                                        | Field/Calculation                                                               |
|-------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|---------------------------------------------------------------------------------|
| VM Frozen         | Total number of blocks marked all-frozen in the visibility map                                                                                                                     | pages_frozen                                                                    |
