Ristic et al. [21] define a model-driven database reverse engineering mechanism through a chain of model-to-model transformations. These transformations are applied between physical database schema and generic relational schema. A similar model-to-model transformation approach is followed in [22] for automatically achieving a form type data model again from a generic database schema. Hence, the form type specification represents a platform independent prescription model of both future screens and report forms which can be generated later for a complete application. Popovic et al. [23] propose a DSL, called IIS*CFuncLang, to specify application-specific functionalities of business applications for different domains at the platform-independent model level. The DSL enables modeling the system to be developed and generalization of the required executable codes is realized via some model transformations. Hence, specifications defined with the DSL can be converted into executable PL/SQL program codes. These studies bring valuable MDD solutions on database processing, query generation and reverse engineering of databases. However, the metamodels, the transformations and the DSLs defined in these studies do not consider the Elasticsearch engines and hence, deriving an MDD framework for generating queries, structured according to Elasticsearch specifications on various query types, is not covered in these studies.

Research on Elasticsearch has been recently emerged due to novelty brought into query structures. Kononenko et al. [3] discuss how Elasticsearch differs from the traditional relational databases and give some concrete applications of using Elasticsearch queries. In addition, they give their assessment on the strengths and the weaknesses of Elasticsearch for querying new software repositories. Elasticsearch's inverted index capabilities are used in [28] for implementing an optimized intelligent search algorithm. Query optimization with using this algorithm is employed in the retrieval of medicine data. Finally, a social media analysis system is introduced [29] in which features of Elasticsearch are used on analyzing Big Data. Two ways of giving Twitter data as input to Elasticsearch are defined and their performances are compared by means of consuming hardware resources and the capacity of processing tweets. Our work contributes to the research on Elasticsearch by introducing a DSML and its supporting IDE which can be used to facilitate and expedite the creation of Elasticsearch queries by following a MDD process.

VI. Conclusion

A DSML, called DQL, for supporting MDD of Elasticsearch queries has been introduced in this paper. Based on the derived metamodel of Elasticsearch queries, a graphical concrete syntax is provided for query modeling inside the IDE of the language. All required constraint checks and query validations are automatically performed on the models prepared inside this IDE and Elasticsearch queries are generated from these models. Furthermore, IDE is capable of executing these auto-generated Elasticsearch queries on remote repositories and creating reports covering the execution results. The conducted evaluation showed that the use of the language significantly decreases the development time required for creating Elasticsearch queries. Finally, qualitative assessment, based on the developers' feedback, exposed how DQL facilitates the development of Elasticsearch queries.

In the future work, our aim is to extend DQL's coverage on different types of Elasticsearch use cases. Also, we plan to enrich DQL's query modeling environment with improved visualization components especially for reporting Elasticsearch results. In order to determine how these new components enable more feasible query generation, the evaluation performed on DQL will be improved and experiment settings will be structured with including some sort of hypothesis testing as being considered in similar efforts like [30-32].

***Abstract*—Behavior of UML state machines can be a source of interpretation problems in model to code transformation. Different solutions to the semantic variants could be defined as a special kind of mutations, similarly as in the mutation testing. State machines together with class models can be a source of an Model-Driven Software Development process aimed at building an executable application. We have compared several approaches to creating applications based on models in which semantic mutation operators of state machine behavior are used. The most promising approach has been utilized to extend the Framework for eXecutable UML (FXU) with semantic mutation facilities. The framework supports code generation from UML classes and their state machines as well as developing C# applications according to selected mutations of state machine behavior. The tool has been used in evaluation of a case study.**

I. Introduction

AUTOMATIC code generation in Model Driven Software Development (MDSD) can be based not only on structural models, like UML classes, but also on behavioral models, e.g. state machines [1]. One of the obstacles is not sufficient support for generation and verification of applications of this kind.

Mutation testing is used for evaluation of test suites and generation high-quality tests [2]. Syntactic changes injected into a source code are supposed to be detected by test cases. Modified programs, so-called ***mutants***, are run against tests. An abnormal program behavior confirms ability of the tests to detect the type of faults introduced by ***mutation operators*** during mutant generation.

Mutation testing approach has been extended for different software artefacts to be mutated and tested in a software development life cycle. A mutated source can be a model or specification [3], including state machines [4], [5]. A special kind of mutation testing is focused not on syntactical changes of an input, i.e. code, model, or another artefact, but on changes in its semantic or other implementation features [5]-[7].

In this paper we focus of different architectural approaches to combine semantic mutation of state machines into an MDSD process. It is assumed that an executable application is created based on UML classes and hierarchical state machine models [8]. The final code project is built with all necessary library notions, so the target application can be run as any other general–purpose application in a standard environment. The developed application should reflect system requirements that are specified in the input models, therefore the final testing is performed at application level, and not at model level.

Presentation of this idea and possibility of its realization is the main contribution of the paper. We compare different approaches to performing such semantic mutation in regard to their applicability in practice and complexity of realization (Sec. III). Complexity analysis of the approaches helps to select the best one which has been implemented in FXU – a tool that supports MDSD from UML classes and their behavioral state machines with the target to C# applications (Sec. IV). Therefore, we have also shown how the semantic mutation testing can be practically combined into an MDSD process. To the best of our knowledge it is the first implementation of such mutation approach.

II. Related Work

The main background of this work originate from areas of code generation from state machines, interpretation of state machine behavior, and mutation testing.

UML model to code transformation based on class models can be extended with state machine models [1]. Tools that support this usually respect only a subset of notions, omitting complex concurrency issues. Some solutions that apply comprehensive set of state machine concepts do not support C#, apart from FXU [8].

The UML specification has included some semantic variation points, in particular concerning behavior of state machines. They should be resolved in different ways while a model has to be interpreted or a model-based application executed. In most of implemented solutions, there are different resolutions of behavioral interpretation problems, often without precise statements about selections taken.

Mutation testing approach has been used to applications in different programing languages [2], including C# [9]. This idea was also used to mutate UML models, e.g. class

models [3], or automata-based models, mainly dealing with syntactical changes of diagrams [4].

Behavioral models, including state machines, have been also considered as an object of semantic mutation [6], in some variants called also an implementation mutation [4], [5]. In this kind of mutation there are no changes introduced into a model graph structure, but different semantic interpretations are considered [7].

III. Different Approaches to Combining Semantic Mutation of State Machines into MDSD

In a model-based process of software development mutation testing can be used at different levels, applied to various software artefacts, and with evaluation of effects in different process stages. Realizations of mutation of model semantics can be classified into three main types [6]:

1) Simulation/interpretation of a model with different parameters mimicking semantic variants.
2) Semantic expressed in a set of configurable rules that is combined in an executable model or a target application.
3) Imitation of semantic mutations using syntactic changes of elements in a model or in a code.

In this paper we focus on approaches that belong to the second realization type, discuss mutating of input model semantic, but testing the final code application.

A. Categories and Strategies of Mutation Operators

The following general mutation categories which refer to elements mutated in MDSD can be distinguished:

A) design or construction mutation
B) semantic mutation
C) semantic consequence-oriented mutation

The first category includes typical mutation testing defined for programming languages, as well as modifications of input models. However, in this paper we do not deal with this category.

Semantic faults can be imitated by semantic mutation, or semantic consequence-oriented mutation, or such structural mutations that reproduce semantic faults [5]. In comparison to design mutation, semantic mutations do not modify an intermediate source form of a model or code but apply another interpretation of it. Transformation rules from a source to an intermediate form are modified.

The third mutation category is associated with realization of a given meaning of modelled programming concepts. System realization consistent to a given semantic determines a final system behavior. However, according to a semantic, behavior of a system or its part can be nondeterministic. This mutation category is aimed at imitation of different behavioral combinations.

This kind of mutation was considered as implementation-oriented mutation [5] specified in the context of the Harel statecharts. However, an approach to realization of such mutations proposed in this paper is different to those from Trachtenbrot [5]. The details of the semantic operators are beyond the scope of this paper and will be published in [10].

A mutation operator could be applied in many places of a program, but in the ***first order mutation,*** code is changed in one place per one mutant [2]. In general, the number of generated mutants will be denoted as *MN*, and equal to:

$$MN = \sum_{i=1..N} OP_i \quad (1)$$

where N is a number of operators and OP_i is the number of program places in which the *i-th* operator can be applied.

Considering behavior variants, we generally assume that only one operator is applied. However, the application of such operators can be mutually dependent. It means, for example, that only after operator OP_x had been selected, a variant determined by another operator OP_y could be used. Taking into account such dependency of operators, the final mutant can still be counted as a first order mutant under application of a composite operator OP_xOP_y.

A model usually includes many state machines, thus the same operator could be used to one or many state machines at the same time. Hence two strategies could be considered:

1) ***all state machines***, i.e. the same mutation operator refers to all state machines in a model to be transformed,

2) ***one or selected state machines***, i.e. only selected state machines (usually one) have different behavior determined by the operator.

In the first strategy, the number of generated mutants depends linearly on the number of operators and is lower than in the second approach. The interpretation of the behavior is also simpler. The latter strategy could result in higher number of mutants, especially for complex systems with many state machines. The number of all possible mutants is of order of $N*K$ where N is a number of mutation operators and K is the number of state machines.

B. Approach I – Multiple Code Generation

This is a simple approach based on a straightforward creation of code in a MDSD process. For each mutant, i.e. for a pair <model, semantic>, a separate process towards a target application will be performed. A result of the transformation would be a code that implements model with the semantic. The application code might be slightly different for each mutant. Each mutant has its own code project and requires to be compiled.

The main process metrics are summarized in Table I. Approach I is simple and independent of a code generator, but have many disadvantages. The new code has to be written in each mutant while a method body is supplemented. Moreover, it could be repeated before adjusting a mutant to any test run. Therefore, the approach could be used for a quick verification of a semantic mutation operator, but it not convenient for the mutation testing in MDSD.

C. Approach II – Multiple Libraries

Drawbacks of the first approach imply that mutation testing process should be independent from model-to-code transformation and from supplementing of the generated code. This idea has already been partially supported if we

separate code generation and run-time libraries, where the library deliver the semantic of state machines.

The rules of a state machine behavior could be encapsulated in a library, therefore we could mutate the library and not a generated code that could be independent. Model transformation and code supplementing would belong to one process which is independent from the mutation testing process. The model to code transformation is performed only once, and we could also extend some code one time, if necessary. In dependence of a selected mutation, an appropriate library could be chosen and used to build the final target application.

The main drawback of this approach is necessity to maintain many versions of the library (Table I). The number of versions is equal to the product of supported mutation operators and their possible interpretations. Hence, the complexity rises up quite fast.

D. Approach III – Mutants with Common Base

This approach extends the library with different variants of classes that represent various concepts of state machine. The whole idea is similar to the *Strategy* design pattern. Each class implements a single interface that corresponds to one state machine notion. All classes are gathered into one library that could be added to a final application. Based on an input model and selected mutation operators, multiple classes are created for each state machine.

A base class specifying behavior is generated for each model class that has its state machine. This base class could include methods originated from the model class as well as additional methods for initialization of the state machine of a default semantic. Moreover, for each mutant a class derived from the base class is created. Each such inherited class redefines methods for initialization of the state machine corresponding to the semantic of a given mutant.

If a method body is supplemented in the generated code, it can be done once in the base class. Creation of an executable application requires one compilation of all mutants together. Tests should be defined for a base class in order to be run for all generated mutants.

An advantage of this approach is a single implementation of additional code. Selection of mutation operators in experiment iterations, i.e. updating a variant, could be realized by substitution of a constructor in the generated mutant code that would require changing in the code generator, which is not a flexible solution.

E. Approach IV – Configurable Library

In the fourth approach we combine advantages of approaches II and III. Considering a set of mutants, we can use a pair <model, a set of semantics> instead of a set of pairs <model, semantic>. Moreover, the source code generated from a model is explicitly separated from the library code. The generated code can use the library only by dedicated interfaces, placed in an additional intermediate layer. The generated code does not depend on the library classes that implement those interfaces.

In result, one version of code is generated for each state machine of a model. It would be used in an original application and a mutated one. Therefore, supplementing of a method code body is performed only once. We need also only one compilation of the application.

Furthermore, mutation testing process uses one consistent run-time library. Consequently, maintenance and extending of the semantic mutation operators would be uncomplicated. In a single mutant, various state machines can be executed according to different semantic variants, if desired.

This approach has many advantages, but creating of objects of state machines could take more time due to reflection mechanism used in the intermediate layer. On the other hand, this activity is performed only once during the live time of an object that includes a state machine.

F. Comparison of Approaches

The approaches are summarized in Table I. We have compared some relevant metrics of the process and product complexity. Only in the first primitive approach we have to build many code projects (row 1) and supplement the same code in many applications (row 5). In other cases one project is used for all mutants regardless of the number of operators and the number of their interpretations.

When multiple variants are introduced into libraries, only one class in the source code corresponds to one model class (row 2). The second approach requires many libraries (row 3), while the others can use a single one. An important time overhead is associated with multiple compilation, which is necessary for two first approaches only (row 4).

Summing up quantitative data in the upper part of the Table (rows 1-5), we can conclude that the fourth approach has the lowest complexity (1 in all metrics).

The bottom part of the Table assesses the mutation testing process flexibility and extensibility. Here, also the last approach would be the most beneficial. Iterative mutation testing can be easily performed, and new semantic mutation ideas could be easily introduced.

IV. Realization of Semantic Mutation with FXU

Framework for eXecutable UML (FXU) creates executable C# from UML models [8]. It was the first tool that supported transformation of state machines to C#, and still belongs to comprehensive tools that covers all notions of behavioral state machines, with complex, orthogonal states, different pseudostates, also history, etc. [1]. The FXU Generator transforms UML classes and their state machines into C# code. The FXU Library contains implementation of all state machine concepts. The final application is built as a project including the generated code and the library.

Basing on the analytic evaluation of the approaches, FXU has been extended to support semantic mutation of state machines using the fourth approach - configurable library. Both strategies, all-state machines and one selected state machine, have been implemented. The reconfigured FXU Library provides versatility of state machine semantic mutation opera-

TABLE I.
COMPARISON OF APPROACHES I-IV (MN – NUMBER OF MUTANTS)

Metric	I	II	III	IV
1 Number of generated projects	MN	1	1	1
2 Number of code classes originated from a model class which has its state machine	MN (one in a project)	1	MN +1	1
3 Number of run-time libraries	1	MN	1	1
4 Number of compilation runs	MN	MN	1	1
5 Number of spots where the same code is placed in project(s)	MN	1	1	1
6 Mutant creation process independent of code generation	No	Yes	No	Yes
7 Separate compilation needed to create any executable mutant	Yes	Yes	Yes	No
8 Easy extensibility with other semantic mutations	High	Med ium	Med ium	High
9 Difficulty in performing an iterative mutation testing	Low	High	Med ium	Low

tors, including semantic mutations and semantic consequence-oriented mutations (Sec III).

Evaluation of the mutation testing process with the extended FXU has been performed on a case study used in the previous MDD experiments [11]. It referred to modeling of a presence server in a social network. Here, we have focused on the application verification, showing different application alternatives reflecting activities consistent with various semantic variants of UML state machines.

A set of unit tests for the application was developed. The test project was supplemented with a configuration file of state machine semantic. The tests followed two schemata, in which (i) we checked a correctness of only one class and its behavior specified by its state machine, or (ii) a whole subsystem was verified. An example of the latter case could be servicing of a data publishing request. It was verified if a valid status was set in appropriate places. In case of tests that check one class and one state machine, semantic for the whole was mutated. In case of subsystem tests, two types of mutants were configured. (A) All state machines behaved according to the same semantic variant within the same test run. (B) Different state machines of the involved classes used various semantic variants within the same test run.

All tests were run against the created mutants and positively evaluated in the environment. The behavior of the mutants corresponded to expectations given in the input models and semantic variants.

V. CONCLUSION

Different approaches to introducing semantic mutation of state machines have been compared. The best solution in terms of complexity and flexibility has been implemented in the FXU, the framework transforming class and state machine models into C# applications. While using this tool support selected behavioral variants to state machines were accomplished and verified in mutation testing experiments.

***Abstract*—Cyber-physical systems consist of many hardware and software components. Over the life-cycle of these systems, components are replaced or updated. To avoid integration problems, good interface descriptions are crucial for component-based development of these systems. For new components, a Domain Specific Language (DSL) called Component Modeling & Analysis (ComMA) can be used to formally define the interface of such a component in terms of its signature, state and timing behavior. Having interfaces described in a model-based approach enables the generation of artifacts, for instance, to generate a monitor that can check interface conformance of components based on a trace of observed interface interactions during execution. The benefit of having formal interface descriptions also holds for legacy system components. Interfaces of legacy components can be reverse engineered manually. In order to reduce the manual effort, we present an automated learner. The learner can reverse engineer state and timing behavior of a legacy interface by examining event traces of the component in operation. The learner will then generate a ComMA model.**

I. Introduction

THE high-tech industry creates complex cyber-physical systems. The architectures for these systems consist of many hardware and software components. These components can be self-created or made by a third party supplier. Components interact with each other using software interfaces. Good interface descriptions are crucial for component-based development of cyber physical systems. Typically, however, software interfaces are only described in terms of their signature, i.e., the set of operations. Sometimes also the allowed sequence of operations is specified, for instance in terms of a state machine or a few example scenarios. The timing behavior of an interface is almost never described. For instance, the expected frequency of notifications and the allowed time between the call of an operation and the corresponding response. Violations of assumptions about timing behavior, however, are an important source of errors over the complete life cycle of these systems.

To overcome the drawbacks of current interface definitions, we have developed a Domain Specific Language (DSL), called ComMA as an abbreviation for Component Modeling and Analysis. ComMA [1] is currently used at the business unit Image Guided Therapy (IGT) of Philips for the formal definition of signature, state and timing behavior of software interfaces. ComMA specifies the signature of a server, i.e., the operations it offers to clients and the notifications it can send to clients. In addition, a ComMA interface definition includes a state machine which specifies the allowed interactions between client and server, timing constraints on sequences of operations, and data constraints on the parameters of operations.

Based on a ComMA specification, a large number of artifacts are generated automatically, for example:

- A visualization of state machine, timing and data constraints by means of plantUML[1].
- A Microsoft Word document according to the prescribed Philips template with the interface specification; this also uses comments in the ComMA specification including Doxygen-style comments[2].
- A simulator of the interface based on the state machine.
- Proxy source code in C++ and C# for the middleware technology SSCF of Philips IGT for transparent deployment of software components. SSCF is an abbreviation of Simple Service Communication Framework.
- A monitor which can be used to check whether an implementation of the interface conforms to the specification. This is done based on an execution trace that is recorded or sniffed during the usage of the implemented interface. The monitor checks conformance to the specified state machine and the timing and data constraints.

The monitor is very useful to check interface compliance after software updates or hardware upgrades. The monitor stores the timing information from the trace that is used to check the timing constraints. This information can be visualized to obtain insight in the timing characteristics. This is, for instance, useful when an updated hardware component is obtained from a supplier. Then the impact on the Philips part of the interface can be determined based on the differences between the characteristics of the old and the updated component.

Given the benefits of the ComMA approach, all new major system interfaces of Philips IGT are modeled and checked using ComMA. There are, however, hundreds of existing interfaces and it would be beneficial to apply the power of

[1]www.plantuml.com
[2]www.doxygen.org

the ComMA framework also to these interfaces. A manual transformation would require a large reverse engineering effort. Hence, the goal of the work described here is to support this transformation automatically such that the manual effort is reduced significantly.

Our approach is based on model learning techniques to obtain a first version of an interface state machine in ComMA. The main contribution is that we also learn the timing constraints. Since the learned interface may not be complete and states will not have meaningful names, manual changes will be needed. These changes are validated by the monitor generated by ComMA.

Concerning the model learning techniques, we have experimented earlier with active learning which stimulates the system under learning actively and infers an hypothesis based on the responses of the system [2]. Active learning requires the implementation of an adapter to connect the System Under Learning (SUL) with the learner. This adapter has to deal with behavior of the SUL that does not match the assumptions of the learning techniques, such as a SUL which is not input enabled or a SUL which sends no output or multiple outputs after a stimulus. This technique also requires frequent resets of the SUL which may be time consuming. Furthermore, nondeterminism of the SUL is a problem for active learning.

To avoid these issues, the approach described here is based on passive learning [3] where traces of SUL behavior are used to derive an hypothesis about the state behavior. Our algorithm is based on regular inference [4]. In particular, we use the algorithms described in [5], [6].

A disadvantage of passive learning is that only the behavior that is represented in the used traces will be in the resulting state machine. Hence, compared to the active learning approach, the model might be less complete. In our case, however, this is acceptable since the learned model is intended as a starting point for subsequent manual editing.

Related work

There are several model-based techniques to formally describe interfaces. Related to our approach is the Analytical Software Design (ASD) method [7] which includes formal interface specifications represented as state machines. An ASD interface model plays a similar role as a protocol state machine of UML [8]. An ASD interface not only describes the services offered by the server; it also specifies the operations allowed by the client. So it can be seen as a contract between client and server, similar to the Design by Contract approach [9]. Franca[3] is a related domain-specific language for the definition and transformation of interfaces.

All these approaches lack the ability to describe the timing aspects of the interface behavior and to check if an existing implementation conforms to an interface specification which includes timing constraints. Testing of real-time behavior by means of UPPAAL-TRON is described in [10]. In an industrial case, a timed automata model is obtained by first manually modeling the behavior of the system and next manually tightening the timing tolerances in an iterative ways using model-based testing.

An approach to obtain timing information of a component from execution traces is described in [11]. Models include worst case execution times of method calls. Downside of this approach is that the source code needs to be instrumented to acquire the execution traces and by doing so the timing behavior is influenced. In addition, only the time of a method call is captured, not the timing between events. In our approach the code does not need to be instrumented and timing between all event types is captured.

Structure of this paper

The paper is organized as follows. Section II provides a brief overview of the definition of interfaces in ComMA. Next we describe in Section III how an interface model can be obtained for an existing interface by manual editing. Automated support for reverse engineering of state behavior is presented in Section IV. Next, Sections V & VI, addresses the reverse engineering of state and timing behavior respectively. Results of experiments with our approach are presented in Section VII. Section VIII concludes the paper.

II. Model-based Definition of Interfaces

In this section, we introduce ComMA as far as needed to understand the remainder of this paper. The ComMA framework consists of the following four main languages:

- A language to describe the signature of an interface, see Section II-A.
- A language to capture observed interface interactions in the form of timed traces, see Section II-B.
- A language to describe the behavior of an interface, see Section II-C.
- A language to specify the generators to be used, see Section II-D.

The languages are illustrated by a test interface, called ITest, of a power control unit, see Figure 1. For the sake of explanation we made few modifications to the language instances. A predecessor of this unit has been introduced in [12].

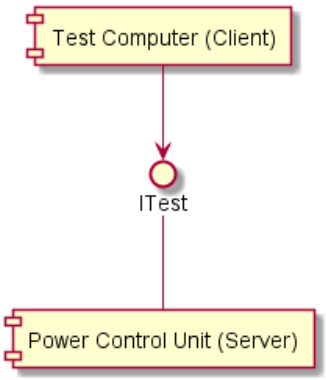

Fig. 1: Interface ITest of a power control unit

[3]franca.github.io/franca/

A. ComMA Signature

In a ComMA interface three types of operations are distinguished:

- *Commands* are synchronous operations from client to server. The client receives a *reply* from the server.
- *Signals* are asynchronous operations from client to server. Signals do not have a reply.
- *Notifications* are asynchronous operations from server to client. Notifications do not have a reply.

Listing 1 shows the signature of the ITest. First it defines two enumeration types, Stimulus and State. Next two commands are defined: 1) operation InjectStimulus with one parameter of type Stimulus; it replies a boolean value 2) operation GetState which replies a value of type State. Finally, the notification StateUpdate with one parameter State is defined. Observe that this example does not include any signal.

```
signature ITest {
  types
  enum Stimulus { VideoOnButton SystemOffButton ..}
  enum State { VideoOn VideoOnTransitioning SystemOff ..}

  commands
  bool InjectStimulus(Stimulus s)
  State GetState

  notifications
  StateUpdate(State state)
}
```

Listing 1: Example of a signature

B. ComMA Trace

The trace language is used to represent observed interface interactions. They can be, for instance, the captured network traffic or events written to a log file. An event is the occurrence of an operation. The language is independent of the technology used to record interactions; converters transform a technology-specific sequence of observed events to an instance of the ComMA trace language. An example of a ComMA trace is given in Listing 2. This example is based on an interface with the signature described in Listing 1. The listing shows two events, a command and its reply. Note that the time delta (in microseconds) between this event and its predecessor is denoted by "Timestamp" and the keyword "OK" indicates that this is a reply of the preceding command.

C. ComMA Interface

The behavior of an interface in terms of the allowed sequences of operations can be expressed in ComMA by the combination of a state machine and a number of constraints. The state machine describes the allowed order of the events between server and client. As an example, Listing 3 presents interface "ITest" which imports the signature of Listing 1.

Listing 3 shows the following:

- A variable "systemStateNotificationPending" is defined and initialized.
- The initial state is "SystemOff".

```
Timing: 1464181458.066471
Timestamp: 0.000000
src address: 192.168.32.1
dest address: 192.168.32.2
Interface: ITest
Command: InjectStimulus
Parameter: ITest::Stimulus : ITest::Stimulus::VideoOnButton

Timing: 1464181458.072651
Timestamp: 0.006180
src address: 192.168.32.2
dest address: 192.168.32.1
Interface: ITest
Command: InjectStimulus OK
Parameter: bool : true
```

Listing 2: Fragment of a ComMA trace

```
interface ITest{
  variables
  bool systemStateNotificationPending

  init
  systemStateNotificationPending := false

  initial state SystemOff {
    transition trigger: ITest::GetState do:
      reply(ITest::State::SystemOff)
      next state: SystemOff

    transition trigger: InjectStimulus(ITest::Stimulus s)
      guard: (s == ITest::Stimulus::VideoOnButton) do:
        systemStateNotificationPending := true
        reply(true)
      next state: VideoOnTransitioning

    ..
  }

  state VideoOnTransitioning {
    transition trigger: ITest::GetState do:
      reply(ITest::State::VideoOnTransitioning)
      next state: VideoOnTransitioning
    OR
      do: reply(ITest::State::VideoOn)
      next state: VideoOn

    transition guard: systemStateNotificationPending do:
      systemStateNotificationPending := false
      StateUpdate(ITest::State::VideoOnTransitioning)
      next state: VideoOnTransitioning

    ..
  }

  state VideoOn { .. }
}
```

Listing 3: Example of a ComMA state machine

- The first transition is triggered by the "GetState" operation. The replied state value is "SystemOff". This is a self-transition.
- The second transition is triggered by "InjectStimulus" with parameter "VideoOnButton". After replying value "true", the state machine transitions to state "VideoOnTransitioning".
- The second state is "VideoOnTransitioning".
- The first transition of this state is triggered by the "GetState" operation. The replied state value can be either "VideoOnTransitioning" or "VideoOn". This non-determinism is indicated with the "OR" keyword.

- In the second transition there is “StateUpdate” notification with parameter “VideoOnTransitioning”. Observe that this notification happens only once in the “VideoOnTransitioning” state which is coded by the “systemStateNotificationPending” variable.

Note that implicitly any behavior that is not defined in the state machine is not allowed.

In addition, a ComMA interface definition allows the specification of the timing behavior as a set of timing constraints. Listing 4 shows two examples of timing constraints:

- TimingRule0 describes the allowed time between an occurrence of command “GetState” and its reply. The Lower Specification Limit (LSL) is 2.4 ms and the Upper Specification Limit (USL) is 3.8 ms.
- TimingRule1 shows how constraints on more than two events can be grouped. It describes the allowed time between an “InjectStimulus” event and its reply, and the allowed timing between the reply and an occurrence of the “StateUpdate” notification.

```
timing constraints

TimingRule0
command ITest::GetState
  and reply(ITest::State::SystemOff)
  -> [ 2.4 ms ..  3.8 ms ] between events

group TimingRule1
command ITest::InjectStimulus(
    ITest::Stimulus::VideoOnButton)
  and reply(true)
  -> [ 5.9 ms ..  7.3 ms ] between events
  - [ 76.7 ms ..  165.3 ms ] -> notification
    ITest::StateUpdate(ITest::State::VideoOnButton)
end group
```

Listing 4: Example of a few timing constraints

Note that the ComMA trace of Listing 2 satisfies constraint TimingRule1, since the observed time delta between command and reply in this trace is approximately 6.2 ms which is between 5.9 ms and 7.3 ms.

D. ComMA Generator Specification

ComMA contains a separate language to specify which artifacts should be generated and it also allows the definition of parameters for these generators. An example is given in Listing 5 for a project called “Test” which imports the ITest interface. The project includes multiple generators:

- A “Monitor” to check if a ComMA trace conforms to the ComMA interface; in this case it takes file “Test.traces” as input.
- “SscfHeader”, is a generator that is explained in Section IV of this paper. The generator takes a “ITest.sscfheader” file as input.
- “Minedmodel”, is a generator that is explained in Sections V & VI. The generator takes a “Test.traces” file as input, excludes some parameters and filters out some unsolicited events as explained later.

```
Project Test {
  Compound Interface ITest {
    version
    ``1.0"

    description
    ``Demo project with Test component."
  }

  Generate Monitor {
    trace files
    ``Test.traces"
  }

  Generate SscfHeader {
    header files
    ``ITest.sscfheader"
  }

  Generate Minedmodel {
    trace files
    ``Test.traces"

    exclude parameters int string

    unsolicited events
    "dummyCMD2M"
    "dummyM2CMD"
  }
}
```

Listing 5: Example of a generator specification

III. Manual Reverse Engineering

Existing interfaces can be modeled manually in ComMA. This manual approach is depicted in Figure 2 and consists of the following steps:

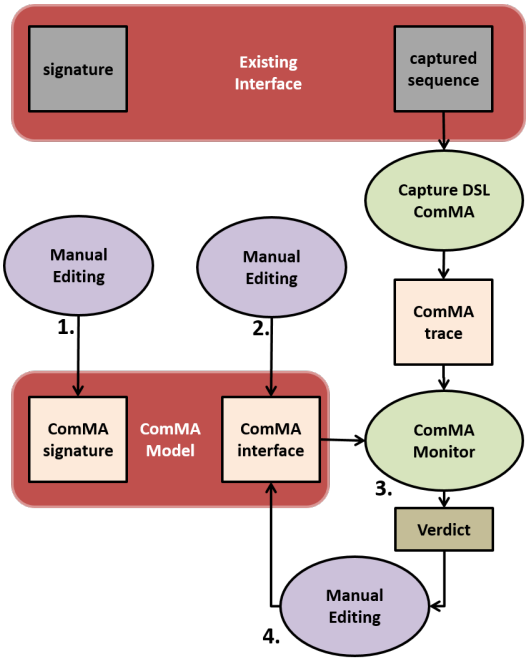

Fig. 2: Manual approach

1) The signature of the interface is defined manually.
2) A first version of the behavior of the interface is defined manually.

3) a) An interaction sequence of the existing interface is captured during execution or testing, for instance by sniffed network traffic or logging of events. From this recorded sequence, a ComMA trace has to be created. Typically this is done by a dedicated DSL.
   b) From the ComMA trace and the manually defined ComMA interface, a monitor is generated using the existing ComMA generator. With this monitor we check if the captured trace conforms to the defined ComMA model.

   In Figure 2, "Verdict" is the outcome of the interface conformance check.
4) The verdict of monitoring leads to three possibilities, assuming the used trace is correct:
   - Fail and the ComMA generator lists the issues; fix the issues in the model.
   - Pass; there are two options:
     - Done, the model captures all required behavior; the engineer has to decide this based on domain knowledge or, for instance, design documents.
     - Not done, extend the model with new behavior.

IV. Automated Reverse Engineering Support

In this section, we describe our reverse engineering approach. It can be seen as an extension of the manual approach presented in Section III, where we automate steps 1 and 2 of Figure 2. The automated approach is depicted in Figure 3.

The automated approach consists of the following steps:

1) We assume the signature of an existing interface is available in some representation. This can, for instance, be an IDL file in case of a COM interface or a header file using macros in C++ for another technology. The aim is to generate a ComMA signature from this representation. This requires a parser that accepts instances of an interface representation. Next a generator to generate a ComMA signature file has to be constructed.

   At Philips IGT, most signatures are available in the SSCF format. Hence, we created a DSL for the translation of a C++ header file with SSCF macros to a ComMA signature file. Listing 6 depicts an example of the SSCF interface description. From this example, the generator will automatically generate Listing 1. We do not discuss this DSL in more detail since the transformation is trivial for the Philips specific SSCF technology. The generator is called "SccfHeader" and requires an SSCF header file as input. Listing 5 show how this generator can be used.
2) Similar to step 3 of the manual approach, the behavior of a legacy interface is manifested by some sequence of events which are translated into a ComMA trace. In this case, the so-called ComMA Learner is used to construct a state machine and timing constraints based on one or more ComMA traces. Hence, we assume that the traces used in the learning are correct.

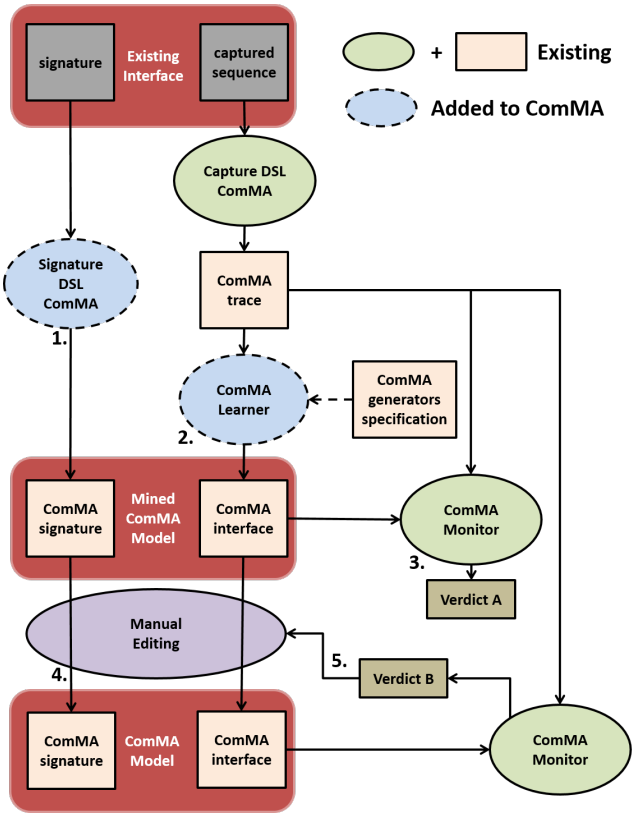

Fig. 3: Interface mining approach

```
SSCFTS1_BEGIN_INTERFACE(ITest)
  SSCFTS1_BEGIN_METHODS(ITest)
    SSCFTS1_INTERFACE_METHOD_1(bool, ITest,
      InjectStimulus, in(Stimulus))
    SSCFTS1_INTERFACE_METHOD_0(State, ITest, GetState)
  SSCFTS1_END_METHODS
  SSCFTS1_BEGIN_EVENTS(ITest)
    SSCFTS1_INTERFACE_EVENT_1(ITest, StateUpdate, State)
  SSCFTS1_END_EVENTS
SSCFTS1_END_INTERFACE
```

Listing 6: Fragment of an sscfHeader file

   a) The generation of a state machine by the ComMA Learner is described in Section V.
   b) The generation of timing constraints by the ComMA Learner is described in Section VI.

   Listing 5 shows how the ComMA Learner is called; the exclusion of parameters is explained in Section V.
3) Next, the existing generator of ComMA is used to generate a monitor and to check if the trace which is the starting point of step 2 indeed conforms to the learned interface. If the learner works correctly, the result should be a pass, so this is mainly a consistency check before continuing with the next steps.

The next two steps should be executed incrementally such that the changes on the model are small and can be easily reverted when they make the monitoring fail.

4) To create a more readable, complete and maintainable

version of the learned ComMA model, it is edited manually. For instance to add meaningful state names, reorder states, or to merge states and transitions.

5) As before, we use the generated monitor to check if the trace of step 2 still conforms to the edited ComMA interface. If not, the error has to be corrected, otherwise more changes can be made.

V. Learning State Behavior

In this section, we describe the learning of state machines. Figure 4 depicts the internal components of the Leaner. The "Serialize" component is used to format ComMA traces into a format which can serve as input for the "Algorithm" component. The "Deserialize" component converts the output of the "Algorithm" component into a ComMA interface.

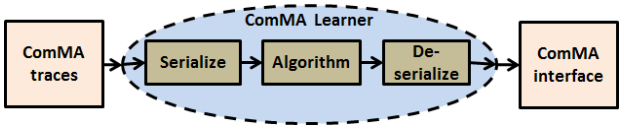

Fig. 4: Components of the learner

The general assumption is that the ComMA traces are correct, i.e., they represent valid behavior of the component.

A. Serialize

The "Serialize" component takes ComMA traces as input. It converts these traces into event strings. An event string starts with an interface name, followed by an event name, all parameter values, and finally the event type (command, reply, signal, or notification). Note that the conversion ignores all timing and address information in a trace.

B. Algorithm

The "Algorithm" component constructs a state machine based on the work described in [5], [6]. It uses a set of triggers, in our case *Commands* and *Signals*, and a set of listed actions, in our case *Replies* and *Notifications*. Triggers lead to transitions and action lists to states, following the pattern of a Moore machine where the output depends on the state only [13]. Based on one or more sequences of event strings, as a result of the previous component, the algorithm will construct a minimal (non-deterministic) finite state machine consistent with all input sequences. States with the same list of actions are merged, uniting the sets of their incoming and outgoing transitions. Note that this is different from (evidence-based) state merging [14] because the algorithm we use is linear and the resulting state machines might be non-deterministic.

C. Deserialize

The "Deserialize" component represents the output as a ComMA interface state machine. This means that the resulting Moore machine of the algorithm has to be transformed into a Mealy state machine where output depends on the state and the input trigger [15]. Moreover, a few restrictions on ComMA state machines have to be taken into account, such as limitations on the number of notifications on a transition. These restrictions are needed to enable the generation of monitors.

Listing 7 contains an example of a learned state machine for the "ITest" interface. Since the traces do not contain state information, the learned states are numbered. Notifications take place on transitions from a separate state with an underscore "_" in the state name. These states are added by the "Deserialize" component to meet the ComMA constraints mentioned in the previous paragraph. Observe the "OR" keyword which indicates that a reverse engineered state machine can be non-deterministic.

```
interface ITest{
  initial
  state s0 {
    transition trigger: ITest::InjectStimulus(
        ITest::Stimulus arg0)
      guard: (arg0 == ITest::Stimulus::VideoOnButton) do:
      reply(true)
      next state: s0_0_0
  }

  state s0_0_0 {
    transition do:
      ITest::StateUpdate(ITest::State::VideoOnTransitioning)
      next state: s1
  }

  state s1 {
    transition trigger: ITest::GetState do:
      reply(ITest::State::VideoOnTransitioning)
      next state: s1_0_0
        OR do:
      reply(ITest::State::VideoOnTransitioning)
      next state: s12
  }

  state s12 {
    transition trigger: ITest::GetState do:
      reply(ITest::State::VideoOn)
      next state: s13
  }
}
```

Listing 7: Example of a learned ComMA state machine

D. Tuning the Learner

The ComMA Learner can be tuned to ignore certain parameter values of events. For instance, an *int* parameter that acts like a cookie and is increased every transition might be excluded from the learning process. If we would not ignore the cookie, then the resulting state machine would become very large and restrictive. Hence, a new trace with different cookie values would not be accepted by the monitor. In such cases parameter values can to be ignored. Listing 5, shows how the parameters values for *int* and *string* are excluded from the learning algorithm. This means that the "Serialize" component does not include the *int* and *string* parameter values in the generated string.

VI. Learning Timing Constraints

In this section, we describe how we learn the timing constraints introduced in Section II. The timing constraints are

created during step 2b of our automated reverse engineering approach.

Our algorithm assumes that the client initiates the observed interface communication. Hence, observed events from the server are assumed to be triggered as a consequence of a *command* or a *signal* sent by the client. Clearly this holds for a *reply* event since it is caused by a *command* from the client. Our assumption means that a *notification* event is triggered by a *command* or *signal* from the client.

This pattern is used to avoid race-conditions by design. The latter is consistent with the solicit communication scheme in other approaches like ASD [16]. To avoid that *notification* events are triggered by unsolicited events, e.g. periodic alive events, unsolicited events can be filtered out of a trace by instrumenting the ComMA Learner as has been done for the "dummyCMD2M" and "dummyM2CM" events in Listing 5.

As shown in step 2 of Figure 3, the algorithm is fed with a trace of event observations. To learn timing characteristics, it is useful if the trace is long and contains many instances of events occurring in timing constraints. The algorithm performs the following steps on this trace:

1) Step 1 of the algorithm groups events according to the occurrence of trigger events of the client. Hence every event group starts with either a *command* or a *signal*. When in the trace the next event is a *command* or a *signal*, a new event group is created. Otherwise, the event is either a *reply* or a *notification* and it is added to the current event group. *Replies* and *notifications* have two attributes that represent minimum and maximum time differences with the previous event. These attributes are called LSL (Lower Specification Limit) and USL (Upper Specification Limit). In step 1 they are equal and initialized to the value of "Timestamp" of the event (note that this represents the delta time with the previous event). Figure 5 illustrates the event grouping. The output of this step is a list of event groups.

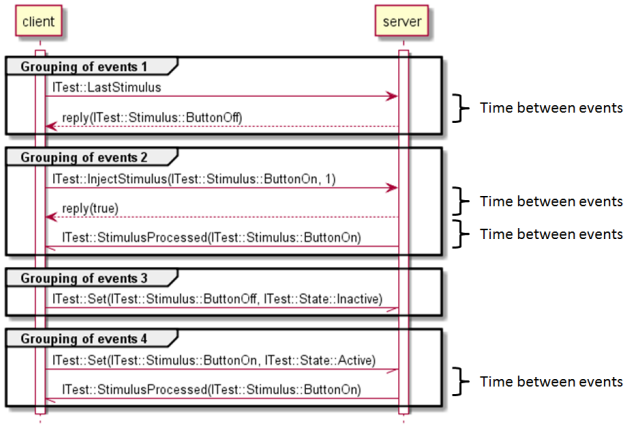

Fig. 5: Example trace timing

2) The list of the previous step will typically contain many groups that have the same events. For instance, many groups consisting of signal S and notification N. Only the time difference between S and N might be different. In step 2 the first occurrence of such groups is placed in a new list. Every event group in the new list will become a timing constraint.
3) Next the algorithm iterates over the event groups list of step 1 and matches every event group in it to a unique event group in the list of step 2. When a match is found, the LSL value of an event of the unique group is compared with the matched group. If the LSL value of an event of the matched group is smaller than the LSL of the unique group, then the unique group LSL value is updated with the value of the matched group. Likewise, the USL value of an event of the unique group is compared with the matched group. If the USL value of an event of the matched group is larger than the USL of the unique group, then the unique group USL value is updated with the value of the matched group.
4) Finally, the LSL and USL values of the unique event groups are used to create the timing constraints. The resulting constraints can be reviewed and the LSL and USL values can be relaxed manually in step 4 of our automated reverse engineering approach of Figure 3.

A more detailed formulation of this algorithm is given by the following methods. Method *CreateEventGroups* implements step 1 of the algorithm. It creates the event groups.

CreateEventGroups$(events)$ ::=
$group \leftarrow \emptyset$
$groups \leftarrow \emptyset$
FORALL $evt \in events$ **DO**
  IF $evt.type$ is Command **THEN**
    IF $group \neq \emptyset$ **THEN**
      $groups \leftarrow add(groups, group)$
      $group \leftarrow \emptyset$
    FI
    $group.trigger \leftarrow$ *Command*(evt)
    $previousEvt \leftarrow group.trigger$
  FI
  IF $evt.type$ is Signal **THEN**
    IF $group \neq \emptyset$ **THEN**
      $groups \leftarrow add(groups, group)$
      $group \leftarrow \emptyset$
    FI
    $group.trigger \leftarrow$ *Signal*(evt)
  FI
  IF $group \neq \emptyset$ **THEN**
    IF $evt.type$ is Reply **THEN**
      $action.string \leftarrow$ *Reply*$(evt, previousEvt)$
      $action.LSL \leftarrow evt.timestamp$
      $action.USL \leftarrow evt.timestamp$
      $group.actions \leftarrow add(group.actions, action)$
    FI
    IF $evt.type$ is Notification **THEN**
      $action.string \leftarrow$ *Notification*$(evt, previousEvt)$
      $action.LSL \leftarrow evt.timestamp$

$action.USL \leftarrow evt.timestamp$
$group.actions \leftarrow add(group.actions, action)$
FI
ELSE
Trace does not start with Signal or Command.
FI
OD
RETURN $groups$

As an example, consider the trace of Listing 2. Observe that the time difference between the command and its reply is described in the value after the Timestamp keyword of the reply. This time stamp is stored into the LSL and USL attributes of the reply event.

Next we present a helper method that is used in subsequent methods. Method *AreTheSameGroup* determines if two event groups are the same, that is, they have the same trigger and actions.

AreTheSameGroup($group0, group1$) ::=
$areTheSameGroup \leftarrow true$
IF $group0.trigger = group1.trigger$ **AND**
$group0.actions.size = group1.actions.size$ **THEN**
FORALL $i \leftarrow 0; i < group0.actions.size; i := i + 1$ **DO**
IF $group0.actions[i].name \neq$
$group1.actions[i].name$ **THEN**
$areTheSameGroup \leftarrow false$
FI
OD
ELSE
$areTheSameGroup \leftarrow$ *false*
FI
RETURN $areTheSameGroup$

The method *FindUniqueEventGroups* implements step 2 of the algorithm and returns a new list of unique event groups.

FindUniqueEventGroups($groups$) ::=
$uniqueGroups \leftarrow \emptyset$
FORALL $group \in groups$ **DO**
isUnique $\leftarrow true$
FORALL $group' \in uniqueGroups$ **DO**
IF *AreTheSameGroup*($group, group'$) **THEN**
isUnique $\leftarrow$ *false*
FI
OD
IF $isUnique$ **THEN**
$uniqueGroups \leftarrow uniqueGroups \cup group$
FI
OD
RETURN $uniqueGroups$

The method *DetermineTiming* implements step 3 of the algorithm. It takes the output of steps 1 and 2 as input and returns an updated unique groups list.

DetermineTiming($uniqueGroups, groups$) ::=
FORALL $group \in uniqueGroups$ **DO**
FORALL $group' \in groups$ **DO**
IF *AreTheSameGroup*($group, group'$) **THEN**
$action.LSL \leftarrow min(action.LSL, action'.LSL)$
$action.USL \leftarrow max(action.USL, action'.USL)$
FI
OD
OD
RETURN $uniqueGroups$

Using these methods, we create an algorithm to acquire timing constraints in the following way:
$groups =$*CreateEventGroups*($events$)
$groups_{uniq} =$ *FindUniqueEventGroups*($groups$)
$timingRules =$ *DetermineTiming*($groups_{uniq}, groups$)

As a last step, the timing rules are added to the interface file after the state behavior.

VII. Results

In this section, we present the results of our experiments and an analysis of the results.

A. Experiments

To validate the ComMA Learner we used two cases for which we already constructed an interface manually earlier: the power control unit and a third-party operating table [17]. For the power control case we use a trace called "Trace 1". For the operation table, two traces were used, called "Trace 2" and "Trace 3". The latter two traces are recordings of two different scenarios. Table I shows the characteristics of these traces by listing the number of commands, replies, signals and notifications, together with the types of the parameters.

We experimented with the ComMA Learner on the three traces and the exclusion of certain parameter types. The experimentation results are shown in Table II. In the last column, "Verified" refers to step 3 of the approach described in Figure 3, i.e., the monitoring; "yes" means that we could create a monitor and the verdict was that the trace is accepted by our generated monitor while "no" denotes that we could not generate a monitor because of the size of the state machine.

As explained in Section V-B, the algorithm can take more than one trace as input. Observe that learning based on Trace 2 and Trace 3 separately leads to 33 and 32 unique event groups, respectively, when excluding string and int. Using both traces leads to 55 groups, hence 10 groups are part of both traces. In the "Verified" column, "yes & yes" means that the monitor accepts both traces.

```
interface ITest {
  in all states {
    transition trigger: ITest::dummyCMD2M
    transition do: ITest::dummyM2CMD
  }

  initial
  state s0 { .. }
}
```

TABLE III: Results of second learning experiment with filtering of periodic events

Experiment			Learner Output				
Trace	Excl.	Unique Groups Nr.	Timing Rules Nr.	States	Transitions	Time (in ms)	Verified
2	-	676	19	1971	2637	7	no
2	string int	25	1	74	93	1	yes
3	-	191	30	468	649	1	yes
3	string int	26	2	76	96	2	yes
3	all	25	0	75	96	2	yes

The model of the third party operating table is very large and unreadable. The main reason is the number of operations and the fact that the system components periodically exchange keep-alive events. These periodic events become part of the action lists which increases the number of possible states significantly. Because of this we have improved the instrumentation of the ComMA Learner by filtering out periodic events from a trace.

As an example, Listing 5 specifies that the unsolicited events "dummyCMD2M" and "dummyM2CMD" have to be removed from the input trace. Then the generated state machine contains a part that allows the corresponding operations in all states. Listing 8 provides an example where "dummyCMD2M" is a *Signal* and "dummyM2CMD" a *Notification*.

Table III is an update of Table II where these two events are filtered from Traces 2 and 3. Observe that filtering reduces the number of states and transitions of the resulting model.

B. Analysis

When inspecting the learned models, we observed that the state machine for the power control case is quite readable. For this case, Listing 3 presents a fragment of the manually crafted model and Listing 7 presents a fragment of the generated model. Next we compare both state machines:

- States "s0" and "SystemOff" map because the VideoOnButton can be injected in this state. The "GetState" was not present in the observed trace and therefore not in the learned state machine
- The "VideoOnTransitioning" state in the manually crafted model is presented by the "s0_0_0" and "s1" states of the learned model. The learned state machine does not use state variables, but encodes this behavior in separate state. Observe that the learned model is more restrictive because "StateUpdate" needs to come before "GetState" while this is not required for the manual crafted model.
- States "s12" and "VideoOn" map because the GetState operation replies "VideoOn".

VIII. Concluding Remarks

We presented a manual and automated approach to reverse engineer existing legacy software interfaces. The benefit of the automated approach compared to the manual approach is that less manual labor is required for the creation of a ComMA model. Based on sequences of observed operations, a ComMA model is automatically generated that describes the external visible behavior of a software component in terms of its state and timing behavior.

We applied our approach on two cases for which we had

manually crafted ComMA models and traces available. In our experiments, the ComMA monitor generated from a learned model accepts all traces that were used to learn the model.

We observed that the learned state machines can become very large and restrictive. For example, when an operation has an integer as a parameter and the trace has many occurrences of this operation with many different values for the integer, then the Learner will create a transition for every different value. However, this parameter value might be irrelevant for the state behavior of the learned component. In such situations, it is desirable to exclude integer values from the state machine learner and we instrumented the learner to allow this.

A general strategy could be to first learn a state machine without excluding any parameters and then incrementally exclude parameter types until the resulting state machine is manageable. The final step then would be a manual editing of the state machine.

With our approach the quality of the traces is very important. All behavior that is not in the input traces will not be in the resulting model.

In the future, we will apply our approach on legacy interfaces for which we do not have a manually crafted model.

Acknowledgments

We are grateful to the anonymous reviewers for useful comments and suggestions.

6th Conference on Multimedia, Interaction, Design and Innovation

MIDI Conference provides an interdisciplinary forum for academics, designers and practitioners to discuss the challenges and opportunities for enriching human interaction with digital products and services.

The main focus of MIDI Conference is exploring design methods for creating novel human-system interaction, developing user interfaces and implementing innovations in user-centred development of advanced IT systems and on-line services.

Topics

Topics of interest include (but are not limited to) the following areas:

- interactive multimedia and multimodal interaction design
- novel interaction techniques, voice interfaces, interactive multimedia
- ubiquitous, multimodal, pervasive and mobile interaction, wearable computing
- novel information visualization and presentation techniques, Augmented/Virtual Reality
- design methods for usability, accessibility and outstanding user experience
- prototyping of user interfaces and interactive services
- human-centred design practices, methods and tools, user interface design
- unfolding trends in HCI research and practice, customer experience, Service Design
- advances in user-centred interaction design
- understanding people and interactions: theory, concepts, models and methods
- understanding people and interactions: contextual, ethnographical and field studies
- critique and evolution of methods, processes, theories and tools for human-computer interaction
- novel methodologies for conceptualization, design and evaluation of interactive products and services

Optimizing the Number of Bluetooth Beacons with Proximity Approach at Decision Points for Intermodal Navigation of Blind Pedestrians

Jakub Berka, Jan Balata, Zdenek Mikovec

***Abstract*—Navigation in urban environments is very challenging for blind pedestrians. Although many navigation approaches using various principles or sensors to help visually impaired people exists nowadays they still have problems to navigate in complex buildings, find entrances to buildings or to navigate to correct public transport stops. Current solutions use a large number of sensor that needs to be installed in the environment needed to track every single move of the user. We present a solution to reduce the number of installed sensors by using previously developed set of landmark-enhanced navigation instructions allowing us to lower the necessary number of Bluetooth beacons by using them only for proximity notification at indoor decision points, indicating public transport station and entrances. The evaluation in the field study (N = 8) suggests a good potential of the approach, especially in terms of usability, recovery from going astray and beacon deployment cost. Further, we provide guidance on beacons placement in the environment.**

***Index Terms*—BLE, beacons, intermodal, navigation, blind pedestrians**

I. Introduction

FOR the visually impaired people, it is vitally important to be able to travel independently and freely. The limitation in travel related activities has a negative impact on their quality of life and can result in worsening psychical condition and low self-esteem [1].

Many electronic devices, navigation aids, and navigation systems are now widely available for blind pedestrians. They are based on various principles of positioning such as Global Satellite Navigation System (e.g. GPS[1], GLONASS[2]) based systems for outdoor navigation (Blind Square, Ariadne GPS, Kapten Mobility); Bluetooth Low Energy beacons (NavCog), RFID[3] readers [2], or cameras [3] for indoor navigation. However, positional error for GPS in a city is about 28 meters for 95% of the time [4]. Similarly, indoor positioning systems often require high deployment costs and are not suitable to be used in other than indoor environments moreover, there is no global standard for indoor navigation systems yet.

In this paper, we propose a method for decreasing the number of Bluetooth beacons used for indoor positioning. We have identified various places on typical routes where the beacons are necessary because of complicated navigation and orientation, e.g. entrances to buildings, public transport stations, open spaces/areas (hallways, courtyards) and indoor decision points (location, where navigation instruction is needed because of multiple routes, can be taken such as corridor crossing). In the rest of the routes, we replace the beacons with landmark-enhanced navigation instructions, which provide necessary guidance when traveling. Instead of continuous location tracking, we use Bluetooth beacons for proximity estimation.

[2]Global Navigation Satellite System
[3]Radio-frequency identification

II. Related Work

In this section, we describe approaches related to indoor and outdoor navigation of blind pedestrians. Furthermore, we focus on methods that use Bluetooth Low Energy beacons for navigation or proximity estimation.

A. Pedestrian navigation of blind

Successful navigation depends on the spatial knowledge about the environment. There are three levels of environment knowledge applied for navigation in cities: knowledge of landmarks, knowledge of route and overview knowledge [5]. Landmarks can be defined in various ways as says Golledge in [6], a landmark is something capable of attracting attention, i.e. it has dominance visible form and stands out from the surrounding environment. For navigating visually impaired people outdoors the suitable landmarks can be e.g. street corners and their different shape, pedestrian crossings, steps, etc. For indoor navigation visually impaired people still use the landmarks because the three levels of environment knowledge are valid indoors as well, only the characteristic of landmarks change (e.g. door, stairs, type of rooms).

B. Bluetooth Localization

Work of Gorovyi et al. [7] shows the application of beacons for real-time users positioning based on trilateration calculation using Received Signal Strength Indicator (RSSI) values from three or more beacons. Performed accuracy test showed

that beacon calibration improves system efficiency (1-2 meters in their case).

The Bluetooth technology used for indoor localization is often combined with utilization of other sensors to improve the accuracy of the navigation in an indoor environment (Accelerometer, Barometric sensor). Czogalla and Naumann [8] developed indoor navigation for 8000 m^2 public indoor environment with 35 beacons installed. The route is presented to users by visual map and directions by vocal instructions.

Commercial solutions for indoor location or positioning based on the beacons often use a triangulation/trilateration approach such as Indoo.rs[4]. The difficulty of these solutions is mainly in a large number of beacons required. To achieve their proposed accuracy 1-3 meters it is necessary to install beacon every 7-10 meters, e.g., with Infsoft indoor navigation[5].

C. Indoor Navigation for Blind

Work of Ahmetovic et al. [9] resulted in *NavCog* system, which relies on Bluetooth beacons installed in an environment and provides sub-meter precise localization with a minimum of 1 beacon every 6 meters and navigation assistance for people with visual impairments. They achieve it by representing the environment in the one-dimensional graph which results in lower number of beacons to be used and further, they use multi-modal probabilistic state estimation algorithm and Particle Filtering framework to more precisely estimate user's position. *NavCog* system gives to user the "turn-by-turn" metric navigation instructions, distance announcements inform the user about the distance to next action (e.g. "18 meters"), action instructions give information about turning direction or transit information (e.g. move between floors). It also provides accessibility instruction (e.g. if there is a curb that is easy to trail with a cane) or surrounding information (e.g. building description) on request.

To help visually impaired children in school to move and play independently Freeman et al. [10] used Audible Beacons as wearable bracelets that support wireless communication and provide audio output. Beacons are also placed in the school environment. They presented various scenarios based on their solution. Beacon bracelets can inform children about their nearby points of interest, by playing a specific sound of this POI[6]. As the children get closer to the POI the sound is played louder. It can help to find sighted friends, who are wearing bracelets as well. Bracelets and beacons placed in the environment can help to learn the layout of the school including entrances.

Guo et al. [11] developed Landmark-based Mapless Indoor Navigation called FreeNavi that requires only WiFi fingerprints collected on the device. This system applies knowledge of humans being able to navigate through and identify the environment by landmarks. FreeNavi constructs a virtual map only by landmarks descriptions and their connectivity relations. Virtual map construction algorithm is based on WiFi signal strength data and also landmark fingerprints and the user traces, this data is crowdsourced and then the map created. The generated map does not contain information of turning directions (left or right), i.e. users have to find out by themselves at the junctions in which direction they have to continue to next landmark.

Finding entrances to the desired building was subject of researchers focused on crowdsourcing. The study says that almost 65% of blind and visually impaired people suffered the mobility hindrance of hard to find entrances in the international survey by Zeng and Weber [12]. To solve this issue authors used collaborative method for collecting information about entrances and buildings and they also created reference point for each entrance, their concept does not use GPS data but it is expected to use some GPS-base tool to navigate to reference point, when user approaches the entrance s/he gets structured and also unstructured collected information by other users. [12].

Our proposed solution is based on automatically generated landmark-enhanced navigation instructions for outdoor [13], indoor [14] environments and their combination for different environments transitions and usage of public transportation [15]. For automatic generation of the navigation instructions it is necessary to use specially modified GIS which contains information about sidewalk network and special features of the urban environment (slope, surface quality, railings, corners) as it is presented in [13]. In our work, we aim to address the issue of finding the entrances [12], as well as a large number of installed Bluetooth beacons [9] by using them only for notification of progress at decision points without trilateration.

III. Navigation Application Prototype

We developed a prototype of the navigation application which provides navigation instructions for outdoor, public transport and indoor navigation for blind pedestrians. The transition between different modes are seamless – at the transition from one mode/environment to the other, the application provides summarized description of the mode/environment such as the description of the public transport lines and stations or description of the building. In selected locations, the application provides notification about user's progress on the route triggered by Bluetooth beacons.

A. Route itinerary

The route itinerary contains detailed navigation instructions for each segment of the route, which consists of a description of the surrounding environment and action to be performed by the user. Construction of navigation instructions is based on the sidewalk-based GIS[7] for outdoor environments [13], template system for public transport stops and stations and environment transitions (e.g., from outdoor to indoor) [15] and landmark-enhanced navigation instructions for indoor [14]. Navigation instructions are stored in the navigation application in the graph data structure (see Fig. 1 and Tables I, II).

TABLE I
EXAMPLE OF THE NODES DATA IN GRAPH DATA STRUCTURE.

Node	isOnRoute	BeaconID
A	true	undefined
B	true	ODUM
C	true	vf3i
D	false	4vXL

B. Beacons Installation

The navigation application uses RSSI from beacons to estimate its proximity. There are several factors influencing the signal transmission: the signal can be absorbed by other persons moving nearby beacons; the signal can be interfered by other devices working on the same frequency spectrum as beacons (2.4 GHz, same spectrum used by Wi-Fi 802.11); many materials can act as barriers for Bluetooth signal such as plaster, concrete, bulletproof glass, or metal materials[8]. These limitations have to be taken into account during beacon installation.

In the indoor environment, the beacons are installed only at the decision points – corridor junctions, corridor bents, floor mezzanines and complicated stair system. We placed the beacons mainly on the walls 2.5 – 3.5 meters above ground (see Fig. 2).

At public transport stations, the suggested place for installing the beacon is the info-table. Same as in indoor environment the beacon should be placed above the people's heads. In our case, we placed it at the tram station oriented towards the sidewalk.

To help users with environment transitions we placed the beacon near the building entrances. The beacon should be placed with respect to possible directions of the user's approaches to the entrance. If possible, as much as possible in the sidewalk level. When placing the beacon at the entrance our intention was first to slow down or stop the user. Second to let the user read the detailed description of the entrance from route instructions and find the correct door.

Moreover, we placed the beacon at the decision point in the semi-outdoor environment (university campus courtyard). This environment is composed of the roadways rather than sidewalks, and the users have to navigate through open spaces.

[8]Apple – https://support.apple.com/en-us/HT201542

Fig. 2. Beacons installation at the suitable places.

To help them find the decision point at the roadway turns, we placed the beacon on the building near it at 3,5 - 4 m high.

After the beacons installation, we configured beacons to avoid interferences of two or more beacons in mind and adjusted advertising interval and transmission power to ensure sufficient signal coverage. Finally, we collected RSSI to determine the thresholds to trigger location about the progress on the route.

C. Route Progress Notifications

The route is represented as an oriented graph.

The graph has two types of the nodes, *correct* and *error*. The correct nodes represent the decision points on the generated route. The *error* nodes currently used only for indoor segments represent the wrong turns off the route. E.g. if the route contains junction of corridors with one correct turn-off and two wrong turn-offs the graph will have one *correct* node and two *error* nodes. If there is a beacon installed at a particular decision point, its ID is stored in the node. For outdoor segments of the route, we store IDs only for nodes at entrances and public transport stops.

The edge represents a route segment. Edges on the correct route hold data about the segment number and the navigation instruction. Edges off the correct route lead to an error node. The part of the route graph we created for the evaluation purposes can be seen in Fig. 3.

We use the proximity-based approach – beacons serve as proximity traps at decision points, therefore the number of installed beacons is highly reduced. Route graph representation enables us to provide users with error prevention and also error recovery at the more complicated decision points – when the user goes astray s/he is notified and can use backtracking to get back on the route. Beacons ID are tied to navigation instruction displayed on a screen of the phone.

D. User Interaction

The navigation application was implemented in multiplatform Ionic framework version 3. The user interface provides controls for navigating between individual navigation instruction and for manual location verification. The user can

TABLE II
EXAMPLE OF THE EDGES DATA IN GENERATED GRAPH DATA STRUCTURE.

Edge	isOnRoute	Segment Nr.	Segment Description	Segment Action
1	true	1	You are at the turning of the road, the building E is in front of you.	Turn left and go approximately 30 meters through open space to pyramidal stairs, by your right hand. There is an entrance to the building E.
2	true	2	You are by the entrance to the building E. Above the pyramidal stairs there is big wooden door and glass swing door right behind, leading inside the building.	Go up the stairs and through the doors inside the building.
3	false	undefined	undefined	You are on the wrong way, return back to the beginning of the segment.

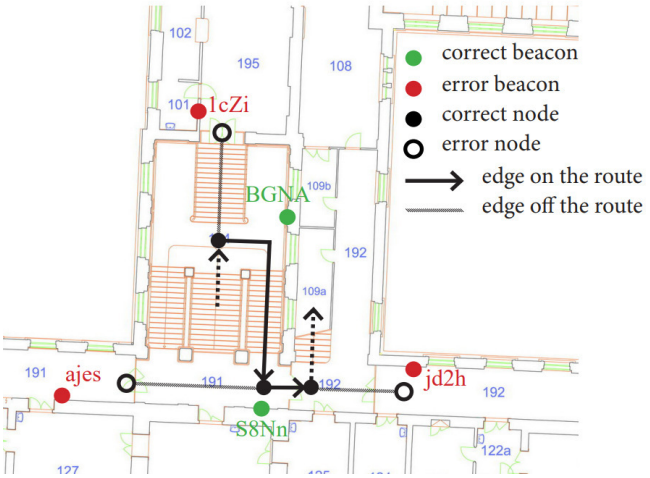

Fig. 3. Part of the experimental route represented as an oriented graph. With positions of installed beacons.

navigate between individual navigation instruction by pressing the buttons "Next Segment" and "Previous Segment".

When the user approaches the correct beacon, the application automatically notifies the user by vibration and text *"You are near the end of the segment."* Similarly, when the user turns off the route and approaches in the nearby of the error beacon from an actual segment, the application will four times short vibrate and announce to user *"You are on the wrong way, return to the start of this segment."*

These two notifications from application happen automatically when the user is in the vicinity of the corresponding beacon. However, the application also provides the possibility to manually verify user's position. When the user presses "Verify location" button the 5 seconds timeout starts and application is ranging for correct or error beacons. When the 5 seconds limit expires and the user is not in the nearby of any beacon application will announce *"Verification of your location was not successful."*

IV. EVALUATION

The navigation application supported one experimental route with an outdoor-indoor combination and usage of public transportation. Navigation instructions were automatically generated for outdoor (using Naviterier[9]) and manually prepared for the indoor, public transport and environment transitions.

A. Participants

Eight visually impaired participants were recruited via email leaflet (in the leaflet we mentioned that touchscreen smartphone will be used for the experiment). They were aged from 33 to 53 years ($mean = 40.25$, $SD = 7.27$). Five participants were congenitally blind and 3 were late blind. Three participants had Category 4 visual impairment (light perception) and 5 participants had Category 5 (no light perception) [16]. One participant had a guiding dog. All of the participants were native Czech speakers.

B. Apparatus

Route. The experimental route was located in city centre of Prague, Czech Republic with the combination of outdoor, semi-outdoor and indoor environments and use of public transportation (ride with tram).

It was approximately 700 m long (excluding tram ride), consisted of 36 segments. Twenty six Beacons Pro and 1 Tough Beacon[10] were installed on the route in total, 16 beacons were placed on the route decision points and 11 beacons were placed on the turnoffs from the route. The beacons for public transport station and at the first entrance were held by 2^{nd} experimenter glued on the paper folder above the head (as we did not get permission for long term placement).

Equipment. The participants were equipped with HTC One 801n smart-phone – Android 5.0.2, with running Talk Back screen reader set to Czech language and with the installed navigation application. The smart-phone had a lanyard that participant could hang on his/her neck, to have free hands when necessary. We also gave participants chip card that is needed to open a door inside the university campus buildings.

Data Collection. During each route walk-through, we were shadowing participants and recording third-person video. The navigation application records a log file containing data with timestamps about the interaction with the application, i.e. button presses, location notifications (triggered automatically)

[9]Naviterier – https://www.naviterier.cz/en
[10]Kontakt.io – https://kontakt.io/

Fig. 4. Photos from tram station and entrance to first building, show how the second experimenter hold the beacon.

and location verification requests (triggered by the user), and data about ranged beacons during the walk-through, with information about beacon ID and current RSSI.

C. Procedure

The experiment lasted around 1 hour. At first, we explained to the participant the purpose of the experiment, collected the demographic information and explained the operation and control of the application.

Then we accompanied the participant to the start of the route and we explained the task: *"Imagine, you were invited to participate in a study at the University Campus in a building E, room 317. To reach the destination use the navigation application, which will give you navigation instructions and it will notify you whether you are going the correct way at public transport stops and at indoor locations where you will also be notified if you go astray."*. They were instructed to proceed as if they were alone. However, whenever they felt unsafe, they should ask for our assistance.

After the participant finished the route, s/he was debriefed and asked about subjective judgement about the level of safety (*"I felt safe during the route walkthrough."*), efficiency (*"I think that thanks to application and navigation instructions I proceeded efficiently."*), information sufficiency (*"The Information I received from application was sufficient."*), comprehension (*"The instructions in decision points of the route were comprehensive."*) and confidence when finding entrances (*"I felt confident thanks to application when finding entrances to buildings."*) and tram station (*"I felt confident thanks to application when finding tram station."*) on a 5 point Likert scale as a level of agreeing with presented statements.

V. Results

All participants successfully completed the route. The average completion time was 44.2 minutes (SD = 8.7 minutes).

A. Tram station

Participants P1, P6, P8 found the tram station successfully, the beacon triggered the automatic notification.

Further, participants P2 and P3 misheard the notification from the application when finding the tram station, but the manual verification of location afterward was successful and helped then find the tram station. P7 also misheard the notification from the application, missed the info table at tram station, and continued further on the sidewalk (went astray) until we stopped him and returned him to the route.

Participants P5 and P8 confused the telephone booth, which was about 20 meters before the tram station with the info table of the tram station. They both tried to verify the location there and the application correctly responded. Afterward, P5 was able to find the tram station without the location verification as he switched to next segment early and P8 found it successfully with help from automatic notification from the navigation application.

Participant P6 was impressed by the automatic notification at the tram station, he said: *"As a blind when I am finding the tram station I have to walk near the building due to public notice so it is hard to find the station at the sidewalk, the automatic notification is very helpful."* P8 had the same opinion about stations: *"It is not necessary to receive the notifications everywhere but at tram station or near the entrances it is very good."*

B. Semi-outdoor.

At the courtyard, P1 did not follow the curb curved to the right and he continued in a straight direction. He complained about the missing information about curved curb. P3 and P4 skipped to the next segment before they reached the turn, but they continued without problems. Participants P6 and P7 had trouble with the manual location verification as they tried it few meters after they passed the beacon. P7 did not receive the automatic notification when he was near the beacon on the road turn however he continued without problems. Rest of the participants did not have problems when walking through the university courtyard and received the location notification.

After the experiment P7 explained that he lacked information about the distance and direction to the beacon: *"I would welcome the information about the distance to the decision point, now I am not sure if it is in front or behind me."*

C. Entrances

Entrance to building A (in the second niche of the protruding facade): Participants P1, P3, P4, P5 and P6 found the correct entrance to the first building. P3 found the entrance without the automatic notification but afterward verified the location manually twice and twice it was successful. P2 missed the entrance to the first building, the beacon triggered late, after a while we stopped him and returned him back to the route. P7 and P8 missed the entrance to the first building, the beacon did not trigger. P7 tried to verify location manually in the first niche, but the beacon did not trigger.

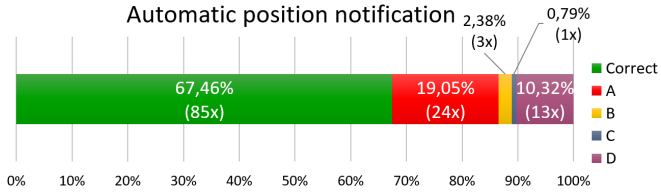

Fig. 5. Results of automatic notifications at decision points (total=126).

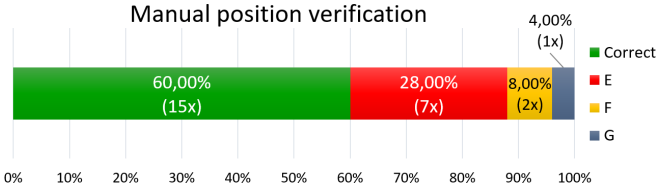

Fig. 6. Results of the manual position verification (total=25).

Entrance to building E (with pyramidal stairs): Participants P1, P2, P5 and P7 found the entrance with help of automatic notification from the application. P3 found the entrance but skipped to the next segment too early before the beacon can trigger. P4 found the entrance but the beacon did not trigger. P6 was proceeding to the entrance along the building and so the signal from beacon was shielded by the building, but participant found the entrance correctly. P8 stopped near the entrance when he got the notification at the right moment, but then continued straight and missed the stairs on the right, because he was proceeding on the very left side of the road during the segment leading to entrance stairs.

D. Indoor

Only P2 (once) and P4 (twice) went astray during the walk-through indoors. The error beacons triggered correctly and participants were notified that they should return to the start of the segment. P2 recovered from the error successfully alone. P4 at first recovered with an assistance and on the second error turn recovered alone successfully. P1, P3, P5, and P8 needed an assistance when finding the chip card reader next to the door. All participants but P5 found the correct door in the final segment.

Participant P6 mentioned that *"The vibrations and notifications were very accurate, it vibrated where it should for example at the last step of the stairs."* P3 noted that it would be beneficial at public transport stations and building entrances and in large buildings *"It would be great to have it for example in big hospital compounds."* Participant P2 was not satisfied with automatic notification at several indoor parts of the route: *"... in atrium it gave me the notification too early."*

E. Beacons

The automatic notification about the user position near the beacon was expected to happen 126 times in total during the whole experiment with 8 participants. Not always was the notification triggered as expected. In Figure 5 we present the results of the automatic triggering. The reasons why the automatic notification failed are various, e.g. signal interference, bad configuration of a beacon. Bellow, we present the detailed list of the different types of failures.

A: Notification did not trigger, near the beacon. Due to signal distortion or interference, bad configuration of the beacon or the signal covered by participant's body when turned away from the beacon. In two cases the users were behind the thick wall which absorbed the beacon signal.

B: Notification triggered too early, on the beginning of the actual segment. It happened during the short segments indoors. The distance it should trigger was to approximately 4 meters, but it triggered 8-10 meters away. The signal could be mirrored by a metal surface.

C: Notification triggered too late, when the participants just passed the end of the segment, therefore, they missed the decision point.

D: The application is ranging only for beacons in particular segment displayed on the screen. For more information see Section III-D. Some of the participants were reading the segments in advance and did not return to the actual segment in the application. We do not evaluate this situation as a failure.

The manual verification was used by participants 25 times in total during the experiment. Some participants tried to verify their location after they received the automatic notification and continued few steps ahead. The manual verification then could fail, because they stepped out of the beacon's range, or they covered the signal with their body. In Figure 6 we present the results of the manual position verification. Bellow is the list of various types of the manual verification failures.

E: Manual verification did not trigger the notification, near the beacon. Due to the signal distortion or interference, bad configuration of the beacon or the signal covered by participant's body when turned away from the beacon.

F: Manual verification failed, after the correct automatic notification. Participants stepped out of the range of the beacon, or the signal was covered by their own body.

G: Manual verification was successful on the second attempt.

F. Subjective judgement

Fig. 7 shows that 50% of the participants strongly agreed on information sufficiency they obtain from the application, one participant disagreed. 63% of the participants strongly agreed on comprehension at the synchronization points, one participant disagreed. 38% of the participants agreed about confidence when finding entrances, 2 participants disagreed. 63% of the participants agreed about the confidence when finding the tram station, 2 participants disagreed. 25% strongly agreed on safety and efficiency, one participant disagreed on safety and one disagreed on efficiency.

G. Discussion

The results clearly show that correct setting of the beacons is crucial for the proper functioning of this navigation system.

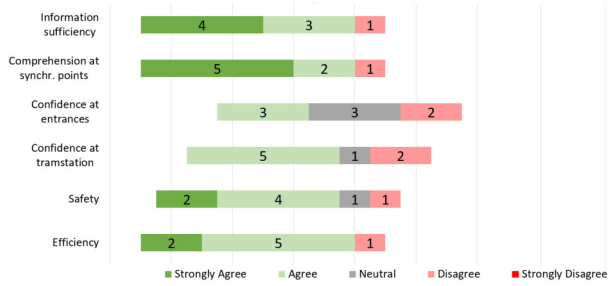

Fig. 7. Subjective judgements about level of information sufficiency, comprehension, confidence, safety and efficiency (N=8).

When placing a beacon at the entrance to a building, it should be remembered that users can come from different directions and that all of them should be covered by the signal. If it is a proportionally complicated entrance, it can be considerate to place a larger number of beacons to cover user's arrivals from all directions. It is not necessary to have beacons installed on each segment, sometimes it is not even physically possible, specifically on very short segments there may be a problem that the correct and error beacon will be very close to each other, which may result in an error location notification to the user even he is near the correct beacon or vice versa.

We experienced that there can be spaces where it is really difficult to correctly configure the beacons. In our case, it was the atrium with metal glass construction connecting two buildings. We tried to place there two beacons on the opposite sides of the atrium. But the signal distortion was too high, we decided to install there only one beacon to prevent the signal interference with the second beacon.

During the evaluation, some of the beacons triggered the position notification too early or too late. This issue can be solved either by the reconfiguration of the beacon or by moving the beacon 1 meter forward/backward.

The automatic notification often did not trigger because the user switched to the next segment. In our current solution the application is ranging the beacons only for the currently displayed segment. In future, this should be improved and the user notified about the surrounding information when arrives near any of the beacons.

Two of the participants took the wrong turn during the evaluation. They were able to recover from this error. We can say that even without the distance and direction information our proposed combination of navigation instructions with beacons only at decision points can solve the user's walkthrough errors using backtracking.

The manual location verification feature did not result in higher reliability. The participants tend to stop using this feature during the walkthrough. It happened that the automatic verification of the location worked correctly, but the manual verification afterward did not. The main reason was that the participant crossed the decision point by few steps and tried to verify the location beyond the beacon range. This could have influenced the user's confidence level at the decision point. We think that this feature can be omitted from the application.

If we compare our approach to NavCog [9] in terms of the number of beacons necessary, for the indoor and semi-indoor (courtyard) parts of the route (250 meters and 26 segments) we needed 26 beacons in total including error beacons. If we placed the beacons every 6 meters we would need approximately 42 beacons to cover only the route excluding error beacons.

VI. Conclusion

We designed a prototype of navigation application that has two main building blocks, the landmark-enhanced navigation instructions and the location synchronization system that uses the minimum number of beacons possible and that is also capable of error prevention and error recovery.

We conducted a qualitative study of high-fidelity prototype of this system with 8 visually impaired participants. As previous studies shown [13] the landmark-enhanced navigation instructions are suitable navigation for blind pedestrians, still there are many difficulties which we wanted to solve with utilizing beacons as synchronization points, i.e. finding entrances, public transport stations, help when identifying the landmarks and give users more confidence during the walk-through.

As we found out, the synchronization points successfully complement the navigation system using only navigation instructions. The main benefit of our solution lies in the use of a low number of beacons. But maintaining the effectiveness of navigation thanks to detailed and landmark-enhanced navigation instructions.

For the future, we see a potential in installing the beacons only on the most used and hard-to-find decision points namely at public transport station and entrances to public buildings.

***Abstract*—Sketching is a method used in user-centred design to visualize first drafts of a product. In corporate environments, sketching is often employed in ideation workshops with participants of various disciplines including end users. The aim of sketching is to promote communication and create a better understanding between stakeholders. However, participants are sometimes reluctant to engage in the activity for fear of inferior drawing skills. In order to counteract this phenomenon, we designed a mixed reality application that supports users in sketching, particularly in workshop settings. Two independent user studies showed conflicting results depending on the assumed perspective. First hand users find that the application effectively supports them in creating high quality sketches with high enjoyment in the process, although they do not see creativity enhancements or higher time efficiency. In contrast, third parties that rate the produced artifacts could not distinguish between application supported and free hand sketches in terms of uniformity, comprehensibility and quality.**

I. Introduction

PROTOTYPING is a method for early evaluation of product designs in the user-centred design process. In prototyping workshops, hand-painted drawings called sketches serve to visualize initial design ideas quickly and easily. This promotes communication between participants which iteratively contributes to a better result [1]. Sketches vary according to the draftsman's knowledge and skills. This happens, for example, because users do not recognize sketched elements, such as buttons or icons.

Our contribution is to support users in sketching and to improve the quality of sketches. We aim to improve understanding of sketches. In this context, we evaluate if a mixed reality application for the Microsoft HoloLens meets the requirements as a supporting application for sketching in prototyping workshops.

A. User-centred design process

User-centred design is an iterative process of defining and specifying user requirements [2]. A prototype serves as a "representation of all or part of an interactive system, that, although limited in some way, can be used for analysis, design and evaluation" [2]. In the creation of products, multidisciplinary teams support creativity and create better solutions. Workshops thus provide a suitable framework for the creation of prototypes. Buxton defines sketching as the process of quickly creating handmade drawings to visualize first drafts [1]. According to the author, sketches mainly serve as means of communicating design ideas. They can be distributed to potential users for feedback. Criticism and suggestions for improvement are most valuable in early stages of development. Sketches also serve as documentation for the design process in order to keep early design decisions comprehensible later on. In sum, sketching promotes communication in design creation, enables experimentation and supports the creative process.

This work was supported by Daimler AG

B. Requirements analysis

We determine the context of use on participants of prototyping workshops. One target group we address consists of persons that are well versed in the development of digital applications but cannot draw well. The other target group consists of end users of a planned product who have no experience in sketching user interfaces.

Based on the context of use, we establish the following hardware requirements for a tool that supports sketching:

1) Displaying drawing templates: The hardware should provide a possibility of displaying drawing templates that users can trace. Templates help the target group to draw professionally looking sketches and support them in sketching.

2) Use of pen and paper: In the design process, designers prefer the use of pen and paper rather than computer devices [3], [4]. That's why we determine that users do not have to sketch on computer devices. This implicates that users need their hands free for holding a pen and interact with physical objects.

3) Fast and easy set-up: As workshops take place in different premises, we set a mobile solution that includes a fast and easy set-up as a further requirement.

We determine further requirements for the software. These are derived from the definition we gave about sketching in section I-A.

4) Improvement of the quality of sketches: We aim to improve sketches by offering support to users for the drawing process. We try to establish conventions for elements in sketches. Consequently, sketches will look consistent no matter

which user has drawn it. By this, we try to achieve a better understanding of the sketches.

5) Not limiting creativity or discussion: Our solution supports sketching and should not interfere with the goals of the method. By definition, sketching aims to support creativity. Furthermore, sketches motivate workshop participants to communicate and discuss. A requirement that we define is thus not to limit creativity or discussion.

6) Joy of use: Positive feelings while using a product supports creativity [5]. Thus we aim to develop a solution that users like to use.

C. Related Work

Studies that support paper prototyping with overhead projector and camera have been rated positively by participants and experts [6], [7]. Such a hardware setup is time-consuming. A study that solves this problem concerns the use of mobile devices [8]. In this approach, the drawing is not done on paper but on the devices. However, it has already been proven that in early stages of design creation, designers prefer the use of pen and paper rather than computer devices [3], [4].

Another study supports drawing with pen and paper by applying the onion skinning technique [9]. The draftsman holds a mobile device with one hand and draws underneath the device with the other hand. According to the authors, feedback was mostly positive but users considered the device too heavy and discomfortable to hold. For further work, the authors propose a solution for see-through displays.

SketchAR [10] is an application with drawing templates for Augmented-Reality. The device projects drawing templates onto a surface in the room. Users then trace the projected lines with a pen. The application includes drawing templates of everyday objects, such as animals, plants, and humans. However, elements that are necessary for use in the context of sketching digital products are missing.

An application that meets the requirements that we defined in section I-B has not been found during research. However, in the presented work, users accept applications supporting prototyping positively.

II. Sketching Tool

Microsofts' HoloLens [11] meets the hardware requirements of a supporting tool for sketching defined in section I-B. The head-mounted device makes it possible to project digital content onto a surface with fixed world anchors. The advantage over smartphones is that the device is head-worn, leaving hands free for drawing. There is no need of further technical equipment and cables. This is suitable for workshops, as these are often held in external premises where technical equipment varies. As hardware requirements are met with the HoloLens, the following section examines how to meet software requirements defined in section I-B.

A. Concept

The tool offers graphics of UI elements for sketching, which a user may then trace. For a better overview of the available UI widgets, they are classified into categories. Users access the sketching mode by choosing an UI widget from the menu. A graphical visualization appears in front of a whiteboard. As support in sketching, we employ the onion skinning technique as it has been positively received in previous studies. Users step in front of the whiteboard and trace the lines of the projected element with a pen. Users can re-position, scale or rotate the element. If users have painted the element, they remove the digital projection. The hand-painted element remains on the whiteboard.

User interact with the tool by hand gestures. Audio output and speech commands are not used. We assume that audio output and speech commands distract users and create distance between user and workshop participants.

B. HoloLens prototype

The implemented prototype is shown in Fig. 1. We captured the prototype in the Unity Editor. The first image shows the sketch elements menu. The second image includes an UI widget in sketch mode and the main menu below the element. The third image displays the bounding box that allows users to scale and rotate the sketch element.

III. User study I: User tests with the prototype

We evaluated the suitability of the HoloLens prototype in sketching workshops. We asked users to create sketches with and without the application. Afterwards, they gave feedback and rated their experiences in a questionnaire.

A. Participants

We selected test users without extensive experiences with sketching to prevent influence through routine. The sample represented users that are insecure with the sketching process. We carried out user tests with five female and four male participants. The age range was between 21 and 33 years. The mean values were 4.89 for the previous experience with smartphone apps, 1.89 for head-mounted displays and 2.89 for sketching.

B. Design

In order to evaluate the effect of the application, we conducted a within subjects design. Each test person performed one task per condition: once only with pen and paper and once with the aid of the HoloLens application.

In each condition the task for the participants was to sketch an application that was defined beforehand. It was assumed that participants were familiar with smartphone apps. We selected apps based on a survey on the use of smartphone functions [12]: chat, music player, picture gallery, news articles, and public transport. We also added a task planner app. A textual specification of the use cases ensured that participants concentrated on creating sketches instead of spending effort to understand the task. We aimed to define an environment similar to workshop situations and offered test users to address the moderator for questions regarding the content of the use case.

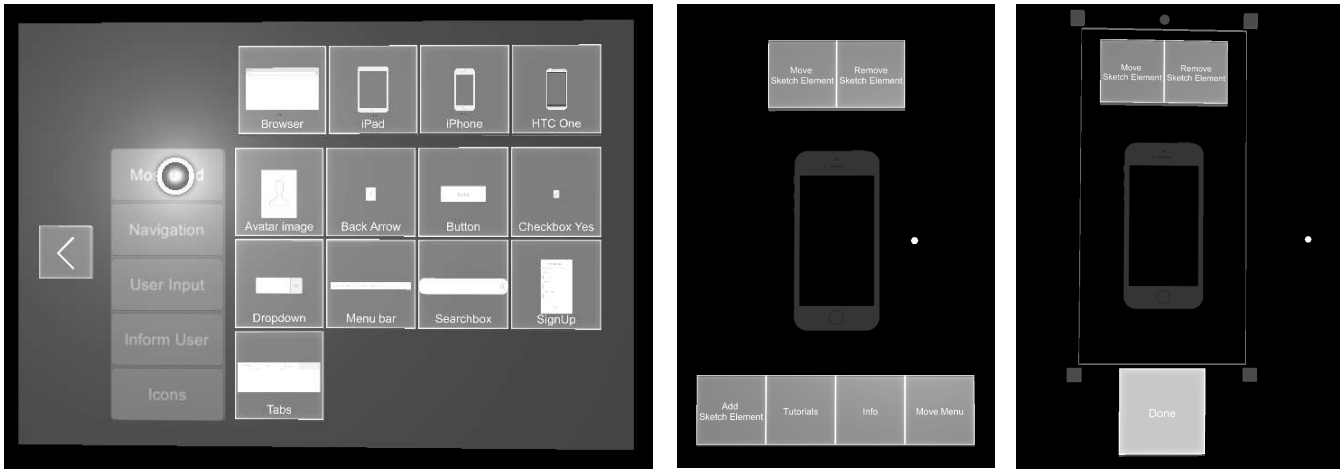

Fig. 1. Images of the HoloLens prototype from the Unity Editor. The first image (from left to right) shows the sketch elements menu, the second image shows a UI widget in sketch mode and the main menu. The third image displays the bounding box that allows users to scale the sketch element.

For each participant, we randomized the use cases and the order of conditions to avoid carry over effects. Furthermore, an equal distribution of the factors gender and prior experience was considered.

C. Questionnaire criteria

Participants rate criteria on a questionnaire after having performed the two tasks. The criteria included requirements from section I-B and were derived from similar work [7], [8]. In the questionnaire, users rate their extent of agreement on a Likert scale. The criteria were as follows.

1) Effectiveness: In order to answer whether the developed application is suitable for creating sketches, the effectiveness is evaluated. It is defined that the application is effective if the content needed to achieve the task is available.

2) Creativity: By definition, the method sketching supports the creative process [1]. Therefore, we evaluate whether the test users think that the application supports them in creativity.

3) Time-efficiency: Experts determine rapid execution as an important property of prototyping tools [7]. Since time of execution is an uncontrollable constant that varies between people, it is not feasible to measure it. Instead, we query an assessment of the test users.

4) Enjoyment: Positive feelings support creativity [5]. An expert also classifies enjoyment as important for prototyping tools [7]. We ask users whether the solution of the task was more fun with the support of the application.

5) Quality of results: We assume that the application is more likely to be used if users consider the results to be more professional than without the application.

D. Procedure

We carry out the user tests with each test person individually. After an introduction, test subjects read through the first task and start with the head-worn HoloLens. All test users operate the HoloLens by hand. Test users solve the tasks uprightly in order to simulate the workshop scenario.

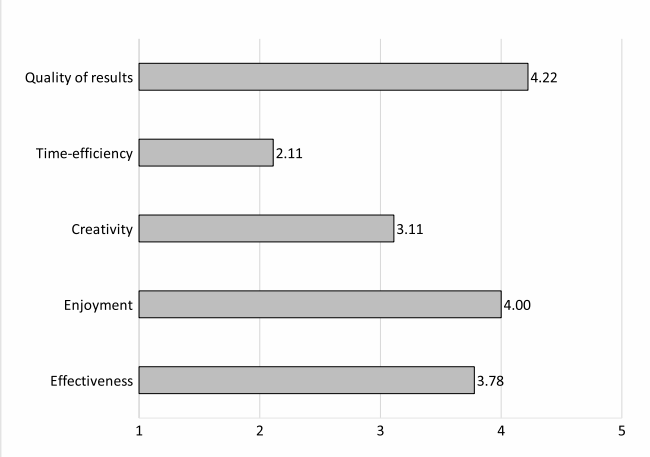

Fig. 2. Mean values of the criteria quality of results, time-efficiency, creativity, enjoyment, and effectiveness. The scale ranges from one (This does not apply) to five (This applies)

They start to sketch with a ballpoint pen on paper sheets. After completing the first task, the test users read and solve the second task. The moderator removes the sheets of the first round so that the user can no longer look at them. The test users fill out the questionnaire after completing both assignments.

E. Results

The questionnaire evaluates the criteria quality of results, time-efficiency, creativity, enjoyment, and effectiveness. The results are shown in Fig. 2. The graphic includes the mean value of the ratings from the test users per criterion.

The mean value for the quality of results represents the highest value (M=4.22, SD=0.83). The test users agreed that the solution of the task was more fun with the system (M=4.00, SD=0.87). They slightly agree that the application offered the contents they needed (M=3.78, SD=0.83). They neither agree

nor disagree in average that the application supports their creativity (M=3.11, SD=1.36). The only statement that test users do not agree with is the time-efficiency of the application (M=2.11, SD=1.27).

In a free text field for further notes, test users referred to the HoloLens application and noted more consistency in sketches; usage became easier after adaption; more enjoyment; added value of support with drawing templates; suitability for large elements instead of small elements; usage for small elements is time-consuming and impractical; no additional support of creativity; support for visualization of symbols; usage better for copying the element instead of tracing lines directly from drawing template.

IV. User study II: Evaluation of the sketches

We decided to conduct a subsequent study in order to evaluate the sketches from study I. Another group of participants evaluates the sketches which were created with and without the help of the application.

A. Participants

We select participants without any specific prior knowledge for the assessment of sketches. As this work is supported by Daimler AG, we determine German employees of the company as population and select a random sample. The number of employees of Daimler AG on 31.12.2017 in Germany was 172,089 [13]. In the online survey, 70 male and 25 female persons participate. The age is given in ranges of 20-29 years (31 participants), 30-39 (34 participants), 40-49 (16 participants), 50-59 (13 participants) and 60-69 (one participant). No person is younger than 20 years or older than 69.

B. Design

We plan the study with a within subjects design. We use the resulting sketches from the first study as stimulus. Each participant evaluates sketches with both features, i.e. with and without HoloLens application. Participants give their rating on a Likert scale in an online questionnaire.

Each participant evaluates three out of six use cases of each stimulus. To ensure that the same prerequisites apply to both stimuli, the tool stores each use case once per stimulus. We randomize the selected use cases and order of their occurrence. We give no information about the context in which the sketches were created. Users evaluate each use case independently of the other.

C. Questionnaire criteria

With the criteria we selected, we aim to evaluate if the application supported sketches look better.

1) Comprehensibility: Sketches are used to communicate design ideas in an understandable way [1]. By this criterion we determine whether participants recognize concepts and elements, such as buttons, arrows or icons.

2) Basis of discussion: Sketches serve as a basis of discussion and means of getting user feedback [1]. The survey participants evaluate if the sketches serve as a basis of discussion.

3) Uniformity: We assume that more uniformity in the presentation of the sketches leads to a better understanding. We define uniformity in sketches if users have chosen the same representation of elements.

4) Quality of results: The representation of sketches varies depending on the draftsmans' skills or the degree of maturity of the sketches. To counteract this effect, the application aims to improve it. Participants evaluate whether the sketches appear to be made in a professional context, for example by an experienced team or with the help of a tool.

D. Procedure

Participants evaluate the sketches in an online survey. Each questionnaire starts with an introduction to sketching and the evaluation criteria. Each of the following six pages shows a use case consisting of three sketches and a Likert scale.

E. Results

For the results we only consider questionnaires where the participant reached the last page. Table I shows mean values and standard deviations for the evaluated criteria.

TABLE I
Mean values and standard deviations for the evaluated criteria in user study II.

Criterion	Conventional sketches		HoloLens sketches	
	Mean	SD	Mean	SD
Uniformity	3.14	1.35	3.18	1.35
Comprehensibility	3.25	1.7	3.06	1.47
Basis of discussion	3.26	1.74	3.19	1.37
Quality of results	2.36	1.11	2.66	1.34

V. Discussion

The suitability of the application for sketching is derived from the criteria time-efficiency and effectiveness, which were evaluated in the user tests. The results show that sketching takes longer. Users needed time to familiarize themselves with the device and the application. Test users searched for suitable elements. Additionally, they needed more time to draw elements. Interactions are unfamiliar with first-time users. However, these limitations can be improved through training. Not all test users stated that the required content was provided. This can be improved easily by adding additional elements.

Based on user study II, we do not see any clear effects in the application supported sketches. We could not prove that sketches get more uniform with our tool. It follows that we cannot assess whether more uniformity in the presentation of sketches has a positive effect on comprehensibility.

Nevertheless, we recognize that test users were positive about our application. Test users believe that they have achieved more professional results. In addition, they enjoy solving the task with the application. We assume that an improvement in hardware and the application will lead to better results in time-efficiency.

In summary, the evaluation revealed that test users rate the application positively in terms of quality of results and enjoyment. Accordingly, the added value of using HoloLens

for sketching lies more in the use of the application than in resulting sketches. The application seems suitable to solve inhibitions of participants of prototyping workshops towards the method sketching. Thus, the application appears to be useful to familiarize participants with sketching. As test users say they have had more fun and think that the resulting sketches are more professional, it is conceivable to involve participants of workshops in the sketching process. Through the increased involvement of participants, we could encourage communication and discussion. Since this is one of the main reasons to use sketching, we suggest further investigation about the benefits of the application.

VI. Conclusion and Future Work

We investigated how a mixed reality application supports the method sketching in prototyping workshops. We described the suitability of the Microsoft HoloLens as a device for an application in sketching. The target group for the application are participants of prototyping workshops. We proposed drawing templates to support the sketching process and familiarize participants with the method.

We implemented a prototype on HoloLens. The device projects drawing templates onto a wall where users then trace the element with pen on a paper. In user tests, we evaluated the added value of the tool. As a result, the application has been well received by users. We therefore propose to carry out further studies. It seems interesting to put the focus of evaluation on user experience to determine the involvement of participants in the sketching process.

For better results in an evaluation of usability and user experience, we suggest to continue development of the prototype by expanding the range of UI widgets and improving the interaction concept. We suggest minimizing direct interaction by the user within the application.

Another relevant criterion is technology acceptance. If users do not want to use the device in workshops because they feel restricted or not taken seriously, the application will not be used. In addition, we suggest the evaluation of the suitability in collaborative group work. The application can furthermore be extended so that several HoloLens devices can be connected so that users can work together in remote work scenarios.

***Abstract*—The paper compares the advantages and disadvantages of a variety of Graphics Application Programming Interfaces (APIs) from the perspective of obtaining stereoscopy in applications written for a CAVE virtual reality environment. A number of problems have been diagnosed and an attempt has been made to solve them using OpenGL, DirectX 11 and 12, Vulkan, as well as the Unity Engine which can internally use DirectX, OpenGL and Vulkan, but has problems and limitations of its own.**

I. Introduction

STEREOSCOPY (stereo imaging) is a technique for producing an illusion of depth by delivering two different 2D images (generated from two different points of view) to each of the viewer's eyes. It is based on predator (and human) way of 3D perception by means of binocular vision (stereopsis). Stereoscopy can rely on direct delivery of two images on separate screens mounted in front of each eye (stereoscope, HMD – Head-Mounted Display) or displaying two images on a common screen visible for both eyes and using special filtering glasses separating images (3D cinema, CAVE – CAVE Automatic Virtual Environment). Filtering glasses can use various technologies: active (separation in time by shutter glasses) and passive (spectrum separation or polarization separation) [1, 2, 4].

The Immersive 3D Visualization Lab (I3DVL) located at the Faculty of Electronics, Telecommunication and Informatics of the Gdańsk University of Technology contains three CAVEs of various sizes: closed BigCAVE with six screen-walls, open MidiCAVE with four screen-walls and MiniCAVE based on four 3D monitors [3, 5, 7]. Immersive 3D visualization in these CAVEs requires stereoscopy and its synchronization on all screen-walls. The popular game engine Unity serves as the basic development tool in I3DVL. Unfortunately, it offers limited support for the creation of software for CAVEs and needs some adaptation.

CAVE systems put a number of unique requirements on applications, such as the need to synchronize a large number of screens or projectors, or the need to support active and passive stereoscopy, preferably at the same time. This in turn may necessitate the use of a quadbuffer (a screen buffer with room for four screen-sized pictures) or similar solution, if graphical artifacts are to be avoided. Rendering has to happen at the correct frequency (120 Hz for our BigCAVE system), or else frame skipping may happen – or worse, stereoscopy is disrupted if frames intended for one eye are displayed to the other eye. Latency should also be minimized, as delays in rendering are known to induce discomfort and dizziness in viewers, sometimes preventing them from extended use of virtual reality.

Most of the applications run on our CAVE system have been developed in the Unity engine, using a third party, proprietary library to achieve synchronization and stereoscopy. However the library had major limitations, including unsatisfactory performance and inability to work with Unity versions past 5.0.2. We also wanted a solution where we'd have access to the source code, so that students and researchers could implement not only applications, but also make changes to or expand the library itself if necessary. This forced us to start working on a new library, since the existing ones were either outdated or had proprietary licenses.

For a long time, the Unity Engine itself had no native support for stereoscopy, while also limiting direct access to the underlying graphics APIs – particularly during the initialization stage. Thus, the only way to achieve synchronization and stereoscopy was to render the scene to a texture, then use a separate rendering context – created outside of Unity – to display the resulting image. Since the contexts

This work was supported in parts by Entity Grant to Finance the Maintenance of a Special Research Device (SPUB) from the Ministry of Science and Higher Education (Poland) and DS Funds of the Faculty of ETI at the Gdańsk University of Technology

were separate, it was possible to use different graphics APIs for each task, so our testing included using DirectX 11 and OpenGL in Unity to render images for both eyes, while using OpenGL, DirectX 12 or Vulkan in another window to display those images at the correct frequency and synchronized between projectors and with active glasses.

II. Single camera stereoscopy

One of our attempts involved the simplest way to achieve stereoscopy in Unity – by alternating the placement of the camera every other frame. To achieve fluid stereoscopic animation, the camera is synchronously (on all client computers) moved back and forth between points A and B, representing the position of left and right eye respectively. This needs to happen exactly 120 times per second (for our setup), each frame shown for the exact same time. It also needs to be synchronized with the active 3D glasses, which alternate between darkening left and right LCD shutters at the same rate.

While alternating the camera's position between frames is trivial, implementing the synchronization with glasses in Unity is problematic. Even when configured to keep a fixed frame rate of 120 frames per second, it's common for frames to vary in length, depending on unpredictable changes in rendering times. This results in the viewer often seeing either two overlapping pictures, or reversed pictures, where the left eye sees the picture intended for the right eye and vice versa – a (dizzying for the viewer) occurrence referred to as a desynchronization.

Attempts to reduce the issue by increasing the frame rate to 240 Hz didn't solve the problem, even when the number of frames between switching camera positions was adaptively adjusted based on the amount of time a frame actually took to render. Increasing the frame rate further (360 Hz) was barely possible, since even an empty scene in Unity, with no running scripts, physics or camera movement, typically oscillates around 300 to 330 frames per second.

In best cases, using this method resulted in stereoscopy that would switch between correct and reversed pictures every few seconds, and after less than a minute resulted in complete desynchronization. Most likely the problem lies in the fact that the Unity Engine is not designed with constant frame rates in mind. Additionally, this method is useless in applications that – due to their complexity – suffer from occasional or frequent drops in frame rates. Such applications would need to be better optimized and tested – which most applications don't do sufficiently for this method to work. This is especially true if they don't normally (for use without stereoscopy) need a constant frame rate of 120 frames per second – such as when the movement is very slow.

III. Stereoscopy support in Unity

To properly display stereoscopic graphics in a CAVE installation, a number of tasks needs to be done. Each screen requires two images rendered from two points – representing the left and right eyes. Each of the viewer's eyes can view any part of any screen at any time, in contrast to HMD (head mounted display) devices which split the display into parts visible by one eye only. In a CAVE, the left and right eye images need to use the same area of the display screens. To obtain correct perspective, the position of the eyes in regard to the display surface is crucial – it is calculated using the head tracking system. The interpupillary distance is then used to position both cameras correctly in eye positions. The images on screens that share an edge need to be consistent. This is achieved by correctly setting the projection matrices and view matrices, achieving an asymmetric frustum with edges passing through the corners of the display. The display surface is where the images for both eyes converge. Unlike in HMD devices, the frustum does not follow the rotation of the viewer's head, but rather is always facing the same direction. If the technology used (such as active shutter glasses) requires the left and right eye images to alternate, it is crucial to synchronize this between all screens, so that they all display images intended for the same eye at the same time – especially if each screen is governed by a separate instance of the application. To achieve this, the usual solution is to prepare two images every application update, then pass the task of displaying the correct one to synchronized graphics cards such as NVIDIA Quadro Sync (used in I3DVL).

When OpenGL is used to write software, one can use quadbuffers to achieve stereoscopy [9]. Firstly, one needs to set the `PFD_STEREO` flag in the `PIXELFORMATDESCRIPTOR` structure using the `SetPixelFormat` function [11]. This can only be done during context initialization. This in turn makes it possible to render to the left and right backbuffers, switching between them using `glDrawBuffer(GL_BACK_LEFT)` and `glDrawBuffer(GL_BACK_RIGHT)` calls.

In the Unity3D engine, rendering is done with the `Camera` component. To configure it for each CAVE screen the `projectionMatrix` and `worldToCameraMatrix` fields have to be set with appropriate matrices. We tried to use quadbuffering in Unity, but it proved impossible due to the lack of low-level access to the graphics device during the initialization step. It was not possible to set the aforementioned flag. We found two workarounds to this problem.

The first one was to inject a modified DLL library during application launch. The library would intercept the `SetPixelFormat` function call and set the `PFD_STEREO` flag, resuming with normal initialization afterwards. A program launched this way could use two cameras, switching between the target back-buffers in the `OnPreCull` camera event from the native plugin level. A native plugin in Unity is one that is compiled from non-virtual machine languages such as C and C++. The disadvantage of this solution is that it's hard to implement and requires a separate piece of software for injecting the DLL at application launch.

The other workaround is to create a separate OpenGL window (from a native plugin) which is only tasked with displaying the images, while the Unity application renders those images to a virtual texture and passes them to the OpenGL window. When launched, the Unity application would create the window (which needs to belong to the same process) with a new graphics context initialized with

the PFD_STEREO flag. Using the wglShareLists function we can enable the Unity context and the OpenGL window context to share a single display-list space. On the Unity side the two cameras create RenderTexture objects, the virtual textures, which are set as targetTexture of the cameras. This results in Unity rendering the image for left and right eye to those textures. The GetNativeTexturePtr function gives us pointers to these textures which can be passed to the OpenGL window. Thanks to resource sharing, the window can then bind those textures with the glBindTexture function. All that is left to do is for the window to draw those textures to the correct backbuffers.

This workaround has a number of disadvantages. One is the slightly lowered performance because the main unity application is now considered by the operating system to be running in the background, while the OpenGL window which does almost no work is in the foreground. This can result in suboptimal assignment of processing power to the threads, since modern operating systems tend to prioritize foreground windows. Another problem is that input from devices such as keyboard and mouse will be directed to the foreground window, which may require redirecting the input events to the Unity application.

Unity3D has been offering support for VR (virtual reality) applications for a while, but their focus is on HMD devices [8]. Since 5.4 version, they extended support to include stereoscopy-capable flat panel displays. The newly added "Stereo Display (non head-mounted)" option makes it possible to obtain stereoscopic images which can be rendered using a variety of graphic APIs – OpenGL, Vulkan, Direct3D 11 and Metal. At the time of this writing, it doesn't work with Direct3D 12 yet. The Camera object can be set to render images for both eyes or we can use two Camera objects each responsible for one eye. The matrices for these cameras are set using the SetStereoProjectionMatrix and SetStereoViewMatrix functions. We can also set in the project options whether rendering should alternate between left and right images or if we want to render both images simultaneously (known as the Single-Pass Stereo rendering optimization [10]).

Using Unity's engine for stereoscopy has a number of advantages. The engine unifies the implementation of stereoscopy for the different graphics APIs and operating systems. The engine itself also performs a multitude of optimizations (such as the aforementioned Single-Pass Stereo rendering) [8]. Creating and launching the application is easier – no need for injecting libraries or intercepting control devices input from the second window. However, there are also drawbacks. The main one is that (non-HMD) stereoscopy support in Unity is fairly new and a niche need, and thus software bugs and instability are common. Common problems include the random freezing of rendering for one of the eyes, especially with HDR (High Dynamic Range) or MSAA (Multi-Sample Anti-Aliasing) on. Other problems were encountered with Reflection Probes and

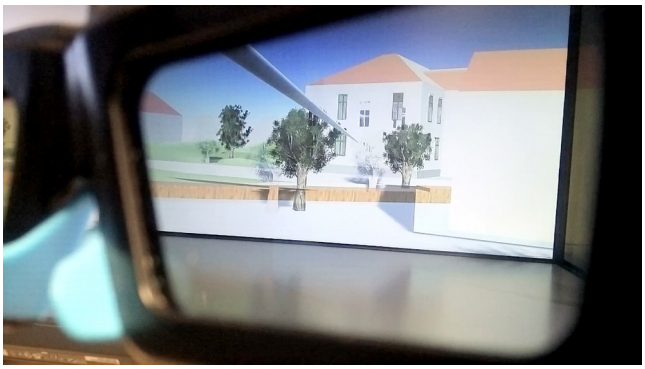

Fig 1. Improperly displayed tree shadows in Unity, as seen through active glasses.

Terrain objects (such as trees) improperly displaying shadows, which were rendered to the wrong eye or not at all, as shown in (Fig. 1).

IV. DirectX 12 and Vulkan in separate context

Vulkan is a modern 3D graphics API, released in 2016. Its main goal is to provide a low-level alternative to OpenGL as a multiplatform API, and thus offer better efficiency and more direct control over computations [12]. Compared to older APIs it excels at using multiple CPU cores in parallel (through support for multithreading), and the CPU load at runtime is reduced greatly by precompiling shaders to SPIR-V, an intermediate form that allows drivers to be much simpler [6].

Despite its advantages, Vulkan has a few drawbacks too. It is more verbose, requiring more code, and thus work, to get it to do things that are easier done in higher-level languages. This also means more room for bugs and harder maintenance. Another problem is the novelty, which means the API might see frequent changes as it matures. People looking to learn the API may have fewer options compared to older APIs that have hundreds of books and tutorials available. People who run into problems are less likely to find solutions on the internet. Few development tools, third-party libraries and game engines have support for Vulkan.

For our purposes, Vulkan would offer a few significant advantages – the ability to run linux-based applications on the CAVE being the primary one. This would be a benefit for applications that intend to use the Triton supercomputer which is connected to our CAVE and runs Linux (having both the front-end and back-end run on Linux isn't strictly necessary, but might be beneficial for some applications, especially if using the high-speed Infiniband connection and/or distributing computations between Triton and the client computers in our CAVE). However, at the moment most applications developed for our CAVE use the Unity engine and thus run on both Windows and Linux, with Windows having better support. Additionally, not all of our utility software (for managing projectors, tracking, and management of virtual reality applications themselves) are available for Linux. Other advantages of Vulkan, such as lower latency and better performance, are shared with DirectX 12. Thus, for applications that want to push graphics

quality as far as possible, or use very complex scenes, while still maintaining the high frame rates necessary for comfortable VR experience and stereoscopy, either of those two APIs can be used.

Microsoft DirectX is a collection of APIs for multimedia functionality in applications, such as games and video, on Microsoft platforms: the Windows operating system and Xbox gaming console. Direct3D – the component dealing specifically with the rendering of 3D scenes, is the flagship part of DirectX and thus names DirectX and Direct3D are often used interchangeably. The DirectX software development kit (SDK), which is now a part of the Windows SDK, contains binary libraries, header source files and documentation. The latest edition of Direct3D is version 12, sharing many similarities with Vulkan – such as the low level approach, lowered CPU utilization and better support of multithreading [13].

Unity Engine allows rendering to texture, a mechanism which can be used to display a stereoscopic image with a separate application – e.g. using DirectX 12 or Vulkan. It is crucial to keep the latency low, because otherwise virtual reality can cause discomfort for users. Thus, to speed up communication between the Unity application and the window used for display, shared memory can be used. The Unity Engine would write rendered images to the shared memory, while the window would read and display them on the screens, properly synchronized with the active glasses. The engine offers the `Camera` object, which gives us control over rendered images. From the `Camera`, we can retrieve a `TargetTexture` and assign it to a `RenderTexture` object. This creates a new `Texture2D` object with the `Camera`'s texture. Calling the `GetNativeTexturePtr` method results in a resource address, which we can use to retrieve all the necessary data that needs to be shared with the DirectX 12 or Vulkan process. The process takes the raw data and needs to recreate the resource objects. Once the resource objects have been created, they need to be updated every frame. The resource objects need to be linked with the previously written `Shader`, which is tasked with separating the left and right eye pictures into appropriate 'backbuffers'. Using a `Quadbuffer` allows for fluent rendering of stereoscopic images, since the engine can render two images (back left and back right) at the same time, while two other (front left and front right) are beings displayed – either one after the other (in case of active stereoscopy) or simultaneously if passive stereoscopy is used.

V. Conclusions

We found out that the Vulkan and DirectX 12 APIs offered enough low-level control to serve for our purposes, while also offering possible performance benefits. Vulkan is also supported on more platforms, which might make it the best choice for applications that require the computing power of a supercomputer – such as the Tryton cluster connected to our CAVE, which runs on Linux. However, these APIs have disadvantages as well – due to their low level design and novelty, maintaining a library based on them would require extra work.

The Unity Engine, over time, began to support different stereoscopy technologies and other virtual reality technologies. Their main focus were HMD (Head-Mounted Display) devices, but it was also possible to use these new features for CAVE systems. However, unlike HMDs which are now mass-produced to a few specifications, CAVE systems vary a lot, each being a unique installation, with different resolutions, sizes, projector positioning, tracking systems, etc. which means many parameters have to be set by hand (such as projection matrices, viewports). Nevertheless, using Unity's native support mechanisms has many benefits – the engine unifies the implementation of stereoscopy for the different graphics APIs (DirectX 11, DirectX 12, Vulkan, OpenGL Core, Metal) and operating systems. There's also no need to share textures between two rendering contexts – thus speeding up and simplifying the application. The engine itself also performs a multitude of optimizations (e.g. Single-Pass Stereo rendering). Support of control devices is also easier – especially now that there was no need for a second rendering window.

In conclusion, using the Unity Engine as basis for our library proved to be the easiest solution, offering many advantages in terms of simplicity and ease of use, both from library and application developer point of view. The main drawback is that it forces applications to be developed in Unity, which may not be the preferred development environment for all developers. It also has other limitations, and we may have to eventually expand our library to directly use graphics APIs, likely Vulkan or Direct3D 12, when the need to develop applications using other engines (such as the Unreal Engine or VBS engine) arises in our CAVE.

***Abstract*—The growing practice of accumulating personal data to generate predictions about users, leverages the need for mechanisms that allow people a more effective control of their data. An emerging field of studies called Human-Data Interaction (HDI), proposes the inclusion of human at the center of the data flow, providing mechanisms for citizens to interact explicitly with the collected data. Researches in HDI have discussed ways to offer Transparency Enhancing Tools (TETs), i.e., tools that support people on HDI issues related to privacy and personal data protection. Many works conducted about TETs focuses on usability issues, exploring aspects such as efficiency, user satisfaction and ease of learning. In this work, on the other hand, we aim to assess the communicability of HDI mechanisms in TETs. Hence, we applied the Semiotic Inspection Method (SIM) to investigate if and how HDI concepts are applied in two different TETs used for personal data management. We triangulated results from the study with findings from another investigation about communicability issues carried out in the same domain, but by observing and interviewing users.**

I. Introduction

The evolution of mobile devices, such as smartphones, tablets and sensors, influenced the society lifestyle as a whole by making more flexible the access to various services on the internet, and, eventually, by bringing advances in processing capacity and agility in mobile communication. As a result, people have begun to consume and share a significant and ever-increasing amount of data on their daily lives, which encompasses, for example, social information, events, health, lifestyle and consumption habits [1].

In ubiquitous computing scenarios, data collected by monitoring the user's activities can be used in analyzes and inferences to extract information about the behavior of individuals [2], [3]. In this scenario, data is used to make predictions related, for example, to the health status of people [4] or consumption trends [5]. Thus, the growing practice of accumulating personal data and generating inferences or predictions from them, leverages the need for research and creation of mechanisms that allow people a more effective interaction in this process of data manipulation [6].

Given this scenario, an emerging field of studies called Human-Data Interaction (HDI) proposes the inclusion of human at the center of the data flow, providing mechanisms to citizens to interact explicitly with these systems and the associated data [7]. The purpose is to enable users to understand by whom and in what form their respective data is used, and how to promote desirable effects and avoid undesired consequences [1].

Research in HDI is still incipient and has been gaining strength in the last five years, although some works in the Information Systems area reflect similar questions, among which are: transparency through open data, storage and use of personal data on the daily life of individuals [8] and privacy of information [9], [10]. Other works [11], [12], however, discuss ways to offer tools that support people on HDI issues related to privacy and personal data protection, and propose Transparency Enhancing Tools (TETs).

In [11], for example, the authors consider aspects of usability for TETs, proposing an interface prototype that seeks to offer the user a comprehensive view of their data stored and made available in different online services. This prototype is based on visualization techniques, seeking to associate the personal data of a user to the service for which this data was shared. The purpose is to provide transparency to users about their personal data collected by online services.

In [12], the authors presented PrivacyInsight, a software that allows the user to access their personal data, as well as the flow of data between interested entities involved in the storage and processing of this data. In addition, the tool enables the user to perform actions on their data in an indirect manner, i.e., through requests for correction or removal, thus providing means to exercise their right granted by law. This tool is based on the European Data Protection Directive (Council of European Union. 2016. Council regulation (EU) no 679/2016 - General Data Protection Regulation 95/45/EC[1]) and on usability requirements identified in the design of this solution.

Finally, in [13] the authors propose two Privacy Design Standards to facilitate the development of applications through solutions to recurrent privacy problems, focusing on trans-

[1]https://eur-lex.europa.eu/eli/reg/2016/679/oj

parency as a measure to establish broad control for users about their personal data. These standards are based on a set of factors, such as objective, user profile, usage context, problem, solution and consequences.

Such works, therefore, focus on usability issues in TETs, exploring aspects such as efficiency, user satisfaction and ease of learning. Our work, on the other hand, deals with the communicability [14] of mechanisms that enable Human-Data Interaction. For this purpose, we adopt a theory that considers the interaction of human beings with the interfaces of computational systems as a particular case of metacommunication, called Semiotic Engineering [15]. Some research questions are raised in the light of this theory, among which we highlight: How concepts of HDI can be communicated to users through TETs?; How interfaces can create means for the users to act in the data manipulation process?; and Which interactive elements can be used to communicate to the user about opportunities to use the data and its associated value?

In this context, this paper aims to investigate if and how HDI concepts are efficiently communicated (communicability) in two different TETs used for personal data management. For this, we apply the Semiotic Inspection Method (SIM) for scientific purposes [15]. We triangulated results from the study with findings from another investigation about communicability issues carried out in the same domain, but by observing and interviewing 5 (five) users. This work is organized as follows. In Section 2, we set the theoretical framework for the addressed theme. In Section 3, we present the methodology used in this work. In Section 4, we discuss the results obtained. Finally, in Section 5 and 6 we present the triangulation and final considerations, respectively.

II. Theoretical Framework

In this section, we present the theoretical basis necessary for the generation of this work.

A. Human-Data Interaction

The HDI area is an emerging field of interdisciplinary studies, which aggregates elements not only from the various branches of Computer Science, but also from areas such as Law, Psychology, Behavioral Economics and Sociology [1].

The literature presents some papers that address HDI with a focus on data analysis based on aspects of embedded interaction. In this approach, HDI is related to "Human manipulation and making sense of large complex and unstructured datasets". In [16], HDI is defined as "the customized delivery problem, creating the context of data understanding from large datasets". Thus, those proposals are based on aspects of HDI for the design of visualizations that allow to generate insights on large volumes of analyzed data.

There is a second approach, based on the proposals of Mortier *et al.* [7], which considers broader and more complex aspects, seeking mainly to address the problem of the management and use of personal data in society in general [17]. In other words, HDI is related to the manipulation of data, mainly personal, based on human factors [7].

The former approach is the one adopted in this work. It is related to the scenario in which the development of technologies and services for data generating, sharing and manipulating have, in general, allowed people to be in contact with digital tools and artifacts for consumption or production of information. Thus, people can produce data both Consciously (profile data in social networks, use of physical activity tools), and Unconsciously (robots monitoring our search history, cookies recording our browsing history, inferences of interest created from our purchase or search history) [7], [1].

Such data can be accumulated by different organizations that can perform inferences about sensitive issues related to our lives (health or emotional state, consumption habits or political preferences, for example) [7], so that these different analyzes make it possible to influence the user's behavior in a variety of ways [1]. Based on this perception, research in HDI seeks to address the new issues arising from the use of this ecosystem of personal data between different interested entities and their impacts on the actions of individuals and in society.

In [7], the authors establish three fundamental principles which address the challenges tackled in Human-Data Interaction, such as: Legibility, Agency and Negotiability. Legibility is concerned with making data acquisition and analytic algorithms more transparent and understandable to users, since, in general, interactions with data flows and processes are often obscure to people. Agency aims to provide individuals with the means to manage their data and their access by third parties, as well as to seek effective ways of acting in these systems, to the extent that individuals find it appropriate. This includes not only the ability to opt in or out of data collection and processing, but also the broader ability to engage with data collection, storage and use, and to understand and modify data and inferences. Finally, Negotiability is concerned with the various dynamic relationships that arise from data processing. This topic covers, for example, how understanding and individual attitudes change over time.

B. Semiotic Inspection Method

In this research, we used the Semiotic Inspection Method (SIM) for scientific purposes [15], a method of qualitative evaluation in Human-Computer Interaction (HCI), based on Semiotic Engineering [14]. With this method, the evaluators can analyze the communicability of the interactive artifacts [18]. The focus is to inspect the metacommunication from designer to user with the objective of identifying possible breakdowns in communication. First, in the preparation stage, the evaluation focus, the user profile and the inspection scenario are defined. In the evaluation stage, the evaluator examines the interface and classifies the signs as metalinguistic, static or dynamic.

Metalinguistic signs are the first to be analyzed, since they explicitly express and explain other parts of the metacommunication of the designer. This class of signs is usually found throughout the interface, either in instructions, explanations, warnings and error messages, with a focus on online help and user's manuals [19].

Static signs are those that communicate their meaning regardless of cause and effect relationships and can be interpreted from instant canvas pictures. Thus, they express the state of the system at a given time. They are represented by the elements present in the interface screens (or equivalents in non-visual interfaces), such as labels, images, text boxes, buttons, menus, etc., as well as layout, size, color, font and other characteristics. Its analysis should consider only the interface elements presented in each screen at an instant of time, without examining neither the behavior of the system, nor the temporal and causal relationships between interface elements [19].

The inspection of dynamic signs requires that in the analysis, the evaluator inspects the interaction process that the user can experience through the interface. These signs are perceived through changes in the interface that communicate to the user the behavior of the system as a result of user actions (clicking the mouse, pressing enter, changing the focus from one form field to another, etc.), by external events (receiving email, Internet connection failure, etc.) or over time. Dynamic signs are usually represented by animations, opening and closing dialogues, transitions between screens, or modifications to the elements of a screen (for example, activating a button, updating a text or image, modifying the layout of some interface elements, etc) [18].

To inspect the interface, SIM proposes 5 steps to be followed by the evaluator [20]. In the first three steps, the main goal is to reconstruct the metacommunication of the designer for each category of signs (metalinguistic, static and dynamic), using the following meta-model of the designer [20]: *"Here is my understanding , who you are, what I learned that you want or need to do, in what preferred ways and why. This is the system that I have therefore created for you, and this is how you can or should use it for meet a variety of purposes that fall within this version"*. The steps are:

- Step 1: Inspection of metalinguistic signs. In this step, the evaluator explores the documentation and help system.
- Step 2: Inspection of static signs. In this step, the evaluator inspects the static signs of the interface.
- Step 3: Inspection of dynamic signs. In this step, the evaluator inspects the signs that emerge from the interaction.
- Step 4: In this step, the evaluator contrasts and compares the metacommunication messages from steps 1, 2, and 3 and records possible problematic interpretations that may occur in user interaction time.
- Step 5: Appreciating the quality of metacommunication. In this step, the evaluator produces a report containing the communicability problems encountered, which may frustrate or prevent the user from understanding the message intended by the designer, affecting his productivity. In this method, the evaluator is the advocate of the user.

SIM can be used in scientific contexts and generate valid knowledge in HCI [15]. To do so, two other steps must be considered when applying the method. During the preparation phase, it is necessary to define the research question that researchers are looking for an answer. Also, after the application, a Triangulation step is added to the analysis. Triangulation involves the generation of other results (e.g. by other specialists or through compatible methods) which valides scientifically the results obtained through SIM.

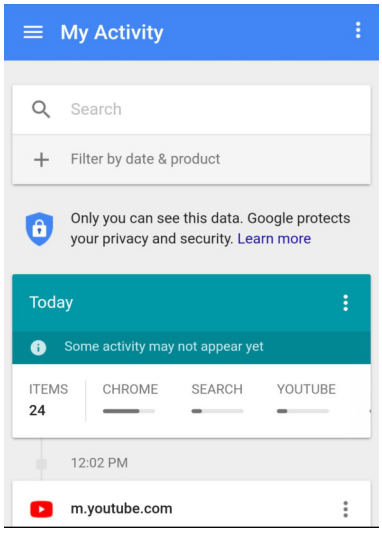

Fig. 1. MyActivity home screen.

III. Methodology

The methodology used in this work consists, in large part, in the application of the Semiotic Inspection Method (SIM), described in the previous section, with the focus on the evaluation of the communicability considering the concepts presented by the HDI theory. We use, therefore, the predictive paradigm, making use of an interpretative and qualitative method [21]. The inspections were carried out by two evaluators together, being one a junior level evaluator and the other a senior level evaluator (specialist). Based on the application of the SIM steps, we sought to answer two research questions (RQs): (i) Which are the communication strategies that potentially enable Human-Data Interaction?; (ii) What is the relationship among the elements found in the first question and the main concepts of HDI proposed by Mortier *et al.* [7], i.e., Legibility, Agency and Negotiability?

There are few TETs tools for data management that provide ways for controlling data. In addition, there are no records that these tools were designed based on the concepts that we adopt as the foundation of HDI. Thus, we performed two studies (S1 and S2) to identify traces of the application of the fundamentals of HDI in TETs. To do this, we have selected two tools: Google MyActivity [22] and Privacy Badger [23].

MyActivity allows users to exercise greater control over the data generated by the monitoring of their activities in Google's services and products. Privacy Badger is a add-on that aims to restrain the action of third-party domains that seek to collect data through unauthorized monitoring of user activity while he is browsing the web. Figures 1 and 2 show the interface of the home screen of both tools.

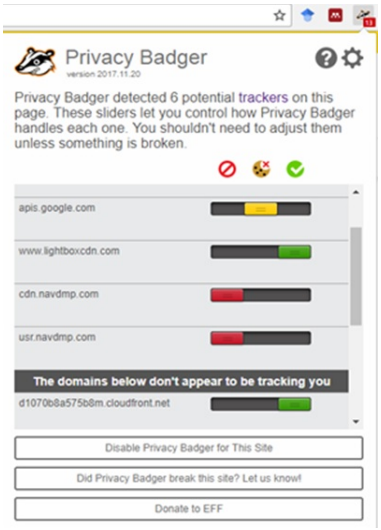

Fig. 2. Privacy Badger Home Screen.

These tools were chosen because they seek to offer the user an understanding of how their personal data are being collected or used by interested entities. Moreover, both tools provide the user with forms of control over the access and use of their data. The evaluation focus, the user profile and the reference inspection scenario in both tools were defined in the preparation stage of S1 and S2, as described below:

A. Preparation Stage for MyActivity

In what follows, we describe the evaluation focus, the user profile and the inspection scenario defined for the evaluation of MyActivity.

- User profile: The user uses mobile devices or computer to browse the internet, searching for leisure and entertainment options, and to make online purchases. He gets surprised to have the possibility of exercising control over his personal data.
- Inspection scenario: Ane performs various tasks through her smartphone. Every day she accesses social networks, conducts research of professional and personal interest and seeks to find the best path in traffic. Ane has always opted to make her personal data available to her applications and services from large companies like Google. With this, Ane seeks to experience a navigation based on their tastes, interests and types of content consumed, thus avoiding receiving unnecessary notifications or content. Recently, Ane was notified by Google about MyActivity, their Data Management tool. According to MyActivity's proposal, Ane has found that she can manage the Google's services to made them more useful. Ane was surprised to know that she can exercise control over her data or activities carried out through her smartphone. Hence, when Ane accesses Google's MyActivity, she wants to perform the following tasks: (a) To find out what types of data are being stored or monitored by Google; (b) To exercise some intervention in the availability and access to her data.

B. Preparation Stage for Privacy Badger

In what follows, we describe the evaluation focus, the user profile and the inspection scenario defined for the evaluation of Privacy Badger.

- User profile: The user uses mobile devices or a computer to browse the internet, searching for leisure and entertainment options, or shopping online. However, he is concerned about his privacy, i.e., preserving data about his browsing history against third parties.
- Inspection scenario: Bob uses his personal computer often to read news, emails, search products, shop online, access Internet banking, interact in social networks and search about leisure options. Bob manipulates his personal information to perform a good part of these actions. Thus, concerned about the risk of invasion of privacy by tracking robots (trackers), he resorted to some tools, among them, the Privacy Badger. Hence Bob wants to accomplish the following tasks when using this tool: (a) Identify all possible trackers that can monitor his activity when using the internet; (b) Block monitoring trackers.

IV. Results

In this section, first, we present the classes of signs found with the SIM inspection. Then, for both studies (S1 and S2), we tried to answer research questions (i) and (ii). For this, we analyze the main communication strategies found during the inspection, which involve the communication of mechanisms that enable Human-Data Interaction. These communication strategies were identified from traces of the application of the three main concepts of HDI theory: Legibility, Agency and Negotiability. Finally, we performed a comparative analysis between studies S1 and S2.

A. Classes of Signs

In this section, we present some visual design options that were identified through SIM. These options represent visual cues used to interact with systems and have been adopted by the designers of these applications. The MyActivity tool uses all of the identified types, while the Privacy Badger tool does not offer the 'Cards' and 'Modal' classes, as follows:

- **Cards** are the registered activities of the user. Each activity is represented by a title (showing the service used), a link for the activity performed preceded by a keyword that characterizes the type of activity recorded, such as 'Watched' (Videos), 'Visited' (Web Pages), 'Searched' (Google Search) or 'Viewed Area' (Use of Maps), for example. In addition, 'details' or 'delete' options are displayed in each activity log. Generally, a figure can be associated with an activity, and activity groupings can be done automatically to summarize the display of records. Thus, an option is displayed in the card footer if the user wants to view items that have been deleted. It is interesting to note that all activities compose a

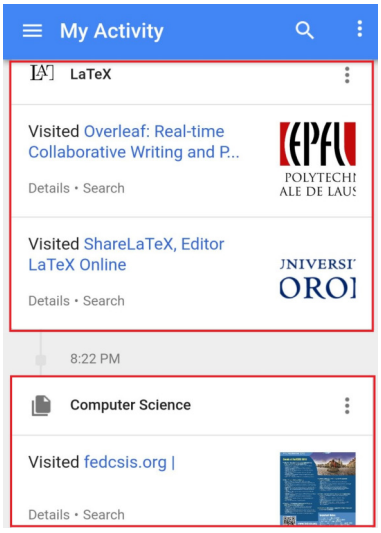

Fig. 3. Example of MyActivity 'Cards'.

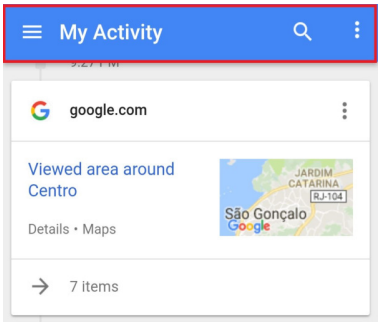

Fig. 4. Example of MyActivity Persistent Menu.

record history, so that these records are distributed in their respective days. Each card, which may be an activity or a grouping of records, is linked by a timeline with an associated timestamp. Figure 3 shows an example of cards.

- **Persistent Menu** allows the user to access a set of options at any time during their interaction with the tool. See the example in Figure 4.
- **Modals** are alerts usually displayed to confirm user actions, with texts that briefly describe their consequences. Figure 6 shows an example of a Modal in MyActivity.
- **Search Filters** allow the user to refine the view of records by context. For example, in MyActivity, you can select service types, date range, and more. In Privacy Badger, you can choose the status associated with the domain, for example. Figure 5 shows the example of a filter used by the Privacy Badger.
- **Sliding Buttons** represent user preferences regarding his privacy, i.e., what can be seen about him by entities interested in his personal data. Figure 7 shows examples of Sliding Buttons in Privacy Badger.

B. Communication Strategies in MyActivity

Based on the mapping of metalinguistic, static and dynamic signs, and their respective metamessages, the communication strategies identified in the MyActivity tool were:

- **CS1:** Provide different categorizations of the collected data;
- **CS2:** Show monitored activities and the level of use of products/services;
- **CS3:** Offer forms of intervention on data collection;
- **CS4:** Provide alerts of actions performed by the user;
- **CS5:** Provide means to report problems or collaborate with ideas.

About Communication Strategy (CS1), MyActivity, linked to MyAccount, gives the user a list of categories of data that can be collected about him, such as 'Location History' or 'Device Information'. For each category, a brief description of the purpose of the collection is presented. If he would like more information on this, the 'learn more' link will direct him to the 'Help' page. From this categorization, MyActivity also provides more specific categories of user activity on Google services, such as "Feedback no interest in YouTube" and "Location responses". In doing so, we believe that design intent was to provide a means for the user to have a comprehensive view on what types of data can be collected by Google, as well as to understand the company's objectives in acquiring the data of its users. In our interpretation we evaluated that this strategy points to some aspects of the concept of Legibility in HDI, since the tool makes available to the user information about who is monitoring him, the means used to perform the data collection, what types of data will be collected, and the intended interest in that process. However, we did not find explanations about the algorithms and methods used to generate inferences from the user data.

About Communication Strategy (CS2), MyActivity allows the user to access and review the history of activities he performed. By default, the most recent activities are displayed at the beginning of the history, i.e., in reverse chronological order. In addition, the user has access to the 'details' option that provides explanations on how monitoring is performed. The search engine helps the user find a specific set or activity in their activity history, giving the user better navigability, since a large number of records are expected. MyActivity also offers two types of activity view: packet-based (records are listed individually), or product/service-based (groups a sequence of records by their respective product/service). He can also check how often he uses the services each day. The activity history query should be based on its category. However, initially this may not be communicated appropriately to the user, since, by default, when accessing MyActivity, activities related to a category, usually 'Web and Apps Activity', are listed. Hence, we can observe indications of the concept of Legibility in this strategy, since the tool provides resources that inform the user about the capture of his activities in Google services and products.

Fig. 5. Menu filter in Privacy Badger.

About Communication Strategy (CS3), MyActivity, linked to MyAccount, offers the user ways to intervene on the data collected about him. For each data collection category, he can define whether monitoring is enabled or not. By default, some monitoring types are already enabled and others are disabled (paused). However, the user has the right to intervene, at any time, on the type of monitoring that he wants to pause or enable. The tool uses color to distinguish monitoring status, applying grayscale to 'paused' monitoring, and color to 'enabled' monitoring. In this case, we understand a possible intention to use colors is to communicate to the user about possible benefits from collecting their data. MyActivity also allows the user to delete activity logs. In this case, excluding records implies disregarding such data in the aggregation and processing made by Google. Therefore, we can perceive in this strategy the perspective addressed by the concept of Agency, so that the user has mechanisms to determine what types of data can be accessed and collected, as well as how his records are generated and deleted.

About Communication Strategy (CS4), MyActivity provides alerts when the user wants to take actions on his data, such as pausing/enabling a type of monitoring or deleting an activity, for example. These notifications tell the user about the implications of the intended action, generally seeking to encourage him to make his data available to Google, showing how this reflects benefits in delivering services or products. In addition, clarifications on how to collect and store such data are also communicated, thus proposing clarity and transparency, aiming at user confidence. From this, we can notice a link with the concept of Legibility, because this strategy seeks to deal with the user's concerns about his data and the processing that is performed from them.

About Communication Strategy (CS5), MyActivity presents a space that offers the user a feature to report usage problems or errors in the activity log. In this way, however, it is necessary to wait for the analysis of the request before it can be acknowledged. This mechanism also acts as a channel for sharing ideas or suggestions. Thus, we can establish a link with the concept of Agency, because this strategy allows the user means to inform and correct the data provided.

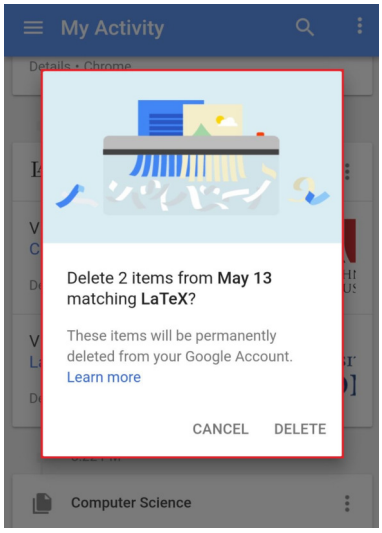

Fig. 6. Modal Example in MyActivity.

C. Communication Strategies in Privacy Badger

Based on the mapping of metalinguistic, static and dynamic signs, and their respective metamessages, the communication strategies identified in the Privacy Badger tool were:

- **CS6:** Offer forms of intervention regarding the use of data;
- **CS7:** Show the third-party domains identified.

About Communication Strategy (CS6): In general, the content of a web page can come from a number of different sources, i.e., third-party domains. On an e-commerce page, for example, the display of products will be carried out by a virtual store, the search engine can be from a company hired to make this service available and the ads will be from an advertising company. In this way, Privacy Badger analyzes the behavior of all identified third-party servers as the user navigates through different domains, applying one of the following statuses: 'Blocked', 'Partially Blocked' and 'Allowed'. If any domain is attempting to monitor the user's browsing record via cookies without permission, then PB will automatically block the content coming from that server. If this domain is providing an important content type for the page to work, then Privacy Badger will allow connections to this server, but will block its cookies injection in the browser. Finally, Privacy Badger will allow third-party content to be injected if no monitoring activity is detected.

The tool also allows the user to modify the applied status, thus offering the power to intervene in the result of the classification algorithm. In this way, this domain will be classified according to the decision of the end user. In addition, PB offers a local white-list where the user can add domains he trusts, so that they are out of the Privacy Badger analysis. Thus, we can observe a correlation with the concept of Agency in supporting the user to exercise control over access to their browsing data. However, the tool does not allow the user to

Fig. 7. Sliding Button in Privacy Badger.

define which types of data he wants to make available, for example.

About Communication Strategy (CS7): The Privacy Badger provides a list with the address and status of each identified third party domain, allowing the user to be aware of which third-party domains are active, as well as those who have attempted to perform some kind of hidden monitoring. However, the tool failed to communicate information about the identified domains, such as the type of content or what functionality a particular server was attempting to enter, which could assist user understanding of how third-party domains act. Thus, we can point out, in this strategy, a reference to the concept of Legibility based on the identification of which domains have attempted to collect the user data. However, the user will not be informed about some important aspects of the data collection, storage and processing, such as the purpose of the data collection or what types of data, in fact, can be collected about him.

D. Comparative Analysis between S1 and S2

One of the main challenges observed during the inspections was the partial application of the aspects advocated by the concepts of HDI, pointing to possible barriers or limitations in the adoption of human factors in relation to the use and storage of personal data by third parties. On the other hand, we have identified the possibility of enabling Human-Data Interaction without all traces of its concepts being present.

Regarding the concept of Legibility in HDI, we identified some of its aspects present in Communication Strategies CS1, CS2 and CS4 (Study S1) and in Communication Strategy CS6 (Study S2). We understand that this concept represents the first step in enabling Human-Data Interaction, setting guidelines that support people's understanding of the actions of third-party that are interested in their personal data. The communication problems encountered may point to resistance in making more transparent the algorithms used to infer new knowledge about people. This corroborates Mortier's observation in [7], when mentioning the conflict in making public such algorithms that are intellectual property of companies. However, it was possible to identify important mechanisms related to Legibility aspects, such as the classification of monitored data, the identification of those who want to access personal data, the forms of collection used and the intended goals of the interested parties. However, from the possible communication problems reported in S2, we noticed the more timid use of this concept by the Privacy Badger tool.

In relation to the concept of Agency in HDI, traces of this concept were also perceived in both tools. We can see that the comprehensive use of Legibility offers a more propitious context for the adoption of Agency aspects. In other words, if people are not aware of who they are interested in collecting their data, what their intended data are, their collection methods and desired goals, then the ability of people to act on their data is limited, so that there will be no important information available to users in order to support them in their decisions or to assist in the creation of more adequate criteria and controls on the access and use of their data by third parties. Therefore, we note that the MyActivity tool communicates these aspects more clearly, reflecting the concept of the Agency more comprehensively.

Finally, no traces of the application of the aspects related to the Negotiability concept were found in the strategies identified. This may point to the difficulty in defining mechanisms that allow identifying characteristics that are expressed in data and are likely to change over time, such as individual attitudes and interests, for example. However, these issues are relevant in the context of processing and generating inference from personal data. The Table 1 summarizes the answers by each research question.

TABLE I
SUMMARY OF THE ANSWERS TO OUR RESEARCH QUESTIONS OBTAINED IN S1 AND S2.

RQ(i)	RQ(ii)
CS1: Provide different categorizations of the collected data.	Legibility
CS2: Show monitored activities and the level of use of products/services.	Legibility
CS3: Offer forms of intervention on data collection.	Agency
CS4: Provide alerts of actions performed by the user	Legibility
CS5: Provide means to report problems or collaborate with ideas.	Agency
CS6: Offer forms of intervention regarding the use of data.	Agency
CS7: Show the third-party domains identified.	Legibility

V. TRIANGULATION

Triangulation is a standard procedure in the validation of qualitative research results [24]. In this case, we validated the results obtained from applying the SIM (S1 and S2), comparing them with the results obtained from a set of interviews and observation sessions with users, thus seeking to identify convergences and divergences, ensuring the scientific validity of the results.

The triangulation step counted on 5 (five) participants. Before starting the tests, a consent form was presented to the

participants, with information about the data collection and use conditions performed in this research. With due acceptance, the next step was to make a brief presentation of HDI for each participant, exploring the three main concepts proposed by Mortier *et al.* [7] . Then the tests were started.

We also used the inspection scenario described in sections III-A and III-B, with some adaptations in their tasks to carry out this study with participants, in order to generate a good comparability of the results obtained in S1 and S2. After completing each task, participants responded verbally to a post-test questionnaire. With the participants' speech, it was possible to identify and highlight the convergences and divergences, regarding research questions proposed in this paper. The convergences and divergences identified will be presented in the following subsections A and B. The Table 2 summarizes these results obtained in the triangulation step.

TABLE II
SUMMARY OF THE CONVERGENT AND DIVERGENT RESULTS IDENTIFIED IN THE TRIANGULATION STEP.

	Convergences		Divergences	
CSs	RQ(i)	RQ(ii)	RQ(i)	RQ(ii)
1	P1, P2, P3, P4, P5	P1, P2, P3, P4	-	P5
2	P1, P2, P3, P4, P5	P1, P2, P3, P4, P5	-	-
3	P1, P2, P3, P4, P5	P1, P2, P3, P4, P5	-	-
4	P2, P3, P4	P2, P3, P4	P1, P5	P1, P5
5	P2, P3, P4, P5	P3, P4, P5	P1	P1, P2
6	P2, P3, P4	P2, P3, P4	P1, P5	P1, P5
7	P2, P3, P4	P3, P4	P5	P1, P2, P5

A. Convergences

In this section will be presented, for each communication strategy, the discourse excerpts that show the convergences identified, related to the answers questions RQ(i) and RQ(ii).

As evidence for the CS1, provide different categorizations of the collected data, the following discourse excerpts were collected:

P1: "From my point of view, Google is keeping an eye on my interests, especially those that move my everyday life. So it seeks to monitor my clicks, texts, videos, comments and where I went. This is related to the concept of Legibility."

P2: "... I realize that Google wants to know your location, the places you've visited, what you search for (search engines, Youtube and Play Music) because this will help them in their recommendations. This is related to the concept of Legibility because the tool shows what Google is interested in doing with this data, but not in depth. That is, it tells what to do and with what, but does not say how it will do."

P3: "You can easily see what data Google has about you. In this case, it is the concept of Legibility involved."

P4: "Google has pretty much everything about me, like location, places I've visited and the time that happened, what I watched or did on Youtube, my vocal signature... The Legibility is not completely applied because I realize that there is still a certain lack of transparency on forms of using my data and its purposes."

P5: "Yes, for example the location, types of songs, what I see on Youtube."

As evidence for the CS2, show monitored activities and the level of use of products/services, the following discourse excerpts were collected:

P1: "I can see what Google has recorded about me. This is associated with Legibility, since there are texts or words like "Learn More" that help you understand what has been recorded."

P2: "It is possible to visualize, including the circuit that the user performed in a locality, a kind of history of how you visited a place. Thus, it is possible to associate with the concept of Legibility because you are aware about what it is monitoring."

P3: "It is possible to consult the records by means of histories, such as the one of location, that allows to identify even the route accomplished, in an easy and organized way for the user. So, this view fits into the concept of Legibility, because it is very clear what was recorded i.e., a query."

P4: "MyActivity shows the history of all these types of activities ... so it's Legibility."

P5: "MyActivity logs (in the case of Chrome), not only which site I've visited, but which sections of the site I passed. Here I think it's Legibility because it shows exactly what I did."

As evidence for the CS3, offer forms of intervention on data collection, the following discourse excerpts were collected:

P1: "I didn't trust too much in controlling my data because we don't have a policy or something that makes that control more present in our everyday lives. However, with the option of downloading my data, I was more reassured. This is tied to the concept of Agency."

P2: "I realized that in some cases these options are hidden. But you can control what they can and can't access your data. It's related to the Agency, by allowing action on the data."

P3: "It is possible, for example, to both exclude and prevent them from continuing to monitor you. So there are Agency these options that give you control over your data."

P4: "I can erase history, intervene in some things ... the minimum exists, which is the case of being able to delete, modify, allow or deny. Agency, but in this case, I can not manage for third parties, but only for myself."

P5: "It does provide an option of what I can release or not. I think it's Agency, because it's a way to conduct management over my data, it's you showing what you want to happen."

As evidence for the CS4, provide alerts of actions performed by the user, the following discourse excerpts were collected:

P2: "The pros and cons of letting them monitor their activities are clear. These alerts reinforce what your action will cause, not allowing the user to simply take action, forcing the user to heed it. Thus, the concept of Legibility appears again."

P3: "They provide more in-depth information about your data. Soon, it becomes Legibility."

P4: "It gives me more in-depth information when I click activate or when I want to pause. Legibility."

As evidence for the CS5, provide means to report problems or collaborate with ideas, the following discourse excerpts were collected:

P2: "It is possible to report problems, but it is not known whether this will be answered or not."

P3: "MyActivity even allows screenshots to be sent to help identify the problem. They even allow modifications for legal reasons, and as it is a global company, then it is important to have that same option. It is related to Agency."

P4: "It offers a way to report legal issues, but no issues with third parties. However, the screen passes generic information so I guess it could be for any kind of problem as well. On the other hand, the system provides a 'learn more', so maybe it is the case to go and read more about it. It would be the Agency."

P5: "In case it is the feedback option. This option allows me to participate, either to complain or to suggest or make some kind of contribution. So I think it's more related to the Agency than to the other two concepts."

As evidence for the CS6, offer forms of intervention regarding the use of data, the following discourse excerpts were collected:

P2: "I've been able to distinguish the intentions of third-party domains by colors and by some domain names, i.e. those that are interested in my behavior or not. This identification can relate to the concept of Legibility."

P3: "The total he gives you easily before you click. And when you click, it gives you the names, so it's very easy to identify these things in it. This relates to Legibility (a bit), because it gives you just that this domain is trying to monitor you, but you do not know what it's registered for, i.e., it's the minimum level of Legibility."

P4: "I found it very good to be able to identify because he showed me many domains that may be monitoring me, but on the other hand lacked more transparency because he does not describe very well the purpose of these possible trackers are acting. I think if I knew that, I could allow monitoring if it was to benefit people. It is related to the principle of Legibility."

As evidence for the CS7, show the third-party domains identified, the following discourse excerpts were collected:

P2: "I can enable and disable, for example, third-party domains. This is related to the concept of Agency. But the concepts applied here are weak, because it could provide more information about what each third-party domain wants to do, or what behavior the third-party domain has presented to the PB to block."

P3: "I managed to block some domains, but since it does not provide information on the consequences of this action, it might impact the functioning of the page. It is related to the concept of Agency, but only to the part of managing access."

P4: "The Privacy Badger allows me to perform the blocking or the release, so it is the minimum of management. Therefore, it is associated with the Agency concept."

B. Divergences

The divergences identified in the triangulation step can be classified into two cases: The first case comprises the participants who didn't identify some communicative strategy and, therefore, couldn't answer the RQ(i) and RQ(ii). The second case comprises the participants who were able to identify communication strategies as mentioned in the SIM, but associating them with other concepts of HDI, different from those pointed out during the SIM. In this case, the perceived divergences apply only to RQ(ii).

Regarding the first case, some communicative strategies were not perceived by a few participants, for many reasons. The examples identified were: P1 and P5 had contact with CS4. However, they did not consider it as an alert, but rather as another textual information presented in the view. P1 was also unable to locate CS5 nor understand CS7, as follows: *"The identified names of third-party domains made no sense to me."*. In addition to these examples, P5 couldn't to evaluate the Privacy Badger, because this tool did not offer the language desired by the user, as evidenced in his report: *"The interface does not make sense to me, because I do not know English, so I would not manipulate this program."*

Regarding the second case, for example, from the textual description presented for each activity category in MyActivity through CS1, P5 understood that activity monitoring allows users to better understand themselves over time through a possible processing of their historical records. This new understanding may be relevant in subsequent data exchanges, allowing the sharing of new reassessments in relation to their behavior or interests expressed in data, with others interested in their data. So, P5 linked CS1 with Negotiability concept, as reported: *"I think it's Negotiability, because we may want to be monitored for certain types of activities at some point, maybe for benefits. By knowing what types of activity I am monitored, it allows me to set up your profile and perceive, over time, changes in behavior or interests about me. It may be interesting that other people might know about these changes."*

In a second example, P2 considers that CS5 is related to the concept of Negotiability, because it understood that reporting problems can serve not only to report system failures, but also to express its considerations about the use of its data by third parties, as reported: *"It may have to do with Negotiability, because it allows you to negotiate about your data, saying what you disapprove of the use of data."*

There were two other divergences over CS7. P1 considers it to be related to the concept of Legibility because Privacy Badger automatically performs a possible block on a third party domain. Thus, the tool suggests that it is not necessary for the user to modify such controls, but only to observe the type of constraint applied to a particular third-party domain, as reported: *"The option to block a third-party domain may refer to the concept of Legibility because it is in my discretion to block it or not."* Finally, P2 considers that CS7 is linked to the Negotiability concept because *"it allows me to not only block or enable, but make a middle ground by blocking*

only the cookie and letting the third party domain perform its functionality on the page."

VI. Conclusion

This work aimed to identify and evaluate the communicability of strategies that enable Human-Data Interaction, through the application of the main HDI concepts proposed by Mortier *et al.*[7], in the context of personal data management. For this, the Semiotic Inspection Method was used to inspect the MyActivity and Privacy Badger tools. A methodology was established based on Semiotic Engineering theory [14], contributing to the consistency of the evaluation and results obtained.

The tools were inspected by two evaluators and, through the results obtained, it was possible to answer the research questions raised in this work. We found out evidences (see section IV) of high and low communicability in some Strategies to communicate Legibility, Agency and Negotiability. For instance, in CS1, because they are not explaining the algorithms and methods used in generating inferences from the user data (low legibility). In CS3, because the user has mechanisms to determine what types of data can be accessed and collected (high agency). The results also allowed us to present problems related to the partial application of the inherent aspects to the concepts of Legibility and Agency. However, it was observed that, even without the identification of all concepts related to HDI, it was possible to observe traits that allow Human-Data Interaction.

This paper brings three main contributions. The first is the application of SIM in an yet unexplored context of HDI related to the use of TETs, showing that the application of the method was relevant in that context. The second contribution is the identification of a set of communicative strategies and the classes of signs used by designers to make the HDI feasible. Such strategies may support designers of other TETs in their decisions about which strategies to use. Finally, the research results of the model proposed by Mortier *et al.* [7] in association with the application of the SIM, i.e., the inspection and evaluation by model, has shown to be promising in the HCI evaluation of applications that seek to provide means for Human-Data Interaction. The results presented here were validated (as is typical in validation of qualitative research) through an endogenous triangulation [25]. This motivates us to carry out new empirical studies with HDI designers to explore the practical effects of designing TETs with the communication strategies.

VII. ACKNOWLEDGMENTS

The authors want to thank the Brazilian funding agencies that support this project in different ways: CAPES, CNPq and FAPERJ. They would also like to express their gratitude to the volunteers who participated in the study.

***Abstract*— We have developed a method that enables better taking into account of need of space of actions of moving objects in a building when Building Information Modeling (BIM) is used. The 3D spatial objects for real space requirements of actions created with our method can be used with various design tools as such in dimensioning or to generate video game colliders defining the need of space. Together with the gamified model of the structure from BIM they enable dimensioning in designs and simulations. We can dimension spatial objects for example related to safety. There are a lot of needs and applications for our methods. It is possible to design buildings and other structures that fit their purpose well.**

I. Introduction

In this article we present the utilization of the Functional Design Method (FDM) "Value Add Data / VAddD" together with the Gamified BIM Information Model during the simulation of emergency evacuation from a supermarket. The simulation relates to the joint R&D and piloting effort of the S-E Finland University of Applied Sciences (XAMK) and our industrial construction partners. The Functional Design Method is based on the Finnish patent by our senior lecturer and Licentiate of Science Jukka-Pekka Selin. The patent was derived from an earlier internal innovation report [1], [2], [3].

The core idea in the FDM is to capture the space requirements of real action in three dimensions and then create a new 3D spatial object. The new 3D objects represent the maximum spatial space requirements of actions. When using Construction CAD these objects can be used in dimensioning different spaces. The goal can be both to fit an action to a space or alternatively ensure that an object can reach all the needed places in a space. If the Information Model in the form of an IFC (Industrial Foundation Classes) file is gamified it becomes possible to use the spatial objects to realise e.g. adaptation capable game colliders around game objects. In that case we can test the fitting of different actions or reaching capabilities of objects to stationary parts of the construction. We can also perform simulations.

In our piloting program we used a real construction project of our industrial partner, a Finnish supermarket [4]. In piloting we simulated the emergency evacuation from a supermarket with a gamified model by utilising AI (Artificial Intelligence) based navigation of moving avatars in the model of the market. In the simulation we had avatars with individual behavioristic profiles and sets of rules. We made the avatars evacuate themselves using an AI engine and individual parameters along evacuation routes that were rapidly chosen after a fire alarm.

II. Methodologies and Software Used in the Research

The maximum space requirement in dimensions x,y and z can be derived from video clips of real human actions. In this method the real actions are videoed with at least two video cameras that are situated at right angles. The need of space from the actions in three dimensions is measured and a corresponding geometrical object is created. This 3D object in IFC file format is compatible with different CAD software. The goal is to ensure that the required actions can fit the space under design [1], [2], [3].

During the research program the application that is BIM compatible and is meant for Lifecycle Management of Building Data, and the application extension Value Add Data of Xamk R&D, were used for creating 3D objects. The application extension realizes the functionality of the FDM. The Colliders describing the space requirements for different actions to the gamified model were created via the execution of the Value Add Data software [5].

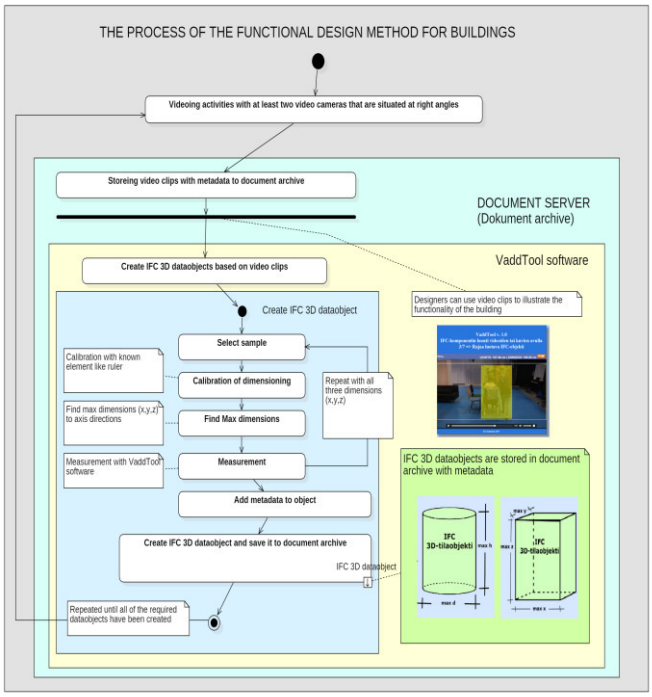

Fig 1. The process of the FDM for Buildings [5].

The Information Model used with the supermarket consists of several submodels that have been created by the designers of architecture, structures and different subsystems, with different CAD tools. As an example, the architecture model has been designed with the ArchiCAD software by Graphisoft SE. All submodels of the supermarket have been received for piloting in the IFC format [4], [6]. The submodels have been converted by the tools of the Open Source software family IfcConvert to the OBJ format [7]. The files that were in the OBJ format have been further optimized and shortened with the Open Source software MeshLab.

The metadata that are in the IFC files have been transferred by using the XML format. The conversion from IFC into XML has been performed with the IfcConvert. The gamification itself has been performed with the Unity game engine. When simulating the emergency evacuation we used the Navigation extension of the Unity engine. This extension brings possibilities to use AI based navigation schemes [8].

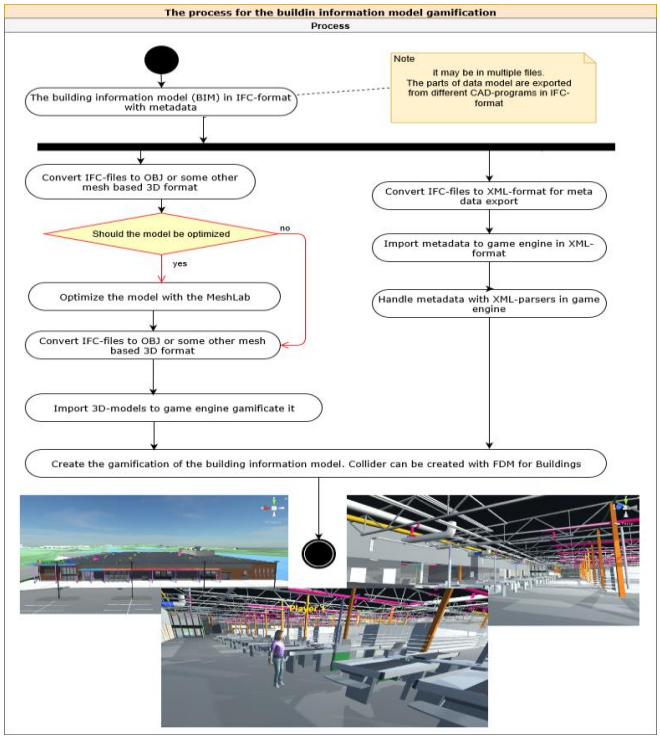

Fig 2. Our process for gamifying Information Models.

The schematic above describes the process developed by us to gamify Information Models of buildings. The basic principle of the process is that the gamification should be possible independent of the choice of the original CAD design tool. The only requirement is that the CAD tool supports the IFC format and can export both data and metadata into an IFC file according to the BIM recommendations [6].

Into a model gamified this way we can bring spatial objects generated by our FDM. These VAddD spatial objects can also support designs as such or if further converted into Game Colliders.

III. The Functional Design Method for Buildings Together with Gamification of Information Models Help to Design Safer Buildings

We created pilots to study different possibilities and applications for the FDM. We utilized an Information Model of a real supermarket. Our partner, the construction company U.Lipsanen Oy is currently building the supermarket. We received the Information Model as several IFC submodels, so we were able to test our procedure to gamify models represented according to the recommendation IFC (Fig 2) so that also the metadata can be input to the gamified model [4].

The main goal was to be able to use open software. For that reason we ended up to use the IfcConvert software from the IfcOpenShell library to convert IFC files into mesh models supported by game engines. Among the formats of mesh model formats we selected the OBJ format. We had a need to optimize and radically reduce the amount of polygons approximating the surfaces, especially related to pipes. To do this we chose the open MeshLab software that has support for the OBJ format. We also used the IfcConvert to create XML files from IFC and to bring the metadata of the models together with the 3D model into the game engine [6], [7].

With the aid of the gamified Information Model we piloted the usage of FDM in the emergency evacuation with an AI navigation control used in a Unity game environment [8]. We placed profiled or individually parametrized avatars randomly inside the supermarket and then commanded the avatars to proceed to the closest emergency exit with the aid of the AI engine. Around each avatar we placed game colliders that described the space needed for the avatar when mobile, according to the avatar profile. Such avatar can use different aids to overcome limited mobility when moving. An avatar using an aid like a rollator usually needs more space than an average person. Each of the avatars also possessed an individual moving speed.

With FDM we generated the 3D spatial objects representing spatial needs for actions. The description of the cases for avatars can be seen in the following table (Table 1).

TABLE I.
MAXIMUM SPACE REQUIREMENTS FOR THE DIMENSIONING OF THE COLLIDERS CREATED BY THE FDM

The dimensioned Action	Space Requirement (m)
A walking person	0.50 x 1.90 x 0.70 (x,y,z)
A running person	0.65 x 1.90 x 0.90 (x,y,z)
The assistant walks with the wheelchair user on behind the wheelchair	1.30 x 1.90 x 1.00 (x,y,z)
The wheelchair user without the assistant	1.00 x 1.50 x 1.00 (x,y,z)
The user with rollator	0.90 x 1.90 x 0.75 (x,y,z)
The user with crutches	0.90 x 1.90 x 1.00 (x,y,z)

From each of the cases we generated an avatar prototype that has colliders corresponding to the table. In this pilot the characteristics of the colliders were specified on a relatively common level. We felt that this accuracy is adequate from

the piloting of simulation method point of view. The avatar profiles could well be much more individual and more different types of avatars representing different customers of the supermarket could be created.

For accurate and realistic simulations corresponding to real situations it is necessary to increase both the number of variables and to increase the number of movement functions that have a partially random outcome. The number of simulation drives should be high when we want to apply statistical methods to the outcomes of the individual simulation drives. The results of the statistical studies would show how well the supermarket supports safety and show hints how to further increase safety by design. Different building designs could be simulated and compared. After iterating with different designs it is possible to reach the functionality requirements.

In our piloting we were mainly interested in the feasibility of the FDM in this kind of dimensioning and simulations. We used in our pilots some randomness in the collisions in between different objects to increase realism. The piloting was performed by using the Unity game engine and the C# programming language. We added a simulation extension to the gamified Information Model of the supermarket. The simulation extension creates a predefined number of avatars with different characteristic profiles. In the beginning of the simulation the avatars are located at their initial locations around the floor area, derived from random values of parameters. The characteristics for different types of avatars are in the table above (Table I).

In the simulation we used the Navigation tools of Unity, based on AI. With the tool we could create a navigation map situated on the floor level of the supermarket. More generally, the map could include any stationary objects of the gaming world. With the aid of the navigation map an avatar can now be commanded to progress to the needed target area so that the AI tool steers the movement of the avatar. The events during the navigation phase can be controlled by numerous different navigation parameters. Among the features that can be controlled are the maximum physical difficulty level of obstacles that can be over- or sidewise passed, and the intensity of effort in movement.

We realized the simulation in a way that the customer avatars with spatial needs according to their profiles are moving and directed by the AI towards emergency exits. The situation can be monitored by virtual cameras situated in the gamified Information Model. Each of the avatars are also carrying their own cameras that can be switched on when necessary.

The development of the situation can now be monitored from all angles. With the simulation application developed You can quickly control e.g. the number of customers, randomness of events and navigation parameters. It is also possible to change and define quickly the target-objects that are the destinations of the avatars. The avatar game objects that represent supermarket customers and are used in the simulation can in principle look like whatever the artist decides, but we increased the realism of the simulation by creating 3D avatars that look like typical shoppers. We also made them move according to kinetic data from an earlier human motion capturing session with cameras. Their movement looks therefor quite natural.

The realism of the simulation can be enhanced by adding different effects. Here we wanted to simulate a fire in a supermarket and we added a smoke effect to the gamified model. The progress of the fire follows a well known Fire Intensity Curve that is a generalized model about how the fires progress (Fire Intensity against elapsed time) [9]. The following picture (Fig 3) visualizes a generalized Fire Intensity curve that represents the intensity of the fire in majority of cases. In addition, the picture visualizes the phases of the evacuation and parameters used in the case of a supermarket.

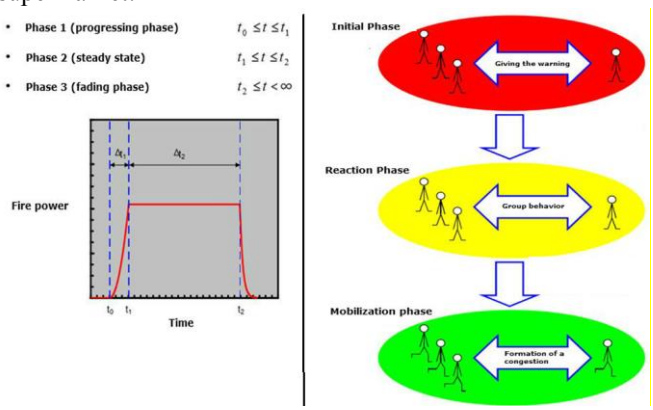

Fig 3. On the left side a generalized Fire Intensity curve that represents the intensity of the fire in majority of cases. On the right side the phases of an emergency evacuation [9].

The fire develops inside a building usually so that the environment becomes intolerable for humans. The cause can be different poisonous and irritating gases and the heat. Because of the fatal environment one should remove humans from the building as quickly as possible [9].

At the University of Lund the research aimed to find out how long it takes before the environment close to the fire becomes intolerable for humans. Also the VTT Technical Research Centre of Finland Ltd has performed research on the topic. In both research programs the critical factor was found to be the smoke occupying the whole volume of the building. The scattering of the research results is however relatively high [9], [10].

Based on the before mentioned research results we set the critical elapsed time after the start of the fire to 25 minutes with a standard deviation of 8 minutes. We put 500 customers into the supermarket corresponding to the daily rush hour. Our simulation can however adapt easily to a wide range of parameters for each case. The evacuation of humans from the buildings can be divided into three main phases. The phases are called the preliminary phase, the reaction phase and the mobilization phase. The total time elapsing in the evacuation follows the formula t = t(initial) +t(reaction) +

t(mobilization). The durations of these times are naturally very individual, so we need to include random variables related to the behaviour of people to our calculations. We realized the simulation application of an emergency evacuation by utilizing scientific studies mentioned above. We set the parameters of the dangerous situation (here a fire) so that the situation can be divided into the above mentioned phases. It was possible to freely change the durations of the phases. We also designed the customer (avatar) profiles so that there is randomness in the profiles and the process follows the phases of an evacuation [9].

The following picture (Fig 4) shows a view from the simulation application on the display during the run of a process performed by the Unity game engine.

Fig 4. A simulation application realized with the Unity game engine. A game collider corresponding to the spatial need of an avatar is visible on the picture.

The event that causes the need for evacuation can be parametrized and the seriousness and location can be varied. We can test a situation where a fire restricts access to a certain area and can even prevent using certain emergency exit.

After the simulation starts the game objects corresponding to profiled supermarket customers begin to move towards the selected emergency exits. The following picture (Fig 5) visualizes a situation where the fire simulation is active and the profiled customers are trying to move towards the emergency exits. Their spatial needs and profile settings affect their moving speed and route when they navigate past shelves and other structures, while interacting with the other customers. We can observe how the customers occasionally prevent each other using the most direct routes.

Fig 5. The simulation is active and smoke begins to enter the interior of the supermarket. The profiled customers (game objects) are rushing in chaos towards the defined emergency exits under the control of the AI engine (the reaction phase and the mobilization phase).

The structure of the simulation application is such that it saves the movements of the profiled customers to a log file. The applications also recorded for every customer the moment when he moved from a phase to the next. We also recorded to the log of the collisions with the other avatars and the moment of time when the customer was able to exit the building. Then the avatar reached the emergency exit that was the target location of the navigation.

The simulation was built so that the profiled customers possessed randomness according to the range found out in the studies [9], [10] and [11] during the initial and reaction phases. The simulation run specific log file generated gave a lot of valuable data about the functioning of the building in an emergency. With the aid of the logs it is e.g. possible to study the success level of different safety increasing measures. The log includes data for e.g. finding out when 90% of the customers have left the building or how much a new exit reduces the time of evacuation and also what the best place for a new exit is. In the exemplary simulation presented here all of the 500 customers could exit the building in 15 minutes. Over 90% of the customers had exited already in less than 10 minutes from the beginning of the fire. The last ones to exit were the individuals who have long reaction times and who are using aids for reduced mobility. When we made the distance between the shelf units narrower the evacuation times increased significantly especially with high numbers of people. Correspondingly, extra exits shortened the evacuation times, as expected. According to this simulation the supermarket was found to be safe enough in fire situations with the designed types of corridors and exits.

We also tested during the simulations a situation where the cameras are videoing from the point of view of the customers. We gave each customer an own camera enabling us to switch to the view from any of these cameras. It was especially interesting to note how an aged customer using mobility supporting aids and moving slowly suffers from collisions with other customers moving move swiftly. The following picture visualizes the emergency evacuation event from the point of view of e.g. an older customer moving slowly and using a rollator. This fact could also be found from the generated log files. The following picture (Fig 6) visualizes the emergency evacuation event from the point of view of e.g. an elderly.

Fig 6. Simulation showing the point of view of a slowly moving elderly using a rollator.

Finally we simulated a situation where the viewer is a TPC-type object (Third Person Controller) who tries to exit the building. Also in this case we have a set role and spatial needs that were dimensioned by using the FDM. We conclude that this could be an excellent way to practice doing the emergency evacuation. By using the multiplayer functions of Unity we could simulate situations where several players are practicing emergency evacuation or generally any co-

operation with other players. The following picture (Fig 7) visualizes a situation where each of the players of the simulation is moving a profiled avatar that has settable parameters. The players can do different roles like rescue or leading the evacuation operation. In the picture the player has entered the supermarket and encounters there customers who are rushing out. This way we could practice beforehand the actions during emergencies from the point of view of different actor roles.

Fig 7. A TPC player (Player1) has entered the supermarket after having received an alarm, performs rescue and assistance work and encounters customers who are rushing in panic.

The approach of this pilot appeared to be very interesting and relevant. The FDM brought clear added value to the piloting, because the different individual spatial needs could be taken into account in the simulation. According to our industrial partner the principle to combine the simulation of emergency evacuation with the usage of the FDM is a very good idea. We are planning to further develop these methods in our current research project.

The insertion of multiplayer functionality and co-operation of a community into this kind of simulation was especially rewarding. When the Information Model is gamified and we crowdsource the emergency evacuation simulation we could get valuable knowledge and ideas from a large group of people to enhance the accessibility and safety of a supermarket. We plan to develop these methods and tools further in the future.

IV. Results and Conclusions

The pilots presented strengthened our view that the Functional Design Method VAddD developed earlier is a useful and practical tool for designing buildings and that it is flexible to cover different purposes and application environments. The method suits also to different design challenges of infrastructure and built environment in addition to building design. It helps to perform the designs based on end users' activities in the buildings. The method is also independent on what CAD ecosystem was used to design the first 3D model. The pilot presented belong to our research program for the construction and building industry.

We conducted a small scale interview among our R&D partners related to the research results. We interviewed the industrial contact persons who are either managers or designers from the construction industry. One of the designers interviewed was specialized on gaming.

As a summary from the results of the interviews the usage of BIM, the gamification of Information Models and the Lifecycle Management of the Information Model were seen very welcome and needed development paths for the construction industry. The interviewed also said that the FDM is a very good idea for taking the human actions into account in all kinds of design challenges better than before. All new methods belonging to this category of methods were seen as welcome development. The partners thought that the simulation of the emergency evacuation scene was successful and stated that the FDM brings clear added value and new feasibility because You can now profile the users of the building and create individual characteristics and spatial needs to the avatars used. This way the simulation can be made very realistic and the results really bring new data about the building design and its functionality.

The partners of our R&D program think that the FDM for buildings and the pilots utilizing the methods are interesting, bring added value to the design processes and so are definitely worth further studies. Exactly to this direction should the design of buildings according to their opinion be developed in the future. When this pilot analysis cases are combined with further analysis of other actions in the building we have a large number of analysis results from a complete toolset of analysis fulfilling the needs in structural design, simulation, building automation design, training and even lifetime measurement and control during the whole lifecycle. Our vision is to adapt and expand the methods to develop virtual user interfaces or digital twins to buildings for the whole lifetime, beginning from the design phase.

***Abstract*— Computer games represent a very popular form of entertainment. Therefore, playing games became an object of interest for researchers. The research on the brain activity of players when playing a game is an experimental contribution to the neurophysiology of the central nervous system, and it also supports marketing research.**

Devices that register electromagnetic waves generated by the brain, e.g. EEG (Electroencephalography) can be used by psychologists studying the impact of games on users when the game. Our goal was to analyze emotion changes while playing video games, based on EEG signal registered with EMOTIV EPOC headset, and identify the strongest emotions accompanying the game. We also wanted to link emotions to particular elements of the game. Game developers, especially educational and therapeutic, can use the outcomes of this work in the practical implementation of the brain-computer interfaces in their products, in order to create better and more engaging games.

I. Introduction

ELECTROENCELOGRAPHY (EEG) is a noninvasive examination of brain function, using electrodes attached to the scalp. These electrodes record the electric field (electric potential) generated by the brain. Analysis of EEG records provides information on the activity of specific areas of the brain. EEG examinations are performed routinely as part of neurological diagnostics of the central nervous system. An important medical application of EEG is the diagnosis of coma and of brain death. EEG is also used as a tool in neurophysiological and psychoneurological tests, for example during the examination of the level of anesthesia, in the study of sleep disorders [1], and the analysis of the effects of drugs on the central nervous system. EEG is also used in neurophysiological research, including studies of cognitive and emotional processes. The emergence of instruments enabling low-cost registration of EEG signals contributes to the increase of interest in the use of such measurements in various fields of study.

The possibility of registering brain activity is also attractive in areas far from medicine. Unlike routine medical procedures, the research on brain activity does not focus on detecting anomalies that may indicate pathological changes, but on linking the recorded activity of the brain with received stimuli, cognitive activities, progress in training various skills [2], degree of relaxation, etc.

As a non-invasive method, and also more widely available recently, EEG is a natural candidate for use in the work on the brain-computer interfaces (BCI). In this work we will discuss some of the results of research in this area.

Game developers, especially educational and therapeutic, are particularly interested in the practical implementation of BCI in their products. EEG registering the reaction of players and the emotions accompanying the game is an interesting source of information for game designers, striving to create a game model that is satisfying for each user. EEG tests are also used by psychologists in studies on the impact of games on users.

II. Consumer EEG devices

Standard EEG measurements are performed using a stationary device, in an outpatient or laboratory setting. At present, various solutions are available on the market that allow recording EEG signals using portable devices [3], [4], [5]. Since these devices are inexpensive and easy to use, they can be applied in many areas, including using them as BCI interfaces in consumer applications. The usability of commercial EEG devices was tested in [6].

The EMOTIV EPOC+ wireless headset provides 14 channel EEG, plus 2 reference channels. Saline based wet sensors allow avoiding sticky gels. The headset is quite flexible, but its plastic structure limits the ability to adapt the device to untypical sizes or the shapes of the head. The signal is sent through Bluetooth or proprietary wireless communication. Battery life is up to 12 hours when using proprietary wireless, and up to 6 hours when using Bluetooth.

III. EMOTIV EPOC in applications and research

The EMOTIV hardware and software evoked great interest. The authors in [7] compared EPOC with the research EEG system (Neuroscan Synamps) for measuring

This work was partially supported by the Research Center of PJAIT, supported by the Ministry of Science and Higher Education in Poland

auditory event-related potentials. Their findings suggest that EPOC compare well with Synamps in such tests, and EPOC is easier to use because of its quick and clean set-up. On the other hand, EPOC may perform significantly worse than a medical device, as shown in [8]. The authors of [8] tested the ANT medical grade system and EPOC on P300 responses. P300 is an involuntary positive potential that is evoked about 300 ms after the user has perceived a relevant and rare stimulus. EPOC indicated lower SNR (signal-to-noise ratio), so the authors suggested choosing EPOC only for non-critical applications such as games, as it is not reliable enough for medical purposes such as prosthesis control.

IV. Experiment design

The aim of the experiment was to register EEG of players while playing computer games, and analyze emotions, depending on the type of game. During testing, EEG of 15 males aged 23-28 were registered. Persons who often play computer games were selected for our experiments.

Two computers were used in the experiments. The EMOTIV headset was connected to one of them and EEG data were recorded. Only the experimenter had access to this computer. The second computer was used for gaming, and this computer was used by the players. Three games with different gameplay characteristics have been selected for these experiments.

At the beginning of each experiment session, the experimenter puts the EPOC headset on the player's head. Next, the experiment adjusts the headset while checking the readings from EPOC, to assure the best possible quality of the signal. Afterwards, the experiment session is performed. The session consists of 7 parts. The player is informed before each part what he is expected to do, and how long it will take. These 7 parts (stages) of the experiment session are listed below:

1. Initial EEG measurements - the tested player closes his eyes, tries to relax, and not think about anything. The purpose of this stage of the experiment is to register EEG readings from the resting-state of the brain, for comparison with reading acquired in the next stages of the experiment.
2. Square game - the player plays the Square game, which is a team based game. His activity is monotonous, neither requiring mental effort nor psychically engaging. The registered EEG are to reflect moderate brain activity, typical of normal computer use.
3. Rocket League played with bots - the test player plays a 5 minute match with a computer-controlled player (bot).
4. Rocket League played online – the player plays a 5 minute match with other players (persons) over the Internet.
5. Watching high level game – the player watches a 5 minute match of the Rocket League, played by advanced players.
6. Super Bomberman game against bots – the player plays 3 matches of the Super Bomberman game against bots.
7. Super Bomberman game with another player – the test player plays a match of the Super Bomberman game with another player (person) against 2 bots.

As mentioned before, we selected 3 games of different characteristics. EEG readings were acquired using two methods. In the first method, each 0.5 the average power of theta, alpha, beta, and gamma waves was acquired (for beta waves, separately for low and high subbands). The wave ranges are as follows: theta 4–8 Hz, alpha 8–13 Hz, beta 13-30 (low 13–20 Hz, high 21–30 Hz), gamma 30–80 Hz.

The second method consisted in collecting emotion data using Emotiv software, for the following emotions: boredom, meditation, frustration, instantaneous excitement, and long-term excitement, scaled from 0 to 1. The Emotiv software is needed to acquire emotion data, facial expressions, and access mental commands.

After the preliminary analysis of the collected emotion data in the first round of tests, we decided to reject boredom and meditation, because of very low level of the obtained signals.

We also experienced technical problems with the EPOC headset we used, as 2 electrodes, A3 and AF3, did not work properly (and the readings from these electrodes had to be discarded, as they represented noise only). Therefore, we had to replace this headset with another one. This shows that this equipment is delicate and prone to failures. Accessories for EPOC are available, but it takes time to obtain these accessories.

V. Results

In our research, we describe emotions in 2-dimensional valence/arousal plane [9]. Based on the readings from the EPOC electrodes, we can calculated valence values, indicating positive or negative emotional states, and estimate arousal levels. Since beta to alpha ratio is a reasonable indicator of arousal state [10], we estimate arousal index E_A, as the indicator of arousal state, according to the following formula:

$$E_A = \frac{E_\beta}{E_\alpha}, \tag{1}$$

E_β - average beta power, E_α - average alpha power.

The valence index can be calculated for a particular electrode, or brain regions. Typically, this index is calculated for frontal (F) and antero-frontal (AF) electrodes, as beta and alpha waves are most pronounced and can be most easily measured in the frontal and the middle part of the brain [11]. Therefore, data from A and AF electrodes are the best choice when estimating valence [12].

It is suggested that greater left frontal activity is associated with positive affect and/or approach motivation, and that greater right frontal activity is associated with negative affect and/or withdrawal motivation, although in [13] the author found that the frontal asymmetry is responsive to

motivational direction and not affective valence. Still, since we had symmetrically placed electrodes at our disposal, we decided to use the following measure of valence E_V, calculated by comparing the alpha power and beta power between the right and left hemispheres [10]:

$$E_V = \frac{E_\alpha^r}{E_\beta^r} - \frac{E_\alpha^l}{E_\beta^l}, \quad (2)$$

r – right hemisphere,
l – left hemisphere.

E_V was calculated for the readings of symmetrically placed electrodes, or for averaged power calculated over selected brain parts. Positive E_V values indicate positive emotions, and negative values indicate negative emotions.

In the presented graphs we illustrate outcomes for the data collected in the 3rd stage of experiment, i.e. when playing Rocket League with bots:

- E_V for readings from electrodes F3, AF3 and also T7 for E_α^l and E_β^l, and readings from electrodes F4, AF4 and also T8 for E_α^r and E_β^r
- Instantaneous Excitement calculated using Emotiv software
- arousal index E_A for readings calculated for frontal parts of the brain

	Stimulus	Avg. Ex.	Ex. var.	Avg.Fr.	Fr. var.	TE	TF
1	Meditation	0.541	0.153	0.541	0.09	12%	3%
2	Squares	0.549	0.207	0.5	0.127	16%	4%
3	„Rocket League", bots	0.564	0.244	0.526	0.186	21%	10%
4	„Rocket League", persons	0.504	0.228	0.512	0.168	14%	8%
5	Watching „Rocket League"	0.518	0.266	0.483	0.153	20%	3%
6	„Super Bomberman", bots	0.621	0.2	0.568	0.144	22%	7%
7	„Super Bomberman", persons	0.579	0.224	0.537	0.153	23%	7%

Avg. Ex - Average Excitation; Ex. var. - Excitation variance; Avg. Fr. - Average Frustration Fr. var.- Frustration variance; TE - % time with excitation > 0.8; TF - % time with frustration > 0.8

We chose F3 and F4 as suggested in [10], and we additionally chose another symmetrically placed pair, AF3 and AF4, located close to F3 and F4. Additionally, electrodes T7 and T8 (temporal part of the brain) were chosen, as suggested in [14], where the authors indicate that information from the temporal part of the brain is significant in emotion classification.

The comparison of E_V values for various pairs of electrodes, i.e. F3 and F4, AF3 and AF4, T7 and T8, shows differences in brain activity for frontal and temporal parts of the brain.

Instantaneous Excitement calculated using Emotiv software shows large variability, and the results are directly related to game events.

The valence measure E_V and the arousal index E_A for frontal electrodes are not related directly to particular game events. The calculated values do not indicate stimulate from the game.

Therefore, we decided to use Emotiv software in further investigations. Instantaneous Excitement for the game and Long-Term Excitement for meditation show, that Excitement is related to game events.

The assessment of the emotion readings was done on the basis of average Instantaneous Excitement and Frustration, as well as Meditation and Boredom, calculated using Emotiv software. Average values and variance, as well as the percentage of time when Frustration or Excitation level was high (above 0.8) are shown in Tab. I. Initially, we also calculated these values for the Emotiv headset with damaged electrodes, but the results were inconsistent, so we decided to use another headset.

The values were averaged over all test participants, separately for each stage of the experiment.

As we can see, our experiment consisted of non-engaging (mentally, technically) as well as of highly engaging parts. Meditation, playing Square, or watching a game was rather non-engaging, whereas active playing games requiring high mental and motoric involvement (Rocket League, Super Bomberman) was highly demanding.

Excitement results show that average Excitation and the time of high Excitement when playing with other persons are greater than when playing with bots. For less engaging activities, the test results are similar, but variance is lower.

Frustration remained approximately constant during engaging activities, but variance increases when playing Rocket League with other persons, compared to playing with bots. Frustration results for non-engaging activities are a bit surprising; this is in line with results obtained in other investigations.

The highest meditation level was obtained for mentally non-engaging activities, but the difference in meditation level is small.

The highest boredom level was obtained when watching Rocket League match. This agrees with the relations of the tested players, as they emphasized their boredom during this part of the experiment.

Emotion levels when playing Rocket League match and EV values calculated for various electrodes are shown in Fig. 1. Unfortunately, the results from Emotive software are not perfect neither, as some exciting parts of the match are not reflected with the Excitement graph. For instance, only slight emotion changes can be observed between 180th and 230th second of the match, and rapid change can be seen during the scored goal only, whereas during this part of the match the ball was very close to the goal, and the player shot several times. After the 320th second of the match the excitement

suddenly drops almost to zero, whereas it is not reflected in the game, as the player was constantly defending goal during this part of the match. Frustration graph shows similar changes, but frustrating actions like loosing goal do not evoke frustration in this graph. In the final part of the match both scoring and defending goal correspond to surprisingly high frustration in this graph. The meditation and boredom levels also do not correspond to the gameplay.

The comparison of meditation and boredom levels registered in various experiments shows that these values are averaged over long runs. Therefore, such results are not very useful for estimating emotions while playing computer games.

VI. DISCUSSION

Our experiments confirm that playing a game causes brain activity changes, and these changes can be associated with strong emotions evoked by some parts of the gameplay. Similar observations were made in [16], with the focus on the changes of brainwaves power during high intensity and low intensity game events.

The analysis of the acquired data shows that the equipment and software are not sufficient to identify game-evoked emotions.

The literature we analyzed suggests that satisfactory results might be achieved only after complicated analysis and processing of the EEG data [17][18][19]. The use of neural networks is suggested. Deep neural networks are very often used recently, but since neural nets require large amount of data, are data are not sufficient for such analysis.

VII. SUMMARY AND CONCLUSIONS

The Emotiv software quite successfully detects excitement and frustration. Still, it is difficult to assure if the readings were accurate enough. The analysis of video recordings of the experiments is necessary to assess which parts of the gameplay correspond to the observed changes of emotions, and how to interpret these changes.

The algorithms implemented in the Emotiv software are not publicly available. Therefore, we cannot verify directly how various emotions are processed by these algorithms and what readings are reported for particular emotions. The values returned by these algorithms as meditation level (Meditation) and boredom level (Boredom) do not show large variability. The returned levels of excitement and frustration present larger variability, related to the gameplay as expected, but for each of these readings we can find parts of the play when these readings do not reflected emotions associated with playing the game. Since we cannot access these algorithms, nor formulas for calculating the readings, we are not able to assess whether the obtained values are correct or random. Similar problem was described by Harrison in [20].

The analysis of literature on emotion identification shows problems which must be addressed in order to achieve efficient detection and identification of emotions while playing computer games, based on EEG data. One of the issues to solve is to objectively identify game-related emotions. Various persons subjected to similar stimuli may experience different emotions. In the case of computer games, the player preferences may influence the experienced emotions. In the literature in the psychology domain [9] difficulties in the objective classification of emotions were reported, as the subjects may attribute various meaning to the same labels of emotional states, so the reported emotions may be ambiguous.

The method of evoking emotions and the emotion time should also be taken into account, no matter what emotion

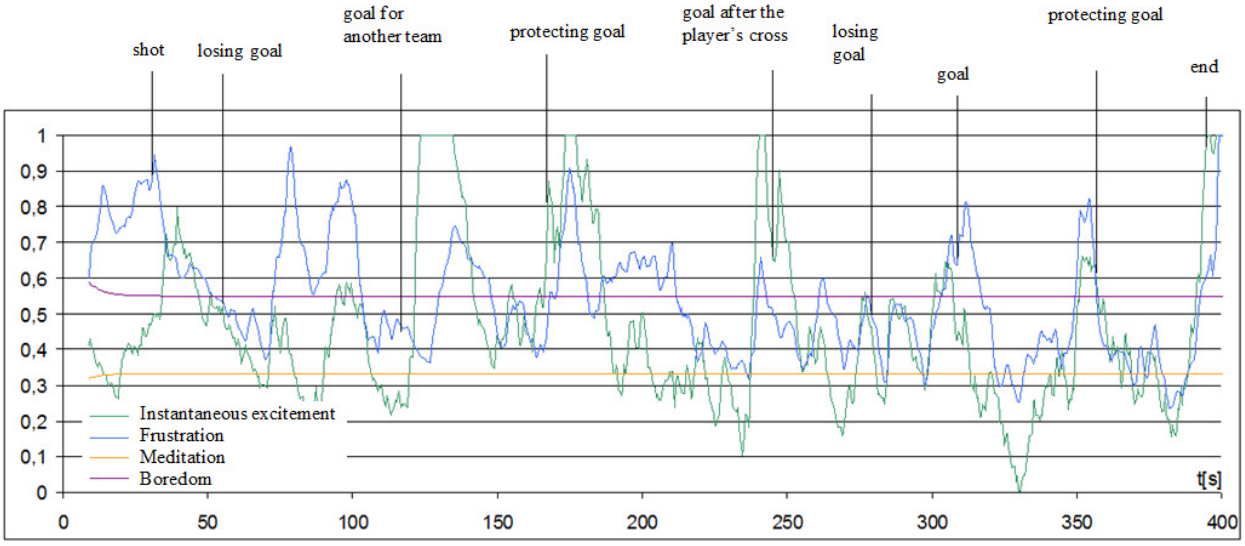

Fig.1. Emotions during the Rocket League match, calculated using Emotiv software

classification method was applied.

Depending on the type of stimulus and other experiment conditions, the registered EEG may represent emotional states of various intensity, duration, and co-occurrence of motor or cognitive activity. Even successful classification of emotional states, based on EEG data, can be less accurate for other stimuli or experiment conditions.

Computer games represent quite a specific type of stimuli, evoking emotions. Various types of gameplay may evoke different emotions in various players; the intensity of these emotions may also vary between players. In the case of typical computer games, intensive cognitive activity accompanies the playing, and at least medium motor activity. The player has to understand the gameplay, and actively control the game by means of the appropriate controller (at least until BCI interfaces are not efficiently and broadly implemented as game controllers). In typical games, there are numerous unforeseen events, to avoid experiencing boredom. Therefore, intensive emotions are expected, and they must quickly change in time.

As mentioned above, we cannot rely on the emotions reported by players when we want to analyze their emotions experienced while playing a computer game. This was reported by Salminen and Ravaja in [15], as well as McMahan et al. in [16]. Also, negative emotions experienced while playing, e.g. fear or frustration, cause experiencing positive emotion of satisfaction at the end of the game, which is specificity of computer games. The player is aware of the game convention and he or she is distanced to the experienced emotion, so the player subjectively assesses emotions as less intense. Without further investigations it is difficult to answer the question whether these differences can be seen in EEG.

Depending on the type and dynamics of the game, and also on the type of emotions to be analyzed, the analysis should be performed on shorter or longer time segments. The analysis of the power of brainwaves assumes averaging of the registered potentials, both over time and over frequency. In our experiment, we registered 2 readings of the Emotiv EPOC headset per second. Therefore, we can perform the analysis of psycho-neurological phenomena of medium duration. In the literature, short time EEG readings are also reported, i.e. of order of hundreds of readings per second, also in investigations on emotion detection. The Emotiv EPOC headset can also provide such data, when using appropriate software library [7], [8]. However, such analysis requires much more complicated experiment planning, as precise synchronization of the EEG readings with stimuli is necessary [19]. Additionally, in order to obtain high signal to noise ratio, numerous repetitions of stimuli are necessary. On the other hand, quick repetition of similar stimuli should be avoided. Therefore, such experiments are behind the topic of this work for now.

***Abstract*—This paper investigates the potential of using an electromyographic gesture recognition armband as an everyday companion for operating mobile devices in awareness-requiring contexts and suggests the fields, in which further developments are advisable. The Myo armband from Thalmic Labs is a fully functional motion controller, based on gesture recognition through EMG muscle sensing. The device has been applied for audio control, and the usability and relevance of the gestural interaction have been examined. Participants were asked to operate on a recording while cycling, and a reference group performed similar task in leisure context. The gathered answers suggest decent potential of gestural interaction manner for environments requiring high visual attention, eg. driving or cycling. However, the current state of the solution acts in too sensitive way, as processing numerous misinterpreted gestures highly decreases the system's usability. Moreover, gestures employed are perceived as too apparent and intrusive for social interactions.**

I. Introduction and Related Work

NOWADAYS, mobile devices are common everyday companion for various types of activities. However, in some of those contexts, the user's attention shall not be drawn towards the device operation, maintaining the control almost unnoticeable, both for the user and the environment. Therefore, various interfaces are being developed to meet those expectations.

Eyes-free Interface Technology

While mobile and wearable computing have been rapidly growing fields in the recent years, the approaches towards user interaction were dominated by vision-based techniques. However, restricted input and output capabilities of mobile devices, as well as limited screen space cause those approaches to be of a reduced usability [1]. Moreover, the visual perception of information is likely to be disadvantageous or even intrusive due to number of factors, such as: 1) *Competition for Visual Attention* - crucial in multiple mobile contexts eg. driving, running, cycling; 2) *Inconvenience* - as using the display requires the user to reach the device from a pocket or a bag; 3) *Technological Limitations* - such as reducing the battery life or the screen being illegible in bright sunlight [2].

Therefore, multiple interaction techniques employing senses other than sight have been developed in recent years. The most popular approaches make use of speech and gesture as the means of communication with the system [3]. Acoustic and haptic modalities have been adopted for assisting the interaction with mobile devices, both in terms of feedback and command, emerging the branch of eyes-free interfaces.

The most classical approach uses camera-based gesture recognition [4]. While real-time image processing and gesture recognition is no longer a challenging issue, the attitude still posses several constraints. The system intended for everyday use would need to be robust against environmental noise and obstructions of vision range, require minimal or first-use calibration and analyse comprehensible set of gestures and react with minimal delay. Moreover, a huge issue is connected to lightning conditions required by the system, which are out of control for rapidly changing environments. An attempt to bring such solution into practice was performed by Akyol et al. [5] for automobile use of acoustic messages. However, the necessity of assembling a complex camera-based setup makes this approach inappropriate for mobile scenarios.

An insightful endeavour towards applying gestures to audio control for on-the-go contexts was performed by Brewster et al. [1]. The study shown that metaphorical gestures are an intuitive and efficient way of interacting with an MP3 Player. However, the presented solution employed a device that the user was to swipe his finger at, therefore not solving the issue of inconvenience of hand-occupying device. A related solution was proposed by Zhao et al. [2], employing touch-input and auditory feedback for the purposes of menu browsing. This concept has been further explored by Kajastila and Lokki [6], providing further insights on menu operation using wii-like controller for eyes-free operation.

User Experience

The technological means of control are not the only challenge in designing appealing mobile interaction. It is the user experience and the emotions it brings that would make the novel interface become an everyday companion. Therefore, the social and behavioral aspects of operation are the essential issues to be addressed. Yi et al. [7] present an extensive analysis of key factors determining typical user motivations for using eyes-free interfaces. Apart form technological limitations mentioned in [2], these are the effort and social

reception of the performed actions which significantly affect the system perceiving. Hence, the users indicated that it is desired to obtain low perceived effort and entertaining manner of operation. Moreover, the users specified a strong need for the manner that would not interrupt social activities or cause anxiety. The command over the device shall be organised in a way that would not draw undesired attention of the people in the nearest environment, which is the challenge that speech-recognition interfaces fail to successfully address [8] [9]. Those concerns are especially crucial in on-the-go scenarios of mobile device operations. Further, wireless and hands-free devices are desired, employing gestures with little human-to-human discursive meaning and being difficult to misinterpret [10].

EMG Gesture Controllers

The above-mentioned requirements may be met through employing gesture-recognition system that would enable to perform subtle and discreet movements, with minimal attention required. The technology which is capable to offer that functionality is an electromyographic sensor. EMG can convey information about muscle electrical activity, which could be applied for designing intimate mobile interfaces. An extensive study on the capability of this approach in terms of social-acceptance and user perception has been performed by Constanza et al. [11]. However, the system used, while offering satisfactory and promising interaction pattern, maintained of a hardware that was highly inconvenient through the necessity to apply electrodes on the users' bodies.

The most recent commercial solution of an appealing EMG controller have been delivered by Thalmic Labs, the Myo Armband [12]. The device consists of mutually aware set of electromyographic electrodes. Moreover, the device is equipped with 3D gyroscope, 3D accelerometer and a magnetometer for extended movement analysis. The band communicates via Bluetooth connection and enables controlling systems using set of predefined gestures. The precision and capability of the solution have been examined during the evaluation of the band for musical interaction application [13].

In our study, we explore the potential of gesture-capturing armband for the purposes of everyday interaction, using the case of audio playback control. The research aimed to verify whether EMG-driven solution is truly capable to meet the requirements of the subtle and convenient interaction, while maintaining sufficient precision and resistance against misinterpretations and environmental noise. The armband has been tested in two different context - one while performing moderately attention-requiring activity and the other in leisure context.

II. System Evaluation

In order to consider possible application of the system for everyday purposes, several criteria must be taken into account. The examined solution of an armband shall perform as an efficient tool for playback control, offering the desired user experience. Therefore, we decided to investigate following questions and concerns:

- establishing whether the Myo armband can perform as efficient audio controller,
- assessment of the usability of the gesture-based operation manner,
- examining the perceived effort and attention needed for Myo operation,
- inspecting the risk of performing undesired action due to gesture misinterpretations,
- studying social perception and emotional comfort of the gestural interaction,

Experimental Setup

The armband was configured to control a simple audio player. For this purpose only EMG sensors was used. The experimental setup employed three gestures to be interpreted: 1) *double tap* - resulting in play/pause toggle, 2) *wave in* - for switching to previous file/rewinding the recording 5 seconds back and 3) *wave out* - for switching to next file/rewinding the audio 5 seconds forward. These gestures were chosen because the device is excellent at recognizing them. The gestures are presented in figure 1.

Fig. 1. Gestures used in system: left - double tap, middle - wave in, right - wave out.

Prior to the test, the Myo armband was calibrated for the user and quick introduction was given. Then, first task for evaluation was introduced. The player was turned on into music preset - so the song switching gestures were made available. Each user was asked to operate the player for a while, pausing and playing songs and switching between them.

Following, the main podcast-based task was introduced - the player was preset in a way that rewinding became assigned to wave in/out gestures. The user was briefly introduced to the topic of the 12-minute long podcast on airplane crew cooperation [14]. The users were asked to listen to the recording and establish the answers to four content-relevant questions. The task was not time-limited and the users were encouraged to rewind or pause the recording if the find it necessary.

1) Scenario A - cycling activity: The users were asked to perform the task while cycling around the park. In such setting, additional muscle activity is present due to the necessity to control and steer the bicycle and overcome obstacles. Further, the issue of competition for users' attention and ease of control is emphasized. Moreover, the context enables analysis of the system's sensitivity towards noise and whether non-intended gestures are recognized. The setup described is depicted in figure 2.

Fig. 2. Setup used in bicycle scenario.

2) Scenario B - leisure activity: The control group were asked to perform the same task in leisure setting in a cafe. This scenario highlights the aspect of social perception of interaction and enables comparison for the assessment of the undesired gesture recognition influence on the usability (Fig. 3).

Fig. 3. Setup used in cafe scenario.

After completing the task, users were asked to fill-in System Usability Scale [15] and NASA TLX [16] questionnaires. Further, a wider post-study interview was performed. Participants were asked to share their views on the following issues:

- whether the system is conducive for everyday use,
- whether the gestures are intuitive and convenient,
- whether the system performed as desired and what problems were determined,
- to describe their feelings and perceived effort,
- whether they liked the system operations,
- to mention other contexts of potential use,

and encouraged for some free discussion about the tested device and their experience.

III. Results

The experiment was performed on a group of $N = 11$ participants, of various age and gender. Each participant took part in a single scenario - 7 participants in scenario A and 4 participants in scenario B. All of the participants from scenario A performed the activity on a sunny day between 12 and 16 PM. The assessment was performed based on the questionnaires answers and the interview commentary provided by the users.

A. Scenario A - cycling activity

Overall, the cycling task was rated as less challenging than the leisure one, with the exception of perceived temporal demand. However, participants felt less successful with fulfilling the task requirements. Averaged results of NASA TLX [16] task analysis are presented in figure 4.

Quantitative analysis of system usability using System Usability Scale [15] brought an average score of 69,64 points (STDEV 13,18), with the range of gathered scores between 47,5 - 80 points. This result suggests moderate usability, which comprises with qualitative analysis of the interview answers.

Users performing the cycling task appreciated lack of reaching the device out of a pocket. The gestures applied were commented as intuitive and easy to learn, and have been perceived as non-intrusive. The most significant drawback of the system was the tendency for gesture misinterpretations - the users complained that numerous undesired operations were recorded by the armband while steering the bicycle, especially while riding on rough road surfaces. Users felt lost, as multiple actions were performed one after another with no clear feedback on their sequence. Users commented: *Once I got into bumpy road, it messed up totally. I lost track of the podcast as it paused and resumed randomly. Every time I wanted to take a sharp turn left, it rewinded the recording*. On the other hand, the users appreciated that the operation of the recording requires relatively low attention and they can keep their vision focused on the road - *It was cool not to have to slow down or stop to safely operate the recording*.

Concerning the experience of armband operation, the participants stated that they feel confident with operating the device, does not feel ashamed or embarrassed using the device. However, some users commented that the gestures might be misinterpreted as turn signifying in traffic contexts. Multiple users shared the view that the device might be a convenient companion to control audio during driving - where the chance for undesired gestures is reduced, while the advantage of maintaining the sight on the road is even more significant. Yet, the same users confessed that they are not willing to use the device while on foot, as they believe it would misinterpret common gestures and might become inconvenient during social interactions, especially while not covered by the clothing.

B. Scenario B - leisure activity

Surprisingly, the task was perceived as more effort-demanding and more frustrating during operation in the leisure environment, while the users rated themselves more successful. The detailed analysis of the task effort measured is depicted in figure 4.

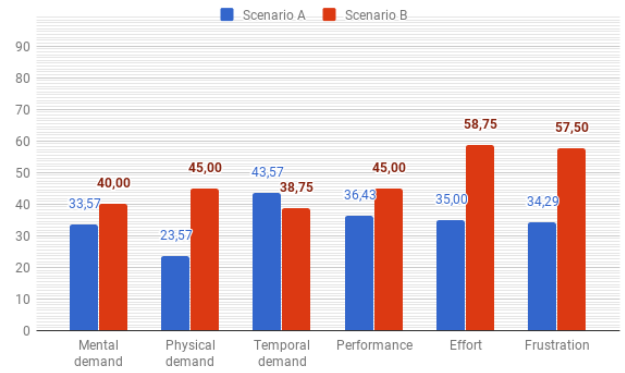

Fig. 4. NASA TLX Results - Scenarios A and B compared.

The system usability measured provided the average score of 71,25 points (STDEV 35,38), with the range of gathered scores being 20-98. The spread between assessments is significant, as issues connected to device calibration highly affected the operation manner for individual participant. It were the anatomic factors which seemed to be significant for proper system setup, as similar problems were encountered for different applications, such as [13]. Therefore, the score calculated on basis of median results seem to depict this assessment more accurately, providing the score of 82,5.

The most significant difference in regard to cycling scenario is the number of misinterpreted gestures reported - in the cafe environment undesired actions are less significant and limited to other movements performed by the user. The set of interaction gestures was commented as intuitive, while being easily mis-performed during common movements - eg. holding a mug, grabbing items. Moreover, some users felt uncomfortable when made to perform a particular gesture multiple times, which drawn attention of other people in the room. The users commented: *I feel quite weird sitting here and waving a hand to myself.*; *I might use it at home, while cooking or reading in my couch, but I don't feel alright with hitting the street with it*. Asked about other contexts of use, they suggested using the armband during jogging, cycling and driving.

The general impression from all participants consisted of the device being too sensitive and performing a lot of undesired operations. A group of 7 users reported that they do not feel comfortable enough with system operation to use it in public, as they would feel embarrassed. Moreover, when informed about the price of the device, majority of users stated that they would not spend that much money, even if the device were applied for contexts suggested by themselves. On the other hand, supporting phone and audio control while driving was the most frequent idea for possible application of the device.

IV. Discussion and Future Work

The performed study clearly highlights several drawbacks of the current state of the technology. While the EMG-driven armband offers satisfactory precision and technological capability [13], it does not offer the desired user experience. The metaphorical gestures chosen by the Myo designers act properly, offering decent level of intuitiveness and enabling quick learning of system principles. However, the social reception of system control draws too much of an undesired attention and may cause anxiety during interacting with others, which is a huge drawback when concerning the device as possible daily companion [7] [2]. Therefore, further improvements in recognition of more discrete gestures shall be applied to enable convenient control of the device in social contexts.

Furthermore, the task assessment shows that using the device is seen as more demanding when the eyes-free interaction manner is not a clear advantage. Occasional need for performing a particular gesture multiple times, combined with quite apparent and explicit movements is perceived more demanding than habitual on-screen operation [17]. This reception results in extended frustration while the device is misoperating, as a well-known alternative naturally arises. However, the effect is no longer present when engaging the sight is clearly unfavorable [18].

A drawback reported to be the most frustrating during armband operation was the excessive sensitivity, causing numerous undesired actions to be performed unconsciously. Misinterpretations turned out to be the most significant flaw noticed, highly affecting the comfort of use - while the users rated the concept as interesting and worth exploring, they were not willing to use the device in the current state due to difficulty of maintaining control over its reactions.

In terms of improving usability, a new concept for decreasing the number of redundant tensions being processed is necessary. Reduced sensitivity is clearly not a suitable solution, in presence of the need for more subtle gesture recognition. Hence, deeper investigation is advised to facilitate greater control over the armband. One of the possible approaches employs using an interpretation window triggered with a highly unique gesture. However, such method requires extensive investigation both in terms of efficiency and the effort and social - related criteria [19] [7].

Analysis of the gathered results enables to observe that the armband performs efficiently when used with decent focus on its operation. Therefore, it might be advantageous to apply the device as a controller in direct contexts, such as interacting with large displays [20] or for controlling rapid visualisation techniques for dynamic real-time process imaging [21] [22] [23] [24] [25] [26] [27], semi-automatic data analysis [28] [29] and crowdsourcing analysis of industrial images [30] [31]. High precision of the movement processing may be employed for mapping the movements of users' forearm onto other kinds of motile devices, such as drones and robots [32]. Further investigation is advocated in the field of ergonomics and potential consequences of long-term operation of the armband, as mid-air interaction pose several challenges in terms of arm fatigue, as signified in [33].

V. Conclusions

The concept of an armband is a successful endeavour towards providing an accessible EMG gesture-recognition controller, having several interesting and efficient applications. However, the examined device poses additional challenges to its users in terms of everyday use. Excessive actions performed due to misinterpreted muscle activity highly affect the system's versatility and decreases the comfort of use. Nevertheless, the armband presents enormous potential for developing eyes-free interactions, employing exceptionally capable technology for gesture recognition. Further efforts for designing more subtle and restrained user experience are necessary for providing efficient and convenient eyes-free interface, suited to support mobile contexts where vision-awareness shall be drawn towards other factors. The proposed solution is promising in terms of alleviating users' problems with operating screen-based devices in contexts where it is unfavorable, but also create an engaging and enjoyable experience of operation.

2nd International Conference on Lean and Agile Software Development

THE evolution of software development life cycles is driven by the perennial quest on how to organize projects for better productivity and better quality. The traditional software development projects, which followed well-defined plans and detailed documentations, were unable to meet the dynamism, unpredictability and changing conditions that characterize rapidly changing business environment. Agile methods overcame these limits by considering that requirements are not static but dynamic, while customers are unable to definitively state their needs up front. However, the advent of agile methods divided the software engineering community into opposing camps of traditionalists and agilists. After more than a decade of debate and experimental studies a majority consensus has emerged that each method has its strengths as well as limitations, and is appropriate for specific types of projects, while numerous organizations have evolved toward the best balance of agile and plan-driven methods that fits their situation.

In more recent years, the software industry has started to look at lean software development as a new approach that could complement agile methods. Lean development further expands agile software development by adopting practices from lean manufacturing. Lean emphasizes waste elimination by removing all nonvalue-adding activities.

TOPICS

The objective of LASD is to extend the state-of-the-art in lean and agile software development by providing a platform at which industry practitioners and academic researchers can meet and learn from each other. We are interested in high quality submissions from both industry and academia on all topics related to lean and agile software development. These include, but are not limited to:

- Combining lean and agile methods for software development
- Lean and agile requirements engineering
- Scaling agile methods
- Distributed agile software development
- Challenges of migrating to lean and agile methods
- Balancing agility and discipline
- Agile development for safety systems
- Lean and agility at the enterprise level
- Conflicts in agile teams
- Lean and agile project and product management
- Collaborative games in software processes
- Lean and agile coaching
- Managing knowledge for agility and collaboration
- Tools and techniques for lean and agile development
- Measurement and metrics for agile projects, agile processes, and agile teams
- Innovation and creativity in software engineering
- Variability across the software life cycle
- Industrial experiments, case studies, and experience reports related to all of the above topics
- Gamification
- Affective Software Engineering

EVENT CHAIRS

***Abstract*—Communication plays an important role in Agile Software Development (ASD). In each ASD practice (e.g., stand-up or retrospective meetings), different communication practices and channels are adopted by different companies. Several works have analyzed the impact of communication channels and practices. However, there are no secondary studies summarizing their impact on ASD. This study presents a Systematic Mapping Study (SMS) that aggregates, summarizes, and discusses the results of 25 relevant primary studies concerning the impact of communication channels and practices in ASD. We followed the well-known systematic mapping methodology in software engineering and analyzed empirical studies published before the end of June 2018. The results of our study have yielded several strategies that can be adopted by practitioners. Communication practices are context dependent. In the case of a distributed team, blended usage of rich-media communication tools, such as shared mind-map tools, videoconferencing, and promoting the exchange of team members between teams, is beneficial. In conclusion, communication can be expensive if teams do not apply the right strategies. Future research direction is to understand how to maximize product quality while reducing communication cost and how to identify the most beneficial communication strategy for the different stages of ASD.**

***Keywords*—communication practices, communication process, agile software development, scrum, extreme programming**

I. Introduction

Constant communication and sharing information about a project's development among the whole team is essential. Agile methods preaching the empowered and self-organizing development teams where focus is on constant communication and information sharing [18]. One of the most important factors for project success is continuous and active communication with the customer and the team members [16], effective communication among developers, operations, support, customers, management, and business areas [19]. During the development process, communication plays an important role in terms of coordination among the different teams involved, in order to manage dependencies between the actors in the process [6] [7] [8]. Communication can be considered as a mediating factor that influences both coordination and control activities during the development process [9].

In software development, it is of crucial importance to have effective communication starting from the project beginning, from the definition of the Minimum Viable Product [5]. Poor team communication is often leads to failure for engineering projects. Such poor communication become more complex in distributed software development. When the teams are unable to find good communication strategies or channels, it affects the quality of the product. However, communication is not always beneficial and can even decrease productivity [17].

Communication in Agile teams can be formal or informal. Formal communication includes specification documents and review meetings [10], while informal communication takes place via conversations among the teams within a company [10] and is usually based on telephone or video calls, audio or video conferences, email, and face-to-face meetings [11]. As suggested by Henttonen and Kirsimarja [11], face-to-face meetings can increase trust among the team members and, consequently, the quality of the development process and the final product.

ASD requires constant communication and information sharing within the team and between the team and the customers [20], [21]. Communication in ASD can be further classified as internal and external. In internal communication, developers and project leaders are the main actors involved in the process, while the development team and the stakeholders are the ones mainly involved in external communication [11]. Regarding the type of communication used, we can distinguish between active and passive. Active communication is mainly based on physical and synchronous approaches, such as face-to-face meetings, while passive communication is based on asynchronous approaches, such as email [20].

Various studies highlighted the problem of identifying the most effective communication channel [16][18][19]. Moreover, besides selecting the appropriate channel, practitioners still face the issue of selecting the most appropriate communication processes and practices [19][22].

In recent years, research has focused on the communication aspects in the Agile development process [12],[13],[14],[15], investigating key success factors [17],[18],[19] and the most effective communication channels that lead to positive effects on the process [22]. To the best of our knowledge, no secondary studies comparing the advantages and disadvantages of communication channels in the context of ASD exist to date.

Therefore, the aim of this study is to provide a systematic mapping review on the benefits and issues of the different communication practices and channels adopted in ASD. We also identify best practices and lessons learned in order to help teams working with Agile development processes in order to communicate more effectively.

Other reviews investigated communication practices in ASD from different point of views. Rizvi et al. [27] investigated distributed agile software engineering for years 2007–2012. Their main goal was to investigate reasons for adopting agile methods to GSD as well as risks. Alzoubi et al. [28] investigated the communication challenges in distributed teams that adopt agile, classifying challenges in six categories, but their focus is different to ours because agile practices are not taken into account. Hossain et al. [29] conducted an SLR on Scrum and GSD, but in contrast to our SLR their focus is limited to Scrum. Vallon et al. [30] performed a SLR on the application of agile practices in GSD. Finally, Hoda et al.[31] performed a tertiary study providing an overview of the SLRs on ASD research topics.

This paper is structured as follows. Section 2 presents the systematic mapping review protocol. In Section 3 we report the obtained results. In Section 4, we describe the threats to validity, and in Section 5, we draw conclusions and present an outlook on future work.

II. RESEARCH METHODOLOGY

The section outlines the adopted systematic mapping study (SMS) process, which follows the established guidelines and procedures proposed by Petersen et al. [2]. The motivation to conduct a SMS is to focus on the "*classification and thematic analysis of literature on a software engineering topic*" [23] [24]. SMS guidelines involves the following tasks: (1) defining the research questions; (2) outlining the search strategy; (3) extracting and analyzing the data.

A. Goal and Research Questions (RQs)

The goal of this study is to investigate the role of communication in ASD, focusing on channels and practices used during the communication process. We aim at identifying best practices and lessons learned in order to help ASD teams to communicate more effectively. To achieve goal of this study we addressed the following Research Questions (RQs):

(RQ1) What is currently known about communication in ASD?
(RQ2) Which communication channels have been studied in ASD?
(RQ3) What are the best communication practices commonly adopted in ASD?

A. Search Strategy

The search strategy adopted in this SMS is depicted in Figure 1. We first identified the bibliographic sources, then we defined the inclusion and exclusion criteria and selected the search keywords. Based on these, we carried out the selection process and finally extracted the data from the selected papers.

*Bibliographic Sources Identification***.** We selected the list of relevant bibliographic sources suggested by Kitchenham [4]: ACM Digital Library, IEEE-Xplore, Scopus ScienceDirect, Citeseer Library, Inspec, Springer. The selected databases are pertinent to this study as they are adopted by most of the literature reviews.

Search Keywords Definition. We defined search keywords based on the PICO structure [4]. We extracted the keywords from Population and Intervention terms. As suggested by Kitchenham [4], the Outcome and Comparison terms cannot always be considered in software engineering if the research focuses on general investigation.

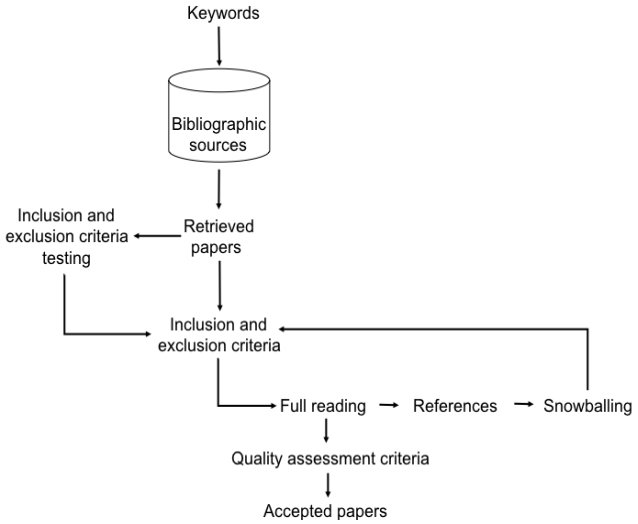

Fig. 1. Search Strategy process

Table 1. Search keywords

Population	**Intervention**
P: Agile development	**I:** Communication
P terms: Agile, Scrum, Extreme Programming	**I terms:** Communication

Based on the identified search keywords, we derived the following query:
(agile OR scrum OR "extreme programming") AND communication)

Inclusion Criteria Definition. Papers were eligible for inclusion in the SMS if they presented data related to communication in ASD. The inclusion criteria used were:

- Papers reporting communication practices in Agile;
- Papers reporting lessons learned, advantages, or disadvantages regarding the usage of communication channels;
- Papers reporting the influence of communication on the process;
- Study written in English and published before 07/2018;
- If published in more than one journal/conference, the most recent version of the study.

Exclusion criteria. Papers not fulfilling any of the inclusion criteria were left out, according to the following criteria:

- Papers not written in English;
- Duplicate articles;
- Not peer-reviewed scientific papers (books or book chapters, presentations, prefaces, gray literature, etc.);
- Simulation studies (e.g., mathematical modeling);
- Papers adopting the term "Agile" for purposes other than ASD (e.g., Agile manufacturing)
- Short papers, workshop papers, and work plans (papers not reporting results).

Search and Selection Process. The application of the search keywords in the selected bibliographic sources returned 2042 unique papers. Next, we applied the inclusion and exclusion criteria to the retrieved papers, regarding both title and abstract. As suggested by Kitchenham [4], we tested the applicability of the inclusion and exclusion criteria as follows: 90 papers randomly selected out of the 2059 were used as a sample; The three authors applied the inclusion and exclusion criteria to 60 papers each (each paper was reviewed by two authors); There was disagreement on 9 of the 90 selected papers (10%). For these 9 papers, the third author provided his/her opinion.

We applied the inclusion and exclusion criteria, for both title and abstract, to the remaining 1969 papers, and we included in this step 600 papers. Then, after the full reading process we selected only 82 papers.

In order to retrieve the most relevant papers, we integrated the procedure, taking into account also forward and backward systematic snowballing [3] on the 74 remaining papers. Regarding backward snowballing, we considered all the references in the papers retrieved, while for forward snowballing, we evaluated all the papers referencing the retrieved ones. We added another two papers and thus ended up with a new set of 84 papers as primary studies.

Assessing the Suitability of the Papers. In this last step, we checked whether the quality of the selected papers was sufficient to provide the required information needed to support the goal of our study. We considered all 76 papers obtained from the search and selection process. Each paper had to provide us with the following information:

- **Communication processes.** The paper had to report the communication process adopted during various development process phases and the research method adopted.
- **Communication channels.** The paper had to report the channels used for communication among the team, the stakeholders, and each partner involved in the process.
- **Best Practices or lessons learned** on the usage of communication channels in ASD.

The final dataset was reduced to 25 papers for the review, as reported in Table 2. In Appendix A, we present the list of the selected Primary Studies (PS).

Table 2. Search keywords

Step	# Papers
Retrieval from bibliographic sources	2059
Inclusion and exclusion criteria (title)	-1266
Inclusion and exclusion criteria (abstract)	-193
Full reading	-518
Snowballing process	+2
Assessing the papers' suitability	-59
Primary Studies (PS)	**25**

Data Extraction and analysis. Once the primary studies are selected, two of the authors analyzed and extracted the data, and the third one verified the correctness of the extraction. This practice helps to avoid researcher bias which is validity threat. The primary studies were analyzed based on study properties:

- **Context Data:** Study type of the paper; paper's goal(s); purpose of the communication; type of teams (distributed teams, collocated, distributed different times, different countries); communication stakeholders.
- **Process Data:** Communication definition; communication frequency; communication channels; communication tools; reported communication challenges for each communication channel.
- **Outcome**: Future direction from each paper; strength of evidence for each communication channel; Best Practices.

All primary studies have been analyzed separately by each author and then a combined peer-review has been conducted. In cases of disagreement, the third author was requested for his input. Finally, the author four ensure consistency in the analysis and consolidation of the results.

III. RESULTS

This section presents the results from the analysis of the 17 primary studies, which is based on the research goal previously mentioned in Section II. The results represent summary of results regarding the communication channels adopted in the primary papers, and then classify the lessons learned. The results identified the usage of four synchronous and two asynchronous communication channels as shown in Table 3.

The PS highlighted communication channels that are the main medium of contacting and exchanging information in ASD teams. In synchronous communication channels, face-to-face communication is the most frequently adopted channel, including both formal and informal communication. Phone calls are used mainly by project managers, while other roles commonly rely on video-conferencing, chat, or email [P1] [P2] [P16]. In case of asynchronous communication, ASD teams often use email, even in the case of co-located teams, while documentation is rarely adopted.

The PS reported that in Global Software Development (GSD), temporal distance challenges play an important role. Coordination between teams increases in complexity with increasing difference between time zones. Face-to-face communication is seldom employed in GSD, except in rare cases such as kickoff meetings. However, unexpectedly, even in GSD, pair programming (via videoconference) can be easily applied and turns out to be highly beneficial [P2].

For instance, Holmström et al. [P2], exemplified that developers with up to eight hours-time differences can work efficiently in pairs, supported by video-conferencing, but they need to shift their working hours so that they can have at least six overlapping hours per day. There is not silver bullet for communication channel, each channel has its own purpose. However, the PS recommended to experiment and blend various tools based on the team requirements and projects purpose to solve information sharing issues in ASD.

3.1 General Communication Channels Benefits in ASD

The PS reported that Agile teams use a variety of channels for communication to ensure open and multidirectional interaction.

Table 3. Classification and description of the communication channels adopted in the studies

Channel	Description	Primary studies (PS)
Synchronous		
Face to face	Can be either formal or informal. Includes communication during Agile ceremonies, pair programming, or any other face-to-face communication related to the project under development.	P1, P2, P3, P6, P8, P9, P10, P12, P13, P16, P17, P18, P19, P21, P22, P23, P24, P25
Video-conference	Used as medium for high-level discussions between non-co-located teams or between teams and customers.	P1, P7, P10, P11, P23, P24
Telephone/ Audio conference	Includes phone calls and any other audio conference tools adopted, such as Skype conferences (only audio) or phone calls.	P1, P2, P4, P5, P7, P10, P11, P14, P16, P19, P19, P21
Online chat	Instant Messaging applications such as Skype or Facebook chat. Mainly used as a means for exchanging technical information between co-located teams (e.g., passing information such as short configuration files) or for quick and informal communication between distributed teams.	P2, P7, P8, P5, P15, P16 P22
Asynchronous		
Documentation	Documentation is another form of communication that occurs between developers who need to report a set of written information. In the two PS, Wiki was the only tool reported and was used to communicate with other teams during project implementation or to keep track of technical choices.	P1, P10, P19, P20, P21, P24, P25
Email	Email is used for different purposes in ASD. Can be used both formally and informally.	P1, P2, P4, P5, P7, P8, P10, P16

Table 4 exhibits benefits, presented in the PS. It is important to identify tools for communication in early phases of a project, based on context and needs. Customers play a critical role in terms of identifying the communication tools to be used in a project. Such early identification is beneficial for Agile teams to achieve optimal performance and strengthen the relationship with the customer.

In all PS it is discussed that face-to-face communication yields a lot of positive outcomes compared to the use of other communication channels. For example, in case of requirement gathering is preferred way of communication [P5]. The face to face communication helps to reduce the capability of conveying ambiguous information [P1]. However, when face-to-face communication is not possible, online communication tools can be used efficiently. Video conferences, supported by rich media such as mind-mapping tools or desktop sharing [P15], improve the quality of the communication, while voice calls (Skype or telephone) are not as effective and should only be used for unofficial meetings. Chat is deemed to be more effective and useful for daily, informal information exchange or asking question from an expert about software functionality [P5].

Email was recognized as more formal way of communication and is more effective in case of getting approval on documents or requirements from the customer (where an email message constitutes a sort of contract) [P5]. On the other hand, the PS highlighted it as concern regarding effectiveness in the use of email for person-to-person communication or formal approval of documents [P5]. However, blended usage of different tools for different purposes can solve most information-sharing issues [P5]. Further, continuous Integration tools useful and helps to facilitate and to communicate the project status from development to final delivery.

Communication effectiveness decreases paired with the level of interaction provided by the communication channel.

3.2 Communication Benefits and Challenges in Agile Practices

ASD includes several practices prescribed by the different Agile approaches, such as Scrum, Extreme Programming (XP), and others. Some practices are shared by different approaches while others are not. In Table 5, we report the list of Agile practices along with their communication related benefits from PS.

Many software companies practicing pair programming. One reason is that pair programming helps to improve individual commitment and efficient way to implement code review [P2]. However, it is very challenging to use them on a daily basis as they are time and resource consuming [P6].

All PS highlighted that scrum meeting (e.g. daily standup, retrospectives) yields various benefits such as help to keep track of the project status, increase communication, enhance collaboration, reduce temporal distances and culture barriers. It is very important to note that the meeting which are conducted in front of project board are appreciated. One reason is that visibility and open discussions in the team/organization helped the spread the information and solve issues quickly. For example, in daily standup meeting, the visual board with different color cards is useful for keeping track of different types of stories [P12].

Table 4. Findings regarding communication benefits and issues.

Practices	Findings and PS
Open Communication	- Open communication must be encouraged and assured in order to get the benefits of Scrum [P11]. - Direct peer-to-peer communication between developers must be enabled to achieve successful results [P4]. - Frequent communication may be a symptom of a good and trusting relationship [P9]. - Team members communicate more with those they are aware of or with those they know can help [P8]. - Collocated teams over-communicate overheard problems [P12]. - A multicultural environment stimulates and increases productivity and creativity [P5].
Face-to-Face	- Preferred communication for collecting requirements [P5]. - Informal face-to-face communication should be encouraged to increase knowledge transfer [P14].
Videoconference	- Distributed teams should be equipped with video-conferencing instead of only using audio-conferencing or telephone [P7][P14][P18][P19][P21]. - Should be accessible to the entire team for regular meetings [P11].
Telephone, Chat	- Useful for unofficial meetings [GSD P11]
Email	- When face to face is not feasible, use email to increase the chance of response and encourage prompt, useful, and conclusive responses [GSD P4]. - Asynchronous communication due to temporal distance impacts coordination mechanisms [GSD P7]. - Effective to approve customer requirements when email message constitutes a sort of contract [P5].

Tool-supported Communication	- Use globally available project management tools to record and monitor project status on daily basis [P3]
	- Blended usage of different tools for different purposes can solve most information-sharing issues [P5].
	- Mind-mapping tools increase communication effectiveness and help mediate issues between distributed teams [P15].
	- Continuous Integration tools are
	  - Useful to communicate the current status of the project to testers, thus making system testing activities easier [P6];
	  - Facilitate testing. Help quality engineers get information on the status of the end product.

There is misconception that documentation is not important in ASD. The PS pointed out the importance of documentation, it helps both current and future team to work more efficiently and understand the logic easily. Code documentation is an important channel when there is needs to modify the code, helps traceability and test validation [P17]. In general, Agile teams rely on ad hoc communication and dynamic patterns of knowledge sharing [P8].

3.2.1 Team-related Communication Practices

Table 7 summarizes the findings of the PS on team-related communication practices. Leaders should be aware of a variety of culturally sensitive behavior and values. At the same time team members should respect the leader's views and should not be underestimated. A mutual trust is essential and it is duty of management to build such trust between developers and their first level manager [P5][P8].

It is also very important to exchange members in teams which are working on same or similar projects. The PS highlighted that a visiting engineer or outside expert is highly beneficial to support inexperienced teams during the first iteration [P10]. It is important for both co-located and distributed teams. Frequent exchange visits of team members are beneficial at the beginning of the project or in critical phases to get in touch with other members and learn how to work together [P11].

The primary studies stress that open communication should be encouraged among software development team members. This is helpful in various ways. For example, it improves team interaction and fosters good understanding between project team and management; in multicultural environments, it stimulates and increases productivity and creativity.

To increase interaction between teams, it is good to exchange team members in distributed project or interdependent teams. This helps them to interact more closely and fosters interpersonal relationships within teams. The use of emergent members helps to spread/share knowledge. Further, pair programming helps to increases mutual understanding and collaboration within and between teams [P2] as well as reduces social and cultural distances [P2]. However, it is difficult and problematic practice for daily use [P6].

Customer communication and close collaboration is crucial for development team and project success. During requirement elicitation customer absences bring challenges for challenge and it more difficult to perform remotely [P5]. The situation become more complex in distributed teams, where customer requirements are presented by other teams. It is also argued that upfront fixed requirements should be less ambiguous than deliberately vague agile requirements.

Table 5. Communication Benefits and Challenges in Agile practices.

Practice	Findings
Pair Programming	+ Increases time overlap and reduces temporal distance [P2] + Efficient way to implement code reviews [P6] + Increases mutual understanding and collaboration within and between teams [P2] + Reduces social and cultural distances [P2] - Difficult and problematic practice for daily use [P6]
Scrum/Sprint Planning Meetings	+ Set the scene for iterations involving negotiations with the customer [P12] + Reduce geographical distances[P2][P23] + Help to keep track of the project status [P6] + Increase awareness of the next iteration in the whole project team [P6][P23] + Provide close interaction among distributed project stakeholders [P7] + Help to minimize misunderstandings and misinterpretations regarding project standards [P2] [P19] [P21] [P23] + Increase mutual understanding and collaboration within and between teams [P2] + Help to reduce the confusion about what to developed from both the developers' and customer perspectives[P6]
Reflection Retrospective Reviews	+ Provide an efficient way to deploy and improve Agile practices [P6] + Good to use for assessing teamwork in completed sprint [P7] + Help to understand project standards among distributed project stakeholders [P7] + Increase project visibility and transparency [P7] + Help project managers with more efficient project supervision [P7]
Daily Standup Meetings	+ Increase awareness of project status among developers, product leaders, and customers [P6] + Help to quickly respond to changes in the project [P14] + Reduce coordination breakdown caused by temporal and geographical distance [P7] + Reduce cultural issues (e.g., perception of authority/hierarchy, frames of reference) [P7] + Convey strategy to the stakeholders [P7] + Increase knowledge sharing, thereby fostering a collaborative approach to problem solving [P12]
Story/Task Board	+Provides project status information to all stakeholders [P6] [P12]
Story Cards	+ Different color cards are useful for keeping track of different kinds of stories [P12]
Test-driven Development	+ Helps to maintain a shared standard view [P7] + Improves understanding of the functionalities required from the customer perspective [P7]
Refactoring	+ Improves communication, simplifying it and adding flexibility [P7]
Documentation	- Code documentation is an important communication channel when the customer needs to modify the code [P17] [P19] [P21] [P23] [P24] [P25]. - Documenting decisions is important in order to communicate them to future team members [P17]. - Test documentation helps to communicate information about traceability and test validation [P17].
Note: + (plus sign) indicates benefits; – (minus sign) indicates a challenge.	

Korkala et al [P1] exemplify that due to some reason project manager and customer group did not help developers and architects to analyze the requirements as well as deliberately hiding information. The companies should carefully plan their practices and recommended to follow people- vs. process-oriented control strategy [P1]. Further, some tools and practices can improve collaboration with the customer even in the case of geographical distance. In any case, the customer's role must be defined upfront and the customer should be enabled to make conclusive decisions regarding the project's functionality and scope [P3].

3.2.2 Organizational Responsibilities

The primary studies reported that in order to utilize the optimal capacity and skills of Agile teams, it is essential to provide proper method, process, and tool training (see Table 6).

Management should provide support along with a combination of internal and external coaching [P10] [P13]. Management should also provide access to everything that is necessary for the team's work, so that dependencies can be avoided easily. In the case of distributed development teams, the manager needs to understand the languages in which the various stakeholders communicate and needs to be sensitive to culture differences. The management need to make developers aware that they should be careful about other cultures. For instance, nobody felt the need to point out any cultural factor that would be disturbing or (even more surprising) stimulating [P5].

The introduction of new practices should be clearly communicated to the whole team paying attention to adapt

the process to the team needs, instead of forcing the team to adopt to the process as prescribed. The management needs to avoid practices which are process- vs. people-oriented control. "*Weak customer relationship and organizational politics that restrict information sharing may cause any communication medium to become inefficient*". The management should focus on creating an efficient customer relationship and environment that enables effective communication [P1]. Afterwards, management can focus on communication channels and tools.

Another interesting point highlighted by primary studies is an open office environment. In the case of co-located development work, it helps to decrease documentation and reduces the number of email communications. In an open office environment, the team members can easily keep up to date with the whole project view and notice obstacles in their colleagues' work [P6] [P17].

Table 6. Organizational responsibilities

Practices	Findings
Management role	-Training on ASD is needed if the team has never used it before. -Reading documentation is not enough [GSD - P10] [P13]. -Necessary resources (corporation intranet, documentation …) must be available to all team members [GSD [P5]. -The project manager should speak all the languages of the developers involved in the project [GSD P3]. -The project manager should collaborate on a daily basis with all the distributed teams [GSD P3]. -Project managers are key players in distributing information to others and being aware of others [GSD P8]. -The role of project managers is essential to the development of project requirements [GSD P8]. -Focus and practice people- vs. process-oriented control [P1].
Open office spaces	-Help to decrease the need for documentation [P6] -Enable everybody to have knowledge of the project status and common goals [P6] -Co-located office spaces close to the customer improve customer relationships since they foster communication [P17].

Table 7. Team-related communication practices and benefits.

Practice	Findings
Leadership & Trust	-Team leaders need to trust other team members [P5]. -The role of the team leader cannot be underestimated [P5].
Effective management	-Effective management helps to balance power [P5]. -Lack of necessary resources (corporation intranet, documentation) can lead to frustration and lower the motivation of the team [P5]. -Effective management makes projects successful [P5].
Emergent team members	-On-demand involvement of emergent members in a team helps to smooth out difficulties rather than getting stuck on a certain point that may lead to delay and failures [P8]. -Gathering information from outside members (i.e., support team, management team, executives…) is more necessary at the start of the project [P8].
Exchange of team members	-A visiting engineer or outside expert is highly beneficial to support inexperienced teams during the first iteration [P10]. -Frequent exchange visits of team members are beneficial at the beginning of the project or in critical phases to get in touch with other members and learn how to work together [P11]. -Exchange visits of team members and visiting schedules must be properly planned without the focus on saving traveling budget [P11]. -Agile teams need to consist of experts. Novices should be introduced to stakeholders gradually [P13].
Customer communication	-The customer must be readily accessible for communication with the development team [P3]. -Daily communication with customer reduces effort overrun [P9]. -Information hiding and lack of efficient customer relationship may lead to inefficient communication [P1] [P10][P19][P20][P21]. -Face-to-face communication between customer and development team is beneficial during project inception to discuss project goals [P14].

IV. DISCUSSION

Communication plays a crucial role in software, services, and systems development. The literature suggests synchronous and asynchronous communication channels in both co-located and distributed ASD. Many communication

challenges can be avoided with the right strategies. When face-to-face, synchronous communication is infeasible, the use of email increases the chance of getting a response and encourages prompt, useful, and conclusive responses. The blended approach of using various kinds of technology-mediated communication helps to avoid communication gaps among various development sites and/or teams. Software development teams need to promote, and be encouraged to maintain, healthy cooperation. Daily stand up meetings with the aid of various communication tools ensures a synchronous communication environment, as result build mutual understanding among distributed project stakeholders [P7].

The "teamness" and one-team attitude is a good strategy. It brings together team members across different locations and encourages cooperation between the team and the customer. Scrum planning meetings help increase "teamness" and reduce geographical distance. To get effective communication among team members, non-verbal communication is very important. In this regard, communication in co-located and distributed teams is not the same. Body language and hand gestures are difficult to observe in distributed teams. However, we can address such challenges to some extent by using technology-mediated communication. Minimizing the physical distances and using heavily technology-mediated communication can help software development teams build trust and work efficiently. The use of video-conferencing, the exchange of developers between different sites, and the deployment of emergent members, which helps in knowledge sharing, play a significant role in enabling effective communication in ASD teams. Furthermore, the PS discussed that Extreme Programming is useful for the more technical and coding aspects of GSD projects, whereas Scrum practices are good for GSD planning and tracking [P2].

Management needs to understand that spending some of the budget on exchanging team members among various sites fosters understanding of different cultures and facilitates communication. The challenges related to communication do not always stem from the use of the various communication media themselves, but may also be due to other reasons, such as fixed requirements, process-oriented control, lack of efficient customer relationship, proxy customer with no conclusive decision power. This results in inefficient communication and reduced efficiency of the communication media. These challenges can be avoided through various strategies, such as: defining the role of the customer up front and providing conclusive decision power regarding the project's functionality and scope; customer being readily accessible; customer having a vested interest in the project. Furthermore, the use of globally available project management tools is recommended in order to record and monitor the project status on a daily basis. To avoid low motivation of co-located and distributed software development teams, they should be granted access to the necessary resources (e.g., corporation intranet, email, product documentation, etc.). Additionally, it is recommended providing the necessary methodology training (e.g., Scrum, Kanban) and allow teams to experiment or pilot the new method in their work. Such training should be followed up with internal coaching to reap maximum benefits.

V. THREATS TO VALIDITY

In this section, we report the threats to validity, applying the structure suggested by Yin [1]. We identified and how we mitigated them based on SMS guidelines [2-5]. Moreover, the guideline proposed by Petersen et al. [2] suggests an objective checklist for assessing the quality of a study. The checklist considers information about activities conducted in the review, the need of the review, the search strategy adopted and its evaluation, extraction and classification process. We achieved an excellent score of 72% compared to the average (33% - 48%) of similar studies [2]. This value is the ratio of the number of actions taken in a review compared with the total number of actions required by the checklist.

Internal Validity. We defined the protocol based on the guideline proposed by [4] in a rigorous manner. As this protocol is the one most frequently used by researchers in the software engineering domain, we are sure that we have avoided any possible bias regarding the design of the methodology.

External Validity. Regarding the representation of the state of the art on communication in Agile development processes, we avoided this issue in our search and selection strategy by using a combination of automatic search in the bibliographic sources and backward-forward snowballing on the references of the selected studies. We did not consider papers that were not peer-reviewed in order to obtain high quality in our results.

Construct Validity is about bringing the right measures for the concept being investigated [2]. In order to reduce this threat, a data collection process was designed as suggested by Kitchenham and Charters [4]. We iteratively refined the inclusion and exclusion criteria by selecting a set of initial papers on which we tested their performance with regard to our goal. We also guaranteed inter-researcher agreement during the search and selection process.

Reliability. The results obtained from the selected papers allowed us to answer the defined research questions in the best possible way. This means that the data extraction process was well designed. Performing our SMS according to the guidelines [3] and providing raw data, will allow other researchers to easily replicate this study.

VI. CONCLUSION

In this work, we investigated communication channels and practices adopted in Agile software development using a Systematic Mapping Study. The 25 primary studies provide a detailed background regarding communication in ASD. It is identified that synchronous communication (i.e. face to face and phone calls) is dominantly used in ASD compare to asynchronous communication channels. It is evident that, even in GSD, pair programming with help of

videoconference easily applied and turns out to be highly beneficial. Various Agile practices such as Scrum/Sprint planning Meetings, reflection, retrospective reviews and daily standup meetings are beneficial in both ASD and GSF. However, the team managers and leaders should know that variety of culturally sensitive behavior and values. Further, along with the identified communication practices and channels, we found the following strategies for promoting effective team interaction in development teams:

- *Leadership & Trust: proactive role of management;*
- *Promoting the exchange of team members between sites;*
- *Active role of customer with conclusive power;*
- *Establishment of open office spaces in the case of co-located teams;*
- *Necessity of good information sharing tools selection at the beginning of project especially in case of GSD;*
- *Blended use of technology-mediated communication channels;*
- *Management should avoid in assigning work beyond capacity because teams easy burn and excused;*
- *Practice people- vs. process-oriented control*

The primary studies highlighted that practicing these strategies promotes team interaction between members from different sites/locations/units. These strategies are not the only ones for promoting communication; other strategies might exist but did not emerge from our analysis. Future works will include a set of industrial case studies and surveys to validate the results presented here.

***Abstract*—Model Driven Architecture (MDA) and Agile Methods (AM) are two principal domains that are in the way of improvement and evolution in order to facilitate the development of IT projects. However, these areas evolve separately despite the great number of research that focuses on improving project' development techniques. Thus, our proposal aims to provide a method describing how can Agile Methodologies benefits from MDA, and how MDA can automate activities within AM. In this paper, we present a state of the art of existing works that combine a Model Driven Architecture approach and Agile Methodologies. Then we present our analysis of this combination to identify with which Agile methods, the MDA approach is more adequate. We also propose our vision about how to combine MDA with the selected Agile Methodologies and evaluate the strengths and weaknesses of each methodology during its combination with MDA and finally we present a case study of Rental Car Agency.**

I. Introduction

THE constant evolution of information system leads companies to search how to improve their productivity, their effectiveness and their profit margins in order to stay competitive. They are in a permanent quest for reliable tools that will cover the maximum of features.

In this context, two major domains have emerged in recent years and made an important place in companies' business: Model Driven Architecture and Agile Methodologies. On one hand, MDA has emerged as a new paradigm of software development that tends to use models as main artifacts in a higher level of abstraction, as well as the separation of the functional and technical specification. Indeed MDA has changed the view of software development: while classic methods concentrate on writing code, the MDA proposes a new method that focuses on analysis phases.

On the other hand, Agile Methods focus on the definition of best practices of information systems programming and their integration in the development process. It is an approach that defines a disciplined management of software development projects: Agility recommends an iterative and incremental method to develop software systems.

Agility puts the customer at the center of the development process of a project [1] and aims to develop software projects in the shortest possible time that satisfies all customer requirements and take into account requirements change, which is a fundamental principle of Agility.

Several works have been made on these two domains that help them to evolve and improve but separately. However, few of them focus on how to combine MDA and Agility.

The main idea in this paper is to present a state of the art of previous studies made in the context of combination of MDA and Agility.

We propose in this paper an analysis of Agile methodologies to define which are more appropriate to combine with MDA. We also give propositions on how to combine MDA and some Agile methodologies that we find appropriate to this combination.

This paper is organized as follows: after this introduction, the second section contains an overview of concepts in which this work is based, namely: MDA, Agile Methodology and RUP. Section 3 presents related works made in the context of combination of MDA and different agile methodologies. In section 4 we describes our analysis and proposed approach to combine MDA with V lifecycle in Scrum sprints. Section 5 is reserved to some perspectives of our future works, and finally we finish by a conclusion.

II. Overview of Concepts

A. Model Driven Architecture

The MDA (Model Driven Architecture) is an initiative of the OMG (Object Management Group) released in 2000 [2] The basic idea of the MDA approach is the separation of the functional system specifications and its implementation on a particular platform.

The MDA approach lies in the context of the Model Driven Engineering which involves the use of model and metamodels in the different phases of development lifecycle of an application[3], MDA defines three viewpoints:

- CIM (Computation Independent Model): the objective of this model is to represent the application in their environment independently of any computation information.
- PIM (Platform Independent Model): the role of the PIM is to give a static and dynamic vision of the application regardless of the technical conception of it.
- PSM (Platform Specific Model): This model depends on technical platforms, it represents a template of code that facilitates code generation.

B. Agile Methodologies

The ' Agile Manifesto ' published in in February 2001 [4] based on analysis of previous experiences that allow to propose good practices to developers, The agile principle introduced by the agile manifesto is related to time invested in analysis and design.[5]

Agility, a paradigm for a new vision of an organization, asserts itself as an alignment and coherence tool between internal forces and external challenges that give dynamism to an enterprise [6]. Agile methodology is a loom to project management, classically used in software development to manage IT projects development. It helps teams to respond to the changeability of building software through incremental, iterative work cadences, known as iterations.

III. STATE OF THE ART

The basic idea behind both Model Driven Engineering and Agile Methodologies is to create systems that can respond quickly to frequent changes, they propose different approaches resolve mentioned requirements; the agility focus on a methodological aspects that concerns an individual product, while Model Driven Engineering is more concerned by an architectural aspect defined by its specific variant MDA (Model Driven Architecture) that aims to separate system features from its implementation in technical platform.

Being aware of the importance of the agility and MDA in the development of software system, many works were focused on combining these areas, in this section we present some works previously made on this context.

In their paper [7] S.Hansson and al. collects different works made in practice on the context of the Model driven Agile Development and analyse the result of each approach, this approach consider that the basic idea behind the Model Agile Development approach is to benefit from practices proposed by agile methodologies, authors of this paper summarize the empirical literature made in the MAD context in order to extarct the lacks of this domain.

P.Cáceres and al. proposes in their paper [8] a case of study of an Agile Model Driven Development integrated in MIDAS framework which combines Model Driven Architecture approach and Agile practices based on eXtreme Progrming (XP). MIDAS is a model driven methodology for Web Information Systems (WIS) agile development, the architecture of MIDAS combines both MDA and n-tiers architecture, this combination is in order to propose a model of a WIS respecting the independence of the platform according to the MDA and in the same time take account of a middleware architecture of the Web services development platforms, while the process of the MIDAS methodology framework is based on Agile Modeling Driven Development practices that aims to write code progressively in agreement with the model. We mention that authors in this paper details the architecture of the MIDAS framework while it does not explain how the Agility is integrated in the process of MIDAS tool, moreover we note that the XP practice is dedicated specifically to the development phase during the software system development, which allows us to note that this approach does not implement all the aspect of the MDA approach.

In their paper [9] M.B.Nakicenovic presents an Agile Model Driven Development process developed in consideration of lean and agile practices, the paper aims to provide an approach that shows that MDD and agility can work together exploiting the benefits of each domain, the approach is applied on both forward and reverse engineering in order to respond to two issues; accelerating the re-engineering process of the MDD solution, how benefit from agility and lean while producing MDD solution within a short time frame. The paper describes an approach that combines MDD and agility based on lean, the implementation of the approach was made on the Market Server Capabilities (MSC) project proposed by SunGard company.

F.P.Basso and al. presents an approach that combines a Model Driven Architecture approach and Agility in the context of Rapid Application Prototyping (RAP) [10]; RAP allows the validation of software requirements before acceptance tests which in order to obtain a quick feedback from clients. This approach aims to take account of the agility principles in the context of MDA based on RAP methodology to generate front end and models based on MVC pattern, the implementation of this approach was applied on the generation of the Web Information System based on scrum methodology and MDE practices. The authors aims to ensure several benefits within this approach; better organization of source code, simplicity of changing the source code, simple and rapid design of models, and they still expecting to benefits from reuse of designed models. We note that this approach can't be generalized to all types of software systems, indeed it was dedicated to develop Web Information System, we also mention that in this approach authors do not detail how to integrate the MDA and scrum, i.e. they do not propose where to use each level of MDA in scrum methodology.

V.Kulkarni and al. discuss and argue in their paper [11] why agile methodology can't be used with Model Driven Engineering, then they propose a modification to make on agile methodologies in order to combine them with MDE. Indeed this paper describes a new Software Development process that combines Scrum and MDE, in this approach authors proposed the use of Meta-Sprints that run in parallel to Sprints in order to validate models, they suggest two to three months as timescales for meta-sprints where clients must provide feedback on models and prototyping , which is opposite to agility principles; indeed agility recommends that the feedback

of clients must be in period less than what was proposed in this approach.

H.Alfraihi in its paper [12] analyses the challenge of combining Agility and Model Driven Development, the paper describes an approach that aims to increase the adaptability of these domains by proposing a framework that facilitate Agility and MDD, this approach proposes recommendations, guidelines, and procedure to can use Agile MDD in practice. We note that even if this approach proposes some practices to implement the Agile MDD it does not take account of the architecture of the MDD, Model Driven Architecture, and how to benefit from the different abstraction levels to produce sustainable software systems.

In the paper, H.Wegener [13]presents a study made on the context of the combination of agility and Model Driven Development, then to propose issues that show how this combination affect organizations, process and architecture, this paper presents a comparison of different approaches proposed to use Agility and Model Driven Development.

In their paper [14] V.Mahe and al. presents their first reflections about the fusion of the MDA and Agility in order to have a combination with improved properties than the additions of the two approaches, they propose a canvas based on processes and agile practices in both modeling and meta-modeling level.

V.Nikulsins and al. propose an implementation of the MDA into RUP as presented in figure bellow:

- CIM covers the Business Model and requirements as well as planning for the development of the PIM metamodels.
- Elaboration is the main phase impacted by the MDA project, which is covered by PIM.
- PIM also cover part of the construction.
- In the construction phase the transformation of PIM model to PSM model starts.
- PSM covers transition phase

Burden et al. [15] have conducted a systematic literature review by proposing two research questions with the goal to investigate the empirical evidence of the state of art of integration of agile and MDD approaches and what is lacking in that area. The study shows that Agile MDD is still in its early stages and there is a need for detailed experience reports.

In their paper [16], H.Alfraihi and al. presented a systematic literature review to complement the results of [15] where fifteen primary studies were reviewed. The main characteristics of Agile MDD approaches besides their benefits and problems are highlighted. Both systemic literature review studies provide broader coverage, but they are less in-depth than interview study.

Eliasson and Burden [17] have conducted an exploratory study at Volvo Car Corporation (VCC). At VCC, individual teams adopt Agile practices with MDD while the organisation at large still use plan-driven process. The aim of this exploratory study is to investigate how Agile practices can be extended to the organisation level. In specific, it aims to answer the following question: Which are the challenges and possibilities for a more Agile software development process on a system level?. They interviewed 17 engineers to identify the challenges of the current process at VCC and how to improve it. The results of the interviews revealed two main challenges: first, the developers have to wait long before getting feedback which forced them to make premature assumptions leading to unwanted side-effects and faults; second, the use of MDD tools force developers to employ a waterfall process. The main finding of this study is that there is a need for a more Agile way of working to obtain earlier and faster feedback. They conclude that Agile MDD can be useful in automotive development. However, their study is context specific to VCC to examine its case and limited to automotive domain which is difficult to be generalised.

IV. OUR PROPOSITIONS

To ensure the good combination of MDA and agility we have to answer four questions:

- What are the reasons that motivate integrating Agile practices and MDD processes?
- How are Agile practices and MDD integrated?
- What are the benefits of integrating Agile and MDD on development process?
- What are the challenges of integrating Agile and MDD?

In their paper R.Matinnejad [18] defined that the integration of Agile in MDD process can be developed by:

- MDD-based: introducing Agile method to a current MDD process which is called.
- Agile-based: applying MDD process to an agile method.
- Assembly-based: integrating some fragments from Agile and other from MDD to develop the process

Although, both Agile and MDD processes have been introduced for more than a decade, the basic principles on how to integrate them together are not well-known. In this regard, the use of agile and MDD do not follow a well-defined process or systematic guidelines to guide through development. As a consequence, development teams introduce practices of Agile and MDD in an ad-hoc manner or based on their personal experiences.

In following, we discuss our reflection and analysis about different software methodologies and also agile ones and the possibility of their combination with MDD depending on each methodology criteria. To this end, we choose the most popular and used methodologies:

- eXtreme Programing
- 2TUP
- RUP
- V Life Cycle
- Scrum

A. *eXtreme Programing*

eXtreme Programming is a discipline of software development based on values of simplicity, communication, feedback, and courage. It works by bringing the whole team together in the presence of simple practices, with enough feedback to enable the team to see where they are and to tune the practices to their unique situation.

The eXtreme Programming is a software development discipline that organize people to develop higher quality software system and be more productive. XP defines four activities that are performed with software development process: Coding, testing, listening and designing. [19]

Analysing the definition and principles of the eXtreme Programming we deduce that this process is more appropriate to development phase in the process of software development.

According to XP and MDA approaches principles we deduce that it is not possible to combine both of these domains taking into account the fact that XP is dedicated to manage the development phase while MDA approach is an architecture based on different level of conception using models to finally generate automatically the source code.

B. 2TUP: Two Track Unified Process

2TUP is an instantiation of the UP (Unified Process) proposed by Valtech company, it takes into account constraints of rapid business changes of software system.

The fundamental principle of the 2TUP is to decompose and treat at the same time the business requirements, following two axis; functional one and technical one. At the end of the evolutions of the functional model and technical architecture, software development phase consists on combining the results of these two branches of the process as described in the figure bellow.

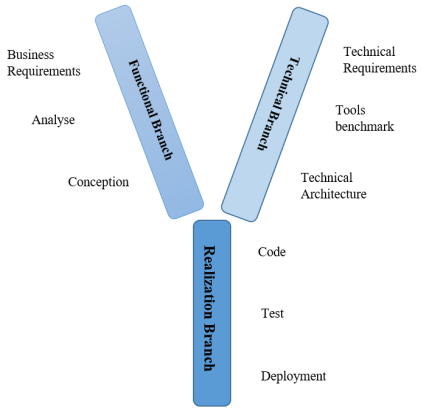

Fig. 1: 2TUP methodology

Analyzing 2TUP methodology we conclude that it can't be combined with MDA, indeed the MDA approach proposes to generate technical conception from functional one through model transformations which are the core of MDA approach. There are two types of model transformations; Model to Model (CIM to PIM and PIM to PSM) , and Model to Text (PIM to source code), while in 2TUP methodology the functional and technical conception work in parallel to finally combine their results in the development phase.

C. RUP: Rational Unified Process

The Rational Unified Process is a Software Engineering Process. It provides a disciplined approach to assigning tasks and responsibilities within a development organization. Its goal is to ensure the production of high-quality software that meets the needs of its end-users, within a predictable schedule and budget. [20][21]

It is closely related to the Unified Modeling Language (UML); this model proposes to manage the IT developments using a model of activities divided in 4 categories described in table 1:

TABLE I: Description of RUP phases

Phase	Description
Inception	• Establish a business case of the system • Define different actors and use case
Elaboration	• Analyze the problems of the domain • Establish the system architecture • Define the project plan
Construction	• Develop, test and integrate the components of the project
Transition	• Forward the project to users

The general architecture of the Rational Unified Process is characterized by two dimensions:

- The horizontal axis represents time and shows the progress of the lifecycle of the process; this first dimension reflects the dynamic aspects of the process that is expressed in terms of cycles, phases, iterations and milestones.
- The vertical axis represents major patterns of activities which include activities according to their nature; this second dimension reports the static aspect of the process that is expressed in terms of components, processes, activities, artifacts and workers.

Analyzing the RUP method and its structural phases, we conclude that it is possible to combine it with MDA approach, in the following part of this section we propose our view of implementation of MDA into RUP that consists on:

- CIM level covers the inception phase, this level is modeled by Use Case diagram to represent a static and functional aspect, and Activity diagram to represent a dynamic aspect.
- The elaboration phase is covered by the PIM level obtained from a vertical transformation of CIM model, this level is presented by Class Diagram representing a static view while a dynamic one is represented by a Sequence Diagram.
- PSM level covers a construction phase after enriching a PIM models and transform them using vertical transformation into Design Class Diagram and Interaction Diagram.
- Transition phase is covered by a code obtained with Model to Text transformation.

We summarize our approach in the following table:

TABLE II: Description of RUP phases

RUP/MDA	Inception	Elaboration	Construction	Transition
CIM	• Use Case diagram • SBVR			
PIM		• "Business" Class Diagram • "System" Sequence Diagram		
PSM			• "Design" Class Diagram • "Detailed" Sequence Diagram	
Code				• Source Code

D. Scrum

The Scrum method is an agile method, founded in 2002, It relies on the Division of project into iterations still named "sprints". A sprint can have a duration which varies generally between two weeks and a month.

The estimation of task in time and complexity is made before each sprint using several methods, in order to plan the deliveries and also estimate the cost of each task for the customer.

Features called user stories are the subject of the sprint that constitute a "sprint backlog" that can be a deliverable product at the end of the sprint.

There is difference between the sprint backlog "product backlog", corresponding to all of the features expected for the product on all of the sprints.

The Scrum method is also characterized by a "melee" daily, called "morning" or "stand up", in which employees (project managers, developers and functional managers) in turn indicate tasks that they have performed the day before, the difficulties and finally this whereupon they will continue their work the next day. This allows to evaluate the progress of the project, resources where they are most needed, but also to provide assistance to workers facing difficulties when these have already been encountered previously by other members of the team.

To combine MDA and Scrum we can use in each sprint of the project the MDA principles, i.e. in each sprint we apply our approach of generating source code from business requirements, in scrum we have a sprint backlog that describes system' features, the combination can be described as follow:

- As first step we model the requirements in sprint backlog by the UseCase Diagram and OMG standard SBVR to represent the CIM level.
- After modeling the CIM level, these models are transformed automatically to PIM level which is modeled by "Business" Class Diagram and "System" Sequence Diagram.
- Models in PIM level are also transformed into "Design" Class Diagram and "Detailed" Sequence Diagram in the PSM level
- The last step is the automatic generation of Source Code from PSM level.

This combination of MDA in every sprint of Scrum methodology have many advantages:

- Reduce the duration of the sprint that influence also the total duration of the project.
- Facilitate the management of requirements' changes of the system view that models and code are generated automatically.

E. Combination of MDA and V lifecycle in Scrum

As known scrum methodology proposes best practices to develop a qualitative software system respecting Agility principles, most of time developers prefer to combine scrum with life cycles to ensure the good management of the project development; in each sprint of Scrum, V life Cycle is used to define steps of the development of system, in this part of this section we will propose a combination of MDA and Scrum+V life Cycle.

V model means Verification and Validation model. Just like the waterfall model, the V life cycle is a sequential path of execution of processes. Each phase must be completed before the next phase begins; based on the requirement document that contains specifications of the system, developer team started working on the design and after completion on design start actual implementation and testing team starts working on test planning, test case writing, test scripting. Both activities are working parallel to each other.

Before presenting the combination of MDA and V lifecycle in scrum we present our MDA approach that consists on :

- Describing system requirements in CIM level by a structured English using SBVR.
- Transforming automatically Business Vocabulary and Business Rules of SBVR into Use Case Diagram (UCD) in CIM level [22]
- Applying transformation rules to generate Business Class Diagram (BCD) and System Sequence Diagram (SSD) from SBVR and UCD of CIM level to represent the PIM level [23].
- Generating PSM level of MVC architecture represented by Detailed Class Diagram (DCD) and Detailed Sequence Diagram (DSD) from PIM level using automatic transformation rules.
- Generating application source code from PSM level.

We mention that the automation of the two last steps of the approach will be implemented as an eclipse plugin which is the continuity of the previous one.

Choosing previous diagrams to model MDA levels is depending on different aspects that each level should cover according to OMG specifications:

- For CIM level, we define three aspects; Static and Dynamic that are covered by SBVR, while the Functional aspect is covered by UCD.
- For PIM level, we define two aspects; Structural aspect covered by BCD and Dy-namic one covered by SSD.
- For PSM level, we define in our approach 4 aspects; Static aspect covered by Model classes of DCD, Structural one covered by Class Diagram, Dynamic aspect covered by Controller classes and Behavioural one represented by DSD.

In this approach, we automate the two types of transformations Model-to-Model (M2M) and Model-to-Text (M2T). For M2M, we use QVT language while for M2T we use Acceleo transformation language. Transformation rules between the different levels of MDA are implemented as an Eclipse plugin to ensure automation and traceability of transformation rules. The figure below describes an overview of our approach:

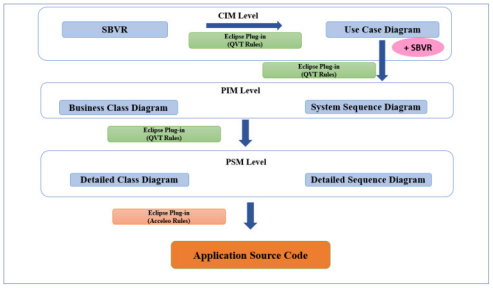

Fig. 2: Overview of our MDA transformation approach

Combining MDA and V life cycle in Scrum can be described as follows:

- Covering Requirements and functional specifications steps in V life cycle by CIM level of MDA which is represented in our approach by SBVR. The UCD and Business Rules generated at the CIM level are then used generate "Validation tests" to validate if the developed system responds to described requirements.
- Generating the High-level design represented in our approach by the PIM level which is generated automatically from CIM level (To generate PIM level from CIM one, we use our approach defined in our previous works (Essebaa and al, 2017). This step is represented by BCD and SSD for each use case element. We then generate "Integration tests" from these diagrams (BCD and SSD) to test the correct functioning between different elements of the system.
- Generating the low-level design represented by PSM level which is modelled by CD and DSD (The approach we propose to automate transformations between PIM and PSM levels will be discussed in our future works). We generate "Unit tests" from this level to test the generated code.

The figure 4 below describes the presented approach:

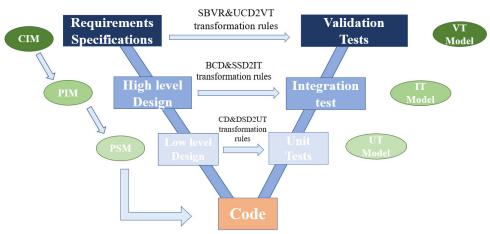

Fig. 3: Combination of MDA and V life cycle

To generate tests from Models in our approach, we defined three main rules that are detailed in our previous work [24]; Rule 1: Generate Validation tests from CIM level: Validation tests are generated from SBVR and Use Case Diagram. Rule 2: Generate Integration tests from PIM level: Integration tests are generated from PIM level which is represented using Class Diagram and System Sequence Diagram. Rule 3: Generate Unit tests from PSM level: Unit tests in our approach are generated from PSM level using Detailed Sequence Diagram and Detailed Class Diagram. The table 3 below summarize these rules:

TABLE III: Test generation rules

Rule	Model	Target
SBVR&UCD2VT	Use Case Element	Requirement to validate
	Fact Type	Sub feature to test
	Business rules of a fact type	Validation tests
BCD&SSD2IT	Actor and DataObject lifecycle	Classes to test
	Relationship between classes	Integration tests
DCD&DSD2UT	Messages	Operation to test
	Operation in classes	Unit tests

In the previous part we present how we automate transformations in MDA and combine with V lifecycle to generate different type of tests, in this part we will present our approach of managing system' requirement using MDA inside a V lifecycle in scrum method. Our proposal is divided into 5 main steps:

- Step 1: Defining system requirement by Backlog Product.
- Step 2: Planning features in a RoadMap.
- Sprint to Begin:
  - Step 3: Apply our approach that combine V lifecycle, MDA and MBT presented in parts 3.1 and 3.2 of section 3.
  - Step 4: Adding code missing parts manually preceding them with "@added" annotation.
- Step 5: Validation and planning of following sprints. In this step we define two cases:
  - If there is no system evolution:
    - Restart from step 3 for the next sprint
  - If there is an evolution:
    - Restart from step 1 and keep the old code except the parts preceded by "@added" annotation of features that still exist in the system (added code of deleted features is deleted automatically after the new execution)

In the figure 5 below we describe an overview of the presented approach in this paper:

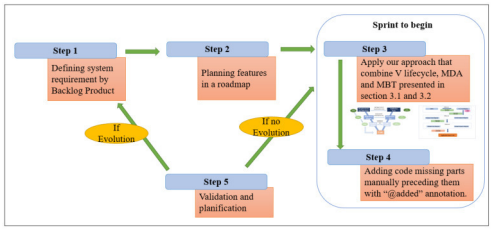

Fig. 4: Overview of a combination of MDA, MBT, V lifecycle in scrum

V. Implementation of our approach

To automate defined transformation rules in our approach, we need tools that allow to create input elements (UML Diagrams), and tools that support the generation of output elements (UML diagrams for PSM level and Source code). After analysing and testing existing tools, we decided to use Eclipse platform with different needed plugins to implement our approach, for example we choose Papyrus Modelling plugin because it supports all UML diagrams elements. According to this we choose to implement our solution as an eclipse plugin that will be a continuity of the previous developed plugin presented in [23] that automate transformations from CIM to PIM. Implementing our approach as an eclipse plugin is in order to facilitate the use of our transformation approach by designers and developers, and also to benefit from existing plugin in Eclipse.

To implement our transformations, we have to use a transformation language; there exist many models of transformations language for both types of transformations M2M and M2T, in our case we chose to use QVT language for M2M transformations and Acceleo language for M2T transformations.

These transformation rules are automated in our Eclipse plugin that take in an input a CIM level and generate PIM, PSM and source code.

The figure 6 shows "Transforms" menu that contains different items that allow the automation of rules:

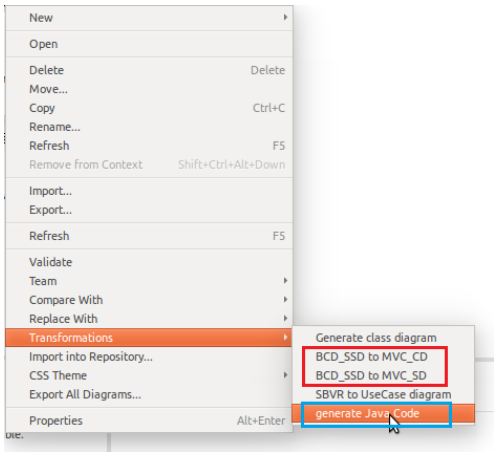

Fig. 5: Transforms menu of our plugin

VI. Case Study

To well illustrate our approach and transformation rules defined, we present in this section their application on a Rental Car Agency system. The case study must provide the following features:

- Visualization of available cars.
- Customers subscription.
- Cars booking.
- Visualization of reservations.
- Management of reservations (accept/decline) by a manager.
- Management of cars.
- Management of customers' accounts.
- Management of Managers' accounts.

The application has three users' profiles that have different privileges:

- Customer: A person who can view the cars available in the agency, rates and promotions and may subscribe. A client must register and authenticate in the system to search for available cars and book a car by indicating the reservation date and time.
- Manager: A Manager must also authenticate to view all cars, add, edit or remove cars. He can also view the bookings made by customers waiting for validation to decide to accept or refuse them.
- Administrator: Once authenticated into the system, the administrator has the privilege of modifying and deleting a customer account, as well as the management of managers account (add, change or delete)

We can also define some management rules as below:

- A customer can rent at least 1 car.
- A car can be rented by at least 1 customer.
- A manager can manage at least 1 car.
- A car is managed by at least 1 manager.
- An administrator can manage at least 1 customer account.
- An administrator can manage at least 1 manager account.

In the following part we present an application of our approach' steps on Rental Car Agency System example:

1) Defining a Backlog product by system requirements: After analyzing system requirements, the first step in our approach is to define the backlog product of the project then plan the RoadMap that describes different sprints of first project' requirement before any evolution, in this example we plan three sprints to develop the system, we define 3 sprints where each one takes 2 weeks. The figure 7 below describes the roadmap of Rental Car Agency system:

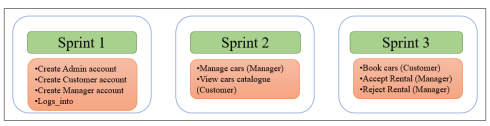

Fig. 6: Scrum RoadMap of Rental Car Agency System

2) Modelling user stories of the first sprint by SBVR and UCD to cover CIM level of MDA: The next step after dispatching features on sprints is to describe CIM level of first sprint by Business Vocabulary and Business Rules using SBVR standard as described in following figure 8.

```
account
login
    General_concept: text
password
    General_concept: text
account has login
    Synonymous_form: login is_property_of account

account has password
    Synonymous_form: password is_proprty_of account

customer owns account
    Synonymous_form: account is_owned_by customer

customer manages account
    Synonymous_form: account is_managed_by customer

admin owns account
    Synonymous_form: account is_owned_by admin

admin manages account
    Synonymous_form: account is_managed_by admin

manager owns account
    Synonymous_form: account is_owned_by manager
It is possible that customer owns at most 1 account.
It is possible that admin owns at most 1 account.
It is permitted that admin manages account.
It is possible that manager owns at most 1 account.
```

Fig. 7: Examples of SBVR of the first sprint of Rental Car agency

In the same level of MDA, we apply horizontal transformation rules, implemented as an eclipse plugin, to automatically generate UCD from SBVR. The figure 9 below represents the generated UCD of the first sprint for Rental Car Agency system.

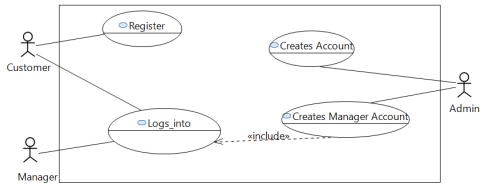

Fig. 8: UML Use Case Diagram of the first sprint of Rental Car Agency System

3) Generating Validation tests from CIM: As in our approach we use V lifecycle process combined with MDA, after defining CIM level, we can generate Validation tests from this level as described for "Logs-into" feature in table 4 below:

TABLE IV: Validation tests generation from PSM level

Source			Target		
Use Case element	Fact Type	Business rule	Requirement	sub feature	validation test
Logs_into	System requests user credential	It is obligatory that the system requests user credential if customer logs into system	The system must allow the customer to logs_into the system	Requests user credential	The system must request user credential if a customer try to logs into the system
	customer sends user credentials	It is necessary that customer sends user credentials if system requests user credential		sends use credentials	The system must allow customer to send user credential
	System verifies user credentials	It is obligatory that the system verifies user credentials if customer sends user credential		verifies user credential	The system must be able to check user credential
	System accepts user credentials	It is possible that system accepts user credential		accepts user credential	The system must be able to accept user credential

4) Applying transformation rules on CIM to generate BCD and SSD of PIM level: Generating PIM level is the first vertical Model-to-Model transformation that aims to automatically generate BCD and SSD from CIM level for Sprint 1 using our Eclipse plugin that implements transformation rules, the figure 10 below represents a BCD of PIM level of Rental Car Agency system:

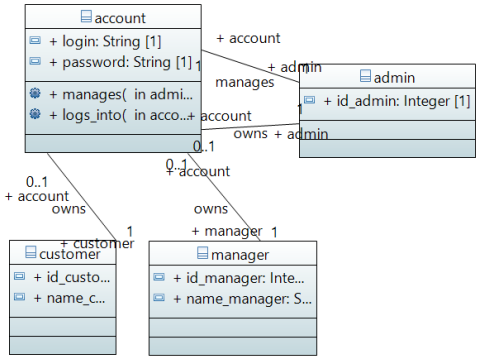

Fig. 9: Generated BCD of PIM level of the first sprint of Rental Car Agency System

The dynamic aspect of PIM level in our approach is represented also by different System Sequence Diagrams, the figure 11 describes System sequence diagram of "logs_into" feature in rental car agency.

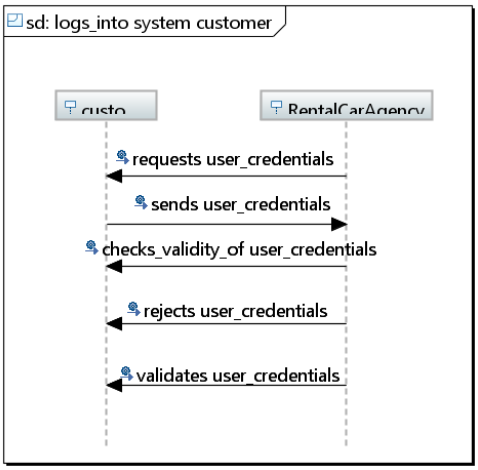

Fig. 10: Generated SSD of PIM level of the first sprint of Rental Car Agency System

5) Generating Integration tests from PIM: According to V lifecycle used in our approach, Integration Tests are automatically generated from PIM level that covers high level design of V lifecycle, the table 5 below describes Integration test for "logs_into" feature in sprint 1:

TABLE V: Integration test generation form PIM level

Source		Target	
Requirements	SD Connection	Classes	Integration tests
Logs_into	The operation requires connection between "Customer" and "Account	Customer	Customer owns 1 account
		Account	Account belongs to 1 customer

6) Applying transformation rules to generate DCD and DSD of PSM level from PIM: The last level before code is PSM level, which is the result of M2M transformations applied on PIM level to automatically generate DCD and DSD, the figure 12 below defines DCD of PSM level of sprint 1:

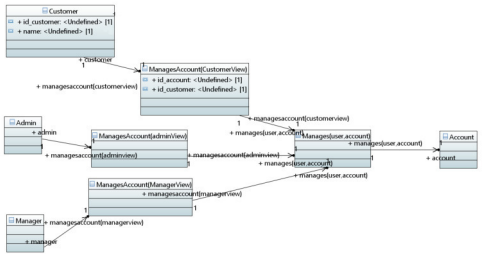

Fig. 11: Generated DCD of PSM level of the first sprint of Rental Car Agency System

The dynamic aspect of PIM level in our approach is represented also by different System Sequence Diagrams, the figure 12 describes Detailed sequence diagram of "logs_into" feature in rental car agency.

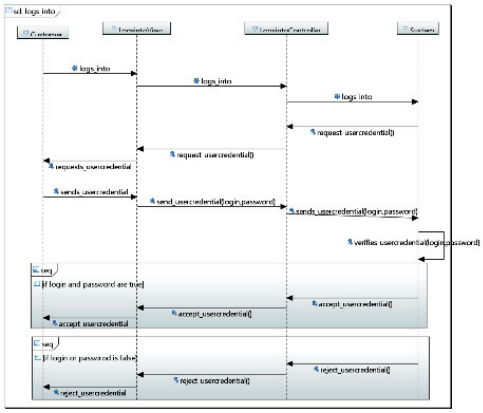

Fig. 12: Generated DSD of SIM level of the first sprint of Rental Car Agency System

7) Generating Unit tests from PSM: Unit tests in our approach are generated from low level design step of V lifecycle covered by PSM level, the table below describes example of Unit test of "logs_into" feature in sprint 1:

TABLE VI: Unit tests generation from PSM level

Source		Target	
Requirements	SD Messages	Operation to test	Unit tests
Logs_into	System requests User_credential	Request(User_credential)	Test "requests" operation
	Customer sends User_credential	Sends(User_credential)	Test "sends" operation
	System verifies User_credential	Verifies(User_credential)	Test "verifies" operation
	System accepts User_credential	Accepts(User_credential)	Test "accepts" operation

8) Generating application source code: The last transformation in our approach is automatic code generation which is the result of M2T transformations that takes as an input a DCD and DSD of PSM to generate as an output source code for MVC web application.

9) Adding missing parts of code manually: The last step in each sprint is to add manually the missing parts of code to complete the system' feature, this code must be preceded by "@adding" annotation.

Evolution of Rental Car Agency system' requirements

In this section we will make some evolutions to the system (addition, deletion and modification of features) in order to visualize the process of models' transformation and test generation in V lifecycle combined in scrum, the evolution will be as follow:

- *Modifications*: "View car catalogue" feature will be available for all users not only customers, this modification engender a new actor "User" that it will be a generalization of "Customer" actor, this modification requires changing the actor of "register" method too.
- *Addition*: In the new system, "Customer" will be able to validate its rental by "payment", The addition of a feature may engender some modifications to old ones, for example the verification of car availability will be made automatically by a system.
- *Deletion*: The addition of "payment" feature requires to delete "Manage rental" feature of "Manager" that allowed him to accept or reject the rental, in the new system the customer can validate its rental from the system, before proceeding to payment option the system must be able to check if the chosen car is available for date specified by the customer.

After studying system requirements' evolution, we have to make another feature dispatching on next sprints as presented in figure 14:

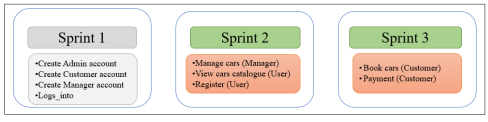

Fig. 13: Scrum RoadMap of Rental Car Agency system after requirements' changes

The next step is to develop the second sprint following same steps previously presented in an example for the first sprint even test cases that will be automatically generated.

VII. PERSPECTIVES AND FUTURE WORKS

This paper is an introduction to our future works on which we aim to combine MDA and Agility in order to propose an new method to develop software systems.

To combine MDA and Agility we aim in our future works to:

- Ensure the traceability between levels to manage requirements changes, as we know among agility principles is the adaptation to changes
- Propose an approach of Agile Model Driven Development appropriate to different types of Software systems (Web, Desktop,...)
- Propose a new Agile methodology that regroup all best practices proposed by other methodologies.

VIII. CONCLUSION

The basic idea in this paper is to combine the MDA approach and Agility in order to propose a new software development method, to well identify and situate the idea in the context, we describe in this paper a state of art of previous approach made in this context.

After analyzing previous works we conclude that proposed methods wasn't implemented to be applied to all types of software systems, we also present our analysis and reflexion on some existing agile methodologies in order to choose those more appropriate to be combined with MDA.

In this paper we propose to combine MDA and Scrum agile methodology in order to improve sprints of scrum and benefit from MDA principles, in this work we proposed to use V life cycle in each sprint of the project where we combine another variant of MDE, to generate automatically different tests applying MBT principles.

As previously mentioned this paper is an introduction to our future works on which we aim to propose a new methodology base on Agility and MDA.

***Abstract*—Scrum has been the most widely adopted Agile methodology over the past decade with Scrum and Scrum variants offering alternatives to the old software development methods. While Scrum plays an important role in the success of Agile development, it does come with its own challenges. In previous research challenges have been analyzed at the organizational and team level, primarily via case studies. However, fundamentally, Scrum needs to be adopted at the individual level. Furthermore, challenges such as inexperience, poor communication, specialization, lack of teamwork, low-quality, organizational culture and Scrum compatibility, have been identified as contributors. This paper therefore discusses the Scrum and Agile adoption challenges faced both globally as well as within the South African borders, from the findings of a narrative review. Secondly, a custom model adapted from the Diffusion of Innovation theoretical model was developed to detect the Scrum adoption challenges experienced within software organizations at the individual level. The custom model referred to as the Scrum Adoption Challenges Detection Model (SACDM) consists of four constructs, namely; individual factors, team factors, organizational factors and technology factors. The constructs are composed of nineteen independent variables that assists in understanding which factors contributes towards an individual either adopting or rejecting Scrum within a software organization. SACDM is therefore used to detect the adoption or rejection of Scrum as the dependent variable based on the independent variables being tested within the four constructs. The model can further be used with a survey questionnaire to provide generalized awareness of Scrum adoption challenges allowing software organizations to make more informed decisions when adopting Scrum. Future research is to allow the model to contribute towards Scrum adoption challenges predictive analysis.**

***Index Terms*—Adoption Challenges, Agile Methodologies, Scrum, Software Engineering, Software Organization.**

I. Introduction

"SOFTWARE development has become one of the world's most important practices. The software we produce today is rapidly becoming the embodiment of much of the world's intellectual property. Simply put, our modern world depends on software" [1].

Scrum, in the context of this paper, refers to an Agile methodology with emphasis on project management structure and communication between all stakeholders including clients and business representatives, regularly setting sprint time limits for software completion, reviewing changes and applying retrospection before working on the next product backlog requirements [2]. The software organization we refer to in this paper is any company, firm or organization that has a software development division or group of two or more individuals responsible for developing and maintaining software, for the benefit of the software organization or the client they service.

Scrum was developed in the early 1990's by Ken Schwaber and Jeff Sutherland [3]. Scrum is currently the most widely adopted Agile methodology, based on the 2017 VersionOne survey [4]. The reason for its high adoption rates could be its simplicity, as it can be easily understood by both business and Scrum teams alike.

Agile adoption (which includes Scrum) has its challenges such as work specialization, organizational culture, resistance to change, and lack of communication to name a few, however, what is certain is the fact that successful adoption improves numerous aspects of the business operation. Business operations include project visibility, manage change priorities, better aligned Information Technology (IT), increased productivity and enhanced software quality [4]. As stated by Rogers [5], "A technological innovation usually has at least some degree of benefit for its potential adopters".

What is evident from the reviewed literature is that, whilst there are common problems and challenges identified, there are very few empirical studies on the Scrum adoption challenges experienced by individuals. Most research focused on qualitative methods with emphasis on case studies [6]. A descriptive and explanatory case study done by Noruwana and Tanner [7] on Agile processes with emphasis on Scrum alludes that there is a knowledge base to unearth on adoption challenges.

To get an overview of adoption challenges faced by individuals within software organizations, it is necessary to get to the core of the challenges, i.e. what are the Scrum adoption challenges experienced in practice? Is there a relationship to be discovered with the adoption challenges and Scrum adoption outcomes? Will the knowledge and understanding point to a potential correlational or causal outcome?

Multiple theories, models and frameworks such as Diffusion of Innovation (DOI), Technology Acceptance Model (TAM), Perceived Characteristics of Innovations, and Theory of Planned Action, have been used to better understand the adoption and implementation of methodologies in software development [8].

We looked at the Scrum adoption challenges experienced through the lens of the DOI theoretical model. The DOI theoretical model was chosen instead of alternate theories because it was the only theory at the time to have been used both at the individual level and organizational level of IT adoption research, which meets the author's requirement. The custom model was divided into four constructs identified as individual factors, team factors, organization factors, and technology factors. The four constructs combine to form a holistic representation of the individual's belief, its relation to people, how they perceive management, and their perception of the methodology being used [6].

The aim of this paper is to propose a model which can be used to detect Scrum adoption challenges experienced by individuals within software organizations. The constructs of the custom model are an adaptation of the DOI theoretical model and the conceptual framework of the object-orientated technology (OT) study by Sultan and Chan [31]. The independent variables within the model's constructs are generated using the narrative review method. The proposed model will be used to differentiate adopters from non-adopters of the Scrum methodology, respectively.

Section II provides a brief background on Scrum as an Agile methodology, followed by the global and South African (SA) Scrum adoption challenges compiled from extant literature. Section III lists the constructs with a discussion of the variables with its hypothesized relationship to Scrum adoption and section IV explains the composition of the proposed SACDM. Section V concludes the paper.

II. Scrum Adoption Challenges

The Scrum Guide written by Schwaber and Sutherland [1] states the following about Scrum: "A framework within which people can address complex adaptive problems, while productively and creatively delivering products of the highest possible value. Scrum is:

- Lightweight
- Simple to understand
- Extremely difficult to master"

Scrum is a value-driven method (as opposed to a plan-driven method such as the waterfall method) which is iterative and incremental development [9]. The Scrum value-driven method continuously reassesses the problem while making small software feature increments in short time blocks within small teams [10]. Scrum is so flexible and abstract in its definition and implementation that it is often used outside of the Software Engineering (SE) practice [2].

Adoption challenges, in the context of this paper, refers to the challenges faced by software organizations when choosing and following an Agile methodology [11]. As mentioned in the introduction we used the narrative review method to generate the custom model's independent variables. Before we were able to generate the independent variables, we first had to identify the adoption challenges faced within the global and SA context. The Scrum and Agile adoption challenges were acquired through the narrative review method, which was as follows;

- Data sources was relatively recent i.e. all except one paper was less than ten years of age.
- It has been cited in other literature.
- If not cited, the source must have been published by an accredited publisher, e.g. Springer, Pearson, Institute of Electrical and Electronics Engineers (IEEE), International Journal of Environmental Science and Technology (IJEST), etc.
- If not published by an accredited publisher, the source must have been presented at a known institution, e.g. Agile Africa conference, Johannesburg Centre for Software Engineering (JCSE).
- Alternatively, the source is a recent dissertation or thesis paper.
- The primary search terms were 'Scrum', 'Scrum adoption', 'Scrum challenges', 'Agile challenges', 'Scrum South Africa', 'Agile South Africa' and 'Agile adoption'.
- The sources where carefully perused and relevant literature was ear marked for further investigation.
- These pre-selected literature sources were filtered based on the content it provided, i.e. Do the literature sources contain challenges and issues experienced during Scrum and Agile adoption? Or is the literature describing adoption challenges on irrelevant Software Development Methodologies (SDM)?
- Identified challenges within the literature was collated and the frequency of occurrence was recorded.

Table I is a consolidated list of global Scrum and Agile adoption challenges taken from twenty-one literature studies Stray et al. [12], [32], Asnawi et al. [13], Santos et al. [14], Fægri [15], Marchenko and Abrahamsson [16], Overhage et al. [17], Heikkila et al. [18], Kapitsaki and Christou [38],

Bjarnason and Regnell [39], Irrazabal et al. [40], Hoda et al. [41], [42], Dorairaj et al. [43], Senapathi et al. [44], Ressin et al. [45], [46], Santos and Goldman [47], Kim and Ryoo [48], Ihme [49], and Allisy-Roberts et al. [4], with publication years ranging from 2008 to 2017. Of the listed challenges, the one that is very peculiar comes from the mixed mode study by Heikkila et al. [18], which recorded that cross functional generalist teams were not plausible in the environment. This is contradictory to the Scrum philosophy of well-balanced redundant knowledge teams with the ability to work on various aspects of projects without the dependency of team member specialization.

TABLE I.
GLOBAL SCRUM AND AGILE ADOPTION CHALLENGES

No.	Global Scrum and Agile Adoption Challenges	Frequency
1	Lack of knowledge/training/skills	11
2	Organizational culture/mindset	9
3	Teamwork/communication issues	9
4	Lack of documentation	5
5	Budget and schedule constraint	2
6	Escalating commitment	2
7	Hard to scale	2
8	High management overhead	2
9	Lack of senior support	2
10	Work specialization	2
11	Cross functional generalist teams	1
12	Increase stress and workload	1
13	Lack of quality	1
14	Lack of top management support	1
15	Long time to market	1
16	Low user satisfaction	1
17	Over engineered solutions	1
18	Over optimistic task estimates	1
19	Project team size	1
20	Requirements creep	1
21	Retrospective inadequacy	1
22	Too many meetings	1

Top Management Support (TMS) has been found to significantly affect the user's perception of an IT technology, and the organizations IT adoption and diffusion, respectively [19], [20]. Therefore, the inclusion of lack of TMS is probably expected, considering the impact management support have on IT adoption [21]. It should be noted that although TMS is important for the adoption and diffusion of a methodology, it cannot save a project that is failing, and too much support might hinder the adoption and diffusion success [19].

Table II is a consolidated list of SA Scrum and Agile adoption challenges taken from six literature studies Mnkandla and Dwolatzky [22], Du Toit [23], Tanner and Khalane [11], Tanner and Mackinnon [24], Tanner and Wallace [31], and Noruwana and Tanner [7], with publication years ranging from 2004 to 2013. The rational for displaying the global and SA adoption challenges separately was to allow the authors to compare the two tables and identify if region had a role in challenges experienced. Most of the challenges within the SA literature was experienced globally, however, within the SA literature, organizational challenges were prevalent within the top challenges (by frequency), and while globally team challenges were more predominant.

It should be made clear that when referring to communication problems, it includes clients, and not just the individuals within the software organization. Especially in Scrum, clients are expected to be more collaborative, knowledgeable and representative, and committed towards the projects [26]. The importance of customer's active involvement in the development process is crucial to the success of Agile development [52]. The greater the involvement of customers during the development process the greater the chance of success [6].

Mohan and Ahlemann [27] says that the use of the Information Systems Development (ISD) process is determined by the rational and hierarchy of the organizational culture. Often the needs, beliefs and values of the users of the methodology are not considered, which is like the subjective norm situation, whereby the developer's views are not always the determinant to the Agile methodology adoption decision. As Hardgrave et al. [28] puts it; "Developer's intentions are directly influenced by their perceptions of usefulness, social pressure, compatibility and organizational mandate". Chan and Thong [26] indicates that prior SDM studies focused on the developer views of the SDM such as perceived ease of use and perceived usefulness, however, failing to realize the importance of management (e.g. management style) and people-related (e.g. competency levels) challenges.

TABLE II.
SA SCRUM AND AGILE ADOPTION CHALLENGES

No.	SA Scrum and Agile Adoption Challenges	Frequency
1	Lack of knowledge/training/skills	6
2	Organizational culture/mindset	5
3	Lack of structure/planning	5
4	Requirements creep/story changes	5
5	Communication issues	4
6	Motivational issues	4
7	Lack of resources (labor and non-labor resources)	3
8	Management inefficiencies	3
9	Workload	3
10	Team distribution	2
11	No/lack of individual recognition	1
12	Team size	1

Due to the nature of software development being a social phenomenon, and Agile being at the forefront of this complex human interaction activity [25], expectations that noise or disturbance by team members would have been identified as one of the challenges encountered, are aroused. However, surprisingly this is not the case, and the study by Eccles et al. [29] states, on the contrary, employees welcome it.

The next section discusses the independent variables and their hypothesized relationship with Scrum adoption, which forms part of the custom model's four constructs.

III. The Custom Model Constructs and Variables

The custom model was constructed with DOI being the theoretical base, but we tailored the model to match the context of the application, i.e. Scrum adoption challenges [31]. Not all DOI constructs were used in the study, the three that have been included, due to it being consistently relevant in innovation studies are compatibility, complexity, and relative advantage [28]. The custom model is discussed in section IV. Scrum Adoption Challenges Detection Model (SACDM).

The narrative review method produced the independent variables which were collated and coded, and subsequently used as the input to the model. These independent variables were assigned to either one of the four custom model factors, namely; individual, team, organization and technology. Therefore, the independent variables were tailored towards the specificity of the innovation [30], [31]. The nineteen independent variables affecting Scrum adoption are discussed in this section.

A. Individual Factors

The first set of variables found in the literature deals with the Scrum challenges experienced by individuals within the organization.

Escalation of Commitment: Escalation of Commitment in the software industry context, its defined as continuously assigning resources to projects that indicates signs of failure. Statistics of 30 to 40 percent of software projects that experiences escalation of commitment have been recorded [32]. We have included escalation of commitment to the individual factors construct because it has often been caused by individual developers within Scrum teams who persist with a task even though it is not adding value to the project. The sooner the Scrum team notices this problem (usually in daily stand-ups) the greater the chances of limiting resource wastage.

H1: Thus, it has been hypothesized that escalation of commitment negatively affects the adoption of Scrum within IT organizations.

Experience: While experience may be seen as being knowledgeable and skilled on an event or subject, it also refers to the project team member having mastery of multiple skills sets such as programming languages, management skills etc. The mastery of multiple skill sets is usually obtained by working on various tasks, projects, and teams over a period of time [26]. Experience has also been identified as a contributor to performance of programmers [33].

H2: Experience is therefore hypothesized to have a positive influence on individual willingness to adopt new innovations.

Over Engineering: Over engineering or over engineered solutions can be summarized as software that has more features and functionality added to it than what was required from the client. Reasons that could lead to software being over engineered are lack of communication with stakeholders, bad planning or limited domain knowledge by the Scrum team [14]. This variable has been included as an individual factor because the developers within the development team are responsible for completing the sprint backlog. The development team is included in the sprint planning meeting and if anything related to the backlog item is unclear to the developer during the sprint he or she may liaise with the Scrum team to clear any confusion. We therefore think that over engineering affects innovation adoption negatively.

H3: Over engineering is negatively related to adoption of Scrum. Over engineering will be lower for adopters.

B. Team Factors

The second set of variables is concerned with the individual's perception of team related challenges based on the literature.

Communication: Communication is the act of exchanging information from one individual or group to another using a common system of behavior [26].

H4: Lack of communication therefore have a negative impact on adoption. Communication will be higher for adopters.

Teamwork: Teamwork is the process whereby individuals work together as a team to complete tasks and achieve a common goal or objective [26]. However, teamwork challenges within Agile development methods is a reoccurring problem. Activities which have been documented as important to increase team as well as organizational performance, are, recognizing other's achievement, responding constructively to team member opinions, assisting and supporting others, and showing greater leniency towards team members [12].

H5: More teamwork amongst team members will affect Scrum adoption positively. Adopters will be in a team that show greater signs of teamwork than non-adopters.

Specialization: The term specialization is the process of an individual having a high degree of knowledge and skills within a domain of interest, improving the individual's

proficiency and expertise within his or her role. Agile software development teams prioritize the idea of self-organizing teams in which team members share overlapping skills which improves flexibility. The problem with work specialization is that it doesn't make provision for interchangeable roles [15].

H6: Specialization within a Scrum team negatively affects adoption. Specialization will be less for adopters.

Sprint Management: Sprint management is defined as a time boxed activity that monitors and manages the progress of a sprint. Events that prevents sprint cycles from operating optimally includes scope creep, lack of timeous feedback, lack of planning and lack of team cohesion [11], [24].

H7: The better the sprint management within the team the more likely there will be adoption. Adopters will have better sprint management.

Change Resistant: Resistance to change within the context of the work environment is a process in which the employee sees change as disruptive and intrusive [34]. With Agile process introduction, developers tend to display signs of cautious optimism, skepticism, and enthusiasm with the problem of some developers not welcoming the change, resisting it without much thought put into it [35].

H8: Teams that are reluctant to change their ways of doing things are more likely to be non-adopters. Adopters will have a lower degree of change resistance.

C. Organization Factors

The third set of variables deals with the individual's perception of organizational challenges encountered within literature.

Training: Training is the acquisition of skills and knowledge through teaching and learning which improves the competency areas of the individual or group. The training within this research study applies to employees going for training to achieve the goals and objectives of the organization they represent [26].

H9: It is hypothesized that staff training is higher in organizations that adopted Scrum. Lack of staff training is hypothesized to negatively affect adoption.

Recognition: Recognition from a business point of view, is seen as matching remuneration, rewards and benefits with the productivity levels of the workers [36]. The study by Noruwana and Tanner [7] identified that individuals were unhappy with the lack of recognition for their contributions within the team because the recognition was given on a team level which does not distinguish between team member productivity levels.

H10: Therefore, individual recognition is hypothesized to improve the likelihood of adoption. Recognition contributes positively towards adoption success.

Quality: The quality that is being referred to is that of software quality and how its correctness contributes toward software projects meeting the business requirements and user expectations. There have been many attempts to improve the quality of software project throughput, yet many software projects continue to fail [11].

H11: Higher degree of throughput quality is positively correlated to Scrum adoption.

Resources: Resources in the context of this study refers to any asset or service, whether it is staff, materials, money etc. that allows the organization to operate sufficiently in producing products and services requested by clients. An exploratory case study conducted by Noruwana and Tanner [7] on a SA company identified lack of labor resources ranging from Agile experience, skillsets, and team members having to perform more than their fair share of responsibilities.

H12: Supply of labor and non-labor resources are more for adopters than non-adopters. Lack of resources is hypothesized to have a negative impact on adoption.

Collaboration: Included in the Agile Manifesto is the statement "Customer collaboration over contract negotiation". What this suggests is that individuals, teams and organizations need to work closely together with clients to achieve a common goal instead of spending most of their effort on securing the deal. Research indicates that many organizations and customers within Agile environments do not abide by this principle. Some of the challenges faced by the lack of collaboration are Agile teams being overly committed, loss of business and productivity, products and user requirements not aligning, and poor feedback mechanisms [37].

H13: Adopters have more collaboration with their clients than non-adopters. Collaboration is positively correlated to adoption.

Management Support: Management support allow organizations to look at innovation adoption from a positive perspective, and this creates a conducive environment for innovativeness [26]. Two findings that are of interest for this study is firstly, management that penalizes employees for mistakes made does not encourage innovativeness, and secondly, management support has a direct effect on the adoption of innovation [31].

H14: Therefore, management support is hypothesized to be a crucial contributor to the adoption of Scrum. Management support will be higher for adopters.

Organizational Culture: Organizational culture which is so eloquently defined by E.H. Schein (1990) is quoted as saying "a pattern of basic assumptions invented, discovered or developed by a given group as it learns to cope with its problems of external adaptation and integration that has worked well enough to be considered valid and, therefore, is to be taught to new members as the correct way to perceive, think, and feel in relation to those problems" [26].

H15: A supportive company culture is positively related to Scrum adoption. Individuals who adopt Scrum will be in firms with a supportive organizational culture.

Organizational Structure: The organization structure is a system with defined activities which governs how individuals within roles, and procedures are coordinated to achieve the goals and objectives of the organization. Evidence from previous studies indicates that organizations that allow for an open and integrated environment with a less hierarchical structure improves the innovation adoption rates [31]. Whilst previous studies have broken up organizational structure into the three components of centralization, formalization and integration, the authors however kept it as a single variable for reasons of simplicity.

H16: Organizational structure contributes negatively towards Scrum adoption. Lack of structure is hypothesized to be higher in organizations who adopt Scrum.

D. Technology Factors

The fourth set of variables relates to the DOI theory and the individual's perception of the Scrum methodology as an innovation.

Relative Advantage: Relative advantage is measured (within the context of this study) as the degree to which Scrum has made a positive contribution to the existing conditions of the individual and organization [31].

H17: There is a linear relationship between perceived relative advantage and Scrum adoption. Adopters will perceive higher relative advantage in the methodology.

Complexity: Complexity is the degree of difficulty experienced by individuals and organizations when adopting Scrum as an innovation [31].

H18: There is a linear relationship between perceived complexity and the adoption of Scrum. Non-adopters will perceive a higher degree of complexity in Scrum than adopters.

Compatibility: The compatibility of Scrum against the existing values of the company and the individuals whom it employs provide an indication to the likelihood of individuals adopting or rejecting it [31].

H19: There is more compatibility with adopters of Scrum than companies and individuals that rejects it. The higher the compatibility the more likely there is the potential of adoption.

The following section is dedicated to proposing a practical application model to detect the presence of Scrum adoption challenges encountered by individuals within software organizations. The aforementioned hypotheses are tested with the use of this model.

IV. Scrum Adoption Challenges Detection Model (SACDM)

While DOI as a theoretical model covers both the individual and organizational aspects of IT adoption studies [31], it is not enough though for complex methodologies within Agile, such as Scrum.

According to Chau and Tam [30], diffusion variables are not sufficient enough as a predictor of complex organizational innovation adoption, as the independent and control variables it provides might be of limitation. Bayer and Melone [50] provides a few failures of DOI due to its limitations, two of the failures being the lack of theoretical justification for the five adopter categories without sufficient empirical support for the classifications used, and not taking the interactions between various social systems into account.

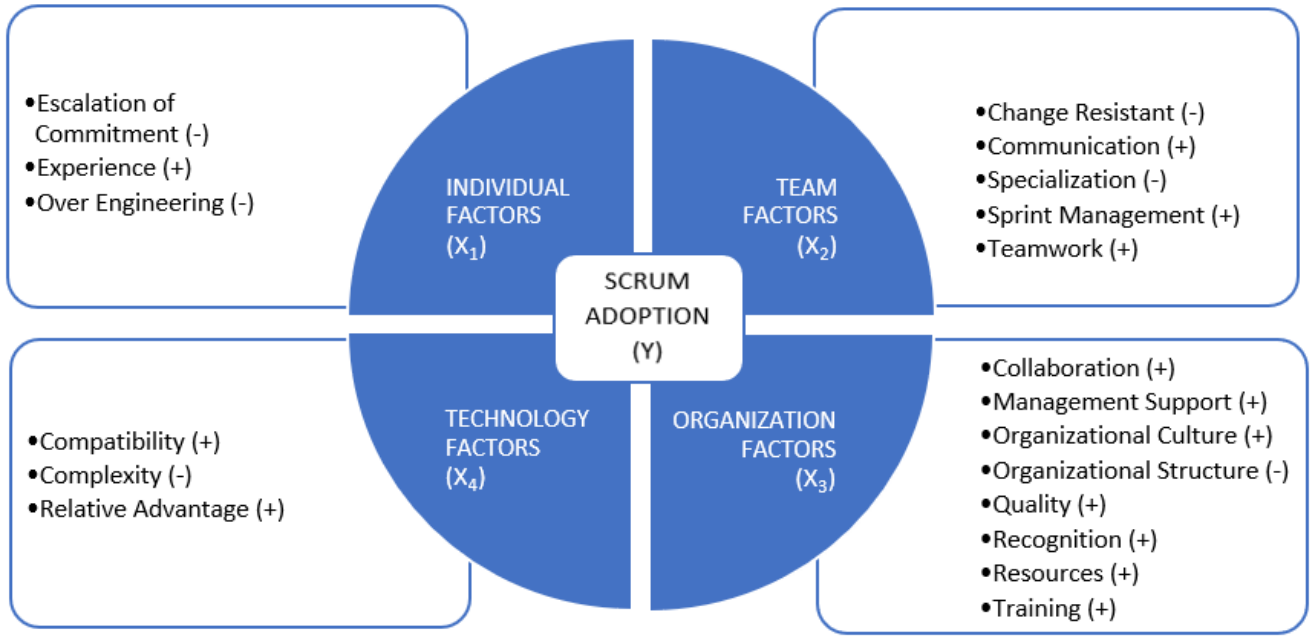
Because the Scrum methodology is a social phenomenon with strong emphasis on project management, it is important that we develop a model that include behavioral aspects to it, which unfortunately, haven't received much attention by previous IS adoption studies [51]. As Chan and Thong [26] so eloquently puts it, "There is an urgent need to conduct a critical review of the extant literature to develop a conceptual framework (CF) for Agile methodologies acceptance."

We used the idea of Senapathi et al. [44], who developed a CF based on a synthesis of past research in DOI, agile implementation, and IS implementation literature. Their five factor groups are agile innovation, organizational, sociological, team, and technological factors, which have been adopted from agile, XP, DOI, and IS frameworks and literature.

With a similar approach this study uses a CF which is a synthesis of research composed of theoretical models, DOI, Agile adoption, Scrum adoption, SDM adoption, and IS innovation literature.

As indicated in the introduction of this paper, a model will assist to detect Scrum adoption challenges within software organizations. The detection of the challenges can be generalized with the help of a quantitative survey research design. In future studies the model can contribute towards predictive analysis of Scrum adoption. The custom model is adapted from the study by Sultan and Chan [31], which looked at the adoption of OT in software companies. The authors propose a Scrum adoption challenges detection model, incorporating the DOI theoretical model, by extending the theoretical model to include constructs such as organizational factors, team factors and individual factors (SACDM) as displayed in Fig. 1.

Fig. 1 displays the custom model with the four constructs comprising of nineteen independent variables, and one dependent variable. The model for this research indicates the variables which are hypothesized to have an influence in adoption of a new methodology such as Scrum by individuals, and the proposed directionality of these relationships.



Independent variables are depicted as X_1, X_2, X_3 and X_4.

Dependent variable is Y with $Y = f(X_1.X_2.X_3.X_4)$.

When Y = 1, the individual within a software organization is an adopter of Scrum.

When Y = 0, the individual within a software organization is a non-adopter of Scrum.

Note: The hypothesized relationships are shown by the symbols in parenthesis.

Fig. 1. Scrum Adoption Challenges Detection Model.

The final list of independent variables is displayed below, in ascending order.

- Change Resistant
- Collaboration
- Communication
- Compatibility
- Complexity
- Escalation of Commitment
- Experience
- Management Support
- Organizational Culture
- Organizational Structure
- Over Engineering
- Quality
- Recognition
- Relative Advantage
- Resources
- Specialization
- Sprint Management
- Teamwork
- Training

This model will be used to differentiate adopters from non-adopters of Scrum, which is important to understand which constructs and variables significantly contributes towards the acceptance or rejection of Scrum. The dependent variable in this study (Y) is the adoption of Scrum. This will be related to the independent variables included in the four sets of variables shown in Fig. 1: (X_1) individual factors; (X_2) team factors; (X_3) organizational factors; and (X_4) technology factors.

This paper concludes by providing a summary of the SACDM and the potential advantages it may have for software organizations looking to improve on their project management operations.

V. Conclusion

Scrum is the most widely used SDM at present, providing many organizations with a simple to understand methodology to complete project management tasks. While the advantages to using this methodology are easily noticed by adopters, the challenges during the adoption stage are currently not quantitatively detected. Most research on the

adoption challenges primarily focused on qualitative measures for detection with case studies being the most implemented strategy. The inability to easily detect these adoption challenges can lead to teams and individuals within software organizations not using Scrum correctly or not adopting Scrum altogether, which could potentially limit the successful outcomes of a project.

It is proposed that a practically applied Scrum adoption challenges detection model such as SACDM, will aid in the awareness of the challenges faced by software organizations, and thus potentially limit the negative effects these adoption challenges might have on the individuals and organizations using Scrum. The extant Scrum adoption challenges were acquired through a narrative review of Scrum adoption challenges, both within the global and SA context. The SACDM was developed to detect Scrum adoption challenges with the objective of equipping adopters with the knowledge and awareness to overcome them.

Future research will aim to improve the SACDM, by designing an automated Scrum adoption challenges self-evaluation questionnaire. This questionnaire will allow the authors to gather and analyze the response data, which will be used to create a generalized result-set for the benefit of potential adopters to improve their awareness of Scrum adoption challenges and the correlation to Scrum adoption. The long-term vision of the SACDM is to allow individuals and organizations to predict Scrum adoption with the help of a research database and algorithms used to perform Scrum adoption predictive analysis.

***Abstract*—Requirements Engineering and Business Analysis are known as very important to software project outcome but also difficult activities, coping with many problems and challenges. The work reported in this paper was preceded by a survey which revealed most common requirements-related problems in Polish IT industry. We addressed ten most frequently reported problems by reviewing the literature for recommendations how to cope with those problems. The resulting set of recommendations is included in the paper. Next, we conducted interviews with three experienced IT analysts asking them to assess effectiveness of particular recommendations, based on their experience. The results show significant differences in assessments and indicate that effectiveness is dependent on contextual factors to a large extent. Our conclusion is that a follow-up work is required to document more recommendations and to annotate them with guidelines about applicability, intended context of use and possible pitfalls.**

I. Introduction

REQUIREMENTS are an essential element of virtually any software project. Regardless of which term is used to describe requirements-related activities – Requirements Engineering (RE) or a more recent, broader term of Business Analysis (BA) - delivery of an effective IT solution depends on identifying and managing business goals and stakeholders' needs. Negligence and flaws in RE/BA processes too often result in unpleasant consequences affecting the whole software project, including its failure and cancellation [1]–[3].

RE/BA is known as a difficult software project area [4]–[6] and as such is a subject of surveys aimed at identification of the most frequent and/or severe problems encountered by practitioners dealing with requirements e.g. [7]–[9]. Also, knowledge about such problems is disseminated by reporting experience [10]. To a large extent, RE/BA problems are therefore known and described in literature since a long time [11]. Yet, they are still present in industrial practice and recognized as causes of project failures even by very recent studies [3]. It raises a question what counter-measures exist to address such problems and how effective they are.

We intended to answer these questions in the context of IT industry in Poland. The first step was to identify relevant RE/BA problems to be addressed. Despite the fact that a number of surveys were conducted in several countries [7]–[9], it is hard to assume the results would be the same for e.g. different countries or different software development approaches – in fact differences are reported [9] and for that reason surveys on RE/BA problems are replicated in different settings [3].

In 2017 we conducted a survey among IT analysts from Poland to identify RE/BA problems which were most frequently encountered in their professional experience [12]. It provided us with a starting point to the research described in this paper, guided by the following research questions:

- RQ1: What recommendations are known to remedy most frequent requirements-related problems of Polish IT industry?
- RQ2: What is the effectiveness of applying such recommendations in practice?

To answer these questions, first we searched for recommendations by reviewing books on RE/BA and other sources reporting on industrial practice. For each of the top problems from the survey, we found several recommendations about how to deal with them and we documented them. Next, we interviewed 3 experienced analysts asking them to select recommendations they had applied in response to particular problems and to assess whether such recommendations turned out to be effective or not according to their experience.

The main contribution of this paper is the set of recommendations concerning 10 requirements-related problems, provided with assessments of their effectiveness from interviewed experts.

The remainder of the paper is structured as follows. In Section II we review the related work. Section III briefly describes the survey and its results, which provide input to the research study reported here. The study is presented in Sections IV-VI which cover: the search for recommendations and its results (IV), assessment of recommendations effectiveness through interviews with experts (V) and discussion of results and their validity (VI). The paper is concluded in Section VII.

II. RELATED WORK

In our study we address requirements-related problems by interviewing RE/BA experts. Interviews are dedicated to the assessment of the effectiveness of recommendations on how to mitigate these problems. Below we outline other works situated in the RE/BA domain, concerning recommendations to problems or good practices to be followed, identified on the basis of industrial experiences.

Several studies on addressing known RE/BA problems were reported. El Emam and Madhavji [13] interviewed practitioners, which resulted in identifying seven key issues of greatest concern in RE practice at the time and issuing recommendations for improving RE processes w.r.t. these issues. Bjarnason et al. [14] reported a case study of large software development company transitioning towards agile processes. Its employees were asked whether particular agile RE practices mitigate known problems of traditional RE and what new challenges those practices can introduce. De Oliveira Neto et al. [15] looked into the practices influencing both RE and system testing. They used knowledge gathered from interviews with practitioners to map the practices to the challenges encountered in large-scale agile development. Alsaqaf et al. [16] investigated to what extent and how are the non-functional requirements (NFR) included in agile large-scale distributed development projects. They interviewed practitioners to learn about existing practices as well as associated challenges with the ultimate goal to develop a set of good practices concerning NFRs in that kind of projects.

Recommendations and good practices can also be identified from experience of practitioners, without mapping them to the problems. Hickey and Davis [17] interviewed 9 well-known RE experts to determine which requirements elicitation techniques they would select in various situational characteristics of software projects. As a result, recommendations about the applicability of particular elicitation techniques were derived. Cao and Ramesh [18] focused on agile RE practices and used interviews, observations and documentation reviews to learn about implementations of 7 agile RE practices and associated benefits and challenges. Paul and Tan [19] conducted interviews with expert analysts to gather their opinions about the role of business analyst, his/her contribution to software project success and essential skills.

Our aim was to address particular problems identified in our survey conducted in Poland [12]. Problems, challenges and practices described in the abovementioned sources differed from our case, so no results could be used directly and a dedicated study had to be conducted.

TABLE I.
TOP REQUIREMENTS-RELATED PROBLEMS ACCORDING TO SURVEY RESULTS

ID	Problem	Description	Mean value
P1	Unrealistic expectations of stakeholders	A stakeholder has unrealistic expectations (e.g. large functionality to be delivered in a very short time or at low cost)	2,95
P2	"Obvious" requirements not communicated	Some requirements are so obvious to stakeholders that they do not even mention them	2,80
P3	Scope creep	Constant changes to project scope, modified or expanded requirements (scope creep)	2,80
P4	Too short time for analysis	Too short time for analysis is planned in project schedule	2,75
P5	Stakeholders' low availability	A stakeholder has little time available to commit to the project	2,73
P6	Solutions issued instead of requirements	Stakeholders describe solutions (e.g. detailed UI design) instead of requirements	2,62
P7	Requirements in the form of change requests only	Stakeholders are not able to express their requirements, they express them later as change requests to working software	2,56
P8	Conflicting requirements	Different stakeholders have mutually contradicting (conflicting) requirements	2,53
P9	Stakeholders ignore business goals	Stakeholders focus on requirements only, they do not define business goals or do not consider them important	2,49
P10	Requirements exceeding project scope	Stakeholders define requirements which are clearly outside project's scope established earlier	2,44

III. SURVEY AND ITS RESULTS

This section briefly describes the survey and the top problems reported by respondents, which provide input to further research presented in the next sections.

The survey took place in Spring of 2017. We prepared a web-based questionnaire (in Polish), published it and invited respondents through websites and social network groups for IT analysts. We received 55 answers. As only analysts were targeted, we included a question about respondent's experience in RE/BA. The distribution of answers was as follows:

- 3 (6%) – less than 1 year;
- 9 (16%) – over 1 but less than 2 years;
- 21 (38%) – over 2 but less than 5 years;

- 14 (25%) – over 5 but less than 10 years;
- 8 (15%) – over 10 years.

The questionnaire included 64 RE/BA problems gathered from the review of literature and the direct communication with a number of analysts [12]. For each problem, the survey respondent was supposed to assess how frequent such problem had been encountered in his/her work experience. The following answers were available: never (0); rarely (1); sometimes (2); often (3); always (4). The numbers in parentheses indicate numerical values that were used when processing and analyzing the survey results. We used them to calculate metrics, which represent frequency of occurrence of each problem and provide a basis for a ranking. Despite the fact that ordinal scale was used to represent answers, we calculate means values, not medians, as for a 5-point scale it is unlikely to spot differences comparing medians.

Table I gives a summary of survey results – 10 problems assessed as most frequent by survey respondents. For each problem, the table includes its artificial ID (to be used as reference in the remainder of the paper), short name of a problem, a longer description (used in the survey questionnaire) and the calculated mean value of answers, which is used as a metric representing frequency.

IV. RECOMMENDATIONS

The search for recommendations addressing the problems listed in Table I included books dedicated to RE: [20]–[23]. We consider them representative, as both internationally recognized items and positions limited to Polish readers are included. Most of them were published in recent years, except the book by Leffingwell and Widrig, which we included due to its influence (number of citations). Additionally, the training materials issued by RE/BA professional associations as well as the on-line courses were reviewed w.r.t. the potential solutions to the abovementioned problems.

Below, we present recommendations we were able to find, divided into sub-sections dedicated to particular problems. Descriptions of the recommendations were shortened and unified when multiple sources mentioned a similar way of dealing with a given problem. Recommendations are assigned the identifiers used in the remainder of the paper. The identifier Rx.y denotes a recommendation number y to a problem number x.

A. P1 - Unrealistic expectations of stakeholders

Two major sources of this problem can be identified and, thus, two groups of recommendations are distinguished.

Unrealistic expectations can stem from stakeholders' attitude to issue all requirements they can think of, even those unfounded by business needs or concerning very distant (and uncertain) future. In such case, expectations can be toned down by reducing the number and scope of requirements by the following actions:

- R1.1: Identify business goals as a reference point for requirements.
- R1.2: Identify what does the customer actually expects after the product is deployed (it may not be explicitly articulated without guiding questions).
- R1.3: Verify quality of issued requirements (rationale, unambiguity, feasibility) and do not proceed with requirements of low quality.
- R1.4: Conduct requirements analysis and verify how particular requirements support business goals.

Another possibility is that requirements are consistent with business needs, but their scope is not adjusted to the project constraints. The point of view of at least some of the customers can be to get as much as possible, as fast as possible and at minimal cost, which is a clear violation of the "iron triangle" [24] constraints and is not feasible in real-life projects. To mitigate such situation it is recommended to:

- R1.5: Precisely define product's scope agreed between the supplier and the customer.
- R1.6: Develop a realistic project schedule and manage it during the whole development process.
- R1.7: Estimate development costs (including all relevant categories) and monitor expenses to keep the project within its budget.
- R1.8: Continuously monitor requirements' statuses to be aware which ones are satisfied by the current version of the system under development.

B. P2 - "Obvious" requirements not communicated

Stakeholders can assume that some requirements are so obvious that they do not even have to mention them. Unfortunately, it leads to incomplete requirements. Especially non-functional requirements can be omitted this way. Missing requirements are harder to detect than e.g. conflicting ones and thus they can be identified late e.g. during acceptance tests. To prevent this:

- R2.1: Research the literature on the problem domain as well as the similar existing software systems (even before eliciting requirements from human stakeholders).
- R2.2: Make sure that all stakeholders and points of view relevant to the developed system are identified (using e.g. stakeholder map or onion model techniques).
- R2.3: Involve technical experts (on e.g. security, usability) into requirements elicitation and analysis processes.
- R2.4: Use appropriate requirements elicitation techniques, preferably a combination of several techniques including group work (e.g. workshops, focus groups).
- R2.5: When specifying requirements, use Software/ System Requirements Specification templates, which include the sections covering various categories of requirements, goals and constraints.

- R2.6: Apply requirements analysis techniques (e.g. checklists, CRUD tables) aimed at the identification of inconsistent, incomplete or missing requirements.

C. P3 - Scope creep

Requirement changes are to be expected in virtually any project, but continuous and uncontrolled changes will probably lead to scope creep. Such situation is considered harmful, especially when such changes are avoidable (e.g. result from communication flaws). Moreover, applying a change usually requires additional resources, but it is often not recognized by the customer. The following recommendations address the scope creep problem:

- R3.1: Include a "buffer" – some surplus when estimating project resources (budget and schedule) – it allows (to some extent) adjusting to changes. It is especially advised when no prior experience can be used as a reliable estimation base.
- R3.2: Define project scope from the beginning. This task must involve key stakeholders and result in defining, agreeing, confirming and documenting high-level requirements: business goals, product vision, product scope and main constraints. Requirements which are known but will not be implemented within the current project should also be documented and assigned appropriate statuses.
- R3.3: Change request issued by the customer should be processed by the change control process. Its first step is the impact assessment. Apart from analyzing influence on other requirements, it should include: verification of compliance to business goals and estimation of required resources.
- R3.4: Use requirements priorities assigned by customer representatives to distinguish essential and secondary requirements.
- R3.5: Include requirements sign-off activity in a project (i.e. the customer should confirm in writing that documented requirements are valid).
- R3.6: Approved scope changes should be immediately communicated to all stakeholders.
- R3.7: Approved scope changes should result in adjusting the project's budget and schedule.
- R3.8: Apply prototyping technique to prevent changes stemming from misunderstandings between stakeholders and developers (as mockups and other throw-away prototypes are relatively cheap to develop).
- R3.9: If impact analysis reveals change proposal to be harmful (e.g. impossible to implement within given constraints, not consistent with the business goals) – confront the customer with it.

D. P4 - Too short time for analysis

Reduced time available for analysis can be just a planning flaw, but often it is rather a result of the customer's pressure to produce software as soon as possible and reduce or skip all activities not directly resulting in code development. The customer can e.g. refuse to pay for RE/BA activities or insist on planning them very short and/or only at the very beginning of the project. It is very likely that such attitude would lead to misunderstandings, rework, delays, and increased costs, so it should be prevented by e.g.:

- R4.1: The most essential thing is to raise customer's awareness. The customer often has a limited knowledge about software project organization and does not understand the importance of the RE/BA activities. Information about benefits of well conducted RE/BA activities as well as risks caused by reducing them should be provided to the customer.
- R4.2: It is important to build an atmosphere of trust in customer-supplier cooperation. The customer should be convinced that activities and techniques used in RE/BA are selected because of their contribution to the project success and not in order to increase costs.
- R4.3: Negative examples can be used to convince the customer e.g. cases where invalid requirements led to significant rework effort and related costs.

E. P5 - Stakeholders' low availability

A stakeholder is likely to be busy with his/her everyday work duties and thus unable to contribute much time to the project e.g. to be interviewed by the analyst or to validate the specified requirements. Stakeholders are however indispensable for the acquisition of the domain knowledge as well as the elicitation and validation of the requirements. In order to win their commitment and to minimize their additional effort, the following practices can be considered:

- R5.1: At the beginning of the project present the customer with the RE/BA plan. The plan should define the activities and their phases as well as clearly indicate what kind of stakeholders' involvement is required and when.
- R5.2: When the representatives of key stakeholders are already identified, inform the customer's executives about the need to add tasks related to the participation in RE/BA to the representatives' responsibilities and schedules.
- R5.3: When the information from human stakeholder is to be obtained, a direct communication or video-conference is preferred, as other communication means would probably prolong this process. An analyst should however strive to minimize disruptions to the customer organization's processes and to the stakeholders' tasks by appropriate planning of the meetings.
- R5.4: Each meeting between an analyst and the stakeholder(s) should have clearly assigned participants and goal (when it is achieved, the meeting ends). Also the maximum duration of the meeting should be planned ahead.

- R5.5: Number of the meeting participants should be limited because otherwise the discussion is difficult to control (because of subgroups emerging, some participants getting frustrated with topics they do not comprehend or find not interesting to them etc.).

F. P6 - Solutions issued instead of requirements

RE/BA should be focused on identifying requirements which are then processed to design the best solutions (within given constraints) that fulfil them. It is however quite typical that what a stakeholder describes is neither a requirement nor a constraint, but a particular solution (which may not be optimal at all, considering the bigger picture). The following recommendations were identified to deal with such problem:

- R6.1: When information obtained from a stakeholder turns out to be a solution instead of a requirement, it should not be ignored as it is a valuable lead for further inquiry. An analyst should note it down, assign it to a separate category (other than requirements) and use in further interviews as a means to steer the discussion.
- R6.2: A particular solution described by a stakeholder may indicate that he/she already knows a similar software (perhaps a legacy or competitor system). An analyst should study such system and review its features with stakeholders, trying to derive requirements. Missing requirements can be identified as a side effect.
- R6.3: Stakeholders often prefer to discuss solutions because they perceive it as something more concrete and easier to comprehend. It is important for an analyst to have a sufficient knowledge about problem domain (acquired earlier) and use it when interviewing a stakeholder to generalize discussed concept and express it as a requirement.
- R6.4: A feasible way to discover an actual requirement behind a design solution is to ask „why" questions i.e. request a stakeholder to provide the rationale behind that particular solution he/she describes.
- R6.5: To derive a requirement from a design solution, an analyst has to paraphrase and generalize the input received from a stakeholder. Applying a combination of requirement elicitation techniques is beneficial, because more diversified information can be obtained this way and provide a better basis for derivation of requirements.

G. P7 - Requirements in the form of change requests only

Requirements elicitation is usually a difficult task as stakeholders can have problems with articulating their needs or even realizing them. It leads to a situation when stakeholders "don't know what they want, but know what they don't want when presented with it" and issue change requests to the published release of a developed system. To prevent it, the following practices can be considered:

- R7.1: When human stakeholders turn out to be uncooperative, requirements can be elicited (to some extent) from other sources through e.g. document analysis - reviewing organizational charts, procedures, existing process models, memos etc.
- R7.2: The main scope of the developed system's functionality and other essential features are probably included in the contract document, which can be used as a starting point for requirements elicitation.
- R7.3: If the system under development is to support existing or modified business processes in the customer organization, observation technique can be used to allow the analyst to gather the information firsthand by witnessing the work activities.
- R7.4: Existing IT systems used in the customer's organization can be a valuable source of requirements. Moreover, discussing obsolete, missing and suboptimal functions of the existing system with the stakeholders can be much more effective than just asking them about their needs.
- R7.5: After identifying initial requirements, an analyst should facilitate a workshop to present and discuss them with a group of stakeholders. Despite being rather generic and not validated, such requirements can constitute the basis for discussions. It is essential to present the requirements in a communicative way e.g. by using prototypes. A facilitated discussion during which the stakeholders can refer to the initial requirements can enable them to communicate requirements they were unable to articulate earlier.

H. P8 - Conflicting requirements

Requirements elicitation is followed by requirements analysis which is likely to uncover issues like ambiguous, incomplete and, last but not least, conflicting requirements. Conflicting requirements may be attributed to mistakes, but more likely they are the result of different points of view, needs and expectations of various stakeholders and, as such, should be properly managed:

- R8.1: It is worth to identify an authorized customer's representative, who would be capable of resolving conflicts in case stakeholders cannot do it themselves.
- R8.2: When conflicting requirements occur, the first step should be to verify their consistency with the business goals and project scope. The requirements that fail such a test can be revealed as unfounded and, as a result, the conflict may be solved.
- R8.3: An analyst needs to acquire domain knowledge to be able to determine the degree to which particular requirements contribute to the achievement of the business goals and to the project success. It can be used as a criterion to choose one option from the conflicting ones.
- R8.4: When conflicting requirements occur, this matter should be discussed at a meeting with all involved

stakeholders. The analyst should moderate the discussion and aim at explicitly presenting the trade-offs, suggesting ways of resolving conflicts and reaching the consensus.

- R8.5: Two or more conflicting requirements (concerning e.g. a function) can be replaced with a single one (more generic or more complex) that addresses the goals/rationales of each of them.
- R8.6: If substantial effort has been made and still stakeholders cannot (or are unwilling to) reach consensus, such issue can be delegated to a decisive entity e.g. a project sponsor or the senior management of the customer organization.

I. P9 - Stakeholders ignore business goals

Business goals defined by authorized customer representatives are the very reason behind customer's decision to acquire an IT system and start a software project. Also a primary indicator of the project success is whether the developed software allowed to achieve the business goals. If business goals are not precisely specified or even completely ignored, then there is no point of reference to determine which requirements contribute to the business benefits of the customer organization. It is thus advised that:

- R9.1: An analyst should consult key representatives of customer organization and insist on defining business goals before eliciting lower level requirements. Business goals (specified in precise and unambiguous way) should then be disseminated among all parties involved, both from supplier and customer sides.
- R9.2: Business goals should be maintained during the whole project schedule. If business goals change (due to e.g. market situation), all parties involved in software project should be notified and requirements need to be reviewed w.r.t. the new goals.
- R9.3: Even if substantial effort was made to identify business goals, it is possible that some goals were omitted. When dealing with a requirement that cannot be associated with any goal, a possibility that the set of goals is incomplete should be considered. It may lead to defining an additional goal.

J. P10 - Requirements exceeding project's scope

When project scope is agreed between the customer and the supplier, usually the associated project constraints (budget, schedule) are defined in accordance with the scope. A situation that stakeholders define requirements exceeding this scope is dangerous, because it will likely also result in project not meeting its constraints. It may however be caused by invalid scope assumed at the beginning of the project. To avoid the problem, the following actions can be taken:

- R10.1: It is important to ensure that the definition of the project scope involves several stakeholders, selected on the basis of their domain knowledge and authority. It should prevent invalid scope definition.
- R10.2: Change management process needs to be defined and followed. Such process should treat the cases of requirements exceeding the scope as changes to the project scope. Impact analysis should be conducted for such changes and include the analysis of the change's influence on schedule and budget.
- R10.3: The agreed project scope should be documented and formally approved by an authorized customer representatives. An analyst can refer to such a document when particular stakeholders insist on adding requirements which surpass that scope.

V. Interviews with experts

After collecting the recommendations, the next step was to assess their effectiveness. This assessment was supposed to be based on real-life experiences, not speculations. We decided to interview experts for this purpose. We selected 3 analysts whom we considered to be experts in RE/BA domain, with regard to their knowledge (confirmed by trainings completed and certificates obtained) and professional experience (work history including several companies and projects from various business domains). Their brief characteristics are given below:

- Expert A – 6 years of experience as an analyst (11 years in IT in total). Software projects from the following business domains: transportation, logistics, medical, financial. PhD in computer science, REQB FL certificate holder.
- Expert B – 8 years of experience as an analyst (10 years in IT in total). Software projects from the following business domains: public administration, telecommunications, transportation. IIBA CBAP certificate holder. Active participation in RE/BA professional association (local chapter board member).
- Expert C – 15 years of experience as an analyst. Software projects from the following business domains: insurance, public administration, government, electronics and telemetry. REQB FL certificate holder. Job history including middle- and high-level management positions and the role of coach in several commercial RE/BA courses.

Each expert's task was to review the presented recommendations and provide his/her feedback. For each problem, an expert had to answer the following questions:

- Have you encountered this problem in your work experience as an analyst?
- Which of the listed recommendations have you tried to address this problem?
- Which among the applied recommendations turned out to be effective?
- Which among the applied recommendations failed to mitigate the problem?

TABLE II.
ASSESSMENT RESULTS FOR RECOMMENDATIONS TO PROBLEMS P1-P5

Problem	Recommen-dation	A	B	C	Remarks
P1	R1.1	Y	U	Y	A: The recommendations proved effective but only when used altogether and not selectively e.g. the identification of the business goals only. B: The communication and education of the customer is the key (none of the recommendations would succeed if used without it). It is also useful to define the Minimum Viable Product and other versions with enhanced functionality, estimate the cost of each version. C: If possible, try to simplify the solution (e.g. scope of functionality) in a way not compromising the business goals.
	R1.2	Y	U	Y	
	R1.3	Y	U	X	
	R1.4	Y	U	U	
	R1.5	Y	U	Y	
	R1.6	Y	U	N	
	R1.7	U	U	N	
	R1.8	U	U	X	
P2	R2.1	U	Y	X	A: Interviews (unstructured, including apparently obvious matters) and workshops are the most effective elicitation techniques to address this problem. B: R2.1 is a reasonable recommendation in general, but an analyst should be aware that sometimes it may fail (a specific customer deviating from standard processes known in problem domain, an existing system which is poorly tailored to the needs). B: R2.5 requires good understanding of the template contents - if a template is used with an attitude to leave no section empty and there is no focus on quality of the content, then nothing good comes out of it. B: An additional way to address this problem is the prototyping which often reveals missing "obvious" requirements. C: It is the requirements validation rather than the requirements analysis (R2.4) that can reveal hidden requirements. C: Additional recommendations: 1. Requirements validation through a dedicated meeting; 2. Business process modelling with mapping between the processes and the requirements.
	R2.2	U	Y	Y	
	R2.3	Y	U	Y	
	R2.4	Y	Y	Y	
	R2.5	U	U	X	
	R2.6	U	Y	N	
P3	R3.1	U	U	N	A: Minimum Viable Product concept is also useful here. B: Presented recommendations are good ideas, but none of them guarantees the scope creep prevention e.g. a buffer (R3.1) may be insufficient, some customer representatives do not feel obliged by sign-off and reject earlier agreements etc. B: Other recommendations could be: 1. accept small changes (up to a specific effort estimation) and move bigger ones to future releases; 2. develop iteratively in time & material mode; 3. acquire knowledge about problem domain and customer organization (structure, processes) to get better understanding of the possible scope definitions and avoid surprises.
	R3.2	Y	U	Y	
	R3.3	Y	U	Y	
	R3.4	Y	U	X	
	R3.5	U	U	N	
	R3.6	U	U	X	
	R3.7	U	U	X	
	R3.8	U	U	Y	
	R3.9	U	U	Y	
P4	R4.1	U	U	Y	B: All 3 recommendations are good ideas but some customers still just say "no" and refuse to listen to any arguments B: Other ideas: 1. make project phases/activities non-negotiable, the project should be "sold" to the customer only as a whole; 2. develop iteratively and demonstrate the results (analysis will be divided into many smaller tasks spread over time and the customer will get partial result earlier); 3. try to negotiate stakeholders' commitment e.g. analysis will be shorter if a given stakeholder joins the development team for a week. C: It is crucial to develop the RE/BA plan (consistent with overall project plan and customer's expectations) which should specify who is to be involved from customer's side, in which activities and why such involvement is necessary.
	R4.2	Y	U	Y	
	R4.3	U	U	N	
P5	R5.1	N	U	Y	A: Stakeholders' tasks and expected input have to be precisely defined. B: Again, recommendations are worth trying, but if the low availability is not due to the lack of awareness but e.g. heavy workload then none of suggested actions will change that. B: Additional recommendations: 1. Escalation - ensure stakeholders' availability by talking to their superiors (executives, project sponsor etc.); 2. Include the specific clauses about maximum response time and minimal effort required from customer's side in the project contract.
	R5.2	U	U	X	
	R5.3	Y	U	Y	
	R5.4	Y	U	Y	
	R5.5	U	U	Y	

The summarized results of the assessments are presented in Tables II and III. Both tables have the same columns: problem ID; associated recommendations IDs; assessments by experts A, B and C; additional remarks made by experts.

The following symbols are used in the table to denote the assessment results:

- X – Recommendation was not used by an expert to mitigate a given problem;

- Y – (Yes), recommendation was used and proved effective;
- N – (No), recommendation was used and failed to mitigate the problem;
- U – (Uncertain), recommendation was used but it is not possible to determine its exact contribution to the problem-solving or the outcome of applying the recommendation differed from project to project;

In addition, the colors are used to distinguish the assessment results. Only expert A denied experiencing some of the enumerated problems (P7, P9 and P10), thus X values are used for all associated recommendations.

TABLE III.
ASSESSMENT RESULTS FOR RECOMMENDATIONS TO PROBLEMS P6-P10

Problem	Recommen-dation	A	B	C	Remarks
P6	R6.1	U	U	N	A: It is not recommended to review an existing system with a stakeholder, because it results in closing his/her mind to the options other than present in that system. B: Some people are stubborn and resistant to any reasoning. They will most likely insist on a particular solution even when presented with strong arguments against it. C: Education of stakeholders, so they know what a requirement is and how to express it - such issue should be brought to the main customer's representative.
	R6.2	N	U	Y	
	R6.3	U	U	Y	
	R6.4	U	U	N	
	R6.5	Y	U	N	
P7	R7.1	X	U	Y	B: R7.2 does not make much sense - if stakeholders cannot articulate their needs, how to determine the scope/features to be written in the contract? B: Alternative sources of requirements (documents, observation, existing systems) may not provide all the necessary information or be unavailable (e.g. no existing IT system used, new business processes not implemented yet and impossible to observe). B: Prototyping or incremental development can be effective as the cost of changes is lower. C: Additional recommendations: 1. Business process modelling with mapping between the processes and the requirements; 2. Specify the stakeholders' points of view.
	R7.2	X	N	N	
	R7.3	X	U	N	
	R7.4	X	U	Y	
	R7.5	X	Y	Y	
P8	R8.1	X	U	X	B: Relying on an authorized representative is a good idea, provided that such person is willing to take responsibility and make difficult decisions. B: Some stakeholders may insist on "their" requirements regardless of the consistency with the business goals. B: Additional recommendation: use multi-criteria assessment (including priority, difficulty, cost, conformance to standards etc.) and apply it to the conflicting requirements to choose the optimal one (w.r.t. those criteria).
	R8.2	X	U	Y	
	R8.3	X	U	N	
	R8.4	Y	Y	Y	
	R8.5	Y	U	X	
	R8.6	Y	U	Y	
P9	R9.1	X	U	Y	B: If stakeholders refuse to define the goals, no one can force them or do it on their behalf. B: Additional recommendations: 1. Educate the stakeholders about the importance of business goals and the risk of ignoring them; 2. Try to define business goals on the basis of elicited requirements and ask the stakeholders to validate them (but be aware of a risk that they will confirm the goals without actually considering them). C: Specify the stakeholders' points of view.
	R9.2	X	U	Y	
	R9.3	X	U	N	
P10	R10.1	X	U	N	B: Additional recommendation: A workshop during which the stakeholders associate their requirements to business goals/high-level requirements. C: Specify the stakeholders' points of view. Constantly monitor the scope.
	R10.2	X	Y	Y	
	R10.3	X	U	Y	

VI. DISCUSSION

A. Discussion of results

Recommendations found cover all the problems we intended to address and there was no single case that a given problem was not recognized by literature or without any suggestions how to cope with it. The list of recommendations we assembled is however far from being complete, as analysts we interviewed reported several additional remedies to these problems from their experience. Keeping in mind that it was a very small scale study (3 interviewees), we should expect more recommendations if a larger group of analysts were involved.

The recommendations differ according to their nature: some are just choices of a particular technique (for e.g. requirements elicitation), some are rather related to the processes and organizational issues (e.g. planning/ monitoring activities, participation of particular people), while other concern cooperation and relationships (e.g. educating stakeholders, atmosphere of trust). Quite often, multiple recommendations benefit from being used together.

Assessments of the recommendations' effectiveness collected from the interviews are inconclusive at best.

Knowing the complexity of the RE/BA processes (and the software development in general) as well as the differences between the organizations, projects and business domains, we did not expect the same answers from each interviewee. However, differences in their assessments are greater than expected - there are literally two cases in which all 3 experts made the same assessment. To some extent it can be attributed to differences in experts' perception/attitude. It is clearly seen that expert B avoided giving definite answers (very few Y or N, mostly U assessments). This person was however the most active in providing additional remarks about e.g. factors influencing recommendations' effectiveness or situations that they would not work. The remaining two experts were more willing to summarize their experiences in a yes/no answer.

We considered this interview study as an initial validation of the recommendations found. Results of the study clearly indicate that it is better to be careful with using recommendations, as the outcome can differ in various domains, projects and other settings. Thus, such a list as the one assembled by us has a limited use, as it is neither complete nor provides enough guidelines about the context a given recommendation should or should not be used. We see two possible improvements. The first is to extend the list with additional recommendations identified through the literature reviews, interviews, surveys etc. Such list can grow and become more difficult to use, but it seems necessary as apparently no problem (at least not those listed in Table I) can be mitigated by a single action with a 100% effectiveness. The second improvement is to annotate the recommendations with guidelines about their applicability, limitations, trade-offs etc. (perhaps in a similar way as for the design patterns).

Another issue worth addressing in future is to consider problems and recommendations in a wider context. RE/BA does not exist in isolation but is a part of an overall software development process and strongly influences e.g.: software architecture [25] or testing (also verification & validation in general) [26]. When developing and presenting recommendations, it would be worthwhile to take into account contextual factors and consequences to software project activities and artefacts other than just those directly related to RE/BA.

B. Discussion of validity

We are aware of several limitations of our study. The number of interviewees is the most important one, as small scale studies cannot be considered as very convincing. A larger group of experts would make results more valid.

Another issue is the competence and representativeness of the interviewees. Knowledge and experience were applied as criteria for interviewee selection. Moreover, the diversity of projects and business domains each of them worked for is an argument for their credibility. We did not analyze their representativeness among the general population of analysts though, which is a possible validity threat, especially if results were to be generalized as applicable worldwide.

The quality of input data should be considered. In this case, such input was the list of recommendations presented to interviewees. Although an effort was made to assemble it on the basis of multiple sources, it certainly was not exhaustive, but that was not necessary – interviewees were only supposed to assess each of the presented recommendations and optionally report others known to them.

A common validity threat to interview-based research is the honesty of interviewees. We mitigated this threat by arranging interviews with volunteers only and assuring that they would remain anonymous. Subjectivity is also an inevitable aspect of interviews – despite our instructions to give assessments on experience basis, no strict, quantitative criteria were defined and interviewees could differ in their judgements. For example, a recommendation which was successfully applied in many cases but proved unsuccessful once could be classified as effective (Y) by one expert and uncertain (U) by another.

Finally, researchers can be the source of validity threats too by their possible bias regarding e.g. conviction about the effectiveness of particular recommendations. We addressed the first issue by providing interviewees problems and recommendations in a written form, without any additional suggestions and by interpreting the outcome separately by 2 researchers and then comparing their opinions.

VII. CONCLUSION

In this paper we reported a research study aimed at identifying and assessing known recommendations that address top requirements-related problems in the IT industry in Poland. Answers to the research questions formulated in the introductory section were obtained through reviewing relevant sources (RQ1) and interviewing experienced analysts (RQ2). These answers were presented in Section IV – Recommendations (RQ1) and in Tables II-III (RQ2).

The insight gathered from the study can be briefly summarized as follows. There are many recommendations available and described in various sources. They can be considered accurate in general – there was not a case of our experts rejecting a recommendation unanimously as inapplicable or invalid (maybe with the exception of R7.2). Recommendations are, however, not the "silver bullets" that can be used in any context with a guarantee of success. Experience-based assessments made by a small number of experts proved to be very diverse, which, on the basis of the interviews, we attribute to the contextual differences (domain, customer and supplier profiles, project organization etc.). Such applicability context is not necessarily specified as part of the documented recommendations.

The possible future research include: identifying a larger set of recommendations (by e.g. literature reviews, surveys, interviews), specifying their applicability context and other constraints (if such issues are not provided together with a

recommendation itself, they can be established by surveying/ interviewing practitioners), and making additional assessments of recommendations' effectiveness (in a more specific context, by a larger group of experts). The possible outcome is a sort of "catalogue" of recommendations that practitioners could review and select recommendations to apply in their project as a response to encountered problems.

ACKNOWLEDGMENT

We are grateful to the interviewed experts for their participation and sharing their experiences.

Agile to Lean Software Development Transformation: a Systematic Literature Review

Filip Kišš and Bruno Rossi
Faculty of Informatics
Masaryk University, Brno, Czech Republic
Email: {390917,brossi}@mail.muni.cz

Abstract*—*Context: **Lean development has been often proposed as an adaptation to agile for scaling-up to larger contexts.** ***Goals:*** **we wanted to better understand the "agile-to-lean" transformation, in terms of: i) reported benefits, ii) challenges faced, iii) metrics used.** ***Method:*** **we performed a Systematic Literature Review (SLR) about "agile-to-lean" transformations.** ***Results:*** **reduced lead time, improved flow, continuous improvement, and improved defect fix rate were the main reported benefits. Adaptation to lean thinking, teaching the lean mindset, identification of the concept of waste, and scaling flexibility were the main challenges. Lead time was the most reported metric.**

I. Introduction

NOWADAYS, many software organizations use agile methodologies for their software development processes, finding benefits for process improvement [1]–[3]. Lean software development [4] has been used to optimize development processes, mainly due to the concept of waste reduction involved in the optimization of all activities producing inefficiencies [4]. This view is complementary to agile principles, more focused on all activities that create value for the customer.

The term lean software development originated from the work of Mary and Tom Poppendieck [4]. Lean software development can be characterized as a combination of lean manufacturing with the lean IT principles and their application into software development [5]. This approach is driven by a series of seven principles: eliminate waste, decide as late as possible, amplify learning, deliver as fast as possible, empower the team, build integrity in, and see the whole [4], [5].

Many authors suggest that lean thinking can be used as guiding principles to implement and adopt agile development practices [4]. Wang [1] has identified and analyzed various combinations of lean and agile as reported by previous research: lean principles can either be used to adapt existing agile practices or to scale-up the agile software development practices [1]. However, there is no universal type of "agile-lean" combination that can be used for every situation [1].

The goal of this paper is to identify benefits, challenges, and metrics used in *"agile-to-lean"* transformations. Identification of such factors can allow to better understand *"agile-to-lean"* transformations, providing more evidence about how such transformation is happening.

II. SLR

A Systematic Literature Review (SLR) is a process which summarizes, organizes, and documents previous research of a field in a systematic way [6]. To conduct the review on "agile-to-lean" transformations, we followed the SLR guidelines by Kitchenham and Charters [6].

A. Needs for an SLR

"Agile-to-lean" is a less explored research area compared to "waterfall-to-agile" (e.g., Middleton [7]). There are other SLRs performed on lean methodologies but they are focused either at the business level [8], or at the level of metrics used in lean / agile software projects within industry [9]. One literature review on the "agile-to-lean" transformation [10], focused on categorizing and comparing the transformations including 30 experience reports. Compared to the study by Wang et al. [10], our study is more focused on benefits, challenges and metrics.

B. Research questions

RQ1. *What are the **benefits** that have been reported after the adoption of lean principles in the context of an ongoing agile development process?*

RQ2. *What are the **challenges** that have been reported after the adoption of lean principles in the context of an ongoing agile development process?*

RQ3. *Which **metrics** have been used to measure the "agile-to-lean" transformation?*

C. Search strategy & study selection

We have collected research papers available online in three digital repositories: Web of Science (WoS), IEEExplore, ACM Digital Library (DL) (on 2017-06-10, Fig. 1). We used *"lean software development OR agile transformation OR lean transformation"* as search string, as we preferred to start with a more general query and filter out results later.

The first stage of search strategy (automated search in online databases) included only studies written in English. The EndNote reference manager software was used for excluding duplicates and narrowing down the initial search results from 1,787 to 856 research papers (Fig. 1). We have included journals and conference papers published since 2003, after the work of Mary and Tom Poppendieck [4].

In the second stage (filtering based on title and abstract), multiple search criteria have been applied such as the exclusion of papers that involved lean manufacturing or any other subject areas outside software engineering. A total of 131 papers have passed the second stage of the search strategy (Fig. 1).

Stage three (full-text filtering) was performed manually going through the remaining entries. 18 papers were included based on full text reading. Quality criteria (section II-D) were applied to find papers involving organizational transformation from agile to lean. After quality assessment, a total of 8 papers were included in the final SLR list (Fig. 1).

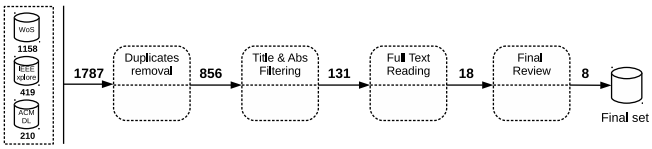

Fig. 1. SLR papers selection process

D. Study quality assessment criteria

After 18 papers were selected (Table I), we have conducted a quality assessment process to select the papers fitting the exact purpose of this research:

- C1. *Is the agile methodology at the initial state of the transformation?*
- C2. *Is the reported company making a transformation towards lean software development practices?*
- C3. *Does the paper provide metrics used for the transformation and states clear outcomes?*

Papers were given points from 0 (meaning *"no"*), 0.5 (*"partly"*) to 1 (*"yes"*). All papers reaching the score marked as ≥ 2.5 for $sum(C1, C2, C3)$ (Table I) were included for conducting the literature review (Table II).

TABLE I
QUALITY ASSESSMENT OF THE SELECTED PAPERS

SLR	Article	C1	C2	C3	Score
S1	Hayata et al. [11]	yes	no	no	1.0
S2	Jakobsen and Poppendieck [12]	yes	yes	yes	3.0

S18	Walter et al. [27]	yes	yes	partly	2.5

III. SLR RESULTS

A. Benefits (RQ1)

To answer our first research question (RQ1, Fig. 2), we have reviewed and categorized the reported benefits.

1) Reduced lead time: The most common benefit that has been reported is reduced lead time as it was found in six studies [2], [16], [17], [19], [23], [27]. Middleton and Joyce [2] describe lead time as the total time recorded from a customer request to the completed work delivery. Reducing

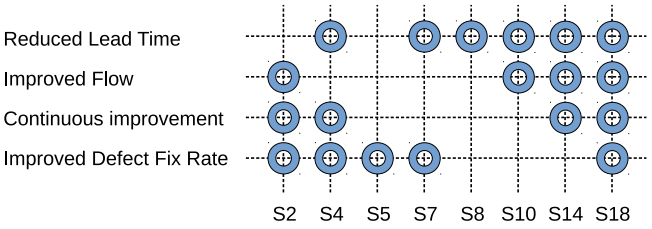

Fig. 2. Benefits mapped to papers. O = benefit reported in the paper

lead times contributes to flow improvement so that activities are organized continuously, enabling smooth deliveries to the customer. Middleton and Joyce [2] also state that they have experienced 47% less variance and on average 37% shorter lead time to deliver software, which is a significant improvement. Moreover, Walter et al. [27] have recorded an enhancement of approximately 70% which can dramatically increase the time-to-market responsiveness. Early feedback from the customer implies frequent integration, an important factor to improve the software product quality.

2) Improved flow: Improved flow was reported in four cases [12], [19], [23], [27]. Walter et al. [27] have discovered that the secret to improve the flow is to control Work-in-Progress (WiP) items. By reducing the number of simultaneous tasks they have reached lean flow state with constant throughput. Flow can be seen as the number of WiP items, so that lowering the number of such items can speed-up the whole process and more features can be implemented and eventually delivered. Therefore, to speed-up the flow, it is essential to remove waste in the inventory to avoid piling up user stories. Rodríguez et al. [19], Middleton and Joyce [2] state that limiting WiP is an important element for achieving flow. Limited WiP leads to more organized activities so that the improved flow can lead to smooth deliveries [19]. Additionally, continuous integration and test automation significantly supported the flow by frequent and smaller builds [19]. According to Swaminathan and Jain [23], tracking and acting on the visual indicators provided by the cumulative flow diagram helped to maintain a uniform flow. Moreover, it also helped to identify and remove bottlenecks and improve the efficiency of the process. This increase in efficiency also enforced rapid development and continuous improvement to software delivery [23]. Jakobsen and Poppendieck [12] have improved the flow of story implementation from 30% to 60%. The flow was improved in various areas such as test, development, project start-up and customer activities related to contracting and ongoing clarifications, major benefits for the company.

3) Continuous improvement: Four studies [2], [12], [23], [27] experienced continuous improvement as a benefit of their transformation. In Swaminathan and Jain [23], the story rate per iteration was used as a metric to measure continuous improvement, which was proved by the evidence of cumulating story points. On the other hand, the basis for the continuous improvement in Walter et al. [27] was established by letting each team self-organize and set their own WiP size.

Continuous improvement carried out on a daily basis showed a significant increase in the software delivery pre-

dictability [2]. Moreover, data collected over a twelve months period showed significant improvement as the time taken to resolve issues was reduced by 81%.

4) Improved defect fix rate: Adopting lean principles to an ongoing agile process has reflected in improved defect fix rate in five papers [2], [12], [14], [16], [27]. Lean promotes finding and fixing defects early, so there is a better and control over quality from the beginning. Therefore, continuous integration tools are often widely used in lean software development paradigm. Middleton and Joyce [2] not only managed to fix issues in a shorter period, but also experienced a lower amount of bugs. As the bug rate decreased, the team had reportedly more time for completing customer stories. Better product quality was reported by Misaghi and Bosnic [14] with the reduction of time spent on bug fixing. Similar to the study by Middleton and Joyce [2], fewer errors were released because of the higher amount of time for new features and improvements [14]. Another success story of enhanced software quality has been achieved with 50% bug reduction as reported by Walter et al. [27]. Two experimental groups for measuring defect rate had been observed during the experiment by Perera and Fernando [16]. One group adopted the combination of lean and agile, the other one just pure agile methodology. The pure agile group experienced a lower amount of defects at the beginning. However, this situation swapped at later stages and the lean-agile sample had a minimal defects rate [16]. A higher number of defects for the agile group was probably due to unfixed hidden defects at the early stages.

B. Challenges (RQ2)

In general, it was difficult to extract information about the challenges from the papers (RQ2, Fig. 3), as controversial/negative aspects might be omitted from papers.

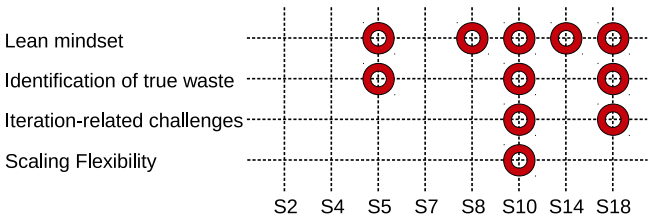

Fig. 3. Challenges mapped to papers. O = metric reported in the paper

An ”agile-to-lean” transformation brings a series of challenges. Maintaining process visibility, managing sustainability, and communication among teams are seen often as key challenges [5]. The improvement of the testing process is also reported as a key challenge, as the driving principle is perfectionism and identification of root-causes for software defects [5]. As such, placing lean on top of agile brings even more importance to the testing process. Acquiring the proper mindset can be seen as a challenge in lean adoption [14], [20], as lean requires a different mindset compared to the application of pure agile practices. Another challenge of ”agile-to-lean” is to integrate the concepts of waste minimization and quality improvements that are part of the lean philosophy, bringing to a more complete development and management process [16]. Lean on top of agile brings more the focus on the end-to-end value flow of the whole development process, thus putting lots of emphasis on different tools and their support, like value stream mapping or Kanban [17]. Constant management of flow is also a relevant issue [27], together with building a lean mindset towards defects reduction [23]. Scaling flexibility, business management involvement and waste reduction were found as challenges, with scaling flexibility problematic due to the management of the whole value streaming, making flexibility more difficult to reach [19].

1) Adapting to the Lean Mindset: In general, resistance to change is a common problem when trying to adopt new ways of working. This was the case in the reviewed studies [14], [17], [19], [23], [27]. Therefore, getting the commitment to this new paradigm is required from the longtime perspective as it is a continuous process that needs to be enforced. Misaghi and Bosnic [14] state that defining the criteria to implement the *”lean mindset”* into the organization is a main challenge. On the other hand, even though there are some tough challenges at the beginning to get the team to think end-to-end and work in a new way, once the team starts to see the added value, such way becomes naturally accepted within the team [23].

2) Identification of ”true waste”: Waste reduction is the key principle to maintain when working with a lean mindset. Rodríguez et al. [19], Walter et al. [27] found that it can be hard to identify *”what a true waste is”* within the organization and it may be even more challenging to eliminate such waste. Although setting-up teams and establishing self-organization within teams have not been hard to achieve, scaling flexibility and involvement of business management tasks were much more challenging in the lean way of working [14]. Aspects like people multitasking, which may seem at first appropriate to be more efficient, can also be seen as a waste as they might be the major cause slowing down productivity [14].

3) Iteration-related challenges: Studies have faced challenges also with coaching, estimates, pair programming, all during the run of development iterations [27]. In Walter et al. [27], team coaches had difficulties to ensure that tasks were delivered on time and with quality. For this reason, the coaching process adopted some more visible indicators (physical flags). Formation of pair programming couples and iteration estimations were adapted to the needs of the process [27]. In Rodríguez et al. [19], teams complained about too long feedback loops, caused by the involvement of business management in the whole value stream mapping process.

4) Scaling Flexibility: Scaling flexibility was defined as the easiness of performing changes during the software development process and was found as one of the key challenges in Rodríguez et al. [19]. The issue in "agile-to-lean" is that flexibility needs to pass through the whole value stream, making the process more complex than in pure agile contexts [19].

C. Metrics (RQ3)

To answer our third research question (RQ3, Fig. 4), we have reviewed and categorized findings of metrics that have been used to measure the lean transformation.

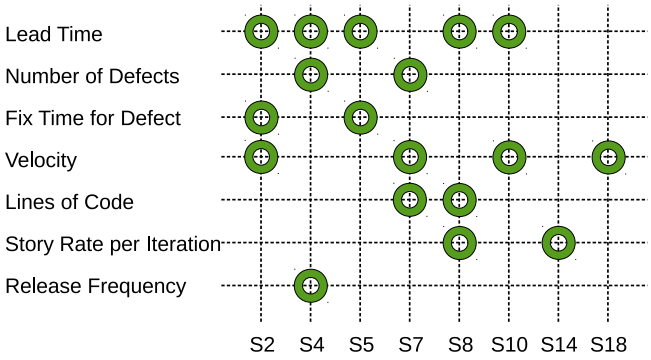

Fig. 4. Metrics mapped to papers. O = metric reported in the paper

1) Lead time: Five studies [2], [12], [14], [17], [19] have used lead time as one of the metrics to measure the progress of their organizational transformation. As we have described earlier (Section III-A about the benefits), lead time represents the duration from the customer request until the time the product is shipped to the customer. Lead time is usually measured in working days and it is stopped when user acceptance testing is complete and the product is ready for release [2]. Petersen and Wohlin [17] achieved higher responsiveness to customer needs by means of reduced lead time, managing to decrease time for delivery. Petersen and Wohlin [17] claim that this metric is highly important as the customer often needs frequent changes. The ability to respond to these changes quickly is a powerful competitive advantage. Along with this metric, Middleton and Joyce [2] reported using also cycle time, that can be considered as a sub-value of lead time. Cycle time is the time from actual initiation of the feature development (start of the working on the item) until the work on the feature is completed.

2) Number of defects: The number of defects per given time period was used as a metric in two studies [2], [16]. The main focus of Perera and Fernando [16] was on minimizing the number of defects. However, this study points out that higher number of defects at the early stages is expected, as described in section III-A4. Therefore, number of defects need to be measured with a long time perspective in mind. Middleton and Joyce [2] were measuring the number of defects per week for a twelve-month time period. The mean numbers of bugs open each week of their issue tracking system declined [2].

3) Fix time for defect: Similarly to the previous metric, two other studies [12], [14] examined defects from the fixing time perspective. Misaghi and Bosnic [14] have observed that, as the time spent on developing new features increased, the time spent on bug fixing decreased. The overall quality of the product improved as the releases contained fewer defects [14]. Measurements have been observed for the period of one year, that shows the positive long-term effect of lean.

4) Velocity: We have found this metric in four studies [12], [16], [19], [27]. Velocity can be measured by dividing the expected time of task completion by the actual time the task has been closed. Walter et al. [27] have improved their velocity by categorizing the time estimates using different sizes (extra-small, small, medium, big, extra-big). The number of hours was estimated based on their historical values and added to each category [27]. In Jakobsen and Poppendieck [12], velocity was measured as a sub-flow for story implementation, ensuring that the stories were developed in a smooth flow, eliminating the waste associated with context shifts and handovers. To verify whether the project is achieving the goals related to its schedule, expected work and actual work levels were also used by Perera and Fernando [16]. However, this time the metric was slightly modified by dividing the divergence between actual and expected work level with the expected work level [16].

5) Lines of code: Two studies [16], [17] have been measuring lean performance by evaluating the number of Lines of Code (LoC) developed. The outcome of the study by Perera and Fernando [16] was that the hybrid lean-agile approach produced more LoCs. Perera and Fernando [16] evaluated this metric from various perspectives such as new LoCs, removed LoCs and changed LoCs. On the other hand, Petersen and Wohlin [17] used this metric in a slightly different way, by measuring value efficiency: the difference between the value of output and value of input within a given time-frame [17].

6) Story rate per iteration: Customer requirements are captured in the form of user stories, which are afterwards estimated and prioritized [28]. For visualizing the long-term effect with this metric, data have been displayed mostly in story flow diagrams and cumulative story flow diagrams to measure continuous improvement from the longtime perspective, which also helped to identify the piling up of inventory [23]. Depending on the time dedicated to development, each story was given a story point value discussed and sorted out by the developers of the team. Usually, developers were estimating the story size as small and even, to better structure

their work. Swaminathan and Jain [23] measured story rate per iteration as the total number of story points approved and closed by the customer in the given iteration. The flow of requirements through the software development life-cycles was the key topic also in Petersen and Wohlin [17]. However, this study was measuring hand-overs within the stories as well as the variance, to better predict the development cycle [17].

7) Release frequency: The only study which used the number of releases was Middleton and Joyce [2], defining it as the number of items released to customers. Time-frame for measuring the frequency of releases was set to one month. Even though this metric does not reveal how much value is being delivered to the customers, it showed an eight-fold increase in releases for a two years period [2]. This is indicating an improvement in configuration management discipline and capability [2], as the more frequent releases are reducing technical and market risks, as the customer can evaluate a real product in smaller increments rather than just seeing temporary results from progress reports.

IV. Conclusion

The goal of this paper was to better understand the "agile-to-lean" transformation process regarding benefits, challenges, and metrics that primary studies reported in transformations within companies. To reach the goal, we conducted a Systematic Literature Review (SLR) [6]. The most represented benefits were reduced lead time, improved flow, continuous improvement and improved defect fix rate. Seeking the challenges faced, the common problems were the adaptation to the lean mindset, teaching and maintaining the "lean mindset", maintaining development flexibility, and the identification of the concept of waste. The most used metric to measure a lean transformation was lead time.

***Abstract*— The aim of the paper is to identify the problems and solutions of the software design in Scrum project as well as to analyze the effectiveness of the solutions. Through a series of workshops with 4 experts from IT industry and academia we have identified 52 problems and 99 unique solutions. In this paper we present a list of 10 common problems and 5 solutions for each problem selected by the number of sources. The effectiveness of the solutions to the given problems was evaluated in an opinion survey by 39 respondents with experience both in software design and in the Scrum framework. This evaluation provided for our initial recommendations on the choice of solutions to particular problems.**

I. Introduction

Software design is one of the key elements of software engineering [1], [2]. Systematic approach to architecture, code structure, data processing, and other aspects is required for many types of systems based on their size, complexity, distribution, and quality factors e.g. safety, security [3], [4]. Development practices such as pair programming, continuous integration, test driven development [5], [6], design patterns, refactoring [7] or clean code principles [6], [8] provide solutions to many problems, but their application in practice is challenged by the development methodology, technology, team, customer and many more.

Scrum defines only the roles, artifacts and events of the development process on a general level and leaves the room for specific decisions and actions to the Scrum Team [9]. This includes the design, programming and testing of software, where the Scrum Team should be multifunctional to cover all the competencies necessary to deliver the product [10] and include the role of a software architect if necessary [11]. Additionally, Scrum promotes working product increment after each sprint leaving little time for detailed approach to architecture and design [6], [10]. It is recommended to design as little and as late as possible to avoid negating the design by changing requirements [12], [13], [14]. This approach results in increasing technical debt which is related to the low quality of design and code [12]. It is also not possible to apply in case of complex systems and scaled Scrum [15].

Some of the recent research studied the relationship between the architecture-centric design and the agile development, but the authors focused either on the eXtreme Programming framework [16] or the agile projects in general [17]. This shows that the integration of the software design principles and the Scrum framework is not straightforward and calls for a detailed inquiry.

Our research goal was to analyze the problems and solutions of software design in Scrum projects. To achieve this goal, 3 research questions were formulated: (RQ1) What are the problems with software design in the Scrum projects? (RQ2) What are the solutions to the software design problems in the Scrum projects? (RQ3) Which solutions to the problems with software design can be recommended to the Scrum projects?

The contribution of this paper is the identification of the problems and solutions of software design in Scrum projects as well as some initial recommendations of the effective solutions to the most common problems.

The paper is organized as follows. Section II describes the research method, the workshops with experts and the online survey. Section III presents the list of the top problems and their solutions as well as the evaluation of these solutions together with some recommendations. Section IV discusses threats to the validity of this research followed by the conclusions in Section V.

II. Research Method

Our research method comprised two techniques: the workshops with experts to identify the problems and their solutions, and the online survey to evaluate the perceived effectiveness of the solutions to particular problems.

The workshop was designed as a structured multi-phase brainstorming session with the following steps:

1. introduction to the workshop, explanation of the goals and the scope,
2. individual identification of problems,

This work was supported by DS Funds of ETI Faculty, Gdansk University of Technology.

3. discussion of the problems identified in step 2, aggregation of duplicate problems,
4. individual identification of the solutions to the problems resulting from step 3 (a solution may solve more than one problem),
5. discussion of the solutions identified in step 4, aggregation of duplicate solutions.

The workshop involved a domain expert and one of the researchers (K. Kajdy) as a moderator. The scope focused on the specific aspects of the Scrum agile framework: development in short iterations, changing requirements, self-organized teams, and little documentation. Additionally, the aspects of software design were restricted to the following: component integration, architecture, design patterns, NoSQL or relational databases, user interfaces, modularization, and refactoring.

We have carried out workshops with 4 experts with at least 2 years of experience in both software design and the Scrum framework. The experts played the roles of developers and/or Scrum Masters. Each workshop resulted in a distinct list of problems and solutions to these problems. Finally, a compiled list of problems and their solutions was built from the results of all 4 workshops. The merging was based on keyword analysis.

We have selected 10 problems and 5 solutions to each of these problems for the evaluation survey (50 solutions in total) to limit the size of the survey and increase the rate of feedback. The problems and solutions were selected primarily based on the total number of indications in the source workshops.

The effectiveness of each solution in relation to a given problem was assessed in a Likert-type 5 level scale of 1 to 5, where 1 meant "a solution is totally ineffective to the problem" and 5 meant "a solution is very effective to the problem" with an escape answer "I don't know". We have also asked about the respondents' experience in software design and in the Scrum framework. Although Likert-type scale is ordinal, in the data analysis we have treated it as numerical with assigned values of 1 to 5. The evaluation of each solution's effectiveness was calculated as a weighted average, where weights represented the respondents' experience: 0.1 – under 1 year; 0.3 – 1-2 years; 0.6 – 2-3 years; 0.85 – 3-5 years; 1 – above 5 years.

III. Results

The identification workshops were carried out in May and June 2017. On average, the experts identified 25.75 problems, 31 unique solutions and 75.75 total solutions per workshop. In total, they have identified 52 problems, 99 unique solutions and 231 total solutions to all problems. The detailed results of the workshops as well as the full list of merged problems and solutions are available in [18].

The evaluation survey was carried out in August and September 2017 with Google Forms. It was promoted among the IT practitioners via e-mail and social media. In total, 39 respondents took part in the survey. 22 respondents (56%) had at least 2 years of experience with software design and 20 respondents (51%) had at least 2 years of experience with Scrum.

Table I and Table II present the identified problems and their evaluated solutions. The columns are as follows: identifier, problem/solution name, evaluation with a weighted average and weighted standard deviation in parentheses, survey sample size (N), and number of indications in the workshops (n). The problems are ordered by the number of indications (n) and the solutions for each problem are ordered by their evaluation (avg.).

Most of the top evaluated solutions reached a score close to 4 or more than 4. Problem P2 is the exception with a top evaluated solution of 3.49. This indicates the need for further research on its better solutions. Problems P3, P4, P5, P7, P8, and P10 can be assigned a clear leading solution with top score of more than 4. Additionally, more than one solution for problems P7 and P8 have reached the score of 4. The top scoring solutions for problems P1, P6, and P9 have an evaluation of slightly below 4, but the top solutions are still significantly ahead of the rest except for the problem P6, where 4 top solutions are enclosed within the range of 0.1.

As for the lowest scoring solutions, it can be observed that the solutions S1 and S36 are evaluated as least effective for all problems they were assigned to (S1 to problems P1, P7, P9, and P10; S36 to problems P5 and P6) with sample size of more than 30. They were, however the top solutions in the identification phase resulting from 4 and 3 sources respectively. The experts' belief in their effectiveness has been significantly challenged by the survey. It may indicate that these solutions strongly depend on factors specific to business environments (e.g. personnel, culture, type of products), which can be further studied in future research.

It should be noted that some of the solutions can be hard to apply in a strictly agile environment. Formal review of projects (S4) can go beyond the visibility and transparency principles of Scrum and Agile Manifesto leading to an overly monitored and manually managed team. Task estimation and accounting recommendations such as S25 or S31 can also hamper the customer-developer trust Agile is based on. S34 refers to the role of a project manager, which is outside of the Scrum framework and calls for a project management methodology on top of Scrum. This can be considered a non-agile practice.

Some solutions are also technology or architecture dependent e.g. NoSQL databases (S24), API versioning (S52) or microservices (S61), which also limits their application. It may not be beneficial or possible at all to implement such solutions in particular systems.

The proposed list of problems and their evaluated solutions has mostly educational use by Scrum developers, Scrum Masters and coaches. The application of a solution in a particular project shall always be discussed and accepted within the Scrum Team.

TABLE I.
PROBLEMS P1-P5 AND THEIR EVALUATED SOLUTIONS

Id	Name	Avg.	N	n
P1	**Team work assessed mainly with of code increments and new functionalities**			**8**
S3	Promoting quality and designing in the organization and to the client	3.88 (1.35)	34	2
S2	Avoiding creating fast and large increments at the expense of design and quality of code	3.53 (1.34)	36	2
S4	Formal review of projects	3.20 (1.39)	32	2
S5	An organization's policy that only part of the time is devoted to working with the code	3.18 (1.10)	34	2
S1	Professional Scrum Master teaching team communication and promoting issues of architecture and design at the meetings	3.12 (1.38)	33	4
P2	**Problems with expanding and modifying the production database in the client's environment**			**6**
S17	Automation of creating data models from code	3.49 (1.45)	32	1
S24	NoSQL databases	3.05 (1.49)	18	1
S21	Designing the database changes one sprint earlier or at the very beginning of the sprint	2.96 (1.19)	31	1
S20	Small database design at the beginning (the less data collected, the less data to update)	2.78 (1.48)	30	1
S16	Making modifications to the database once every few sprints	2.61 (1.22)	30	3
P3	**Recognizing refactoring as an increment by the client, despite the client's resistance**			**5**
S28	Doing refactoring partially in each sprint, not all in one sprint	4.04 (1.21)	38	1
S29	Using the refactoring automation tools	3.87 (1.02)	29	1
S25	Including the refactoring costs in the price of an expensive task	3.77 (1.08)	33	5
S27	Educating the client and obtaining approval for corrective and maintenance actions	3.50 (1.12)	36	2
S26	Introduction of stabilization sprints for code maintenance	3.36 (1.30)	33	2
P4	**Improperly defined tasks that hamper planning and design**			**5**
S30	Grooming before planning - examining and presenting details of a given User Story	4.09 (0.77)	33	3
S31	Overestimating tasks to leave time for "unpredictable"	3.89 (1.06)	36	1
S32	A business analyst present on the planning and available to the team	3.73 (1.09)	33	1
S34	Project Manager that accurately defines the tasks	3.71 (1.01)	36	1
S35	Behavior Driven Development - Gherkin language	3.07 (1.10)	17	1
P5	**Difficulties with introducing new functionalities due to architectural errors**			**5**
S42	Separation of views, data and business logic	4.50 (0.64)	35	1
S38	Applying the initial conceptual and design phase before the actual implementation	3.97 (0.88)	36	2
S39	A team using design patterns, standards, diagrams	3.90 (1.01)	33	2
S37	Making the client aware of the time needed for the design and that it will pay back	3.82 (1.18)	35	2
S36	Preparation of prototypes and preliminary design in "sprint 0"	3.33 (1.14)	35	3

TABLE II.
PROBLEMS P6-P10 AND THEIR EVALUATED SOLUTIONS

Id	Name	Avg.	N	n
P6	**Problems resulting from the selection of project technology in advance, before the implementation**			**3**
S38	Applying the initial conceptual and design phase before the actual implementation	3.98 (0.95)	35	2
S48	Careful selection of technologies - proven technologies for large projects, experiments with fast Proof of Concepts	3.94 (1.08)	36	1
S44	Checking the technologies available on the market as part of the task of the increment	3.91 (1.02)	34	2
S37	Making the client aware of the time needed for the design and that it will be pay back	3.88 (0.98)	35	2
S36	Preparation of prototypes and preliminary design in "sprint 0"	3.30 (1.07)	36	3
P7	**Problems with developing a uniform communication interfaces between modules**			**3**
S52	API versioning	4.37 (0.76)	32	1
S39	A team using design patterns, standards, diagrams	4.10 (0.95)	31	2
S3	Promoting quality and designing in the organization and to the client	3.90 (0.90)	32	2
S51	The design created 1 sprint earlier or at the very beginning of the sprint	3.37 (1.15)	33	1
S1	Professional Scrum Master teaching team communication and promoting issues of architecture and design at the meetings	2.90 (1.18)	31	4
P8	**Problems with technological debt and poor quality due to rush in implementation**			**3**
S54	Applying SOLID practices and adhering to the rules of clean code	4.37 (0.77)	33	1
S56	Multiphase code reviews	4.15 (0.89)	35	1
S28	Doing refactoring partially in each sprint, not all in one sprint	4.04 (1.18)	37	1
S27	Educating the client and obtaining approval for corrective and maintenance actions	3.85 (1.01)	36	2
S26	Introduction of stabilization sprints for code maintenance	3.75 (1.29)	35	2
P9	**Difficulties with breaking down tasks into smaller tasks**			**3**
S60	Transferring detailed design problems to separate meetings of selected people	3.94 (0.86)	36	1
S25	Including the refactoring costs in the price of an expensive task	3.58 (1.19)	30	5
S61	Application architecture based on microservices	3.38 (1.06)	29	1
S39	A team using design patterns, standards, diagrams	3.34 (0.97)	34	2
S1	Professional Scrum Master teaching team communication and promoting issues of architecture and design at the meetings	2.94 (1.20)	32	4
P10	**Mutual blocking of implementation tasks**			**3**
S30	Grooming before planning - examining and presenting details of a given User Story	4.16 (0.85)	35	3
S50	Informal conversations and arrangements (helping to avoid blocking tasks)	3.83 (1.05)	37	1
S39	A team using design patterns, standards, diagrams	3.71 (0.84)	32	2
S62	Assigning tightly related tasks to one developer	3.61 (0.95)	37	1
S1	Professional Scrum Master teaching team communication and promoting issues of architecture and design at the meetings	2.93 (1.24)	34	4

IV. Validity threats

A. Threats to construct and internal validity

We have controlled the workshop moderator's bias and his impact on experts with the structure of the workshop, which included the steps of individual identification (steps 2 and 4). Only then were the identified problems and solutions discussed and merged. The moderator was open to further expert's explanations.

The incorrect interpretation of the output from experts was controlled by writing down the output on the post-it notes and then discussing it to clearly understand the experts intentions. The moderator preserved all post-it notes after the workshop and built the resulting list of problems and solutions directly after the workshop referring to the notes and his fresh memory. For details on the workshop design see section II of the paper.

The interview experts represent the above average experience of our sample. Only 7 of 39 survey respondents had more experience, which puts the interview experts in the top quartile of the survey sample. What is the most important, the interview experts were able to identify large number of problems and solutions from their experience.

Our weight system is arbitrary at the moment, but it was designed to represent the assumed learning curve of software design and the Scrum framework based on the university syllabus and the authors' work experiences. We plan to study the learning curve of the Scrum framework in the future.

B. Threats to external validity

The number of experts was limited to 4 due to several factors. First, the set of data collected after 4 workshops was very satisfactory and we agreed on finishing this phase of research at this stage. Second, we required our experts to have experience both in software design and in the Scrum framework, which significantly limited the available sample. We have involved experts from various business environments: academia, technological start-up, small company, and large multinational corporation. The number of respondents was also limited due to the specific set of competencies required for the survey.

Our sample is not statistically random, but the experts and respondents were identified and contacted with various channels such as personal contacts, business contacts, social media, and recommendations from identified experts. This provided for a reasonably diverse group of practitioners.

We have based our research on data from experts and respondents working in the Polish market. This forms the natural limitation to our current results.

V. Conclusion

We have carried out 4 workshops with IT practitioners and identified 52 unique problems and 99 unique solutions. We believe that these results form a valuable answer to the research questions RQ1 and RQ2. Due to the limitations of this paper, we have presented only the 10 most commonly indicated problems as well as 5 solutions per problem selected for the survey.

We have acquired some evaluation of the effectiveness of the solutions to the 10 selected problems. We could point out some of the highly evaluated solutions as our initial recommendations as well as indicate the lowest evaluated solutions as risky. It should be considered, however, that the evaluations are based on the opinion poll only. This provides only a preliminary answer to the research question RQ3. Further and more detailed verification of the solutions' effectiveness in practice requires careful observation of a number of projects and can be done in future research.

Acknowledgment

The authors thank all the experts and respondents who took part in the identification workshops and the survey.

Abstract—*The article presents the results of research conducted in an international enterprise responsible for IT project implementation. The carried out analysis of the case study with the use of surveys and data synthesis allowed the major factors causing problems connected with project management to be identified. The identified factors were aggregated and then, by using four key variables, a rhomboidal model adaptation was proposed to facilitate the choice of the best method of project management. The proposed solution may aid Project Managers choosing the most appropriate method of project management as well as measuring and monitoring risk indicators.*

I. Introduction

The development of methods and tools of project management is a challenge for people responsible for project management [1, 5]. High dynamics of changes taking place in IT projects regarding client expectations and awareness means that it becomes more and more challenging to achieve the final success of the project [4, 8].

It is therefore necessary to continue to explore solutions that, based on the experience of completed projects, facilitate taking the right decision on the choice of methods of IT project management because incorrect decisions made in the initial phase of the life cycle are much more risky for the project. The high costs associated with removing the consequences of wrong decisions transfer into a project and are often not accepted by customers [7].

II. The development of IT project management

Current reference books outline a lot of methods of project execution [2]. They concentrate on three main approaches: classic [5], agile [4] and hybrid [8].

The classic approach, as the name suggests, uses a classic method for project management (i.e. PRINCE2, PMBOK - collection of good practices). This approach places a particular emphasis on precise project planning in such a way that later, in the project execution phase, it works towards maintaining the base plan adopted earlier. Classic methods are also characterized by a high level of formalization and they use a cascade approach to product or service development. The further stages of the project come one after another, without returning to the previous stage. The advantage of this approach is higher control and predictability of the project budget. Less flexibility regarding the necessity of implementing changes and the identification of the customers' needs are disadvantages.

The agile approach uses adaptation methods for project management (i.e. SCRUM, Extreme Programming, Lean). Agile methods have a low level of formalization and they assume an incremental and iterative way of product or service development. The spiral model of development used in this approach allows for returning to the earlier stages of the projects depending on the needs. The advantage is the possibility of having a flexible approach to the project and increased interaction with the product or service users [6]. The frequent problems related to project scope control and, as a consequence, related to budget control are a disadvantage. The higher engagement of the users in relation to classic methods increases the costs of product manufacturing but minimalizes the risk of making mistakes related to wrongly defined customer requirements.

The hybrid approach combines both the above approaches to project management alternately (i.e. classic and agile). Depending on the project structure, it uses both classic methods, mainly in the layer of management processes, and agile methods, mainly in the layer of production processes [7]. Thanks to such an approach, benefiting from the advantages of both methods described above is possible. Difficulty connected with the efficient estimation of the place and scope of using particular methods, as well as the necessity for Project Managers to have higher competences may prove to be disadvantages.

III. Research Methodology

In the presented research the following testing method was adopted: (Fig. 1)

Fig. 1. Research Methodology

This work was not supported by any organization

Step 1: Book references analysis. The objective of this step was to conduct an analysis of the research problem on the basis of the available reference literature. Within the analysis, a review of the main approaches to project management (classic, agile and hybrid), taking into account both advantages and disadvantages, was performed.

Step 2: Variables identification. The objective of this step was to identify and describe the variables causing problems related to project management. It was conducted in three stages:

- Phase 1: Identification of the variables of the analysis of the accomplished IT projects.
- Phase 2: Identification of the variables of the opinions provided by participants of the IT projects.
- Phase 3: Evaluation of the characteristics of real projects for the correctness of choosing the project execution method.

In this step, a survey questionnaire was used. It allowed the acquisition of opinions from participants of the projects. The provided data was subjected to synthesis, which allowed the main factors determining the choice of the particular project management method to be distinguished. Within this research, the characteristics of variables appearing in real projects were identified on the basis of a quality analysis of the current situation present in the examined enterprise.

Step 3: Decision model development. The objective of this step was to create a decision model which, thanks to the adaptation of a rhomboidal model, would ease decision making regarding the choice of the IT project management method.

The criterion of the appropriate selection of the project management method was defined as the general satisfaction of the project stakeholders with the delivered product or service within the executed project. Among the methods of project execution, three approaches were distinguished, i.e. classic, agile and hybrid.

Step 4: Model validation. The objective of this step was to verify the correctness of the assumed diagram model construction, the usage of which would allow the correct selection of the IT project management method on the basis of the identified variables. The model was subject to validation on the basis of the projects conducted in the examined enterprise.

IV. VARIABLES IDENTIFICATION

The examined enterprise accounts for the large business sector, employing approximately two thousand people. Within the overall structure, the IT Department was created. It is responsible for the design, realization and implementation of IT projects for internal clients' needs. The company executes their projects mainly according to the classic approach, i.e. PMBOK or PRINCE2. Every time, project documentation is created before the project launch and completed regularly throughout the project duration. The decision regarding the choice of projects for realization is made by the office in charge of the project portfolio selection, in consultation with the company's management.

Forty-two employees of the company took part in the research. The participants were people involved in the execution of IT projects. The participant structure of the survey is presented in Table 1.

TABLE I.
PARTICIPANT STRUCTURE

Respondent's role in a project	Percentage [%]
Designers	7
Developers	27
Management	18
Implementation Specialists	35
Remaining participants	13

The respondents of the research are people present in all stages of the project life-cycle, which means designing, creating and implementing. A substantial number of people (18%) were represented by management of the project, which means decision-makers, responsible for the possibility of making changes in the scope of the selection of the project realization methods.

The results of the survey research were presented in the form of percentages. In the case of multiple choice questions, the percentage estimates the ratio of people who indicated a particular answer from all of the research respondents.

The first question referred to the evaluation of the effectiveness of the project execution. It required the respondents to list the main problems encountered during the project execution. The obtained results are presented in Fig. 2.

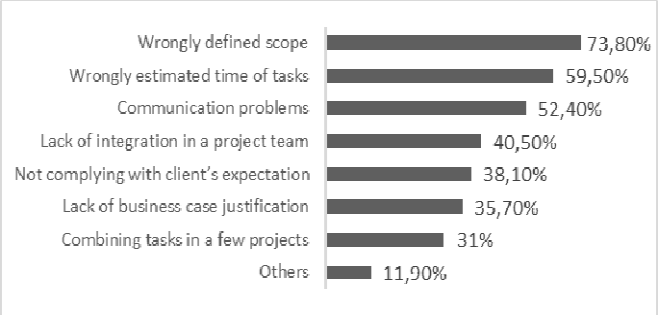

Fig. 2. Problems present in projects

The results of the analysis show that the main problem which occurred in the projects was a wrongly defined scope. This is a particularly essential factor of the project, which, in the event of failure, infringes the classical triple constraint. A significant proportion of the employees also pointed out communication problems. Despite the communication tools available in the company, communication is not satisfactory. This problem may result from an inappropriate information flow, not from a lack of available technical solutions, but from incorrect work organization in a project. This may be caused by the low effectiveness of employees' work or by a bad estimation of the task duration time made by those responsible for project execution.

Another question referred to the identification of the factors influencing the quality of the products or services delivered within the performed projects. The results are shown in Fig. 3.

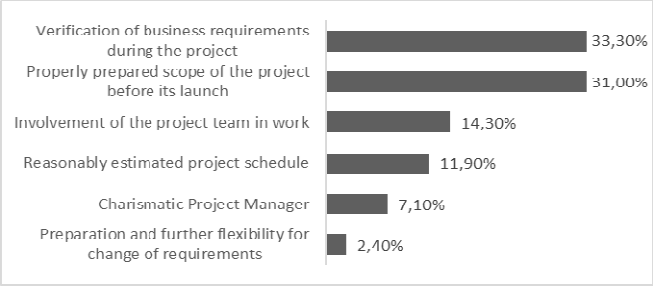

Fig. 3. Factors influencing the quality of products or services delivered

In the respondents' opinion, the biggest influence on the high quality of the product delivered within the project is the possibility of verifying and adjusting the requirements to the business expectations of the company. This is crucial for the changeable environment which IT technologies are. The method of project execution must be flexible enough to be able to adjust to the clients' requirements going beyond the traditional project triple constraint. This factor was probably particularly visible because the leading methodology of conducting projects in the examined company is the classic method concentrating on maintaining the project in a classical triple constraint.

Another question was related to the indication of other factors which according to the respondents' opinion may also influence an increase in the quality of delivered products or services within executed projects. The results are presented in Fig. 4.

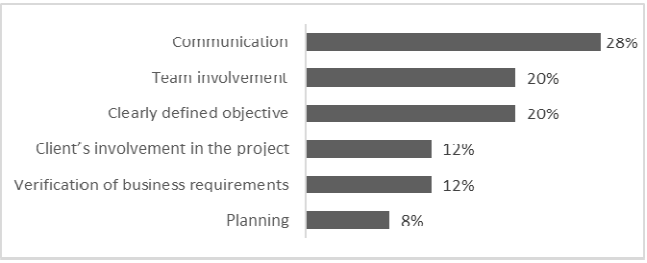

Fig. 4. Factors influencing the quality of delivered products and services – open question

The achieved answers in the majority of cases confirmed problems connected with communication in a project, involvement and willing for cooperation among the participants, a properly defined objective and scope, the verification of requirements and the correct definition of responsibilities in a project. Less frequently, the significance of good planning, work scheduling and solution verification in every stage of project realization were indicated.

The last question required the indication of the preferable methodology of project execution. Thanks to a question formed in such a way, the attitude of the IT project participants towards the possibility of using another (than classic) methodology of project execution could be checked. The results are shown in Fig. 5.

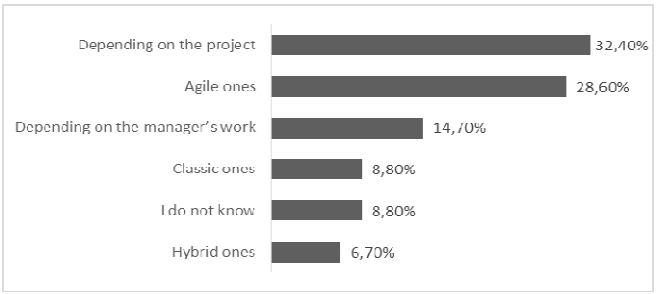

Fig. 5. Preferred methodology of IT project management

The majority of respondents conclude that the best method of project management is a method individually adjusted to the project needs (32,4%). Another group of people support projects run using the SCRUM method, which means performed according to the agile approach (28,6%). Approximately 15% of respondents say that the preferable method of project management depends on the Project Manager's working methods. This means that the method used in the project should undergo changes during its realization under changing project conditions – the hybrid approach. This may imply that the use of the classic approach to project management in a company does not meet the expectations of all of the project participants.

V. Decision Model Development

The conducted surveys allowed key problems to be identified related to the implementation of projects, for which the solution should be the correct choice of IT project management. In connection with the above, in order to solve the identified problems, the usage of a decision model was proposed. This would ease the Project Managers' selection of the best approach to project management (agile, classic or hybrid). The proposed solution should allow for an overview of the project from the perspective of all project participants. It should also allow for its analysis and be an attempt of deviating from the classical triple constraint in the direction of adaptive solutions. Each project is unique and creating one method for all projects may not be efficient enough.

The proposed model is an adaptation of a rhomboidal model [3], which allows for the classification of the project (Fig. 6.)

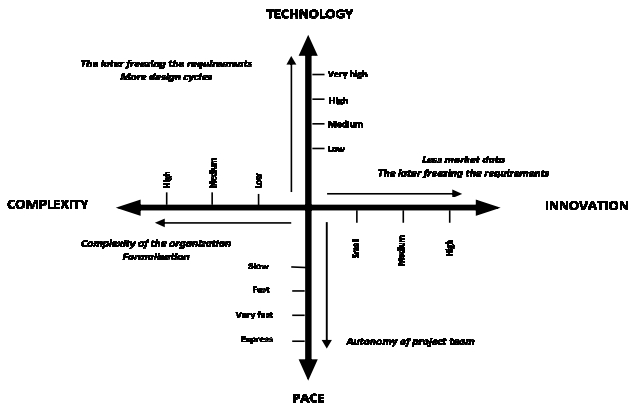

Fig. 6. The rhomboidal model

The presented model covers four basic variables characterizing the project, meaning: [3]

Innovation: the variable estimating the uncertainty of the product or service delivered within the project. It estimates the level in which we are able to evaluate the requirements and needs of further users. The variable is described by three levels of values.

- *Small* – means that the result of the project refers to classic and repetitive products which can possibly expand the products existing on the market,
- *Medium* – means that the result of the project refers to products which are a new series replacing earlier solutions,
- *High* – means that the result of the project refers to totally new projects being innovative solutions.

Technology: the variable estimating technical uncertainty and its influence on the project. It is described by four levels which characterize projects in the following way:

- *Low* – means using well-known technology exclusively,
- *Medium* – means using well-known technology with elements of innovation,
- *High* – means that the majority of used technologies is not well-known yet but is available on the market,
- *Very high* – means that the used technology does not exist yet and the solution will lead to the designated aim using totally new technology.

Complexity: the variable describing the level of difficulty and formalizing the project scope. The variable is described by three levels of values:

- *Low* – means that the product delivered within the project is simple and/or creates a single set of elements,
- *Medium* – means that the product delivered within the project consists of many subsystems influencing each other, and fulfils different functions,
- *High* – means that the product delivered within the project is very complex and is part of a set of distracted systems.

Pace: the variable describing the pressure of time connected with project realization, taking into account the consequences of the non-respect of the project deadline. The variable is described by four levels of values:

- *Slow* – means that the time of making the product or service is not a measurement of the project success,
- *Fast* – means that possibility of faster project accomplishment is an added value and competitive advantage but it does not determine the success of the project,
- *Very fast* – means that the project has a precisely estimated time of accomplishment regarding upcoming developments and its realization in time determines the failure or success of the project,
- *Express* – means that the project is urgent, with no delays accepted and its execution determines the solution of some problem or crisis.

As a result of the conducted analysis of variables in the examined enterprise and the evaluation of the influence of the variables on project quality, a decision model was developed, (Fig. 7). The model indicates certain tendencies for the project variables. Therefore, it is possible to conduct its analysis, which makes the selection of the project management method easier.

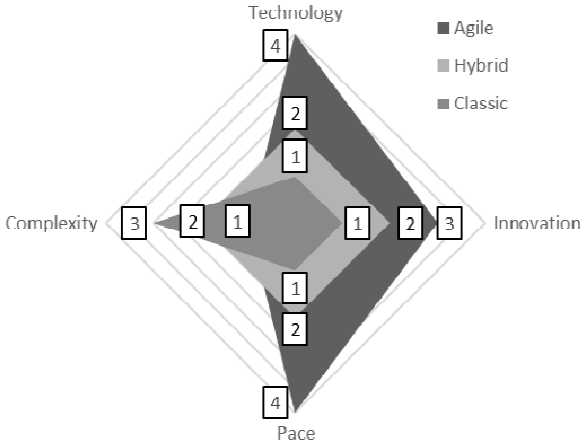

Fig. 7. Rhomboidal model adaptation

The areas where a particular method of management is used were indicated with different colors. In the case of areas not covered with a recommendation, for example, because of high complexity and very advanced technology, the selection of the methodology belongs to the Project Manager.

The more advanced the technology used, the later the freezing of the requirements for the project should take place, because there is more time to change. Therefore, in this case, it is proposed to use the agile approach, which allows for the smooth registration and implementation of changes in particular stages of the project. This is opposed to the situation when the project uses less advanced technology. Often, in such a situation, the requirements are already well-known before launching works. In connection to this, it is suggested to use the classic approach. Similarly, the same is in the case of high innovation. The more innovative the product is and the less the clients' expectations are known, the more agile or hybrid the approach of project management is recommended to be used.

The pace of conducting the project is essential and may be considered in two ways. An additional meeting is a waste of precious time which may be spent on work connected with the direct creation of the product. From the other side, it is time allowing for the earlier verification of the product and the implementation of possible changes. Therefore, in the case of a high pace of project realization, it is recommended to use the agile approach. If time is not so relevant, the classic approach may be used. For a medium pace, the agile or hybrid approach is proposed to be used.

The last issue taken into account in a model is the project complexity, which is a domain of well documented classic methodologies. In the agile approach, the activities are always first and the documents are treated as subsidiary. Therefore, the more complex and documentation demanding

the project is, the more the classic approach is proposed. However, for solutions demanding a medium level of formalizing, the hybrid model is recommended, particularly in the case of huge technical progress and innovation.

VI. Model validation

At the validation stage, the presented model was verified using data coming from the project accomplishment. The data achieved in this way was analyzed using the rhomboidal model. Next, the data was verified taking into account the opinions of Project Managers. This allowed the identification of whether the used model could enable the selection of the correct project execution method.

The analysed project referred to the implementation of a platform for investments and debts services. The project was conducted according to the classic approach (PMBOK) and unfortunately failed.

The innovation of the product was estimated at level 2 (medium). The projected platform was supposed to replace the existing solution by using various channels for information access. It was supposed to be available for the client in a new, friendlier way.

The technology used was evaluated at level 3 (the highest). It means that the product created within the project was very advanced and the majority of technologies were not known in the company. Nevertheless, this technology was already available on the market.

The complexity of the project was evaluated at level 3 (the highest). In the examined organization it was a very complex and demanding project. It required collating a lot of data which often was not presented on a daily basis and had to be taken from clients from different databases.

The pace of the planned work was established at the highest level - 4 (express). The project had to finish fast because the solutions implemented in this company were also used by competitors, which required priority action.

The statement of the above variable values with the use of the rhomboidal model recommended using the hybrid approach for project execution. The project demanded huge autonomy of the project team and was performed at an express pace. It was characterized by late freezing of requirements with a high level of innovation and using advanced technology. Unfortunately, the project was executed according to the classic approach, which meant that it was not realised in a sufficiently flexible way. According to Project Managers, using hybrid methodology would allow for the creation of detailed documentation and agile team management. The project conducted in such a way would involve more frequent verification of requirements in connection with the business. This would imply that the project is accomplished with success.

In the same way, the proposed rhomboid model has been validated on the basis of three completed IT projects. The validation carried out in this way confirmed the effectiveness of its use.

VII. Summary

The presented model is an attempt to support the people responsible for making decisions in the scope of the selection of the project realization method. The proposed solution allows the analysis of key project parameters (complexity, innovation, technology) and eases the selection of the optimal approach for project management (classic, agile, hybrid).

The advantage of the model is an overview from the wider perspective, which means taking into account the factors and indicators surrounding the project. It can be used for supporting the decision-making process regarding the selection of the best project management model.

The disadvantage of the model may be the necessity of conducting an additional analysis, which is time-consuming. Thus, as results from research, the efficient selection of the project management method is the factor which increases the probability of accomplishing the project with success.

The possibility of model adaptation in organizations is wide. It should be remembered that the problem of the examined enterprise was the fact that all the projects finished with apparent success. The reason for such a situation was the fact that the end user was an internal client. It was the internal client who in every case reported the demand for the product or service and defined the requirements. All project changes (scope, duration, etc.) were realized with the acceptance of the internal client and from a formal point of view, the project was always accomplished with success. In a longer perspective, the project was not successful. It was characterized by low effectiveness and a low client satisfaction level. The presented approach in the examined company was not typical. Therefore, the possible limits and doubts should be verified in the process of further research.

***Abstract*— The aim of the paper is to identify the role of the software product manager depending on the size of the company and the characteristics of the product they are working on. This has been achieved in cooperation with 15 experts from the IT industry. The companies were divided into 4 levels of size: micro-enterprises, small businesses, medium businesses and large enterprises. The characteristics of the products were divided into business-business (B2B) and business-customer (B2C). This way, 8 personas of software product managers have been developed. Differences in this role were mainly related to the staffing, its scope of responsibility, tools and techniques used as well as the mode of work with the target customers. Many common aspects of this role have also been identified that made it possible to define archetype persona of a software product manager. All personas have been validated by experts who offered their improvements.**

I. Introduction

MARKETING definition of "a product" is: "a product is anything that can be offered to a market for attention, acquisition, or consumption that might satisfy a want or need" [1]. Since 2007, it is known that systematic product management increases the success rate of software projects [2]. Product management responsibilities are crucial in software companies, as they support decision making process and developing products according to the company strategy. By definition, product management is different from project management, however in many software companies the roles of product manager and project manager are mixed [1].

Similarly to project managers, the product managers must have high level management skills, as very often they lead teams, projects or even departments [3]. Communications skills are important in order to efficiently manage stakeholders and cooperate with development teams to execute product roadmap [1]. The approach to product management often follows the principles of lean management as in the Lean Start-up method [4]. Product managers design and verify the business models in the market [5] with various techniques and tools [6].

This work was supported by DS Funds of ETI Faculty, Gdansk University of Technology.

Product management spans the entire product-life cycle: strategy, concept, market entry and development, evolution [7]. Product managers do not only follow the product-life cycle, they own it. They are responsible for the success of the product, which require them to take care of wide technical and business activities: product strategy, product planning, strategic management, orchestration of the organization's functional areas [1]. It is difficult to start career as a product manager without experience in adjacent disciplines, e.g. marketing or development [8].

There is a role defined in Scrum that is responsible for requirements and business value – the Product Owner [9]. Spectrum of activities and responsibilities of the product manager is much wider than the Product Owner role [10]. Depending on the organization's size, the product manager and the Product Owner roles may be separated or a product manager can assume the Product Owner role, however "in most environments, it makes more sense to have the two roles product owner and product manager separated" [1]. Additionally, earlier research has shown that the approach to projects is related to the business environment [11], [12].

The goal of our research was to understand the current role of product managers in software companies. To achieve this goal, 3 research questions were stated: (RQ1) What is the software product manager's role depending on the company size and characteristics of the product? (RQ2) What are the differences in the role of a software product manager depending on the company size and product type? (RQ3) What are the common characteristics of a software product manager independent of the company size and product type?

The contribution of this paper is the identification of the characteristics of the software product manager's role in different business environments as well as the elaboration of the archetype of this role based on the elements common to all environments.

The paper is organized as follows. Section II discusses the work of other researchers to which we relate our study. Section III describes the research method, the experts and techniques. Section IV provides the personas of product managers specific to different business environments as well

as the archetype common to all environments. Section V presents the two phase validation of the proposed personas and archetype. Section VI discusses the threats to the validity of this research followed by the conclusions in Section VII.

II. Related Work

In 2013, research on software product management was conducted in Lappenranta University of Technology, and its main research question was: which common roles do software product manager fulfill in the organizations? The result of the research is a framework that reveals the role of product managers. Four stereotypical roles were identified in the studied organizations: experts, strategists, leaders and problem solvers [8].

An expert is a person who has a deep expertise in some specialization (e.g. marketing or development), but does not have the responsibility for product management activities. It is a kind of informal product manager, who works close to product and knows it very well. He is involved in the implementation to decide on feature priorities. The strategist is a product manager who has an impact on the company product vision and roadmap. As the authority of the strategist grows, he becomes the third profile, the leader, who has access to product resources and can manage it. The fourth profile is the problem solver who manages stakeholders and resolves product-related issues, but it is the management who defines the strategy and roadmaps [8].

The framework was developed empirically based on interviews with companies' representatives and by researching the documentation. Besides the framework mentioned, super categories with properties were also identified based on the grounded theory [21] analysis:

- access to resources – ownership of the product budget, possibility to hire people, information resources,
- influence on the product – orchestration of development, definition of tactical actions, participation in strategy planning, creation of roadmaps,
- authority – product leadership, power of decision making,
- influence on collaboration – ability to resolve problems between departments, level of communication.

In 2014, Christof Ebert and Sjaak Brinkkemper defined product management key success factors, their effect on business and challenges that stand ahead of the product management [13]. They also described 4 best practices for systematic product management. They stated that during the research the majority of product managers that have been found in software companies had: "a strong technical background and rather weak finance, marketing and general management skills" [13].

"Software Product Management" book, published in 2017 by H. Bernand Kittlaus and Samuel A. Fricker [1] is a review of software product management and many terms related to it like: management of software as a business, product strategy, product planning, strategic management, orchestration of the organization's functional areas. It also introduces the Software Product Management Framework, which is an integration and consolidation of three other frameworks that were invented:

- Reference Framework for Software Product Management developed by Inge van de Weerd, Willem Bekkers, Sjaak Brinkkemper, and colleagues at the University of Utrecht, Netherlands in 2006 [14]. This framework describes the core activities of a software product manager in specific areas: portfolio management, product planning, release planning, requirements management.
- Pragmatic Marketing Framework developed by Kittlaus and Clough [15] that describes the aspects of product management, product marketing and defines the role a of product manager and product marketing manager ultimately.
- a paper by Ebert on the impacts of software product management [2], a proposal on how to manage software along the product lifecycle phases.

Software Product Management Framework indicates the main functional areas of a software organization: strategic management, product strategy, product planning, development, marketing, sales and distribution, service and support. Each area has related activities assigned.

Product management is gaining popularity every year, however it has been topic for a scientific research only few times in the recent years. Of 3 researches on software product management described above only one of them is focusing strictly on the product manager's role, however it does not analyze if this role depends on the company size and product type.

III. Research Method

Our research was carried out as a qualitative study using grounded theory [21] as a research method. The identification of the role of the software product manager has been achieved in cooperation with 10 experts with more than 2 years of experience in research and business projects in the IT industry. The experts worked as:

- a product manager,
- an employee with product management responsibilities but named differently,
- an employee working in close cooperation with a product manager.

The companies were divided into 4 levels of size (ranged in size of number of employees): micro-enterprises (1-10), small businesses (10-50), medium businesses (50-250) and large enterprises (250+) [16]. The characteristics of the products were divided according to the product delivery model into business-business (B2B) and business-customer (B2C) [17]. Combining these dimensions, we analyzed the software product manager's role in 8 different environments. The characteristics of the experts are presented in Table I.

TABLE I.
CHARACTERISTICS OF THE INTERVIEWED EXPERTS

Identifier	Position	Company	Size	Delivery model
E1	Vicepresident of Projects	UXpin	medium, large	B2B, B2B, B2C
E2	Vicepresident	Rocket Studio	large, large	B2B, B2C
E3	Product manager	Spartez	medium, large	B2C, B2B
E4	President	RoomAuction .com Ltd.	micro, small	B2B, B2C
E5	Product manager	Better Solutions	small	B2B
E6	Business analyst	Net PC	small	B2B
E7	Product manager	AirHelp	medium	B2C
E8	Project manager	dr Poket	micro	B2C
E9	Product manager	Young Digital Planet	large	B2C
E10	Product manager	AirHelp	micro, small	B2C, B2C

We have used the technique of a persona [18] to describe the identified roles of a software product manager. This technique aims at building a profile of a representative member of a particular group of people. Such profile may include various attributes. Based on our research goals and the literature we have selected a set of attributes of the software product manager's role and taken them as the model of our personas. This model with the description of all the attributes is presented in Table II. Further in the research, this model was used to define 8 personas of product managers from various business environments.

The main instrument of the data collection were the structured interviews with experts conducted in the form of face to face meetings in May 2016. We have asked the experts the following questions based on the persona model:

- What is your experience in product management area?
- How many years you have been working as product manager or as related role?
- Who else was responsible for product management?
- What were the goals and responsibilities of product managers?
- What was the product lifecycle?
- Who did you cooperate with?
- What techniques did you use?
- What tools did you use?
- What are the first steps to become a product managers? How in your opinion young people interested in this path of career can get first experience?

TABLE II.
A MODEL OF A SOFTWARE PRODUCT MANAGER'S PERSONA

Attribute	Description
Introduction to the environment	The specificity of the environment and its approach to product management.
Objectives	The objectives of the Product Manager or the role with his responsibilities, depending on the size of the organization.
Responsibilities	The responsibilities of the Product Manager's role, depending on the size of the organization.
Product Life Cycle	The development phases of the product, on which the approach to project management depends.
Main competences	The required competences of product managers including soft and hard skills.
Cooperation with other teams	Teams and roles that product manager cooperates with.
Roles in the product team	The location of the product team within the organization and its characteristics.
Techniques	List of techniques used by the product manager including techniques for: verification of the product vision and strategy, product delivery management, user research.
Tools	List of tools used by the product manager to: manage tasks and backlog, user research, store documentation, prototype and collaborate with other roles.
First steps	Career opportunities as a product manager and specific steps that can be taken to become a product manager.
Other positions	Other positions or roles responsible for product management.

Each interview lasted from 30 to 60 minutes and was recorded, analyzed, and documented. The recordings allowed to fill up the model properly with the data. The templates for the interviews were filled by the researcher, however later on they were validated by every expert (see section IV). Many interviewed experts provided insights to more than one business environment as a result of their experience. The coverage of the analyzed business environments with the interviews is presented in Table III.

TABLE III.
NUMBER OF INTERVIEWS FOR EACH COMPANY SIZE AND DELIVERY MODEL

Size / Delivery model	B2B	B2C
micro	1	2
small	2	2
medium	1	2
large	3	3

Additionally, we aimed at the identification of the most inherent aspects of the software product manager's role which seem independent from the business environment. To capture this viewpoint we employed the concept of an archetype which is a common recurring motif or pattern assumed to represent fundamental characteristics of a thing [19]. We have built an archetype of a software product

manager which can be viewed as a super-persona, a more general or abstract persona than the personas specific to different business environments (in object-oriented modeling the archetype would be a superclass of the classes of specific personas, hence the name super-persona).

The software product manager's archetype was built using the following rules: (1) include common elements that repeat in each specific persona; (2) find a classification or a generalization of elements that do not repeat directly in the specific personas; (3) include the classes or generalization of elements identified by rule 2. Considering each specific persona as a set of values of the attributes, the resulting archetype can be considered an intersection of these personas focusing on their commonalities.

TABLE IV.
SOFTWARE PRODUCT MANAGER IN A MICRO-ENTERPRISE, B2C

Attribute	Description
Introduction to the environment	Responsibility for the product management and all tasks associated with the role of product manager are handled by the company's founders. Generally there is no strict product manager position.
Objectives	To recognize customer needs and develop a valid business model
Responsibilities	Project management, prototype development (MVP), team-building, tasks related to marketing and sales, gathering users' feedback, fund gathering, resource management.
Product Life Cycle	Idea, business model verification, introducing functional prototype to the market, sales and product development, maturity, decline. Different approach to product management depending on the phase.
Main competences	Understanding of the problem domain, cooperation skills, openness, communication skills, entrepreneurship, visionary, priority management.
Cooperation with other teams	Mutual cooperation of the company's founders (partners), cooperation with the development team (internal or external), cooperation with mentors and investors, cooperation with external entities (i.e. design agency)
Roles in the product team	Multidisciplinary team of several people with different competences.
Techniques	Business Model Canvas, Product Roadmap, Product Backlog, Agile techniques, Personas, Product Map, Statistical analytics, Workshops with end users, Usability labs, Prototyping
Tools	Podio, Trello, Mixpanel (free version), Google Analitycs, Microsoft Office, Physical board, Posts-its
First steps	Learn the company, the product specifics and the users' needs e.g. while working in customer support team or at a technical position.
Other positions	Chief Executive Officer (CEO), Analyst, Project Manager, Developer

IV. RESULTS

This section presents the proposed personas of software product managers depending on the business environment (the organization size and the product delivery model), initial observations on the differences of the product manager's role among business environments as well as the final super-persona of an archetypical software product manager. The section follows the increasing company size. Sections A, B, C, and D are related to RQ1, section E to RQ2 and section F to RQ3.

A. Micro-enterprises

The personas of a software product manager in a micro-enterprise are presented in Table IV (B2C delivery model) and Table V (B2B delivery model). It could be observed that in the companies of this size the product manager's role is not assigned to a distinct post but is rather fulfilled by the company owner or the CEO.

TABLE V.
SOFTWARE PRODUCT MANAGER IN A MICRO-ENTERPRISE, B2B

Attribute	Description
Introduction to the environment	Responsibility for the product management and all tasks associated with the role of product manager are handled by the company's founders. Generally there is no strict product manager position.
Objectives	To recognize customer needs and develop a valid business model
Responsibilities	Project management, creating the product strategy, setting the short-term goals, coordinating work to achieve the goals, market research, tasks related to marketing and sales, acquiring knowledge from experienced "business sharks", establishing relationships and networking with prospecting clients, gathering customer feedback, business analytics, close cooperation with the founders.
Product Life Cycle	Idea, business model verification, introducing functional prototype to the market, sales and product development. Different approach to product management depending on the phase.
Main competences	Consistency and persistence, data analysis and synthesis, understanding customer needs, soft skills, flexibility, inquisitiveness, openness and the ability to establish business contacts.
Cooperation with other teams	Mutual cooperation of the company's founders (partners), cooperation with the development team (internal or external), cooperation with mentors and investors.
Roles in the product team	Multidisciplinary team of several people with different competences.
Techniques	Business Model Canvas, Product Roadmap, Product Backlog, Agile techniques, Personas, Workshops with clients, Usability tests, Web analytics,
Tools	Asana, MindMaster, Trello, Slack, Skype, MS Office, Physical board, Posts-its
First steps	Read a lot, create something of your own or start a career in technical positions.
Other positions	Chief Executive Officer (CEO), founders, president

B. Small enterprises

The personas of a software product manager in a small enterprise are presented in Table VI (B2C delivery model) and Table VII (B2B delivery model). It could be observed that the companies of this size start to hire the product manager as a distinct post.

TABLE VI.
SOFTWARE PRODUCT MANAGER IN A SMALL ENTERPRISE, B2C

Attribute	Description
Introduction to the environment	Responsibility for the product management is on the founders of the company. At some point, the Product Manager is hired to support the founders.
Objectives	Co-creation and execution of the product strategy, support in defining the company's business goals.
Responsibilities	Product development, incremental product delivery, negotiation of priorities with the stakeholders, prototyping, cooperation with external suppliers, solving users' problems.
Product Life Cycle	Idea, introduction to the market, growth, maturity, decline. Very high work dynamics in the phases of introduction and growth. Different approach to product management depending on the phase.
Main competences	Project management, data analysis, ability to work in a dynamic environment, communication, negotiations, empathy.
Cooperation with other teams	Cooperation with the founders, project manager, customer support, and development team.
Roles in the product team	A multidisciplinary team: product manager, project manager, graphic/UX designer.
Techniques	NPS (net promoter score), product roadmap, product backlog, agile techniques, user stories, interviews, prototyping.
Tools	Trello, Google Analitycs, Mixpanel, Skype, Axure, Gdrive
First steps	Begin a career in the development environment, for example as a project manager, tester, or developer. Observe the product development process and get to know the product. Observe and learn from experienced product managers.
Other positions	Chief Executive Officer (CEO), founders, president, Chief Technology Officer (CTO), Chief Marketing Officer (CMO), project manager.

TABLE VII.
SOFTWARE PRODUCT MANAGER IN A SMALL ENTERPRISE, B2B

Attribute	Description
Introduction to the environment	There is or there is not a defined role of the Product Manager depending on the relationship with the client. In the latter case, the roles that share the responsibility for product management are Project Manager and Business Analyst.
Objectives	Co-creation and implementation of the business goals of the company, delivering the product to the customer according to the requirements.
Responsibilities	Defining, clarifying and specifying the requirements, contacting the client, prototyping of interfaces, prioritizing tasks according to the client's needs, proposing solutions, building customer relations, examining customer needs.
Product Life Cycle	If company offer universal product for all b2b customers: Idea, introduction to the market, growth, maturity, decline. If company offers custom solutions for enterprises: Tender specification, cost valuation stage, bidding, product implementation (or its development, maintenance), closing the project. Permanent cooperation with the client is also possible. Different approach to product management depending on the phase.
Main competences	Analytical thinking, accuracy, project management, communication skills, decision-making, negotiations, empathy and understanding of customer needs, forming business relationships.
Cooperation with other teams	Cooperation with project manager, business analyst customer support, and designers
Roles in the product team	A multidisciplinary team: product manager, project manager, business analyst, graphic/UX designer.
Techniques	Product backlog, product roadmap, use cases, wireframes, UML diagrams, interviews, workshops with clients, project plan, requirements specification.
Tools	Jira, Mantis, Axure, Proto.io, UXPin, Balsamiq, Enterprise Architect.
First steps	Read about project management and analysis. Begin a career in the position of: analyst, project manager, programmer, tester.
Other positions	Project manager, business analyst.

C. Medium enterprises

The personas of a software product manager in a medium enterprise are presented in Table VIII (B2C delivery model) and Table IX (B2B delivery model). It could be observed that the companies of this size build product management teams around the product manager.

TABLE VIII.
SOFTWARE PRODUCT MANAGER IN A MEDIUM ENTERPRISE, B2C

Attribute	Description
Introduction to the environment	Software companies aware of the need for product management. Defined role of the Product Manager.
Objectives	Defining the product strategy in line with the company's business goals and its implementation.
Responsibilities	Defining the way to achieve company's business objectives, confirming the expectations of the stakeholders, communication of results to the stakeholders, gathering requirements, defining needs or problems, analyzing numerical data, user research, refining and describing initiatives, projects and tasks, confirming priorities with stakeholders, coordination of project implementation, communication of initiatives and reporting of achieved goals after implementation, cooperation with development team - daily communication in order to specify requirements, participation in Scrum meetings (primarily in planning meetings).
Product Life Cycle	Idea, Introduction, Growth, Maturity, Decline. Different approach to product management depending on the phase.
Main competences	Communicativeness, openness, assertiveness, ability to create visions, analytical mind, understanding of users' needs.
Cooperation with other teams	Cooperation with: designers, developers, testers, stakeholders (leaders of other teams i.e. customer service or sales), management board, other product managers (often goals and initiatives are shared).
Roles in the product team	The product team consists of: product managers, designers, user research specialists, conversion specialists, and translation specialist (multilingual support for the product). Some competencies may be outsourced.

Techniques	Product roadmap, user stories, personas, user research, interviews, wireframes, A/B tests, NPS (Net Promoter Score), workshops with stakeholders, story mapping.
Tools	Jira, Confluence, Slack, Skype, Proto.io, HotJar, Google Analitycs, Mixpanel.
First steps	Participation in workshops, presentations, trainings on product management and project management, individual learning, online courses. Membership in non-profit organizations to develop soft skills recommended. Career can be started at another job position to learn the product and then the change of the role might be possible.
Other positions	Product Owner, brand manager, project manager, business analyst.

TABLE IX.
SOFTWARE PRODUCT MANAGER IN A MEDIUM ENTERPRISE, B2B

Attribute	Description
Introduction to the environment	Software companies aware of the need for product management. Defined role of the Product Manager.
Objectives	Defining the product strategy for business customers, in line with the company's business goals.
Responsibilities	Responsibility for many aspects, both technical and business, defining product strategy, market analysis, researching customer needs, creating a product roadmap, defining product goals, working close with main executives.
Product Life Cycle	Idea, Introduction, Growth, Maturity, Decline. Different approach to product management depending on the phase.
Main competences	Curiosity of the world, data-based analysis, openness, empathy, understanding people, leadership skills.
Cooperation with other teams	Cooperation with all departments in the company: sales, marketing, business development, customer support, project managers.
Roles in the product team	Product managers are gathered in one operational team together with designers and user researchers.
Techniques	Product roadmap, user research, interviews with prospects and clients, user recordings, A/B tests.
Tools	ProdPad, Target Process, Microsoft Office, Keynote, UXPin.
First steps	Start a career in the software company as developer, tester, customer support specialist, project manager. Start your own startup.
Other positions	Designer, tech lead, project manager.

D. Large enterprises

The personas of a software product manager in a large enterprise are presented in Table X (B2C delivery model) and Table XI (B2B delivery model). It could be observed that the companies of this size can employ multiple product managers on the per project or per department basis.

TABLE X.
SOFTWARE PRODUCT MANAGER IN A LARGE ENTERPRISE, B2C

Attribute	Description
Introduction to the environment	In many large enterprises, the role of product manager is taken by persons from departments within which a new project is initiated or a product is developed. The product management is not their only responsibility. They also perform other duties resulting from the specificity of their positions. Only some software companies (mature, product-driven and agile) employ dedicated product managers who define the product strategy and roadmap.
Objectives	Defining a product strategy in accordance with the company's business strategy, achieving goals.
Responsibilities	Defining the scope, contact with stakeholders, collecting requirements and opinions, receiving product increments and accepting the work done by the development team, reporting to the steering committee, cooperation with the development team (sometimes this responsibility is transferred to the project manager), presenting the product inside the company, acquiring the budget for specific actions, data analysis, cooperation with roles with different competences (analyzes, trends, interfaces).
Product Life Cycle	A product is created in a project (initiation, planning, development, closing phases) or along with the product idea a project is launched to verify its business value (concept phase, running an experiment and gathering feedback from the market, implementation of a functional prototype, sales and development). Different approach to product management depending on the phase."
Main competences	Leadership skills, impact on people despite the lack of authority, negotiation skills, assertiveness, ability to prioritize and make decision, business knowledge, creativity, listening to others, taking criticism, teamwork skills, useful technical knowledge, presentation skills, knowledge about techniques and tools.
Cooperation with other teams	Cooperation with: development team, project manager, steering committee, project sponsor, stakeholders, directors of sales, marketing, and customer support departments. Cooperation with subcontractors. Horizontal and vertical communication (reporting to the board).
Roles in the product team	Depends on the organization structure. Mainly multidisciplinary teams working on one product, one product is one department or division. As part of the operational team: product manager, project manager, research specialists, UX experts. Rarely a dedicated product team, possibly in mature technology companies that have grown up on product-driven work (e.g. Atlassian).
Techniques	Product roadmap, product backlog, Business Model Canvas, personas, user research, MindMap, goRoadmap, interviews and surveys, market trends analysis, statistical analysis, predictions, correlations.
Tools	Google Analytics, Mixpanel, Jira, Jira Portfolio, Asana, Redmine, Trello, Sharepoint, Confluence, MS Project, Microsoft Office, Intercom, HotJar, SurveyMonkey.
First steps	Learn about techniques, tools, good interface design practices, learn systematic work e.g. by running a project. You can start your career as: programmer, tester, UX designer, analyst, or starting your own startup. You can also hire as a product manager's assistant and train under his supervision. Develop communication skills and work in a group, e.g. by leading non-profit projects.
Other positions	Project manager, product development manager, product owner, brand manager, marketing director, business analyst (in case the product is an in-house system)

TABLE XI.
SOFTWARE PRODUCT MANAGER IN A LARGE ENTERPRISE, B2B

Attribute	Description
Introduction to the environment	In many large enterprises, the role of product manager is taken by persons from departments within which a new project is initiated or a product is developed. The product management is not their only responsibility. They also perform other duties resulting from the specificity of their positions. Only some software companies (mature, product-driven and agile) employ dedicated product managers who define the product strategy.
Objectives	Collection of requirements from the customer and delivery of the ordered product. The Product Manager the most often has no impact on the company objectives and product strategy, implements elements of the company's overall strategy.
Responsibilities	Contact with the client, collecting requirements and opinions from the clients, cost estimation, managing the budget, ordering additional resources (e.g. usability research), proposing solutions, planning team work, supervising the implementation, presentation of product increments to the client, synthesis of a large number of development threads. Responsibilities depends on how product manager role is set up - sometimes product manager doesn't own budget and doesn't work on any cost estimations.
Product Life Cycle	If company offer universal product for all b2b customers: Idea, Introduction, Growth, Maturity, Decline. If company offers custom solutions for enterprises: Signing a contract for the creation of a new product or contact for the development of an existing system. Initiation, planning, production, closing the project. Different approach to product management depending on the phase.
Main competences	Communication skills, listening to others, data analysis and synthesis, interdisciplinary.
Cooperation with other teams	Cooperation with: project manager, development team, other departments (e.g. to allocate human resources to the project).
Roles in the product team	Depends on the organization structure. Mainly multidisciplinary teams working on one product, one product is one department or division. As part of the operational team: product manager, project manager, research specialists, UX experts. Rarely a dedicated product team, possibly in mature technology companies that have grown up on product-driven work (e.g. Atlassian).
Techniques	Product roadmap, product backlog, workshops with clients, requirements templates, requirements specification.
Tools	Jira, Confluence, Microsoft Office.
First steps	Acquiring broad knowledge from various fields: marketing, sales, UX, project management. Starting a career in positions: project manager, analyst, programmer, tester, architect.
Other positions	Project manager, product development manager, product owner, brand manager, marketing director, business analyst (in case the product is an in-house system)

E. Differences among business environments

Our research suggests several differences in the approach to product management and the role of the software product manager depending on the size of the organization. Different roles are responsible for product management in the early stage, the responsibilities are spread between founders and the core team. As the company grows it is more often when dedicated software product manager appear on board. It can also be seen that large companies use more advanced tools and techniques, and often specialized competences are outsourced. Additionally, the impact of the software product manager on the company's vision and business objectives seems to decrease along with the size of the organization.

Roles in the product team also depend on the company size. In micro-enterprises there is a multidisciplinary team of several people with different competences. Responsibility for the product management and all tasks associated with the role of a product manager are handled by the company's founders. Generally there is no strict software product manager position. In small-businesses there is a team of product manager, project manager, UX designer and sometimes other roles like business analyst (B2B). When company grows and becomes a medium business it invests more in the product team and hires even more specialists such as conversion specialist, translation specialist. In large enterprises the roles in the product team depend on the organization structure.

The product characteristics seem also to influence the role of the software product manager at some point. For example, working in the B2B model requires negotiations with the client, as well as creating additional documentation specifically for business clients. There are some specific techniques that software product managers in the B2B model use i.e. workshops with clients. On the other side, products in the B2C model require understanding of the users, their segmentation, source of origin, and their behavior in order to adapt the product to the target group with the highest business potential.

Regarding tools that software product managers use no differences have been identified when we compare business environments, however there are some techniques and tools that can be used only when the number of customers reaches certain point. For example, our research shows that A/B testing is not used by product managers in micro-enterprises.

The product lifecycle seems to be very similar in different environments, however there are some exceptions e.g. the standard product lifecycle in B2B companies offering custom solutions for enterprises is affected by tender specification, cost of the evaluation stage, bidding, custom product implementations. In large B2C companies the product can be created as a result of an internal project or along with the product idea a project can be launched to verify its business value.

F. Archetype of a software product manager

Table XII presents the archetype of a software product manager based on the product managers' personas specific to different business environments.

TABLE XII.
ARCHETYPE OF A SOFTWARE PRODUCT MANAGER

Attribute	Description
Objectives	Achieving goals by implementing the product strategy and consistent product vision.
Responsibilities	Defining goals, proposing solutions, prioritizing projects or tasks, user research, analysis of requirements, market analysis, stakeholder management, cooperation with the development team.
Main competences	Soft skills: communication, negotiations, teamwork, decision-making, curiosity of the world, open-mindedness, assertiveness, understanding of human behavior, inquisitiveness, networking, leadership predispositions, consistency and perseverance. Hard skills: ability to understand the problem domain, data analysis and synthesis, knowledge of business analysis and project management, interface prototyping, willingness to learn.
Cooperation with other teams	Cooperate with all product stakeholders and development team.
Techniques	Techniques that support: verifying a product vision and strategy, product delivery, user research.
Tools	Tools that support: task and backlog management, data analysis, user research, documentation, prototyping, remote cooperation.

V. VALIDATION

The first phase of the validation began on June 7, 2016. It has started by sending an email to 10 experts (the same who participated in the interviews) with a link to the document containing the initial versions of the personas. Until 5 July 2016, the experts expressed their opinions on the personas and suggested changes in their presentation and content. In total, we have received 33 suggestions of corrections and remarks on the misinterpreted or incomplete content. They were all taken into account to build the second version of the personas.

The second phase of the validation took place in 2018 and began on January 25th and ended on February 21st. The validation method was the same as in the first phase but this time we engaged new experts who didn't participate in the interviews and the first validation phase. The characteristics of the experts of the second validation phase are presented in Table XIII.

New experts provided 29 remarks in the second validation phase. They did not challenge the personas but rather suggested possible extensions, more competencies, techniques, and tools. The final personas presented in this paper include all the expert's remarks.

TABLE XIII.
CHARACTERISTICS OF EXPERTS IN THE SECOND VALIDATION PHASE

Identifier	Position	Company	Size	Delivery model
E11	Technical Product Manager	Dynatrace	large	B2B
E12	Product Manager	Zalando SE	medium, large	B2C, B2C
E13	CEO	Cux.io	micro	B2B
E14	Senior Product Owner	STX Net	micro, medium, large	B2B, B2C, B2B
E15	Product Manager	Smartly.io	micro, medium, large	B2B, B2C

In total, we involved 15 experts who provided input and comments to the proposed personas of software product managers. The coverage of particular business environments with the experts involved in the validation is presented in Table XIV.

TABLE XIV.
NUMBER OF EXPERTS FOR EACH COMPANY SIZE AND DELIVERY MODEL IN THE VALIDATION PHASE

Size / Delivery model	B2B	B2C
micro	4	2
small	2	2
medium	1	5
large	5	5

VI. THREATS TO VALIDITY

A. Threats to construct and internal validity

We have identified the following threats to the construct and internal validity of our research: (a) interviewer's bias and impact on interviewees, (b) misinterpretation of the interviews with experts, (c) invalid model of the software product manager's persona, (d) subjective construction of the software product manager's archetype.

We have controlled the interviewer's bias and their impact on experts with the semi-closed structured interview design. Each expert was asked the same set of predefined open-ended questions with no suggested answer. The interviewer was open to further expert's explanations. For details on the interview design see section III of the paper.

The incorrect interpretation of the output from experts was controlled by recording each interview, listening to it several times while extracting data to the personas as well as further validation of the personas with the same experts. Experts verified if the personas correctly represented their statements. For more details on the validation of personas see section V.

Our model of the software product manager's persona covers the aspects of this role we assumed important and worth studying. The technique of a persona allows to use the

set of attributes which suit the modeling goal. The selected attributes allow for the generalization of the expert's output as well as cover different aspects of the role. More specific aspects can be studied in further research.

We have built the software product manager's archetype using only the data from the personas specific to different business environments. No raw data was added directly to the archetype. We have identified the common elements in all specific personas and put them into the archetype, adding some classification and generalization when appropriate. The archetype was validated by the experts, however it should still be considered a preliminary result of this research. We plan to work on improvements, verification and application of this archetype in the future.

B. Threats to external validity

We have identified the following threats to the external validity of our research: (a) low number of experts, (b) experts selected as a convenience sample, (c) experts sample limited mostly to Polish market.

The first two threats result from the fact that the software product management is a relatively new topic both in research and in practice, therefore access to experienced product managers in IT is naturally limited. We have mitigated these threats by having our experts experienced in several business environments from working in different companies, experiencing the growth of a company (e.g. from small to medium) or working on products with different business models (i.e. both B2B and B2C). As a result, most of the business environments were covered by at least two experts (for details see Tables III and XIV). Furthermore, all experts took part in the first validation phase, where they reviewed all personas, not only those they provided input to. Additional 5 experts from various environment reviewed all personas in the second validation phase, where they mostly proposed some minor extensions (for details see section V).

The experts were identified and contacted with various channels such as personal contacts, business contacts, subscribers and readers of the Product Vision blog [20], and recommendations from identified experts. This method provided for a fairly diverse group of experts with different background and experience (see Tables I and XIII).

We have based our research on data from experts working in the Polish market (apart from one foreign expert involved in the second validation phase). This forms a natural limitation to our current results. The specifics of the product manager's role in different markets, if any, is yet to be investigated. We plan to engage more experts from abroad in our future work.

VII. Conclusion

The aim of this research was to analyze the approach to software product management and the role of the software product manager depending on the size of the organization and the characteristics of the projects.

We have interviewed 10 experts from various IT companies on the role of a software product manager as well as involved a total of 15 experts in the validation of the results. Based on this work we have proposed the personas of a software product manager for 8 different business environments that answer the research question RQ1.

Then we have identified some of the biggest differences between the software product manager's roles in various environments. The key differences are related to the staffing of this role, its scope of responsibility, tools and techniques used as well as the mode of work with the target customers. This partially answers the research question RQ2 and suggests the directions of further research.

Our research also indicated some common elements independent of the area which helped us to create an archetype of the software product manager. The important skills of the product manager are highly developed soft skills, basic hard skills, knowledge of techniques and tools, and empathy towards the customer or user. The product lifecycle seems to be very similar in different environments. The product can be in one of four phases of life and depending on where it is, the product manager must manage its development. In general, the software product manager is responsible for implementing the company's strategy and its business goals. The software product manager's archetype forms the preliminary answer to the research question RQ3.

Additionally, our analysis has revealed the problem of understanding the role of software product manager and common lack of knowledge related to software product management. Interviews with experts have confirmed that people who in fact deal with the software product management may have different job titles (i.e. project manager, function manager, brand manager, product delivery manager), which can result in their lack of awareness of their duties and responsibilities. This may translate later on into making wrong business decisions that have a negative impact on the development of entrepreneurship, companies and products. Also, the relation of the software product manager and the Product Owner and the collaboration of the product manager with agile teams [22], [23] needs further research.

The proposed personas may be used as a guidance and learning targets for software product managers and the top-level management, where the possible practical applications include: (1) education and training of software product managers both in the industry and academia; (2) self-development of the current software product managers, in particular seeking to switch the business environment; (3) support for the managers of the organizations planning to hire software product managers or build a software product management team; (4) increasing the awareness and understanding of the software product manager's role by other members of the team and organization. Users can learn on the various details of the software product manager's role from the personas and possibly find their own missing skills, new tools to master or new techniques to apply.

The research shows that there are many aspects of software product manager's role that require further research: (1) how Software Product Manager interplay with other roles, (2) which roles in the software engineering process have competences to become a software product manager (3) what affects how product teams are structured and how many software product managers are employed.

ACKNOWLEDGMENT

The authors thank all the experts that took part in the collection of data and the validation of the results.

***Abstract* — Providing stimulating and real-life experiences is a key component in teaching software project management in Computer Science or Software Engineering programs. The diversity of topics that need to be addressed and restrictions that should be considered in university courses make a challenging task of it. This paper presents a serious game, called "White Crow PM" whose objective is to make students aware of the risks they might face during software development projects. The paper describes the game design steps and provides results of its validation in Computer Science programs in two Mexican universities. The collected data showed that the participants had fun playing the game and its content is relevant for software project management courses. Although the game needs to be validated in other settings with more participants, we conclude that it fulfills the goal of motivating discussion and increasing awareness of project management concerns among students.**

I. Introduction

DEVELOPING software systems require organizations to implement appropriate software project management practices. Industrial standards, such as ISO/IEC 12207 [1] or ISO/IEC 29110 [2], include specific processes to address activities and tasks for planning, monitoring, and controlling a software project. Indeed, software project management activities represent a core knowledge area in Software Engineering (SE) [3] and teaching them is supported by organizations such as IEEE and ACM through guidelines for curricula development [4].

SE curricula guidelines recommend students carry out activities in which they develop projects for a real client or get involved in software development during professional training [4]. However, in the area of software project management, a future IT professional lacks practical skills given that most project management syllabi are highly theoretical [5]. In addition, to understand technical challenges, software professionals also need to understand nontechnical issues such as management, communication and teamwork [4] [6].

In contrast with current practice of teaching SE topics by means of lectures, addressing these topics in SE courses require learning strategies that promote application and transfer of knowledge to authentic contexts where knowledge supports making decisions in real-life scenarios [7]. Furthermore, other constraints, such as class duration and instructor's effort impact on the extent project management practices can be carried out in either real or simulated scenarios [6] [8].

An attractive approach to address the aforementioned issues, within a risk-free environment, is the use of games with learning objectives as outcomes [5]. Educational games, also known as *serious games*, pursue the purpose of teaching, changing an attitude or behavior, or creating awareness of a certain issue [9].

Games offer enjoyment, motivation, social interaction and gratification; factors that support learning process [10]. Besides, serious games provide a variety of approaches for learning and teaching, becoming a complimentary tool to achieve specific learning outcomes [6]. According to [11], using games motivates students, immerses them in learning materials and supports learning from their own mistakes.

Several serious games have been proposed to achieve learning goals in SE. They address knowledge areas such as software process, software design, and professional practice [6]. However, few serious games proposals have been evaluated in the computer science domain and even less in software project management [5]. Therefore, given the complexity of SE topics, specificities of teaching SE in universities, and the variety of domains related to software project practices, there is a necessity to explore the advantage of using serious games in supporting SE related learning outcomes.

Serious games can be classified as digital or non-digital. While the former might be a computer application game, the latter might include card games and board games, among others [5]. Board games, in particular, are easy to use, allow interactivity between players, and provide a platform to carry out frequent and inexpensive updates [10].

This paper presents a board game whose objective is to make students aware of risks they might face during a software project and practices they can apply to mitigate them. The board game simulates an environment of a small organization carrying out a software project during a month. The game is targeted to undergraduate students in Computer Science and SE programs who already have introductory knowledge of project management.

This paper is organized as follows, Section II presents the concept of serious games and project management board games. Section III presents White Crow, the original board game. The adapted board game and its validation are

described in Sections IV and V respectively. Finally, conclusions and future work are presented in Section VI.

II. Background

A. Serious Games in Software Engineering

A game is defined as "an activity engaged in for diversion or amusement" [12] as well as "an activity…usually involving skill, knowledge, or chance, in which you follow fixed rules and try to win against an opponent or to solve a puzzle" [13]. While preserving the element of entertainment, a serious game focuses on achieving learning outcomes or educational goals, such as learning specific skills and concepts [6].

The increasing use of serious games inject more fun in both learning and training context due to the power of game to motivate players and the capabilities of them to facilitate cognitive gain, awareness and behavioral change [14]. The use of games on different educational levels has been demonstrated to motivate players to achieve goals, to stimulate interaction, and to encourage players to learn by doing, among other benefits [15]. Although digital games provide a lot of opportunities to incorporate multimedia resources to improve the user experience, they can be prototyped in paper [16].

Thus, working with non-digital games, such as board games, provides the opportunity to explore and gather the initial ideas on the game by the developer team and other stakeholders. In addition, learning from one another while at the same time having fun are experiences that a board game can provide [15].

In the context of SE, the use of games is motivated by the fact that traditional lectures barely address in practical way real life experiences where students make decisions and explore scenarios [6] [10]. Limitations on time or students' availability for participating in software projects are challenges that make deployment of software practices in real-life contexts difficult [6]. Indeed, providing real life experience in managing projects becomes almost impossible in SE education [6].

There is a growing presence of studies related to serious games in SE. Souza et al. [6] reported 86 papers that describe the use of serious games in SE education, and whose learning goals are related to the knowledge areas of software process, software design and professional practice. However, the authors do not decompose the 'software process' category in order to identify studies related to software project management. In a literature review on serious games in education, Calderón and Ruiz [5] reported that only 10% of papers correspond to the Computer Science domain and only two papers present games related to software project management.

B. Board Games for Project Management

Board games support understanding and learning of abstract concepts; their immersive nature facilitates attention, concentration and motivation [17]. Board games allow a learning-by-doing approach; in addition, game competitiveness urges players deeply understand the rules behind the game, and promotes reflection and discussion among players [17].

However, board games for project management are barely addressed in the education domain [5] [18]. Telukunta et al. [19] developed a game called StrateJect, which is similar in design to the Monopoly game. It is a computer game in which players experience consequences of executing or neglecting important project management functions in alignment with PMBoK 5 concepts. Taran [10] proposed a risk management board game in which students gather experience in making decisions involving risks. The game does not include teaching specific practices for risk management because it expects students to learn by their own experience.

Another board game is Deliver! [8]; its objective is to reinforce and teach the application of earned value management concepts targeted to students in undergraduate computing programs. In addition to the perceived potential to learn earned value management concepts and procedures, the game is reported to have a positive effect on social interaction, engagement, immersion, attention and relevance to the course objectives [8].

Other proposals address games for either training software practitioners in daily scrum meetings or learning software processes. In the first case, Yilmaz [20] provides a case study in which the focus is on identifying issues in testing scenarios related to the way a daily scrum meeting is conducted. Within a virtual reality environment, learners interact with virtual personas that have distinct personalities traits in order to trainees get clues about the issue presented in a scenario.

With regard to software processes, Aydan et al. [18] proposed a serious game, called "Floors", to introduce a preliminary training about both vocabulary and processes of the ISO/IEC 12207. The game was designed to visualize a virtual office environment and 3D character models that explain definitions and activities of the processes. Based on quests and dialogues, players can follow the processes organized by a software life cycle model.

C. Evaluating a Serious Game

The primary method to assess a serious game is a questionnaire that is typically applied after the game is played [5]. Questionnaires may include both quantitative and qualitative questions, however, the Likert scale is the most common method to gather participants' perceptions of the game [5]. Students' perceptions are measured by such variables (constructs) as belief, motivation state, expectations and emotions [8]. Actually, "evaluation from student's perceptions represents a simple, quick and less intrusive alternative to obtain feedback" [8].

We used a questionnaire from Wangenheim et al. [8], which focuses on evaluating students' feeling after playing a serious game; we adapted this standardized questionnaire and added concepts from the Kirkpatrick's evaluation model [21]. Altogether the questionnaire assesses motivation, game user experience, learning aspects, and students' perceptions.

Observation is another method used to evaluate serious games [5]. Observations are carried out by facilitators who observe game sessions either to get a general impression or to monitor any particular aspect of interest.

Several aspects can be evaluated in a serious game. Calderón and Ruiz [5] report that learning outcomes, usability and user experience are the most commonly evaluated. The first aspect refers to what learners should know or be able to do as a result of playing a serious game. Usability evaluates both ease of use and learnability while user experience assesses behavior, attitude and emotions.

Other commonly assessed aspects are user's satisfaction (user's attitude towards the serious game), motivation (how the serious game influences users' attention and behavior towards learning outcomes), and enjoyment (whether the serious game is able to provide a fun experience), among others [5].

There are few frameworks to design and evaluate a serious games [16] [22] [23] where mechanics-dynamics-aesthetics (MDA) model is a relevant one. Hunicke et al. [24] proposed this model to understanding games considering both designer and player perspectives in the context of three levels of abstraction: mechanics, dynamics, and aesthetics. The game creators design the mechanics of the game in order to provide a player experience, while player address the game from the aesthetics of the game, i.e., the user experience of playing the game. The model can support the specification of design goals, provides a means to discover game enhancement opportunities and allow to determine the measures to assess the progress in an improvement effort.

The MDA abstractions levels are described as follows [24]. Mechanics defines the game components, including actions, behaviors and control mechanisms. Some game mechanics are levels, tokens, questions and answers, game turns, resource management, and movement [23]. On the other hand, dynamics focused on the behavior of the game considering inputs and outputs. This abstraction level works at systemic level in order to create aesthetic experiences. The aesthetics level is related to the emotional responses of the players when interact with the game. This level can include a fun vocabulary composed of concepts such as: sensation, fantasy, narrative, challenge, fellowship, discovery, and expression.

D. Agile and Lean Approaches for Teaching Project Management by Means of Serious Games

Several games have been proposed to learn principles and practices of lean and agile methods in managing a software project. For lean approaches, Przybylek and Olszewski [25] proposed a game-based extension to Open Kanban. They suggested 12 games to address the four principles: visualization of the workflow, learn and improve, limit work in progress and lead using a team approach. As a result of validating the game-extension of Open Kanban, authors reported improvements in participants' communication, commitment, motivation, and the teams understood the main values and practices of Open Kanban [25]. Another proposal presented a collaborative Kanban board game for a software project management course [26]. The game's learning goals addressed both general description of the Kanban process and detailed aspects of the relationship between work in progress limits, lead time, and bottlenecks. The empirical results showed that learning goals were partially achieved. As for the attitudes towards the game, the participants' feedback reported a positive and highly motivating experience [26].

Incorporation of Scrum in the industrial sector has also been addressed. Several researchers have developed serious games to introduce and reinforce scrum practice. For instance, Przybylek et al. [27] [28] proposed to equip Scrum teams with a set of serious, collaborative games to address social aspects of software development. In turn, De Souza et al. [29] designed SCRUMI, an electronic serious board game for teaching Scrum concepts. In order to move forward through the game, participants have to answer questions on Scrum practices, which are grouped into five phases: preparation, analysis, execution, monitoring and control, and closing. Having evaluated the game, the authors reported that students felt motivated, satisfied and had fun playing the game [29].

SCRUMIA, on the other hand, is a manual paper and pencil game to reinforce the application of Scrum in undergraduate computing programs [30]. The game's main objective is to create artifacts while executing the Scrum process. In the validation results, the authors reported that SCRUMIA was effective, efficient and engaging for teaching Scrum practices [30]. Authors in [30] [31] mention several other games centered on different learning goals related to Scrum; however, despite the relevance of agile and lean methods, there is still a shortage of games addressing these topics [26].

III. WHITE CROW BOARD GAME

The board game presented in this paper is based on a Russian board game called Belaya Vorona (Белая ворона), which is White Crow in English. The label "white crow" in Russian describes a person who is different and stands out in the crowd; it may have a negative connotation similar to "black sheep". As the inventors of the game wrote, "try on the feathers of a white crow: break free and get individuality". The game was created in the post-soviet period, pursuing the idea of changing and embracing the world of business.

The game simulates a month of economic life with the objective of maintaining a healthy economic status by doing business. In the course of the game, the players are constantly affected by unexpected situations that impact their finances for the better or for the worse and, if they do not act accordingly, may result bankrupt.

The original board game consists of:

- A dice
- Five tokens
- A game board (see Fig. 1)
- Play money
- 64 mail cards
- 16 business cards
- A notepad for tracking loans and investments.

During the game, the players get familiar with such concepts of business and banking as investments, deposits, loans, rates, bank shares, clients, profits and expenses. It also shows the importance of risks, luck, enterprise and caution.

Fig. 1. Game board. Image taken from the original game Belaya Vorona produced by Design Studio Art Lestnitsa, Centre of Prospective Projects.

Each player decides their banking policy in advance: whether they will invest or ask for loans. Besides, at the beginning of each round, players receive an amount of money, with which they can buy businesses (square Бизнес "business") and cover unexpected expenses. Any business they own pays back in case the player gets on the square Клиент "client". The unexpected expenses are either laid out on the game board or come by mail (square Почта "mail"). Each month corresponds to one round, and the winner is the player who saves the biggest amount of money by the end of the game.

A business can be bought by any player who lands on the square Business. The player must take a business card and decide whether to use the opportunity or to discard it. For example, Fig. 2 shows a business card Subway "Falcon". If a player decides to invest in this business opportunity, she/he must pay 1,500 units of play money[1], which is indicated in the first upper line as плата "charge", to the bank.

The investment pays off when the player lands on the square Client. In the case of the card in Fig. 2, the lucky player receives 2,000 rubles as indicated in the second line by the word цена "price", thus obtaining a 500 rubles profit.

The third, bottom line комиссионные "commission" indicates the amount of money that is given to another player. To do so, all the players except the business card owner roll the dice, and the player with the highest points receives the "commission" money, 150 rubles in the case of Fig. 2 card. In the adapted version of the game, this transaction was omitted for reasons of simplification.

Fig. 2. Business card. Image taken from the original game Belaya Vorona produced by Design Studio Art Lestnitsa, Centre of Prospective Projects.

If a player lands on the square Mail, he/she must take a mail card and to act according to its instructions. In Fig. 3 mail card the player must pay 150 rubles, indicated in the left top corner as оплатить "to pay", to the bank for an emergency surgery the player had to undergo, which is explained in the right top corner of the card while the bottom of the card contains the name of the charging establishment.

We considered the White Crow board game to be suitable for adaptation due to its similarity with running a software project. The adapted game, White Crow PM, is based on simulating software project related activities and is meant to convey concepts of project management, risks and decision making. Similar to the original game, in the adapted version, players decide how to manage their money working on a software project during a month.

Fig. 3. Mail card. Image taken from the original game Belaya Vorona produced by Design Studio Art Lestnitsa, Centre of Prospective Projects.

One of the main goals of the adapted game is to make players aware of unexpected risks and associated expenses in software project management alongside with helping software engineering students realize what can go wrong or right and how well they can be prepared for it.

[1] In the case of the original game, rubles are used.

IV. WHITE CROW PM FOR SOFTWARE PROJECTS

A. Ad-hoc methodology to adapt the game

In order to narrow the general business-related scope of the original game and to shift its focus onto software projects context, we adopted an ad-hoc methodology, which was composed of 7 major steps.

The first step was to play the game to ensure it had an acceptable level of entertainment and challenge. Then it was translated from Russian into Spanish by two of the authors.

The second step was to analyze the original translated game, looking for the elements to be modified in order to simulate a software project without affecting the game's logic and flow. The 64 mail cards and the 16 business cards were reviewed, concluding that the prices were to be preserved but the number of cards might be increased. Moreover, the commission related rules were eliminated in order to simplify the game.

The third step consisted in rewriting the mail and business opportunity cards to suit software project related situations. The situations were designed by Computer Science students and professors, which was part of the final assignment of a Software Engineering advanced course and were based on their practical experience. In addition, selected papers and books were provided by the professors as a source of ideas for the students.

The fourth step was to develop a proof of concept for the new version of the game. The game was played by Computer Science students; the following aspects were examined:

- A1. Readability and clarity of the game rules.
- A2. Coherency and accuracy of the situations.
- A3. Students' perception of gaining knowledge.
- A4. Level of entertainment of the game.
- A5. Duration of the game.

Once the aspects to be improved were identified, a new version of the game was created.

During the fifth step we carried out a beta test of the game with students enrolled in an introductory Project Management course. 10 Applied Mathematics and Computation students, divided in 2 groups of 3 and 1 group of 4, played the game.

Afterwards, they answered an online questionnaire that measured aspects A1 to A4 using a Likert scale (1 to 5 scale values) while aspect A5 was measured by the two authors of the paper who observed the activity.

The results of the survey were as follows. For A1. Readability and clarity of the game rules, a median of 4.0 (42 out of 50 points) was obtained. For A2. Coherency and accuracy of the situations described in the cards and board, a median of 5.0 (46 points) was obtained. A3. Students' perception of gaining knowledge produced a median of 4.5 (45 points). Lastly, A4. Level of entertainment reached a median of 5.0 (50 points).

Regarding A5. Duration of the game, it was noted that a round to the board took 19 minutes in average while a recommended duration was two rounds. Overall, a 60 minutes class provides enough time to present the game, explain its rules, play two rounds and discuss the outcomes.

Through the same questionnaire we collected improvement suggestions to the board game, most of which concerned the game board and cards aesthetics. However, an important adjustment to the rules was suggested. The first round of the games was perceived as "slow" by the participants because of the "small" amount of money they received at the beginning of the game, hampering the possibility to invest and take advantage of the business opportunities early in the game. With that in mind, the players will receive a one-time initial bonus at the beginning of the first round.

The sixth step consisted in validating the new version of the game. This step is described in detail in Section V.

The last step was the socialization of the game, making it available to other professors and students.

B. White Crow PM [2]

In this subsection, the latest version of the board game is presented.

At the beginning of the game a bank manager is appointed, and each player decides their banking policy: they can either make savings or ask for loans. The purpose of this restriction is to offer the players a moment of decision making, facing up to its consequences later. The rates and interest can be agreed upon, those recommended by the game are 10%. Each player receives a one-time bonus of 1,000 units of play money and decides how much money they want to keep or deposit.

The game is best suitable for 3 to 5 players and it includes: a game board (see Fig. 4), 72 email cards, 20 Opportunity cards, tokens, a dice and play money. These components correspond with the Mechanic abstraction level of the game, according to the MDA model.

The Dynamic abstraction level of the game is described as follows: When a player gets to:

Email square: they have to take an email card. Email cards describe various aspects of a software project, such as Process related (Planning, Monitoring, Closure, Requirements, Design, Construction, Integration, Testing); Product related (Functionality, Reliability, Usability, Efficiency, Maintainability, Portability, Compatibility, Security) or Team related (Organization, Collaboration, Communication, Environment), which are indicated on the left side of the card. At the top, there is a short title of the situation, followed by an indication to pay or to receive, and a more extended description of the situation. The majority of the email cards requires the player to pay for some unexpected expenses while the rest recover money for the player.

[2] The White Crow PM latest version (in Spanish) can be downloaded from https://goo.gl/NjqMKo

Fig. 4. White Crow PM board

Fig. 5 shows email cards related to the Team communication and the Integration phase in a project. All the transactions must be made at the moment of getting the card. In case an email card indicates the amount to be paid per month (see Fig. 5, right), the player must multiply this amount by the number of months already played. This type of cards contains situations that have a wider impact on software projects, for example, an appearance of bugs in modules from first iterations. The rationale behind this modification was the importance of timing in discovering and solving issues.

Improvement opportunity square: the player has to take an Opportunity card and decide whether they want to use it or not. An Opportunity card offers an improvement related to software projects and mitigates unexpected expenses from email cards. The player must pay an indicated price to use it, however, they may choose to discard it without using.

The Improvement opportunity cards replaced the Business opportunity cards from the original game. An opportunity card does not provide any financial benefit for the player; it, however, mitigates risks or expenses from Email cards.

Fig. 6 shows an Improvement opportunity card, in which an investment in a software architect mitigates possible extra costs related to software construction and maintainability, while Fig. 7 shows an agile oriented opportunity.

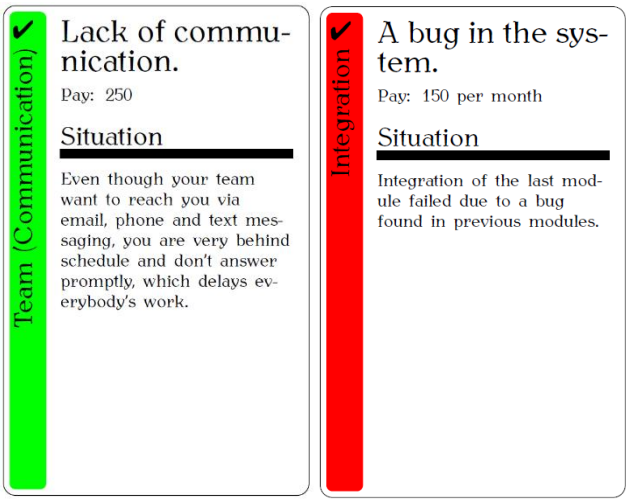

Fig. 5. Email cards, from White Crow PM

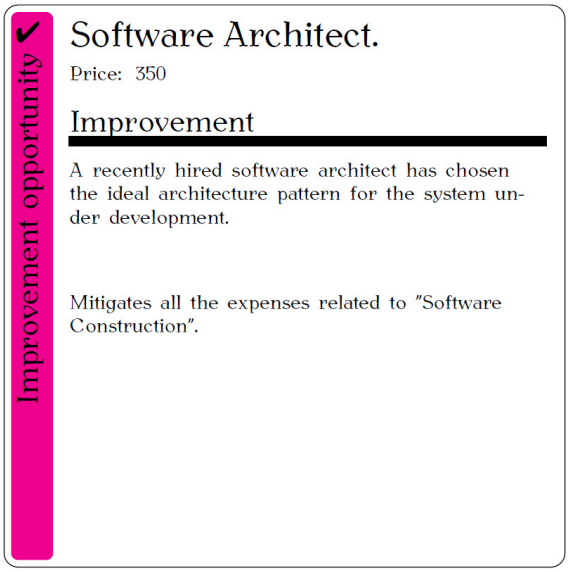

Fig. 6. Opportunity card, from White Crow PM

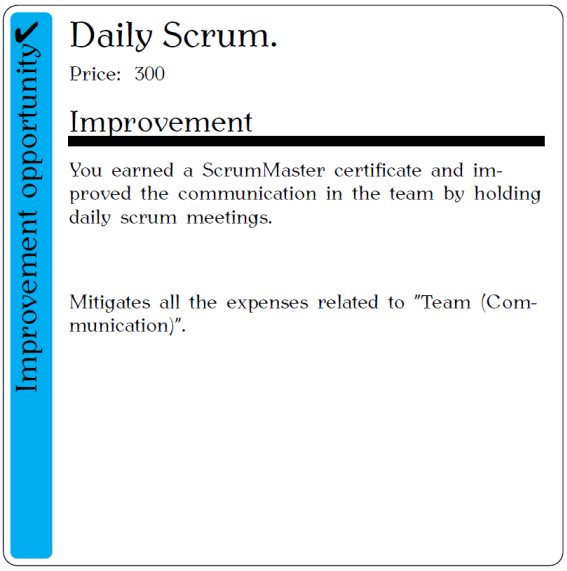

Fig. 7. Opportunity card, from White Crow PM

Bonus: players follow the instructions on each respective Bonus space, which always have a positive effect.

Expense: players follow the instructions on each respective Expense space, which always have a negative effect.

Gambling: each player bets 100 units of play money and throws the dice. The player to get the highest number wins all the money. This feature is preserved from the original game; it highlights occasional good or bad luck and gaming experience.

Last minute change: every player must go back one space and follow its respective instructions. Students become aware of unexpected changes in the project development.

A new project manager on the team: each player must hand over 50 units of play money. The money is kept in the space at the bottom of the board till one of the players gets a six on a dice roll and collects all the money.

Special offer: the player's expenses for the next two weeks will be reduced by 50%.

Break: players take a "day off".

Day of the White Crow: each player must pay any rates generated by bank loans, and receive 325 units of play money and interests, if any.

The game finishes by the end of the agreed number of rounds, and the player with the biggest amount of money is announced the winner.

V. Validation and Results

The hypothesis that guided this work is defined as follows: educational games contribute positively to achievement of learning objectives, motivate students, and promote a pleasant user experience.

With the aim of testing this hypothesis, the board game was validated in four groups of students from two Mexican universities. In total, 15 participants played the game; Table I presents a summary of the groups composition. The 4 groups were considered to have a homogenous academic background, cultural context and interest in the topic.

Table I.
Groups composition

Summary of groups			
University	**ID**	**Size**	**Degree**
A	Group 1	4	3 Engineering 1 Mathematics
	Group 2	3	3 Computer Science
B	Group 3	4	4 Computer Science
	Group 4	4	4 Computer Science

To obtain feedback and the student's perception of the game, a 4-section questionnaire was applied to the participants:

- **Basic information (5 questions):** questions in this section targeted students' academic background and experience, if any, in software projects.
- **Gaming Experience (15 questions):** questions in this section were based on the questionnaire presented in [8], and evaluated motivation, user experience and learning components. We used a Likert scale with response alternatives ranged from "strongly disagree" to "strongly agree" on a five points scale from 1 to 5.
- **Emotions (18 options):** this section consisted of a list of emotions, and each participant was invited to choose those experienced during the game.
- **General opinion:** the last section invited the participants to suggest improvements and to write their perceptions and opinion. We also included a question to evaluate how similar email and opportunities situations were to real projects, which was graded using Likert scale.

Table II shows a summary of the results of the Gaming Experience section, column M represents the median.

The analysis of the results points out that the participants had fun playing the game (5.0) and found it easy to understand (5.0). Moreover, they believe that the game content is relevant to their interests (4.0), is connected to other knowledge they already acquired (4.0) and suits their way of learning (4.0). As a whole, the dimensions of relevance, fun, satisfaction and learning were graded highly.

TABLE II.
GAMING EXPERIENCE SECTION RESULTS

Motivation	
Attractiveness	**M**
1. The game design is attractive.	**4.0**
2. The form, content and activities helped me to stay focused on the game.	**4.0**
Relevance to learning interests	
3. The content of the game is relevant to my interests.	**4.0**
4. The way the game works suits my way of learning.	**4.0**
5. The game content is connected to other knowledge I already have.	**4.0**
Confidence	
6. It was easy to understand the game and start playing it as learning material.	**5.0**
7. While playing the game, I felt confident that I was learning.	**4.0**
Satisfaction	
8. I feel positive because I know I will have opportunities to use what I learned playing this game in practice.	**4.0**
User experience	
Social interaction	
9. I had fun playing with other people.	**5.0**
10. The game promotes moments of cooperation and/or competition among players.	**5.0**
Fun	
11. This game has an adequate level of challenge for me; the tasks are neither too easy nor too difficult.	**4.0**
12. The game progresses at an adequate pace and does not become monotonous; it offers new obstacles, situations or task variations.	**4.0**
Competence	
13. I had fun playing the game.	**5.0**
14. When interrupted at the end of the class, I was disappointed that the game was over.	**4.0**
Learning	
Short-term learning	
15. I achieved the goals of the game applying my knowledge.	**5.0**

The participants' comments highlight learning aspects of Risks, Planning and Resource Management, in their own words: "Risks can affect and hamper my projects"; "It is better to be prepared to face them"; and "Good investment can help me to avoid risks". The comments also point to an increased PM-related awareness among students; measuring PM-related learning is out of the scope of this research stage.

An important factor to take into consideration was students' feelings and emotions while playing. Their evaluation allows us to gain insight into the user's experience and attitude towards the game.

This information was collected in the Emotions section, in which the participants were offered a list of emotions to choose from. These data is a first approach to describe the Aesthetics abstraction level of the game.

The results are shown in Table III. Positive emotions are preceded by a plus sign (+) while negative emotions are preceded by a minus sign (-). The number in the second column indicates how many participants chose the respective emotion.

TABLE III.
EMOTIONS QUESTIONNAIRE RESULTS

Emotions	
+ Interested	13
+ Eager	7
+ Optimistic	7
+ Focused	6
+ Confident	6
+ Happy	5
+ Capable	5
+ Relaxed	4
+ Immersed	4
+ Challenged	4
+ Satisfied	3
+ Encouraged	2
+ Useful	2
- Angry	2
- Bored	2
- Sad	1
- Lost	1
- Stressed	0

It can be noted that the negative emotions where chosen by far less frequently than the positive ones.

Finally, the last section of the questionnaire provided improvement suggestions and opinions of the game. On the one hand, the general opinion expressed was positive; it was fun, interesting, and a good idea that could be used more frequently in classrooms. The similarity of the presented situations with real projects obtained a median of 4.0, which we consider a positive score.

The participants mentioned: "It was a game but those things (situations presented) might happen in real life"; "My

interest for the subject increased"; "Very entertaining and easy to play, moreover, it gave me a good perspective of a software project"; and "I had a lot of fun, I like it, the situations are real".

On the other hand, creation of more opportunity cards was suggested; reading them before the game starts in order to have a wider vision of the game possibilities was also mentioned.

Another repeatedly commented aspect was the possibility to increase opportunities for collaboration between players. Lastly, an inclusion of a tip or advice in the email cards is seen as a possible path to provide more leaning opportunities. These improvements will be tackled in a future version of the game.

A. Threats to validity

In order to mitigate threats to validity, various factors were considered during the board game design and validation. Different causal relations were examined:

- **The number of participants.** Although the number of participants is not large, we consider the sample to be representative of students enrolled in Computer Science courses. However, validating the game with a small set of participants reduces the possibility of generalizing the results.
- **The questionnaire's trustworthiness.** The applied questionnaire is an adaptation of a recognized and proven instrument specialized in the evaluation of training and learning resources [8]. We are aware, however, that such aspects as game appropriateness and engagement are difficult to measure and were captured through subjective measures.

In spite of the limited number of students that participated in the validation, each student can be categorized as a typical Computer Science student, which is the target audience of White Crow PM. The selection of the participants was not intentional; the students who participated in the validation expressed their interest in participating.

Another factor to highlight is that the game applications were guided by several facilitators, 3 out of 4 groups were guided by professors not familiar with the game before. This factor supports the easy to use and apply claim.

The case studies were carried out by three researchers and the results were constantly triangulated to third parties, such as colleagues and members of the research group.

In order to improve the validity of this study the following approaches cited in [32] were taken into account:

- **Triangulation** was possible due to an active participation of two professors in the data collection process. Thus we were able to analyze different data sources: questionnaires and direct observations.
- **Peer debriefing** took place in all game applications. In addition, findings and results were periodically discussed with other members of the research group.

The game board applications demonstrated that the objective for which it was created was achieved, as it made students aware of risks they might face during a software project and of practices they can apply to mitigate them. In addition, the board game motivated students and promoted a pleasant experience.

Finally, the limitations of the case studies can be summarized in two points:

- The sample size is small, which therefore limits the power of generalization. It is necessary to apply the game in bigger populations.
- Bias in the game application could have occurred due to the participants' feeling of being observed and evaluated. This may have led to an alteration in their actual behavior.

VI. Conclusions and Future Work

Simulating a software project and making students face consequences of their decisions pose a challenge due to diverse internal and external factors. Therefore, games and simulations play an important role in creating abstractions and simplifications of real life software development [6].

Serious games represent a powerful learning tool in the field of education. Their teaching potential and entertaining aspect provide an alternative to traditional learning process in the classroom. Moreover, serious board games are cheaper and easier to apply, and allow educator to identify on-site advantages.

White Crow board game, adapted to the software projects context, resulted in a successful and useful resource to introduce students into software project management, and make them aware of its complexity, unexpected variables and the importance of decision making.

The students' opinions obtained through the questionnaire and the observations allowed us to conclude that the game supports enjoyment, motivation, social interaction and gratification; factors that support learning process.

As future work, improvements on the cooperative factor of the board game are considered, for example, being able to make agreements between players and the bank as well as between players. Besides, since cultural aspects also count, and this version of the game is based on the Mexican way of running a project, the situations in the cards could be tailored to other cultures.

Another interesting future research line might be creating an agile-oriented version, based on a 30-day sprint with players using a product backlog and specific PM events explicitly included in the board. More validation forms, such as in-depth interviews with experts and participants, are considered in order to enrich the qualitative analysis of the results.

Acknowledgment

The authors would like to thank Computer Science students Mauricio Esquivel Reyes, Anahí Quiróz Jiménez, Nancy

Matias Hernández and Karla Andrea Contreras Maya, who collaborated in the adaptation and validation of the game.

Also, special thanks to the professors Guadalupe Ibargüengoitia González, Gabriela Martínez Quezada and Maribel Santiago Luna, who kindly agreed to apply the game in their groups.

Usability attributes revisited: a time-framed knowledge map

Paweł Weichbroth
Faculty of Management, WSB University in Gdansk,
ul. Grunwaldzka 238A, 80-266 Gdansk, Poland
Email: pawel.weichbroth@hotmail.com

***Abstract*—Software usability plays a major role in the quality perceived by its users. However, a variety of definitions and associated attributes shows that there is still no consensus in this area. The overall purpose of this paper is to present the results of a critical and rigorous literature review, the aim of which is to demonstrate all the relevant usability definitions and related attributes introduced till now. This comprehensive view, depicted by a time-framed knowledge map, provides an in-depth understanding of the observed evolution on the one hand, and also serves as a guide for usability engineers to address some non-functional requirements, on the other.**

I. Introduction

DISCUSSING usability in general is one thing, but explaining its nature in detail in an applicative manner is another. An ordinary user of any application or device would point to ease of use when asked about the primary attribute of its usefulness. Indeed, in an article for Time Magazine, Tim Bajarin, while discussing "*6 Reasons Apple Is So Successful*", placed this answer in second place [O1]. Beyond this, market success is the hard work of not only the sales department, but mostly, visionary usability engineers.

To design and produce usable software, the concept of usability must be understood. However, till now, a plethora of definitions and related attributes, on the one hand, do not make it easy, while on the other, a flood of buzz words make it even worse. To fill this gap, we investigate existing models and standards to find answers to the research questions: (RQ_1) what is software usability? and (RQ_2) which attributes most frequently contribute to the software usability?

The reasons for performing this study are twofold. Usability is a major concern in every stage of the design process, and now design thinking is regarded as a system that fosters innovation. Secondly, in face of the observable shift from desktop to mobile application, nowadays, usability again captivates the interest of software vendors in adapting their products to the new settings.

The rest of the paper is organized as follows. In Section II, the research method is depicted, followed by the recognition and definition of usability attributes identified in multiple standards and models (Section III). Finally, we conclude the paper and point out future research directions (Section IV). The paper's contributions are: outlining past research, highlighting its drawbacks and providing one synopsis in the form of a time-framed knowledge map (Table I).

II. Research Method

In order to provide the relevant answers to the research questions, the literature survey was based on the approach of Webster and Watson [O2]. A rigorous search process was applied to the existing body of knowledge to identify norms, scientific papers and books, as well as technical reports that contribute to the subject field. The term "rigorous" stands for the reliability and validity of the search process. The former refers to the extent to which its outcome is consistent over time and an accurate representation of the total population under study, and if the results of the study can be reproduced under a similar procedure. The latter is the degree to which the literature search accurately uncovers the relevant sources. The research was composed of three stages, namely, literature search, literature analysis and selection of attributes.

The literature search embraced databases of widely recognized publishers whose scopes correspond to computer science, information systems or similar (e.g. ergonomics). In particular, ACM, Elsevier, IEEE and Springer were searched for the keywords *usability* and *software usability*, followed by a search of aggregated databases that store records of numerous publishers, namely EBSCOhost, Scopus and Web of Science. An electronic search was performed against the metadata of all the publications. Next, only articles published in relevant journals or books were taken into account. However, the abundance of search results pushed us to redefine our query by limiting the search fields to the title, keywords and abstract. Although this search was not exhaustive, it submitted a comprehensive input.

The literature analysis aimed to identify adequate content for the research questions (see Section I). To achieve this goal, firstly, the publications were reviewed to eliminate those biased by a context (user-specific attributes such as: age, occupation, sex or system-specific support features like visually impaired, disability), unrelated to computer systems or tailored to specific project constraints. Secondly, the remaining publications were read completely with a focus on their parts devoted to the subject, in order to catalog valid data.

The selection of attributes stage was based on the following, mutually nonexclusive criteria, applied to all the classified items: (*a*) published in English, (*b*) related to usability studies, (*c*) published by an international standard-

setting body or governmental institution, (*d*) referenced in research papers. The 'charting' technique was adopted to synthesize and interpret gathered qualitative data by sifting, charting and sorting information chunks according to key issues and themes. The final outcome is twofold: a narrative review of the recent research, and a time-framed knowledge map (Table 1) as the research summary.

III. Usability Attributes

Among efforts to explain what the term means, Shackel claims that the definition of usability was probably first attempted by Miller in 1971 in terms of measures for "ease of use" [1].

In 1977, McCall defines usability as "the effort required to learn, operate, prepare the input and interpret the output of a program" [O3]. However, the fact that it was already included as a quality factor did not really imply attention from software engineers, but it was regarded as an extension of general data processing system design. This perspective was typical of its time.

From the late 1970s, through the 1980s, it was in fashion to discuss software and other hardware-based artefacts which were easy to use as being "user-friendly". The question of "what is user-friendly" had little credibility; however, the problem of the efficiency of computer programs was often deliberated. These two issues were recognized together by several researchers, including Bennet (1984) and Shackel (1986), who introduced comparable definitions [O4, O5].

Shackel framed usability in terms of the system: *effectiveness*, the *easiness to learn*, its *flexibility* and user *attitude* [O5]. A formal definition, established in 1991, says that it is "the capability in human functional terms to be used easily and effectively by the specified range of users, given specified training and user support, to fulfil the specified range of tasks, within the specified range of environmental scenarios" [1]. The notion is next split into four attributes: *effectiveness*: "in terms of performance (e.g. time, errors, number of sequence activities) in learning, relearning and carrying out a representative range of operations", *learnability*: "within a specified time from the installation and start of user training" and "the amount of training and user support", *flexibility*: which allows "adaptation to some specified percentage variation in tasks and/or environments beyond those first specified" and *attitude*: "within acceptable levels of human cost in terms of tiredness, discomfort, frustration and personal effort". However, despite the interest that has been aroused around this approach, it appears to have limitations. Flexibility is particularly difficult to specify, communicate and test in a real system development environment. Among others, Preece et al. [O6] also draw heavily on its rationale. Today, flexibility is seldom considered explicitly.

In 1987, the FURPS model was first introduced by Grady and Caswell [2]. In 1992, the original model "was extended to empathize various specific attributes" and re-designated to FURPS+ in which usability is described by four attributes: *aesthetics, consistency*, *documentation* and *human factors* [3].

In response to the need of the software industry to standardize the evaluation of software products using quality models, in 1991, the ISO Organization issued a standard, namely ISO 9126, that specifies six areas of importance for software evaluation, including usability, defined as "a set of attributes of software which bear on the effort needed for use, and on an individual assessment of such use, by a stated or implied set of users" [4]. This standard puts forward three attributes (named as sub-characteristics): *understandability*, *learnability*, *operability* (see also: [O7] and [O8]).

In 1993, Kirakowski and Corbett presented the SUMI (Software Usability Measurement Inventory) method to measure users' perception of software usability, providing three different layers of output. The second layer has five sub-scales: *affect*, *efficiency*, *learnability*, *helpfulness* and *control* [5].

Nielsen (1993) associates usability with five attributes: *learnability*, *efficiency*, *memorability*, *errors* and *satisfaction* [6]. Every definition starts with words "the system should be or have" which, in particular, applies to its capability of being easy to learn, efficient to use, easy to remember, free of errors and pleasant to use. Nielsen emphasizes learnability as "the most fundamental attribute of usability, since most products need to be easy to learn, and since the first experience that most people have with a new product is that of learning to use it", and also relates it to novices' ability to reach a reasonable level of performance rapidly, which indicates the direct relation between learnability and efficiency, i.e. the user interface should be easy to learn so that the user is able to complete a given task successfully in a certain time.

ISO 9241-11 (1993, 1998) [7, 10], along with Bevan (1995) [9], consider *effectiveness*, *efficiency* and *satisfaction* as usability measures. These standards relate to usability as a high level quality objective, which is reflected by its definition: "the extent to which a product can be used by specified users to achieve specified goals with effectiveness, efficiency and satisfaction in a specified context of use". Today, this is the most recognizable usability definition.

IBM's CUPRIMDSO (1994) quality assurance system includes customer *satisfaction* only, with a five-point scale for evaluating the value of the product that results from its effective usage [8].

Constantine and Lockwood (1999) propose five facets, as different aspects of a system and its user interface that contribute to usability: *learnability*, *rememberability*, *efficiency in use*, *reliability in use* and *user satisfaction* [11]. The authors declare that software which "leads its users to make fewer mistakes will be more reliable in use", that is, "in how it functions in combination with its users and in how it promotes reliable human performance". Reliability in use

is more closely tied with the user interface design than with coding and debugging.

Ten years after the introduction of ISO/IEC 9126:1991, the standard was refined by a group of software engineer experts to ISO/IEC 9126:2001. Even though it does not cover all aspects of software quality from the product perspective, it is still the most comprehensive model developed to date. Here, usability is specified as "the capability of the software product to be understood, learned and liked by the user, when used under specified conditions", construed as five attributes: *understandability*, *learnability*, *operability*, *attractiveness* and *usability compliance* [12].

Abran et al. (2003) developed an Enhanced Usability Model, by integrating process-related (ISO 9241) and product-related (ISO 9126) standards, which includes five attributes: *effectiveness*, *efficiency*, *satisfaction*, *learnability* and *security* [13]. To justify the last one, they provide a list of five arguments, particularly referring to ITSEC (Information Technology Security Evaluation Criteria) and to three normative standards (IEC 300, ISO 13407: 1999, ISO/IEC 9126), and eventually closing by indicating that "security is a characteristic of CHI, which is particularly important in an industrial context".

Seffah et al. (2006) elaborate the QUIM model by consolidating ten attributes (originally named factors): *efficiency*, *effectiveness*, *productivity*, *satisfaction*, *learnability*, *safety*, *trustfulness*, *accessibility*, *universality* and *usefulness*, each of which corresponds to a specific facet of usability, identified in an existing standard or model [14]. These ten factors are decomposed into a total of 26 sub-factors or measurable criteria that are further broken down into 127 specific metrics. It seems that the novelty of this work brings into view a complete and legitimate instrument to evaluate usability.

In ISO 9241-210:2010 [15], the usability definition is adapted from ISO 9241-11:1998 [10], along with its set of attributes as well.

The ISO 25010:2011 standard on quality models updates

and brings together previous standards, defining three views of quality: internal quality, external quality and quality in use [16]. Of particular interest in ISO 25010 is the standard's new breakdown of quality in use and usability. The former is defined as "the degree to which a product or system can be used by specific users to meet their needs to achieve specific goals with effectiveness, efficiency, freedom from risk, and satisfaction in specific contexts of use", while the latter is defined the same as in [10, 15]. Usability can either be specified or measured as a product quality characteristic in terms of its subcharacteristics, or specified directly by measures that are a subset of quality in use [O8]. The standard delineates its six attributes (subcharacteristics) [16]:

- *appropriateness recognizability*: degree to which users can recognize whether a product or system is appropriate for their needs;
- *learnability*: degree to which a product or system can be used by specified users to achieve specified goals of learning to use the product or system with effectiveness, efficiency, freedom from risk, and satisfaction in a specified context of use;
- *operability*: degree to which a product or system has attributes that make it easy to operate and control;
- *user error protection*: degree to which a system protects users against making errors;
- *user interface aesthetics*: degree to which a user interface enables pleasing and satisfying interaction for the user;
- *accessibility*: degree to which a product or system can be used by people with the widest range of characteristics and capabilities to achieve a specified goal in a specified context of use.

Compared with the 2001 edition (ISO/IEC 9126-1) [12], two new subcharacteristics were introduced: *user error protection* and *accessibility*, while usability compliance was withdrawn. It is worth noting that understandability was renamed to appropriateness recognizability, along with attractiveness to user interface aesthetics [16].

Similarly (see: ISO 9241-210:2010 and ISO 25010:2011), in ISO 9241-11:2018 [17] the usability definition is adapted from [15] together with its three attributes.

IV. Conclusions

Table 1 shows the final list of all usability attributes, together with the representative references, including also standards from the International Organization for Standardization (ISO), covering usability in human-computer interaction. From the list, the most frequent are *efficiency* and *satisfaction* (each supported by 10 references), *learnability* (9) and *effectiveness* (8). The least frequent are *understandability* and *operability* (3), *memorability*, *errors*, *attractiveness* and *accessibility* (2), while the rest attributes occur only once. The next research step is to determine usability facets relevant for mobile applications.

***Abstract*—Emotions affect every aspect of human live, including work. Numerous studies in software engineering have shown that negative emotions can lower the productivity of programmers. Unlike traditional approaches to managing software development, modern methods, such as Agile and Lean, take into account human aspects of programming. To thoroughly investigate the impact of negative emotions on the work of programmers, a malicious integrated development environment (IDE) was developed. This tool allow a observer to trigger malicious behavior of the IDE. Conducted study have proved its usefulness. Participants reported that it mostly invoked frustration and angry.**

I. Introduction

RESEARCH on the role of emotions in the work of software developers has been deeply conducted in recent years. Finding the relationship between emotional state and productivity, or the quality of the developed code, may lead to the new methods of IT project management, and consequently to improve software development processes. This type of research corresponds to the current trend of research on social aspects in software development projects [1].

The field of affective computing in recent years has provided many algorithms and tools for recognizing the emotions of computer users. However, despite continuous development, they are still imperfect, especially in applications in unusual situations. Therefore, there is a huge demand for input channel data, such as a video clips or biometric data that are labelled by emotions. They can be used to teach algorithms or check new methods of recognizing emotions. Such data sets, especially those consisting of multiple channels, are not widely available to the public.

In the case of the analysis of emotions in the work of programmers, generic solutions are mainly used. With popular algorithms, such as recognizing emotions based on facial expressions, this approach is acceptable. However, the specificity of the work of programmers allows the development of other, dedicated algorithms. One of such approaches is recognizing emotions based on the analysis of patterns of typing and mouse movements [2]. To develop and learn such algorithms, it is necessary to gather data labelled with emotions. However, such data are extremely difficult to obtain from the real working environment. Therefore, laboratory studies are used for this purpose.

Quigley et al. identified thirteen laboratory emotions induction techniques [3]. However, most of them are not suitable for evoking the emotions of programmers during work. They usually rely on inducing emotions through exposure of the participant to visual or audible stimulus. The exception are three approaches: *peripheral physiological manipulations*, *motivated performance* and *physically real stimuli* [3]. In the case of software engineering studies, the first one is not suitable for general use because it requires direct stimuli in physiological systems, e.g. by injecting drugs. Others can be adapted to induce emotions of programmers.

For the purposes of laboratory studies on the emotions of programmers, a malicious integrated development environment, *MaliciousIDE*, has been developed at the Gdańsk Technical University since 2015. The goal of the project is to provide a solution that will induce negative emotions of programmers while working. It is adaptation of the *physically real stimuli* induction technique. In addition, the *motivated performance* was studied during a validation, which involved putting participants under the time pressure.

The rest of the paper is organized as follows: Section II describes the methods used so far in recognizing the emotions of software developers, Section III describes the concept of the MaliciousIDE plug-in, a survey that verified assumptions and architecture of the solution. In Section IV a study in which MaliciousIDE was used as a method to evoke emotions is described. Finally, Section V concludes.

II. Background

So far, a number of research has been conducted in the field of software engineering, which involved recognizing the emotions of IT teams members. Numerous attempts were made to identify emotions using various available channels. However, to the best of our knowledge, there have not yet been proposed methods of inducing emotions developed for the specifics of the work of programmers.

In some studies, general approaches to evoking emotions were used. Khan et al. in their studies tried to induce emotions of software developers by showing video clips, before performing the tasks [4][5].

However, in most studies there were no attempts to evoke emotions at all. In most cases, the researchers only collected

the data useful for recognizing emotions and, at most, obtained information on emotional states based on self-assessment of participants.

The most comprehensive research on utilizing physiological sensors during software developers work was conducted by Müller and Fritz[6][7][8]. During their study [6] on 17 software developers, they collected the following data: electroencephalography (EEG) using a Neurosky MindBand sensor, temperature, electrodermal activity (EDA) and blood volume pulse (BVP) using an Empatica E3 wrist band, and eye-tracking using Eye Tribe. The results of the experiment showed that EDA tonic signal, the temperature, brainwave frequency bands, and the pupil size were most predictive to classify progress of software developers, and brainwave frequency bands, the pupil size, and the heart rate to classify their emotions. Nevertheless, they noted strong individual differences with respect to the correlation and classification of physiological data [6]. Similar differences have also been found in our other studies on the use of sensors to monitor the physiology of computer game players [9].

A relatively new approach, which can be well suited to recognize the emotions of programmers is keystroke dynamics and mouse movements analysis. It is completely non-intrusive and does not require any additional hardware [10]. There have already been attempts to use this method to monitor software developers [2].

However, one of the most popular methods of recognizing emotions, widely used also in the field of software engineering, is the analysis of facial expressions [11][12][13]. It has gained popularity mainly as a universal and non invasive approach. Algorithms analyze video frames to identify face muscle movements and based on the Facial Action Coding System (FACS) [14] assess user's emotional state.

III. Solution

In studies that used real world stimuli methods to evoke emotions, researchers used, among others, widely regarded as horrible, or disgusting animals (spiders, snakes), extreme sports (sky diving, mountaineering), or various types of food [3]. In order to exert an equally significant impact on the emotional state of software developers, we decided to prepare a programmer's nightmare – an unstable programming environment.

An integrated development environment (IDE) is an software which is used to write code, build project and run it. It is a fundamental tool used by the vast majority of programmers. To verify the importance of IDE for the work of programmers and check if its behaviour can affect emotional states, a survey was carried out on a group of 44 software developers, most of whom (61.4%) have professional experience longer than 4 years. Respondents answered three questions regarding the impact of the programming environment on emotions:

- How often do you encounter errors in the IDE?
- Would you change the IDE if it hinders your work?
- Are you getting angry when you can not complete the task because of problems with IDE?

Provided answers, shown in Fig. 1, confirmed that the IDE work and behaviour has an impact on the emotions of programmers. Among all, 68.2% of respondents confirmed that problems with IDE make them angry, and 77.3% would consider changing the IDE in such a situation.

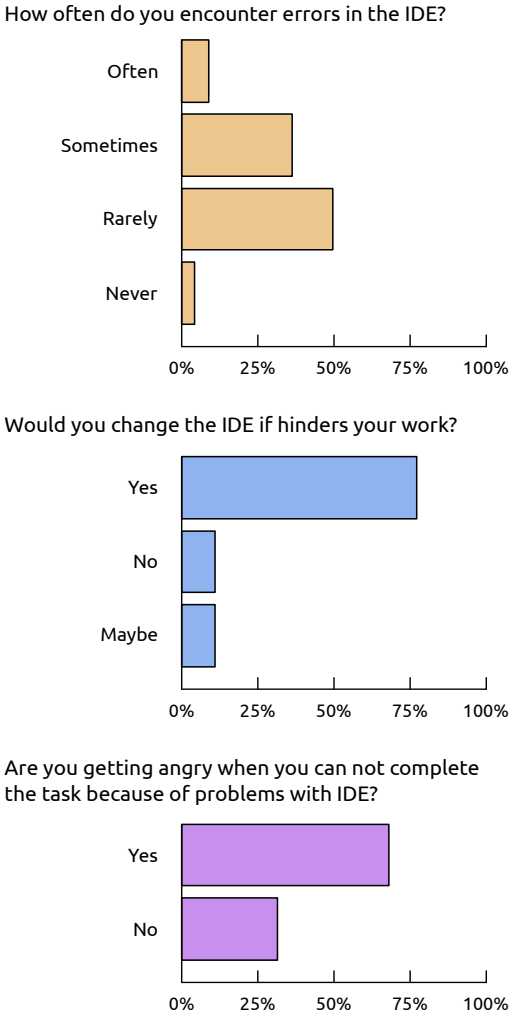

Fig. 1. Survey on the impact of IDE on the emotions of programmers.

In addition, information on the errors encountered by respondents in development environments were collected. It allowed to define seven malices that has been implemented in MaliciousIDE:

1) Clean the clipboard.
2) Delete all semicolons.
3) Freeze whole environment.
4) Hide IDE window.
5) Duplicate keys pressed by participant
6) Minimalize IDE window.
7) Move mouse pointer.

Instead of developing MaliciousIDE from scratch, it was decided to use the plug-in mechanisms, which allows third-party developers to extend the functionality of the program.

The NetBeans was chosen as IDE, on the basis of which malicious behaviour was implemented in the form of a plug-in. It is Open Source, well recognized environment written in Java language.

Preliminary tests of the tool have shown that automatically triggered malices may cause insufficient number of events. For example, users may not notice that the content of the clipboard have been cleaned if it was not used in a particular task. Therefore, it was decided that malices will be triggered manually by the observer, using a remote dashboard (Fig. 2). Thus, an appropriate number of events was ensured. Too few events might not induce emotions, but too much could lead to the disclosure of the malicious activity of the observer.

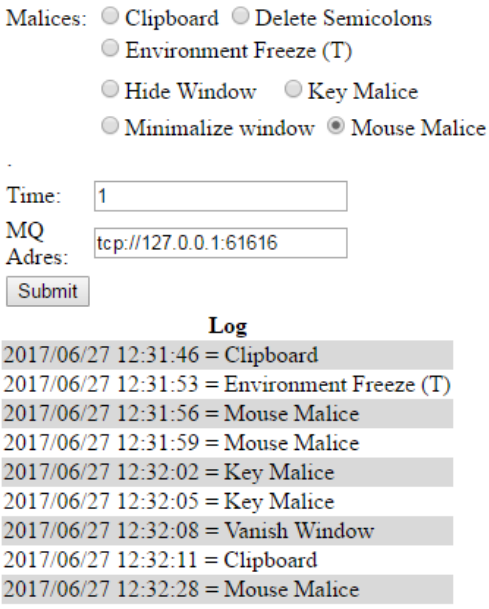

Fig. 2. MaliciousIDE dashboard

Both the plug-in and the dashboard were developed in Java, and in the latter, the Struts 2 framework was additionally used. In order to ensure reliable communication between the two parts of the tool, the Apache ActiveMQ message broker was utilized. MaliciousIDE is released as an Open Source project[1] and can be used freely to conduct research on the emotions of software developers.

IV. Validation

The developed tool, MaliciousIDE, was used during the study conducted in April and May 2017 at a biometric stand [15] in the "Laboratory of Innovative IT Applications" at Gdansk University of Technology (GUT). The aim of the study was to check which input channels can be used to recognize the emotions of programmers during work [16]. Together 35 undergraduate computer science students, including 6 women

[1]http://www.popi.pl/maliciouside

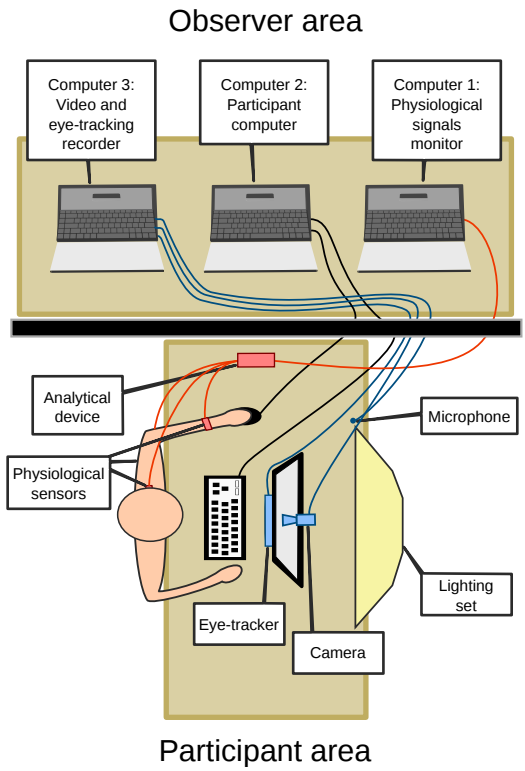

Fig. 3. Study stand

and 29 men, participated in the study. A single session consisted of 5 programming tasks and lasted between 30 and 45 minutes.

During the entire session, the observer was present and controlled MaliciousIDE to evoke the participants' emotions. The most commonly triggered malices were: adding additional characters while entering text, changing the position of the mouse pointer, freezing the environment for 7 seconds, clearing the contents of the clipboard, and temporarily hiding the IDE screen. These actions were carried out to disrupt the work, but in a way that would seem to be a natural behaviour of the application. The frequency of events was manually adjusted so that users remain unaware of the observer's intended actions.

In addition, during the last task of the session, the observer was verbally announcing that the time required to complete the task must be shortened. The purpose of this action was to induce time pressure.

The room was divided into two parts, one for the participant and one for the observer (Fig. 3). On the participant's desk there was a monitor, a keyboard and a mouse connected to the Computer 2, on which the tasks were performed. At the top of the monitor a video camera was located, followed by a lighting set, supplied with Noldus FaceReader software, which was used to recognize emotions based on facial expressions [17]. Underneath the monitor eye-tracker device was located. A number of sensors were attached to the participant body, and were linked through the Coder FlexComp Infiniti by

Thought Technology analytical device with the Computer 1, which was located in the observer area. The observer also has a monitor, a mouse, and a keyboard connected to the participant's Computer 2. A data acquisition program for keystrokes' analysis was also available on the same computer [2]. MaliciousIDE Dashboard was running on Computer 3 and was used to control NetBeans plug-in on participant computer. It also collected all other data for the emotions recognition.

After completing all tasks, the participant was asked to complete a survey implemented using the Google Forms service. Among other questions, participants were asked to name the emotions caused by the unstable IDE. In the answers the most frequently appeared irritation (42.86%), anger (28.57%), followed by nervousness (25.71%) and frustration (11.43%). Four of the respondents (11.43%) indicated amusement (Fig. 4). A post-study informal interview revealed that it was related to the fact that these participants figured out that this unstable work was due to the deliberate action of the observer. The other emotions were pointed out by only one or two people.

On the other hand, the attempt to simulate the approaching deadline by shortening the time of the last task almost completely failed. Nearly half of the respondents indicated that this had no effect on their emotions at all. However, 7 participants indicated that shortening the time was a mobilizing factor, thus having a positive impact on the work attitude.

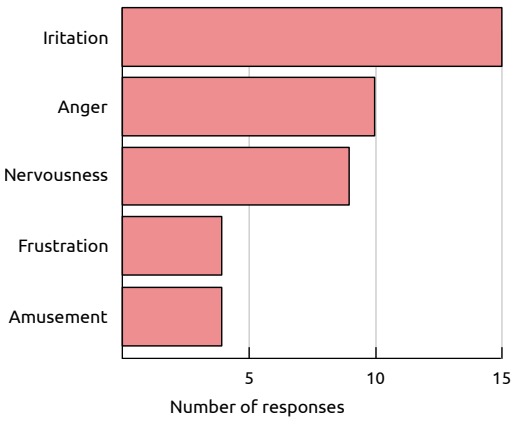

Fig. 4. Emotions induced by malicious behavior of the IDE

V. Summary

MaliciousIDE has been developed to allow researchers to induce the emotions of programmers in a laboratory environment. The presented approach and developed tool can be included to the group of real world stimuli methods of inducing emotions, as it provides a nightmare of programmers – an unstable development environment, which is additionally controlled by the observer.

During the study, emotion inducing method based on the MaliciousIDE has been evaluated. The developed plug-in has proven to be successful mechanism to trigger negative emotions of programmers. While the second approach, shortening the duration of one task, did not turn out to evoke emotions on a significant number of participants.

Joint 38th IEEE Software Engineering Workshop (SEW-38) and 5th International Workshop on Cyber-Physical Systems (IWCPS-5)

THE IEEE Software Engineering Workshop (SEW) is the oldest Software Engineering event in the world, dating back to 1969. The workshop was originally run as the NASA Software Engineering Workshop and focused on software engineering issues relevant to NASA and the space industry. After the 25th edition, it became the NASA/IEEE Software Engineering Workshop and expanded its remit to address many more areas of software engineering with emphasis on practical issues, industrial experience and case studies in addition to traditional technical papers. Since its 31st edition, it has been sponsored by IEEE and has continued to broaden its areas of interest.

One such extremely hot new area are Cyber-physical Systems (CPS), which encompass the investigation of approaches related to the development and use of modern software systems interfacing with real world and controlling their surroundings. CPS are physical and engineering systems closely integrated with their typically networked environment. Modern airplanes, automobiles, or medical devices are practically networks of computers. Sensors, robots, and intelligent devices are abundant. Human life depends on them. CPS systems transform how people interact with the physical world just like the Internet transformed how people interact with one another.

The joint workshop aims to bring together all those researchers with an interest in software engineering, both with CPS and broader focus. Traditionally, these workshops attract industrial and government practitioners and academics pursuing the advancement of software engineering principles, techniques and practices. This joint edition will also provide a forum for reporting on past experiences, for describing new and emerging results and approaches, and for exchanging ideas on best practice and future directions.

TOPICS

The workshop aims to bring together all those with an interest in software engineering. Traditionally, the workshop attracts industrial and government practitioners and academics pursuing the advancement of software engineering principles, techniques and practice. The workshop provides a forum for reporting on past experiences, for describing new and emerging results and approaches, and for exchanging ideas on best practice and future directions.

Topics of interest include, but are not limited to:

- Experiments and experience reports
- Software quality assurance and metrics
- Formal methods and formal approaches to software development
- Software engineering processes and process improvement
- Agile and lean methods
- Requirements engineering
- Software architectures
- Design methodologies
- Validation and verification
- Software maintenance, reuse, and legacy systems
- Agent-based software systems
- Self-managing systems
- New approaches to software engineering (e.g., search based software engineering)
- Software engineering issues in cyber-physical systems
- Real-time software engineering
- Safety assurance & certification
- Software security
- Embedded control systems and networks
- Software aspects of the Internet of Things
- Software engineering education, laboratories and pedagogy
- Software engineering for social media

Improved Analogy-based Effort Estimation with Incomplete Mixed Data

Ibtissam Abnane and Ali Idri
Software Project Management Research Team,
ENSIAS, University Mohammed V, Rabat, Morocco
{Ibtissam_abnane, ali.idri }@um5.ac.ma

***Abstract*—Estimation by analogy (EBA) is one of the most attractive software effort development estimation techniques. However, one of the critical issues when using EBA is the occurrence of missing data (MD) in the historical data sets. The absence of values of several relevant software attributes is a frequent phenomenon that may cause inaccurate EBA estimations. The MD can be numerical and/or categorical. This paper evaluates four MD techniques (toleration, deletion, k-nearest neighbors (KNN) imputation and support vector regression (SVR) imputation) over four mixed data sets. A total of 432 experiments were conducted involving four MD techniques, nine MD percentages (from 10% to 90%), three missingness mechanisms (MCAR: Missing Completely at Random, MAR: Missing at Random and NIM: Non-Ignorable Missing) and four data sets. The evaluation process consists of four steps and uses several accuracy measures such as standardized accuracy (SA) and prediction level (Pred).**

The results suggest that EBA with imputation techniques achieved significantly better SA values over EBA with toleration or deletion regardless of the mechanism of missingness. Moreover, no particular MD imputation technique outperformed the other techniques overall. However, according to Pred and other accuracy criteria, EBA with SVR was the best, followed by KNN imputation; we also found that toleration instead of deletion improves the accuracy of EBA.

***Index Terms*—Estimation by analogy, missing data, imputation.**

I. Introduction

SOFTWARE development effort estimation (SDEE) is the process of predicting the effort required to develop a software system. It is a challenging and substantial activity when managing a software project. The challenge arises due to the complex relationship between effort and various software attributes related to the personal, product, and/or platforms used in the project [1], [2].

Machine learning (ML) based estimation techniques are gaining increasing attention in SDEE research, as they can model the complex relationship between effort and software attributes (cost drivers), especially when this relationship is not linear and does not seem to have any predetermined form [2]. Estimation by Analogy (EBA) is one of the most attractive ML techniques in the SDEE field, and is essentially a form of Case-Based Reasoning (CBR)[3]. The idea of analogy based estimation is to determine the effort of the new project as a function of the known efforts from similar historical projects. Wen et al. [2] carried out a systematic literature review of ML SDEE techniques published between 1991 and 2010 and found that EBA is the most investigated ML technique in SDEE (37% of selected studies).

The intensive and increasing use of EBA is due to its several advantages including simplicity, mimicking human reasoning, ease to understand and no assumption is made about the form of the relationship [1], [4]–[10]. Moreover, EBA can handle both quantitative and qualitative data [5]–[7], [11], [12]. Nonetheless, several studies pointed out that EBA still has some limitations such as dealing with missing data (MD) which is a widespread problem that can affect the ability to use data to construct effective EBA techniques [3], [8], [13], [14]. However, little attention has been given to handling missing data in EBA [3]. In fact, the mapping study of Idri et al.]21] found that until 2015, only one paper was published to deal with MD in EBA.

In a prior work [8], we evaluated two EBA techniques in terms of SA criterion on seven data sets when used in conjunction with three MD techniques (toleration, deletion and KNN imputation method), different missingness mechanisms (MCAR, MAR and NIM) and nine percentages of MD (from 10% to 90%) [8]. This was with the aim of determining whether the KNN imputation method, instead of deletion and toleration techniques, could improve the performance of EBA when predicting software development effort with incomplete data. The findings suggest that EBA using KNN imputation outperformed EBA using deletion or toleration regardless of the missingness mechanism and the MD percentage.

However, the study [8] has three limitations: (1) it only dealt with numerical data , (2) it used one imputation technique (KNN), and (3) it used one accuracy criterion (SA), which is insufficient to conclude about EBA accuracy [15], [16].

Thus, this paper improves our previous work with: (1) the use of both numerical and categorical data, 2) the use of a new imputation technique: Support Vector Regression (SVR), in addition to KNN, and (3) the use of a set reliable accuracy criteria (e.g.. Pred(0.25), Mean Absolute Error (MAE), Mean Balanced Relative Error (MBRE), Mean Inverted Balanced Relative Error (MIBRE) and Logarithmic Standard Deviation (LSD)), in addition to SA, in order to investigate if they would confirm the findings of [8].

Therefore, this study carry out an empirical evaluation of EBA using four MD techniques: toleration, deletion, KNN imputation, and SVR imputation with different percentages (from 10% to 90%) and three missingness mechanisms (MCAR, MAR and NIM) over four mixed datasets including

both numerical and categorical attributes (ISBSG R8, COCOMO81, USP05_FT and USP05_RQ).
Toward this aim, four research questions were discussed (RQs):

- (RQ1) Is there evidence that the use of KNN and SVR imputations rather than toleration/deletion improves the accuracy of EBA in terms of SA when using mixed datasets?
- (RQ2) Is there evidence that SVR imputation instead of KNN imputation would improve EBA accuracy measured in terms of SA?
- (RQ3) Is there evidence that the missingness mechanism and the MD percentage affect the accuracy of EBA over mixed datasets?
- (RQ4) Does the performance of EBA in terms of Pred(0.25), MAE, MBRE, MIBRE and LSD confirm the findings of SA?

The structure of the paper is the following: Section II presents the concepts of MD and EBA. Section III describes the data sets used. Section IV presents the empirical design which includes the process of generate MD and the empirical evaluation process. The results are presented and discussed in Section V. Section VI concludes by discussing the findings as well as some directions for future work.

II. BACKGROUND

This section presents the concepts of MD and an overview of the software effort estimation by analogy process we used in this study.

A. Concepts of MD

This section gives an overview of the different missingness mechanisms (i.e., different ways in which data can be missing) and the different MD techniques.

1) Missigness mechanism

Understanding the missing data mechanism is a key stage in comprehending the impact of the missing data on a specific analysis, or missing data methods [17], [18]. Rubin's classification of Missing Data Mechanisms has been regarded as being "fundamental to the modeling of incomplete data" [19] and is in common use in the field of missing data. Little and Rubin classified missing data mechanisms as[17]:

- **Missing completely at random (MCAR)** is when the probability that an observation is missing does not depend on either the observed or the missing values.
- **Missing at Random (MAR)** means that the probability that an observation is missing depends only on the values of the observed data.
- **Non-Ignorable Missing (NIM):** means that the missing data mechanism is related to the missing values.

2) MD techniques

There are three approaches to this problem: MD deletion technique, MD toleration techniques, and MD imputation techniques [13], [20].

a) Toleration

MD toleration technique is an embedded strategy in which analysis is performed directly on the data set with MD[8], [18]. Despite its simplicity, toleration is not a reliable approach, sometimes even providing estimates that are less efficient than estimation from deletion technique [8], [17].

b) Deletion technique

Deletion is the most commonly used technique for dealing with missing data among researchers [8], [21]. It omits all cases with missing values from the analysis and only includes those cases for which all measurements are observed. This method has many advantages since it is easy to use. Also, it produces unbiased estimates for the parameters if the assumption that the data are MCAR holds. Nevertheless, deletion is not generally recommended since omitting cases with MD would result in a significant loss in power and precision due to the reduced sample size. Moreover, if the MCAR assumption does not hold, this method can result in biased parameter estimates as it is ignoring potential systematic differences between the complete and incomplete cases. Consequently, deletion can only be justified if the missing data mechanism in operation is MCAR and the MD percentage is small [22].

c) Imputation technique

MD imputation replaces missing values by suitable estimates and then applies standard complete-data methods to the filled in data [17].This method is attractive to practitioners because the resulting completed data can be handled using standard software for rectangular data sets. Imputation uses available data to impute the missing data and hence, an important characteristic of a good imputation method is that it makes good use of information in the incomplete cases. Moreover, it is important to take into account the missingness mechanism while using imputation technique [8], [18].

B. Effort estimation by analogy: An Overview

EBA is based on the use of historical information from completed projects with known effort [10]. It is based on the following affirmation: *similar software projects have similar costs*. It has been deployed as follows. EBA has been proposed since a long time as a valid alternative to effort estimation by parametric effort estimation and/or expert judgment [23]. In 1997, it has been presented in the form of a detailed estimation methodology and has been applied on a set of historical software projects data sets [10]. EBA consists of three steps:

1) Identification of cases: each project is described by a set of attributes that are believed to be significant in determining similarity and can influence effort.
2) Retrieval of similar cases: several distance metrics can be used to calculate how much the new target project differs from the other projects based on their attribute values. In this study, we used the Euclidean and the overlap distances for numerical and categorical software attributes respectively [10], [24].
3) Case adaptation: involves two phases in order to generate an estimate of the new project. First, we decide on the number of similar projects and second we define the

adaptation strategy. The number of analogues (*k)* refers to the number of most similar projects used to generate the estimation. Several studies in SDEE analyzed the impact of the number of analogues [9], [25], [26]. This study varied the number of analogues between 2 and 5. The second phase consists on selecting the adaptation strategy to provide an effort estimate. We used the arithmetic mean [10], arithmetic median [27] and inverse ranked weighted mean [28].

In order to select the best variant of ABE, we varied the adaptation strategy and the number of analogues as described above and chose the best configuration of ABE, i.e. having the lowest Mean of Absolute Error (MAE).

III. DATA DESCRIPTION

This study uses four available data sets: ISBSG repository (release 8), COCOMO81[23], USP05_FT[9] and USP05_RQ[9]. Table I provides an overview of these datasets, including number of attributes (numerical and categorical), observations, and previous use. The minimum, mean and maximum of effort and size are given.

Since the aim of this study is to deal with missing numerical and categorical data, the solution adopted was to use (1) all the attributes for the COCOMO81 data set, (2) 11 attributes for USP05_FT and USP05_RQ data sets, and (3) 20 attributes for the ISBSG data set. The attributes chosen for USP05_FT, USP05_RQ and ISBSG data sets are the results of our previous studies related to software effort estimation [4][7][8] . Table III shows the attributes chosen for ISBSG, USP05 and COCOMO81 data sets, where (N) and (C) indicate numerical and categorical attributes respectively.

IV. EXPIREMENT DESIGN

This section describes the experimental process used in this study. It consists of four main steps: data removal, complete data set generation, EBA evaluation using SA, and EBA evaluation using Borda count method based on Pred(0.25), MAE, MBRE, MIBRE and LSD. A similar process was followed in [8]. The study was designed to apply EBA with nine percentages of incomplete mixed data (from 10% to 90%), three different MD mechanisms (MCAR, MAR and NIM), and four MD techniques (toleration, deletion, KNN imputation, and SVR imputation) over four data sets. Hence, the experimental design consists in evaluating 9 percentages × 4 MD techniques × 3 MD mechanisms × 4 datasets = 432 different effort estimation experiments.

A. Step 1: Data removal

The first step in the experimental process requires a complete data set to work with. For this purpose, we first preprocessed the four datasets by deleting cases with MD to obtain the corresponding seven complete data sets. We then used the complete datasets to artificially generate MD by mimicking the different mechanisms. A similar approach was followed in [8], [20]. By combining the four datasets, three missingness mechanisms and nine percentages, we obtained 4×3×9 =108 incomplete data sets at this stage.

B. Step 2: Complete data set generation

This step uses four MD techniques: toleration, deletion, KNN imputation and SVR imputation to generate complete datasets from those of Step 1. After applying the four MD techniques on the 108 incomplete datasets of step 1, we obtained 432 complete datasets.

a) Deletion

Under the deletion technique, projects with missing values at any attribute are omitted in the experiments.

b) Toleration

The toleration technique uses a special value *NULL* to replace a missing value in a data set. A similar approach was used in [8], [13], [14]. Hence, the following operations on *NULL* are defined for distance metrics:

$(P_1)\ \delta(\text{b}, \text{NULL}) = \delta(\text{NULL}, \text{b}) = (\text{NULL}, \text{NULL}) = \text{NULL}$

(P_2) W+ NULL = NULL + w = w

where δ is the distance used in Classical Analogy (e.g. Euclidean distance).

It can be seen from the above discussion that the effect of the *NULL* is to ignore the participating attributes that have MD in searching similar objects. Therefore, the more *NULLs* in the data set, the fewer attributes will be participating in searching analogues through similarity measures.

c) KNN imputation

Figure 1 shows the KNN imputation (KNNI) process. KNN imputation belongs to the analogy based algorithms; it is computationally simple and has proven to be effective approach to estimate missing values of attributes in different software engineering datasets [21]. Using KNN for imputation requires adapting the three analogy steps of Section II.B: (1) Identification of cases, (2) Retrieval of similar projects, and (3) Case adaptation. In the following, we present how we adapted each step to serve the imputation process.

The identification of cases step mainly aims to calculate the distance between each incomplete project and the complete projects. The most similar complete projects were used as source analogues in the imputation process. To determine the distance between the incomplete project and the complete projects, we use a combination of two distance measures. Hence, the distance between an incomplete case P_i and a complete case P_j is calculated using Equation (1).

$$\mathbf{d}(\mathbf{P_i}, \mathbf{P_j}) = \mathbf{d_n}(\mathbf{P_i}, \mathbf{P_j}) + \mathbf{d_c}(\mathbf{P_i}, \mathbf{P_j}) \qquad (\mathbf{1})$$

where:

- $d_n(P_i, P_j)$is the Euclidean distance used to calculate the similarity between P_i and P_j taking into consideration only the numerical attributes. It is calculated using Equation (2):

$$d_n(P_i, P_j) = \sqrt{\sum_{l=1}^{n}(P_{il} - P_{jl})^2} \qquad (2)$$

- $d_c(P_i, P_j)$ is the hamming distance used to evaluate the similarity between P_i and P_j taking into consideration only the categorical attributes. The formula of $d_c(P_i, P_j)$ is given by Equation (3):

$$d_c(P_i, P_j) = \sum_{l=1}^{n} \delta(P_{il}, P_{jl}) \qquad (3)$$

where $\delta(P_{i1}, P_{j1})$ is the hamming distance between P_{i1} and P_{j1}. The Hamming distance between two sets of binary digits is the number of corresponding binary digit positions that differ divided by the number of comparisons made [31]

The case adaptation step matches the imputation phase. First, we decide on the number of analogous projects, *k*. we varied k from 1 to 5. Thereafter, to impute the missing values, we had to decide also on the adaptation strategy. For numerical attributes, we choose the weighted mean since it allows the higher similar projects to have more influence than the lower ones. For categorical attributes, we imputed a missing value with the attribute value of the most similar project to the incomplete project.

d) SVR imputation

Support vector machine has been developed by [32] and it is a supervised learning approach based on statistical theory. It has been gaining popularity due to its attractive features and promising empirical performance. Based on the structural risk minimization (SRM) principle, SVM is able to control the complexity of the model and its generalization ability, which can be used for solving two-class or multi-class classification and regression problems in various fields [33]–[35]. SVM possesses many advantages including fast-learning, global optimization, and excellent generalization abilities due to minimizing the tradeoff between the complexity of the model and its generalization ability compared with other approaches such as artificial neural networks [36], linear regression and radial Basis functions neural networks (RBFNs) [37].

With the introduction of Vapnik's ε-insensitivity loss function, the regression model of SVMs, called support vector regression (SVR), has received increasing attention to solve nonlinear regression problems. The investigation of SVR for software development effort estimation was originally carried out by Oliveira [37]. They found that SVR outperforms both linear regression and RBFNs for software effort estimation over NASA data set.

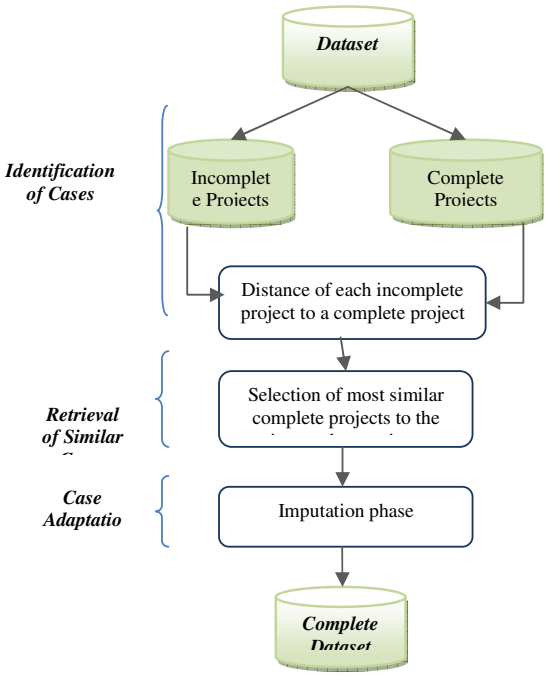

Figure 1 KNN imputation process

The main challenge when dealing with SVR is how to solve the dual problem [38]. The traditional quadratic programming (QP) algorithms solvers are slow, particularly for large problems[34], [35]. In addition, those algorithms can be complex, subtle, and difficult for an engineer to implement [34].

Specific algorithms were developed in order to make easier the use of SVR, such as Vapnik's chunking [39] and Osuna's decomposition [40]. Those algorithms make the training of SVR possible by breaking the large QP problem into a series of smaller QP ones and optimizing only a subset of training data patterns at each step. The subset of training data patterns optimized at each step is called the working set. Thus, these approaches are categorized as the working set methods. Based on the idea of the working set methods, [34] proposed the Sequential Minimal Optimization (SMO) algorithm that selects the size of the working set as two and uses a simple analytical approach to solve the reduced smaller QP problems. Thereafter, [38] ascertained inefficiency associated with Platt's SMO and suggested a modified version of SMO that can solve the SVR QP problem without any extra matrix storage and without using numerical QP optimization steps at all. Hence, this work uses the SMO-SVR algorithm of [38]. Moreover, An important factor that influences the performance of SVR is how to adequately select model parameters (C, ε, γ), which play an important role for a good generalization performance [41]. This paper uses a selection methodology based on Particle Swarm Optimization (PSO) to search global solutions of the optimal parameters (ε, C, γ) [42], [43].

Before proceeding to imputation, SVR transforms categorical variable into numerical ones. In fact, SVR maps each possible value for a categorical attribute into a number.

Unlike KNN imputation technique, SVR imputation (SVRI) requires building a model for each missing value in the dataset. Fig.2 shows the imputation method based on SMO-SVR. Let X be a N×D matrix of N projects described by d *attributes*. For each attribute i, we construct:

1. A complete dataset, Complete_X_i containing all projects P_j for which the values $x_{j,i}$ were not missing.
2. An incomplete dataset, Incomplete_X_i, containing all projects P_j for which the values $x_{j,i}$ were missing

Next, the i^{th} attribute X_i is set as the dependent attribute of Complete_X_i and Incomplete_X_i datasets. Then, the SMO-SVR model is trained using Complete_X_i. Firstly, the PSO algorithm is used to determine the optimal values of ε, C and γ. Next, those optimal values were used to train the SMO-SVR model. Finally, the missing values were imputed by the SMO-SVR model by using the Incomplete_X_i as the test set.

C. Step 3: EBA accuracy evaluation using SA

The accuracy of EBA was assessed using the Jackknife method in which the target project is excluded from the historical dataset and its effort estimation is calculated using the actual effort values of the remaining projects[44].

The accuracy of EBA was assessed in four steps:

1) Evaluation using SA

The first evaluation step aims to compare the accuracy of EBA with random guessing using the Standardized Accuracy (SA) suggested by Shepperd and MacDonell [45]. SA evaluates how good a SDEE technique is in comparison to random guessing. It is based on the Mean of Absolute Error (MAE) and is defined by Equation (4):

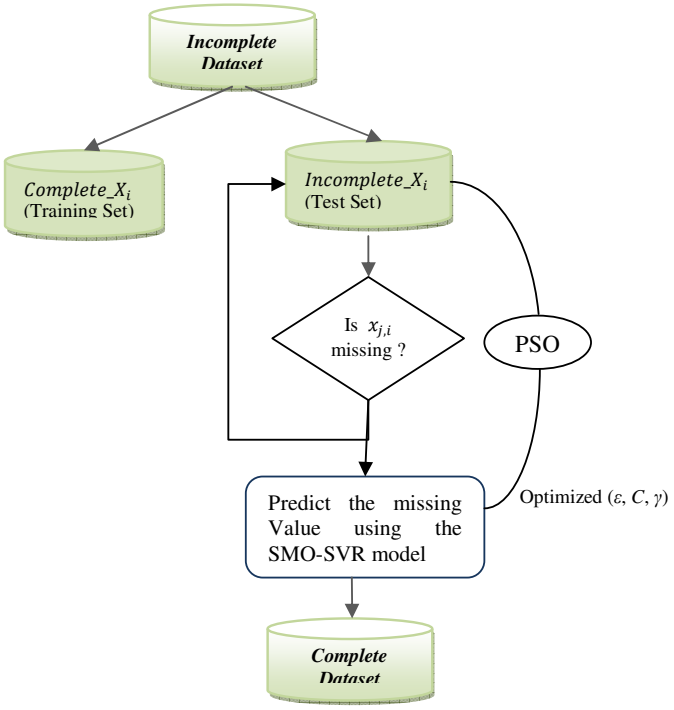

Figure 2 SVR imputation process

$$SA_{P_i} = 1 - \frac{MAE_{P_i}}{\overline{MAE}_{p0}} \times 100 \quad (4)$$

where MAE_{P_i} is defined to be the MAE of the estimation method P_i and MAE_{P_0} is the mean of a large number of (in our case 1000) random guessing. In the random guessing procedure, a training instance is randomly chosen with equal probability from the training set and its effort value is used as the estimate of the test instance. SA gives us an idea of how good an estimation method is in comparison to random guessing. Since the term MAE_{P_i} is in the nominator, the higher the SA values, the better an estimation method is.

The interpretation of SA is that the ratio represents how much better it is as a predictive model (P_i) than the mean or random guessing (P_0). A value close to zero is discouraging and a negative value would be worrisome. The positive sign of SA means the predictive models are better than mean or random guessing. Meanwhile the negative sign is shows how bad the predictive models are against the mean as an estimator. Unlike MRE-based error measures which have been criticized for being biased and favoring underestimation, SA is an unbiased and standardized accuracy measure.

2) Hypothesis testing

The second step aimed to statistically investigate the significance of the results found in step 1. Awareness about statistical validation of the published results had increased among machine learning researchers, in particular is software effort estimation [46].

Hypothesis testing is the process of inferring from a sample whether or not a given statement about the population appears to be true [47]. The first step in hypothesis testing is

establishing a null hypothesis. The null hypothesis is typically a statement contrary to what the researcher is attempting to confirm; we assume the null hypothesis to be true, and use data to try and refute it [47]. The statement that the researcher would like to prove is called the alternative hypothesis. We often establish a significance level (i.e. α-levels). It is is a limit on how unusual a result we will accept. An α-level of 0.05 means that if our observations from our collected data would occur less than 5% of the time given that the null hypothesis is true, then we will reject the null hypothesis [47].

However, null hypothesis testing is not sufficient to analyze and interpret data. A more refined goal of statistical analysis is to provide an evaluation of certainty or uncertainty of the size of an effect [45],[48]. The American Psychological Association (2001) has suggested that researchers report the confidence interval for research data. A confidence interval is an inference to a population in terms of an estimation of sampling error. More specifically, it provides a range of values that fall within the population with a level of confidence of 100*(1 - α) % (i.e. the level of confidence is 95% for α =0.05). Confidence intervals (CIs) offer much more information and allow us to move beyond dichotomous thinking and adopt an "*estimation thinking"*. Estimation thinking focuses on how big an effect is; this is usually more valuable than knowing whether or not the effect is zero, which is the focus of dichotomous thinking. Confidence intervals convey information about magnitude and precision of effect simultaneously, keeping these two aspects of measurement closely linked [49]–[51].

This study used the Wilcoxon statistical test which is a non-parametric procedure used to test whether there is sufficient evidence that the median of two probability distributions differ in location [52]. All statistical tests were two-sided and performed at α=0.05 significance level. Confidence intervals were calculated using Hodges-Lehmann estimates of shift [53], [54]. To adjust for multiple testing, we used the Holm-Bonferroni method [55].

3) Effect size results

To verify how meaningful is the improvement and how important are the results, the effect size criterion defined by Equation (5) was used:

$$\mathbf{\Delta} = \frac{MAR - \overline{\mathrm{MAR}_{\mathrm{P}_0}}}{SP_0} \quad (5)$$

where SP_0 is the sample standard deviation of the random guessing. The Δ values can be interpreted in terms of the categories proposed by Cohen [56] of small (around 0.2), medium (around 0.5) and large (around 0.8). A medium or large value of Δ indicates an acceptable degree of confidence on the model predictions over random guessing.

D. Step 4: EBA accuracy evaluation using Borda Count

The use of SA enabled us to explore the influence of the missingness mechanisms and MD percentages and techniques on the prediction ability of the EBA technique. In fact, SA determines if EBA is reasonable (i.e., is actually predicting, and how much better is it than random guessing), but does not evaluate its accuracy [16]. Thus, SA alone is not sufficient to conclude about EBA accuracy and should be used with other metrics [15], [16].

Hence, we evaluated The EBA technique using a set of reliable accuracy measures that are believed to be less sensitive to bias and asymmetry. These measures are: Pred(0.25), Mean Absolute Error (MAE), Mean Balanced Relative error (MBRE), Mean Inverted Balanced Relative Error (MIBRE) and logarithmic standard deviation (LSD) as shown in Equations (8)–(12), respectively. Using a set of accuracy measures would ensure that different aspects are captured and would give more confidence in the results obtained compared with using only one accuracy measure. Similar approach was used in [57]–[59].

We evaluated the EBA variants (i.e. with four MD techniques and three missingness mechanisms) according to those performance measures and used Borda counting method to rank them over the four datasets in order to identify which variants were the most accurate. The Borda count method was used for the first time in SDEE by Azzeh et al. [59] and then by Idri et al. [58] and it allows to take into consideration different aspects of prediction performance since it is based on five performance measures.

$$AE_i = |e_i - \hat{e}_i| \quad (6)$$

$$MRE = \frac{AE_i}{e_i} \quad (7)$$

$$Pred(0.25) = \frac{100}{N}\sum_{i=1}^{N} \begin{cases} 1 \; if \; MRE_i \leq 0.25 \\ 0 \; otherwise \end{cases} \quad (8)$$

$$MAE = \frac{1}{n}\sum_{i=1}^{n} AE_i \quad (9)$$

$$MBRE = \frac{1}{N}\sum_{i=1}^{N} \frac{AR_i}{\min(e_i, \hat{e}_i)} \quad (10)$$

$$MIBRE = \frac{1}{N}\sum_{i=1}^{N} \frac{AR_i}{\max(e_i, \hat{e}_i)} \quad (11)$$

$$LSD = \sqrt{\frac{\sum_{i=1}^{n}(\lambda_i + \frac{s^2}{2})^2}{n-1}} \quad (12)$$

where:

- e_i and $\hat{e}_i$ are the actual and predicted effort for the *i*th project.
- $\lambda_i = \ln(e_i) - \ln(\hat{e}_i)$
- s^2 is an estimator of the variance of the residual λ_i.

V. RESULTS

This section presents and discusses the experimental results when evaluating the accuracy of EBA using MD.

A. EBA Evaluation using SA (RQs 1-3)

The first objective is to investigate the effect of the MD techniques on the accuracy of EBA in terms of SA. Figures 3a-c show the median SA values for EBA applied to the four data sets with three mechanisms of missingness, different MD percentages and four MD techniques. In general, we notice that the SA values decrease as the MD percentage increases regardless the mechanism of missingness.

For the MCAR mechanism, we observe that the imputation techniques outperformed toleration and deletion (SA values at 10% of MD: 41% for SVRI, 41% for KNNI, 37% for toleration and 34% for deletion). Moreover, Fig.3-a shows that toleration outperformed deletion (SA values at 10% of MD: 37% for toleration and 34% for deletion). Note that SVR and KNN imputations performed almost the same.

For MAR mechanism, Fig.3-b shows that the imputation techniques have the same performance (SA values at 10% of MD: 35% for SVRI, 34% for KNNI). Moreover, they both outperformed toleration and deletion (SA values at 10% of MD: 31% for Toleration, 31% for Deletion). Moreover, we notice that toleration and deletion gave the same performance.

As for NIM mechanism, we notice that the imputation techniques gave similar performances (SA values at 10% of MD: 32% for SVRI and 32% for KNNI). Moreover, toleration and deletion performed the same (SA values at 10% of MD: 26% for toleration and 27% for deletion).

1) Hypothesis testing

In the previous section, we found that imputation techniques (KNN or SVR) instead of toleration and deletion improved the performance of EBA. This section investigates whether this improvement is statistically significant. Moreover, we investigate whether the improvement varies with the mechanisms of missingness. To do that, we compared the median of SA values across data sets for each MD percentage using the Wilcoxon t-test. We drew the following hypothesis:

NH1: The prediction performance of EBA is not affected by the MD technique.

NH2: The prediction performance of EBA when using MD techniques is not affected by the mechanism of missingness.

Each null hypothesis was evaluated separately for the MD techniques and the three missingness mechanisms. Tables II and III sum up the results of the Wilcoxon t-test conducted to evaluate NH1 and NH2 respectively, where p(α) denotes the p-value of the Wilcoxon test, α' denotes the significance level corrected by Holm-Bonferroni correction and CI denotes the confidence interval. Table II shows the results of Wilcoxon test on NH1. We notice that the difference between SVR and KNN imputations is not significant regardless of the mechanism of missingness. The confidence intervals also reflect this finding. We notice that for MCAR and MAR mechanisms, the confidence intervals have negative values. This means that no imputation technique is always superior to the other. For MCAR mechanism, we observe that the difference between KNN and SVR is between -1.679 and 0.416. This means that KNN outperformed SVR by 1.679 and SVR outperformed KNN by 0.416. The case of MAR is the similar to MAR. However, under NIM, we observe that SVR outperformed KNN and the magnitude of the difference is between 0.484 and 0.7

Table II also shows that imputation techniques often significantly outperformed toleration and deletion. We notice that the magnitude of the difference is larger with deletion compared to toleration. The improvement given by the imputation techniques over toleration/deletion is larger when using MCAR or NIM compared to MAR. This is due to the fact that, under MCAR mechanism, imputation techniques outperformed largely toleration and deletion. Moreover, under NIM mechanism, toleration and deletion gave the worst results (negative values of SA). Under MAR mechanism, the performance of imputation techniques decreased and the toleration/deletion gave acceptable performance which explains the small CI.

To evaluate the impact of the missingness mechanisms on the accuracy of EBA, Table III reports the results of the statistical tests of NH2; it can be noticed that:

- The difference between MCAR and MAR is significant when using SVR, KNN and toleration. However, the difference is not significance when using deletion.
- The difference between MCAR and NIM is in general significant.
- The difference between MAR and NIM is significant for SVR, toleration and deletion. However, it is not significant in the case of KNN.

2) Effect size results

To ensure that the results are not generated by chance and to assess if there is effect improvement over random guessing, we evaluate the effect size measured by means of Equation (5). Table VII reports the median values of the effect size Δ of EBA using the four MD techniques under three mechanisms of missingness and nine MD percentages across the four datasets where the baseline method is random guessing.

From Table VII, we notice that the Δ values are higher than 0.5, which means that the results obtained by EBA in terms of SA are more likely not to be due to chance under:

- MCAR mechanism when using: 1) imputation, 2) toleration/deletion with MD percentage less than 80%.
- MAR mechanism when using: 1) KNN imputation with MD percentage less than 90%, 2) SVR imputation, toleration or deletion with MD percentage less than 80%.
- NIM mechanism when using: 1) SVR/KNN imputation with MD percentage less than 90%, 2) toleration with MD percentage less than 60%, 3) deletion with MD percentage less than 70%.

B. EBA Evaluation using Borda Count (RQ4)

Although SA results would confirm if EBA outperform random guessing, they are not sufficient to conclude about the accuracy of EBA [15], [16]. This section evaluates EBA with four MD techniques and three missingness mechanisms using a set of reliable performance measures as explained in Section V.C. Thereafter, we rank the four variants of EBA (i.e. with the four MD techniques) using the Borda count method. Table VI shows the ranking over the four datasets.

We notice that EBA with SVR imputation generally outperformed the other EBA variants except for USP05FT under MAR and USP05RQ under NIM.

Moreover, we notice that toleration generally improves the EBA accuracy compared to deletion except for ISBSG under MAR/NIM and USP05FT under NIM.

Furthermore, we compared the four EBA variants across the four datasets. Table VII shows the results of this ranking. We notice that EBA with SVR imputation was the best, followed by KNN imputation, toleration and lastly deletion regardless the missingness mechanisms.

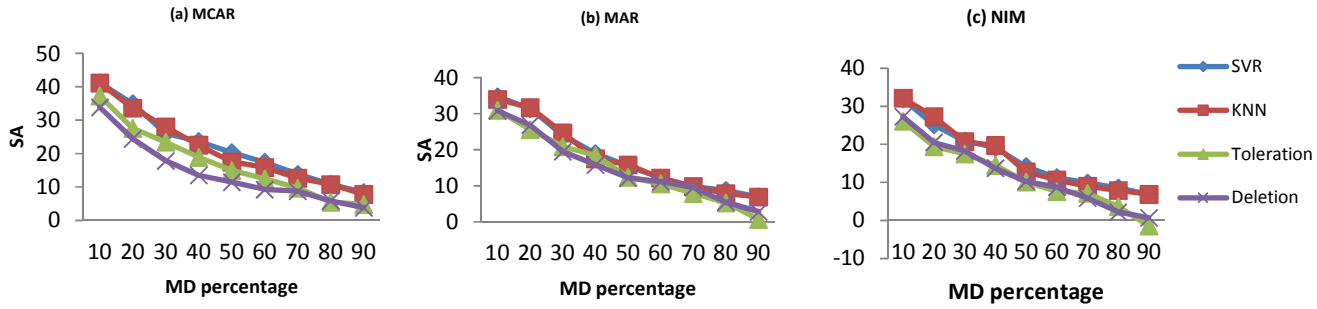

Figure 3(a-c) SA values of Classical Analogy applied to four data sets with three mechanisms of missingness, different MD percentages and four MD techniques

VI. Conclusion and Future Work

This study evaluated EBA using four MD techniques: toleration, deletion, KNN imputation, and SVR imputation with different percentages (from 10% to 90%) and three missingness mechanisms (MCAR, MAR and NIM) on four datasets (ISBSG R8, COCOMO81, USP05_FT and USP05_RQ) with mixed data (numerical and categorical).

four research questions RQs 1-4 have been discussed. The findings when answering RQs 1-4 are as follows:

(RQ1): Is there evidence that the use of KNN and SVR imputations rather than toleration/deletion improves the accuracy of EBA in terms of SA when using mixed datasets?

We found that EBA with imputation techniques achieved significantly better SA values over EBA with toleration or deletion regardless of the mechanism of missingness.

EBA with toleration provided significantly better SA over EBA with deletion when the missingness mechanism is MCAR. However, under MAR or NIM mechanisms, the improvement provided by toleration over deletion is not significant. Moreover, EBA outperformed random guessing when using imputation techniques. However, when using toleration/deletion at high percentages of MD, EBA underperformed random guessing.

(RQ2): Is there evidence that SVR imputation instead of KNN imputation would improve EBA accuracy measured in terms of SA?

In terms of SA, we found that the performance difference between the imputation techniques KNN and SVR was not significant.

(RQ3): Is there evidence that the missingness mechanism and the MD percentage affect the accuracy of EBA measured in terms of SA over mixed datasets?

We found that EBA with MCAR instead of MAR achieved significantly better SA values when using imputation or toleration. However, when using deletion, the improvement of EBA with MCAR instead MAR is not significant. EBA with MCAR instead of NIM achieved significantly better SA values regardless of the MD technique used. EBA with MAR instead of NIM achieved significantly better SA values when using toleration/deletion. However, when using imputation, the difference is not significant.

(RQ4): Does the performance of EBA in terms of Pred(0.25), MAE, MBRE, MIBRE and LSD confirm the findings of SA?

When using the Borda count based on five accuracy criteria, we found that EBA with SVR was the best, followed by KNN imputation. We also notice that toleration instead of deletion improves the accuracy of EBA. These findings confirm those of [14], [15] stating that different measures capture different aspects of EBA performance: SA determines if a technique is reasonable (i.e., is actually predicting, and how much better is it than random guessing) while other accuracy metrics measure how close a prediction is to its correct value.

Future work aims to confirm our finding with different variants of EBA techniques (e.g. Fuzzy Analogy) and other software effort estimation techniques. Moreover, other imputation techniques may give different results.

***Abstract*—A cloud federation gives to cloud service providers (CSP) the opportunity to collaborate in order to offer a better QoS to customers at a lower cost. To do so, CSPs make some spare resources available to others at a reduced cost. One of the most critical resources is the storage system as it represents the main system bottleneck. From this point of view, how to efficiently place data in a federation of Clouds with heterogeneous storage systems is a real challenge. To address this issue, one needs to accurately estimate the data placement cost. In this paper, we propose a cost model for hybrid storage systems in a cloud federation for a Database as a Service (DBaaS) application. It takes into account the storage system characteristics, customers I/O workloads and SLA. The proposed cost model considers both 1) Internal customers data placement cost including local placement, outsourcing, back-migration and penalty costs, and 2) External customers data placement cost including insourcing and geo-migration costs. It can be used to help in the decision-making process which aims to enhance customers QoS and reduce CSPs costs in a federation. Simulation results showed the relevance of the considered costs. We have shown that mis-considering some sub-costs may lead to a 95% cost error for external customers data placement and 80% for outsourcing customers. This may cause significant financial loss.**

***Index Terms*—Cloud, federation, hybrid storage, cost model.**

I. INTRODUCTION

CLOUD federation [1], [2], [3], [4] is a computing paradigm that consists in making several Cloud Service Providers (CSPs) cooperate by sharing resources. These CSPs insource and outsource their customers' data and services to provide continuous provisioning by exploiting temporal and spatial availability of resources [2] while reducing their cost. Cloud federation need was driven by novel applications such as mobile cloud, IoT, and big data. It came to address many limitations such as resource contention [5], [6], service interruption [7] and Quality of Service (QoS) degradation that may be due to the geographical distance to cloud resources.

DataBase as a Service (DBaaS) is one of the most important application processing Cloud service offered to cut the IT costs. For such a service, I/O performance and network latency are the two main metrics considered by the customers. Indeed, I/O system is one of the main system bottlenecks [8]. Moreover, it takes about 90% of the transaction execution time in some database queries [9].

Some cloud companies [10] already include latency guarantees in their Service Level Agreements (SLAs) and customers may pay extra charges for reducing I/O latencies.

In order to handle I/O bottlenecks, CSPs rely on the heterogeneity of storage devices. While Hard Disk Drives (HDDs) are used mainly to provide large storage volumes thanks to their low cost per GB, flash based Solid State Drives (SSDs) are integrated to reduce access latency and increase the I/O bandwidth [27], [28]. However, their higher cost does not allow for a massive use [29]. So, according to customers' QoS requirements, a CSP may use this heterogeneity to migrate or replicate their data between different storage classes or to other partner CSPs in the case of a Cloud federation. Dealing with such local and external storage system heterogeneity makes data placement strategies very challenging and needs an accurate cost estimation in order to make adequate decisions when placing data objects.

The cost of operating a Cloud is too significant to be ignored [30], as a matter of fact, using an accurate cost model is a critical issue. In effect, cost models are frequently used for optimization sake. Several state-of-the-art studies dealt with cost estimation of storage systems. We classified them in two categories. The first category is related to studies on centralized Clouds such as [12], [13], [16], [15], [11], [31]. They investigated several issues related to I/O efficiency in case of heterogeneous storage systems, see Table Ia. The second category is related to the cost estimation in the case of interconnected Clouds. These cost models dealt with different operations such as: initial placement of VMs [6], [17], [25], storage cost and geo-migration [21], [18], [32]. However, none of these studies took into account hybrid storage systems and I/O related cost, see Table Ib. They mainly used a fixed storage cost related to data volume without considering I/O operations cost (IOPS or latency).

In the case of a Cloud federation, for an accurate storage cost estimation, CSPs must consider both local and external storage costs. Indeed, it might be more cost effective to store a customer's data on a distant HDD than on a local SSD in case of customer mobility for instance. To consider this issue, the cost estimation must take into account both the details of the storage system and the properties of the Cloud federation. To the best of our knowledge these issues were not considered simultaneously in the existing work.

In this paper, we propose a model to evaluate the storage cost of object placement for DBaaS applications in a federated Cloud. We define an object as any logical entity of a database such as a table, a view, or an index. Our model consists of:

(b)

- Internal customers object placement cost: It takes into account (1) the cost of object placement for internal customers in the local infrastructure, (2) the cost of outsourcing local customers objects, that is buying resources from the other federation CSPs, (3) the cost of prospective back-migration that is the cost induced by bringing back previously outsourced internal customers objects and finally (4) the penalty cost related to the violation of customers SLAs.
- External customers placement cost: this is the cost of managing external customer objects. It consists of (1) the cost of insourcing external customers objects and (2) the cost of sending back these objects to their home or other clouds of the federation when requested.

We have evaluated the cost model and showed that the considered sub-costs are all relevant. With a simple use case, the lowest considered sub-cost part was 6%. Our cost model makes it possible to investigate whether outsourcing is relevant in a federation according to the resource cost and workload properties. It also provides the CSP with a mean to evaluate the penalty cost related to outsourcing some objects and to tune the resources to provide for the federation.

The paper is organized as follows. In Section 2, we discuss some related work, then, we define the system model and formulate the problem in Section 3. In Section 4, our cost model is presented and it is evaluated in Section 5. Finally, we conclude and give some perspectives in Section 6.

II. Related work

In this section we discuss existing studies about hybrid storage systems and interconnected clouds cost models.

A. Hybrid storage system cost models for the Cloud

Many efforts have been made to estimate the cost of data placement in hybrid storage systems. Existing work focused mainly on single clouds. In [13], [14] the storage system cost was estimated using occupation and energy costs. Authors of [11] considered only the wear out while migration cost has been modeled in [12]. Recently, in [15], a cost model has been proposed taking into account four factors: energy, wear out limit, migration between storage classes and penalties. The authors in [16] have extended the previous study with the storage occupation cost. This is summarized in Table Ia.

B. Interconnected cloud cost models

Many existing studies [18], [19], [20] have dealt with the cost of running big data applications, such as social networks, and scientific computing [33]. These studies consider storage, computation and bandwidth to evaluate the cost of data geo-migration and storage in distributed data-centers. All these cost models have used a fixed storage cost mainly related to the storage occupation. The running I/O workload has not been considered. Other studies investigated the cost of distributed clouds (eg: Amazon, Google, etc.). Cost models in this category addressed different aspects: Data center construction [34], energy cost [22], [23], [24], and bandwidth cost [24]. Finally, various cost models for federated clouds have been proposed. Toosi et al [6] designed a cost model which sets dynamically the cost of federated VMs according to the amount of idle resources of the CSPs, as well as a revenue model to maximize the CSP profit. In [17] a cost model, including insourcing and outsourcing costs of virtual resources was proposed. In [25], [26], the cost model consists in local, insourcing, outsourcing and network traffic costs.

Existing hybrid storage cost models are not applicable when it comes to interconnected clouds because data placement in this case implies other factors related to the distributed environment. Regarding federated clouds, the cost of I/O system has not been considered in detail. Indeed this cost has been generally considered as constant and was not related to application workloads.

In this paper, we propose a cost model for the storage system in a federated Cloud taking into account in one hand, the detailed cost of the storage system and in the other hand, the distributed nature and federation properties.

III. System model and Problem definition

In this section, we first describe the system model and then we formulate the cost modeling problem.

A. System model

We consider a federation F composed of D CSPs F= $\{CP^d, d \in [1..D]\}$ cooperating in a peer-to-peer intercloud fashion as depicted in Figure 1. This architecture is inspired from [35] and was used in several studies [6], [25], [17]. The figure emphasizes on the d cloud provider view.

Each CP^d has one datacenter and accommodates different types of storage classes $SC = \{sc_j, j \in [1..J]\}$. We limit our study to two storage classes in this work: SSDs and HDDs. Each sc_j has a limited capacity c_{sc_j}, a maximum IOPS per operation $iops_{op,sc_j}$, a wear out wo_{sc_j}, and a purchase cost p_{sc_j}. We assume that a CSP buys a bandwidth bw from an Internet provider with a purchase cost p_{bw}.

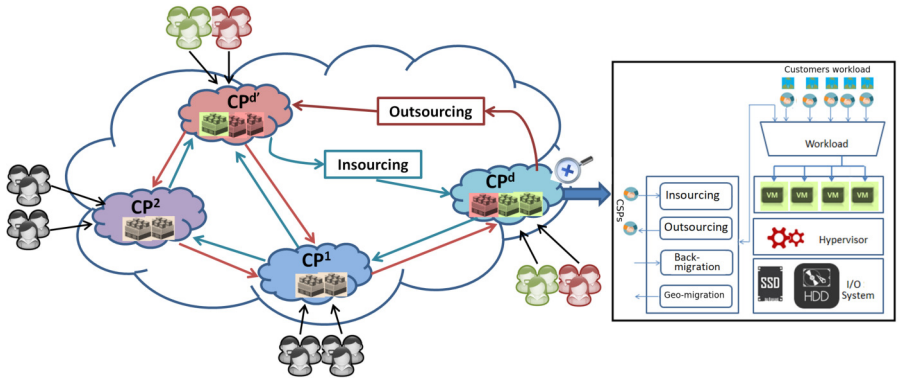

Fig. 1: Federated cloud based hybrid storage system

CSPs may outsource their customers objects to other federation members (called partners), for instance, when they cannot meet customers QoS requirements.

Therefore, each CP^d has two types of customers:

1) internal customers: that are the customers of $CP^d, U_{int} = \{u_k, k \in [1, K]\}$,
2) external customers: that are partner CSPs $\{CP^{d'}\}$ customers whose objects are outsourced to $CP^d, U_{ext} = \{u^{d'}_{k'}, k' \in [1, K']\}, CP^{d'} \in F - \{CP^d\}$. These customers' objects are insourced by CP^d.

We assume that each internal customer u_k:

1) has a set of objects $\{o_{i,k}, i \in [1..N]\}$. Each object has a size denoted $s_{o_{i,k}}$.
2) generates an I/O workload wl_k representing the I/O operations generated by the set of queries issued by the customer. According to the access pattern (sequential, random) and the operation type (read, write), We distinguish four I/O patterns as in [16]: sequential read (sr), sequential write (sw), random read (rr) and finally, random write (rw).
3) a requested QoS (SLA) in terms of IOPS and latency $iops_{sla,k}, ltc_{sla,k}$.
4) A penalty function pn_k composed of two parts, one related to storage performance : $pn_{iops,k}$ and the other to the latency: $pn_{ltc,k}$.

The same notation is used for the external customers.

Based on customers' SLA requirements and the amount of available storage resources, objects are served locally (placed and migrated between different storage classes), insourced, geo-migrated or geo-replicated to partner clouds. To clarify the system model, we introduce the following definitions:

Outsourcing [6], [36], [25], [3]: the ability that CSPs have to send some internal customers objects to other federation members. Outsourcing maybe achieved through either geo-migration or geo-replication.

Geo-migration [21], [18]: the process of moving objects to other clouds without caring about local copy synchronization.

Geo-replication [21], [37]: the process of maintaining multiple copies of objects on multiple sites (CSPs) for a better performance, availability, and reliability.

Insourcing [25], [26], [36], [3]: the opposite process of outsourcing. CSPs make available part of their unused resources to respond to requests from other members.

Inner migration [16], [15]: is the movement of some objects between different storage classes within the same infrastructure. A CSP CP^d migrates periodically some objects between the different storage classes. $O_{m,int}$, $O_{m,ext}$: represent the set of internal (external, respectively) customers objects to migrate between internal storage classes.

Back migration: This operation consists in bringing back previously outsourced objects to the local infrastructure.

The primary objective of a CSP is to reduce the used resources cost while meeting customers QoS needs. The cloud administrator has to take decisions about: (1) which objects need to be moved locally between different storage classes, (2) which ones need to be outsourced and to which partner CSP, i.e. which ones to be replicated or migrated, (3) which other CSP customer objects need to be insourced, (4) and finally, which previously outsourced internal customers objects, need to be brought back to the local infrastructure.

Periodically, the cloud administrator makes decisions about object placement. We note by T the time period during which monitoring is executed to extract objects I/O patterns and to compute the cost of outsourced objects in order to evaluate the overall placement cost as in [16], [15]. We assume that each cloud maintains two matrices, one for internal customers objects (A) and the other for external customers objects (B) such as $A[i, j](T) = 1$ when an internal object is placed in the cloud CP^j and $B[i, j](T) = 1$ when the object is an insourced object to cloud CP^j.

In our study, we assume that a given CSP charges its partners for insourcing actions. Reduced prices are used in order to foster cooperation within the federation. As in [6], each CP^d dynamically adjusts the price of its contributed storage resources according to the amount of idle resources. Let $Cap_{max_{rsc}}$ and $Cap_{idl_{rsc}}$ be the total and idle capacities for a given resource rsc of the provider CP^d. rsc maybe the storage occupation (occ) or performance in IOPS $(iops)$. If p_{rsc} is the price paid by internal customers for the resource rsc, its insourcing price F^d_{res} is obtained from the expression

in eq. (1) from [6]. For each time period T, CSPs will use eq.1 to adjust their insourcing prices.

$$F^d_{rsc} = \frac{Cap_{max_{rsc}} - Cap_{idl_{rsc}}}{Cap_{max_{rsc}}} * (p_{rsc}) \quad (1)$$

From the network resource point of view, only outgoing network (Internet) traffic is charged for customers in a given CSP, be it a local or an outsourced customer (in this case, the hosting CSP charges the external network traffic cost for outsourcing one).

In this paper, we assume that each CP^d dedicates a fixed part of storage and bandwidth resources for its internal customers $(sc_{j,int}, bw_{int})$ and another part for the external customers $sc_{j,ext}, bw_{ext}$ as noted in eq. 2.

$$\forall CP^d, \begin{cases} sc_j = sc_{j,int} + sc_{j,ext} \\ bw = bw_{int} + bw_{ext} \end{cases} \quad (2)$$

B. Problem formulation

In the following, we define our problem by giving system inputs and outputs.

Input: A CSP of the federation that has : (1) a set of storage classes, (2) an Internet bandwidth with maximum capacity and purchase cost, (3) a storage and outgoing network bandwidth costs for partner Clouds. (4) a set of internal customers, (5) a set of external customers, (6) two sets of objects $O_{m,int}$ and $O_{m,ext}$ to move between the local storage classes. (7) a monitoring period T, and (8) two matrices: $A(T)$ and $B(T)$.

Output: The monetary placement cost of all customers' objects for a given time period T.

IV. Storage cost model in a Cloud federation

A. Overview

We model the cost of object placement for a cloud CP^d, $d \in [1..D]$, belonging to a federation F for a given period of time T. The model is built hierarchically, see Figure 2.

The total object placement cost $Cost_{plc,T}$ is the sum of the placement cost of the internal customers ($Cost_{plc_{int},T}$) and the external customers ($Cost_{plc_{ext},T}$) as shown in eq. 3.

Note that non-recurring costs which do not depend on the objects placement like maintenance cost, human resources cost, air-conditioning costs are not considered in this paper. We do not also consider the cost related to data security.

$$Cost_{plc,T} = Cost_{plc_{int},T} + Cost_{plc_{ext},T} \quad (3)$$

B. Internal customers object placement cost (see (2), Figure 2)

This is the cost of placing internal customers objects. It includes the local placement cost $Cost_{lcl_{int},T}$, the outsourcing cost ($Cost_{out_{src},T}$), the back-migration cost ($Cost_{bck_{mgr},T}$) and the penalty cost $Cost_{pnt_{int},T}$ as shown in eq. 4.

The local placement cost is the storage cost of internal customers objects in the local infrastructure. The outsourcing cost is related to the placement of internal customers objects in partner CSPs. The back-migration cost represents the cost of bringing back the previously outsourced objects to the home infrastructure. Finally, the penalty cost represents the additional monetary cost caused by SLA violations.

$$Cost_{plc_{int},T} = Cost_{lcl_{int},T} + Cost_{out_{src},T} + Cost_{bck_{mgr},T} + Cost_{pnt_{int},T} \quad (4)$$

1) Local placement cost (see (4), Figure 2): It is obtained from the storage cost $Cost_{stg_{int},T}$ of internal customers objects and the inner migration cost (between storage classes within the CSP infrastructure) $Cost_{mgr_{int},T}$ of the set of objects $O_{m,int}$ as shown in eq. 5.

$$Cost_{lcl_{int},T} = Cost_{stg_{int},T} + Cost_{mgr_{int},T} \quad (5)$$

The storage cost: As in [16], $Cost_{stg_{int},T}$ is related to the occupation $Cost_{occ,T}$, the energy $Cost_{erg,T}$ and the wear out cost $Cost_{edr,T}$ due to I/O workload (see eq. 6).

$$Cost_{stg_{int},T} = max[Cost_{occ,T}, Cost_{edr,T}] + Cost_{erg,T} \quad (6)$$

The occupation cost is the amortized cost of the storage system over the period T. The energy cost is the energy consumed by the storage system to execute the I/O workload multiplied by the energy unitary price which we consider constant. Finally, the wear out cost is caused by the execution of the I/O workload which impacts the lifetime of the devices. For SSD, this cost is related to the amount of written data while for HDD, it depends of the amount of both read and written data. For more details see [16].

The migration cost: it consists in reading the set of objects $O_{m_{int}}$ from the source storage device and writing them to another destination storage device. It includes the energy and endurance costs.

2) Outsourcing cost (see (5), Figure 2): It is composed of geo-migrating and geo-replicating internal customers objects and the storage cost in the partner CSPs generated by these two geo-operations as in eq. 7.

$$Cost_{out_{src},T} = Cost_{geo_{mgr},T} + Cost_{geo_{rpl},T} + Cost_{ext_{plc},T} \quad (7)$$

The geo-migration cost (see (11), Figure 2): geo-migration of objects incurs local read operations $Cost_{rd,T}$ and internet bandwidth usage $Cost_{bw,T}$.

The set of objects concerned by the geo-migration $O_{g_{mgr}}$ is obtained from the difference between the matrix A at the period $T-1$ and the current period T where $o_i, A[i,d](T-1) = 1 \wedge A[i,d](T) = 0$. Geo-migration cost is shown in eq. 8.

$$Cost_{geo_{mgr},T} = Cost_{rd,T} + Cost_{bw,T} \quad (8)$$

The local read operation cost incurs energy $Cost_{rd_{erg},T}$ and wear out $Cost_{rd_{edr},T}$ costs.

$$Cost_{rd,T} = Cost_{rd_{erg},T} + Cost_{rd_{edr},T} \quad (9)$$

The Internet bandwidth cost is related to the bandwidth consumed by the geo-migration of objects to external clouds.

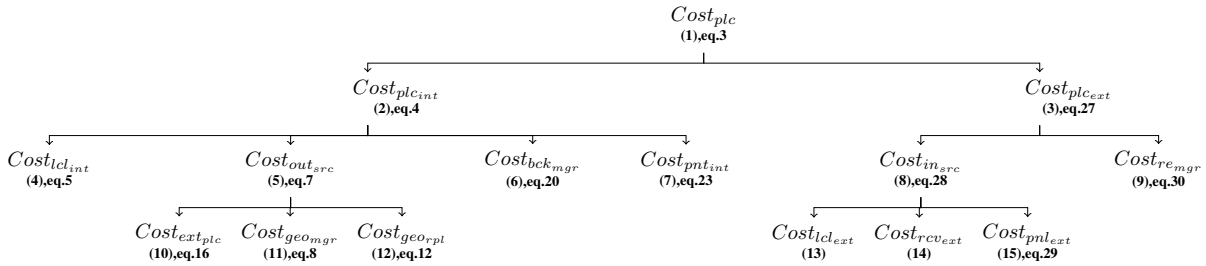

Fig. 2: The overall cost model

We calculate this cost by multiplying the size of all objects to be migrated by the amortized bandwidth over one unit of time $Cost_{bw_{amz},1}(bw_{int})$.

$$Cost_{bw,T} = \frac{\sum_{o_i \in O_{gmgr}} (S_{o_i}) * Cost_{bw_{amz},1}(bw_{int})}{bw_{int}} \quad (10)$$

We calculate the amortized bandwidth cost over one unit of time by distributing the purchase cost of bw_{int} over the subscription time period T_{sp}.

$$Cost_{bw_{amz},1}(bw_{int}) = \frac{p_{bw} * \frac{bw_{int}}{bw}}{T_{sp}} \quad (11)$$

The geo-replication cost (see (12), Figure 2): geo-replicating objects over multiple CSPs consumes supplementary storage and network costs. The geo-replication consists in adding, deleting and synchronizing replicas. So, its overall cost is the sum of the aforesaid operations costs as shown in eq. 12. Deleting replica cost is assumed to be nil.

$$Cost_{geo_{rpl},T} = Cost_{add_{rpl},T} + Cost_{syc_{rpl},T} \quad (12)$$

The cost of adding replicas is the same as the geo-migration cost without deleting the original copy and considering the set of objects $\{O^{d'}_{g_{rpl}}, d' \neq d\}$. They are obtained from matrix A.

$$Cost_{add_{rep},T} = \sum_{CP^{d'} \in F - \{CP^d\}} Cost_{geo_{mgr},T}(O^{d'}_{g_{rpl}}) \quad (13)$$

Concerning replica synchronization either CP^d forwards the synchronization or receives it. $O^{d'}_{s_{rpl}}$ is the list of objects sent to, or received from $CP^{d'}$ for synchronizing replicas. When CP^d forwards the synchronization, its cost is the sum of the read operations induced and the consumed Internet bandwidth costs, see eq. 14.

$$Cost_{syn_{rep},T} = \sum_{CP^{d'} \in F - \{CP^d\}} Cost_{geo_{mgr},T}(O^{d'}_{s_{rpl}}) \quad (14)$$

Whereas when CP^d receives the synchronization, this cost consists of writing operations, local Internet bandwidth use, and outgoing network costs (i.e back-migration cost, see later in eq. 20) as shown in the next equation 15.

$$Cost_{syn_{rep},T} = \sum_{CP^{d'} \in F - \{CP^d\}} Cost_{bck_{mgr},T}(O^{d'}_{s_{rpl}}) \quad (15)$$

The external placement cost (see (10), Figure 2): Once the objects have been migrated to other clouds, the CSP needs to pay partner clouds for hosting the objects. Therefore, the external storage cost includes the external occupation cost $Cost_{ext_{occ},T}$, the external workload execution cost $Cost_{ext_{wld},T}$ and the external penalty cost $Cost_{ext_{pnl},T}$. The penalty cost here is the charge paid by the partner clouds in case SLAs are violated for the outsourced objects.

The purchased resources are billed according to eq. 1.

$$Cost_{ext_{plc},T} = Cost_{ext_{occ},T} + Cost_{ext_{wld},T} - Cost_{ext_{pnl},T} \quad (16)$$

The external occupation cost: represents the cost of storing the migrated or replicated internal customers objects on partner clouds. We calculate this cost by using the federated occupation cost $F^{d'}_{occ}$ of $CP^{d'}$ as noted in eq. 17

$$Cost_{ext_{occ},T} = \sum_{d' | CP^{d'} \in F - \{CP^d\}} (\sum_i A[i,d'] * S(o_i)) * F^{d'}_{occ} \quad (17)$$

The cost of workload execution represents the amount of expected IOPS consumed by internal users. It is calculated the same way as in the eq. 18 where $F^{d'}_{iops}$ is the cost of one IOPS in the cloud $CP^{d'}$

$$Cost_{ext_{wld},T} = \sum_{d' | CP^{d'} \in F - \{CP^d\}} (\sum_i A[i,d'] * IOPS(o_i)) * F^{d'}_{iops} \quad (18)$$

The penalty cost is a percentage $\alpha\%$ of the total charges paid by C^p to the partner cloud, as in Amazon Cloud.

$$Cost_{ext_{pnl},T} = \alpha * (Cost_{ext_{occ},T} + Cost_{ext_{wld},T}) \quad (19)$$

3) Back migration cost (see (6), Figure 2): $Cost_{bck_{mgr},T}$ is the cost of bringing back the previously outsourced objects to the local infrastructure. It is composed of the cost of data transfer (outgoing network cost) from the partner clouds $Cost_{ntw_{out},T}$, the local Internet bandwidth cost $Cost_{bw,T}$

corresponding to the bandwidth consumed locally to receive the previously outsourced objects, and the cost $Cost_{wr,T}$ to write the received objects on the local storage, see eq. (20).

$$Cost_{bck_{mgr},T} = Cost_{wr,T} + Cost_{ntw_{out},T} + Cost_{bw,T} \quad (20)$$

The set of internal customers objects to be brought back $O_{b_{mgr}}$ is deduced from the matrix A.

The local write cost: is the cost of placing previously outsourced objects in the local storage system. This cost involves the cost of energy $Cost_{wr_{erg},T}$ consumed by the storage devices and the wear out cost of these devices $Cost_{wr_{edr},T}$ caused by the write operations. Some of these objects are placed on HDD and others on SSD, see eq. 21.

$$Cost_{wr,T} = Cost_{wr_{erg},T} + Cost_{wr_{edr},T} \quad (21)$$

Outgoing network cost: This cost is charged by partner CSPs when CP^d brings back their internal customer objects to the local infrastructure. We calculate this cost by multiplying the size of the objects to bring back by the cost of outgoing network $Cost_{out}(CP^{d'})$ of the partner.

$$Cost_{ntw_{out},T} = \sum_{CP^{d'} \in F - \{CP^d\}} (Cost_{out}(CP^{d'}) * (\sum_{o_i \in O_{b_{mgr}}} S_{o_i})) \quad (22)$$

Local Internet bandwidth cost is calculated with eq. 10.

4) Penalty cost (see (7), Figure 2): The violation of SLA terms by the CSP entails a penalty that should be paid. As in [16], we calculate the overall penalty as the sum of all internal customers penalties.

$$Cost_{pnt_{int},T} = \sum_{u_k \in U_{int}} (Cost_{pnt,T}(u_k)) \quad (23)$$

Internal customer penalty cost is composed of a penalty related to the IOPS $Cost_{pnt_{iops},T}(u_k)$ and another one related to the latency $Cost_{pnt_{ltc},T}(u_k)$.

$$Cost_{pnt,T}(u_k) = Cost_{pnt_{iops},T}(u_k) + Cost_{pnt_{ltc},T}(u_k) \quad (24)$$

The IOPS penalty cost is calculated as in [16], it is proportional to the ratio between the offered IOPS $iops_{offered}(u_k)$ and the requested one ($iops_{sla,k}$). The requested IOPS is defined in the SLA while we calculate the offered IOPS from the time needed to handle the I/O workload of the customer u_k and the total number of I/O requests issued to their objects. It is calculated as follows:

$$Cost_{pnt_{iops},T}(u_k) = pnt_{iops,k}(\frac{iops_{offered}(u_k)}{iops_{sla,k}}) \quad (25)$$

The latency penalty cost: In our model, we assume that customers pay extra charges to have a reduced network latency. If the latency offered $ltc_{offered}(u_k)$ to customer u_k is lower than the one requested $ltc_{sla,k}$, then a penalty is applied to the CSP. This penalty cost is proportional to the violation degree and the number of requests nb_{rqt}, as noted in Table VI. We calculate the latency penalty cost as follows:

$$Cost_{ltc_{iops},T}(u_k) = \sum_{i=1} nb_{rqt}(pn_{ltc,k}(\frac{ltc_{offered}(u_k)}{ltc_{sla,k}})) \quad (26)$$

TABLE II: Latency penalty per request

$ltc_{offered}$	Penalty (%)
$[0..B_0]$	0
$[B_i..B_{i+1}]$	x_i
$> B_n$	x_n

C. External customers placement cost (see (3), Figure 2)

This cost $Cost_{plc_{ext},T}$ is the sum of the cost of insourcing external customers objects $Cost_{in_{src},T}$ and the cost generated when some objects of the external customers are geo-migrated to other clouds or taken back by their home clouds (re-migration cost) re_{mgr}, see eq. 27.

$$Cost_{plc_{ext},T} = Cost_{in_{src},T} + Cost_{re_{mgr},T} \quad (27)$$

1) Insourcing cost (see (8), Figure 2): The insourcing cost is composed of receiving external customers objects cost $Cost_{rcv_{ext},T}$, the local placement cost $Cost_{lcl_{ext},T}$ and the penalty cost $Cost_{pnt_{ext},T}$.

$$Cost_{in_{src},T} = Cost_{rcv_{ext},T} + Cost_{lcl_{ext},T} + Cost_{pnt_{ext},T} \quad (28)$$

Receiving cost (see (14), Figure 2) of the external customers objects is the cost of writing these objects, calculated from eq. 21, and the cost of the consumed local Internet bandwidth, calculated with eq. 10. The set of external customers objects to be received $O_{e_{rcv}}$ is deduced from the matrix B

The local placement cost (see (13), Figure 2): of the external customers objects is calculated from eq. 5.

The penalty cost (see (15), Figure 2) is the sum of penalty costs of the external customers.

$$Cost_{pnt_{ext},T} = \sum_{u_{k'}^{d'} \in U_{ext}} (Cost_{pnt,T}(u_{k'}^{d'})) \quad (29)$$

In the federation, resource prices are dynamically set (see eq. 1), so the penalty cost is set accordingly and is related to the unused storage resources β which is calculated as follows:

$$\beta = \frac{Cap_{max_{rsc}} - Cap_{idl_{rsc}}}{Cap_{max_{rsc}}} \quad (30)$$

With rsc being a combination of the storage space and performance requested. The penalty cost of an external customer $u_{k'}^{d'}$ is thus given in eq. 31:

$$Cost_{pnt,T}(u_{k'}^{d'}) = \beta * Cost_{pnt_{iops},T}(u_{k'}^{d'}) \quad (31)$$

2) The re-migration cost (see (9), Figure 2): This cost is driven by the decision of home clouds to geo-migrate their customers back to their infrastructure or to another cloud. This incurs local read operations and Internet bandwidth costs as described in eq. 8. The set of objects concerned by the re-migration is deduced from the matrix B by the difference between the period $T-1$ and the current period T where for $o_i, B[i,d](T-1) = 1 \wedge B[i,d](T) = 0$.

V. Evaluation

This section presents an evaluation of the proposed cost model. Our aim is twofold: (i) validating the relevance of the sub-costs used in our cost model and comparing to state-of-the-art models, (ii) showing the flexibility of the cost model through the investigation of the impact of different parameters on the placement cost.

A. Experimental Settings

We used CloudSim simulator [38]. The simulated scenario is composed of a federation of 9 geographically distributed CSPs. Each CSP is composed of one datacenter running 1000 VMs as in [6]. Some of these VMs (set to 20% in our experiments) are devoted to the federation. Each CSP has an internet bandwidth of 1Gbps bought from an Internet service provider (the price was set to 1500$ per month). We used a standard VM configuration with 8 cores, 8 GB of RAM and a hybrid storage system. Characteristics of the storage system is provided in Table III.

TABLE III: Storage devices specifications

Characteristics	HDD	SSD($)
Price ($)	230	200
Size	1 TB	128 GB
Performance	Seek time:8.5 ms	rr:10000 IOPS, rw:40000 IOPS
	read/write: 9.5 ms	sr:540 MB/s, sw: 520 MB/s

Each CSP manages a set of databases (DBs) built using TPC-H and TPC-C benchmarks with different sizes and varied workload, we used the configuration given in [16]. For more details about the different DBs and storage system specifications see Table IV. The amount of storage penalty is set to 30 % of the total charges paid by the customer as in Amazon Cloud. The storage price is fixed according to Amazon gp2 price model (0.1$/GB/month) while the energy cost is set to 0.1$ per kWh as in [13].

Some of the customers are mobile and ask for a good latency by paying some extra charge. Their home CSP generally migrates their objects to the nearest CSP that meets the latency constraint otherwise the home CSP may undergo a penalty. Mobile customers are supposed to have a 1 week duration mobility. The price of latency is given in Table V [10] and its related penalty in Table VI. The evaluation is conducted over a 1 month with one-hour time period for dynamic resource price update. The insourcing prices are dynamically set by CSPs using equation (eq. 1) and changed each hour (period T). We assume that the outgoing network cost is set to 50% of amazon's which gives 0.09$/GB.

TABLE IV: Data bases specifications

Data base	Bench.	Reqs. nbr (op/h)	rr(op/h)	rw(op/h)	sr(op/h)	sw(op/h)
DB1(32GB/HDD)	TPC-C	432000	136800	46800	108000	32400
DB2(60GB/SSD)		28800000	601200	104400	5436000	147600
DB3(147GB/HDD)	TPC-H	331200	10800	216000	3600	18000
DB4(34GB/HDD)		355200	32400	216000	7200	10800
DB5(381GB/HDD)		15360	1080	8280	360	1080

TABLE V: Latency price/req.

Latency (ms)	Price by request ($)
< 200	0.0000001
< 400	0.00000005
< 600	0.00000002
> 600	0

TABLE VI: Penalty/req.

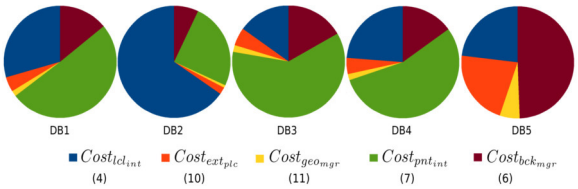
Latency (ms)	Penalty ($)
< 200	0
< 400	0.00000005
< 600	0.00000008
> 600	0.0000001

B. Evaluation results

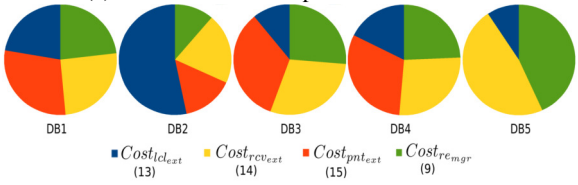
1) Relevance of the sub-costs: The first experiment concerns the relevance of the used sub-costs. In this scenario, the network latency between each pair of cloud infrastructures is assigned randomly between]200ms, 700ms]. First, we evaluated all different sub-costs for one CSP, then, we calculated the average placement cost of (1) insourced databases see (8), Figure 2 and (2) outsourced databases see (5), Figure 2, and compared the resulting costs with those of some state-of-the-art studies [18], [19], [21], [6], [25]. These costs were chosen as they are the higher ones.

Figure 3a and Figure 3b show the different sub-costs of our cost model (leaf nodes of Figure 2). In this evaluation, geo-replication costs were not considered (only geo-migration has been shown). We observe that all the modeled costs are relevant as each cost is high enough for at least one tested database. We observe that the local placement and penalty costs of internal customers are the highest ones. This is due to the fact that only a small part of customers are mobile (20%) and for small periods (1 week). Also, the database size affects directly the external placement cost because the storage in this case is bought from others CSPs. The database size affects likewise all the costs including geo-migration and back-migration, while the remaining costs are affected by the storage device type and workload patterns.

Figure 4a and Figure 4b show the cost of insourced and

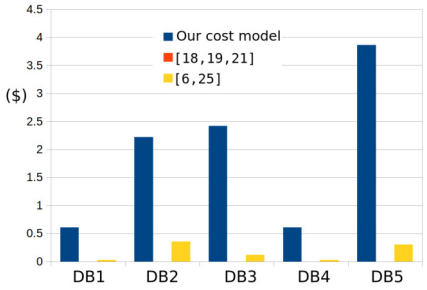


(a) Internal customers placement sub-costs

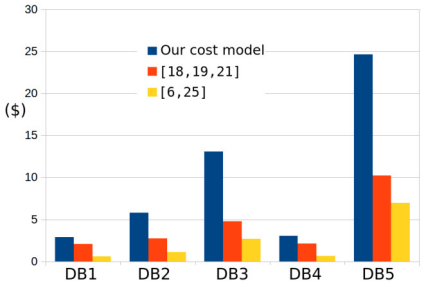


(b) External customers placement sub-costs

Fig. 3: Sub-costs of the simulated placement cost.



(a) Insourced database cost



(b) Outsourced database cost

Fig. 4: The average per week placement cost of the insourced and outsourced databases for a given CSP.

outsourced databases for a given CSP for our cost model as compared to state-of-the-art models. A first observation one may draw is that models from [18], [19], [21] do not consider the insourcing cost. In addition, the cost of storage services for outsourced objects is fixed to 1 GB/unit of time. In [6], [25], only the occupation cost is considered with no geo-migration cost which can lead, in the worse case, to a difference with our cost model of 95% for the external customers placement cost and 80% for the outsourcing cost. Furthermore, the penalty cost is ignored in those studies while in our work it can represent up to 61% of the placement cost of internal customers and 32% of that of external customers.

2) Spare resources pricing model evaluation: The objective of this part is to show how the proposed cost model makes it possible to easily evaluate the spare resource pricing model used according to the ran workload.

Figure 5.a shows, from one hand the cost of running insourced databases and from the other hand, the price billed to the partner clouds. As one can observe, the financial gain of insourcing objects highly depends on the nature of the ran workload. Insourcing large volumes of data generating a low number of queries (DB5) is of course more interesting.

Figure 5.b shows the outsourced objects cost when buying resources from partner clouds as compared to buying them from an external cloud. This Figure illustrates the ability of the model to highlight the gain obtained for a given CSP knowing its outsourced objects and the used federation pricing model. This may help to optimize the outsourcing decision.

3) Impact of latency and penalty, Federation vs DCC vs single Cloud: The designed cost model makes it possible to compare the cost of running a Cloud infrastructure within or out of a Cloud federation. In this part, we compare the average placement cost of mobile customers databases by varying the latency between clouds for three scenarios: (1) Geo-migration using a federation, (2) Geo-migration using a distributed cloud computing platform (DCC) and (3) Single Cloud without geo-migration (see Table 6). The aim of this part is to show the impact of the violation degree and the network latency on the average placement cost for the three configurations.

We notice, from Figure 6, that generally, the cost without outsourcing mobile customers increases with the increase of the network latency. For databases with heavy workloads (e.g. DB2) it is always interesting to outsource objects. In fact, outsourcing is interesting as long as the amount of outsourced data is small and the workload is heavy. This is not the case for data with small workload and large size. This is because geo and back-migrating these data implies a high network traffic cost (e.g. DB5). For some databases with large sizes and medium workloads, it is not cost-effective to outsource them as long as the violation of the latency is not high. However, when the degradation of network latency reaches a certain level, it becomes interesting to be outsourced. For instance, for DB3 the cost without migration (with penalty) is lower than the cost with migration when latency is $< 400ms$ but it is the opposite when the latency becomes $> 600ms$. Our cost model allows to make a trade-off between all these parameters for optimizing the overall cost of running a Cloud into a federation.

VI. Conclusion

A CSP can meet its customers QoS and minimize the cost of data placement by using either local or partner resources in a Federation. In this work, we have proposed a cost model for data placement on hybrid storage systems in a Cloud federation. Our model extends state-of-the-art work by considering geo-migration, penalty, back-migration, and geo-replication costs.

For future work, we will first investigate placement optimization strategies to find the optimal internal and/or external placement for CSP objects. We will also design pricing strategies for resources in a Federation.

The performed evaluations proved the relevance of the considered costs. It also pointed out that outsourcing and insourcing is a complex task that requires taking into account a large number of parameters. Even though our model is storage oriented, it can be used and integrated in a broader cost model considering other resources (e.g. CPU and memory).

APPENDIX A: NOTATION TABLE

Symbol	Meaning
Federation	
F	Federation of a set of CPs
CP^d	cloud provider d
$Cap_{max_{res}}$, $Cap_{idl_{res}}$,p_{rsc}	The total and the idle capacities of storage resource res and its price.
F^d_{res}	The insourcing price of storage resource res of CP^d
Customers	
U_{int}, u_k	The set of internal customers and kth customer
U_{ext}, $u^{d'}_{k'}$	The set of external customers and k'th external customer of CP^d(internal customer of the cloud $CP^{d'}$)
wl_k	the workload of u_k
$iops_{sla,k}$, $ltc_{sla,k}$	The requested performance in terms of IOPS and latency
pn_k, $pn_{iops,k}$, $pn_{ltc,k}$	The penalty function, and its parts iops penalty and latency penalty
$iops_{offered}(u_k)$	The IOPS offered to customer u_k
$ltc_{offered}(u_k)$	The latency offered to customer u_k
Storage	
SC, sc_j	The set of storage classes, The jth storage class
$sc_{j,int}$, $sc_{j,ext}$	The internal and external customers storage parts
c_{sc_j}, p_{sc_j}, wo_{sc_j}	The capacity, price and wear out of sc_j
Bandwidth	
bw, p_{bw}	The bandwidth and its purchased cost
bw_{int},bw_{ext}	The internal and external customers bandwidths
Objects	
$o_{i,k}$, $s_{o_{i,k}}$	The ith object of customer u_k and its size
$req_{op,o_{i,k}}$	The average IOPS of type op issued to the object $o_{i,k}$
$O_{m,int}$, $O_{m,ext}$	The set of internal (external, respectively) customers objects to migrate between internal storage classes
$A[i,j], B[i,j]$	the internal and external customers objects placement matrices
General	
T	Period of time
T_{sp}	The internet subscription period
Costs	
$Cost_{plc,T}$	The total placement cost
$Cost_{plc_{int},T}$	The internal customers objects placement cost
$Cost_{plc_{ext},T}$	The external customers objects placement cost
$Cost_{tcl_{int},T}$	The local placement costs of the internal customers
$Cost_{tcl_{ext},T}$	The local placement costs of the external customers
$Cost_{pnt_{int},T}$	The penalty costs of the internal customers
$Cost_{pnt_{ext},T}$	The penalty costs of the external customers
$Cost_{pnt_{iops},T}$	IOPS penalty costs
$Cost_{pnt_{ltc},T}$	Latency penalty costs
$Cost_{stg_{int},T}$	The storage cost of the internal customers objects
$Cost_{stg_{ext},T}$	The storage cost of the external customers objects
$Cost_{mgr_{int},T}$	The inner migration costs of the internal customers objects
$Cost_{mgr_{ext},T}$	The inner migration costs of the external customers objects
$Cost_{out_{src},T}$	The outsourcing cost
$Cost_{in_{src},T}$	The insourcing cost
$Cost_{geo_{mgr},T}$	The geo-migration cost
$Cost_{bck_{mig},T}$	,The back-migration cost
$Cost_{re_{mgr},T}$	The re-migration cost
$Cost_{geo_{rpl},T}$	The geo-replication cost
$Cost_{add_{rep},T}$	The cost of adding a replica
$Cost_{syn_{rep},T}$	The cost of synchronizing replicas
$Cost_{rd,T}$	The local read cost
$Cost_{rd_{erg},T}$	The read energy cost
$Cost_{rd_{edr},T}$	The read wear out cost
$Cost_{wr,T}$	The local write cost
$Cost_{wr_{erg},T}$	The write energy cost
$Cost_{wr_{edr},T}$	The write wear out cost
$Cost_{bw,T}$	The local consumed internet bandwidth cost
$Cost_{bw_{amz},1}$	The amortized internet bandwidth over one unit of time
$Cost_{ntw_{out},T}$	The external outgoing network cost
$Cost_{ext_{occ},T}$	The external occupation cost
$Cost_{ext_{wld},T}$	The external workload cost
$Cost_{ext_{plt},T}$	The penalty cost

***Abstract*—This paper presents a novel approach to synthesise hybrid controllers. A two-phase multi-objective evolutive algorithm was used to generate Unified Enhanced Timed Petri Net (UETPN) models. These models combine capabilities of timed Petri-nets, fuzzy logic systems and simple arithmetic operators. They can handle both event-like and continuous inputs (and outputs). The first phase of the algorithm uses Koza style genetic programming combined with multi-objective methods such as NSGA-II and SPEA2 to obtain an initial model. The second phase improves the initial model with recombining the fuzzy rules with genetic algorithm GA. In order to generate UETPN models (with GP), an intermediate language was designed, called UETPN Lisp. Four example are presented to exemplify the potential of the proposed framework.**

***Index Terms*—hybrid control, Petri nets, genetic programming**

I. Introduction

HYBRID controllers have a substantial practical importance because almost every real application from simple temperature control to complex robotic agents can have both event-like inputs and outputs, and continuous ones. Well-known examples of problems solved by Genetic Programming (GP), such as the artificial ant and obstacle avoiding robot (presented by Koza at [1]), are formulated in a way that only one domain is involved. In this paper, a two-phased evolutionary algorithm is presented, which is capable of synthesising controllers for discrete event systems, discrete time systems and hybrid systems as well.

Unified Enhanced Timed Petri Net (UETPN) models are used as the target platform for the proposed evolutionary framework. They are based on Delayed Time Fuzzy Petri nets [2]. For an effortless expression of control algorithms, they were completed with mathematical operators. Their ability to competently model reactive applications is shown in [3]. They are fit for handling continuous (real number) variables and fuzzy logic variables and for performing simple arithmetical and logical operations. They are capable of modifying the execution (split, join, select or block) depending on some external or internal value.

The proposed platform generates a complete UETPN model with GP, and in the second phase, it tries to improve it by recombining the fuzzy rules with genetic algorithm (GA).

The overall proposed framework needs a fitness evaluator for the given problem as input. This fitness evaluator consists of a fitness function and a light-weigth simulator. The ouput is an UETPN model which can be employed to control the specified system.

In order to widen its applicability, the presented framework supports the usage of Pareto front-based multiobjective methods such as NSGA-II [4] and SPEA2 [5]. These methods can also help to reduce the bloat, an issue which typically affects GP [6]. The presented experiments highlight the general applicability of the framework. The proposed method is applied to four different problems, for which the fitness function has been changed.

II. Evolving Petri nets

Fuzzy Petri nets are applied in various fields: path-tracking control problems; adaptive task assignment; fault estimation, detection, and diagnosis for power systems; urban and rail traffic control and many more [2]. Despite the vast range of applications, surprisingly few attempts were made to generate them automatically. Wong in [7] presents a framework called LOGENPRO used to extract knowledge from databases. LOGENPRO uses GP applied to logical grammars, based on place-manipulation and transitions-manipulation operators (such as sequential or parallel division). These operators modify the predefined fuzzy Petri net (FPN). However, the overall process restricts the structure of the FPN. The overall result lacks any internal state, timing and inner loops. These restrictions limit the applicability of the proposed framework in control applications.

Nobile in [8] introduces a new type of PN called Resizable Petri Net. This have divided the places and transitions into two groups: hidden places (or transitions) and normal ones. In the proposed framework only the number of the hidden nodes varies, the resulted PNs resemble binary trees.

An entirely different approach is presented in [9], which evolves some parameters. Based on these parameters and a template the final PN is assembled. This approach allows the use of the traditional real-coded genetic algorithm. Nevertheless, it can be applied only in case the structure of the PN is known upfront. Another approach presented by [10] addresses a biological problem modelled by PNs. In this case,

TABLE I: Mapping table (i. e. MT) associated with *t4* of the first example (only the indices of the rules are marked)

$P9/P8$	X_{-2}	X_{-1}	X_0	X_1	X_2	ϕ
X_{-2}	ϕ	ϕ	ϕ	ϕ	ϕ	-2
X_{-1}	ϕ	ϕ	ϕ	ϕ	ϕ	-1
X_0	ϕ	ϕ	ϕ	ϕ	ϕ	0
X_1	ϕ	ϕ	ϕ	ϕ	ϕ	1
X_2	ϕ	ϕ	ϕ	ϕ	ϕ	2
ϕ	-2	-1	0	1	2	ϕ

the authors establish the number of the places based on the problem specification, traditional GA evolves only the arcs. The presented problem is solved, still, their approach is far too restrictive to be applied in a broader domain.

A more general idea is presented in [11], using traditional GA. The gene, a transition-place pair, is decoded as an arc linking them. They use their framework to synthesise PNs starting from a structural and behavioural specification. Following the evolutionary process, additional steps are needed to improve the result and to reduce its size. This approach has potential, yet we believe that GP is abler to discover and re-utilise building block in the case of a PN-like structure.

III. Unified Enhanced Timed Petri Net

The UETPN models ([12]) incorporate transitions that have associated mapping tables (MT) and optional arithmetic operators. The MT is an organised form of the fuzzy rules which determine the bahaviour of the transitions. The input token(s) can activate the rules and if there is no operator, these rules define the output of the transition and they decide whether a transition is executable. UETPN supports transitions with one or two input places and one or two output places.

The mapping of a transition can be defined as a function between the current marking of the pre-places and post-places.

MT can have different shapes based on the numbers of inputs and outputs. An MT with two inputs and one output is exemplified in Table I, while another with one input and two output in Table II. If the current marking of a place is marked with x_p, then one cell represents the following fuzzy rule:

$$IF\ x_{i0} is X_0 \wedge x_{i1} is X_{-2}\ THEN\ x_{o1} is X_1 \wedge x_{o2} is X_2 \quad (1)$$

Each place has an associated scale (s_k). The token t_k set in a place is always in $([-s_k, s_k] \cup \phi)$, where ϕ means *no information*. Petri nets express *no information* leaving the place empty, nevertheless, in the case of the UETPN a place always has a marking.

When a transition executes, the input tokens are fuzzified in the first step. The limits of the membership functions are defined based on the scale of the input place. Simple triangular membership functions are used. Secondly, the fuzzy rules in the MT are executed, the result is collected and defuzzified by the center-of-gravity method. The scale of the output place(s) determines the defuzzification intervals.

If an arithmetic operator is assigned to the transition, the following equation is applied:

$$map_i(x_{i1}, x_{i2}) = (x_{i1} \circ x_{i2}) \star FL_{MT}(x_{i1}, x_{i2}) \quad (2)$$

TABLE II: Mapping table (i. e. MT) associated with *t3* of the first example (only the indices of the rules are marked)

X_{-2}	X_{-1}	X_0	X_1	X_2	ϕ
$0, \phi$	$0, \phi$	ϕ, ϕ	$\phi, 0$	$\phi, 0$	ϕ, ϕ

where $\circ \in \{+, -, /, \times\}$, and $FL_{MT}(x_{i1}, x_{i2})$ stands for the result of the mapping table deffuzified in the interval $[-1, 1]$. The fuzzy rules can alter the original result, but, if all the conclusions are X_2, the result of the operator is unchanged. The obtained value is truncated based on the scale of the output place. Only the transitions with two input places can have operators.

The existence of every fuzzy rule is not compulsory for MT construction. ϕ signals the missing rules. The MT also has ϕ columns and rows, which supports the definition of rules even if one (or both) of the input tokens are ϕ.

Another role of the MT is to decide whether a transition is executable (referred to as enabledness). A transition is allowed to fire if there is at least one fuzzy rule with $non-\phi$ consequence (in the MT) which applies to the current input marking.

This definition of enabledness and the possibility to put ϕ in some cells of the MT facilitate the implementation of inhibitor arcs, reset arcs, and transitions which are always enabled or blocked.

A precise description of communication with the outside world is pivotal for the UETPN to model hybrid controllers. UETPN models represent input channels as input places. The tokens set in these places can emerge from the exterior world (environment) only. The output channels are represented as output transitions. The output transitions do not have post-places, they send the tokens outside the current component. Multiple UETPN components can be connected in the previously described way.

A. Definition of UETPN

[3] contains not only the complete definition of the UTPN models, but some significant examples and applications also. In this section, only a brief introduction is given. The examples do not resolve a real-life problem, however they illustrate some of the capabilities of UETPN models (and they exemplify the UETPN-Lisp introduced in the next section as well).

The definition of UETPN is:

$$UETPN = (P, T, pre, post, D, S, EFS, Map, Inp, Out, \alpha, \beta, \delta, \mathbf{M}, M^0)$$

where:

- P is the place set, T is the transition set ($P \cup T = \emptyset$), while $pre \subset (P \times T)$ contains the arcs from places to transitions, $post \subset (T \times P)$ includes the arcs from transitions to places. D is the delay set. δ is a mapping $\delta : T \to D$, which associates delays to transitions. Their meaning corresponds to the ones from classic Petri nets.
- $Inp \subset P$ are the input places (channels), $Out \subset T$ are the output transitions (channels).

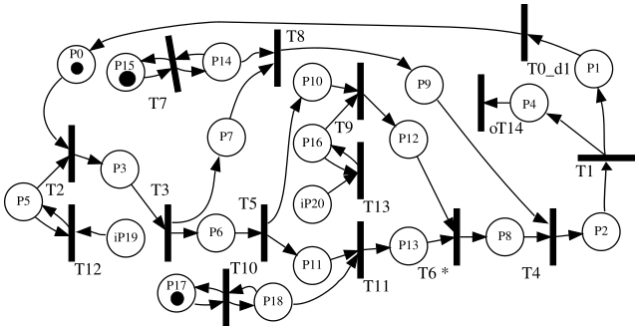

Fig. 1: Structure of the expression *(# (@ (@ i:br:0 (% (* i:br:1 c:2.0) c:0)) o:c:0) d:1)*

[t]

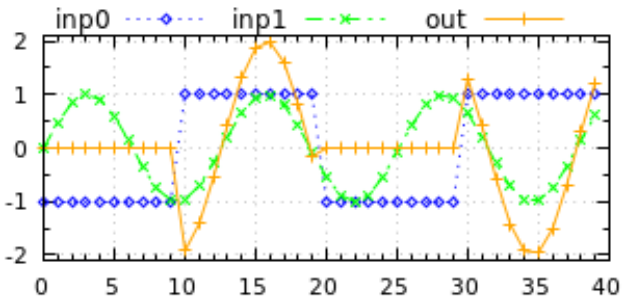

Fig. 2: Behavior of the first example

- $S = \{s_0, s_1, s_2 \ldots, s_m\}$ is a set of real numbers representing the scale factor set or bound set, α is a mapping such that $\alpha\colon P \to S$, it assigns a scale to each place from the set P.
- **M** is the marking vector, while M^0 is the initial marking vector.
- EFS is the extended fuzzy set $\{X_{-2}, X_{-1}, X_0, X_1, X_2\} \cup \phi$,
- $Map = \{map_i | i = 0, 1, 2, \cdots, n\}$ is the set of mappings. A mapping consists of one particular fuzzy logic rule set, expressed in a form of mapping table (MT) and an optional arithmetic operator. β is a mapping $\beta\colon T \to Map$, it assigns a mapping from the set Map to each transition

B. Example of a UETPN model

The first example illustrates how UETPN models can alter their execution based on the value of an (input) token. It demonstrates how mathematical operations can be implemented too.

Figure 1 represents the structure of the first example of a UETPN model. It has two input places and one output place. If the zeroth input channel has a positive non-ϕ token, the output equals two times the first input. Else, the output returns a constant zero token. The transition t3 has a key role in this behaviour. Its MT table returns a token to P6 if the value in P3 is positive, and to P7 if it is negative. Table II specifies the mentioned MT table. The constructions P17-t10-P18 and P15-t7-P14 are responsible for providing the constant values, P15 and P17 contain an initial token with the value of 2.0 and 0, respectively. T6 multiplies the input read from iP20 (via P12) with the constant from P17 (via P13). T4 has to have an MT table which enables if there is a non-ϕ token in P9 or P8, because only one main branch is executed simultaneously. Table I presents this MT. The transition oT14 fires the result to the outside world. Note, that t0 has one delay before the whole cycle starts over.

Figure 2 displays the behaviour of the described example. It can be observed that when the zeroth input is -1 (between the 0th and 10th time tick and between 20th and 30th time-tick), the output is zero. When the zeroth input is 1, the output doubles the sine wave of the first input.

The second example also alters its execution, however, in a completely different way. In contrast with the first example, the execution flow depends on whether a transition is executable. Note that the definition of the UETPN models does not prioritize the transitions, however, one can be sure that the executor tries to fire the transitions with the lowest delay at first. Another restriction is that in the case of conflicting transitions, the executor behaves in a deterministic way.

Figure 3 displays the structure of the second example. This example has two inputs and one output. All the places have 1.0 as scale. It contains an inner loop which executes until the outside environment inserts a token to iP11, which in turn is transmitted to P5. When a token appears at P4, t1 becomes executable, and the model stops its execution. The inner loop returns a token to the output oT9 if in the input place iP10 has a token which activates the X_0 rule of t5. Table III specifies the MT of t5. If t5 is not fireable, T4 starts firing. After T4 finished its firing (it has one tick delay) the whole cycle begins over via T3.

Figure 4 shows the behaviour of the second example. The output is activated when the zeroth input is in the interval $[-0.5, 0.5]$ which corresponds to the activation of rule X_0 after fuzzification. It is also observable that after an event appears in the first input (at the 30th time-tick), there is no more output regardless of the inputs.

Note, that the transitions t12 and t13 from the first example, t8 and t7 from the second example have the role in copying the new input token regardless of the existence or value of the previous inputs (stored in the buffer places after these transitions). These structures are not essential from the functional

TABLE III: Mapping table (i. e. MT) associated with *t5* of the second example (only the indices of the rules are marked)

$P2/P8$	X_{-2}	X_{-1}	X_0	X_1	X_2	ϕ

point of view, but since these models are direct correspondents to some UETPN Lisp expressions, it would be imprecise to omit them.

IV. Model construction

The semi-automatic way of fabricating a UETPN model has two phases. In the first one, an initial model is generated with GP and UETPN Lisp. It constructs a complete UETPN model, which is executable and evaluable with a fitness function. However, the available MT tables are predefined, which limits the possible behaviours. The result of the first phase is not only the UETPN model itself but also a meta-data about the context of transitions. Based on this metadata the MTs of some transitions can be re-trained with GA. This preselection of the transitions is necessary because in most cases the models yielded by the first phase have so many transitions that it is infeasible to optimize all of the MTs with GA.

There can be several reasons to employ the second phase. First of all, if the fitness value produced by the result of GP is not satisfactory, there is a chance that the second phase will improve it. Secondly, the fitness itself can be adjusted, taking into account other evaluation criteria. Thirdly, the parameters of the problem can also be modified. In this case, the re-training of the UETPN model achieved in the first phase may lead to significant improvement.

Although the entirely automatic synthesis is possible, it is highly recommended to analyse and evaluate the solutions manually after the first phase. It is recommended to ensure that the found solution has the desired behaviour, because the GP often can find a workaround to achieve a high fitness value without satisfying the real fitness criteria. The length of the

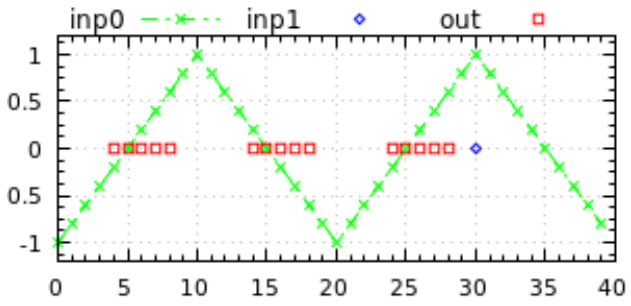

Fig. 4: Behavior of the second example

simulation for fitness evaluations is always a compromise, because the longer the simulation is, the more time it takes to run the algorithm. It is advised to execute the first phase several times and to choose a suitable solution before performing the second phase. Also, the types of transitions whose MTs are optimised have to be selected manually.

Finally, it has to be mentioned that in the case of problems which do not benefit from the effect of fuzzy rules, the second phase has no benefit. In these cases, the problem has to be solved in the first phase.

A. First phase:GP with UETPN Lisp

In the first phase, classical tree-based Koza style GP is used. The overall algorithm and the genetic-operators are not specified here, they are applied as in the literature ([13] and [1]). The focus of this section is on the UEPN Lisp, which is a small language used by GP framework. It presents the operators and the operands and exemplifies he conversation from UETPN Lisp to UETPN model.

UTEPN Lisp is transformed to UEPN model by breadth-first traversal. Every sub-expression is built up between two places. The algorithm starts by adding the two principal places. The root node is built between these. The first place has an initial token which begins the execution of the model. Both in case of the first example (Figure 1) and the second example (Figure 3), this starting token is placed in P0.

All of the operators of the UETPN Lisp have two operands. The sequence operator denoted by @ is the simplest one, it indicates that the two operands come after each other separated by a place. In the second example, the place P7 separates the transition T5 and T6, a structure which is the result of decoding a sequential sub-expression "*(@ i:eiz:0 c:c0)*". The selection operator (marked with *?*) builds up both of its children between its original starting and ending place. It can be noticed that either the transition t4 or the structure t5-P7-t6 executes from the second example. This is the result of a sub-expression of *(? (@ i:eiz:0 c:c0) d1)*. The loop operator (#) produces a similar structure, however, the direction of the second child is reversed. In the second example, T3 is the second child of a loop operator. T0 is the second child of a loop node in the first example.

The structures produced by the concurrency operator (&), positive-negative split operator (%), sum operator (+) and multiplication operator (*) are the same, the only difference are the MT tables and the mathematical operators associated with the transition. In the first example, the structure from P3 to P2 is the result of the sub-expression *(% (* i:br:1 c:2.0) c:0.))*, and the transition T3 and T4 are built as the part of the positive-negative split operator. The T3 has an MT which yields a token into one of its outputs only, based on the sign of the input. In the structure mentioned above, the fragment staring from P6 to P8 is built as the result of the sub-expression *(* i:br:1 c:2.0)*. The transitions T5 and T6 were added as a result of the multiplication operator.

In case of the second example, the root of the expression is a concurrency node. The transitions t0 and t1 are added as

part of this operator. As the name suggests, in this case, both branches are executed independently, and t1 becomes fireable if both finish their execution. If the sum or multiplication operator is used, T1 has the corresponding associated operator.

The most crucial operands are the input and the output operands. They connect the main flow of the model to the input place or output transition. They also have a type which specifies the MT tables used in the connection transition. For example, the input node *i:eiz:0* means that the zeroth input is read with a transition which is enabled if the input token activates the X_0 rule. In this case, the MT mentioned above belongs to t8 (second example), and iP10 is the zeroth input.

The P8 is a buffer place where each input node has a copy of the original input token, and t7 is an auxiliary transition, responsible for placing the new token to the buffer place. This role is essential in the case of models which use the same input multiple times. Other types of inputs are the blocking reader ("*br*"),non-blocking reader ("*nbr*"), enable if non-ϕ ("*enp*"), enable if phi ("*eip*"), enable if zero ("*eiz*"), enable if not-zero ("*enz*"). The type of the input is essential in case of the second example, where the zeroth input has " enable if zero" type. If the evolutive framework mutates it into "enable if not-zero" ("*enz*"), the behavior of the model is inverted. If changed to something else, the execution of the model would be dramatically different. Note that these input types help the framework to deal in a completely different way with event-like and continuous inputs . The ones with *"enable"* in their names block the token in the main flow without modifying its value. The *"reader"* ones copy the value of the input token into the main flow.

Similarly to input leaves, outputs also need auxiliary constructions. In the second example, P9 acts as a buffer place connecting T6 to the real output transitions oT9, which is the result of the leaf *o:c:0*. Outputs currently can be only *copy* type, however, defining new types is as easy as to define a new MT table. (This applies to the input types as well.)

Other operands are the delay nodes (*d:nr*), which insert transitions into the flow with a certain delay, the constant (*c:nr*) leafs that provides a mathematical constant, blocking leaf (*b*), whose role is to insert a transition which is never executable, negation leaf (*n*) which negates the sign of the tokens, inversion leaf (*v*), and memory leaf (*m:nr*) which delays the value of the token, but it does not block the execution of the model. Some of these (memory, inversion, constant) are implemented with complex structures, others are single transitions with unique MT tables and/or mathematical operators.

During the decoding, the created transitions are categorised as follows: input, output, split-starter, split-merger, auxiliary, others. These categories (one or more) can be selected for optimisation by the second phase. The early experiments showed that in the majority of the cases optimising the input, the output and the split-merger transitions yielded the same results as adding any other category to this group. What is more, widening the set of optimised transitions means larger search space for the second phase.

B. Second phase: GA for the fuzzy rules

Similarly to the previous section, the GA itself and the genetic operators are not presented here, they are used in the well-known way ([14]). Simple binary encoding is used. The user of the algorithm decides which type of transitions have to be optimised.

In order not to change the behaviour drastically, only the non-ϕ rules were marked to be re-trained by the presented GA, and they can trun to other non-phi rules. Three bits can represent the five possible rules. A three-bit unit was chosen as the gene, their sequence composes the chromosome for GA. Since three bits can represent eight values, three of them is not used. The crossover, the mutation and the creation of initial population were modified in order not to produce the unused combinations.

V. Experiments

A. Control of a first order system

A simple task was choosen to exemplify the working of the framework: control of a first order system. Firstly, a known structure is optimized. Secondly, the complete framework solves the problem.

The fitness functions used for these problems take into account the absolute error (e_a) and the steady state error(e_s) of the controlled system. All of the experiments use the same fitness function:

$$f(i) = 1/(1 + \alpha * e_a + \beta * e_s)$$

where α and β are constants set to 0.8 and 0.2.

Firstly, a proportional integral (PI) controller was manually defined in UETPN Lisp. The rules of the input, output and the split-merger transitions were optimised. After 50 runs, the average fitness was 19.46. One of the average results is presented on the upper part of the Figure 5.

Secondly, GP solves the same problem with the same fitness function. The after 50 runs, the average fitness of the results was 25.39. An average result is displayed in the middle part of in Figure 5. Not only that the second result has hogher fitness, but the difference is also conspicuous, the overshoot is better, and the overall error is smaller.

Thirdly, GA is applied to optimise the rules of the previous result. The average fitness in this case is 27.88, which means smaller increment, however, the differences (the lower part of the Figure 5) still can be noticed.

Additonally the result of the second step was re-trained with GA to control another modified first order discrete system. The solutions have superior performance than the orginal controller, however, they do not overperform a re-traned PI controller.

B. Artificial Ant Problem

The Artificial Ant is a classic GP problem used by Koza at [13] to illustrate GP. The previously presented UETPN Lisp has the disadvantage of being more general, in contrast to Koza's solution (and many other papers), which use specialised operators and operands. As it is anticipated, the

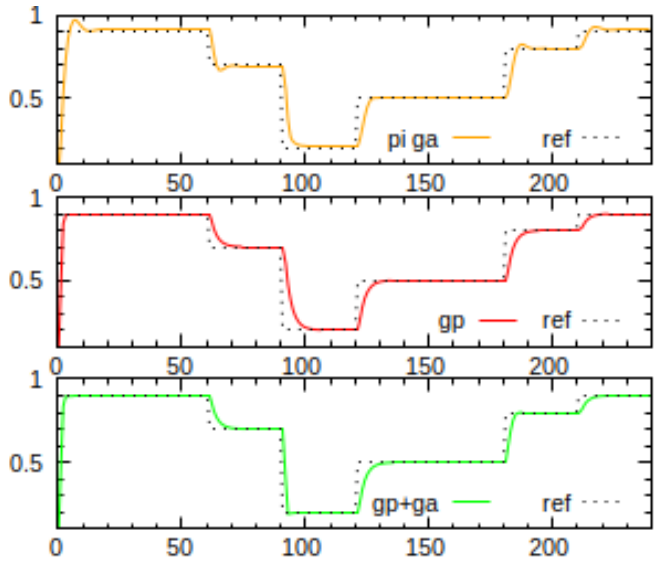

Fig. 5: Comparison of different results for the original system (PI optimized, GA only and GA+GP)

performance of the general framework does not match the specialised one.

An artificial ant is capable to turn left or right and to move forward. The single input is activated if food is ahead. The controller has three event-like outputs and one even-like input. The fitness function is the number of food units eaten. The ant is placed in the well-known Santa Fe trait.

The overall problem is known to be difficult to solve and it was used by several researchers to demonstrate features of their algorithm. A comprehenesive review of the problem can be found at [15]. The advantages of flexible genome show up in the case of this problem, because fixed length genome can represent only restricted number of program states.

Since this problem requires higher population number and iteration than the previous one, bloat presents a more serious complication. Bloat is the phenomenon when tree-sizes grow exponentially fast, wasting the computational time and filling up the overall genetic material of a population with useless fragments. The proposed framework implements traditional methods such as various form of Parsimony Pressure, which essentially means that the size of the individual is part of the fitness.

The problem with these methods are that it is hard to assess the size compared to the original fitness value. The demonstrated framework can also apply static and dynamic simplification over UETPN-Lisp. These methods replace the sub-expressions, which can be expressed simpler and delete the unused ones. Although they are effective on compacting the potential solutions, they cannot entirely solve the bloating phenomenon.

A robust method in the case of UEPN-Lips applied to the artificial ant problems is to use NSGA-II with two fitness functions. The first of them is the number of food eaten (f_f), the second one is the number of eaten multiplied by the size factor (f_s). This way the second objective favours candidates which are small and fit. This idea gives better results than the one presented [5] where the second objective evaluates only the size. The size factor (f_s) is calculated by:

$$f_s = (s_i - s_{prf})/(s_{max} - s_{prf})$$

where s_i is the size of the individual, s_{max} is the maximum allowed size, while s_{prf} is the preferred size. In these experiments $s_{max} = 500$ and $s_{prf} = 20$, outside these limits f_s is defined as 1 (if $s_i < s_{prf}$) or 0 (if $s_i > s_{max}$).

The original solution presented by Koza needs to evaluate $450 * 10^3$ individuals for an acceptable average solution ([15]), similar results can be obtained with $500 * 10^3$. The best algorithm proposed by [15] is equipped with problem-specific base language but also specialised crossover and mutation, and it has a far better success rate with $51 * 10^3$ evaluated individuals.

C. Room temperature control

This experiment is a hybrid application with two inputs: the reference temperature and the actual reading from the heat sensor in the room. There are two event-like outputs: one of them starts the heating, the other one stops it.

A discrete time system simulates the room temperature. It is based on the temperature differences:

- $\delta_{ht}[k] = t_{hw}[k] - t_r[k]$ is the difference between the temperature of the heating water (t_{hw}) and the room temperature (t_r).
- $\delta_o[k] = t_r[k] - t_o[k]$ is the difference between the outside temperature (t_o) and the room temperature.

The room temperature is simulated in the following way:

$$t_r[k+1] = t_r[k] + c_{ht} * \delta_{ht} - c_{wl} * \delta_o - c_{wi} * \delta_o$$

, where c_{ht} is the heating constant set to zero if the heating is turned off. c_{wl} is the wall constant, and c_{wi} is the window constant set to 0.0 zero of the window is closed. The opening and closing is the disturbance of the overall system. In this case, the temperature of the heating water is considered constant. Another important point is that the sensor reading is delayed compared to the simulated room temperature.

A elementary fitness function can be defined with the help of the sum of the error. However, this would lead to controllers which do not react to the input values but rather turn on/off the heating periodically. The problem can be solved by adding a lot of test scenarios with hectic temperature changes. This would lead to slower evaluation of a solution candidate, hence longer overall runtime. The approach used here evades the elongated run-time: the number of the minutes when the temperature is outside the interval of $t_{ref} \pm \delta$ is mesured, where δ was chosen to be 0.5. The behaviour of a solution found in the first phase (with GP) is presented in Figure 6. The controller turns the heater on only when it is necessary, and the heater stays on until a certain limit is reached. The desired behaviour is achieved, however the GA was not able to improve it.

In the second part of the experiment, the parameters of the room model were changed. The disturbance effect was higher

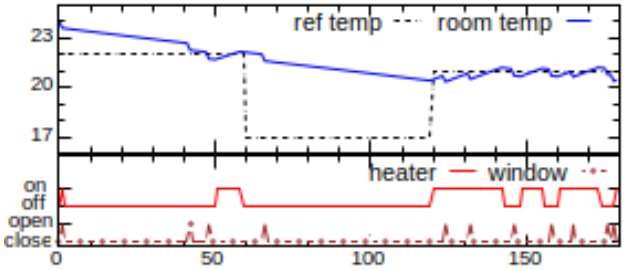

Fig. 6: The evolution of room temperature in case of GP

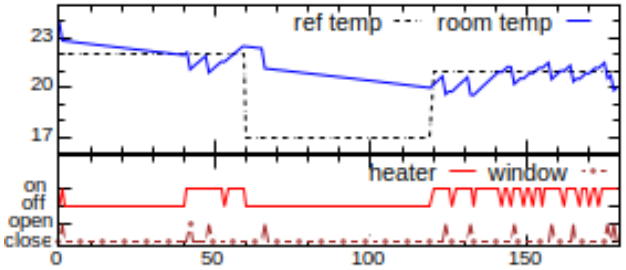

Fig. 7: The evolution of room temperature in case of the modified system

than in the previous experiment (presumably because the window is larger or the volume of the room is smaller compared to the window), while power of the heater was increased. In this case, the original controller performed poorer. The behaviour of a solution which has the same structure as the original one but it was re-trained with GA taking into consideration the new room model. The new behaviour of is shown in Figure 7. The presented solution was able to respond to the new challenge.

D. Room and Water Heater Temperature control

In this section, the desired controller has to control the temperature of the heating water, in contrast with the previous part where it was considered constant. This way the controllers have three outputs, first two of them have same functionality as in the previous section.The third has continuous behavior, aimed to control the water temperature in the heater tank. There are four inputs: the actual temperature of the room, the reference temperature of the room, the actual temperature of the water and the reference temperature of the water.

With the objective to simulate the temperature of the heating tank, the following intermediate variables are defined:

- $\delta_w[k] = t_{hw}[k] - t_pw[k]$ is the temperature difference between the heating water (t_{hw}) and the water from the pipe (t_{pw}).
- $\delta_{cmd}[k] = t_{max} - t_{hw}[k]$ is the difference between the maximum water temperature (t_{max}) and the current heating water.
- $\delta_t[k] = t_hw[k] - t_t[k]$ is the temperature difference between the heating water and the room.

The temperature of the heating water is given by the following discrete time equation:

$$t_{hw}[k+1] = t_{hw}[k] - c_h * \delta_w + c_{cmd} * u[k] * \delta_{cmd} - c_t * \delta_t$$

where c_h, c_{cmd}, c_t are constant, c_h is set to 0 if the heating is off. $u[k]$ is the output of the controller. The rest of the system is identical to the one mentioned before.

This system can be viewed as the combination of the first order system, and the setup presented in the previous section. Although it is self-explanatory that the framework can express the desired controller, it is hard to come up with the adequate fitness objective(s). The only known solution needs multi-objective optimization and far more evaluated individuals than any of the examples presented here.

The first objective is similar to the one in the previous section it counts the number of the minutes when the room temperature and the temperature of the water is off limit. The second fitness objective sums up the error and of the room temperature and the temperature of the water relative to the references. (The reference for the water temperature is constant 60). The third one is identical to the first one, except that it takes into account the size factor presented in the section related to the artificial ant. SPEA2 is known to handle better more than two objectives than NSGAII [5], hence it was chosen as the base algorithm for the experiment.

As it has turned out, the boiler is too weak compared to the room model. In practice, this means that when the heating is turned on in the room, the temperature of the water drops fast and constant temperature cannot be maintained for more than two or three minutes. In the real world, this would be a severe design problem, but the proposed framework overcame this flaw.

Figure 8 presents the behaviour of one solution found after GA is applied as well. This controller starts to heat up the water in the heating tank before the temperature of the room drops to a critical temperature. This way when the controller turns on the heating in the room, the water is already heated above the reference temperature, and the heating can remain on for a longer time. It is not the expected solution, but it is unarguably a creative one.

Figure 9 displays the operations of an another solution. This solution turns on the heating for a minute or two only in order to maintain the constant water temperature. This approach performs weaker in the first hour of the presented scenario than the previous one. However, in the rest of the time it has an adequate performance.

The first solution performs better from the perspective of the first fitness objective, while the second fitness objective favours the second solution. In this experiment, multiple fitness scenarios were needed in order to reduce the number of solutions which perform a cyclic behaviour, which fits the average cases, without reacting to the current situation.

The presented framework is capable of finding an acceptable solution in 10% of the cases. The population size was 3200 combined with 200 iteration. This took in average five hours, more than 50 experiments were performed.

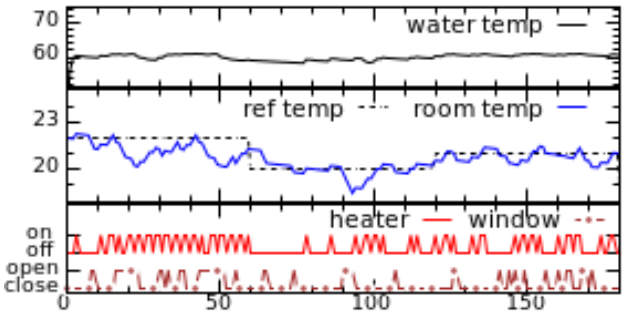

Fig. 9: The behavior of the second solution for Room and Water Heater Temperature control

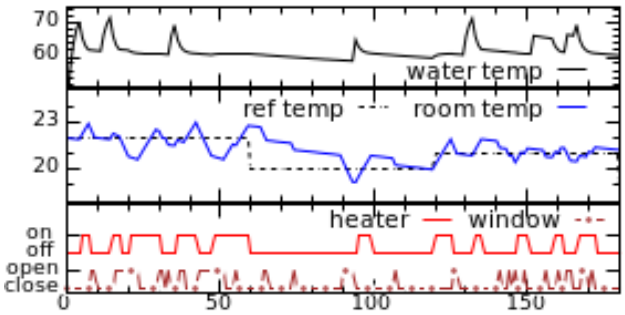

Fig. 8: The behavior of the first solution for Room and Water Heater Temperature control

VI. Conclusion

The current work focuses mostly on the capabilities of the framework and the effects of the two phases of the development. All of the presented experiments are reproducible with the code released [1] under an open-source license. Based on these experiments, it can be concluded that the given framework has the potential to generate controllers for hybrid systems. The presented experiments also highlight the fact that a complete base-language is not enough to tackle complex problems, the primary evolutive framework is at least that important.

The importance of multi-objective methods based on Pareto-fronts cannot be overstated. They have a strong focus on exploiting the known Pareto-front and on trying to improve in one way or another. This behavior is essential in case of controlling the bloat when shorter individuals are preferred, however, individuals with high fitness should not be deleted based on their size only. Yet, these algorithms have the disadvantage of being more disposed to early convergence to sub-optimal solutions. The explicit diversity control may be needed in the future.

Future development directions could focus on the compiling of the UETPN-model to machine code or Java Virtual Machine byte-code with the objective to make the evolution of a proposed solution faster. Another important direction is to conceive a method to deploy UEPN-models directly into micro-controllers with the aim to apply the presented result in real-life.

***Abstract*—The literature describes examples of software frameworks providing developers with generic and reusable functionality for building healthcare applications. Using concepts and technologies from Information Retrieval, Machine Learning, and Semantic Web, we present a novel software framework called HSSF (Health Surveillance Software Framework) which aims to facilitate the development of applications to support health professionals in the prevention of chronic diseases. The main contribution of this paper includes lessons learned distilled from (i) the reuse and evolution of the HSSF components on the development of three new health surveillance applications, and (ii) a quantitative evaluation of the HSSF reusability in terms of time spent and artifacts reused on such development task. Lessons learned are summarized as advantages and drawbacks regarding HSSF reusability. The HSSF allows healthcare applications not only to relate scientific research evidences, exams and treatments, but also to incorporate them together into the clinical practice.**

I. Introduction

THE practice of software reuse can potentially make information technology products more efficient for clients and cheaper for the production. Reuse is not limited to the source code or to the machine code; in a broader sense, documents, coding styles, components, models, patterns and knowledge items may be reused.

One way to promote reuse is to create software frameworks as abstraction of functionalities to build and deploy applications. We consider software frameworks as reusable designs of all or part of a software system described by a set of codes, libraries, tools, APIs, and mainly by abstract classes and the way that instances of these classes collaborate [1]. Therefore, the main goal of a software framework is to create new software more efficiently by means of reuse.

As in other knowledge domains, there are various examples of software frameworks targeting the development of healthcare applications. For instance, OpenMRS [2] [3] describes data items such as clinical findings, laboratory test results or socioeconomic data that can be stored by medical systems. OpenMRS consists of a concept dictionary to avoid the need to modify the database structure to add new diseases. This framework supports the programming of new functions without the need to modify the core code when the focus is the reuse of concepts and/or database models. IBM has developed the SpatioTemporal Epidemiological Modeler (STEM), which models infectious and vector borne diseases. STEM provides developers with a plug and play software architecture for the development of simulations of disease spread, e.g. in bioterrorist crises [4].

In terms of reuse of services, the service-oriented architecture (SOA) paradigm is used as a software framework that aims at facilitating the support for clinical decision [5]. At the level of classes reuse, the virtual reality domain also offers frameworks such as (i) ViMeT [6], which focuses especially on the development of applications that simulate biopsy exams, and (ii) SOFA [7] [8], which targets research into medical simulation. Still considering medical simulation, TES [9] carries out computational simulations of transcranial electrical stimulation.

Despite of the large amount of software frameworks support in healthcare, institutions, professionals and patients are still burdened with the amount of information created due to the mass adoption of the Internet and to the availability of several types of documents, including health records, social websites for health, medical images, among others. Furthermore, the information contained in such documents is too complex and semantically rich for traditional search engines to make sense of. This scenario can benefit from health surveillance systems which can recommend information related to the medical records of a given patient [10], or to a similar user, for example, to provide informational and emotional support in on-line social websites for health [11].

This paper (i) presents the Health Surveillance Software Framework (HSSF) as an evolutionary and reusable design of software components to support the development of health surveillance applications [10], (ii) evaluates aspects of the HSSF reuse, and (iii) lists the lessons learned along the evolution of the HSSF architecture.

The HSSF diagram, an object-oriented application framework, allows distinct health surveillance applications to be created by instantiation of its abstract classes. HSSF has been developed by evolving our previous software which were

This work was supported by the São Paulo Research Foundation (FAPESP - Proc. 16/13206-4) and the National Council for Scientific and Technological Development (CNPq)

designed as a reusable set of functionalities for surveillance systems. Hence, we built HSSF by generalizing software components from three previous endeavors: the *Automatic-SL* [12], the *CISS* [13], and the *FREDS* [14].

The *Automatic-SL* system assists healthcare professionals in their decisions recommending Surveillance Levels (SLs) to identify patients' healthcare needs. It can be used to recommend pediatric procedures in primary healthcare, and it also identifies significant risk factors and protective factors associated with the patients and their families. The *CISS* establishes associations between chronic diseases (cardiovascular diseases, diabetes and obesity) reported in scientific papers and a given patient's clinical record with genetic and epigenetics[1] risk factors. Finally, the *FREDS* effort focuses on the definition of conceptual mappings between the content of medical images and the textual information contained in medical records, applied in a scenario of computer-aided diagnosis in thyroid cancer.

By reusing HSSF components, developers have created three new healthcare applications: the *CISS+* [16], the *CISS-SW* [17] and the *QASF* [18] [19]. They answered a questionnaire that helped us understand the reuse of the HSSF mainly in terms of the number of reused artifacts and the time spent on reuse activities. Finally, lessons learned were elaborated from this whole experience with the HSSF components.

As far as we know, there has been no related research to HSSF in terms of two perspectives: (i) the same underlying theory and technology, including Information Retrieval, Machine Learning, and Semantic Web; and (ii) the health surveillance support, i.e. aiding the prevention of chronic diseases by alerting healthcare workers about risk factors through retrieval of published scientific papers with information on epigenetic risk factors, or even classification of patients into risk groups. Most frameworks in the healthcare domain have proposed reusing services (mainly simulations, electronic health records and medical decision support) and data model (ontologies, dictionaries and databases).

This paper is structured as follows: Section 2 the development of the HSSF framework; Section 3 describes the evaluation carried out as an attempt to understand the HSSF reusability. Finally, Section 4 discusses the lessons we have learned along the process, and Section 5 brings final remarks and perspectives for future work.

II. The development of HSSF

Here we briefly present how the HSSF was developed and evolved in terms of its software components architecture and its core systems including the *Automatic-SL* [12], the *CISS* [13], and the *FREDS* [14] systems. Further details can be found elsewhere[2] [10].

[1]People exposed to risk factors (e.g. food shortage) at the beginning of life can have altered the gene expression, which can impact adult life by posing higher risk of developing chronic diseases. Epigenetics studies those changes in the gene expression [15].

[2]Source code with documentation, papers and reports with UML models are available at the official HSSF website – *http://dcm.ffclrp.usp.br/hssf/*.

A. The HSSF architecture

The architecture of the HSSF is comprised of three main layers — *Presentation*, *Business*, and *Storage* — so that each layer contains its own modules to process documents, as depicted in Fig. 1.

The *Business* layer consists of abstract classes and external packages of utilities, both two in the target domain, as well as two connector layers, called *Communication* layers, which provide the required communication components to the *Presentation* and *Storage* layers.

The *Presentation* layer presents different views and templates such as Graphical User Interfaces (GUIs), which allows access by two main types of users: (a) healthcare professionals, who can analyze risk groups automatically classified by means of surveillance services, or who can receive recommendations of papers related to a given patient's clinical record (e.g. during a medical appointment); and (b) researchers interested in investigating the relationship between risk factors, chronic diseases, risk groups and patients' records.

The two *Communication* layers are composed of connectors for tools, ontologies and knowledge sources. The upper *Communication* layer allows the presentation of recommendations to end users (healthcare professionals and researchers) via GUIs. The bottom *Communication* layer integrates the *Business* layer with features provided by the tools (e.g. classifiers) and knowledge sources (e.g. pre-processed collections of scientific papers and ontologies), and also comprises modules for communication with databases.

In the *Business* layer, the *Search For Papers* module interacts with public repositories of scientific papers. This module collects and updates a collection of papers. Currently, the repository crawler uses concepts from ontologies of target domain to focus the crawler on topics of interest. There is no crawler for clinical records because all clinical records of interest are considered to be associated with scientific papers.

Also in the *Business* layer, the *Textual Processing* module is composed of programming utilities and modules for *Paper Processing*, *Clinical Record Processing* and *Natural Language Processing*. *Textual Processing* module processes textual information from a set of clinical records and collected scientific papers, which are all stored in the *Storage* Layer. Each document (clinical record or paper) is processed, so *Paper Processing* and *Clinical Record Processing* modules can identify simple and complex terms. The *Natural Language Processing* module applies natural language processing, such as processing of n-grams, stemming, removal of stopwords and recognition of concepts. The recognized terms are statically weighted and stored. The processing of clinical records is similar to the processing of scientific papers.

The *Concept Recognition* module manipulates linguistic and knowledge resources, which in turn support the association between different lexical concepts. Clinical records can be manipulated in one language and papers can be processed in another language. For instance, the *Concept Recognition* module exploits classes and methods from the Unified Medical Language System (UMLS) [20] to identify concepts

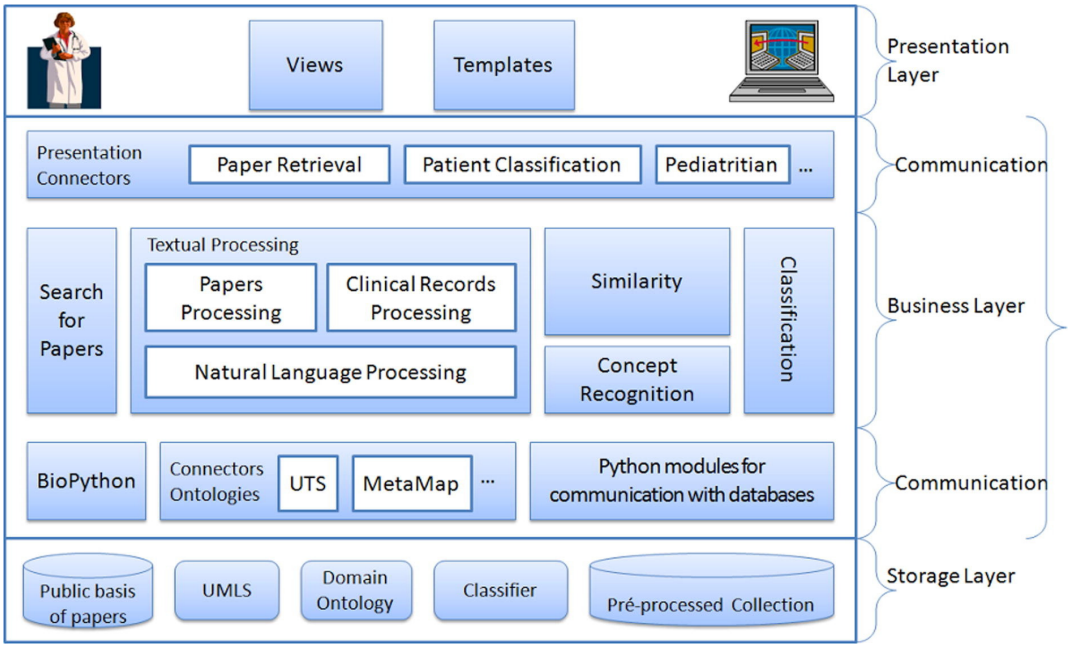

Fig. 1. The HSSF architecture [10].

from health topics such as epigenetics. The overall textual processing of the HSSF, supported by linguistic resources, includes the removal of stopwords, the processing of n-grams, the recognition of concepts, and the computation weights for concepts. The removal of stopwords for the papers and clinical records collections is based on lists of stopwords from programming utilities such as Snowball[3]. The processing of n-grams uses the open source Python NLTK[4] set of modules, linguistic data and documentation for research and development in natural language processing and text analytics.

The processing of clinical records is not identical to the processing of papers: after the processing of n-grams and the identification of concepts, a query array containing the remaining concepts is built for clinical records, whereas a weight matrix is composed of the scientific papers. Both the query array and the weight matrix are submitted to the *Similarity* module, which is in charge of computing similarities. The architecture of HSSF allows the *Similarity* module to calculate similarity measures between papers and clinical records, and it can also apply automatic relevance feedback.

B. The HSSF core systems

This section describes three health surveillance systems that we developed: the *Automatic-SL* [12], the *CISS* [13], and the *FREDS* [14] systems. Together these systems contribute with their main software components so as to build the HSSF architecture previously presented.

The *Automatic-SL* system aims to identify children with developmental problems and therefore assists healthcare professionals in their decisions and in reassessing recommendations as a multidisciplinary team [12]. After each medical appointment at a pediatric care center, this system collects patient information to automatically assign it a Surveillance Level (SL) measure which in turn indicates the type of healthcare procedure and service that a patient needs. Exploiting machine learning techniques, the *Automatic-SL* identifies significant risk and protective factors associated with patients and their families. Therefore, it provides surveillance indications that support preventive care to avoid diseases in adulthood.

As another surveillance service, the *CISS* system retrieves scientific papers that relate chronic diseases to genetic and epigenetic risk factors found in patients' clinical records [13]. From the PubMed repository, a *CISS* module routinely searches and retrieves new scientific papers in the domain of genetic and epigenetic risk factors for chronic diseases. Next, *CISS* processes textual information of that collection of papers for later retrieval of relevant papers according to a clinical record submitted by a healthcare professional.

To associate papers with a clinical record, *CISS* also processes its textual content and then calls a module which calculates the similarity among documents. In turn, this module accesses the pre-processed version of the collection of scientific papers to retrieve papers with the highest degrees of similarity to the clinical records. Selected papers are then presented to a healthcare professional with risk factors associated with the record previously submitted. By using this approach, healthcare professionals should be able to create a clinical routine with families and set up the best possible growing conditions.

Finally, the *FREDS* system was included during the design phase of the HSSF. Aiming to support decision making sys-

[3]A small string processing language designed for Information Retrieval purposes; documentation is available at http://snowballstem.org/.

[4]Documentation is available at https://www.nltk.org/.

tems in terms of diagnosis of diseases, the *FREDS* system establishes conceptual relationships or mappings between microscopic images content and textual information crawled from clinical records [14]. The main idea is to extract complementary information from exams that describe cell components similar to those identified in the microscopic image evaluated by a pathologist. The aim is to contribute with the reduction of the semantic gap between the computational retrieval of medical images and the human interpretation of their content. The *FREDS* system advocates that the semantic mapping can support the generation of knowledge.

The HSSF software framework has then emerged from the experience of developing the three aforementioned health surveillance systems. The orchestration of those systems as software components and their respective (required/provided) interfaces are summarized in Fig. 2.

The *CISS* component provides developers with classes supporting important functionalities: *Scientific Papers Searching*, *Medical Record Processing*, *Article Processing*, *Textual Processing*, *Natural Language Processing*, *Concept Recognition*, and *Similarity*. These functionalities are provided via *ClinicalRecordProcessing* to the *Automatic-SL* component so as it can classify patients according to surveillance level measures automatically computed. The *DocumentProcessing* is used by the *FREDS* component so as it can relate image reports to imaging exams on an automatic way.

The *FREDS* component offers classes to the *Image Feature Extraction*, the *Image Segmentation*, *Image Classification*, and the *Imaging Report Retrieval*. The *ImagingExamProcessing* provides these services. Finally, the *Automatic-SL* component serves a classification functionality to be reused by other applications via *SurveillanceLevelProcessing*.

III. The deployment of HSSF

In previous section, we described how HSSF was originally built by means of its fundamental software components which provide multiple services including clinical record processing, imaging exam processing, among others.

Throughout this section, we present how those components were reused to develop three new health surveillance applications as proofs of concept to the HSSF framework.

A. CISS+

As an evolution of the original *CISS* system, the first application developed by means of the reuse of HSSF components is called *CISS+* [10]. It augments the semantics of terms and concepts of scientific papers and clinical records by means of the use of the UMLS metathesaurus [20] and the MetaMap tool [21]. Experiments with UMLS and MetaMap demonstrated the effectiveness of the concept recognition task with a reduction of roughly 90% of terms.

Also as novelty, the *CISS+* employs automated techniques of relevance feedback to refine queries. The *Similarity* class of the CISS component calculates similarity measures among scientific papers and clinical records and runs automatic relevance feedback using three approaches: (i) using meta-information from the Medical Subject Headings (MeSH)[5] of scientific papers from the PubMed database; (ii) considering the whole set of documents with identified concepts after n-grams processing of medical records as relevant documents; and (iii) considering meta-information from the "Publication Type" field of PubMed papers.

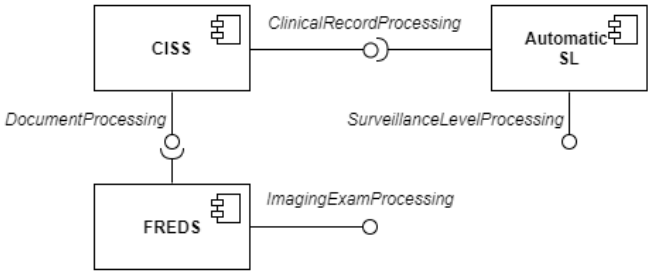

Fig. 2. The component diagram of HSSF.

Hence, the *CISS+* reuses mainly paper searching, textual processing, extended recognition of concepts, and mechanisms of query expansion in the *Similarity* and *Concept Recognition* classes of the CISS component.

B. CISS-SW

Using Semantic Web concepts and technologies, the *CISS-SW* is a search system that enables physicians to retrieve a scientific paper related to a patient's clinical record [17].

After the textual processing, the *CISS-SW* maps terms of papers into RDF triples[6] [22], stores them in a Triple Store[7], and composes a SPARQL [23] query by using the clinical records. With this query, the system retrieves form the triple store the papers related to the clinical records.

Therefore, the new functions of the *CISS-SW* include the processing and retrieval of scientific papers with Semantic Web support. In general, it reuses the classes related to the textual processing of clinical records provided by the HSSF.

C. QASF

A question-answering system returns short and direct answers to users. The *QASF* (Question Answering System in Chronic Diseases) application receives a question about chronic diseases and epigenetics information, and then looks for answers in collections of scientific papers [18] [19]. The aim is to help healthcare professionals to rapidly find focused related answers in the domain of chronic diseases.

The *QASF* architecture essentially consists of three modules: (i) *Question Processing*, (ii) *Answer Processing*, and (iii) *Document Processing* [18].

[5]The U.S. National Library of Medicine's hierarchically-organized terminology for indexing and cataloging of biomedical information.

[6]An RDF triple is a data entity composed of subject-predicate-object, like "John knows Steve" or "Steve is 42". RDF triples are the standard information exchange format in the Semantic Web.

[7]A triplestore is a purpose-built database for the storage and retrieval of RDF triples through semantic queries usually written in the SPARQL syntax.

The *Question Processing* module converts the question a user submits in natural language to a query that helps to search and select answers. This module applies pattern recognition and machine learning algorithms to handle the type and the content of the question, respectively. The *QASF* exploits linguistic and knowledge resources (e.g. WordNet and SNOMED) to support the processing of learning healthcare information.

As the only module reused from the HSSF architecture, the *Document Processing* module retrieves documents (e.g. scientific papers) that might have the answer to the user question. From each candidate document, this module also extracts excerpts that should be the answer.

Finally, the *Answer Processing* module processes all the potential right answers and classifies them according to a similarity value. Currently, the *QASF* considers the cosine between the user question and the candidate answer as the similarity value. Hence, the user is given the "n" first answers.

IV. Evaluation

Considering the software engineering literature, reusability is the degree to which an asset (e.g. a module or component) can be used in more than one software system, or in building other assets. In this section, we describe how we measured the reusability of the HSSF components in developing the systems described in the previous section.

Although the number of reused lines of code is a commonly used unit of measure, a software framework is more than lines of code. In the case of reuse, another well-known measure is the developer hour, which refers mainly to the time spent on searching, analysis and integration/modification. The time spent on these activities must be less than the time that is necessary to develop the artifact to be reused.

In order to evaluate the benefits of the HSSF framework, we requested each developer of the *CISS+* (one participant), *CISS-SW* (one participant) and *QASF* (two participants) applications to answer a questionnaire we elaborated, as illustrated in Fig. 3. The analysis of the corresponding answers was an attempt to understand the reuse of the HSSF components in terms of the time spent and the artifacts reused.

The *QASF* developers answered the questions together, then we have considered only one answer. We have disregarded the amount of time required to locate/search the HSSF as a tool to be reused because all the developers belong to the same group.

A. Questionnaire answers

Regarding the question 1, developers have considered classes, lines of code, and external packages as the software artifacts the most reused assets of the HSSF. From the answers to question 2, we identified that the most useful classes were the *Paper Search* and the *Paper Processing* classes, followed by *Natural Language Processing* and *Concept Recognition*. Regarding the question 3, despite analyzing from 20 to 25 classes, *QASF* developers reused from 1 to 4 classes without modification as well as from 1 to 4 classes with modifications. The *CISS+* developer analyzed between 15 and 19 classes and reused all of them without modifications. However, this person has actively participated in the creation of the HSSF. Finally, the *CISS-SW* developer analyzed from 5 to 9 classes and reused between 5 and 9 classes without modifications.

Considering the answers to question 4, as the *QASF* developers have not found proper documentation, they spent months to understand the model, to integrate the classes, and to understand and extend source code. The *CISS+* developer did not spend time on any of those activities because she is member of the *CISS* development team. Finally, the *CISS-SW* developer spent days reading the documentation and only weeks understanding the model and the classes, integrating these, and understanding and extending source code.

Another interesting result is the number of attempts that each developer made before reusing the HSSF components (question 5). Disregarding the *CISS+* developer, the other developers have only carried out between 1 and 3 attempts before the reuse. This small number of attempts is a good indicator of the HSSF reusability.

The last question of the questionnaire confirms this finding because the two developers have stated that they earned weeks and months regarding the development of their systems when they reused the HSSF. The developers of the *QASF* considered they did not earn much time, but we noticed they did not find any documentation (papers, reports, models, manuals, and help documentation) about the HSSF. Such documentation is available at the official HSSF website. *QASF* was recently created, hence the difficulty of reuse can be due to the need of updating many technologies exploited by the HSSF.

B. The average time spent on reusing HSSF classes

A look at the answers of the questionnaire has motivated us to find an ad hoc measure to quantify the time spent on the reuse of HSSF classes. To assess whether the reuse of classes yields a positive result besides the costs with the modification and integration of the reusable item of the HSSF in the current project, we have defined *the average time needed for classes reuse* as

$$T^{(a)} = \frac{T_c^{(u)}}{C} + \frac{T_c^{(m)}}{C_r} \tag{1}$$

in which:

- $T_c^{(u)}$ is the time associated with understanding of the classes;
- C is the number of classes analyzed;
- $T_c^{(m)}$ is the time spent integrating or extending the classes by source lines of code; and
- C_r is the total number of classes reused without modifications.

We ignored the risk of wasting time on the search for classes because the developers belong to the same team. Therefore, we only considered the questions 3.a, 3.b, 4.b, and 4.d (or 4.e) which are C, C_r, $T_c^{(u)}$, and $T_c^{(m)}$, respectively.

Questionnaire: An attempt to understand the HSSF reuse experience

1. What kind of artifacts did you reuse from CISS? (you can select more than one)

[ ] Models [ ] Classes
[ ] Tools [ ] Lines of code
[ ] Libraries [ ] API
[ ] External Packages [ ] Other:_____

2. If you **reused classes**, which components were more useful for your application? (you can select more than one)

[ ] Natural Language Processing [ ] Paper Processing
[ ] Paper Search [ ] Clinical Record Processing
[ ] Textual Processing [ ] Classification
[ ] Concept Recognition [ ] GUI
[ ] Similarity [ ] Other:_____

3. If you **reused classes**, please answer the following (a., b., c.) questions:

a. How many classes did you **analyze** to reuse from CISS?

[ ] 1 to 4 [ ] 10 to 14 [ ] 20 to 25
[ ] 5 to 9 [ ] 15 to 19 [ ] zero

b. How many classes (without modifications) did you **reuse** from CISS?

[ ] 1 to 4 [ ] 10 to 14 [ ] 20 to 25
[ ] 5 to 9 [ ] 15 to 19 [ ] zero

c. How many classes did you **extend/modify** from CISS to be reused?

[ ] 1 to 4 [ ] 10 to 14 [ ] 20 to 25
[ ] 5 to 9 [ ] 15 to 19 [ ] zero

4. How much **time** did you spend in the following activities to reuse CISS?

a. Reading documentation:

[ ] hours [ ] months
[ ] days [ ] Other: _____
[ ] weeks

b. Understanding/analyzing the model:

[ ] hours [ ] months
[ ] days [ ] Other: _____
[ ] weeks

c. Understanding/analyzing the classes:

[ ] hours [ ] months
[ ] days [ ] Other: _____
[ ] weeks

d. Integrating the classes:

[ ] hours [ ] months
[ ] days [ ] Other: _____
[ ] weeks

e. Understanding/analyzing lines of source code:

[ ] hours [ ] months
[ ] days [ ] Other: _____
[ ] weeks

f. Extending by coding:

[ ] hours [ ] months
[ ] days [ ] Other: _____
[ ] weeks

5. In average, how many **attempts** did you make **before** reusing an artifact from CISS?

[ ] 1 [ ] 4 to 5 [ ] More than 8
[ ] 2 to 3 [ ] 6 to 7 [ ] zero

6. Do you consider the reused artifacts **saved time** of the developing a new application?

[ ] Yes. How much ? Estimative:_____ hours. [ ] No.

Fig. 3. Questionnaire answered by developers who reused HSSF.

Using the answers given by the developers of the *CISS+*, *CISS-SW* and *QASF* applications, we have listed the results for this equation in Table I. This includes the average time (T^a) spent on reusing the classes of the HSSF by developers of the *CISS+*, *CISS-SW* and *QASF* applications. T^a, $T_c^{(u)}$ and $T_c^{(m)}$ are measured in terms of days. C and C_r, in turn, represent numbers of classes.

TABLE I
THE AVERAGE TIME (T^a) SPENT ON REUSING HSSF CLASSES

Developer	C	C_r	$T_c^{(u)}$	$T_c^{(m)}$	T^a
CISS+	19	19	7	6	**0.68**
CISS-SW	9	9	7	7	**1.55**
QASF	25	4	30	30	**8.7**

Table I also shows that the *CISS+* developer spent 0.68 days reusing each class of the HSSF. This was expected because she collaborated with the development of many HSSF classes before developing the *CISS+* application. The *CISS-SW* developer spent 1.55 days reusing each class of the HSSF, whereas the *QASF* developers spent much more time (8.7 days) than the other two developers. This was also expected because *QASF* developers did not find documentation about the HSSF and needed to update HSSF classes and packages.

Besides questions 3.a., 3.b., 4.b., and 4.d. (or 4.e.), some other quantitative answers to the questions can help to measure the HSSF reuse, but the reuse of the model, class, and source lines of code must be related because they consist of artifacts reused at different levels of design abstractions. In other words, our ad-hoc equation previously presented considers independent variables only.

In a near future, we intend to augment this initial effort including other time of reuse of other levels of design abstractions. Another situation to verify includes measures of the topology of the model, which includes connectivity, and between, among others, and should help us to infer coupling of classes, for example. Some literature works have presented result metrics in terms of reuse [24] [25].

V. ANALYSIS, LESSONS LEARNED AND RESULTS

When thinking about reuse, we must consider that the process of creating and updating of a *software framework* should never end. It is fundamental to reuse the framework while aiming to receive the developers' feedback on the development of new versions of the reused framework.

The creation of the HSSF framework has been a long process that has relied on collaborative work including ideas, software requirements, designs and development, augmentations, results and publications. This process started in 2007 with the initial development of the *Automatic-SL* system [12], which was followed by the creation of the *CISS* system [13] and *FREDS* [14]. In the end of 2014, we agreed on a version of the HSSF; and in 2015, we developed two new systems to validate the HSSF, the *CISS+* [16], and the *CISS-SW* [17] systems. Finally, in 2016, we included new classes in the HSSF after we developed the *QASF* system [18] [19].

The HSSF framework provides hot spots that are easy to manipulate such as:

- the insertion of other scientific information resources besides PubMed;
- the use of another domain ontology to create queries and to filter scientific papers from the desired information resources;
- the exploration of other ontologies and/or thesauri aiming at the recognition of medical and biomedical concepts besides UMLS;
- the manipulation of different types of clinical records or other documents in the healthcare domain; and
- the use of other classification and clustering techniques.

Given those hot spots, the less flexible one is the exploration of other ontologies and/or thesauri aiming at the recognition of medical and biomedical concepts besides UMLS. The HSSF carries a multilingual processing (mainly English and Portuguese), so it is necessary to apply a linguistic resource that can relate multilingual concepts and bring semantic relationships. In the healthcare domain, UMLS still represents the best option to recognize concepts, justifying the natural inflexibility. However, an extension of our framework to manipulate other linguistic resources besides UMLS has already been designed.

As frozen spots of the HSSF framework, we can mention abstract classes that allow each hot spot cited, for instance, an abstract class to illustrate ordinary attributes of different sets of documents and another abstract class to represent attributes of different document types. Other frozen spots consist of classes for textual processing (e.g. stopwords elimination and *n*-grams processing) as well as for the identification of relationships among documents.

In 2016, we presented the first version of HSSF as a software framework, which consisted of an architecture and a class diagram depicted elsewhere [10]. After we created the *QASF*, we were able to extrapolate and to update that diagram to integrate *Automatic-SL*, *CISS*, *FREDS* and *QASF*, as depicted in Fig. 4. By analyzing our own reuse experience, we have distilled some lessons learned and also classified these as advantages or drawbacks with the HSSF reuse.

In terms of **drawbacks** of the HSSF reuse, we can consider:

- the need to learn technical aspects of the programming languages, packages and ontologies to generate a steep learning curve that is necessary for the developers to know how the framework works before they can reuse it; and
- the cost in terms of demand of development expertise.

Considering these limitations, the HSSF faces problems in a specific abstraction domain. For years, some authors have advocate that the reuse of software frameworks degrade the performance/efficiency of the application and its security issues [26] [27]. However, HSSF users have not noticed any of these two points yet. Moreover, security is not an essential requirement of the *CISS+*, the *CISS-SW*, and the *QASF* applications.

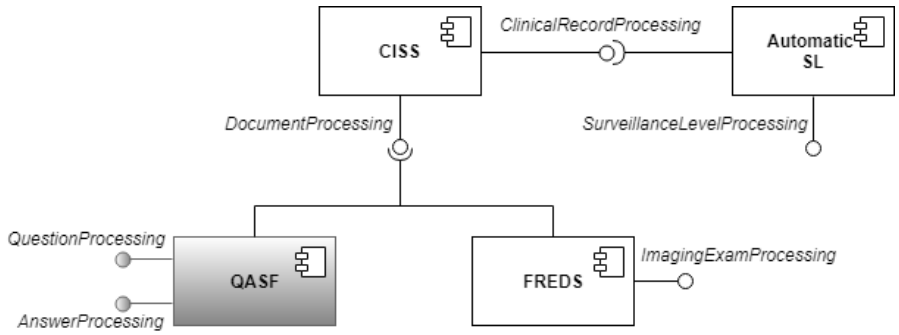

Fig. 4. The HSSF framework extended with two *QASF* services available to developers: *QuestionProcessing* and *AnswerProcessing*.

On the other side, the use of the HSSF offers the following **advantages**:

- the HSSF reduces the time and the energy spent on developing the *CISS+* and *CISS-SW* systems because the developers have the standard infrastructure and diagram of the HSSF providing the organization of modules and the classes of application;
- as a consequence from the previous advantage, developers can devote more time to requirements and user interfaces;
- the source codes of the three systems (*CISS+*, *CISS-SW* and *QASF*) are more organized and well documented because they follow the coding convention of the HSSF, which makes the source codes clean and easy to understand; and
- the use of the HSSF infrastructure affords three well-separated applications and defined business and logic layers from the user interface, making the code cleaner and extensible.

Finally, we believe that the HSSF improves the quality of the applications because the developers focus on the unique requirements of their application instead of spending time on infrastructure. Two of the users of the HSSF consider that their performance during the developing of their applications were improved reusing assets of the HSSF.

VI. Conclusion

The *Automatic-SL*, *CISS* and *FREDS* systems could be abstracted because they had common classes, purposes, and collaborations. For instance, the Relevance Feedback (RF-SL) classifier of the *Automatic-SL* system generates structured information from medical records and transforms it into bags of words; this system also eliminates stopwords and conducts stemming to produce a term-weight matrix. This matrix resembles the concept-weight matrix used by the *CISS* to compute similarity between scientific papers and medical records.

The main difference is that the matrix of the *CISS* uses UMLS concepts instead of simple terms. Nevertheless, the application recognition of concepts and the construction of the weight matrix according to these recognized concepts are perfectly applicable not only to the RF-SL module of the *Automatic-SL*, but also to other classifiers of the latter system. On the other hand, *FREDS* is composed of medical image processing classes that can also be related to textual processing.

Between 2007 and 2012, when the *Automatic-SL* and the CISS systems were created, the HSSF had its first classes designed for reuse with a focus on the processing and classification of healthcare-related information. Some years later, newcomers and specialists of our research group have used the HSSF, which has resulted in three new applications, the *CISS+*, the *CISS-SW* and the *QASF*. The developers of these systems have answered a questionnaire as an attempt to understand the reuse of the HSSF basically in terms of types of artifacts and time spent on reuse. The answers have allowed us to measure the average time that is necessary to reuse HSSF classes and to distill experiences such as lessons learned.

The HSSF is a software framework still under development. In a near future, it will be included a new set of class diagrams with more details for novel types of reuse, allowing much more general applicability. Besides this ongoing work, the results reported herein open new research directions that include:

- extension to the Chronic Disease Ontology (CDO) with knowledge obtained from scientific papers on epigenetics mechanisms and epigenetics risk factors for chronic diseases retrieved by the CISS;
- use of text entailment to map risk factors for chronic diseases;
- integration of new computational tools to map new concepts;
- modelling of an electronic medical record system coupled to *CISS* for use by the pediatric team; and
- investigation into the use of pediatric consensus by the HSSF.

By extending and reusing HSSF capabilities, our main goal is to allow healthcare applications developers to relate science research results, exams and treatments, which may be all incorporated into the clinical practice.

***Abstract*—In this paper, we describe the deep object comparison (DOC) algorithm, which is used for comparison of general objects in Java programming language based on their internal structures and values of primitive attributes. The DOC algorithm was designed to be utilized in our interface-based regression testing of software components, which enables to uncover subtle changes of the behavior of a component-based application under test with a newly installed version of a software component in comparison to its behavior with an old version of this component.**

I. Introduction

THE component-based software development is a part of software engineering for nearly two decades. It utilizes isolated reusable software parts called *software components*, which provide and/or require functionalities called *services*. The services are accessible using public interfaces of the components and the components are expected to interact solely using these interfaces. Specific details depend on the utilized *component model*, which defines the behavior, features, and interactions of software components and is implemented by a *component framework* [1].

Regardless the utilized component model, a common situation using the component-based software development is that a component can be used in different applications and an application consists of multiple components, which can originate by different manufacturers [1]. This underlines the necessity for the testing, not only of the individual components, but of the entire component-based application as well.

Additionally, many components exist in several versions, which can mutually differ by the internal behavior (i.e., there are different computations), by the external behavior (i.e., different interactions with other components), or by the public interface (i.e., different required and/or provided services). In theory, the change of the component's internal behavior should not affect its external behavior and therefore should not affect the behavior of the entire component-based application. Nevertheless, in reality, an unwanted error can be introduced into the new version of the component, a side effect of a method invocation can be added or removed, a computation can be prolonged leading to a time-out to expire, and so on. So, when installing a new version of a component to a functional component-based application, adequate regression testing is desirable even when there are no apparent external changes of the new version of the component in comparison to the old version [2].

During our previous research, we developed an approach for interface-based regression testing of software components, whose source code is not available (e.g., third-party software components). The approach is tailored for the situation when there is a new version of a component installed in a component-based application and we want to check if it exhibits the same behavior within the application as its old version [2].

The experimental implementation of the approach, which was described in [2] in detail, was designed for the OSGi [3] component model for Java programming language, but the ideas behind it can be used for other component models and programming languages as well. The overall process starts with the analysis of the services and their methods of the software components of the entire component-based applica-tion under test. For each method of each service of each component, a set of invocations is generated. Then, the invocations are performed in an iterative phase. In each iteration, all invocations are performed and their conse-quences are being observed and stored. New consequences of the same invocations can emerge, because the inner states of the components can change between iterations due to the invocation of the methods. Besides the consequences, new invocations can emerge during this phase as consequences of different invocations. Both the new consequences and new invocations are stored only if they are not already stored. This requires comparison of the already stored items with the newly created items. The process stops when no new consequences are created. The result is a testing scenario

This work was supported by Ministry of Education, Youth and Sports of the Czech Republic, project PUNTIS (LO1506) under the program NPU I and by European structural and investment funds (ESIF), project CZ.02.1.01/0.0/0.0/17_048/0007267.

with actions (i.e., invocations) and their consequences, which can be saved to a file. If this process is performed prior and after the installation of a new version of a component to the component-based application under test, the detailed comparison of these two saved scenarios can uncover changes in the behavior of the application caused by the new version of the component [2].

In our experimental implementation, we used the standard `equals()` method for the comparison of the objects associated with the consequences and the invocations (e.g., return values, values of the parameters). Although this can work in many cases, it cannot be used universally. Some objects do not implement the `equals()` method, which leaves them with the default implementation corresponding to the identity (only the same objects are considered equal). Even if the `equals()` method is implemented in the object, it can be implemented incorrectly, as pointed out in [4], [5], or [6]. And even if it is implemented correctly, it does not mean that it considers all primitive values of the object recursively [7]. So, it is possible that, although the `equals()` method returns `true` for a pair of objects, their internal structures can be different and/or contain some different primitive values. These subtle differences can be important for our approach, since they could mean different behavior, which we want to detect.

In order to mitigate this problem, in this paper, we describe the deep object comparison, which will replace the utilization of the `equals()` method. The deep object comparison enables to compare two objects based on the "shape" of their internal structures and all the corresponding primitive values. So, no changes in the objects are missed. This deep object comparison is suited to be used both during the generation of the scenario and during the comparison of two scenarios of our interface-based approach for regression testing of software components. The algorithm was implemented within our Interface Analysis Tool (InAnT). The deep object comparison was first tested as a stand-alone algorithm, before it will be incorporated into our approach. The description of the deep object comparison algorithm along with the description of the performed tests is the main contribution of this paper.

The paper is structured as follows. The interface-based regression testing of software components is briefly described in Section II. Related work is discussed in Section III. In Section IV, the deep object comparison is described in detail. The performed tests and results are described in Section V and the paper is concluded and the future work is discussed in Section VI.

II. Interface-based Regression Testing of Components

As it was mentioned in Section I, the interface-based regression testing of software components is designed to uncover any changes in a component-based application's behavior after the installation of a new version of a component [2]. The changes are detected during comparison of the testing scenario generated and stored from the application with the old version of the component and the scenario generated and stored from the application with the new version of the component [2].

A. Generation of the Testing Scenario

Our approach assumes that the entire component-based application is under test, because the components within it interact with each other. Their interactions are observed during the generation of the scenario in order to uncover the behavior of the particular components [2].

First step in the generation of the testing scenario is the determination of all methods of all services of the components of the application under test. This can be done by any method capable to retrieve complete method signature. We use standard OSGi methods and Java reflection [8] for this purpose in our experimental implementation [2]. The components, their services, and their method are inserted into a tree data structure, which forms the basis of the testing scenario (see Fig. 1a).

For each method of this structure, an initial set of invocations is generated and added into the structure. Each invocation contains a unique combination of values for all the parameters of the method.

The invocations are then successively performed (i.e., the methods are invoked with the parameters stored in the invocations in the tree data structure) in the iterative phase, one at a time, and the consequences of each invocation are observed (i.e., what happened when the method was invoked). The possible consequences are a thrown exception, a return value, a value change in "out" parameters of the method, a subsequent invocation of a service method of ano-

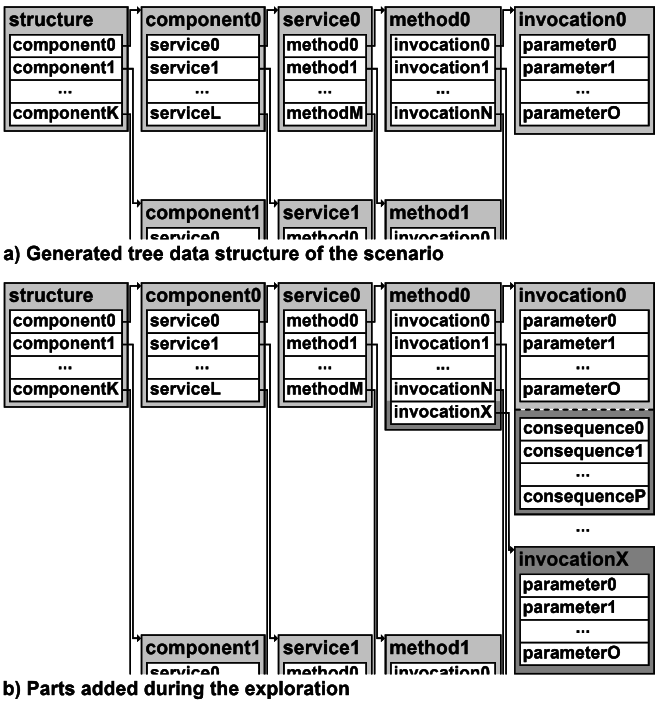

Fig. 1 The tree structure of the scenario

ther component, and a change of the inner state of the component. The last consequence differs from the others, since it is not easily observable from outside. So, it is not considered by our approach. There can be several consequences per method invocation. All the observed consequences are added to the tree data structure to the invocation, which caused them (see Fig. 1b), but only if they are not already present. Each type of consequence contains its type and type-dependent data (e.g., the return value, the instance of an exception, the changed value of an "out" parameter, etc.) [2]. Based on the type and the data, the consequences can be mutually compared, which is necessary for the determination, whether a new consequence is already present or not.

The most important consequences are the subsequent invocations. Each subsequent invocation is defined by the method, which it is invoking, and by the unique combination of its parameter values. When this consequence is observed, it is added to the tree data structure (if not already present) similarly to other types of consequences. Moreover, the invocation that the consequence represents is added to the invocations of the corresponding method into the tree data structure (again, only if not already present). These invocations are valuable, since their parameter values are genuine, originating in the internal logic of the component, which invoked the method [2].

The invocations contained in the tree data structure are performed several times in the iterative phase in order to exploit the subsequent invocations. The subsequent invocations generated in nth iteration can be performed in $(n + 1)$th iteration and their consequences can be thus observed. The iterative phase is stopped when no new consequences are generated in the current iteration. At this point, the testing scenario represented by the tree data structure is complete (see Fig. 1b). All invocations and consequences contain a number representing the iteration, in which they were added to the structure (starting with 1). The initial invocations created prior the iterative phase have this number set to 0. The generated scenario is saved to a XML file [2].

B. Comparison of the Testing Scenario

When a new version of a component is installed into the component-based application under test, the process described in Section II.A is repeated and a new scenario is created. The saved scenario is then loaded from the XML file and both tree data structures are compared. The comparison is performed on each level of the structures, starting from the component level [2].

On each level, it is checked, whether there are corresponding items (i.e., components, services, methods, invocations, consequences) in both tree data structures. If so, their subtree is expanded and the comparison continues on the lower level. If not so, the difference (item is missing in one or second tree data structure) is reported, this item is not expanded and its lower levels are not considered further [2]. The example of the result of the comparison is depicted in Fig. 2.

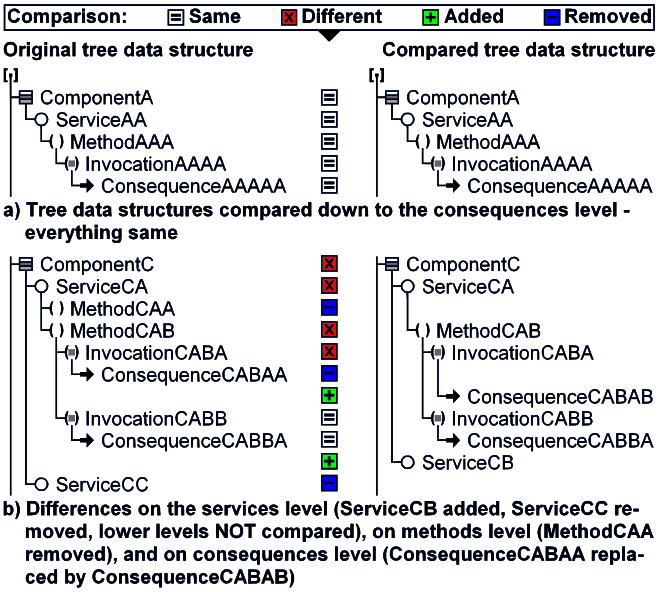

Fig. 2 Result of the comparison of two scenarios (tree data structures)

The most important differences are on the invocations and invocation consequences levels. These differences mean different behavior of the application under test with the old and the new version of the component. Differences on the methods or services levels imply that there are changes in the public interface of the component. Our approach of course detects these changes, but, unlike the changes in the behavior, these changes can be detected by other means as well, such as advanced static analysis methods (e.g., see [9]) [2].

C. Object Comparison Issues

Both during the generation of the scenario and during the comparison of two scenarios, we need to compare general objects, which is problematic.

During the generation of the scenario, the comparison of general objects is necessary in the iterative phase when new consequences and invocations are generated. They are added to the tree data structure only if they are not already contained, requiring their comparison to other consequences and invocations. It should be noted that due to the tree nature of the data structure, a newly generated consequence is compared only to the consequences of the corresponding invocation. Similarly, a newly generated invocation is compared only to the invocations of the corresponding method. So, the number of comparison is limited, it is not necessary to compare the consequence or invocation to all consequences or invocations.

Nevertheless, the comparison of two consequences lies in the comparison of their type and, if the type is the same, in the comparison of the type-related data. If the type of both compared consequences is the return value, then the associated return values are compared. The comparison is

trivial if the return values are of primitive types, but ambiguous if they are objects. In the experimental implementation of our approach, we use the standard `equals()` method for objects, which are not `null`. This can work in many cases, but cannot be used universally.

For example, some objects do not implement the `equals()` method, which leaves them with the default implementation corresponding to the identity (only the same objects are considered equal). An example of such object is in Fig. 3a. The `Point3D` class represents a point in space, but does not override the `equals()` method, leaving it with its default implementation (from the `Object` class). When a method returns a new instance of the `Point3D` in every invocation (see Fig. 3b), the comparison of this instance to another instance using `equals()` will always return `false`, even with the same values of their corresponding coordinates (see Fig. 3c). If an invocation of the method depicted in Fig. 3b were performed repeatedly during the iterative phase, its return value consequence would always seem different, because the return values would not be identical (based on the `equals()` method), although they would contain the same values of their corresponding coordinates. So, each newly generated consequence would be added to the tree data structure in each iteration. The iterative phase would not stop until an out-of-memory exception would occur. This problem can be mitigated (not solved) by introduction of the maximal number of iterations, but it is clear that this is not the intended behavior.

Moreover, there are further issues. Even if the `equals()` method is implemented in the object, it can be implemented

```
class Point3D {
  public int x;
  public int y;
  public int z;

  public Point3D(int x, int y, int z) {
    this.x = x;
    this.y = y;
    this.z = z;
  }
}
```

a) A class representing a point in space without overridden `equals()` method

```
...
public Point3D asPoint(int x, int y, int z) {
  return new Point3D(x, y, z);
}
...
```

b) A method returning a new instance of the `Point3D` class in every invocation

```
...
Point3D p1 = asPoint(1, 2, 3);
Point3D p2 = asPoint(1, 2, 3);
boolean comparison = p1 == p2; //comparison false
...
```

c) Two results of the method with the same primitive values compared

Fig. 3 Example of a class without overridden `equals()` method and of following problems

incorrectly, as pointed out in [4], [5], or [6]. And even if it is implemented correctly, it does not mean that it considers all primitive values of the object recursively [7]. So, it is possible that, although the `equals()` method returns `true` for a pair of objects, their internal structures can be different and/or contain some different primitive values. These subtle differences would not be detected using the `equals()` method.

The described problem is not limited to the return value consequences. The same problem is with the comparison of consequences representing a change in the "out" parameters of a method and with the comparison of invocations. Each invocation contains the combination of parameter values of a method and these values, which can be general objects, are compared during the comparison of the invocations.

During the comparison of two scenarios, the comparison of general objects is needed for the comparison of invocations and consequences, similarly to the generation of the scenario. Comparison of methods and higher levels of the tree data structure are based on data types and names, not general objects. The problem with the comparison of general objects is more pronounced here, though. The reason is that at least one of the compared scenarios is loaded from a XML file. In order to utilize the `equals()` method for the comparison, it would be necessary to recreate all the objects during the loading of the scenario. This would necessitate full-scale serialization of general objects during the saving of the scenario to the file. Hence, in the experimental implementation of our approach, the general objects contained in the invocations and consequences were compared only based on their classes and `null` values.

More specifically, the information stored to the XML file for an object was its real class or `null`. Hence, during the comparison of two scenarios, it was only checked, whether both compared objects are `null` or whether both compared objects are of the same class. In these two cases, the objects were considered equal. The exception was the instances of the `String` class, which were compared using their content. The reason is that the `String` instances can be easily saved and loaded to/from a file. It is clear that this significantly reduces abilities of our interface-based regression testing of software components. The entire approach works correctly and is able to detect changes in behavior of the application under test (see [2]). However, many subtle differences in the compared scenarios can remain hidden, because the information is lost during the saving of the scenario to a file. So, some changes in behavior of the application under test could remain undetected.

In order to solve all the described problems, we designed the deep object comparison (DOC) described in Section IV in detail. The DOC will be incorporated into our interface-based regression testing of software components where it will replace the `equals()` method during the generation of the scenario and the class-based comparison during the comparison of two scenarios.

III. Related Work

The issue of object equality in object-oriented languages is discussed in scientific literature mainly in relation to memory optimization and to object equality implementation. Both branches are discussed in following subsections. Although none of these branches is related to software testing, the algorithms described in the discussed papers solve problems similar to our deep object comparison.

We focused mainly on the papers regarding the Java programming language, since our current implementation is written in this language. However, the principles can be used in similar languages (e.g., C#) as well.

A. Memory Optimization

There are several papers focused on the optimization of memory management in languages, which utilize garbage collection (i.e., automatic disposal of objects, which are no longer in use by the program). The main idea behind these works is that there are a number of equivalent objects in the memory during the execution of a program, which can be replaced by a single instance while preserving the same behavior of the entire program (see [7], [10], [11], [12], etc.).

In [7], a tool enabling detection of equivalent objects in a Java application, which can be replaced by a single instance, is described. The investigated application is instrumented and, during its execution, all relevant heap activity is recorded. After the execution, the post-mortem analysis is performed. The objects of the application are separated into equivalence classes. Each equivalence class can be replaced by a single instance. No automatic optimization is performed. The tool only uncovers and reports the sites (i.e., positions in source code) of the program with the potential for an optimization by replacing more equivalent objects with a single instance [7]. In order to determine, whether an object can be replaced by another object without affecting the behavior of the application, it is necessary to compare these objects thoroughly. It is pointed out that a full comparison requires checking of two potentially cyclic labeled graphs for isomorphism. As a large number of comparisons is required in this approach, a hash value is calculated for each object, which is then used for faster comparison of the objects [7].

Similar approach is described in [10], although it is intended for a different programming language (Pharo). Again, the relevant heap activity is recorded during a run of the application under test and the post-mortem analysis is performed after the run. The main difference is that, in [10], the objects are divided into several types and only certain types of objects, which are susceptible to redundancy (e.g., instances of the `String` or `Point` classes), are considered as optimization opportunities. Directed vertex and edge labeled graph is used for the representation of the internal structure of objects for the comparison purposes. Based on it, a hash value is calculated for each considered object to speed up its comparison to other objects [10].

In [11], the conditions, which an object must satisfy to be considered for caching, are discussed. The paper is focused on immutability of objects, which is in some form often required by caching and similar techniques (including techniques described in [7] and [10]). It is pointed out that the border between construction and mutation of an object is not always clear [11].

In [13], an advanced method for the reduction of the duplication of strings is described. The comparison of objects is straightforward in this case, as the compared objects are instances of the `String` class.

In [12], a similar yet different technique to [7] and [10] is described. Similarly to the [7] and [10], the technique searches the sites (i.e., positions in source code) in an application, which have the potential to be optimized by reusing existing objects or data structures [12]. Unlike [7] and [10], the technique is focused not only on finding equivalent objects, but on finding reusable instances as well. The idea is that it is not necessary to create a new (possibly internally complex) instance when there is another instance of the same class available, which is no longer in use. In that case, it is only necessary to change settings of its primitive values, but it is not necessary to create new object and its entire internal structure. Moreover, since the unused object is reused, its garbage collection is saved. Thus, the techniques tend to utilize objects, which are relatively short-lived. So, unlike [7], [10], which are focused mainly on the reduction of the memory consumption, [12] is focused also on the reduction of computation time. For the representation of the internal structure of the objects, modified balanced parenthesis algorithm is used [12].

In contrast to [12], the technique described in [14] is focused on the long-lived objects, which are candidates for caching. For the speedup of the object comparison, a form of hash value called “fingerprint” of the object is used. In standard classes from the `java.lang` package, the `equals()` method is used [14].

In [15], the performance of the hash-consing (i.e., utilization of a global cache of objects) is discussed. The comparison of objects is based on the `equals()` method even when this method does not consider all attributes of the object. The authors also define weak immutability of an object based only on the values of the attributes, which are considered by the `equals()` method. Again, a hash value is used for the description of the objects [15].

B. Object Equality Implementation

The other group of scientific papers regarding the object equality is focused on the implementation of the `equals()` method. In majority of this papers, the required features of the `equals()` method are cited – the *reflexivity*, *symmetricity*, and *transitivity* [4]. In some works, it is pointed out that many textbooks contain flawed implementations of the `equals()` method (e.g., [4], [6]).

In [4], a checker of the `equals()` methods is described. The checker is focused on the features of the `equals()` methods under test and reports any violation of these features. However, it is not focused on comparison of the entire internal structure of complex objects [4]. In [6], the right design of the `equals()` method using design patterns is discussed.

A generator of the `equals()` methods for complex objects is described in [16]. In this work, the objects are compared on per-field basis. There are several "depths" of equality defined. Depth-0 corresponds to the referential equality, meaning that the objects are equal if both are the same object (corresponding to the comparison operator "=="). Depth-1 (shallow equality) means that, for all corresponding fields of two objects, the referential equality holds. The deep equality then means that, for all corresponding fields of two objects, the deep equality holds [16].

IV. Deep Object Comparison

As it was mentioned in Section II.C, the deep object comparison (DOC) is designed for our interface-based regression testing of software components. It will replace the comparison of general objects using the `equals()` method during the generation of the testing scenario and the comparison of general objects using their classes and `null` values during the comparison of two scenarios. Hence, the DOC algorithm has two phases – the forming of the graph representation of the object and the comparison of two graphs of the compared objects. The main advantage of this approach is that the graph representation of the object can be easily saved to and loaded from a file. So, no information will be lost during the saving of the scenario.

A. Object Equality

As arises from Section III, there are various views on the equality of two objects. Nevertheless, since our goal is to uncover any difference of the compared objects, however subtle, we have to adopt the view of the deep equality described in [16]. Similar definitions are described also in [7], [10], or [11]. Nevertheless, all the definitions of the equality described in these works are recursive. Since the DOC algorithm creates a graph representing the internal structure of the object, our definition is based on this graph. It is not recursive, but expresses similar conditions as the definition of the deep equality described in [16].

Suppose there are two compared objects `a` and `b` and the graph representations of their internal structures were created (see Section IV.B). Objects `a` and `b` are considered equal if and only if they are of the same class, their graph representations are isomorphic (i.e., have the same "shape"), and all values of the corresponding primitive attributes in the corresponding vertices of the graphs are of the same type and equal. Fig. 4 shows several examples of pairs of objects, which are considered equal or different.

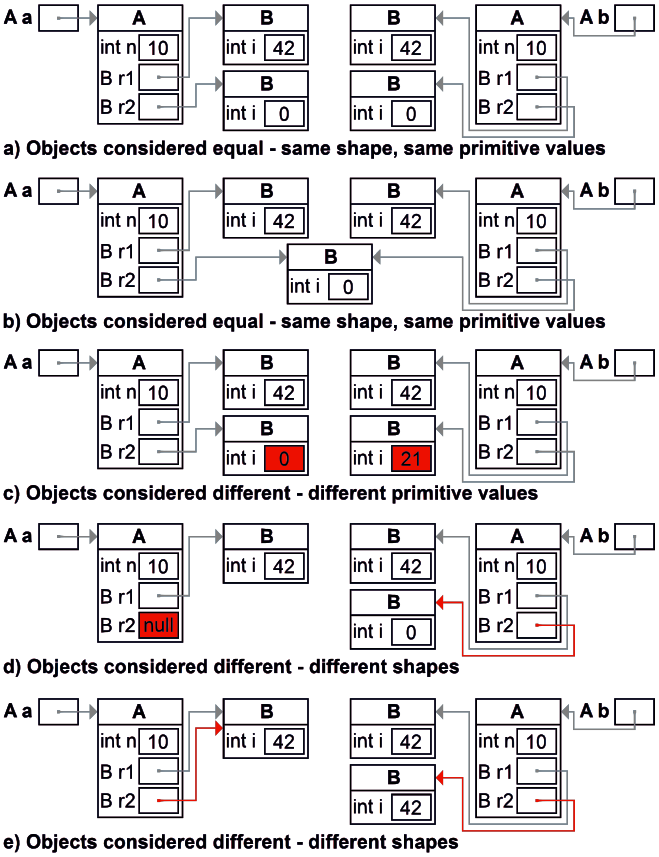

Fig. 4 Examples of objects considered equal and different

B. Forming of the Graph of an Object

When we compare two objects, it is checked whether both objects are not `null` and whether they are of the same class. If not so, the objects are considered different. If so, the DOC algorithm is used. Its first step is the creation of the graph representations of both compared objects. The representation is a directed vertex- and edge-labeled graph.

Each vertex of the graph corresponds to a single object of the internal structure of the object that we want to compare. The starting vertex of the graph corresponds to the object that we want to compare. Each vertex incorporates the ID, the state that is used during the comparison of two graphs (see Section IV.C) and the reference to the object that this vertex represents. It also incorporates a list containing types, names, and values of all primitive attributes of the object that this vertex represents.

Each directed edge of the graph represents a reference attribute of the object and points to the vertex, representing the object, to which the reference attribute is pointing. Each edge incorporates the type (i.e., the class) and the name of the reference attribute it represents.

The reference attributes that are arrays are treated specifically. If the attribute is an array of primitive values, each value is considered a primitive attribute with the name created from the name of the array attribute and the index of the value. If the attribute is an array of references, each value is considered a reference attribute, which means that it is

represented as an edge in the graph. The name is again constructed from the name of the array attribute and the index of the value. Similar approach is used for multi-dimensional arrays. As these arrays are represented as an array of arrays in Java, each inner dimension of the array is treated as an object (i.e., it is represented by a vertex in the graph) with attributes corresponding to the values on particular indices. Since these attributes do not have names, their indices are used instead. The reference attributes, which are `null`, and array attributes pointing to empty arrays are treated as primitive attributes.

The forming of the graph is based on the breadth-first search (BFS) algorithm starting in the object that we want to compare. There are a queue and a list of all vertices of the graph, which are empty at the start. First vertex is created from the object that we want to compare and is inserted to the list and to the queue. The forming of the graph then continues while the queue is not empty. First vertex is removed from the queue (current vertex) and all attributes of the object that is represented by this vertex are determined using reflection [8]. All primitive attributes are added to the list in this vertex. For each reference attribute, a new vertex is created. If this vertex is not in the list of all vertices, this new vertex is added to the queue and an edge is formed from the current vertex to the newly created vertex. If it is already present in the list, it is not added to the queue and a new edge is formed from the current vertex to the vertex from the list.

The presence of the vertex in the list is determined using the sequence searching and the comparison of objects that the vertices represent using the comparison operator "==". This way, it is ensured that already visited objects (e.g., due to cyclic references) are not visited again.

```
allVertices = List();
queue = Queue();
vertex = Vertex(comparedObject);
allVertices.add(vertex);
queue.add(vertex);
while (!queue.isEmpty()) {
  vertex = queue.remove();
  vertex.primitives=getPrimitives(vertex.object);
  references = getReferences(vertex.object);
  for (r: references) {
    neighbor = Vertex(r.object);
    index = allVertices.indexOf(neighbor);
    edge = Edge(r);
    if (index >= 0) {
      edge.vertex = allVertices[index];
    }
    else {
      edge.vertex = neighbor;
      queue.add(neighbor);
      allVertices.add(neighbor);
    }
    vertex.addEdge(edge);
  }
}
for (i = 0; i < allVertices.length; i++) {
  allVertices[i].ID = i;
}
```

Fig. 5 Pseudocode for the forming of the graph representation of an object

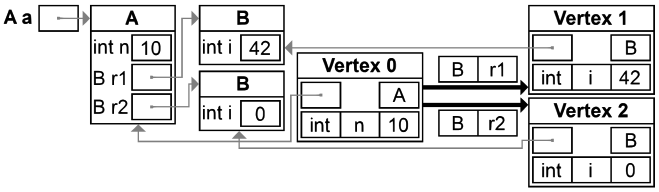

Fig. 6 The resulting graph (on the right) with references to the object (on the left)

When the queue is empty, the graph is fully formed. The last step is the assignment of the IDs to all vertices based on their indices in the list. These IDs are used during the saving of the graph to a file. The algorithm is described in Fig. 5 in pseudocode. The resulting graph for the object `a` from Fig. 4a is depicted in Fig. 6.

C. Comparison of Graphs

Two graphs created as described in Section IV.B can be easily compared without the references to the original objects, from which they were formed. The structure of each graph is represented by its vertices and edges, which also incorporate all necessary information – the values of primitive attributes and the names and types of all attributes. This is important, because the graph can be saved to a file and then loaded from this file and it is not necessary to recreate the original object, from which the graph was formed.

The graphs are compared using their parallel BFS exploration. Basically, in one loop, both graphs are explored.

```
v1 = graph1.rootVertex; v1.state = GRAY;
v2 = graph2.rootVertex; v2.state = GRAY;
queue1 = Queue();
queue2 = Queue();
queue1.add(v1);
queue2.add(v2);
equal = true;
while (!queue1.isEmpty()) {
  v1 = queue1.remove();
  v2 = queue2.remove();
  if (v2 == null) {
    equal = false;
    break;
  }

```

Fig. 7 Pseudocode for the comparison of two graphs

For each node, it is checked, whether they have the same count of primitive attributes with the same values. If a difference is found, the loop is ended prematurely and the objects are considered different. The objects are also considered different, when the graph of one of the objects is fully explored and the other is not. The algorithm is described in Fig. 7 in pseudocode.

V. Validation and Results

The described DOC algorithm was thoroughly tested using two sets of tests. In the first set, we focused on the correct functionality of the algorithm. The second set of tests was focused on the performance of the algorithm. All tests were performed on a standard notebook computer with dual-core Intel i5-6200U at 2.30 GHz with HyperThreading, 8 GB of RAM and 250GB SSD/500GB HDD. The software environment consisted of the Windows 7 SP1 (64 bit), Java 1.6 (32 bit), and Equinox OSGi framework.

A. Correct Functionality of the DOC Algorithm

The correct functionality of the DOC algorithm was tested by comparison of pairs of similar or equal objects. There were 5 pairs with variously complicated internal structures. The structures of all objects were created manually using the `A` class depicted in Fig. 8. The class and the objects were designed to test various situations, which can occur in internal structures of general objects – primitive attributes, reference attributes, arrays, and lists. Similarly, the changes introduced into one object of each pair of equal objects in order to create a similar but slightly different object represent various differences, which can occur in general objects – different lengths of an array, different values of an primitive attribute, different references, different elements of an array and/or a list. The internal structures of the objects were reasonably small (see Fig. 9) in order to enable controlled manual introduction of the changes and checking whether the results of the DOC algorithm are correct.

For each pair of objects, four tests were performed. In two tests, both objects of the pair were identical. In the remaining

```
import java.util.List;

public class A {
  private A parent;
  private int number;
  private String string;
  private List<A> list;
  private A[] array;

  public A(A parent, int number, String string,
      List<A> list, A[] array) {
    this.parent = parent;
    this.number = number;
    this.string = string;
    this.list = list;
    this.array = array;
  }
}
```

Fig. 8 The class `A` used for the testing of the functionality of the DOC algorithm

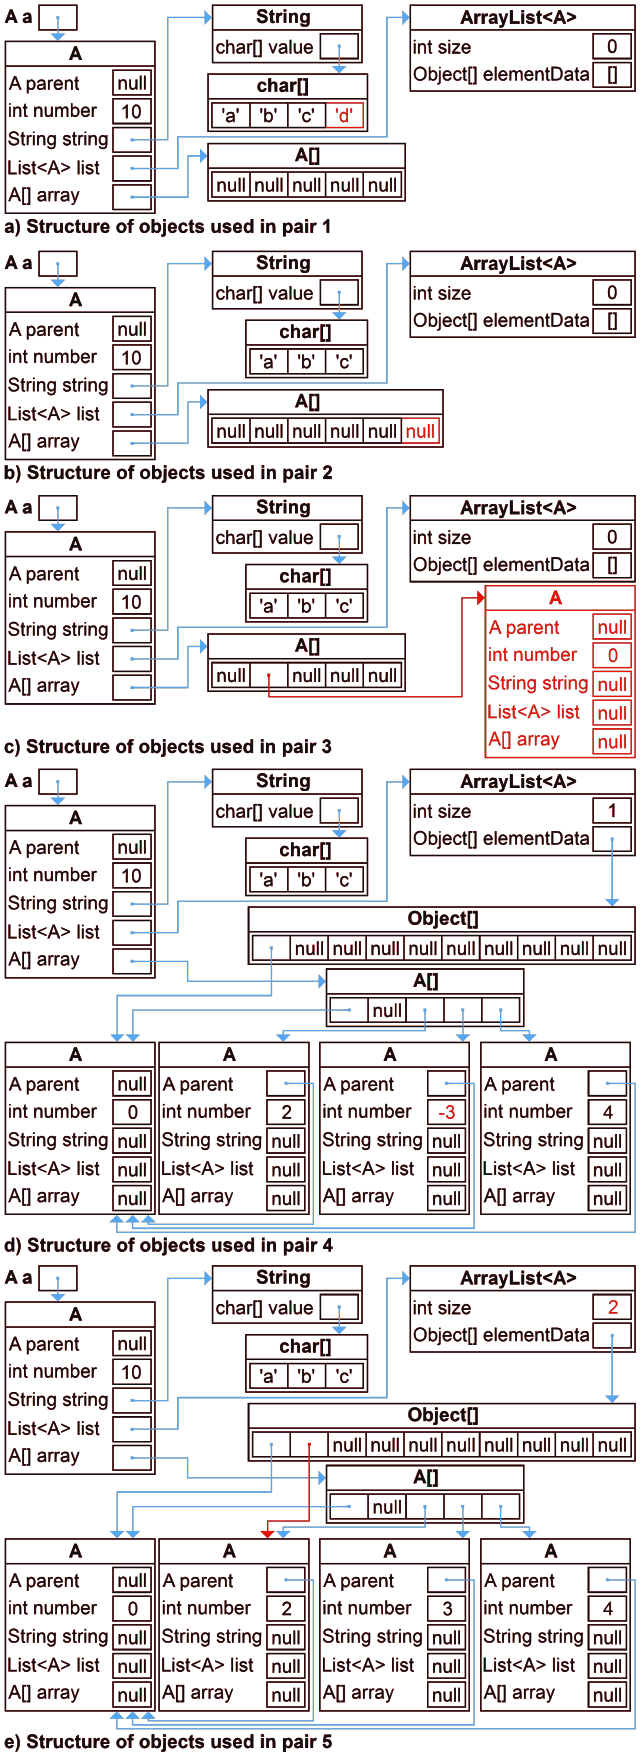

Fig. 9 Structures of objects used for the testing of the functionality of the DOC algorithm with highlighted differences

TABLE I THE RESULT OF THE COMPARISON OF PAIRS OF OBJECTS USING THE DOC ALGORITHM

Pair of objects	Both objects in memory		One object saved & loaded	
	Equal	Different	Equal	Different
1	`true`	`false`	`true`	`false`
2	`true`	`false`	`true`	`false`
3	`true`	`false`	`true`	`false`
4	`true`	`false`	`true`	`false`
5	`true`	`false`	`true`	`false`

two tests, one object was similar but slightly different. The differences are highlighted in Fig. 9. This way, both required results of the comparison (i.e., `true` and `false`) were tested. The graphs were created for both objects of the pair and then compared (once for identical objects and once for similar objects). Moreover, one of the graphs was saved to and loaded from a file and the comparison was performed again (once for identical objects and once for similar objects). This way, it was tested that the saving of the graph to a file will not affect the comparison.

For pair 1, the objects were instances with empty lists, arrays with 5 `null` elements, `null` parents, but with set values of numbers and strings. The difference introduced into one object was one character longer string (see Fig. 9a). For pair 2, the objects were the same, only the difference was that one array was one element longer (see Fig. 9b). For pair 3, the objects were again the same and the difference was that one array has one element (with index equal to 1) not `null`. Instead, it pointed to another instance of the `A` class with all attributes set to `null` or 0 (see Fig. 9c).

For pairs 4 and 5, the arrays had 5 elements, one element (with index equal to 1) was `null` and the remaining elements were instances of the `A` class with `null` strings, arrays and lists, but with parents set to the zeroth element of the array (with the exception of the zeroth element, which had the parent set to `null`) and the number set to the index in the array. The list contained one element corresponding to the zeroth element of the array. For pair 4, the difference was a different number value in the fourth element of the array (see Fig. 9d). For pair 5, the difference was one added element to the list (second element of the array – see Fig. 9e).

The results of the testing are summed in Table I. The algorithm returned the expected value (`true` or `false`) in every instance.

B. Performance of the DOC Algorithm

The performance of the DOC algorithm is important, because there is a significant number of object comparisons during both the generation of the testing scenarios and the comparison of two scenarios. Nevertheless, the number of comparisons is still far lower than it is necessary for the caching and similar techniques described for example in [7], [10], or [12]. For the testing, increasingly complex objects created using the `A` class were generated and compared. The compared objects were always equal. Different objects would cause premature ending of the comparison, because it is stopped on first uncovered difference (see Fig. 7). The results are summed in Table II.

TABLE II THE PERFORMANCE OF THE DOC ALGORITHM

Vertices count	Edges count	Graphs construction time [ms]	Graph comparison time [ms]
33	42	1.9	0.1
333	442	7.6	0.7
3 333	4 442	110.7	4.6
33 333	44 442	10 131.2	28.8

As can be seen in Table II, the graph construction phase is far more time-demanding than the graph comparison phase. There are several reasons for this. In the graph construction phase, the graphs of both the compared objects are created sequentially, which means that roughly half of the time is necessary to create the graph of a single object. More importantly, the sequential searching of the list of already visited objects is employed during this phase (see Fig. 5). Lastly, Java reflection is used during this phase, which is inherently slow [8].

The graph construction is not needed during the comparison of two testing scenarios, where the graphs are already constructed. However, it is necessary during the generation of the testing scenario for the comparison of invocations and consequences. Nevertheless, although these comparisons are numerous, the graph must be constructed only once per object. Multiple comparisons can then be performed using the graph representations of the objects only. So, the construction of the graph representations of the objects have a significant performance benefit in addition to the ability to easily save the graph representation to a file.

VI. CONCLUSION AND FUTURE WORK

In this work, we described the deep object comparison (DOC) algorithm. The algorithm was designed for our interface-based regression testing of software components for the comparison of general objects based on their internal structures and values of primitive attributes. Based on the performed tests, the algorithm works correctly for arbitrary objects, which can incorporate primitive and reference attributes, lists, and/or (single- or multi-dimensional) arrays. The performance of the algorithm seems to be reasonable, since the slower graph construction phase is expected to be performed by an order of magnitude less often than the faster graph comparison phase.

In our future work, we will incorporate the DOC algorithm to our interface-based regression testing of software components. We will then perform thorough testing focused on the resulting performance of the entire approach as well as on its increased ability to detect subtle changes in behavior of the component-based applications with new versions of components.

We will also consider the use of the DOC algorithm in another project focused on the generation of complex testing data (i.e., objects with complex internal structures). We plan

to employ particle swarm optimization [17] and/or combinatorial testing [18] to minimize the amount of generated data. The DOC algorithm can be utilized for the comparison of generated objects and/or their parts to remove any duplicity.

5th Doctoral Symposium on Recent Advances in Information Technology

THE aim of this meeting is to provide a platform for exchange of ideas between early-stage researchers, in Computer Science and Information Systems, PhD students in particular. Furthermore, the symposium will provide all participants an opportunity to get feedback on their studies from experienced members of the IT research community invited to chair all DS-RAIT thematic sessions. Therefore, submission of research proposals with limited preliminary results is strongly encouraged.

Besides receiving specific advice for their contributions all participants will be invited to attend plenary lectures on conducting high-quality research studies, excellence in scientific writing and issues related to intellectual property in IT research. Authors of the two most outstanding submissions will have a possibility to present their papers in a form of short plenary lecture.

***Abstract*—Physical exercise is widely recognized as beneficial to the cardiovascular system. However, intense exercise may also carry fatal risk. Investigation of this phenomenon is one of the primary purposes of the North Sea Race Endurance Exercise Study (NEEDED). This paper describes analysis of electrocardiograms (ECG) and heart rate signals collected from amateur athletes, participants of the race, to facilitate non-invasive estimation of the level of cardiac troponin I (cardiovascular risk biomarker) and detection of coronary artery disease (CAD). It was demonstrated that the combination of ECG and heart rate parameters can predict CAD with high specificity (up to 98%) and relatively good sensitivity. Moreover, while troponin level assessment is unlikely to be reliably performed using regression techniques, it might be possible using a new, probabilistic classification-based model. Further evaluation of the latter requires the use of additional data, which is one of possible directions for the future work.**

I. Introduction

CARDIAC troponins T and I (cTnT, cTnI) are protein subunits involved in contraction of the heart muscle. Their increased blood levels are widely associated with an occurrence of damage to the myocardium of diverse etiologies, including coronary artery disease (CAD) [1], [2], [3]. Nonetheless, recent studies have reported increase in cTnT and cTnI levels incident to prolonged, high-intensity physical exercise in presumably healthy individuals, predominantly recreational athletes [4]-[9].

This phenomenon was observed also in the frame of the North Sea Race Endurance Exercise Study (NEEDED) conducted at the University of Stavanger and Stavanger University Hospital in Norway [10], [11]. Aiming to explore the impact of long-term physical effort on the physiology of the cardiovascular system, the study recruited its participants from recreational cyclists competing in Nordsjørittet (the North Sea Race) - an annual cycling competition, organized in Rogaland, Norway. In 2014, over a thousand study subjects were examined i.a. for blood levels of cardiovascular biomarkers (including cTnI) and electrocardiograms (ECG). Supplementary data was retrieved from some of the participants' sports watches. Herein described research work was concerned with analysis of the abovementioned data. The main hypothesis stated that blood level of cTnI and presence of CAD can be predicted based on parameters of ECG and heart rate (HR). In particular, the prediction might be guided by physical effort-induced changes in not explicitly pathological ECG.

II. Study population and the dataset

The investigated population comprised 160 presumably healthy individuals. A total of 53 individuals were assessed by coronary computed tomography angiography, 6 of whom were diagnosed with CAD. In these 6 and further 14 cases, at least one cTnI level was elevated (>190 ng/l [10]). The analyzed data included:

- blood levels of cTnI, measured at: 24 h before, 3 h after, and 24 h after the race;
- 10-second 12-lead ECG recordings, collected at the same measuring time points as the cTnI data;
- clinical data: participants' age and BMI;
- formerly processed [12] HR data from sports watches.

III. Data preparation

A. ECG preprocessing and segmentation

The ECG was preprocessed by: filtering (band-pass Butterworth infinite impulse response filter, order: 5, cut-off frequencies: 1 and 40 Hz) and baseline offset removal. Subsequently, the signal was segmented into heartbeat templates using tools implemented in BioSSPy toolbox. Key points of the ECG (vertices, onsets, and endpoints of P, S, and T waves) were determined based on averaged beat templates from lead I similarly to our previous work [13]. Onsets of positive waves (P, T) were searched for within a window preceding the maximal ascending slope of the wave (n_{ms}): $[n_{ms}–w,\ n_{ms}–s]$, with w - window size, s - additional spacing to compensate for a possible 'M pattern'. Onset candidates were points $n \in [n_{ms}-w,\ n_{ms}-s]$ satisfying conditions:

$$N_c = \{n:\ |y'(n)| \leqslant |k \cdot y'(n_{ms})| \wedge y''(n) \geqslant 0\} \quad (1)$$

TABLE I: Parameters of detection of M and W patterns.

Wave	Pattern	Lead	k	l
P	M	I, II	0.2	3
R	M and W	V1, V5, V6	0.2	2
S	W	I, V6	0.3	2

where: y - the signal; k - a threshold factor. Selection criterion, depending on point type, was of form:

1) $arg \min_{n \in N_c} g(n),\ g(n) = |y(n) \cdot y'(n)|$, or
2) $arg \max_{n \in N_c} y''(n)$

Detection P and T waves endpoints was performed analogically on the descending slopes of the waves. For S wave (negative wave) endpoint, the respective segment was inverted. The parameters: w, s, and k were tuned separately for each point type based on standard durations of the waveforms.

IV. Feature extraction

A. ECG signal

ECG features described below were defined in three areas: time domain, frequency domain, and correlation analysis.

1) Features from lead-I signal measurements: basic time-domain features, including:

- heart rate,
- QT interval duration corrected for HR (according to the formula of Fridericia [14]),
- ST segment duration,
- ST elevation,
- P wave shape coefficient, i.e. the ratio of width and amplitude of the wave.

2) M and W patterns: notches in P, R, and S waves[1](see Fig. 1). An M pattern was deemed to be present in the signal if a sufficient number l of samples n of given wave satisfied the following criteria:

$$\begin{cases} y'(n) < 0 \ \wedge \ y(n) > k \cdot y(n_{max}) & for\ n_{on} < n < n_{max} \\ y'(n) > 0 \wedge y(n) > k \cdot y(n_{max}) & for\ n_{max} < n \leqslant n_{end} \end{cases} \tag{2}$$

where: n_{on}, n_{peak}, n_{end} - indices of onset, peak, and endpoint of the given waveform; y - signal values; k - threshold factor: minimal portion of the peak amplitude. For detection of W patterns, the signal was inverted. Parameters k and l were determined empirically for each wave type, as summarized in table I.

3) Heart axis: direction[2] estimated using a pair of perpendicular leads: I and aVF:

$$\theta = arctan\left(\frac{V_{net,aVF}}{V_{net,I}}\right) \tag{3}$$

[1]Depending on wave and lead of their manifestation, M and W patterns might be symptoms of atrial hypertrophy, left or right bundle branch block, and other conditions [15].

[2]The mean direction of the electric field vector (in the coronal plane) throughout an ECG cycle. Its significant deviation may be a symptom of disorders affecting the conduction system (e.g. bundle branch block) [16]

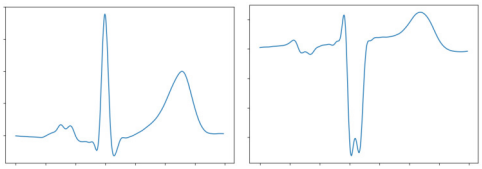

Fig. 1: Exemplary averaged beat templates: (left) M pattern in a lead-I P wave; (right) W pattern in a lead-V1 R wave.

V_{net} denotes net QRS potential in a lead, calculated as:

$$V_{net} = \begin{cases} max(V_{QRS}) & if\ min(V_{QRS}) \geqslant 0 \\ max(V_{QRS}) - |min(V_{QRS})| & otherwise \end{cases} \tag{4}$$

where $V_{QRS}(t)$ - voltage of the QRS complex [17].

4) Lead-I QRS templates correlation: used to assess internal morphological consistency of a recording. The parameter was calculated as the mean value of the upper-triangle elements (excluding the diagonal) of correlation matrix of QRS templates from a single lead-I signal.

5) Frequency-domain features: derived from power spectra of the QRS complexes. QRS-only signal was extracted by a mask: QRS selection windows (rectangular with half-Gaussian slopes), replicated at locations of the R peaks. Parameters derived from power spectrum of the masked signal included:

- two slopes characteristic for log-transformed low-frequency moiety of the signal, calculated over frequency ranges: [3 Hz, 8 Hz] and [15 Hz, 19 Hz] (as in [18]),
- the mean of power spectral density signal over frequency range [150 Hz, 300 Hz] (upper half of the range).

B. Heart rate

HR signal from sports watches, resampled and processed in the previous works, was a base for calculation of two parameters:

1) HRp99: mean of 99th percentile HR samples:

$$HR_{p99} = \frac{\overline{\{hr \in HR \ : \ hr \geqslant P_{99}(HR)\}}}{HR_{max}} \tag{5}$$

where: HR_{max} - maximal predicted age-dependent HR: $HR_{max} = 208 - 0.7 \cdot Age$ [19].

2) HR90 time: a portion of the race time in which participant's HR was above 90% their individual HR reserve:

$$t_{HR90} = \frac{\sum_{i=1}^{n} i\ [HR_i > (HR_{rest} + 0.9 \cdot HR_{reserve})]}{\sum_{i=1}^{n} i} \tag{6}$$

where: n - the number of samples, HR_{rest} - resting HR (from ECG prior to the race), and $HR_{reserve}$ - individual HR reserve: $HR_{reserve} = HR_{max} - HR_{rest}$ [4].

C. Clinical data and parameters from the previous work

- participants' age and BMI,
- max and mean HR from Tinghaug hill segment (a major steep climb of the race, associated with substantial effort and strain to the heart) [12], normalized by HR_{max}.

Following the hypothesis on the importance of changes versus momentary state, parameters from days 2 and 3 were

expressed as ratio (for HR) or difference with respect to day 1. To sum up, there were: 14 parameters from the ECG (each day), 4 from the HR, and 2 from the clinical data - in total, 48 features. A general assumption was to use data gathered prior to, or simultaneously with collection of blood for troponin assay. Thus, there were three sets of input parameters for cTnI level assessment, with 16, 34, and 48 features. CAD detection was performed on two sets: one with the 48 features and the second, additionally including cTnI levels (51 features).

V. Experiments setup

The data analysis had two main objectives: cTnI level estimation (separately for each day) and CAD prediction - together, four problems. The small size and strongly nonuniform distribution of the data motivated the use of leave-one-out cross-validation (LOOCV) approach.

A. CAD detection

Two methods were applied for this binary classification task:

1) Automatically optimized classification: a search for the best classifier launched with the use of TPOT - genetic programming-based software providing tools for model selection and tuning [20]. The number of generations and population size were set to 7 and 70 respectively.

2) Grid-search-optimized decision tree classifier: the classifier was optimized in terms of i.a. class weights and maximal depth. The best estimator instance was passed to LOOCV loop.

The results were evaluated using two types of metrics: confusion matrix and the area under the receiver operating characteristic (ROC) curve, weighed by counts of true positive (TP) and true negative (TN) observations.

B. cTnI level estimation

Due to a strong bias towards the lowest values and vast dispersion of the highest readings, the cTnI values were log-transformed before analysis. Estimation of the cTnI level - as a continuous variable - was approached using two techniques:

1) Automatically optimized regression approach: determination of an optimal regression model with the TPOT software (7 generations and population size of 70).

2) Probabilistic classification-based approach: an intermediate class definition was obtained by stratification of the log-transformed cTnI levels for a given day into 2 to 10 layers of equal breadth. Test samples were classified using a logistic regressor with probabilistic classification output. Next, in the LOOCV scheme, the cTnI level for each test sample was estimated by computing a weighted average of the class centers (medians, $\mathbf{c_{cTnI}}$) with class probabilities vector $\mathbf{p}$ as weights:

$$cTnI \;=\; 10^{(\mathbf{p^T}\,\cdot\,\mathbf{c_{cTnI}})} \tag{7}$$

VI. Results and discussion

A. CAD detection

The results of CAD prediction are summarized in Table II. Results were influenced by a random component (randomly seeded decision tree classifier; obtaining a deterministic output is possible, but might introduce a bias to the results). The information on the true cTnI levels significantly influenced the results, in particular in terms of the false positive (FP) detections. When the cTnI data was included, all FP results were from the elevated cTnI group; otherwise, all FPs belonged to the low cTnI class.

TABLE II: Summary of the results of CAD prediction; TP = true positive, TN = true negative, FP = false positive, FN = false negative (given in counts of observations).

Dataset	Approach	Model specification	Confusion matrix	ROC area
Without cTnI data	TPOT optimization	gradient boost. classifier	TN 154, FP 0, FN 6, TP 0	0.42
	Decision tree + grid search	number of features: 5	TN: 152, FP: 2, FN: 3, TP: 3	0.74
With cTnI data	TPOT optimization	gradient boost. classifier	TN 154, FP 0, FN 6, TP 0	0.83
	Decision tree + grid search	number of features: 5	TN: 151, FP: 3, FN: 1, TP: 5	0.91

Formerly [12], CAD detection based on the HR and clinical data with the best true positive rate (TPR) of 0.86 (6/7 cases) and the same true negative rate (TNR). Herein described experiments were performed with a greater scope of parameters (from the ECG signal), but with reduced number of CAD-positive observations (by one sample, i.e. 14%). TPR decreased to 0.5 (3/6 cases). However, TNR was noticeably higher, reaching 0.98 (152/154 cases). With the cTnI data, TPR increased to 0.83 (a single undetected case). Most significant factor contributing to TPR decrease is the depletion of the positive class strength.

The results do not unambiguously prove that features derived from the ECG signal improve CAD prediction rate (compared to HR only). However, they clearly demonstrate the value of ECG in excluding otherwise suspected CAD in healthy individuals.

B. Troponin level determination

1) Regression approach: this approach failed to establish a reliable prediction model. In none of the cases, the scores reached positive values (while 1 denotes a perfect prediction, and 0 - a constant model). One of possible explanations lies in the physiology of the circulatory system: the differences in ECG and HR parameters between the individuals did not sufficiently correlate with differences in cTnI level over the range of the values. Indeed, it should not be assumed that e.g. the duration of the QT segment would increase proportionally to the increase in the extent of CAD, associated with elevation in cTnI. The negative conclusion was confirmed by an independent team at the University of Stavanger [21].

2) Probabilistic classification-based approach: exemplary results (for day 3) are presented in Fig. 2. The highest true value was excluded from the plot to provide a better plot scale for analysis of the results. The estimation was strongly biased towards the lowest level, containing majority of the observations. Additionally, there are some false high predictions. However, there is a group of observations actually

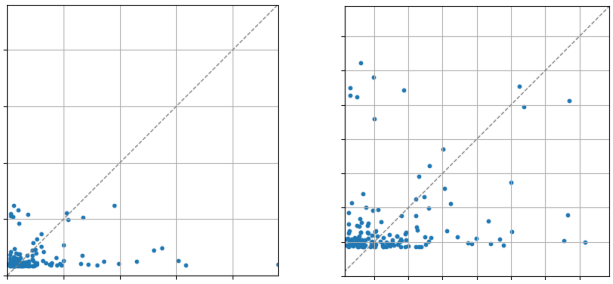

Fig. 2: cTnI level determination with probabilistic classification: results for day 3; horizontal: true, vertical: predicted values; (left) full set, (right) zoom at the lower range.

following the diagonal of the plot. Although they constituted minority of the set, these predictions were fairly accurate.

There were multiple factors hindering the prediction. The number of samples (160) was low. This effect was escalated by data imbalance. In day-1 data, 39% of the samples had the same cTnI level of 1.6 ng/l, and 86% did not exceed the level of 5 ng/l (mean $\pm$ standard deviation: 2.2 $\pm$ 0.8). In the remaining 14% of the dataset, the values spread between 4.9 and 284.8 ng/l (mean $\pm$ standard deviation: 26.9 $\pm$ 55.8). On the remaining days, there were additional substantial, but isolated peaks (5025.9 ng/l for day 2 and 7918.5 ng/l for day 3 - the latter being more than 33-fold larger than any other in the set). Excluding a single high-cTnI sample (in LOOCV) further amplified the imbalance.

VII. Conclusions

The herein reported project was concerned with analysis of data from the NEEDED research program with two main objectives. First of all, the level of circulating cTnI following prolonged, strenuous exercise was to be estimated using information derived from ECG and HR signals. The main conclusion to this problem was negative, though meaningful for the future research: the correlation between cTnI and parameters derived from HR and ECG was not found sufficient to establish a continuous, regression-based model for estimation of the level of the former. However, it is possible that the alternative classification-based approach is more likely to correspond to the underlying physiological mechanisms governing the exercise-induced cTnI response. Nevertheless, both conclusions need to be validated on a greater dataset.

The second goal was improvement of the rate of detection of CAD compared to previously achieved results. ECG was not found to increase the sensitivity of the prediction. However, this refers to a decrease in TP detections by 1 observation with lowered strength of the positive class. On the other hand, the ECG features notably enhanced the detection in terms of its specificity - from 86% to 98%. Best results of prediction of CAD could be achieved by including the cTnI level information into the analysis. The two types of information appear to be complementary - cTnI improves sensitivity of the model (a single undetected case), while ECG and HR data promote its specificity by effectively excluding non-CAD cases of cTnI elevation.

***Abstract*—The Tomatis Method is a rehabilitation technique used in psychology, the main aim of which is stimulating the cochlea in the inner ear by filtered air-conducted and bone-conducted sounds. The system of electronic filters and amplifiers used for this therapy is called the Electronic Ear. Commonly, it is an analog device, that is expensive and after a few years its functionality declines. In this paper, we introduce a digital Electronic Ear system using an STM32F4 family micro-controller and ADC/DAC integrated circuits. The design of digital sound filters allows to adjust more parameters and overcomes some of the constraints of analog systems. In this paper, we provide a short review of the Tomatis Method, the main functions of the Electronic Ear and we describe the designed system with comparison measurements to the analog one.**

I. Introduction

MUSIC therapy has numerous applications in psychology and rehabilitation. It can be used to help patients manage stress, concentration or depression. However, in many cases these methods do not give visible effects, when they are compared with a control group [1-4].

The Tomatis Method (TM) has been shown to help people with various psychological disorders (autism, dyslexia, ADD and more) [10], [11], [12], [13], [14], [15], [16], [17], [18], [20] though in some controlled trials the results were also inconclusive [8],[19]. It uses music, but it is not a music therapy, as it is based on brain and inner ear stimulation by selective sound filtering. The electronic device that implements the filter system for TM is called an Electronic Ear (EE). Most EEs that are commonly used are analog systems, that have their own constraints and high prices. We propose a new, digital Electronic Ear (DEE) system designed for cheaper implementation of TM and its further studies.

II. Tomatis Audio-Psycho-Phonology

Tomatis Laws cover the theory behind the relationship of hearing and speaking. Alfred Tomatis observed that problems with singing or speaking in some particular spectrum are connected with difficulties with hearing in the same spectrum and proposed that the improvement of vocal and voice range can be provided by opening the hearing ability to a specific frequency spectrum. This principle is called the ***Tomatis effect***. Over the years his ideas were implemented in other forms of sound therapy and a generic Electronic Ear tool was developed.

The Electronic Ear is based on the concept of stimulating the basilar membrane (BM) in the cochlea in two ways - by air and bone conduction. ***Air conduction*** is based on the typical ear pathway, with sound vibrations picked up by the eardrum, transferred by the ossicles to the oval window of the cochlea. ***Bone conduction*** is the perception of vibrations travelling through the bone and stimulating the BM either through pressure changes in the cochlear fluid or vibrations of the cochlear wall [5]. Bone conducted sounds reach the brain faster due to the higher density of the medium; however, large part of the acoustic signal is reflected due to the air-bone impedance mismatch. That is why bone conduction mostly favors our own voice. The conclusion drawn by Tomatis from this observation was that air conduction is used to "communicate with the outer world" and bone conduction is used to "listen to oneself". [6],[7].

The next feature that is important for TM is human earedness, i.e. which ear is dominant in the hearing process. Left ear dominance is problematic, because the left ear has the longer path to the left hemisphere. The delay between left and right ear is about 0.4-0.9 ms. People, who are left-eared have a lot of listening problems that can cause various psychological disease, such as dyslexia [6]. One of the main aims of Tomatis Rehabilitation is to increase the role of the right ear for the people who are left-eared. For this reason there are separate delays and adjustable volume levels for left and right channels.

Fig. 1 shows the flow chart of the EE. It is an audio system, the main function of which is amplifying, gating and filtering sound going to the three output channels - air left, air right and bone conduction. Gating is the process of changing the filter type depending on signal level. Below a certain amplitude level the C1 filter is on and above a certain level the filter is switched to C2 filter. The sudden change gives an impulse that theoretically stimulates the brain. The C1 and C2 filters are shelving filters with 1 kHz cross-band frequency. The boost/attenuation level is adjusted by the specialist administering the TM therapy and can be set from -5 to 5 dB. The EE also contains a second filter - a High Pass filter with an adjustable cut-off frequency. It is supposed function is to imitate the medium of a mother's womb. In some cases there is a need to increase or decrease a role of bone conduction in comparison to air conduction. For this reason

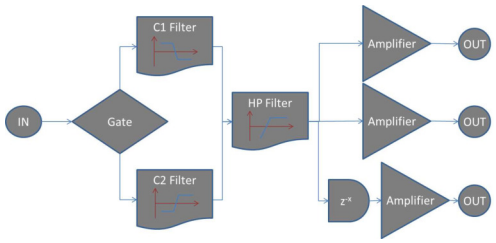

Fig. 1. Flow chart of the Electronic Ear (EE). The Gate depending on the signal level diverts it to the shelving filters C1 or C2. The HP filter cuts off low frequencies. The Delay allows to the air and bone conducted sounds to arrive at different times and the Amplifiers control the level of the three outputs.

there is an adjustable delay between the air and bone channel called ***precession***.

TM is used for many purposes. One of the popular aims is in therapy of autistic children. According to Tomatis theory autism is connected with problems with listening to the external world - in most autistic children bone conduction sensitivity is higher than air conduction. The therapy's aim is to lower this sensitivity in order to open the child up to communication with others. There were many studies carried out to verify the effectiveness of this rehabilitation. One of the most controversial was [8]. It revealed that there was no clear difference between the effects on a control group and an experimental group put under TM rehabilitation. For response to this article there were two follow-up studies [9], [10]. They showed the opposite view and pointed out missteps in the previous research. These two and another one [11] show a significant improvement after the TM rehabilitation measured in the Children's Autism Rating Scale (CARS) or in Gilliam Autism Rating Scale (GARS).

An overview of over 30 TM studies by Gerritsen showed that the majority of studies demonstrated positive effects of TM therapy. Some of the better documented TM treatments include:

- reduction of the Attention Deficit Disorder (ADD) by, similarly to autism, increasing the focus on air conducted sounds versus bone conduction [6],[12],[13].
- treating dyslexia [6],[13],[20] (that is theoretically connected with left-earedness) by increasing the sensitivity of the right ear.
- supporting language learning [14], by setting the C1/C2 filters to frequencies most commonly appearing in a given language. TM rehabilitation has also been successfully used for:
- Epilepsy - visible effect in more than 50
- Cerebral palsy: significant improvement [16]
- Stuttering and hoarseness [13]
- Emotional problems including depression: high effect, compared with a control group [17]
- Music skills improvement: results are divided [18],[19]

Most of tests have shown a positive effect of TM, but there are also those, that did not report any differences when compared to a placebo treatment. We need to consider that negative results can stem from inappropriateness in investigation methods or in the way the EE device was used [9]. This shows that the TM requires further rigorous studies.

III. Electronic Ear Stimulator

In terms of the electronic design main functions of Electronic Ear are: Converting audio signal to digital data (ADC); Pre-processing; Gating; Filtering; Digital-Analog converting (DAC); Amplifying. The device can be divided into four main modules: audio input, audio output, micro-controller and power supply. Three voltage levels are needed:

- 5V - external power supply. It is used as an input for the step-down converter and as an analog power supply for the input section. The transformer power source is used in order to decrease the distortions in the low frequency audio signals.
- 3.3V - it is given by Low Dropout Positive Regulator TC2117 from MicroChip. It is used for digital power supply for μC and for the digital part (communication interfaces) of the ADC/ DAC converters.
- 2.5V - it is necessary for the output analog power supply and it is provided by LP2985-N

In this project external 24-bit stand-alone integrated circuits were used. For input a PCM4201 from Texas Instruments and for output CS432L22 from Cirrus Logic were used. In both cases communication between the audio converter and μC was provided by an I2S interface, the audio data word length is 24 bits and is Left-Justified in the frame. CS43L22 supports I2S and it was working in the slave mode by being connected to four pins: MCLK, LRCK, SCLK and SDO. It has its own transmission interface that has 3 communication ports - BCK (equivalent to SCLK), DATA (equivalent to SDO), FSYNC (equivalent to LRCK) and one system clock port, that is necessary for proper work. The serial interface is very similar to I2S and after a few modifications it can work in high performance mode communicating in master mode. The main difference is that the system clock needs to be 512 times larger than the sampling frequency (256 times larger in I2S mode). To get that result an extra I2S interface was used with a 2 times larger sampling frequency and the MCLK pin connected to the system clock pin in the audio converter. That allows a clean transmission without errors.

The CS43L22 is a DAC converter, but also a headphone amplifier. It allows to prevent from using two independent chips (one for converting, one for amplifying) and minimalizes space on the PCB board. In the project there are two output channels - air and bone channel. In order to support three channels (that are required for the EE) there is used an external adapter that splits the air channel to left and right channels with a build-in balance regulator. CS43L22 has two serial interfaces and except of I2S for data transmission it has also I2C interface for control. It allows to regulate all functions of the chip, for example volume, that is continuously sent to the control register.

For digital signal processing the STM32F407VGT6 microcontroller was used. Data was stored in a float buffer. Its

size was set in order to provide maximum 500 milliseconds delay, which for 48kHz frequency sample gave (24000 + filter order) size. User interface gives possibility to adjust the main parameters of the EE - C1, C2 levels value, frequency, precession and volume and the advanced options as gate upper level and four options for filter order. Changing filter order affects its selectivity and as a result the intensity of stimulation.

There were used filter orders in range of 51 to 101 (only odd orders are used). Every filter was designed as FIR (Finite Impulse Response) filter using the window method. The window that was chosen for this purpose was modified Tukey window (tapered cosine window). It is combination of a rectangular window and a Hamming window with an α coefficient that determines what part of the window should be flat. It makes cosine lobe of width $\alpha/2$ * N (N is filter order) and rectangular window of width (1 - $\alpha/2$) * N at the center of filter function. With α = 0.8 it gives the best results - sufficient filter selectivity providing expected filter band levels even for low cross-frequency (500 Hz is a minimum used value) and low ripple frequency response.

In this project two types of filters are required - simple HP/LP filter and a shelving filter for the C1 and C2 filtering. To obtain a two-level shelving filter it was necessary to use a parallel connection of filters - one for left part (LP filter) and one for right part (HP filter). The cross-frequency is set where the characteristic crosses the 0 dB line. For that reason there was a need to modify one frequency by a coefficient dependent on filter order and C1 and C2 levels.

The big challenge was to appropriately design the filter in case when both shelving filter levels have the same sign. Normally it should not cross the zero decibels line. But measurements of the original EE show, that with this case it should be artificially modified in order to give 0 dB gain at the cross-frequency point. A cascade connection of two filters with similar cut-off frequency was used, but modified regarding to the purpose. For the positive shelving filter levels the gain near the cross-frequency was decreased (frequencies of filters diverge) and for negative it was increased (frequencies converge). Then, obtained filter is serially connected with the normal shelving filter.

In this section the frequency-responses of filters in the designed DEE are showed and compared with those measured for the original, analog EE device.

Fig. 2 and 3 show frequency-responses for 101-order filters for designed device. As it can be seen, passband levels have correct values, remain stable and C1 and C2 filter lines cross near the 0 dB level. In the first case the 500 Hz (the minimal needed value for this project) and in the second 1 kHz (frequency of analog EE) cross-band frequency was set. In figure 3 the filter with two positive levels was shown to provide appropriate gain modification near cross-frequency.

IV. Results

In Fig. 4 and 5 frequency responses measured for the DEE and analog EE are shown for 1 kHz cross-band frequency and [±5, ±5] and [±5, ±1] levels respectively. The unstable

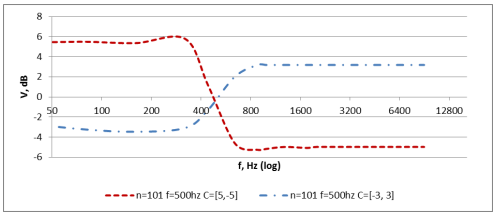

Fig. 2. Frequency-response for n=101, f=500 Hz and passband levels set.

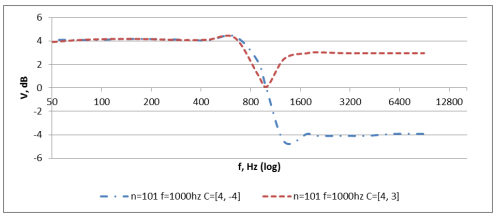

Fig. 3. Frequency-response for n=101, f=1000 Hz and passband levels set.

and exceeded passband levels during the whole frequency bandwidth for analog devices can be seen. In Fig. 5 one can notice the ringing artifacts for the bandwidth above 1 kHz. The cross-point for analog device also has an incorrect value i.e. 850Hz for first case and 865 Hz for the second case.

V. Conclusions

The DEE, which was the topic of this paper was designed properly and it provides all the required functions. It services 2 channels, that with external splitting adapter allow to support three channels. If the right/left channel delay was needed, there would be a possibility to use second, same DAC integrated device for extra output channels. The DEE uses 24-bit audio data with 48kHz sampling frequency. The included filters give the desired effects - the shelving filter levels and cross-frequency value are as expected. It monitors changes at air and bone channels and gates them to C1 or C2 filters depending on the signal level and precession value.

Compared to the analog EE, the designed device has all the same functions, but it has also extra - features allowing to remove some previous constraints. First it is a digital system, so the filter parameters are stable and do not depend on

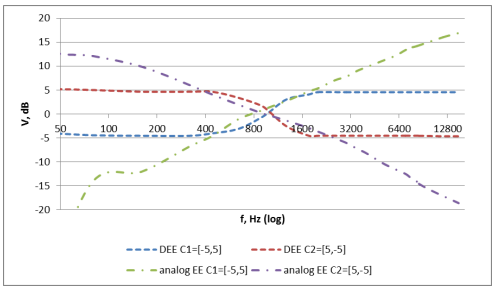

Fig. 4. Frequency-response of C1/C2 filters measured for digital and analog device. Theoretically, the analog EE's pass bands should be flat, but the measurements show they clearly have a linear drop-off.

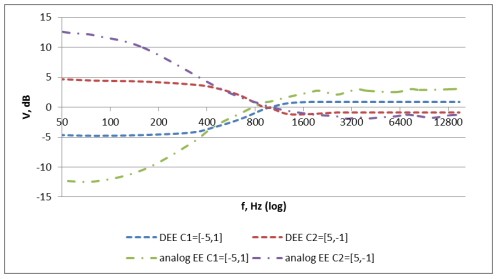

Fig. 5. Frequency-response of C1/C2 filters measured for the proposed digital and the original analog TM device.

the duration of operation or component aging. In Figures 4 and 5 there is visible effect of this occurrence for the analog device - the filter levels are different than expected and are unstable. We can only speculate about the discrepancies between the theoretical spectra and those measured for the commercial EE analog device. One theory is component aging (e.g. degradation of dielectric in the capacitors) or it could simply be a design flaw. Another advantage is that the cost of production of the DEE (less than 200EUR) is much lower than the analog TM device (approximately 10,000EUR). The fact that filters in the designed system are digital also gives an opportunity to develop it in the future, change the parameters or to upgrade it depending on the requirements.

The next advantage is that digitalization allows more parameters to be adjusted by the user. It is possible to set the cross-frequency of the shelving filter. In analog EE C1 and C2 filters have always the same cross-frequency and it is 1 kHz. It has also only one type of filter selectivity. In the designed device four cases for filter order allow to change the intensity of stimulation and pick the best one for the individual patient. The changeable filter frequency allows to modify frequency band, that impacts the most to the listener.

To sum up, a modernized digital version of the device used for the rehabilitation by the Tomatis method was designed and tested. Its performance was measured to be the same or better than the original equipment, while allowing much more control over the functionality.

***Abstract*—In the paper a new grid (potentially linear, nonlinear and even semi-Markovian jump system) was presented. All transition and measurement functions were proposed. Moreover, the transition functions of two types were considered – dependent on one and many different state variables. Also 10 types of measurements were proposed for both nodal and branch cases. Based on the obtained results one can see, which measurement functions are "easy", and which are "hard" for state estimation task.**

I. Introduction

PARTICLE filter (PF) is potentially very good estimation method because is based on the optimal solution – Bayes filter. The biggest disadvantage of PFs is their need for computational power – number of calculations grows exponentially with a system variables number [1]. This is the reason why PF methods are usually used only for very small plants.

Some solutions to this problem are hybrid filters, e.g. Rao-Blackwellized PF (RBPF) [2]-[3], or Marginalized PF [4], in which state variables are divided into two groups – one group is estimated using PF method, and the second group – using Kalman Filter (KF) methods (linear, extended or unscented).

Another solution was proposed in [5] – all state variables are divided into groups; however, the disadvantage of this method is loss of information contained in measurements, which uses state variables from two or more groups.

Dispersed Particle Filter (DPF) was proposed by the authors in one of the previous works [6] – this method assumes that dependences between state variables and measurements are relatively sparse (transition and measurement models depend on relatively small number of different state variables). Unfortunately, previously used plants – the power systems – have number of state variables two times higher than number of nodes. Additionally, based on studies from [7], the reasonable number of particles should be about 4 to the power of plant variables number. This caused reduction of plant dimension and simultaneously increase the number of nodes is needed.

This work was not supported by any organization

For this reason the authors proposed a new grid for further research. In this network, one node is associated with one state variable – thanks to this, considerations on the network structure will be possible for systems with relatively small state vector length. Proposed grid is very general and one can model both linear and highly nonlinear models (for both transitions and measurements).

In the second section particle filter algorithm is described. In Section III the proposed grid is presented. Prepared simulations and obtained results are shown in the fourth section. The last section contains drawn conclusions.

II. Particle Filter

An object in state space can be written as

$$\begin{cases} \mathbf{x}^{(k+1)} = \mathbf{f}\left(\mathbf{x}^{(k)}, \mathbf{u}^{(k)}, k\right) + \mathbf{v}^{(k)} \\ \mathbf{z}^{(k)} = \mathbf{h}\left(\mathbf{x}^{(k)}, \mathbf{u}^{(k)}, k\right) + \mathbf{n}^{(k)} \end{cases}, \tag{1}$$

where $\mathbf{x}^{(k)}$ is a state vector, $\mathbf{u}^{(k)}$ is input vector, $\mathbf{z}^{(k)}$ is output vector, and vectors $\mathbf{v}^{(k)}$ and $\mathbf{n}^{(k)}$ are internal and measurement noises, respectively – all at k-th time step. The main task of particle filter is to estimate state vector based on the measurements and input signals.

The particle filters operation principle is based on the recursive Bayesian filtering [8]

$$\overbrace{p\left(\mathbf{x}^{(k)} \mid \mathbf{Z}^{(k)}\right)}^{\text{posterior}} = \frac{\overbrace{p\left(\mathbf{z}^{(k)} \mid \mathbf{x}^{(k)}\right)}^{\text{likelihood}} \cdot \overbrace{p\left(\mathbf{x}^{(k)} \mid \mathbf{Z}^{(k-1)}\right)}^{\text{prior}}}{\underbrace{p\left(\mathbf{z}^{(k)} \mid \mathbf{Z}^{(k-1)}\right)}_{\text{evidence}}}, \tag{2}$$

where $\mathbf{Z}^{(k)}$ is a set of measurement vectors from the first to k-th time step, $p(\mathbf{x}^{(k)}|\mathbf{Z}^{(k)})$ is a posterior Probability Density Function (PDF), $p(\mathbf{x}^{(k)}|\mathbf{Z}^{(k-1)})$ is a prior PDF, $p(\mathbf{z}^{(k)}|\mathbf{x}^{(k)})$ is a likelihood, and $p(\mathbf{z}^{(k)}|\mathbf{Z}^{(k-1)})$ is an evidence.

The key idea in PF is to implement the posterior PDF as a set of particles. The i-th particle is represented by a pair $\{\mathbf{x}^{i,(k)}, q^{i,(k)}\}$ – value (state vector) and weight. Higher weight increases probability that the value $\mathbf{x}^{i,(k)}$ is close to the real state vector. If the number of particles, N, is high enough, the information about the posterior PDF contained in particles set is the same as in continuous function.

The first particle filter was proposed in 1993 by Gordon, Salmond and Smith [9] and was called Bootstrap Filter. Operation principle of this PF is presented in Algorithm 1.

Algorithm 1 – Bootstrap Filter

1. Initialization. Draw N initial values $\mathbf{x}^{i,(0)}$ from initial PDF $p(\mathbf{x}^{(0)})$, set time step k=1.
2. Prediction. Draw N new particles from the transition model $\mathbf{x}^{i,(k)} \sim p(\mathbf{x}^{(k)}|\mathbf{x}^{i,(k-1)})$.
3. Update. Compute the particle weights based on the measurement model $q^{i,(k)} = p(\mathbf{z}^{(k)}|\mathbf{x}^{i,(k)})$.
4. Normalization. Normalize weights so that their sum be equal to 1.
5. Resampling. Draw N new particles using the posterior PDF obtained in previous steps (the chance that particle will be drawn is equal to normalized weight).
6. End of iteration. Calculate the estimated state vector, increase the time step k=k+1, go to the second step.

PF can be used for both non-Gaussian distributions and complex transition models. Example of such complex system model can be semi-Markovian jump system [10], in which the whole system model can switch itself (with some probability) into other structures (other equations), and also can go back to the previous "system states".

For more information about PFs, references [11]-[15] are recommended.

III. Proposed Network

The authors proposed grid, which on the one hand can be easily prepared, but on the other hand provides wide possibilities in creation of new plants. This is why there are many complex and maybe even illegible options presented below; however, the most common networks will be presented in a very simple way. Moreover, if one needs to add any dependence, which was not specified, still there is a possibility to present this on the scheme.

The proposed network is composed of nodes and lines (branches). Two different nodes can be connected by line. With every i-th node exactly one state variable x_i is associated with. Nodes can be represented in two ways – by circles or by squares. Transition function f_i depends on the shape of i-th node.

Filled figures are associated with measurements that when placed on lines (branches), refer to state variables that are associated to those lines (branch measurements), and when placed near the nodes (or on the nodal branches), refer to state variables in those specific nodes (nodal measurement).

It was assumed that networks are autonomous and thus any designation for input signal is not presented.

Expressions for different transition functions of the first type (circles) are presented below, and their connections with scheme designations are described in Table I.

TABLE I.
EXPLANATION OF DESIGNATIONS – NODES, PART 1, FOR TRANSITION FUNCTIONS WHICH ARE BASED ONLY ON I-TH STATE VARIABLE

Eqn.	Designation of node	Explanation
(3)		α and n should be given on the scheme. However, if one parameter is omitted, it is assumed that this value is equal to 1. Also both parameters can be omitted (α=1 and n=1).
(4)-(5)		When all three values are given, one must take into account that α should be written before β (above or on the left side of β). If any parameter (α, β or n) is not presented, it is assumed that it is equal to 1; however, one should keep in mind that β can be omitted only if α is also omitted. Designations for equation (5) are the same, but triple lines (through circles) should be used.
(6)		p_J should be written outside of the circle as J's sub- or super-script (also from the left). If p_J is omitted, it is assumed that p_J = 0.5.
-		To use another function (which must be explain in a text) a double circle should be used.

$$x_i^{(k+1)} = \begin{cases} \alpha\left(x_i^{(k)}\right)^n + v_i^{(k)} & n \in \mathcal{Z} \\ \alpha\left|x_i^{(k)}\right|^n + v_i^{(k)} & n \notin \mathcal{Z} \end{cases} \tag{3}$$

$$x_i^{(k+1)} = \begin{cases} \dfrac{\alpha\left(x_i^{(k)}\right)^n}{\beta + \left(x_i^{(k)}\right)^2} + v_i^{(k)} & n \in \mathcal{Z} \\ \dfrac{\alpha\left|x_i^{(k)}\right|^n}{\beta + \left(x_i^{(k)}\right)^2} + v_i^{(k)} & n \notin \mathcal{Z} \end{cases} \tag{4}$$

$$x_i^{(k+1)} = \begin{cases} \alpha\left(x_i^{(k)}\right)^n \cdot \cos(\beta k) + v_i^{(k)} & n \in \mathcal{Z} \\ \alpha\left|x_i^{(k)}\right|^n \cdot \cos(\beta k) + v_i^{(k)} & n \notin \mathcal{Z} \end{cases} \tag{5}$$

$$x_i^{(k+1)} = \begin{cases} f_i\left(x_i^{(k)}, \mathbf{u}^{(k)}, k\right) + v_i^{(k)} & \text{with prob. } p_J \\ -f_i\left(x_i^{(k)}, \mathbf{u}^{(k)}, k\right) + v_i^{(k)} & \text{with prob. } (1 - p_J) \end{cases} \tag{6}$$

For the second type of transition functions, connections between nodes matter. Branch between i-th and j-th nodes has a value $\mu_{i,j}$=$\mu_{j,i}$≠0, whereas if there is no connection between i-th and j-th nodes, branch value $\mu_{i,j}$=$\mu_{j,i}$=0. It is also assumed that $\mu_{i,i}$=1.

There are specified three types of lines, which differ in line functions $fl_{i,j}$ (where i is the number of node from which line function "was called"). These functions are written

below, and their connections with scheme designations are described in Table II.

$$fl_{i,j}^{(k)} = \begin{cases} \left(x_j^{(k)}\right)^m \cdot \mu_{i,j} & m \in \mathcal{Z} \\ \left|x_j^{(k)}\right|^m \cdot \mu_{i,j} & m \notin \mathcal{Z} \end{cases} \tag{7}$$

$$fl_{i,j}^{(k)} = \begin{cases} \sin\left(\left(x_j^{(k)}\right)^m - x_i^{(k)}\right) \cdot \mu_{i,j} & m \in \mathcal{Z} \\ \sin\left(\left|x_j^{(k)}\right|^m - x_i^{(k)}\right) \cdot \mu_{i,j} & m \notin \mathcal{Z} \end{cases} \tag{8}$$

$$fl_{i,j}^{(k)} = \ln\left(0.001 + \left|x_j^{(k)}\right|^m\right) \cdot \mu_{i,j} \tag{9}$$

Line functions $fl_{i,j}$ can be used in both, transition and measurement functions. Proposed types of transition functions, which use values of other state variables, are presented below, and their designations are described in Table III.

$$x_i^{(k+1)} = \begin{cases} \alpha\left(x_i^{(k)}\right)^n \cdot \sum_{\substack{j=1 \\ j\neq i}}^{N_x} fl_{i,j}^{(k)} + v_i^{(k)} & n \in \mathcal{Z} \\ \alpha\left|x_i^{(k)}\right|^n \cdot \sum_{\substack{j=1 \\ j\neq i}}^{N_x} fl_{i,j}^{(k)} + v_i^{(k)} & n \notin \mathcal{Z} \end{cases} \tag{10}$$

$$x_i^{(k+1)} = \alpha \cdot \sum_{\substack{j=1 \\ j\neq i}}^{N_x} \frac{fl_{i,j}^{(k)}}{\beta + \left|fl_{i,j}^{(k)}\right|^n} + v_i^{(k)} \tag{11}$$

$$x_i^{(k+1)} = \alpha\left(\cos\left(x_i^{(k)} \cdot \beta k^n\right) + \sum_{\substack{j=1 \\ j\neq i}}^{N_x} \cos\left(fl_{i,j}^{(k)} \cdot \beta k^n\right)\right) + v_i^{(k)} \tag{12}$$

$$x_i^{(k+1)} = \begin{cases} f_i\left(\mathbf{x}^{(k)}, \mathbf{u}^{(k)}, k\right) + v_i^{(k)} & \text{with prob. } p_J \\ -f_i\left(\mathbf{x}^{(k)}, \mathbf{u}^{(k)}, k\right) + v_i^{(k)} & \text{with prob.} \left(1 - p_J\right) \end{cases} \tag{13}$$

The type of internal noise one can describe in a text or mark on the scheme. PDF type with parameters should be connected with specific node by dashed line. Examples have been presented in Fig. 1.

Measurements are marked by filled figures on the scheme. Measurement designations on branches have different meaning than designations associated with nodes. Moreover, one should keep in mind that measurement location matters (the first index indicates near which node the measurement is located), because measurement functions generally are not symmetric. Possible nodal measurements in i-th node (P_i, Q_i, R_i, S_i, T_i) are described by equations (14)-(18), whereas possible branch measurements between i-th (at this node measurement is placed) and j-th nodes ($P_{i,j}$, $Q_{i,j}$, $R_{i,j}$, $S_{i,j}$, $T_{i,j}$) are described by equations (19)-(23). Designations of specific measurements are presented in Table IV. To use another measurement function one can simply use new filled figure on the scheme (function should be explained in text).

TABLE II.
EXPLANATION OF DESIGNATIONS – LINES

Eqn.	Line designation	Explanation
(7)-(9)		Values m and μ should be written on the scheme near to line center. Also information about branch type, in the form of diagonal lines (one for (7), two for (8) and three for (9)), should be presented there. If $\mu_{i,j}$=1, one can omit this value. If m=1 it also can be omitted. If branches in whole grid are only of first type, diagonal lines can be omitted.
-		For another line function (must be explain in text), double line should be used between nodes.

TABLE III.
EXPLANATION OF DESIGNATIONS – NODES, PART 2, FOR TRANSITION FUNCTIONS WHICH ARE BASED ALSO ON OTHER STATE VARIABLES

Eqn.	Designation of node	Explanation
(10)		n value should be written inside a square bracket. If α is omitted, it is assumed that α=1. If value n is omitted, it is assumed that n=1.
(11)-(12)		When all three values are given, one must take into account that α should be written before β (above or on the left side of β). If any parameter (α, β or n) is not presented, it is assumed that it is equal to 1; however, one should keep in mind that β can be omitted only if α is also omitted.
(13)		p_J should be written outside of the square as J's sub- or super-script (can be also from the left side). Omitted p_J means that p_J = 0.5.
-		To use another function (which must be explain in a text) double square should be used.

$$P_i^{(k)} = z_o^{(k)} = \begin{cases} \alpha \cdot \left(x_i^{(k)}\right)^m + n_o^{(k)} & m \in \mathcal{Z} \\ \alpha \cdot \left|x_i^{(k)}\right|^m + n_o^{(k)} & m \notin \mathcal{Z} \end{cases} \tag{14}$$

$$Q_i^{(k)} = z_o^{(k)} = \alpha \cdot \prod_{\substack{j=1 \\ \mu_{i,j}\neq 0}}^{N_x} x_j^{(k)} \cdot \mu_{i,j} + n_o^{(k)} \tag{15}$$

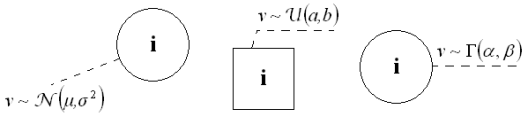

Fig. 1 Examples of internal noise designation

$$R_i^{(k)} = z_o^{(k)} = \alpha \cdot x_i^{(k)} \cdot \sum_{\substack{j=1 \\ j\neq i}}^{N_x} fl_{i,j}^{(k)} + n_o^{(k)} \tag{16}$$

$$S_i^{(k)} = z_o^{(k)} = \\ = \alpha \cdot \sum_{j=1}^{N_x} x_i^{(k)} x_j^{(k)} \mu_{i,j} \sin\left(x_i^{(k)} - x_j^{(k)} - \mu_{i,j}\right) + n_o^{(k)} \quad (17)$$

$$T_i^{(k)} = z_o^{(k)} = \alpha \cdot x_i^{(k)} \cdot \\ \cdot \sum_{\substack{j=1 \\ j \neq i}}^{N_x} x_j^{(k)} \mu_{i,j} \cos\left(\frac{x_i^{(k)} - x_j^{(k)}}{\ln\left(1.01 + \left|fl_{i,j}^{(k)}\right|\right)}\right) + n_o^{(k)} \quad (18)$$

$$P_{i,j}^{(k)} = z_o^{(k)} = \alpha \cdot \left(x_i^{(k)} - x_j^{(k)}\right) + n_o^{(k)} \quad (19)$$

$$Q_{i,j}^{(k)} = z_o^{(k)} = \alpha \cdot x_i^{(k)} \cdot x_j^{(k)} + n_o^{(k)} \quad (20)$$

$$R_{i,j}^{(k)} = z_o^{(k)} = \alpha \cdot \\ \cdot \left(x_i^{(k)} + x_j^{(k)} \cdot \sin\left(\left(x_i^{(k)} + x_j^{(k)}\right) \cdot fl_{i,j}^{(k)}\right)\right) + n_o^{(k)} \quad (21)$$

$$S_{i,j}^{(k)} = z_o^{(k)} = \alpha \cdot \\ \cdot \left(x_i^{(k)^2} - x_i^{(k)} x_j^{(k)} \mu_{i,j} \cos\left(x_i^{(k)} - x_j^{(k)} - \mu_{i,j}\right)\right) + n_o^{(k)} \quad (22)$$

$$T_{i,j}^{(k)} = z_o^{(k)} = \alpha \cdot \frac{\max\left\{x_i^{(k)} + x_j^{(k)}; x_i^{(k)} \cdot x_j^{(k)}\right\}}{0.01 + \left|\min\{A; B\}\right|} \cdot fl_{i,j}^{(k)} \\ A = \log_2\left(0.01 + \left|x_i^{(k)} x_j^{(k)}\right|\right); \; B = -0.1\left(x_i^{(k)} + x_j^{(k)}\right)^2 + 2 \quad (23)$$

The measurement noise should be marked in the same way as the internal noise – by description in text or using dashed line on the scheme. Examples of measurement noise designations are presented in Table IV.

IV. Simulation results

The simulations were performed for the networks presented in Fig. 2-4. Measurements were considered for 5 different cases – P, Q, R, S, and T. In each case all possible measurements of specific type were taken into account (10 branch measurements and 4 nodal measurements). However, one can see that differences between the second and third objects are only in line functions $fl_{i,j}$. hence only experiments for R and T cases were repeated for Ob403.

The average Root Mean Square Error was used to describe estimation quality and it can be written as

$$\text{aRMSE} = \frac{1}{N_x} \sum_{j=1}^{N_x} \text{RMSE}_j \,, \quad (24)$$

where N_x is the number of state variables, and

$$\text{RMSE}_j = \sqrt{\text{MSE}_j} = \sqrt{\frac{1}{M} \sum_{k=1}^{M} \left(x_j^{(k)} - x_j^{(k)+}\right)^2} \,, \quad (25)$$

where value with plus is the real value of state variable and M is the length of the simulation (set on the 1000 time steps in experiments).

All simulations were repeated 4000 times for Ob401, Q and T measurements, and 400 times for other cases. All results are presented in Fig. 5.

TABLE IV.
EXPLANATION OF DESIGNATIONS – MEASUREMENTS (BRANCH AND NODAL)

Eqn.	Measur. designation	Explanation
(14), (19)		Nodal measurements should be placed near the node or should be connected with node by the dashed line. The second case is needed if one want to add information about measurement noise or about measurement scaling. Branch measurements should be placed on the specific line. One should keep in mind that measurements are different at both ends of the branch, so the position of sign should be unambiguous. If one want to add information about measurement noise or its scale, also a dashed line should be used. Measurement designations can be marked in one orientation or if one wish – can be rotated; however, one should use one approach.

(18), (23)		

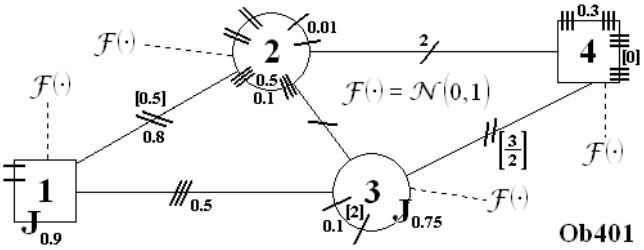

Fig. 2 Scheme of the object Ob401

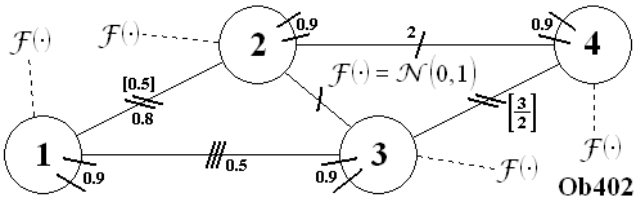

Fig. 3 Scheme of the object Ob402

V. Conclusions

Based on the obtained results one can say (by comparison results of the same cases for objects Ob401 and Ob402) that linearly changed state variables can be better tracked than ones changed nonlinearly. Moreover, the best estimation quality was obtained for linear object (linear transition model and linear measurement functions).

It is also visible (by comparison of results for R or T cases for all three objects) that complexity of measurements also impact on estimation quality (easier measurements provide better tracking).

The increase of aRMSE with higher number of particles for object Ob401 and cases Q and T is probably caused by higher chance that specific set of drawn values, which are

wrong, will match the measurements (index in one of dozens simulation had very high value). Simultaneously it is clearly visible that Q and T measurements are the hardest for estimation task. One can see also that for others measurement types even object with jump functions (Ob401) can be properly estimated.

It is also interesting that estimation quality for case Q in object Ob402 is rather weak for small number of particles *N*, but is very good for high particles number, whereas for case Q in object Ob401 the results are worst of all examined cases and objects. This is probably caused by jump functions in Ob401.

Proposed network will be widely used by the authors for further research.

***Abstract*—The information generated by a computer vision system capable of labelling a land surface as water, vegetation, soil or other type, can be used for mapping and decision making. For example, an unmanned aerial vehicle (UAV) can use it to find a suitable landing position or to cooperate with other robots to navigate across an unknown region. Previous works on terrain classification from RGB images taken onboard of UAVs shown that only static pixel-based features were tested with a considerable classification error. This paper proposes a robust and efficient computer vision algorithm capable of classifying the terrain from RGB images with improved accuracy. The algorithm complement the static image features with dynamic texture patterns produced by UAVs rotors downwash effect (visible at lower altitudes) and machine learning methods to classify the underlying terrain. The system is validated using videos acquired onboard of a UAV.**

***Keywords*—Image processing, Texture, Machine Learning, Terrain Classification, UAV**

I. Introduction

Nowadays, due to UAVs' higher availability and capabilities, there is a research trend to explore innovative applications of UAVs useful to the society. They are having a major impact on search and rescue missions, in logistics, in precision agriculture, among other applications. Key issues are to provide a safe and reliable operation and to perceptionate the surrounding area. This latter, within this paper, will be to identify the underlying terrain. Terrain classification is a crucial functionality for a wide range of autonomous vehicles [1]: either for ground vehicles to avoid water bodies, aerial vehicles to determine suitable landing areas, or surface vehicles to detect safe passageways. As further explained in section II, several approaches have been used for terrain classification. However, there is still margin for improving accuracy by extracting more complex image features. When at lower altitudes, UAV's rotors downwash effect create singular image texture patterns depending on the type of terrain, which can be used to differentiate them.

The main goal of this paper is to propose a computer vision algorithm that using RGB images captured by a camera onboard of a UAV is capable of classifying a terrain by analysing static image features (colour and texture) and rotors downwash effect on the underlying surface. There are several issues that must be addressed in order to achieve this goal, namely: Which terrains can be more accurately classified using the downwash effect? Which are the texture and motion patterns of each terrain (water movement for example)? Which static and dynamic image features can be extracted to classify the terrain? To address these challenges, new optimization procedures and techniques will be proposed in this paper, aiming the best possible performance.

This paper is structured with six sections starting with an introductory section and followed by a presentation of related works. In the experimental setup section the system background, namely the hardware and the terrain types, are described. On the Terrain Classification Method the system architecture, the static and dynamic texture features and the machine learning classifier will be presented. The article finishes with the experimental results and drawn conclusions.

II. Related Work

UAVs (Unmanned Aerial Vehicle) play an important role on the new generation of information technology and is predicted to have a major impact in the human life in the near future [2]. One of the areas is in computer vision, where it is possible to acquire, process, analyse and understand aerial images. Many researchers have proposed terrain classification systems based on features derived from colour information [3], texture patterns [4], [5], [6] and from additional sensors, as is the case of laser scan systems [7], [8], [9]. Although many of these algorithms are for terrestrial unmanned ground vehicles, currently there is a shift towards UAVs, where the visual features have wider importance.

One of the most recent works of terrain detection and classification is presented in [10]. The authors use the concept of optical flow to detect the water texture direction in images acquired by an RGB camera onboard of a UAV. From the directions of the textural features, the algorithm determines if the terrain, where the UAV is flying over, is water or non-water. One of the problems identified is that the UAV must be stable over the target while identifying the type of terrain, which, in the best case, takes four seconds to execute. Another reason that requires the UAV to be stand still during calculations is that the computer vision algorithm does not compensate the UAV movement. Thus, when the directions of the features are calculated, the results do not represent the reality.

A classification method using colour features was proposed in [3]. The proposed method converts a RGB image into an image entitled "normal RGB", where each pixel is divided by the square root of the three colour channels. Thus, each terrain will emphasize the colour that represents it (for example, green for vegetation). The proposed method was limited due to the fact that it varies significantly with illumination.

Laser scanners have proven to be important to distinguishing between land and water as presented in [7], [8] and [9].

However, in low water depths the laser sensor produces incorrect results, due to the fact that it captures reflections from the seabed and misclassifies it as non-water terrain. Therefore, this laser scan approach, by itself, reveals to be insufficient and requires additional equipment.

III. Experimental Setup

The dynamic of different terrains when exposed to wind provoke singular texture patterns that can be used in their identification. In this paper we study the importance of static image features, such as colour and texture, when compared with the dynamic features exhibited by the downwash effect, for terrain classification.

In this work three different terrain types (water, vegetation and sand), which can benefit from the downwash effect for their identification (Figure 1) were identified. It can be seen that the downwash effect produces: on water a circular dynamic texture; on vegetation a linear spread from inside outwards; and on sand it is almost stable or it moves outwards.

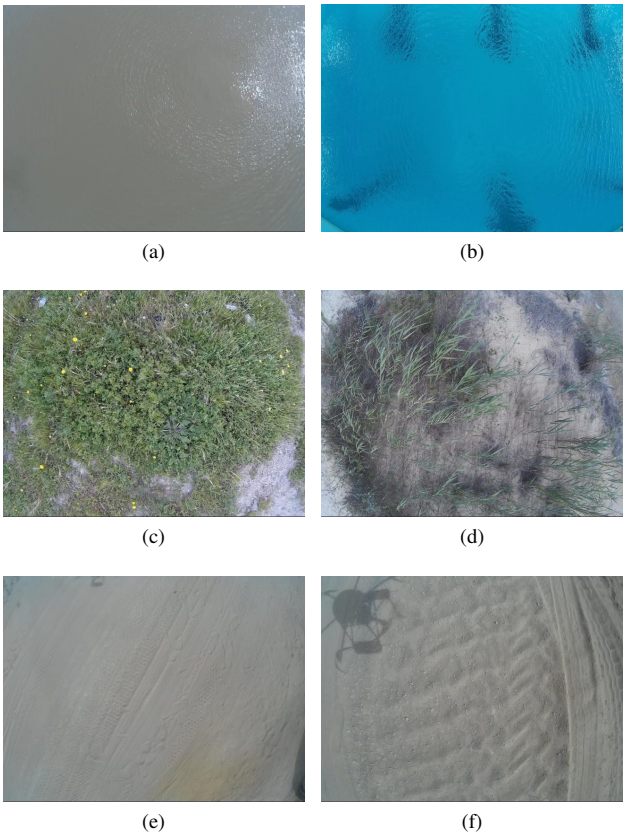

Fig. 1. Examples of terrain types: water (a)(b); vegetation (c)(d); and sand (e)(f).

IV. Terrain Classification Method

If different types of terrain behave differently when exposed to UAV rotors downwash effect, then it should be possible to obtain unique information for their identification. Based in this research hypothesis, it is possible to obtain some conclusions. When exposed to the downwash effect, water particles' movement is always greater than in vegetation and sand terrains. Also, regarding static texture, usually vegetation has a more rough texture than sand or water terrains; water only presents roughness when exposed to wind and downwash effect; and sand (fine grains) has a lower roughness. It can also be seen that sand depends on the patterns already in the terrain, showing usually a more irregular texture (figures 1.e and 1.f) when compared with water that shows a unique signature and regular texture when exposed to wind (figures 1.a and 1.b).

A. System Architecture

The proposed system architecture to classify the terrain using texture information is shown in Figure 2. As previously identified in sections I and IV, two texture features are proposed to classify the terrain, namely, static and dynamic textures. At this stage it were also assessed the features that can be computed in parallel, in order to speedup the system execution time.

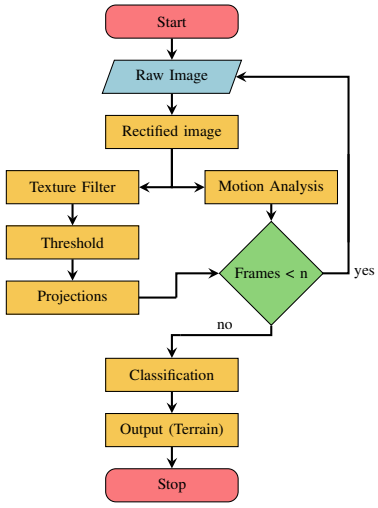

Fig. 2. Proposed system architecture.

Five main processes were identified in the architecture (figure 2), namely:

- **Rectified Image:** Performs lens geometrical corrections;
- **Texture Filter:** Extracts terrain's static textural information using Gabor filters;
- **Threshold:** A thresholding is applied to the static texture image to highlight the terrain roughness;
- **Projections:** Vertical and horizontal projections were applied to the thresholded image, extracting unique features that help differentiate the different types of terrains;
- **Motion Analysis:** Extracts information from dynamic textures. Optical flow and thresholding techniques are used to identify the moving parts;
- **Classification:** The extracted features are used as inputs of an automatic classified to identify the type of terrain. Machine learning techniques already proved to be efficient for terrain classification [11], [12], [13].

B. Static Textures

This section presents the proposed method for extracting terrain's static textures, based on the Gabor filter to be able to choose multiple texture directions. This filter is the impulse response formed by a multiplication of a sinusoidal signal with a Gaussian envelope function and can be computed using the following complex equation:

$$G(x,y,\lambda,\theta,\psi,\sigma,\gamma) = e^{\left(-\frac{x'^2+\gamma^2 y'^2}{2\sigma^2}\right)} e^{\left(i\left(2\pi\frac{x'}{\lambda}+\psi\right)\right)} \quad (1)$$

Its real and an imaginary components can be obtained by equations 2 and 3, respectively:

$$G(x,y,\lambda,\theta,\psi,\sigma,\gamma) = e^{\left(-\frac{x'^2+\gamma^2 y'^2}{2\sigma^2}\right)} \cos\left(2\pi\frac{x'}{\lambda}+\psi\right) \quad (2)$$

$$G(x,y,\lambda,\theta,\psi,\sigma,\gamma) = e^{\left(-\frac{x'^2+\gamma^2 y'^2}{2\sigma^2}\right)} \sin\left(2\pi\frac{x'}{\lambda}+\psi\right) \quad (3)$$

where:

$$x' = x\,\cos(\theta) + y\,\sin(\theta) \quad (4)$$

$$y' = -x\,\sin(\theta) + y\,\cos(\theta) \quad (5)$$

These equations (1, 2 and 3) require as input parameters:

- **x and y:** Filter coordinates, where x represents the columns and y the rows;
- **Lambda** (λ): Represents the sinusoid's wavelength;
- **Theta** (θ)**:** Defines the Gaussian envelope orientation;
- **Psi** (ψ)**:** Symbolizes the phase offset;
- **Sigma** (σ)**:** Describes the Gaussian envelope size;
- **Gamma** (γ)**:** Reflects the shape of the ellipse in the gabor filter space.

In this work we used only the real component of the Gabor function (equation 2). After obtaining the multiplication of a Gaussian with a sinusoidal function, i.e. the kernel of the filter, it will be convolved with the original image (equation 6). The result of the Gabor filter applied over a water surface is presented in Figure 3.

$$f[x,y] * g[x,y] = \sum_{-n1}^{n1}\sum_{-n2}^{n2} f[n1,n2]\cdot g[x-n1,y-n2] \quad (6)$$

As can be seen in figure 3, it is possible to obtain the texture of a water-type terrain when it is affected by the downwash effect of the UAV. From the binarized image, a vertical projection was made to see the singular features of this terrain type (Figure 4).

From the observed vertical projection of water type terrain (figure 4) it can be seen that it produces an undulatory effect with a local minimum in the centre of the downwash. This effect in water type terrains is due to the lower roughness

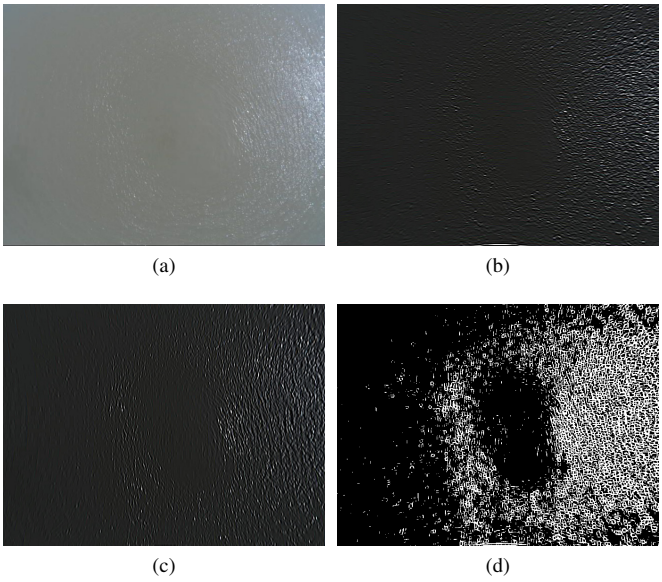

Fig. 3. Example of a static texture extraction: a) Raw image; b) c) Convolution with the Gabor filter θ-0 degrees (b) and θ-90 degrees (c); d) Sum of images b) and c) after thresholding.

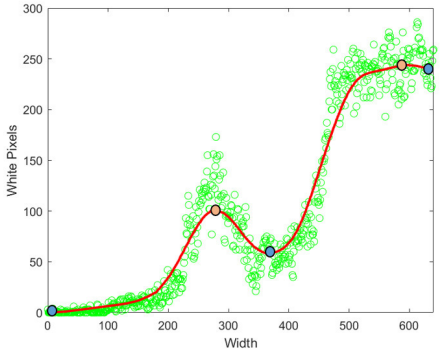

Fig. 4. Vertical projection of the example in Figure 3.d.

in the centre of the downwash. However, due to the water movement, around the centre a higher roughness is observed (white pixels in the binarized image in figure 3.d). The next step was to translate this observed feature into a computational model.

By calculating the local maxima and minima of the vertical projection in figure 3.d, it is possible to calculate a line (red line in Figure 4) that most closely approximates these points. A polynomial regression was used.

After obtaining this smoothed projection, new local minima and maxima are calculated and used to obtain two features: Area measured between the local minimum and its respective two local maxima; and Integral between the local minimum and its two respective local maxima. The first has the advantage of being relative to minima and maxima values, while the integral gives an absolute value and will vary for lower and higher roughness.

C. Dynamic Textures

This section presents the proposed method for extracting dynamic terrain textures.

As mentioned in section IV, water-type terrain only exhibit dynamic texture when exposed to the downwash effect. However, in spite having a dynamic texture, when analysing the optical flow it is never stronger than the dynamic observed for sand and vegetation. As referred in section III, the optical flow method can calculate the distance travelled by block matching features in a given frame sequence. In this paper, the Farneback algorithm [14] was used to detect the movement of these features. One of the advantages to using the Farneback algorithm is the direct flow, F_d , return of features between two frames.

With the obtained flow is then used to calculate the distance travelled (trajectory) by each feature in a sequence of frames:

$$Travel_{distance} = \sum_{i=2}^{n} \sqrt{A_x(i) + B_y(i)} \tag{7}$$

where:

$$A_x(i) = \left[x_1 - x_{i-1} + F_{dx}\right]^2 \tag{8}$$

$$B_y(i) = \left[y_1 - y_{i-1} + F_{dy}\right]^2 \tag{9}$$

and x_i and y_i are the positions in x and y in the most recent frame (n), x_1 and y_1 are the initial positions ($n = 1$) and F_{dx} and F_{dy} are the flow displacements between frames n and $n-1$. We used normalized x and y coordinates for the calculations.

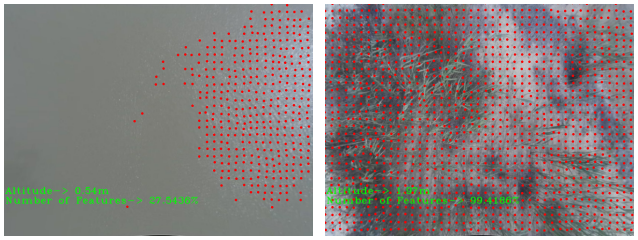
To eliminate features that did not move or were almost static in a sequence of frames, we filtered those not exceeding a pre-defined empiric threshold (1%). Then, knowing the maximum number of features, we calculate the percentage of dynamic features that appear in the image (equation 10). An example is shown in Figure 5.

$$Dynamic_{feature} = \frac{filtered\ features}{Total\ features} \cdot 100\% \tag{10}$$

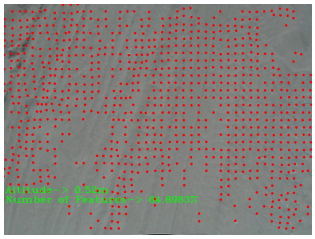
D. Classification

To increase certainty and automate the classification of the type of terrain, a machine learning technique was used, namely a feed-forward neural network (NN). The architecture of the designed neural network, was composed by two layers, a hidden layer with 10 neurons and an output layer with 3 neurons (water, vegetation and sand). A sigmoidal function was used as activation function and the final classification was derived from the output neuron with highest activation value.

The training dataset was composed by 251 samples, from which 70% were for training, 15% for testing and 15% for validation. After training the NN, it was obtained 92.9% accuracy with the training set and 93.8% with the test dataset.



(a) (b)



(c)

Fig. 5. Dynamic textures detection by Farneback algorithm and distance travelled calculation. a) water; c) vegetation and d) sand.

V. Experimental Results

To validate the proposed static and dynamic texture features for terrain classification, a total 251 frames from several types of terrains were used to validate the proposed system. From these 90 frames were for water, 88 frames for vegetation and 73 frames for sand.

Regarding the static texture feature the area and integral were calculated and displayed in Figure 6. It is possible to observe a clear separation between water, vegetation and sand, even with some outliers. In water type terrain, the three clusters that can be noticed for the integral feature, were mainly due to different water environments (lake and pool).

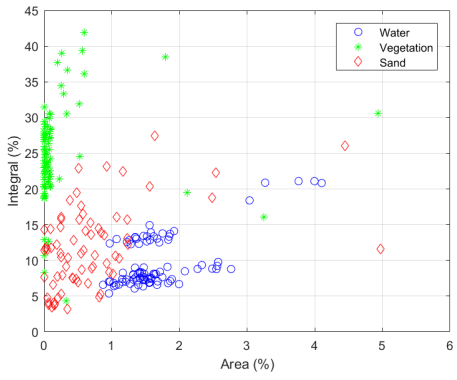


Fig. 6. Static Texture - Relation in area with respect to the integral of minimum and maxima locals.

To validate the dynamic texture feature it was calculated in a three frame period ($n = 3$) and plotted against the area feature from the static texture. This feature shows the same discriminant level to separate the different terrains. From Figure 7, it can be seen that water type terrain obtained a lower dynamic texture value ($< 45\%$), which can due to a higher

concentration of these dynamic features in the downwash centre and outside hasn't exceed the threshold. Sand and vegetation shown a more uniform pattern, obtaining a higher number of features. On average, sand presents a percentage between 55% to 90%. Finally, vegetation with a percentage of features between 90% and 100%, is the terrain with highest dynamic texture, i.e., moving features.

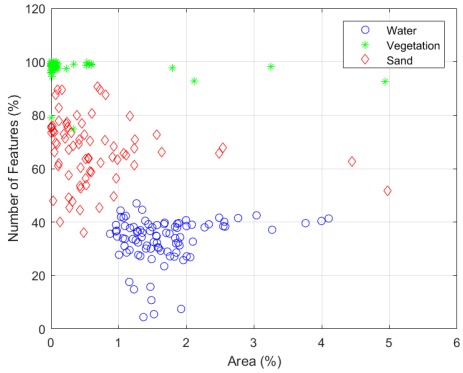

Fig. 7. Dynamic Texture - Relation in number of features with respect to the integral of minimum and maxima locals.

Finally, these features were extracted from the figures 1.a-f and shown to the neural network classifier, which outputted the automated terrain classification. The extracted features and the classification result is shown in Table I. As expected the proposed features and classification method, shown good results by classifying correctly all the six examples, reinforcing the idea that a combination of static and dynamic texture can be used to automatically extract terrain type from RGB images.

TABLE I. EXPERIMENTAL RESULTS

Figure	Static Texture		Dynamic Texture	Classification
	Area (%)	Integral (%)	Number of Features (%)	
1	1.44	8.32	32.88	water
2	1.55	7.59	36.70	water
3	0.01	27.42	98.32	vegetation
4	0.05	23.71	98.69	vegetation
5	0.24	14.67	63.74	sand
6	0.07	4.07	59.30	sand

VI. CONCLUSIONS

The main objective of this paper was to design a computer vision system capable of extracting static and dynamic image features, such as optical flow and texture features, to identify the type of terrain with improved accuracy by taking advantage of the the UAV's rotors downwash pattern effect. For this, it was necessary to conduct a research into detection methods already implemented and of interest to this work.

Texture features, such as Gabor filtering (static textures) and optical flow (dynamic textures), were studied to improve terrain classification aiming the best possible performance.

We emphasize that by implementing the static textures filter, vegetation-like terrains were found to have a higher texture than sand and water type terrains. On the other hand, water-type terrain, also presents a singular characteristic due to the downwash effect provoked by the UAV, which can be decisive to different it from other terrain types.

ACKNOWLEDGMENT

This work was partially funded by FCT Strategic Program UID/EEA/00066/203 of the Center of Technologies and System (CTS) of UNINOVA – Institute for the Development of new Technologies. In last, this work was not possible without the support and commitment of several fellow colleagues and friends, namely: Ricardo Mendonça, Francisco Marques, André Lourenço, Eduardo Pinto and José Barata.

***Abstract*—In recent years, research has been conducted aimed at finding alternative asymmetric systems other than traditional systems such as RSA (Rivest–Shamir–Adleman algorithm) and ECC (Elliptic-curve cryptography). One of the most promising is code-based cryptosystems since their security is based on well-known NP-hard problems. Especially, the most interesting cryptosystem is system proposed by Misoczki et al. based on QC-MDPC codes which use the modified BitFlip algorithm as the decoding algorithm. This work presents a comparison of different variants of MDPC decoding algorithms and their impact on the cryptosystem. We present a complete analysis of modification of this algorithm and new results of the likelihood of correct word decoding for security systems which ensure security level 2^{128} and 2^{256}.**

I. Introduction

ASYMMETRIC cryptography is one of the most important cryptographic mechanism currently in use. It provides a number of options such as secure cryptographic keys exchanging over a public channel, digital signature and secure messaging. Most of those systems are based on number theory's problems, such as factorization of a large number (RSA) and the discrete logarithms in an elliptic curve. an important limitation of the indicated security systems is the fact that using Shor's algorithm [10] can solve these problems on the quantum computer so it means that they are not safe in the long-term security.

If a large-scale quantum computer is built for, that algorithm will become one of the most useful tools in cryptoanalysis, especially in public key cryptography. Nowadays there is a lot of interest in alternative systems that are not based on numerical problems. From that reason, NIST has initiated a process to solicit, evaluate, and standardize one or more quantum-resistant public-key cryptographic algorithms.

Promising alternative is code-based crypto algorithms those security is based on the General Decoding Problem were extensively studied for their usage in small and embedded systems. The first cryptosystems relying on coding theory was proposed by J.R. McEliece in 1978 [8]. It uses binary Goppa codes as a basis for the construction. This system presents many advantages: it is very fast for both encryption and decryption and the best-known attacks are exponential in the length of the code. Although it has proved resistance against all known attacks, it has one big flaw: the size of the public key. The public key size for the original parameters that provide security 2^{80} proposed by McEliece has 67072 bytes, against 256 bytes of a 1024-bit modulus instance of RSA.

In order to reduce key sizes, several alternative approaches for code-based cryptography were proposed. One idea to shorten key is to use codes with particular structures.Unfortunately, most of the modifications of the code structure result in the cryptosystem sensitivity to the so-called structural attacks. Such attacks aim to exploit the hidden structure, in order to recover the private key.

Another idea is to replace the binary Goppa codes with another linear code which generates matrix rolled representation and has no vulnerability to structural attacks. One of the promising algorithms was proposed by Misoczki et al. [9] They proposed to modify the McEliece cryptosystem by using a quasi-cyclic Moderate Parity Check (QC-MDPC). They achieve a very fast cryptosystem with a relatively small public key size (about 4801 b with secure level 2^{80}), lightweight implementation and still preserving the security properties of the cryptosystem. Unfortunately, in 2016 a very powerful attack was shown. The attack can recover a secret key for a system with security 2^{80} using a chosen ciphertext attack [4]. It means that this system is impractical for the encryption scheme, but still can be used as secure Key Encapsulation Mechanism.

The next section will present the motivation for the research. In the third section basic definitions and necessary statements will be presented. In the 4th section, the McEliece algorithm based on the QC-MDPC codes will be presented and in the fifth section, the decoding algorithms will be presented. Section 6 contains a description of the assumptions during the research. Section 7 contains the obtained results and their analysis. The 8th section contains a summary of completed research.

II. Motivation

The McEliece system based on QC-MDPC codes is a very interesting contribution because it has a very good performance on embedded systems and limited resources. MDPC code extends the concept a low-density parity-check (LDPC) codes [3] by using the parity check matrix with moderated sparse. Unfortunately, this leads to a significantly degraded error correction performance. However, in cryptography, We

are not interested in correcting a large number of errors, but only the number ensuring an adequate level of security.

The probabilistic decoding algorithm used in the cryptosystem is known as the modified bit flipping algorithm. During the last few years this probabilistic aspect was very intensively examined by community [1], [7]. The results of this research increased error-correcting capability for the tested systems for security 2^{80}. The quality of the solution was measured by the decoding failure rate and the number of iterations required to decrypt the message.

In the submission for the NIST standardization project, an IND-CPA[1] secure ephemeral Key Encapsulation Mechanism (KEM) based on the Quasi-Cyclic Moderate Density Parity-Check (QC-MDPC) McEliece encryption knows as QC-MDPC KEM was presented. In this work, we investigated several ways to efficiently decode erroneous MDPC codewords, especially for such codes as were proposed for the McEliece cryptosystem with security 2^{128} and 2^{256}. Additionally, we have proposed and evaluated a new way of choosing the parameter b for systems with security 2^{256}. This optimization leads to reduced decoding failure probability and fewer decoding iterations.

III. Preliminaries

In order to unify the notations and definitions, we will present a few definitions of the necessary concepts. All considerations will be conducted on finite field $\mathcal{F}_2$

The **Hamming weight** (or simply weight) of vector $x \in \mathcal{F}_2^n$ is the number of nonzero components denoted as $wt(x)$

A **binary** (n, r)**-linear code** $\mathcal{C}$ of length n and dimension r is an r-dimensional vector subspace of $\mathcal{F}_2^n$. It is spanned by the rows of a matrix $\mathbf{G} \in \mathcal{F}_2^{r\times n}$, called a generator matrix of $\mathcal{C}$. Also, it is the kernel of a matrix $\mathbf{H} \in \mathcal{F}_2^{(n-r)\times n}$ called a parity-check matrix of $\mathcal{C}$. The codeword $c \in \mathcal{C}^n$ of a vector $m \in \mathcal{F}_2^r$ is $c = mG$. The syndrome $s \in \mathcal{F}_2^{n-r}$ of a vector $\epsilon \in \mathcal{F}_2^n$ is $s = \mathbf{H}e^T$

An (n, r)-linear code is a **quasi-cyclic code** (QC) if there is some integer n_0 such that every cyclic shift of a codeword by n_0 places is again a codeword. Additionally when $n = n_0 p$ for some integer p, it is possible to have generator and parity check matrices composed by $p \times p$ circulant blocks which are completely described by their first row (or column).

An (n, r, w)-LDPC or MDPC code is a linear code of length n, dimension r which admits a parity-check matrix of constant row weight w. LDPC and MDPC codes differ in the magnitude of the row weight w. We assume for MDPC codes row weight whose scale is $O(\sqrt{n \log n})$. On the other hand, the constant row weight is usually less than 10 for LDPC.

A. MDPC and QC-MDPC code

An random (n, r, w)-MDPC code is easily generated by selecting a random parity-check matrix $\mathbf{H} \in \mathcal{F}_2^{r\times n}$ of row weight w. We only have to check that the rightmost $r \times r$ block is full rank. If not, wecan swap a few columns to get a full rank matrix. The general definition of MDPC codes can be found in [9]. For the purpose of this article, construction using $n_0 = 2$ will be discussed.

The (n, r, w)–QC-MDPC codes where $n = 2p$ and $r = p$. So then the parity check matrix has the form

$$H = [H_0|H_1]$$

where H_i is a $r \times r$ circulant block. To define the parity-check matrix $\mathbf{H}$ we pick up a random first row of weight w and the other $r - 1$ rows are obtained from $r - 1$ quasi-cyclic shift of this first row.

A generator matrix $\mathbf{G}$ in the row reduced echelon form can be easily derived from the H_i's blocks. Assuming that the block H_1 is non-singular (which particularly implies row h_i of matrix H_1 has $wt(h_i)$ odd) we construct a generator-matrix

$$G = \left[\quad I \quad \middle| \left(H_1^{-1} \cdot H_0\right)^T \right]$$

IV. QC-MDPC McEliece variant

In order to define a McEliece variant based on t-error correcting (n, r, w)–QC-MDPC code we need to fix some MDPC decoding algorithm equipped with the knowledge of $\mathbf{H}$ (denoted as Ψ_H). Encryption, decryption and key generation for the QC-MDPC McEliece variant cryptosystem are defined as follows.

Key Generation. The key Generation procedure consists of two steps. First we generate a parity-check matrix $\mathbf{H} \in \mathcal{F}_2^{r\times n}$ of a t-error-correcting(r, r, w)–QC-MDPC code by choosing the first row of the parity-check matrix. The second step is to generate the corresponding generator matrix $\mathbf{G} \in \mathcal{F}_2^{r\times n}$ in the row reduced echelon form.

The public-key of this system is the tuple $(\mathbf{G}, t)$ and the private-key is matrix $\mathbf{H}$.

Encryption. In order to encrypt message $m \in \mathcal{F}_2^r$ we need to generate random vector $\epsilon \in \mathcal{F}_2^n$ of $wt(\epsilon) \leq t$ and compute

$$x \leftarrow m\mathbf{G} + \epsilon$$

where $x \in \mathcal{F}_2^n$ is a ciphertext.

Decryption. To decrypt $x \in \mathcal{F}_2^n$ into $m \in \mathcal{F}_2^r$ we compute

$$m\mathbf{G} \leftarrow \Psi_H(x)$$

If the generated matrix $\mathbf{G}$ is in the row reduced echelon form, we extract the message m from the first r position of $m\mathbf{G}$.

A. Security and Parameter Selection

Theoretical security of the QC-MDPC McElice cryptosystem has been presented [9]. In particular, an analysis of the safety and impact a quasi-cyclic structure on the security was presented. Recently, new attacks on system using those codes have been proposed. The most important is very powerful attack using a quasi-cyclic form of the parity check matrix [4]. The attack leverages the fact that there is some probability, termed the Decoding Failure Rate (DFR), that the decoding may fail to compute the errors.

Parameters for the examined systems are based on analyzes carried out in the work [11]. The suggested parameters are presented in Table I. The tests have been carried out using these values.

[1]Indistinguishability under chosen-plaintext attack

Table I
SUGGESTED PARAMETER SETS FOR CLASSIC SECURITY AND QUANTUM SECURITY [11]

System	Classical security	Quantum Security	n	r	w	t	Public Key size
McEliece	80	58	9602	4801	90	84	4801
McEliece	128	86	19714	9857	142	134	9857
McEliece	256	154	65542	32771	274	264	32771

V. DECODING ALGORITHMS

Decoding in the McEliece cryptosystem is a more complex operation than encryption. For lightweight embedded systems, the best solution seems to be the variant of the Gallager's bit flipping algorithm [3], dedicated to the LDPC code. Positive aspects of this solution are its simplicity and lack of floating-point arithmetic. On the other hand, the disadvantage of this solution is that we find the codeword with some probability determined by threshold b, which will be later discussed.

The algorithm works as follows. At each iteration, the number of unsatisfied parity-check equations associated to each bit of the message is computed. Each bit associated with more than b unsatisfied equations is flipped and the syndrome is recomputed. This process is repeated until either the syndrome becomes zero or after a maximum number of iteration is reached. We name this algorithm Algorithm 1.

The algorithm has complexity $O(nwI)$, where I stands for the average number of iterations. The most important difference from the algorithm proposed by Gallager is how threshold b is determined. The first proposition was to precompute thresholds for each iteration i. The threshold is set as the maximum number of unsatisfied parity-check equations $b = max(\sigma_i)$. In [9] the authors suggest to use $b = max(\sigma_i) - \delta$, for some small δ (suggested in [9] is $\delta \approx 5$). In [7] the authors propose incrementing the precomputed thresholds by $\Delta = 1$ and in the case of a decoding failure increase it to $\Delta = \Delta + 1$. Decoding is restarted with the adapted Δ until reaching a predefined $\Delta_{max} = 5$. The survey of this optimalization is included in Table II

Algorithm 2 Modified Gallager's bit flipping algorithm

Input: $x \in \mathrm{F}_2^n$
Require: $H \in M_r^n, r_{max} \in \mathcal{Z}_+$
Output: $m \in C$ lub $error$
    $s \leftarrow xH^T$
2: **for** $r \in \{0, \ldots, r_{max-1}\}$ **do**
        for $i \in \{0, \ldots, n-1\}$ **do**
4: $\sigma_i \leftarrow \langle s, h_i \rangle \in Z$ $\star$
            if $\sigma_i \geq b$ **then**
6: $x_i \leftarrow x_i \oplus 1$ $\star\star$
                $s = s \oplus h_i$
8: **end if**
        end for
10: **if** $s = 0^r$ **then**
            return x
12: **end if**
    end for
14: **return** $error$

$\star$ $\langle \cdot, \cdot \rangle$ – means scalar product of two vectors, h_i – means i-th column of matrix H
$\star\star$ x_i – means i-th position in vector x

A. Effective implementation

Code-based systems allow lightweight and effective implementations in devices with limited hardware resources and all operations are much less complex when compared to the other post-quantum systems.

Encryption involved simple operations such as vector-matrix multiplication followed by an addition.

Decoding is a more complex operation, but it is possible to reduce the cost of this operation by some improvements. In [7] they propose to improve the syndrome computation. They observe that if i-the bit of ciphertext is flipped, the new syndrome is equal to the old syndrome accumulated with row h_i of the parity check matrix. The authors suggest updating the syndrome directed after flipped i-th bit. This modified algorithm is presented as algorithm 2.

Key generation is a very simple operation, as it mainly uses a pseudorandom generator. In this paper, we do not investigate selecting pseudorandom generators appropriate for the code-based systems. Some research focused on software implementations in this area is presented in [2].

VI. EXPERIMENTAL SETUP

In this work we focus on the parameter selection of decoding algorithms for the proposed McEliece systems based on QC-MDPC codes and corresponding to other security levels according to the Table II a total 10000 random decoding trials were evaluated on a computer equipped with an Intel Core i7 2670QM running at 2.20 GHz.

The research was conducted to investigate the impact of choosing the parameter value of the Decoding Failure Rate (DFR) and to examine the number of rounds needed for correct decryption of the ciphertext. The generation of plaintext and error pattern was based on a uniform distribution.

As part of the study, particular attention was paid to decoding algorithms that use the maximum value of the coefficient $sigma_i$ to calculate the b parameter. In this work the results for the following algorithms will be presented: Decoder:

Decoder A Algorithm 1, threshold b value chose using Misoczki method,

Decoder B Algorithm 2, threshold b value chose using Misoczki method,

Decoder C Algorithm 2 with method choosing threshold b proposed in this work with increment δ by two (starting from 5 to 9) every two iterations,

Table II
PROPOSED METHOD OF CHOOSING THRESHOLD b

	Proposed by	Year	Method	Comments
1	Galager [3]	1962	$b_i - const, i \in \{1, \ldots, r\}$	$b_i \in < 28, 26, 24, 22, 20 >$
2	Huffman and Pless [6]	2010	$b = \#max$	$\#max$ means the maximal value σ_i
3	Misoczki [9]	2013	$b = \#max - \delta$	Decrement δ from 5 to 0 for every incorrect decoding
4	Heyse [5]	2013	$b = b_i + \delta$	Decrement δ from 5 to 0 for every incorrect decoding
5	This paper	2018	$b = \#max - \delta$	Increment δ every two iterations by two starting from 5 to 9
6	This paper	2018	$b = \#max - \delta$	similarly to the Misoczki proposal, only the starting point is different for each level of security, starting from 5 to 7 respectively

Decoder D Algorithm 2 with method choosing threshold b proposed in this work similar to the Misoczki proposal, only the starting point is different for each level of security, starting from 5 to 7 respectively.

The method proposed by Huffman and Pless is a special case of the method proposed by Misoczki et al. and, therefore, it will not be considered in the study. [7]

VII. RESULTS

In the beginning, we focused on the analysis of the average distribution of σ_i coefficients depending on the chosen security level. The graph for these values is presented in Figure 1. The average distribution of the parameter σ_i represents the first distribution before any coding algorithm is used. As can be seen, the values of the parameter σ_i for systems with security 2^{80} and 2^{128} are similar to each other while for the 2^{256} security system, the average values σ_i are much higher and more intense.

These are the first symptoms that the decoding parameter δ for the safest system will need to be modified. An interesting relationship is that if we take the average distribution for σ_i for the files corresponding to the word correctly decoded, we can say that it is different depending on the choice of the decoding algorithm. an example of a distribution for the system with security level 2^{128} is shown in Figure 2. The given property can be used to distinguish, which decoding algorithm was used.

The Decode Failure Rates for the tested algorithms are listed in Table III for all levels of security considered in the table I.

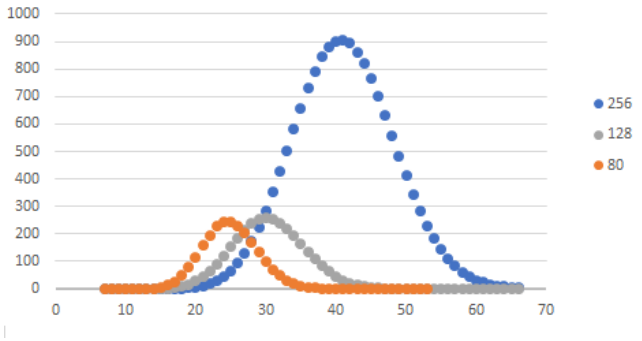

Figure 1. The average distribution of σ_i coefficients depending on the chosen security level.

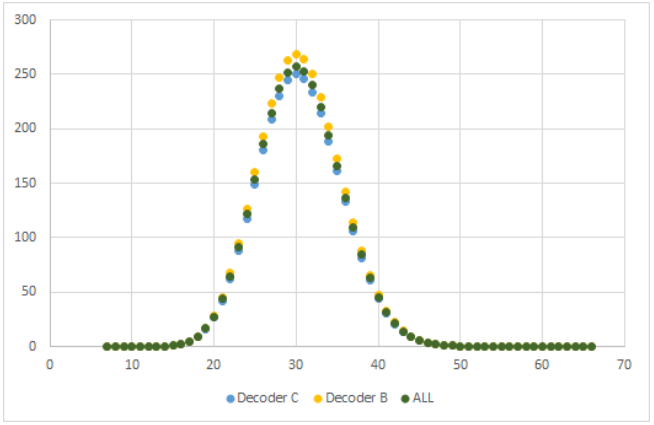

Figure 2. The average distribution of σ_i coefficients depending on the chosen decoding algorithm.

Analysing the results obtained for the Decoder A, which was proposed in the original work, it can be seen that for higher security levels it is not useful. Especially for the level 256, wherein any of the examined cases, the message was properly decoded.

Comparing the two decoders from literature (Decoder a and Decoder B), in Decoder B provides much better decoding failure rate for higher security. However, it still has too high DFR to be practically used. Our proposition to change the δ value for higher security level has a very strong impact on the decoding failure rate. In addition, our solution led to a smaller average number of decoding iterations, respectively 13% and 26% less.

Comparing decoders B, C, D we can see that the decoding failure rate and the number of decoding iterations are not strongly correlated. The improvement of the DFR level does not always result in an improvement in the number of decoding iterations. If we properly manipulate the parameters of decoding algorithm, we can get properties adapted to the specific application.

Additionally, as part of the study, the decoding failure rate was analyzed depending on the distribution of words with the desired Hamming weight. The test assumes that the codewords have the Hamming weight equal to $r/2$. It was noted that the DFR, as well as the number of rounds, increased slightly.

Table III
EVALUATION OF THE PERFORMANCE AND ERROR CORRECTION CAPABILITY OF THE TESTED ALGORITHMS. NOTE, A DFR OF 0 MEANS THAT NO DECODING ERROR OCCURRED DURING OUR EVALUATIONS BUT THE DECODERS ARE STILL PROBABILISTIC.

Name	80		128		256	
	DFR	Round Number	DFR	Round Number	DFR	Round Number
Decoder A	0.00000*	6.30000	0.21400	9.65600	1.00000	–
Decoder B	0.00000*	3.02850	0.00499	6.31087	0.16400	8.69617
Decoder C	0.01600	3.98831	0.07304	5.45662	0,00300	6,72700
Decoder D	0,00000*	3.02850	0.00440	5.54209	0,00000*	6.87500

VIII. CONCLUSIONS

In this work, we examined various variants of the decoding algorithm depending on the choice of the threshold. Additionally, we presented the method of selecting the threshold for codes used in high-security levels systems.

Additionally, as part of the work, an analysis of the possibility of improving the bit-flipping algorithm in applications to MDPC codes was presented.

An interesting fact is that if we use algorithms with a relatively high DFR coefficient, we can distinguish these algorithms based on the analysis of histograms discussed in Section VII. However, it should be noted that when using low-DFR decoding algorithms, the corollary analysis does not apply.

In the light of the achieved results, it can be concluded that the modified Bit Flipping algorithm can be successfully applied to various types of key encapsulation mechanism based on QC-MDPC codes. Especially, for the QC-MDPC-KEM algorithm reported to a process to solicit, evaluate, and standardize one or more quantum-resistant public-key cryptographic algorithms organized by NIST.

In further work I will focus on compare and analysis of other algorithms for decoding QC-MDPC codes, in particular the "One-round Bit Flipping" algorithm and their use in the KEM QC-MDPC system.
