Our analysis was focused on two groups of projects in the film category: the documentary film vs non-documentary projects (for example: music video, fiction film). Tab. II presents the general overview of the documentary projects compared to the non-documentary projects on both Polish platforms. Average documentary film projects received funding of over 14 thousand złotych on the polakpotrafi platform, and nearly 16 thousand złotych on the wspieramkulure platform. The average documentary film project gathered the about 130 supporters. The statistics indicate a high level of diversification of projects, and a higher level of support for the documentary film projects compared to other film projects.

In order to identify the clusters for analyzed projects listed on polakpotrafi.pl, we used the following variables in the K-Means analysis:

a. The type of film project: documentary or non-documentary;

b. The level of overfunding the project received. The projects vary on the level to which the actual funding exceeded the financial threshold. We categorized the film projects into three categories based on the ratio 'the actual

TABLE I.
THE DESCRIPTIVE STATISTICS OF ANALYZED PROJECTS - KICKSTARTER.COM

	19 successful projects from the 100 projects taken from 'end day' search				**Top 10 documentary projects from the search 'most funded'**			
	Average	**Minimum**	**Max**	**Standard deviation**	**Average**	**Minimum**	**Max**	**Standard deviation**
Actual funding	$16 196.21	$555	$16 3517	$37 885	$476 224	$239 020	$1 126 036	$303 684
Financial goal (financial threshold)	$12 683.89	$250	$14 3436	$33 206.85	$303 543	$60 000	$650 000	$210 368
Ratio: actual funding/financial goal	1.52	1.04	2.6	0.52	2.02	1.10	5.4	1.3
Number of backers	164	14	1 685	384	7 074	2 621	16 850	4 169
Funding per a backer	$89.36	$18.28	$296	$58.94	$72.59	$28.33	$129.61	$31.68
Number of new backers	122	2	1 455	327.78	3 669	1 254	6 853	1 804.63
Percentage of new backers	66%	10%	90%	18%	57%	29%	87%	21%

Note: the currency of projects varied – there were British pounds, Australian dollars and American dollars. The data in the table is based on calculation of all the projects' funding in American dollars

funding/aimed financial goal for project'. Therefore, we identified three groups of projects: 'just reach' – ratio 100-119%, 'medium overfunding' – ratio 120-149%; 'high overfunding' – 150-199%, and 'exceptional' – ratio above 200%;

c. The numbers of sponsors – the project with 'low numbers of sponsors': 1 to 49; 'medium number of sponsors' – from 50 to 99 supporters; 'high numbers of sponsors' – from 100-199 supporters; 'very high numbers of sponsors' – above 200 supporters.

The K-Means analysis indicated six clusters for projects (Tab. III): three clusters for documentary films and three clusters for non-documentary projects. The three clusters of documentary projects are as follows:

- The largest cluster is the group of documentary films which 'just reach' the financial goal with few or relatively few supporters;
- The second cluster of documentary films is the group of projects which 'just reach' the financial goal, but these projects managed to engage high numbers of supporters;
- The third cluster is the group of documentary films which exceeded the level of financing on a medium level and attracted high numbers of supporters;

IV. Polish filmmakers' views on crowdfunding

A. The methodology of conducting the survey

In the next phase of research, we asked professionals – filmmakers - about their attitude to crowdfunding. A group of 37 professionals (20 women, 17 men) - producers and the students of film production - took part in the survey which aimed to gather information about the barriers for crowdfunding film projects, the preferable structure of the rewards, and future trends on the market. We included the group of students as our respondents due to various reasons: 1. they are likely to seek funding outside the usual procedures, 2. they are likely to implement the Internet in their work, 3. their attitude will impact the development of the film industry as they soon enter (or they have just entered) the film market. In our research we used a

CLUSTERS OF FILM PROJECTS – POLAKPOTARFI.PL

	Type of film project	**Number of sponsors**	**The level of funding**	**Number of cases**	**Percentage (%)**
1	Documentary	LOW	JUST REACH	26	24.07
2	Documentary	HIGH	JUST REACH	7	6.48
3	Documentary	HIGH	MEDIUM OVERFUNDING	11	10.19
3	Non-documetnary	LOW	JUST REACH	39	36.11
5	Non-documentary	HIGH	HIGH OVERFUNDING	8	7.40
6	Non-documentary	MEDIUM	JUST REACH	17	15.74

questionnaire with closed and open questions. The survey was conducted in April, 2016.

B. The barriers for film crowdfunding

The filmmakers' opinions about the barriers were highly diversified. The experts perceived and assessed factors which can hinder the development of crowdfunding differently (see Tab IV). To sum up the filmmakers' responses, we point to the following conclusions:

a. An important barrier in using crowdfunding for film projects lies in the sponsors' uncertainty of the project execution. Over 80% of experts agreed with the statement that the important barrier for financing film is the sponsors' uncertainty in whether the money would be spent in a reasonable way. Also about 70% of experts shared the view that sponsors can be uncertain of whether the film would be produced at all.

b. There is no major crowdfunding platform developed exclusively for filmmakers on Polish market (almost 60% of experts pointed to this barrier).

c. Lack of knowledge about crowdfunding. Half of the group of experts expressed the view that Polish filmmakers lack detailed knowledge about the terms and rules of crowdfunding. Over 60% of experts claimed that Polish filmmakers do not 'trust' this way of financing film projects.

d. Uncertainty about the legal aspects of crowdfunding. Almost 60% of experts shared the opinion that the Polish legal regulations for crowdfunding can be perceived as 'vague'.

e. The majority of experts do not perceive that the barriers lie in: 1) the lack of a proper schema of rewards, 2) the high cost of seeking financial support using crowdfunding, or 3) sponsors' concerns about online privacy.

TABLE IV.
EXPERTS' VIEWS OF BARRIERS FOR FILM CROWDFUNDING ON POLISH MARKET

The stated barrier	To what extent the experts agree with the statement (1-strongly disagree, 4 -strongly agree)	The percentage of experts which agree with the statement (4 or 5 points)
The sponsor's uncertainty that the money would be used in a reasonable way for film production	3.1	81%
The sponsor's uncertainty that the film would be produced at all	3.1	68%
There is no major crowdfunding platform developed for filmmakers on Polish market	2.8	59%
Lack of filmmakers' trust in crowdfunding	2.7	62%
Vague legal regulations for crowdfunding	2.8	59%
Lack of filmmakers' knowledge about crowdfunding	2.7	51%
The prospective sponsors' lack knowledge about crowdfunding	2.6	49%
High costs of crowdfunding for film projects	2.3	41%
Sponsors' concerns about their privacy and data gathered by crowdfunding platforms	2.2	41%
Too low reward schema for sponsors offered by Polish filmmakers	2.1	30%

TABLE V.
THE FILMMAKERS' ASSESSMENT OF THE REWARD OPTIONS

The reward	To what extent the reward is suitable for Polish film market (1 – not suitable at all; 5 – highly suitable)	The percentage of experts perceiving the reward schema as suitable for the Polish film market
Involving backers in events connected with the film, e.g. film premiere, thank you note on social media website	3.6	92%
The copy of the film on DVD as a reward	3.6	89%
The opportunity for a sponsor to be engaged in film production e.g. playing small parts in a film	3.4	86%
Film merchandise as rewards, e.g. T-shirts, mugs	3.0	65%
Sharing the profit earned by a film project with backers	2.1	32%

C. Developing a reward schema

In the next part of the survey experts were asked how they perceived different forms of rewarding backers (see Tab. V). The results are:

a. Majority of respondents perceived the following rewards as suitable for film production: involving backers in film events, offering a copy of the film DVD and engaging the supporters directly in the film production process, e.g. playing small parts in the film. The offering film merchandise was perceived as suitable by 65% of experts.

b. The experts do not agree with the idea of sharing the film profit with backers. Only one third of the experts consider the reward schema based on sharing the film profit with sponsors as a suitable solution on the Polish market.

D. The experts' views about their involvement in crowdfunding and future trends

We asked experts the question based on the following scenario: "Imagine that today you are planning the process of film production. To what extent do you consider crowdfunding as a way of funding for your film project?".

a. Over 90% of experts – 34 of the 37 respondents – stated that they consider crowdfunding as a supplementary way of funding the film project.

b. Three respondents stated that they would not consider crowdfunding at all.

c. None of respondents aimed to fund the film project mainly with crowdfunding.

The filmmakers also perceived the future role of crowdfunding differently. The group of experts was split almost in half in their assessment.

a. 51% of respondents agreed with the opinion that during the next five years the importance of crowdfunding for film projects would be growing significantly;

b. 49% of respondents expressed the opinion that during the next five years crowdfunding still remains only an 'additional' – not significant – way of funding film projects.

The experts also estimated the probability of success of the documentary film project differently.

a. Almost half of respondents (46%) stated that documentary films would probably be less successful than other film projects.

b. 24% of experts estimated the chances of success for documentary films as being similar to other film projects.

c. Almost 30% of experts perceived the documentary films as being probably more successful than other film projects.

V. Conclusions

This exploratory study, based on the analysis of selected film projects on crowdfunding platforms and the results of a survey conducted among Polish filmmakers, led to the following conclusions:

A. The statistical data indicates that the 'average documentary film' on the Polish market reaches a higher level of funding compared to non-documentary projects, and higher numbers of supporters.

B. The analysis indicates six different clusters of film projects on Polish crowdfunding platforms. Three clusters include documentary film projects:

- first cluster: documentary films 'just reaching' the threshold of funding, with relatively few sponsors;
- second cluster: documentary films 'just reaching' the threshold with a high number of sponsors;
- third cluster: documentary films reaching 'medium level of overfunding' with a high number of sponsors.

Although overfunding may seem be the indicator of film success and, at first glance, has only a positive effect on movie projects, the overfunding of film projects is also linked with possible problems connected with the growing scale of the project (for example, it can change the scale of producing and delivering the film merchandise)

C. The filmmakers taking part in the survey strongly differed in their views about crowdfunding in general, and specifically, the crowdfunding for documentary films. Such diversity of opinions and attitudes may be linked to the novelty of crowdfunding and therefore, the experts' difficulty of assessing the present and future state of crowdfunding.

D. As the majority of film projects are reward-based crowdfunding, it is important for project creators to develop properly working reward options. This study shows that over 85% of experts agree with the sponsor's involvement with film production. Such high level of expert agreement for sponsor-filmmaker cooperation is important, as one of the major trends of consumer behavior is based on the 'being a prosumer' attitude.

This study is as an exploratory study; therefore, the obtained result is difficult to generalize. However, this exploratory study gives the background for future research, particularly in such areas as:

- building trust between sponsors and founders in crowdfunding for filmmaking;
- the promotional role of crowdfunding and its incorporation in the promotion of a film project;
- the role of crowdfunding in marketing research for the film industry.

***Abstract* — The increasing digitalization of business and society leads to drastic changes within companies. Nearly all enterprises have to face enormous challenges when dealing with topics such as Industry 4.0/Industrial Internet. One of these challenges represents the realistic classification of the company's own IT infrastructure. In this paper we present a maturity model (SIMMI 4.0 – System Integration Maturity Model Industry 4.0) that enables a company to classify its IT system landscape with focus on Industry 4.0 requirements. SIMMI 4.0 consists of 5 stages. Each describes several characteristics of digitization, which allows a company to assess itself. Additionally, recommended activities are presented for each stage of digitization, which can enable a company to reach the next stage of maturity. We also present several possible topics for future research to improve and refine the developed maturity model.**

I. Motivation

ONE of the most important challenges that companies currently face is the digitization of business processes and of the enterprise itself. They have to join in global digital networking, improve automation of individual or even all business processes, and reengineer existing business models to gain momentum in digital innovation. It has never been more important for enterprises to be able to rely on IT-enabled capabilities, as well as to count on a deep understanding of information technology in general and in digital innovation in particular. Without a doubt, nearly all enterprises have to undergo an increasing digital transformation to remain competitive in global markets. In these efforts, the specific challenge for companies is to realize the increasing integration of virtual, digital programs with real objects or products in their everyday business in order to subsequently adapt, enhance, or optimize the processes [1]–[4].

For a while, trends such as Industry 4.0/Industrial Internet affected mainly large companies, especially since small- and medium-sized enterprises (SMEs) often judged such topics as too complex and expensive and partially classified them as not relevant. However, digitization is no longer limited to large companies and does not only concern separate functional areas such as the IT department. Rather, it takes place throughout the entire value chain of all companies [5]. Overall, together with this increasing digitalization of companies, the definitions of value-adding and supportive processes become vague, whereby the traditional supply chain of a company with its downstream processes develops into a holistic supply/value network. Thus, also SMEs open themselves for the complex topic of Industry 4.0 and try to reshape their business processes and business models in this direction. To face up to this development the use of adequate information and communication technology (ICT) is essential. However, what is missing at this point is the companies' level of knowledge concerning their own digitization. A number of studies already exist applying to this topic (e.g., [6], [7]). By using various interrogation techniques, the authors figure out which information and enterprise systems are used in business (especially in SMEs) and in what shape the IT-infrastructure of the company appears. There is, however, the question of how an IT landscape must be designed so that a company can "move" in the field of Industry 4.0. Recognizing and evaluating what systems are needed, and in which way and for what purpose, still embodies a challenge for companies.

This is where the present paper comes and this results in the main research question for our research:

What should a maturity model look like to assess a company's IT system landscape in the context of Industry 4.0?

Industry 4.0, as the fourth stage of the industrial revolution is entitled, consists of an increasing digitization of products and systems, together with their interconnectedness. Thereby, the physical world is connected to the virtual world. The characteristics of Industry 4.0 are: e.g., horizontal integration across whole value networks, strong vertical integration within the company, and a digital

transparency of the engineering across the entire value chain [8], [9]. However, a universal definition for the term "Industry 4.0" does not exist. From the aforementioned descriptions and further characteristics of Industry 4.0 we deduce a working definition as the foundation for our research:

Industry 4.0 describes the transition from centralized production towards one that is very flexible and self-controlled. Within this production the products and all affected systems, as well as all process steps of the engineering, are digitized and interconnected to share and pass information and to distribute this along the vertical and the horizontal value chains, and even beyond that in extensive value networks.

To answer the research question we present a tool (a maturity model) that enables companies to classify their own provided IT system landscape in the needs of an Industry 4.0 system landscape. This is also the core of our paper. We describe the components (dimensions and stages) of "SIMMI 4.0" (System Integration Maturity Model Industry 4.0) necessary to fulfill the requirements of an Industry 4.0 environment. Afterwards we finish with a short summary and an outlook for future research in this field.
Furthermore, related work with detailed insight into the field of Industry 4.0, as well as in the field of existing maturity models and into the development of our maturity model "SIMMI 4.0" are given in [10].

II. SIMMI 4.0 – System Integration Maturity Model Industry 4.0

As a starting point for model development, a further literature analysis was conducted. Contrary to the related work literature analysis in [10], the aim of this analysis was to gain an understanding about the existing level of knowledge about Industry 4.0, and, therefore, to deduce the essential requirements for IT systems in the context of Industry 4.0. Several databases (e.g., EBSCO, ScienceDirect, SpringerLink, and Google Scholar) were searched using the following terms and combinations of these terms: Information systems, Industry 4.0, Maturity models, Integration, Digitization, Internet of things and services, Cyber-physical systems, Value networks, IT systems, Enterprise systems, and Business information systems. Some of the resulting requirements from this literature analysis are presented as follows.

A. Requirements for IT systems in the context of Industry 4.0

In their final report about Industry 4.0, [8] highlighted three key requirements fostered by Industry 4.0 and thus should be supported by the enterprise application system landscape:

Vertical integration along the hierarchical levels of a company: While the different enterprise systems support their own tasks very well, the data of the respective systems, such as Enterprise Resource Planning (ERP) systems, Supply Chain Management (SCM) systems, Management Information Systems (MIS), Product Life cycle Management (PLM) systems, etc., is often stored in separate databases (sometimes data interfaces are provided) and partly stored in different formats. This sub-optimal level of integration must be improved for implementing Industry 4.0 business processes and activities.

Horizontal integration across value networks: For the implementation and use of different enterprise systems, failures and leakages throughout the flow of information must be avoided. In fact, the information must be accessible and useable at the right time in the right "place" along the entire supply chain and therefore for all business partners. Furthermore, the exchange of such information flows must be (completely) automatized.

Digital continuity of engineering: This means supporting a product's engineering consistently and continuously along the entire supply chain by using adequate and appropriate enterprise systems and includes the production system development process as well.

Also, stemming from the literature review (especially from analyzed study results), cross-sectional technologies were identifiable as an important part of the enterprise systems. These technologies are defined below and their relevance to Industry 4.0 will be explained:

Service-oriented architecture: For example, the project "Platform Industry 4.0" has published a whitepaper that names the development of a reference architecture based on a Service-oriented architecture (SOA) as an important prerequisite for the implementation of Industry 4.0 [11].

Cloud Computing: Industry 4.0 not only leads to a digitization of separate production facilities, but also that of the enterprise's information technology at the production plant(s) as well as all companies digitally interconnected along the supply chain. Considering cloud computing, these aspects are provided as different services; therefore, this could help enterprises operate in the field of Industry 4.0 effectively and efficiently.

Information aggregation and processing: In this context, aggregation of information implies that data can be easily identified from various integrated enterprise systems through different ways of treatment, such as clustering, filtering, and correlation. In a next step, this data is made available to every user or machine that needs it. This illustrates not only that the data of the production floor/of the production systems (e.g., various interconnected machines, (semi-) products, sensors etc.) is aggregated and transferred towards the company's higher levels and enterprise systems (e.g., ERP systems, SCM systems), but also that the data needs to be transferred in the opposite direction to the production floor [12].

IT security: In Industry 4.0, the company will be connected with/to the internet not just at an operational or higher level.

As part of the Internet of things and services, the production level/production floor, maybe even the control level of several machines themselves, as well as all levels up to the strategic level of companies will be connected through a continuous link to the internet. For this reason, IT security will be a major challenge for establishing different kinds of IT systems. Here, IT security is defined as adequate protection of all information available in form of electronic data. In addition, it must be ensured that the IT systems themselves and their services are available at all times for the users and work properly [13], [14].

B. Components of SIMMI 4.0

Depending on its aims and strategic positions as well as on its arrangements in terms of Industry 4.0, not every company needs to fully implement all the dimensions of SIMMI 4.0. There are several gradations per dimension, which in turn result in different stages within the maturity model. These dimensions can have different characteristics in terms of scope and intensity for each company. Therefore, Table I in the Appendix gives a summary of our proposal for SIMMI 4.0. In the following chapters, the dimensions and stages of SIMMI 4.0 are described in detail.

B.1 Dimensions of SIMMI 4.0

Several dimensions of the development of SIMMI 4.0 are deduced from the requirements from our literature analysis. With these dimensions, SIMMI 4.0 can enable a company to assess its IT system landscape.

Dimension – Vertical integration: This dimension focuses on the components of the lowest level of an enterprise, where different physical things ((semi-) products, machines, etc.) need to exchange information throughout the level itself and with the levels above. The most important criterion here is that this exchange is possible in both directions.

Dimension – Horizontal integration: Industry 4.0 requires horizontal integration across the different value networks. Accordingly, an essential criterion has emerged from the requirements above. An automated and integrated information flow is necessary along the horizontal enterprise level as well as beyond the enterprise borders. Without this information flow, a business-wide value network is not realizable, meaning that the various enterprise systems of the different partners in the value networks require interoperability at the data level. Therefore, a continuous and consistent information flow is needed [15], [16].

Dimension – Digital product development: For the engineering's digital continuity it is especially important that each process step is represented digitally. For this purpose, at least one enterprise system should be integrated into each respective process step. In addition, the resulting data and information of each step must be forwarded to the next and previous step/enterprise system.

Dimension – Cross-sectional technology criteria: This dimension focuses on assessing the extent to which technologies are used across all different fields of Industry 4.0. Based on the requirements, the respective fields are: Service-oriented architecture, Cloud computing, Big Data, and IT Security. In addition, the level of support that enterprise systems can provide for these fields should be evaluated in this dimension.

B.2 Stages of SIMMI 4.0

SIMMI 4.0 is divided into five stages. Additionally, key activities for each stage, which must be conducted in order to be able to achieve a higher stage, are briefly specified.
This five-stage division is justified by the fact that in the middle of this stage-model, in the third stage, the implementation of an intelligent factory (Smart factory) is completed. This foundation for Industry 4.0 should be and must be implemented in each company before stable, robust, and versatile value networks can be realized. By implementing an intelligent factory, a company can gain operating experience before the company and its systems are connected to other companies [15].

Stage 1 – Basic digitization level:
The company has not addressed Industry 4.0. Requirements are not or only partially met.
The enterprise systems along the enterprise's value chain support only their respective fields of activity. When integration is achieved, it is with specially implemented and complex interfaces. In addition, the processes are not or are only partially digitized. Product prototypes are designed in a costly way because of product development activities are not digitized. The company does not pursue service-oriented and cloud-based approaches.
The data of the enterprise systems are aggregated only for strategic decisions. In addition, the confidentiality of the data is not provided. The company's data is not protected against industrial espionage for example, incurring enormous damage annually. Anytime and continuous availability of data is not ensured. Sometimes, users cannot receive the data when they request it or access is not provided.

Activities:
- *Start of engagement with focus on Industry 4.0*
- *First explorations of service-oriented approaches*

Stage 2 – Cross-departmental digitization:
The company is actively engaged with Industry 4.0 topics. Digitization has been implemented across departments, and the first Industry 4.0 requirements have been implemented throughout the company.
Information can be (partially) exchanged automatically among different departments and business areas. This level of integration no longer contains data islands within the company. In addition, several production plants are connected but instead through cloud solutions they are

connected through the exchange of information in other ways (paper-based, email, FTP, etc.). Production and product development is supported by several enterprise systems. However, data and information exchange is not automatized. Therefore, the previous and following steps are not optimized. The company starts to implement an SOA. Legacy systems are broken down, and their functionalities are encapsulated into services. New systems are implemented directly following the SOA principles. Thus, initial processes can be built as services. In addition, an enterprise service bus (ESB) is implemented to replace enterprise application integration principles and to enable direct connection between new systems.

Activities:

- *Implementing an SOA*
- *Achieving cross-departmental integration*
- *First approaches for an IT security model*
- *First developments of mobile applications*

Stage 3 – Horizontal and vertical digitization:

The company is horizontally and vertically digitized. The requirements of Industry 4.0 have been implemented within the company, and information flows have been automated. The product development is consistently supported by enterprise systems. Information from the respective process steps can be forwarded to the next or previous process step.

The company has established an SOA. All the functionalities of the integrated systems are provided as services. The (semi-) products are part of this SOA and provide services themselves.

To exchange information within the enterprise, cloud principles are applied. Services are available company-wide and can be accessed anywhere. Employees are able to retrieve information everywhere through mobile devices. In addition, machines and (semi-) products are displayed on the mobile devices as soon as they come into the device's range. With this feature, the devices can display additional information about the machines (e.g., current processing step, maintenance status, etc.).

Various data from the production plants will be aggregated and processed together. Using this data and information gained from production, production itself can be optimized in real time and can be adapted to prevailing or changing conditions when necessary.

IT security is increased through the use of an advanced security model. Access to data is continuously protected, and data is transmitted in an encrypted state within the enterprise. The data's confidentiality, availability, and integrity are completely guaranteed.

Activities:

- *Connection with other companies to build value networks*
- *Development of a cloud-based platform to offer services across the company border*

Stage 4 – Full digitization:

The company has been completely digitized, even beyond corporate borders, and integrated into value networks. Industry 4.0 approaches are actively followed and anchored within the corporate strategy.

Consequently, the level of integration can be described as enterprise-wide and cross-corporate horizontal and vertical integration. In order to optimize processes, the product development steps automatically pass information to previous and following production steps.

The company has established a service-oriented and cloud-based platform that offers services in the value network in order to exchange information along the supply chain in real time. Machines can be maintained globally, regardless of their location (in terms of their software). Data is aggregated and processed company-wide as well as provided via entire value networks. The production floor in general is at a highly optimized level.

In addition to enterprise-wide data encryption, encryption is also used within the value networks. Users can access data anywhere by using established authentication measures.

Activities:

- *Beginning collaborations with companies within the value networks for end-to-end solutions and the optimization of information flows*

Stage 5 – Optimized full digitization:

The company is a showcase for Industry 4.0 activities. It collaborates strongly with its business partners and therefore optimizes its value networks. Through these collaborations, new business models and new end-to-end solutions are developed and enabled. During this development process each step inside and outside the company is digitized.

Within the value networks physical value and information flows can also be represented digitally, so the entire added value can be simulated in real time. Thus, it is possible to automatically perform necessary adjustments for all companies of the value network.

Furthermore, the IT security adjusts promptly to new risks. Occurring security problems are immediately solved. Encryption is optimized in cooperation with the partners the along the value networks.

III. Summary and Future Aspects

The aim of our research is to provide a maturity model for the classification of a company's IT system landscape in the context of the Industry 4.0 requirements. Through a systematic literature review [10], we could demonstrate that no maturity model currently exists that meets the needs of Industry 4.0 in terms of a company-wide and even a cross-corporate IT system landscape. However, due to the drastic changes produced by the digitalization of businesses and society itself, it becomes necessary for enterprises to assess their IT system landscape in a realistic way. Therefore, an

easy-to-handle tool could provide adequate support for assessment.

With this in mind, we designed a new maturity model (SIMMI 4.0 – System Integration Maturity Model Industry 4.0) for assessing the readiness of a company's IT system landscape in terms of Industry 4.0. However, this design process is not described in detail in this paper but can be found in [10].

Within this paper we present the first version of our maturity model SIMMI 4.0. Thus, the model's development is not yet fully complete. The next steps include: (1) conducting several expert interviews and model adjustments based on the interviews if necessary (2nd iteration); (2) group interviews with companies to test the model's practicability (3rd iteration). After these steps, evaluation of the maturity model will follow. This should be based on the concrete application of the model within several companies. The resulting design decisions based on the iteration steps, the transfer and evaluation in terms of the model's dimensions and stages, more detailed evaluation steps, and the model's scientific as well as practical contributions will be addressed in subsequent papers.

Beyond the development of SIMMI 4.0 (here primarily based on the literature review in [10], the comparison of existing maturity models), we identified additional links and needs for further research. For example, some maturity models already exist for the field of Industry 4.0 that deal with organizational aspects or system-specific aspects in detail. A mapping of these maturity models would be necessary to combine their different points of view. For example, different maturity level assignments and dimensions between these models should be developed to enable companies to fully classify themselves in terms of Industry 4.0 requirements in all levels of their enterprise. With this work, companies would be able to determine their overall maturity in the field of Industry 4.0.

A further aspect to investigate in the future is the data quality within various enterprise systems along the supply chain. Since companies in an Industry 4.0 environment must exchange data in large amounts and on an automated basis, a certain data quality is necessary to ensure efficient company-wide and cross-corporate business processes. Therefore, those companies should implement adequate master data management and data quality management. On this topic, two questions arise: (1) What design elements and components should be part of master data management and data quality management in the context of Industry 4.0? (2) How can master data management be integrated in maturity models addressing the IT systems landscape of Industry 4.0 companies? We will address those two questions in further research projects.

To conclude this contribution, some limitations must be recognized. Currently, SIMMI 4.0 has not been evaluated or tested. It is a maturity model that was derived from the literature by combining aspects of IT-related maturity models with Industry 4.0 requirements. In this respect, the development process of SIMMI 4.0 must continue. In the next iteration steps, we will clarify and review the model's components based on expert and company assessment. Additionally, SIMMI 4.0 must prove its practicability and usefulness in an enterprise environment. We will address both aspects of the model's limitations in our research project's future steps focusing the field of Industry 4.0.

V. APPENDIX

TABLE I.
OVERVIEW OF SIMMI 4.0

Dimension **Vertical Integration**	Dimension **Horizontal Integration**	Dimension **Digital Product Development**	Dimension **Cross-sectional technology criteria**
Stage 5 – Optimized full digitization: The company is a showcase for Industry 4.0 activities. It collaborates strongly with its business partners and therefore optimizes its value networks.			
Continuous cross-corporate integration that is constantly optimized.	Continuous cross-corporate integration and collaboration in value networks.	Product development is processed digitally inside and outside the company (digitized end-to-end solution).	Simulation and optimization of value and information flows in real-time within the value network. IT security adjusts promptly to new risks. Occurring security problems are immediately solved. Encryption is optimized along the value networks.
Stage 4 – Full digitization: The company is completely digitized even beyond corporate borders and integrated into value networks. Industry 4.0 approaches are actively followed and anchored within the corporate strategy.			
Continuous cross-corporate integration.	Continuous cross-corporate integration in value networks.	Product development information are digitally forwarded.	Service-oriented cloud-based platform. Services are offered for the partners in the value networks. Information and data are exchanged in real-time along the supply chain. Optimization of the entire production through Big Data solutions. Access to data is protected. Cross-corporate encryption of data and authentication for global access.
Stage 3 – Horizontal and vertical digitization: The company is horizontally and vertically digitized. Requirements of Industry 4.0 have been implemented within the company, and information flows have been automated.			
Complete internal/enterprise-wide integration of all enterprise systems and machines.	Complete internal/enterprise-wide integration of all enterprise systems and machines.	Product development is continuously digitally supported.	SOA has been established. All functions are provided as services. (Semi-) products and their functionalities are available as services. To exchange information within the enterprise, cloud principles are applied. Production is adjusted and optimized in real-time. IT security is increased through the use of an advanced security model. Access to data is continuously protected, and data is transmitted in an encrypted state within the enterprise.
Stage 2 – Cross-departmental digitization: The company is actively engaged with Industry 4.0 topics. Digitization is implemented across departments and first Industry 4.0 requirements are implemented throughout the company.			
Cross-departmental integration	Cross-departmental integration	Production and product development is supported by several enterprise systems. Data and information exchange is not automatized.	Implementation of first services (SOA with an enterprise service bus (ESB)). First experience with Big Data and its applications. Development of the first IT security models
Stage 1 – Basic digitization level: The company has not addressed Industry 4.0. Requirements are not or only partially met			
Integration of enterprise systems only departmental-specific. The enterprise systems along the enterprise's value chain support only their respective fields of activity	Integration of enterprise systems only departmental-specific. The enterprise systems along the enterprise's value chain support only their respective fields of activity	Product development is not digitally supported	No service-oriented or cloud-based approaches. Data and information flows are not used for product improvement/optimization. Confidentiality, availability and integrity of the data are not guaranteed.

***Abstract*—The aim of this paper is to analyze available maturity models in the context of assessment of the maturity of IT systems that support communication processes in HCM. The paper presents theoretical issues connected with the evolution of information systems in context of support Human Capital Management (HCM) in a modern organization. Selected problems connected with assessment of maturity were presented, and examples of models for maturity assessment were analyzed in the context of their use for evaluation of HCM Information Systems. As a conclusion, the paper indicates necessity to create a new dedicated method for assessing maturity of the systems analyzed.**

I. Introduction

MODERN organizations still search for tools that would be able to ensure them advantage over their competitors. A necessary condition for an efficient functioning of an organization is the use of all kinds of solutions that will enable optimization and improvement of processes taking place in an organization. In the context of the development of an organization, it is especially important to support basic processes aimed at knowledge acquisition and processing as well as its skilful use in practice.

Employees of an organization may turn out to be the basic factor guaranteeing its development and achievement of advantage. For performance of tasks assigned by managers, employees use available knowledge. Knowledge can be acquired, processed and distributed as a result of creation and maintenance of efficient communication channels, both within an organization and between an organization and its environment. The use of mature IT systems supporting the performance of communication processes makes it easier to fulfill this task. As a result of these changes, traditional organizations turn into knowledge-based organizations and concentrate their activities on human resources, that are the most important of immaterial resources at the disposal of an organization.

The first part of the paper will discuss the evolution of the role fulfilled by employees in a modern organization, from human resources to emergence of human capital. Further, the paper will discuss tools supporting the performance of communication processes in HCM in an organization, with particular reference to IT systems.

Next, it will analyze preliminary results of research on IT systems designed to support processes of human capital management in Polish organizations. Next part will feature a review of several models in the context of evaluation of the maturity of IT systems designed to support communication processes in HCM.

II. Evolution of the Role of Employees in a Modern Organization

Not so long ago, employees were treated as one of the resources that an organization acquired and had at its disposal. For those managing an organization, it was important that the individual resources, including human ones, were at a specified level [1]. Management of human resources was concentrated mainly on the quantitative and economic aspect of managing staff - the so-called "hard HRM" [2]. HR managers mainly dealt with administration of remuneration, handled all the issues connected with labour law, management of an organization and working time [3]. Attention was paid to employees' skills - including even the definition of the level of competencies required for employment at a specific - but their use was optimized by managers by means of traditional methods and techniques covering acquisition, development and use [4], [5].

Most modern theories of HR management definitely depart from treating employees like objects. This new approach is based on the concept of the so-called soft HRM proposed in work [3]. The soft HRM makes employees committed to their work by encouraging them to identify with the objectives and mission of the organization and by involving them in defining further tasks [1]. A HR strategy more and more often recognizes and takes into account employees' talents, becoming the foundation of a modern view of the role of people in an organization. Human capital plays a key role in every organization, determining the differences between organizations and constituting the actual basis for competitive advantage [6]. Appropriate people can be the fundamental success factor, but inappropriate ones may contribute to failure of an organization. Summing up: human capital mainly involves

the knowledge of an organization's members, their skills, experience, ability to solve problems, willingness to create and introduce innovations [7], qualifications, creativity and loyalty towards an organization. The human capital at the disposal of an organization should be efficiently managed, which requires the use of reliable tools supporting the basic processes related with this task. Human capital management (HCM) is a set of practices related to people resource management. These practices are focused on the organizational need to provide specific competencies and are implemented in three categories: workforce acquisition, workforce management and workforce optimization.

III. TOOLS DESIGNED TO SUPPORT THE PERFORMANCE OF COMMUNICATION PROCESSES IN HCM IN AN ORGANIZATION

In the free-market economy, the impact of the external environment and conditions of operation are similar for all organizations. Basically, all organizations competing on the market have free access to employees and supporting technology. In such a situation, the main factor determining an organization's competitive advantage is acquisition, creation and appropriate use of its human capital. In order to be able to fully use employees' potential, it is necessary to not only ensure their development, but also to try to make the most valuable of them stay in the organization. We should, however, bear in mind that all organizations can support employees using generally available solutions for that purpose.

Efficient performance of basic processes connected with human capital management requires the use of various available solutions and technologies. Particular emphasis should be placed on systems designed to support broadly understood communication processes. As a response to this demand, more and more IT solutions are created to support the performance of processes connected with human capital management. The use of the latest IT technologies supports learning processes, and the traditional HR processes implemented by an organization are transformed into knowledge-based HCM processes, which leads to the emergence of a new model of an employee, the so-called knowledge worker. Employees' knowledge, skills, abilities, motivation and values are becoming increasingly important and constitute the basic element determining the role of people and related human capital in a modern organization [8]. Without IT support, process improvement may take too long to perform traditional activities connected with administration of a large amount of paper documentation, training materials, instructions describing the performance of assigned tasks, reports or current HR and payroll documents. Implemented IT systems are expected to unify HR processes, systematize the work of the HR department, and support managers in managing subordinate teams. [9]

Employees of an organization more and more often have basic or extended knowledge of modern IT technologies. This knowledge is necessary to fully take advantage of the potential offered by the different technologies. Although there is growing awareness of the role fulfilled by these technologies in supporting communication processes connected with HCM, organizations should take actions aimed at improvement of their employees' competencies connected with the use of such technologies.

This thesis is confirmed e.g. by results of a survey concerning applications of selected modern IT technologies in the different processes connected with acquisition, creation and maintenance of human capital in a knowledge-based organization. The quantitative studies were conducted at the beginning of 2015 by the technique of paper questionnaire interviews (PAPI), on a randomly selected sample of 196 people at different ages, with different place of residence, education and employment relationship. The group consisted of students and graduates of I degree and II degree full-studies and post-graduate studies. Although the studies were conducted mainly in the territory of Silesia, the respondents came from or lived in different regions of the country and abroad.

Results of the studies show that the use of solutions designed to support communication processes is quite widespread in Poland. Of 196 respondents, 121 people (61.73% of the sample) were employed at the moment the survey was conducted. Of those employed, as many as 117 (96.69 % of all those employed) declared that their employer had a corporate website or a different service supporting information exchange. Slightly fewer, i.e. 92 employers (76%) used a computer network or advanced IT systems. 56 respondents (46.28% of all employees) declared that their organization had mechanisms in place to enable exchange of knowledge with its environment. 32 of them (62.75% of all employees) claimed that their employer had or planned to implement in the near future procedures or agreements the subject of which was acquisition, creation or exchange of knowledge with other enterprises or external institutions. 51 respondents (42.15% of all employees) declared that their organization acquired, shared and exchanged knowledge with its environment apart from performing basic business processes. Of this group, 28 people (23.14% of all employees) definitely declared that their organization was focused on knowledge management processes, noticing at the same time the need to use IT solutions to support these activities.

The same studies also revealed which of the IT systems had the largest potential in supporting processes connected with HCM. Processes connected with HCM in an organization were divided into three areas:

- acquisition of human capital
- creation, development and improvement of human capital
- maintenance of human capital.

The studies conducted confirmed the dominating role of solutions supporting processes connected with internal and external communication in all three areas of HCM.

In processes connected with acquisition of human capital, local and wide area computer networks as well as solutions whose operation is directly based on them (Internet) (77.78%) are most significant according to respondents. Business social networks such as Goldenline or Linked in, as well as discussion groups (77.78%) were rated as the most important. Slightly less useful (75.56) are, according to respondents, traditional recruitment portals and social networks (Facebook, Twitter,...) as well as interface agents which are often encountered on various services in the form of virtual advisers. Respondents were equally interested in agent solutions used to search for information (62.22%) and agent solutions used to search the Internet (66.67%).

In processes connected with creation of human capital, a particularly important role was played by IT systems that used computer networks (82.22%). Of similar importance are traditional social networks, followed by discussion groups (77.78%), which in this context enable exchange of knowledge between their users, and interface agents that support training processes.

In the third area, significant importance of social networks, or virtual advisers (71.11%) was highlighted in processes connected with maintenance of human capital. Social networks facilitate knowledge distribution and exchange with the environment, whereas interface agents support users using knowledge possessed by an organization Respondents showed slightly lower trust in discussion groups supporting information exchange (68.89%).

Currently, the situation on the market of IT solutions designed to support the performance of processes connected with HCM is increasingly better. Producers deliver an increasing number of less or more advanced IT systems that use all available IT technologies. However, only "the best", most tailored IT systems can meet an organization's expectations. It is thus very important to possess reliable tools for evaluation of applied software to identify its strengths and weaknesses. Well adjusted tools can fully support processes connected with HCM.

IV. Evaluation of the Adequacy of IT Systems Used to Support Communication Processes in HCM

The key to achievement of effective HCM is to ensure efficient knowledge distribution; it is necessary to make communication channels available and to involve employees in cooperation using these channels. Recognizing the necessity to improve the performance of the different processes connected with reliable communication channels for information exchange as part of HCM processes, companies often allocate large budgets for implementation of IT systems, but are unable to find out whether the solutions used actually support the performance of processes to a sufficient extent. A lot of money is spent on training courses, but managers are unable to determine the actual increase in competencies of employees that participated in them. Thus, it is often argued that investments in IT systems that support communication processes and in training courses do not result in the improvement of their performance, and training courses completed by employees do not lead to acquisition of competencies relevant to a company.

In order to achieve the expected performance and the quality of the functioning of the new methods of software development organizations it is necessary to apply new tools offering the ability to manage this process. One of such methods of evaluation is to examine the maturity level. The term of maturity is defined in the Dictionary of the Polish Language as: "...the state of having taken on the final form, achievement of the final stage of the development or process of shaping... " [10]. The concept of maturity was initially used in psychology to refer to "achievement by an individual of a certain desired mental or emotional state" [11]. In management studies, it appeared in the 1970s. [12]. It was accepted in the theory of management that apart from the extreme states of immaturity and maturity, there is also a certain number of intermediate states [13]. In the broadest sense, the concept of maturity can be examined in relation to an organization as a whole. In the context of management of processes performed within an organization, maturity can be viewed as managerial maturity, process maturity in the area of technology, quality, knowledge or culture as well as praxeology. Integrated maturity of an organization includes responsibility, reliance on trust in the business activity and striving after perfection. Specialized maturity takes into account process and technical approaches, quality, culture, management of knowledge, intellectual capital and, above all, management of human capital [14]. In the context of IT systems, the concept of maturity is usually associated with the field of software engineering [15].

In practice, this concept is most often examined in the following contexts:

- process maturity [16] [17], [18],
- project maturity [19],
- quality maturity,
- implementation maturity,
- different combinations, e.g. process and project maturity

As was already mentioned, in a modern organization, the performance of processes of HCM is inseparably connected with the use of appropriate IT systems that support communication processes, enable efficient management, automation, monitoring and optimization of these processes, allowing thereby higher levels of process maturity to be achieved. At the same time, IT systems, the process of their creation and degree of their use in an organization may also be evaluated [12]

For maturity assessment, flexible tailor-made models are used. Models designed to evaluate the level of maturity allow an organization to assess its methods and processes in accordance with the best practices of management and based on clearly defined external reference values. There is a range

of models designed to evaluate the maturity level of models, from Crosby Quality Management Maturity Grid developed in the 1970s [20] to models dedicated to maturity evaluation developed based on internal assumptions of specific organizations. Models differ from each other in the scope of maturity level measurement which can be performed in various areas of an organization's activity. Many of them were taken into account in their research and described in their works by [21], [13].

Maturity modelling for the purpose of management and control of processes taking place in an organization is based on the method of evaluation of an organization. Its level of maturity can be evaluated on a scale from 0 (lack) to 5 (optimal). This approach is based on the maturity model developed in 1991 by Software Engineering Institute (SEI) - a model for assessing maturity of development processes and potential (capability) of IT system (software) development (Capability Maturity Model for Software) CMM [22], [23].

HCM is a specific area, as it deals with processes connected with the most spontaneous and unpredictable of the resources at the disposal of an organization - its employees. The dynamics accompanying processes taking place in the HR sphere justifies creation of detailed models designed to assess the maturity level of IT systems connected with acquisition, creation and maintenance of human capital. Although there are no models that directly refer to maturity of such systems, there is a range of models that focus on the one hand on assessment of the maturity of IT systems, while on the other hand - on assessment of process maturity. There are also models designed to measure maturity of skills offered to an organization by its employees [24].

An example of such a model in the area of human capital management is PCMM. The model was developed to support processes connected with improvement of employees' skills which are one of the most important premises for creation of an organization's human capital and are regarded as key factors leading to success achieved by knowledge-based organizations. PCMM allows an organization to identify necessary activities to support employees' development depending on the current level of an organization. The model indicates competencies that are of key importance for proper operation of an organization in a changing environment, increasing effectiveness of HCM [25].

In available sources, researchers and practitioners give a lot of attention to the problem of maturity of IT systems. There are also a few models designed to assess maturity of systems connected with HCM in an organization.

One of more interesting examples is HCM applications implementation maturity model proposed by K. Jones [25] describing five levels of progressively more mature HCM applications implementation capability.

Presented model describes four levels of progressively more mature HCM applications implementation capability

1 st., Level: Technology-Centric - focused strictly on technology, with lacks a compelling business case to implement new software supporting HCM,

2 nd. Level: Process Automation – implementation process of information systems supporting HCM in organization providing a team implementing new software without ongoing and future software upgrades,

3 rd. Level: HR Customer-Centric – where implemented systems have inconsistent communication with stakeholders & audiences,

4 th., the highest Level: HR Customer-Centric – where software changes are driven through documentation of preexisting business, with project consolidation and rationalization of business processes and continual communication and engagement of stakeholders and audiences,

The above-described examples of the models, as well as many other presented in sources, enable assessment of the maturity of processes taking place in HCM, assessment of the maturity of "people capability", maturity of IT systems and implementation of HCM Information Systems (HCMIS) in an organization. These are, however, general models which treat HCM in a comprehensive way.

Effective HCM embraces an integrated approach that requires concepts and practices that are tested and proven. Practical management tools are required to help HR leaders diagnose problems quickly, then prioritize and implement reforms along an HCM maturity model in an environment that has many and, at times, conflicting sources of priorities.

The aim of the author was to attempt to match a method to assessment of process maturity of IT systems designed to support processes connected with communication processes taking place in HCM in an organization.

Although many general and specialized models designed to assess maturity in various contexts can be found, there are no detailed works that directly address research on maturity of IT systems that support the performance of communication processes as part of HCM in an organization. In order to fill this gap in methodology, it is necessary to develop a model and new method that enable assessment of maturity of such solutions. The basic task in this situation is to develop tools that will make it possible to determine maturity levels, and then to find out what is the maturity level of an examined solution.

V. Conclusion

The aim of the paper was to indicate tools that would enable organizations, an assessment of the adequacy of IT systems used to support communication processes in HCM. IT systems are a necessary element required to support processes connected with information exchange in HCM (e.g. knowledge distribution). Only the use of reliable solutions will allow an organization to create human capital which will give it a chance to gain competitive advantage. For an organization to be able to use appropriate solutions, it

needs a reliable method for their assessment. The paper was an attempt to relate known methodologies for examining a system maturity to IT systems designed to support communication processes. It analyzed three selected models supporting assessment of maturity in three aspects connected with the selected research subject. This, however, does not exhaust the subject, although their use at a further stage of research creates significant chances in this aspect. My research shows that such systems function in almost every organization, with many organizations attaching great importance to them. However, given the lack of direct references in the academic literature to the issue of maturity of IT systems used to support communication processes in HCM, a few initial assumptions have to be made. The area of using IT systems to support HCM is nowadays intensively explored both in research and practice. There are already applications that support the different HCM processes, and over time they will fulfill an increasingly important role. Therefore, it is very important to ensure tools that will allow the usefulness of such solutions to be verified.

Given the volume of knowledge and literature, it is difficult to discuss all the aspects impacting the use the model to assess the maturity of HCMIS. None of the available maturity models takes into account all the conditions accompanying the introduction of modern communication technologies into HCM. It is thus necessary to create a new model that is based on the models available on the market, but, above all, takes into account all the conditions connected with implementation of HCMIS in an organization. Despite a large number of available models, not a single one that would enable a comprehensive assessment could be indicated. Necessary features were showed by a few models. It is thus justified to conduct appropriate research and propose a new model that would enable such assessment, defining maturity levels based on e.g. the level of knowledge representation. Although research is conducted, unexplored areas still exist. For instance, there are no solutions designed to assess maturity of IT systems that support communication processes and assist employees in their careers. However, with increasing availability of necessary tools, the possibilities to assess IT systems in their support of communication processes will increase, and the number of their successful applications in the area of HCM will undoubtedly grow.

An article is a background for my future researches focused on bridging the gap in methodology and creating new model that enable assessment of maturity of IT systems supporting communication processes in HCM.

ACKNOWLEDGMENT

The issues presented constitute a beginning part of the authors research into the aspect of improving communication processes in Human Capital Management

***Abstract*—This paper describes a framework designed to establish vital conditions of information security for *ubiquitous* services (U-Government) both in district and province municipalities (departments' capitals) within the Peruvian electronic (e-government) government structures. The framework contains current regulations concerning information security, data privacy, business continuity, and natural disasters management based on good international practices, including but not limited, ISO 27001, ISO 27002, ISO 22301 standards. The aim is to help implement security controls in the use of mobile services which are part of the e-government services catalogue. The framework structure is closely related to the COBIT 5.0 process model.**

I. Introduction

At present, electronic government structures include a solid component of services oriented to the use of devices and mobile solutions [1]. These services are intended to take advantage of the widespread use of this type of devices by citizens and their knowledge of mobile applications [2]. Most local (municipalities) electronic government initiatives in Peru are focused on this type of services rather than web services as displayed in Figure 1:

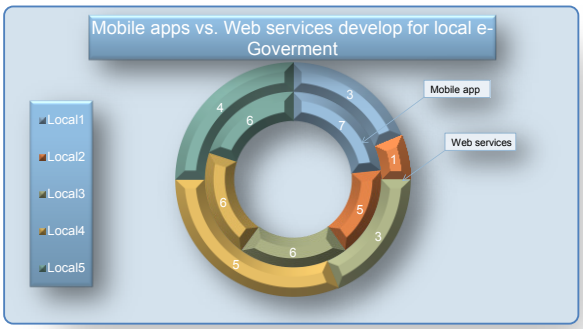

Fig. 1 Comparative table taken from http://www.movil.softwarepublico.gob.pe/ (2015)[1]

New technological developments and innovations are setting the stage for a higher demand of U-government services. This will lead, in turn, to new services for the government which will be forced to increase their number and take into account pertinent restrictions, e.g., information security for regulatory compliance [3], [4], [5], [23].

As there are doubts about the information security in the mobile applications (apps) and due to the huge amount of information to be protected by governmental institutions rendering services through them [6], [22], it is mandatory to develop a framework that facilitates the implementation of controls and the follow-up of good international practices on information security both in the implementation projects of U-Services (ubiquitous services) in Peruvian local governments and the assurance of the already existing apps. The proposed framework must comply with current domestic regulatory framework.

This paper discusses the general structure of a security framework based on COBIT 5.0 and above all its process reference model (PRM) [7] in ISO 27001, ISO 27002 and ISO 31000 standards.

Likewise, the current Peruvian regulations including the Personal Information Protection Law[2] and Peruvian Technical Standards on security will be referred to[3].

II. Ubiquitous Government

A. Ubiquitous computing

Ubiquitous technology (ubicomp, English acronym ubiquitous computing) is an extension of mobile informatics based on access technologies through mobile or handheld devices [8]. It consists of re-orienting ITs to propose mobile technology-based solutions for access, consumption and exploitation of information in an effort to render services as a support to business processes; thus paving the road on which companies and organizations would modify their strategies to meet the needs of clients and stakeholders.

[1] Local label represents a Peruvian public institution

[2] Personal Data Protection Law N°29733

[3] NTP ISO/IEC 17799 and NTP ISO/IEC 27001

B. U-Government

Ubiquitous computing has been closely linked to the electronic government on the premise that it will assure availability and multichannel connections to electronic services offered by the government to the citizen by means of mobile or web-based solutions. Ubiquitous government or u-government mirrors the new manner of interaction and transaction between the government and citizens and other stakeholders in such a way that access to these services is available through entry points (multi-purpose single windows) anywhere and anytime, from different types of mobile electronic devices [9], [13]. Precisely, the main concern of U-services implementation relates to security around the involved transactions and sending of information.

C. Information Security requirements in U-services

Most e-government implementations entail the design of web pages and services offered to citizens from these portals [10]. There are three types of said services: statics information, data consultation (mild interaction that may not imply personal data entry) and transactions (advanced interaction encompassing business transactions such as payments and personal data entry) [11], [20].

Below are the chief considerations on the security related regulatory compliance [14], [21]:

- Is there personal data involved in the service?
- Are digital signatures and certificates being used to authenticate the citizens for transactions?
- Are transactions encrypted? [12]
- Are there VPN infrastructures between local government (Website) and citizens to conduct the transactions involved in the services?
- Do services require the intervention of a payment gateway?
- Do services require the intervention of external payment methods (e.g. PayPal)?

D.Regulatory Requirements of Peruvian Local Governments

Peruvian local governments (province and district municipalities) set forth the following regulations with respect to information security, e-government, and data privacy:

- Mandatory use of the Peruvian Technical Standard "ISO NTP/IEC 27001:2014 Information Technology. Security Techniques. Information Security Management Systems. Requirements 2nd Edition",
- Open Government Action Plan (Open Data Plan AGA) 2015-2016
- Compliance of the Electronic Government Domestic Politics 2013 – 2017
- Personal Data Protection Law N° 29733
- Digital Signatures and Certificates Law N° 27269
- Law N° 29985 of Electronic Money as a financial inclusion tool

Local governments are bound by the current regulations to:

- Formulate the electronic government plan
- Establish the e-government structures needed to render U-services
- Implement the controls needed for U-services that require digital signatures and certificates for citizen authentication.
- Identify personal data sources held and managed by local governments, and comply with data privacy regulations.
- Set up an information security management system (ISMS) in accordance with ISO 27001 and ISO 27002 standards.

E. Applications involved in U-government in Peru

The nature of mobile applications involved in local government U-services in Peru is basically intended to load and report tax information, property tax, and information about traffic offenses. Only a few are focused on *payment transaction* of taxes, local duties, traffic offenses and the like. However, there exist regulations aimed at gradually increasing transactions by using, for example, electronic money in which mobile devices will serve as payment wallets for these procedures.

All these mobile services imply use, storage, handling and traffic of data of a personal nature, all of them regulated in Peru since 2013. Personal data-handling organizations are responsible for implementing – and stating their status as such – a series of ISO 27002 security controls, whereas governmental organizations must establish ISMS based on ISO 27001.

Nevertheless, the methodological gap identified shows lack of a suitable implementation guide for controls and good information security practices required for said cases [15], [16].

The proposed framework intends to fill this gap for U-services, which are part of more complex e-government organizational structures.

III. PROPOSED FRAMEWORK

A. Framework's General Structure

The framework has been divided into four parts:

- Stakeholders' needs
- Alignment matrix between business goals and information security goals for U-services supporting business goals.
- Information Security Process reference model (ISPRM) containing the relevant information security domains for the applications included in the U-services, and for the respective compliance, in light of the previous regulations.

- Current process implementation guide in the ISPRM.

The following paragraphs detail each of these components.

B. Stakeholders' Needs

In this case, by making an analogy with the COBIT 5.0 presentation, we can establish up to five related business objectives:

i. Optimize investments
ii. Optimize risks
iii. Comply with current and competent regulations
iv. Optimize resources
v. Satisfy citizens

Corporate and information security goals will be added to the above objectives in the following alignment matrix.

C. Alignment Matrix

The alignment matrix is introduced in two tables whose dimensions are those of the Balance Score Card. Table 1 shows the framework's corporate goals, whereas Table 2 lists the information security goals regarding development and delivery of U-services, which are in line with the business objectives. Letters P and S within the cells containing objectives mean that the goal is directly related to such objective.

Table I provides the 11 corporate goals related to e-Government and, intrinsically, to delivery of U-services. These goals have been adapted from [7]:

1. Value for stakeholders from the investments in e-Government
2. Portfolio of U-services
3. Risks of managed business
4. Compliance of laws and external rules with regard to e-Government
5. Orientation towards citizens
6. Continuity of U-services
7. Optimization of costs in delivery of U-services
8. Optimization of business processes involved in delivery of e-Government services
9. Compliance of internal policies and procedures related to delivery of e-Government services
10. Trained and motivated staff
11. Innovation culture in e-Government services, especially in the U-services

On the other hand, Table II shows the 12 proposed security goals, which have been adapted from [17]:

1. Alignment of the information security towards the business.
2. Contribution of information security to the compliance of e-government related regulations
3. Business risks regarding information security and compliance managed.
4. Top Management's commitment to decision-making related to information security of U-services.
5. Delivery of secure U-services according to business requirements
6. Adequate use of applications and information and other technologies for U-services development.
7. Design of appropriate U-services to citizens' needs
8. Optimization in the use of information, resources and capabilities of ITs in e-government services, especially U-services.
9. Adequate delivery of U-services to meet citizens' needs and compliance of the business requirements.
10. Compliance of security policies and current regulations in U-services
11. Skilled and motivated staff responsible for information security.
12. Knowledge, awareness and training in information security as part of the innovation process in delivery of e-government services.

The *so-called goals cascade* proposed by COBIT in order to conduct the respective alignment between business and security [18] will depend on each particular company and on their services provided as a part of its e-government. The goal cascade is not included in our research for an organization, however we do recommend it.

D. Information Security Process reference model (ISPRM)

As the next component, our research has put forward a series of processes both for government and information security management specific for development, acquisition, and maintenance of U-services.

After a first division by government processes and management processes, four domains of security management have been determined: planning and organization, acquisition and implementation of U-government, delivery of U-services and monitoring of U-services. Below are the definitive processes listed in Table II.

Government Processes:

1. Establish and maintain over time government structures for information security
2. Make sure risk optimization includes information security risks in e-government services
3. Secure resources optimization needed for establishing the information security government and its continuity over time

Management processes of U-Services' information security:

Planning and organization domain:

4. Manage and maintain the information security management framework
5. Prepare and maintain the information security strategy
6. Define the Ubiquitous architecture for services corresponding to e-government.

TABLE I.
CORPORATE GOALS IN EUFRAME-SECURITY

Balance Score Card Dim.	Corporate Goal	Obj i.	Obj ii.	Obj iii.	Obj iv.	Obj v.
Financial	1. Value for stakeholders from e-Government Investments	P			P	
	2 . U-services portfolio	S			P	P
	3. Managed risks		P	S	S	
	4. Compliance with laws and regulations related to external e-Government			P		
Client	5. Citizen orientation			S		P
	6. U-services continuity	S		P	P	S
	7. Cost optimization providing U-services	P		S	P	S
Internal	8. Optimization of business processes involved in provision of e-Government			S	P	S
	9. Compliance with internal policies and procedures related to provision of e-Government			P	S	S
Learning and knowledge	10. Personal prepared and motivated		P	S	P	
	11. Culture of innovation in e-Government services and in particular in the U-services		P	S	P	S

TABLE II
GOALS RELATED TO INFORMATION SECURITY IN EUFRAME-SECURITY

Balance Score Card Dim.	Information Security Goal	Obj i.	Obj ii.	Obj iii.	Obj iv.	Obj v.
Financial	1. Alignment of the information security towards the business	P			P	
	2. Contribution of information security to the compliance of e-government related regulations		S	P	S	
	3. Business risks regarding information security and compliance managed		P	P	S	
	4. Top Management commitment to decision-making related to information security of U-services	S			P	S
Client	5. Delivery of secure U-services according to business requirements		S	S	P	P
	6. Adequate use of applications and information and other technologies for U-services development		S	S	P	P
Internal	7. Design of appropriate U-services to citizens' needs		S	S	P	P
	8. Optimization in the use of information, resources, and capabilities of ITs in e-government services, especially U-services.	S			P	S
	9. Adequate delivery of U-services to meet citizens' needs and compliance of business requirements.			S	P	P
	10. Compliance of security policies and current regulations in U-services		S	P	S	
Learning and knowledge	11. Skilled and motivated staff responsible for information security		P	S	P	
	12. Knowledge, awareness and training in information security as part of the innovation process in delivery of e-government services		P	S	P	S

7. Manage U-services portfolio
8. Manage service level agreements (SLA) of U-services
9. Manage information security risks in U-services
10. Manage risks of non-compliance in U-services
11. Manage information security in the process of designing, developing, acquiring, and maintaining U-services within the e-government.

services based on this type of aplications. The list of procedures is as follows:

Governance procedures for the implementation of government processes[4].

- Define information security policies
- Determine the people responsible for the information security across all the organization

TABLE III
INFORMATION SECURITY PROCESS REFERENCE MODEL (ISPRM)

Government	1. Alignment of the information security towards the business	Monitoring U-services
	2. Contribution of the information security to the compliance of the e-government related regulations	19. Assess performance of U-services
	3. Business risks regarding information security and compliance managed	20. Assess compliance of information security regulations of U-services
Planning and Organization	4. Manage and maintain the information security management framework	Acquisition and implementation of U-government
	5. Prepare and maintain the information security strategy	12. Manage U-services implementation projects
	6. Define the Ubiquitous architecture for the services corresponding to the e-government	13. Define information security requirements at e-government structure level with emphasis on U-services
	7. Manage U-services portfolio	14. Manage availability and capacity of U-services
	8. Manage service level agreements (SLA) of U-services	15. Manage information assets taking part in U-services
	9. Manage information security risks in U-services	Delivery de los U-services
	10. Manage risks of non-compliance in U-services	16. Manage appropriate operation of U-services
	11. Manage information security in the process of designing, developing, acquiring, and maintaining U-services within the e-government	17. Manage problems and incidents of security with U-services
18. Manage continuity of U-services operations		

Acquisition and implementation of U-government domain:
12. Manage U-services implementation projects
13. Define information security requirements at e-government structure level with emphasis on U-services
14. Manage availability and capacity of U-services
15. Manage information assets taking part in U-services

Delivery of U-services Domain:
16. Manage appropriate operation of U-services
17. Manage problems and incidents of security with U-services
18. Manage continuity of U-services operations

Monitoring of U-services Domain
19. Assess performance of U-services
20. Assess compliance of information security regulations of U-services.

E. Implementacion Guide

The guide provides a series of procedures to implement the above listed processes. Our proposal focuses on transaction mobile applications dealing with information of a personal nature (Personally identifiable information – PII o Sensitive Personal Information - SPI), that is why proposed procedures lay emphasis on security and compliance of

- Conduct a risk management methodology at an organizational level, including information security risks.
- Determine the people in charge of conducting the risk analysis including information security risk analysis.
- Incorporate the resources deemed necessary into the budget to establish and maintain the information security government
- Prepare the electronic government plan
- Define e-government structures necessary for delivery of U-services
- Adjust e-government structures to comply with the Peruvian National Police of the 2013 – 2017 Electronic Government.

Below are the procedures for management processes within the security Planning and Organization domain:

- Define a framework for the information security management within the e-government structures.
- In the business strategy and information technology plans define information security

[4] Each procedure may include a series of related projects to be executed and in doing so achieve a complete related process(s)

strategies for e-government structures and services.
- Define U-services as a part of the e-government plan.
- Set up a management mechanism for IT services including U-services.
- Conduct the risk analysis including information security risks of U-services.
- Define Peru's Open Government Action Plan (Open Data Plan AGA) for 2015-2016
- Design an information security management system (ISMS) in accordance with ISO 27001 and ISO 27002 standards in order to comply with the mandatory use of the Peruvian Technical Standard "ISO NTP/IEC 27001:2014 Information Technology. Security Techniques. Information Security Management Systems. Requirements 2nd Edition"

Below are the procedures for management processes within the Acquisition and Implementation of U-government domain:
- Define a framework for projects management of acquisition, implementation, and deployment of U-services.
- Define information security requirements for outsourcing, which supply service assets of U-services or complete delivery.
- Identify personal data sources held and managed, and comply with data privacy regulations.
- Define security requirements and those responsible for compliance of Personal Data Protection Law N° 29733.
- Implement security controls needed for U-services requiring use of signatures and digital certificates for citizen's authentication.
- Define security requirements and those responsible for compliance of Digital Signatures and Certificates Law N° 27269.
- Define security requirements and those responsible for compliance of Law N° 29985 of Electronic Money as a financial inclusion tool.
- Maintain service level related to availability and capacity of U-services.
- Mantain service assets involved in delivery of U-services.

Below are the following procedures for management processes within the Delivery of U-services domain:
- Deliver U-services.
- Set up a help desk for incidents and problems management of the information security of e-government services, including U-services.
- In the business continuity plans and information technologies continuity plans include procedures to maintain continuity of U-services deemed critical.

Finally, below are the procedures for management processes within the domain Monitor U-services,:
- Set up and maintain an internal control system.
- Define metrics and performance indicators of U-services.
- Define metrics and satisfaction indicators of citizens in the use of U-services.
- Conduct measurements of all metrics and indicators of U-services.
- Identify non-compliance of information security within U-services.

F. Good Practices in the Implementation Guide

The guide is based on a series of good practices in which ISO 27000 standards are the most important ones. Table 4 shows the mapping among the above proposed procedures for each domain in line with clauses of the ISO 27002 standard [19].

IV. CONCLUSIONS

The lack of frameworks for the implementation of information security governments results in non-compliance of relevant regulations by local and municipal governments, above all in data privacy matters.

The proposed eUframe-security framework provides a basic guide for consolidating the information security government, thus filling the procedural gap to address the U-government needs.

Next step (which is part of the future work of this paper) is to establish a testing mechanism to validate the model.

Table IV
Mapping ISPRM procedures versus ISO 27002

Domains	Implementación Guide Procedures	Clauses ISO 27002
Government	· Define information security policies.	**5**
	· Determine the people responsible for the information security across all the organization.	**6**
	· Conduct a risk management methodology at an organizational level, including information security risks.	**6**
	· Define the people in charge of conducting the risk analysis including information security risk analysis.	**6**
	· Incorporate the resources deemed necessary into the budget to establish and maintain the information security government	**6, 7, 8**
	· Prepare the electronic government plan	**6**
	· Define e-government structures necessary for delivery of U-services	**6**

	· Adjust e-government structures to comply with the Peruvian National Police of the 2013 – 2017 Electronic Government.	**6**
Planning and Organization	· Define a framework for information security management within e-government structures.	**5, 6**
	· In the business strategy and information technology plans define the information security strategies for e-government structures and services.	**6**
	· Define U-services as a part of the e-government plan.	**6**
	· Set up a management mechanism for IT services including U-services.	**6**
	· Conduct the risk analysis including information security risks of U-services.	**6**
	· Define Peru's Open Government Action Plan (Open Data Plan AGA) for 2015-2016	**6**
	. Design an information security management system (ISMS) in accordance with ISO 27001 and ISO 27002 standards in order to comply with the mandatory use of the Peruvian Technical Standard "ISO NTP/IEC 27001:2014"	**5-18**
Acquisition and implementation	· Define a framework for projects management of acquisition, implementation and deployment of U-services.	**8, 14, 15**
	· Define information security requirements for outsourcing which supply service assets of U-services or complete delivery.	**7, 14, 15**
	· Identify personal data sources held and managed, and comply with the data privacy regulations.	**8, 9, 10**
	· Define security requirements and those responsible for compliance of Personal Data Protection Law N° 29733.	**18**
	· Implement security controls needed for U-services requiring use of signatures and digital certificates for the citizen's authentication.	**18**
	· Define security requirements and those responsible for the compliance of Digital Signatures and Certificates Law N° 27269.	**18**
	· Define security requirements and those responsible for compliance of Law N° 29985 of Electronic Money as a financial inclusion tool.	**18**
	· Maintain service level related to availability and capacity of U-services.	**12**
	. Maintain service assets involved in delivery of U-services.	**8, 12**
Delivery	**· Deliver U-services.**	**12**
	· Set up a help desk for incidents and problems management of the information security of e-government services, including the U-services.	**12, 16**
	. In the business continuity plans and information technologies continuity plans include the procedures to maintain continuity of the U-services deemed critical.	**17**
Monitoring	**· Set up and maintain an internal control system.**	**18**
	· Define metrics and performance indicators of U-services.	**18**
	· Define metrics and satisfaction indicators of citizens in the use of U-services.	**18**
	· Conduct measurements of all metrics and indicators of U-services.	**18**
	. Identify non-compliance of information security within U-services.	**18**

Abstract— **Website quality evaluation is an important research task. Evolution and a growing set of available methods are observed. The article presents the authors' evaluation methodology of the quality of websites named PEQUAL. The formal foundation of the proposed methodology is the broadening of the classical EQUAL method with aspects of preference modelling and evaluation aggregation used in Multi-Criteria Decision Analysis (MCDA). Its empirical verification has been carried out for top e-commerce websites. The conducted research has revealed significant practical possibilities of analysis and interpretation of obtained final rankings.**

I. Introduction

ELECTRONIC commerce is one of the most prominent areas of e-business with increasing sales year by year and estimated 28.3 trillion dollars of worldwide retail sales in 2018 [1]. Estimation of digital buyers shows that 47.3 percent of global Internet users will purchase products online in 2018 what creates an increasing interest in this area [2]. E-commerce is dependent on the development of new technologies and with the growth of infrastructure, improvements of hardware and software accessibility and has changed its character since first applications [3]. The dynamic development of online sales platforms [4] and dedicated user interfaces [5] together with supporting technologies like personalization engines [6], recommending systems [7], online payment systems [8] and online marketing systems dedicated to electronic commerce [9] is observed.

The constant growth of a number of Internet stores intensifies competition between entities that offer goods and services online [10]. To improve results and maximize profits entrepreneurs use sophisticated analytic software [11], web mining techniques [12] or conversion maximization systems [13]. Together with the market growth more and more important is identification of factors affecting the performance of electronic commerce systems and customer loyalty [14]. Key elements of strategies are based on building trust [15], improving the quality of the systems [16], levels of security and privacy [17], their accessibility [18], development of international versions [19], solving cultural issues [20] and implementing new features towards consumer satisfaction and web usability [21].

For studying the quality and usability of e-commerce services and similarly for studying various types of Internet services, different types of methods based on the identification of key factors [76] influencing the perception of a given service by users are employed i.e. [22]. The methods differ especially in terms of assessment criteria and theoretical foundations on which they are based [74] [75]. Since evaluation of websites is a multiple-criteria problem, in the literature one can see attempts of using Multi-Criteria Decision Analysis (MCDA) methods for evaluating websites.

The objective of this article is to construct a quality assessment model of the most popular world e-commerce websites. An attempt to combine selected classical methods for evaluating the quality of websites (e.g. eQual) with a formal background used in the MCDA methodology constitutes a methodological research basis, which at the same time is the authors' contribution. However, it is assumed that additional application of the MCDA methodology will make it possible to carry out a wide analysis and verification of, obtained in the research, website rankings, and of users' preferences. This issue is of great importance and website quality evaluation methods used nowadays allow conducting this type of analyses only to a limited extent. Paper is organized as follows: Section II includes literature review, Section III presents methodological framework of proposed approach, Section IV presents results from the empirical study with conclusions within the Section V.

II. Literature review

A. Website evaluation methods

Website evaluation methods described in the literature employ different quality models, consequently, they differ in criteria used as well their quantity and structure [23]. In order to obtain an opinion on websites, they most often use questionnaires, and grades are expressed on an n-degree Likert scale [24]. Among website quality evaluation methods one can distinguish presented with references and key characteristics in the Table I : eQual, Web Portal Site Quality, Ahn method, SiteQual, Website Evaluation Questionnaire, Website Quality Model, E-S-QUAL and E-RecS-Qual,WAES.

The eQual method was constructed on the basis of Quality Function Deployment which is a structured process ensuring means of identification and providing users' opinion on the quality of a product on subsequent stages of its manufacturing process [25]. The eQual method was successfully used to evaluate: e-commerce [26], e-government [25] [27] [28], university [29] and WAP [30] websites.

Web Portal Site Quality came into existence on the basis of a Technology Acceptance Model. The TAM is to explain the influence of perceiving, by the user, information system characteristics on his or her acceptance of the given system. It is based on two quality dimensions, that is, perceived usefulness and perceived ease of use [31]. The Model of Information Systems Success by DeLone and McLean includes information quality and system quality [32][33]. The WPSQ method is used in evaluating portals delivering broadly defined information and services [34].

The Ahn method, similarly to Web Portal Site Quality, was devised with the use of Technology Acceptance Model [35]. The first version of the Ahn method was to study the influence of trust to bank websites on the acceptance by users [36]. When working on the method, the original TAM model was extended with subsequent elements which were important from the perspective of the Internet: information quality, system quality and service quality. These elements were borrowed from an extended Model of Information Systems Success of DeLone and McLean [37][38]. Also, quality characteristics regarding trade: the quality of a product and its delivery were added [39].

The SiteQual method [40] came into being as a combination of the SERVQUAL [41] and Data Quality [42] models. The SERVQUAL model was to reflect service quality, whereas Data Quality was to be responsible for information quality. This model was constructed on the basis of questionnaires concerning music e-commerce websites [43].

When preparing the Website Evaluation Questionnaire method, criteria used in the Website User Satisfaction (WUS) model were used [44]. As in WUS, in every characteristic there is one negative criterion, which is used to verify reliability evaluation [45]. This method came into existence in order to examine e-government websites, but it can also be employed to assess other types of websites which are to provide their users with knowledge and information [46].

The E-S-QUAL and E-RecS-Qual methods stem from the SERVQUAL method used for studying and evaluating service quality [47]. They are a result of adjusting the SERVQUAL scale to the needs of service quality assessment on the Internet. Here, some evaluation criteria in the SERVQUAL model were kept and new criteria essential for determining e-service quality were introduced. The E-S-QUAL method contains the core of the e-SERVQUAL scale, that is criteria perceived by customers who do not have questions and problems related to e-services. On the other hand, the E-RecS-QUAL method comprises additional criteria which are vital when the user encounters problems when using services. These methods were used to evaluate service quality on bank websites [48] as well as e-commerce [49] websites.

While preparing the Website Quality Model method [50], Kano's quality model was used, in which there are defined three levels of customers' expectations with regard to the quality of a product or a service: basic, performance, and exciting [51]. The evaluation of news websites, among other things, CNN.com [52], was carried out by means of this method.

The WAES (Website Attribute Evaluation System) method is designed for assessing office and administration websites. It consists of two groups of characteristics describing transparency and interactivity of a website. An expert's evaluation on a binary scale is employed in the method [53].

In Table I one can see characterized individual quality evaluation methods of websites. For methods using questionnaires it is assumed that the number of users evaluating a website should at least amount to 30 [54].

The most interesting method, out of all analyzed ones, seems to be eQual, which is characterized by the highest formalization level and which in many cases proved to be highly universal. The method is based on 22 criteria in the form of questionnaire questions. When evaluating, a Linkert scale, which ranges from 1 to 7, is used. Weights of individual criteria are determined in the same way. Apart from criterial evaluation, respondents also provide overall evaluation of a website. On the basis of this assessment, the reliability of partial opinions of every user is verified [27]. When a collection of questionnaire results has been gathered, an analysis of the questionnaires is conducted with regard to reliability and internal cohesion. To determine the reliability of results of a questionnaire in the eQual method, Cronbach's alpha is employed. It is assumed that the reliability of results is appropriate, if the value of coefficient alpha amounts to at least 0.6 [28]. In the method the result of evaluation is the European Quality of Government Index (EQI) calculated on the basis of the formulas (1), (2), (3) and (4):

$$EQI = \sum_{k=1}^{m} EQI_k / m \tag{1}$$

$$EQI_k = \left(Score_k / Max_k\right) \cdot 100\% \tag{2}$$

$$Score_k = \sum_{i=1}^{n} (o_i(k) \cdot w_i(k)) / n \tag{3}$$

$$Max_k = \sum_{i=1}^{n} (7 \cdot w_i(k)) / n \tag{4}$$

where: m – the number of criteria, n – the number of polled users, $o_i(k)$ – the evaluation of a website with regard to the n-th criterion, given by the i-th user, $w_i(k)$ – the weight of the k-th criterion given by the i-th user.

The problem related to a practical use of the method is to gain weights of criteria by means of questionnaires, because explicit declaration of users' preference may generate errors in the research [55]. This is also confirmed by the authors' research, in which it was demonstrated that weights of crite-

TABLE I.
CHARACTERISTICS OF SELECTED METHODS OF WEBSITE QUALITY ASSESSMENT

Method	Application	No of criteria	Method determining weights of criteria	Assessment scale	Method of examining websites	No of evaluators	Theoretical basis of method	Verification of solution	Reference

ria received by means of questionnaires lead to incorrect decision solutions [56][57].

B. Evaluation of websites with the use of MCDA methods

Apart from "classical" methods, discussed in part A, in the literature there are also attempts at employing MCDA methods for evaluation. It is justified since assessment of websites is a multi-criteria problem, in which one needs to take into consideration many dimensions of quality [58]. For instance, Lee and Kozar [59] used the AHP method to evaluate e-tourist and e-commerce websites. Chmielarz widely uses his original scoring method to asses a wide range of websites, i. a. e-commerce as well as e-banking [60][61][62]. Sun and Lin [63] evaluated e-commerce websites with the use of the fuzzy TOPSIS method. Del Vasto-Terrientes et al. [64] evaluated tourist destination websites by means of a new ELECTRE-III-H method. Furthermore, in the works of Lin [65] as well as Kong and Liu [66] in the fuzzy AHP method was used to determine the significance of quality evaluation criteria of e-learning and e-commerce websites. To assess websites, hybrids of various MCDA methods are also used. In the paper by Bilsel et al. [67] determining the weights of criteria was conducted by means of the AHP method, whereas a ranking of hospital websites was constructed with the use of the fuzzy Promethee method. Similarly, Kaya [68] employed the fuzzy AHP method to define weights of criteria, and used the fuzzy TOPSIS method to construct an e-commerce website ranking. A combination of MCDA methods was also used by Huang et al. [69], where solutions were compared with the use of, among other things, Simple Additive Weighting, Multiplicative Exponent Weighting, TOPSIS, concordance and discordance analysis methods. Weights of criteria in above-mentioned were determined by means of the OWA method.

The analysis of application of MCDA methods in website evaluation indicates that most of them used questionnaires to collect assessments of websites. As for determining weights of criteria, pairwise comparison matrices and the AHP method are most often used for this purpose. Since a significant number of such comparisons might be problematic, a limited number of criteria are usually used. It should be emphasized that for constructing a model of criteria only a few papers used theoretical bases identifying the need for presenting both specific quality measures and criteria. Moreover, only in some papers the sensitivity/robustness analysis of results were carried out. However, applying MCDA methods to evaluate websites has a greater potential than just constructing a ranking. This can be proved by a model of a decision process defined by Guitouni [70] wherein critical steps are exploitation and recommendation stages. On the operation stage, one can conduct the analysis of an obtained solution, such as examining its stability [77] [78] or the analysis of decision-makers' preference.

III. PEQUAL Methodological Framework

A. Selection of an MCDA method for evaluating websites

Every decision problem can be attributed to the problematics the decision problem deals with. The problematics result from the aim which is expected from the decision process [79]. In the problematics of description (P.δ), preparing a description of potential actions and the identification of a criterion or a family of criteria pose a problem. In the problematics of choice (P.α), supporting the decision-maker is concentrated on selecting a small number of "good" variants. The problematics of sorting (P.β) is concentrated on attributing a variant to one of classes available. Finally, in the problematics of ranking (P.γ), a ranking of decision variants according to defined criteria is prepared [80].

The MCDA method, which is used in evaluating websites, should especially take into consideration indifference and preference relations, which will make it possible to differentiate the quality of evaluated websites. Moreover, it should not allow an indifference relation to appear, since it is essential that the website ranking is total. Taking into account acceptable compensation criteria, it is reasonable to assume that certain website elements can convince users to use it, even though in some respects it falls short of expectations. Therefore, compensation of low-marked criteria by high-marked ones seems to be legitimate. Measuring data, on which the method will work, cannot be determined as reliable, since these are subjective users' opinions expressed in questionnaire on a quantitative scale. Nevertheless, such data unreliability may be expressed by defining a proper value of an indifference threshold. The problematics considered by individual MCDA methods is of importance, because a method ought to consider, first of all, the problematics of a ranking. It allows putting websites in order according to their synthesized quality, expressed on a quantitative scale. What is more, one can consider methods comprising also the problematics of description, what allows analyzing the obtained solution in a broader way. For the reason that quality is assessed by many users, a method should also offer a group evaluation mechanism. The analysis of characteristics and abilities of individual MCDA methods [71][72][73] with relation to the requirements discussed points out to the fact that the Promethee II [88] method along with its group development, i.e. Promethee GDSS, can be used in evaluating websites.

B. Framework of website evaluation

The authors' methodology of website quality evaluation named PEQUAL (Promethee - eQual) is based on the eQual method, which has its foundations in Quality Function Deployment. To do empirical research at first, questionnaires were collected from 41 users. In the research sample, there were computer literate users who are experienced in doing the shopping online. All of them evaluated 10 e-commerce websites: Alibaba, Amazon, Apple, BestBuy, eBay, Macy's, Rakuten, Staples, Target, and Walmart. The reason for selecting the e-commerce websites was the result of analysis of valid rankings of top e-commerce websites presented, among other things, in [81], [82], [83], [84], [85]. Thus, 410 questionnaires were collected which then were verified in terms of consistency reliability and Cronbach's alfa was determined. Questionnaire evaluation was conducted with the use of criteria and an evaluation scale of the eQual method and the results of the questionnaires were aggregated with the use of the Promethee method. Also, on the basis of this method, the broad analysis of the obtained solution was carried out. The research took into consideration two scenarios of aggregation of partial evaluations in a overall ranking. The input data had been obtained in the questionnaires. In the first scenario, partial evaluations were averaged, and next, the aggregation of mean criterial evaluations into a overall evaluation, with the use of the Promethee II method, was conducted. The second scenario consisted in determining individual rankings by means of the Promethee II meth-

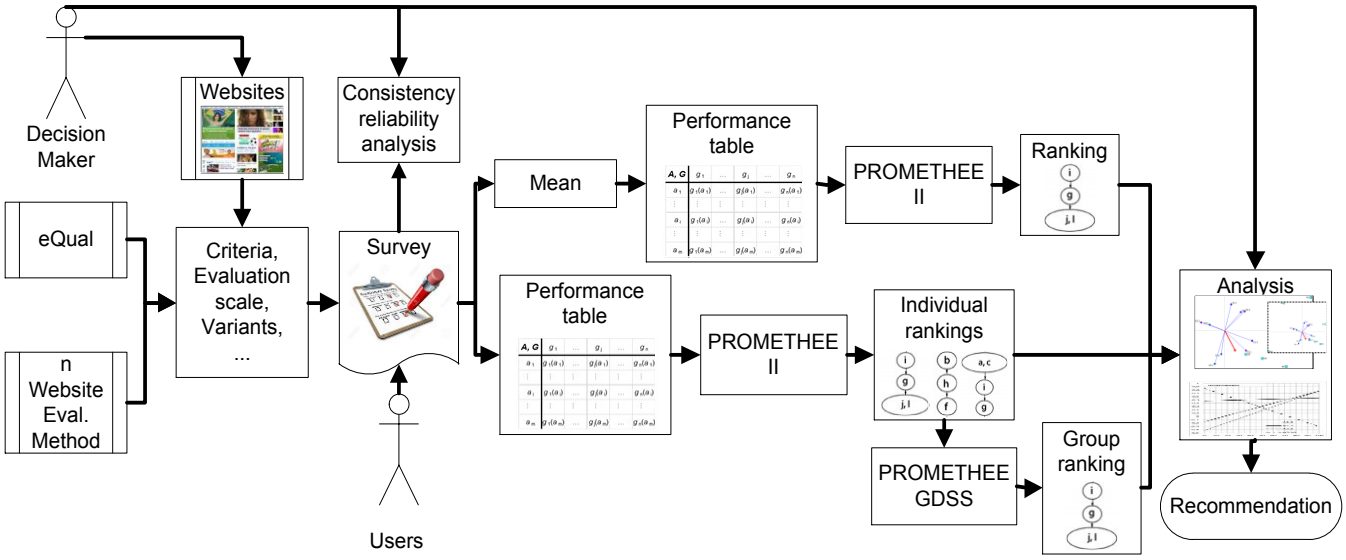

Fig. 1 PEQUAL methodological framework of website evaluation

od on the basis of partial evaluations and then aggregating individual rankings in a group ranking by means of the method Promethee GDSS. After generating rankings, the analysis of the solution obtained was carried out in every scenario with the use of the GAIA method and the analysis of ranking robustness to the changes of weights of criteria, which are an integral part of the Promethee method. On the grounds of the transparency of the conducted analysis, it was assumed that the weights of all criteria are equal. Moreover, it was assumed that the partial evaluations obtained in the questionnaires can be characterized by some degree of uncertainty. Therefore, an application of various indifference variants was considered, and consequently the influence of minor errors in partial evaluations on the obtained results was eliminated. The presented practical approach is depicted in Figure 1. What is more, at first, the aggregation of questionnaire results into a final evaluation with the use of the eQual method was carried out. This was aimed at conducting a comparative analysis of obtained results with reference to the results of eQual.

IV. Results

A. Empirical research

After gathering the results of the questionnaires, their consistency reliability analysis was carried out. The value of Cronbach's alpha obtained in the research amounted to 0.95. All scores of the consistency reliability analysis, including the value of Cronbach's alpha for individual groups of criteria, are presented in Table II. The values of Cronbach's alpha indicate high reliability of the conducted questionnaire, since it exceeds the boundary value of 0.6 [28].

Next, in accordance with the eQual method a overall value of eQual Index and values obtained for individual criteria and their groups were determined. The scores of the total value and groups of criteria are depicted in Table III.

In another research the scores of questionnaires were averaged and calculations were made with the use of the Promethee II method. Average criterion evaluations of questionnaire scores, which constitute a performance table, are depicted in Table IV (average values are in accordance with values used for the eQual method). In the Promethee II method for each criterion a preference model with a preference V-shape function, for which an indifference threshold q=0 and a preference threshold p=7, was used. A preference direction was maximized. The selected preference model was assumed in order to reflect, as accurately as possible, the model used in the eQual method. A website ranking obtained according to the Promethee II method, with the use of the given preference model, is presented in Table V. The sequence of variants in the obtained ranking is in accordance with the sequence in the eQual method.

B. Graphical analysis of Promethee solution

After determining the ranking, its analysis, based on the GAIA methodology, was done. Figures 2-4 depict the scores of this analysis separate for: clusters (Figure 4), groups (Figure 3) and individual criteria (Figure 2).

TABLE III.
ASSESSMENT RESULTS OF WEBISITES ACCORDING TO EQUAL METHOD

Website	Evaluation Quality Index									
	Alibaba	Amazon	Apple	BestBuy	eBay	Macy's	Rakuten	Staples	Target	Walmart
Usability	70.30%	78.66%	79.62%	70.56%	82.93%	71.17%	70.47%	69.08%	68.38%	72.65%
Site design	69.25%	75.09%	83.01%	62.46%	69.34%	68.21%	62.28%	65.68%	60.80%	67.16%

	C21	4.780	5.268	5.561	4.829	5.293	4.610	4.268	4.390	4.610	4.732

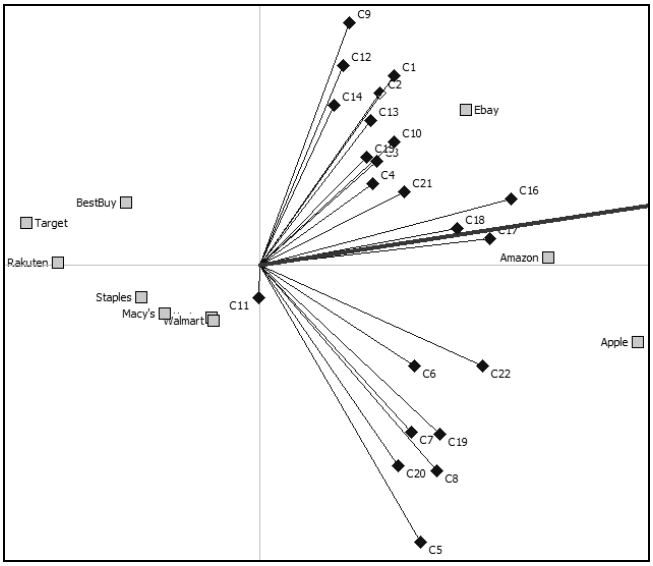

Fig. 2 GAIA analysis for criteria

The analysis of Figure 2 demonstrates that almost all criteria, except C11, support three leading variants in the ranking, i.e. Apple, Amazon and eBay. This observation is confirmed by a detailed analysis of numbers contained in Table IV. Moreover, a criterion C11 is in conflict with C9, C12, C14, C1, C2, C13 and also partially with subsequent criteria placed in the first quarter of the system of coordinates. It means that variants which are highly evaluated with regard to the criterion C11 get lower evaluation in terms of other criteria mentioned. Furthermore, the length of C11 vector points out that this criterion has the least influence on the final website ranking.

An analysis of Figure 3 allows finding out that users evaluate Usability and Information Quality of individual websites in a similar way. In other words, if an examined website gets high marks for criteria in the Usability group, it is usually highly marked with regard to criteria in the Information Quality group. However, evaluations of criteria in the Usability and Site Design groups are independent of each other. This piece of information is important, because criteria in the groups belong to one cluster of criteria, therefore, their evaluations should usually be similar to one another. Similarly, criteria evaluations of Empathy and Trust, which also belong to one cluster, are independent of each other. Moreover, one can state that the most significant influence on the final ranking have criteria belonging to the Site Design and Usability groups, since their vectors are longest. Furthermore, the final ranking of websites most strongly overlaps with the criterial evaluations of the Trust group.

The presentation of clusters of criteria (Figure 4) on the GAIA plain indicates that evaluations of variants with regard to criteria belonging to the Usability and Service Interaction clusters and they are independent of the Information Quality cluster. It may seem contradictory to the conclusion drawn

when analyzing Figure 3 which expresses the similarity of evaluations with regard to the Usability and Information Quality criteria groups. However, one needs to bear in mind that the Usability cluster contains the Usability and Site Design criteria groups. When considering the impact of individual criteria clusters on the final ranking, it should be noted that this ranking is, to the highest degree, dependent on the criteria belonging to the Information Quality and later Service Interaction clusters. The criteria belonging to the Usability cluster have the lowest influence on the ranking.

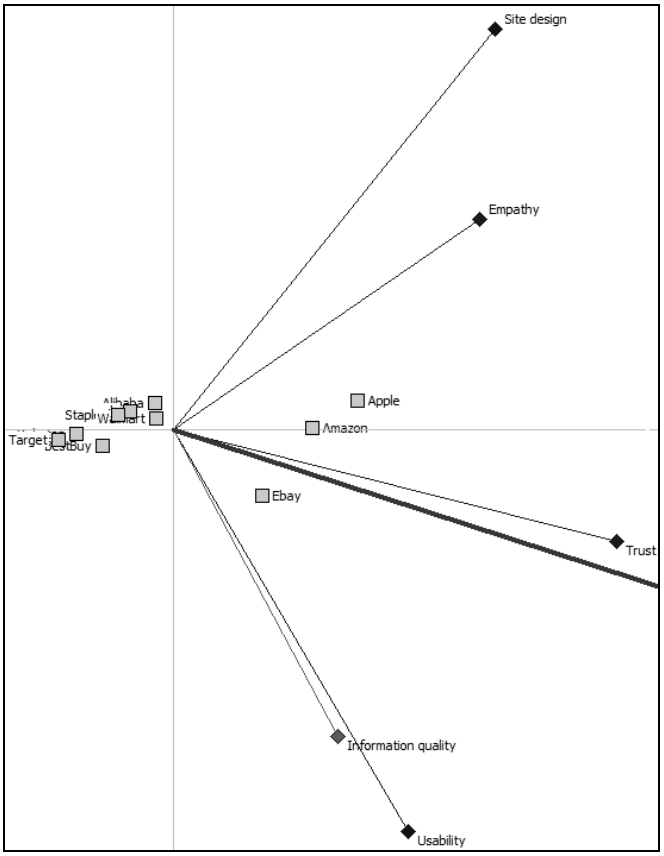

Fig. 3 GAIA analysis for groups of criteria

C. Robustness analysis of solution

Apart from the GAIA analysis, also, the robustness analysis, taking into consideration changes in weights of criteria, of the ranking was carried out. Figure 5 depicts, one by one, the scores of the analysis for weight changes of subsequent criteria clusters, i.e. Usability, Information Quality and Service Interaction. Also, Figure 5 presents the robustness analysis of the ranking for changes of weights of criteria belonging to the Usability cluster. It must be explained that the weight changes regarded all clusters, for instance, when a weight of Usability was 0, the criteria in other clusters obtained a weight of 7.14%, whereas when a weight of Usability was 100%, all of its criteria obtained a weight of 12.5%. Analogically, weights for the robustness analysis of the Information Quality and Service Interaction clusters were determined. The results of the robustness analysis indicate that three top positions in the ranking are very stable, because only increasing weights of criteria in the Information Quality cluster above 80% (that is over 11.5 for each criteria of the cluster) may cause changes on these positions. Therefore, one can assume with the high level of probability that, independent of weights of criteria, the obtained ranking is correct.

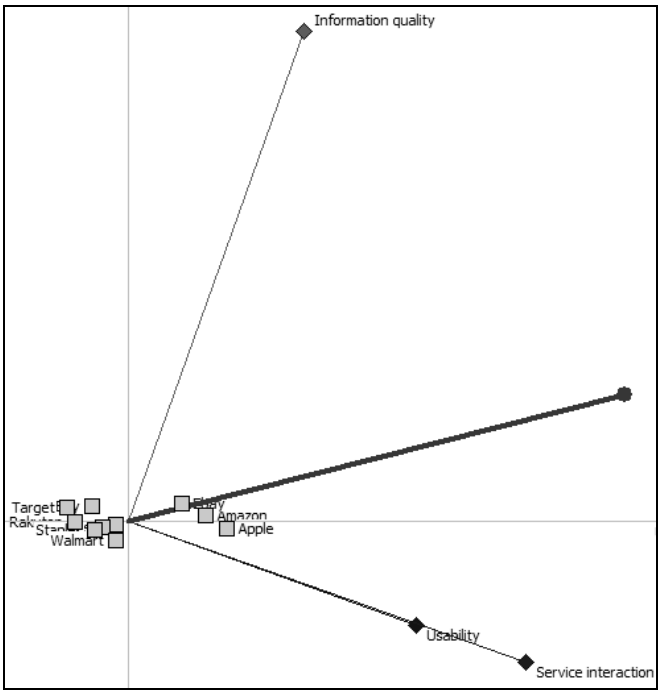

Fig. 4 GAIA analysis for clusters of criteria

D. Uncertainty analysis

The next step in the conducted analysis was to verify the influence of uncertainty of partial evaluations on the sequence of variants in the ranking. Therefore, a new ranking of variants was determined on the basis of a modified preference model, in which a preference function V-shape with an indifference area, where the indifference q=1 and preference p=7 thresholds were used, was applied. Using the indifference threshold was to eliminate the influence of potential mistakes in users' evaluation, which consists in considering one website slightly better than another one. It should be noted that the threshold q=1 for averaged values provides a

TABLE V.
RANKING OF WEBSITES BASED ON PROMETHEE II AND AVERAGED CRITERIA EVALUATIONS

Website	Alibaba	Amazon	Apple	BestBuy	eBay	Macy's	Rakuten	Staples	Target	Walmart
ϕ_{net}	-0.0137	0.0822	0.1037	-0.0343	0.0629	-0.0272	-0.0559	-0.0380	-0.0607	-0.0191
Rank	4	2	1	7	3	6	9	8	10	5

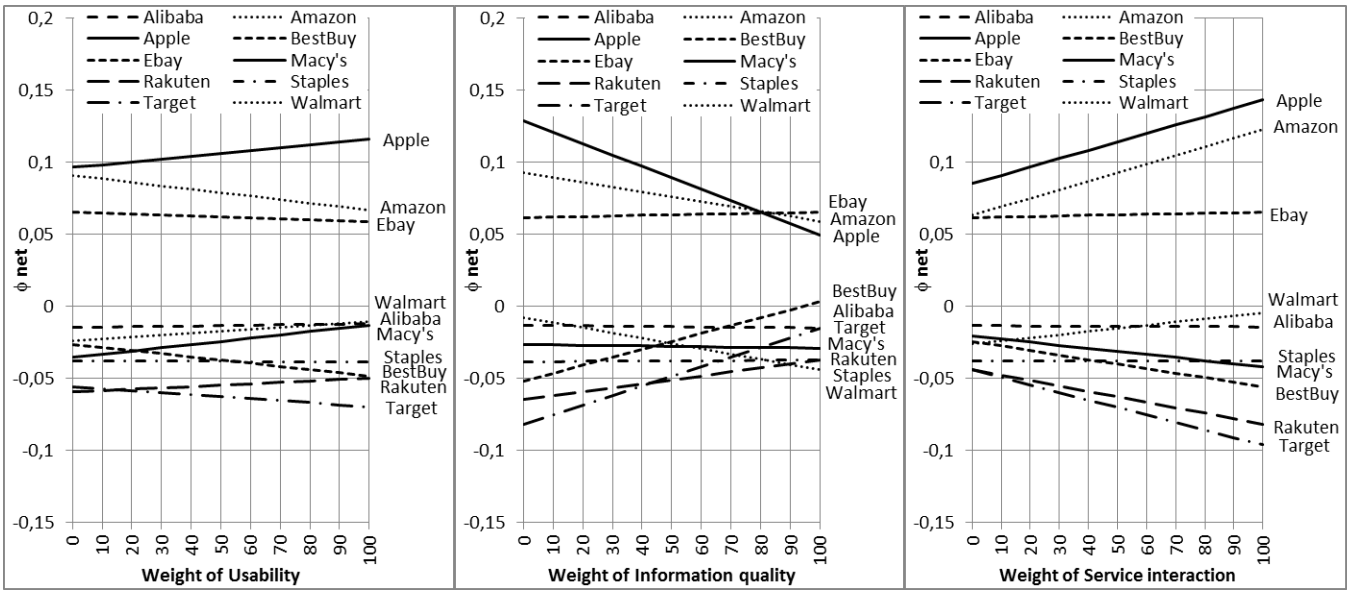

Fig. 5 Robustness analysis of criteria clusters

significant error of margin, and with regard to many criteria almost all variants are considered indifferent. However, the ranking obtained has variant shifts only on further positions. To be more specific, there was a change of websites on positions 4 and 5 (Alibaba a Walmart) as well as 7 and 8 (Staples and BestBuy). Therefore, it can be assumed that the basic ranking which was obtained with the use of the Promethee II method is reliable. The ranking obtained with the used of the described preference model is depicted in Table VI.

E. Comparison of averaged ranking with group ranking

Another part of the conducted research consisted in conducting, by means of the Promethee II method, an aggregation of partial evaluations for individual questionnaires and determining individual rankings. They were generated next to the preference model, which had been used for averaged evaluations, i.e. with the preference function V-shape and thresholds q=0, p=7. Later, the individual rankings were aggregated into a group ranking with the use of the Promethee GDSS method. The ranking is presented in Table VII and its analysis indicates that the obtained sequence of websites is the same as in the ranking obtained before, which was based on averaged evaluations, presented in Table V. The values of evaluations ϕ net are also similar.

The next step was to conduct a GAIA analysis for the group ranking. For the reason of clarity, Figure 6 depicts the GAIA plane for 10 respondents.

The projection of decision-makers' preferences on the plane shows that everybody, except DM6, supports to some extent five best websites in the ranking. However, it should be noted that evaluations of users DM7 and DM8 are contradictory, similarly to users DM4 and DM6. Moreover, the highest influence on the final ranking, out of 10 presented users, have DM8, DM9 and DM10, whose vectors are longest. As far as the respondents' individual rankings are concerned, their analysis was carried out analogically to the analysis conducted for averaged evaluations.

V. CONCLUSION

In the proposed approach the multi-stage construction of the model was realized with regard to the criteria taken from the eQual method with the use of the Promethee method (PEQUAL). It extends earlier approaches by introducing MCDA based multi stage evaluation and analyses. In the article, 10 most popular world e-commerce websites were evaluated. On the basis of the presented research, one can state that e-commerce websites most highly valued by users are: Apple, Amazon and eBay. The conclusions were confirmed by verifying the obtained ranking with the use of the analysis of robustness to changes of weights of criteria and examining the influence of evaluations on the final ranking.

Furthermore, the use of the Promethee GDSS method and the GAIA analysis, which is an integral part of the Promethee method, made it possible to indicate users' individual preferences. Also, the GAIA analysis allowed examining mutual dependences between individual groups and clusters of criteria on the basis of graphic data. The interpretation of the GAIA plane is less time-consuming and easier than the analysis of number values of evaluations, and the conclusions drawn on its basis are equally essential [86] [87].

The research framework of the quality of websites presented in the article can be the basis for their evaluation along with the correctness verification of obtained evaluations and preferences of the respondents. As it has been demonstrated in the presented research, this solution is functionally richer than classical MCDA-based methods of website evaluation methods which have been used in the literature to date.

***Abstract*—The main aim of this article is to analyze the use of marketing mechanisms on the Internet. To meet this objective, the authors conducted a study limited to a selected group of individual users - students of the University of Warsaw. The paper presents the characteristics of the application of marketing tools as well as the users' opinion on the usefulness of these tools in broadly defined e-commerce. The article also presents the discussion and the findings of the present study.**

I. Introduction

THE MAIN objective of this paper is to analyze the possibilities of using the Internet on mobile and desktop devices for marketing purposes, under the circumstances of the dynamic development of both mobile devices and mobile applications running on them. This article aims to examine the situation where basic marketing tools are used by clients on the desktop (PC) or portable equipment (e.g. a laptop) as well as the devices combining the advantages of a phone and a computer, i.e. smartphones and tablets.

There are numerous definitions of e-marketing presented by scholars and academics. They are as follows: electronic marketing may be defined as activities of an organization which through applying new technologies, in particular the Internet, uses the potential of the market (Meng X., 2009). Internet marketing is a combination of communication efforts undertaken by organizations, operating both in the physical and virtual markets, to satisfy individual and collective needs in the electronic space, with the application of information technologies, especially the Internet, in order to make a profit (Chmielarz, 2007). It encompasses among other things: the study of the behavior of Internet users, the development of new products as well as e-promotions, e-distribution and e-service. In addition, the definition of e-marketing may be extended to include also the approach which states that it comprises all marketing activities aimed at fulfilling the operational goals via the Internet. From a theoretical point of view, it is a result of a combination of modern marketing, management and risk management theories as well as the application of modern communication technologies (Sun, 2011; Hasan, 2011).

Mobile marketing may be defined as a part of electronic marketing, one of the methods of direct marketing, practiced via mobile devices such as e.g.: cell phones, smartphones, tablets, PDA, MDA and notebooks. In m-marketing the messages with commercial or non-commercial content are communicated with the application of such technologies as SMS, MMS, NFC and others (Hovancakowa, 2011; Bernauer, 2008). It includes also advertising activities taking advantage of mobile phones' functionalities (Wikipedia, 2016). The Mobile Marketing Association defines mobile marketing as any marketing, advertising or promotional activity, targeted at clients and transmitted using a mobile channel (Salo J., Sinisalo J., Karjaluto, 2008).

The phenomena of e-marketing and m-marketing have been examined in numerous studies (ÅőwierczyÅĎska-Kaczor, 2012; Wielki, 2012; Kiba-Janiak M., 2014; Gao T., Sultan F., Rohm A. J., 2010; Roach G., 2009), including those carried out on a large scale (IAB, 2015; InternetStandard, 2015). Nevertheless, the majority of them took place before the most rapid development of smartphone and tablet applications or not takes into account this phenomenon. Fast, or rather rapidly growing, market of new mobile devices and the increasing pace of eliminating older devices from the market results in the fact that for the purpose of this article the authors have applied an additional division between traditional electronic marketing via the devices such as PC and laptop and a new mobile marketing, operated on smartphones and tablets. Unfortunately, in the present research the authors were not able to make a distinction between the traditional electronic marketing on the devices such as personal computers or laptops and mobile marketing used via these devices in browsers (browser marketing) and mobile marketing employed in applications (app-based marketing), because respondents are not always even aware of the distinction. Nevertheless, it allowed evaluating both forms of marketing used on smartphones and tablets.

The authors of the article hoped to indicate certain basic implications concerning the new phenomena impacting the directions of development of mobile marketing. Thus, they undertook a study whose main aim was to analyze the use of e-marketing and m-marketing among the users of different kinds of computer devices providing Internet access. The findings presented in the article constitute a summary report of the research examining a selected group of users in Poland at the beginning of 2016.

II. Research methodology

Due to few and fragmentary studies concerning the sphere of e-marketing and m-marketing applications as perceived by an individual client in national and foreign literature, the present research was based on the authors' own approach [Chmielarz, 2015) consisting of the following stages:

- analysis of a selected group of users on the basis of a quantitative and qualitative survey (CAWI (Computer Associated Web Interview method)),
- making an online version of a questionnaire available on the servers of the Faculty of Management at the University of Warsaw, and subsequent testing and verifying it,
- conducting user surveys,
- analysis and discussion of findings,
- drawing conclusions from the obtained findings on the current state of e-marketing and m-marketing and future directions of their development, based on the opinions of users.

The detailed scope of the survey, which consists of twenty-five questions, divided into five sections, is presented below:

- the place and role of the Internet in marketing,
- the assessment of e-marketing as a source of information about products/services,
- the assessment of the effectiveness of e-marketing media and their acceptance by the client,
- the assessment of the utility of e-marketing from the point of view of a client,
- assessment of m-marketing.

The article presents the findings of the analysis of completed questionnaires. The survey was carried out in March-April in 2016. The selection of the group was not quite random; it was the case of convenience sampling: the respondents were students of part-time and full-time BA and MA studies at the University of Warsaw. The choice of students groups were random. The surveys were distributed electronically, the level of responsiveness slightly exceeded 80%, despite the fact that students constitute a group which is particularly open to all kinds of innovations, especially those related to mobile devices. This group in Poland is the most active buyers in Internet.

A limitation in this sort of selection was an expected high participation of people owning smartphones, tablets, laptops and cell phones - not necessarily of high quality, but with a high usage time. The survey was completed by 130 people, with 106 respondents (81.54% of the sample) who completed the questionnaire correctly in its full form. Among the respondents, there were 65.09% women and 34.91% men. An average age of the respondent was 23.08 years, and the median value was 19 years of age. It is the typical age for the students of first years of part-time and full-time BA studies and the first years of MA studies, the interviewees who were asked to fill in the questionnaire. The oldest of the respondents was 51. Among the respondents, there were 65.09% of only students, 32.08% of working students and 23.89% professionals. Respectively, 66.98% declared having secondary education, and 27.36% of the respondents completed BA studies. Higher education and post-graduate studies were indicated by only 5.66% of the interviewees. Almost 36% of the respondents stated that they reside in cities of more than 500,000 inhabitants, over 12% came from cities of 100-500,000 inhabitants, more than 11% from cities with 50-100,000 residents, almost 21% of the sample were from towns with 50,000 inhabitants, and 19.81% from rural areas. The simplicity of the survey did not cause many distortions in the process of its completion.

III. Data analysis and discussion of findings

Respondents provided answers to twenty-five substantive questions. Here we concentrate on aspect of m-marketing in the frames of e-marketing, but survey had more wide context. The most important findings are listed below.

The first group of questions concerned generally the place and role of the Internet in marketing. Over 95% of respondents said that they use the Internet several times a day, 3.77% at least once a day, and only one respondent stated that he/she seldom uses the Internet.

The most popular device used by the respondents when accessing the Internet is a smartphone (33%), or a smartphone interchangeably with the laptop (32%). The laptop is used by slightly over 11% of students. Almost 8.5% of the survey participants use a personal computer for this purpose. This indicates a significant reorientation of Internet users towards the device which they have learned to use relatively early in life and use it for the longest time, that is, handheld mobile devices, especially a smartphone (the tablet itself is used by only by 3.77% of respondents).

Generally, the Internet is seen as a very good marketing medium by 52% of the respondents, or as a good marketing medium by 33% of the sample. Only 15% of the interviewees perceive the Internet as average or sufficient. Nobody has rated it as unsatisfactory. What lies at the core of such discrepancy between the level of using the Internet, making online purchases and a very good or good opinion on internet marketing? It appears that it stems not only from the specific shift of emphasis towards communication (as it is the main purpose of using smartphones) but also from the fact that the Internet has become the basic source of information on the reality, not only an economic one. The obtained information on products and services can also lead to making purchases in a traditional way, not only via websites. Also, one needs to consider the fact that the Internet, apart from its communication and information function plays a more and more important role as a means for providing entertainment (films, music, e-books, computer games, etc.). The last question in this section of the survey concerns the statement whether internet marketing is - in the opinion of the Internet users - better than traditional marketing. The majority of responses - i.e. 53% claimed that the best option is a combination of traditional and internet marketing (marketing mix). Interestingly, almost 40% of responses show that internet marketing is better than traditional marketing, and only 7.5% of the responses point out that it is just the opposite. The first thing which comes to the fore is the question why

internet marketing might be seen as better than its traditional form. The opinions concerning the reasons were divided. In almost 25% of responses of participants of the survey, they paid attention to its continuous accessibility and 23% to the possibility of gathering information about a particular product or service. The third place with the score of 22% was taken by the opportunity to use internet comparison engines, directly supporting the purchase process with special software. The fourth position was taken by the possibility of direct purchase after clicking on the link (19%). It should be noted that the difference between the evenly distributed attributes, in total, amounts to only six percentage points. Information about products and services on the Internet are mainly collected through search engines (almost 49% responses). Social media take the second position with the score of 28%, which is nearly 20 percentage points higher than the source which is in the first position. The blog entries and links to banners were at the level of 10% of responses. At the same time in order to verify the importance of the above information, the authors examined the percentage of people who perceive the Internet as the main source of information. Actually, in the examined group of respondents the Internet undoubtedly gained considerable recognition as a source of knowledge about products and services - 33% of responses. The next, second position was taken by information provided by friends (28% - word-of-mouth advertising). As the survey shows, television still enjoys a strong position (16% responses). The press and advertising materials in shops reached a similar level of about 8% of responses. However, the role of the radio and leaflets is markedly depreciated. The research also pointed to the low score of the opinions of the industry experts in the ranking.

Interestingly, information about the products and services is mainly used by the participants of the survey to make purchases in traditional stores (47% of responses), which would confirm the thesis concerning the importance of the Internet with regard to its informative function. Nevertheless, an almost equally large group of users (42% of responses) use the information to buy items in online shops and 10% on online auctions. This partly justifies the low percentage of Internet users declaring shopping in the electronic sphere - a considerable group use the information available on the Internet to make purchases in traditional stores.

The next section concerns the evaluation of the usage of e-marketing media and their acceptance by the client. For the Internauts, the presence in social media with the score of 30% of responses turned out to be the most significant factor. Nearly 22% of responses of students admitted that the most important factor inducing the purchase was an attractive website design. The least attention among the respondents assigning good scores was paid to e-mailing (nearly 5% of responses). In total, the presence in social media has obtained 46% of very good and good scores, and the clear and attractive website has gained 44%, which is a slightly lower score. Consequently - the greatest number of negative scores was obtained by e-mailing (more than 50%) and a newsletter 23% of responses.

The fourth section of the survey concerns the evaluation of the usage and the success of e-marketing from the point of view of a client. The ranking of marketing media inducing customers to make purchases corresponds with the previous results. In the last six months, the clients were most inclined to buy goods when attracted by the clarity and graphic design of the website (over 16%) and the presence in social media. The economic factor is not without significance - the third position with the score of 11% of responses was taken by the discounts offered when customers exceeded a specific value of the purchases. The worst in the ranking are brandmark and e-mailing (spam), running an internet forum and pop-up/under windows. Among other factors affecting purchases, the respondents indicated: discount codes/coupons available on the Internet.

The next element of the survey is the specification of a technical element - the tool which draws clients' attention to e-marketing to the greatest extent. Here the elements which are clearly visible on the screen, such as video - 27% of responses, or billboards - 23% of responses were decisively advantageous. Static and dynamic banners seem to be of lesser importance - 20% of responses. The respondents pay the least attention to buttons or pop-up/under windows.

The last, most comprehensive section of the survey examined m-marketing functioning on mobile devices such as a smartphone or a tablet. The questions concerned people who simultaneously use traditional devices (PC/laptop) and modern mobile equipment (smartphone/tablet). Generally speaking, if we consider the respondents' approach to electronic marketing it is nearly in one-third of responses (31%) negative. It appears that they prefer internet marketing on traditional hardware (40%). Only 15% answers of respondents indicated the preference for marketing on modern devices, and 14% of survey participants' responses claim that they like both types of marketing.

Over 65% answers of respondents claim that marketing on traditional hardware and modern mobile devices is different, in 28% of responses - have no opinion on the subject, and only in 7% answers - think that such differences do not actually exist.

Among the factors which are most disliked by customers in the manifestations of mobile marketing, the frequent comments concern greater problems with closing them (25% of responses) and their taking proportionally larger space on the screen (24%). Nevertheless, the statements related to problems encountered when communicating with the device are almost at the same level (23%). A half answers of the respondents still draws attention to the fact that displaying ads on mobile devices extends the time needed to roll the screens. Further positions are taken by the worse level of readability, connected with lower resolution, or excessive conciseness. Among other problems, the survey participants paid attention to the fact that older devices may be overloaded, and they tend to crash (see Fig.1).

Among the advantages of m-marketing, the respondents indicate the concise content (61% of responses), lower level of

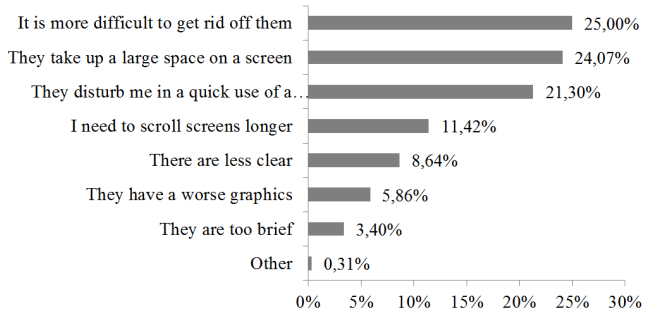

Fig. 1. Disadvantages of m-marketing in the respondents' opinions (%% of responses); n=314

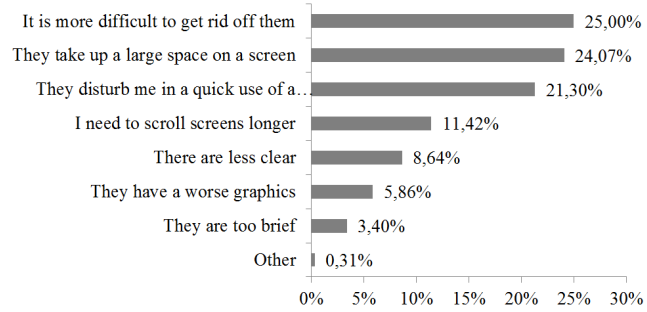

Fig. 2. The most important features of m-marketing (%% of responses); n=281

intrusiveness of the tools (25%) and the fact that, in general, they are easier to use (14%). The responses show that the feature which is indicated by some users as a disadvantage (e.g. excessive conciseness), may be seen as an advantage by others (content which is limited to the minimum, i.e. brevity).

Detailed analysis of the above responses was conducted through the prism of the most important features of mobile marketing. In over 27% of responses it was indicated the facts that m-marketing is always available, and it guarantees the precise and fast way to reach out to the target group (18%) are its most important features. The third position is taken by easy, dynamic and flexible interaction with the recipient (17% of responses). The high level of effectiveness of this type of marketing raises serious doubts (see Fig. 2).

The next question concerned the types of m-marketing tools which are most frequently used by the respondents. The greatest number of users indicated the use of mobile applications (28% of responses). The next positions are taken by SMS marketing - 26% of responses - and the use of geolocation and mobile navigation - 16%. The lowest scores are assigned to designing mobile websites and the use of NFC technology and QR codes (about 9% of responses). It appears that among the respondents few people used railway tickets (QR codes) or maps and guides (e.g. TatrzaÅĎski Park Narodowy). With regard to the question concerning the most visible forms of m-marketing the respondents pay the greatest attention to graphic advertising (73% of responses), next to application ads 12% and text ads 10%. In less than 5% answers of survey participants believe that the advertisements designed with the application of Google Web Designer technology prove to be most effective. Among m-marketing technologies operated on smartphones or tablets, the most efficient are graphic ads (43% of responses), then graphic application ads and the application ads (about 17% each). True View ads used to promote applications (about 1% of responses) and text ads (nearly 8%) are seen as less effective. The last question concerned the form of mobile marketing, which the respondents used most frequently in the last six months. The most popular forms were mobile applications (e.g. product placement or display ads), which amounted to 28% of responses. SMS marketing took the next position. The use of other forms of m-marketing was 5-6 percentage points lower in the ranking. The least popular forms were NFC (Near Field Communication) technology or QR (Quick Response) codes - generally at the level of 9% of responses.

IV. Conclusions

The conducted and presented studies point to the following conclusions:

- In the present study, all respondents of the survey were students, which was clearly indicated in the obtained findings. The higher the year of study, the less interest in completing the survey and its conclusions. It is probably caused by the greater effort required not only for the studies but also students' involvement with temporary or regular jobs (working students constitute more than 32% of the sample). On the other hand working students are very often used e-commers and have to do with e-marketing.
- The frequency of the use of the Internet in the examined sample was high - over 95% of respondents replied that they use the Internet several times a day, and nearly 4% at least once a day; they were connecting to the Internet only via their smartphone (1/3 of the sample), the second most popular option was laptop. It is the generation that has learned how to use a mobile phone/mobile device relatively early in their life and later on switched to smartphones or tablets; the change has been fairly easy and natural for them. The transition was supported by a relatively low price, in comparison to a laptop, and a large number of free applications available on all three operational systems (Android, iOS, Windows) running on smartphones,
- In the examined group fewer than 50% of respondents do their shopping on the Internet several times a month, up to a few times a day, which indicates a specific shift of the role played by the Internet from the economic role to a more communicative-informative one, i.e. the change in the main function of mobile phones at present is no longer focusing on business relations (only 6% of the sample use the Internet at work). The core aspect of the mobile sphere starts to prevail over the desktop one.

- At the same time, the Internet is generally perceived as a good and very good marketing medium - 85%. As far as the high level of internet purchases is concerned, the users declare that purchases made outside the Internet may be seen as the outlet for marketing activity,
- Simultaneously respondents claim that internet marketing is better than a traditional one due to its: continuous availability, a quick way to broaden the knowledge about a product or service and a possibility to use comparison engines - including mobile tools,
- Information about goods and services continue to be gathered by means of browsers (almost 49% of responses); social media take the second position, and the role of blog entries is gaining in importance, other sources of information are marginalized,
- Among the elements which respondents pay the greatest attention to with regard to e-marketing, we may list general graphic design and an advertised product or service,
- Among the technical elements of marketing, the Internet users see the advantage of the elements which clearly stand out on the screen: video (short film), or billboards. Static or dynamic billboards seem to be slightly less important,
- Marketing tools are positively perceived mainly in social media, on corporate blogs, on websites and in online shops. It emerges that in social media and on websites they are seen as both eagerly viewed and irritating - apparently to equal degree,
- A third of the "mobile generation" sees electronic marketing as a negative phenomenon, more people prefer to see it applied on traditional hardware rather than mobile devices,
- Over 65% of respondents believe that marketing via traditional equipment (PC, laptop) and modern devices (smartphone, tablet) are different,
- Among negative factors concerning m-marketing we experience greater problems with removing the ads from the screen, taking proportionally greater space and interfering in operating the device,
- Among the positive factors in m-marketing, the respondents mainly paid attention to concise contents, limited to a minimum, lower intrusiveness of the tool and the consequent greater comfort in using it,
- The most important feature of m-marketing is common availability, the guarantee of precise and fast access to the target group and easy, dynamic interaction with the recipient. However, there emerge certain doubts concerning the effectiveness of this form of marketing,
- The most popular type of m-marketing tool among the respondents were the ads available through mobile apps, SMS marketing as well as using geolocation and mobile navigation,
- The most noticeable forms of m-marketing are banners and much less (6 times less) noticeable app ads and text ads, and here lies, in the opinion of users, their greatest effectiveness,
- Most recently the respondents most frequently used the app-embedded ads (e.g. product placement and display) and SMS marketing.

The above conclusions constitute a proper basis for the continuation of the research as well as extending it to include the effects, consequences and results of using m-marketing in business activity.

The Role of ICT Solutions In the Intelligent Enterprise Business Activity

Monika Łobaziewicz
University College of Enterprise
and Administration in Lublin,
Poland
e-mail: ml@un.pl

***Abstract*— During the last years the number of innovative ICT systems, applications and tools has been growing still to support intelligent business performance. However, advanced ICT solutions are only means to the end of better process performance, not a substitute for it. Intelligent enterprises running their activity in increasingly more dynamic, complex and uncertain environment. The aim of paper is the discussion about the wide spectrum of ICT solutions used by the intelligent enterprise and their meaning in the management of intelligent organization. This is the first approach in this case that the author is going to continue in the advanced research.**

I. Introduction

There are many definitions of an intelligent enterprise. Undoubtedly, it has a high abilities to learn from experience, adapt to new situations, understand and handle abstract concepts, and use knowledge to manipulate the business environment. Problem solving, comprehending complex ideas, learning quickly, and learning from experience are crucial for the intelligent enterprise. Companies today are looking to boost operational productivity and performance while addressing the full range of information requirements throughout the extended enterprise. In this case, the intelligence in the enterprise management is more than just delivering reports from a data warehouse. It's about providing large numbers of people – executives, analysts, customers, partners, and everyone else – secure and simple access to the right information so they can satisfy their unique reporting or analysis requirements, then share that information accordingly.

The intelligent enterprise provides information for service-oriented purposes and for optimizing operational systems.

The enterprise can be intelligent in two ways:

- ✓ It can behave intelligently or/ and can „utilize" intelligence;
- ✓ For the enterprise to be intelligent, it needs to maximize the extend and utility of its intellectual capital;
- ✓ The intelligent enterprise is an organization which acts effectively in the present and is capable of dealing effectively with the challenges of the future. It meets its objectives both of the enterprise itself and those of its stakeholders and makes trade – offs between them.

Because, the role of ICT in business management is crucial and modern enterprises run their activity using advanced IT systems, applications, tools – the question concerning the differences between intelligent and traditional enterprise appears.

The aim of paper is the discussion about the wide spectrum of ICT solutions used in the intelligent enterprise and their meaning in the management of intelligent organization. This is the first approach in this case that the author is going to continue in the advanced research.

II. The Intelligent Enterprise

Nowadays, the concept of an intelligent enterprise has its source particularly in the following ideas: an organisation based on knowledge and information management, a learning organization, an organisation based on the intellectual capital. On the other hand, from the ICT point of view, the intelligent enterprise is correlated with following terms: business intelligence, artificial intelligence, enterprise intelligence systems. The results of a literature surveys conduct that a discussion about the intelligent organisation has been started in 90. of the 20'th century. The concept of the "intelligent enterprise" was first articulated by J. B. Quinn as follows "the self-sufficient enterprise is becoming anachronistic. Each organization is part of a matrix of merging and evolving ideas and opportunities. Leading companies focus less on positioning and more on patterns of people and institutions they work with – or against" [1] and now it has a special meaning because of the use of advanced tools based on ICT.

Ming & Feng [2], Hopkins Lavalle, Balboni [3], Kruschwitz & Shockley [4], Dayani [5], Quinn [6], Stubbs [7], Tan & Cao [8,9] note that the knowledge management, wireless networking technologies, mobile devices has prompted many modern enterprises to look for management information systems to remotely monitor and control of their company operations in order to increase their flexibility and competitiveness in the market. In other words, the intelligent enterprise operates with knowledge-

based technologies, especially on-line systems for remote work and activities improving the effectiveness of business processes and has important role in creating competitive advantage.

Szczerbicki [10] notices that a modern intelligent enterprise is able to convert intellectual resources using ICT solutions to the end product with a high level of added value.

One should be pointed that now intelligent enterprises use in their business a hybrid approach rather than using a single intelligent system or application to do activities and to make decisions. Modern IT environment includes various interfaces and components completely Web-based and uses XML extensively which can work like shared platform to be accessed by multiple users and decision makers [11]. Enterprises operate on B2B platforms with 'in built' EDI technologies that integrate ERP systems and special applications of business partners, use the workflow, CRM. All of them provide a lot of data and information in the integrated way. Thus, they act like knowledge management systems [12], [13]. Nowadays the main problem for the intelligent enterprise is not be the access to information but the ability to verify it and then to transform it into a useful operational and strategic resource.

Managing of the enterprises that function in uncertain 'information-rich' environment requires greater understanding of the role of information and in systems operation. To gain this understanding, the knowledge is required [14]. In the intelligent enterprise, employees know that ICT tools enable the knowledge sharing, not only fosters collaboration but also facilitates experience and knowledge discovery. Thannhuber emphasizes that IT systems supported by knowledge and intelligence paired together allow to adapt dynamically the enterprise to its environment, provide the framework for making optimal decisions [15]. Moreover, the intelligent enterprise applies automated analytics on data generated by systems and applications to better understand what resources are being used, how well they should be used to support the business processes. The intelligent enterprises create the high ability to measure past performance for the future purposes. ICT solutions deliver knowledge to the right people when and where it is needed, and keep in mind that timeliness is an issue. The issue is that not everybody needs all information, they need just the right information for themselves. In the intelligent enterprise, there is a situation when delivering reports from a data warehouse is an operational action. The intelligence of this organization is about providing large numbers of people – executives, analysts, customers, partners, and everyone else – secure and simple access to the right information so they can satisfy their unique reporting or analysis requirements, then share that information accordingly to the logic of business processes.

According to Dayal [16] the intelligent enterprise is characterized by being able to adapt quickly to changes in its operating environment. It monitors not only its own business processes but its interactions with customers, partners, suppliers and collaborators, as well. The intelligent enterprise understands how the exchange of information among all business participants relates to its business objectives and it acts to control and optimize its operations to meet its business objectives. In this enterprise decisions are made quickly and accurately to modify business processes on the fly, dynamically allocate resources, or change business partners (e.g., suppliers, service providers) and partnerships (e.g., establish new service level agreements).

III. BUSINESS MODELS OF THE INTELLIGENT ENTERPRISE

The results of literature surveys conduct that there are very little discussion about business models of the intelligent enterprise. Most of the conceptions are related to business intelligence (BI) or knowledge management(KM) models. There are a few concepts presented as white papers or presentations exposed at IT conferences.

Professor Larry Lucardie from Knowledge Value Institute defines the intelligent enterprise as lean, agile and learning, which a business model is based on the knowledge value (Fig. 1).

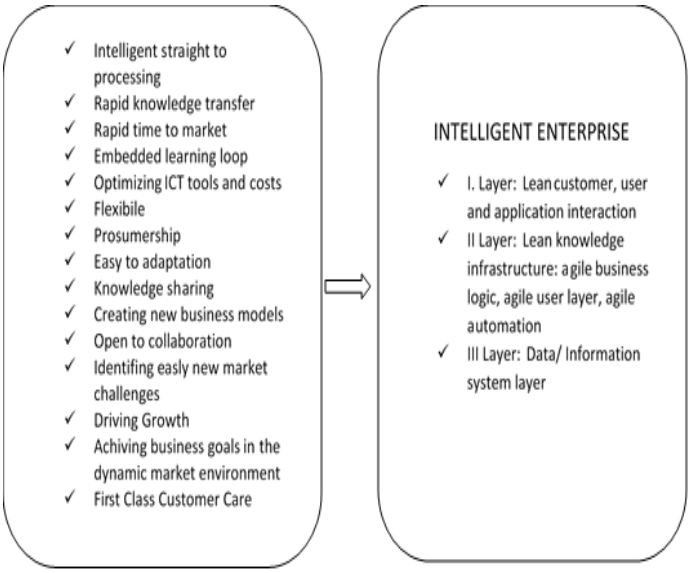

Fig. 1 Intelligent enterprise optimizing the knowledge driven organisation

Andrew Coleman from IBM notices that the business model of intelligent enterprise is based on prediction. The intelligent organisation is able to compare what is happening right now with past experience to predict the future so that it can anticipate the changes needed to proactively optimize the business. Therefore, the intelligent enterprise is a market game changer (Fig. 2).

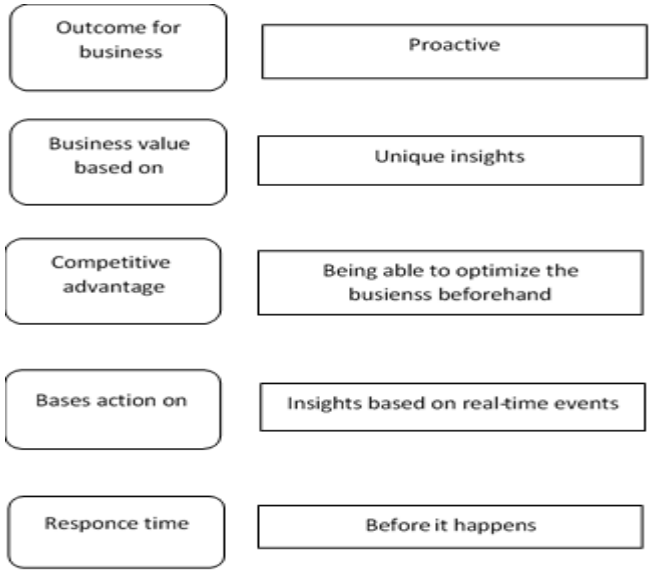

Fig. 2 Predictive intelligent enterprise model

The research conducted by IBM in a group of 225 business leaders worldwide, show that enterprises are operating with bigger blind spots and that they are making important decisions without access to the right information. They recognize that new analytics, coupled with advanced business process management capabilities, signal a major opportunity to close gaps and create new business advantage. Those who have the vision to apply new approaches are building intelligent enterprises and will be ready to outperform their peers [17]. IBM have pointed the essential characteristics that describe an enterprise ready to exploit advanced analytics and optimized performance (Fig. 3).

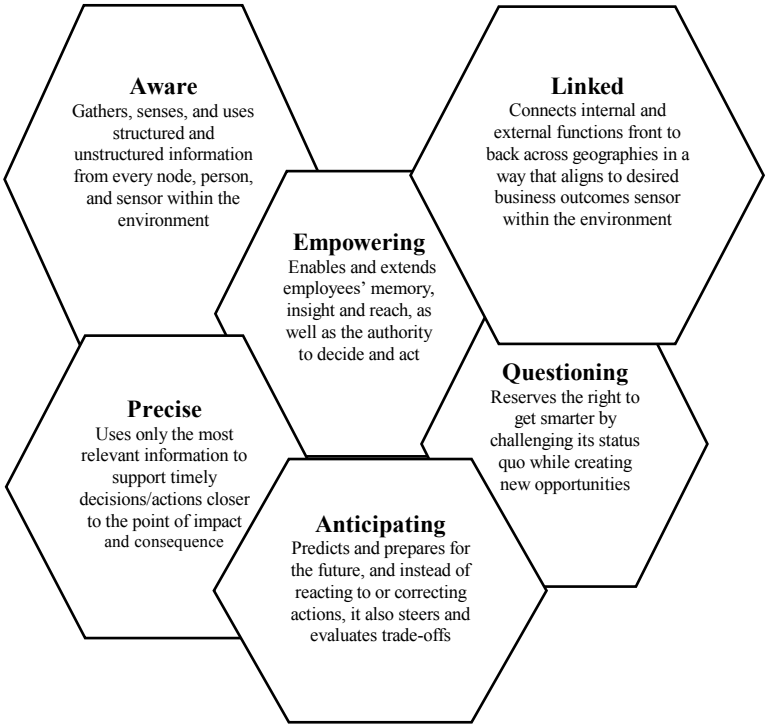

Fig. 3 Characteristics of the intelligent enterprise in IBM conception

Intelligent enterprises operate in increasingly complex IT systems what is the result of business processes complexity. Autonomous subsystems are still be interrelated and embedded in larger systems. Intelligent enterprises opposite to traditional organizations are able to integrate their strategy and the knowledge management with IT systems, applications and tools (Fig. 4).

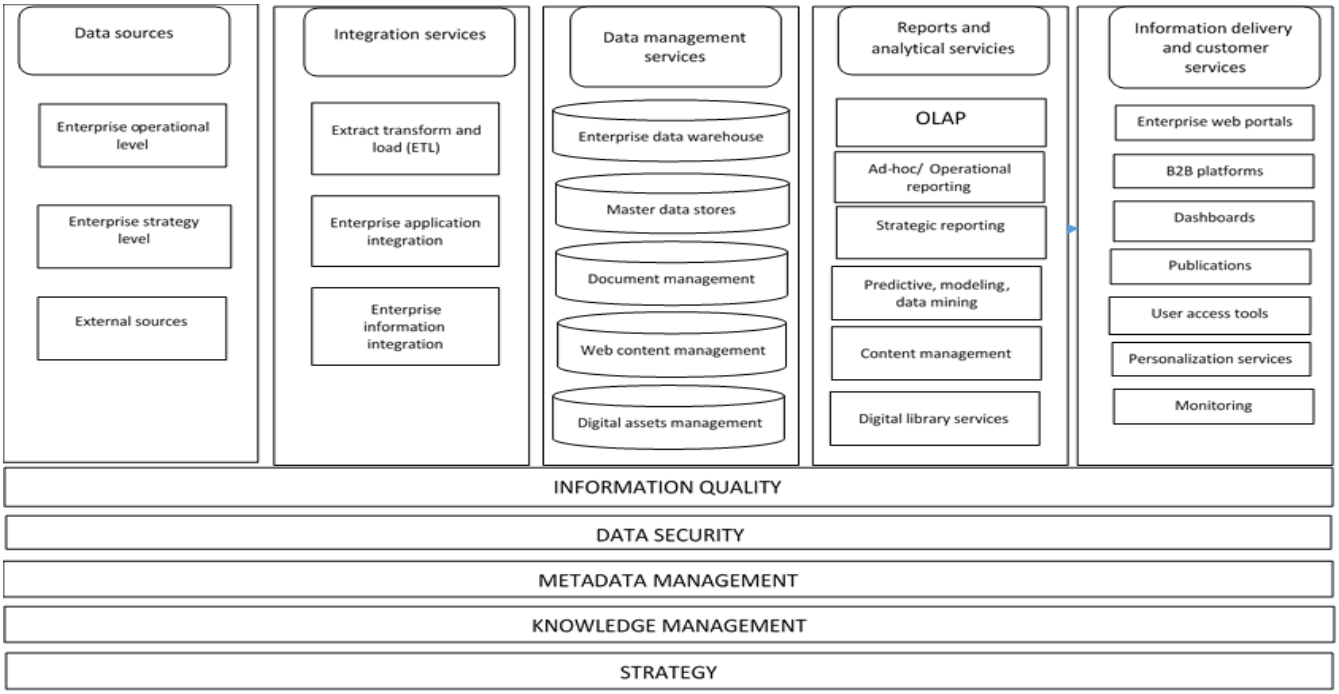

Fig. 4 Integrated intelligent enterprise model

Building the business model of the intelligent enterprise provides for a strategy and technology infrastructure that ensures that accurate and timely information is effectively incorporated into the decision making process so that the organizations can exploit this information through process, knowledge and visualization based technologies to manage their business effectively.

IV. THE RESEARCH OF INTELLIGENT ENTERPRISE

The study show that there is a lack of advanced surveys devoted to the intelligent enterprises.

Up to date, in Poland the only research concerning intelligent enterprises was carried out by Polish Agency for Enterprise Development (PARP) in 2010 on a group of 300 small and medium-sized enterprises (SMEs). One of the purpose of the research was finding an answer to a question what are the characteristics of the intelligent enterprise in Poland and whether they use ICT solutions more effectively than other organisations.

In the research carried out by PARP it was assumed that an intelligent organisation has following features:

- it has a long term strategy of development to achieve goals;
- it has an advanced human resources management (HRM) policy;
- it has a company website and intra network as well as it uses specialised ICT business management tools;
- it uses the knowledge management.

Surveys have shown that 26.5% of SMEs had a long term strategy, 31.6% had the HRM policy, 47% used developed ICT tools and 38% used the knowledge management. In contrast, 63% of big companies had both the strategy and the personnel management policy well developed. Therefore, the bigger organisations meet the criteria of intelligent organisation to a larger extent than SMEs.

In Poland, intelligent organizations do not have a clear innovative profile yet established. Now, when the Operational Programme Intelligent Development 2014-2020 started, it is known that a type of innovation is not a factor differentiating companies in terms of their willingness to implement solutions typical for intelligent organizations. More often are process innovations (28%), organizational innovations (24%) and product innovations (21%). The tendency to introduce the solutions adequate for intelligent organizations to the business practice increases with the size of company turnover. From the business sector point of view, intelligent organisations have the biggest share among industrial companies (14%), as well as trade and service companies.

The research indicate then a stronger focus on technological development among intelligent organizations, their better adaptation to the challenges of the knowledge based economy, the speed of access to knowledge and the possibility of its use are key competitive factors.

Intelligent organizations in Poland more often use ICT solutions to support management processes in comparison with other organizations. The most popular are e-workflow, databases and data warehouses management (83%), as well as Intranet (76%). The further are Customer Relationship Management (twice more often than organizations that do not meet criteria for intelligent organizations) and solutions supporting a team working, every fifth - HRM and every sixth - Business Intelligence (three times more often than other organizations).

The last problem concerning ICT solutions that support the management of intelligent organizations is their effectiveness assessment. The few critical comments were focused on low efficiency of databases and data warehouses. Very positively were evaluated Supply Chain Management (78%) and Customer Relationship Management (70%). As far as the effectiveness of various ICT tools by intelligent organizations is concerned, it is worth to emphasize that generally ICT tools are assessed as less effective by small businesses than by middle sized and large. This is due to the specific nature of these tools, which do not necessarily have to be effective in organizations with a low developed organizational structure and not very complicated business processes [18].

In 2010 MIT Sloan Management Review and the IBM Institute for Business Value conducted a research among nearly 3,000 executives, managers and analysts working across more than 30 industries and involved intelligent organizations of various sizes in more than 100 countries. There were also interviewed academic experts and subject matter experts from a number of industries and disciplines to understand the practical issues facing intelligent organizations [19].

As a result, there are following results:

- Intelligent enterprise is focused on the highest value uses each business opportunity, starting with questions, not data opposite to traditional organizations. It should first define the insights and questions needed to meet the big business objective and then identify data needed for targets. They can target specific subject areas, and use readily available data in the initial analytic models;
- Intelligent enterprise drives actions and delivers value. This means that new methods and tools to embed information into business processes, ICT analytics solutions, optimization, workflows and simulations are making insights more understandable and actionable;
- Intelligent enterprise develops existing capabilities adding new ones. To do this, they use sophisticated modelling and visualization tools based on ICT, but that does not mean that spreadsheets and charts should go away. On the contrary, new tools should supplement earlier ones, or continue to be used side by side, as needed;

- Intelligent enterprise uses an information agenda to do plan for the future. Big data is getting bigger. Information is coming from interconnected supply chains today. Strategic information arrives through unstructured digital channels: social media, smart phone applications and an ever-increasing stream of emerging Internet-based gadgets. The information agenda identifies foundational information practices and tools while aligning IT and business goals through enterprise information plans and financially justified deployment road maps. This agenda helps establish necessary links between those who drive the priorities of the organization by line of business and set the strategy, and those who manage data and information. A comprehensive agenda also enables managers to keep pace with changing business goals. It provides a vision and high-level road map for information that aligns business needs to growth. [3]

Summing up, intelligent enterprises are combining the new systems and tools based on ICT with expertise in business process management. They are able to extract the precise information they need – highly relevant and contextualized – and predict the most likely outcomes of key decisions and events. They are able to shape their own futures.

V.ICT DRIVERS EMPOWERING THE INTELLIGENT ENTERPRISE

The results of theoretical study and the research conducted by PARP and MIT Sloan Management Review and the IBM Institute for Business Value became the background to develop a scientific discussion about the intelligent enterprise and the role of ICT in this organization. Taking into account the wide spectrum of ICT solutions used in the intelligent enterprise management, there are some areas to analyse.

5.1 Mobile workforce integration

The access to professional knowledge is critical in the intelligent enterprises and mobile connections to operating systems, applications, platforms are important, especially in the fast – paced business environment. Mobile technologies drive technical innovation to improve networks, ensure employees remain fully integrated with their company and clients wherever they are. Thus, in the intelligent organization its coherency is determined by the intelligence of its network that becomes the organization with wireless tentacles spreading from it to embrace location-aware services.

5.2Smart virtual workplace

As the approaches to virtualization of IT infrastructure, networks and storage devices continue to mature, infrastructures become software-driven. Smart virtual workplace provides end to end desktop virtualization allowing employees to access applications, data safely over any network from the device of any choice. New trends show that business will increasingly turn to hybrid cloud solutions to enable scalable business processes. Hybrid clouds can quickly scale to a company's needs and services can be paid for as needed. They combine the best of two worlds, offering true benefits to intelligent enterprises aiming to stay ahead in their markets.

5.3 E- Collaboration

E-collaboration is the standard for business communication today, nearly eliminating the need to meet face to face. While knowledge sharing increases, formal and informal groups become e- collaborative communities to reach organizational goals. Intelligent enterprises continue to integrate these into their business processes and reinvent their customer engagement models.

In the intelligent enterprise ICT tools allow disparate teams to work together in real-time, enabling multiple individuals to interact as efficiently and effectively with co-workers, clients, and suppliers.

5.4 Business flexibility

The intelligent enterprise can be called as the designer of changes where the business flexibility is crucial. ICT solutions are very helpful in this case. They must now be highly flexible and resilient in order to seamlessly communicate and interoperate with disparate technologies and systems. The IaaS model becomes very useful. It makes it easier the internetworking and deploying servers and endpoints from multiple sources.

5.5Scalability and customization

Intelligent enterprises align their IT infrastructure capabilities with business requirements. Modularity of systems, applications allow companies to have only what is needed at present, trimming up-front costs and leaving open the possibility of expanding or incorporating new technologies in the future. With the increase of consolidation, intensive virtualization, the traditional data center will transform to the 'hyperscale' data center. It requires a fundamentally different approach than that taken with typical enterprise IT systems. Rather than building 'monolithic' platforms, distributed architecture design is implemented around distributed processing frameworks. That requires software and ICT tools that automate node deployment, recover from failure (rerouting of workloads), and other management and monitoring tools.

5.6Business continuity

It is obvious that intelligent companies need to have 24 hours a day access to their data. Data digitalization and rapidity of their processing require more accurate, reliable

and sophisticated ICT tools converting all data into intelligence for better business outcomes. On the other hand, managers need them to be not complicated in their use. Moreover, for a high level of operational uptime, infrastructure components must be fault tolerant with the ability to recover from complex failures and data storage must be secure.

5.7 Converting data into business intelligence

Advanced ICT solutions enable extracting from huge amounts of data collected from the real cyberspace. Intelligent enterprises are able to manage Big Data to drive better business processes, product development, and customer service. The important is the fact that they enable to use effectively unstructured data captured from different systems, mobile devices, social media, log files, emails to perform real-time context analytics to understand received information, its content to make right decisions in the right time.

Therefore, intelligent enterprises are not only the users of advanced tools based on ICT technologies to optimize business practices, drive workforce engagement and create a competitive edge, but they are also able to leverage and to create value from the date and information generating by ICT solutions.

VI. CONCLUSIONS

The discussion about intelligent enterprise is at the beginning stage. There are more theoretical disputes then surveys in this case. There are no in depth research devoted business models of these organizations or effectiveness, strategy or management in this organizations, especially with use of ICT solutions.

In the paper, there were presented two surveys that can be the good start for the future research about intelligent enterprises. Poland is at the stage of an intensive investing in the research and development, therefore Polish companies are still learning how to create the intelligence and how to be intelligent organizations. This is especially a challenge for companies from the SMEs sector.

The research conducted by MIT Sloan Management Review and the IBM Institute for Business Value show that for the intelligent enterprise, the new reality is this: personal experience and insight are no longer sufficient. New analytics capabilities are needed to make better decisions.

The above premises encourage the author to continue the scientific discussion about intelligent enterprise with a special attention to ICT solutions. The advanced research will be continued.

22nd Conference on Knowledge Acquisition and Management

KNOWLEDGE management is a large multidisciplinary field having its roots in Management and Artificial Intelligence. Activity of an extended organization should be supported by an organized and optimized flow of knowledge to effectively help all participants in their work.

We have the pleasure to invite you to contribute to and to participate in the conference “Knowledge Acquisition and Management". The predecessor of the KAM conference has been organized for the first time in 1992, as a venue for scientists and practitioners to address different aspects of usage of advanced information technologies in management, with focus on intelligent techniques and knowledge management. In 2003 the conference changed somewhat its focus and was organized for the first under its current name. Furthermore, the KAM conference became an international event, with participants from around the world. In 2012 we’ve joined to Federated Conference on Computer Science and Systems becoming one of the oldest event.

The aim of this event is to create possibility of presenting and discussing approaches, techniques and tools in the knowledge acquisition and other knowledge management areas with focus on contribution of artificial intelligence for improvement of human-machine intelligence and face the challenges of this century. We expect that the conference&workshop will enable exchange of information and experiences, and delve into current trends of methodological, technological and implementation aspects of knowledge management processes.

TOPICS

- Knowledge discovery from databases and data warehouses
- Methods and tools for knowledge acquisition
- New emerging technologies for management
- Organizing the knowledge centers and knowledge distribution
- Knowledge creation and validation
- Knowledge dynamics and machine learning
- Distance learning and knowledge sharing
- Knowledge representation models
- Management of enterprise knowledge versus personal knowledge
- Knowledge managers and workers
- Knowledge coaching and diffusion
- Knowledge engineering and software engineering
- Managerial knowledge evolution with focus on managing of best practice and cooperative activities
- Knowledge grid and social networks
- Knowledge management for design, innovation and eco-innovation process
- Business Intelligence environment for supporting knowledge management
- Knowledge management in virtual advisors and training
- Management of the innovation and eco-innovation process
- Human-machine interfaces and knowledge visualization

EVENT CHAIRS

- **Hauke, Krzysztof,** Wroclaw University of Economics, Poland
- **Nycz, Malgorzata,** Wroclaw University of Economics, Poland
- **Owoc, Mieczyslaw,** Wroclaw University of Economics, Poland
- **Pondel, Maciej,** Wroclaw University of Economics, Poland

PROGRAM COMMITTEE

- **Andres, Frederic,** National Institute of Informatics, Tokyo, Japan
- **Chmielarz, Witold,** Warsaw University, Poland
- **Christozov, Dimitar,** American University in Bulgaria, Bulgaria
- **Helfert, Markus,** Dublin City University, Ireland
- **Jan, Vanthienen,** Katholike Universiteit Leuven, Belgium
- **Jelonek, Dorota,** Faculty og Management of Czestochowa University of Technology
- **Kania, Krzysztof,** University of Economics in Katowice, Poland
- **Kayakutlu, Gulgun,** Istanbul Technical University, Turkey
- **Korczak, Jerzy,** Wrocław University of Economics, Poland
- **Ligęza, Antoni,** AGH University of Science and Technology, Poland
- **Mach-Król, Maria,** University of Economics in Katowice, Poland
- **Mercier-Laurent, Eunika,** University Jean Moulin Lyon3, France
- **Nalepa, Grzegorz J.,** AGH University of Science and Technology, Poland
- **Sobińska, Małgorzata,** Wroclaw University of Economics, Poland

- **Surma, Jerzy,** Warsaw School of Economics, Poland and University of Massachusetts Lowell, United States
- **Vasiliev, Julian,** University of Economics in Varna, Bulgaria
- **Zhelezko, Boris,** Belorussian State Economic University, Belarus

Knowledge Acquisition at the Time of Big Data

Francis Rousseaux, Stéphane Cormier
Reims Champagne Ardenne University, France
Email: {first name.name}@univ-reims.fr

***Abstract*—What is exactly 'Big Data', and for what purpose and application is it really efficient? Between the commercial promises made by the industrial actors and the Cassandra's cautions from some whistle-blowers, we propose a singular Big Data field to investigate with Inductive Data-Driven Algorithms: developing collections. Last but not least, we investigate the innovative possibility to curate 'figural' collections, characterized by Jean Piaget as follows: *"A figural collection composes a figure, through the spatial relationships between its elements, whereas non-figural collections and classes are free of any figure"*. Thus, we incidentally disclose some important Abstract Truth of Big Data.**

***Index Term*—predictive analysis; inductive data-driven algorithms; big data; figural collections; digital societies; search by similarity.**

I. Introduction

THE classical processes of Information Technology (IT) – including Artificial Intelligence approaches – were traditionally based on deductive knowledge modelling and simulation, so that explanation and theory, based on validations or refutations [13], were never far from engineering.

Things turn different within Inductive Data-Driven Algorithms and Big Data, because practitioners do not need anymore domain theories and explanation-based processes to succeed in providing useful results.

Those new features and paradigmatic evolutions introduce some important epistemological breakthrough in the IT classical environment, with important consequences.

At least, our digital societies are about to revisit an old utopia a human dream, close to our day live: the management of our overabundant and oversized collections, as lighten by contemporary art.

II. Predictive Analysis through Big Data: a Tsunami in IT

A. What changes has the arrival of Inductive Data-Driven Algorithms and Big Data made in the data ecosystem?

The title of the document is placed in appropriate frame on the top of the document and is formated with style `Title`. Do not capitalize short words (a, and, the, and so on).

In the world of computing, we are currently living through a period in which the epistemological nature of data is being thoroughly changed, as Big Data seems to be revolutionizing most of the methods and approaches of digital decision-making tools and processes. Indeed it is as if the Curse of Dimensionality and the pitfall of the Combinatorial Explosion that limited computer science in the 20th century have been left behind us. Natural allies of Data Mining and Machine Learning, the tendency is now towards Big Data and Data-Driven Intelligent Predictive Systems (DDIPS).

These systems are called Data-Driven because they mobilize Big Data to make connections or analogies, aiming to create certain configurations or to anticipate situations that might cause delays or predictive challenges. They are called Predictive because, unlike 20th century computer systems, their performances are measured more by their ability to predict or to discover rather than to understand, explain or theorize.

They are called Intelligent because they frequently make use of input from supervised or unsupervised automatic learning techniques, data mining, and even Deep Learning based on Convolutional Neural Networks, which contribute to performances that far outstrip the preceding generation's.

Because of this epistemological turnaround, and with the help of DDIPS, a flood of predictive data are being added to the usual data, although this new type of data has never been directly input or calculated by determinist or classically deductive methods [6], [19]. Thus Predictive-Data – to be distinguished henceforward from other types of data – are considered an additional raw material to be exploited, even if their reliability must be closely scrutinized.

B. What about the current positions and statements made by main actors?

IT professional and industrial companies, but also start-ups working in that domain, are putting forward on promising business and marketing opportunities, furnishing and putting tool and technical solutions on market places[1].

But in parallel observers and researchers, often coming from social sciences fields, forewarn potential users from a new calculus order that could mean their end of autonomy. To mention only a few of them:

1) The end of Theory

Following George Box saying: *"All models are wrong, and increasingly you can succeed without them",* Chris Anderson [1], after he has been the editor-in-chief of WIRED magazine, puts forward that: "The Data Deluge Makes the Scientific Method Obsolete".

He claimed that: *"Petabytes allow us to say: Correlation is enough. We can stop looking for models. We can analyse*

[1]See for example http://www.bigdataparis.com/guide/BD14-15_Guide_BD_14136_2.pdf

the data without hypotheses about what it might show. We can throw the numbers into the biggest computing clusters the world has ever seen and let statistical algorithms find patterns where science cannot".

2) "Technological Solutionism"

In one of his recent bestseller books Evgeny Morozov [6], the Byelorussian expert analyst Evgeny Morozov explained: *"There is something, to me, that is very worrying about the idea of replacing causality with correlation, because if you do want to engage in reform, you do need to understand the causal factors that you will be reforming. If you just focus on correlations, all you'll be doing is basically adjusting the behaviour of the system without understanding the root causes that are driving it".*

And also: *"So the proliferation of big data and the ability to track things that we do is good only if we can actually understand why we engage in those behaviours. The ability to understand why I think is fundamental to understanding what it is that needs to be changed".*

3) "Algorithmic Governementality"

The European researcher Antoinette Rouvroy says [17]: "La rationalité post-moderne [engendrée par le Big Data] est fondée sur la découverte de corrélations entre des données recueillies avec des intentions et dans des contextes extrêmement divers, hétérogènes les uns aux autres, et qui ne sont reliés entre eux par aucun lien de causalité. C'est le renoncement au savoir causal, la dévaluation de l'expérience sensible elle-même au profit du calcul".

And also [16]: *"Operations of collection, processing and structuration of data for purposes of data mining and profiling, helping individuals and organizations to cope with circumstances of uncertainty or relieving them from the burden of interpreting events and taking decision in routine, trivial situations have become crucial to public and private sectors' activities in domains as various as crime prevention, health management, marketing or even entertainment. The availability of new ICT interfaces running on algorithmically produced and refined profiles, indiscriminately allowing for both personalization (and the useful, safe and comfortable immersion of users in the digital world) and preemption (rather than regulation) of individual and collective behaviours and trajectories appears providential to cope with the complexities of a world of massive flows of persons, objects and information, and to compensate for the difficulties of governing by the law in a complex, globalized world. The implicit belief accompanying the growth of 'big data' is that, provided one has access to massive amounts of raw data (and the world is actually submersed by astronomical amounts of digital data), one might become able to anticipate most phenomena (including human behaviours) of the physical and the digital worlds, thanks to relatively simple algorithms allowing, on a purely inductive statistic basis, to build models of behaviours or patterns, without having to consider either causes or intentions. I will call 'data behaviourism' this new way of producing knowledge about future preferences attitudes, behaviours or events without considering the subject's psychological motivations, speeches or narratives, but rather relying on data. The 'real time operationality' of devices functioning on such algorithmic logic spares human actors the burden and responsibility to transcribe, interpret and evaluate the events of world. It spares them the meaning-making processes of transcription or representation, institutionalization, convention and symbolization".*

C. Our point: Towards a scientific study of opportunity

Many of our modern computerized activities, may they be personal, professional or even artistic, involve searching, classifying and browsing large numbers of digital objects.

Until recently, the usual tools we had at hand, however, were poorly adapted as they were often too formal, because the current models for information search often assume that the function and variables defining the categorization are known in advance.

In practice, however, when searching for information, experimentation plays a good part in the activity, not due to technological limits, but because the searcher does not know all the parameters of the class he wants to create. He has hints, but these evolve as he sees the results of his search. The procedure is dynamic, but not totally random.

The collector's experimentation is always carried out by placing objects in temporary and metastable space/time. Here, the intension of the future category has an extensive figure in space/time. And this system of extension gives as many ideas as it does constraints. What is remarkable is that when we collect something, we always have the choice between two systems of constraints, irreducible one to the other. This artificial 'undifferentiation' for similarity/contiguity is the only possible kind of freedom allowing us to categorize by experimentation.

Nowadays, our software design could strongly become backed up by both artistic and psychological knowledge concerning the ancient human activity of collecting, which can be described as a metaphor for categorization in which two irreducible cognitive modes are at play: aspectual similarity and spatiotemporal proximity.

Inductive Data-Driven Algorithms and Big Data could help, definitely, to allow the creation of a new operational space, in between formal classes/categories and radical singularity.

III. The need for computer-aided collections management tools

A. An illustrative example

Let us illustrate this situation. First, let us suggest that looking for new material and classifying are two important processes involved in collecting. Indeed, when someone decides to start building a collection he usually already possesses a few items. Then, to extend this collection, new items must be added. In order to do so, the collector goes into the world and looks for these new items. Then as the collection builds up, the need to arrange the items into categories will become clearer, as the collection cannot simply remain a messy stack of unordered items [14].

Let us describe a particular example: the music collector. This collector will surely possess some initial items; these

may be some CDs or vinyl records. His first action involved in extending his collection could be a visit to the record shop for example. Here, the music is classified conformingly to the record companies' desires, which can sometimes be confusing for our collector, who is a fan of Jimi Hendrix, and just does not know where to look for his albums: in the blues section? Rock section? Is there a 'sixties' section? Anyway, despite finding them rather practical at first sight, our collector didn't create these labels, and finds it difficult adapting to them. However, as he browses through the shop, he also notices some nicely illustrated records, and discovers new artists he is interested in because their records are sitting next to Jimi's. Finally, when he has bought enough music records, and come back home, he will be able to start arranging his collection in a very personal and satisfying manner, which will be pleasing to the eyes, and also allow him to retrieve items quickly.

If he had decided to collect digital music, and go online to find new items for his collection, the process would have been rather similar. Commercial music download sites allow the user to browse through predefined music categories, thus implementing a kind of virtual record shop with the same problems mentioned earlier. The search tool however can come in handy, and allow the user to search for the name of an artist, a song, an album or even musical genre. All these are still editorial information, which aren't necessarily the most useful to the collector. Then, when the music is downloaded, the album consists of a group of compressed audio files, containing preset meta-tags, again storing editorial information. When browsing these files in his audio player, the songs are defined and classified automatically, not always according to the collector's desires. His final attempt is then to create a set of folders on his disk, and arrange his items in these folders. But how does he name these folders? What if he wants to arrange and browse the items in multiple ways? What if a particular item doesn't fit in any folder, or could be placed in two or three different categories?

As we see from this example, the tools that the everyday user has at hand are too formal, and are poorly adapted to the growing activity of collecting multimedia contents. Indeed, what we have said for music can also be said for the other kinds of media, and can also be said for information research, file sharing, etc.

Attempts have been made at putting the human user back in control of the collecting process, rather than relying purely on predefined categories and automated research algorithms.

However, it has become obvious that the other extreme of handing complete control over to the user isn't optimal either. Let us take a look at online content sharing sites, such as the famous FlickR™. There is no categorization here, but there are three main strategies when looking for photos: date, location, and tags. The first two are self-explanatory, but the tags are more interesting here. When someone uploads a photo to the website, they can link a certain number of keywords, called tags, to this photo. Then, we can either browse through the most popular tags, or type a tag into a textbox for a more precise search. The users then have complete freedom on the way they choose to define their photos. But the problem is that many photos aren't tagged, and the photos that are, often have poorly named tags, making them difficult to retrieve. Therefore, we believe that an optimal solution to the problem of digital collections could lie somewhere between these two polarities: predefined categories and total user creativity.

B. Artists and philosophers' fascination for collection regimes

As a matter of fact, artists and philosophers have always been fascinated by the rebellious nature of collections and have demonstrated this in their own way ([2], [20]).

Here, for example, is the analysis of [20] on the status of excess in a collection: *"Excess in a collection does not mean disordered accumulation; it is a fundamental principle: for a collection to exist as such-in the collector's eyes the number of objects must exceed the physical possibilities of exposing and storing the entire collection at home. Therefore, someone who lives in a studio can have a collection: it is only necessary for him to have at least one work he cannot hang in his studio. That is why the reserve is an integral part of collections. Excess also applies to the capacity of memorization: for the collection to exist, it is necessary for the collector not to be able to remember all the works he owns. In fact, the number of objects he owns must be so important that it becomes too important, so that the collector can forget one of them or leave a part of his collection outside of his home. To sayd it ifferently, for a collection to exist, the collector must not have full control over his collection anymore".*

And also: *"The scene of a collector is not his own apartment, it's the world. The main part of his collection is not at his place — his collection is to be, still scattered across the world, and every gallery and every fair is a way for him to go and find his future collection"*

As far as [2] was concerned, he had a very personal view on the subject: *"The art of collecting is a form of practical recollection, and, of all the profane manifestations of proximity, it is the most convincing. Everything that is present to memory, to thought, to consciousness, becomes a base, a frame, a pedestal, a casket for the object possessed".*

And also: *"What is decisive, in the art of collecting, is to free each object from its primitive functions, in order to establish a relationship as close as possible with similar objects. This relationship is diametrically opposed to usefulness, and belongs to the remarkable category of completeness. What is that completeness? An imposing attempt to go beyond the absolutely irrational nature of the simple presence of the object in the world, by integrating it in a new historical system, especially created, that is the collection".*

Thus, collections strongly differ from class, series, set, group, heaps, cluster, juxtaposition, accumulation, but also from organic whole/family.

C. Collections, between order and disorder

Until recently, a trend was mobilizing computers for the organization of our collections, considered like a group of

objects waiting to be organized in ad hoc classes that must be created simultaneously ([4], [9], [10]).

Because our collections seem to be nearer to order than disorder, attempting to assimilate them in classes is not so surprising. At least, collections look like they are waiting for their completion within a classification order, with the aim of turning into canonic achieved structures made of objects and classes. But something is also resisting this assimilation, as artists and philosophers have always noticed.

Undoubtedly impressed by artists and philosophers who considered the strange status of collections, computer program designers understood that computer modeling of object collections would necessarily involve the creation of hybrid structures including private characteristics – by which the collected objects are usually referred to – but also including characteristics that come from the activities in which these objects collectively engage.

Often, the approach implicitly chosen to characterize a collection is parsimonious and consists of over-determining the private referencing of the collected objects through a minimal description of the collective activity's context, even if it means predicting that the collection shall become a class or set of classes.

This practice presents the unquestionable advantage of not fundamentally opposing the traditional modeling of objects. However, it does not always live up to the collectors' high standards.

Here it is important to distinguish between figural and non-figural collections. This subtle distinction, introduced in the 1970s by Piaget and his research teams of child psychologists [12], brings more light to the situation. If it is certain that (non-figural) collections that adapt well to the aforementioned parsimonious approach exist, it is because they are completely independent of their spatial configuration. In that, they are already close to classification, of which they can only envy the formal completeness. On the other hand, there are collections we can label as *figural* because both their arrangement in space and the private properties of the collected objects determine their meaning.

D. Collections versus classes

In their book *La genèse des structures logiques élémentaires,* Jean Piaget and Bärbel Inhelder ([11], page 25) provide a precise distinction between figural and non-figural collections, which are still called classes or categorical collections. For the authors, a class requires only two categories or relationships, both necessary and sufficient, for its actual definition as a class:

1. The qualities common to its members and to those of the classes it belongs to, as well as the specific differences that distinguish its own members from the members of other classes (comprehension);
2. The relationship of a part to the whole (membership and inclusion) determined by the quantifiers "all", "some" (including "one") and "none" applied to the members of the class in question and to other members of the classes it belongs to, defined as extensions of that class.

For example, cats share in common several qualities owned by all cats, some being specific and some others belonging also to other animals. But no spatial considerations ever enter into such a definition: cats may be grouped or not in the space without any change concerning their class definition and properties (1) and (2).

Piaget then introduces figural collections, in which meaning defined by properties (1) and (2) is linked to the spatial arrangement of its elements. He claimed that: *"A figural collection composes a figure, through the spatial relationships between its elements, whereas non-figural collections and classes are free of any figure"*.

E. Figural versus non-figural collections

It is precisely these figural collections that computing is promising more and more an effective modeling of, pushed by an ever-growing social demand for on-line digital media browsing and information research amongst multiple sources.

But as we now understand, figural collections adapt poorly to their assimilation into non-figural collections or classes. Although according to Piaget, collections are destined to become classes, in the same way as subjects will grow psychologically so as to improve their cognitive capacity to classify. Still referring to [11]: *"It is a radical lack of differentiation that nudges figural collections out of the classical modeling field"*.

So classical IT approaches were unable to address and tackle the target of figural collections modeling.

On that particular point, we do not agree with Piaget, considering that, with the support of Inductive Data-Driven Algorithms and Big Data, even non-figural collections are about to be computerized.

IV. How Could IDDA & Big Data Help Supporting Our Figural Collections Deployment?

A. ReCollection: an experimental software for the creation of multimedia collections

ReCollection is a computer program for searching, arranging and browsing digital content, developed by Francis Rousseaux, Alain Bonardi and Benjamin Roadley [15].

As our collecting activities vary from one context to another, it is too ambitious to seek a general solution to the problem. Rather, particular application areas must be defined and isolated, in order for a specific answer to be given, however always relying on a set of basic principles. Here, we shall discuss the software prototype we have created for the digital opera/open form opera Alma Sola (designed by Alain Bonardi [3], and first performed at *Le Cube,* Issy les Moulineaux, October 2005).

1) The reserve

The ReCollection software has two main modes: reserve and gallery. The reserve allows us to store our objects that aren't exposed in the gallery. There are many objects in the reserve, and these are not always labeled; also they are rarely arranged in an orderly and tidy manner. So when we visit the reserve, we have no choice but to wander around,

picking up objects, inspecting and identifying them one at a time.

Fig 1. The reserve

The reserve can also be compared to the attic, in which our family possessions are stored similarly. As we explore our attic, we can happen to pick up an old photo album, which we had completely forgotten about. This item will surely bring back memories and emotions. We can then choose to keep this album under our arm, as we continue to explore the attic, or we can leave straight away, and put it on our fireplace, for example, making it visible to visitors. It is all these pleasant and familiar experiences, which we believe can be recreated thanks to the modeling of the reserve in our computer program.

The user can create any number of reserves. However, he must create at least one, and store at least one object in this reserve. When he is in reserve mode, he can only view one object at a time. When he decides to view another object, it is chosen randomly from the remaining items in reserve. During a visit, each object is viewed only once. If the user wants to view an item he has already visited, he may go through the history of items on the left side of the screen, as shown in figure 2. When he finds an object of interest, he can move it to the gallery. It will then be removed from the reserve, and saved in memory, with a group of objects waiting to be imported in the gallery. Then, in gallery mode, the user will see this heap of objects, and will be able to import it in the desired gallery, at the desired location.

2) The objects

The items in the Alma Sola collection are made up of three components:

1. A photo of the performance;
2. A sound recording of a few seconds of the singing;
3. A text: the line that is sang in the corresponding sound file.

These are all regular files stored on disk (bitmap, wave and .txt formats). Each item also has a name. In a more general context, the objects can be made up of any one of these types of media, a video (though not implemented in this version), or any combination of these.

Also, each object has a set of descriptors attached. There is a specific set of descriptors for each type of media, which describe the contents of the object, for example the average volume of the sound, the brightness of the photo, the number of words, etc. Depending on the application, we could also include editorial information, such as date, author, etc.

These descriptors may be assimilated to the private properties of traditional computer objects. But in the context of collecting objects, we also need to account for other properties that come from the activities in which these objects collectively engage.

3) The gallery

A collective activity involving a number of objects at a time is their relative arrangement in the gallery space. To the location of objects in this space, we have added their color; these two properties make up an extra conceptual layer, which is the framework for the creation and management of our collections.

In ReCollection, there is always at least one gallery, and the user can create as many as he wishes. There is always at least one item in a gallery, some basic content that the user can interact with, a starting point for his collection.

The objects can be placed and arranged manually in the gallery space, using click and move, just as in common user interfaces. The user can also rely on two algorithms to automatically dispose the objects. The first one, inspired by cataRT software [18], calculates the objects' positions and colors according to descriptors chosen by the user. The second calculates the positions depending on a sample of objects selected by the user. A Principal Components Analysis (PCA) finds out which descriptors vary most amongst the objects of the sample, the system can then rearrange the whole gallery according to these descriptors, as in the first method.

The arrangements resulting from the algorithmic calculations can always be modified manually in order to correct them (in the eventuality of rather subjective descriptors), to build up a global figure, or to bring items together. This way, through creative human-computer feedback loops, meaningful global figures can emerge through the arrangement in space of collected items, as well as local figures, soft pseudo-categories which are heaps of objects brought together by the system and/or the human user. These pseudo-categories are the building blocks for the classes the collection is implicitly aiming for. They are easily and constantly updated; items are added and removed instantly by being moved in space. They are loosely defined and never completely closed off from others, allowing some objects to be lost somewhere in between several heaps, when they cannot be placed in any one category. In a nutshell, this system allows for the creation of collections in which classes are in constant evolution, and are built by exploiting not only the objects' degree of similarity, but also their relative location in space and time.

Furthermore, the user may wish to search for objects in the gallery or in the reserve, in order to build on these categories, look for new kinds, or even fill in gaps in the gallery space. For this, the ReCollection system has two search tools

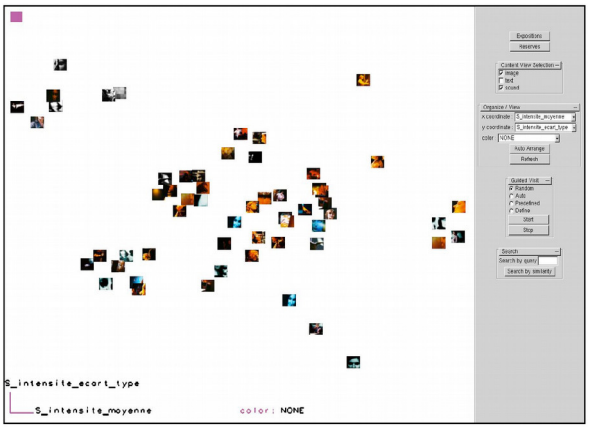

Fig 2. Gallery mode

he can use. The first is a simple 'keyword query', which searches for a keyword within the text or names of the objects. The second is a 'search by similarity'. The user selects an object, or group of objects, and the system searches for items that are similar (according to the descriptors). In both cases, the search is carried out in both the gallery and reserve, and a list of results is displayed in the gallery, ordered by similarity.

B. ReCollection at the time were IDDAs & Big Data technologies are now available

Once all the items of interest have been imported from the reserve, through browsing or searching, and once they have been arranged in the gallery space, the user has a first disposition he can play with. When he will browse the gallery space, his experience will be influenced by the fact that certain objects are close in space, and in time of visitation. Although this is interesting in itself, the system can help the user go further, by defining a set of guided visits, which are simply an order of visitation of selected objects in the gallery.

The type of interface we have chosen to implement these functionalities is a 2D zoomable user interface, inspired by Ken Perlin's Pad [5]. All objects are in the same 2D space, which has no borders. The point of view can be moved vertically and horizontally, and the user can zoom in and out. If he zooms in on an item, until it fills the screen, the sound is played back. This kind of interface has been experimented: Its intuitive approach is seducing to us, particularly in our goal of intuitively collecting digital media. Finally, the spatial metaphor takes advantage of the users' spatial memory and cognitive abilities [7].

ReCollection has typically been designed for supporting figural collections deployment, as the time where IDDAs & Big Data technologies were not yet available. That is why our 'search by similarity' tools were mainly based on PCA.

Nowadays, we are developing some IDDAs to allow the collectors to search by new kind of similarities through remove virtual digital reserves, distributed along the Web.

V. Conclusion

Inductive Data-Driven Algorithms really allow us to explore differently digital 'Big Data', if we waive the deductive requirement and permit the inductive heuristics to apply.

But technically, IDDA is not easy to develop, and ethically, it could be dangerous for our decision autonomy because of the lack of traceability that characterizes those IDDA approaches, readily producing 'results' without any linked explanation.

However, we have discovered a 'Big Data' field where IDDAs are fully legitimate and powerful, namely: 'figural' collections constitution, content curation and deployment. This task is much more important for human beings that it looks like, and the lack of efficient tools to support that was clearly identified.

Incidentally, that discovery has disclosed some important Abstract Truth of Big Data: if we accept, against Piaget, that collecting is more native than classifying or categorizing but not less powerful and intelligent, Big Data is the reserve of our future personal digital collections.

Abstract—**Companies have both large certified enterprises and small unauthorized service providers as their competitors in the automotive supply industry. As technology related industries undergo more intensive competition, churn detection and prediction become essential to be precautious about leaving customers. The literature for churn detection offers numerous statistical and intelligent methods. In this study, Artificial Neural Networks and Decision Trees are applied to detect the churn in and analyze the validity of these methods for the automotive supply industry. The problem involves both categorical and continuous numerical decision inputs which cannot simultaneously fed into Decision Trees. In this case, continuous inputs should be divided into binary categorical ones by splitting into various intervals which are called buckets. Particle Swarm Optimization algorithm is implemented for finding optimal buckets for the churn problem data. Results indicate that while both algorithms are promising, the bucket tuning for Decision Trees complicate the churn detection process.**

I. Introduction

Retaining existing customers has become the main objective of Customer Relationship Management (CRM) departments in markets with fierce competition [1]. Automobile service industry stands for a real example when fierce competition is mentioned in Turkey. Maintenance and hard repairs are the most profitable cases in automobile service market, and every one of the authorized and non-authorized services are trying to take a big pie of this market. Developed subsidiary industry of automobile spare parts and low labor costs of non-authorized services are challenging automobile companies to retain their customers, making churn prediction an important part of this challenge. Retaining a customer is more profitable than acquiring a new one so that companies are willing to know which customer will churn like in other markets. Preventive actions, new marketing strategies and long term service contracts can be made in case of foreknow the churners. Churn prediction must be as accurate as possible to ease decision making. It is known that the cost of earning new customers is a lot more than sustaining existing ones. Hence, it becomes essential to select the best churn detection methods given company data [2].

In literature, there are various methods for data mining in churn prediction; yet, the common point of these methods are that they yield a classification and/or clustering decision where the customers are grouped as "churned" and "not churned" [3]. The methods applied for grouping customers for churn can mainly be subsumed under statistical, intelligent and hybrid methods. Statistical methods involve approaches that intend to minimize incorrect classification using statistical data processing tools such as Decision Trees or Regression [4]. Learning algorithms and intelligent methods make up the recent trend with the contribution of computer technologies in churn mining where methods such as Neural Networks and metaheuristics are implemented [5]. Lastly, hybrid methods that combine statistical and learning methods are stated to provide more accurate results [5]. These methods will be elaborated in the next section.

The literature of churn prediction is intensified in the service industry; especially in telecommunication and banking [3, 6-8]. Emerging from these industries, churn prediction is now known to contribute to companies in other industries, as well. In this study, we have applied two different data mining techniques on the problem of churning customers in the automotive supply industry. Artificial Neural Network and a hybrid method (Particle Swarm Optimization (PSO) based ID3 Decision Trees)s are used for determining the churn and their accuracies were compared in order to provide a better detection performance.

The structure of this paper is as follows: The next section provides a literature review on churn determination and prediction together with the motivation of this study. The third section introduces the methodology and an application is provided in the following section. Finally, the conclusions are presented in the last section.

II. Literature Review

Churn analysis and prediction aims to detect churn customers and/or predicting how likely the customers are to be churned [3]. The literature of churn analysis is intensified in industries where high rate of competition exists; such as

This work was not supported by any organization

the telecommunication industry where the churn rate reaches its peak with an annual average of 27% [9].

The implementation of data mining techniques in churn analysis is inevitable, since the extraction of patterns in churned customers is essential for determining and predicting churn [10]. An analytic view of the methods in churn analysis can be analyzed three-fold: statistical, intelligent and hybrid methods. The most exploited method in statistical churn analysis is Decision Trees and Random Forests [4]. Ahn et al. [11] use Factor Analysis in telecommunication industry and state that customer status is the most important criteria. Bin et al. [12] implement Decision Trees in phone sales. Wei and Chiu [3] implement decision trees that extract rules with C4.5 algorithm for churn prediction. Lariviére and Van del Peol [13] implement logistic and linear regression models and extend the Decision Tree approach and execute random forests in telecommunication industry. The implementation of decision trees is also diversified. For instance, Lemmens and Croux [14] use Bagged & Boosted Decision Trees in Telecommunications Industry.

The execution of intelligent and learning methods have been the focus of literature of the past two decades. In particular, Artificial Neural Networks (ANNs) methods, both supervised and unsupervised, represent the majority of studies in this branch. Hadden et al. [5] implement basic Back Propagation algorithm on Feed-Forward Neural Networks. Buckinx and Van den Poel [15] compare the performance of Random Forests and ANNs and conclude that the prediction by ANNs is more robust in case of FMCG industry example. Other variations of ANNs involve Support Vector Machines (SVMs) and Self Organizing Maps (SOMs). Coussement and Van den Poel [16] construct and SVM model to predict churn customers in telecommunications industry, whereas Tsai and Lu conduct a similar study where they implement an unsupervised approach by SOMs [17]. Even though, ANNs are known to be stronger churn predictors than Decision Trees, they are known to have disadvantages such as early convergence or being stuck at local optima [5]. Hence, these models are enhanced with other metaheuristics or Artificial Intelligence methods. For example, Karahoca and Karahoca [18] implement an Adaptive Neuro Fuzzy Inference System model integrated with a fuzzy clustering method which highly outperforms ANNs.

Hybrid methods are known to provide better comprehension of the churn structure. Xia and Jin [19] first find out the criteria that affect churn using Factor Analysis and using these criteria, they build an SVM model in order to predict churn. Idris et al. [9] find the optimum decision tree using Particle Swarm Optimization and conclude that metaheuristic-based decision trees outperform in terms of classification accuracy.

In this study, one main statistical method - Decision Trees - and one main intelligent method - ANNs - are tested on automotive supply chain determination. The very basic ID3 algorithm is used for Decision Trees. However, the ID3 (Interactive Dichotomizer 3 (ID3) algorithm for Decision Trees only operate when all variables are categorical and the data on hand involves continuous numerical variables. Hence a separation scheme is mandatory. The optimum separation points are found by Particle Swarm Optimization algorithm, yielding a hybrid method. A comparison of a hybrid and an intelligent method is constructed in terms of automotive supply industry perspective.

The factors used for classification in literature are observed to depend industry-wise. Telecommunication industry related studies - GSM churn, to be concise - are mainly focused on minutes of usage, monthly number of calls or monthly bills, which are specific to this industry [3]. Hence, it is essential to find out the criteria that are specific to the industry. However, the literature on automotive supply industry does not offer many criteria; which is why, mainly interviews with industry experts have determined the criteria for this study.

III. METHODOLOGY

Decision Trees and ANNs will be compared for this study, since they are the basic decision making.

A. Decision Trees

The basic ID3 Algorithm is used for Decision Trees. Proposed by Quinlan [20], the algorithm uses information gain in order to decide the splits or branches of the tree, which is calculated as given below:

$$IG(S) = \sum_{k=1}^{N} -p(k)\log_2 p(k) \quad (1)$$

where S is an element of the input attribute set I, N is the number of unique attribute values, $p(k)$ is the probability of this attribute value k [20-21].

For each node, the attribute that provides the most information gain is split until final branches (called leaves) are reached. The algorithm builds a decision tree from the data which are discrete in nature. The data in the case of automotive supply industry churn involves continuous variables such as mileage. In this case, the data of continuous attributes should be discretized. One way to handle such continuity problems is to assign separation or split points for the data and convert them into binary variables. This process is called “splitting into buckets” where each bucket is a class that specifies a range of values and a data point is subsumed under one of these ranges or buckets [22]. For example, if the range of a continuous variable is [0,10] and the separation point is 5, then, the buckets are [0,5] and [5,10]. A value, say 3, is classified in a binary fashion as 1 and 0, for two buckets, respectively. Moreover, the selection of separation points affects the structure of the input data, and hence, largely impacts the accuracy of the decision tree. Therefore, these separation points should be tuned. This tuning is achieved by the PSO algorithm.

B. PSO Algorithm

The PSO algorithm offered by Kennedy and Eberhart [23]. The steps of the conventional PSO algorithm are given below:

Let p_i be the i^{th} particle in the swarm which consists of N particles and let each particle have n variables.

Step 1. The particle velocities and positions are initiated as priorities

$$x_{i,j} = x_{min} + r(x_{max}\text{-}x_{min}), \quad i = 1, \dots, N, j = 1, \dots, n \quad (2)$$

$$v_{i,j} = \alpha \frac{x_{min} + r(x_{max}\text{-}x_{min})}{\Delta t} \quad i = 1, \dots, N, \ j = 1, \dots, \quad (3)$$

where x denotes the position, v denotes the velocity and is constant in the range [0,1].

Step 2. The objective function values of particles are calculated as $f(x_i)$.

Step 3. The best position for each particle and the global best position for the swarm are updated.

$$\text{If } f(x_i) < f\left(x_i^{pb}\right) \text{ then } x_i^{pb} \leftarrow x_i \quad (4)$$

$$\text{If } f(x_i) < f\left(x_i^{sb}\right) \text{ then } x_i^{sb} \leftarrow x_i \quad (5)$$

where pb denotes the particle best and sb denotes the swarm best.

Step 4. Particle velocity and particle position are updated, that is, the new velocities and positions are calculated for each particle.

$$v_{i,j} \leftarrow wv_{i,j} + c_1 r_1 \left(\frac{x_{i,j}^{pb}\text{-}x_{i,j}}{\Delta t}\right) + c_2 r_2 \left(\frac{x_{i,j}^{sb}\text{-}x_{i,j}}{\Delta t}\right), i = 1, .. \quad (6)$$

where $wv_{i,j}$is the separation term, $c_1 r_1 \left(\frac{x_{i,j}^{pb}\text{-}x_{i,j}}{\Delta t}\right)$is the alignment term and $c_2 r_2 \left(\frac{x_{i,j}^{sb}\text{-}x_{i,j}}{\Delta t}\right)$ is the cohesion term.

Step 5. Step 2 is returned until a termination criterion is satisfied.

C. ANNs

ANN models are basically derived from nervous systems which are able to perform functional input-output mapping such as machine learning and pattern recognition [24-25]. In this study, feed forward neural networks with back-propagation learning algorithm are utilized.

ANNs are constructed by layers of cells which are called neurons as can be seen in Figure 2. Neurons connect to other neurons in consecutive layers by a certain weight value. Inputs of each neuron are the weighted sum of the weights of incoming neural connections and a bias. This sum is subjected to a transfer or an activation function within the neuron [23]. The input of a neuron is calculated as

$$n = \sum_i w_i \cdot x_i + bias \quad (7)$$

where n is the input of a neuron, w_i is the weight of the i^{th} neuron in the previous layer and x_i is i^{th} input value.

The Back-propagation algorithm is a learning structure that minimizes the forecasted output of the network and the actual output by adjusting weights of the network. In order to achieve this error minimization, the data are first fed into the network and the error term obtained is propagated back into the network to adjust weights with formula given below

$$\Delta w_{ji}^k(n+1) = \text{-}\eta \frac{\partial E}{\partial w_{ji}^k} + \Delta w_{ji}^k(n) \quad (8)$$

where n is the index for iterations, η is the learning rate and E is the error term. Note that the derivative of the error term with respect to the weights yields the weight adjustment.

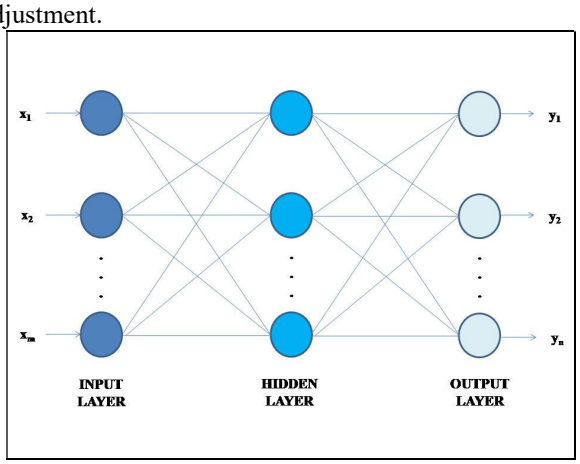

Fig. 2 The structure of an ANN

IV. APPLICATION AND RESULTS

In the last decade, there has been an increase in fleet customers in automotive market. Instead of buying a new car, companies started to rent fleet of cars. So that, detecting a fleet car has become critical because detecting one of the fleet car's churning means losing all of the cars and profit from that fleet.

In this study, the churn determination of customers of a leading car seller of Turkey is achieved using a PSO-based ID3 Decision Tree and ANNs. The criteria for churn evaluation are extracted from the interviews with industry experts and company's academic consultants.

The criteria for churn evaluation are listed below:

1. Annual penetration of 2013: It represents the total amount of cash inflow that customer did throughout the year 2013. It is a continuous attribute; hence, it should be bucketed.
2. Annual penetration of 2014: It represents the total amount of cash inflow that customer did throughout the year 2014. It is a continuous attribute and it should be bucketed as in the previous year's case.

3. Annual penetration of 2015: It represents the total amount of cash inflow that customer did throughout the year 2015. Just like the previous years, it is bucketed.
4. Annual frequency of maintenance of 2013: It represents the number of times that the car was taken to maintenance services throughout the year 2013. It is a discrete variable.
5. Annual frequency of maintenance of 2014: It represents the number of times that the car was taken to maintenance services throughout the year 2014. It is a discrete variable.
6. Annual frequency of maintenance of 2015: It represents the number of times that the car was taken to maintenance services throughout the year 2015. It is a discrete variable.
7. Year of purchase: It represents the year that the car was purchased by its owner. It is a discrete variable.
8. Insurance: It represents if the car is insured. It is a binary discrete variable.

Discretization of the continuous variables is achieved by splitting into buckets for the first three criteria; hence, PSO algorithm should be applied in order to find the optimum separation points. However, the optimum number of buckets is not known a priori; and thus, number of buckets are found by trial and error. The splits for bucket construction of 2, 3, 4 and 5 buckets are tuned by the PSO algorithm.

The performance measure (objective function) of the algorithm is taken as the rate of misclassifications. There are a total of 500 data points and their churn conditions are known. Two sample data points are shown in Fig. 3. The first customer is a churn and the second customer has not churned. 70% of the data are used for training and the rest is used for testing. PSO parameters are adjusted as 20 for the swarm size, 1 for the inertia coefficient (w), 2 for the cognitive coefficient (c_1) and 2 for the social coefficient (c_2). The learning rate (η) of the ANN is 0.7. Table 1 shows the average and the standard deviation of 30 runs of training of the PSO-hybrid and ANN results, respectively. Table 2 shows the same results for the testing data.

PSO-based Decision Trees yield the best result when the number of buckets is 2 for the training data and the testing data. Additionally, the PSO-hybrid with 2 buckets has one run without any error for the training data; whereas the ANN has one run without any error for testing data. In order to analyze if the results of these 30 runs are statistically significant, t tests among the algorithm results is applied. Tables 3 and 4 display the p values of the t test results of methods in a pairwise comparison fashion. The lower parts of the tables are not filled because the tables are symmetrical. For example, the value that is in the intersection cell of PSODT2 and PSODT3 also applies to the value of the intersection cell of PSODT3 and PSODT2.

TABLE I.
ALGORITHM RESULTS FOR TRAINING DATA

Method	Average misclassification Percentage (μ)	Standard deviation of the misclassification percentage (δ)
PSO – based Decision Tree with 2 buckets (PSODT2)	0.086	0.12
PSO – based Decision Tree with 3 buckets (PSODT3)	0.118	0.05
PSO – based Decision Tree with 4 buckets (PSODT4)	0.150	0.07
PSO – based Decision Tree with 5 buckets (PSODT5)	0.114	0.04
ANNs	0.109	0.02

TABLE IIII.
ALGORITHM RESULTS FOR TESTING DATA

Method	Average misclassification Percentage (μ)	Standard deviation of the misclassification percentage (δ)
PSODT2	0.154	0.05
PSODT3	0.170	0.03
PSODT4	0.167	0.05
PSODT5	0.198	0.04
ANNs	0.160	0.03

TABLE II.
SAMPLE DATA POINTS

	Annual Penetration			Annual Maintenance Frequency					
Rack Number	2013	2014	2015	2013	2014	2015	Year of purchase	Insurance	Churn
XXXXXXXXXX	0	478,546	647,431	0	1	1	2013	1	1
YYYYYYYYY	0	12,37	0	0	1	0	2012	0	0

TABLE IV.
P VALUES OF T TESTS FOR TRAINING DATA

	PSODT2	PSODT3	PSODT4	PSODT5	ANNS
PSODT2	-	0.2113	0.0640	0.7335	0.3047
PSODT3		-	0.0340	0.8648	0.4793
PSODT4			-	0.0175	0.0031
PSODT5				-	0.5427
ANNs					-

TABLE III.
P VALUES OF T TESTS FOR TESTING DATA

	PSODT2	PSODT3	PSODT4	PSODT5	ANNS
PSODT2	-	0.1383	0.3181	0.0004	0.5752
PSODT3		-	0.7791	0.0330	0.2018
PSODT4			-	0.0103	0.5134
PSODT5				-	0.0001
ANNs					-

The less the p value is, the more statistically different the results of the two methods compared. For example, for the training data, the p value between PSODT2 and PSODT3 is 0.0640. If a significance level of 10% is assigned, the given p value is less than 0.1, that is, the results of PSODT2 and PSODT3 are statistically significantly different. Moreover, from Table 1, it can be seen that the misclassification error rate of PSODT3 is larger, which means that PSODT2 provides better results that PSODT3. According to Table 3, for the training data, apart from PSODT4, other algorithm results are not statistically significantly different from each other. In terms of the testing data (see Table 4), PSODT5 is the worst result providing algorithms and other algorithm results are similar. Using these results, the non-dominated algorithms are PSODT2, PSODT3 and ANNs. ANNs provide better results for both training and testing data. Likely, the results of PSODT2 and PSODT3 are also as good; yet, in terms of Decision Trees, the bucket numbers have to be optimized. Moreover, considering the accuracy of the models, it is concluded that the criteria determined by industry experts are valid for churn detection.

V. CONCLUSION

Churn detection is difficult in industries where the competition is fierce. The churn is intensive in especially technology related industries. Even though not being as technologically intensive as online markets or telecommunication industries, automotive supply industry is also one of the industries that suffers from frequent churn. Therefore, churn detection and prediction becomes essential.

In this study, ANNs are constructed for churn prediction for automotive supply industry. Traditional churn approaches also offer the implementation of Decision Trees to be a powerful means of churn analysis. However, in the presence of non-categorical (numeric – continuous) data, the implementation of Decision Trees with raw data may be misleading. For this reason, it is obligatory that the continuous data are converted to binary and categorical data. This process is achieved by using 'buckets'. PSO algorithm is used for optimizing the number of buckets and the split values of the data. Once the data is processed into buckets, it can be fed into the decision tree. The results indicate that while both methods can be equally strong, the number of buckets is an important factor for determining the optimum decision tree.

Future studies that aim misclassification error reduction may involve improved ANN techniques such as dynamic networks, etc. Hybridization of decision trees with other metaheuristics and changing the decision tree structure are also worth analyzing. Additionally, different churn data would be helpful for the validation of the results. This study does not involve temporal predictors of churn; these predictors should be integrated into the churn model.

***Abstract*—Business Process models help to visualize processes of an organization. In enterprises, these processes are often specified in internal regulations, resolutions or other law acts of a company. Such descriptions, like task lists, have mostly form of enumerated lists or spreadsheets. We present a method how to generate a BPMN process model from a spreadsheet-based representation. In contrast to the existing approaches, our method does not require explicit specification of gateways in the spreadsheet, but it takes advantage of nested list form.**

***Index Terms*—Business Process Model and Notation (BPMN), process modeling, spreadsheets, spreadsheet-based modeling**

I. Introduction

PROCESS models constitute a useful knowledge representation. They are commonly used by organizations to depict the workflow of the company, especially to specify alternative flows of tasks and events. Such aspects are often specified using textual description in internal regulations, resolutions or other companies law acts. These descriptions consist of the specification of the steps taken to achieve the specific goal. Such steps can be easily specified using a spreadsheet or an enumerated list (an ordered list of steps can be almost directly transformed into a spreadsheet format).

In this paper, we present a method of generating BPMN process models from spreadsheet-based representation (see Fig. 1). A process can be described using one of the spreadsheet applications like MS Excel, Google Docs or OpenOffice Calc. Based on the CSV file of the model exported from the application, a graphical process model in BPMN can be generated according to the specified transformation rules.

According to the studies [1], up to 60% of the time spent on process management projects can be consumed by the acquisition of process models, which mostly is done manually by process designers or business analytics. Thus, generating or transforming the existing representation to models can shorten this time.

In the field of transforming some kind of process description into a process model, there are various research directions.

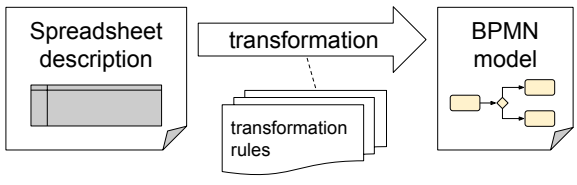

Figure 1. Overview of the spreadsheet-based approach

II. Related works

One of the existing methods is generating models from text description. A text can be provided in natural language [1] or in structured language. A part of the SBVR standard is SBVR Structured English [2]. There are methods of tranforming SBVR business rules into UML activity diagrams [3] (which are similar to BPMN models) or BPMN [4], [5]. Some papers consider the extended versions of SBVR, like SBPVR (Semantics of Business Process Vocabulary and Process Rules) [6] or sSBVRMM (simplified SBVR metamodel) [7]. There are also methods for analysis and validation of processes which use natural language generation [8] or spreadsheets [9].

Another method which provides good quality models is translation from other representation. An example of transformation approach is transformation of the Unified Modeling Language (UML) use case diagrams [10], [11]. The broad family of process model generation methods is process discovery, which is one of the process mining techniques. There are many existing algorithms, mostly implemented using the ProM process mining toolkit. Among them, there are algorithms to mine BPMN models [12].

The most similar approach to ours was presented by Krumnow and Decker in [13], [14]. They proposed three different approaches for business process modeling using spreadsheets:

1) Simple approach – this solution concerns simple processes modeled only using sequences of activities.
2) Branching approach – concerns not only sequences, but also more complex flow structures. It uses such elements like successors in order to represent complex control flow, as well as gateways and events. For the condition, the "Description" column is used. In the case of several successors, this can be realized by using a comma-separated string of row numbers as property value.
3) More Properties approach – extends the branching approach with additional specified explicitly properties like the assigned roles, input documents, etc. It allows for adding customized properties as new columns to the spreadsheet, which are not presented in the model.

The second and third approaches require from the user some kind of familiarity with business process modeling notation. According to these approaches, the user has to specified such elements like gateways or successors.

In our research, we propose a new approach, which solves the problem of familiarity with business process modeling notation. The solution is described in the following section.

Table I
SIMPLE EXAMPLE OF A XOR-GATEWAY IMPLEMENTATION

Order	Activity	Condition	(..)
4a	Send Ticket	Payment registered	
4b	goto 6	else	
5	...	...	
6	...	...	

III. TRANSFORMING SPREADSHEET INTO BPMN MODEL

The translation method presented in this section transforms a spreadsheet-based representation into a BPMN 2.0 model. In the following subsections, we describe the requirements and assumptions that we took into account during method development, the supported representation, as well as we provide the detailed description of transformations along with transformation procedure.

In order to make the solution widely applicable and simple to use, some assuptions were made. The following requirements need to be considered while providing a spreadsheet-based representation of a business model:

- The user should be able to create a business process model using his favourite popular spreadsheet application (e.g. MS Excel, Google Docs, OpenOffice Calc).
- A graphical model should be created using a CSV file (an exported spreadsheet).
- Only one pool is considered and the term "Who" is used instead of swimlane to distinguish different task executors.
- Logical gates are eliminated from the model. A process should be described as a set of phases. If two tasks are executed in the same phase, it means that there are parallel or connected by an inclusive or exclusive alternative (OR/XOR). The relationship between tasks is determined by a condition stored in a separate column (no condition – AND, two different conditions – OR, condition and „else" statement - XOR). Table I shows how logical gates can be represented.
- Loops are represented by "goto" tasks, which link one phase with another.

In the proposed solution, a business process is represented by a spreadsheet table, where rows correspond to tasks (or phases). Columns contain properties of the selected phase. Task and condition names should start with a capital letter, while all instructions are written in lowercase. Following column types are used:

- Order – number of the corresponding phase (starting from one). If two or more tasks are performed in parallel or alternatively, we use letters to distinguish different branches.
- Activity – name of the performed action or instruction. For example, if there is a need for a loop or skipping the phase, this field should be filled with a „goto" statement and number of the desired phase, e.g. „goto 7".
- Condition – a condition needed to perform the selected action. If the task executes every time this field should be left empty. In order to implement a XOR-gateway this field should be filled with an appropriate condition and the word „else" for the other task performed in the same phase. In order to implement an OR-gateway the fields mentioned before should be filled with two separate conditions.
- Who – a department or person that executes the task. This field corresponds to a swimlane in BPMN.
- Subprocess – information if the selected task contains a subprocess. If so, this field should be filled with „yes" and a sheet with a name of this subprocess should be created. Otherwise the field should remain empty.
- Terminated – information if the selected task terminates the process. If so, this field should be filled with „yes". Otherwise the field should remain empty.

Supported process elements and their spreadsheet model

1) Start events: In the proposed model an assumption is made, that a business process starts in one specified moment, which is called the „0 phase". First 3 rows of Table II present examples of none, message and timer start events.

2) End events: End events are represented by the statement „yes" in the column „Terminated". The field "Activity" can either contain the name of the last activity or remain blank. In 4th and 5th row of Table II the examples of none and message end events are presented.

3) Tasks: The name of a task is stored in the „Activity" column and should start with a capital letter. To skip a phase or go back to a previous phase it is possible to use the „goto" statement in the activity field.

4) Collapsed subprocesses: If a task is a collapsed subprocess, the „Subprocess" field should be filled with „yes" and the subprocess should be then modelled in a separate spreadsheet.

5) Parallel-, Exclusive- and Inclusive-gateways: Gateways are represented by alternative branches in the sequence (phase) flow. A phase preceded by a logical gateway is named as follows: NxM, where N is the (natural) number of the phase in the main process branch, x is a letter (a-z) corresponding to the alternative branch and M is the number of the phase in the selected branch. If the branch contains only one task M can be omitted. We assume that the branching is always ended by the same type of gateway that started it. It may be perceived as a limitation, but in fact it prevents model unconsistency.

The representation of a simple AND-gateway was presented in the 6th row of Table II. In order to implement an XOR-gateway, the field „Condition" should be filled in with the appropriate condition and with the word „else" for the other task performed in the same phase, but in another branch. An example of a simple XOR-gateway was presented in Table I. In order to implement an OR-gateway the fields mentioned before should be filled with two separate conditions. An example of an OR-gateway within multiple gateway spreadsheet representation was presented in the last row of Table II.

6) Pool/lane: Only one pool is considered. Different swimlanes are represented by the field „Who" containing the appropriate department or name.

Our spreadsheet-based approach is dedicated to people who are unfamiliar with business process modelling and that is

Table II
TRANSFORMATION RULES FROM SPREADSHEET-BASED REPRESENTATION TO BPMN PROCESS MODEL STRUCTURE

why it is important to transform the created spreadsheet into a BPMN diagram in a simple way. Such a diagram is a correct BPMN model, however, it can still contain some behaviour anomalies if the spreadsheet contains some loops [15].

The proposed set of transformation rules can use a CSV file that can be created from any spreadsheet software. The table containing information about the business process is represented as an array of structures, where each row is a unique part of structure with some element fields in the row.

Table III presents the overall comparison of our approach to the existing approaches in terms of supported elements by these solutions. One can noticed that our approach supports fewer elements than such complex approaches as Branching or More Properties approaches. However, the other approaches support the elements in a straightforward way, requiring the deeper knowledge of business process elements, even in the case of such simple structures like gateways.

Moreover, there are several points, in which our approach has the advantage over the existing approaches:

- We do not use explicit notion of XOR/OR/AND gateways, thus the user does not have to think about the kind of flow branching. Instead, in our model it is modeled in the implicit way.
- For describing condition, we use the ”condition” column, what is more clear than using the ”description” field.
- We do not use the notion of ”Successor” as it does not always show clearly the flow in the spreadsheet representation. Thus, in our opinion, a well-known jump statement ”goto” (one-way control flow transfer), existing in many computer programming languages, in this particular usage performs better, as it is clearly visible in the Activity field.

IV. CONCLUSIONS

In the paper, we present a new method of generating a BPMN process model based on its spreadsheet-based representation. In contrast to the existing approaches, our method does not require explicit specification of gateways in the spreadsheet, but it takes advantage of the spreadsheet with numbered rows in the form of a nested list. Thanks to this, our method does not require the knowledge of the BPMN notation or any business process notation.

As future works, we plan to extend the method in order to support multiple pools, message flows, as well as more type of events, including boundary events.

***Abstract*—Rules and processes constitute powerful representation forms. Although the same notions can be expressed in both of these representations, there is a significant difference in abstraction levels between processes and rules. In practice, rules are mostly used for the specification of rule task logic in processes. In this paper, we present various options where and how rules can be perceived in business processes. We introduce rule-based pattern perspective for process models, focusing on BPMN 2.0 Business Process Models.**

***Index Terms*—BPMN, Business Processes, Business Process Hierarchization, Business Process Configuration**

I. Introduction

BUSINESS Process (BP) [1] models constitute visual representations of processes of an organization. BPMN is a dominant visual modeling language used for describing processes. A BPMN model should be easy to understand for non-business users. However, sometimes such a model becomes illegible or unclear due to its complexity. One of the ways of reducing complexity is to introduce rules in order to specify low level business logic of the process. Such Business Rules (BR) [2] can describe business policies, goals, strategies or guidelines, in a form of declarative statements, constraints or predicated actions. Another issue of improving comprehensibility of the model is to use the notation in a proper way.

As BPMN specifies only a notation, thus there can be several ways of using it. There are style directions how to model BPs [3], or guidelines for analysts based on BPs understandability (e.g. [4]). However, a proper business process modeling is still a challenging task, especially for inexperienced users.

Design patterns in software engineering propose reusable solutions independent from the implementation technology. Similarly, workflow patterns address business requirements independently from specific workflow languages, and describe the problem, conditions that should hold for the pattern in order to be aplicable, examples of business situation, as well as its realization or implementation [5]. As the existing workflow patterns perspectives does not take into account rules, we propose rule-based pattern perspective for process models.

The paper is organized as follows. In Section II we present the motivation for our research. Section III provides a short overview of related approaches. In Section IV we present our proposal of Rule-based Pattern Perspective for BPMN Process Models. Section V summarizes the paper.

II. Motivation

Although it is possible to express the same notions (concepts, objects, system behaviour description etc.) using processes as well as rules. These two approaches are not suitable for this purpose, as they use different languages, depict different aspects of a system, and thus there is a significant difference in abstraction levels between processes and rules. However, this is neither standardized nor obvious which method is better for expressing a particular semantics.

During modeling a system using processes and rules, several questions can arise, from the simple ones like which representation is better for a specific purpose, through the integration of proceses and rules, to detail aspects of representation pragmatics. Thus, in order to organize the knowledge about process models with rules, rule-based pattern perspective for processes is introduced. Based on workflow patterns, we selected several attributes which are applied to rule-based patterns in process models. Presenting the patterns, we focused on their BPMN representation. Such patterns can help in designing models with rules and increase the comprehension level of the model.

Similarly to other languages, in the BPMN modeling language, three aspects can be distinguished: syntax, semantics and pragmatics. In the case of syntax, the current BPMN 2.0 specification [6] describes it in detail, and our research is consistent with the specification describing the syntax of rule related elements (event, tasks). BPMN semantics have also been considered in several papers [7], however, not with an emphasis on rules. As in practice, the pragmatics of language use is essential, a short overview of the BPMN pragmatics is presented in the following section.

III. Related works

In the case of the BPMN pragmatics the following particular issues can be considered: modeling techniques and styles, workflow patterns, as well as domain patterns. These issues are elaborated in the next subsections.

A. Workflow Patterns and Domain Process Patterns

As design patterns provide reusable solutions [9] independent from the implementation technology, workflow patterns address business requirements independently from specific workflow languages. Such patterns describe conditions that should hold for them in order to be applicable, examples of business situation, description of the problem, as well as realization or implementation in current languages [5].

Table I
FRAGMENT OF IMPLICIT TERMINATION PATTERN SPECIFICATION[1]

Implicit Termination Pattern	
Description:	*A given process (or sub-process) instance should terminate when there are no remaining work items that are able to be done either now or at any time in the future and the process instance is not in deadlock. There is an objective means of determining that the process instance has successully completed.*
Motivation:	*The rationale for this pattern is that it represents the most realistic approach to determining when a process instance can be designated as complete. This is when there is no remaining work to be completed as part of it and it is not possible that work items will arise at some future time.*
Solutions:	*For simple process models, it may be possible to indirectly achieve the same effect by replacing all of the end nodes for a process with links to an OR-join which then links to a single final node. However, it is less clear for more complex process models involving multiple instance tasks whether they are always able to be converted to a model with a single terminating node. Potential solutions to this are discussed at length by Kiepuszewski et al. [8].*

Originally, van der Aalst et al. identified a set of 26 patterns that describe the control-flow perspective of business processes [5], [10]. Table I presents an example of a typical structural control-flow pattern for implicit termination of a process[1]. In the case of the BPMN notation, this pattern is directly supported from the very beginning (version BPMN 1.0) by ending every thread of a process with an end event. When the last token in the process generated by the start event is consumed, the process instance terminates.

Over the years, the existing workflow patterns have been evaluated [11], [12], [13], revised [14], [15], and extended to cover new perspectives like the data and resource perspectives [16], [17], or time perspective [18].

Until now, much more workflow patterns have been identified. The Workflow Patterns Initiative[2] distinguishes:

- 42 control-flow patterns,
- 43 workflow resource patterns,
- 40 workflow data patterns,
- 12 abstract and 8 concrete syntax modification patterns,
- over 100 exceptions patterns of various exception types.

Such patterns serves not only as good practices but also for a pattern-based evaluation of tools or standards [19], [20], [21].

What is more, one can also distinguish patterns concerning the process of modeling itself [22], [23], like fixation patterns during process model creation [24], or abstract and concrete syntax modifications patterns [25], [26].

Another kind of patterns – Domain Process Patterns (DPP) [27] – represent functions of process model fragments that are applicable to some modeling domain. They were introduced as a result of the investigation of business processes from the order management and the manufacturing production domains. Such patterns describes some domain related business operations representing a small fragment of the process. Although it is possible to consider involving rules in DPP, e.g. in *Inventory Pattern* one can consider rules involved in inventory management, it is not a purpose of DPP.

[1]An example can be accessed at http://www.workflowpatterns.com/patterns/control/structural/wcp11.php.

[2]See: http://www.workflowpatterns.com.

Neither workflow patterns nor domain process patterns do not consider the integration of processes with rules.

B. Business Rule Patterns

A business rule taxonomy that serves as a rich source of business rules can be found in [28], [29]. The authors specified more than 60 business rule structures that for a specific process instance: restrict the number of allowed instances of a specific process elements, restrict the coexistence of process elements of different types, specify the influence of specific data elements on the occurrence of process elements, a time restriction on process elements, or a property for a process element at a predefined process state. These rules were used for a comprehensive rule-based compliance checking approach. However, they were not analyzed from the business process representation perspective.

In the following section, we present a short overview of 10 selected rule-based patterns, analyze the rules from the business process representation perspective, and show how they can be observed in the BPMN process models.

IV. RULE-BASED PATTERNS IN BPMN PROCESS MODELS

In order to specify the rule patterns in BPMN process models, we use the following attributes:

1) **Pattern Name**: Descriptive name of the pattern.
2) **Description**: Description of the pattern.
3) **Motivation**: Description of the pattern purpose or a problem that is addressed by the pattern.
4) **BPMN Elements**: The list of the BPMN elements used in the pattern.
5) **Process Place**: Where in the process model the pattern can be applied: Start – at the beginning of the process, Intermediate – during the course of the process, or End – at the end of the process.
6) **An example**: An illustrative example presenting the pattern.

In the following subsections we present 10 selected rule patterns that can be observed in BPMN process models: Conditional Flow, Conditional Triger, Conditional Task/Subprocess Interruption, Conditional Process Interruption with Initiation, Rule-based Task, Simple Conditional Choice, Rule-based

Choice, Deferred Conditional Choice, Conditional Task Multiplicity and Task Performer Assignment.

A. Conditional Flow

Description: Conditional Flow provides the ability to control the flow of a token based on the evaluation of the *condition* expression in the process instance.
Motivation: Controlling the flow using conditional expressions serves as an additional building block for process model that allows for detailed controling of the flow of token through the branch of sequence flow. This pattern provides a condition for a sequence flow and is a variant of Data-based routing pattern[3] in the Data-based perspective.
BPMN Elements: Conditional Sequence Flow
Process Place: Intermediate
An example: Conditional flow with the condition: *An amount has to be higher than 100* is presented in Fig. 1.

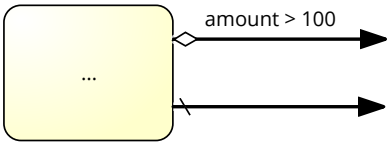

Figure 1. Conditional flow example

B. Conditional Triger

Description: Conditional Triger provides the ability to triger the flow of a token based on the evaluation of the *condition* expression in the process instance.
Motivation: This pattern provides a means of triggering the initiation or resumption of the token flow when a *condition* in the process instance is satisfied. The pattern provides a condition for an event and is a variant of Data-Based Task Trigger pattern[4] in the Data-based perspective.
BPMN Elements: Conditional Event
Process Place: Start / Intermediate
An example: Conditional Triger which trigers when *a customer credit rating will be higher than 4* is presented in Fig. 2.

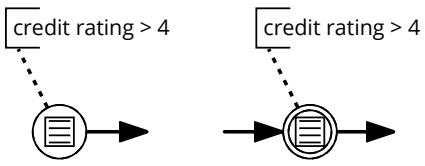

Figure 2. Conditional triger examples

[3]See: http://www.workflowpatterns.com/patterns/data/routing/wdp40.php
[4]See: http://www.workflowpatterns.com/patterns/data/routing/wdp39.php

C. Conditional Task/Subprocess Interruption

Description: When a specific condition is satisfied, a task/subprocess is interrupted and its further execution is abandoned.
Motivation: Conditional Task Interruption pattern provides the ability to abandon the execution of a task/subprocess based on fulfilling a *condition* of the Conditional Triger. The pattern is related to Cancel Task pattern[5] in the Control Flow perspective.
BPMN Elements: Interruptive Boundary Conditional Event attached to a Task or a Subprocess
Process Place: Intermediate
An example: A task that will be interrupted when *Credit rating is below minimum* is presented in Fig. 3.

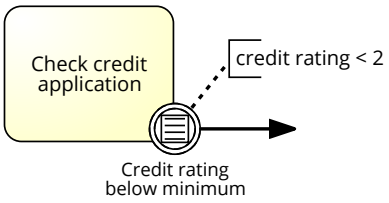

Figure 3. Conditional task interruption example

D. Conditional Process Interruption with Initiation

Description: When a specific condition is satisfied, the current process is interrupted and its further execution is abandoned, and a fragment of the process is started from the Conditional Triger. A started fragment is not part of the regular control flow.
Motivation: Conditional Process Interruption pattern provides the ability to abandon the execution of a process based on fulfilling a *condition* of the Conditional Triger and initiates a new subprocess not instantiated by normal control flow. The pattern is related to Cancel Case[6] and Cancel Region[7] patterns in the Control Flow perspective.
BPMN Elements: Event Subprocess with Conditional (Interruptive) Start Event
Process Place: Intermediate
An example: A Process will be interrupted when *a customer credit rating is invalid*. Then a procedure of handling the invalid credit rating will be initiated (see: Fig. 4).

E. Rule-based Task

Description: Rule-based Task allows for specification of the task logic using rules and delegating work to a Business Rules Engine in order to receive calculated or inferred data.

[5]See: http://www.workflowpatterns.com/patterns/control/cancellation/wcp19.php
[6]See: http://www.workflowpatterns.com/patterns/control/cancellation/wcp20.php.
[7]See: http://www.workflowpatterns.com/patterns/control/cancellation/wcp25.php.

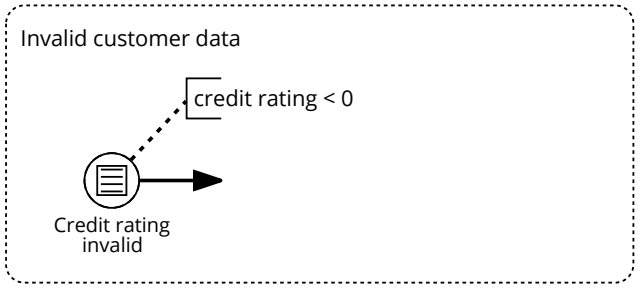

Figure 4. Conditional Process Interruption with Initiation example

Motivation: This pattern provides a means of using Business Rules Engine for execution of rules related to the task.
BPMN Elements: Business Rule Task, Business Rule Task (Call Activity)
Process Place: Start, Intermediate
An example: An example of Rule-based Task which determines a credit card type according to the defined rules is presented in Fig. 5.

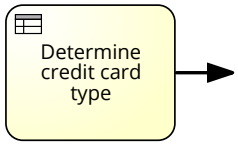

Figure 5. Rule-based Task example

F. Simple Conditional (Exclusive/Multi-Choice/Complex) Choice

Description: Simple Conditional Choice diverges a branch into two or more branches, and according to specified type of choice (Exclusive/Multi-Choice/Complex) the token from the incoming branch is passed to one or more outgoing branches based on the evaluation of the $condition$ expressions of the branches in the process instance with support of a mechanism that can limit the number of the outgoing branches.
Motivation: This pattern provides a means of detailed controling of the flow of token through the branches of sequence flow. It is a variant of Exclusive Choice[8] and Multi-Choice[9] patterns in the Control Flow perspective.
BPMN Elements: Exclusive Gateway, Inclusive Gateway, Complex Gateway
Process Place: Intermediate
An example: In Fig. 6 an example of Conditional Exclusive Choice is presented. In this example the choice is made according to the account limit (*either higher or equal 1000, or lower than 1000*).

[8]See: http://www.workflowpatterns.com/patterns/control/basic/wcp4.php.
[9]See: http://www.workflowpatterns.com/patterns/control/advanced_branching/wcp6.php.

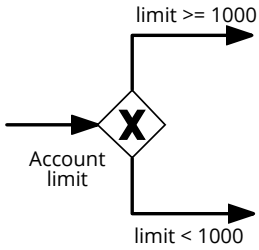

Figure 6. Simple Conditional Exclusive Choice example

G. Rule-based Choice

Description: This pattern is essentially an extension (combination) of the Rule-based Task and the Simple Conditional Choice pattern described above. It provides the Simple Conditional Choice behaviour, but ensures that a decision is made based on the output of the Rule-based Task (the result of inference).
Motivation: This pattern provides a means of detailed controling of the flow of token through the branches of sequence flow based on the on the output from the Business Rules Engine.
BPMN Elements: Gateway preceded by a Business Rule task
Process Place: Start, Intermediate
An example: In the example in Fig. 7, the choice is made according to the verification result (positive/negative) which is a value obtained from customer verification. The customer verification is performed automatically by a Business Rule Engine using the predefined rules.

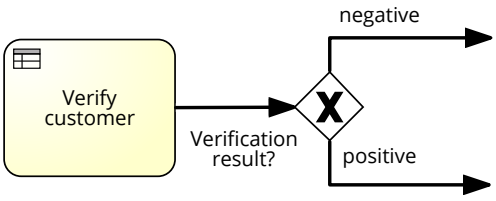

Figure 7. Rule-based Choice example

H. Deferred Conditional Choice

Description: Deferred Conditional Choice determines a point in a process where one or more branches are chosen according to the Conditional Trigers (see Sect. IV-B). The difference from the Simple Conditional Choice pattern is that in this pattern the decision is deferred and depends on the Conditional Trigers.
Motivation: This pattern provides a means of defering the moment of choice in a process to the last possible time and is based on the conditional trigers. The pattern is a variant of the Deferred Choice pattern[10] in the Control

[10]See: http://www.workflowpatterns.com/patterns/control/state/wcp16.php.

Flow perspective.
BPMN Elements: Event-based Gateway followed by Conditional Events.
Process Place: Start, Intermediate
An example: The choice in Fig. 8 is deferred to a point in which either a customer credit rating will be below minimum or a customer has more than 2 unpaid loan installments.

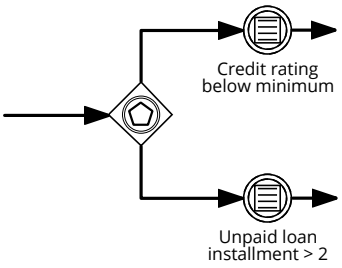

Figure 8. Deferred Conditional Choice example

I. Conditional Task Multiplicity

Description: Within a given process instance, multiple instances of a task can be created according to a condition specified in the rule.
Motivation: This pattern provides a means of rule-based specification of the task multiplicity. The pattern is related to the Multiple Instance Patterns[11] in the Control Flow perspective.
BPMN Elements: Multiinstance task with the specified attributes
Process Place: Start, Intermediate, End
An example: *Credit card application has to be approved by 2 bank employees* (see Fig. 9).

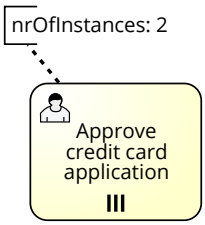

Figure 9. Conditional Task Multiplicity example

J. Task Performer Assignment

Description: This pattern specifies who performs which tasks in a process.
Motivation: This pattern provides a means of a kind of deontic rule that specify the performer role assigned to particular tasks. The pattern is related to the Role-Based Distribution pattern[12] in the Resource perspective.
BPMN Elements: Lanes
Process Place: Start/Intermediate/End
An example: See Fig. 10: *An approval task has to be performed by a supervisor.*

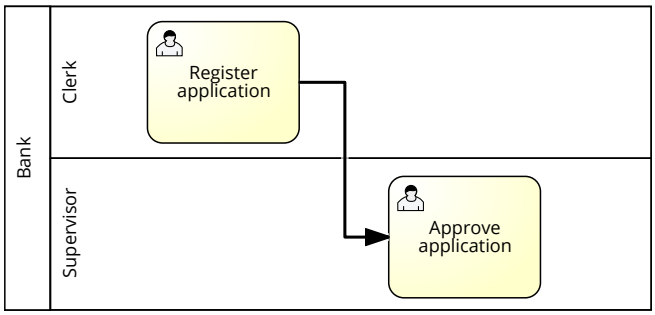

Figure 10. Task Performer Assignment example

V. Concluding Remarks

In the paper, various types of workflow patterns and domain process patterns were presented. However, these patterns does not take into account rule-based aspects. Thus, we considered various options where and how rules can be perceived in business processes.

The original contribution of this paper is presentation of rule pattern perspective for process models. We described 10 selected rule-based patterns and showed the examples of such patterns in BPMN 2.0 Business Process Models. We focused on the BPMN 2.0 notation, as it is standardized process representation use both by researchers and enterprises.

As future work, we plan to supplement the patterns with other decision aspects in BP models and extend them by investigating other process languages as well as extensions of the BPMN notation [30]. Furthermore, we plan to evaluate these patterns empirically using real-life process models as well as to check the possible anomalies that these patterns can induce [31].

We also want to include design issues using the proposed patterns [32]. as well integrate the pattern library with a process editor [33]. especially for model recommendations based on patterns during the design [34].

***Abstract*— This document describes the concept of urban knowledge. Main aim of this paper is to define term, describe assumptions and possibilities of use. The paper consists of introduction, five chapters and the summary. In introduction author presents background of conducted research. First chapter is the explanation of the urban knowledge phenomenon. Second presents further characteristic with brief classification. Later, author presents how urban knowledge can be managed. In the last chapter, author is trying to point possible methods of urban knowledge acquisition based on available ICT solution. In the summary author will describe chances of application for presented model.**

I. Introduction

As the priority issues, which are defined by the National Spatial Development Concept 2030[18]., are considered: the low competitiveness of major urban centers and Polish regions against European, poor territorial cohesion of the country, the low level of infrastructure (especially transport, social, information, including information technology) areas urban and rural areas, the lack of a coherent system of environmental protection, insufficient resistance to the spatial structure of internal and external threats and spatial disorder.

According to the author's knowledge, a key element for the pursuit of development in line with the reasons stemming from the macro-cities is an urban knowledge. Taking into account the results of enterprises market functioning and the results that achieve through the use of knowledge management processes, the author believes that urban knowledge may be an aspect that will allow raising the competitiveness of cities, seeking to ensure the integration of infrastructure (mainly in the area of information technology, social and governance) and achieving spatial cohesion. Thus, the author believes that the improvement of management processes in the cities, on the basis of knowledge can contribute to the real fulfillment of assumptions NSDC 2030 in Poland.

This work was not supported by any organization

II. Urban knowledge definition

To be able to explain the urban knowledge concept, it is necessary to localize it roots in the concept of organizational knowledge.

Knowledge is not only one of the most important assets of an organization, but also the basis, the starting point used to define a strategy, especially for the implementation of management information systems. Knowledge, for the purposes of computing is based on data and information, where data is understood as a set of facts, measurements, statistics and information as the structuring of the data. In this sense, knowledge is a set of information that can be used in practice. However, the organization cannot exist without human capital. [9]

In the theory of knowledge management, there is the explicit and discreet knowledge. [6] Explicit knowledge (formal), as general, considers formal documents created by the organization. Discrete knowledge (informal) is defined as skills, qualifications and experience of human capital. This knowledge is not written anywhere, it is in minds of employees, what really constitutes a barrier to obtaining confidential knowledge. However, there are no barriers that cannot be overcome. [4]

In order to ensure the proper transformation of tacit knowledge into explicit one, as the first condition, it has to be pointed and realized by the organizational culture in the enterprise. [2] Secondly human resources have to be ensured in adequate mechanisms of facilitation the knowledge sharing process in a fair and codified why. It is therefore necessary to create appropriate procedures and systems which should enable knowledge capturing, processing and sharing according to requirements. [7] The weak point of this attitude is still the will of the employee, if they wants to share knowledge or not.

What it is the urban knowledge? The spine of the concept is equal to definitions presented above but in authors opinion it is needed to extend the classification.

First, it is needed to distinguish tacit and explicit knowledge of the city, bearing in mind that the city consists of municipal decision-making units and its external and

internal environment. Therefore, the explicit knowledge of the city can be considered as all kinds of documents, law, statistics, forecasts, reports, documentation, information, demands, portals relevant to public services or stakeholders, available for the public by each of the entities functioning within the city. Whereas the tacit knowledge of the city considers the qualifications, experience, skills, knowledge of both: employees of the administrative and governing units and knowledge of stakeholders, as well as citizens.

To have a comprehensive description of the urban knowledge, presented basics should be extended by several features important from the point of view of tacit knowledge. Urban knowledge is created independently by entities operating both inside and outside the structure of the city. This kind of knowledge must be gathered and stored in a very specific way, which will provide its uniqueness for a long time.

Urban knowledge is created by the local authorities, politicians, social activists, educational institutions, healthcare entities, religious, environmental bodies, research and development, administrative units, business, science, citizens and other stakeholders. According to the model of intelligent city, author decided to classify urban knowledge on six key aspects described in table 1.

TABLE I.
TYPOLOGY OF URBAN KNOWLEDGE

Urban knowledge type	Components
Economical knowledge	Cooperation, Productivity, Entrepreneurship, Finance/budgeting , Public relations/marketing, Planning, Infrastructure
Social knowledge	Social difference and classes, Social problems, Social needs, Believes
Environmental knowledge	Natural resources, Access to resources, Eco services, entrepreneurships, Pollution, Environment protection, Policy of sustainable environment
Mobility knowledge	Services, condition and sources of public transport, External sources of public transport, Availability and stability of ICT infrastructure, Transport systems
Governance knowledge	Public and private sector, Citizens involvement, Suppliers and recipients in decision-making processes, Clarity of managerial processes, Rules of sustainable development, Perspective of cities development
Quality of life knowledge	The attractiveness of available objects and events in the city, region, Health condition, access to medical units, Safety of residents and businesses, Living conditions, Education level, Tourist attractiveness,Social cohesion

All the presented in the table 1 aspects of urban knowledge will be characterized briefly in the next chapter.

III. THE ESSENCE OF URBAN KNOWLEDGE

The essence of the urban knowledge is to provide the most comprehensive knowledge of its stakeholder, resources, processes, conditions or predispositions. Proving, that in the context of smart city, transformation of the city is geared strictly to the needs of citizens, can be found in just presented the characteristics of the knowledge city.

A. Economical knowledge

Category of economical knowledge of the city revolves around the existing cooperation between the city and specific subjects. It focuses on information about potential cooperation, development opportunities, possible investments. Collaborations, which in the past have produced adverse effects are included as well. An important point of economic knowledge is also a problem of productivity of the city. It is not just about the number and quality of public services provided, but also about the knowledge associated with the ability of the city to meet the needs of its residents. The productivity of the city is an indicator of the level of wages, benefits, profits, and taxes provided for urban residents. Knowledge of entrepreneurship in the city is the basis for defining, classifying the level and direction of development of the city.

B. Environmental knowledge

Urban knowledge also focuses on the area related to the natural environment. "Talking about the natural environment of the city is so reasonable that urban development and functioning of the technical infrastructure largely transformed original, natural conditions and makes the individual elements of the natural environment in the city acquire specific characteristics." In this regard, the managers are obliged to collect and update the knowledge on natural resources and access to these resources. Ecological services available in the city needed to be implemented.

C. Mobility knowledge

Mobility of the city is also important for defining the urban knowledge. It is a very difficult area of decision-making for the city. Very often the local authorities must make decisions based on conflict of information or conflict of society needs or both of them in the same time. In order to facilitate a process of planning and then implementing solutions in due to meet the needs of society, it is important to acquire, collect and use of information and knowledge related to public transport services, its technical condition and possible alternatives in the form of external transport services. As well, access and the stability of ICT infrastructure supporting the management of transport and traffic in cities became crucial. Gathering such knowledge, and its subsequent use is mainly aimed at meeting the needs of ensuring a well-functioning, safe and optimal public transport in the city.

D. Managerial knowledge

Knowledge management within the city has to be concerned with the transparency of management processes, functioning on the basis of rational, prospects for the development of the city and make rational decisions based on their knowledge and experience. The source of such knowledge are certainly laws, their distribution task for all public administrations and local self-government, participation of citizens in the process of creating a vision

and strategy for the city, the characteristics of private and public sector, suppliers and recipients in decision-making and knowledge about the condition of the city, held resources and needs to meet. Possession of such knowledge by policymakers in the city can provide an excellent basis for constructing a holistic view on some issues, including defining the correct relationships of cause and effect.

E. Social and quality of life knowledge

Each of the six selected aspects of the urban knowledge concerns directly or indirectly on social layer. However, in the authors opinion, two aspects – social and quality of life knowledge, speak directly about the needs of the residents of the city.

IV. URBAN KNOWLEDGE MANAGEMENT

Knowing that each city of democratic country is obligated to develop and realize their own strategies, especially based on knowledge, it is possible to claim, that urban knowledge management involves the effective use of urban knowledge and transforming it into the lasting value for city's stakeholders and managerial staff. [2], [14] Urban knowledge management is clearly defined and systematic management of dynamic knowledge for the city and its associated processes of creating, gathering, organizing, diffusion, use and exploitation of knowledge, carried out in pursuit of the objectives of the city. [16]

Urban knowledge management can be also treated as a specially designed system that helps cities to acquire, analyse the use (re-use) of urban knowledge in order to make faster, smarter and better decisions, so that they can achieve a competitive advantage in case of covering cities stakeholders needs. [10] Urban knowledge management covers management of information, knowledge and expertise available within the city, i.e. mobility, environment, social, managerial, economical by the creation, collection, storage, sharing and use, to ensure the cities future development based on well prepared decision plans. Urban knowledge management deliberates cities strategy, which selects, distils, stores, organizes, packs and provides information relevant to the cities stakeholders in a way that improves efficiency and competitiveness of the city in the end. [5], [3]

A properly selected integrated management information system now enables the efficient management of the entire city, carrying out city's management functions with regard to both its internal environment and external, and thus, proper management of urban knowledge. "The selection of specific solutions and technologies in the field of urban knowledge management in the city should be carried out depending on the specifics of the city, its profile, individual economic situation, its strategy and approach to knowledge management. Each city or its institution should be regarded as an organization with its characteristic organizational culture, creative employees, principles and standards prevailing within it and look at it through the prism of ongoing business processes. In addition, each city must be aware that the overall urban knowledge management system cannot be based only on properly chosen technology" [17].

Resource management of urban knowledge, with respect to the characteristics presented in the article, the requirements of the assumptions Knowledge Based Economy or observable development solutions, can be supported by specialized tools of ICT dedicated for the specified area. As the main tasks carried out, supported by solutions that support urban knowledge management, include[1], [14]:

- the acquisition of knowledge from a variety of, often heterogeneous resources,
- creating and coding different elements of urban knowledge in order to incorporate them into basic information system in the city,
- supporting the exchange of urban knowledge and providing comprehensive operation of teamwork.

These examples of tasks supported by dedicated tools for urban knowledge management include: distribution of documents and their monitoring, defining and monitoring over the course of project implementation, communication between stakeholders and cities management, workflow control and monitoring of teamwork. Knowledge in these tools is treated very flexibly - starting with the classification of unstructured documents and finishing on the formal knowledge bases [11], [12].

V. ACQUISITION OF URBAN KNOWLEDGE

Ensuring constant contact with the public by means of ICT solutions, e.g. knowledge exchange platform, can contribute to enhance the competitiveness of the city, leveling of social inequalities, mitigate conflicts, alleviate the problems of infrastructure, economic, or investment. In addition, it will help to ensure consistency of information in the city.

As the purpose of the existence and operation of ICT infrastructure in the city is the integration of key information generated by its users, which provide a complete list of requirements, guidelines for maintenance and improvements in many aspects, including those associated with improving the quality of life by better knowledge management in the city. Because of this, it is a smart city project, the concept of a better life for the citizens, there is nothing surprising in fact, that talks about the need for citizens:

- a comprehensive contact, including the implementation of intelligent technology and information resources public, allowing the systematization and increase citizens' access to information and knowledge of using ICT infrastructures,
- full integration, assuming that the basic infrastructure scheme operating system of the target group heterogeneous information generated by specific entities are together entirely integrated into a single portal for example, and the assistance available to the presentation layer, respectively specific audiences,

- incentives for innovation (called encouragement for innovation), covering all the action of the city authorities for enterprises and public institutions, in order to propagate their use of new technologies as a means of enabling equality technological society,
- collaboration (called collaborative operation), based on intelligent infrastructure, critical systems and cooperating users (including public bodies, local authorities, professionals, non-governmental bodies, excluded people, etc.), which helps to improve effectiveness in the developing the public services.

Presented solution enables the integration of the information needs of citizens and all the entities interested.

For platform users, platform becomes a compendium of knowledge about the urban knowledge (economy, people, environment, mobility, governance, living).

As we can see, ensuring citizens by the city's authorities can contribute to the objectives of the NSDC 2013, which points combating low competitiveness of major urban centers and Polish regions against European, poor territorial cohesion of the country, low level of infrastructure (especially transport, social, information, including information technology) urban and rural areas, the lack of a coherent system of environmental protection, insufficient resistance to the spatial structure of internal and external threats and spatial disorder.

VI. Conclusion

Proposed in the paper approach with use of ICT solutions to gather urban knowledge, is unfortunately so idyllic that it does not take into account the problems which for centuries is faced by all cities of the world, i.e. excluded, homeless, not involved in the social life of the city, the mismatch solutions to the needs of users , lack of willingness to change thinking among municipal authorities, resistance among employees of local government, political, economic phenomena robbery, the gray zone, the fear of citizens, and cyber security.

Of course, each of these problems are trying to be solved by finding and implementing various solutions, but it not always provide the desired effect. On the other hand, not handling problems in case of improving quality of lives most of citizens by authorities would be a crime, which is governed in Poland by the Criminal Code (intentional act to the detriment of the customer, citizen, entity). As we can see, the decisions of investment and development in cities do not belong to the easiest. Their implementation is also not trivial.

However, author believes that the reestablishment of order and consistency in the city's functioning should be a top priority for the governments of each city in Poland. We have to remember also, that attempts of achieving it are determined by current investment decisions and made improvements. Therefore, it is essential that all urban transformation which are going to happen should include the use of information and communication technologies, systems operating in harmony and in favor of the environment and conducting researches on city's sustainable development based on knowledge.

Described in the paper concept of the urban knowledge provides the basis for further consideration on city's development determined by new management techniques. To produce a resource in the form of urban knowledge is not only to achieve positive economic impact on the city, region, or country but mainly aims to prepare themselves to meet the future needs of civilization, currently generated by the society, classified as information. In the information society the dominant role plays nothing else but knowledge. That why every city in Poland, according to the author assumptions, should seek to create, to clarify their urban knowledge. Especially, when it is in line with the objectives of knowledge management. It means, that city can contribute to make better decisions, accelerate information processes, reduce unnecessary costs, increase satisfaction or level citizens' lives quality.

***Abstract*—**Knowledge Management methods, techniques and experience can bring a considerable help in preventing all kind of risks. The current economic context amplified the existing risks and introduced new ones such as environmental, political and social. Among the most critical risks of this century is this of lost of knowledge and "memory" in particular in industry involved in long-term activities.

After listing the principal risks and recalling of main approaches and techniques of Knowledge Management and its application for risk management an example of nuclear industry is given. Discussion follows in final conclusion and some perspectives are presented.

I. Introduction

HUMANITY have always been exposed to all kinds of risks - natural, industrial and those related to human activity and human nature, including motivations and passions. While the management of "soft" industrial risks is well established, the serious, unpredicted and rare risks are managed after the disaster.

Knowledge management approaches powered by artificial intelligence techniques can bring considerable help in risks prevention and management, but they are not sufficiently used.

This paper presents a broad spectrum of today risks and main works connecting these two topics. A short recall of principal knowledge management methods and disciplines follows. Some techniques for risks prevention and fixing are mentioned. These purposes are illustrated by a case study in the field of nuclear energy management. This paper ends by conclusions and perspectives for future work.

II. Typology of Risks

Among the industrial risks we can distinguish those caused by a malfunction or by the "human factor".

Risks resulting from human activity such as air and water pollution, destruction of natural ecosystems and global warming are the consequence of the ignorance of natural ecosystems, that we are the part, of the context and motivations as selfishness and desire to become rich quickly.

The pride and power can also lead to irresponsible decisions at high political and management levels, as for example wrong choice of strategy.

Other risks arise from human nature and motivations, such as sabotage, crime and cybercrime, wars, and lack of communication or of compromise. Risks arising from ignorance, obscurantism or indoctrination can cause unwanted destruction, bombings and wars.

The perpetuation of the same mental patterns is a risk of not finding the right solution when solving problems, which is a strong barrier for innovation. For example, onboard car computers are programmed using traditional decision trees and the user wanting to go to a given place has to choose step by step instead of making a direct voice request. Some of them are still equipped with a mouse and using such a system when you drive may lead to accident.

The recent risks are related to the use of technology, digitization, virtualization, security of sensitive data on clouds, the unexpected impact of biotechnology, nanotechnology and others [1, 2]. The precautionary principle, very strong in France [3], is applied in some cases when the impact is not known or not considered. An alternative of applying systematically such a principle is the understanding and simulation of the potential impacts by a multidisciplinary and experienced team possessing the related knowledge.

Another risk could come from the lack of management of the intellectual capital. Consequently, knowledge and know-how are not explored because little known at the strategic level.

A simplified ontology of risks is presented in Figure 1.

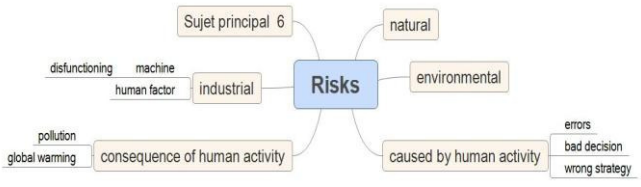

Fig. 1. Simplified ontology of risks.

The ISO 31000 norm considers as a high risk a theft, loss, obsolescence, no recovery and the lack of the use of knowledge. All have the negative effect on the achievement of objectives.

III. Related Work

The industrial interest in risk management is not new. We can find numerous work devoted to managing risks in energy [5, 6, 7, 8], in chemistry and pharmaceutical industry [9, 10, 11, 12] aeronautic and space [13, 14], automotive [15] and recently those related to the use of information technology [16, 17]. Other fields are also concerned, such as finance and banking [18], insurance and health [19].

In France there is a long tradition of managing industrial risks using statistic methods, recently extended by Bayesian and some data mining [20, 21]]. The Institut pour la Maîtrise des Risques (IMdR) groups research and industrial actors involved in this area and organize Lambda Mu, scientific conference and other events aiming in sharing experiences and solving problems collaboratively [22].

The approaches and techniques of Artificial Intelligence such as experts systems, case-based reasoning and multi-agent systems have been successfully used for managing risks as well for prevention as for fixing [23].

The development of methods for risks management and operating reliability, based on probabilistic networks from 1990 has been complementary to expert systems.

The bayesian networks, belief networks and Valuation Based Systems provide graphic representations of knowledge, more comprehensive by the user. These techniques are well suited to the uncertain context and in particular to epistemic uncertainty and are a part of toolbox currently used by engineers of risk control or operational safety, such as fault tree and Bayesian network [21]. These tools are currently used after collecting related data.

The professionals of risk management and operating reliability are used to apply known methods to existing data, opposite to the "knowledge thinking" approach based on problem understanding and collecting or mining the related knowledge vital for solving a given problem [23, 24]. The risk related to intellectual capital such as loss of knowledge and of competency, know-how is still weakly managed [4].

Globalization and hyper-competition has increased the risk in business. Political push to create start-ups should be associated with adapted policy, which is not the case today. The collected feedback from these experiences will be very helpful to improve the innovation policies.

The recent collogue of French Ministry of Defense pointed out the influence of climate changes on the raise of criminality [25]. Over twenty presentations with various points of views demonstrated the cause-to-effect dependence of delinquency and terrorism with climate change. But it is not only influence; the others factors such as unemployment and lack of the clear vision for the future and professional perspectives for young, low educated people, enhance the probability that they may choose Jihad.

To anticipate and manage such risks, it is necessary to gather and manage the related multidisciplinary knowledge and skills and use the right approaches and tools.

IV. Role of knowledge in risks management

Globalization, reinforced by the development of various modes of transportation, Internet and other information and communication technologies has changed the way we learn, work and do business and have introduced other risks. In search of cheaper workforce, companies relocate production and customer service taking a risk of knowledge loss and of customers' deception.

Production of spare parts in low cost countries may entail a risk of quality caused by the lack of conformity with the specifications and the use of alternative materials that can degrade the performance of given equipment.

Internal transfers, retirements, turnover and cross-competition generate impacts such as loss of know-how, loss of time to reinvent and remake what has been already done, additional costs, loss of competitiveness, responsiveness, security/safety flaws, which are the factors determining differentiation in an open economy. The knowledge transfer "at time", the use of decision support systems, knowledge base of products, projects and customer relations, managing the feedback from experience, e-learning and m-learning systems integrated to the overall knowledge flow connecting may help the involved actors in preventing and managing the risks.

The relocation may also lead to other risks, such as loss of employment and exclusion in developed countries.

Faced with the economic crisis in developed countries, governments consider innovation as the only remedy that can improve growth and boost the job creation. But entrepreneurship requires risk taking and know-how of managing a start-up for success cannot be acquired only in school, but mostly by doing or with an experienced mentor.

Innovation needs multidisciplinary knowledge to succeed and many products and services are knowledge intensive. Sometimes ignoring ergonomics and the real needs of users and customers may lead to the risk of non acceptation of given software or other products. Such products will not be used and may cause a company fail.

Computers and other technological devices and applications, currently used in industry are now present in all fields and their development accelerates. Computers, sensors and other electronic devices are more and more embedded into products. The products such as IoT, conceived according to the designers' vision only, autonomous devices, M2M communication and fully automatic client support systems raise the risk of elimination of human from the decision making.

If the machine thinks instead of us, it may influence the progressive lost of human cognitive capacity.

Can we trust the perfect operation of fully automated systems?

Internet is considered by many as a source of knowledge, but what is the reliability of information found on the web?

Decision taking based only on information found in various wikipedia, forums, and social networks maybe risky.

Can we find a reliable knowledge or information only in such results? Is it helpful and sure to avoid risks in the future? Is it efficient for knowledge discovery?

The prevention and management of all kinds of risks require an understanding of all facets, contextual knowledge and a method that fits to these components while the most of risks managers use the data and statistics.

A. *Prevent or fix?*

The industrial risks management methods include preventive maintenance, annual and five or ten-year controls of nuclear power plants, aircrafts and other complex equipments and feedback. The feedback is usually recorded in a large database conceived for all related professionals. The data processing after collection uses mainly statistics and the results are available to those concerned. Data is often missing because the persons that should record then do not understand what they have register because of weak adapted interface; sometimes we can find errors related to the data value such as missing comma, shifted, wrong or missing data [35].

In a few critical cases we manage the crisis after it happens (Tchernobyl, Fukushima, AZF Toulouse and others - http://www.aria.developpement-durable.gouv.fr/).

This involves repairing of the effects, as in Western medicine, but how to prevent these accidents using efficiently existing knowledge and expertise?

Practical experience demonstrates that sometimes a given problem, i.e. terrorist attack, may be detected considering weak signals often ignored. It is vital to collect all related knowledge including contextual and check consistency, especially when it comes from several sources.

While industrial maintenance is usually well managed, the related knowledge is often not organized and poorly managed. Nevertheless, knowledge plays a central role in our activities. But what is the necessary knowledge to collect and preserve in aim to avoid and control risks? What to preserve, how and why? It depends on the organizational/company strategy, that decides about the key knowledge and strategic competencies to maintain develop and preserve. Than the best adapted approach and tools will support the realization of this task.

V. KNOWLEDGE MANAGEMENT

In the early 1990s we saw the emergence of a new management method - Knowledge Management or business based on knowledge [26]. It has been a foundation of a new economy of knowledge [27].

The term "Knowledge Economy" is not new. Although it was proposed in the 1980s, such economy has always existed. It is about generating value from knowledge, know-how and experience. This is a radical change for companies that must now recognize and manage this intangible capital.

In this context, knowledge management can be defined as "*an integrated system of initiatives, methods and tools designed to create an optimal flow of knowledge within and throughout an extended enterprise to ensure stakeholders success"* [28, 29]. Stakeholders are partners, distributors and customers. Success includes among others leadership, industrial performance, efficiency, quality and safety.

The purpose of this approach is to organize and manage knowledge applicable or applied by the company or organization, for its activities related to current or future business.

Our research focuses on critical knowledge and know-how of experts, which in majority of cases is not formalized. While knowledge transfer has always been the scope of the trainers, we often ignore that knowledge can also be "transmitted" to the computer using something else than traditional databases [7]. Artificial intelligence has invented very early methods and techniques for knowledge acquisition, discovery and processing by computer. They have been tested successfully for over 50 years and are now encapsulated in tools.

Many decision support systems have been designed to assist users through expert systems, help in process control, in medical and industrial diagnostics, to provide design assistance, solve complex problems with constraints such as logistics, scheduling, planning and others. AI techniques are also useful for intelligent e-commerce, effective matching of offer and demand, very useful for recent platforms. All these applications should be organized as a Knowledge Flow. Knowledge modeling methods such as KADS for conceptual modeling, ontologies and other models [24] should be adequate to the nature of given knowledge. Graphical interface will facilitate their collection for preservation and sharing, but also reusing for a variety of applications.

The development of methods based on probabilistic networks in risk management and operational safety in the early 1990s also focuses the use of expertise. Bayesian networks, transferable belief models (TBF), the Valuation Based Systems use a graphical representation of knowledge which facilitates the understanding of data. These techniques seem well adapted to the context of uncertainty (including epistemic uncertainty) and generalize the methods commonly used by traditional engineer in risk management or operational safety, such as fault tree and Bayesian network. Current applications include risk analysis, reliability analysis, and analysis of the human factor [21].

Deep learning, born from the experience and the need to explore appropriately gigantic amounts of data connects several automatic machine learning techniques (machine learning) as data mining, natural language processing and image mining, among others.

At this stage a distinction between thinking "data" and "knowledge" must be considered. While the first focuses on the collection of data, the second focuses on the collection of

knowledge, essential for knowledge-based problem solving.
Knowledge transfer from human to computer via different knowledge models is now mastered and should be generalized. Many knowledge bases exist, but the knowledge capitalization process is not widespread. It is very often postponed, due to lack of time and underestimated by many companies. But it is a false excuse, because they continue losing time using still "data approach" which generates huge amount of data that should be "cleaned" and analyzed.
"Knowledge approach" may seem difficult for those who are used to work with data, because it requires changing a mental schema. However the trend of knowledge management and a necessity to preserve knowledge of retiring experts handed capitalization up to date.

For over two decades, companies and organizations have experimented Knowledge Management, beginning with their motivations and perspectives - as integrated in a company strategy, by managing of Intellectual Capital, Business Intelligence or by industrial applications [23].
Many companies have taken steps, but for the most part, without considering the feedback from Artificial Intelligence. Internal networks of experts (communities of practice) are among the "easy and quick" initiatives aimed at mitigating the risks related to the loss of knowledge and experience, allowing the sharing of "best practice", such networks requires a facilitator, who can progressively become Chief Knowledge Officer.

Two major factors hindering the implementation of KM as a management method are following:

- is the necessity of demonstrating the utility of this approach and its ROI,
- misunderstanding of the role the Chief Knowledge Officer must play; it is not a social position, but a cross communication and facilitation.

The initial objective of Knowledge Management remains improving of the innovation capacity of enterprises and organizations by better use of talents, knowledge, detection of opportunities, integration of feedback and use of the best fitting technologies.
As Knowledge Management involves stakeholders, the respect of ethics and trust are vital to achieve a common goal – to be successful together.
It is not easy to implement because it involves spending time to understand before doing, thinking "knowledge" and to change attitudes: listening instead of push, collaborating instead of competing, collecting and sharing experience and feedback, evaluating the benefits in terms of tangible and intangible values.

The knowledge to preserve includes not only this associated with long life technical equipments, such as nuclear power plants, but also the ability to solve problems. This is an art to gather individual and collective knowledge serving to solve a specific problem, but also the know-how in considering the various contexts that influence decision taking.

If we consider the risk of crime and cybercrime, solving this problem is not just to find the guilty and put him to jail, but to understand the real causes and motivations of involved persons and their environment. As mentioned before, the study of French Ministry of Defense has demonstrated the link between climate change and crime. For example, the drought caused by deforestation and intensified cultures lead to the depletion of the earth, causing famine and pushed more vulnerable to selling drugs or stealing.

The risk prevention requires awareness of their existence and their possible consequences, the ability to solve complex problems, holistic and system thinking and to select the necessary knowledge to prevent, minimize the causes, and impact. If this approach had been applied in the case of German Wings the company could have prevented the accident because the knowledge on the health of employees and their relations are part of the overall approach.

Finally the KM approach producing the best results is those that starts with an application addressing the real needs, developed with an incremental approach "do small and think big".

VI. EXAMPLE: NUCLEAR INDUSTRY

In France we have 18 nuclear plants, as shown in Fig 2.

Fig. 2. Map of French nuclear power plants [30].

Some of them have been built over 60 year ago. Nuclear plants represent three main risks: loss of initial knowledge, ageing of component materials and management of pollution at the end of life. Designers of these plants are retired. The initial knowledge and context of the whole lifecycle related to plants has been transmitted through documents and reports. There are still some elements lost because all details of lifecycle, replacement of elements, minutes from meetings, verbal experts' exchanges are not transmitted. Reports from the programmed control also exist, but it is a known fact that everything is not written [7]. Related database contains only data. Some expert systems have been

developed in specific critic fields, such as ageing of materials and their consequences on maintenance [36], mastering of ageing,

Last year Paris has been hosted the COP21 and the strong international lobbying claims to stop the oldest power plants. On the other hand, the management of nuclear waste is a long term process and requires an updated long term memory. ANDRA (Agence Nationale pour la Gestion des Déchets Radioactif) involved in managing nuclear waste is aware of the problem and has initiated a Knowledge Management activity [31]. As there are not only one organization involved in the whole nuclear plants cycle of life they initiated with ANR (Agence Nationale de Recherche) a collaborative program supposed to bring together all stakeholders in aim to organize and manage the related knowledge [33]. The task is not trivial, because the majority of involved actors retains knowledge and do not realize the consequences of such an attitude. We expect their awakening.

Despite a global awakening on planet and living protection the most of industrial people focus on quick business and do not assess the multiple impacts of their activity on our biosphere [34].

VII. Conclusion

Facing the systemic risks generated by globalization, quick business, vertiginous progress in technology and replacing human by machines requires different way of thinking and problem solving. Preventing and management of such risks require the "knowledge thinking" and considering the multidisciplinary knowledge and the related context. Deep problem understanding will guide the choice of Knowledge Management method and well suited tools. AI techniques support the managing the flow of knowledge by systematic collection and exploration of related knowledge and experience and knowledge. However a global awakening and change of attitudes is required. It can be done using i.e. serious games and various simulators. The future work related to risks management focus on the risks prevention by understanding the key factors through the games.

***Abstract*—In this article we introduce QtBiVis - a novel software intended for the comparative analysis of biclustering results. This modular tool has been efficiently implemented in C++ with Qt framework GUI. It may be successfully used for coverage analysis of the results of biclustering as well filtering or sorting biclusters by Gene Ontology (GO) identifiers or bicluster enrichment values. It may also be useful for parameter studies of biclustering algorithms. In future releases we plan to add different modules for visualizing and comparing different GO terms and biclusters.**

I. Introduction

MICROARRAY technology has become a subject of multiple biological experiments since its theoretical foundations in 1980's and first application in 1995 [1]. As labeled nucleic acids immobilized on a solid surface proved to be capable of monitoring the expression levels of nucleic acids molecules, the technology has been predominately used for measuring in parallel multiple gene expression patterns. It has also gained wide scope of application in disease diagnostics, drug discovery and comparative genomics.

The result of microarray experiment after background adjustment, normalization and summarization at the probe level is structured into a data matrix of real numbers, in which each value corresponds typically to a gene expression level under the specified condition. The whole microarray data may contain up to tens of thousands of gene expressions. Biclustering algorithms have been applied to identify groups of genes that show resemblance under particular subsection of conditions. Multiple biclustering methods have been developed so far [2], [3], [4]. Different metrics have been adapted to measure gene expression level [5], [6]. The collection of the most recognizable biclustering approaches applied to GDS datasets is included in Eren et. al. [7].

A. Methods of visualization of biclusters

The most popular way to visualize a single bicluster uses a heatmap, in which cells are colored based on the gene expression level. This perspective has been implemented in multiple software tools among which the most popular are BiVoc [8], BiVisu [9], BicAT [10] and its extension BicAT-Plus [11], BicOverlapper [12], [13], Furby [14], Bicluster Viewer [15] or BiGGEsTS [16]. A single bicluster is usually resorted and drawn in the upper left corner with its rows and columns rearranged.

The second popular visualization method, which is very useful for gene expression profile comparison, uses parallel coordinates, in which conditions are vizualized on horizontal axis. Gene profiles are represented by lines, which join corresponding values of corresponding conditions. This perspective is popularly used by multiple software tools (including BiVisu, BicAT, BicOverlapper or Bicluster Viewer).

A widespread visualization method for multiple biclusters uses heatmaps or heatmaps with dendograms. For example hierarchical biclustering is represented by a tree and a heatmap, in which rows are reordered to fit the recognized bicluster. This perspective is offered for example by BiGGesTS.

There are also more sophisticated visualization perspectives, which are provided by some of the available tools. For example BicOverlapper offers a transcription regulatory networks view, wordcloud or bubble map perspective. Furby presents graphically the attracting force between each pair of the biclusters. This resembles a class diagram, which is popular in relational databases. The number of rows and columns shared between each pair of biclusters are reflected by the transparency of the interconnecting line.

B. Motivation

The major motivation for QtBiVis is to provide a fast and reliable software, which would be able to support the researchers in parameter study of the biclustering methods. We believe that the analysis of biclustering experiments based on the inspection of biclusters' coverage may provide a novel insight for assessment of biclustering methods capabilities. It may also become helpful in determining the optimal setting of parameters for each algorithm.

The second justification of QtBiVis emergence are limitations of the available software. As the majority of the tools has been implemented in Java, existing tools encounter different performance issues during analyzis of hundreds or thousands of biclusters. This limits analysis of complex experiments in which thousands of biclusters need to be visualized and compared simultaneously. QtBiVis has been implemented in C++ with Qt used for graphical user interface.

II. METHODS

In this article we present QtBiVis, an open-source toolbox, which implementation may be found at github.com/Archi0/QtBiVis. In this section we present an overview of QtBiVis and detailed information about its design.

A. Main features of QtBiVis

The QtBiVis tool, which is herein presented, has been implemented in C++ programming language with Qt 5.5 framework used for graphical interface design. A Dynamic_bitset from Boost C++ library has been used for performing bitwise operations. The main features of QtBiVis include:

- loading main data set which contains microarray data,
- loading files with biclusters with Gene Ontology ID (GO ID) and p-values,
- filtering biclusters by a specific GO ID,
- calculations, plotting and saving results of the degree of coverage of the bicluster environment,
- displaying information about a single bicluster with its values, labels, level of coverage, GO IDs and p-values,
- plotting statistics of the bicluster based on average of values in columns and standard deviations of the values in columns in examined cluster,
- calculating, plotting and saving information about the relation between number of occurrences of value in different biclusters and size of the bicluster,
- drawing a heatmap based on the number of occurrences of a given value in the loaded clusters.

B. Overview of application

The main workflow of QtBiVis includes loading a microarray dataset and definitions of series of biclusters from multiple biclustering experiments. Information about loaded biclusters is shown in the table on the right-hand side of the main window (see Fig. 1). Each row of the table contains a Gene Ontology ID, p-values (before and after multiple test correction) and the identifiers of rows and columns of the bicluster. Filtering is applied for biclusters after entering a value in "GO Filter" text area.

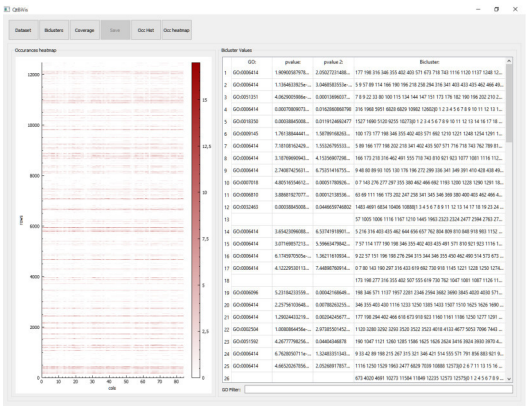

Fig. 1. The main window of QtBiVis.

The application provides access to a standard overview of a single bicluster (i.e. its expression values, labels of rows and columns and parallel coordinates plot), as well as tools for visual comparison of relations between multiple biclusters. This includes the statistics of coverage and the frequency of occurrences of expression values presented in form of heatmap and histogram.

C. Analysis of a single bicluster

A single bicluster analysis overview, which is demonstrated in Fig. 2, contains biclusters values with rows and columns names, gene ontology ID's with p-values before and after correction and neighborhood of the selected bicluster with percentage values.

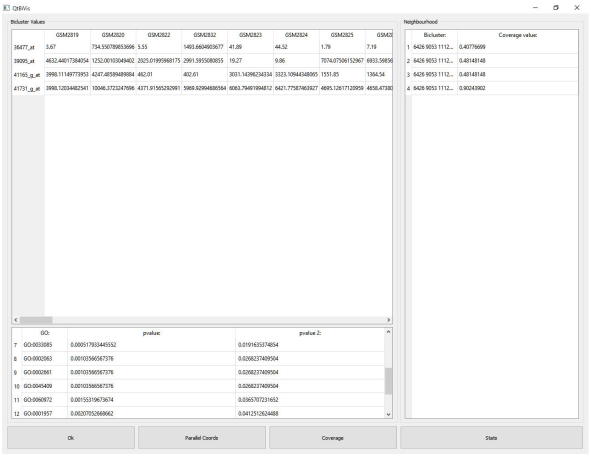

Fig. 2. A single bicluster overview.

This perspective offers access to three different analysis tools. The first one, called "Parallel Coords", provides access to profile analysis using parallel coordinates plot (see Fig. 3).

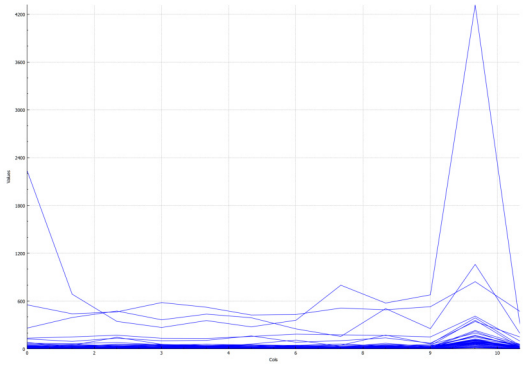

Fig. 3. Gene profile analysis of a single bicluster.

The second one, named "Coverage", displays a histogram, which presents the level of bicluster overlap with respect to other biclusters (see Fig. 4). A histogram presents on horizontal axis a degree of coverage (i.e. a percentage of shared area with the bicluster) and on vertical axis - a number

of occurrences (i.e. number of biclusters that share the same area).

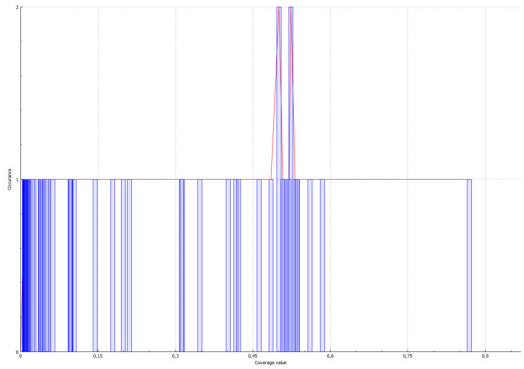

Fig. 4. Coverage analysis of a single bicluster.

The third one, "Stats", shows means and standard deviations of particular columns of a bicluster. In current version, for each column the plot displays mean and standard deviations as dots, whilst the average standard deviation of all columns is represented by a line (see Fig. 5).

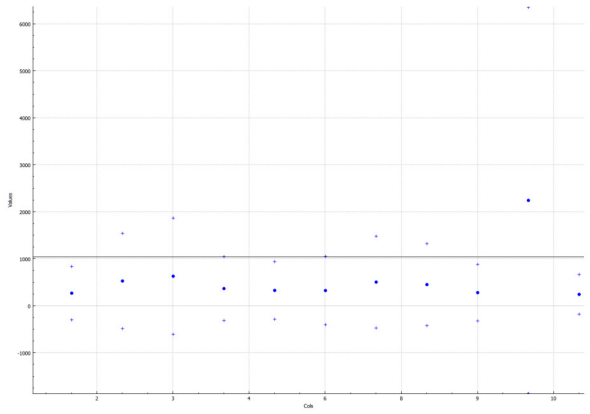

Fig. 5. Statistics of mean and standard deviation of the whole bicluster and its values in columns.

D. Coverage statistics

Another statistics, which is provided by QtBiVis, is analysis of the degree of bicluster intersection. Degree of overlap for two biclusters (A and B) is determined by Jaccard index (1), which takes into account the number of intersecting biclusters' elements with respect to the total area occupied by both biclusters.

$$J(A,B) = \frac{|A \cap B|}{|A \cup B|} \tag{1}$$

Clicking on the "Coverage" button on main window calculates the percentage coverage for every loaded bicluster, which is presented on a histogram (see Fig. 6). The button "Save" stores the results in a selected file.

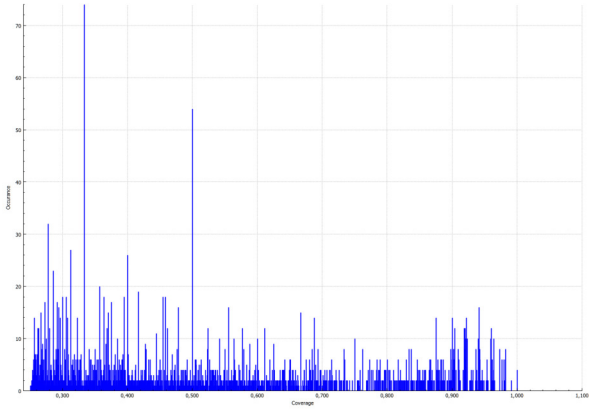

Fig. 6. A histogram presenting the degree of coverage of multiple biclusters with each other.

III. Implementation

QtBiVis has been designed as a modular application. Each module is responsible for providing a different perspective. Several coding optimizations have been used to reduce the computation time of certain calculations. For example row and column of a bicluster are represented in application by bits. If the row or column belongs to a bicluster it is set to '1', otherwise it remains '0'. Bitsets are used for computations of their intersections or unions.

A. Application design

The class diagram of the application is presented in Fig. 7. The main components of the application have been presented hereafter.

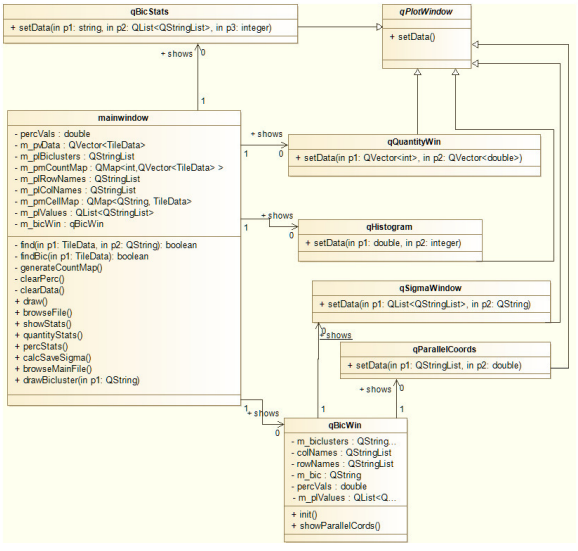

Fig. 7. Class Diagram of QtBiVis.

1) MainWindow: The MainWindow module is responsible for loading microarray data as well as loading, displaying and filtering the biclusters.

2) QBicWin: This module is used for displaying statistics about a single bicluster: its values and rows and columns labels. The module also presents the neighboring biclusters by showing the percentage of coverage. Different modules for single bicluster analysis may be triggered from here (i.e. qBicStats, qParallelCoords and qSigmaStats).

3) QBicStats: This module calculates of degree of coverage for the examined biclusters with the rest of biclusters.

4) QHistogram: The QHistogram module is responsible for calculation and presenting a histogram based on degree of coverage for every detected bicluster.

5) QSigmaStats: QSigmaStats is another module, which calculates and shows common statistics of values in bicluster, such as an average of values, a standard deviation and an average of standard deviation of values in each column of bicluster.

6) QParallelCoords: The QParallelCoords module is responsible for vizualization of a single bicluster with parallel coordinates perspective.

7) QQuantityWin: QQuantityWin is used for displaying the histogram based on the number of occurrences of values in microarray data.

IV. Results

For demonstration purposes eight GDS datasets have been taken, which have been previously used by Eren et al. [7]. As the original dataset haven't been provided by the authors in supplementary materials, we downloaded their copies from Gene Omnibus and tried to follow the authors' preprocessing procedure (i.e. missing value imputation, validation and Benjamini-Hochberg multiple value correction [17]). Unfortunately, we didn't manage to obtain similar results to the authors. The reason for this is that Eren et al. specify neither the method of missing values imputation, nor the method of gene universe creation (i.e. algorithm used for filtering features from an ExpressionSet, which exhibit a little variation or where GO or Entrez Gene identifiers are missing). Thus, we decided to parse the original file with their biclustering results, which have been publicly available. The file has been split into separate folders corresponding to each dataset and divided into the separate files for each biclustering method respectively.

The detailed analysis of the results of coverage of each biclustering method remains out of scope of this paper and has been mentioned only to demonstrate the usage of the QtBiVis.

V. Conclusions & future work

The QtBiVis tool performs extraordinarily fast for analysis of multiple biclusters and their coverage. Its capabilities include filtering by a specific GO term across all detected biclusters and sorting by p-values. Based on this, we hope to assess if the relation between the uniqueness of the detected biclusters and their biological significance exists.

We also plan to use the software for parameter study of biclustering algorithms. By analyzing the results obtained from a series of biclusters, each run with different input parameters, QtBiVis may allow us to support analysis of the most commonly detected biclusters by a specific algorithm. Thus, we hope to assess how the input parameters affect the stability of the results.

The current version of the algorithm doesn't take full advantage of the enrichment level of specific biclusters. In future releases of the software we plan to add different statistics, which would present the impact of the biclustering uniqueness on biological significance. This may be performed for example by visualizing only those biclusters or GO terms, which significance is higher than the adjustable threshold.

Acknowledgments

This research was funded by the Polish National Science Center (NCN), grant No. 2013/11/N/ST6/03204. This research was supported in part by PL-Grid Infrastructure.

***Abstract*—Effective project management requires the development of a realistic plan which aims to ensure the success of the project and ultimately deliver a high quality product to customers. However, experience shows that the majority of software vendors managing projects suffer from numerous problems to provide usability in IT solutions and complete a project in a given time with success. In this paper we discuss, analyze and synthesize the outcomes of a study conducted among IT firms in Poland. As a result, we have identified eight stimulants and three non-stimulants that affect the usability of software products, which later were stratified into three levels. Finally, we outline some of the lessons learned, summarized and expressed as a set of eleven goal-oriented rules.**

I. Introduction

PROJECT management is now one of the fastest growing areas of science, and its development and continuous improvement is sure to be a long-term up-to-date research topic. Many firms, during the realization of new IT projects, come across problems with their completion in line with the starting assumptions (i.e. budget, scope and schedule). Strong competition on the market may force them to make difficult decisions to optimize costs. Thus, they aim to find more effective methods of project management which allow them to increase project effectiveness. On the other hand, they look for adequate methods to manage a given project, best suited to its specific needs. However, in practice they have to face many different kinds of problems and obstacles, associated with the usability of the developed product, which directly translates into the success of the entire project. Evidently, a low-end usability product, as a whole, will be perceived as low-quality by its customers.

In this paper, we present and discuss the results obtained from a survey conducted among IT firms located across Poland. Our research includes the main findings of the survey, conducted among project managers, and an analysis of project documentation. We have identified, and later described, the factors (stimulants and non-stimulants) that affect the quality of software products in selected IT projects. In the end, we outline a set of eleven goal-oriented rules as a guideline for software vendors, regarding pro-usability organization and cooperation with end-users.

II. IT Product Life Cycle

The dynamic pace of change and the development of the IT society bring about numerous problems related to the choice of effective methods of project management, as well as their use and interaction with IT products. Taking appropriate action in the early stages of the development of IT products and services plays a significant role in effective product management (Fig. 1).

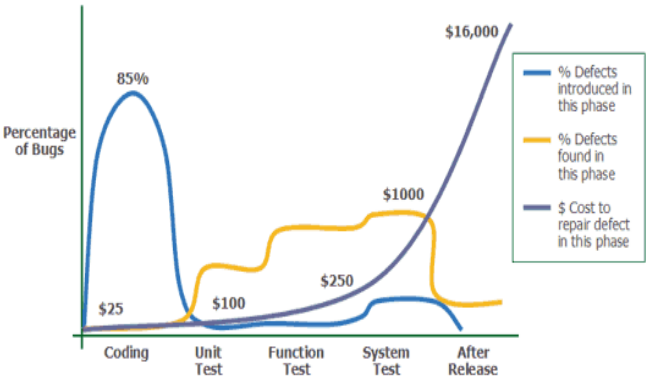

Fig. 1. Cost of the removal of defects implemented in stages of an IT project [1].

Defects implemented in the product in its initial stage of development are particularly costly from the perspective of the product life cycle. They may lead to the eventual failure of the entire project if their number exceeds permissible limits. Hence, it is particularly important to start the process of product quality provision at the earliest possible stage of any IT project.

III. The Development Of IT Project Management

The awareness of business decision-makers related to IT product development for end-users is constantly changing. Until the 1980s developers were only focused on software design and perspectives, entirely excluding end-users from the development process. Fortunately, from the early 80s till now, the end-user role has changed. The software vendors have realized that a user-oriented approach can advance product quality on a higher level. In such a way, end-users gradually began to be actively involved in projects, and their

importance over the years successively increased [2]. Among others, the so-called "human factor" has become an important and relevant element in ensuring high usability of the final product. To put it simple, the problem was to ensure efficiency, effectiveness and satisfaction with everyday use. On the other hand, as a result of a lack of acceptance on the part of the end-users, the sales value of new products can significantly fall, along with the profit of the software vendor.

A user-oriented approach is reflected in changes in both the technology of IT product development, as well as in the methodology of IT project management. Currently, one can particularly observe an intensive usage of soft approaches in project management. For example, the Agile manifesto states that "*our highest priority is to satisfy the customer through early and continuous delivery of valuable software*". In our opinion, the customer is all different kinds of users, with respect to such values as trust and transparency in communication facility. In turn, in literature of Human-Computer Interaction (HCI), one can distinguish an approach that addresses user-oriented design, defined as User Centered Design (UCD). This approach is characterized by active user participation in the whole design process (analogously to Agile), whilst putting the biggest emphasis on the fulfillment of the requirements and needs of the expected users. However, on the one hand, the goal is to close a project within a given time and budget, while, on the other hand, to deliver a product with high usability. In such a case, an impartial and tenable compromise between each project stakeholder group is a must.

The attempt to identify the factors affecting the provision of high product usability, undertaken in this analysis, is particularly important, because the correct identification of these factors allows us to determine not only the changes taking place in current developments in IT projects, but also to indicate the relationship occurring between selected factors and stakeholder groups.

IV. Usability Factors

We undertook both quantitative and qualitative research among five IT firms:

- *Infovide-Matrix JSC* (IVMX), a company which, according to the IDC report [3], is in the top 10 IT services companies in Poland, with revenues of USD 56.12 million, and employing up to 500 people; the company specializes in consulting, developing and deploying product solutions and technologies in the IT area;
- *Aiton Caldwell JSC*, a firm specializing in providing SaaS services (Software as a Service), based on remote software sharing via the Internet. The leader of the Polish market of hosted telecommunications services for SMEs and individual clients. The company employs about 50 people, and has about 40% of the Polish market share of VoIP (Voice over Internet Protocol);
- *Kolibro LLC*, a company specializing in consulting and deploying internal communication management systems, i.e. corporate intranet portals and dedicated applications for business process management. The company employs about 40 people, and has mainly used Microsoft SharePoint technology and Enterprise Project Management;
- *One2tribe LLC*, a firm specializing mainly in game development for mobile devices. It has, in its portfolio, a number of applications used in popular social networks for marketing purposes. The company employs about 40 people and has been present on the market for eight years;
- *Webstruments GP*, a firm specializing in the development and implementation of Internet and intranet applications. The company employs about 10 people and has been in business for 7 years, having a portfolio of very interesting projects for major firms, mainly from the public sector.

We purposely selected miscellaneous firms to examine, offering a diverse range of IT products, varying in the total number of employees, annual income, scale of operations and duration of business activity. In fact, the study included the largest IT companies in Poland, which have vast experience and resources involved in projects (taking into account workforce, materials and costs), but also micro-enterprises, which often equally effectively compete in the market with the biggest market participants. The major goal of the study was to identify the factors affecting the assurance of usability in IT projects, and to assess their impact on the final success of a given project. The study has been divided into two parts:

- The first part was to *conduct interviews* with project managers, who, whilst sharing their insights, would point to the factors which, in their opinion, influence product usability and the final success of a project.
- The second part was to *analyze the documentation* of a given project, which described how the project was realized, and indicated the methods and measures applied in order to assure product usability by the personnel responsible for the project.

Next, the identified factors were examined, using an electronic questionnaire in which respondents answered the following questions:

- In your opinion, *what was the product usability like*? The answer was represented by a 5-point quality scale (very poor, poor, average, good, and very good), where 1 stood for very poor quality, and 5 for very good quality.
- In your opinion, *did the project end in success*? The answer was represented by a 5-point quality scale (total success, partial success, hard to say, partial failure, and total failure), where 1 stood for total failure of the project, and 5 meant that the project was totally successful. The study was conducted on a group of 30 respondents (participants of IT projects).

The obtained results allowed factors from the first part of the evaluation and the relationship between them to be verified, and juxtaposed with their usability in IT projects.

Factors with a positive impact (stimulants) on product usability in IT projects are:

- s_1: *product specification,* is a set of documented requirements to be satisfied by the software product;
- s_2: *user participation,* refers to the assignments, activities and behaviors that a user (human) performs during the product development process; these can take a variety of forms: direct (individual action) or indirect (represented by others), local (physical attendance) or remote (physical non-attendance), formal (using legal agreements, documented and obliged) or informal (through informal relationships, discussions, and tasks), performed alone or in collaboration with others (in groups or teams), moderated (driven by other individuals) or liberated.
- s_3: *project analysis*, is a retrospective inspection of the finished project;
- s_4: *project team size,* is the total number of hired staff, assigned to perform a particular set of tasks;
- s_5: *project team experience,* is the total number of similar projects finished by the assigned group of people;
- s_6: *project team knowledge,* is the collective, tacit and incorporeal expertise in a specific domain, demonstrated by the assigned group of people;
- s_7: *project manager experience,* is the ability to manage and mitigate risks, and skills gathered in using risk management methods in previous projects;
- s_8: *project manager knowledge,* reflects the mastery of domain expertise in project management as applied to a particular field or multiple fields, which brings natural authority and solid strategic insight.

On the other hand, we distinguished three factors with a negative impact (non-stimulants) on product usability in IT projects, including:

- d_1: *project innovativeness,* is originality by virtue of introducing a new software product (newness to the developing firm);
- d_2: *project implementation method,* reflects the assumptions, principles and best practices that are used in the software product life cycle.
- d_3: *project outsourcing,* is the presence of external services hired in the project to perform particular tasks.

In addition, we distinguish three separate groups of factors, embodied in three dimensions named, respectively from top to bottom: project, team and project manager (table below).

TABLE I.
THREE DIMENSIONS OF USABILITY FACTORS

level	stimulants	non-stimulants
project	s_1, s_2, s_3	d_1, d_2, d_3
team	s_4, s_5, s_6	-
project manager	s_7, s_8	-

Each individual factor was assigned to a distinct level and each is subsequently represented by a goal-oriented rule in the next section. The project level is the most general and is the only one to have all three non-stimulants assigned as well as the first three stimulants.

The project team and the project manager experience (s_5 and s_7) are particularly important to ensure high project usability. It is also recommended to carry out a so-called post-project analysis after completion of a project. This allows usability errors to be significantly eliminated in subsequent projects. The analysis of the projects surveyed also indicated that a certain level of formalization of the project documentation favored ensuring high usability in a project.

Among the non-stimulants that could negatively affect product usability in IT projects, project innovativeness (d_1) was highlighted. This factor greatly conditioned the participation of end-users in a project. Firms that developed projects of a rather reproductive nature (and thus largely repetitive), would substantially, or even entirely, resign from user participation in a project, thereby aiming to reduce the cost of the entire project. In this case, the risks associated with the failure to provide usability were attributed to the project manager or the whole company responsible for the project. The analysis of the methods used in the surveyed IT projects indicated that there is no direct relationship between one method of project implementation (classic, agile, informal), and the usability of a product. A project which ended in complete success would primarily use informal methods of project management, which combined two main approaches used in project management: the classic and the agile. Moreover, project outsourcing (partial or full range), proved to be a factor negatively influencing product usability. Companies carrying out projects based on the services of external companies fared far worse compared to companies independently pursuing projects.

Therefore, analyzing the development of project management methodologies (see par. 2), it should be stated that there is a continuous tendency to increase the active participation of end-users in projects. However, despite the fact of the increased importance of their participation [4], practice among businesses can be seen to limit the participation of users in selected types of projects. This applies mainly to projects where the product being developed is repetitive and imitative. The active participation of the user in a project corresponds to the necessity to increase the budget of the project, since their presence increases the total costs of the project. Hence, companies willing to increase the chances of a project being realized, and increase the probability of acquiring new customers, deliberately restrict user participation in their projects. Reducing the costs associated with user involvement in a project is, in fact, a significant part of the project budget. The experience of those responsible for the project is, therefore, particularly important for ensuring product usability.

V. Lessons Learned

Rule no. 1 states that *the higher the degree of documentation formalization, then the higher the usability and quality of the product being developed*. In other words, if you and your client pay more attention to detail, use formal specifications and modeling languages, and share the same dictionary, then the product will demonstrate perceivable values to its users concerning accuracy, efficiency, and satisfaction.

In current practices of usability testing we observed four prototype methods: thinking-aloud, subjective ratings, history files and eye-tracking. The major goal of usability testing is to identify and eliminate obscure problems with the user interface. Rule no. 2 states that *the higher the user participation in the life-cycle of software design, then the higher the usability and quality of the product being developed*. An important step in addressing these issues is the recent effort to develop a better measure of user participation, constructed by combining different methods.

The post-project analysis documents the results of conducting a deep and broad project assessment from its kickoff to finalization. Rule no. 3 states that *the higher the degree of comprehensive post-project analysis, then the less expense and risk together with higher usability are expected in future solutions*. A unified analysis should capture successes and failures, challenges and threats, in such areas like: planning, resources, scheduling, development and design, testing, communication, team and organization, solutions and tools.

On the team level we identified three stimulants that concern its size, experience and knowledge. Rule no. 4 states that *a bigger project team size boosts a richer essence in knowledge flow between its members and engages more experience and skills, which together move toward higher usability of the product being developed*. We also have to keep in mind an adequate arrangement of members of a goal-oriented team.

Satisfaction (subjectively pleasing) is one of Nielsen's five usability attributes, especially important in home computing environments (e.g. video games) where entertainment value comes first, before compatibility, efficiency and reliability that, on the contrary, play a major role in work-related environments. Rule no. 5 states that *a more experienced team delivers a technology more preferred by a user, reflected by higher satisfaction of usage.*

The ISO 9241 presents a set of usability heuristics which applies to the interaction of people and information systems. In this standard this interaction was called a "dialogue" and the following seven "dialogue principles" were defined: conformity with user expectations, controllability, error tolerance, self-descriptiveness, suitability for individualization, suitability for learning and suitability for the task. They apply to broad and narrow groups of artifacts. The former includes two sets of recommendations: (1) a presentation of information, defined in three main areas such as: organization of information, graphical objects, and coding techniques and (2) user guidance that covers general advice: prompts, feedback, status information, error management and on-line help; the latter includes four sets of recommendations: menu dialogues (such as pop-up, pull-down and text-based menus), command dialogues (command line interface), direct manipulation dialogues and form-filling dialogues. Rule no. 6 states that *the higher the knowledge capital of the team developing a particular artifact, then the less ambiguous the dialog between the end-user and the product will be.*

One of the most desirable attributes of the project manager is action management, which means acting in such a way that leads to the achievement of expected results through the successful and timely completion of activities and the delivery of the product. Rule no. 7 states that *the higher the experience of the project manager, then the more proper usability practices are applied.*

Rule no. 8 states that *the higher the knowledge demonstrated by the project manager, the more relevant the allocation of time and resources to various means*. Regarding rules no. 7 and 8, a skilled project manager should wield knowledge, skills and experience commensurate with the complexity, risk and size of the project.

In a low level innovative project, its specification is often created *ad hoc*, based on the project manager's experience and knowledge. However, knowing your audience is key to any successful innovation and this is notably true for new products [5]. Rule no. 9 states that *higher project innovativeness requires a higher degree of documentation formalization*. On the other hand, the level of active user participation in testing usability should always be considered in conjunction with the project innovativeness.

The context specificity of explicit users' requirements does not allow usability to be compared across different IT systems, unless they share comparable functionalities and user interfaces [6]. Rule no. 10 states that *the context of use analysis sets up the borders of usability heritage between heterogeneous systems*.

Numerous undesirable consequences of IT outsourcing have been reported so far i.e. service debasement, absence of cost reductions, disagreements. Rule no. 11 states that *the higher the level of outsourced resources hired in the project then the lower the internal usability of captured know-how*.

***Abstract*—In computer architecture, speculative execution is the process of executing instructions ahead of their normal schedule[1]. Grama et al.[2] introduce the concept of speculative decomposition as a possibility to execute one or more of possible branches in parallel with computation which are expected to determine the branch choice. The following paper introduces the method of speculative query execution in relational databases. Query queue can be seen as a line of sequential instructions and thus changing their order can result in some errors. Author introduce a middleware called the Speculative Layer which, based on a specific graph representation, executes some additional Speculative Queries. Results of those Speculative Queries can be used while executing queries from the queue providing a befit which is a shorter response time. The paper describes the process of graph modelling for groups of queries in order to initiate speculative computations, metrics used to evaluate Speculative Queries and experimental results for a test database and a group of input queries.**

I. Introduction

ORIGINS of the speculative execution are the early works of branch prediction[3][4]. The sequential semantics imposes a certain order in which instructions should be loaded, decoded, executed and ended[5]. Code branches, usually dependent on some logical conditions, disturb the fluency of loading and executing, causing delays. As an attempt to prevent delays there were experiments to predict a branch direction and to execute an instruction or a group of instructions in advance.

In general, there are three types of Thread Level Speculations (TLS)[6]:

- Control Speculation – origins from branch prediction strategy. The assumptions could be made based on some static (e.g. op codes) or dynamic values [7][8].
- Data Dependence Speculation – If two instructions are fully independent, only then the parallel execution is possible. Before memory access instructions are executed, the addresses they refer to are often undetermined. To prevent data load from an address where store should be executed earlier, a certain secure mechanism should be introduced[8].
- Data Value Speculationis – is expected to prevent data dependency with the value prediction mechanisms which allow to propagate data values to succeeding instructions in advance.

II. Related Work

There is already much research done around the world in adopting speculative execution in database computations.

Polyzotis N. and Ioannidis Y[10]. introduce speculation as a parallel, intelligent technique of query processing assistance. Exploiting idle time[11] of the system the application processes some asynchronous database manipulations which in case of success would be beneficial for the final query.

Barish G. and Knoblock C.A.[12][13] in order to overcome the limits imposed by binding patterns between data sources propose mechanisms of applying speculative execution for Information Gathering Plans. The general process of speculative execution involves issuing operations ahead of their normal schedule based on data (hints) received earlier in the plan.

Hristidis V. and Papakonstantinou Y[14] analyse speculative computations for ranked queries. Authors create a speculative version of a ranking algorithm which in case of a slower data source assumes speculatively that there are no tuples satisfying the preference function and thus can return top-N results faster but with some inaccuracies.

Reddy P., Kitsuregawa M.[15], Ragunathan T., Krishna R.P.[16][17] deal with speculative execution for transaction protocols in database systems. They introduce the speculative protocol (SL). With SL the waiting transaction is able to access locked data as soon as blocking transaction produces its images.

III. The Speculative Layer

An inspiration for this experiment is an idea of speculative execution briefly described in the previous section. Authors proposes a speculative execution mechanism for relational databases executing SQL queries of accepted structure which are CQAC queries with additional IN and LIKE operators. What is important, an analysed database must show a specific use template. Databases which suit our interests usually have to execute similar queries from different users. What's more, data modifications are rare and usually concentrate around some fixed points.

A queue of queries awaiting for execution, called the input queries, presents an interesting analogy to the sequential order of instructions. The consecutive queries can, like sequential instructions, show some dependencies. On the other hand,

978-83-60810-90-3/$25.00

carefully identified similarities allow to use some of the results many times[18][19][20].

A model described above is implemented as an additional middleware between users and DBMS called the Speculative Layer, which dynamically supports execution of input queries. The Speculative Layer, based on precise Speculative Analysis, creates a subset of data in RAM called further a Speculative DB. The data from the Speculative DB used while executing an input query improves system throughput and shortens users waiting time.

All actions of the Speculative Layer are controlled by the main worker thread called the Manager. In each step N input queries are analysed. This group of input queries is called the Window of Speculations. Based on those analysis, supported by a specific graph representation described in Sections IV and V, Manager assigns tasks to K Worker Threads.

In particular Manager implements the following functions of the Speculative Layer:

1) System Start.
   All initial actions required for the first run of the Speculative Layer. In particular graph representations are created for N input queries from the Window of Speculation. Next, those representations are combined to create the Queries Multigraph ready for the Speculative Analysis.
2) Nonspeculative Query Execution.
   Process of executing the first input query from the Window of Speculation, called the Nonspeculative Query. If there are Executed Speculative Queries assigned to the Nonspeculative Query, then it must by modified so it would use those results. If there are more than one Executed Speculative Query assigned, then the choice which to use is based on the values of the defined metrics - Horizontal an Vertical Selectivity. Vertical Selectivity models the reduction of the number of columns while the Horizontal Selectivity approximates of number of records returned by the Speculative Query.
3) Speculative Analysis.
   Process of the Queries Multigraph analysis which identifies speculation points and generates Awaiting Speculative Queries. The other result of the Speculative Analyses is a Speculative Queries Multigraph i.e. Queries Multigraph with additional speculative edges representing points and types of speculations.
4) Window of Speculation Move.
   After the Nonspeculative Query is executed and its results are returned to the user the Window of Speculations moves. It means that the representation of executed Nonspeculative Query in the Queries Multigraph is replaced by the representation of the next input query from the queue.
5) Speculative Query Execution.
   If there are idle Worker Threads then, if it is possible, they should be assigned available Speculative Queries from the Awaiting Speculative Queries List, according to the values of aforementioned metrics. The highest execution priority should have those queries which provide the highest potential reduction of records or/and can be used by the most of Input Queries.
6) Executed Speculative Query Assignment.
   After an Awaiting Speculative Query is executed and becomes an Executed Speculative Query, it has to be assigned to the specific Input Query/Queries from the Window of Speculations, which marks the possibility to use its results.
7) Speculative DB Refreshment.
   When the Speculative DB reaches its maximum size, it has to be reduced. The reduction process consists in removing the results of chosen Executed Speculative Queries based on its characteristics. First to remove are always those queries with the highest Vertical and Horizontal Selectivity and those which are used the least often.

IV. Query Graph

A. CQAC queries

Each accepted CQAC query is represented by its Query Graph $G_Q(V_Q, E_Q)$. Graph creation rules follow the example of [22][23] works, and are as follows. Each Query Graph Vertex is one of three types:

- Relation Vertex (R_i) – one for each relation,
- Attribute Vertex (A_j^i) – one for each attribute,
- Value Vertex $(\Omega) = \{Val_j^i | A_j^i\}$ – one for each value or set of values.

Each Query Graph Edge is one of the following types:

- Membership Edge – $e_\mu : R_i \underline{^\mu} A_j^i$ – one between relation R_i and each of its attributes A_j^i from SELECT clause,
- Predicate Edge – $e_\theta : A_j^i \underline{^\theta} \{Val_j^i | A_k^m\}$ – one for each predicate of WHERE clause $A_j^i \theta \Omega$, where θ is one of accepted operators. Ω is a single value or a set of values (Val_j^i) or an attribute (A_k^m) for JOIN condition.
- Selection Edge – $e_\sigma : R_i \underline{^\sigma} A_j^i$ – one for each predicate of WHERE clause $A_j^i \theta \Omega$, where θ is one of accepted operators. Ω is a set of values (Val_j^i) or an attribute (A_k^m) for JOIN condition.

B. Embedded queries

Each embedded query q_m is represented by its own query graph joined with its parent query Q graph in the following way – for each predicate $A_j^i \theta A_k^m$ where $A_j^i \in (Q$ WHERE clause) and $A_k^m \in (q_m$ SELECT clause), there is a predicate edge between A_j^i and A_k^m.

C. Modifying queries

Next to SELECT queries there are also modifying queries which are accepted by the Speculative Layer and thus need to have a proper graph representation. For each type of modifying query there is another edge type representing a possible change in the database state:

- DELETE: $e_\delta : R_i \underline{^\delta} A_j^i$ and $e_\delta : A_j^i \underline{^{v\theta}} \Omega$ where θ is one of accepted operators and Ω is a set of values,

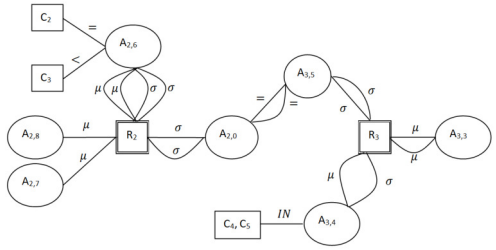

Fig. 1. Queries Multigraph

- INSERT: $e_\eta : R_i \underline{\eta} R_i$
- UPDATE: $e_\upsilon : R_i \underline{\delta} A_j^i$ and $e_\upsilon : A_j^i \underline{\upsilon\theta} \Omega$ where θ is one of accepted operators and Ω is a set of values.

V. Queries Multigraph

To represent a group of queries with one graph some additional rules have to be defined. Such graph $G_s(V_s, E_s)$ will be called the Queries Multigraph or QM. QM Vertices set is an union of Vertices of all component query graphs: $V_s = V_{q1} \cup V_{q2} \cup \ldots \cup V_{qn}$. QM Edges set is a multiset of all component query graphs edges: $E_s = E_{q1} + E_{q2} + \ldots + E_{qn}$. This way multiple edges of the same type are allowed. It is important for the Speculative Analysis process raising the importance of some edge connections. Fig.1 presents the Queries Multigraph representing three following component queries:

- SELECT $A_{3,3}, A_{2,6}, A_{2,7}$ FROM R_2, R_3 WHERE $A_{2,0} = A_{3,5}$ AND $A_{2,6} = C_2$
- SELECT $A_{2,6}, A_{2,8}$ FROM R_2, R_3 WHERE $A_{2,0} = A_{3,5}$ AND $R_2.A_{2,6} < C_3$
- SELECT $A_{3,3}$ FROM R_3 WHERE $R_3.A_3, 4$ IN (C_4, C_5)

VI. Types of Speculative Queries

The process of Speculative Analysis is expected to determine a set of Speculative Edges. Those edges represent different strategies of creating Speculative Queries. Based on the results usage, there are three types of Speculative Edges which represent three types of Speculative Queries:

- Speculative Parameter – those edges/queries relate to the presence of embedded queries. Due to separating an embedded query as a Speculative Query, it is possible to use its results as a parameter in a parent query. The Speculative Parameter Speculation is identified the moment the query with an embedded select enters the Window of Speculation. An embedded query as a whole is added to the head of the Awaiting Speculative Queries List (Q^i_{PS}). As a consequence those queries are always first to be executed by the Worker Thread.
- Speculative Data – the aim of those speculative queries is to obtain and save in the Speculative DB a specific subset of records or/and attributes of a relation. The main goal is to create this subset so as it could be used while executing as many input queries as possible. Speculative Data queries are the most frequent in the group of identified speculations.
- Speculative State – those edges/queries relate to the presence of modifying queries. If there is a modifying query in the Window of Speculation then both Executed and Awaiting Speculative Queries are in danger of processing invalid data. Speculative State edges are referring to the modifying queries represented by $e_\delta, e_\eta, e_\upsilon$ edges. If a modifying query has a number K in an input queries queue, then all succeeding queries (K+) are in danger of processing invalid data.

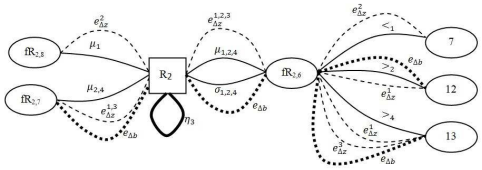

Fig. 2. Multigraph with Speculative Data and Speculative State edges

The Fig. 2 presents an example of Queries Multigraph with Speculative Data and Speculative State edges.

VII. Experimental Results

The Speculative Layer was implemented with C++ and Visual Studio 2013 with Pthread library and SQLite 3.8.11.1. Experimental results were obtained in Windows 8.1 64b with Intel Core i7-3930K and 8GB RAM.

A. Test Database and Test Input Queries

The Database used for experiments was generated with the TPC[21] data and structure generator. It consists of 8 relations storing 1GB data. It represents 150 000 orders from 150 000 customers which include chosen from 200 000 products delivered by 10 000 suppliers. Such database is a fine example of a medium sized Internet store. Eight SQL Query Templates were prepared and used to generate a set of Input Queries executed with the Speculative Layer.

B. Window of Speculation Size and the Number of Speculative Threads

At the beginning the series of experiments were conducted to determine the size of Window of Speculation and the number of Speculative Threads for which the experiments would continue. The size of the Window of Speculation stands for the number of input queries represented by the Query Multigraph and thus it determines the number of generated Awaiting Speculative Queries. Fig.3 presents how the Size of Window of Speculation affects the number of generated Awaiting Speculative Queries.

The number of executed Speculative Queries depends on the number of active Speculative Threads and not on the size of the Window of Speculation itself. In the Fig.4, two series of data are presented. First one, marked with black squares, presents the number of Executed Speculative Queries for the number of active Speculative Threads. The second one, marked with

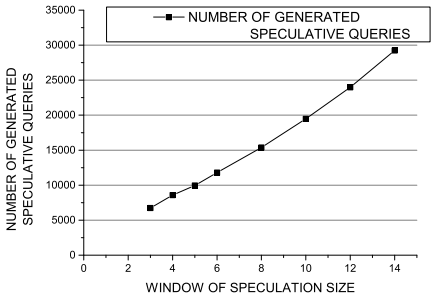

Fig. 3. The number of generated Awaiting Speculative Queries.

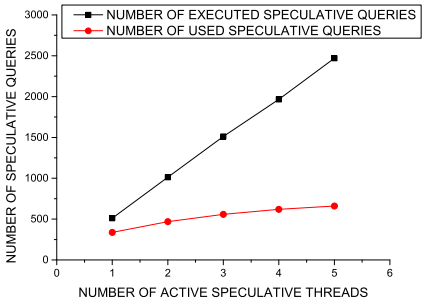

Fig. 4. The number of executed and used Speculative Queries.

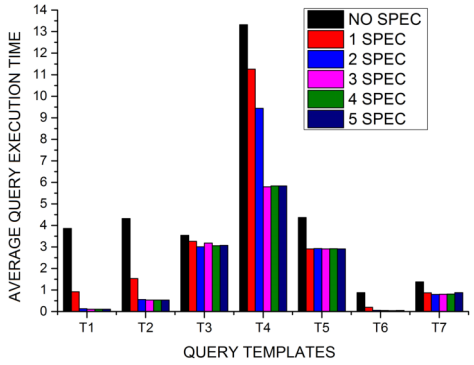

Fig. 5. The average Execution Time for Each Template for 0-5 Active Speculative Threads.

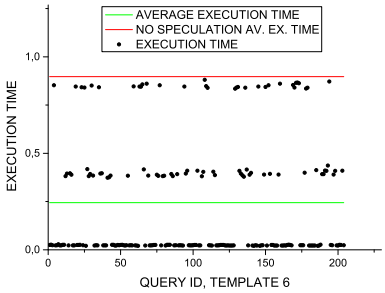

Fig. 6. Query Execution Times for Template 6.

red dots, presents the number of Used Speculative Queries for the number of active Speculative Thread. The experiment was carried for the Window of Speculation Size = 5.

Fig. 3 shows almost linear dependency between the Size of the Window of Speculation and the number of generated Awaiting Speculative Queries. Fig. 4 also presents almost linear dependency between the number of executed Speculative Queries and the number of active Speculative Threads. On the other hand the number of Used Speculative Queries hardly changes for the number of threads 3 and more and thus the percent of Used Speculative Queries is decreasing. Based on those observations it was decided that the further experiments would be carried for the Window of Speculation Size=5. The experimental results are presented for the set of 1000 input queries generated from Templates T1-T8. The size of Speculative DB is 700MB RAM.

C. Query Execution Times

Fig. 5 presents the reduction of average execution time for input queries of each Template. First column represents the sequential execution time when there were no active Speculative Threads. The following columns represent execution times obtained for each query Template for 1 to 5 active Speculative Threads, which execute Speculative Queries. It appears that the highest execution time reduction was obtained by initiating the first Speculative Thread (up to 55% execution time reduction for Template 1). Further improvement, up to 20% brings the second active Speculative Thread. Activating more than two Speculative Threads doesn't affect the Average Execution Time.

Fig. 6 presents execution times of input queries for Template 6, with the Window of Speculation Size=5 and 2 active Speculative Worker threads. In the picture there are two additional lines presented showing the average execution time with (green line) and without (red line) speculative execution. Template 6 was chosen for presentation as its queries show an interesting behaviour. There is a clear division for three groups of input queries. First group are the input queries executed without the opportunity to use results of Executed Speculative Query. They have the longest execution times and thus are located close to the red line. The remaining two groups are input queries which were able to use the results of Executed Speculative Queries, however, the obtained execution times vary significantly. It turned out the group with the lowest execution times had an opportunity to use results of the Speculative Query with the Horizontal Selectivity equal to 0,01. The rest of them had to use the results of Speculative Queries with the Horizontal Selectivity equal to 0,9 which are almost full copy of the original ORDERS relation.

Fig. 7 presents how many Input Queries of each Template were executed using results of the Executed Speculative Query. It is expressed as a proportional dependency where each column stands for 100% of Input Queries of each Template. As you can see Templates T3 and T4 are the least responsive

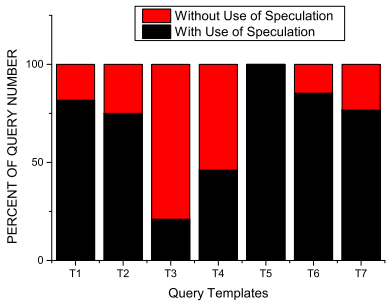

Fig. 7. The number of Input Queries which used the Executed Speculative Query Results as a proportional relation to the total number of Input Queries of each Template.

to Speculation and thus the average execution time reduction of those templates (Fig.5) was also the lowest. The reason is that those queries has low occurrence density (10%) in the Input Query Set. As a consequence its multigraph vertices has low Selection Degrees and thus they are rarely chosen to be executed by Speculative Threads. What's more, in both those Templates, T3 and T4, IN and LIKE operators are dominating. Those operators refer to the narrow subgroups of attribute values, making it especially difficult to generate Speculative Queries useful for more than one query from the Window of Speculation.

VIII. Conclusion

The following paper presents a model of Speculative Execution to support SQL query execution in relative databases. The Speculative Layer executing Speculative Queries is carefully described. In particular the details of an adopted query graph representation are presented. Experimental results obtained for the test database and a group of 1000 input queries are very promising. In case of Template 5, 100% of input queries were execute using the results of executed Speculative Query. Templates: 1, 2, 6 and 7 show around 75% and above execution with Speculative Query. All groups of queries show its execution time reduction: from 10%(Template 3) to 70%(Template 6). Further work should concentrate on the improvement of the number of input queries executed with the Speculative Query results (especially for Template 3 and 4). Worth consideration is also allowing more flexible structure of accepted queries and intensifying the number of modifying queries which would require more sophisticated speculation validation methods.

***Abstract*—This paper aims to extend current research in the area of on-line business-to-business clients preferences. A quantitative research in a form of transaction log analysis (TLA) performed by the authors allow to conclude that search log and shop basket logs are sources of viable information about business customers. Transaction log analysis allows to identify different customer groups, such as searchers and buyers. It also allows for better customization of cloud of tags, so that the results are better tailored to customers' preferences. It turns out that a large list of products (result of search process) is not a deterrent to purchasing on-line. However, in order to facilitate the purchasing process b2b platform should offer additional filtering mechanisms.**

The main results of the research could be used by managers of professional e-commerce b2b platforms to better understand customers' needs and develop strategies to build long lasting partnerships.

Research limitations. The authors examined single b2b platform that may limit the findings generalizability, so the future research of other b2b platforms should be explored to validate the results.

Our future research should be performed to obtain the interplay between quantitative and qualitative methods of b2b clients' analysis and online shopping. It will allow for better understanding of customers' engagement and clients' unique organizational culture that may have an impact on purchasing decisions and building long time relationship.

I. Introduction

To avoid many pitfalls b2b companies should systematically analyze clients' decision making processes and improve supplier-client relationship. The Gallup research shows that in many cases b2b companies don't know the business clients opinions and needs, therefore they hardly need the feedback from the customers in order to sustain and develop business relationships [3]. The source of that feedback can be data stored in the Internet, social media platforms, that can be automatically summarized by IT systems [25, 26]. Data can be also collected by b2b platforms in a form of transaction logs (TL). Transaction logs are collected automatically and can be generated by applications, operating systems, network devices and other programmable hardware. Transaction log analysis (TLA) can be a good starting point for better understanding the purchasing preferences of business customers.

A. Collecting the data about b2b customers

E-commerce is rapidly developing phenomenon. Using information systems (IS) allows for gathering a lot of data about customers' behavior. Many companies believe that more data give better customer insights, however Gallup stated that it is not always true in b2b relations [1]. It is difficult to build lasting partnerships offering only good product or service price. This price related relationship will continue until the client finds a cheaper supplier.

In order to improve relations with customers Gallup advises to take the following steps [3]:

- Asses the company's knowledge about the business clients.
- Analyze the customer engagement drivers.
- Take the ownership of the relationship.

The above steps lead to better understanding the customer engagement and determine the strengths and weaknesses of the relationship. The weak points should be quickly identified and corrected and the strengths properly maintained. Taking the ownership of the relationship needs dialog with customer and continuous questioning about what was done well, in what areas the relation could be improved, what was missed, etc. The change should be sustainable.

As Gallup research shows fully engaged customers buy more and more often. The organic growth of the b2b business needs the understanding of business clients' needs. Some customer characteristics could be derived from the transition log analysis (TLA). Transaction logs are files that contain data collected automatically by b2b platforms. These files can consist of data about customers' search preferences: search phases, search time, session duration; buying preferences: price, discount, payment method; transportation preferences: duration, cost, volume, and many more. Therefore, the analysis of these files can be a good starting

point for exploring needs of business customers. To better understand these needs we should distinguish data stored in logs, generated by bots from the traffic generated by business users [27]. Well-identified needs are the foundation for further good relationships with customers.

The main drivers for purchasing decisions in b2b market are functionality, utility of the product and information about vendor. However in some cases just as important are some factors related to business customer personality [8]. Sometimes business clients act as common consumers and have human qualities. Therefore in order gain more profound knowledge about preferences of b2b clients pure quantitative research like transaction log analysis or knowledge extraction from the professional e-mails [28] should be complemented with psychological analysis. Chlupsa, Döhl, Lean and Hanoch claim that decision making processes are influenced by implicit motives [9]. In order to obtain a complete data describing customers some additional qualitative research like in-depth interviews, observations, and focus groups should be performed.

B. B2b customers purchasing decisions

When customer wants to buy a product he has to go through buying decision process. Psychologists have developed many models describing this process [11] most of them goes across the stages from the need to the purchase decisions. For example Engel's, Blackwell's, Kollat's model consists of five stages: need recognition, search for information, alternatives comparison, purchase decision and post-purchase behavior.

Business e-commerce customers need some tools preferably in the form of b2b platform that will allow them to convert needs into purchase. Therefore b2b platform should offer not only the mechanisms for searching the right product but also give the possibility for product comparison and finally offer a simple mechanism for filtering and purchasing. Furthermore, the additional mechanisms should collect information about the course of the purchasing process and also store the purchase history. This functionality results in higher hardware requirements but allows for better fitting the IT system to the needs of the business consumer and build customer loyalty.

IT solutions are not sufficient condition for the success. Khan, Naumann and Williams [12] examined factors that drive customer satisfaction and repurchase intentions. They explored Japanese business-to-business service customers. According to their findings personal interactions have great impact on repurchase intentions. The researchers observed that in Japanese context, product perception is less important than personal contact. They claim that personal business relationships are very important.

Belonax, Newell, Plank [13] investigated buyer perception of trust and expertise of the salesperson. They claim that this perception was higher in less important purchases than extremely important purchases. They also confirmed positive relationship between trust and expertise. Perception of trust and expertise is positively affected by the frequency of purchase contacts.

Cano, Boles and Bean [14] examined the communication media preferences in business-to-business transactions. They concluded that in most cases buyers and sellers prefer face-to-face or telephone communication rather than other types of communication tools. The communication ways vary throughout process purchase. For the efficiency of the sales process salesman must understand buyer's communication needs and adapt to this type of communication. Finally researchers conclude that communication process should be managed in order to be cost efficient in short time but also build stable long-run relationships.

There can be concluded that the purchase act in business to business environment is preceded by a number of preparatory steps. The buyer has to trust the seller and believe in his expertise. Good communication is crucial for building the trust. The communication preferred by b2b customers should be face-to-face but in many cases, through the development of technology it can be successfully supported by b2b platforms.

C. Building relationships with b2b clients with IT

Trusting and more satisfied clients are more likely to continue cooperation. Attracting and keeping customers can be achieved no only through functionality, utility of the product and information about vendor but also by offering additional services i.e. shipping cost and duration, payment form and conditions. Mingming and Parlar [10] used leader-follower game to check whether buyer is willing to increase the purchase value to get free shipping.

B2b platform can be also the tool for building customer loyalty. The structural equation modeling was used by Hsu, Wang and Chih [5] to explore how web platform characteristics influence customer loyalty and positive opinions. It was found that web site characteristics has a positive influence on relationships. Performed research showed that web site attributes can be good predictors for customer's loyalty, high-quality e-commerce platform results in more satisfied user.

Sila [6] collected surveys form 275 North American companies using b2b electronic commerce and found that the biggest contributor to b2b usage is scalability.

Taehee, Jonghoon, Junho, Sang-goo showed that the quality of b2b platform can be improved by using ontology-based product recommender system instead of systems based on the text-retrieval technique [7]. They addressed the results ranking problem by modeling the product ontology as a Bayesian belief network.

As we can see, there are many ways to build relationship with customer e.g. price, quality, delivery terms. B2b platforms can be an important part of maintaining

relationships with business customers. They play the role of an organization business card but in some sense also a kind of expert system. Moreover, the data recorded by the platform in the form of transaction logs can be a source of valuable information about customers' purchase preferences and can be used for increasing the efficiency of trade.

D. Shopping basket analysis

B2b platform can be used as a tool for collecting data about customers, tool for building relations with customer or image building tool. An interesting data for the analysis that can be collected by the b2b platform are the shopping baskets. Analysis of the shopping cart can provide a valuable information about the needs and behavior of on-line and off-line consumers. We can find many researches in the area of: what (and when) is being purchased [15][19], shopping basket size and value analysis [16], effect of sales promotions on shopping basket [17][18], the cart filling time [20], the influence of smart shopping card on shopping behavior [21], or determinants of consumers' online shopping cart abandonment [22][23][24].

Mallapragada, Chandukala and Qing [15] investigated the impact of what product and where being shopped. They examined 773,262 browsing sessions resulting in 9,664 transactions and noticed that website communication tools are positively correlated with basket value. They confirmed also that number of products available in the on-line store is positively associated with duration of the visit and the value of the basket.

Anesbury, Nenycz-Thiel, Dawes and Kennedy [20] examined in details behavior of 40 shoppers by recording (screen recording) online shopping trip of new, inexperienced grocery customers. They concluded that shopping process is quite fast. The 12 item shopping took less than 10 minutes. Clients mostly have chosen items from the first results page. Customers used rather default display options presented on the on-line store. Finally researches stated that in terms of time and efforts grocery on-line clients are quite similar to off-line shoppers.

List of the determinants of consumers' online shopping cart abandonment was presented by Kukar-Kinney and Close [22]. They confirmed that categories of cart abandonment determinants should include entertainment value (using web page only for information purpose), concern about costs, waiting for better price, privacy and security concerns. They concluded that customers leave the basket not only because of dissatisfaction with the product. They often use on-line platform just for tracking prices. The basket leaving does not necessarily mean abandoning the purchase. Some clients are going to decide to buy selected products in the near future, e.g. waiting for right time or maybe better price.

Mentioned researches were mainly related to retail customers. The above cases confirm that the shopping cart analysis provides valuable information that can be used to build clients loyalty and improve platform conversion rate.

In this article we want to present the shopping cart analysis of the customers of the technical articles wholesale. In order to describe searching process and better understand purchase decisions of b2b clients.

II. Methodology and Research Model

A. Research questions

The main research questions are:

- What are the main characteristics of the search phrase?
- How many items are returned in a single search procedure?
- What kind of users buy products using the business-to-business platform?
- Do b2b clients use during search procedure the advanced manual filtering mechanism to complete the purchase?
- What is the average size of the list returned by the query? This may describe both the ability to find the right product by the customer and product range offered by the platform.
- What is the optimal size of results list allowing to finalize the purchase? It seems that too small or big size of the results list is not conducive to adding items to the shopping cart.
- How many shopping baskets were filled by single user during the examined period?

B. Explored data

The Authors' explored log files generated by users of the online technical articles wholesale. The use case diagram of explored b2b platform is presented on Fig. 1

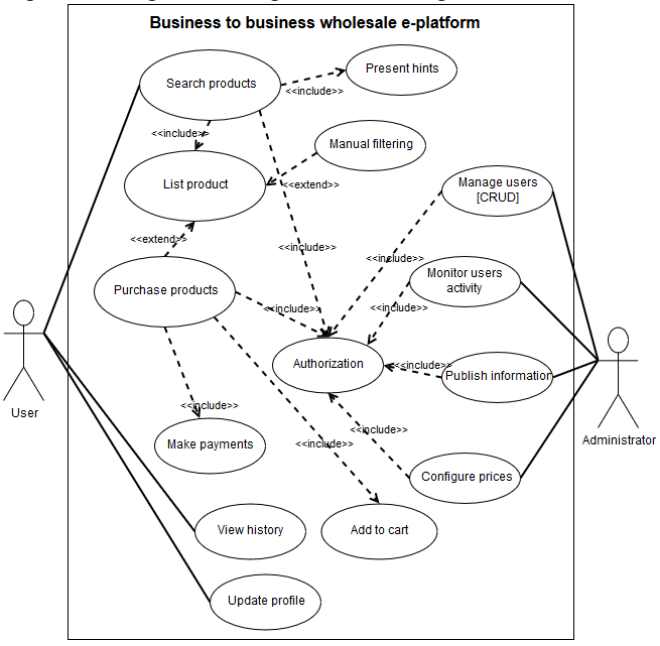

Fig. 1 The use case diagram of explored b2b platform

The explored b2b platform is technical articles wholesale. It has two groups of actors: business users and administrators. Registered business customers can use the platform to search for the products, view products characteristic, make a purchase, make a payment or view purchase history. Administrators can create and manage users' accounts, monitor users' activity, configure prices or promotions and finally add news.

The sample screens of searching mechanism of investigated b2b platform were shown on Fig. 2 and Fig. 3.

Fig. 2 Search inbox and prompt screen

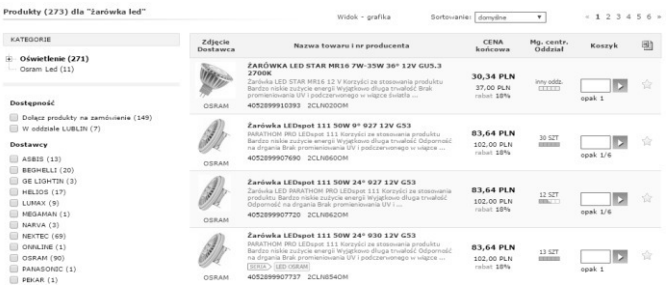

Fig. 3 Product list filters

We explored 596130 logs generated between September 1st 2015 and October 31st 2015. The logs were generated by 4824 b2b customers.

A log file collected by the platform contained information about search phrase, search date and time, customer ID, number of products found (Fig. 4).

```

Fig. 4 Part of an analyzed log file

C. Research procedure

The research procedure was presented on Fig. 5. We divided the procedure into the following stages: data collection, data selection, data completion, basket linking, quantitative data analysis and conclusions.

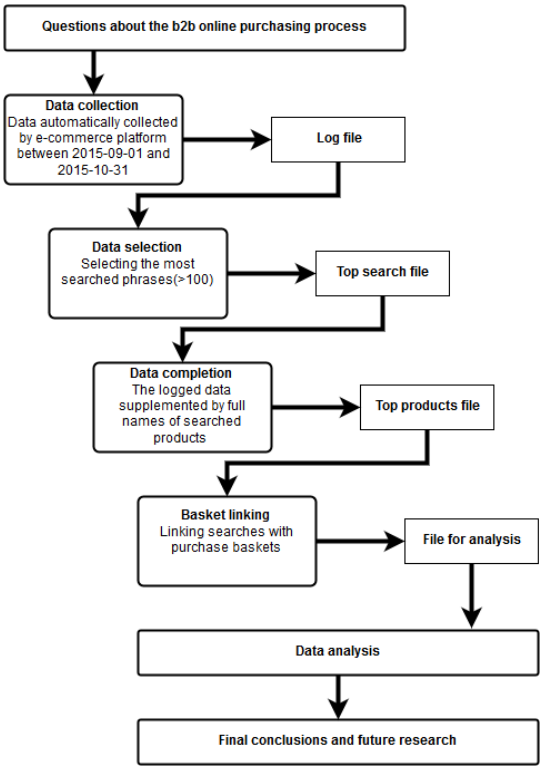

Fig. 5 The research procedure

- The mechanisms implemented on the b2b platform allowed for the collection of transaction logs without the need to turning on the debug mode.
- The automatically generated log file was limited to the most popular phrases. We selected the phrases that were searched more than 100 times in the period of two months. As the result we obtained the list of 367 the most popular phrases (Table 1).
- The list of the most popular search phrases has been supplemented with the list of full products names that were returned by searching mechanism. We used SQL command `[select product from product_list where product_name like "*searched_phrase*"]` This extension was performed only for the 367 most popular search phrases.
- Knowing the indexes of searched products we linked them with shopping basket logs stored in the system. The obtained file became the input for further quantitative analysis.

III. Data Analysis

The qualitative analysis of the incidence of search phrases showed that the most frequently occurring phrases are: pipe, pump, LED, boiler, valve, heater, sink. Mainly pure text phrases (3-11 characters) that included general name of searched object or the manufacturer name. The "word cloud" of the most popular search phrases used by b2b customers was presented on Fig. 6.

Fig. 6 The most frequent search phases (Polish spelling)

The number of products returned by search mechanism for less popular phrases (100-500 searches) is 10-100. For the more frequently used search phrases, the number of returned products is from 100 to 1000. We can say that these are the most popular group of products but also their recognition in the form of phrases, it is very inconvenient for the user. The search phrase that returns 1000 items creates about 20 result pages. Therefore to find the right product user have to use the additional filtering mechanism. In the explored case, clients used additional filtering mechanism which is reflected in a large number of baskets containing these products (Fig. 7).

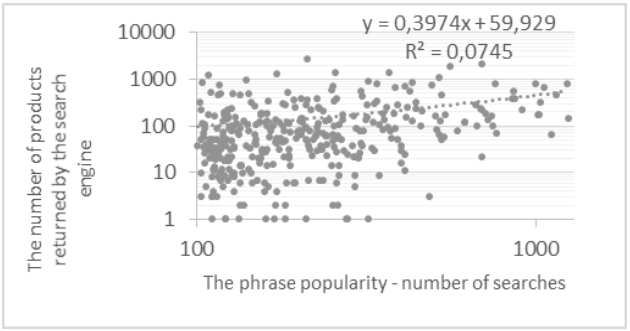

Fig. 7 Phrases popularity vs. the number of products returned by the search engine

In the second study we analyzed how the number of products in search results affected adding them into the shopping baskets. Some search processes returned a lot of products (>1000 items that is >20 pages). That should not foster adding products to the shopping carts. This seems to be problematic for the customer because there are too many items to analyze manually. However, it turned out that these common phrases were source of many purchase decisions. The most shopping carts consisted of items that were chosen from the lists of more or less 250 products (about 5 pages).

From the Fig. 8 we can conclude that the optimum number of products fostering the purchase act is from 30 to 150 items (1 to 3 pages). A larger number of results gives a minimal purchase increase till the point where we have again an increase in the number of items in a baskets. The second area of purchase increase is observed in the range from 600 to 800 returned items. However we assume that it is due to product attributes but not due to the user's convenience. We can say that this kind of inconvenience does not prevent the user from buying. Users seem to continue buying process using manual filters. The question for the future analysis is what kind of additional filtering has been applied to finalize the purchasing process? Currently, the platform does not register information about usage of manual filter.

TABLE I.
THE NUMBER OF PRODUCTS RETURNED FOR A PARTICULAR SEARCH PHRASES

Number of items	Phrase count
1-10	56
11-20	25
21-30	31
31-40	32
41-50	18
51-60	18
61-70	15
71-80	19
81-90	8
91-100	13
101-110	6
111-120	10
121-2720	7 - 1
Total	367 phrases

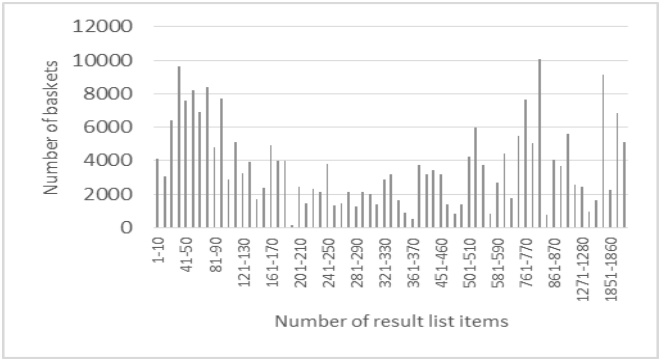

Fig. 8 The most frequent search phrases

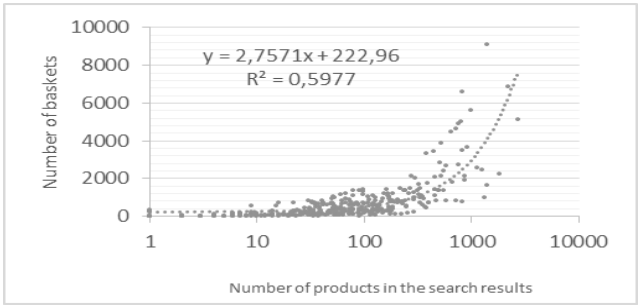

Fig. 9 Search results vs the number of baskets

In the next study we tried to find how the search results are distributed among the population of users. Fig. 10 shows that the majority of users receive less than 200 products as the search results (1-4 pages). That amount of results is possible to read and familiarize with the offer. Larger lists of products was obtained by much smaller group of users.

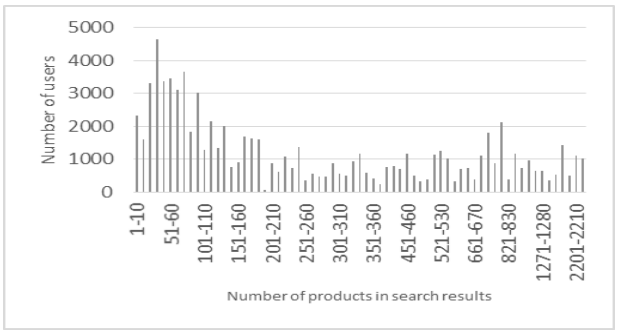

Fig. 10 The number of users obtaining a given number of products as a search results

We also examined how many baskets per customer was created using the same search phrases (Fig 11).

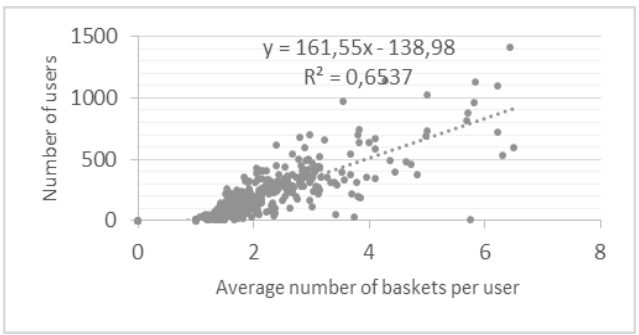

Fig. 11 The average number of baskets per user

As it was shown on Fig. 11, it turns out that during the two-month period it was only from 1 to 4 baskets. As for the b2b shopping it is not a staggering number.

IV. Conclusion

The performed research gave an answer to many questions connected with b2b clients purchasing process. However, were also the source of many new questions. The conducted analysis shows that:

- Transaction logs are source of viable information about customers' behavior and functioning of the b2b platforms. They can be used to investigate customers' purchase decisions and improve the efficiency of b2b tools.
- The examined platform users, specialists in electrics, hydraulics, ventilation used mostly short (from 3 to 11 characters, 1-3 words) text search phrases like pipe, valve, LED, pump, boiler, which as a result gave many pages of items. Thus, the effective platform should include easy-to-use tools that allow for selecting one particular item from an extensive list.
- The performed research was complicated by a set of search phrases resulting in a large number of products found. It turns out that large result lists does not stop customers from finalizing the purchase. However, we weren't able examine how business clients passed from the results list to selecting one specific item. We assume that they used additional manual filtering mechanism rather than reading page after page.
- Our analysis allowed to discover three groups of customers: buyers (few searches and a lot of items in cart), searchers (a lot of searches and few items in cart) and regular ones (few searches and few items in cart).
- The search phrase used by the customer indicates the search engine what subset of offered products should appear on the screen. The user can view presented list and decide whether to make a purchase. The search phrase belongs to customer every-day language and it is not precise. We can say that it is a client's way of naming the class of products. Frequently used short, text phrases gives from 1 to 2720 results. But the most popular phrases returns less than 120 items (3 pages) (Fig. 7, Table 1). In our opinion it is acceptable result for the next manual analysis. The question is the fit and the usefulness of returned results. The conclusion is that most of phrases returns reasonable number of product, so it shouldn't result in inconvenience of shopping and stopping the customer from buying. However we must clearly state the assumption that examined search process was performed with the intention of purchase and there were no obstacles for an effective purchase.
- Fig. 10. shows that users got mostly 1 to 4 results pages. So they were able to read and analyze presented items and finalize the purchasing process. The b2b clients used the same search

phrases only to complete from 1 to 4 shopping baskets.

- The optimal number of products in search results list allowing to finalize the purchase is from 30 to 150 items (1 to 4 pages). However the users with the score of 20 results pages also weren't discouraged from making purchases.
- Search mechanism "clouds of tags" should be reconfigured in order to return less than 200 items (1-4 pages) as a response to the commonly used search phrases.
- If search phrase gives more than 1000 items, client should be supported with additional filtering mechanism or advanced search mechanism allowing for more precise searching.
- The additional extended tests should be performed in order to determine if, in fact, a large number of products in the results discourages customers or makes it difficult to buy the right product (lack of purchases). To perform this research we should use search phrases of similar popularity that gives different number of products found.

V. Future Research

As The Gallup research indicated to build better b2b strategy the companies should combine quantitative (automatically collected) data with a qualitative "small-data" approach [1]. In the future studies we want to obtain interplay between quantitative and qualitative methods so we intend to examine small groups of b2b platform users using in-depth semi-structured interviews and focus groups to measure customers' engagement, and know better client's unique organizational culture. The interesting material for deeper analysis could be obtained also by recording (screen recording) the on-line shopping process [20]. The authors examined single b2b platform that may limit the findings generalizability so in the future research other b2b platforms should be explored to validate the results [2].

***Abstract*—Social Media has become indispensable for market penetration. It is a beneficial communication platform for understanding the customer focus. Effective use of this media for image creation, customer access, knowledge accumulation and trend analysis, creates competitive advantages. This research is designed to analyze social media strategies of global enterprises and evaluate the value of social media usage. Analytical Hierarchy Process (AHP) is used to model the performance decisions. The model is constructed based on the major evaluation criteria used by the global companies. AHP model expresses cause and effect relationships between companies and social media effects. Cases will be applied for Coca Cola, Turkish Airlines and Starbucks. Enterprise awareness and success of different evaluation criteria are benchmarked.**

***Index Terms*—Analytic Hierarchy Process, Social Networks, Strategic Planning and Management**

I. Introduction

THE Internet has been evolved from a basic tool of communications into an interactive market of products, services to global community and worldwide business transactions. Many enterprises attempt to embrace the digital revolution and using internet is now a necessity for the enterprises. As a result of the increased use of the Internet, using social media also became competitive advantage for the growing companies, they attempt to differentiate their products and services from competitors.

The past decade development and change of the usage of the Internet, it is difficult to differentiate in the global community only with one-way communications from seller to buyer thus, companies aim to interact more with their customers as well as to allow their customers to interact more with them (Winer, 2009). Since social media content has become indispensable to millions of users, it becomes wide source of big data and allows companies to reach more people at a lower costs. Social media is a great opportunity to communicate with customers for the companies, it provides to collect a big data of the users through their expectations, experiences, ideas and reactions for the product. Another benefit of social media is the quick interaction. The ability to receive quick reaction, in terms of ensuring a positive brand image is of great importance. It may take a second customers to respond a message posted on social platforms thus it helps companies to measure the pulse of the customers' ideas based on their positive or negative comments.

The objective of this study is to analyze the value of social media and social web data for businesses to differentiate in the global competition, and propose a theoretical explanation by analyzing social media strategies of the Turkish Airlines, Coca Cola and Starbucks which are global companies. This study involves main titles; firstly, importance of the social media analyzes for the enterprises' success across the globe will be studied. Secondly, Analytic Hierarchy Process method will be explained in steps, which contains explanations and the description of formulations. Thirdly, to analyze companies' awareness on social media, the main goal, criteria and alternatives for the AHP method will be obtained and explained in detail. Then, the sample using AHP method from the literature will be examined. Finally, results will be evaluated and by using AHP method an expressive cause and effect relationships between companies and social media effects are established.

II. Literature Review: Knowledge Management In Social Media Strategies

The widespread use of the social media in recent years it has become an important marketing strategy for the companies to meet directly with the customer in easiest, cheapest and fastest way. Social media helps reshape business models through opinions and emotions owing to fact that it opens up many possibilities to study human interaction and collective behavior. Many companies today are using social media to develop targeted campaigns that reach specific segments and engage their customers.

The past decade development and change of the Internet, numerous social networking sites have been drawing people together and creating new forms of communication. There are various social media forms; people write encyclopedia articles, online marketplaces recommend products via user shopping interactions; and community movements benefit from new forms of collective actions (Tang, Liu, 2010).

According to Feng and Qjan, "Facebook has about one billion users and there are about 3 million photos uploaded by users each day" (2013). LinkedIn is another example, the user can create a professional profile, establish connections to other users, and exchange messages, follow the current news. Tanbeer, Leung and Cameron stated that "social entity is connected to another entity as his or her next-of-kin, friend, collaborator, co-author, classmate, co- worker, team member, and/or business partner" (2014).

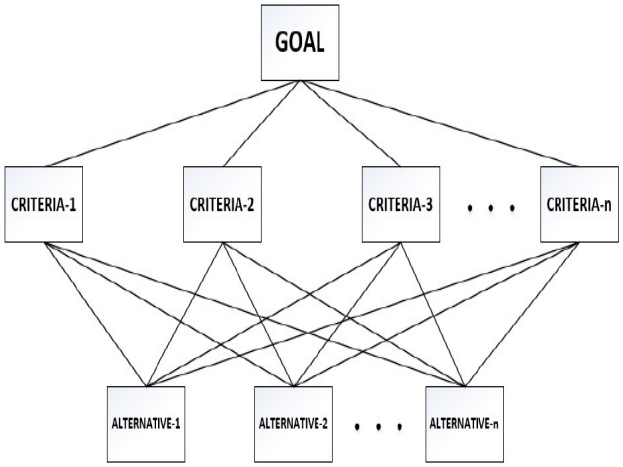

Fig 1. Hierarchical Structure of AHP

Mentioned connection might be used as a power to reach more customer. Thus the social media Websites are the ideal platforms to facilitate the products recommendation and market popularity. Social media has become wide source of big data for the companies. It is significant to analyze the social media entirely for the companies considering their target. Analyzing Social Media includes theories and methodologies from different disciplines such as computer science, data mining, machine learning, social network analysis, sociology, ethnography, statistics, optimization, and mathematics (Zafarani, Abbasi and Huan, 2014). The correct analysis of social media data is considered as the very important step of a successful marketing strategy for the growing companies.

III. Methodology Implemented: Analytic Hierarchy Process (AHP)

People make their decisions in two ways; the first is heuristic approach that develops very fast and is usually not objective. The second is the logical analysis that requires an analytical method. Analytic Hierarchy Process is a quantitative decision-making method according to multiple criteria and alternatives based on mathematics and psychology. Saaty stated that "a hierarchy is a representation of complex problem in a multilevel structure whose first level is the goal followed successively by levels of factors, criteria, sub-criteria, and so on down to bottom level of alternatives" (2006).

AHP lead the way that yield best in order to reach the goal/solve the decision problem instead of stating correct decision. The decision problem dissociated into hierarchy that contain criteria and alternatives. The hierarchy shows cause-effect relations in linear chain. After identifying the problem or stating the goal, hierarchy is created considering main decision point, middle level criteria and the lowest level of the possible alternatives (Figure 1).

Once hierarchy is built, the decision maker evaluate its elements (criteria and alternatives) by comparing their impact/effect on an element in the hierarchy between each other. In comparison, concrete data, judgments, expert opinions or survey results etc. are used as resource by decision maker in order to determine the degree of importance between elements. The importance scale table is used for comparison (Table 1).

Table I.
Importance Of Scale AHP

Definition	Degree of importance
Equally important	1
Moderately important	3
Strongly important	5
Very strongly important	7
Extremely important	9
Intermediate values between two adjacent judgments	2, 4, 6, 8

The importance or numerical weights (according to degree of importance) are obtained for each criteria and alternative in the hierarchy so that benchmarking is made in a consistent and rational way. Finally, according degree of importance numerical importance are calculated for each decision alternatives. This evaluation shows ability of alternatives to achieve the goal (attracting customer through social media).

In this study, computer software "Super Decisions" is used for calculations so mathematical formulas not stated in detail. Steps are required to be resolved in a decision-making problem with AHP are summarized as follows:

Step 1. Model the problem as a hierarchy containing the decision goal, the alternatives for reaching it, and the criteria for evaluating the alternatives.

Step 2. Establish priorities among the elements of the hierarchy by making a series of judgments based on pairwise comparisons of the elements. For example, when comparing potential purchases of commercial real estate, the investors might say that location is five times important than price and price is three times important than timing.

Step 3. Synthesize these judgments to yield a set of overall importance for the hierarchy. This would combine the investors' judgments about location, price and timing for properties A, B, C, and D into overall importance for each property.

Step 4. Check the consistency of the judgments.

Step 5. Come to a final decision based on the results of this process. (Saaty, 2008)

IV. Creating the Model

A. Determining the Goal of AHP Model

In this study, "attracting customers through social media" is chosen as main goal for the hierarchy tree.

B. Determining the Criteria of AHP Model

The criteria will be studied on three of the most common social media tools which provides companies have the opportunity to reach very large data, are chosen; LinkedIn as

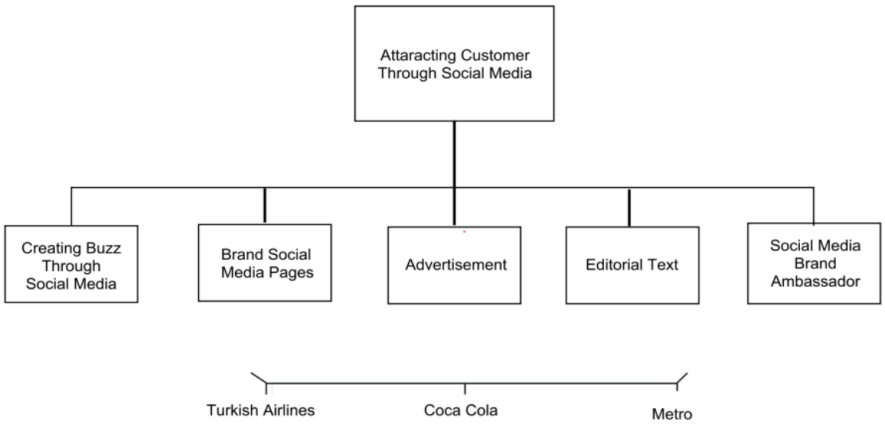

Fig 2. AHP decision tree

professional social media tool since people share their business information, resume and career histories in, Twitter as entertainment and news social media tool since people share their thoughts worldwide and Facebook as associational social media tool since it has become one of the most widely used tools for advertisement and reaching users (Drury, 2008). Determined criteria are as follows:

Brand Social Media Pages: Through social networking profiles of a brand it is possible to analyze demographics of the customers/followers, their interests, location information in order to devise new strategies.

Social Media Advertising: The most commonly adopted approach to the social media advertisement is to advertise on the social networks with the consultation of businesses, which have proved themselves with their experience on social media.

Editorial Text on Social Media: This kind of a communication will not force the customer to buy goods. It is built on arousing curiosity, giving information and offering benefits to the customer.

Social Media Brand Ambassador: Companies find the social network celebrity that suits the brand. It is of course a must for this person to have enough followers on certain networks too.

Creating Buzz Through Social Media: According to this marketing trend, volunteers found by a company convey their experience with a specific product to the people who they encounter with at any time.

C. Determining the Alternatives of AHP Model

The alternatives: three global companies are determined as follows:

Turkish Airlines: Recognized as a global brand Turkish Airlines (Turk Hava Yolları / THY) took 3rd place as one of the most active brands in social media. THY actively use social media, broadcasts in Turkish and English languages. In addition to Company has 8 million over Facebook fans and has over 1 million followers on Twitter. The profile of the brand via Facebook Turkish Airlines Euro league, Barcelona and Manchester United sponsorship or related information, campaigns and current developments can be followed.

Coca Cola: Coca Cola is actively using the Facebook and Twitter both products and campaigns. According to Social Media Principles of the social media strategy of the company is that more than 150,000 associates in more than 200 countries to join conversations take place online about Coca-Cola, represent the company, and share the optimistic and positive spirits of the brand (Coca Cola Company, 2013). Coca-Cola among the best in the world with more than 97 million members on Facebook and it has more than 170 thousand fans from Turkey. A. On Twitter also it has 93 thousand followers.

Starbucks: Starbucks has 640 thousand over Facebook fans and has over 74 thousand followers on Twitter.

After decision of the main goal, criteria, and alternatives; Hierarchical Structure of AHP is created. (Figure 2)

V. Application

A. Applying the Model on a Software

AHP/ANP software that is called Super Decisions is used in the scope of this study. Clusters and nodes are created according to Figure 2 and illustrated in Figure 3.

According to importance level that are shown in Table 1. the nodes of criteria cluster; the nodes of criteria cluster and the nodes of alternative cluster; the nodes of alternative cluster and nodes of criteria cluster are compared two by two (several importance table are shown in Appendix 1).

Companies are utilized according to usage of such social media tools:

- Professional social media tools (LinkedIn),
- Entertainment, new social media tool (Twitter),
- Associational social media tool (Facebook)

Some examples;

With respect to Coca-Cola, creating buzz trough social media is moderately more important than brand social me-

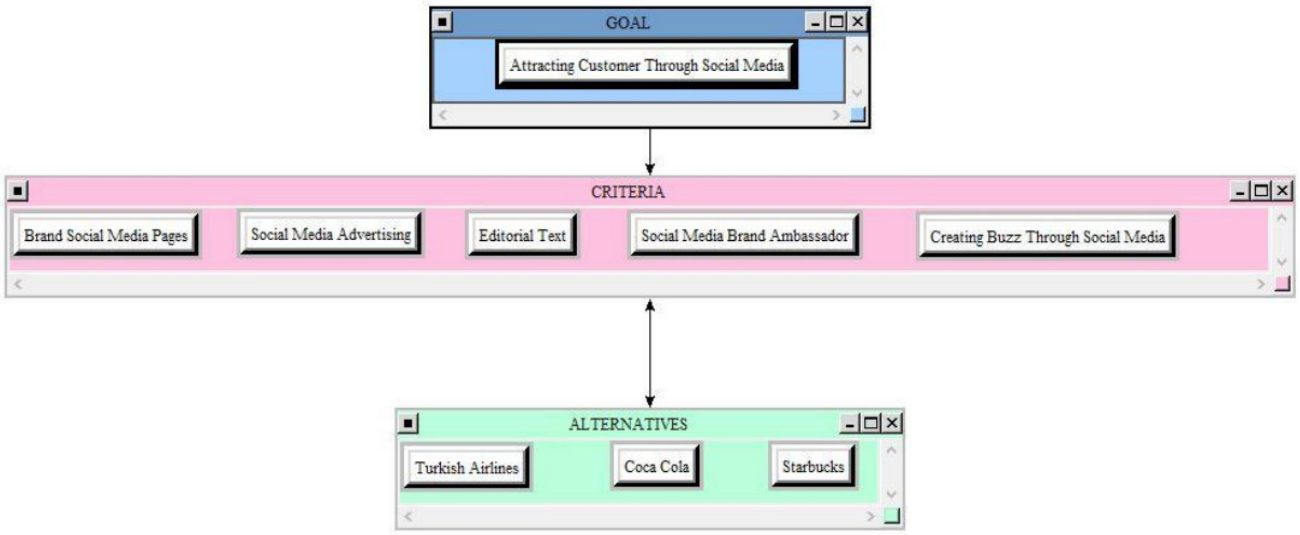

Fig 3. AHP decision tree

dia; brand social media is strongly more important than editorial text and so on.

B. *Results and Discussions*

According to our observations and reviews with alternative companies in Turkey, the importance of the each social media tools is different for each company (approximate values are shown in Table 2).

Software reports are shown in Table 2 and Table 3, accordingly.

As it seems in Table 3, in the scope of social media (LinkedIn, Facebook, Twitter), in order to attract the customer Coca Cola is using social media tool more effective than Turkish Airlines; Turkish Airlines is using social media tool more effective than Starbucks.

VI. Conclusion And Recommendations

Social media is important trend, the company has become an important marketing opportunity to meet directly with the customer. Social media allows businesses to communicate

Table II
Main structure in Super Decision report

Alternative(s) in it	• Coca-Cola • Starbucks • Turkish Airlines
Network type:	Bottom level
Formula:	`Not Applicable`
Clusters/Nodes	• **Alternatives:** ◦ **Coca-Cola:** the importance of LinkedIn %30, Facebook %40, Twitter %40 ◦ **Starbucks:** the importance of LinkedIn %25, Facebook %40, Twitter %35 ◦ **Turkish Airlines**: the importance of LinkedIn %25, Facebook %35, Twitter %40 • **Criteria:** ◦ **Brand Social Media Pages:** social networking profiles ◦ **Creating Buzz Through Social Media:** volunteers found by a company nconvey their experience with a cpecific products ◦ **Editorial Text:** giving information and offering benefits to the customer ◦ **Social Media Advertising:** advertise on the social networks with the consultation of businesses ◦ **Social Media Brend Ambassador:** social network celebrity that suits the brand • **Goal:** ACTSM as Business Success Strategy ◦ **Attracting Customer Through Social Media:** drawing customer attention via social media

TABLE III
ALTERNATIVE RANKING IN SUPER DECISIONS REPORT

Graphic	Alternatives	Total	Normal	Ideal	Ranking
	Coca Cola	0.2170	0.4340	1.0000	1
	Starbucks	0.0781	0.1562	0.3600	3
	Turkish Airlines	0.2049	0.4097	0.9440	2

with the costumers in lower costs and greater efficiency than traditional media tools (Kaplan and Haenline, 2010).Recently one of the most important issues of the businesses involved in social media is to measure the success of social media and events. Therefore, to measure the success of social media marketing, and it has become important to determine the measurement criteria to guide the social media marketing, according to information obtained.

The aim of this study was to analyze social media strategies of the global enterprises and raise enterprises awareness by understanding the value of using social media tools in order to differentiate in the global competition. For this purpose, some global company examples are named which are Turkish Airlines, Coca Cola and Starbucks then social media main criteria are determined and show how the methodology of analytic hierarchy process is executed through main criteria that enterprises are able to use.

As a result, in the scope of social media (LinkedIn, Facebook, Twitter), in order to attract the customer, Coca Cola is using social media tool more effective than Turkish Airlines; Turkish Airlines is using social media tool more effective than Starbucks.

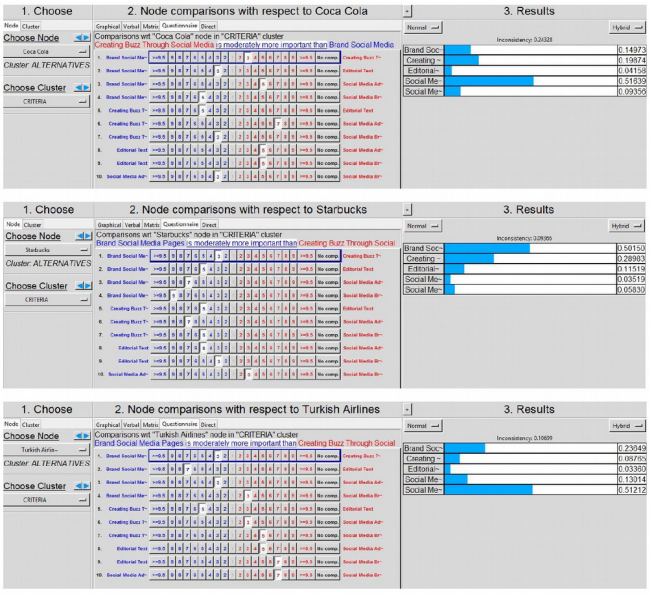
VII. APPENDIX

Some of importance comparison table are as follows.

With respect to Coca-Cola, creating buzz trough social media is moderately more important than brand social media.



2nd International Workshop on Ubiquitous Home Healthcare

POPULATION aging is a phenomenon affecting many countries around the world. For example in Europe the life expectancy increased from 45 years in the early twentieth century, to 80 years now. Significantly longer life leads to age-related problems and diseases. In parallel, the cost of hospital care is increasing and additionally, a lack of the qualified caregivers is observed. Development of ubiquitous healthcare technologies can improve the quality of life of assisted citizens and can curtail growth in healthcare spending fueled by aging populations, and the prevalence of obesity, diabetes, cancer and chronic heart and lung diseases. In particular, information systems integrated with wearable, mobile devices and sensor networks at home can continuously assist persons while moving out or staying at home. Ubiquitous healthcare systems used as assisted living solutions will not only help to prevent, detect and monitor health conditions of a person but will also support of elderly, sick and disabled people in their independent living.

The goal of the UHH 2016 workshop is to gather researchers and engineers working in the field of ubiquitous healthcare to present and discuss new ideas, methods, and applications of assisted living IT technologies.

TOPICS

The workshop welcomes all work related to ubiquitous healthcare, but with a focus on the following themes (this list is not exhaustive):

- Ubiquitous healthcare information systems,
- Information processing algorithms for UHH,
- Ubiquitous services for home and mobile applications,
- Human-system interaction in UHH,
- Wearable sensors and systems,
- Smart glasses and smart watches in UHH,
- Data mining and knowledge discovery in ubiquitous healthcare,
- Integration of sensors and devices for UHH,
- Security of ubiquitous healthcare systems,
- Ensuring the Availability, Transparency, Seamlessness, Awareness, and Trustworthiness (A.T.S.A.T.) of home and mobile systems,
- Standardization in ubiquitous home healthcare,
- Applications of UHH for elderly, sick, and disabled people,
- Elderly care monitored dosage systems,
- Welfare technology for UHH.

The proposed papers should emphasize at least one of the following aspects:

- Assisted living,
- Home care,
- Self care,
- Mobile care.

BEST PAPER AWARD

During the closing ceremony the best paper award will be presented. Selection criteria will be based on results of the reviewing process and the quality of the presentation.

EVENT CHAIRS

Abstract— **With the evolution of mobile technology, many devices are introduced with very limited screen sizes like smart glasses. This technology must be accompanied with new visualization techniques. A classic interface can't meet the expectations of the user who becomes increasingly hard to please. The challenge is to display information and allow the user a better navigation with less effort especially in situation of mobility. This paper explores a fisheye view on tiled user interfaces for smart glasses that uses the semantic relationships of items of information contained in the tiles. We propose a reformulation of the degree of interest function and a semantic model for tiled interfaces that supports this reformulation. We developed a prototype to demonstrate the feasibility of our approach and to improve our design approach in our future work.**

keywords— *smartglasses, information visualization, semantic fisheye view, degree of interest*

I. Introduction

SMART glasses are glasses with a wearable technology, including advanced electronic and IT components (embedded processor, display screen, sensors, camera ..). They allow the visualization and interaction with a large information space. Ergonomics, user-friendly interface and comfortable viewing should be made on these glasses to minimize the time and effort provided by the user during navigation. As smart glasses offer many services, it is necessary to find a display mode that convinces the user by giving him easy access to any service with more information.

The concept of tiles [1] allows the creation of a customized user interface with high flexibility [2]. In use, if we need to make changes to configure the tiles for the user, adjusting the position and size will be easily implemented according to our need. The tiles can contain the services provided by smart glasses, a service can be graphics, text or other visual data. Also, the user can point to a tile and make it active. In addition, the tiles can provide users with fast and direct access to launch the services available through the mobile device [1][2].

We consider that the concept of tiles is suitable for smart glasses. However, a large number of tiles (i.e. services) cause some problems. First of all, it is very difficult to represent all that information on very limited space like the screen of smart glasses and navigate easily. In addition, we cannot link the services together easily if we cannot see all the tiles in the same view. It is also very important to have the global view of services and bind them.

We can overcome these problems with the different techniques that address the access to large data spaces on a limited display area [3] but efficient solution is needed.

In this paper, we present a new concept for a user interface on smart glasses based on the concept of tiles and visualization techniques from a wide data space on a small screen. The rest of the paper is organized as follows. We present in the next section (section 2) the fisheye technique and a related works to our work.

In Section 3 we present our approach and applying it after to a prototype in section 4. We expose after perspectives and our future work that we consider interesting in section 5 and we will finish with section 6 that will conclude our work.

II. State of the art

A. Presentation techniques for large data spaces

There are different techniques of presentation and visualization for large data spaces. They can be categorized into two main techniques: distortion-oriented and non-distortion-oriented [3].

The technique of non-distortion can display some information with scrolling or paging to access to the rest of the information. This technique is less effective if the data space is very large, because the user can be lost during navigation.

On the other hand, distortion technique allows the user to simultaneously visualize a local part with a high level of detail, and to have a vision of the global context with less detail on the same screen. In this technique, there are different types of deformations available that differ in their transformation function [3]: polyfocal display, bifocal display, fisheye view and perspective wall.

Fisheye view technique is the technique adopted by our approach. We will focus on this technique in the following section. The strength of this technique is based on the degree of interest (DOI) that measures the interest of each element of information to present to the user. It enables to present the relevant information in detail and irrelevant information with less detail.

B. Fisheye view

The fisheye view is initially proposed by Furnas 1986 [4]. Like other distortions techniques mentioned in the previous section this technique can give a detailed view while keeping the global context. This technique is naturally useful because it is based on the importance and relevance of the information presented to the user.

This technique is inspired by the fisheye lens camera that magnifies near objects and reduces distant objects for a local view in detail and a view of the global context.

1. DOI function:

The fisheye technique uses the degree of interest (DOI) function given by:

$$DOI_{fisheye}(i|.=f_u) = API(i) - D(i,f_u) \quad (1)$$

where $DOI_{fisheye}$ is the degree of interest for a user to an element i given that the current focus element is f_u.

The degree of interest function assigns to each item i of the information a value composed of *A Priori Importance* $API(i)$ of the item i and the distance $D(i,f_u)$ between the item i and the current focus item f_u. The importance $API(i)$ is static and doesn't depend on the current focus item.

The value of the degree of interest increases with the importance and decreases with distance. We can set a threshold k and display only the information items that have a higher degree of interest than the threshold $DOI_{fisheye}(i|.=f_u) \geq k$.

This technique was extended by Sarkar and Brown 1992 [5] defining the mathematical formulas for graphics applications. They proposed four functions: the position, size, the amount of detail to display and visual worth of each vertex of a graph.

2. Emphases algorithm:

The degree of interest function of Furnas quantifies just the importance of each item of information but without detailing how to present it. It is important for the user to distinguish between the different degrees of interest visually. Emphases algorithm makes the mapping between the degree of interest attributed to an item of information and its encoding in graphics visualization variables such as size, color...

Many techniques exist in the literature. Noik [6] has distinguished 4 types:

- Implicit: an order in the placement of the items, for example. It is generally static.
- Filtered: the items that have a lower degree of interest than the threshold will be filtered.
- Distorted: this technique deforms the size, shape, and position.
- Adorned: emphasizes an item of information using other graphic variables such as color, thickness …

Many applications used the fisheye view was developed but few of these that integrates semantics. Research work related to our problem is the semantic zoom introduced in several applications such as Pad ++ [11]. It displays more details on an item of information according to the meaning.

The combination of semantic zoom and fisheye technique was introduced in some research work. Zizi and Beaudouin-Lafon (1995) [12] used the web of documents and information retrieval techniques to provide an interactive map. Van Ham and Van Wijk (2004) [13] used a clustering algorithm to represent semantical distortions for interactive visualization of small world graphs. Janecek & Pu (2002, 2005) [14] [15] developed a framework for a flight itinerary using relationships between itineraries. Our research has a similar goal of using semantic in a fisheye view with a different approach that we present in the next section for tiled user interface on a promising area application: smart glasses.

III. PROPOSED APPROACH

We propose in this section a reformulation of the degree of interest function of the fisheye proposed by Furnas[4] and transform the a priori importance $API\ (i)$ to that takes into account the current point of focus. We also propose an approach that uses this function to compute the degree of interest based on a rich semantic model that considers several concepts.

A. DOI function

The new proposed formula of the degree of interest is given by:

$$DOI_{fisheye}(i|.=f_u) = API(i,f_u) - D(i,f_u) \quad (2)$$

where $DOI_{fisheye}$ is the degree of interest for a user to an item i given that the current focus item is f_u.

Unlike the Furnas formula cited above, the API of an information item is not static. It depends of the current user item focus. In other words, the importance of an item of information i will be dynamic over the item of current focus f_u. It does not have the same importance if the user point out two different items.

The main purpose of this reformulation is to provide useful additional information under certain user focus conditions. Thus, the user could discover new items which are strongly linked to the current focus item. This formula can also increase the usability; the user will discover surprising and interesting information which will be useful for him.

We expect that users using a fisheye interface based on this formula can achieve their tasks faster than a using typical fisheye based on previous formula of Furnas.

The DOI function is typically used for hierarchical data structures, structured text, calendars. We want to apply this function to a tiled interface for our smart glasses. Through our approach, we want to access to tiles with a semantic view and meaning.

B. Semantic model

Each tile provides a service to the user; our goal is to magnify the tiles services that are semantically related when the user hovers on a given tile.

So we need to make comparisons between different services. For this we need a semantic description based on

the analysis of each service to detect what they have in common in terms of content. We can make this description based on metadata and attributes of these services, but the main challenge is to select attributes that are meaningful to the user.

In figure 1, we propose a semantic model focused on the service that defines the main concepts that allow computing our measure of semantic similarity between the different services.

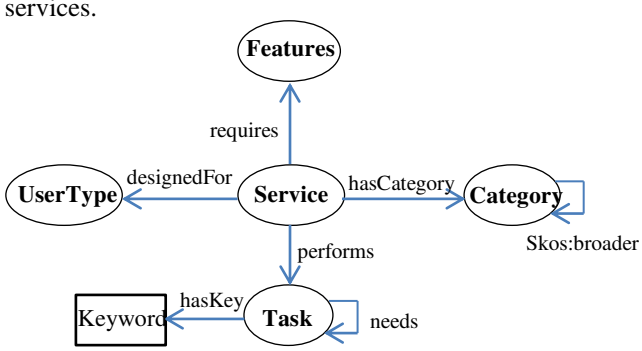

Fig. 1 Semantic service model

Our semantic model uses 4 concepts:

- Category: modeled by a tree structure, each category can have several sub categories (e.g. multimedia category can have two sub categories: audio and video).
- Task: performed by some services. A service can perform one or more tasks, so two services that have several common tasks to execute are probably similar. The goal is not just to identify similar services, but also services that are connected in some way to a service.
- User type: Two services can have the same category and perform the same tasks but are not designed for the same type of users.
- Features: A service may require authentication, internet connection and a camera to operate. Such requirement can give meaning to the proximity between the two services.

After building the model, we must define a similarity measure that quantifies a semantic relatedness with a numeric value between two services from our model. The similarity between two services can be defined by common properties. The services that have more common properties are more similar [7].

Each property has a type; it can be organized hierarchically (e.g. Category) or not organized hierarchically (e.g. Tasks) or a literal (we don't have this type in our model). Different measures of semantic proximities according to property nature are present in the literature [8].

Our calculation has to integrate different types of properties to have a single numeric value that represents the similarity between two services. We describe here the similarity measures that we have chosen for each type:

Properties hierarchically organized:

This type is based on hierarchies of properties. Wu and Palmer measure [9] uses the depth of the two properties and the depth of the least common subsummer (lcl). It's defined as:

$$sim_{Wu,Palmer}(p_1, p_2) = \frac{2\times depth(lcl(p_1,p_2))}{depth(p_1)+depth(p_2)} \quad (3)$$

Properties not hierarchically organized:

The similarity is computed with Jaccard measure [10] which takes into account the number of common properties compared to the total number of properties. It's defined as:

$$sim_{Jaccard}(p_1, p_2) = \frac{\{p_{11}\dots p_{12}\}\cap\{p_{21}\dots p_{22}\}}{\{p_{11}\dots p_{12}\}\cup\{p_{21}\dots p_{22}\}} \quad (4)$$

where $\{p_{11}\dots p_{12}\}$ and $\{p_{21}\dots p_{22}\}$ are respectively the values of the proporities p_1 and p_2.

After computing a similarity value for each property (hasCategoy, needs, performs, requires). We can make a similarity vector based on these similarities. Each component of the vector contains a similarity value of a property. We need to aggregate this vector into a single value using an aggregate function. We choose the weighted average as function on the hypothesis that the semantic concepts don't have necessarily the same importance.

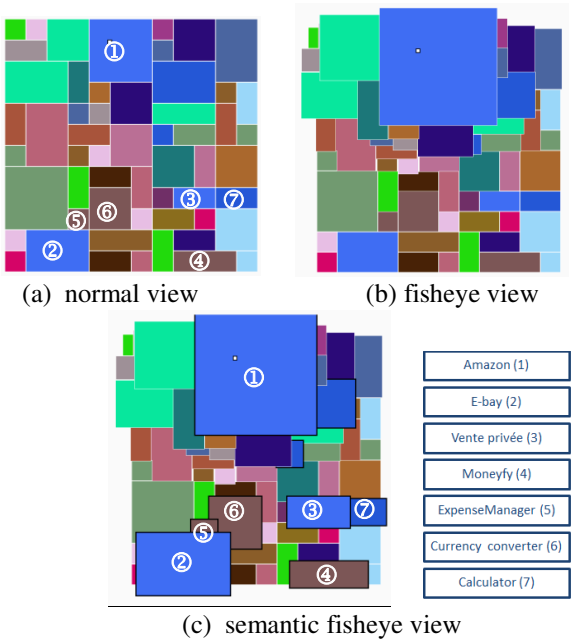
The similarity between two services S_1 and S_2 is given by:

$$Sim(S_1, S_2) = \frac{\sum_k w_k \times Sim_k(p_{S_1}, p_{S_2})}{\sum k} \quad (5)$$

where w_k is the weight of the property p for S_1 and S_2. And the DOI function becomes:

$$DOI_{fisheye}(i|. = f_u) = sim(i, f_u) - D(i, f_u) \quad (6)$$

IV. A PROTOTYPE: PROOF OF CONCEPT



(a) normal view (b) fisheye view

(c) semantic fisheye view

Fig. The proof of concept

Our prototype developed is a tiled interface on android platform for smart glasses. The semantic model is built by Protégé[1] integrating 56 services, each tile in the interface contain a service. We use Jena[2] Framework to be able to compute different similarities from the model. We consider

[1] https://jena.apache.org/
[2] http://protege.stanford.edu/

in our prototype only the category to compute similarities from the model.

Figure 2.a shows the tiled view without any fisheye view. Figure 2.b takes into account only distance to magnify tiles for a fisheye view.

The semantic model is activated in figure 2.c. The associated service to the tile (1) is Amazon. From the computation in our model, it has a similarity of $sim = 1$ with e-bay (2) and Vente-privee (3) because they belong to the same sub-category Shopping. The services: Monefy (4), ExpenseManager(5), CurrencyConverter (6) and the service: Calculator (7) belong respectively to Banking and Shopping categories whose main category is Business which is also the main category of Shopping. So they have a similarity of $sim = 0.5$ with the Amazon service.

We have taken a similarity threshold $k = 0.5$ to emphases a tile. We are aware of the need of building a good emphases algorithm that will be the subject of another work in the future. For this prototype, when the user hovers over a tile, we compute all sizes of tiles to allocate more space for important tiles on relation with the focus item. The size of a tile in the fisheye view depends on the size of the tile in the normal view, the distance from focus tile and the importance of the item that the tile contains. We notice that the tile (3) and (4) had the same size in normal view but was not magnified with the same degree because their services don't have the same similarity with Amazon services.

V. PERSPECTIVES

In this paper, we described a reformulation of the degree of interest introduced by Furnas [4] for fisheye view. The importance of an item is dynamic and depends also on the current focus item. Building a semantic model that takes into account the user context (location, time ...) and preferences to determine the degree of interest of an item is our major improvement axis that has a strong impact on the navigation of the user with smart glasses. Also, a more sophisticated aggregate function that replaces the weighted average is necessary for computing the global similarity.

In terms of visualization, fisheye view must support changes in the context and user preferences with flexibility using different emphases techniques.

We are planning an evaluation of our approach through the recruitment of users for an experiment by creating two interfaces: one with a classic fisheye view and the second with our semantic fisheye view to accomplish tasks on smart glasses and make a comparison on different criteria.

VI. CONCLUSION

Using of wearable devices like smart glasses is continually increasing. Smart glasses have a wide services area on a limited screen size. This involves viewing problems and interaction.

It becomes important to offer carefully designed interfaces that fit with small screens and overcome their limitations in order to improve the user experience. They should help users to easily navigate and understand the information presented to perform their tasks quickly and efficiently.

We aimed to address this problem by proposing a semantic fisheye view on tiled interfaces which allows enriching the user navigation using the relationships between the different services contained in the tiles.

Research on these aspects has a strong impact on the support of the mobile technology and the rise of using smart glasses.

ACKNOWLEDGMENT

This work was performed within the eGLASSES project, which is partially funded by NCBiR, FWF, SNSF, ANRand FNR under the ERA-NET CHIST-ERAII framework. The authors thank Arthur DOQUET for his help with the development part.

***Abstract*—The paper presents an alternative approach to the monitoring of the cardiovascular system. The study depicts configurations of the utilized system and preliminary results of electrical and mechanical parameters of the cardiac system which can be measured using a head-worn device.**

I. Introduction

THE continuously progressing miniaturization in modern electronics results in the creation of miniature, yet powerful devices that can be battery powered and network connected. Many of such devices are wearable. The permanently increasing computational power, characterised by a reasonable runtime and fitted with batteries, creates new possibilities.

Wearable electronic eyeglasses can be regarded as an example of such devices. In fact, the eyeglasses are a miniaturized computer that fits in the frame resembling traditional glasses. Many of such devices are available - equipped with various configurations. Most of them have a local near to eye display. These eyeglasses can be either semi-transparent or completely isolating (non-transparent). Most of these electronic glasses are equipped with a single camera for observing the front scene in relation to the person wearing the device.

A major disadvantage of the majority of the commercially available platforms is the limited potential for future expansion. In fact, most of the modifications are limited to writing new applications that will utilize the hardware available on the platform or the hardware wirelessly connected by means of Wi-Fi or Bluetooth interfaces [6], [7].

As a result of the ERA-NET-CHIST-ERA II project *The interactive eyeglasses for mobile, perceptual computing (eGlasses)* a new open platform in the form of the glasses was designed and developed [1]. It is considered as an open platform that can be extended by means of adding local hardware using various interfaces.

The eGlasses consist of a powerful computer running the Linux or Android system. Expansions might regard various aspects of the device's usage. As an example, an Infrared camera allows them to operate in the darkness or can help the user to estimate the object's temperature. The eyetracker camera enables user interface navigation in a hands-free mode [2]. Additional proximity sensors might be used for obstacle detection [3].

One type of possible platform extensions are biomedical measuring units for measuring biosignals such as ECG, EEG, EMG, and the body temperature of the person wearing such a platform [4].

This paper focuses on the measurement of the cardiovascular system. The measurement of the electrical biopotentials from the cardiac muscle (ECG) is usually measured from the contacting electrodes located on the chest - close to the cardiac muscle. A wearable platform such as eGlasses should not be large nor complicated in application. We are limit measuring electrodes location to close to the ordinary glasses frame. There exist known works related to the estimation of the cardiac potentials with ballistic data collected on the head [8].

This paper is organized as follows. In section II, the eGlasses platform is briefly discussed and an experimental set-up is proposed. Section III presents the results of measurements, and section IV outlines the conclusions.

II. Materials and Methods

A. The eGlasses platform

The eGlasses are designed to be expandable. They consist of three major boards referred to as the "base board", "side board" and "T-board". The connection between the boards is made using flat flexible connectors (FFC) and is shown in Fig. 1. The main unit is the base board. Currently, it is based on the DART4460 board from Variscite [5]. The board is based on the dual-core OMAP 4460 with 1GB RAM and internal FLASH memory (8GB). The DART 4460 module is located on the larger board where level converters, position sensors, DC-DC power sources and peripheral connectors are located. In the future, this board might be replaced by a more powerful one. There is a QUAD core board with IMX6 SoC on board in its preparatory stage. The main board is designed to be located in the right panel of the eGlasses. On the opposite side - the right panel - there is a battery holder with an additional board carrying mainly the USB hub with a USB-to-serial converter. In the front panel, in the centre, the T-shaped board carrying the front camera is located. This board additionally holds the IR camera and is used as an interconnection for signals between the base board and the side board.

The major advantage of the eGlasses platform is the amount of available IO ports. User can have several USB ports,

This work has sponsored by the ERA-NET-CHIST-ERA II project *The interactive eyeglasses for mobile, perceptual computing (eGlasses)* and partly from Gdansk University if Technology - Faculty of Electronics, Telecommunications and Informatics statue funds.

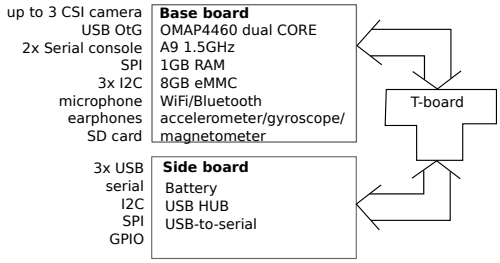

Fig. 1. Block diagram of the eGlasses platform

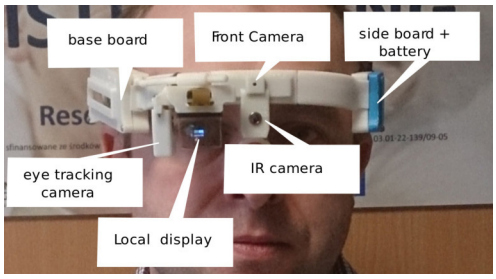

Fig. 2. The eGlasses and location of major components

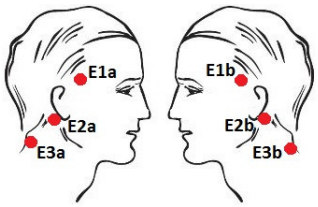

Fig. 4. ECG electrode's placement on the head

serial, SPI, I2C and USB ports for interfacing with additional extensions. The eGlasses prototype is shown in fig. 2.

B. Cardiac measurements

Self-diagnostics can play an important role in several fields of life. One of the most frequently explored types of vital systems are those related to the cardiovascular system. There is a variety of different methods for cardiac measurements. One of the simplest and cheapest techniques is an electrical cardiac potentials measurement. The ECG signal is generated by dedicated cell groups inside the heart. Outside it can be regarded as a current dipole. A conventional ECG test measures a difference of potentials between specific locations on the chest. In the case of the eGlasses we raise the question if it is possible to measure the ECG signal on the head. Therefore, we have selected an electrode location on the both sides of the face in front of the ears. In order to improve the CMRR, the ECG measurement system uses a dedicated electrode that returns the inverted common potential back to the body, i.e. the DRL (Driven Right Leg) solution is utilized. A middle point between measurements electrodes was selected as the location of the DRL electrode (Fig. 3). The ECG signal observed is characterised by a weak amplitude. In order to measure such a signal, we have designed a custom single channel ECG measurement system with five times greater gain when compared to an ordinary chest-based system.

Another signal coming out of the cardiac system is blood pulsation in vessels. A piezoelectric transducer was used to measure blood pulsation. We have used a temporal artery to access the mechanical pulsation. Moreover, the optimal position of the electrodes has been tested. We have prepared one more module, allowing simultaneous measurements of four differential signals. The first channel has been used for traditional ECG measurement, thus two electrodes were placed on the examined person's chest. The other three channels were used to measure the ECG on the head. Electrodes were placed on the temples (ECG1), behind the ears (ECG2) and on the neck (ECG3). Signals were recorded with 24-bit resolution and 250 Hz sampling rate. Each channel has been filtered with a 50 Hz notch filter in digital domain. The base line drift has been removed using a median filter (Fig. 4).

C. Experiment setup

In order to conduct the experiment, we have prepared two modules of ECG and a piezoelectric sensor (Fig. 5). The module marked as ECG1 with ordinary amplification was used for the chest as a reference module, and ECG2 with five times greater amplification was used for head measurements. We have used a piezoelectric sensor and a simple amplifier. The signals were connected to the digital storage oscilloscope and recorded on a USB stick. We have collected data from five volunteers aged 22-46 to prove the system's performance. To acquire ECG signals, standard adhesive and disposable electrodes were used.

III. Results

An experimental set-up has been created on the prototyping bread-board (Fig. 6). The ECG1 and ECG2 amplifiers were assembled on separate printed circuit boards (PCB). The piezoelectric transducer amplifier was assembled using trough hole components located directly on the bread-board. All operational amplifiers enabled the operation from a single power supply. We used a 5V DC power supply with medical class separation from the mains.

As a piezoelectric transducer we have used FT-27T-4.0A transducer with 4kHz resonant frequency, 200Ω of resonant resistance and 25nF capacitance. The unfiltered signals were

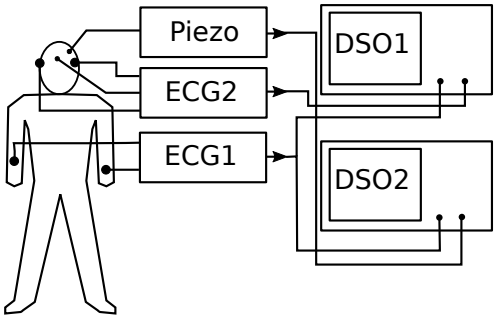

Fig. 5. Block diagram of the experiment setup

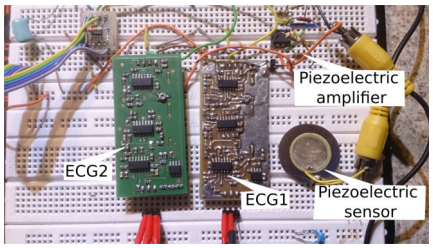

Fig. 6. ECG measurement boards

connected to two digital storage oscilloscopes (DSO), simultaneously recording data (Fig. 7). In order to synchronize the data streams, we connected output of the ECG1 signal to both instruments. It allowed us to estimate the time shift between the instruments.

Based on the raw data, one might notice a similarity between the ECG recorded using the standard procedure and the signal obtained from the head. Additionally, the data recorded from the pulsating vessel resembles arterial pulse (Fig. 8). The signals recorded reflect the standard Wiggers diagram, where atrial pressure peaks are in relation to the ECG signal. In Fig. 8, T-peaks of the electrocardiogram are coinciding with the arterial pressure peaks related to the opening of the mitral valve.

The relations between the ECG signals recorded by elec-

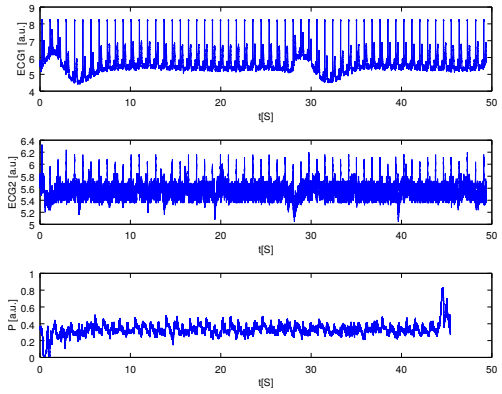

Fig. 7. Results of measurements - raw signals from the top: ECG signal from the chest, ECG signal measured on the head and piezoelectric pulse

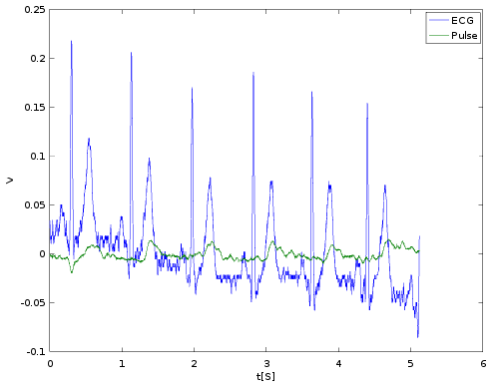

Fig. 8. Results of measurements - ECG data with recorded pulse signal measured by the piezo sensor

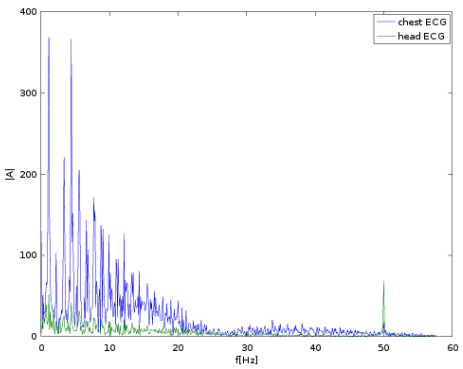

Fig. 9. Simultaneous measurements of the chest ECG with ECG recorded from the head spectrum of modulus

trodes located in different places on the body (chest and head) were examined (Fig. 11). The amplification of the head ECG is about five times greater than the chest ECG. Moreover, the recorded QRS amplitude is much smaller for the head-measured signal.

The components of both signals were examined by means of the Fourier transformation (Fig. 9). The spectrum of the signals was restricted to 60 Hz. The spectrum data showed a peak of the component at 50Hz. After filtration, the 50Hz component disappeared and simultaneously the head ECG became more ”clear” (Fig. 10). When analysing the signal from Fig. 10, QRS peaks are visible and the heart-rate can be calculated, however, the ratio of the detected QRS periods is about 10% smaller than that from the signal acquired on the chest.

Finally, the optimum position of the electrodes has been selected in order to obtain the highest amplitude of the QRS complex (Fig. 11). The amplitudes of the QRS complexes for the examined leads can be found in Tab. I.

IV. Conclusion

The measurement of the ECG signal using electrodes located on the head is possible, however, a custom design of the acquisition system should be prepared. The ECG signal

TABLE I
AVERAGE QRS COMPLEX AMPLITUDE MEASURED ON THE VARIOUS POSITION ON THE HEAD

	Chest ECG	**ECG1**	**ECG2**	**ECG3**
QRS amplitude	$650\mu V$	No QRS	$30\mu V$	$30\mu V$

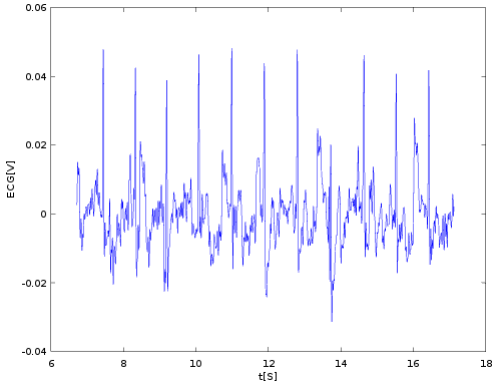

Fig. 10. Low-pass filtered ECG signal measured on the head (bandwidth 0.05-30Hz)

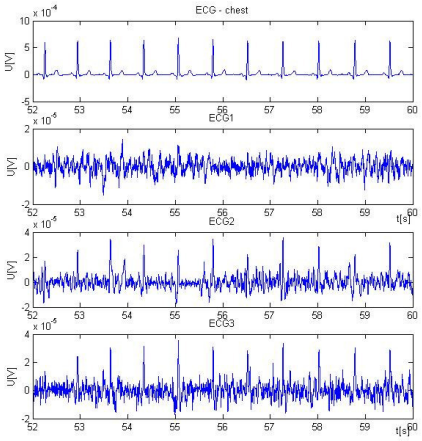

Fig. 11. ECG signals recorded on chest (upper plot) and on the head (ECG1-3)

measured on the head is nosier, but it is still possible to recognize the QRS periods and calculate the heart rate.

It is not possible to acquire the proper ECG signal from any electrode combination over the head. A detailed analysis should be performed to choose the best electrodes set-up. A preliminary study shows that it is possible to record the QRS complex using electrodes located on the neck, or behind the ears. However, the recorded signal is approximately 20 times smaller than the signal measured in a conventional way. Assuming that the ECG will be measured using the eGlasses platform, the preferable position of the electrodes is just behind the ears. In this case, the electrodes could be embedded in the earpiece of the glasses.

Additionally, it is possible to measure the blood pulsation component on the head using a temporal artery. Unfortunately, the localization of this artery on the head is difficult. In the study presented, traditional disposable and adhesive ECG electrodes were used. In the case of a wearable platform, long-term electrodes should be considered.

Abstract—In t**his paper we describe possibility of use the RSSI signal (Radio Signal Strength Indication) from Texas Instruments SensorTag CC2650 for indoor positioning purposes. This idea is not a new but in our opinion it is possible to use SensorTags with Bluetooth LE wireless interface for positioning inside buildings in such applications as people findings in hospitals, senior come care, etc. RSSI is mostly selected as the sensor localization method in the indoor circumstances. In this paper, we aim to analyze accuracy, calibrate and map RSSI to distance by doing a series of the experiments. Obtained results are very promising and shows possibility of use this technique for position estimation.**

I. Introduction

IDEA of position localization basing on wireless networks is widely known for mobile phones where using information about signal strength from BTS (Base Transceiver Station) one can determine the position of mobile phone speaker [1]. However, this is a coarse location, which is not suitable for indoors use.

Many technologies have been investigated to bridge the gap and bring positioning indoors, such as a combination of AGPS, accelerometer and magnetometer [2], Bluetooth [3], Ultrawideband [4], ZigBee [5]. Wi-Fi is one of most discussed of them, and is considered as the most promising one as the infrastructure and user equipment is already widely available, e.g. in public buildings, public area like parks, airports or railway stations, and it is able to deliver accuracies in the range of a few meters. An exemplary distribution of wireless networks in the building of the Faculty of Electronics, Telecommunications and Informatics of Gdansk University of Technology is shown in Fig. 1. One can choose the best configuration for signal strength scanning. Wi-Fi fingerprinting was pioneered in [6], and has since attracted considerable interest, mainly focused on increasing the accuracy of the technique.

But the use of Wi-Fi network access points can be limited due to different artifacts such as different sensitivity of chipsets in mobile devices [7][8]. Some efforts have also been made in the literature to reduce the effects of RSS variations due to channel impediments by using a compressive sensing (CS) principle such as in [9].

For private home position localization more suitable will be use of bluetooth devices called beacons or like e.g. Texsas Instruments BLE SensorTag CC2650 [10]. This is cheap devices for controlling environmental parameters like ambient temperature, humidity, air pressure, luxometer data and accelerometer data. A good example of implementation of the indoor positioning system is Nashvile project: Mayor, Music City Center Unveil Wayfinding App [11].

II. Material and Methods

A. Bluetooth LE

The Bluetooth 1.0 standard was introduced by SIG in 1999 [12]. The new specification of Bluetooth 4.0LE improved technology that helps everyday gadgets stay paired longer while using less power. Bluetooth 4.0 enables a new class of gadgets such as fitness trackers, medical devices, key fobs for car, beacons sensors and even home lighting controls.

B. Bluetooth and Wi-Fi possible interference

Because both Wi-Fi and Bluetooth wireless technology share 2.4GHz frequency and spectrum and will often be located in close physical proximity to one another, there is concern for how they may interfere with one another. Fig. 1. shows the Wi-Fi networks and spectrum at Faculty of Electronics, Telecommunication and Informatics GUT. Wi-Fi and Bluetooth fail gracefully in the presence of interference. By this is meant that the communication protocols are very robust and include mechanisms for error checking and correcting, as well as requesting that corrupted packets be resent. Therefore the result of increasing levels of

This work was supported by ERA-NET-CHIST-ERA II eGLASSES – The interactive eyeglasses for mobile, perceptual computing; and by European Regional Development Fund concerning the project: UDA-POIG.01.03.01-22-139/09-03 -"Home assistance for elders and disabled – DOMESTIC", Innovative Economy 2007-2013, National Cohesion Strategy

interference is almost always confined to a slowing of the data rate as more packets need to be resent.

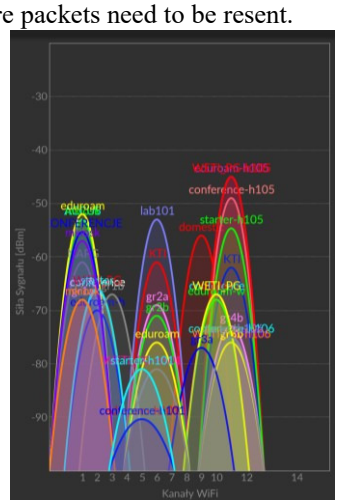

Fig. 1 Wi-Fi network spectrum measurements

C. RSSI measurements and distance calculations

Received signal strength indication (RSSI) is a measurement of the power level received by sensor. Because radio waves propagate according to the inverse-square law, distance can be approximated based on the relationship between transmitted and received signal strength (the transmission strength is a constant based on the equipment being used), as long as no other errors contribute to faulty results. Various experts have given nice theoretical ideas of the model propagation. These theoretical ideas prepares ground for starting and estimating the parameters.

$$RSSI = -10\mathrm{n} \cdot \log(d) + A\,, \qquad (1)$$

where d = distance, A = txPower at distance of 1m, n = signal propagation constant, usually in free space n = 2, but it will vary based on local geometry - for example, a wall will reduce RSSI by ~3dBm and will affect n accordingly and [RSSI] = dBm.

However, practically you need to measure RSSI value at different known and convenient distances and prepare chart. This measurements should be done in various seasons (day, night, dry, cold, rainy). These charts will provide you procedure of extrapolation or intrapolation of the distance.

D. Position estimations

Based on the coordinates of three reference nodes: ST#1(x1, y1), ST#2(x2, y2), and ST#3(x3, y3), and the corresponding distances (calculated from RSSI measured signal) from each reference node to the target node: R1, R2, and R3, we can obtain the following equations [13]:

$$\begin{aligned} (x_1 - x)^2 + (y_1 - y)^2 &= R_1^2 \\ (x_2 - x)^2 + (y_2 - y)^2 &= R_2^2\,, \\ (x_3 - x)^2 + (y_3 - y)^2 &= R_3^2 \end{aligned} \qquad (2)$$

where (x, y) denotes the (unknown) coordinates of the target **P**.

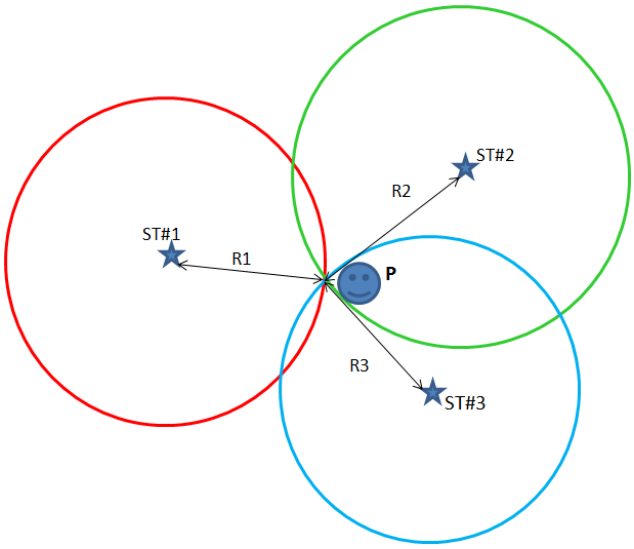

Fig. 2 Position estimation basing on three distances from SensorTags ST#1. ST#2, ST#3

III. EXPERIMENTS AND RESULTS

We perform several experiments in different configurations. Two of them are shown in Fig. 3. Firs case is called direct view because SensorTags array was in direct view with receiving smartphone without any obstacles, the second one was called with wall obstacle because the sensor array was hidden behind the wall's corner.

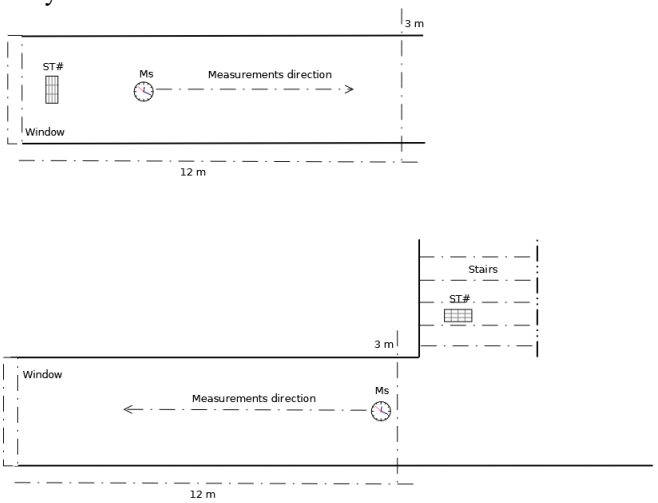

Fig. 3 Configuration of measurements procedure of RSSI (CC2650); a) direct view, b) with wall obstacle

Measurements was done using the written application (Fig. 8) - equipment: smartphone: One Plus One, Android 5.1.1, API 22 TI Sensor Tag CC2650. For fixed distance (range: 0.1m up to 6m) it was read RSSI value for the three devices that radiate towards the receiver (n=10 readings for each device). Results for both configuration are shown in Fig. 4 and Fig. 5.

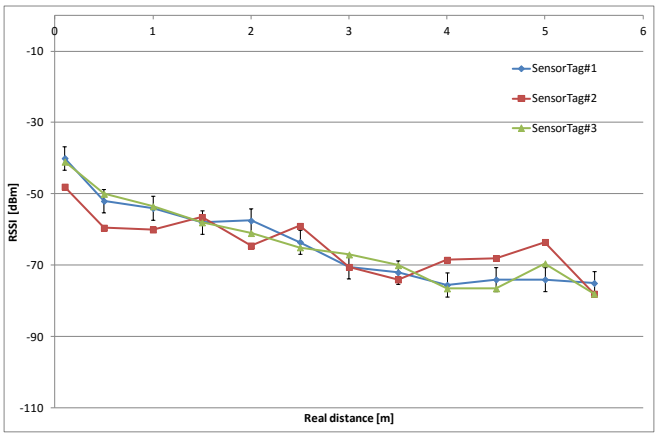

Fig. 4 RSSI vs distance measurements for three TI CC2650 SensorTags - direct view

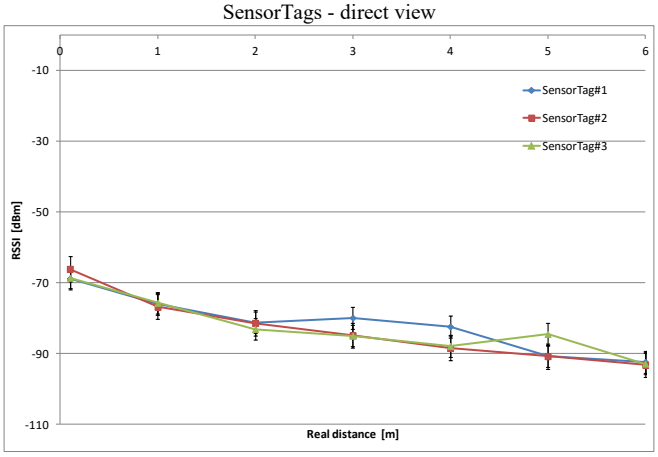

Fig. 5 RSSI vs distance measurements for three TI CC2650 SensorTags with wall obstacle

Basing on obtained readings the mean values and standard deviation values were calculated and plotted (RSSI vs "known" distance) on the charts - Table I. Next the data were fitted to polynomial model according to equation (3).

$$RSSI = \mathrm{A} \cdot d^2 + B \cdot d + C\,, \qquad (3)$$

where: A, B, C - parameters, d - distance.

It seems to be the best way to calibrate the system according to flat/home configurations such as walls, furniture and other obstacles. Example of fitted curve for measured data for SensorTag#3 in direct view experiment is shown in Fig.6.

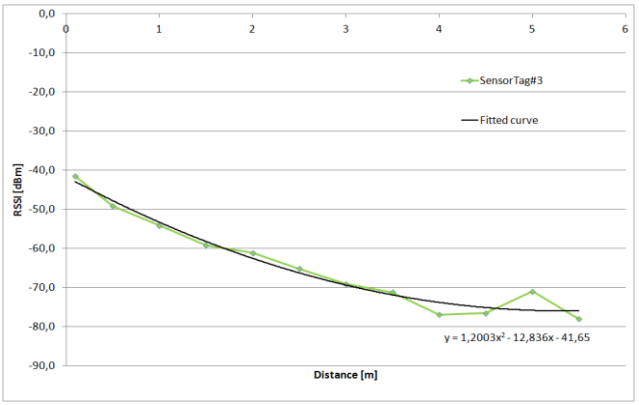

Fig. 6 Dependency between distance and RSSI. The continuous line represents the linear regression model. Dots are mean value of 10 measurements for each distance

IV. Application

Possible scenarios for the use of the proposed method include: a hospitals, nursing homes, senior homes but also museums, airports or train stations.

One example [14] is shown in Fig. 7. and Fig. 8. Inside the senior's flat one can place TI CC2650 sensors for remote monitoring of the environmental conditions (ambient temperature, humidity, luminance). Added value of such Bluetooth LE (BLE) system is possibility of indoor target localization. Dedicated application (Fig. 8) with possibility of import flat schema and localization of sensor allows for calibration measurements of RSSI signal. Basing on this procedure it is possible to track target among short distances.

As there is no fixed standard which manufacturers are required to follow, signal strength indications are to be used for indication only and do not indicate the true absolute signal strength received. These values are reported by a piece of software which allows the operating system to use the wireless card – i.e. the drivers. These drivers feature the role of controlling and reporting the status of the card, and

4.5	-73.0	-74	-68	-76.5	-70.4	-76.5	4.2	6.5	6.2	9.05	3.49	13.12	3.84	4.36	6.89
5	-73.6	-74	-63.5	-69.5	-65.4	-71.0	5.7	4.5	4.0	9.63	2.03	7.43	4.03	2.73	3.31
5.5	-76.0	-75	-78	-78	-77.2	-78.0	5.2	3.6	4.8	12.30	6.99	15.22	6.20	6.99	6.99

therefore the strengths reported by the card are highly dependent on the mapping which is established between hardware analog to digital converse values and RSSI values reported by the driver.

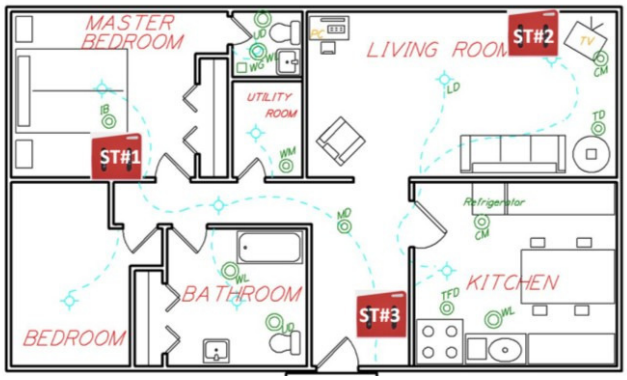

Fig. 7 Example of possible implementation in home environment for three TI CC2650 SensorTags

Different device design and usage by end users could also lead to different signal levels due to human influences. Furthermore, differences in the environment from interfering access points and devices, as well as human traffic and changes in furniture layout will cause different RSSIs to be received in the same location.

Fig. 8 GUI of mobile application for BLE indoor positioning

Disadvantages of the method:

- acceptable minimum version of Android is 4.2 (API 19)
- CC2560 - lack of continuous operation mode,
- very unstable RSSI readings.

V. Conclusion

It was argued that there are many factors which can affect the RSSI returned by a BLE devices, including the antenna design, hardware design, drivers and the environment. Given the large number of factors governing the received RSSI, calibration is unlikely to be able to compensate for all of them, leading us to conclude that there is an inherent limit to the accuracy of a BLE positioning system especially when multiple devices are used.

Small scale signal variations (e.g. multipath) may greatly affect the RSS measurement. Variations of up to 30-40dB have been reported [15]. We have measured at least 2-6dB variations in indoor deployments of low power Bluetooth LE networks. Therefore, we would suggest that instead of using a single RSSI measurement to estimate distance, try using the average or median value of N measurements collected on the same spot (at least N>20) so that you can reduce the effect of small scale fading. Then you can use the log-distance model with more accuracy. If you have more measurements, extract the basic characteristics of the propagation environment first (like path loss exponent etc), to achieve better results. Another interesting issue is the question of the deployment of BLE tag's in the home environment for optimal readings and determination of the position.

Abstract – **A technique for the acquisition of an increased number of pupil positions, using a combined sensor consisting of a low-rate camera and a high-rate optical sensor, is presented in this paper. The additional data are provided by the optical movement-detection sensor mounted in close proximity to the eyeball. This proposed solution enables a significant increase in the number of registered fixation points and saccades and can be used in wearable electronics applications where low consumption of resources is required. The results of the experiments conducted here show that the proposed sensor system gives comparable results to those acquired from a high-speed camera and can also be used in the reduction of artefacts in the output signal.**

I. Introduction

THE rapid development of wearable electronics has meant that this technology is ever-present in everyday life; the number of such applications and solutions for human-machine interactions is constantly increasing. However, the miniaturization of these devices and the growing array of functionalities require the development of new interfaces. For many applications, for example septic-type interactions [1], the eye-tracking interface is a very convenient option. With just a glance from the user, it is possible to execute commands. This technology has many possible applications [2, 3]; however, it is still under continuous study [4, 5]. In addition, research to enhance video-based gaze tracking is needed to increase both the quality and the amount of data acquired by the system [6] as well as to increase the speed of real-time processing [7].

Since modern wearable electronics like smart glasses are multitasking devices, the design of interfaces within the constraints of the processor unit's computational power is a challenge. In modern eye-tracking interfaces, the camera frame rate is a factor that can increase the potential number of applications of the interface. With the advanced image processing required for reliable estimation of eye and gaze position, the eye-tracking interface is the device which consumes the majority of the power resources. In addition, a need for high computational power and the excessive power consumption are difficult requirements to fulfil.

In gaze-tracking interfaces, it is important to achieve a correct image acquisition, an accurate calculation of the fixation point and the appropriate processing of these data. In practical applications, the time required by the CPU/GPU to process the data is significant [8] and the reduction of this time results in lower consumption of power, which is also important when considering the design of a battery charging circuit. It should be emphasized that studies which have presented new integrated circuits (ICs) have achieved effective results with software and hardware data processing, but these ICs are not in widespread use [9].

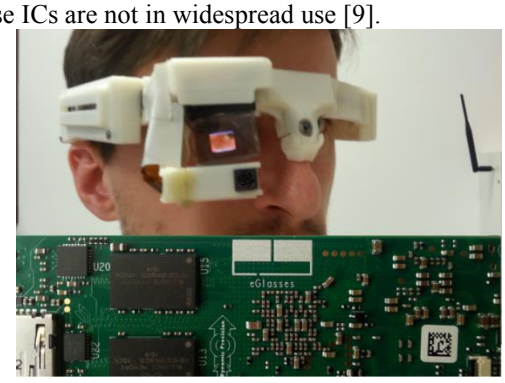

Fig. 1 Prototype of the eGlasses platform

The eGlasses (Fig. 1) electronic eyewear is a multisensory platform capable of running on both Linux and Android operating systems. The eye-tracking module is one of the eGlasses input interfaces. It allows operation by graphic user interface, controlled by gaze, and also provides data that can be used in interaction with everyday objects. The core elements of the eye-tracking module hardware are infrared LED-based eye surface lights, the camera that registers eye movements (eye camera) and the camera that registers the scene images (scene camera). In the current prototype, the eye-tracking module allows a 30 Hz sampling frequency at a resolution of 320x240 pixels. This sampling rate significantly decreases for higher resolutions (e.g., it is only 15 Hz for an image of 640x480 pixels resolution). The

This work has been partially supported by NCBiR, FWF, SNSF, ANR and FNR in the framework of the ERA-NET CHIST-ERA II, Project eGLASSES – The interactive eyeglasses for mobile, perceptual computing and by statutory funds from the Faculty of Electronics, Telecommunications and Informatics Faculty, Gdansk University of Technology.

use of an optical sensor with low power consumption allows a high frame rate to be maintained, while preserving a high resolution in the eye-tracking camera. This study presents a technique for increasing the eye-tracker sampling frequency by combining the low-rate camera with the additional optical sensor. So far such an idea has been used mostly in non-wearable electronic equipment to minimize errors caused by head rotation [10].

The rest of the paper is organized as follows: Section 2 describes the methods, experimental stand and algorithm. The experimental set-up and results are presented in Section 3. Section 4 contains a discussion and potential applications for this new concept. Section 5 presents the conclusion.

II. Methods and Materials

The underlying concept of this research was to use an eye-tracking camera and an additional simple optical sensor to increase the number of registered pupil positions. The principle of operation of the additional sensor was based on measurements of eyeball displacements. To evaluate this idea, a custom-built eye-tracker allowing measurement of pupil movements with a 180 Hz sampling rate was utilized. The optical sensor was then added to complement the eye-tracker. An appropriate test stand was built to conduct the experiments in a controlled environment.

A. Experimental Stand and Data

The experimental hardware equipment consisted of the three main components: the eye-tracking camera, the optical motion sensor, and a model of an eyeball made of plastic. The model was of spherical shape and contained an artificial pupil (Fig. 2).

The stand was equipped with two bearing servomotors (HD3688MG) and the frame was constructed using 3D printer technology. The construction had two degrees of freedom: horizontal (x) and vertical (y). The servomotors were controlled by a PWM signal from the microprocessor. This approach allowed independent movement in both the x- and y-directions.

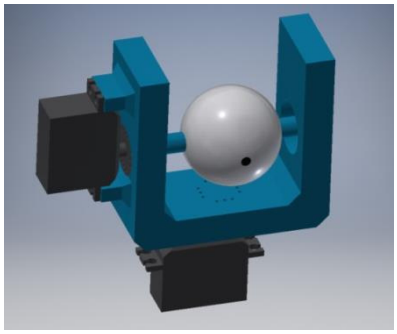

Fig. 2 The 3D frame (Fr) with the eyeball model controlled by servomotors (Sv)

The servomotors allowed the eyeball position to be changed up to 25 times per second. With this frequency it was possible to simulate saccades that lasted 40 ms. Healthy eye movements were therefore able to be simulated [11]. The camera captured the pupil position with a frequency of 180 Hz. The basic parameters of the eye-tracker are presented in Table 1.

Table I
Basic parameters of the eye tracker used

Parameter	Value
Eye-tracking technique:	Dark Pupil, Pupil Centre Detection
Eye-tracking:	Monocular (left eye)
Data rate:	180 Hz
Accuracy:	0.7°
Precision:	0.5°
Light condition restrictions:	No
Eye-tracking camera resolution:	320x240 px

The eye camera was connected to a PC computer with the eye-tracking software installed and running on Linux OS. The main classes of the eye-tracking software covered eye and scene camera image acquisition, pupil-detection algorithms, video for Linux camera support, gstreamer and opencv camera support and fixation and gaze-tracking algorithms. The eye-tracking software offered three algorithms for pupil centre detection; this study was conducted using the most accurate one, based on the selection of pupil boundary candidate points and ellipse fitting.

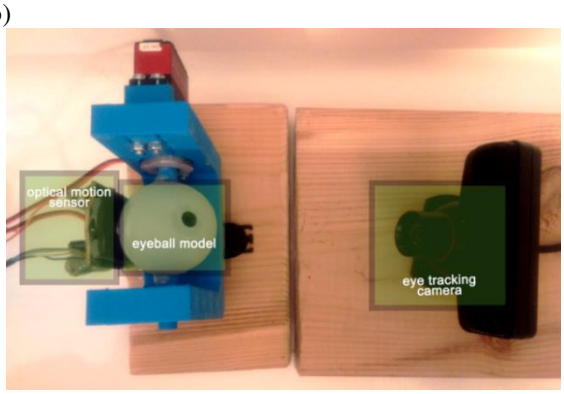

Fig. 3 Configurations of a) the experimental stand and b) its implementation

To track the eyeball motion, the PAN3101, a low cost CMOS optical sensor integrated with DSP, was used. The

DSP serves as an engine for the estimation of non-mechanical motion. The optical navigation technology used in this optical sensor enabled investigators to measure changes in position by optically acquiring sequential surface images (frames) and mathematically determining the direction and magnitude of movement. The current x and y movements can be read from the registers via a serial port. The sensor required additional optics. The one used in this research (HDNS-2100) allowed application of the sensor at a distance of 7.5 mm from the eyeball model. In fact, this is currently a primary impediment to *in vivo* use of this sensor. However, it appears to be possible to increase the distance between the optical sensor and the eyeball, although this would require some changes to the angle between the mirrors and the focal length of the lens. The IR LED diode power should also be adjusted in accordance with safety limits [12]. During experiments, the sampling rate of the sensor was set to 125 Hz. The optical sensor was connected to the additional PC unit. All data acquired by the sensors were transferred using the UDP protocol to the external server for further integration and processing.

There were certain discrepancies in the parameters measured by each sensor. The camera was used to acquire pupil positions frame by frame in an absolute coordinate system, while the optical sensor measured the total eyeball movement (total shift between the last two frames). The shift was the sum of the movement before and after camera sampling, so the value of this shift had to be split proportionally between the frames (Fig. 4).

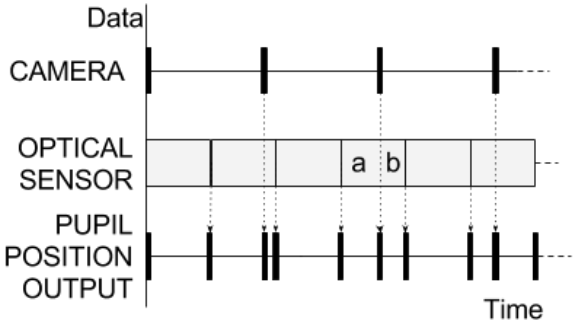

Fig. 4 Output pupil positions and incoming data from both sensors: at a point (the eye camera) and proportional to a shift in time (the optical sensor)

B. Data Acquisition and Fusion Algorithm

The concept underlying of this project was to insert a high frequency signal into a low frequency one (Fig. 5). The algorithm developed for this comprised two major parts. The first was a calibration procedure, while the second was devoted to calculating the additional pupil positions from data registered by the optical sensor, with reference to those captured by the camera. A description of the algorithm is as follows:

1. Start, set the first pupil position from the camera and reset the shift register in the optical sensor (timestamp = 0).
2. Get data from the optical sensor (timestamp, x and y movement).
3. Calculate a new pupil position by adding to the previous pupil position the scaled shift obtained from the optical sensor.
4. Repeat points 2-3 until new data from the eye-tracker is ready.
5. Get data from the eye camera (pupil position and timestamp t_1) and update to a new fixation point.
6. Get data from the optical sensor and split information proportionally to time before and after timestamp t_1.
7. Calculate a new pupil position based on data after t_1.
8. Go to point 2.

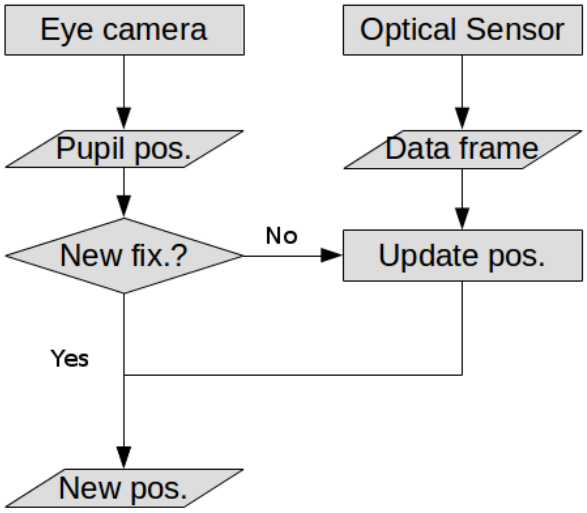

Fig. 5 Block diagram of the proposed algorithm

C. Experiments

To evaluate the concept of extending a set of pupil positions recorded by the eye tracking camera using data acquired by the optical sensor, several experiments were conducted. In the first experiment, a set of pupil positions were recorded over a certain period by both the reference eye-tracking camera (180 Hz sampling rate) and the optical sensor (125 Hz sampling rate). This was done in order to check the similarities of the paths recorded by the sensors. Pearson correlation coefficients were calculated separately for the x and y coordinates:

$$corr_x = \frac{\sum_i (px_i - p\bar{x})(mx_i - m\bar{x})}{\sqrt{\sum_i (px_i - p\bar{x})^2}\sqrt{\sum_i (mx_i - m\bar{x})^2}}, \quad (1)$$

$$corr_y = \frac{\sum_i (py_i - p\bar{y})(my_i - m\bar{y})}{\sqrt{\sum_i (py_i - p\bar{y})^2}\sqrt{\sum_i (my_i - m\bar{y})^2}}, \quad (2)$$

where px_i, py_i are the x and y coordinates of a pupil position, mx_i, my_i are the x and y coordinates of the sample registered by the optical motion sensor, $p\bar{x}$, $p\bar{y}$ are the average values of pupil position samples along the x- and y-axes, and $m\bar{x}$, $m\bar{y}$ are average values of eyeball positions along the x- and y-axes, registered by the optical motion sensor.

Following this, a set of experiments exploring different patterns of movement were performed. Square-shaped

movements (Fig. 7) were used to calculate the proper constant ratio between the measurements from both sensors. A set of pupil positions from the camera was recalculated by using perspective transformation to compensate for the viewing angle. After calibration, various sequences of the eyeball movement were tested (ellipse, triangle and random) with a fixation duration of between 140 and 530 ms. Each session lasted for ten repeated sequences, and the measurements were stored with a synchronized timestamp.

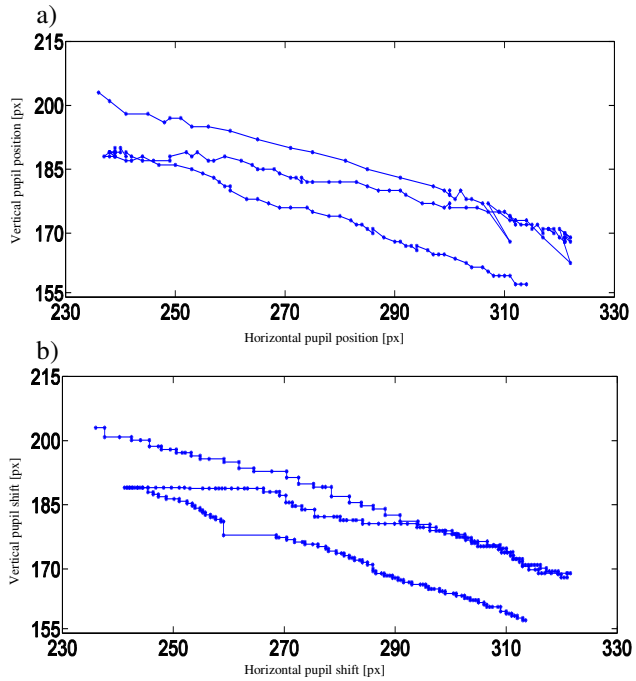

Fig. 6 Similarities between the eyeball movement recorded by the camera and optical sensor: a) The plot of consecutive pupil centre positions detected by the eye tracker b) The plot of the eyeball motion (x, y) coordinates detected by the optical sensor

The sampling rates remained the same; 180 Hz for the camera and 125 Hz for the optical sensor. Next, the original 180 Hz raw data were reduced to simulate recording with 5, 10, 30 and 60 Hz sampling rates. This allowed the creation of a set of data that could be extended by the optical sensor readings and which fully corresponded to the reference data. The results were compared to both: the high-speed 180Hz camera reference as well as the theoretical, programmed ideal eyeball movement. The signals from the optical sensor, the camera and the new combined set had different lengths, and all data were therefore resampled to 1ms using interpolation. The similarity between signals was checked by calculating the mean square error:

$$MSE_x = \frac{1}{n}\sum_{i=1}^{n}(\hat{X}_i - X_i)^2 \,, \quad (3)$$

$$MSE_y = \frac{1}{n}\sum_{i=1}^{n}(\hat{Y}_i - Y_i)^2 \,, \quad (4)$$

where n is number of samples, $\hat{X}_i$and $\hat{Y}_i$ are signal pupil positions in the horizontal and vertical dimensions, and X_i and Y_i are pupil positions from the reference signal (ideal movement or high speed camera).

III. Results

The similarities between the pupil positions recorded by the camera and the eyeball movement acquired by the optical sensor are presented in Fig. 6. The calculated correlation between waveforms recorded by the eye camera at 180 Hz and the optical sensor at 125 Hz were strongly positive:

$$corr_x = 0.91$$

$$corr_y = 0.89$$

In the next experiment, data square movement was implemented to calculate the ratio between sensors. The results are presented in Fig. 7 and numerical values are given in Table 2.

Following this, experiments were performed to check for dependencies between the information gain and the signal variability. The eyeball motion was programmed for fixation duration of 140 ms and data from 30, 10 and 5 Hz camera frequencies were enhanced by the optical sensor. The calculated pupil positions were compared to both reference signals: the high-speed camera and the theoretical route. For greater clarity, the results are presented in Figs. 8-10 and in Table 3. The axes of the coordinate system are pixels (except for the optical sensor figure) and the values plotted are the centred pupil positions.

Shape 5 Hz - ideal move	30.71	113.25	9.00	20.57

IV. DISCUSSION

These experiments confirmed the assumption that data captured with the eye-tracking camera can be expanded using additional samples gathered by a faster optical sensor.

Some older studies state that the minimum sampling frequency to record saccades should be 300 Hz [13], but newer research shows that a 50-60 Hz sampling rate is sufficient [14]. The additional data acquired from the optical sensor (which can be set up to 3 kHz) should be sufficient for measurement of both fixations and saccades. The system developed here can be used in applications where a low computing time is required, e.g., in systems containing many peripherals that involve computational complexity [15].

Analytical study of the data obtained by means of the dual sensor system gives the expected results. The eyeball movement direction changed 9 times per second. When the camera sampling rate was three times larger than the signal variability, there was no new information gain after combining the data. When the signal fluctuates fast enough when compared to the camera sampling rate, the information gain increases. This can be used to find the optimal usage of computational resources with an acceptable quality of eye tracking in any mobile device.

The additional value of this system emerges from the first and last experiments conducted (Fig. 6 and Fig. 11). In these recordings, the camera eye-tracking algorithm shows small fluctuations or artefacts. In contrast, the optical sensor during the same timestamp shows no distortions. This feature can be used as redundancy and may result in increased reliability of the system.

V. CONCLUSIONS

The study performed here shows that it is possible to extend the number of pupil positions captured by the camera based on data provided by a much faster optical sensor. A high level of similarity between the expanded and reference datasets proves that the proposed algorithm is correct and reliable. The algorithm developed here may influence the implementation of the eye-tracing procedures utilised in wearable electronic devices such as smart glasses. The possibility of extending the number of pupil positions using the optical sensor allows for a significant reduction in the eye-tracking camera sampling rate, and thus enables reduction of the required computational power and power consumption.

***Abstract*—Newly developed mHealth tools need to be tested in standardized conditions without possible patient harm before implementation. One possible approach to secure these two conditions is to analyze the mHealth tool in a medical simulation center. Medical simulation centers create realistic routine or emergency scenarios with the aid of computer-operated mannequins. Medical simulation is widely established, especially in emergency medicine, because it combines theoretical knowledge and practical skills. To evaluate a mHealth concept in the field of prehospital emergency medicine in a medical simulation center, distinctive scenarios should be used. The mHealth concept in this study was a mobile, high definition, real-time video connection between the emergency site and a remote medical expert. Since all participants in this study confirmed that the chosen scenarios were realistic and relevant, a medical simulation center appears to be a suitable model for testing mHealth concepts in prehospital emergency medicine.**

I. Introduction

NEWLY developed mHealth tools need to be tested in standardized conditions without possible patient harm before implementation. One possible approach to secure these two conditions is to analyze the mHealth tool in a medical simulation center.

As AMMENWERTH and co-workers have explained [1], there are three ways of testing a new health information technology. The first way is to evaluate it in a laboratory, but the results are limited by a low external validity. The second way is a field evaluation test, but for this, both software and hardware have to be sufficiently mature to not possibly harm any person. So the solution is often the third way: a study in a medical simulation center, which combines good internal and external validity [1]. Usability studies in medical simulation centers are ideal for objective, structured analysis of new technical devices [2].

The present article has been structured in the context of the LiveCity ("Live Video-to-Video Supporting Interactive City Infrastructure") European Research Project and has been supported by the Commission of the European Communities - DG CONNECT (FP7-ICT-PSP, Grant Agreement No.297291).

Simulations in general provide the facility to evaluate complex systems and the interaction of the different variables [3], [4]. MHealth concepts in emergency scenarios can be tested in computer generated simulation or in medical simulation centers. It could be shown that the former, for instance in the form of virtual reality, is a successful way of analyzing for instance fire emergencies [5]. This paper aims to analyze how the latter can be used to test mHealth concepts. In medical simulation centers (study) participants encounter realistic routine or emergency scenarios, which are created with the aid of computer-operated mannequins [6]. These scenarios are based on predefined, structured protocols, but are adapted dynamically, depending on the action of the participants. Thus, the participants see and feel the consequences of their individual actions [7]. Because medical simulation combines theoretical knowledge and practical skills, it is widely established, especially in emergency medicine [8], [9], [10]. It is frequently and successfully used in training at all stages of medical education and in research [11], [12]. It can be used for both individual settings and group settings and offers the opportunity to standardize while minimizing negative consequences of potential errors [9], [13].

Simulation studies offer the opportunity to conduct experimental cross-over trials with high internal validity. The external validity depends on how realistic the simulated scenarios are. The perception of how realistic a scenario in a simulation centre is, is influenced by three different aspects: the equipment fidelity, the environment fidelity and the psychological fidelity [14]. The equipment fidelity is characterized by the used hardware and software. The environment fidelity is mostly created by the appropriate surrounding for every scenario. Psychological fidelity is the ability of the individual participant to immerse into the simulated situation. Psychological fidelity can be increased by enhancing equipment and environment fidelity [15].

To evaluate a mHealth concept in the field of prehospital emergency medicine in a medical simulation center, distinctive scenarios should be used. Hence, it is important to generate scenarios of emergencies, which occur often and in

which an early start of the right therapy has a huge impact on morbidity and mortality. Three paramount examples are stroke, myocardial infarction and trauma. These emergencies belong to the "First Hour Quintet", termed by the European Resuscitation Council. It describes five emergencies, which are life-threatening diseases, which require fast treatment [16], [17]. Stroke, myocardial infarction and trauma are also among the main causes of death in Europe [18]. Worldwide, they belonged to the group of top 10 leading causes of death in 2004 and prognosis for 2030 predicts them to be within the top 5 leading causes of death worldwide [19]. Thus, there are many approaches to improve the therapy of these emergencies; among them the application of mHealth. It could be shown, that mHealth for stroke in prehospital emergency medicine is feasible and beneficial [20].

To reflect the broad spectrum of emergencies, it is also important to include emergencies, which are especially challenging. Examples for those emergencies could be rare diseases and difficulties during pregnancy. The treatment of rare diseases often lacks standard operating procedures. Additionally, the emergency personnel might not have encountered a similar situation before, which increases the stress level. The complexity of difficulties during pregnancy is caused by the fact that the unborn child has to be considered, too. For instance, there are only a limited number of pharmaceuticals, for which it could be proven, that they can be administered during pregnancy without teratogenic or negative long-term effects for the unborn child [21]. Additionally, pregnancy changes many physiological parameters in women, which have to be kept in mind.

II. MATERIAL AND METHODS

To test the hypothesis, that medical simulation centers are ideal for testing mHealth concepts in prehospital emergency medicine, ten typical emergency scenarios were prepared from five different categories: "Stroke", "Myocardial infarction", "Trauma", "Rare diseases" and "Difficulties during pregnancy". All scenarios were structured to be handled according to the worldwide used "ABCDE"-approach to rapidly evaluate the emergency situation: "A" for airway, "B" for breathing, "C" for circulation, "D" for disability, "E" for exposure. Relevant details of the case have been included to be recognised by "SAMPLE"-history: "S" for symptoms, "A" for allergies, "M" for medication, "P" for past medical history, "L" for last oral intake and "E" for events leading to the illness/injury [22], [23].

The mHealth concept in this study was a mobile, high definition, real-time video connection between the emergency site and a remote medical expert. For this purpose a camera called LiveCity camera was used, which was developed in the European Union funded research project LiveCity [24], [25], [26].

According to usual guidelines in German emergency medicine two paramedics worked together as a team. Together they handled ten scenarios, five of them with a remote medical expert and five of them without. The sequence of the case scenarios and the assignment to the two cross-over categories was randomized.

When paramedics are alerted by the emergency dispatcher, they are provided with information about the location of the emergency, age and gender of the patient and the operation key word. The operation key word is based on the callers description of the emergency and indicates the kind of emergency [27], [28]. For all 10 scenarios in this study operation key words were developed. In general, every scenario followed this pattern:

The paramedics were presented with the operation key words and age and gender of the patient. After that, they entered the simulation room, where the mannequin was postured with additional props, to illustrate the specific emergency scenario. The paramedics then started to ask the mannequin questions regarding the emergency, took the medical history, measured the vital signs and examined the patient. According to the predefined case description, which was developed specifically for every scenario, questions were answered and the vital signs and findings in the physical examination shown. They were dynamically adjusted according to the actions of the paramedics. In the simulation cases with a remote medical expert, the paramedics could decide at which point during the simulation they wanted to start the video consultation. Depending on features of the emergency case (for instance the severeness and the urgency to start the treatment) and on traits of the paramedic (like level of experience and wish for reassurance) the consultation could start either right after hearing the operation key word or after finishing the diagnostics and initial treatment just for confirmation or at any given moment between that, as would be the case after the implementation of this mHealth system. All the scenarios ended, when the paramedics decided to start the transport to the hospital. That endpoint was chosen, because before the beginning of the transport, all major decisions regarding diagnostics and treatment have to be made. If the paramedics did not start transport within 27 minutes, the scenarios were terminated. This time limit was set, because in Germany in 95% the emergency doctor reaches the emergency site within 26.6 minutes [29]. Thus, in the majority of cases there would be an emergency doctor at the emergency site after 27 minutes to take over from the remote medical expert.

For the simulation in this study, the equipment of the paramedics contained all medical devices, that are statutory for an ambulance car in Germany according to DIN EN 1789 Typ C [30], [31]. These are, for instance, monitor of medical parameters (including body temperature, blood sugar level and 12-lead-ECG) and defibrillator, ventilator machine, medical suction machine, stiff neck and medical bag with

drugs, dressing and devices to secure the airway and blood circulation.

The study was performed in the fully equipped high fidelity medical simulation center of the Department of Anaesthesiology at Greifswald University Medicine. To assess the outcome in practical, technical and psychological aspects, paramedics and doctors were interviewed by use of semi-structured questionnaires.

III. RESULTS

A total of 10 emergency doctors and 21 paramedics took part. Among the many aspects assessed by questionnaires in the LiveCity project, three key findings for this study will be presented. Table I shows how doctors and paramedics rated the statement “The scenarios were realistic." Table II shows how doctors and paramedics rated the statement “The scenarios were relevant." Table III shows how doctors and paramedics rated the statement “I took the simulation work seriously.”

Table I: “The scenarios were realistic.”

	Agree	Partly agree	Partly disagree	Disagree
Doctors (10)	4	5	1	0
Paramedics (21)	9	11	1	0

Table II: “The scenarios were relevant.”

	Agree	Partly agree	Partly disagree	Disagree
Doctors (10)	7	3	0	0
Paramedics (21)	14	7	0	0

Table III: “I took the simulation work seriously.”

	Agree	Partly agree	Partly disagree	Disagree
Doctors (10)	6	4	0	0
Paramedics (21)	18	3	0	0

IV. DISCUSSION

In this study, the majority of emergency doctors and paramedics confirmed that the simulation of the scenarios was realistic. They also acknowledged that the chosen scenarios were relevant examples of emergency situations. All paramedics and emergency doctors agreed or partly agreed that they took the simulation work seriously.

Great emphasis was put on high verifiability, fidelity and validity, which are three of the most important concepts of evaluating the quality of simulation [32]. These three concepts are interconnected. To achieve high verifiability, all 10 developed scenarios were tested and adapted beforehand. As mentioned above, the fidelity can be divided into equipment fidelity, environment fidelity and psychological fidelity. To increase the equipment fidelity in this study, the Laerdal mannequin Resusci Anne® (Laerdal Medical GmbH, Puchheim, Germany) was used and the vital signs were dynamically simulated with the monitor iSimulate ALSi® (Skillqube GmbH, Wiesloch, Germany). The Laerdal Resusci Anne is globally used in education and research [33], [34], [35]. To enhance environment fidelity, every scenario had different characteristic accessories, e.g. in one case of simulated heart attack, a patient was watching sports sitting on a sofa with a football flag while eating potato crisps. Psychological fidelity is the ability of the individual participant to immerse into the simulated situation. Because the psychological fidelity depends on equipment and environment fidelity, huge emphasis has to be on increasing both of the latter. In the concept, that the behaviour in the simulated scenario mirrors the behaviour in a real case, high authenticity is essential [36]. In this study all participants took their work very seriously during the simulation, and the majority rated the simulated scenarios as realistic. Thus, the possibility of the participants behaving in the study environment similar to their normal behaviour is very high. This implies a good external validity. Furthermore, all emergency doctors and paramedics partly agreed or agreed that the chosen scenarios were relevant. This is also an indicator for a good external validity.

V.CONCLUSION

Since all paramedics and emergency doctors confirmed that the chosen scenarios were realistic and relevant, a medical simulation center appears to be a suitable model for testing mHealth concepts in prehospital emergency medicine. It offers the opportunity to evaluate mHealth concept without potential patient harm.

***Abstract*—The paper presents an example of model-based estimation of blood pressure parameters (onset, systolic and diastolic pressure) from continuous measurements. First, the signal was low pass filtered and its quality was estimated. Good quality periods were divided into beats using an electrocardiogram. Next, the beginning of each beat of the blood pressure signal was approximated basing on the function created from the sum of two independent distributions: Gaussian and exponential. The nonlinear least square method was used to fit measurement data to the model. The initial conditions for the fitting procedure were selected for each beat on the basis of its parameters. Finally, the diastolic and systolic values of blood pressure and onset were determined.**

I. Introduction

THE BLOOD pressure analysis allows for a certain characterization of the cardiovascular system and thus the patient state. Therefore, it is very important to accurately estimate its characteristic values from noisy data (measurements). The methodology requires that certain steps are performed. First, the signal quality should be estimated in order to skip the fragments of the data which are too noisy. This can be done by using the methods proposed in [1], [2]. Next, the characteristic points of a full beat of blood pressure signal should be estimated. A different method of estimation can be utilized including a windowed and weighted slope sum function [3], a filter bank with variable cutoff frequencies, rank-order nonlinear filters, and decision logic [4], inflection and zero-crossing points of blood pressure, and then combinatorial amplitude and interval criteria to select the onset and systolic peak [5], wavelets [6], principal components [7], waveform descriptor compared with a customized template [8], determined lines and polynomial approximation [9] or Fourier series interpolation [10].

In our studies we have decided to use a model-based approach to obtain signal parameters. In such an approach the approximation results correspond to the selected model. Therefore, it is important that the model has a similar shape to the real signal. A simple solution is to use a polynomial model

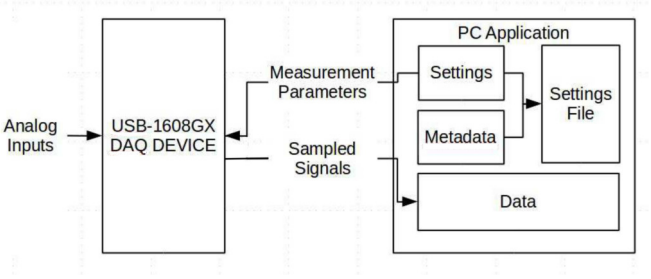

Fig. 1. Communication between DAQ and data receiving software

(like in R-wave estimation [11], which does not guarantee, however, correct results for longer parts of a signal. We have decided to use the more complicated exponentially modified Gaussian function. The exponentially modified Gaussian function was used in different applications like chromatography [12] or cell proliferation and differentiation [13], , but to our knowledge, it has not been used in blood pressure modelling. The practical limitation of such a simple model is that the pressure waveform is a combination of incident and reflected waves. It affects the estimation of systolic pressure. In such an approach, the estimation of model parameters is crucial. Since there is a nonlinear dependence of the model parameters on measurement data, the nonlinear least square approach was used. The model parameters obtained allow to extract diastolic and systolic pressure, but also to compare different pulses using reconstructed parameters. These parameters allow a further data analysis including the dependence between heart rate and blood pressure analysis [14] or estimation of patient condition [15], [16].

II. Material and Method

The continuous blood pressure and ECG were measured using a custom ECG module and CNAP monitor. Both devices were connected to the 16-channel USB Data Acquisition DAQ Module. All data relayed by the DAQ module were recorded by custom software. The block diagram (Fig. 1) presents a general overview of communication between DAQ and the proposed custom recording software.

The rapid measurement and analysis of the ECG signal was enabled by the dedicated ECG optimized pre-amplifier de-

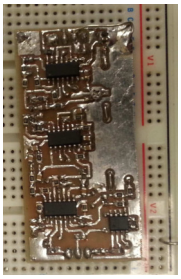

Fig. 2. The prototype of the custom ECG measuring module

signed and manufactured for the purpose of this study (Fig. 2). The overall amplification of the unit was set to approximately 5000. The bandwidth was limited to 0.05 Hz-60 Hz with a dedicated 50 Hz notch filter. A similar solution was used in [17] and [18]. To improve the CMRR, a dedicated DRL circuit was implemented. Blood pressure was measured by means of a standalone CNAP monitor. It enabled the continuous monitoring of blood pressure and pulse rate. All utilized hardware and software came from different vendors which made the integration of the measurements slightly challenging. The CNAP monitor analogue output was connected, next to the custom ECG unit, to the additional PC by means of the DAQ Module. Dedicated software was used for reading the data from the data logger. The measurements were triggered over the network by the UDP protocol. Because ECG and CNAP were registered by means a DAQ data logger there was no delay between measurements. The use of external trigger (over network) allows to extend the measurements by additional parameters like respiration rate, etc. The UDP protocol ensured simple and quick data transfer. Moreover, the UDP allowed for multicast traffic which is very convenient for synchronized measurements of different biosignals.

The data were collected from three healthy men at the age of 28, 33 and 47. The duration of measured signals (including blood pressure, ECG, respiration and eye movement - not used in the present study) was 120 seconds for each person.

The measured signals were sampled with 1 kHz frequency. This relatively high frequency is required to obtain a large number of data for each beat of pressure. This allows to increase the accuracy of the approximation results. First, the continuous blood pressure signal was filtered using a low pass FIR filter (order 1256) with cut off frequency equal to 16 Hz. This made it possible to remove the high frequency noise without modifying the shape of the signal and respiratory influence. The Matlab *filtfilt* function was used, and consequently there was no delay between the raw and filtered data. After blood pressure preprocessing, the R-wave of the electrocardiogram was detected using [19] algorithm. The shape of the blood pressure wave was good enough to skip the above-mentioned quality measure calculations. For each R-wave detected, the minimum of the blood pressure signal was sought. The search was carried out up to 200 ms from the R-wave detected. If there was more than one point of the minimum, than the latest minimum was chosen as a reference (t_{min}). Next, the time of the maximum of the blood pressure was sought at the 400 ms window. If there was more than one point, the latest value was chosen (t_{max}). The last step was choosing the time interval for signal approximation (t_{min}-10 ms, t_{max}+150 ms). Each beat was approximated using the model derived from convolution of two independent additive processes: Gaussian and exponential (ex-Gaussian model)

$$f(t) = C + M\frac{\lambda}{2}\exp\left(\frac{\lambda(2\mu+\lambda\sigma^2-2t)}{2}\right)\times \left(1-erf\left(\frac{\mu+\lambda\sigma^2-t}{\sqrt{2}\sigma}\right)\right) \quad (1)$$

where M is a constant required to stretch the function to the desired range of beat pressure, C is a constant which determines the level of the signal (diastolic blood pressure), μ, σ, λ are parameters describing the properties of the function (μ and σ come from the Gaussian model and λ from the exponential model). The $erf(\cdot)$ is an error function

$$erf(x) = \frac{2}{\pi}\int_0^x e^{-t^2}dt \quad (2)$$

Having t_{min} and t_{max} initial values for fitting were calculated as follows

$$\mu_{init} = t_{max} \quad \sigma_{init} = (t_{max}-t_{min})/2 \quad \lambda_{init} = 10 \quad (3)$$
$$M_{init} = (BP(t_{max}) - BP(t_{min}))/4 \quad C_{init} = BP(t_{min})$$

where BP is the registered continuous blood pressure signal. The *lsqnonlin* Matlab function was used to find the global minimum for the nonlinear least square problem. The systolic and diastolic blood pressure was determined from the minimum and maximum values of each estimated beat. A more complicated issue is onset calculation. In the approach assumed, it was represented by the point of the maximum curvature of the estimated model, where the curvature was determined from

$$curve = \frac{|f"(t)|}{(1+(f'(t))^2)^{3/2}} \quad (4)$$

To allow comparison with other methods, the algorithm was tested on publicly available data. The 037 record from the MIMIC database [20] was used. Since the data were sampled at 125 Hz, the FIR filter was redesigned (order 157). The analysed data were restricted to the beats with SBP<180 mmHg and DBP>20 mmHg. This simple operation was conducted to remove the extremely high and low peaks. The median error for SBP, DBP and onset as well as the RMS error ($RMSE$)

$$RMSE = \sqrt{\frac{1}{N}\sum_{i=1}^{N}(data(i)-approximation(i))^2} \quad (5)$$

were calculated for the first 15000 beats. In equation 5, $data$ represents either SBP, DBP or onset obtained from annotations, while $approximation$ represents the same parameters obtained from the algorithm proposed. The $data$ values are integers so $approximation$ values were convert integers as well.

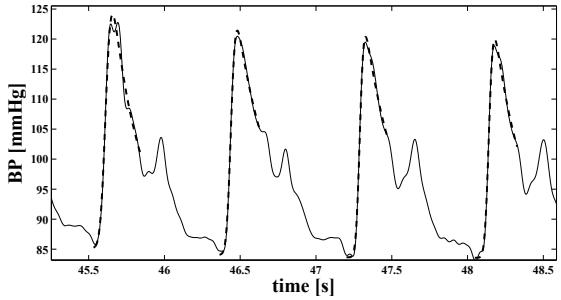

Fig. 3. Filtered signal and its approximation (dotted line)

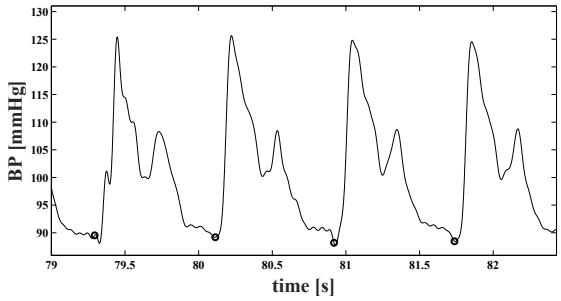

Fig. 4. An example of the onset points (circles)

III. Results

Example of the fitting results (Fig. 3) and founded onset points (Fig. 4) as well as the influence of sampling frequency on DBP and SBP are presented (Figs. 5 - 6).

There were certain difficulties with the analysis of the reference data for 298 of 15000 beats. Modification of one initial data from σ_{init} to $0.6\sigma_{init}$ succeeded in 187 cases, while for the last 111 cases, further modification of one initial data from $0.6\sigma_{init}$ to $0.5\sigma_{init}$ succeeded in 26 cases. Convergence was not obtained for 85 beats. The median error for SBP, DBP and onset was equal to 2 mmHg, 2 mmHg and 0 samples, respectively, while the $RMSE$ error was equal to 4.97 mmHg, 3.23 mmHg and 2.40 samples. Removing 1% of the worst approximation results reduced the $RMSE$ error to 3.08 mmHg, 2.64 mmHg and 2.28 samples, respectively.

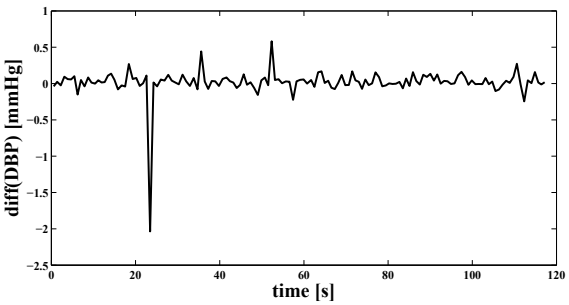

Fig. 5. The difference in estimated diastolic blood pressure (for 1 kHz and 125 Hz sampling frequency)

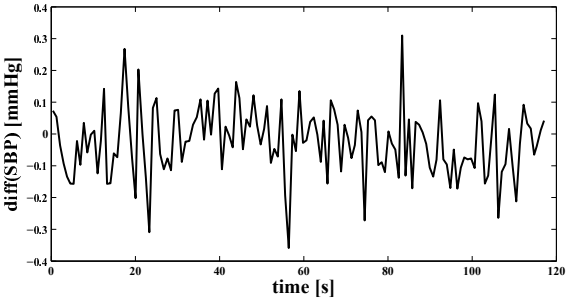

Fig. 6. The difference in estimated systolic blood pressure (for 1 kHz and 125 Hz sampling frequency)

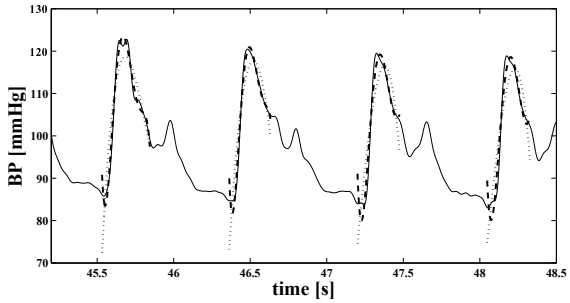

Fig. 7. Filtered signal and its polynomial approximation (dotted line - 3-rd, and dashed line 5-th degree)

IV. Discussion and Conclusions

The results of approximation were highly satisfactory (Fig. 3). In the case of polynomial approximation, the results were much worse. An example of such approximation using 3-rd and 5-th degree polynomial is presented in Fig. 7. The difference between systolic and diastolic blood pressure calculated from low pass filtered data was similar to the approximated one. To reduce the problem of onset detection, the ECG signal was used as a reference. The main problem in nonlinear least square fitting is choosing the starting point for every iteration. Its influence was estimated by perturbing initial conditions. The results of fitting were most sensitive to the μ parameter. Even a change of 5% in the initial value caused poor fitting results. The distortions present in the recorded signal caused problems with the estimation of the fitting error. Thus, the results were compared to the fitting with the initial values. The quality of fitting using the initial values was estimated by visual inspection and a comparison of diastolic and systolic blood pressure with the values calculated for the low pass filtered blood pressure signal (defined as the minimum of blood pressure after R-wave - for the diastolic, and the maximum after DBP for the systolic). The fitting results were much less sensitive to the initial value of σ. Satisfactory results were obtained for values which were as much as ten times smaller and five times greater. Similar results were obtained for the initial λ estimation. The method presented was more

sensitive for the initial values of C and M. Based on the experiment conducted we have assumed that a deviation of 5% is acceptable for C. In the case of parameter M, satisfactory results could be obtained when the value was in the range between 50% and 120% of the initial value.

The nonlinear least squares fitting can use the Jacobian calculated analytically or numerically. We did not notice any significant differences in the results obtained regarding the method of Jacobian calculation. The difference in systolic and diastolic values was lower than 10^{-3} mmHg, while the difference in onset was lower than 0.1 ms.

The sampling frequency did not influence the results obtained. Down sampling of the blood pressure signal from 1 kHz to 125 Hz did not modify the estimation of DBP and SBP significantly (except for one sample) (Figs. 5 and 6).

The diastolic blood pressure can be easily obtained from the model (DBP=C). The analytic estimation of systolic blood pressure requires solving a nonlinear equation. The advantage of the proposed approach is that the calculated parameters: μ, σ, λ can be used to estimate the arteries' condition and their changes.

In our approach the onset estimation bases on finding the maximum curvature of the estimated model curve. To prevent finding the maximum value of the model as the point of maximum curvature, the search was limited to 50 ms after the beginning of each beat. The sampling frequency did not have a large influence on onset detection. The difference between values obtained for 1 kHz and 125 Hz sampling frequency was lower than 7 ms (except for three peaks). The approach adopted for onset detection can be modified by introducing an additional parameter p, which will allow the onset point to be shifted. The curvature will then be defined as

$$\frac{|f"(t)|}{(p+(f'(t))^2)^{3/2}}. \tag{6}$$

In general, the reference ECG signal is not required. The beat localization can be obtained by using only the blood pressure waveform (for example by using the algorithm proposed in [3]), and the proposed model can be then used to obtain signal parameters.

The results obtained from the reference data are satisfactory. Some problems may be due to the relatively low sampling frequency and possible distortions in the analysed signal. Better results can be obtained by further modifying the initial parameters.

The analysis of all the results obtained enables the conclusion that the proposed method of blood pressure parameters estimation using the ex-Gaussian model is suitable to the requirements and reliable.

***Abstract*— Respiration rate is a very important vital sign. Different methods of respiration rate measurement or estimation have been developed. However, especially interesting are those that enable remote and unobtrusive monitoring. In this study, we investigated the use of smart glasses for the estimation of respiration rate especially useful for indoors applications. Two methods were analyzed. The first one is based on measurements of respiration-related body movements using an accelerometer. The second one uses the thermal camera to observe temperature changes in the nostril region. For both methods signals were extracted, filtered and processed using two different respiration rate estimators. Both methods were validated during experiments with the participation of volunteers using the respiration belt as a reference measurement method. Results proved that for both methods it is possible to reliable estimate the respiration rate with Root Mean Square Error lower than 2 breaths per minute, which is sufficient for medical screening.**

Keywords—smart glasses; respiration rate estimation, thermal imaging

I. Introduction

Smart glasses are wearable devices that can extend human senses and capabilities of information processing. Additionally, the near-to-eye display could provide graphical information with much higher privacy than a smartphone or a tablet. Smart glasses can be equipped with different sensors (e.g. accelerometers, gyroscopes, cameras), communication interfaces (e.g. WiFi, Bluetooth), etc. Recently, many devices have been proposed on the consumer market, including Google Glass, Epson Moverio BT-200, Recon Jet, Lumus DK-40, etc. [1]. Many ideas and demonstrations of potential roles of smart glasses in healthcare have been presented. Some include improved visualization of veins locations (Evena Medical [2]), access and visualization of data from medical records [3][4][5], presentation of vital signs on the display of smart glasses (Philips [6]), etc.

In this paper we analyze the possible role of smart glasses in estimation of respiration rate. Smart glasses were previously used to estimate some vital signs [7][8]. Typically, the pulse rate was estimated using photoplethysmography [9] or respiration rate (and pulse rate) using data collected by an accelerometer or gyroscope of the Google Glass [7]. Additionally, for the identified patient (e.g. using face recognition [10] or using graphical markers like QR-code [11][12]) the measured vital signs or other health-related data can be automatically uploaded to the healthcare information system. The goal of this paper is also to analyze two different respiration rate estimators applied to short-time data collected using the accelerometer or the thermal camera. Respiration rate is typically monitored using masks with thermistors, analyzing ECG drifts or using clinical observations. It is especially important in quality of sleep analysis (e.g. for sleep apnea detection [13]). Some remote methods use analysis of video sequences recorded from the chest region [14] looking for respiration-related movements. Those recordings are typically performed using visible light cameras [15] and infrared cameras [16][17]. Thermal recordings were typically performed using cameras with good spatial resolution [18][19] performing respiratory rate analysis in the frequency domain.

The rest of the paper is structured as follows: Section II presents the proposed methods. Results are described in Section III. Section IV present a discussion of results and concludes the paper.

II. Methods

A. Measurement systems

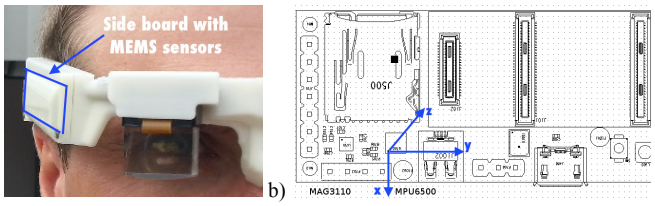
Respiration is important measurement of the body's most fundamental function. Smart glasses can use different sensors to measure or estimate respiration rate (for the observed person and for the wearer). Here, we assume that respiration rate can be estimated using analysis of data captured: with accelerometer/gyroscope sensors - for the user of smart glasses and with the thermal camera - for the observed person. Both measurement methods were implemented in the eGlasses prototype, developed under the eGlasses project (www.eglasses.eu). This experimental platform is dedicated to research activities, so different electronic modules can be changed; it is possible to print another cover using 3D printer, add sensors or electrodes, change the display, etc. The current prototype uses OMAP 4460 processor with 1GB RAM, 1024x768 transparent display from Elvision Company, 5MPx camera, WiFi and Bluetooth 4 wireless interfaces, different sensors (accelerometer, gyroscope, magnetometer, OMRON D6T thermal sensor, etc.), eye-tracker and extension slots. The Android 4.1 OS and Linux Ubuntu OS have been already tested. For the goals of this paper the accelerometer and the thermal camera module were used.

B. Accelerometer and respiration rate

The used single-chip MPU-6500 (Invesense) integrates the 3-axis accelerometer, the 3-axis gyroscope, and the onboard Digital Motion Processor™ (DMP) in a small, 3 mm x 3 mm x 0.9mm package. The device can operate from 1.8V and

This work has been partially supported by NCBiR, FWF, SNSF, ANR and FNR in the framework of the ERA-NET CHIST-ERA II, project *eGLASSES – The interactive eyeglasses for mobile, perceptual computing* and by Statutory Funds of Electronics, Telecommunications and Informatics Faculty, Gdansk University of Technology.

consumes 6.1mW in full operating mode (33µW in low-power mode). The typical offset of the accelerometer is ±60 mg and 300 µg/√Hz of noise. The location of the chip on the base board (Fig. 1) enables the measurement of acceleration in *x* direction (head top to down), *y* direction (back of the head towards face) and *z* direction (ear-to-ear direction).



a) b)

Fig. 1. a) The eGlasses prototype with the indicated location of the (side) base board with sensors. b) The layout of the (side) base board with the indicated axes of the accelerometer and gyroscope.

It is assumed that respiration activities influence body (head) movements so it should be possible to estimate the respiration rate. Typically, the acceleration module is calculated as:

$$|a| = \sqrt{a_x^2 + a_y^2 + a_z^2}\ , \tag{1}$$

where: a_x, a_y, and a_z are the measured acceleration values for particular directions.

In this work, measured signals ($|a|$ or directional a signals) are resampled (to f_s=11Hz) and normalized (mean removal). Next, filtration is used to remove noise and not-respiratory related signal components. The moving average is used (window size $f_s/2$) and the band-pass Butterworth filter (4^{th} order) to pass frequencies between 6bpm and 40bpm. Finally, two respiratory rate estimators are applied (described later).

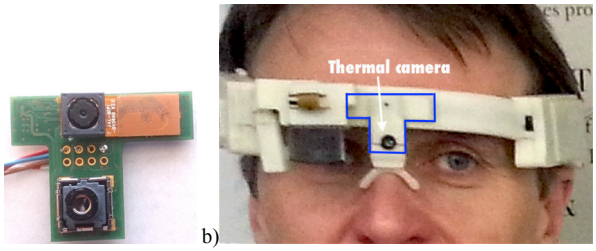
C. Thermal camera and respiration rate

The respiration rate was also analyzed using sequences of thermal images recorded for nostril regions. The FLIR Lepton thermal camera module, located in the designed front board, was used for thermal recordings (Fig. 2). It is characterized by high dynamic range (14bits), small size (<1cm^2) and relatively small spatial resolution (80x60).

The multistep procedure was used for the estimation of respiration rate. First, a sequence of thermal frames was captured during the short time period (30s windows were used in the experiments). Next, in this preliminary study, the nostrils region (a rectangle with width = nose width) was manually selected directly around/below the nose. Then, the nostril ROI was used to calculate the average pixel value inside that ROI. The operation was repeated for each frame producing a 1-D signal (time series) of infrared (thermal) radiation changes. Next the same filtration was used as for signals obtained for the accelerometer (i.e. moving average and Butterworth band-pass filter).

D. Respiration rate estimators

Two respiration rate estimators were analyzed for signals obtained for the accelerometer and for the thermal camera. The first estimator, *eRR_sp,* often used in other studies, identifies the frequency in the frequency domain of the analyzed signal, for the dominating peak in the frequency spectrum.



a) b)

Fig. 2. a) The module with cameras: visible ligth camera (top) and Lepton infrared camera (bottom). b) The location od the module in the eGlasses.

The second estimator, *ePR_ac,* analyzes the periodicity of peaks locations for the autocorrelation function in time domain as a function of time lags. The autocorrelation for different time lags is calculated and the period is determined calculating an average time differences between detected peaks. As a peak detector we used a method looking for a local minimum and a local maximum, for which their difference is grater than the threshold value T:

$$d=s_{fn}(t_{j+1})-s_{fn}(t_j),\ d>T, \tag{2}$$

where: $s_{fn}(t_{j+1})$ - filtered signal value of the local minimum at j, $s_{fn}(t_j)$ - filtered signal value of the local maximum at $j+1$.

The threshold value T was calculated in two phases. In the first phase (T= T_1) as:

$$T_1=T_{K1}*(max(s_{fn}(t))-min(s_{fn}(t))), \tag{3}$$

where T_{K1} was the scaling value set to 0.33.

Then the median of the detected peak-to-peak gradient values was calculated. The scaled (T_{K1}=0.25) median value was used as the threshold value (T=T_2) in the second pass of the algorithm to detect final peaks of each signal.

The calculated frequencies for both estimators were multiplied by 60 to obtain results in breaths per minute (*bpm*, e.g. $ePR\_ac=f_{ac}*60$).

E. Experiments and validation

The analyzed methods for the estimation of respiration rate were validated during experiments with the participation of 11 volunteers (mean age: 39.73y±11.98). Subjects were asked to seat comfortable and not move except natural breathing. Then, separately, data were measured during 1min, by two devices. In parallel, the pressure, chest belt (Vernier RMB) was used as a reference. To synchronize signals subjects were asked to hold the breath at the beginning of data recording. Measured signals were analyzed manually to calculate reference respiration rate (RR) values. According to the RR definition (number of respiration events in time) the complete periods between successive inspirations were indicated and counted in 30s long time windows. The RR was calculated as:

$$RR=(N_{RR}*60)/(t_{le}-t_{fs}), \tag{4}$$

where: N_{RR} – number of respiration events (inspiration to inspiration), t_{le} – time of the end of the last event, t_{fs} - time of the start of the first event.

III. Results

A. Accelerometer and respiration rate

Table I presents results of the respiration rate estimation for measurements performed using the accelerometer of smart glasses and using the reference respiration belt.

TABLE I. RESULTS OF RESPIRATION RATE ESTIMATION FOR THE ACCELEROMETER

	Chest Belt			Accelerometer	
Subject	*RR [bpm]*	*eRR_sp*	*eRR_ac*	*eRR_sp*	*eRR_ac*
S01	15.400	14.650	14.990	10.950	14.160

In Fig. 4a some examples of thermal images captured during inspiration and expiration events are presented. In Fig. 4b examples of the filtered signal of thermal radiation changes in the nostril ROI (subject S01) and obtained results (spectrum for the filtered signal, and autocorrelation as a function of time lags with the detected peaks) are presented.

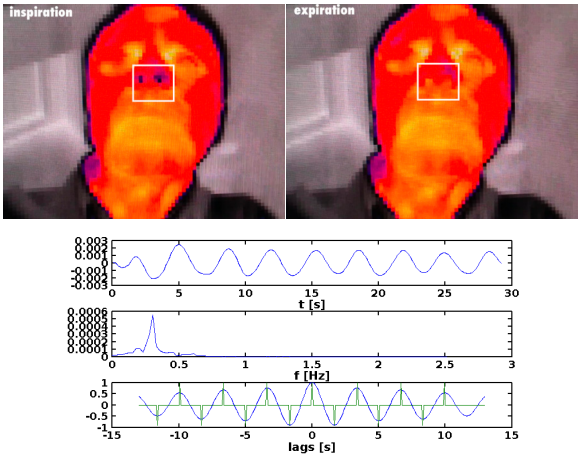

Fig. 4. Top: Thermal images for inspiration and expiration events. Bottom: Filtered signal, spectrum of the filterred signal and autocorrelation signal as a function of time lags with indicated detected peaks.

IV. Discussion and Conclusions

In this study we proposed the use of smart glasses for the estimation of respiration rate using two sensors. The first method was based on measurements performed with the accelerometer. As it could be observed in Fig. 3a respiration-related movements are mainly (for most participants) observed in *y* direction (head backward/forward). This is probably related to head movement during inspiration, when the chest cage/lungs are filled with air causing natural head movement to the back. The calculated *RMSE* value for the *eRR_ac* estimator shows that the respiration rate can be estimated with relatively good accuracy. This is usually good enough for medical screening purposes. For most subjects the accuracy of the respiratory rate was up to 2bpm. However, as it could be observed for S04, in some cases the result is not acceptable. It is important to underline, that the value of respiration rate is always calculated for a particular time window. So manually

calculated RR values for the belt-based signals are a little bit different that values automatically calculated by two estimators. This is also caused by analyzing different time windows. The manually calculate RR values considered only the whole inspiration-to-inspiration periods. Other estimators used all samples. Additionally, the estimator based on the frequency domain has limited accuracy due to the finite frequency resolution. For example, taking *N=330* samples and *fs=11Hz*, then spectral resolution is (11/330)*60=2bpm. For experiments with the use of the accelerometer the *eRR_sp* gave worse results than the *eRR_ac* estimator performing operations in time domain. The experiments were performed under optimistic conditions – subjects did not move. Further research is required to verify the methodology in more natural conditions (head movements).

Experiments performed for the small thermal camera module gave very good results. The respiration rate can be easily and reliably estimated using the described method. The method has of course limits related to required gradient between values of body temperature and ambient temperature. However, when used indoors the required temperature gradient is practically usually fulfilled (e.g. air-conditioning). One of the most interesting finding is that even such a small spatial resolution is not a problem for locating nostril regions and obtaining high dynamics of signals (ambient temperature of the laboratory room when experiment took place was high, 24-27C). In this work we proposed the use of very small thermal camera with small spatial resolution that is used for smart glasses. We also compared two different estimators: one operating in frequency domain, the second one in time domain. Results proved high accuracy of the method and both estimators. However, in this study we used manually selected ROI for nostril area. This can be performed automatically using automatic face detection for thermal images and detection of nostril regions [20]. This will be a subject for further study. It is also important to investigate different signal quality measures that can be used to evaluate if the measured signal (or RR value) is more or less reliable. Such possible measures can analyze the spectral purity of the periodical components (e.g. Hijorth parameters [21], etc.) or other similar parameters (goodness of fit for parametric models [22], periodicity of the autocorrelation function, etc.).

Using smart glasses senses of a healthcare professional could be extended providing additional knowledge about a patient acquired during routine interviews. This is more natural method of observation because it does not influence the patient by using (wearing) additional equipment. Additionally, smart glasses can provide very good source of medical data for self-diagnostics of the smart glasses user. However, practical application of such methods requires comfortable design of smart glasses, which is a task for further research.

SARF: Smart Activity Recognition Framework in Ambient Assisted Living

Samaneh Zolfaghari, Mohammad Reza Keyvanpour
Alzahra University
Tehran, Iran
Email: s.zolfaghari.ir@ieee.org

***Abstract*—Human activity recognition in Ambient Assisted Living (AAL) is an important application in health care systems and allows us to track regular activities or even predict these activities in order to monitor healthcare and find changes in patterns and lifestyles. A review of the literature reveals various approaches to discovering and recognizing human activities. The presence of a vast number of activity recognition issues and approaches has made it difficult to make adequate comparisons and accurate assessment. Introducing the five basic components of activity recognition in the smart homes as a famous environment to remote monitoring of patients and independent living for elderly, the present paper proposes SARF framework to classify each of activity recognition approaches and then it is evaluated based on the proposed classification by some proposed measures. Using SARF proposed framework can play an effective role in selecting the appropriate method for human activity recognition in smart homes and beneficial in analysis and evaluation of different methods for various challenges in this field.**

I. Introduction

IN RECENT years automatic human activity recognition has received considerable attention due to the growing demand in many applications such as healthcare systems for monitoring the Activities of Daily Living (ADL) in smart homes, especially due to the rapid growth of elderly population, in surveillance and security environments to automatic detection of abnormal activities to alert the relevant authorities about the potential criminal or terrorist behavior, in activity-aware services to convert ideas like smart meeting rooms, home automation, personal digital assistants from science fiction to everyday fact and in entertainment environments to improve human interaction with computers [1][2][3].

Due to the many uses of activity recognition in smart homes and the availability of various approaches in this field, comparison and accurate evaluation of existing methods is difficult. Therefore, providing an account of these activity recognition approaches seems to be essential. The main contribution of this paper, after briefly introducing five basic components of human activity recognition in smart homes, is proposing SARF framework to classify different methods in this field. Then, this framework is analyzed in terms of approaches, their characteristics, challenges and also proposed measures.

The remainder of this paper is organized as follows: In Section II, basic definition for human activity recognition and its capabilities in healthcare systems will be introduced. In Section III, the overall structure of human activity recognition process in smart homes will be described in form of five basic components. In Section IV is represented the proposed SARF framework according to various activity recognition approaches and in Section V the proposed classification based on proposed measures will be evaluated.

II. Human Activity Recognition in Ambient Assisted Living

Nowadays learning and understanding the observed activity [2][4] and event mining [5][6] are central to many fields of studies. The activities of an individual affect him/her, the people around him/her, society and environment [1]. Activities refer to complex behaviors consisting of a sequence of actions and/or overlapped and interwoven actions that can be performed by a single individual or several individuals interacting with each other [1][4]. Activity recognition in healthcare systems considered as a way to facilitate the work of healthcare in order to treat and care for patients, reduce the workload of medical staff, decrease hospital stays for patients, reduce costs and improve the quality of life for people who need care [1][2]. Medical experts believe one of the best ways to identify and explore emerging medical conditions is to monitor changes in daily activities, before these conditions become serious [7].

Recently human-activity discovery [8], recognition [9], prediction [10], and abnormalities detection [11], have attracted great interest because of their high potential in context-aware computing systems such as smart environments. Activity recognition in smart homes has made it possible to track occurrences of regular activities in order to monitor healthcare and find changes in activity patterns and lifestyles, so can be a great help in providing automation, security and most importantly remote health monitoring for elderly or people with disabilities [7][8].

Thus, in recent years activity recognition has become one of the application areas in healthcare systems such as AAL and is leading important research activities including CareLab, CASAS, Gator-Tech, HIS, Aware Home, SELF, iDorm, MavHom [12].

In this study, a comprehensive classification and evaluation of human activity recognition techniques in smart homes as an AAL system is introduced which tries to cover all existing approaches.

III. Basic Components in Human Activity Recognition Process

The process of human activity recognition follows five steps including Sensing, Preprocessing, Feature Extraction, Feature Selection and Activity Learning Techniques [1][13]. Fig. 1 represents basic components of human activity recognition. Note that, depending on environmental conditions, the types of sensors used and the type of data collected, some of these steps may not be needed. Each of these steps will investigate in the following sections.

A. Sensing

In the first step sensing is performed by the sensors and the data are collected in a database [4]. In fact, this step is responsible for collecting sensor data from smart home environment [13]. The data is sent as a signal to perform preprocessing. Signals contain information about the object which is observed and measured [1] and can be numeric, time, multimedia or even quality signals.

In order to monitor human activities in smart homes wide variety of sensors have been used and there are different perspectives to sensors classification. The sensor classification from two general perspectives is also shown in Fig. 1.

The discrete sensors including Passive Infra-Red (PIR), Contact Switch Sensors (CSS) and Radio-Frequency Identification (RFID) have binary output. Due to simplicity and unobtrusiveness nature of captured data from detected objects or residents states, they are very popular. Opposite side of discrete sensors are continuous sensors including Physiological, Ambient and Multimedia sensors with simple or complex data streams such as real numbers, images or voices [1][3][14].

In one point of view, sensors are wearable or environmental. The wearable sensors including Inertial (e.g. Accelerometers and Gyroscopes) and Vital Signs sensors (e.g. Bio-sensors) [3]. Individuals use wearable sensors to generate more information about posture, motion, location and people interaction [15]. Environmental sensors are used to capture data about smart home environment such as temperature, humidity, light, pressure, noise, and etc. [14]. They are not customized for a single resident; therefore, they can be used to group activity monitoring but they cannot discriminate between residents motions or actions [1]. The example of gathered sensor data which has a binary output shown in Fig. 2 generated by the CASAS data collection system automatically.

B. Preprocessing

The aim of preprocessing is to reveal information on signal, noise reduction and to remove excess information [3]. Cleaning, completing and normalizing data are the basic tasks in preprocessing including particle filters, median filters, kalman filter, low-pass filter and discrete wavelet package shrinkage and etc. to noise reduction. Also, linear and nearest neighbour and cubic interpolation using to fill in the missing values [3][16]. Because of the continuous flow of sensor-based information, it should be divided into segments to be easily recognizable by a trained classifier [3][17].

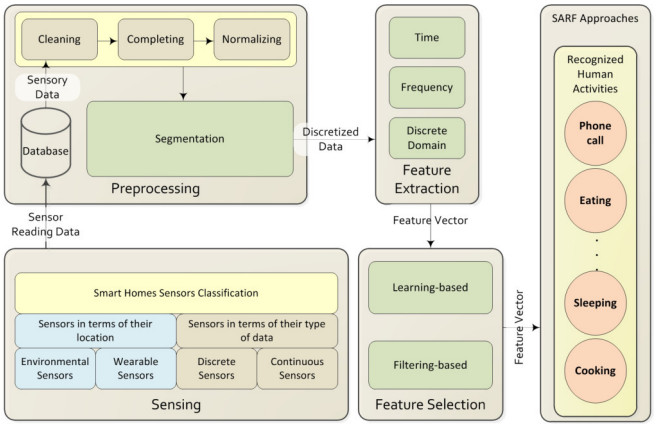

Fig. 1. Basic components of activity recognition process

Various approaches can be used to address segmentation of sensor events for activity recognition such as Change Point Detection (CPD), Time Slice based Windowing (TSW) and Sensor Event based Windowing (SEW) [1][17]. The CPD is an unsupervised segmentation and the idea is to find sudden changes in time series and recognize similar activity borders in real time [1]. The TSW is segment readings provided by inertial sensors and widely used in physical activity recognition. The SEW contains the same number of sensor events and segments the streaming data into sub-sequences [17]. Fig. 3 represents the schema of TSWs and SEWs segmentation.

In some cases (i.e. using supervised learning) at this step data annotation is done [13]. Accurate annotation of activities is important for performance evaluation of recognition models [9]. Annotation methods are divided in to two categories: Offline and Online methods. In Table I characteristics of different approaches in data annotation are represented. The output of this step as discretized data will be sent to Feature extraction step.

C. Feature Extraction

At this step the discretized data is considered as input and the feature vector as output. The purpose of this step is to select and maintain features that contribute to activity recognition. Depending on the kind of data, this step can vary [11]. The most commonly used approaches in this area

TABLE I
COMPARISON OF DIFFERENT ANNOTATION APPROACHES

Annotation Approach		Description	Advantages	Disadvantages
Off-line	Minimum Intervention	Inferences are done by using cameras, video data or recorded voices.	High Accuracy No need to user annotation	Time consuming and computationally expensive Based on resident tracking before data analysis Lack of scalability in resident and activity increasing Lack of privacy preserving
	Indirect Observation	Utilizing self-inference and sensor activation visualization by location, time and sensor location. Annotation has been done by residents and supervisors or just residents. Then these annotated data will store in a database.	High Accuracy No need to user annotation	Time consuming and computationally expensive Based on resident tracking before data analysis Lack of scalability in resident and activity increasing Lack of privacy preserving
Online	Experience Sampling	Utilizing self-report such as record activity information on paper or PDAs. This method is based on periodic alarm in resident environment to do annotation.	Reduce errors Fast Easy to use Better in convergence	Make one-sided or unrealistic data Make interruptions in residents activities Useless in a smart homes with elderly residents with dementia disease
	Direct Observation	In this method supervisor determine specific activities which have to be done by residents so the right activity label even before performing activities are clear.	Accurate annotation	Time consuming
	Time Diary	Use topic models such as LDA in order to provide brief description from activities in data, automatically.	Specify brief description of the activities in data, automatically No need to user annotation	Need to large volume of data Word order does not matter

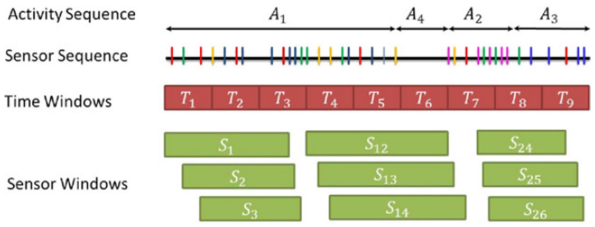

Fig. 3. Illustration of TSW and SEW approaches in Preprocessing step [18]

operate in three fields: time (e.g. Mean, Median, and Standard Deviation etc.), frequency (e.g. Wavelet Transformation and Fourier Transform) and discrete domain (e.g. Euclidean-based Distances and Dynamic Time Warping etc.) [3][15].

Actually, there is no general rule for feature extraction and it depends on the type of problem, our understanding of the problem etc. Thus, it can be done in different ways by different characteristics consideration.

Generally, sensor data features can classify into four groups: Features describing characteristics of the sensor event sequence, Features describing characteristics of discrete sensor values, Features describing characteristics of continuous sensor values, and Activity context [1].

D. Feature Selection

The purpose of this phase is to increase the accuracy of the resulting model by selecting more discriminative features. Also, to provide more robust model, reducing the dimensionality of feature vector and removing features with noise or features with irrelevant information are effective.

It should be noted, additional features will increase computational complexity and classification errors [3][13][19]. There are different approaches to feature selection in human activity recognition approaches including Learning-based and Filtering-based methods.

The Learning-based methods such as Simulated Annealing, Best First Search [1], or Genetic Algorithms [19]interact with the classifier to optimize the feature subset but makes classifier selection become an important process [19]. The idea behind the Learning-based methods is shown in Fig. 4. In the Filtering-based methods such as Minimum Redundancy-Maximum Relevance, the basic idea is not using features which are highly correlated among themselves [13]. Information Gain based on entropy ranks and weights each feature based on its ability to separate the activity instances of different classes [20]. Also Principle Component Analysis [21]

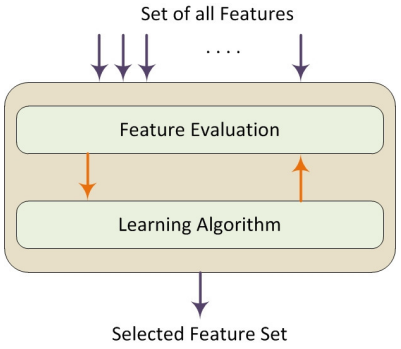

Fig. 4. The Learning-based approach to feature subset selection

TABLE II
COMPARISON OF DIFFERENT FEATURE SELECTION APPROACHES

Feature Selection Approaches	**Method Example**	**Advantages**	**Disadvantages**
Filtering-based Methods	Minimum Redundancy-Maximum Relevance, Information Gain based on Entropy, Principle Component Analysis	Fast Scalable Acceptable computational complexity Independent from classifier	No interaction with classifier Ignore effect of selected feature on classifier Ignore correlation between features Lack of appropriate criteria to specify number of required features
Learning-based Methods	Simulated Annealing, Best First Search, Genetic Algorithms	Choose simple features with low computation Interaction with classifier Consider correlation between features	Dependent to type of classifier Time-consuming in high dimension Suffer from over-fitting

is a linear technique and depends on data scaling. In this method principal components are not always easy to interpret [22]. In fact filter methods are fast, scalable and provide good computational complexity but they ignore interaction with the classifiers [19]. Table II is represented properties of different feature selections approaches in human activity recognition in smart homes.

E. Activity Learning Techniques

In this step machine learning methods are applied for learning activity using selected features [1]. Most smart homes activity recognition studies focus on the Katz index which is usually used in healthcare to evaluate the dependence level, physical and cognitive abilities of elderly people [9]. Generally, new algorithms that correlate the sensor firings, activity labels and predict activities from new sensor firings are required to identify activities from sensor activations alone [23].

A proposed general classification of different methods will address in the following section which tries to cover all existing approaches in human activity recognition in smart homes.

IV. SARF: SMART ACTIVITY RECOGNITION FRAMEWORK IN SMART HOMES

As mentioned before, when the problem of activity recognition in smart home arises, we track occurrences of regular activities in order to monitor health care and find changes in patterns and individuals lifestyle [8]. Since there are different approaches to activity recognition in related areas, presenting a general classification and examining each approach according to the applications and existing challenges seems necessary. Several categories have been presented to classify these approaches and a well-known classification is presented in [4]. This classification must be updated with new concepts and represent new challenges and future work which should be taken into consideration. This work is done by SARF framework.

In our viewpoint, human activity recognition methods can be categorized into three approaches including Bottom-Up, Top-Down and Hybrid approaches which are summarized in Fig. 5. Each of these approaches considers activity recognition intelligible from different perspectives. In this section, the SARF proposed framework will be analyzed.

A. Bottom-Up Approaches

In Bottom-Up activity recognition methods, a learning activity model uses a large collection of user behavior data obtained by the sensor through data mining and machine learning techniques and try to recognize performed activities [24]. These methods can be divided into three categories: Probability-based, Similarity-based and Integration-based methods.

1) Probability-based Methods: These methods improve the generalization ability by modeling the underlying distribution of classes from the obtained feature space [25]. These methods are flexible, since they learn the structure and relationship between the classes by exploiting prior knowledge for a given task such as Markov assumptions, prior distributions and probabilistic reasoning, although the parameters are not optimized [4][26].

An example of a Probability-based approach is to use Nave Bayes [23] classifier that estimates the parameters distribution based on the independence assumption. Let I_{js} which is an activity instances is assigned to the class A_s for which it has maximum posterior probability given by (1) in accordance Bayes Theorem. Each I_{js} observed by R sensors and represented by feature set $F_{js} = \{f_{js}^r\}_{r=1}^R$

$$p(A_s|I_{js}) > p(A_m|I_{js}) \; \forall m.s.t.1 \geq m \leq S, \quad s \neq j \qquad (1)$$

The classifier resulting from the assumption mentioned before is known as the Nave Bayes classifier given by (2).

$$p(A_s|I_{js}) = \prod_{r=1}^{R} p\left(f_{js}^r|A_s\right) \qquad (2)$$

Where $p(A_s|I_{js})$ is the product of the values of features $\{f_{js}^r\}_{r=1}^R$ of an activity instance I_{js} for a given class A_s [27].

2) Similarity-based Methods: The Similarity-based approaches when training data size is large enough, lead to higher efficiency in generalization [25]. However, these methods may suffer from over-fitting, thus making recognition models inconsistent [26]. In these methods, it is important to define the similarity measurement in order to perform patterns selection. Many approaches have been proposed to calculate the distance between different sequences, and one of the most commonly used methods is the edit distance [17].

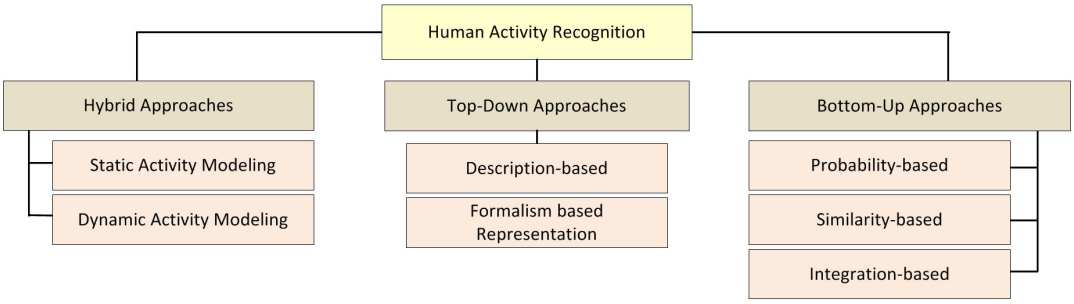

Fig. 5. The SARF proposed framework to analyze various approaches to human activity recognition

Accordingly, the similarity function between two patterns (X,Y) is defined as in (3).

$$Similarity(X,Y) = 1 - \left(\frac{e(X,Y)}{\max(|X|,|Y|)}\right) \tag{3}$$

Where $e(X,Y)$ is the number of edits required to transform an event sequence X into event sequence Y [8].

3) Integration-based Methods: Classification performance and accuracy can often be improved by combining multiple models together, instead of using a single model [28]. This is the basic idea of introducing integration based methods.

In some studies ensembles models are used in human activity recognition in smart homes such as what is done in [29]. Hence, a combination of the models, such as a voting strategy, a simple average among the models [1] and Genetic Algorithm [30] used to combine fusion weight selection of classifier within ensembles, which will decide the winning label for a particular data point and optimizing the output of multiple classifiers.

On the other hand, some studies proposed an activity recognition approach that integrates Probability-based with Similarity-based methods. For example, Fahad and Rajarajan in [28] to improve the reliability of recognitions, integrates the distance minimization and probability estimation approaches. Fig. 6 represents the Block diagram of the proposed activity recognition approach in [28].

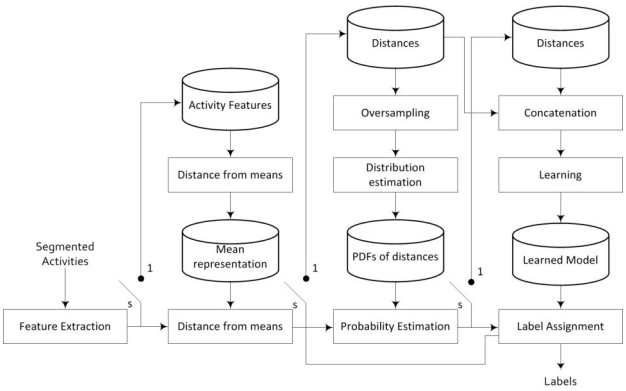

Fig. 6. Block diagram of the proposed activity recognition approach in [28]. Switch s = 1 is training.

B. Top-Down Approaches

In Top-Down activity recognition approaches activity models exploit rich prior knowledge to construct activity models directly using knowledge engineering and management technologies. This usually involves knowledge acquisition, formal modeling, and representation [4]. These methods can be divided into two categories: Description-based Activity Modeling and Formalism-based Representation Methods.

1) Description-based Activity Modeling: The Description-based activity modeling represented activity as an object and models activities as a hierarchy of classes where each class can be described by a number of properties so these approaches including a set of representational concepts [4][31]. The generated activity models are able to capture built-in interrelations between objects and activities such as proposed method in [32]. For example, to detect activity "clean up" which is a complex activity, recognition in the form of the simpler components carried out and the following axioms represented in (4) and (5) are added to the knowledge base [31].

$$CLEANUP \sqsubseteq COMPLEXACTIVITY \sqcap \forall HASACTOR.(PERSON \sqcap \exists HASSIMPLEACTIVITY.PUTINDISHWASHER) \tag{4}$$

$$CLEANUP \sqsubseteq COMPLEXACTIVITY \sqcap \forall HASACTOR.(PERSON \sqcap \exists HASSIMPLEACTIVITY.CLEANTABLE) \tag{5}$$

2) Formalism-based Representation Methods: These methods views an activity as a knowledge model that can be formally specified using various logical formalisms. Activity models generated in these methods are normally used for activity recognition or prediction through formal logical reasoning, e.g., deduction, induction, or abduction [4].

Bouchard, Giroux, and Bouzouane in [33] proposed a formal framework for the recognition process based on lattice theory and action Description Logic (DL). This framework minimizes the uncertainty about observed actors activity by bounding the plausible plans set.

C. Hybrid Approaches

The objective of these kinds of approaches is taking advantage of the features of both Bottom-Up and Top-Down modeling and fusing them in a single modeling approach [24]. Modeling ADLs is a challenging task due to their unique characteristics. For example, there are a large number of ADLs in a variety of categories which can all be modeled at multiple levels of granularity [3]. In addition, most ADLs involve performing a number of actions. The sequence of the actions to be performed is usually dependent on an individuals own preferences [34]. As mentioned before, some actions for different activities may occur together and make overlapped or interleave activities [1][4]. Thus the ideas of using Hybrid approaches have been introduced, which can be divided into two categories: Static Activity Modeling and Dynamic Activity Modeling.

1) Static Activity Modeling: The static activity modeling systems cannot automatically be adapted to accommodate new features in activities performed by the user [35]. Also Top-Down approaches are static and they cannot automatically evolve [24] such as the proposed method in [32]. Some Integration-based Bottom-Up approaches only used to model static characteristics of activities. Dynamic Activity Modeling exposed to discussion due to the modeling dynamic nature of human activities.

2) Dynamic Activity Modeling: The idea of using dynamic modeling is based on the dense sensing paradigm, which establishes the idea of inferring activities by monitoring Human-Object Interactions (HOI) through the usage of multiple multimodal miniaturized sensors [4][24]. Actually in these kinds of modeling want to model high-level activities usually share common sets of physical actions, and are difficult to differentiate based solely on physical signals [36]. To make Top-Down activity recognition systems work in real world applications, activity models have to evolve automatically to adapt to users varying behaviors. The Bottom-Up approaches can be properly addressed to model adaptability and evolution [24]. The goal of this kind of modeling is represented in Fig. 7 as an example.

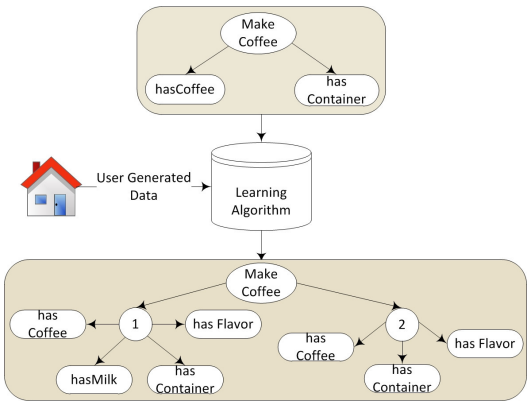

Fig. 7. Dynamic Activity Modeling objective [24]

V. Evaluation of SARF Framework

Due to a wide variety of approaches in human activity recognition, these approaches are classified as SARF framework. Table III represents each of the approaches in this proposed framework according to their characteristics and challenges as a general classification.

Particularly, it is essential to introduce specific measures to evaluate and compare these approaches accurately. The goal of evaluation is analyzing the effects of proposed approaches in human activity recognition and ensure of algorithm performance. Utilizing appropriate measures can lead to well understanding of different approaches for activity recognition in smart homes and also take advantages of them in a systematic and correct way based on the requirements.

A. Proposed Measures

There are different ways to evaluate activity recognition algorithm but generally authors use classifier-based criterias such as F-measure, Precision, Recall and most importantly Accuracy [9][37], and also Sensitivity and Specificity to ignore detailed information about the errors [25] or frameworks such as N-Fold cross validation [37] and Leave-one-day-out [25].

Basically, human activity recognition process has two overall phases: Training and Test. In N-Fold cross validation, the set of data points is split into N non-overlapping subsets. The model is trained and tested N times, on each iteration, one of the N partitions is held out for model testing and the other N-1 partitions are used to train [37]. The performance is averaged over the N iterations. In Leave-one-day-out technique the sensor readings of a whole day are used for testing and the remaining days used for training [38].

In our viewpoint along with other mentioned evaluation measures, there are some important criteria which should be taken into consideration by researchers. Thus, in this section along with Accuracy, as an important measure, these evaluation measures have been proposed.

Data Requirements: In some approaches, due to the needs of large volume of data to support training for each ADL, there is a possibility to face data scarcity which may lead to accuracy and performance reduction [4]. This issue will be increased in the assisted living context which residents are reluctant to reveal their behavioral data due to privacy and ethical considerations [34]. In Top-Down methods there is no data scarcity problem unlike Bottom-Up approaches. Therefore, volume of required data and its importance for human activity recognition in AAL systems such as smart homes must be considered by researchers.

Noise Effect: In general, sensory data are inherently noisy and has untrustworthy nature which leads to lack of reliability in the Bottom-Up, Top-Down and Hybrid approaches [29][31]. As mentioned before, there is possibility of noise existence in annotation process too and lead to accuracy reduction, increase computational complexity and classification error in activity recognition unless some actions such as what is done in [24] using hybrid approaches have been considered.

TABLE III
COMPARISON OF SARF APPROACHES

Activity Learning Approaches		Learning Examples	Main Idea	Characteristics	Challenges
Bottom-UP	Probability-based Methods	Hidden Markov Model[9], Nave Bayes[23]	Probabilistic Classification	Modeling uncertainty and temporal information Generalization Flexibility Dynamic activity modeling	Data scarcity problem Reusability Handling temporal information Dataset annotation
	Similarity-based Methods	Rashidi[8], Conditional Random Field[9], Support Vector Machine[21]	Define the similarity measurement in order to perform patterns selection	Simple and dynamic activity modeling Modeling uncertainty and temporal information Heuristic	Data scarcity problem Reusability Dataset annotation Over-fitting
	Integration-based Methods	Fahad[28], Fahim[29], Chernbumroong[30]	Integration of Similarity or Probability-based methods, or combination of both of these methods	Accuracy Reliability Generalization Efficient Reduce uncertainty in decision making Allow to recognize complex activity	The data scarcity problem Dataset annotation Number and types of classifiers Combination techniques
Top-Down	Description-based Activity Modeling Methods	Zolfaghari[31], Chen[32], Chen[34]	Using semantic and context reasoning to describe concepts and relationships, in a high-level and formal expressiveness	Lack of the data scarcity problem Clear semantic on modeling and inference Interoperability and reusability Preserve decidability Allow to recognize complex activity	Handling uncertainty and ambiguity information Handling temporal information Adaptability Scalability Static activity modeling
	Formalism-based Representation Methods	Bouchard[33]	Logical formalisms inference e.g. deduction, induction, abduction	Lack of the data scarcity problem Clear semantic on modeling and inference	Handling fuzziness and uncertainty information Adaptability Scalability Static activity modeling Flexibility
Hybrid	Static Activity Modeling	Chen[32], Bouchard[33]	Using Probability-based or Similarity-based methods and fusion them with one of Top-Down approaches	Using multiple data sources Accuracy Reliability Allow to recognize complex activity	Limited to initially defined activities Adaptability Performance
	Dynamic Activity Modeling	Azkune[24], Okeyo[35], Wen[36]	Using Probability-based or Similarity-based methods and fusion them with one of Top-Down approaches	Using multiple data sources Adaptability Reusability Allow to recognize complex activity	Common terminology Interoperability Limited to descriptive characteristics Limited to user preferences and implementation tools

Accuracy: Accuracy is the most common criteria in classifier performance analysis and human activity recognition. It should be noted, noise, class-imbalanced datasets and datasets with inappropriate features lead to accuracy reduction [1][7][13]. Higher accuracy of methods leads to error reduction and increase efficiency [16].

Scalability: In general, human activity recognition systems are performing on a particular or public datasets or considering limitation conditions. In fact, the main problem is the needs to real world data which make them inapplicable in other environments with different settings [14]. Furthermore, most of the built models are used for a specific ADL and do not change over time. Also, they do not consider ADL patterns may change due to the dynamic nature of human activities which lead to inconsistency and scalability reduction in built model. In fact, scalability in activity models is an important factor in presence of new activities and new residents in order to constructing a general model for all activities [14], new residents or transfer learning to environment with different layouts [39].

B. Evaluation of Methods According to Proposed Measures

In this section efficiency of human activity recognition approaches classified as proposed SARF framework shown in Fig. 5 is evaluated by proposed measures formerly. Table IV shows the results of this evaluation. It should be noted the values of proposed measures are relative and they are based on research investigation in this field.

As represented in Table IV, due to the Data-Driven nature of Bottom-Up approaches, they require large volume of data to make recognition unlike Top-Down approaches which utilizing prior knowledge and knowledge engineering to human activity recognition in smart homes; therefore, they need to sensory data as lower as other approaches as well as effects of noise on them. On the other hand, there are Hybrid approaches which using Bottom-Up and Top-Down methods all together

TABLE IV
EVALUATION OF PROPOSED SARF FRAMEWORK BASED ON PROPOSED MEASURES

The Proposed SARF Framework		Proposed Evaluation Measures			
		Data Requirement	**Noise Effects**	**Accuracy**	**Scalability**
Bottom-Up	Probability-based Methods	High	High	Medium	Almost Medium
	Similarity-based Methods	High	High	Medium	Almost Medium
	Integration-based Methods	High	Medium	Almost High	Almost Medium
Top-Down	Description-based Activity Modeling	Low	Low	Medium	Almost Medium
	Formalism-based Representation Methods	Low	Low	Medium	Low
Hybrid	Static Activity Modeling	Medium	Medium	Almost High	Medium
	Dynamic Activity Modeling	Medium	Medium	Medium	High

to achieve acceptable scalability along with adaptability to dynamic nature of human behavior especially in dynamic activity modeling. Therefore, in these kinds of approaches we face to sensor data requirement as well as noise effect but not as much as Bottom-Up approaches.

As mentioned in proposed SARF framework, combining multiple methods together can improve accuracy of human activity recognition in smart homes as well as using Hybrid approaches especially static activity modeling due to its static assumption. Furthermore, there is data requirement in Integration-based methods due to its Bottom-Up nature. Also, inherently noisy sensory data can lead to accuracy reduction in these methods. However, the most effective way to reduce noise impacts, as mentioned in preprocessing phase, is cleaning, completing and normalizing. As represented in Table IV, the other approaches can achieve medium and almost acceptable accuracy in human activity recognition in smart homes.

VI. CONCLUSION

In this paper different approaches to human activity recognition in smart homes investigated and described how to evaluate these approaches were classified and presented in the proposed framework, i.e. SARF, using the obtained results. In order to provide a convenient tool for selecting appropriate approaches, results presented in the form of diagrams and characteristics of each group were investigated and evaluate based on proposed measures represented in form of tables.

The results of this study show that there is no unique way to introduce a single approach, as an optimal approach, to human activity recognition in AAL systems. Since each approach is used for a specific purpose comparing the approaches does not make any sense. One of the most important issues in human activity recognition is to remove the challenges and improve the efficiency of algorithms which is a dynamic research domain warranting further investigation. Using the SARF proposed framework in this paper can play an important role in development of our knowledge in this area and a starting point to resolve some of the challenges which were outlined in this paper.

Joint Agent-oriented Workshops in Synergy

JOINT Agent-oriented Workshops in Synergy is a coalition of agent-oriented workshops that come together to build upon synergies of interests and aim at bringing together researchers from the agent community for lively discussions and exchange of ideas. For the first time JAWS was organized during the 2011 FedCSIS Conference. Workshops that constitute JAWS in 2016 are:

- MAS&S'16 - 10^{th} International Workshop on Multi-Agent Systems and Simulations
- SEN-MAS'16 - 4^{th} International Workshop on Smart Energy Networks & Multi-Agent Systems

10^{th} International Workshop on Multi-Agent Systems and Simulations

MULTI-AGENT systems (MASs) provide powerful models for representing both real-world systems and applications with an appropriate degree of complexity and dynamics. Several research and industrial experiences have already shown that the use of MASs offers advantages in a wide range of application domains (e.g. financial, economic, social, logistic, chemical, engineering). When MASs represent software applications to be effectively delivered, they need to be validated and evaluated before their deployment and execution, thus methodologies that support validation and evaluation through simulation of the MAS under development are highly required. In other emerging areas (e.g. ACE, ACF), MASs are designed for representing systems at different levels of complexity through the use of autonomous, goal-driven and interacting entities organized into societies which exhibit emergent properties The agent-based model of a system can then be executed to simulate the behavior of the complete system so that knowledge of the behaviors of the entities (micro-level) produce an understanding of the overall outcome at the system-level (macro-level). In both cases (MASs as software applications and MASs as models for the analysis of complex systems), simulation plays a crucial role that needs to be further investigated.

TOPICS

MAS&S'16 aims at providing a forum for discussing recent advances in Engineering Complex Systems by exploiting Agent-Based Modeling and Simulation. In particular, the areas of interest are the following (although this list should not be considered as exclusive):

- Agent-based simulation techniques and methodologies
- Discrete-event simulation of Multi-Agent Systems
- Simulation as validation tool for the development process of MAS
- Agent-oriented methodologies incorporating simulation tools
- MAS simulation driven by formal models
- MAS simulation toolkits and frameworks
- Testing vs. simulation of MAS
- Industrial case studies based on MAS and simulation/testing
- Agent-based Modeling and Simulation (ABMS)
- Agent Computational Economics (ACE)
- Agent Computational Finance (ACF)
- Agent-based simulation of networked systems
- Scalability in agent-based simulation

***Abstract*—Internet of Things (IoT) networks are being continually developed in several domains, however no systematic processes for their modeling and simulation exist so far. In this paper, an agent-oriented approach to IoT networks modeling is proposed by exploiting the ACOSO model. Then, agent-modelled IoT networks of different scales are simulated through the Omnet++ simulation platform, with the goal of analyzing issues and bottlenecks at communication level.**

I. Introduction

SMART Objects (SOs) constitute a new generation of enhanced everyday things (able to perceive the surrounding physical environment, elaborate and communicate the acquired information, and hence provide cyber-physical services) that are globally networked and mutually interacting, even without a steady human orchestration [1]. SOs are technologically and functionally heterogeneous, thus their clustering constitutes "Internet of Things" (IoT) networks [2] that look like loose collections of heterogeneous devices and sub-networks requiring distributed mechanisms of communication and management. Whereas defining methods to model, design and simulate IoT networks before their final implementation is an open challenge, no research efforts have currently been devoted to systematically address such issue.

As IoT networks share many substantial features/issues with multi-agent systems (MAS) [3] and SOs may be effectively modeled as agents, in this paper an agent-oriented approach to model IoT networks is presented. In particular, the ACOSO (Agent-based Cooperative Smart Object)-based SO model [4] has been exploited to describe, from the agent perspective, SO main features, relationships and interactions. Moreover, in order to analyze IoT networks at SO communication level, the Omnet++ [5] network simulation platform has been used to evaluate bottlenecks and issues in specifically defined scenarios. The rest of the paper is organized as follows: in Section II, the ACOSO-based SO model and other concrete examples of the Agent-oriented Modeling (AoM) applied to the SO-based IoT context are introduced and compared. In Section III, the designed simulation scenarios, the selected metrics, and the obtained results are presented and discussed. Finally, conclusions are drawn and future work is briefly delineated.

This work has been partially carried out under the framework of INTER-IoT, Research and Innovation action - Horizon 2020 European Project, Grant Agreement #687283, financed by the European Union.

II. Agent-oriented Modeling

Agent-based Computing paradigm has been successfully used over the years for the analysis, modeling and implementation of complex, cooperative and adaptive distributed systems [3]. The *agent* abstraction, indeed, is suitable to model and implement autonomous, intelligent and interacting entities, characterized by different behaviors and goals. Nevertheless is well-established that the AoM [6], differently to other modeling paradigms (e.g. object-oriented, service-oriented, etc.) is able to fully support proactiveness and situatedness, key features in SO-based IoT networks, to date few agent-oriented models are available in the literature in this context.

With reference to the agent-oriented SO modeling, [7] and [8] present coarse-grained models, characterized by a high degree of abstraction and therefore mostly suitable to support the SO analysis phase; the ACOSO-based SO model [4], instead, specializes the SO ecosystem in a deeper degree of detail, thus supporting also the SO design and implementation phases. In detail, in [7] the authors envision an IoT system architecture where each resource (e.g. computer, SO, human user) is represented by an agent and interconnected to the rest of the cyber-physical world by means of specific adapters. Each agent has a role (and not an identifier) that determines its own behaviors, tasks and communication paradigms. Both roles and behaviors are taken from two repositories which are assumed to be managed depending on the application scenario. In [8] the SO model comprises five elements: the execution environment (to run the actual agent task and manage its lifecycle), a repository (which contains both database and knowledge base), a set of physical components (such as sensors and actuators), the agent interface (to enable the intra-agent information exchanges among the aforementioned SO-model elements) and the object interface (for communication with other SOs and with the system).

The ACOSO-based SO model allows the modeling of high-level SO main features (basic information of an SO, its augmentation devices like sensors and actuators, its services, etc.) and it also extensively describes the functional components of the system, their relationships and interactions. Due to such reasons, the ACOSO-based SO model represents one of the cornerstones of ACOSO (Agent-based Cooperative Smart Object) [9], a middleware specifically conceived for the full management and development of agent-oriented cooperating SOs. In detail, the ACOSO-based SO model abstracts SOs in event-driven cooperating agents whose specific objectives are encapsulated in their behavior and modeled as *Tasks*. A Task is an event-driven and state-based component that can refer to the common operations required for the agent lifecycle management (SystemTask) or to specific-purpose operations defining the specific behaviors of the SO (UserDefinedTask). Indeed, SO services are mapped on UserDefinedTask. By means of different tasks the SO exploits different subsystems in order to react to external stimulus, to fulfill specific goals and to exploit inference rules on local/remote knowledge bases. In particular:

- The *DeviceManagementSystem*, through multiple DeviceAdapters, handles the SO augmentation devices that enables SO to interact with the physical world generating Device Events. In particular, the BMFAdapter [10] and the SPINEAdapter [11-13] enable the management of environmental and wearable sensor networks.
- The *CommunicationManagementSystem* provides communication services between agents and external entities. Different kinds of interactions (e.g. intra-agent FIPA-ACL based interactions or inter-entities UDP/TCP-based interactions) are enabled by means of different CommunicationAdapters. Both events generated inside (InternalEvent) or outside (ExternalEvent) the SO are handled by the CommunicationManagementSystem.
- The *KBManagementSystem* exploits local or remote knowledge bases to handle information pertaining the SO, its current status, its inference rules and other useful data that can be shared among the agent tasks.

TABLE I
AGENT-BASED SO MODELS COMPARISON

Agent-based SO Modelling	**[7]**	**[8]**	**ACOSO-based SO model [4]**
SO-Modeling Phase / *SO Characteristic*	Analysis	Analysis	Analysis & Design & Implementation
Augmentation Devices	Adapter	Physical Components	DeviceManagementSystem (DeviceAdapter)
Communication	Role	Int./Ext. Agent Interface	CommunicationManagementSystem (CommunicationAdapter)
Decision-Making	Role	Execution Environment	Set of Task (Agent-Behavior)
Service Provisioning	N/A	N/A	UserDefinedTask, Event
Knowledge	Role	Repository	KBManagementSystem, Behavior

A. Comparison

Table I shows a comparison of the three agent-oriented SO models introduced in this Section. First of all, it has been highlighted that they are suitable in different modeling phases. Indeed, [7] and [8] are mostly suitable to approach the SO analysis phase while the ACOSO-based model support also design and implementation phases. This implies that the three models describe the main SO characteristics (augmentation, communication, decision-making, service provisioning and knowledge) with a different degree of detail. In particular:

- *Augmentation Devices*: in SO models of [7] and [8] sensors and actuators are not explicitly modeled as they are considered minor SO components and their interactions are not elicited. In the ACOSO-based SO model augmentation devices are managed by the DeviceManagementSystem and handled by multiple DeviceAdapters.
- *Communication*: in [7] the SO role determines its communication paradigm and structure, while in [8] internal/external SO communication interfaces are defined. In the ACOSO-based SO model communication is managed through the CommunicationManagementSystem and a set of CommunicationAdapters.
- *Decision-Making*: in [7] an SO/agent autonomously behaves to achieve certain goals depending on its role in the domain (e.g. smart car, smart driver-support or smart road within the smart transportation domain), while in [8] task execution concerns the Execution Environment. Decision-making relies on the agent behaviors in ACOSO-based SO model, defined through tasks.
- *Service Provisioning*: in [7] and [8] the concept of SO cyber-physical service is not completely declined and is mostly reduced to a simple Web Service. In the ACOSO-based SO model services are mapped on UserDefinedTasks (enabled by specific events).
- *Knowledge Base*: in [7] the SO knowledge is stored in repository organized in function of the SO role, while in [8] relational databases record SO-related information. In the ACOSO-based SO model the information is spread between the KBManagementSystem and the agent behavior.

III. Simulation-based Analysis

As highlighted in the previous Section, the ACOSO-based SO model, leveraging on both the agent and MAS concepts, enables the effective modeling of SO-based IoT networks at different development phases. In this Section, the simulation of IoT networks allowing the validation of models, protocols and algorithms before the actual deployment of the network infrastructure, is addressed. Indeed, IoT networks simulation is an important but complex task because, depending of different scales, the number of the SOs may vary from dozens (e.g. home automation or body sensor networks) to thousands (e.g. Smart City scenario), with a different degree of density and different communication paradigms depending on the specific service. In addition, factors unrelated to the applications but specifically associated to the networking (e.g. traffic congestion, wireless signal attenuation and coverage, etc.) influence the SOs interactions and the service provision/fruition. Taking into account these issues and particularly focusing on communication among SOs, the IoT networks previously described through the agent-oriented approach are simulated by means of Omnet++ [5]. The modeling of an agent through an Omnet++ network node is straightforward. In fact, each network node/SO can be considered as an autonomous agent whose behaviors and tasks, which realize SO decision making and service provisioning (see Table I), are implemented at the application layer. All the other tasks related to transport-network-link protocol implementations, wireless connectivity issues, physical environment modeling are carried out by Omnet++.

In particular, Omnet++ makes it possible to design nodes with different communication boards or interface ports (to simulate the connection with external physical devices); in the following simulations, due to the intrinsic wireless nature of the IoT networks, nodes with 802.11 wireless boards have been considered.

Simulations have inspected IoT networks in the Information Exchange phase (IE) by exploiting TCP-based reliable and UDP-based unreliable transport protocols. The round trip time (RTT) and the packet delivery ratio (PDR) have been hence measured considering nodes that exchange empty messages and exploiting either a Client/Server (C/S) or a Peer-to-Peer (P2P) paradigm. Deterministic (1 pk/s) and stochastic Normal (with 0.5 mean and 0.2 variance) data generation models (DGM) have been used. In Table II the communication settings exploited in the simulations for the RTT/PDR measuring are shown.

Table II
Information Exchange (IE) Settings

Parameters	DGM (Data Generation Model)
Patterns	P2P (Peer-to-Peer), C/S (Client/Server)
Protocols	R (Reliable), U (Unreliable)

Both RTT and PDR have been evaluated in the context of small-, medium-, large-scale IoT networks with different SOs density. In particular, simulations took into account:

- The number of involved SOs (#SOs), since network congestion may increase depending of the SOs population. In the following SOs population is considered limited to 100 nodes for small-scale networks, 500 nodes for medium-scale networks and 1000 nodes for large-scale networks;
- SO distribution in a different number of subnetworks (#subnetworks). In the following it is assumed that small-scale networks are constituted by a single network, medium-scale networks comprise two or more subnetworks deployed in the same area so that their coverages overlap, and finally large-scale networks comprise two or more subnetworks deployed in not adjacent area;
- The deployment area in which SOs are located (supposing that they have no mobility patterns) since the proximity of multiple SOs may cause signal interferences in the wireless communications. For sake of simplicity, square grid areas with different side dimensions have been considered.

Table III summarizes the scenarios tested during the simulation phase.

Table III
Simulation Scenarios

	#SOs	**# subnetworks**	**Grid side [m]**
Small Scale (S)	5..100	1	5..100
Medium Scale (M)	20..500	1..10	From 100
Large Scale (L)	20..1000	1..20	From 100

In the following, for the sake of space, only some results of the simulations are shown, and in particular the PDR in the case of small-scale networks with #SOs increasing (see Fig. 1) and the RTT in the other two scales with #subnetworks increasing (see Fig. 2 and 3).

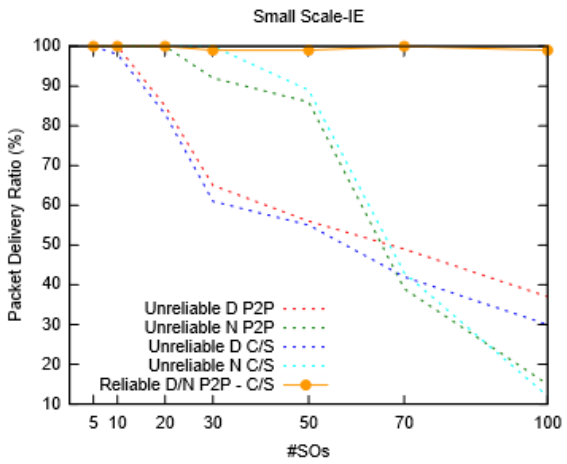

Figure 1: PDR when the #SOs increases in a square grid of side 100 m

Fig. 1, in the case of unreliable protocol shows that (i) with increasing of SOs, PDR decrease due to communication fails caused by interferences; (ii) with the same DGM, C/S and P2P patterns are equivalent; (iii) with a small number of SOs (less than 70) non-deterministic data generation models

outperform the deterministic ones, while with the increase of SOs the trend inverts. In the case of reliable protocol, as might be expected, the PDR keeps the maximum value regardless of the DGM, patterns, and #SOs.

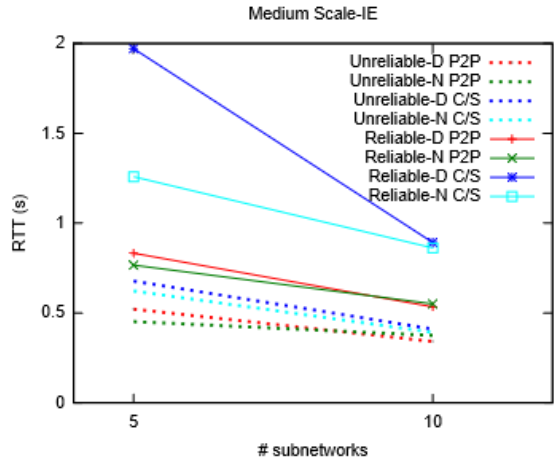

Fig. 2: RTT of 500 SOs equally distributed into 5 and 10 subnetworks

Fig. 2 shows that the RTT decreases if the same number of SOs (500) is deployed on the same area but distributed on more subnetworks (5 and 10 square grids of side 100 m), since the traffic is well-balanced. As might be expected, the unreliable protocols outperform the reliable ones.

Fig. 3 shows that in the large-scale scenario (5, 10 and 20 subnetworks deployed in a squared area of side 100m with 50 SOs each) the absence of interferences among the subnetworks generates RTT values quite stable and lower than the correspondent ones in the medium-scale scenario.

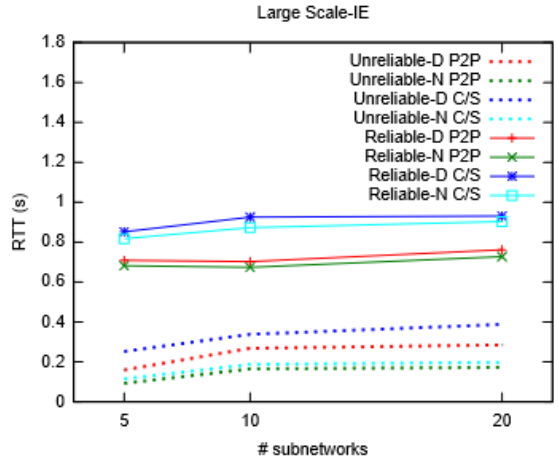

Fig. 3: RTT of 5,10 and 20 subnetworks of 50 SOs each

IV. Conclusion

In this paper the agent-oriented modeling of SO systems through the ACOSO-based SO model has been presented, by considering that (i) SOs and software agents share multiple features, and (ii) agent-based modeling flexibly assists the conceptualizing of dynamic and autonomous distributed systems in different contexts. Beside the agent-oriented SO modeling, IoT networks of different scales have been simulated through the Omnet++ simulator, with a particular attention to the SO communication in order to evaluate performances (focusing on bottlenecks, issues and networks dynamics) and validate network design choices. Simulation results highlight that multiple factors influence the network performance (as the SO number, their more or less dense distribution and the selected communication settings) and thus their combination should be made by following an application-driven approach.

Further research efforts will be devoted to (i) provide a full mapping between ACOSO-based SO model and Omnet++ simulation, in order to translate on such simulator the behavioral/application side of the SO systems, including also the simulation of the device layer; (ii) develop a full-fledged methodology for the analysis, design, simulation, implementation and validation of SO-based IoT systems [14, 15].

***Abstract*—Agent-based modelling is becoming widely used for studies in Social Sciences. However, its application faces limitations coming from its bias to software development, which precludes a more active involvement of social researchers. In order to deal with this problem, this work proposes using domain-specific modelling languages based on the socio-psychological Activity Theory. These languages apply agent research to crystallize that theoretical framework in a formal definition suitable for automated processing but close to Social Sciences. The paper focuses on the language for the specification of group constructions such as organizations, norms and shared knowledge. A case study about contradictory decisions in the space shuttle program illustrates the discussion.**

I. Introduction

AGENT-BASED Modelling (ABM) [1] has become a mainstream technique for research in Social Sciences. Traditionally, this research requires the gathering of data over potentially long periods of time and about large populations that are not fully controlled, which largely increases its costs. The formal description of social systems with models [2] allows applying analysis techniques based on simulation and verification, reducing the needs of eliciting data for the initial testing of hypotheses. ABM facilitates modelling by providing social and intentional computational abstractions that are closer to the concepts used in this research field than those of other approaches.

Despite of its advantages, ABM is limited by its inherent development complexity. The design, implementation and use of an archetypical agent-based model involve different subtasks and roles, which need diverse backgrounds and competences [3]. This situation may lead to misunderstandings between the different stakeholders, which make it hard to guarantee that the model really corresponds to the initial requirements of social science researchers [4]. Available methodologies to develop such ABM models [3], [5], [6] offer little help to address this problem. They focus on the researchers' conceptual models and describe very general tasks for the development. Agent-Oriented Software Engineering (AOSE) also seems not to be a suitable solution, since it mostly deals with the development of standard Multi-Agent Systems (MAS) [7]. On the contrary, ABM focuses more on the translation of the conceptual models of social science researchers to computational models using agent abstractions [5]. Besides, MAS are usually tied to certain architectural patterns, while ABM deals with an enormous heterogeneity of structures [1]. There are also differences about implementation. ABM applications usually require centralized monitoring components that can access the internals of agents in order to gather analysis data [8], and sacrifice the individual agent complexity in favour of huge populations [4]. These aspects are often not considered by AOSE methodologies [7].

Model-Driven Engineering (MDE) [9] with Domain-Specific Languages (DSL) [10] has been proposed as a way to overcome some of these limitations [11], [12]. A DSL for ABM uses a vocabulary grounded on conceptual frameworks from Social Sciences. The DSL has a formal definition which enables the use of automated MDE techniques to process its models, for instance to generate the code for simulations. Such approach reduces the impact of misunderstandings in ABM in two ways. First, social science researchers are able to perform the modelling themselves using a language they are familiar with. Second, transformations from conceptual models to computational ones can be generalized and reused in different projects. This offers improved opportunities for verification and validation. There are some preliminary examples of this trend, but they are still too biased to their foundations in software development [12] or only present partial solutions for some modelling aspects [11]. Especially issues like the management of large populations or centralized supervision are still open.

This paper introduces a DSL for modelling social constructs and organizational interactions. It is part of the ATCAS (Activity Theory for the Computational Analysis of Societies) framework. The Activity Theory (AT) [13] is a well-known paradigm for the analysis of human groups. It focuses on the study of *activities*, which are interactive acts between people and their physical and socio-cultural environment, where both of them act on and mould the other at the same time. ATCAS is intended to provide a general and extensible basis for ABM in social research supporting different applications. The actual representation of AT concepts in ATCAS depends on agent concepts, for instance about inconsistency management [14], code generation [12] and organizational interactions [15]. This last aspect is the focus of the current paper.

From the AT perspective [16], the social aspect of groups regards **communities** of subjects engaged in shared activities. The norms of the *division of labour* organize these activities and *rules* emerging from the socio-cultural environment influ-

978-83-60810-90-3/$25.00

ence and constraint both communities and activities. AT works at the level of abstraction of human societies but the automated analysis of models in MDE requires formalizing them as computational abstractions. ATCAS-IL adopts for this purpose the OperA [15] framework for the specification and analysis of agent organizations. OperA provides predefined modelling primitives for the high-level specification of organizations and the Logic for Contract Representation (LCR), which is an extension of deontic temporal logic, for the fine-grained details. The choice of OperA is motivated by the fact that AT explicitly considers social features that are not embedded in individual agents, but apply to the society as a whole. ATCAS-IL extends OperA primitives with AT concepts and introduces a macro mechanism intended to tailor the language for the specific needs of social science researchers. This gradually increases their autonomy in modelling, as they can define their own abstractions.

The formal description of ATCAS-IL uses metamodels. This is a common technique for language definition in MDE [9] that facilitates language extension and evolution. MDE manipulates models (i.e. instances of metamodels) mainly using standard transformation languages. In this way, engineers do not need to devote effort to the low-level details of model processing, but just to define the transformations for the different purposes. In the case of ATCAS-IL, transformations consider the semantics of the DSL according to AT and agent research. These transformations generate code, for instance, for checking contradictions as [14] and simulation as [12]. This kind of approach has already been successfully tested in other domains [17].

The remainder of the paper further explains the elements in this introduction. Section II presents AT and the case study that guides the discussion in this paper. Section III provides a brief introduction to OperA. ATCAS-IL is introduced in section IV, and section V applies it to the analysis of the case study. Section VI compares the presented approach with existing ABM works. Finally, section VII discusses some conclusions about ATCAS-IL.

II. Activity Theory

The Activity Theory (AT) [13] is a socio-psychological paradigm for the study of human behaviour. It focuses on the mutual dialectics between people and their physical and social environment: the environment shapes human actions and their execution, and is also changed by these same actions. Hence, human acts cannot be analyzed independently of their context. These contextualized acts constitute the minimal meaningful unit of analysis and are called *activities*.

An *activity* [18] is a transformation process driven by people's needs. These needs are satisfied with an *outcome* produced transforming an *object*. Any element used in this process is a *tool*. The active component that carries out the activity is the *subject*. Subjects with a set of common social meanings constitute a *community* [16], which represents the socio-historical context of the activity. Two bodies of social constructions mediate the relationships of communities in the activity: *rules* with the subject and the *division of labour* with the object. Both of them contain similar elements, such as knowledge, implicit assumptions or norms. The key difference is the focus. The division of labour regards task specialization in the community through aspects such as power relationships, goal decomposition or the assignment of responsibilities. On the contrary, rules are guides and constraints not targeted specifically to the activity but affecting it, such as group beliefs, country laws or accepted scientific theories. The different elements can be both physical and mental, so AT considers both types of activities with a unifying analysis. All these elements make up the context of an activity, which is named its *activity system*. Its traditional depiction [16] appears in Fig. 1.

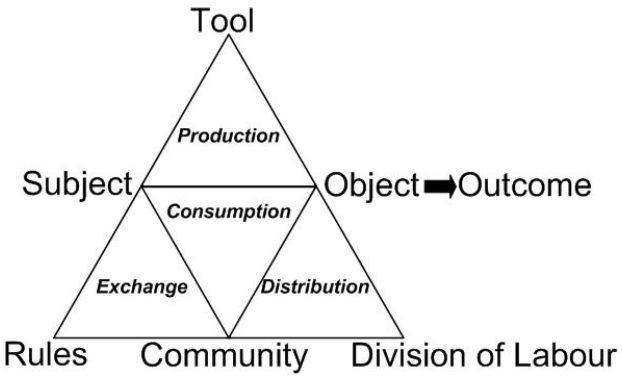

Fig. 1. AT depiction of an activity system.

Activity systems always exist in neighbourhoods of interconnected activity systems linked by shared elements. The execution of an activity produces outcomes that become the artefacts (e.g. subject, tool or rules) needed to execute other activities. Subjects carry out activities in these networks following their own rationality.

AT also considers the hierarchical decomposition of activities. *Activities* pursue high-level *objectives* that meet people needs. These activities are executed through sequences of *actions*, which try to achieve low-level *goals*. These goals do not satisfy by themselves any need, but they contribute or are part of higher-level goals. In their turn, actions are implemented through *operations* that depend on the specific state of the *environment*.

The evolution of activity systems over time depends on their inner *contradictions*. These contradictions are conflicts between the elements in the networks of activity systems, and they can appear both inter and intra systems. Subjects try to remove contradictions through the evolution of the involved activity systems, commonly generating new tensions that produce further evolution.

As an example of AT analysis, this paper considers the work in [19] about the Challenger crash. In 1986, the Challenger shuttle exploded shortly after launching. This accident has been frequently used as a case study about engineer ethics, communication and group thinking. According to Holt and

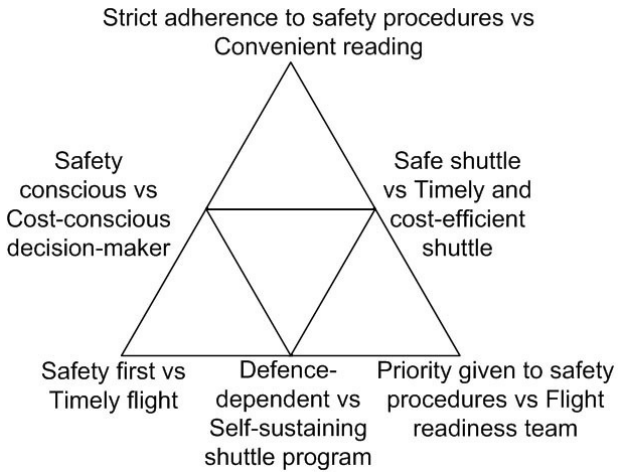

Fig. 2. Shuttle flight readiness activity system in the 1980s adapted from [19].

Morris [19], NASA began in the early 1960s as a tightly coupled set of subsystems aimed at space research and development. Over the 1980s, it became the home of several competing groups. At the same time, the lowering perceived value of the space research in public opinion put the agency under increasing pressure to cut down costs. NASA could not satisfy all its opposing goals, so a critical situation made it inevitable to violate some of them.

The analysis focuses on the readiness activity where the decision is taken to launch the shuttle or not. It discusses how the inner contradictions present in the NASA's organization culture at the end of the 1980s led to the catastrophe, how these contradictions generated the new and culturally more advanced activities in today's organization, and the still existing contradictions in the current forms of activities. Though the case is inevitably simplified, it synthesizes several complex settings and lengthy sources of information. For instance, the report of the Presidential Commission about the accident comprehends 5 volumes of documentation and analysis[1].

Fig. 2 depicts the readiness activity system. The nodes of the triangle show the opposition between the two perspectives about the NASA. The initial NASA from the time of the Cold War had priorities focused on research and safety, and almost unbounded resources. The new cost-aware agency competes with other agencies all over the world for the launching of satellites. The roots of this conflict appear in the object, which is the launching of a shuttle. It opposes the *safe shuttle* need to the *timely and cost-efficient shuttle* need. This opposition permeates all the other elements in the activity system. For the *subject*, it opposes the safety and the cost consciousness of the decision maker. The tools include information, devices and procedures supporting the activity. In this case, they are focused on the safety procedures, confronting a strict adherence to them with a convenient reading, which is only concerned about critical errors and relies on the low probability of certain failures. The social context of the activity shows this same duality. The community includes the NASA *defence-dependent* with high funding of the Cold War, and the one of decreasing funding in the 1980s aimed at getting a *self-sustaining shuttle program*. The division of labour regards work organization. In this case, it defines the acceptable tradeoffs between prioritizing security and the *flight readiness team*. These norms emerge from a wider context of rules where NASA was pushed to have successful and cost-effective *timely flights* more than to guarantee *safety first* beyond any reasonable risk.

These intra-node tensions scale up to contradictions between nodes. When the decision-maker needed to decide about launching, he/she was confronted with the dual nature of its community, tool and rules. Whatever decision this engineer made, it could lead to failure in some of the objectives. This situation is known as a double-bind contradiction [20]. In it, the system trying to satisfy opposed goals is under growing pressure that it can only overcome through its evolution.

This paper uses this case study to illustrate the application of ATCAS-IL to model complex organizations and subsequently analyze particular features of them. Specifically, it shows how its formal specification method supports the automated identification and analysis of the inherent contradictions of the NASA organization.

III. The OperA framework

AT considers that the integrated analysis of the individual and social contexts of activities is key for their understanding. Thus, its formalization as a DSL needs to include and define precisely the behavioural aspects common to the artefacts present in both scopes. For this reason, we have chosen OperA as the basis for ATCAS-IL.

OperA [15] is a framework for the specification of agent organizations. It considers the requirements regarding the structure, norms and external behaviour of these organizations and their members. Being focused on specification, OperA makes no assumption about the internals of the agents implementing the organization, and represents interactions through landmark patterns. These provide abstract representations of families of protocols. As such, OperA specifications enable different actual instantiations. Three models specify its organizations.

The Organizational Model (OM) describes the organization requirements using as main concepts, roles and scenes. The definition of a role includes its objectives and their decomposition, the norms applicable to that role, and the rights or capabilities it has. Scenes describe interactions between roles. They specify the participant roles, the ordering of actions through landmarks, the norms governing the scenes, and the results of their execution. This description makes use of information about the domain and the general normative structure applicable in the system.

The Social Model (SM) specifies the activity of agents in the society. Agents are executable entities able to enact the OM roles. OperA establishes constraints on the behaviour of agents using social contracts, but not their implementation.

[1]http://history.nasa.gov/Shuttlebib/ch7.html

These contracts indicate under which conditions an agent will play a role, and are used, for instance, to describe the benefits that the agent obtains, additional constraints or potential plans.

Finally, the Interaction Model (IM) describes how agents enacting roles participate in the scenes. It specifies the actual execution of the scene through a sequence of actions and adds additional norms for it.

OperA uses the Logic for Contract Representation (LCR) for the specification of contracts and norms in agent organizations. As stated in the introduction, it is an extension of deontic temporal logic that includes the *stit* operator (i.e. an agent *sees to it that*), the temporal operators of the branching temporal logics, and several deontic operators (i.e. obligation, permission and prohibition). Its expressions can be linked to deadlines corresponding to events or observed situations.

The OperA framework includes a graphical tool, OperettA [21], an IDE built as a plug-in of Eclipse. OperettA has facilities for the visual specification of organizations, syntax checking based on the OperA metamodel, static analysis, (e.g. dependent roles have to have a social link) and normative verification (e.g. inconsistencies between objectives and norms).

The formal logical semantics of OperA form a basis for the formal verification of the new specification language ATCAS-IL, as the paper shows in the next section.

IV. ATCAS-IL

ATCAS-IL extends the underlying OperA framework in several aspects determined by three main requirements. The first one is the foundation of ATCAS-IL in AT. It makes activities the focus of the analysis, which takes in turn the environment becoming a first class citizen of the specifications. The second one is the aim of ATCAS-IL for social analysis through automated tools. This requires specifying not only the constraints for the behaviour of the organization, but also some aspects of the actual behaviour of its members. The last requirement is the need of providing support to deal with the complexity of the description of social systems. Since these specifications account for a wide variety of issues and individuals, the language has to provide mechanisms to work with them at different levels of abstraction.

An activity is an act contextualized by its activity system [18]. The activity system includes subjects using tools to transform objects into outcomes, in the context of communities that specify the division of labour and the general rules applicable to that activity. While subjects, communities, and rules and division of labour can be roughly approximated by roles/agents, groups of these, and norms respectively, there are no suitable OperA concepts to describe activities, objects and tools.

Objects and tools are elements of the socio-physical environment. In ATCAS-IL, an *artefact* represents a general element of the environment. Following a widespread perspective in MAS [7], ATCAS-IL characterizes artefacts in terms of an internal state, the operations available to manipulate them, the events they can generate, and the knowledge and norms about their use. An *operation* is a basic act that can be executed when certain constraints are satisfied, and that generates some results. Both the artefact state, and the constraints and results of operations are defined with OperA formulae. *Environments* group artefacts adding specific norms.

Algorithm 1 Definition of the basic artefact. Bold words are ATCAS-IL (or OperA) keywords.

```
Artefact ( basic-id,
    Capabilities:,
    Knowledge:
        state(basic-id, non-available) or
        state(basic-id, available) or
        state(basic-id, blocked)
    Rules:
        FORBIDDEN (rule-0,
            Environmental-contract(
                Instance: _, Artefact: basic-id, Clauses: _ )
        )
        OBLIGED (rule-1,
            state(basic-id, available) BEFORE
            state(basic-id, blocked)
        )
        OBLIGED(rule-2,
            ( blockedBy(Ac1, basic-id) and
            blockedBy(Ac2, basic-id) ) ->
            ( Ac1 = Ac2)
        )
)
```

Algorithm 1 shows an example of the specification of an artefact. It introduces as knowledge the different states in which an artefact can be: *non-available* (i.e. non-created and therefore non-usable in activities), *available* (i.e. usable by activities) and *blocked* (i.e. used exclusively by an activity). Several specific rules limit the behaviour of this basic artefact: *rule-0* states that this is an abstract artefact and therefore no instance of it can be created; *rule-1* indicates that the artefact must be created (i.e. available) before it can be locked for exclusive use (i.e. blocked); *rule-2* states that an artefact cannot be blocked at the same time by different activities. All the artefacts in the case study satisfy this basic specification.

Communities control the access of subjects to *environments*. A community is a group of subjects that share social meanings and artefacts. ATCAS-IL defines them as an extension of the concept of role group in OperA. It comprehends several sets of elements: roles representing the subjects; the environments it has access to; accessibility rules mediating between subjects and artefacts; and knowledge and norms applicable in it. Roles are standard OperA roles whose capabilities are represented as operations. The accessibility rules indicate that when the states of the role and its environment meet some conditions, the role can use the operations of the artefact and be aware of its events.

The previous elements are put together in *activities*, whose definition following AT [16] includes the following elements:

- *Subjects* indicate who are in charge of executing the

activity. OperA roles describe them. *Objects* and *tools* represent the elements of the environment affected by the execution of the activity. *Artefacts* represent them.
- *Communities* determine how the subjects can access the artefacts related with the activity system.
- *Rules* and *division of labour* establish the norms that provide constraints for the execution of the activity.
- *Outcomes* of the activity are modelled as OperA formulae that become true after the activity execution.
- *Patterns* establish intermediate steps in the execution of activities.

As seen in Section II, activities are hierarchically decomposed in actions, which are further decomposed into operations. ATCAS-IL only considers operations in its refinement of activities. Patterns allow specifying the preferred order of generation of the results of operations.

The previous elements (i.e. communities and activities) define general patterns of behaviour, and appear at the level of OperA OM. The elements that actually implement them are the *agents* for the subjects and the *instances* for the artefacts. SM define these elements. An agent is characterized by its objectives, capabilities (i.e. operations), applicable norms and priorities about objectives. Objectives are states of the world that agents pursue defined as OperA formulae. Priorities determine the objectives that agents prefer trying to achieve when their states and that of the accessible environments meet certain conditions. These priorities provide the means to further describe the dynamic behaviour of systems. OM indicate existing objectives and their satisfaction conditions, and the priorities establish a simple way to choose the objective to attempt when several alternatives are available. The instances of artefacts are described in terms of their capabilities, and the knowledge and rules about them.

Finally, IM define for each activity the specific agents and instances that act in it, and sequences of operations to execute it. These sequences of operations must be able to satisfy the patterns included in the definition of the activity.

The division between the conceptual definition of the model (through communities and activity systems) and its actual realization (with instances, agents, and interactions) facilitates two goals in ATCAS-IL. First, it isolates the researchers' hypotheses, which appear at the conceptual level of OM, from the variability of individual elements, which SM and IM define. This allows managing the heterogeneity of individuals in populations, which is relevant to check that the obtained results are really a consequence of the hypotheses and not of specific configurations of the population. Second, it enables the independent evolution of the definition and implementation of subjects and artefacts. This evolution is required to adapt the realization of agent-based models to the requirements of different applications, as the already mentioned centralized supervision and different levels of complexity in the implementation of the individual agents depending on the population size.

ATCAS-IL also incorporates mechanisms to manage the models complexity. ABM [5] is increasingly being accepted as a tool for social research due to the inadequacy of analytical and traditional computational models to deal with large, heterogeneous and non-linear systems. Nevertheless, ABM models can also become quite complex, in cases that: involve several types of agents; where individuals evolve in different ways; or, large bodies of knowledge and rules affect the society behaviour. The management of such complexity requires that approaches incorporate abstraction mechanisms. Besides the decomposition of specifications in several models present in OperA, ATCAS-IL includes an extension mechanism for modelling primitives and the capability of defining macros.

The extension mechanism allows indicating that a given sub-concept extends a super-concept by including all its attributes. This mechanism is available for artefacts, environments, roles, communities, activities, activity systems, agents and instances. It reduces the size of the specifications and allows building conceptual hierarchies of concepts. Such hierarchies highlight the common features of concepts, allow their incremental description, and facilitate the definition of exceptions. For instance, they allow indicating that subjects usually comply with the rules of their communities, but a minority of them are going to break the law, that is, ignoring some of those constraints.

The second mechanism is the definition of macros. Deontic logic, used as formal basis of OperA, does not belong to the standard background of social science researchers, so they need the support of experts to use it. In order to improve the researchers' autonomy when using ATCAS-IL, their experiences are gradually crystallized in a set of tailored macros suitable for a domain. That is, researchers initially determine what they want to specify and experts in logics help them to describe these operators with basic logic primitives. After some studies, this early joint effort defines a researcher-friendly specialization of the DSL for that domain. That specialization includes macros for the most commonly used operators and concepts. Then, researchers can specify models on their own, and only need experts in logics to describe new and unusual properties.

V. Case study: NASA shuttle

This section uses ATCAS-IL to analyze the conflicts existing in the **flight readiness** activity system described in Section II. The AT description of this activity system has been presented in Section II and is depicted in Fig. 2. As stated there, the conflicts emerge from the NASA duality between an agency focused on research and safety, and the modern one trying to reduce costs. It affects the shuttle launching opposing a total guarantee of safety and a reduced one but with a timely launching.

The first step of this analysis is the formalization of the activity system using the primitives presented in Section IV. Algorithm 2 shows a simple mapping for it. The *flight-readiness-activity* extends the *basic-activity*, which includes basic information about activities. Its object has been simplified to focus on the contradictions coming from the community. The two communities reflect the duality of goals in NASA between the

public-funded-agency and the *autonomous-agency*. The knowledge related with the artefacts in this activity is described as part of their definitions.

Algorithm 3 shows a partial definition of the communities involved in the previous activity system. The *basic-community* contains the role *decision-maker*, who is the subject of the activity, and a rule that states that the agency must run balancing its expenses (i.e. functioning and safety costs) and the incoming money (i.e. funding and incomes). As there are

no constraints about artefact accessibility, all the roles have granted full access to all the artefacts of the community. Depending on the type of agency, the specification adds more rules to its description. For instance, the *autonomous-agency* should run without public funding, which is asserted as *knowledge* of that community. Note that the specification of the *autonomous-agency* indicates that it constrains the general *decision-maker* to a *cost-conscious-decision-maker*, so it does not add a new subject but specializes the existing one.

The definition of the rules is illustrated with *safety-first* and *timely-flight* in Algorithm 4, which are also examples of the use of macros introduced by keyword *DEF*. The rule *safety-first* states that the probability of failure cannot be over a given limit, and *timely-flight* indicates that launchings must adhere to the expected planning.

The last type of elements to define is the roles involved

in the activity system. Algorithm 3 introduced the *decision-maker* as the subject of the flight readiness activity system. As also seen in Fig. 2, it is specialized in the safety-conscious and the cost-conscious decision makers. The definitions of these roles can be seen in Algorithm 5. They have available several operations, such as *check-readiness* in the *decision-maker*. All of them produce pieces of information according to the available state of the shuttle. The operation *decide-launch* takes this information to approve or deny the launching of the shuttle, which satisfies the objective *take-decision*.

Algorithms 3, 4, and 5 describe the general behaviour of the activity system. Then, the SM specifies the actual individuals implementing it, and the IM how they carry out the activity.

In this case, the SM just considers one instance per artefact and one agent for the decision maker (in this case an *engineer*) playing the two possible roles, the safety-conscious and the cost-conscious decision maker. This models the kind of situation that faced NASA engineers about launching the shuttle in the presence of non-optimal conditions.

The final element of the specification is the IM in Algorithm 6. It uses the previous instances to implement the activity system. The protocol establishes the sequences of steps that the roles can perform to execute the activity. The operations have been already discussed in this section.

The verification of the previous specification is the second step of the analysis with ATCAS-IL. It finds out the double-bind contradiction pointed out in [19]. When the engineer needs to abort the launching because it does not meet the *safety-first* condition, there is a violation of the *timely-flight* condition as no launching time is scheduled before the planned time. If the engineer decides launching anyway, there is a violation of the *safety-first* condition. This inability to take an action without violating constraints corresponds to the double-bind contradiction [20]. Thus, the verification has been able to automatically find the contradiction and to point out the conflicting properties. Details on the analysis process can be found in [17].

The presentation of the case study has used a textual specification with ATCAS-IL. OperettA supports visual modelling as long as the corresponding Eclipse models with the abstract and concrete syntaxes of the language are available. This step is required to complete a DSL suitable for social science researchers. They can easily grasp the primitives related with AT concepts, as they correspond to a structured textual representation of activity systems. However, the deontic logic used to specify the low-level details do not belong to their standard background. The use of macros and a graphical notation can reduce their difficulties to use it in their models.

VI. Related work

The field of ABM shares with general agent research many of its limitations. The review of Gilbert and Terna [5] about the implementation of ABM points out the lack of conceptually well-defined blocks for modelling and implementation guidelines.

ABM applies models to a large extent as a conceptual tool with only a swallow agreement about what an agent is [3]. Just to discuss some examples, the research in [11], [22], [6], [12] can be considered. The agents in [6] are modelled as sets of simple variables and rules to modify them. There is a set of external parameters not modifiable by agents, and a set of internal parameters that agents can modify with actions. Actions are rules triggered by certain conditions. There are also information links between agents that indicate when changes in their variables are propagated to other agents. The model can consider some noise in the communications to allow non-modelled environmental effects. Works as [22] have a more complex representation of the involved agents. Their condition-action rules include symbolic representations of elements such as goals, tests or capabilities, being therefore closer to traditional MAS. However, they do not represent key elements in MAS like the society, norms or decision making. Some researchers [11], [12] advocate the use of common MAS for ABM. This approach allows for the richer and more abstract modelling of individuals, but overlooks several relevant facts. The first is that MAS abstractions come from software development, and therefore they are not well-suited for social researchers. The second is that ABM usually deals with huge populations that cannot be implemented with computationally expensive agents.

ATCAS-IL aligns with research that promotes MAS for ABM, as it allows making modelling as complex as required. However, its language foundation is in AT, and thus in Social Sciences instead of AOSE. Moreover, ATCAS-IL relies on automated transformations of models to manage the implementation and its tradeoffs. This is an approach already pointed out in [12], though it proposes the use of programming languages instead of model transformation languages [9] as ATCAS-IL does. This last approach is intended to be closer to the concepts of the domain.

The issue of the lack of implementation guidelines was already mentioned in the introduction. ABM methodologies focus on capturing the information of the social systems at a very abstract level, but disregard how to migrate from these conceptual models to computational ones [3]. From the already mentioned works, [11], [22], [6] only consider the general features of agents in their models and the results of their simulations. The absence of general implementation details suggests that they rely on specific implementations for the problem at hand. This constitutes a major problem to validate the models, as it is not easy to know whether some of the results come from unintended features of the coding [4]. Approaches emerging from MDE and promoting the automated transformation of models [11], [12] facilitate to some extent this validation, as the same transformations are applied to different models. Nevertheless, the full validation of models in these example approaches still requires a complete understanding of the program code involved in the transformation. For this reason, model transformation languages [9], which work at the level of models, seem a more suitable approach for this task. Nevertheless, complete development

processes for ABM that guide researcher in the modelling process are still an open issue.

VII. Conclusion

This paper has introduced ATCAS-IL as part of the ATCAS framework for ABM. ATCAS-IL is a DSL to represent social constructions. It is based on two main sources: the socio-psychological AT to define its conceptual framework; the OperA framework for agent organizations for its formal definition. This foundation pursues two objectives. First, it tries to increase the autonomy of social researchers in ABM by directly applying their own concepts. This reduces the misunderstandings that inevitably appear when researchers need to rely on engineers without a background in Social Sciences for the modelling. Second, the formal definition of the language enables the automated processing of its models. ATCAS-IL proposes making these transformations through standard model transformation languages. This implies that the transfer of information between models is partly specified at the level of abstraction of models, and not with code. It is also expected to improve comparability between models: the application of the same transformations to different models of the same hypotheses should generate equivalent results.

The paper has illustrated the use of ATCAS-IL with the problem of the identification of the contradictions that led to a well-known failure in the space shuttle program. While the original AT work relies on the human analysis of data, a suitable model allows the automated discovery of the problem and its potential reasons.

ATCAS-IL has currently three main limitations. First, the domain-specific primitives are not enough to model a complete system. As the case study illustrates, low level-details have to be expressed with logics, which are not suitable for social researchers. Ongoing work is intended to determine the additional primitives required in the language according to AT and agent research. AT also considers recurrent social patterns [16], [14] that can be described with reusable macros. Second, textual specifications are too verbose given the amount of details required in the models. The extensions of the DSL can help to solve this issue. Besides, the use of the visual modelling capabilities of OperettA can simplify the development of the specifications, hiding the repetitive details of modelling. Third, facilitating the development of the automated model transformations is still an open issue, as social researchers are not expected to be experts in transformation languages. Approaches based on the automated generation of transformations from model prototypes are a potential solution.

***Abstract*—There are serious contributions to the theoretical foundations of flocking systems, but there are only few systems which have the capability of autonomous task allocation, however, many use cases demand this functionality. The implementation of a task allocation algorithm could be a serious challenge even in a simulated environment due to the numerous problems arising from the nature of these systems.**

This paper proposes a novel algorithm to find the optimal allocation of heterogeneous agents to heterogeneous tasks by utilizing distributed auctions based on local peer-to-peer wireless communication and exploiting graph theory with a tree-based multicast protocol. The solution was tested over a number of different scenarios and compared to existing algorithms in order to measure and prove its capability in handling autonomous task allocation in different systems as well.

I. Introduction

THE FLOCKING phenomena (the notion of flocking is used as a synonym of collective motion), observed in various fields in nature (such as insect swarms, fish schools, herds of wildebeests, etc.), can be an appropriate solution in many engineering applications as well. Applications of flocking include massive mobile sensing in an environment [1]; parallel and simultaneous transportation of vehicles or delivery of payloads [2]; performing military missions, such as reconnaissance [3], surveillance [4], and combat using a cooperative group of Unmanned Aerial Vehicles (UAVs). A flocking group of robots can perform tasks like exploration of an area, autonomous navigation for deployment, surveillance, or search and rescue operations [5].

In contrast to the huge number of flocking algorithms already published in the literature, most of them handle the group as a whole, no dynamic and autonomous reconfiguration or partition is possible [6]. Several use cases require utilizing autonomous regrouping of the flock, where a subset of the flock can leave the group, move to a given destination and perform various tasks on the spot. Several important uses cases impose scenarios where the flock has a large set of nodes, but only a few are required to move towards a specific location, for example when monitoring the behavior of the crowd during mass events or when observing the condition of a dam at multiple points with cameras. In cases where there is only one operation center broadcasting commands, the selection of the subset of nodes acting on the command and routing those nodes to the event site needs to happen autonomously based on the implemented control algorithm and the peer-to-peer communication between the nodes. This is an autonomous task allocation problem, which is an NP-hard [7] combinatorial problem.

In this paper we propose an algorithm capable of choosing the optimal task allocation based on the actual requirements without any central supervision, relying only on local interactions of the nodes. The algorithm does not depend on the tasks or the requirements directly, since it can select the optimal allocation with respect to the criteria defined by the use case.

II. Related Works

Multi agent task allocation is a problem that arises where a number of agents are working together in the aim of achieving a common goal or task which is subdivided into a number of subtasks. The problem can be formulated as a Multiple Traveling Salesmen problem which is NP hard [8]. Many solutions try to approximate the optimal solution by relying on auctions.

There are fully centralized solutions, such as [9] that require a central task allocator to determine the optimal allocation of tasks for the whole system. This approach certainly has advantages, such as the optimal global cost can be calculated easily, but it is usually not feasible in a real life scenario, especially in scenarios mentioned in Section I, as a fully centralized approach requires complete and perfect communication between nodes and the central task allocator has to keep track of the state of the whole system including internal knowledge of each agent's state.

Some solutions utilize combinatorial auction [10](where bidders can bid on combinations of items) in a centralized manner in order to find the optimal task allocation such as in [11] and [12]. Combinatorial auction compared to centralized task allocation has many advantages, however, a few disadvantages as well. Due to the distributed cost computation, this method does not require a fully centralized task allocator to keep track of the internal state of each node in the system. However, it has the communication and computational disadvantages of a fully centralized approach. Combinatorial auctioning can provide globally optimal solution based only on local interactions but it is well known to be an exponential

978-83-60810-90-3/$25.00

algorithm, therefore, it does not scale well with the number of nodes which can result in extreme energy consumption [13].

Distributed auctions are used to exploit the peer-to-peer communication between nodes in [14] and [12]. This class of methods is the primary mechanism for providing intentional coordination between agents. Distributed auctions have the advantage of not requiring the auctioneer to have a model of each agent (for example a robot). They do not require full communication between the agents and the auctioneer either (which means the network graph does not have to be complete, only connected) and can be robust with respect to communication failures. However, they are inherently suboptimal when a complex global cost function is used.

Fully distributed approaches [15], [16] do not use auctions in a conventional manner, therefore, they do not require direct communication between nodes. Each robot in this case retains local control and chooses its own actions based on its observations of the environment. Cooperative actions however, can be achieved by estimating models of the other agents' strategies. Distributed approaches are robust to communication failures, but can result in worse performance than distributed auctions due to a lack of intentional coordination via an auctioneer.

After studying the listed solutions thoroughly, we have chosen the method of distributed auctions for our algorithm, as it does not require full communication between the agents and being robust to wireless communication failures. The initiator event can be triggered only on one agent, but it uses graph theory solutions to select the most appropriate local auctioneers that do the auctions in a parallel and distributed way. To convey the tasks and the bids between the agents our solution uses tokens which can be transferred via peer-to-peer communication through the whole network.

III. Proposed Distributed Task Allocation Algorithm

We are investigating the problem of allocating a subset of agents based on local events, such as when a node senses disturbances, hazards, etc. or global events: the control center orders nodes to perform tasks. The event can originate from a higher lever entity in the system but the allocation process has to be performed in a self-organized manner among the nodes. A global or local event can be associated with certain requirements, such as a minimum energy level required or various properties of the nodes: speed, agility, maximum operating altitude, presence/accuracy of sensors/actuators, etc. The goal then is to select a subset of the nodes with the best fit with respect to the requirements associated with the event.

A. Problem formalization

An event triggers a request in the system that can be translated into a logical entity called the token. In our terminology a token is a simple data structure which contains the requirements (e.g. in a key-value map) associated with the event and nodes can manipulate it during the allocation process. This is very important, since a node needs to add its own data to the token in order to indicate that it has previously seen the token. A token can be transferred between nodes via wireless communication. It follows that a token is the subject of auctions, since every node is competing for the tokens based on the requirements in the token and the node's properties. Therefore, the selection process can be viewed as a highly distributed auction, where the bidders are the agents in the system and the "goods" are the tokens. The main benefit of the token representation of tasks is that the initial abstract problem can be mapped to a more formal problem which now can be solved by using graph theory and other mathematical tools. Thus the autonomous task allocation problem can be formalized as a token translation step and based on the token a distributed auction between the nodes. In the token translation step the algorithm should translate the requirements of the event to a transferable entity called token. And with distributed auctions (starting from the triggered agent) the nodes in the system can exchange the tokens in a controlled manner. At the end of the auction a task allocation can be done based on the bids contained by the token. In order to guarantee the optimal allocation of tokens to nodes, each node must bid on each token at least once, otherwise there could be a node in the system which did not bid to a token but would be the perfect fit.

In a distributed system limiting the number of local auctions is beneficial, since an auction can consume a huge amount of resources. In this case the auctioning algorithm is coupled with a flocking algorithm that depends on wireless communication to synchronize the state of the nodes such as position, velocity and heading. A naive solution would use no auctions at all but nodes that have the token could bid on it. This solution however involves unnecessarily broadcasted messages, as all tokens have to be transferred to potentially all nodes in the system. This approach is one extremity, where the number of auctions is minimized. Thus the algorithm should find an optimal trade-off between the number of the auctions and the required time to complete the allocation process. To minimize used resources and ensure that an optimal solution is found, our algorithm can be broken down to these general steps:

1) Select the auctioneer nodes based on the network graph
2) Build up a multicast tree in which the source is the node where the event was triggered and the destinations are the auctioneer nodes
3) Use the multicast tree to make communication more efficient in the process of allocating nodes to tokens

In the next subsection we focus on the first sub problem, since the second and third can be solved by enhancing traditional tree-based multicast algorithms (will be described in a later subsection).

B. The auctioneer selection algorithm

As we are considering mobile agents, the graph representing the network connections is not stable and not known a priori, thus some assumptions have to be made. We assume that each node has a local network table, which contains all other nodes in an adjacency matrix. This table is built up using the periodically received topology information (containing

the whole network from the sender's perspective) from the neighbors (similar to the distance-vector routing method [17]). Thus, every node transmits its local network table periodically (like the heartbeat packet in distributed systems) in order to ascertain the node is still operating (since a device can be broken down at any time because of many reasons) and to create a local copy form the whole network topology in all nodes. The next assumption deals with the structure of the network, since in our case the graph is undirected and connected before the task allocation phase. However after it can change, due to for example a task which requires that few nodes from the connected flock move away for a time and do dedicated tasks such as exploration and then join back to the flock. The undirected graph can be guaranteed by allowing only pairwise connections. Thus, if only one node can communicate with the other but the other can not (because of different sizes of transmission ranges) then this asymmetric connection will not be placed in the network matrix and hence the undirected communication graph is guaranteed.

Based on these assumptions auctioneer selection can be formalized and solved by using tools from graph theory. It is a selection problem and the goal is to select the minimum number of auctioneer nodes in the system. Let G denote the graph representation of the whole network, and $G = (V, E)$, where V are the vertices (the nodes) of the graph and E is the set of edges, representing the communication links between the nodes. Thus, the problem is to select a subset (V') from V, which has the minimum number of elements (minimum cardinality set) and can cover all the nodes in the network with the edges covered by the vertexes in the subset. More formally, we are seeking a subset V' of V, such that for all $u \in G$ there exists $(u, v) \in E$, where $v \in V'$ and V' is the minimum cardinality set. This set is very similar to the minimum vertex cover, however, in this case the goal is to cover all nodes instead of all edges.

Assume that every vertex has an associated cost of $c(v) \geq 0$. Then the problem discussed earlier can be formulated as the following integer linear program (x_v is a label which means whether the node is chosen as the element of the minimal set):

$$\text{minimize} \sum_{v \in V} c(v) * x_v \tag{1a}$$

$$\text{subject to} \sum x_u + x_v \geq 1 \ \forall v \in V(G), \ \forall u : (u, v) \in E(G) \tag{1b}$$

$$x_v \in \{0, 1\} \ \forall v \in V(G) \tag{1c}$$

The formulation as an integer linear program can be done in polynomial-time (since from the adjacency matrix the equations can be formulated, processing the whole matrix in O(n^2). As the graph should be processed n times, the reduction can be done in O(n^3)). The 0-1 Integer Linear Programming (a special case of the ILP) problem is one of Karp's 21 NP-complete problems. Thus, we were able to reduce our problem in polynomial-time (i.e. Karp reduction, where $c(v) = 1 \ \forall v$) to an NP-complete problem, therefore, our problem is NP-hard. It follows straight-away from the fact that ILPs are NP hard.

Algorithm 1 Calculating the covering nodes

$V' \leftarrow \emptyset$ (the set of the selected nodes), and $V'' \leftarrow \emptyset$ (the set of covered nodes);
2: **while** $V \neq \emptyset$ **do**
$v \leftarrow$ the node with the maximum degree;
4: $V' \leftarrow V' \cup v$;
$V'' \leftarrow V'' \cup v \cup \forall u$ where $(u, v) \in E(G)$;
6: $E(G) \leftarrow E(G) \setminus (E(G(V'')) \ \cup \ \forall E(u, v), where \ u \in V \ and \ v \in V'')$;
$V \leftarrow V \setminus \forall u$, where $d(u) = 0$;
8: **end while**
return V'

This problem also contains the well-known minimum vertex cover problem as a special case, when in the subject we do not summarize all the neighbors instead one (thus subject to $x_u + x_v \geq 1 \ \forall (u, v) \in E(G)$).

Since the problem is NP-hard, we provide a constructive heuristic algorithm which finds only a suboptimal solution but does it in polynomial time. The main idea behind the algorithm is to select nodes with higher degree as they contain more previously uncovered nodes of the graph. Obviously the degrees of the nodes have to be updated after each selection since the selected node and all of its neighbors are covered. Thus, our algorithm can be described by the following pseudo-code:

Theorem: The Algorithm 1 does find a (sub optimal) solution in polynomial time.

Proof: It is easy to see that the above algorithm does find a solution, since it can stop only after Step 2, and after this step it always stands that $V'' \cup V$ equals to all the vertices in the graph, and it returns only if $V = \emptyset$, thus V'' (which is the set of the covered nodes) contains all the devices in the network. And it can be proved as well, that it stops in polynomial time as the algorithm steps in the loop (Step 1-2) at most n times, where n is the number of vertices in the graph ($n = |V(G)|$). To find the node with the highest degree from the adjacency matrix is O(n) and the update process of the matrix (after removing the vertices and the edges) is O(n^2). Thus, the running time is $O(n*(n+n^2))$ = $O(n^3)$. The $O(n^3)$ time relates to only the auctioneer candidate selection which runs locally on the triggered node and therefore, can be really fast when the adjacency matrices are stored in-memory.

It would be beneficial as well if an upper bound could be determined for the number of selected nodes, since it is a good indicator for the speed of the whole process (includes the distributed auction as well).

Theorem: An upper bound for the number of the covering nodes is $\lfloor |V(G)/2| \rfloor + 1$, where $V(G)$ is the set of the vertices in G.

Proof: It is easy to see, that if we can guarantee this upper bound on a spanning tree of the graph, then the bound is valid for the original graph as well. Since the original graph has more (or at least equal number of) edges than the spanning tree, the nodes we selected based on the spanning tree still

cover all vertices in the original graph. In a tree the set we are looking for is identical to the well known minimum vertex cover from graph theory (since in this case to cover all vertices we have to cover all the edges as well). From the Gallai theorem we know that in a graph the sum of the minimum vertex cover and the maximum independent set is equal to the number of vertices. In a tree the number of nodes in a maximum independent set is equal to or greater than $\lceil |V(G)|/2 \rceil$, since trees are bipartite graphs, thus, can be divided into two distinct sets and the vertices of either set are independent from each other. Therefore the number of nodes in the minimum vertex cover is equal to or less then $\lfloor |V(G)/2| \rfloor$. The additional 1 vertex is added to the upper bound because by using a heuristic algorithm in trees it may happen that it selects the wrong one from the two distinct sets (this happens only when the difference between the two sets is only 1).

In this section we have proposed an algorithm able to select a subset of vertices from a connected G graph covering all other vertices in the graph through their edges. We have proved that the algorithm does the selection in polynomial time and we could define an upper bound for the number of selected vertices. Thus, with the help of this algorithm we are able to determine the agents in the system where the local auctions have to be performed in order to find the optimal task allocation.

C. The tree-based multicast algorithm

We have seen previously that the main problem was divided into 3 sub problems and in Section III-B we have provided a heuristic algorithm to approximate the solution for the first subproblem. In this subsection our goal is to identify the appropriate tree-based multicast algorithm to solve the remaining two problems based on the aforementioned selection process result. Thus, the role of the multicast algorithm is to deliver the tokens from the source node to the selected local auctioneer nodes relying on a multicast tree.

The problem of finding a minimum cost multicast tree is well-known as the minimum Steiner tree problem. According to [18] this problem is also NP-complete, even when every edge has the same cost, by reduction from the exact cover by 3-set. Although it is widely assumed that a Steiner tree is the minimal cost multicast tree, it is not generally true in multihop wireless networks [19]. The problem of minimizing the cost of a multicast tree in an ad hoc network needs to be re-formulated in terms of minimizing the number of the data transmissions. Since in a broadcast medium, the transmission of a data packet from a given node to any number of its neighbors can be done with a single transmission, thus, the minimum cost tree is the one which connects sources and receivers by issuing a minimum number of transmissions, rather than having a minimal edge cost. However, finding this optimal tree in a wireless network is also NP-hard [19], therefore, a heuristic algorithm will be used in this case as well.

There are many heuristic algorithms to compute minimal Steiner trees: for instance, the MST algorithm in [20] provides a 2-approximation, and Zelikovsky [21] proposed an algorithm which obtains a 11/6-approximation. However, these algorithms try to solve the minimum cost tree in general instead in a broadcast manner. Authors in [19] proposed two heuristics (a centralized and a distributed one), both resulting in a tree with lower or equal data-overhead then the MST Steiner tree. Since in our case each node knows the whole network (because of the locally maintained adjacency matrices), the centralized solution seems to be an appropriate choice.

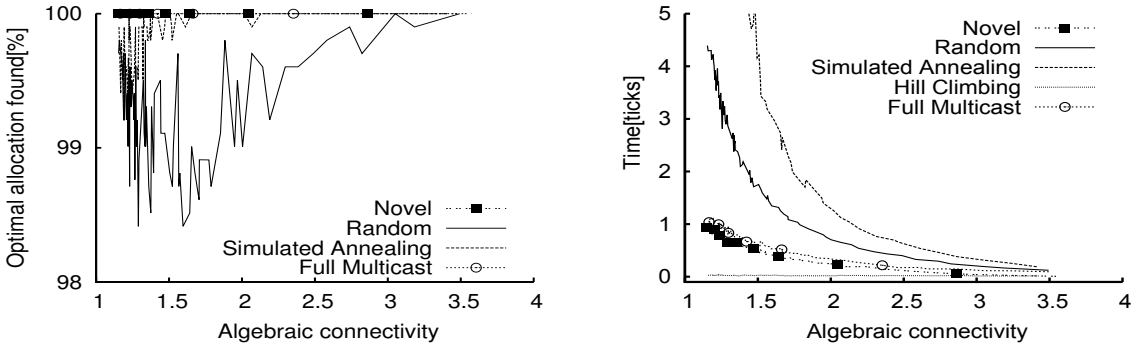
Thus, in the first step of the algorithm it selects the most appropriate auctioneer nodes, in the second step it creates a multicast tree where the multicast receivers are the nodes from the first step. This tree is not only usable for spreading the tokens from the source to the receivers (local auctioneers) but for the opposite direction as well. Therefore, if an auctioneer finishes the local auction, it transfers its token back on the multicast tree to the source. If a node on the path from auctioneer to source possesses two or more tokens at a time, it merges them in order to decrease the number of broadcast transmissions. Finally the first node (in worst case the source) which obtains all the tokens, immediately calculates the winner nodes and instructs them to carry out the tasks formulated in the token. Thus basically, only the auctioneer node selection step runs locally on a single node (where the task allocation event has been triggered) and then the algorithm uses distributed auction backed by multicast trees in order to increase the efficiency of the local auctions.

IV. Performance through Simulation

In the previous section we have proven that our algorithm can find the optimal allocation and does it in polynomial time, but our objective is to evaluate the effect of the proposed auction based task allocation algorithm in the context of a flock environment. Thus we have chosen to conduct a simulation study using the SimPy process-based discrete-event simulation framework [22] in a realistic scenario.

The simulations are based on a static context, thus the agents in our simulation do not move, since primarily our goal is to prove the algorithm can operate optimally in cases where the dynamics of the agents in the system are negligible compared to the communication speed. The nodes in the simulation communicate with each other via a radio interface, such as Wi-Fi, Bluetooth or anything else in a predefined communication range. It is important to note that in the simulation a perfect communication model is assumed as well, therefore, interference and packet loss are not considered.

To model the communication graph we used instances of the connected Watts and Strogatz graph [23], which is a random graph and can be parametrized to resemble the communication graph of flock. The communication network of a flocking system is a type of graph which is similar to a regular grid, therefore the valency of the nodes are nearly the same (since the agents in the flock are placed almost the same distance from each other). We generate a random connected Watts and Strogatz graph by setting the algebraic connectivity parameter as well. The algebraic connectivity of a graph is the second-smallest eigenvalue of the Laplacian matrix of the graph and



(a) For a clearer picture only the optimal or near to optimal solutions are depicted.

(b) Speed of the selected algorithms.

Fig. 1. Simulation results of the autonomous task allocation from all the aspects.

the magnitude of this value reflects how well connected the overall graph is. It depends on the number of vertices as well as the way in which they are connected. In random graphs, the algebraic connectivity decreases with the number of vertices, and increases with the average degree (and is greater than 0 if and only if the graph is connected). The simulations are performed with different algebraic connectivities in order to simulate different kind of flocks. Every graph with a unique algebraic connectivity value was tested 100 times and the results were aggregated in order to minimize the impact of outlier cases.

As it has been stated before, the requirements generated by an input event are translated into a token. However, our framework is capable of handling multiple types of requirements (and cost functions as well) since the algorithm does not restrict it. Thus it is really important to note that the proposed system does not depend on the type of the requirements or the cost function, instead these can be defined differently from case to case and the algorithms will adopt dynamically. In this paper we have considered a simple scenario where a token only contains a minimal energy level as requirement. An energy level is generated for each agent before the simulation, following a uniform distribution between 70% and 100%. In the generated event, the energy requirement is 65%, therefore every node can perform the task to ensure that a solution exists. In this configuration there are optimal and suboptimal allocations based on the generated energy level distribution.

Five different algorithms have been compared against each other in the simulator. The random walk algorithm, which transfers the token (the translated request) on randomly selected edges until some conditions (such as all nodes placed a bid or the token has been transferred at a given threshold) are fulfilled. The well known hill climbing algorithm, that transfers the token only to a node that has a higher bid than the current one, therefore, in our case it means that the tokens move towards nodes with higher energy. The simulated annealing algorithm: it tries to avoid suboptimal selection by allowing temporary worse states (so the selected node's bid is lower than the current highest). The algorithm uses acceptance probabilities of making the transition from a current node to a candidate one, which depends on the energy of the nodes and on a globally-varying time parameter, called the temperature.

A. Simulation Results

The results will be shown in two different aspects. The first is the main focus of the paper, that relates to the success of the task allocation. Measuring the success ratio of finding the optimal allocation among the nodes, 0% to 100% indicates the effectiveness of the used solution. And the second aspect focuses on the simulation time, which indicates the speed of the algorithm. Therefore, the goal is to minimize the time and select the most appropriate agents as quickly as possible.

Figure 1a presents the results from the first aspect. It has to be noticed that the hill climbing algorithm is not depicted since it performs really bad (around 40% at lower density and improves to around 80% in more connected networks) because its performance heavily depends on the location of the initial request event. And obviously the hill climbing algorithm produces the worst selections as it chooses nodes greedily, therefore it terminates at suboptimal nodes (local optimums). Therefore, for a clearer picture only solutions with close to the optimal performance are shown. When observing the percentage of the optimal coverage it could be seen that there are only two algorithms able to achieve the optimal selection regardless of the structure of the network graph: our proposed algorithm and the full multicast algorithm. The full multicast algorithm finds the optimal allocation in any case by definition, since it transfers the token to every node. The simulated annealing algorithm results in an almost optimal selection in all cases, but in really sparse environments (graphs with lower algebraic connectivity) it has some errors. The relatively good results of this algorithm is because it's parameters (such as the initial and the terminating temperature and the transfer rate) have been trained on many networks. The random solution (which passes the token to randomly selected nodes) also achieves a nearly optimal selection in all cases, since its input parameter (the number of token transfers) has also been trained on the same dataset. It is important to notice as well that the results

are improved when increasing the algebraic connectivity of the graphs, as higher algebraic connectivity values mean a denser and more connected network graph. Therefore local information becomes more global, in the extreme case of a fully connected graph each node has global knowledge about the whole graph.

Our final results are depicted on Figure 1b, and it shows the speed (the simulation time measured in ticks by the discrete simulator) of the different selection solutions. As it can be observed, all algorithms except the hill climbing are highly dependent on the algebraic connectivity. The relation between the algebraic connectivity and the speed is not linear but exponential, therefore, a less connected graph results in much slower selection. Hill climbing performs the best with respect to speed due to the greedy optimization: blindly passing tokens to agents with higher utility. On one hand this algorithm can terminate in local optimum instead of a global one (see Figure 1) but on the other hand it provides the fastest coverage. The other four examined solutions perform better if the underlying network graph is more connected, since in that case the network can be covered within less time. The second most efficient solution is our proposed algorithm, which can outperform the other three optimization techniques even by 30-40% in less connected environments. Based on the results from all the aspects, we can conclude that our solution finds the optimal selection in any network and does it in the fastest way among the algorithms which find the optimal or nearly optimal allocations. Only the hill climbing search technique does faster allocation but it can reach an optimal selection only in strongly connected flocking systems.

V. Conclusions

We have proposed and described a novel distributed auction based task allocation algorithm to enhance flocking systems. This task allocation algorithm exploits the network graph maintained locally by nodes in order to build a (sub) optimal multicast path from the source node to the chosen local auctioneers. Using this multicast tree our solution can find an optimal allocation based on the generated requirements.

Real-life flocking examples were used as a case study to evaluate how our novel algorithm can solve the distributed task allocation problem in flocking systems. We evaluated the performance based on multiple environments by varying the algebraic connectivity of the generated graphs. Our experimental results indicate that the proposed algorithm can find the optimal allocation regardless of the algebraic connectivity of the graph and does it relatively fast compared to the other examined solutions such as random walk, hill climbing, simulated annealing and the full multicast algorithm.

***Abstract*—This work presents a multi-agent-based computational model of an artificial fractional reserve banking system. The model is implemented in NetLogo. The computational experiments and simulations we performed to analyse the proposed model show that different scenarios can lead to bank insolvency. We show that both the minimum reserve rate and the loss of confidence have large contributions to the insolvency of a bank, suggesting them as likely destabilizing economic forces driving the dynamics of the model.**

***Index Terms*—agent-based model, agent-based simulation, BDI agents, fractional reserve banking, NetLogo.**

I. Introduction

AGENT-BASED models (ABMs) are computational models consisting of a set of autonomous, self-driven agents that exhibit complex behaviours emerging from their interactions rather than from the complexity of the individual agents. ABMs are usually simulated in frameworks specially developed for these purposes [1]. They have already been applied to the study of emergent phenomena in a variety of domains that include social, political, and economic sciences.

ABMs have several interesting properties. Among them are the following: they are relatively easy to implement, are very practical for analysing the evolution of the simulations step by step, and can show emergent properties that could be difficult to predict. By stepping the simulations, it is possible to analyse the emergence of stylised facts and new equilibrium states, as well as the conditions under which they occur. For example, it is possible to analyse the emergence of pernicious domino effects, which may be achieved by increasing the degree of interdependence between the agents. The domino effects are of special interest to the analysis of financial fragility, in particular bankruptcies cascades, due to the intricate structures of liabilities among heterogeneous agents.

One of the goals of the ABM we present in this paper is to describe a methodological tool that can reproduce some of the stylised facts in fractional reserve banking (FRB) systems. *Fractional reserve banking*[1] is a banking system "in which banks hold only a fraction of their deposits in reserves, so that the reserve-deposit ratio is less than 1" [2]. In other words, some of the deposits are further used by the banks to be loaned out at interest-earning rates to other parties. Yet FRB has received a lot of criticism. For example, there are studies that show the viability of ending fractional reserve banking, as is the case of the FRB in Iceland [3].

Why then a computational agent-based model to simulate FRB? We believe that understanding FRB better could be one of the most important outcomes. Simulating artificial scenarios could help suggesting possible improvements or new policies. This is especially important for scenarios that could eventually be avoided if anticipated by a computational economic model for FRB. The FRB agent-based model presented in this paper can then be used to analyse possible scenarios that arise from evaluating different initial parameter settings of the model. The major purpose of the model is to provide artificial ways to represent and to simulate the impact of the fractional reserve banking system on a time period. It defines a very simple modern banking world that is, by no means, an example of real bank operations or of federal restrictions or monetary exchanges. Instead, it could serve as a basic playground setting, for example, to drive the policies and behaviours of banks before testing their validity in the real world. It could also be useful to find out the sufficient conditions for a banking system to become fragile and unstable.

II. Related Work

Traditional simulation approaches mainly use historical data [4] to analyse the interbank payment interactions. For example, Bedford, Millard, and Yang apply some stochasticity to test different bank behaviours under different hypotheses on the operational rules [5]. They propose a simulation-based framework to analyse large-value payment systems for a variety of worst-case scenarios. The framework shows many similarities to the stress-testing methods that are used to evaluate the robustness of banking systems to financial shocks.

Other researchers have used computer simulations to analyse interbank lending for scenarios with homogeneous and heterogeneous agents. Iori, Jafarey, and Padilla [6] show that, if the banks are homogeneous in size and risk exposure, then the interbank market has strong effects to avoid cascades and stabilise the system. However, if the agents are heterogeneous, then the system may present some cascade effects.

Modern simulation approaches like ABM have also been used to study economic and social systems, where the main

[1] Also known as *fractional deposit lending*.

idea is to describe the behaviour of the agents in the system and to reconstruct the aggregate behaviour by simulating their interactions. Also, some works allow behaviour adaptation based on changes in the different scenarios [7]. By this means, ABM is a methodology bringing together verbal descriptions of component systems and equation-based models [8]. In particular for our investigations, we are interested in ABM for analysing the credit, liquidity, and operational risks of settlement systems. In this type of system, banks are modelled as software agents that follow some behavioural rules and act independently, which leads to stylised facts that result from their interactions in the simulated world.

Simulation tools like StartLogo have also been used to simulate behavioural rules for banks in Real Time Gross Settlement systems. Arciero and co-authors present a model with a money market [9] which, after a critical event, either blocks or limits the activity of the bank. In their model, banks are perfectly informed on all payment requests. Thus, when delays in payments start accumulating, some banks start adjusting their expectations accordingly until the turbulence spills over in the market, needing the intervention of the central bank.

III. An Agent-based Computational Model for Fractional Reserve Banking

A computational model that describes an FRB system using ABM was introduced in a previous work [10]. The model basically consists of three main groups of artificial entities that are simulated by three types of agents, i.e., depositors or investors, debtors or borrowers, and banks, which interact through communication in a multi-agent system. When compared to the approach of Mallet of simply managing a list of accounts with deposits and loans [11], our model differs in that it simulates not only the bank behaviour, but also other parties and the interactions involved. In this paper, we focus on initial experiments with our model rather on extending it.

Each agent in our model pursues different interests. They are modelled in NetLogo,[2] a multi-agent programmable modelling environment [12], by following the BDI paradigm [13]. In other words, they are artificial agents with *beliefs* (B), *desires* (D), and *intentions* (I) that are defined using the NetLogo BDI add-on [14].

All agents follow a deliberation process that determines their subsequent actions and interactions with other agents. For example, depositors aim to create as much capital as possible without running the risk of losing their assets due to insolvency of the bank. They can retrieve the entire deposit or a specific, lower amount. They can also deposit money or do nothing. Figure 1 shows the deliberation process of a depositor agent. After updating her knowledge about the world and depending on both her preferences and trust in the bank, a depositor decides on whether to deposit money or to retrieve it, partially or totally.

[2]Jonathan Wiens implemented the first version of the NetLogo model. Eric Faustmann and Damian Rhein extended it.

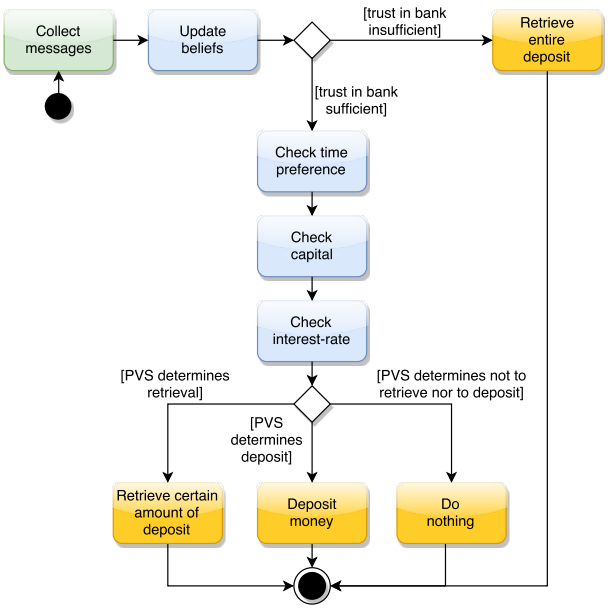

Fig. 1. Deliberation process of the depositor agent. PVS: personal value scale.

Depositors act depending on their own personal value scale. It would not be reasonable for a depositor to deposit 80% of her on-hand cash into a bank she has 10% of trust in, for instance. Other variables influence the decision process, too, like the time preference p, the current capital C, the deposit interest rate β, and the trust t in the bank. Algorithm 1 shows the pseudo-code that drives the depositors' actions, where D is the amount to deposit, W is the amount to withdraw, and S is the current deposits or savings in the bank. If confidence in the bank is lost, i.e., the trust in the bank is less than 30%, then a depositor might withdraw her entire deposits. She might deposit money, however, if the trust has a greater value and depending on both the time preference (a random parameter to simulate the possibly non-deterministic character of each agent's operations) and the interest rate.

Debtors or borrowers behave similarly, only that they have other local variables as well as actions in their repertoire, like borrowing a specific amount of money from the bank. The bank agent serves as a contact partner for depositors and debtors. It accepts or rejects requests from the agents depending on its own state. For example, a bank would award no credit to debtors if its reserves fall below the minimum permissible reserve amount because otherwise it could lead to insolvency. All agents update their information and knowledge about the world, i.e., their beliefs, iteratively, which determines the construction of new desires and intentions that are transformed in later actions.

IV. Experimental Settings

We are interested in finding which parameter values lead to either bank insolvency or to a stationary scenario with no insolvency of the bank, over iterations.

input : Incoming messages IM
output: Action a

begin
  process messages IM;
  update beliefs;
  update desires;
  if $0.5 \leq t \leq 1$ **then**
    $D = C \cdot (p + \beta)$;
  else if $0.3 \leq t < 0.5$ **then**
    $W = S \cdot (1 - p)$;
  else
    $W = S$;
  end
  update intentions;
  $a = selectBestOption()$;
  return a;
end

Algorithm 1: Depositor agent: Pseudo-code of the deliberation process at every iteration.

A bank becomes insolvent when its reserves are lower than the money one or more depositors want to withdraw back from their deposits. Such illiquid state scenarios are reached when both the trust of the depositors decreases, leading to withdrawals, and the reserves of the bank are lower than the withdrawals. Intuitively, the following three scenarios could lead to an illiquid state: (i) the bank does not invest at least some part of the deposits and converts them into profits from the loan interests to at least cover the deposit interests; (ii) the trust of the debtors decreases so that they do not want to get a loan. Thus, the profits of the bank would decrease and the bank will not be able to pay the deposit interests back; (iii) the bank uses a large part of the reserves but even a small withdrawal from a depositor can lead to an insolvency of the bank.

In order to analyse these scenarios, we first perform three computer experiments, i.e., *E1*, *E2*, and *E3*, where we change the values of both the minimum reserve rate and the average loss of confidence rate parameters, while leaving the rest of the parameter fixed, which are: number of depositors (5), number of debtors (5), average income (2000), start capital (5000), starting loan (credit) interest (10%), starting deposit interest (0.2%), and average win of confidence rate (30%). See Table I for those parameter values that differ among the experiments.

TABLE I
PARAMETER VALUES DIFFERING IN ALL EXPERIMENTS *E1*, *E2*, AND *E3*.

Experiment	minimum reserve rate	average loss of confidence rate
E1	1%	30%
E2	1%	50%
E3	5%	30%

V. RESULTS AND DISCUSSION

Different experimental results lead to the insolvency of the bank because of the scenarios mentioned in Section IV. We start by investigating the role of the average loss of confidence rate in the dynamics of the model. Figures 2 and 3 show an example of the evolution of the money warehouse receipts and the reserves over some iterations for an average loss of confidence rate of 30% and 50%, respectively. Note that in Figure 2 both the average loss of confidence rate and the average win of confidence rate are equal, whereas in Figure 3 the average loss of confidence rate is greater than the one depicted in Figure 2.

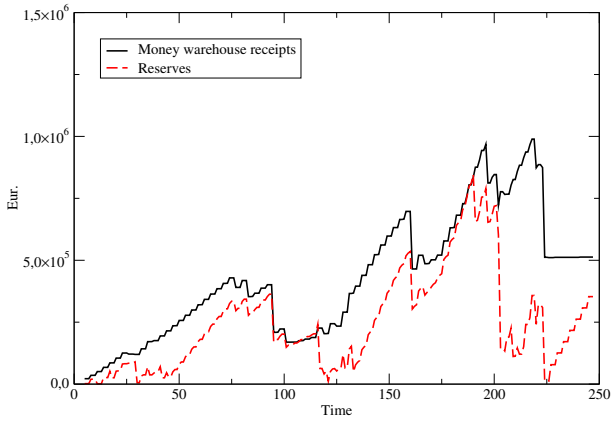

Fig. 2. Experiment *E1* with an average loss of confidence rate of 30% and a minimum reserve rate of 1%.

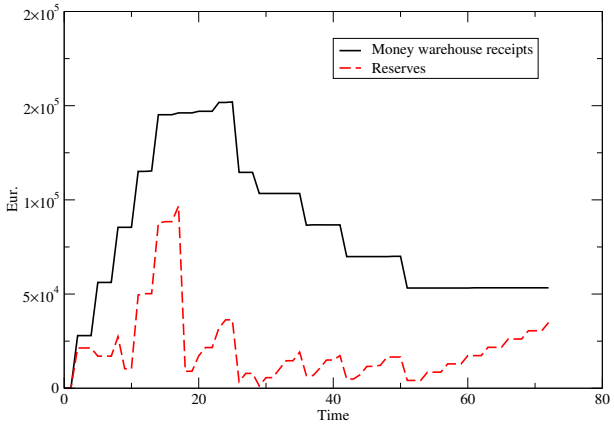

Fig. 3. Experiment *E2* with an average loss of confidence rate of 50% and a minimum reserve rate of 1%.

It can be seen that an insolvency is more probable when the loss of confidence increases, leading to a lesser number of iterations needed for a bank to become insolvent. Thus, when the average loss of confidence is greater than the average win of confidence, then both the depositors and the debtors lose their trust in the bank. Furthermore, if the reserves are low because of a large loan and the bank is not able to pay a deposit back, then all depositors start trying to withdraw their deposits, leading to an insolvency of the bank. This can be

seen in Figures 2 and 3 at the end of the simulations starting at iteration 220 and 50, respectively.

Furthermore, the larger the difference between the average loss and the win of confidence, the faster the depositors start to withdraw their deposits and the faster the debtors stop asking for loans from the bank. Note also that if the average loss of confidence is too great, then the difference between the deposits and the reserves can be so small that the bank may reach a state in which it does not become insolvent but neither does it have any depositors or debtors any more.

Figure 4 shows an example of the evolution of both the money warehouse receipts and the reserves for some iterations for the computer experiment *E3* with a minimum reserve rate of 5%. When comparing this result with the one from the computer experiment shown in Figure 2 where the minimum reserve rate is 1%, we can observe that the amount in Euros is greater in the computer experiment with higher minimum reserves (i.e., the one from Figure 4). It can be seen that the reason for the bank insolvency was the loss of confidence of a single depositor, which led to a cascade of confidence loss and withdrawals from all other depositors.

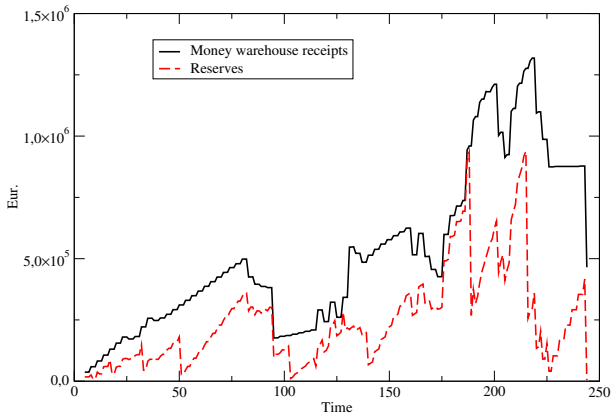

Fig. 4. Experiment *E3* with minimum reserve rate of 5% and an average loss of confidence rate of 30%.

We performed more computer experiments with larger minimum reserve values leading to fewer bank insolvency scenarios. The larger the minimum reserves are, the fewer the cases where the bank is not able to pay the withdrawals of the depositors. Therefore, it is not probable that a bank becomes insolvent unless a large number of depositors decide to withdraw their deposits at the same time.

These computer experiments also show that the minimum reserves do not have a great influence in the model. The reason for this is that there are not so many depositors. Thus, each agent has a large influence in the dynamics of the model. In this context, the loss of confidence of a single depositor can only lead to a withdrawal of 10 to 20% of the deposits in the bank. Furthermore, it was observed that the bank rarely becomes insolvent when the confidence loss has values between 30 and 60% and the re-utilised percentage of money is between 10 and 40%. It was also observed that, for a confidence loss between 30 and 40%, the bank becomes insolvent when a depositor withdraws her deposits just after a loan was granted.

VI. Conclusions

The results of the computer experiments show that the variable that has the greatest influence in the dynamics of the model is the average loss of confidence. This variable is determined randomly in the current version of the model. Further work is to consider different trust reputation mechanisms to make it adaptable, together with the average win of confidence, according to the number of deposits and loans over time.

Moreover, it would be of interest to further investigate the influence of the number of depositor and debtor agents in the model, i.e., whether the dynamics of the model scale in size or not. With respect to the bank agent, it would be interesting to analyse the impact of excluding external sources that would help a bank to pay to the depositors and keep it solvent.

***Abstract*—Currently, bike-sharing systems undergo a rapid expansion due to technical improvements in the operation combined with an increased environmental and health awareness of people. When it comes to the acceptance of such systems the reliability is of great importance. It depends heavily on the availability of bicycles at the stations. But, in spite of truck-based redistribution efforts by the operators, stations still tend to become full or empty, especially in rush-hour situations. This paper builds upon an incentive scheme that encourages users to approach nearby stations for renting and returning bikes, thereby redistributing them in a self-organized fashion. A cooperativeness parameter is determined by the fraction of users that respond to an incentive by choosing the proposed stations. It uses a decentralized control process to calculate alternative rent and return stations for each of the stations. These alternatives are then proposed to the users when they approach an empty or full station. The approach is based on a decentralized control framework that allows to equipping different distributed software systems with the control capabilities needed to realize the coordination efforts required to achieve the desired self-organizing properties.**

I. Introduction

RECENT challenges like climate changes, declining supplies of fossil fuels, noise emissions and congestion lead to discussions about individual means of transportation in urban areas. Especially bicycles (bikes in the following) have received an increased attention in city transportation, as they offer a healthy and environment-friendly way of transportation and allow to reach areas in cities that do not have direct access to public transportation. Combined with technical improvements of the underlying information systems, this results in a rapid extension of bike-sharing systems worldwide [1]. Obviously, bikes have drawbacks in comparison to other modes of transportation, as the usage of bikes strongly depends on weather conditions and the topography of the targeted area. This makes bikes more suitable for short trips [2]. As mentioned before, the increasing success of bike-sharing systems depends strongly on the introduction of information systems supporting the whole renting process (finding available bikes in the departure area as well as renting and returning them) [3]. Today, many cities aim at implementing bike-sharing systems in order to improve inner-city air quality and to reduce congestion [4].

The main challenge for the operation of modern bike-sharing systems in big cities is to ensure the *availability* of bikes at the stations. In rush-hour situations, stations may run out of bikes while others become full, thus reducing the overall *reliability* of the systems. Therefore, the planning and operation of redistribution attempts is essential to ensure reliability and user satisfaction. There are several attempts that have been tested to overcome these problems in scientific research as well as in practice [1] (cf. Section II).

This paper extends previous work [5], where an incentive scheme was investigated, that encourages users to approach nearby stations for renting and returning bikes, thus redistributing them in a self-organizing way. This work is extended by two aspects: First, a decentralized control framework is introduced that allows the declarative description of decentralized coordination processes to control the required coordination efforts among the participating entities in order to achieve the desired self-organizing behavior. Thereby, it shall support different types of heterogeneous applications and systems. The framework is used to replace the coordination processes that were tailored especially for the used RinSim simulator [6] presented in [5] by declarative, generic ones. Second, based on the redesigned control processes, the efficiency of the self-organizing redistribution approach depending on a circular communication range coordination parameter is examined. The communication range determines which other bike stations are within reach of a certain bike station and therefore, receive the status updates emitted from this station as part of the coordination process. There is a direct 1:1 mapping between the communication range and the maximum distance a user is detoured when an alternative rent or return station is proposed to him. Thus, minimizing the communication range is of concern when to ensure user cooperation and satisfaction.

Following the approach described in [5] a microscopic simulation of an idealized Monday based on data from Washington, D.C.'s bike-sharing system (2014) is realized. The simulation will be used to describe the application of the decentralized control framework and to measure the impact of the communication range as a coordination parameter. Washington, D.C.'s bike-sharing system was chosen as a base for the simulation

978-83-60810-90-3/$25.00

as all data concerning the system is freely accessible over the *Capital Bikeshare Dashboard* [7]. The *Capital Bikeshare* system has been started in September 2010 and until May 2013 it was the largest bike-sharing service offered throughout the United States [8]. In 2014, the system had 345 stations and about between 2400 and 2900 bikes were available for usage. Like many other bike-sharing system the pricing is based on the principle that the first 30 minutes of a rental are for free (except a fixed membership fee). Each additional 30 minutes require an extra fee. To ensure the reliability of the system and therefore, both the availability of bikes and free docks at the stations, Capital Bikeshare uses trucks to redistribute the bikes [9]. Fig. 1 shows the rebalancing efforts ventured by Capital Bikeshare in 2014. The figure shows that the operation of such a bike-sharing systems requires a significant amount of redistribution efforts.

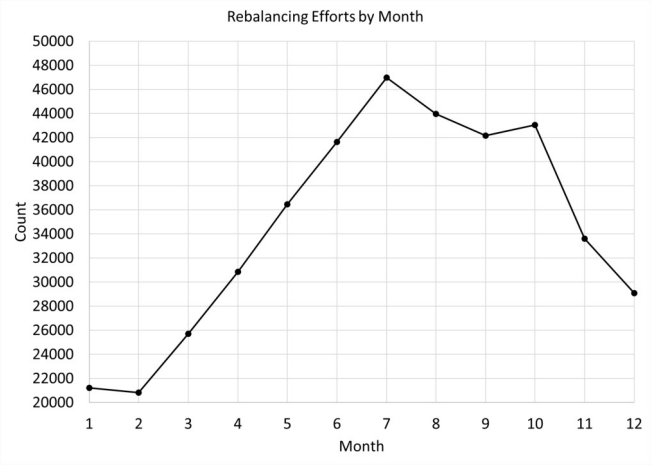

Fig. 1. Capital Bikeshare rebalancing efforts in 2014 (data taken from [7]).

However as shown in Fig. 2 stations still tend to become empty or full. Here the number of full and empty instances per month in 2014 are shown. From the data it becomes visibly, that the amount of empty stations is higher than the amount of full stations, indicating that the stations may be designed to have spare capacities to increase the chance that a bike can be returned at a station. In conclusion, the figure shows that, despite the redistribution efforts that are already carried out, there is potential for further improvement. This can either be an increasing number of truck-based redistributions or the introduction of new approaches, especially to overcome the problem of empty stations, e.g., by a self-organizing approach for the redistribution of bikes by the users.

The remainder of this paper is structured as follows: the next section will introduce related work in terms of the operation and planning of redistribution attempts as well as approaches dealing with the realization of self-organizing behavior based on decentralized control. Section III presents a decentralized control framework designed to allow the construction of decentralized coordination processes for different types of applications and systems. In Section IV, a Multi-Agent-based

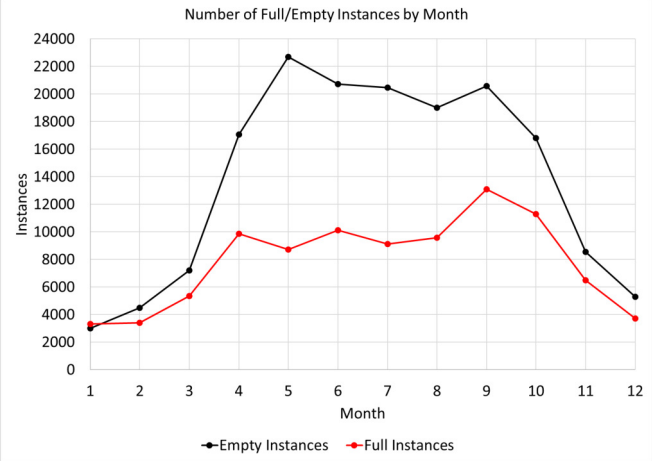

Fig. 2. Number of full/empty instances in 2014 (data taken from [7]).

simulation system of Washington D.C.'s bike-sharing system is introduced and it is described how the decentralized control framework is used to realize the self-organizing redistribution of bikes in the simulation system. Section V presents the results of the simulation and evaluates the impact of the communication range coordination parameter to the self-organizing strategy. Finally, Section VI concludes the paper and presents an outlook on future work.

II. Related Work

Several attempts have been ventured out to overcome the previous mentioned problem of maintaining reliability in bike-sharing systems. The authors of [10] used clustering techniques to identify shared behaviors across stations in order to predict short-term station usage for Barcelona's *Bicing* system. Thereby, they provide a spatiotemporal analysis of 13 weeks of bike station usage to sense and predict the rush on certain stations depending on their location and the time of day. Thus, supporting the operation of the system by providing planning support for the distribution of bikes. Similar work, also focusing on Barcelona's Bicing system was done in [11]. The authors analyzed human mobility data in an urban area using the amount of available bikes at the stations. Based on the data sampled by the system operator's website temporal and geographic mobility patterns within the city have been detected. These patterns were applied to predict the number of available bikes at the stations ahead. The timeliness of the whole bike-sharing topic is elaborated in [12] where the characteristics and commonalities between particular bike-sharing systems with a view to deriving influences on the sustainability of systems is explored. The empirical study analyzes bike-sharing systems in five Chinese cities. As China is suffering from severe negative consequence of high private vehicle usage in large and densely populated cities, it would greatly benefit from an environmentally-friendly way of transportation like bicycling. China has a long history of bike usage in the country and therefore, it provides a great potential for such a green form of travel to be part of public and

private transportation. Therefore, the authors of [12] analyze the effect of different bike-sharing systems in China and draw conclusions based on their success for the development of new systems.

In terms of building self-adaptive and self-organizing systems, there are several approaches which deal with the associated challenges. Research areas like Autonomic [13] or Organic Computing [14] provide approaches to solve these challenges. Both approaches rely on different types of feedback loops based on (usually) centralized control elements. According to [15] feedback loops are a key design element within a distributed system in order to exhibit adaptivity. Feedback loops normally consist of three main components: (1) Sensors are in charge of observing the behavior and the (current) status of the component, respectively the environment it is situated in. (2) Actuators can change the configuration of the system, which can lead to changes in the component's behavior. (3) A computing entity serves as a connector between the system input (sensor) and the output (actuator). It can be very different with regards to its internal architecture and abilities (cf. [16]). The importance of decentralized control to achieve requirements like resilience, robustness and scalability in large distributed systems has been identified in [17]. The work presented there distinguishes decentralized self-adaptive solutions from their centralized counterparts and also proofs some of the key research challenges for the realization of decentralized self-adaptation.

Related work in terms of decentralized coordination is among others presented in [18]. There a framework for the decentralized coordination of ubiquitous web services is proposed. It is based on an Event-Condition-Action (ECA) approach and relies on an XML-based language for describing ECA rules that are embedded in web service-enabled devices. Another example for a self-organizing infrastructure that offers coordination capabilities, inspired by chemical reactions is the *TuCSoN* coordination space concept [19]. It relies on a multiplicity of independent communication abstractions, called tuple centers. These can be spread over Internet nodes and are used by agents to interact with each other. TuCSoN exploits tuple centers as its coordination media, where a tuple center enhances a tuple space with a behavior specification. Therefore, the tuple centers are a communication abstraction whose behavior can be defined to embed an overall law of coordination. This is similar to the approach presented in this paper which utilizes coordination media as communication abstractions. Also similar is the propagation of a clean separation of concerns between application and coordination logic as introduced by [20]. The authors of [20] propagate a loose coupling between the core functionality of an application (computation) and the coordination. Thereby coordination is an orthogonal aspect w.r.t. to the computation when it comes to the realization of distributed systems. According to [20] this increases the generality when the coordination is swapped in a separate model.

However, there is a lack of approaches that support decentralized coordination in general regardless of the used technology and design patterns. The authors of [21] for example present a decentralized framework for the dynamic composition and coordination of autonomic agent applications. As a first step toward such a general decentralized control framework, that will be proposed in the next section, previous work dealt with a middleware supporting the construction of decentralized control in self-organizing system based on the concept of Active Components [22]. Active Components combine the autonomous behavior known from software agents with the service provider paradigm from the Service Component Architecture (SCA). A more detailed description about the concept of Active Components is given in [23].

III. DeCoF: A decentralized Coordination Framework

Today's distributed systems are characterized by an increasing size and complexity, which requires novel engineering approaches. The utilization of self-organizing processes has been proposed to enable adaptiveness of inherently decentralized systems [24]. Self-organization refers to physical, biological and social phenomena, where global structures arise from local interactions of autonomous individuals [25]. It has turned out to be a promising paradigm for the development of advanced distributed applications and systems with strongly decentralized control and high demands for self-adaptive behavior.

The designed decentralized coordination framework is based on the concept that the self-organizing dynamic that causes a system to adapt to external and internal influences is controlled by decentralized coordination processes. The processes describe the self-organizing behavior that continuously structures, adapts and regulates aspects of the application. They instruct a set of decentralized Coordination Media and Coordination Endpoints. Coordination Media deal with the interactions between the components (information propagation), while the Coordination Endpoints handle the adaptation of the components (local entity adaptation). Together they control the microscopic activities of the components, which on a macroscopic level lead to the manifestation of the intended self-organizing dynamic. The integration of the Coordination Endpoints and Media is prescribed by declarative defined coordination processes which structure and instruct their operations (cf. Section IV-A for an example of such a declarative coordination process description).

The Decentralized Coordination Framework (DeCoF) emerges from a tailored programming model for the software-technical utilization of coordination processes as reusable design elements in Multi-Agent Systems (MAS). The DeCoMAS (Decentralized Coordination for Multi-Agent Systems) [26] architecture introduces concepts like Coordination Media for the propagation of Coordination Information and Coordination Endpoints for the observation and adaptation of the local entities. But while the DeCoMAS architecture is especially

designed to equip BDI[1]-agent system with coordination processes and therefore, is limited to such systems, DeCoF aims at supporting distributed systems in general. Thereby, different and also heterogeneous software components in general are supported, allowing to equip not only MAS but component based systems in general with decentralized coordination processes to extend them with self-organizing capabilities. The current reference implementation supports software components written in *Java*. But, it is also applicable to other programming languages in general.

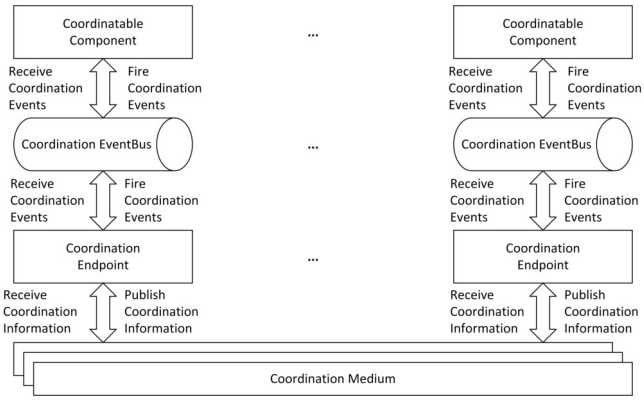

Fig. 3. Architecture of the Decentralized Coordination Framework

Fig. 3 shows the conceptual architecture of the proposed framework. Components respectively agents that should be equipped with coordination capabilities to realize self-organizing behavior based on the aforementioned concepts are labeled as *Coordinatable Components*. As the framework aims at supporting various types of MAS resp. distributed systems in general, there are no inherent characteristics that could be used to monitor or control the behavior of the agents respectively components, e.g. different types of MAS use different scheduling and life-cycle mechanisms, while component-based systems might lack them at all. Therefore, the concept of *Coordination Events* is introduced. These are events that are fired by a coordinatable component, whenever something relevant for the coordination happened inside the component. A coordination event (ce) is a tuple with the length 2 (double or 2-tuple) containing contextual data about the specific coordination event (cd) as well as a representation of the event's originator (eo). A coordination event is thus defined as: $ce = (cd, eo)$.

Following a separation of concerns between the application and the coordination logic as propagated by [20], the actual processing of the coordination events is handled by a related *Coordination Endpoint*. The coordination endpoints are loosely coupled to the coordinatable component via a so called *Coordination Event Bus*. An event bus[2] allows publish-subscribe-style communication between components without requiring the components to explicitly register with one another (and thus be aware of each others). The separation of concerns requirement is fulfilled by the loosely coupling between the coordinatable component and the coordination endpoint realized by the coordination event bus. Thus, the component is only responsible for realizing the application logic and do not need to have knowledge about (the present of) the coordination endpoint.

When a coordinatable component fires a coordination event, it is received by the related coordination endpoint via the coordination event bus. The endpoint then processes the event according to a prescribed coordination process definition. The process definitions defines how different coordination events have to handled by the endpoints. These descriptions contain instructions on *how* to distribute the coordination event to *which* other coordinatable components. The *how* is described by indicating what kind of *coordination medium* should be used for the information dissemination. As described before, coordination media deal with the information propagation among the components. The *which* is realized with a role-concept. A coordination process definition specifies various roles that components might adopt. Thereby, a component can have multiple roles and a role may be carried out by various component types. So to process a coordination event the endpoint encapsulates it and enriches it with additional information about the originating coordination endpoint. The resulting *Coordination Information* (ci) is a 2-tuple containing the coordination event (ce) and information about the originating endpoint (oe), thus is defined as: $ci = (ce, oe)$. Besides prescribing which coordination event, originating from which coordinatable components should be published to which other components, a coordination process definition also prescribes which type of coordination event should be triggered in the receiving components. How the coordination information are actually propagated is part of the implementation of the actual coordination medium. This regards the technical realization of how the information should be distributed, as well as how the subset of receivers is selected. Therefore, simple coordination medium relying on a network-topology for the information dissemination as well as complex ones, where the dissemination of the information relies on, e.g. diffusion processes in an (virtual) environment are possible.

Fig. 4 shows an UML class diagram of the relevant classes and interfaces of the framework. A component that should be equipped with coordination capabilities has to implement the `ICoordinatable` interface. It requires the component to implement two functions. The `getId` function returns an unique string that identifies the component. The `handleCoordinationEvent` function is called whenever a coordination event relevant for the component has been received by its coordination endpoint. Here the

[1]The Belief, Desire, Intention software model is developed for programming intelligent agents. It is characterized by the implementation of an agent's beliefs, desires and intentions and uses these concepts to solve a particular problem in agent programming [27].

[2]See: https://www.github.com/google/guava/wiki/EventBusExplained (accessed April 20, 2016)

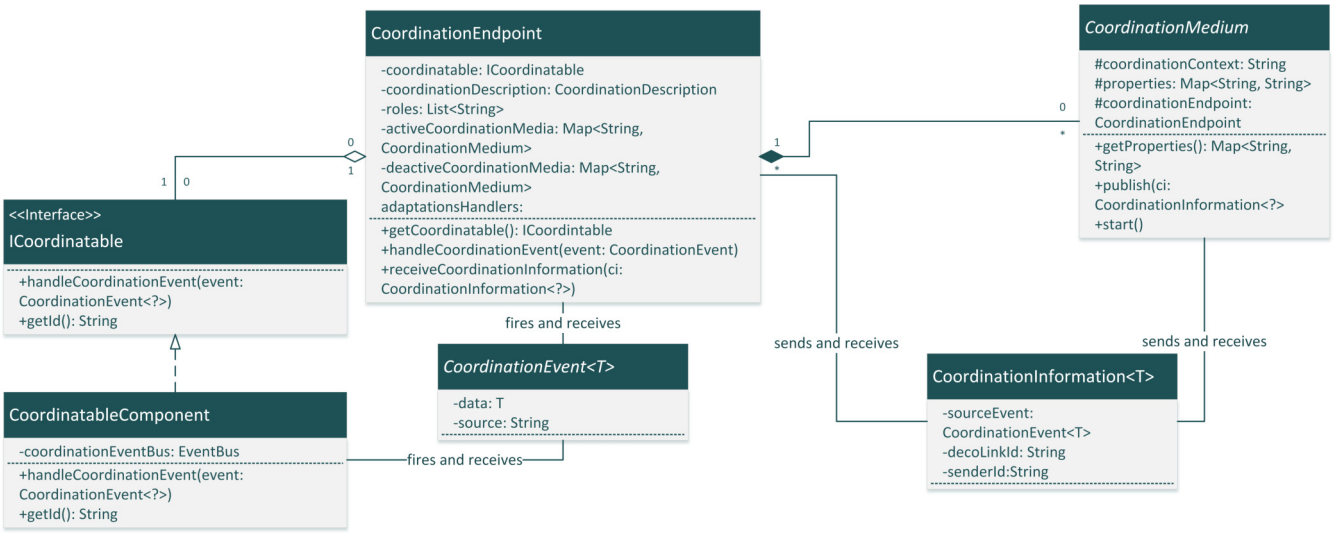

Fig. 4. UML class diagram of the Decentralized Coordination Framework.

component-specific coordination event handling should be implemented. Also, an according coordination endpoint has to created for the component. The framework provides a helper function that creates such a coordination endpoint and connects it to the component with a coordination event bus. The framework provides a ready-to-use implementation of the `CoordinationEndpoint` class as well as a generic implementation of the `CoordinationInformation` class. Abstract super classes exist to implement specific `CoordinationMedium` and `CoordinationEvent` classes. Therefore, if an application should be equipped with coordination capabilities the following steps have to be performed:

1) Writing the XML-based declarative coordination process description that instructs the coordination endpoints.
2) Implementing the `ICoordinatable` interface for the components that should be coordinated.
3) Identifying the relevant coordination events and implementing them using the abstract `CoordinationEvent` super class.
4) Implementing the coordination logic for the information propagation by extending the abstract `CoordinationMedium` super class.

IV. Simulation: Self-Organizing Redistribution of Bikes

The decentralized coordination framework described in the previous section has been used to implement a coordination process in order to control the self-organizing redistribution of bikes in a simulated bike-sharing system. This section will give an overview about the implementation details of the simulation system as well as the usage of the coordination framework. Also, the simulation scenario will be described.

A. Implementation Details

The simulation system is realized using RinSim [6], a logistics simulator written in Java. It supports (de)centralized algorithms for dynamic pickup-and-delivery problems (PDP). The cyclists renting bikes at stations were realized as agents. They are created at a specific station, where they try to rent a bike and if a bike is available at the station, they drive it to their designated destination stations, where they return it. In order to map the road model of Washington, D.C., the corresponding area was extracted from Open-StreepMap (OSM) [28] and transformed into the graph-based road model supported by RinSim. Thus, the movement of the cyclists along the roads can be simulated by moving them on the edges of the resulting graph. Following the PDP-modeling approach, the bikes were modeled as parcels and the bike stations as depots. Time in the simulation system is simulated in a discrete manner, divided into ticks of 60 seconds length. Therefore, the simulation of a whole day consists out of 1440 simulation ticks.

In order to rebalance the availability of bikes at the stations, as a possible addition to the truck-based redistribution efforts ventured by Capital Bikeshare, an incentive scheme for the users to stimulate them to re-distribute bikes in a self-organizing fashion is proposed. The approach is based on the concept that whenever a user tries to rent a bike at an empty or nearly empty station, an alternative rent station with a sufficient amount of bikes is suggested to the user. Equivalent, whenever a user tries to return a bike at a full or nearly full station, an alternative return station with a sufficient amount of free docks is suggested to the user. Thus, the distribution of bikes among the stations will be balanced in a self-organizing way, as users renting a bike are detoured from empty stations to, preferably full or nearly full ones or at least non-empty ones. The same goes for the returning of bikes, where users are detoured from full or nearly full stations to preferably empty or at least non-full ones.

For the simulation the alternative stations are proposed to the user agents whenever they approach a station, in a real world scenario a mobile phone application is imaginable that informs users about alternative rent or return stations before they actually approach them in case they state their intent to approach a station a priori. Possible incentives for a detour are, e.g., free minutes that are added to the users next trips or virtual bonus points that they can exchange for goodies in web shop, similar to the bonus programs of many retail stores. Fig. 5 depicts the whole process from a user's point of view.

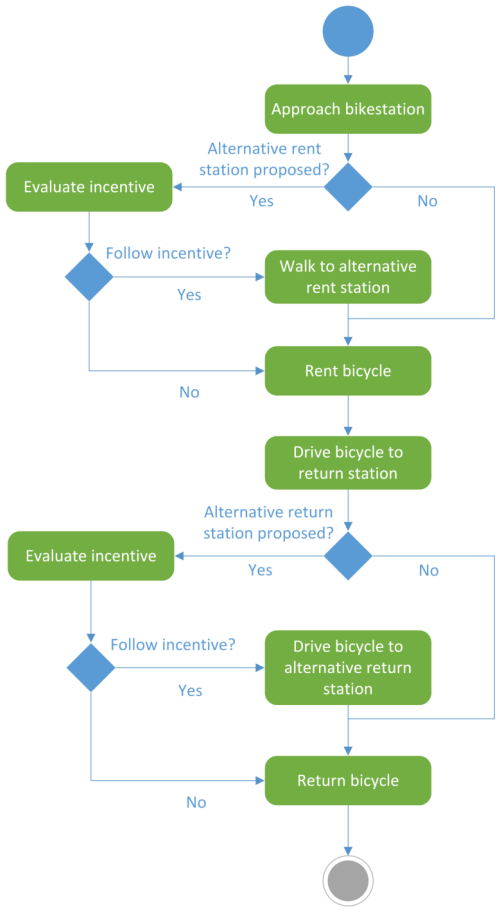

Fig. 5. UML activity diagram describing the rent/return process from a user's perspective.

A decentralized coordination approach is used to calculate the alternative rent and return stations that are suggested to the users. It is realized using DeCoF. Bike stations periodically send their current occupancy rate to all other bike stations within a certain circular communication range. Stations receiving such status updates from other stations collect them and use them to calculate alternative rent and return stations in a decentralized way. Whenever such status updates are received, the receiving bike station determines the station with the lowest and the highest occupancy rate from the list of stations. The station with the lowest occupancy rate is selected as the alternative return station and the station with the highest occupancy rate is selected as the alternative rent station. These alternative stations are suggested to a user whenever it tries to rent a bike at the station when the station is currently empty, respectively when the user tries to return a bike at the station when it is currently full or critical occupied. So, the maximum detour distance equals the communication range of the stations, as only stations that are within a station's communication range are considered. For the simulated scenarios, a critical occupancy rate of 75% is used.

Following the usage instructions of the DeCoF the bike stations that are implemented as RinSim specific depot agents (`Bikestation`), implement the `ICoordinatable` interface and are equipped with a coordination endpoint. Every minute of the simulated time they fire an `BikeStationStatusUpdateEvent` as a coordination event which contains their current occupancy rate. The according coordination endpoint publishes this as part of a coordination information over a `RoadBasedCoordinationMedium`. This medium extends the abstract `CoordinationMedium` super class with RinSim specific coordination logic. Therefore, it has a reference to the simulator's road model, so it has knowledge about the simulation environment and the position of all the bike stations. The circular communication range is a configurable coordination parameter of the medium. Based on the road model the medium selects all bike stations within the communication range and publishes the coordination information to their according coordination endpoints. When receiving such coordination information the endpoints trigger a `BikeStationStatusUpdateEvent` in the coordinatable bike stations and thus, initialize the calculation of the alternative rent and return stations. Listing 1 shows the declarative coordination process description for this application. It shows how the `Bikestation` agent is mapped to the `bikestation` role. This role is used to instruct a decentralized coordination link (`deco-link`). The link definition contains information about the affected roles, the `bikestation` role in this case, and how the coordination events should be mapped to each other as well as which coordination medium should be used for the information propagation. In this case the `RoadBasedCoordinationMedium` is used and it is configured with a `maxCommRange` coordination parameter limiting the information dissemination. In case of the listing a communication range of 1 km is used.

Listing 1. Bikesharing coordination process description (XML).

Fig. 6 visualizes the system's self-organizing dynamic that results from the previous described concepts. The dynamic is composed of two parts, the *Bikestation Coordination* as well as the *User Cooperativeness*, and it results from the interactions between them. The coordination among the bikestations generates the alternative rent or return stations that are proposed to the users. Then the self-organizing dynamic of the systems depends on the users' willingness to follow such a proposal.

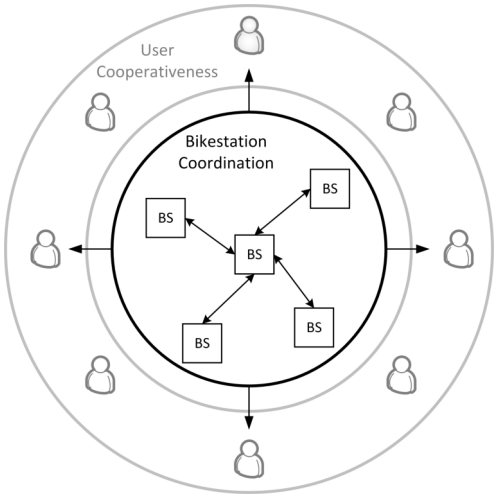

Fig. 6. Self-organizing dynamic of the bikesharing-system.

B. Simulation Scenario

A typical Monday was examined in order to simulate Washington D.C.'s bike-sharing system and to evaluate the impact of the proposed coordination strategy. Therefore, the trip history data of all Mondays (except holidays) from 2014 provided by Capital Bikeshare (the system's operator) was analyzed. To do so, the day was divided into 24 time slices. For each of these 24 time slices the departure probabilities q and the dependent destination probabilities q for the bike-stations were calculated based on the ventured trips: The departure probability p_A for a station A is denoted by

$$p_A = \frac{n_A}{N},$$

with n_A as the number of all trips started at station A while N is the total number of trips. The dependent destination probability q_B is denoted by

$$q_B = \frac{d_B}{D_A}.$$

It is characterized by the fraction of numbers of departures to station B from station A denoted as d_B and the total number of departures from station A denoted as D_A. The simulated scenario starts at 12 a.m. In order to simulate the different rush at different times of the day, the mean total number of trips for each of the 24 hours of the day was determined based on the trip history data. During the execution the simulator generates the number of cyclist agents specified by the rush equally distributed for the currently simulated time slice. As a simplification, all cyclists move with a constant speed along the graph-based road model. In order to find a route from the departure to the destination stations, they use a shortest path approach and traverse the edges of the graph road model, considering the edge weight as the distance to the next node. The simulation was configured to allow an overcrowding of bike stations, when no free docks are available. If a cyclist agent tries to rent a bike at and empty station, this incident is reported and the total number of rides that did not take place is returned as part of the simulation results for evaluation purposes. Fig. 7 shows an extract of the simulated map with the road model and some of the cyclists and bike stations as well as the chosen communication range.

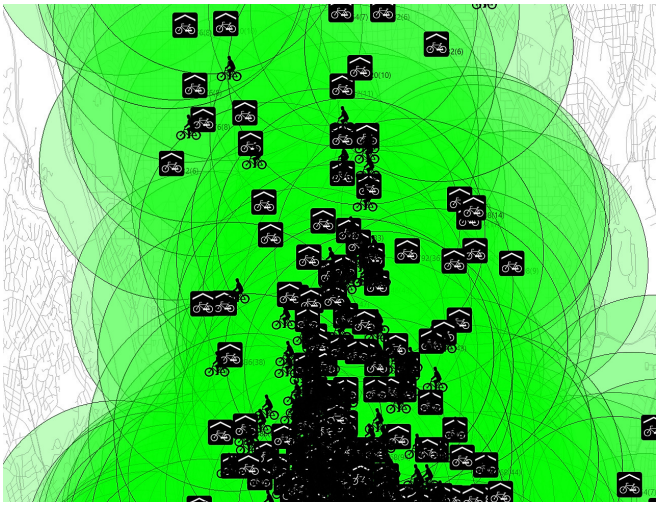

Fig. 7. Extract of the simulated map showing the road model, some of the cyclists and bike stations as well as the chosen communication range.

V. Simulation: Self-Organizing Redistribution of Bikes

In order to evaluate the impact of the self-organizing redistribution strategy depending on the communication range as the relevant coordination parameter, different scenarios with fluctuating communication ranges as well as a reference scenario without any self-organizing behavior were simulated. In all of this scenarios the cyclists moved with a fixed speed of 18km/h. Initially, half of the docks of the bike stations were

occupied. The bike stations' number of docks was extracted from the data provided by operator via the *Capital Bikeshare Dashboard* [7]. For all the scenarios simulating the self-organized redistribution of bikes, a user cooperativeness rate of a 100% was assumed. This means that the users always follow a proposed detour to an alternative rent respectively return station. This assumption was made for a more precise evaluation of the impact of the communication range. A detailed analysis of the impact of the users' cooperativeness rate on the proposed self-organizing redistribution strategy is presented in [5].

Fig. 8 shows and compares the results of a simulation scenario with no self-organizing redistribution of bikes and one with a communication range limited to 1,5 km. The parameters of the simulated scenario are summarized in Table I. The figure depicts the number of stations that are in a normal state (neither full nor empty) for both scenarios. It is observable for both cases, how the number of normal stations declines with the morning rush-hour beginning at around 7 a.m. (minute 420). Over the day, these numbers fluctuate only a little. In the late afternoon (around minute 1000) the number of normal stations recovers a bit. This behavior can be explained by the rush-hour movements of commuters. In the morning they drive from the suburbs to the city center and return in the afternoon. Stations in the suburbs tend to become empty during the morning rush-hour, while stations in the city center tend to become full or over-crowded. The returning commuters in the afternoon take bikes from the overcrowded stations in the city center and refill the empty ones in the suburbs when they return, thus increasing the number of normal stations. The figure gives a first impression about how the self-organizing redistribution of bikes improves the number of normal stations over the whole day.

TABLE I
PARAMETERS OF THE CONDUCTED SIMULATION.

Simulation Parameter	Value
No. of cyclists	7433
No. of stations	345
Cyclist speed	18 km/h
Initial bikestation utilization rate	50%
User cooperativeness rate	100%
Bikestation communication range	1.5 km

In order to further measure the impact of the self-organizing redistribution with regards to the maximum communication range, 6 simulations with different communications ranges (from 0,5 km to 3 km) were performed and compared to the reference scenario. Apart from the fluctuating communication range the same simulation parameters as displayed in Table I were used. The according results are shown in Fig. 9. It contains the mean deviation of the number of normal stations in comparison to the previous described reference scenario with no self-organizing behavior. This value states how many more stations in average over the simulated day are in the normal state in comparison to the reference scenario. The figure shows that with a communication range of 1,5 km a

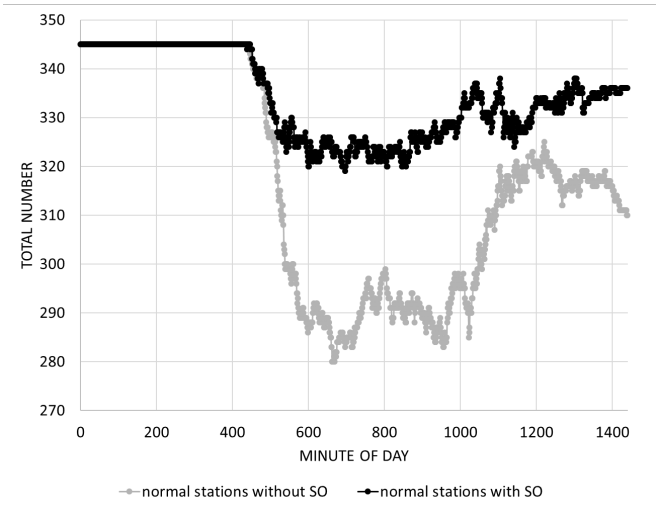

Fig. 8. Results of a simulation scenario with enabled and disabled self-organization.

maximum deviation of 10,7% can be achieved. This means that about 10% more of the total amount of stations are in the normal state in comparison to the scenario with no self-organizing behavior. Considering 345 stations in total, an improvement of 10% of the stations means that about 35 more stations are in the normal state. Fig. 8 shows that without any self-organizing redistribution efforts at least about 280 stations are in the normal state. This results in 65 stations being empty or full/overflown. By increasing the number of normal stations by 10% of all stations to about 315 stations, the number of stations that are empty or full/overflown is reduced by about 55% to 30 stations.

As the communication range is directly related to the distance a user is detoured when he/she wants to rent or return a bike, it is obvious that this value should be as low as possible to increase user acceptance. Also the figure shows that a higher communication range actually may have a negative impact on the results. One potential reason is that the trip time is lengthened and therefore, also the time the bikes are in usage and thus, not available at the stations. In addition, a higher communication ranges may decrease the density of bikes in the area where they are actually needed. For example, they might be detoured from the city center back to the suburbs if the communication range is too high and therefore, no longer available to meet the higher demand in the city center.

VI. CONCLUSION AND FUTURE WORK

The acceptance of bike-sharing systems depends heavily on the availability of bikes at the stations. In spite of truck-based redistribution efforts by the operators, stations still tend to become empty or full, especially in rush-hour situations. In this paper, we explored an approach for the self-organizing redistribution of bike by the users and presented a decentralized coordination framework for the realization of self-organizing systems. It is based on the concept that the self-organizing dynamic that causes a system to adapt to external

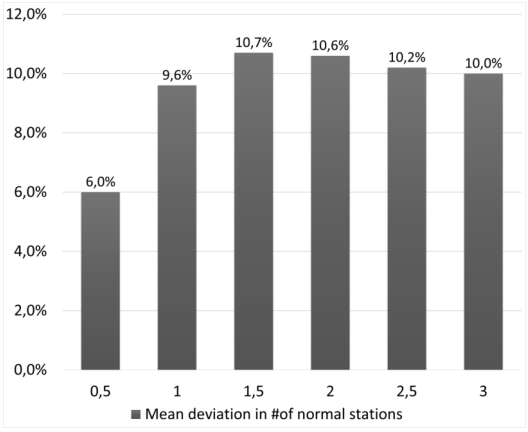

Fig. 9. Mean deviation of the number of normal stations in comparison to a reference scenario with no self-organizing behavior. X-axis denotes communication ranges in km.

and internal influences is controlled by decentralized coordination processes. The processes describe the self-organizing behavior that continuously structures, adapts and regulates aspects of the application. They instruct a set of decentralized coordination media and coordination endpoints. Coordination media deal with the interactions between the components (information propagation), while the coordination endpoints handle the adaptation of the components (local entity adaptation). Together they control the microscopic activities of the components, which on a macroscopic level lead to the manifestation of the intended self-organizing dynamic. The integration of the coordination endpoints and media is prescribed by declarative defined coordination processes which structure and instruct their operations. A microscopic simulation of a bike-sharing system based on data taken from Washington, D.C. (2014) was realized to show how the presented framework can be used to build self-organizing applications. In case of the presented bike-sharing system, a decentralized coordination process was introduced that allowed the bike stations to communicate their current occupancy rate to other stations within a certain circular communication range to calculate alternative rent and return stations for the users. Thereby, we measured and evaluated the impact of the communication range as the relevant coordination parameter for the performance of the self-organizing behavior.

Future work will deal with the structural adaptation of coordination processes. Under certain conditions self-adaptive systems may exhibit a behavior where performance decreases and/or starvation may occur. Structural adaptations are a promising concept under such conditions, that can be used to realize the dynamic exchange or reconfiguration of self-organizing coordination processes. By facilitating the concept of structural adaptations presented in [29] for the proposed decentralized coordination framework it is envisioned to realize the dynamic exchange of the described coordination process. Thereby, another coordination process based on the formation of clusters among the stations, where a random station will take on the role of a super station for this cluster and receive status updates from all stations within the cluster, so it can calculate the optimal alternative rent and return stations for all stations within the cluster, will dynamically replace the existing coordination process at runtime.

***Abstract*—Smart systems have to deal with environmental changes and react for adapting their behavior to changes in the operating conditions, so to always meet users' expectations. This is fundamental for those systems operating in open environments that may change frequently. Smart environments are complex systems that more than others are affected by these issues. In this paper, we propose a normative framework for regulating at run-time system behavior when some situations occur, thus providing system flexibility. The proposed approach includes also mechanisms to identify anomalous situations that can occur in the system due to the run-time injection of new norms.**

I. Introduction

A GREAT challenge in complex systems is to adequately deal with the unpredictability and the dynamics changing of the application context the systems are plugged in. Smart environments are complex systems that more than others are affected by these issues. A way to provide system flexibility is given by implementing statically normative frameworks in which norms for regulating the behavior of the system are specified at design time. This kind of solution is not effective when we face with unpredictable and unexpected situations that have not been considered at design time. Hence, solutions for modifying at run-time norms or injecting new ones into the systems are mandatory.

It is widely accepted that multi-agent systems provide relevant features for implementing smart environments [1][2][3][4]. In such field, norms have been widely employed for regulating the ideal behavior of the system. Norms are considered as a mechanism for controlling multi-agent societies and for ensuring order and predictability [5]. Such norms define standards of behaviors that have to be adopted in the society as well as undesired behaviors that have to be avoided. Hence, normative frameworks rely on a representation of norms by means of permission, obligations and prohibitions that ensure the agents behave within predefined boundaries. In particular, several works have been conducted for addressing theoretical and practical aspects about norm change [6][7][8] providing agents with mechanisms for enacting behavior modification. Typically, new plans/actions have been created for agents to be complied with new norms.

In this paper, we propose a normative framework to be coupled with goal oriented systems in order to introduce more flexibility in smart environment by means of run-time injection of norms regulating system goal fulfillment. In our approach, norms and goals allow to cope with two main aspects of a smart environment. Goals express what is the desired state of the world the system has to result in. Norms regulate the desired state of the world according to the normative context in which the system works.

In order to modify system behaviors when new norms are injected into the system, we implemented some algorithms in agents life cycle for reasoning about new goals to be pursued according to new norms. In so doing, we also manage some anomalous situations that can occur in the system due to the run-time injection of new norms. In particular, we identified three kinds of anomalies:

- the injection of an inconsistent norm, namely containing logical contradictions;
- the injection of a norm that is structurally incompatible with a goal;
- finally, the injection of a norm that creates an antinomy.

Thus, the main contributions of this work are:

- an algorithm for modifying agent goal fulfillment according to norm changing;
- an algorithm for checking the consistency of norms with the system.

In order to show in semi-natural languages some practical examples, we use GoalSpec [9] and SBVR [10] for modeling goals and norms.

Moreover, the normative framework with algorithms was implemented in MUSA [11]. It is a Middleware for User-driven Service Adaptation that provides means for supporting run-time adaptation of a process together with a multi-agent system for executing the activities of the process.

In order to validate our approach, we simulated a smart environment for improving services of a health care home. The simulation has been developed by integrating MUSA with ICasa simulator [12].

The rest of the paper is organized as follows. Section II introduces the theoretical background of the paper. In Sections III and IV, related works and motivation are respectively presented. Section V and Section VI presents the key concepts and the algorithms the proposed normative framework is based on. Section VII illustrates an application scenario of the proposed approach in a simulated smart environment. Finally, in Section VIII conclusions are drawn.

II. BACKGROUND

The main purpose of this work is to introduce more flexibility in smart environments by means of run-time injection of norms for adapting the behavior of the system to new situations. This section introduces the theoretical background of the paper. In particular, it is organized in four parts: the first one presents the features making multi-agent systems more suitable for implementing smart environments; the second one introduces two modeling languages (GoalSpec [9] and SBVR [10]) we use for modeling goals and norms for specifying functionalities and setting regulations the smart environment has to own. The third one provides an overview of MUSA [11], a multi-agent system for the dynamic composition and the orchestration of services in a distributed and open environment we adopt for implementing the functionality of the smart environment. The last one introduces ICasa [12], a dynamic pervasive environment simulator, we use for simulating the injection of norms in a smart environment.

A. Multi-Agent System features for Smart Environment

A Multi-Agent System (MAS) is a distributed system composed of autonomous entities, called agents. The decentralized and loosely coupled nature of such kind of systems makes it possible to design applications that are highly flexible, scalable and adaptive. The multi-agent paradigm provides several features that make them more suitable in order to fit smart environment requirements. Among them:

- *Decentralization* - MASs provide decentralized control based on distributed autonomous entities.
- *Interactions* - MASs support complex interactions between entities, using high level semantic languages. It is essential for smart environments that commonly deal with various, heterogeneous information from physical sensors, services or users preferences.
- *Coordination* - In a MAS, individual entities with limited capabilities are able to coordinate in order to achieve complex tasks. Flexible organization patterns enable groups of agents to create and dynamically reconfigure applications depending on current conditions. In an open, and dynamic smart environment, this feature is highly suitable for dynamic composition of elementary functionality in order to accomplish more sophisticated processes.
- *Heterogeneity* - A MAS is a society of agents with different capacities and roles.

B. GoalSpec & SBVR

GoalSPEC [9] is a language designed for specifying user-goals and enabling at the same time goal injection and software agent reasoning. The concept of goal is central in GoalSpec. Goals are described as states of the world that the user desires to achieve [13]. In GoalSpec, a goal is composed of a *Trigger Condition* and a *Final State*. The trigger condition is an event that must occur in order to start acting for addressing the goal. The final state is the desired state of the world that must be addressed. Trigger conditions and final states must be expressed by using domain ontology predicates. In GoalSpec, uppercase words represent the keywords of the language, and lowercase words represent the predicates constrained by the domain ontology.

Let us suppose we want define in our smart environment system the following common user goal:

If at 07:00 the living-room temperature is below 20 C, the shutter should be closed and the air conditioning turned on at level 6.

In GoalSpec, it could be written as follow:

WHEN on(07:00 pm) AND temperature(T) AND T<20 THE system SHALL ADDRESS closed(shutter) AND turned_on(air_conditioning, level(6)).

In order to define norms in natural language, we adopted the SBVR [10] standard as a modeling language for our system.

The Semantics of Business Vocabulary and Business Rules (SBVR) is an adopted standard of the Object Management Group (OMG). It is designed for business domains for formalizing complex business rules. In business domains, a business rule describes the conditions of a business process execution. A business rule may define the semantics of business concepts, reactions to business events, constraints and preconditions on tasks and activities, as well as the prohibitions, permissions and obligations of business actors and activities. In other words, business rules guide and constrain various aspects of business, including the sequence and timing of activities [14]. SBVR uses 'semantic formulation', which is a way of describing the semantic structure of statements and definitions.

In our approach, we use GoalSPEC for defining expected results of the system in terms of functionality and we adopt SBVR for specifying the normative context the system works in. Hence, by using the same kind of abstraction of SBVR, we can see a smart environment as an organization of entities that are involved in activities for reaching goals. The entities of the smart environment, sharing the same domain ontology (the SBVR vocabulary), constitute a community's body of shared meanings that can understand SBVR rules.
An example of SBVR rules for the previously defined goal could be: *It is prohibited that the system closes shutters if John is at home*.

C. MUSA- A Middleware for User-driven Service Adaptation

The Middleware for User-driven Service Adaptation (MUSA) proposed in [11] is intended to provide a means for supporting run-time adaptation of a process based on a multi agent system for executing the activities of the process. The core element of the approach is the use of Goals for explicitly representing user-preferences into the system (what to address). The injection of goals triggers the re-organization of the agents in hierarchical groups. These self-adaptive structures allow for dealing with dynamic composition and orchestration of services. MUSA provides a platform in which *(i)* it is possible to deploy some capabilities that wrap real services,

completing them with a semantic layer for their smart use; *(ii)* users can inject their goals for satisfying their specific needs. Under the hypothesis that both goals and capabilities refer to the same semantic layer (described as an ontology), then the agents of the system are able to conduct a proactive means-end reasoning for composing available capabilities into tasks for addressing the user request.

D. iCASA - a dynamic pervasive environment simulator

iCasa [12] is a set of integrated tools for the development and administration of pervasive applications. It includes a smart home simulator that allows the creation and removal of a wide range of devices that can be used by the applications. Specifically, iCasa Simulator provides:

- A graphical user interface that displays a map of the house and the localization of the different devices. It allows developers to create and configure devices, create and move physical users, and watch their actual configurations;
- Scripting facilities for controlling the environment and to test the applications under reproducible conditions.
- Notification facilities for notifying users of any modifications in the environment.

III. Related Works

Norms like obligations, permissions and prohibitions have been implemented in multi-agent systems in order to specify (un)desired behavior of agents so that the goals of the system can be reached. They also provide means for coordinating agent activities in order to reach the overall objective of the system they are part of [15]. Norm-governed systems are also known as Normative systems.

Normative systems are commonly defined as systems that specify every possible system transition, whether or not that transition is considered to be legal or not. In other words, Normative Systems specify which actions or which states should be achieved or avoided [16][17][18].

A lot of work has been done about normative frameworks in the field of Electronic Institutions or Virtual Organizations where norms have found a natural implementation. For instance, Alechina *et.al* [19] present a programming framework for developing normative organizations. Such framework is based on N-2APL, a BDI-based agent programming language for implementing norm-aware agents. N-2APL supports normative concepts such as obligations, prohibitions and sanctions. In such a work, the normative system is conceived in such away that the interaction between agents and the environment is regulated by a "normative exogenous organizations", which is defined by means of a set of conditional norms (i.e: conditional obligation and conditional prohibition). Such norms have the form *obligation(l, o, d, s)* that means "*agent l is obliged to establish an environment state satisfying o before deadline d, otherwise it will be sanctioned by updating the environment with s*"[19]. A norm-aware deliberation approach is also proposed. It allows agents to determine the set of plans (to be adopted in order to satisfy a goal) of highest priority which do not violate higher priority prohibitions.

In [20] Kollingbaum and Norman proposed the NoA Normative Agent Architecture. It supports the implementation of norm-governed practical reasoning agents. NoA agents are motivated by norms to act. In the NoA language, all the effects of a plan are declared in a plan specification. These effects are considered by agents for reasoning about plan selection and execution. Moreover, the norms governing the behavior of a NoA agent refer to either actions that are obligatory, permitted, forbidden, or states of affairs that are obligatory, permitted or forbidden. The NoA language enables an agent to be programmed in terms of plans and norms. Normative statements formulated in the NoA language express obligations, permissions and prohibitions of an agent: *Obligations* motivate the agent to achieve either a state of affairs or to perform a specific action. Prohibitions require the agent to not achieve a state of affairs or to not perform an action. The agent is forbidden to pursue a specific activity. Prohibitions represent restrictions on what capabilities the agent is allowed to reach a certain goal. Finally, Permissions allow the achievement of a state of affairs or the performance of an action.

Some works have been conducted for addressing norm change and norm consistency providing agents with mechanisms for enacting behavior modification. Typically, new plans/actions have been created to comply with new norms [8][21][22]. In [23], Jiang *et.al* propose a normative structure, named *Norm Nets* (NNs) for modeling sets of interrelated regulations. NNs aims at verifying whether executions of business process are compliance with process regulations. Authors define a norm as a tuple of elements that specify the type of deontic operator, the pair role-action (the target) to which the deontic modality is assigned, a deadline of norm validity and a precondition that determines when the target is initiated. A formal method for checking norm compliance by using Colored Petri Nets is proposed. In [24] [25], authors propose a means for automatically detecting and solving conflict and inconsistency in norm-regulated Virtual Organization and Electronic Institution.

In the next section, we provide the reasons that motivate our work with respect to the related works.

IV. Motivation

Although a considerable literature exists about norms, it is mainly directed to explore the role of norms inside Virtual Organization and Electronic Institution that are tightly coupled with agents. We take inspiration from those works and we are trying to introduce norms in smart systems as mechanisms that regulate the system at a higher level of abstraction than that where agents work.

The normative framework we defined adopts a norm specification similar to the previous ones. But in our framework, we employ norms at a higher level of abstraction by moving them from activity's regulations to goal's regulations. This choice is motivated by the context of self-adaptive and self-organized systems (SASO) we are working on. Commonly this

kind of systems are able to effectively adapt their behavior to environment changes and self-organize their internal structure for finding composed solutions in order to achieve collaborative goals. In particular, the kind of SASO systems we are considering owns the following features [11]:

- *Openness* - They are open systems that evolve at run-time because: *(i)* new services could be made available for satisfying user requirements; *(ii)* the satisfaction of new user requirements may be demanded to the system;
- *Goal-directed* - They are goal-directed systems. Goals are motivators for these systems providing them the reason for doing something. Goals express user requirements to be satisfied.

The aim of this work is to increase the openness of the system by allowing the run-time introduction of new regulations thus improving the flexibility of such systems. In so doing, we look at norms from a different perspective with respect to the classical one. Starting from the consideration that goals are key elements for the systems we focus on and they are motivators of their behavior, we look at goals as commitments the system engages with users. In other word, goals can be seen as a particular kind of obligation that has to be satisfied when some conditions occur.

Hence, in the normative framework we developed norms that are directly linked to goals where a permission norm relaxes the conditions under which the goal has to be satisfied and a prohibition norm nullifies the commitment under the circumstances expressed by the prohibition. The effect is that norms may act for increasing the opportunity for the system to pursue the goal it is committed to (Permission) or, on the contrary, norms may inhibit system intentions to pursue the goal it is committed to (Prohibition).

By adopting this perspective, the norms operate for regulating *what* the system has to satisfy and not *how* it does that.

In order to provide an example, let us to suppose there is a system that is committed for satisfying the user goal *have lunch* and at the moment of the commitment, the system owns two means to satisfy the *have lunch* goal. Fig. 1 shows a goal diagram where the goal "*have lunch*" can be satisfied by performing the tasks "*book a restaurant*" or "*take a pizza*". Let us suppose that such smart system has to provide its assistance to a diabetic patient. A norm in the system states that "*It is prohibited that a diabetic patient has lunch before taking insulin*". The norm (at the goal level) constraints the requirement that the system can provide by inhibiting its intentions rather than disabling all the possible ways the system can follow in order to satisfy that requirement.

Let us suppose now that a new task "*cook with microwave oven*" is introduced at run time for satisfying the *"have lunch"* goal (see Fig.2). Considering that the norm at the goal level spreads to the task level, we do not need to add/change any system regulations to adapt the behavior of the system to manage the change of its operative context.

Moreover let us suppose that a new norm for the goal "*have lunch*" is injected at run-time in the system. The simultaneous presence of interrelated norms may cause some system conflict or inconsistency. Indeed, when two norms are interrelated, it may happen that being compliant with a norm may cause to be uncompliant with the second one, thus generating conflicts or inconsistencies. In classical approaches, conflicts are generated when an agent wants to perform an action that is simultaneously allowed and forbidden. Inconsistencies, instead, occur when an agent may be forbidden to perform an action that may be essential for fulfilling one of its obligations [26].

In our approach, we characterize the definition of conflict and inconsistency to deal with dynamically changing environments, where the conflicting state of two norms may change according to the particular execution context. In order to address this concern, we introduce some new definitions about conflicts and inconsistencies that are based on a representation of the execution context.

Resuming the previous example, let us suppose that a new norm regulating the "*have lunch*" goal is introduced into the system, that is "*It is permitted that guests have lunch if they have performed sports activities*". This latter norm is interrelated to the previous one because they both refer to the same goal "*have lunch*". The injection of the second norm could cause a system deadlock because if the conditions of both norms are simultaneously valid an antinomy is generated and the system does not know how to behave.

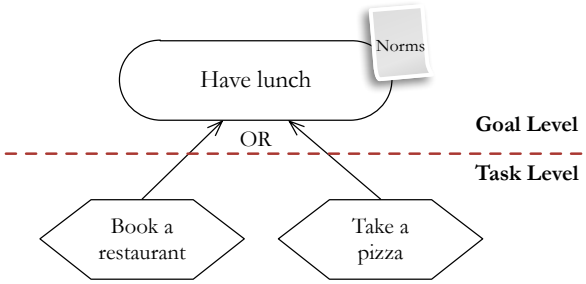

Fig. 1: An example of Means-End Analysis [27]. It introduces two tasks "*Book a restaurant*" and "*Take a pizza*" to indicate two particular ways to fulfill the goal "*Have lunch*".

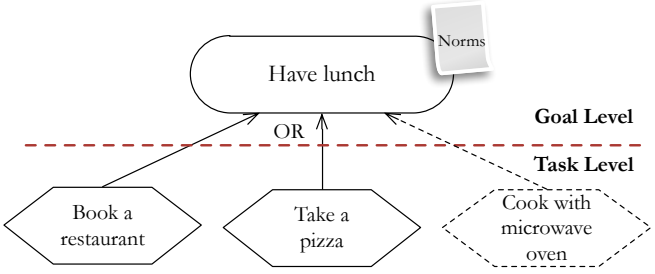

Fig. 2: The availability of the new task "*cook with microwave oven*" gives the system a new mean for satisfying the goal "*Have lunch*".

In the following section, we introduce the key concepts our approach is based on.

V. Theoretical Foundations

The normative framework for introducing more flexibility in smart environments, we propose in this work is based on three key concepts: state of the world, goal and norm. In the following, we formally introduce some definitions.

▼ Definition 1 — *State of the world*

Let $\mathcal{D}$ be the set of concepts defining a business domain. Let $\mathcal{L}$ be a first-order logic defined on $\mathcal{D}$ with $\top$ a tautology and $\bot$ a logical contradiction, where an atomic formula $p(t_1, t_2..., t_n) \in \mathcal{L}$ is represented by a predicate applied to a tuple of terms $(t_1, t_2..., t_n) \in \mathcal{D}$ and the predicate is a property of or relation between such terms that can be true or false.

A *state of the world* in a given time t ($\mathcal{W}^t$) is a subset of atomic formulae whose values are true at the time t:

$$\mathcal{W}^t = [p_1(t_1, t_2, ..., t_h), ..., p_n(t_1, t_2, ..., t_m)]$$

The *state of the world* represents a set of declarative information concerning events occurred within the environment and relations among events at a specific time. An event can be defined as the occurrence of some fact that can be perceived by or be communicated to the smart system. Events can be used to represent any information that can characterize the situation of an interacting user as well as a set of circumstances in which the smart system operates at a specific time. Definition 1 is based on the close world hypothesis[28] that assumes all facts that are not in the state of the world are considered false.

▼ Definition 2 — *Goal*

Let $\mathcal{D}$, $\mathcal{L}$ and $p(t_1, t_2..., t_n) \in \mathcal{L}$ be as previously introduced in the definition 1. Let $t_c \in \mathcal{L}$ and $f_s \in \mathcal{L}$ be formulae that may be composed of atomic formulae by means of logic connectives AND($\wedge$), OR ($\vee$) and NOT ($\neg$).

A *Goal* is a pair $\langle t_c, f_s \rangle$ where t_c (*trigger condition*) is a condition to evaluate over a state of the world $\mathcal{W}^t$ when the goal may be actively pursued and f_s (*final state*) is a condition to evaluate over a state of the world $W^{t+\Delta t}$ when it is eventually addressed:

- *a goal is active iff* $t_c(\mathcal{W}^t) \wedge \neg f_s(\mathcal{W}^t) = true$
- *a goal is addressed iff* $f_s(\mathcal{W}^{t+\Delta t}) = true$

Goals express what is the desired state of the world the system has to result in. Conversely, *Norms* regulate the desired state of the world according to the normative context in which the system works.

▼ Definition 3 — *Norm*

Let $\mathcal{D}$, $\mathcal{L}$, $p(t_1, t_2..., t_n) \in \mathcal{L}$ and $\mathcal{W}^t$ be as previously introduced in the definition 1. Let $\phi \in \mathcal{L}$ and $\rho \in \mathcal{L}$ be formulae composed of atomic formula by means of logic connectives AND($\wedge$), OR ($\vee$) and NOT ($\neg$). Moreover, let $D_{op} = \{permission, obligation, prohibition\}$ be the set of deontic operators. A *Norm* is defined by the elements of the following tuple:

$$n = \langle r, g, \rho, \phi, d \rangle$$

where

- $r \in \mathcal{R}$ is the *Role* the norm refers to. The special character "_" indicates that the norm refers any role.
- $g \in \mathcal{G}$ is the *Goal* the norm refers to. The special character "_" indicates that the norm refers to any goal.
- $\rho \in \mathcal{L}$ is a formula expressing the set of actions and state of affairs that the norm disciplines.
- $\phi \in \mathcal{L}$ is a logic condition (to evaluate over a state of the world $\mathcal{W}^t$) under which the norm is applicable;
- $d \in D_{op}$ is the deontic operator applied to ρ that the norm prescribes to the couple $(r, g) \in \mathcal{R} \times \mathcal{G}$.

$$\text{In particular } d(\rho) = \begin{cases} \rho & \text{iff } d = \textit{obligation} \\ \neg\rho, & \text{iff } d = \textit{prohibition} \\ \rho \vee \neg\rho & \text{iff } d = \textit{permission} \end{cases}$$

In other words, let $\mathcal{W}^t$ be a state of the world, a norm prescribes to a couple (r, g) the deontic operator d applied to ρ if ϕ is true in $\mathcal{W}^t$ [1].

▼ Definition 4 — *State of Norm*

Let a norm $n = \langle r, g, \rho, \phi, d \rangle$ where $g = \langle t_c, f_s \rangle$ and let a state of the world in a given time t ($\mathcal{W}^t$)

A norm can assume the following states:

- n is *applicable at time t* if $\phi(\mathcal{W}^t) = true \vee \phi = \top$
- n is *active at time t* if n is applicable and $t_c(\mathcal{W}^t) = true$
- n is *logically contradictory* if ϕ *is* $\bot$
- n is *in opposition to goal* if $f_s \wedge d(\rho)$ *is* $\bot$

Moreover, let a state of the world (W^t) and let two norms $n_1 = \langle r_1, g_1, \rho_1, \phi_1, d_1 \rangle$ and $n_2 = \langle r_2, g_2, \rho_2, \phi_2, d_2 \rangle$ where $r_1 = r_2$, $g_1 = g_2$, $\rho_1 = \rho_2$

- n_1 and n_2 are *deontically contradictory* iff

$$\begin{cases} \phi_1(\mathcal{W}^t) \wedge \phi_2(\mathcal{W}^t) = true \\ d_1 \neq d_2 \end{cases}$$

It is worth noting that we talk about *logically contradictory* when the contradiction concerns the logical conditions ($\phi \in \mathcal{L}$) under which the norms are applicable. On the contrary, we talk about *deontically contradictory* when the contradiction concerns the semantic meaning of the deontic operator ($d \in D_{op}$) the norms apply to.

Moreover, a norm is in opposition to a goal when pursuing that goal violates always the prescribed norm.

In the next section, we present the algorithms for the injection of norms in a running smart environment.

VI. Algorithms for run-time injections

The aim of the normative framework is to provide some mechanisms that allow to modify the behavior of the smart environment in order to adapt it to unexpected situations that can occur by introducing new norms. The approach we propose is illustrated by the Algorithm 1.

The triple of elements the Algorithm 1 works on is composed of: a *state of the world* $\mathcal{W}^t$ that characterizes the system in a given time, a *set of goal* $\mathcal{G}$ representing the requirements the system is able to satisfy and finally a *set*

[1] It is worth noting that in order to be compliant in $\mathcal{W}^t$ with 1) an obligation ρ must be true, 2) a prohibition $\neg\rho$ must be true 3) a permission ρ or $\neg\rho$ may be true. In the context of this paper, we assume that the system does not violate norms.

Algorithm 1: RunTime injection

Data: $\mathcal{W}^t$, $\mathcal{G}$, $\mathcal{N}$
while *system is running* **do**
  $\mathcal{N}^t_{injected} \leftarrow inject\_new\_norms$;
  ①**for** $j \leftarrow 1$ **to** $length(\mathcal{N}^t_{injected})$ **do**
    $\langle r, g, \rho, \phi, d\rangle \leftarrow n_j$;
    $\langle t_c, f_s\rangle \leftarrow g$;
    if $(\phi \neq \bot) \wedge (f_s \wedge d(\rho) \neq \bot)$ **then**
      add $\langle r, g, \rho, \phi, d\rangle$ to $\mathcal{N}$;
    else
      $revise(n_j)$
  ②**foreach** $g_i \in \mathcal{G}$ **do**
    $\langle t_{ci}, f_{si}\rangle \leftarrow g_i$;
    if $\neg f_{si}(\mathcal{W}^t)$ **then**
      $\mathcal{N}_i \leftarrow \{n \in \mathcal{N} : n = \langle r, g_i, \rho, \phi, d\rangle \wedge \phi(\mathcal{W}^t) = true\}$;
      Ⓐ **if** $card\{\mathcal{N}_i\} = 0 \wedge t_{ci}(\mathcal{W}^t) = true$; **then**
        $pursue(g_i)$;
      Ⓑ **if** $card\{\mathcal{N}_i\} = 1$; **then**
        $\langle r, g_i, \rho, \phi, d\rangle \leftarrow n$;
        if $(d = Permission)$ **then**
          $pursue(g_i)$;
      Ⓒ **if** $card\{\mathcal{N}_i\} > 1$; **then**
        $\mathcal{N}_i \leftarrow Check\_Norms(\mathcal{N}_i, \mathcal{W}^t)$; (see Alg.3)
        $(\phi_{OR}, \phi_{AND}) \leftarrow Compose\_Norm\_Condition(\mathcal{N}_i)$; (see Alg.2)
        $t^{'}_{ci} \leftarrow OR\_composition(t_{ci}, \phi_{OR})$;
        $t^{'}_{ci} \leftarrow AND\_composition(t^{'}_{ci}, \phi_{AND})$;
        $g_i^{'} \leftarrow \langle t^{'}_{ci}, f_{si}\rangle$;
        if $t^{'}_{ci}(\mathcal{W}^t) = true$ **then**
          $pursue(g_i)$;

of norms $\mathcal{N}$ the system has to obey in order to deal with some specific situations. Both $\mathcal{N}$ and $\mathcal{W}^t$ may change during system execution. In particular, the state of the world may change due to some events that can occur or some actions that can be performed in the environment. The set of norms may change due to norm injection.

While the system is running, new norms can be injected. Step ① makes a preliminary check on new injected norms. Such step ensures that among injecting norms neither norms are in opposition to the goal they refer nor they are logically contradictory.

Step ② is the core of the algorithm. The system is in the state of the world ($\mathcal{W}^t$), the norms have effects on the system goals only if they are not addressed yet. Thus, for each goal the system has to satisfy, the set of applicable norms ($\phi(\mathcal{W}^t) = true$) is processed.

Hence, three situations can occur. The most simple one (Ⓐ) is that there are no applicable norms for an active goal (see *Definition 2*). In such a case the system can pursue the goal without restrictions. The second situation (Ⓑ) is a basic case in which the set of applicable norms for a single goal is composed of only one norm. In such case, *(i)* if the norm is a permission it actives the related goal and the system can fulfill that goal despite $t_c(\mathcal{W}^t) = false$. This is because the permissions relax system constraints, giving alternatives; *(ii)* if the goal is regulated by a prohibition, it further constraints the goal activation. The system cannot pursue that goal until $\phi(\mathcal{W}^t) = true$. It is worth noting that generally speaking, an applicable norm influences a goal when it is active. However, a permission norm can influence a goal also when it is inactive.

The last situation (Ⓒ) is a general case in which norms are more than one and they can have different deontic operators. In this case Algorithm 1 allows to modify goals, making them norm compliant. By encapsulating the condition expressed by the norms inside the goal they refer to, it is possible to modify the activation of that goal thus making it compliant with the norms. Such composition (see Algorithm 2) takes into consideration different types of norms and it accordingly modifies the activation of a goal.

Algorithm 2: Compose_Norm_Condition

Data: a list of norms $NormList$
Result: a couple $(\phi_{mergedOR}, \phi_{mergedAND})$
$List\phi\_OR \leftarrow \varnothing$;
$List\phi\_AND \leftarrow \varnothing$;
// Identification of norm types
for $j \leftarrow 1$ **to** $size(NormList)$ **do**
  $\langle r, g, \rho, \phi, d\rangle \leftarrow NormList[j]$;
  switch d **do**
    case *Obligation* **do**
      break;
    case *Prohibition* **do**
      add $\neg\phi$ to $List\phi\_AND$;
    case *Permission* **do**
      add ϕ to $List\phi\_OR$;
// Permissions give alternatives (OR)
if $Size(List\phi\_OR) \neq 0$ **then**
  $\phi_{mergedOR} \leftarrow List\phi\_OR[1]$;
  for $h \leftarrow 2$ **to** $Size(List\phi\_OR)$ **do**
    $\phi_{mergedOR} \leftarrow OR\_composition(\phi_{mergedOR}, List\phi\_OR[h])$;
// Prohibition are mandatory (AND)
if $Size(List\phi\_AND) \neq 0$ **then**
  $\phi_{mergedAND} \leftarrow List\phi\_AND[1]$;
  for $h \leftarrow 2$ **to** $Size(List\phi\_AND)$ **do**
    $\phi_{mergedAND} \leftarrow AND\_composition(\phi_{mergedAND}, List\phi\_AND[h])$;

It is worth noting that, when there are more than one applicable norm in the system (Ⓒ), it is necessary to check for deontological contradictions among norms (see Definition 4) and to remove them. This is performed by Algorithm 3. Deontological contradictions are known in legislative environments as *antinomy*. For instance, if there is an applicable norm *n1* that prohibits to pursue a goal *g1* and another applicable

norm *n2* that obliges to pursue the same goal *g1*, then *n1* and *n2* generate an antinomy.

In legal theory, several criteria exist for solving such antinomy [29]: *legis posterior*, the most recent norms takes precedence; *legis superior* the norm imposed by the strongest institutional power takes precedence; and *legis specialis* the most specific norm takes precedence. In this paper, we assume to work with hierarchically equal norms (i.e: norms with the same authority) thus we adopt the *legis posterior* criterion in order to choice among conflicting norms.

In the following, we show our approach in a simulated smart environment.

Algorithm 3: Check_Norms

Data: a list of applicable norms $\mathcal{N}$ related to a single goal, a state of the world $\mathcal{W}^t$
Result: a list $\mathcal{N}_{out}$ of consistent norms
$\mathcal{N}_{out} \leftarrow chronological\_order(\mathcal{N})$;
$\mathcal{M}_{conflicts} \leftarrow \varnothing$;
for $i \leftarrow 1$ **to** $length(\mathcal{N}_{out})$ **do**
  $\langle r, g, \rho, \phi_i, d_i \rangle \leftarrow n_i$;
  for $j \leftarrow i+1$ **to** $length(\mathcal{N}_{out})$ **do**
    $\mathcal{M}_{conflicts}[i][i] \leftarrow 1$;
    if $r_i = r_j \wedge \rho_i = \rho_j \wedge d_i \neq d_j$ **then**
      $\mathcal{M}_{conflicts}[i][j] \leftarrow 1$;
    else
      $\mathcal{M}_{conflicts}[i][j] \leftarrow 0$;
for $i \leftarrow length(\mathcal{N}_{out})$ **to** 1 **do**
  $n_{current} \leftarrow \mathcal{N}_{out}[i]$;
  for $j \leftarrow i-1$ **to** 1 **do**
    if $\mathcal{M}_{conflicts}[i][j] = 1$ **then**
      $delete(\mathcal{N}_{out}, oldest(\mathcal{N}_{out}[j], n_{current}))$;
      $n_{current} \leftarrow \mathcal{N}_{out}[j]$;

VII. A Simulated Health-care Home

In order to show our approach, we simulated an health-care home provided with a smart system for supporting guest activities.

The simulation framework is responsible for time advancing. In particular, we adopt a discrete time-stepped simulation. The virtual time advances with a fixed interval (i.e.: each time step is 30 minutes).

In the simulated health-care home, each guest is provided with some devices for individual recognition and with wearable sensors for monitoring physiological parameters (i.e: body temperature, heart rate, blood pressure etc...). The smart environment owns a knowledge base containing information about health-care home guests (i.e: diseases, pharmacological therapy, clinical investigations etc...). The health-care home is endowed with a plurality of sensors and devices. The smart system provides each guest with a personal virtual tutor that supports daily activities such as taking medicines, doing medical examinations and so on.

Fig. 3 shows a screen-shot of health-care house simulated with ICasa[12]. It is composed of several bedrooms for guests,

Fig. 3: The simulated health-care house

a medical room and a restaurant. Each room is endowed with a presence sensor that detects the occupancy of a space by people. Some monitors are located in common areas in order to show personalized advertisements to guests.

An excerpt of user goals the system can satisfy is described in the following by adopting the GoalSpec specification.

goal_1: *WHEN is_Time_to_WakeUp(guest) THE system SHALL ADDRESS light(guest_room, on) AND alarm(guest_room, on) AND guest(awake).*

goal_2: *WHEN is_Time_to_Have_Lunch(guest) THE system SHALL ADDRESS restaurant_service(guest, available).*

goal 3: *WHEN is_Time_to_Take_Medicine(guest) THE system SHALL ADDRESS at(guest, medical_room) AND done(took_medicine).*

...

goal n: *WHEN is_Time_to_Meet_Doctor THE system SHALL ADDRESS done(checked, guest)*

The first goal means that the Smart Environment has to reach the desired state of the world in which the light and the alarm of guest's room are turned on and guest is awake. The second one makes the restaurant available to guests. The third one indicated that the smart environment has to fulfill the state of the world in which the guest is at medical room and he takes his medicine. Finally, the system allows to periodically make medical checks for monitoring the wellness of guests.

For the sake of clarity, in the following scenarios we exemplify norms in SBVR language. It is worth noting that our application translates SBVR rule according to Definition 3. In the following we provide an example:

SBVR norm: *It is permitted that guests have lunch if they have performed sports activities*

System norm: *norm(type(permission), role(guest), goal (have_launch), condition(is(guest,diabetic))).*

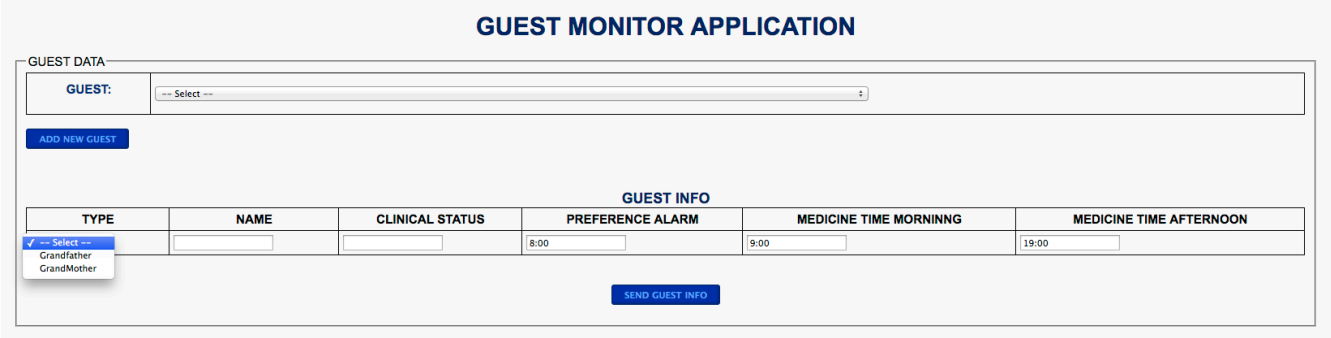

Fig. 4: Guest Monitor Application

We initially assume that the guests of the health-care home are individuals without particular diseases. The system behaves in the same way for each guest thus satisfying the previous goals. Over time, other people with particular illnesses are received and their preferences and clinical status are registered in the system. The manager of the health-care home inserts new norms in the system in order to change system behavior accordingly to the new situations. In particular, we simulated the following scenarios.

a) Permission Norm Injection: During the normal execution of the system, the manager of the health-care home gives the permission to guests that get already had some sports activities to have lunch before the established time. Thus, he introduces into the system the following norm:

norm_1: *It is permitted that guests have lunch if they have performed sports activities.*

In such case, the system differently behaves according to the particular guest. It allows only sportive guests to go to the restaurant before the regular time for lunch (i.e.: 13 o'clock).

In Fig.5 two guests (Paul and Maria) want to go to the restaurant at midday. In such scenario, Paul went to jogging in the morning. Thus, the system permits Paul to go to the restaurant before the regular time for lunch. Conversely, it is prohibited for Maria that has not performed any sport activities.

Fig. 5: The system behaves differently for different users.

b) Diabetic Guest: A new guest (Mark) is received in the health-care home. It is the first diabetic patient of the house. Fig.4 shows a screen-shot of the simulation framework that allows to introduce new guest into the simulated environment along with some guest information and preferences. The following norm is injected at run-time into the system:

norm_2: *It is prohibited that a guest has lunch before taking insulin if the guest is diabetic.*

In such scenario, the diabetic guest goes to the restaurant at 13 o'clock but before taking insulin. In such case, the system does not allow Mark to eat at the restaurant and its virtual tutor advises him that has to take the medicine before lunch (see Fig.6 (a)). Then, Mark goes to the medical area and he takes insulin (see Fig.6 (b)). Thus, the system updating the state of the world will permit Mark to have lunch.

c) Heart-Rate Control: The manager of the health-care home wants to provide better services to his guests. Thus, he introduces a new norm for allowing the system to suggest a medical check when some physiological parameters are out of their normal range.

norm_3: *It is permitted to do a medical check if a guest has an irregular heart rate.*

The introduction of the previous norm modifies the normal system behavior, thus allowing not only periodic medical check but also appropriate ones. In such case, the system that is able to monitor the health of guests, when it perceives a heart rate out of normal range (see Fig.7 (a)), it suggests the guest to go to see a doctor and it alerts the nurses (Fig.7 (b)).

d) Conflict Scenario: In such scenario, the diabetic guest goes to the restaurant after having had some gym and before taking insulin. This particular state of the world cause a conflicting situation among two norms. In such case, the system notifies the manager that there is a conflicting situation due to the simultaneous application of the norm_1 and norm_2. If the manager does not modify anything, the system applies the *legis posterior* criterion thus prohibiting the user to go to the restaurant before taking insulin (see Fig.8).

In the following section, we draw some conclusions.

(a) The guest does not use restaurant services. The virtual tutor advises the guest to take insulin.

(b) The guest goes to medical area and he takes insulin. The system updates the new state of the world.

Fig. 6: Diabetic Guest scenario

(a) The system perceives an irregular heart rate and it alerts the nurses. The virtual tutor advises the guest to go to make a check.

(b) The guest goes to medical area.

Fig. 7: Heart-Rate Control scenario

VIII. Conclusions

Norms are well know means for regulating the behavior of multi-agent systems, thus ensuring the fulfillment of the overall objective of the society the agents live in. This work takes place in the context of self-adaptive and self-organized systems that consider goals as key elements. They are systems conceived for satisfying user requirements that can be also established at run-time. These systems may evolve over time by increasing the objectives they are able to satisfy. In such context, we defined a normative framework that owns a direct link with the goals the system is able to pursue thus hiding the agent level. In our approach we consider the goals as a particular kind of obligation that have to be satisfied under certain conditions. Besides, we see permission and prohibition norms as promoters or inhibitors of the system in pursuing its goals. By introducing norms at run-time we also make the system more flexible to environment changes and able to self-adapt to new normative contexts in which it could be employed.

Moreover, the proposed algorithm takes into consideration the simultaneous presence of multiple norms related to the same goal, thus determining their joint effect. The approach for run-time injection also provides a means for checking norm conflicts and inconsistencies. Such an approach also implements a recovery mechanism based on the *legis posterior* criterion for solving inconsistencies among norms.

Finally, the simulated environment provides us a means for testing new hypotheses about a real system. In particular, in our future works, it will used for studying the consequences of norms injection in order to discover undesired behaviors of the system or new kinds of conflicting situations.

***Abstract*—Agent-Based Modeling and Simulation (ABMS) is a very useful means for producing high quality models during simulation studies. When ABMS is part of a methodological approach it becomes important to have a method for identifying the objectives of the simulation study in a disciplined fashion. In this work we propose a set of guidelines for properly capturing and representing the goals of the simulations and the metrics, allowing and evaluating the achievement of a simulation objective. We take inspiration from the goal-question-metric approach and with the aid of a specific problem formalization we are able to derive the right questions for relating simulation goals and metrics.**

I. Introduction

AGENT-BASED simulation studies are effective tools for addressing problems that in real life require several resources. Despite their power, the key of success in a simulation study is to follow a comprehensive process for building simulated systems that produce acceptable and credible results.

In particular, it is widely known that a very important activity of a simulation study is to clearly establish the simulation objectives. Such objectives, or simulation goals, are the guiding element of a simulation study, thus they have to be defined at the beginning of a simulation process [1][2][3][4][5].

In classical simulation studies, the simulation team should develop a list of specific questions that the simulation model should address and develop a list of performance metrics for evaluating goal satisfaction [1][6]. How to perform this activity is not clear enough. It is often committed to the experience of the simulation team.

We claim that problem formalization assumes a very important role in the identification of simulation goals and in this paper, we propose to identify simulation goals, starting from an ontological representation of the problem domain, and then to identify the performance metrics for evaluating goals. Our approach takes inspiration from the *Goal Question Metric* (GQM) approach proposed by Basili et al. [7].

GQM is an approach for expressing the goal of a software engineering study. It provides a method for defining goals, refining them into questions and finally developing a set of metrics needed to answer such questions.

For a couple of years we have been working on the development of a methodological approach covering the entire life cycle of a multi-agent simulation study taking into account each facet of the agent based modeling paradigm. Such a methodology is founded on the premise that a simulation study is conducted for testing new hypothesis on a model of a real system (i.e.: what happens if). In so doing, we are building our approach according to the phases of classical simulation studies [1][2] but providing specialized guidelines for using agent based simulation techniques. So far, we developed the initial activities of Simulation Problem Analysis phase, namely Problem Formalization [8]. Problem formalization aims at formalizing simulation problems by adopting an ontological representation of the simulation problem domain.

In this paper, we employ such a representation (namely Problem Ontology) as a guide for generating questions and specifying the metrics (and also parameters) for answering those questions thus providing a structured way in order to perform a GQM-like approach in the field of simulation studies.

The Problem Ontology has to be intended as a representation of the domain on which the simulation model is being constructed. Such a domain contains, the objects involved in the problem, their behaviors, rules and organizational aspects; all these elements find a perfect mapping with the elements Basili et al. define for applying the GQM approach.

For the scope of this paper, we want to focus on the elements that can be defined *Problem Ontology*:

- *Active Entity*: an active entity allows to represent concepts that are specified in the problem statement that perform dynamic actions.
- *Action*: an action in the problem ontology represents concepts in the problem statement describing the fact or process of doing something, typically to achieve an aim.
- *Object*: it represents something to which a specified action is directed.
- *Predicate*: It allows to express a property, a state or more generally it allows to specify a concept.

The main contribution of this work is a set of guidelines for applying the GQM approach for simulation studies that use the *Problem Ontology* as an input. Such guidelines result in two workproducts, the Simulation Goal document and the Simulation Metrics document.

The rest of the paper is organized as follows. Section II presents an overview of the GQM approach and points out the main elements and the rationale we used for applying the GQM to our case. Section III introduces the proposed approach for simulation goal and metrics identification by describing the steps to perform for obtaining metrics and

978-83-60810-90-3/$25.00

parameters. Finally, in section IV some discussions and conclusions are drawn.

II. Goal Question Metric Approach

The *Goal Question Metric* (GQM) approach, proposed by Basili et al. [7][9][10][11], is a paradigm that links metrics with the general goal of a process or project. The aim is to generate questions, whose answers are known, thus establishing if all the goals have been reached. Metrics are the means for answering the questions.

GQM approach relates to software metrics, indeed it is based on three main principles, classifying the *entities* to be examined, determining relevant measurement goals and finally determining the level of maturity of the organization. This latter principle is obviously strictly related to software production and has not been considered in this paper. The initial step of a software measurement is to identify the *objects* (i.e: processes, products and resources) and the *attributes* (i.e.: internal or external) to measure. A process is an activity related to software, products are artefacts or deliverable resulting from an activity and a resource is an entity required by a process. Attributes characterize an entity. An internal attribute refers to the entity itself and may be measured by investigating only the entity without referring to its behavior; an external attribute refers to how an entity relates to its environment.

The GQM model is based on three levels: Conceptual, Operational and Quantitative. The *Conceptual level* concerns the definition of *Goals*. In GQM, a goal is defined for an object with respect to various models of quality, from several perspectives and according to a particular environment. The *Operational level* concerns the identification of *Questions*. The questions are articulated for defining models of the object under study and for characterizing the object with respect to a selected quality issue. The *Quantitative level* is related to the definition of *Metrics*. A metric is associated with every question in order to answer it in a measurable way.

GQM is typically described as a six-step process. The first three steps concern how to use business goals for driving the identification of the right metrics. The last three steps are about gathering the measurement data and making effective use of the measurement results to drive decision making and improvements.

Hence, in order to characterize a goal in a quantifiable way, it is necessary to relate the *goal* to an *object*, or an *entity*, that possesses some kind of *attributes* related to itself or to the environment. A goal or a question may be ascribed to, at least, a couple entity - attribute. The answer to a question means that we give a measurement to an attribute. In particular, the GQM approach uses three elements for specifying the goal: purpose, issue and object. We base our work on this assumption and extend the first three steps of GQM. In particular, we provide guidelines for identifying elements the simulation goals are related to by adopting an ontological formalization of the problem domain.

III. Simulation Goal and Metrics Identification

All simulation studies, in general, and agent simulation study, in particular, greatly depend on how the simulation problem analysis is conducted. Simulation problem analysis aims at identifying the goals of the simulation study with respect to the domain under study.

During simulation studies some hypothesis are investigated through manipulating some independent variables that affect dependent variables and consequently the validation of the initial hypothesis. In this process, the identification of the simulation goals during the early analysis phase provides a prerequisite for identifying metrics, or parameters, for the evaluation of the simulation hypothesis.

Sentences like "*Improve the timeliness of change request processing during the maintenance phase of the life cycle of a system*" that can be found in the description of the simulation study, hence the in some kind of *problem statement*, give a hint on what the simulation study is intended for, the objective that has to be reached. Sometimes, it is not obvious or immediate to identify the independent or observable variable related to the simulation goal.

In this section we show the rationale we propose for conducting two activities: the *Simulation Goal Identification* and then the *Entity Parameter Identification*. These activities aim at identifying and modeling the goal(s) of the simulation study and the related parameters to be considered for the agent-based software development. These two activities are strictly tied and are part of a complete methodological approach for supporting agent simulation studies. We claim that the identification and the representation of simulation goals greatly descend from the problem formalization.

Problem formalization is the key element in all engineering activities for producing software products of high quality. Complete and well defined simulation models require a careful analysis of the problem domain and a detailed problem formalization phase [1][12].

We propose to join the problem formalization to the *Goal Question Metric* approach. We already discussed how to perform problem formalization and the proposed results are shown in [8][13]. The result of the *Problem Formalization* activity is a work product, the Problem Ontology diagram, containing all the elements representing the domain under study (see section I). In what we propose, the Problem Ontology may be used as a guide for generating questions and then specifying the measures for answering questions in a GQM like approach.

Using GQM, a goal is expressed through the triplet <*purpose, issue, object*>; it defines an object with respect to a purpose and some quality issues. This kind of triplet, in the GQM, is the starting point for extracting all the useful parameters for a specific situation.

In a simulation problem statement the goal is generally expressed through a sentence and, from the analysis of this sentence, it is possible to identify the previous triplet for applying GQM. Suppose the Problem formalization activity

resulted in a Problem Ontology diagram, where all the active entities, the objects, the actions and the predicates, representing the simulation study, have been represented [1]. The steps we propose are:

- Identify goals - the inputs of this step is the Problem Statement. An analysis of sentences in terms of nouns and verbs is required
  The work to be done starts with the identification of the goal, or the goals, of the simulation study; this activity implies a careful analysis of the Problem Statement in order to identify sentences from which goals may be extracted. Since, as Basili et al. [7] highlight, *"typical goals are expressed in terms of productivity, quality, risk, satisfaction"*, useful sentences are those containing verbs such as assess, improve, evaluate and so on.
  Sometimes, the sentence may be in the affirmative or in the interrogative form and some others it may not be simple to identify the sentence related to the simulation goal. In this latter case a refinement of the problem statement should be required.
- Identify <*purpose, issue, object*> - This step implies to analyze the syntax of the sentence containing the simulation goal. The verb is generally followed by a direct object and then by a genitive case (if not the sentence may be reformulated).
  For instance, the sentence *"Improve the timeliness of change request processing during the maintenance phase of the life cycle of a system"* leads to the triplet <improve, timeliness, change request processing>.
- Prepare questions - The main input of this step is the Problem Ontology diagram (POD). In order to obtain all the possible questions for one goal, it is required to explore all the relationships between the object in the triplet and all the other elements in the Problem Ontology diagram. If there exist a relation between an element of the POD and the object of the goal then there may be some parameters, attributes or metrics that once modified may affect the object of the goal and, at the same time, the overall simulation thus giving means for assessing or evaluating the initial hypothesis the simulation study is created for.
  For instance, suppose that the *change request processing* is related to an object like *time*, then it should be possible that the amount of time is a value of a parameter that may affect the improvement of the timeliness.

It is worth to note that two situations may happen. The POD may present the object of the simulation model or not. The first situation happens when the object is a product or a resource and it has been identified during the previous activity as an «object» or an «active entity». The second situation, instead, happens when the goal's object is a process or simply it has not been identified during *Problem Formalization*, in this latter case a refinement activity of the POD is necessary and should be performed.

[1]The reader may have a look at [8] for a detailed example.

The Problem Ontology diagram is very important in all the previous steps. The way we employ POD is the very contribution of this paper in fact it provides an important means for supporting the analysis and identification of goals and parameters. The efficiency increasing in the identification of the right elements to consider is also obtained.

The work products resulting from the *Simulation Goal Identification* and the *Entity Parameter Identification* are Simulation Goal (SG) document that is composed of two different diagrams and the Simulation Metric (SM) document. The first contains a diagram representing the view on the simulation goal(s), its relationships with the elements of the POD and some possible new goals coming from reasoning about the relationships among the main simulation goals and POD objects. In the second the simulation goal(s) is illustrated with all the new goals identified and the kind of contribution they give to the main goal(s).

A brief example of the resulting work products is given in Fig. 1.a) and Fig. 1.b) as regard the SG and Fig. 1.c) as regard SM. These documents are related to a specific case in which, from the Problem Ontology, the analyst has identified the sentences "How may we improve the value of the throughput of the warehouse?" and "Another aim of this study is to reduce the costs of warehouse managing". The related triplets are: <improve, value, throughput> and <reduce, cost, management>. By Applying the proposed approach and by iterating them on the elements of the POD a portion of the obtained results is shown in the figures. The second work product shows questions and parameters. Obviously, for space reasons, this example cannot be complete and exhaustive but is intended to give a view on the work products.

IV. Discussions and Conclusions

Determining the goals of a simulation study is a very important task because from these we may obtain the set of metrics and test parameters that are typical of scientific experiment, such as simulation ones.

Simulation goals identification is generally a mental and speculative activity tied to the skills and knowledge of the analysts and very few methodological recommendations exist in literature. Since we need to extract some metrics and parameters, that are formal elements, we want to apply a disciplined way in order to avoid the risk of forgetting or omitting some important elements of the problem domain.

In this paper, we have proposed a GQM like approach for determining such a parameters starting from the simulation goal identification. This work is a further step of a more complete one: a complete design methodology for developing agent based simulation studies, this methodology also includes the agent-based system development.

One of the most important parts, already developed, is the problem domain formalization that becomes the most important and necessary input to the simulation goals identification. In some previous works we described how to represent the problem domain as an ontological (POD) representation

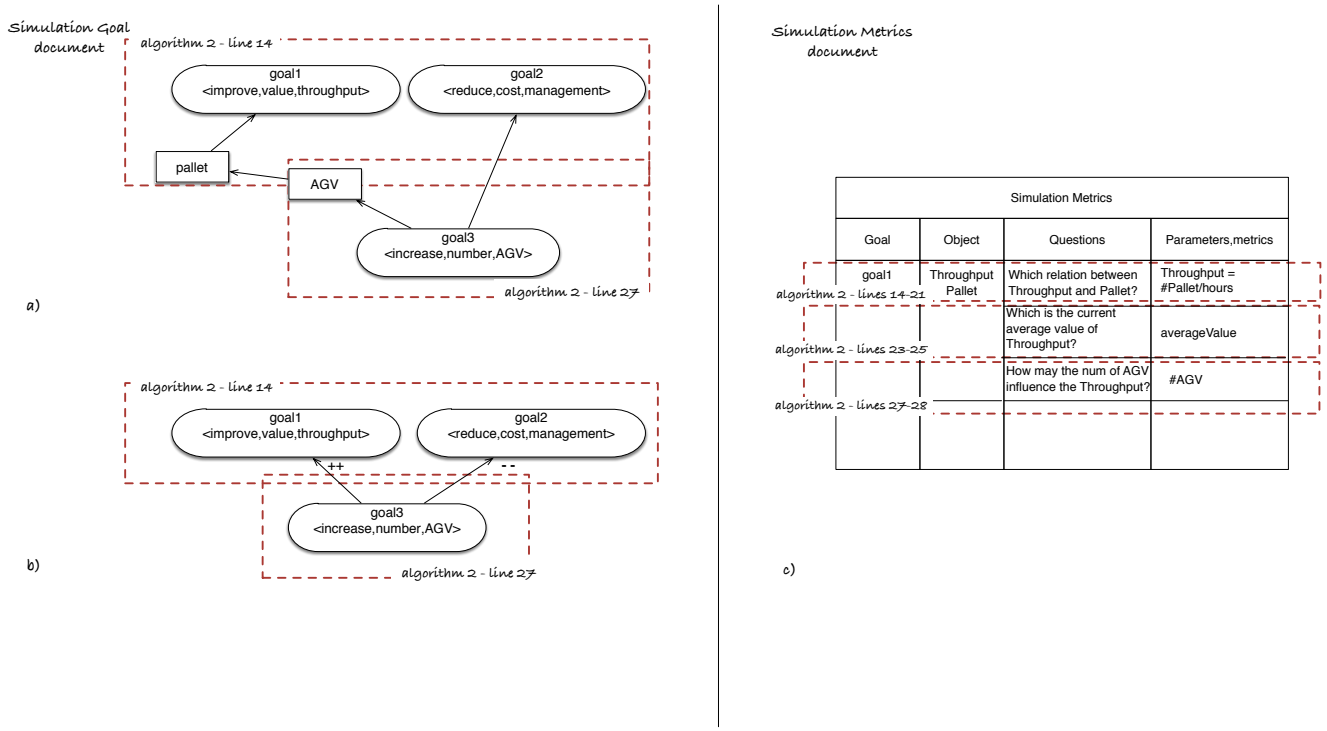

Fig. 1. SG and SM documents - an example

containing objects and entities from which it is possible to identify behaviors and interactions with the environment.

In the present work, we combine that with the well known goal-question-metric approach (GQM) in order to create a disciplined and structured method for the identification of the goals and the related metrics and parameters useful for understanding if the goals have been satisfied for the simulation system.

The use of a problem formalization and of the POD ensures a final result coherent with the domain under study and complete since the POD, while applying GQM, is explored in its entirety. For sure this approach depends on the presence of a good and well done Problem Ontology Diagram but, the GQM approach is a valid support that, once applied, also allows to reason on the problem domain and on the POD and potentially to refine it. The same we make with the Problem Formalization [8], both are iterative and incremental approaches that lead to the goal simulation model and at the same time allow to refine the POD towards a status where, reasonably, nothing has been omitted.

In the future, we plan to complete the methodological approach and to validate the whole approach using the true experimental set up coming from the simulation model.

***Abstract*—Recent works in the context of large-scale adaptive systems, such as those based on opportunistic IoT-based applications, promote aggregate programming, a development approach for distributed systems in which the collectivity of devices is directly targeted, instead of individual ones. This makes the resulting behaviour highly insensitive to network size, density, and topology, and as such, intrinsically robust to failures and changes to working conditions (e.g., location of computational load, communication technology, and computational infrastructure). Most specifically, we argue that aggregate programming is particularly suitable for building models and simulations of complex large-scale reactive MASs. Accordingly, in this paper we describe SCAFI (Scala Fields), a Scala-based API and DSL for aggregate programming, and its integration with the ALCHEMIST simulator, and usage scenarios in the context of smart mobility.**
Keywords — aggregate programming, Scala, DSL, simulation.

I. INTRODUCTION

APPLYING multiagent systems (MASs) in the context of large-scale distributed systems is known to be hard in general, due to the ineluctable need to take into account issues such as communication, robustness, consistency and performance. The situation is then becoming harder and harder especially in recently emerging distributed computing scenarios, such as pervasive computing or IoT, due to the number of computational entities, the complexity of interactions, the presence of natural limitations related to energy, communication and processing, and the tight connection with the physical world and human users—quintessential source of unpredictability. Achieving a sound development of MAS applications in this context, so as to ensure desired properties of robustness and scalability, calls not just for better algorithms and computing frameworks, but possibly for whole new paradigms.

Recent research in collective adaptive software systems proposed *aggregate computing* [1] as a promising approach generalising over several prior models and languages addressing computations over collections of spatially-situated systems [2]. Essentially, aggregate computing allows one to express complex system-wide, global-level computations involving large sets of devices in a fully declarative way, promoting decomposition and resiliency. Aggregate computing can be formally grounded in the field calculus [3], a core language able to express complex patterns of information diffusion and aggregation. Resiliency is guaranteed by self-organisation: aggregate programs can be compiled into repetitive local tasks to be executed by the single agent, promoting identification of robust building blocks of aggregate behaviour [4].

Though naturally applicable to swarm-like reactive MASs, aggregate computing is also of interest when stronger notions of agency enter the picture: as discussed in [5], aggregate programs can be seen as "aggregate plans," namely, operational instructions for deliberative agents that guide the cooperative behaviour of a team.

In order to more deeply investigate the impact of this new paradigm to the mainstream development of large-scale MASs, in this paper we explore and propose an extension of the Alchemist simulator [6] with `scafi`[1] [7], a Scala framework that provides an internal domain-specific language (DSL) for specifying aggregate computations via a simple API that well integrates with the advanced typing features of Scala (inference, genericity, implicits) and its library. This allows to smoothly simulate complex collective adaptive behaviours on top of Scala mainstream programming.

The remainder of this paper is organised as follows: Section 2 introduces aggregate programming, Section 3 presents the `scafi` framework and example specifications, Section 4 depicts Alchemist and the integration of `scafi`, Section 5 discusses case studies in the context of smart mobility, and Section 6 presents related works before finally drawing conclusions.

II. AGGREGATE PROGRAMMING

Aggregate programming [1] is a novel approach to (large-scale) distributed systems engineering that supports the specification of collective behaviours in a simple, high-level, and composable way. The key idea is to shift programming from the traditional single-device viewpoint to a global viewpoint where the programmable entity is the *aggregate* body of computational elements constituting a system. This way, programmers are no longer required to solve the intricate local-to-global problem, i.e., building the desired emergent phenomenon by specifying how each component behaves and interacts with others in a fully bottom-up fashion; instead, it is possible to focus on *what* the system should exhibit, and let the computational platform define – under-the-hood – *how* the computation is carried on by the interaction of individual entities. It essentially solves the inverse, global-to-local mapping problem.

[1] http://scafi.apice.unibo.it

An immediate consequence is the independence of aggregate computations from the physical implementation details of systems, which is realised by suitably abstracting spatial distribution, topology and interaction. More specifically, as realised by space-time programming approaches [2], logical or physical neighbouring of nodes can be exploited to make interaction implicit. In addition, this notion is instrumental for the conceptual connection with systems where locality might play a major role in communication.

The main programming abstraction in aggregate programming is the *computational field* [3] (or field for short), a notion already used in the MAS community [8], [9]. Generalising the notion of (gravitational, electromagnetic) field in physics, a computational field is a function that, at a given moment in time, maps each point in space to a computational object; when considering the space discretised by a networked set of situated agents, each sample represents the outcome of computation for that agent. The key insight of the approach consists in the ability to specify collective behaviours (i.e., aggregate computations) by algorithms expressed as a functional composition of fields: from input fields representing information sensed from the environment, up to output fields representing some form of actuation. In other words, aggregate computations are represented by a declarative specification of functional operations involving collective data structures, though, under-the-hood, they are turned into repetitive, gossip-like interactions between individual agents—namely, relying on known low-level self-organisation patterns [10].

This approach is shown to support a solid engineering methodology, in which composable and reusable high-level library components of aggregate behaviour can be defined that are provably resilient [4].

III. Aggregate Programming in Scala

The aggregate computing idea can be naturally supported by a programming language, used to specify aggregate behaviours. Among different choices one can make to frame one such language (as a DSL, as an API, and so on), in this paper we explore the idea of using the Scala programming language [11] as the host language for building an aggregate programming platform. This is motivated by both technical and practical reasons.

Scala is a modern language for the JVM which integrates the object-oriented and functional paradigms in a seamless way, hence we can combine the typically rich and expressive OO libraries and data structures, with functional programming as promoted by aggregate computing. Scala has a powerful and expressive type system, combining the advantages of static type checking with a concise syntax for productivity—thanks to type inference, the implicits system, generic and functional programming features, and ad-hoc syntactic sugar. This allows library designers to create Scala APIs which actually have a DSL-like flavour, which are thus perceived by users as "embedded languages." Moreover, Scala is now becoming a standard de facto for the construction of platforms for distributed processing (frameworks like Akka actors, and Apache Kafka, Storm and Spark are essentially Scala-based): this makes it the ideal language to target a platform for aggregate computing—though this issue is not discussed here further.

Accordingly, we propose `scafi` (Scala fields) [7], a framework consisting of two main parts:

1) *aggregate programming support*, by a Scala-internal DSL that provides a syntax and the corresponding semantics for the constructs of the computational field calculus [3], by which aggregate computations are naturally expressed and seamlessly combined in code; and
2) *aggregate platform support*, allowing configuration and execution of such code in actual distributed setups.

`scafi` explicitly addresses the construction of concrete aggregate computing applications: however, it can also play the role of a language to validate complex MAS algorithms, as meta-model for simulations—in the next section, in fact, we shall describe its integration with a full featured simulator, Alchemist.

A. Computational field calculus in Scala

An aggregate system consists of a (possibly mega-scale) number of computational devices or agents, all executing the same aggregate program at asynchronous rounds of computation. According to contextual information (e.g, sensor values), different such computational devices may take different branches of computation, i.e., computing sub-fields in different domains of execution. Interaction depends on a notion of locality, i.e., a device can communicate to all its neighbours, as defined by an application-specific proximity relation. The communication is carried out by repeatedly broadcasting the latest computed state to the neighbourhood: the shape of this state, and how it affects and gets affected by computations, is precisely defined by our language semantics [3]. The basic primitives of the field calculus (described below, in turn) are declared in the `Constructs` trait, implemented by the framework and mixed-in in any library of user-defined aggregate functions:

```
trait Constructs {
  def rep[A](init: A)(fun: (A) => A): A
  def nbr[A](expr: => A): A
  def foldhood[A](init: => A)(acc: (A,A)=>A)(expr: => A): A
  def branch[A](cond: => Boolean)(th: => A)(el: => A): A
  def aggregate[A](f: => A): A
  def sense[A](name: LSNS): A
  def nbrvar[A](name: NSNS): A
}
```

The field calculus constructs can be understood and described according to two complementary viewpoints:

1) *Local viewpoint* – refers to the traditional device-centric interpretation where an aggregate computation is considered in the context of a single device. The operational semantics of the field calculus is implemented according to this stance.
2) *Global viewpoint* – it corresponds to the natural semantics and refers to the aggregate-level interpretation of programs as computations running on whole fields

(i.e., spatial data structures mapping each device to some computational object).

B. Working with basic constructs

The most trivial program is one that simply evaluates to a constant value, such as a boolean, a number or a string. For instance, value

```
"Hello, World"
```

should be interpreted as a constant field evaluating that value everywhere; concretely, it results in the string `"Hello, World"` being the return value of the local computation of every device in the system.

Construct `sense` provides the means for reading a value from a local sensor, which enables context-sensitive behaviours. Expression

```
sense[Double]("temperature")
```

gets in any device a double value from the temperature sensor, creating the field of temperatures.

Change over time of a field can be realised via the `rep` construct, which produces a dynamically evolving field by repeatedly applying a state-transformation function. For example, it could be used for counting how many rounds a device performed since the beginning of computation:

```
// Initially 0; state is incremented at each round
rep(0){ _+1 }  // or equivalently: rep(0){ x => x+1 }
```

Note that the frequency at which devices compute rounds and hence send messages to neighbours can vary over time and from agent to agent: the aggregate computing model generally assumes partial synchronicity [12], though in most cases even full asynchrony of rounds can be assumed.

Communication with the neighbourhood is achieved via `nbr`, which gives a map from neighbouring devices to their value of the argument—essentially an observation primitive. Construct `nbr` has to be nested inside a `foldhood` operation, which reduces one such map back to a single value via a monoidal reduction (on top of it, derived `minHood`, `sumHood` and others are defined and will be used in next sections). Example applications of `foldHood` are as follows:

```
// Counting number of neighbours at each device
foldhood(0)(_+_){ nbr{1} } // sum 1 across neighbours

// Is sensor "sns" active in every neighbour?
foldhood(true)(_&&_){ nbr{ sense[Boolean]("sns") } }
```

In addition to local sensors, there is a notion of "environmental" sensor. `nbrvar` allows to extract values from a neighbouring sensor, which gives a sample for each neighbour. Thus, similarly to `nbr`, `nbrvar` has to be used within a `foldhood` operation.

```
def nbrRange(): Double = nbrvar[Double](NBR_RANGE_NAME)

// Compute the maximum distance of a neighbour
foldhood(Double.MinValue)(max(_,_)){ nbrRange() }
// equivalently: maxHood{ nbrRange() }
```

Operation `branch` splits the spatial domain of devices into two parts, or rather two sub-teams, according to a boolean field expressing some condition. Each of the two parts, compute a different sub-field in complete isolation. For example, if we would like to execute some aggregate computation only on a subset of the devices of the network (the complementary subset must not participate), we need a partition:

```
branch(sense[Boolean]("flag")){
  Double.MaxValue // not computing
}{
  compute(...)    // sub-computation
}
```

Construct `aggregate` is used to define the body of a new function that should work on whole fields. The devices running a given aggregate function constitute a partition, i.e., they are able to interact with each other via `nbr`. As an example, `branch` could be entirely rewritten using `aggregate`:

```
def branch[A](cond: => Boolean)(th: => A)(el: => A): A =
  mux(cond)(() => aggregate{ th })(() => aggregate{ el })()
```

The symbol `mux` used in this example is a built-in operator that provides a purely functional multiplexer.

C. Working with combinations

More elaborate aggregate behaviours can be defined by compositions of the basic constructs. In addition, specific parts of the program logic can be encapsulated into Scala functions. Simple examples involving these features include counting neighbours except the device itself:

```
// mid is a special sensor yielding the device unique id
def isMe = nbr{ mid() } == mid()

sumHood{ mux(isMe){0}{1} }
```

The paradigmatic example of computational field is known as gradient [10], computing in each node the distance (hop-by-hop, or estimated) from the nearest node where a `source` field holds a true value:

```
def nbrDist = nbrvar[Double](NBR_RANGE_NAME)

def gradient(source: Boolean): Double =
  rep(Double.MaxValue) { dist =>
    mux(source){ 0.0 } { minHood{ nbr{dist} + nbrDist } }
  }
```

D. Scaling with complexity

Even though the basic constructs of the field calculus are somewhat low-level, they can be further composed so as to define reusable library components that provide higher-level behaviours—in fact, the functional character of the approach promotes systematic factorisation of behaviour into reusable layers of increasing abstraction.

An initial set of general coordination operators has been identified in [1], [4]. These operators capture common patterns of distributed computation and also enjoy the *self-stabilisation* property, which ensures that a system, independently of the current state, will eventually reach a stable state in finite time

that is not affected by transitory events. Moreover, as the self-stabilisation property is preserved by composition [13], it is formally guaranteed that also composite structures and algorithms self-stabilise.

On top of such resilient building blocks, a sound development API can be defined, which in turn can be used to implement application-specific aggregate behaviours.

1) Gradient-cast: `G` simultaneously performs two tasks: i) builds a distance-gradient from the source (`src`) according to `metric`, and ii) builds accumulated values via `acc` along the gradient starting from `init` at the `src`. In `scafi`, it can be encoded as follows:

```
def G[V](src: Boolean, field: V, acc: V=>V, metric: =>Double)
        (implicit ev: OrderingFoldable[V]): V =
  rep( (Double.MaxValue, field) ){  // (distance,value)
    dv => mux(src) {
      (0.0, field)       // ..on sources
    } {
      minHoodPlus { // minHood except myself
        val (d, v) = nbr { dv }
        (d + metric, acc(v))
      }
    }
  }._2 // yielding the resulting field of values
```

The generic type `V` (and, in this case, also `Tuple2[+A,+B]`) must have an (implicit or explicit) instance of the `OrderingFoldable` type-class available so that `minHoodPlus` can work out the minimum value on the neighbourhood (by convention, `*hoodPlus` operators exclude the device itself from the neighbours set).

A `broadcast` operation can easily get built on top of `G`:

```
def broadcast[V](source: Boolean, field: V)
                (implicit ev: OrderingFoldable[V]): V =
  G[V](source, field, x=>x, nbrRange())
```

In the following example, we leverage `broadcast`, to diffuse across the whole network the distance between two devices:

```
def distanceTo(source: Boolean): Double =
  G[Double](source, 0, _ + nbrRange(), nbrRange())

def distBetween(source: Boolean, target: Boolean): Double =
  broadcast(source, distanceTo(target))

def isSource = sense[Boolean]("source")
def isObstacle = sense[Boolean]("obstacle")

distBetween(isSource, isObstacle)
```

and, most notably, we could realise an algorithm that builds a `width`-wide channel connecting a source and a destination:

```
def channel(src: Boolean, dest: Boolean, width: Double) =
  distanceTo(src) + distanceTo(dest) <=
    distBetween(src, dest) + width
```

2) Converge-cast: `C` is the dual of `G`: it collects information distributed across space by `accumulating` values down a `potential` field, starting with `local` at the sources (i.e., devices with no parent, located at the edge of the `potential` field):

```
def C[V](potential: V, acc: (V,V)=>V, local: V, Null: V)
        (implicit ev: OrderingFoldable[V]): V = {
  rep(local){ v =>
    acc(local, foldhood(Null)(acc){
      mux(nbr(findParent(potential)) == mid()){
        nbr(v)
      } {
        nbr(Null)
      }
    })
  }
}

def findParent[V](potential: V)
                 (implicit ev: OrderingFoldable[V]): ID = {
  mux(ev.compare(minHood{ nbr(potential) }, potential)<0 ){
    minHood{ nbr{ Tuple2[V,ID](potential, mid()) } }._2
  }{
    Int.MaxValue
  }
}
```

`C` and `G` can be combined to originate a self-stabilising `summarise` operator that first collects information across the space and then propagates back the computed summary:

```
def summarize(sink: Boolean,
              acc: (Double,Double)=>Double,
              local: Double,
              Null: Double): Double =
  broadcast(sink, C(distanceTo(sink), acc, local, Null))

def average(sink: Boolean, value: Double): Double =
  summarize(sink, (a,b)=>{a+b}, value, 0.0) /
    summarize(sink, (a,b)=>a+b, 1, 0.0)
```

3) Time-decay: The `T` operator can be used to condense information across time by decreasing the `initial` field according to a `decay` function:

```
def T[V](initial: V, floor: V, decay: V=>V)
        (implicit ev: Numeric[V]): V = {
  rep(initial){ v =>
    ev.min(initial, ev.max(floor, decay(v)))
  }
}

def T[V](initial: V)
        (implicit ev: Numeric[V]): V = {
  T(initial, ev.zero, (t:V)=>ev.minus(t, ev.one))
}
```

Given such a function, the implementation of a `timer` is direct. With `timer`, a `limitedMemory` function can be defined, computing `value` until `timeout` has expired and `expValue` thereafter, effectively realising a memory limited in time.

```
def timer[V](length: V)
            (implicit ev: Numeric[V]) = T[V](length)

def limitedMemory[V,T](value: V, expValue: V, timeout: T)
                      (implicit ev: Numeric[T]) = {
  val t = timer[T](timeout)
  (mux(ev.gt(t, ev.zero)){value}{expValue}, t)
}
```

4) Sparse-choice: `S` can be used to create partitions and for selecting sparse subsets of devices in space. Essentially, it realises a local leader election, where `grain` is the mean distance between two leaders and `metric` represents the notion of distance.

```
def S(grain: Double,
      metric: Double): Boolean =
  breakUsingUids(randomUid, grain, metric)
```

The implementation uses `randomUid` to generate a field of unique identifiers:

```
def randomUid: (Double,ID) = rep((Math.random()), mid()) {
  v => (v._1, mid())
}
```

which is in turn exploited to break the network symmetry:

```
def breakUsingUids(uid: (Double,ID),
                   grain: Double,
                   metric: => Double): Boolean =
  uid == rep(uid) { lead:(Double,ID) =>
    val acc = (_:Double)+metric
    distanceCompetition(G[Double](uid==lead, 0, acc, metric),
                        lead, uid, grain, metric)
  }
```

by means of a competition between devices for leadership:

```
def distanceCompetition(d: Double,
                        lead: (Double,ID),
                        uid: (Double,ID),
                        grain: Double,
                        metric: => Double) = {
  val inf:(Double,ID) = (Double.PositiveInfinity, uid._2)
  mux(d > grain){ uid }{
    mux(d >= (0.5*grain)){ inf }{
      minHood {
        mux(nbr{d}+metric >= 0.5*grain){nbr{inf}}{nbr{lead}}
      }
    }
  }
}
```

5) Restriction in space: We have already encountered the operator for doing domain restriction, which is `branch`. With it, a number of interesting computations can be achieved:

```
// Compute distance from 'src', avoiding obstacles
def distAvoidObstacles(src: Boolean, obs: Boolean): Double =
  branch(obs){ Double.PositiveInfinity }{ distanceTo(src) }

// Perform a broadcast within a particular 'region'
def bcastRegion[V](region: Boolean, src: Boolean, v: V)
                  (implicit ev: OrderingFoldable[V]): Option[V] =
  branch[Option[V]](region){
    Some[V](broadcast(src, v))
  }{ None }

// Measure the size of connected components of a region
def groupSize(region: Boolean): Double =
  branch(region){ summarize(S(1,0),_+_,1,0) }{ Double.NaN }

// Remember whether an event has recently occurred
def recentEvent(event: Boolean, timeout: Int): Boolean =
  branch(event){ true } { timer(timeout)>0 }
```

IV. Alchemist as simulation platform

Testing, debugging, and performance assessment prior to actual deployment are key components of a good software engineering process, and aggregate programming makes no exception. However, since the primary target for this emerging paradigm are distributed and situated systems, conventional testing and debugging tools are hardly enough, in particular falling short at capturing the interaction among devices and between them and the underlying environment. In this situation, simulation emerges as a valuable tool for all the phases of software development: early testing and debugging, integration testing, and performance assessment. Of course, simulation cannot entirely capture the complexity of the real system (much like the classic unit testing cannot test every possible situation in classic application development), nevertheless the desiderata is to be as close as possible to a real situation. There are two relevant dimensions in this regard: first, the simulated environment must capture the most relevant aspect of the distributed system under design; second, the code that the simulator executes must resemble as closely as possible the production code. Considering both dimensions, we picked Alchemist [6].

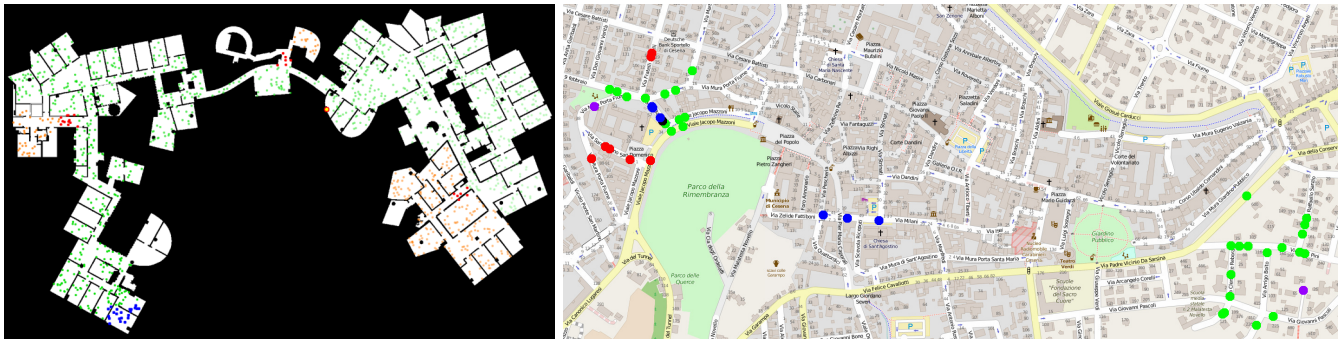
Alchemist is an event-driven simulator, mostly written in Java, tailored to the simulation of pervasive systems with a focus on performance. The model, albeit originally inspired by chemistry, supports complex environments, several flavors of node mobility, and advanced network models. Particularly interesting for real world applications is the possibility of exploiting map data from OpenStreetMap, navigating nodes along existing GPS traces as well as along roads (distinguishing among a handful of vehicles types). Also useful is the support for converting indoor images to Alchemist environments with physical obstacles. Figure 1 shows typical instances of environments frequently simulated with Alchemist.

The Alchemist computational model is generic (it is rather a meta-model), and requires a so called "incarnation" to be developed in order to actually execute simulations. An incarnation is a mapping between the Alchemist meta-model concepts and the concrete entities that the user is interested in simulating. Alchemist, at the time of writing, ships two incarnations, one of them tailored to aggregate programming supporting the simulation of (possibly mobile) Protelis [14] programmed devices.

A. Interfacing Alchemist and Scala

Our goal in interfacing `scafi` and Alchemist was to be able to feed it with the production Scala code, injecting it directly into the simulated environment. A few factors made such integration quite straightforward:

1) Scala and Java are both hosted in the JVM and feature full, bidirectional interoperability;
2) the `scafi` architecture neatly separates its core from the actor-based network backend, this design was key in our pursue to sharing interpreter and Scala code between the actor platform and the simulator;



(a) (b)

Fig. 1: Typical multi-agent scenarios supported by Alchemist: a very dense and intricate indoor environment (Figure 1a), and an urban environment (Figure 1b).

Alchemist meta-model	**Protelis incarnation**	**`scafi` incarnation**
Environment: container of nodes and network model	-	-
Network model	-	-
Node: container of reactions and molecules	Device: container of events and environment variables	Device: container of events and environment variables
Reaction: set of conditions that, if matched, triggers a set of actions with some time distribution	Event	Event
Condition	-	-
Action: any change of the environment	Any Alchemist action, or the execution of a computation round of a Protelis virtual machine, or the dispatch of results to neighbours	Any Alchemist action, or the execution of a `scafi` computation round, included message dispatching
Time distribution	-	-
Molecule, associated with a concentration	Environment variable, associated with a value	Environment variable, associated with a value
Concentration	Value: any Java object	Value: any Scala object

Fig. 2: Mapping between the Alchemist meta-model entities and the Protelis and `scafi` incarnation concepts. Omitted cells indicate that the Alchemist concept is inherited as-is, with no change. Similarities between the incarnations hosting the two aggregate languages are immediately clear.

3) the Protelis incarnation in Alchemist provided an architectural template, that led to a quick identification of the proper conceptual mapping to operate when building the incarnation.

Figure 2 summarizes the mapping effort between Alchemist entities and `scafi` ones, also comparing with the existing Protelis incarnation. As the reader may expect, several entities share the same meaning between the two aggregate programming languages, and as such we believe that an incarnation skeleton for any aggregate programming language could be crafted in Alchemist, further easing the integration of any JVM-hosted aggregate programming language interpreter. In particular, note that sensing of information is supported by means of environment variables in Alchemist, whose evolution over time is controlled when configuring an Alchemist simulation, and which binds to the behaviour of construct `sense` in `scafi`.

V. Case Study

Our goal in this work is to demonstrate the feasibility of using `scafi` in conjunction with Alchemist to realise complex simulations. As such, we do not aim at presenting novel scenarios, but rather we do explain how to recreate some of the results available in literature, validating the proposed framework and showing how convenient is to express complex collective adaptive systems with aggregate computing, `scafi`, and the available APIs. In particular, we focus on two examples that have already been implemented in Protelis and simulated in Alchemist:

1) an example application of smart vehicle counting, which showcases the usage of higher order functions and the possibility of tuning the computational round execution

frequency with Alchemist. The proposed code is derived from [15];
2) an urban crowd tracking scenario featuring the combined usage of all fundamental self-stabilising building blocks exposed in Section III-D [1].

The goal of these simulations, performed prior to actual deployment, would be to evaluate whether the propose collective adaptive system would provide an effective and efficient service for the application at hand.

A. Vehicle counting

Consider a highway, where a sensor is deployed to monitor the number of vehicles passing nearby. We suppose that the vehicles are equipped with electronic components that make them connected with all the other compatible devices within a certain range. We do not consider connectivity issues (which are beyond the scope of this work), and make instead the assumption that every device (vehicle or sensor) is able to communicate with every neighbour within a certain distance. We suppose that all devices are running the following `scafi` "virtual machine", which is able to import any injected procedure from the `snsInjectedFun` sensor:

```
// Dynamically import any computation
def snsInjectedFun: ()=>Double = sense("injectedFun")
// True where the data should get aggregated
def snsInjectionPoint: Boolean = sense("injectionPoint")
// 1 for patrons, 0 otherwise
def snsShouldCount: Double = mux(sense("patron")){1}{0}
// Detection range in meters
def snsRange: Double = 30

def virtualMachine(): Double = {
  deploy(snsRange,snsInjectionPoint,snsInjectedFun,()=>0.0)
}

def deploy[T](range:Double, source:Boolean,
              g: ()=>T, noOp: ()=>T)
             (implicit ev: OrderingFoldable[T]): T = {
  val f: ()=>T = branch(distanceTo(source) < range) {
    G(source, g, identity[()=>T], nbrRange())
  }{ noOp }
  f()
}
```

To monitor the number of nearby vehicles, the sensor device injects the following function, which relies on the `C` building block to realise a convergent sum:

```
def countPatrons() = {
  C[Double](potential = distanceTo(snsInjectionPoint),
      acc = _+_, local = snsShouldCount, Null = 0.0)
}
```

In this scenario, the sensor injects such function after two seconds of simulations, due to a congested block of traffic coming, and turns it off after 10 seconds (by injecting a function returning 0). We executed the same experiment multiple times, varying the round frequency. Figure 3 summarises the results. As expected, values get much closer to reality when the sampling frequency is very high. Moreover, the algorithm exploited to implement `C` is based on a spanning tree, that by its nature is sensible to changes in the network topology: these

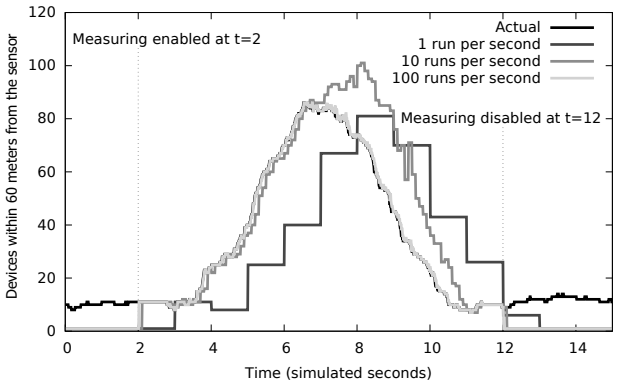


Fig. 3: Number of vehicles counted using the convergent, distributed sum based on `C`. As expected, higher frequencies lead to more precise measurements.

are responsible of the peak in the device count observed with devices running at 1Hz.

B. Crowd tracking in an urban scenario

As second example, consider an IoT environment that provides services for crowd safety at a mass public event, such as a marathon. Such events pose challenging safety issues, because the movement of people in crowded and constrained environments often creates emergent zones of dangerous overcrowding where any small incident can create a panic or stampede that injures or kills people. We simulate here a possible crowd safety service running in an IoT urban environment.

We define three possible crowding levels;

```
val (high,low,none) = (2,1,0) // crowd level
```

a function locally estimating crowd density;

```
def unionHoodPlus[A](expr: => A): List[A] =
  foldhoodPlus(List[A]())(_++_){ List[A](expr) }

def densityEst(p: Double, range: Double): Double = {
  val nearby = unionHoodPlus(
    mux (nbrRange < range) { nbr(List(mid())) } { List() }
  )
  nearby.size / p / (Math.PI * Math.pow(range,2))
}
```

a function mapping each local area to a danger level, depending on the average density sensed locally;

```
def managementRegions(grain: Double,
     metric: => Double): Boolean = S(gran,metric)

def dangerousDensity(p: Double, r: Double) = {
  val mr = managementRegions(r*2, () => { nbrRange })
  val danger = average(mr, densityEst(p, r)) > 2.17 &&
    summarize(mr, (_:Double)+(_:Double), 1 / p, 0) > 300
  mux(danger){ high }{ low }
}
```

and a function yielding true if a situation of danger has remained active for enough time.

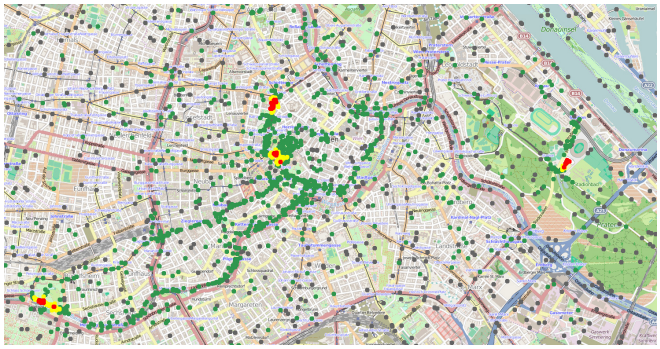

Fig. 4: A snapshot, taken from [1], of Alchemist executing the crowd warning application. Grey dots are stationary devices, not participating the system. Green dots are users in safe areas, red dots users in dangerous areas, and yellow dots are users who are being warned.

```
def recentTrue(state: Boolean, memTime: Double): Boolean = {
  branch(state) {
    true
  }{
    limitedMemory[Boolean,Double](started, false, memTime)._1
  }
}

def crowdTracking(p: Double, r: Double, t: Double) = {
  val crowdRgn = recentTrue(densityEst(p, r)>1.08, t)
  branch(crowdRgn){ dangerousDensity(p, r) }{ none }
}
```

With all those ingredients, we warn the users of those devices located near areas which have remained crowded for a long time.

```
def crowdWarning(p: Double, r: Double,
                 warn: Double, t: Double): Boolean = {
  distanceTo(crowdTracking(p,r,t) == high) < warn
}
```

For the sake of simplicity, the numbers we used for the estimates had been directly written in code. They could get extracted and substituted by parameters, the values proposed are derived from literature [16]. The actual simulation is composed of 1000 stationary devices embedded into the environment plus 1479 mobile personal devices, each following a smartphone position trace collected at the 2013 Vienna marathon [17], [18]. Figure 4 shows a sample screenshot of the system deployed.

VI. Related Work

A. Computational fields and aggregate programming

A wide range of existing approaches to aggregate programming have been proposed, including such diverse approaches as abstract graph processing (e.g., [19]), declarative logic (e.g., [20]), map-reduce (e.g., [21]), streaming databases (e.g., [22]), and knowledge-based ensembles (e.g., [23])—for a detailed review, see [24]. Most of them, however, have been too specialized for particular assumptions or applications to be able to address the aggregate programming challenge at its full complexity in a wide range of different environments.

A unifying model based on *computational fields* has been identified as a generalization of a wide range of existing approaches, surveyed in [24]. Formalized as the computational field calculus [3], this universal language provides a theoretical foundation on which real aggregate programming platforms can be built: both Protelis [14] and `scafi` are practical instances of such calculus.

B. Aggregate programming and multi-agent systems

Aggregate programming targets collective behaviour of systems, which in the MAS literature have typically been addressed in various ways. On the one hand, we have approaches facing the design of relatively small systems of deliberative/cognitive agents: coordination mechanisms and tools (e.g. via artifacts [25] or protocols [26]), social/organisational norms [27], commitments [28], and so on. They provide declarative constraints to agent interaction (abstracting away from the step-by-step operational behaviour of the aggregate), and strongly rely or deal with autonomy of agents, assuming agents have inner mechanisms to dynamically adapt their behaviour to the specific contingency, up to the point of deviating from a previously agreed cooperative behaviour.

On the other hand, collective behaviour of large-scale MASs is mostly studied in terms of swarm-intelligence techniques, assuming that agents are reactive and perform repetitive tasks, with the problem of designing local agent behaviours that can end up in the desired global tasks [29].

Aggregate programming somewhat sits in between these two apparently unreconcilable views of a self-adaptive MASs: it aims at devising a methodology by which the collective behaviour of large-scale ensembles of autonomous, deliberative agents, can be designed so as to manifest inherent properties of self-adaptation, resiliency, and openness.

C. Simulation of aggregates

We claimed in Section IV that simulation is a key step in the development of aggregate programming applications. There are many kinds of simulation tools available: they either provide programming/specification languages devoted to ease construction of the simulation process, especially targeting computing and social simulation (e.g. as in the case of multi-agent based simulation [30], [31], [32], [33], [34]), or they stick to quite foundational computing languages to better tackle performance, mostly used in biology-oriented applications [35], [36], [37], [38].

Alchemist is a discrete-event simulator (DES), since it combines a continuous time base with the description of system dynamics by distinguished state changes [39]. The class of DES more related to our approach are those commonly used to simulate biological-like systems, by which in fact Alchemist was originally inspired. A recent overview of them is available in [38], which takes into account: DEVS [40], Petri Nets [36], State Charts [41], and stochastic π-calculus [35].

VII. Conclusions and future works

In this paper, we introduced `scafi`, a Scala based API and DSL for aggregate programming, equipped with an actor based platform and integrated with the Alchemist simulator. We described the main features of the API/DSL, and demonstrated how `scafi` can be used to realise reusable building blocks that ease the creation of aggregate programs. We presented the integration between `scafi` and Alchemist, a discrete-event simulator targeting pervasive systems, detailing the mapping between the Alchemist meta-model and the concrete `scafi` entities. We were able to push the integration to the point that there exists no difference between the production code and the code required to perform a simulation. We argue that such a deep level of integration will improve the engineering practices when it comes to leveraging aggregate programming for building actual systems, allowing for debugging and testing on a centralized testing platform prior to deployment. We validated the approach by translating complex examples found in literature in `scafi`, using Alchemist as simulation platform.

Further development of this research includes a refinement of the current `scafi` architecture and of its simulator integration. While Alchemist is already publicly available, `scafi` is set to be ready for the general public shortly, as well as the Alchemist incarnation supporting the execution of `scafi` programs in a controlled environment. We expect `scafi` and the related tool chain to boost the adoption of aggregate programming as a new paradigm for the engineering of complex, pervasive systems, such as the typical Internet of Things applications.

4th International Workshop on Smart Energy Networks & Multi-Agent Systems

THE emerging smart infrastructure in energy networks represents a major paradigm shift in resource allocation management with the aim to extend the centralised supply management model, towards a decentralised supply-and-demand management that is expected to enable more efficient, reliable and environment-friendly utilisation of primary energy resources.

Together with this vision, there are new and complex tasks to manage, in order to ensure safe, cost-reducing and reliable energy network operations. This includes the integration of various renewable energy systems, like the photovoltaic or the wind energy, which are able to reduce the greenhouse gas emissions but that are working under greater uncertainty; as well as the interaction of transport and storage systems for energy that are envisioned through techniques like 'Power to Gas' and fuel cells, which are using the electrical and the gas transportation network.

Further tasks can be found in the fact that the market participants (e.g. simply households) are becoming more autonomous and intelligent through technologies like smart metering, which requires a coordinated demand side management for millions of producers, consumers or, if this applies, prosumers by means negotiations and agreements.

Information and communication technologies are key enablers of the envisioned efficiencies, both on the demand and the supply sides of the smart energy networks, where the agent-paradigm provides an excellent first modelling approach for the distributed characteristic in energy supply systems. On the demand side they aim at supporting end-users in optimising their individual energy consumption, e.g. through the deployment of smart meters providing real-time usage and cost of the energy and the use of demand-response appliances that can be controlled according to the user preferences, energy cost and carbon footprint. On the supply side they aim at optimising the network load and reliability of the energy provision, e.g. through active monitoring and prediction of the energy usage patterns, and proactive control and management of the reliable energy delivery over the networks. It is also envisaged that they will be able to influence the demand through the dynamic adjustments of the energy price in order to influence the end user behaviour and energy usage patterns throughout and across the energy networks for electricity, gas and heat.

Although a significant effort and investment have been already allocated into the development of smart grids, there are still significant research challenges to be addressed before the promised efficiencies can be realised. This includes distributed, collaborative, autonomous and intelligent software solutions for simulation, monitoring, control and optimization of smart energy networks and interactions between them.

Topics

- Experiences of Smart Grid implementations by using MAS
- Applications of Smart Grid technologies
- Management of distributed generation and storage
- Islands Power Systems, Microgrid Applications
- Real time configurations of energy networks
- Distributed planning process for energy networks by using MAS
- Self-configuring or self-healing energy systems
- Load modelling and control with MAS
- Simulations of Smart Energy Networks
- Software Tools for Smart Energy Networks
- Energy Storage
- Electrical Vehicles
- Interactions and exchange between networks for electricity, gas and heat
- Stability in Energy Networks
- Distributed Optimization in Energy Networks

***Abstract*—The current transformation process of how energy is supplied attracts great interest from many different market players. As a consequence, many proprietary solutions for "smart" energy applications are flooding the market. This turns out to be rather a problem than part of the solution for the systematic development of future energy grids. Additionally, the absence of necessary standards blocks further developments that enable the creation of novel, market-driven and hybrid control solutions. To overcome these problems, we suggest a standardized control approach for hybrid energy systems by means of a so called Energy Option Model (EOM). This unifying model and the therewith developed decision support system provides the necessary technical understanding and the economic assessment options for network-connected energy conversion systems. Thus, it can be used for single on-site systems as well as for aggregated systems that are controlled in centralized or decentralized manner. This paper presents and discusses exemplary use cases for our EOM that illustrate the centralized as well as the decentralized use of our approach within hybrid energy systems. Overall, we believe that the EOM represents the key approach for a further systematic development of an open hybrid energy grid.**

I. Introduction

THE tendency towards decentralized controlled energy conversion systems and the increasing number of IT-enriched smart systems in general leads towards an energy landscape that consists of complex, globally connected and mainly software driven systems. In order to reach climate targets or just to maximize organizational profit, smart markets need to be provided on top of the underlying technical systems with their inherent flexibility. Concurrently, a stable volatile energy production must be guaranteed. However, global goals, such as the stabilization of a distribution network, require a minimum of adaptive interoperability that has to be expressed in one standard. We believe that the developments in smart grids and related areas are now at a point, were it has to be asked, if we want to build control systems that will create new monopolies, caused by proprietary software solutions, or if we want to support an unbundled and open energy supply that, on the one hand, offers the needed intelligent flexibility and, on the other hand, supports further developments over the next decades? Assuming that the latter is the case, it is obvious that software standards are required that prevent our already highly complex energy supply from becoming more complex and possibly uncontrollable with respect to the technical foundations and market regulations [1].

This paper presents the approach and the framework of our system-centered Energy Option Model (EOM), that permits to comprehensively describe the energetic and the economic behavior of any type of energy conversion system. Additionally, based on this unifying concept, the dynamic aggregation of hybrid energy systems is supported so that coalitions of systems, like virtual power plants, prosumers in a distribution network or even the devices in a Smart House can be represented, observed and optimally controlled. As a consequence of this unifying approach, the EOM can be used for several purposes and in different scenarios. By describing energy systems and their abilities in a comprehensive manner, the EOM can first be used as foundation for complex system simulations. Moreover, connected to real on-site systems, it permits the construction of centralized, partially decentralized or completely decentralized control approaches within Smart Grid and Smart Market scenarios. To demonstrate this capability, we demonstrate here two simple application cases by means of single and aggregated electrical vehicles. Further, we will discuss the consequences for our energy agent approach [2]. For this the paper is structured as follows: The next section provides some background information and motivates our work. Section III will outline the energy agent approach, while IV introduces the basic structure of the EOM. In section V the two mentioned use cases of the EOM will be shown. Subsequently, our solution will be discussed and compared to other approaches, known from literature. The paper end with a conclusion in section VI.

II. Backgroung & Motivation

The ongoing discussions of whether Smart Grid devices or even more complex system aggregations are controlled in a centralized or decentralized manner and under which

market rules they operate, is still an open scientific, organizational and social question. Here, the requirements or goals for such control approaches differ and may address stability issues in distribution networks, the efficient usage of energy resources, a cost and revenue optimization with respect to the actual part of the energy market or simply aspects of a customer's comfort. Based on these different requirements, diverse control solutions were developed. Accordingly, there is a lack of standardized control approaches that provide both, first an investment protection for developer and customer of smart devices and secondly an adaptive flexibility with respect to an organizational affiliation and thus to the actual control solution used with such devices. We will discuss these two aspects in the following.

In the context of control approaches, literature of the recent years presents a significant number of publications, describing the successful applications of agents and Multi-Agent systems (MAS) in specific Smart Grid scenarios, as for example in virtual power plants [3], in Demand-Side-Management systems [4] or within price-based, indirect controlled approaches that are known as Demand Response [5]. Beyond, a few decentralized control approaches were introduced, as for example with [6] and other. Since most of these developments were motivated by the problems that occurred with the increasing number of regenerative and thus volatile energy production systems, they basically focus on aspects around electrical grids and markets. However, such a one-sided focus neglects the flexibility-potentials that could possibly be utilized in order to close the storage gap electrical networks. Research has already introduced a couple of approaches here that are characterized as so called Power-to-X applications [7]. In such applications, electrical excess energy will either be stored, as for example in an electrical vehicles accumulator (Power-to-Vehicle), or it is converted to a different form of energy, such as hydrogen or heat. In this context, [8] provides an overview of different approaches, technologies and strategies that focuses on the management of large-scale schemes of variable renewable electricity. Considerations about such hybrid energy systems, however, are fairly new in a broader range and thus even more far away from any standardization for an open and adaptive control.

The lessons that could be learned with the current state of the art approaches, clearly indicate that any further diversification of control approaches has to be prevented in order to avoid uncontrollable situations that may lead to a chaotic overall system behavior of our energy supply. Additionally, it can be expected that an increasing diversification of self-containing control approaches will also increase the customer's uncertainty about the expectable functionalities, its benefits, the customers privacy and will thus probably prevent the needed investment decisions that would bring the "smart" market into motion [9]. This similarly applies also for the developer and provider of such control solutions, since they have to live with the uncertainty of non-existing or suddenly appearing policies that may destroy their control approach or even their business models.

In contrast to an adaptive control that is know from automation [10], we are using the notion of an adaptive control as a synonym for an open overall system architecture that dynamically allows to adapt and thus to 'understand' any kind of energy conversion process and its inherent flexibility. Here we go by the claim that individual systems, or energy conversion processes respectively, should be arbitrarily integrated into any larger overall system. The reasons for this requirement are versatile. The simplest argument for that is the avoidance of new regional or local monopolies that occur, if proprietary and self-containing on-site solutions are used, as already mentioned in the introduction of this paper. Following the unbundling principle, it is our opinion that a customer should be able to freely select and change its energy supplier, regardless of what specific smart grid device or what actual control approach is used; this freedom must not be prevented by any smart device or software system.

The described bilateral relation between a customer and a supplier, however, does not go far enough, since the number of parties involved in this context is much larger. For example, it is conceivable that the system immanent flexibility of an energy conversion process can also be used by a distribution network operator (DNO) in order to stabilize critical network situations. But this would require that also a DNO is able to utilize a systems flexibility, which is not possible if no unified description of an energy conversion process is used.

In turn, if one sees a unified system description not only as a technical or regulatory requirement, such description would have the potential to be the key enabler for a real sustainable development of a market driven future energy grid. Starting from the scientific point of view, unified system descriptions could be used in order to systematically explore the complexity of large-scale system aggregations and their cross associations, as they can already be found in a single distribution network that is organizationally also connected to different energy suppliers. Using the same base control model for single systems, researchers could get the chance to similarly compute and compare their results and thus their different control approaches. Based on that, the necessary market rules could be derived and thus hopefully help to resolve the current chicken and egg problem in sustainably designing a future energy grid.

Based on that, also the energy market could participate in various ways. Providing an adaptive operation and flexibility model for any energy conversion process involved, could theoretically enable new market mechanisms that would for example allow to buy the needed, task-dependent energy for a single system on the fly. Assuming a suitable accuracy of such model, it could

also be used as a predictive model that provides the information for the needed energy amount. Beyond that, also the change of supplier could be made easier, since the inclusion of a specific system would be based on the same operation and flexibility model.

With above described requirements or even visions, the here introduced EOM was firstly developed as a modular approach, focusing on the abilities and thus also on the flexibility of single energy conversion processes. This modularity concept goes along with our energy agent approach that will shortly be outlined in the next section. Since these energy agents may need to consider multiple systems simultaneously, the EOM and its framework were designed also to manage system aggregations. These can be understood as 'system of systems' and will be explained in more detail in section IV.

III. ENERGY AGENTS

According to our previous publication [2], an energy agent can be understood as the computing entity that manages the concerns between an on-site system and its stakeholder. For this, we see an energy agent as a mediator software system that for the most part is located in between of the local system controller and the outside, possibly "smart" world. An exception is the case, if the actual system being guided through an agent has no own controller; in this case an energy agent may also take the control tasks.

For the interaction with the local system, energy agents need to incorporate a multitude of possible connectivity protocols, as for example serial protocols like *Modbus RTU* or more sophisticated protocols like *OPC UA*, *IEC 61850* and other [11], [12]. By using this connectivity, the energy agent should be enabled to receive or set all relevant information that help to comprehensively monitor or guide the actual system. In the context of the EOM, those information are part of the so called 'system variables' and include measurement values, system set points that can be controlled by the agent and system set points that were configured by an end user, as for example the desired room temperature for a heating system. To cooperate with further agents and software systems, as for example with a web service that provides weather forecasts, the energy agent should be able to use a network connection that allows these interactions. Fig. 1 below visualizes the described system environment and shows the full list of system variable types that are used within the EOM, described in the next section.

With the static information, system specific data models are meant that describe the system abilities in a mathematical, empirical or theoretical manner. Examples can be found with a consumption map of a combustion engine or with a turbine or compressor map of rotating equipment.

The remit of an energy agent depends on the actual scenario definition for which it will be designed. Here we introduced the notion of 'integration level' (IL) that describes the level of sophistication with respect to a scenario and thus also to the inherent complexity and the abilities of an energy agent [13]. In a rough classification, we differentiated between an IL0 that describes the initial construction state of the energy infrastructure for a time, where no decentralized computational entities could be found. Based on that and with increasing and coherent integration level, we assumed a continuous change from centralized controlled system to more and more decentralized controlled systems. Finally, we assumed that a completely decentralized control approach that was described with IL5 is only a theoretical consideration that can't be realized.

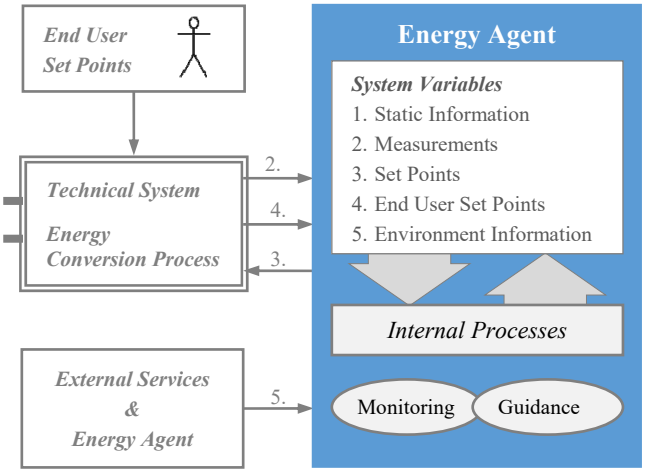

Fig. 1 Energy Agent Connectivity and its System Variables

With the coherent set of integration levels, we also wanted to reflect the fact that local software components as the energy agents will be subject to changing conditions over time. For example, it can be assumed that the regulatory policies will change successively over the next decades. Accordingly, the on-site software has to be further developed and adjusted in order to meet the changing market rules and policies. This, in fact, corresponds to another type of hybrid consideration, since it can be expected that not every system involved will always be updated.

It is our goal to use energy agent in simulations, testbed applications and in real on-site systems across all integration levels. Therefore, we are using the characteristics of software agents that allow to further enrich or exchange specific behaviors. Especially the ability to interact with the underlying technical system and thus to monitor or guide it, represents here the main difference between simulation, testbed or real application. Here it is planned, to either use a simulated or a real input and output behavior for the (virtual) connection to the technical system. However, while in a real system real data can be gathered, in simulations a mechanism is required that allows to simulate the acquisition data that would originally come from the underlying system. Additionally, these data have to dynamically change in case

that an energy agent meets a control decision. That in turn requires a suitable model that allows to describe the dynamic system behavior.

It is obvious that an energy agent requires a suitable model and thus an understanding about the associated technical system for both, for simulations as well as for real applications. This applies not only if a decentralized control solution is to be used or validated, as for example in case of a price-based Demand Response approach. This already applies for the lowest integration level 0, where basically the physical behavior of one or more energy conversion systems is described. Beyond, using a larger number of such dynamic models will further enable to simulate complex infrastructures, such as distribution or transportation networks and their dynamics.

Independent of the here introduced idea of an energy agent, we would like to state that an open description of the capabilities and hence the flexibilities of individual energy conversion systems is essential for a sustainable development of our energy infrastructure. Our approach is presented in the next section.

IV. THE ENERGY OPTION MODEL (EOM)

The fundament for the EOM is a system delimitation that separates the considered energy conversion process (ECP) and its environment. Based on that, a customizable and scalable system definition can individually be modeled. That means that on the one hand small single systems can be described, while on the other hand also bigger systems or multiple simultaneous systems might be modeled at once, in case that the systems effect on the environment (or on the network connections respectively) can reliably be described. Thus, a system definition described by the EOM, can also be the model of a complex plant, even if it consists of several conversion processes in detail.

Based on the first law of thermodynamics [14], that describes the conservation of energy, the EOM allows to capture all network connections and usage types of an ECP. Therefore, the concept of a so called *TechnicalInterface-Configuration* (TIC) was introduced as an anchor for the further modelling that enables to differentiate those cases. Thus the EOM allows to capture different connectivity types (as for electrical vehicles) or to record different execution modes for single systems (as for example the different programs of a washing machine). Each TIC can be further modeled as described in the following.

For the further inventory of an ECP, the EOM allows to capture the actual network connections of the system. For a comprehensive description, the EOM requires information about the used energy carrier with each connection (e.g. electricity, natural gas or heat) and the direction of the energy flow, if relevant. In case that the described system contains an internal energy storage, additionally the storage capacity can be captured with a specific network connection.

To capture the regular operating states and thus the usual system behavior, the EOM allows their modelling with the help of a directed graph *G (V, E)*. Here, the vertices *V* represent the operating states, while the directed edges *E* describe the subsequent order in which the operating states occur. Through a reference to itself, an operating state can be repeated as many times as needed. Each vertex contains further information about the duration and the energy revenues that can be generated in an operating state. Defining the duration of an operating state and repeating it, allows thus a flexible modelling that corresponds to any desired discretization for the behavior of the considered ECP.

The description of an energy flow, in a specific operating state, for a specific network connection and for the chosen duration is a further part of the operating state description that corresponds to one of the above described vertices. The EOM offers various possibilities to describe energy flows. For that purpose, it differentiates between constant, empirical or calculated energy flows that can be used as description for each single network interface. Here, measurements that were statistically evaluated are seen as empirical information. Those data can especially be used in case that an energy flow is not simply constant or if the energy flow can't be calculated by mathematical equations. Thus unsteady or transient operating states can be described by datasets and help to better 'understand' or predict a systems behavior.

For the calculation of energy flows, the framework of the EOM offers the extension of specific classes which then contain the required calculation methods. Based on an operating state and the system variables that were already described in the previous section, any kind of calculation can be executed in order to determine an energy flow. Thus, this adaptive approach enables to use the theoretical knowledge that is especially present in the engineering disciplines.

Up to here, we described the first part of the EOM and its framework, which can be considered as the basic model and thus the fundamental for all further steps. The corresponding data structure of the above described model is also available as an XML scheme [2]. Based on that, the EOM-framework allows the persistence and thus the exchange of ECP descriptions.

The second part of EOM and its framework is aimed to comprehensively generate schedules for the system considered. Comprehensively means here that with the help of the EOM a full description of the system behavior over time can be generated that consist of all time-dependent values of the system variables and all applied energy flows. Furthermore, the converted energy amounts, the energy losses and an individual utility function can be taken into account, which enables an assessment of single system states and thus the assessment of the overall system usage.

To get there, the EOM framework enables to configure the needed evaluation parameters that are first a starting, time-dependent system state and an end time, wherein the evaluation may be terminated. If required, the end time for an evaluation can also be connected to a target system state. This could be for example a fully charged battery of an electric vehicles battery at the end of the evaluation period.

Further information for the time-dependent evaluation of the system can be predictions of specific system variables that are required to calculate energy flows. Such variables can be, for example, temperature or insolation information that are derived from weather forecasts and that are used in order to pre-calculate the heat demand of a house or to predict the energy production of a photovoltaic plant. Here, the framework of the EOM permits again the extension and usage of individual implementations that may provide the needed data by using any type of data source.

For the definition of an individual utility function, the EOM separates between two assessment paths. The first path is designed to enable the assessment of the energy flows and amounts that are transferred over each network interface. Therefore, a corresponding function can be assigned for each energy carrier in combination to a flow direction. Thus, a power feed or consumption can be considered differently. With the second path of the utility function, the EOM enables once more the extension and usage of individual calculation classes. Within such a class, any type of calculation can freely be implemented; its result will finally be added to the utility results of the energy flow assessment. In this way, e.g. depreciation costs for the operation of an ECP can additionally be added or further, more complex relationships.

The settings described above, finalize the preparation of an evaluation process within the EOM framework and an actual evaluation process can be executed. Since the range of goals that have to be considered here may differ, the EOM framework permits once more to define individual so called ‘evaluation strategies’.

Based on the information of the basic model and the evaluations settings, the goal of such a strategy is to produce a system schedule in a predefined data structure. Therefore, the EOM does not restrict the way, nor limits it to a specific algorithm that has to be used. Rather, it leaves the actual approach for the creation of a system schedule deliberately open in order to enable the application of different competitive approaches. That means that a developer is free to decide which algorithm is to be used and how the actual evaluation strategy is designed. This especially enables to reuse already proven and reliable approaches for the generation of system dependent schedules.

Beside the above described open architecture, the EOM framework additionally provides a comprehensive assistance for generating system schedules through an own evaluation strategy. Therefore, a graph based methodology was developed that theoretically can be applied to any kind of ECP. The foundation for this approach is the unique identification of systems states. Since the identification of these states may differ depending on the actual system, the EOM permits to specify the parameters that have to be considered here. By default, the evaluation time, the chosen interface configuration, the operating state, the set points as well as controlled measurements are used in order to specify this identifier. Additionally, also storage loads can be taken into account, if required. For the discretization of unique system states, an increment can be set for each parameter of the state identifier.

Based on those clearly differentiable and discretized unique system states, a graph can be drawn that represents the states and their subsequent states over time. Figure 2 below shows the so called Differences Graph of this evaluation approach.

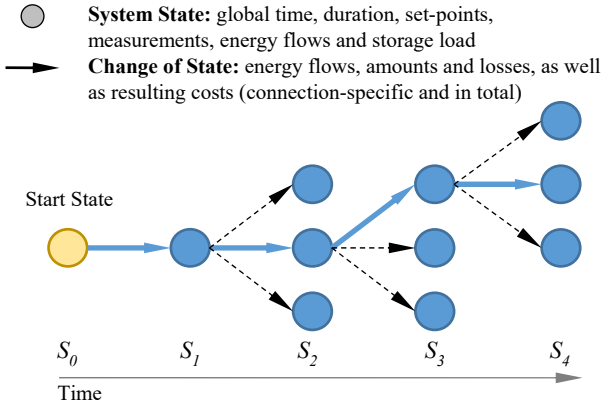

Fig.2: Differences Graph for an evaluation strategy

While the vertices of the graph represent the unique system states, the edges correspond to the actual changes that occur with the transition from one state to another. Thus, a change in a storage level can be determined as well as the changes that occur if an individual utility function is applied. Based on this differences approach, a number of well know graph-based optimization algorithms may be applied (e.g. Dijkstra and many more) in order to optimize the system usage, taking into account certain objectives. Additionally, the EOM framework provides a general algorithm structure that can be used within an evaluation strategy and that proceeds along the graph structure. For reasons of space we skip a detailed explanation here, but we want to point out that an evaluation becomes a sequence of time dependent decision processes that are based on qualified system information, represented by the Differences Graph. Thus, the EOM and its framework may also be considered as a decision support system [15].

The aggregation method for several technical systems that is provided by the EOM is realized in the sense of a ‘system of systems’. Analogously to a single technical system, the aggregator will also be considered as a technical system, summarizing the sub systems in regard to interfaces by energy carrier and by add up energy carrier-dependent

storage capacities. In more complex scenarios, where wider areas are to be considered, an aggregation may additionally require a network calculation, which is also supported by the EOM. Similar to the evaluation strategy for single technical systems, a strategy for aggregated technical systems can individually be designed. In contrast to single systems, decisions must be made for each subordinate system, so that several decision graphs will concurrently be used during an evaluation of aggregated ECP's.

The EOM is available as an end user application and laboratory tool, but can also be used "head-less" within an energy agent. In this case it is the task of an agent to get and provide the needed base information for a single technical system or an aggregation of technical systems (e.g. predictions, cost information and other) and start an appropriate evaluation process, if required.

V. APPLICATION OF THE EOM

To demonstrate the applicability of the EOM, this section describes the modelling and algorithm approach for planning processes of one and more electrical vehicle's (EV) battery. For this, first, the actual system will be described in the next sub-section, while subsequently the used algorithms will be outlined.

A. Single Electrical Vehicle

The chosen EV has a battery with a storage capacity of 24 kWh. According to IEC 62196, it can differently be connected to an electrical network. For the experiments we have chosen a Mode 1 connection, which corresponds to a slow charging from a household-type socket-outlet (230V, 3.5 kW charging or discharging). With this information, the base graph of the operating states was modelled as shown in Figure 3.

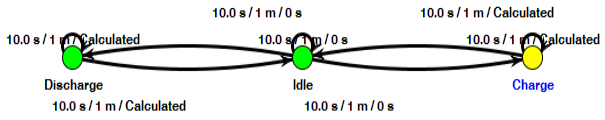

Fig.3: Graph for the operating states of an EV battery

It can be seen that the operation states *Charge* and *Discharge* are modelled in a way that each of them apply for at least 10 seconds. Both times are followed by a minimum and a maximum time in which the system can be kept in the respective operating state. While here the minimum time was defined in order to avoid a too short stay and thus a too quick change of the operating state, the maximum time can only be calculated depending on the current storage load (e.g. a full battery cannot be charged anymore). Further, for the operating state *Idle* no maximum must be defined, since this system neutral state has no time limit in principal.

For the evaluation of the system, we assumed a planning scenario, where the EV has a time frame between 8 p.m. and 6 a.m. for charging. Further, we assumed an initial storage load of 5 kWh, while the car has to be fully charged in the morning. These assumptions correspond to the definition of two system states (an initial and an end system state) with corresponding timestamps. This limits the evaluation period for the developed evaluation strategies. For the assessment of the time dependent system behavior, we used the EOM's cost function approach by means a time variable pricing for the usage of electrical energy.

To create a base for later comparisons, we first developed a simple strategy that's behaves in a regular or Greedy-styled manner. That means, like a non-controlled or scheduled charging process, the EV's battery will directly be charged until it reaches its storage capacity.

Thereon based, another strategy was developed that considers the specified procurement costs for electrical energy over time. Simply by selecting time ranges that have the best prices and put them in an ascending order, the prioritized charging times were determined. Consequently, for the used evaluation strategy, the task of cost optimization results to a fairly simple observation of time and a selection of the desired operating state until the battery reaches it maximum capacity. Figure 4 below shows the used electricity costs and compares the results of the two evaluation strategies.

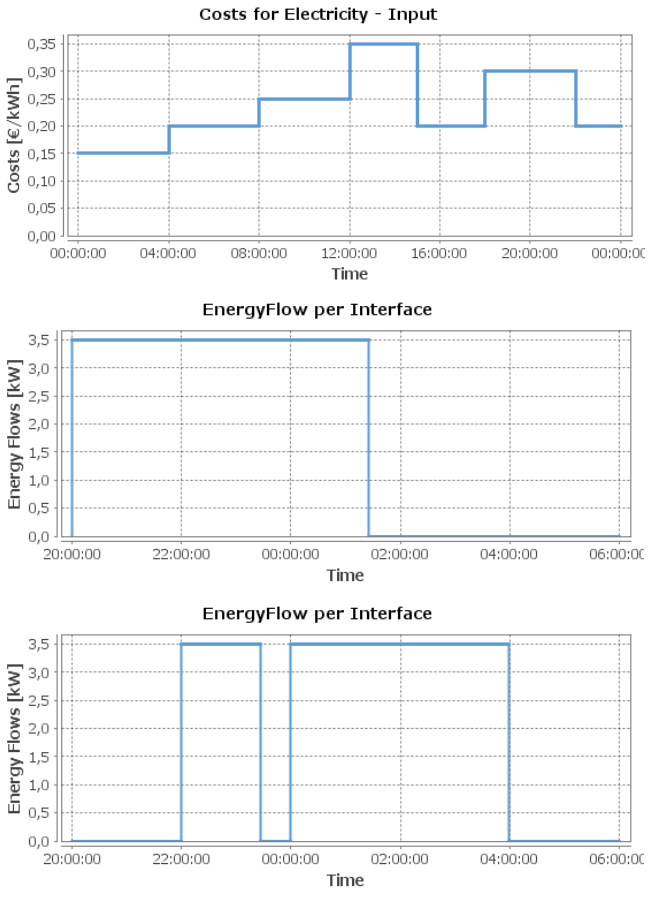

Fig.4: Cost-Optimal Charging of an EV's battery, based on price signals

For the example, a saving of 27% of the procurement costs could already be realized, simply by the described more sophisticated selection process of charging times.

Even the complexity of the used algorithms, or evaluation strategies respectively, were very manageable here, the learning curve for the development of the EOM and its usage as a reasoning model were remarkable. Here we realized that, as first, the development of an evaluation strategy is required that is able to reproduce the regular behavior of an ECP. Only on this basis, the improvements of 'intelligent' algorithms can be found and compared.

Despite the simplicity of the presented example, a very important capability of the EOM is presented here. This is the capability to concurrently apply different evaluation or plan generation strategies in a parallel manner. Since competitive evaluation strategies can be executed concurrently, single energy agents can be empowered to become intelligent agents. Based on the current system state that can be acquired from the system (by means of measured values, set-points, energy flows etc.) and a defined goal, like a cost optimal charging of an EV's battery, the energy agent can execute different strategies, where each results to a different system usage of time. Based on a comparison or assessment of these resulting execution schedules, the energy agent is able to select the best plan and consequently to optimize the systems behavior. With this general approach, the EOM is closely related to the well-known BDI-concept [16], but its focusses on the special needs of the energy domain.

B. Multiple Electrical Vehicles

For the second application case of the EOM, we used the capability to consider several systems within an EOM-aggregation. For this, the EOM supports the dynamic configuration of aggregations by means of a tree organized structure, where the root node represents the overall aggregation and the sub nodes the aggregated systems. Analogously to single systems, the aggregation can be modeled as a system, while the considered sub systems can either be defined as static load curves, as dynamic single systems or as dynamic aggregations again. The base model of the aggregation was defined as shown in Figure 5.

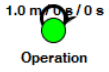

Fig.5: Graph for the operating state of an EV Fleet Aggregation

It can be recognized that the superior system of the aggregation is specified as system with a single operation state *Operation*, where the discrete time step is defined with 1 minute. Further, neither a minimum nor a maximum time is defined.

For the experiments, we used the above described EV model and varied the number of systems between 5, 10, 20, 30, 40, 50 75, 100, 150 and 200 EV's. Since a price optimal charging for the whole EV fleet results to a similar curve in terms of the time course (e.g. 10 EV's, charging by 3,5 kW = 35 kW), we slightly changed the objective of the evaluation strategy. In addition to a possible price optimal charging, an upper bound for the overall energy consumption should not be exceed now.

To archive this goal, the developed strategy first determined the demand of energy for the evaluation period. Further, it again sorted the consumption costs in an ascending manner. Subsequently, and with respect to the maximal available power that was defined by the upper boundary, the needed energy amounts could successively be assigned to the sub systems. Figure 6 below shows the resulting energy consumption for an EV fleet, consisting of 10 cars, where the upper bound was defined with 21 kW.

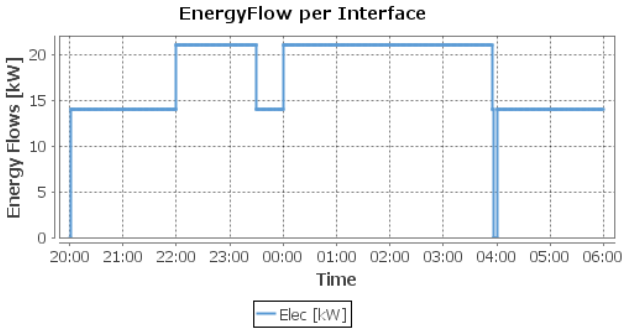

Fig.6: Cost-optimal charging with upper boundary for an EV Fleet

Compared to a simple price-optimal charging without upper boundary, the resulting costs were naturally slightly higher, since energy had to be consumed during periods with higher prices.

The time for the execution of the evaluation strategy and the creation of the execution schedules for each sub system ranged between 0.13 seconds for a single and 37.7 seconds for 200 systems. Figure 7 below shows the determined relationship between the number of systems involved and the thereon depending time for the evaluation process.

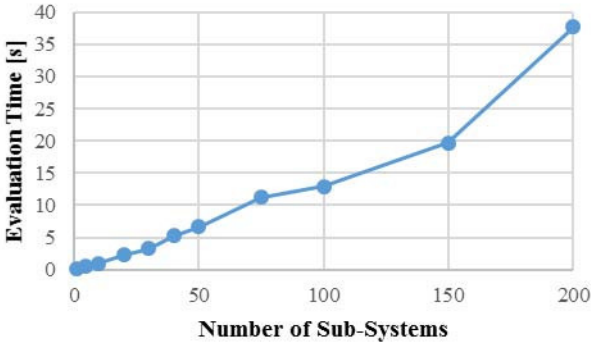

Fig.7: Time consumption for different numbers of sub systems

Since we considered the usage of the EOM within a planning process here, the required times for the evaluations seem to be very promising for us.

In addition to the experiments shown here, further application scenarios for the EOM were already investigated. Here we tested and improved the EOM for the usage with different energy carrier, but also for the real time

application within an electrical distribution network. For reasons of space, unfortunately, these experiments and results can not be explained or shown in this paper and will be part of future publications.

VI. DISCUSSION & COMPARISONS

Starting from the modular perspective, we already mentioned the use of the EOM within an energy agent that is located within or beside an on-site ECP. Here it is the task of the agent to configure the setup for an evaluation as described in the previous sections. Since the EOM also enables the parallel execution of several evaluation strategies, the final result may consist of a number of alternative schedules for the underlying system. As a next step, one plan has to be selected and passed into an execution process. This process then has to care about the system execution according to the selected plan. With the ability to deliberatively provide several plans for an agent, the EOM can also be considered as a kind of BDI concept that is well known in the agent community. In contrast to the general BDI concept the EOM, however, is concretely designed to meet the needs for comprehensively consider hybrid ECP's.

Furthermore, the EOM concurrently provides the ability to consider several ECP's within a system aggregation. This additionally enables to create central control approaches as they are realized in a vast majority today, e.g. in virtual power plants. Assuming the availability of suitable system descriptions, with the help of the EOM, adaptive mechanisms could be realized that enable a flexible integration of any type of ECP. Here the only question is, who initially owns the EOM; in case that this knowledge is located on-site, the model has to be transferred to the aggregator. Analogously to an on-site located energy agent, it is the task of the centralized aggregator process to collect all needed information for the Sub-ECP's and execute one or more evaluations strategies for the aggregation, in order to determine and select the overall and the sub-schedules.

But also for completely decentralized control approaches, the EOM can be applied. Therefore, a sequential turn-based message process can be considered. Instead of the use of the EOM for single systems, however, each system uses the aggregation part of the EOM. Here, the aggregation basically consists of the single local system and a summarizing schedule of all previous systems. The task of the local evaluation process is thus to generate a new local and a summarizing schedule. The latter has to be forwarded to the next ECP or energy agent respectively.

In addition to the above described three application types (local, centralized and decentralized), we believe that further types can be derived combinatorically. For example, several decentralized control processes could be controlled centrally and so on. In our view the EOM can be used for planning as well as for a real time control purposes. A crucial point, however, is the temporal resolution with which processes are modeled. While a fine granular resolution is helpful for real time applications, it will make planning process more expensive in the sense of needed computing time: every discrete step will require to resolve all possible subsequent states and thus to meet a decision for it. We assume that the modelling also requires to find a trade-off for that, but we can't answer this question at this point. Therefore, we will investigate the application of the EOM for further real time process in the near future.

Comparing the EOM with other approaches, requires first to highlight its unique position. Those highlights can be found with several facets that are: a) the comprehensive, system centric consideration of an energy conversion process that enables local reasoning processes for intelligent energy agents, b) the non-exclusive consideration of electrical energy and c) the adaptive characteristic that is offered by the EOM and that enables to realize centralized as well as decentralized control approaches.

Starting with the latter aspect and focusing on centralized control approaches, it is clear that such control approaches are in the main focus of most energy provider currently. Concrete solutions like this are known as energy management systems or can be found with the approach of the demand side management that was already mentioned in the background section of this paper. Here, one well known solution can be found e.g. with the *PowerMatcher* [17] and other. Beyond, also examples for decentralized control approaches were referred in the background section, but compared to the EOM, no solution known to us provides such flexibility for the actual implementation of a concrete control approach (e.g. centralized and/or decentralized).

Further, the consideration of energy conversion systems in general is a quite new aspect in the current Smart Grid research. Thus, similar adaptive and hybrid approaches as they are provided by the EOM are new and could not be found yet. Several general structures for an IT-based, interoperable management of distributed system are provided by the *Common Information Model* (CIM). Since the organizing *Distributed Management Task Force*[1] basically combines the interests of IT organizations and companies, energy specific model definitions like the EOM can't be found here.

Last but not least, the reasoning capability that is provided by the possible parallel execution of different evaluation strategies is a very unique property of the EOM. Even this idea is similar to the general BDI concept, the EOM is the only known, energy specific approach that provides the needed description cardinality for hybrid energy conversion processes. Thus, it has the capability to meet the broad range of requirements and applications in the energy domain.

VII. Conclusion & Outlook

In this paper we presented our concept and the control approach for hybrid energy conversion processes by means a unifying Energy Option Model (EOM). Since this model has the capability to describe all relevant types of energy conversion processes, it provides the foundation for the design of new adaptive control approaches that permit a dynamic aggregation and optimization of aggregations of energy conversion processes.

In the next years, the model will be improved and further developed under the project *Agent.HyGrid*. Here it is planned to close the gap between agent-based simulations and real-world applications in order to produce comparable results for both cases. Thus, a realistic laboratory and test-bed environment will be created for control solution of Future Energy Grids.

Overall, we believe that standards that enable a homogeneous and in particular open development of "smart" energy systems are urgently required; for science as well as for systems used in real applications on-site. We further believe that therefore the concept of a generally accepted energy agent with a unified description of the underlying technical system that we call Energy Option Model is the necessary foundation.

The EOM introduced was registered for a patent. The grant is pending.

***Abstract*—In this contribution we present an approach on how to include local soft constraints in the fully distributed algorithm COHDA for the task of energy units scheduling in virtual power plants (VPP). We show how a flexibility representation based on surrogate models is extended and trained using soft constraints like avoiding frequent cold starts of combined heat and power plants. During the task of energy scheduling, the agents representing these machines include indicators in their choice for a new operation schedule. Using an example VPP we show that our approach enables the agents to reflect local soft constraints without sacrificing the global result quality.**

I. Introduction

IN DECENTRALIZED energy systems, small combined heat and power (CHP) plants, electrical storages and renewable energy units are aggregated both for an integration of these energy units into the energy markets and for the provision of ancillary services for a stable grid operation. Both applications are widely known as virtual power plants (VPP) and expected to be one of the core concepts for distributed energy systems [1]. One of the core challenges during operation of such a VPP arises from the complexity of the scheduling task due to the large amount of (small) energy units in the distribution grid [2]. To this end, multiple scalable scheduling algorithms have been proposed for distribution grid energy unit scheduling for VPP, with many of them using software agents technology and distributed algorithms [3], [4]. During scheduling, both global constraints (i. e. concerning the VPP as a whole) and local constraints (i. e. restricted to a single energy unit) have to be handled in an appropriate way. Both types of constraints may be either hard or soft constraints (cf. Table I). Local hard constraints set defined limits to the operational flexibility of an energy unit, thus defining feasible operation schedules. For the example of a CHP installation including thermal storage, the thermal capacity of the storage sets a hard constraint to the CHP's operation in combination with the current thermal load. Local soft constraints comprise technical or economical preferences, e. g. preferred operation times or the avoidance of technically unfavorable frequent cold starts. Global hard constraints can be market driven, like obligations from existing contracts. The reflection of global soft constraints is out of scope of the work presented here.

This work was partly supported by the Lower Saxony Ministry of Science and Culture through the "Niedersächsisches Vorab" grant program (grant ZN 2764 'Smart Nord'

VPP scheduling is the task of identifying distinct operation schedules for all components of a VPP that are within the flexibility range of the respective components. Thus, the process can be split in two parts: First, the flexibility of the components has to be assessed and modelled, and then a scheduling solution is identified within an optimization process. The overall process thus constitutes a multi-objective optimization problem, with the different types of constraints either being reflected during modelling or during optimization.

In this contribution, we extend a scalable VPP scheduling approach from previous work that takes into account local and global hard constraints with the ability to additionally reflect local soft constraints of individual energy units, thus solving the given multi-objective optimization problem. Individual preferences (i. e. preferences for single energy units and their operation) do not have to be disclosed within the VPP during the scheduling process.

The rest of this contribution is structured as follows: In section II we present relevant approaches for the tasks of modelling and optimization in distributed energy scheduling and identify basic algorithms used for the work presented here. We then elaborate on the chosen approach to model feasible operation schedules using a support vector data description (SVDD) based method and extend this model to include local soft constraints (section III). In section IV the COHDA heuristic is presented. In former work, this distributed algorithm has been used to generate VPP schedules satisfying local and global hard constraints [5]. We show how the modelled local soft constraints can be included in the optimization process

using an apriori-multi-objective optimization approach. Results from a case study evaluating the presented general multi-objective optimization approach are presented in section IV. We summarize and discuss open issues in section V.

II. Choosing the basic algorithms

In recent years, a large body of research has emerged in the field of distributed energy scheduling. For the tasks of constraint modelling and optimized scheduling relevant for the contribution at hand, in the following some basic approaches are presented, along with a discussion on the chosen algorithms.

Flexibility modelling can be understood as the task of modelling constraints. Apart from global VPP constraints, constraints often appear within single energy components; affecting the local decision making. Since these constraints are not of a distributed nature, they can be solved locally using central approaches. A widely used approach is the introduction of a penalty into the objective function that devalues a solution that violates some constraint [6]. In this way, the problem is transferred into an unconstrained one by treating fulfillment of constraints as additional objective. Alternatively, some combinatorial optimization problems allow for an easy repair of infeasible solutions. In this case, it has been shown that repairing infeasible solutions often outperforms other approaches [7]. Another popular method treats constraints or aggregations of constraints as separate objectives, also leading to a transformation into a (unconstrained) multi-objective problem [8]. A hierarchical approach that combines both hard and soft constraints in an explicit model formulation and weighted objective functions has been introduced in [9]. For optimization approaches in smart grid scenarios however, black-box models capable of abstracting from the intrinsic model have proven useful [10], [11]. They do not need to be known at compile time. A powerful, yet flexible way of constraint-handling is the use of a decoder that gives a search algorithm hints on where to look for schedules satisfying local hard constraints (*feasible schedules*) [11], [12]. This approach has been chosen in the work presented here. In section III-A an introduction to the decoder approach is given.

The chosen flexibility representation is the foundation for scheduling algorithms. The work presented by Akkermans, Ygge and Gustavsson in 1996 has been one of the first applications of distributed agent-based control in the electrical energy system [13]. The so-called HomeBots approach was motivated by an expected need for scalability, flexibility, adaptivity and broad applicability for future distributed energy systems [14]. Since this work, many distributed agent-based approaches have been developed in the disciplines of electrical engineering, control and system theory, information technology and information systems. The understanding of what constitutes a distributed system differs a lot, from software agents as gateways to the energy units and hierarchical systems [15] up to fully distributed algorithms [16]. Prior to the work presented here, a requirement based analysis has been done to identify appropriate algorithms for the task of distributed energy scheduling [17]. In the following a short overview on those algorithms already evaluated for energy scheduling tasks is presented.

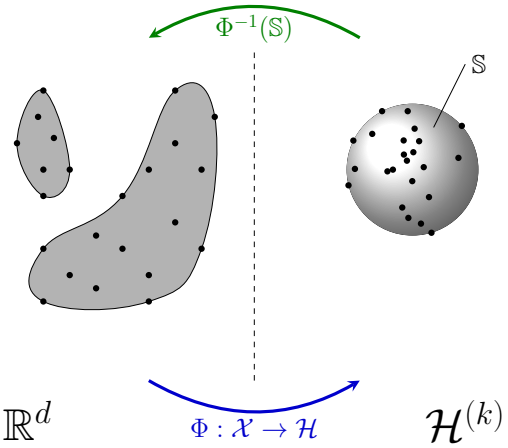

Fig. 1. General support vector model scheme for individual search spaces.

The Holonic Virtual Power Plant (Hol. VPP) presented in [18] was introduced for the reactive rescheduling process in VPPs. In this concept, a dedicated agent performs the task of evaluating a VPP schedule regarding global constraints. The agents presented in the concept are not capable of evaluating the quality of a new VPP schedule but decide on their contributions based on local constraints. The same approach has been chosen for Autonomous Virtual Power Plants [19]. ALMA [20] is a fully distributed and highly dynamic approach implemented for a dynamic supply-demand-matching task. The scheduling task at hand is not solved using a set of feasible schedules but based on a different modeling approach: The energy units communicate comfort levels, thus allowing to operate them flexibly within the defined levels. With COHDA, a fully distributed heuristic has been presented for energy scheduling [16]. The operational limits are modeled using the concept of a set of feasible schedules. Although possible, soft constraints have not yet been integrated in the process.

As COHDA satisfies the requirements regarding our motivating use case, the approach has been chosen as basic algorithm in the work presented here. For the full analysis, cf. [17]. In section IV-A we will introduce COHDA before discussing the concept of soft constraint integration.

III. Flexibility and Local Constraint Modelling

A. Decoder for Local Constraint Handling

In this section we briefly recap the technique for local hard constraint handling used in this work. For handling individual local constraints from different types of energy units, we use a decoder technique. An in-depth discussion of the technique can for example be found in [11], [12].

In general, a decoder is a technique that gives algorithms hints on where to look for feasible solutions and thus allows for a targeted search. It imposes a relationship between a decoder solution and a feasible solution and gives instructions

on how to construct a feasible solution [12]. A simple version without a need for machine learning techniques to deduce a meta-model, a response surface or similar uses directly a given set $\mathcal{X}$ of feasible schedules derived from a simulation model [16]. This approach has the limitation of supporting only discrete combinatorial problems. In [21] a homomorphous mapping between an n-dimensional hyper cube and the feasible region has been proposed in order to transform the problem into a topological equivalent one that is easier to handle. This approach has the problem of introducing additional parameters that have to be tuned and adapted to the problem instance at hand. In order to be able to derive a decoder automatically from any given energy unit model, [22] developed an approach based on a support vector model [23].

Fig. 2 shows the idea of using a so called support vector decoder. The basic idea is to start with a set of feasible example schedules derived from a simulation model of the respective energy unit and use this sample as a stencil for the region (the sub-space in the space of all schedules) that contains just feasible schedules.

We regard a schedule of an energy unit as a vector $\boldsymbol{s} = (s_0, \ldots, s_d) \in \mathcal{S} \subset \mathbb{R}^d$ with each element s_i denoting mean power generated (or consumed) during the ith time interval. As has been shown in [24], it is advantageous from a machine learning point of view to use scaled schedules for learning the feasible region. Thus, we construct the training set $\mathcal{X}$ by a normalization with

$$\begin{aligned} &\mathcal{N} : \mathcal{S} \to \mathcal{X} \subset [0,1]^d \\ &\qquad \boldsymbol{s} \mapsto \boldsymbol{x} = \mathcal{N}(\boldsymbol{s}), \text{with } x_i = \frac{s_i - p_{min}}{p_{max} - p_{min}}; \end{aligned} \tag{1}$$

p_{min} and p_{max} denoting minimum and maximum power respectively. The scaled sample $\mathcal{X}$ is then used as a training set for a support vector data description (SVDD) approach [25] that derives a geometrical description of the sub-space that contains the given data (in our case: the set of feasible schedules). Given a set of data samples, the inherent structure of the scope of action of the respective energy unit can be derived as follows: After mapping the data to a high dimensional feature space by means of an appropriate kernel, the smallest enclosing ball in this feature space is determined. When mapping back this ball to data space, it forms a set of contours enclosing the given data sample.

This task is achieved by determining a mapping

$$\Phi : \mathcal{X} \subset \mathbb{R}^d \to \mathcal{H};\ x \mapsto \Phi(x) \tag{2}$$

such that all data from a sample $\mathcal{X}$ from the feasible region $\mathcal{F}$ is mapped to a minimal hypersphere in some high-dimensional space $\mathcal{H}$. The minimal sphere with radius R and center a in $\mathcal{H}$ that encloses $\{\Phi(\boldsymbol{x}_i)\}_N$ can be derived from minimizing $\|\Phi(\boldsymbol{x}_i) - a\|^2 \leq R^2 + \xi_i$ with $\|\cdot\|$ as the Euclidean norm and slack variables $\xi_i \geq 0$ for soft constraints (here for getting a smoother ball).

After introducing Lagrangian multipliers and further relaxing to the Wolfe dual form, the well-known Mercer's theorem (cf. e.g. [26]) may be used for calculating dot products in $\mathcal{H}$ by means of a kernel in data space: $\Phi(\boldsymbol{x}_i) \cdot \Phi(\boldsymbol{x}_j) = k(\boldsymbol{x}_i, \boldsymbol{x}_j)$. In order to gain a more smooth adaption, it is known to be advantageous to use a Gaussian kernel: $k_G(\boldsymbol{x}_i, \boldsymbol{x}_j) = e^{-\frac{1}{2\sigma^2}\|\boldsymbol{x}_i - \boldsymbol{x}_j\|^2}$ [27]. Putting it all together, the equation that has to be maximized in order to determine the desired sphere is:

$$W(\beta) = \sum_i k(\boldsymbol{x}_i, \boldsymbol{x}_i)\beta_i - \sum_{i,j} \beta_i \beta_j k(\boldsymbol{x}_i, \boldsymbol{x}_j). \tag{3}$$

With $k = k_G$ one gets two main outcomes from the training procedure: the center $a = \sum_i \beta_i \Phi(\boldsymbol{x}_i)$ of the sphere in terms of an expansion into $\mathcal{H}$ and a function $R : \mathbb{R}^d \to \mathbb{R}$ that allows to determine the distance of the image of an arbitrary point from $a \in \mathcal{H}$, calculated in $\mathbb{R}^d$ by:

$$R^2(\boldsymbol{x}) = \ 1 - 2\sum_i \beta_i k_G(\boldsymbol{x}_i, \boldsymbol{x}) + \sum_{i,j} \beta_i \beta_j k_G(\boldsymbol{x}_i, \boldsymbol{x}_j). \tag{4}$$

Because all support vectors show the characteristics of being mapped onto the surface of the sphere, the sphere radius $R_{\mathcal{S}}$ can be easily determined by the distance of an arbitrary support vector to the center a. Thus the feasible region can now be modeled as $\mathcal{F} = \{\boldsymbol{x} \in \mathbb{R}^d | R(\boldsymbol{x}) \leq R_{\mathcal{S}}\} \approx \mathcal{X}$.

The comparably small set of support vectors together with a reduced version of vector $\boldsymbol{\beta}$ that contains non zero weight values (denoted $\boldsymbol{w}$) for the support vectors is sufficient for building the model. The model might then be used as a black-box that abstracts from any explicitly given form of constraints and allows for an easy and efficient decision on whether a given solution is feasible or not. In this way, the model allows for an easy check whether a given schedule is operable or not by using decision function (4).

So far, this surrogate model is just capable of checking feasibility when already given a schedule. In this way, the surrogate may tell feasible and infeasible schedules apart on behalf of the specific simulation model of the energy unit and thus already allows for an abstraction from any model specific implementation. On the other hand, it is not yet a sufficient constraint-handling technique as it still needs externally (e. g. by any optimization algorithm) generated schedules which can merely be checked. But, due to the tiny share of the search space that is actually feasible, it is quite unlikely that a feasible schedule is generated by an algorithm just by chance [28].

Hence, a way is needed to guide an algorithm where to look for feasible schedules. To achieve such systematic search for a good and still feasible solution, a decoder can be derived automatically from the support vector surrogate. The set of feasible schedules is represented as pre-image of a high-dimensional ball $\mathbb{S}$. Fig. 1 shows the geometric situation. This representation has some advantageous properties. Although the pre-image might be some arbitrary shaped non-continuous blob in $\mathbb{R}^d$, the high-dimensional representation is still a ball and thus geometrically easier to handle.

The relation is as follows: If a schedule is feasible, i.e. can be operated by the unit without violating any technical constraint, it lies inside the feasible region (grey area on the left hand side in Fig. 2). Thus, the schedule is inside the pre-image (that represents the feasible region) of the ball and thus

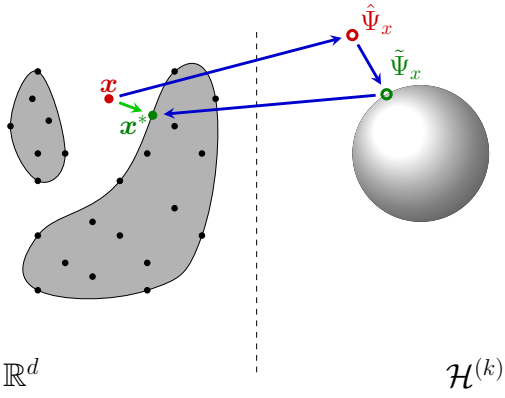

Fig. 2. General support vector decoder scheme for solution repair and constraint handling.

its image in the high-dimensional representation lies inside the ball. An infeasible schedule (e. g. $\boldsymbol{x}$ in Fig. 2) lies outside the feasible region and thus its image $\hat{\Psi}_x$ (generated by the empirical kernel mapping $\hat{\Psi}_x$) lies outside the ball. But we know some relations: the center of the ball, the distance of the image from the center and the radius of the ball. Hence, we can move the image of an infeasible schedule along the difference vector towards the center until it touches the ball. Finally, we calculate the pre-image of the moved image $\tilde{\Psi}_x$ (mover by translation function Γ_a) and get a schedule at the boundary of the feasible region: a repaired schedule $\boldsymbol{x}^*$ that is now feasible. We do not need a mathematical description of the original feasible region or of the constraints to do this. More sophisticated variants of transformation are e. g. given in [22].

Formally, we want to derive a mapping function (the so called decoder Θ)

$$\begin{aligned} \Theta : [0,1]^d &\rightarrow \mathcal{F}_{[0,1]} \subseteq [0,1]^d \\ x &\mapsto \Theta(x) \end{aligned} \tag{5}$$

that transforms any given (maybe in-feasible) schedule into a feasible one. This decoder mapping Θ is derived automatically from the trained SVDD repesentation of the search space using three steps:

$$\begin{array}{ccc} \boldsymbol{x} \in [0,1]^d & \xrightarrow{\hat{\Phi}_\ell} & \hat{\Psi}_x \in \mathcal{H}^{(\ell)} \\ \Theta \downarrow & & \downarrow \Gamma_a \\ \boldsymbol{x}^* \in \mathcal{F}_{[0,1]} \subseteq [0,1]^d & \xleftarrow[\tilde{\Phi}_\ell^{-1}]{} & \tilde{\Psi}_x \in \mathcal{H}^{(\ell)} \end{array} \tag{6}$$

Applying such decoder to some internal solution representation $\boldsymbol{x} \in [0,1]^d$ transforms the solution to some feasible solution $\Theta(\boldsymbol{x}) \in \mathcal{F}_{[0,1]}$.

Thus, we are able to transform any global scheduling problem into a formulation that is unconstrained regarding local hard constraints. Apart from finding a combination of schedules whose sum resembles a given target power profile best, further objectives are usually integrated due to the many-objective nature of energy scheduling.

This procedure of training a decoder has to be done only once prior to the scheduling process. During scheduling the all decoders are merely used for generating feasible schedules. For our experiments, training was usually done within milliseconds. For an in-depth discussion of computational issues of the decoder we refer to [29].

For distributed problem solving, the decoder can serve as a substitute for an often (particularly with regard to a fully automated generation) hardly derivable mathematical model of feasibility. Like in well studied industrial approaches for model predictive control [30] only a simulation model as a source for learning the model is needed. Due to the abstraction from the underlying simulation model (or real unit), no information on which operations are possible and no information on limiting restrictions, cost considerations or soft constraints are needed at runtime. Thus, the ad-hoc integration of arbitrary (even of at compile-time unknown units) becomes easily possible and hence eases the implementation of many control algorithms for the smart grid.

B. Modeling local soft constraints

In general, the satisfaction of a local soft constraint by a defined operation schedule s is modeled as a DER specific function $\mathcal{I}_i$ that assigns a value between 0 and 1 to the respective operation schedule, with i denoting the respective DER within the set of DER regarded in the scheduling task, i. e. the current VPP setup.

$$\begin{aligned} \mathcal{I}_i &: S \rightarrow [0,1] \\ \mathcal{I}_i(s) &= \sigma, \forall s \in S \end{aligned} \tag{7}$$

In the following, we omit the subscript i for reasons of brevity. As the soft constraint evaluation is a component-specific task it is performed locally in all upcoming definitions.

We now define an extended search space S' that integrates the soft constraints into the search space S:

$$S' : \{(\ s,\ \sigma^{(1)}, ..., \sigma^{(m)}\ ) \mid s \in S\} \tag{8}$$

With this definition, the extended search space S' is the set of all tuples of feasible operation schedules s and their respective soft constraint values, with m being the number of modelled soft constraints.

But how to model this extended search space? For the decoder concept presented in Section III-A, a possible integration of indicators has been shown: Data vectors containing the mean power levels for the respective time intervals are extended by one element per indicator to mixed feature vectors. This approach has been proposed for environmental performance indicators [23], but in general, arbitrary indicators can be added as long as a functional relationship exists between the power part and the indicator. In this way, we can build a modified sample $\boldsymbol{x}'$ as

$$\boldsymbol{x}' = (x_1, \ldots, x_d, \mathcal{I}^{(1)}_{[0,1]}(\boldsymbol{x}), \ldots, \mathcal{I}^{(m)}_{[0,1]}(\boldsymbol{x})),\ \boldsymbol{x}' \in [0,1]^{d+m}, \tag{9}$$

with the first d elements denoting real power and m trailing elements denoting indicator values. Whereas $\mathcal{I}$ takes a schedule, $\mathcal{I}_{[0,1]}$ maps an already scaled training vector $\boldsymbol{x}$ instead. This sample is fed into exactly the same support vector training process to build the model. The decoder is derived in exactly the same way. The decoder mapping Θ then likewise maps feature vectors $\boldsymbol{x}' \in \mathcal{X}'$

$$\begin{aligned}[0,1]^{d+m} &\rightarrow \mathcal{F}_{[0,1]} \times [\mathcal{I}_{[0,1]}]^m \\ \Theta(\boldsymbol{x}') &\mapsto (\boldsymbol{x}, \mathcal{I}^{(1)}_{[0,1]}(\boldsymbol{x}), \ldots, \mathcal{I}^{(m)}_{[0,1]}(\boldsymbol{x})).\end{aligned} \tag{10}$$

If $\boldsymbol{x}'$ is given with arbitrary values then $\Theta(\boldsymbol{x}')$ contains a feasible active power schedule in the first d elements as well as m elements evaluating this schedule correctly (slight inaccuracies are possible) with regard to the secondary optimization objectives.

Using this concept of the decoder approach including indicator reflection, we can set up an extended search space from a set of samples (i. e. normalized schedules) as shown in equation 9. For this purpose, we have to add the indicator value $\mathcal{I}$ for the chosen soft constraint to the sample schedule prior to the support vector training phase. In the example chosen here, we want to reduce the amount of cold starts within an operation schedule to minimize motor deterioration. We can infer the number of cold starts directly from the schedules within a preprocessing step. We omit the precise definition of cold starts for reasons of brevity, but usually it is a defined change of switching an engine off and on within a given time span. The indicator value thus matches the soft constraint value as given in equation 7. We now have to define the DER specific soft constraint function as an indicator for the amount of cold starts $\mathcal{I}^{cs}$ precisely to feed it into the SVDD training:

$$\mathcal{I}^{cs}(\mathsf{s}) = \left(1 - \frac{cs_{\mathsf{s}}}{cs_{max}}\right)^2 \tag{11}$$

with cs_{s} as the amount of cold starts in the given schedule s and cs_{max} as maximum amount of cold starts in the given schedule set. Using the squared value, a rising amount of cold starts is punished disproportionally high. For schedule sets without cold starts, the value is undefined – these cannot be used to distinguish schedules using this characteristic.[1]

It can be seen that there is a functional relationship between the schedule and the indicator, thus allowing to use the modified sample definition as given in equation 9 and using equation 1 to map schedule s to its normalized sample x. For each sample x in the given sample set we append the indicator as defined in equation 11 and use it for SVDD training.

As a result of these steps, we yield the extended search space S' and can now integrate this in the scheduling process.

IV. Distributed Energy Scheduling

A. Introducing COHDA

The Combinatorial Optimization Heuristic for Distributed Agents (COHDA, originally introduced in [16]) can be used to solve scheduling problems in VPPs. In the present contribution, we consider predictive scheduling: the goal is to select a schedule for each energy unit—from a given search space of feasible schedules with respect to a future planning horizon—such that a global objective function (e. g. a target power profile for the VPP) is optimized. This target profile is understood as global hard constraint within the scheduling process for the rest of this contribution. We will recap the approach briefly, based on the description in [5].

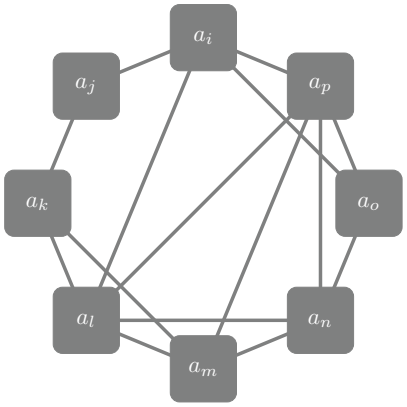

Fig. 3. Exemplary communication topology in the form of a small world topology for a system comprising eight agents.

The key concept of COHDA is an asynchronous iterative approximate best-response behavior, where each agent—representing a decentralized energy unit—reacts to updated information from other agents by adapting its own selected schedule with respect to the global objective. All agents $a_i \in A$ initially only know their own respective set of schedules S_i, so from an algorithmic point of view, the difficulty of the problem is given by the distributed nature of the system in contrast to the task of finding a common allocation of schedules for a global target power profile.

Thus, the agents coordinate by updating and exchanging information about each other. But, in order to preserve privacy, the amount of information that is exchanged is restricted. In particular, the set of feasible schedules S_i is not communicated as a whole by an agent a_i. Instead, the agents try to publish as little information as possible. How these possibly conflicting goals are handled, and how the system is able to converge to sound and satisfying solutions, will be explained in the following.

First of all, the agents are placed in an artificial communication topology (e. g. a *small world* topology, see Fig. 3), such that each agent is connected to a non-empty subset of other agents. To compensate for the resulting non-global view on the system, each agent a_i collects two distinct sets of information: on the one hand the believed current configuration γ_i of the system (that is, the most up to date information a_i has about currently selected schedules of all agents), and on the other hand the best known combination γ_i^* of schedules with respect to the global objective function it has encountered so far.

Beginning with an arbitrarily chosen agent by passing it a

[1]Please note that in the implementation presented here, $\mathcal{I}$ is defined identically for all DER, without limiting the applicability of the presented approach to DER specific soft constraint functions $\mathcal{I}_i$.

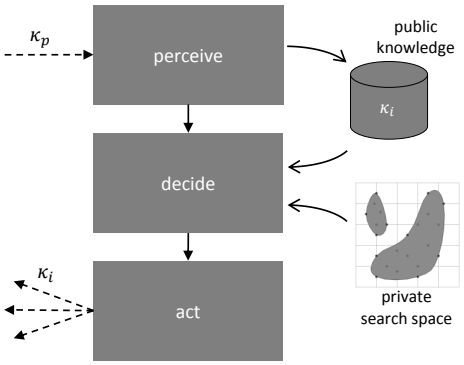

Fig. 4. The *perceive–decide–act* behavioral pattern in COHDA from the point of view of an agent a_i.

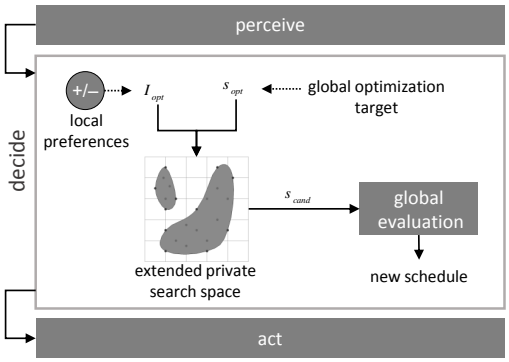

Fig. 5. The *decide* behavioral pattern of COHDA including the reflection of soft constraints.

message containing only the global objective (i. e. the target power profile), each agent repeatedly executes the three steps *perceive*, *decide*, *act* (cf. [5]) as visualized in Fig. 4:

1) **`perceive:`** When an agent a_i receives a message κ_p from one of its neighbors (say, a_p), it imports the contents of this message into its own memory.
2) **`decide:`** The agent then searches S_i for the best schedule regarding the updated system state γ_i and the global objective function, thus respecting the global hard constraints. The reflection of local hard and soft constraints depends on the chosen approach to model the energy unit's flexibility and will be discussed in a later part of this contribution. If a schedule can be found that satisfies both the global and the local objectives, a new schedule selection is created. For the following comparison, only the global objective function must be taken into account: If the resulting modified system state γ_i yields a better rating than the current solution candidate γ_i^*, a new solution candidate is created based on γ_i. Otherwise the old solution candidate still reflects the best schedule combination regarding the global objective the agent is aware of, so the just created schedule selection is discarded and the agent reverts to its schedule selection stored in γ_i^*.
3) **`act:`** If γ_i or γ_i^* has been modified in one of the previous steps, the agent finally broadcasts these to its neighbors in the communication topology.

Following this behavior, only small subsets of the sets of feasible schedules S_i are communicated by the agents. During this process, for each agent a_i, its observed system configuration γ_i as well as solution candidate γ_i^* are empty at the beginning, will be filled successively with the ongoing message exchange and will some time later represent valid solutions for the given optimization problem. After producing some intermediate solutions, the heuristic eventually terminates in a state where for all agents γ_i as well as γ_i^* are identical, and no more messages are produced by the agents. At this point, γ^* (which is the same for all agents then, so the index can be dropped) is the final solution of the heuristic and contains exactly one schedule selection for each agent.

B. Reflecting soft constraints during scheduling

In Fig. 4 an overview on the heuristic COHDA has been given from the perspective of a single agent representing a DER within a VPP. The algorithm is designed originally to optimize for a global objective only: In a two-stepped procedure, first a new schedule is chosen from the agent's a_i local search space S_i. After that, the resulting global result quality is evaluated. However, each agent must be permitted to decide itself which schedule it contributes. This way, technically, economically or ecologically rooted local soft constraints can be taken into account as secondary optimization goals. Moreover, in order to preserve privacy and autonomy of the participating entities, these individual secondary objectives must be treated as private to the corresponding agent, i. e. similar to the set of feasible schedules S_i, the local objectives are not part of the communicated information.

To integrate such local soft constraints into the decision process without compromising the convergence of the distributed algorithm, we modified the first step by replacing the search space S by the extended search space S' as defined in equation 8. During the *decide* phase, the agent thus has surplus information regarding the indicator (see Fig. 5). With this modelling approach, an additional constraint is integrated in the search space. Using the decoder approach as presented in section III-A, the agent can now try to identify a candidate schedule s that enhances the performance regarding the global objective (e. g. energy amount) and additionally enhance the performance regarding local quality as defined by the local soft constraint function $\mathcal{I}_i(s)$ (cf. equation 7). To enable this multi-objective optimization, the *decide* phase of COHDA is extended (cf. Fig. 5): In the first step, the needed schedule s_{opt} to best reach the global optimization target is calculated. The optimal indicator value $\mathcal{I}_{opt}$ (i. e. the best possible soft constraint performance) is added. For multiple soft constraints, additional indicator values would be added. In the next step this combination of needed schedule and indicator(s) is passed to the decoder for a targeted search. While without soft constraint modelling only the schedule best fitting the global

target would be identified, the decoder now returns a schedule depending on both the needed schedule s_{opt} and the optimal local soft constraint performance $\mathcal{I}_{opt}$. Using the decoder concept with an extended search space modelling approach thus leads to an apriori-multi-objective optimization with an implicit weighting of the different constraints. The schedule identified by the decoder is passed as candidate schedule s_{cand} to the evaluation of the global result quality, i. e. the global hard constraint.

In the example chosen here, the indicator gives information regarding the amount of cold starts contained in the schedule. The extended search space S' therefore is built using the indicator $\mathcal{I}^{cs}$ as defined in equation 11. The agent now can choose a candidate schedule that might enhance the performance regarding the global objective and minimize the number of cold starts simultaneously.

In summary, the outlined modelling and decision process yields a reasonable hierarchy of constraint handling in the domain of distributed energy scheduling (cf. Table I in section I): Using the decoder concept as depicted in section III-A, local hard constraints are modelled in such a way that only feasible schedules are returned by the decoder. Local soft constraints are used for SVDD training (see section III-B and guide the decoder targeted search (see section IV-B. Therefore, schedules satisfying the soft constraints are returned preferentially by the decoder. In the last step, the global evaluation is performed, reflecting global hard constraints. With this concept, local hard constraints are prioritized over global objectives, while local soft constraints are being taken into account with least importance.

V. Results

To evaluate the presented approach for the integration of soft constraints in distributed energy scheduling, two hypotheses have been chosen:

- H1 The integration of local soft constraints in the distributed scheduling enhances the performance of the chosen schedules regarding the modeled soft constraint, i. e. the local quality.
- H2 The integration of local soft constraints does not reduce the quality of the chosen solution regarding the global objective, i. e. producing the target power profile.

In the following, we will first introduce the evaluation setup, then discuss the evaluation results using these hypothesis. In all experiments, regarding the local soft constraints, we go with the example of reducing the amount of cold starts within an operation schedule to minimize motor deterioration, as introduced in section III-B.

A. Evaluation Setup

To evaluate the effect of an integration of local soft constraints in the distributed scheduling process, a setup is needed where agents have the choice to either reflect or ignore the performance indicator regarding the amount of cold starts $\mathcal{I}^{cs}(s)$. As the global objective is to fulfill a defined energy profile, enough flexibility within the aggregation of agents is needed to fulfill this objective either using schedules with high or low performance values regarding cold starts. In the experimental setup we therefore choose a mixed set of agents representing small CHP plants ($4.7\ \mathrm{kW_{el}}$): For 15 CHP plants, the conventional search space is used, without adding the indicator value. For additional 15 CHP plants, the search space is extended, thus allowing these agents to reflect the indicator during scheduling. For the support vector training phase, we need a set of schedules that can be distinguished regarding cold starts: On a winter day, CHP plants are expected to run nearly the whole day. Therefore, schedules of a CHP for a winter day are not suitable for the evaluation task. The opposite holds for a summer day. We chose a spring day and generated schedules from a CHP simulation for this task. The largest number of cold starts (cs_{max}) within this set has been 9. Thus, a schedule with 9 cold starts within one day might have been chosen without reflecting this constraint for each CHP.

For this aggregation of 30 CHP plants, different target profiles have been defined manually in such a way that fulfilling the profile is possible with more than 90 % accuracy, thus covering a range of possible target profiles. Each target setting has been simulated 100 times with different random seeds for generating the training set for reasons of statistical soundness.

B. Local Quality (Hypothesis H1)

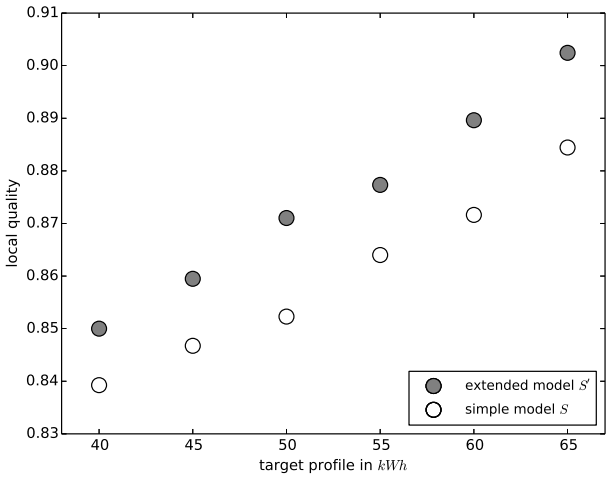

Fig. 6. Simulation results for a VPP with 30 CHPs and different target profiles. Mean values from 100 simulation runs are shown.

In Fig. 6 the results for the simulative experiments are shown regarding local quality: The horizontal axis denotes the different target profiles. On the vertical axis the mean local quality is shown. With only one soft constraint given in our scenario, we define σ as the local quality of a schedule under evaluation (cf. equation 7). The filled circles depict the mean value of 15 CHP plants over 100 simulations for the agents reflecting the amount of cold starts in their search space, whereas the unfilled circles show the mean local quality of

those 15 CHP plants over 100 simulations for the agents that do not consider this local soft constraint.

It can be seen that the local quality is higher for all target profiles, if soft constraints are integrated in the scheduling process. Additionally a trend can be seen: The higher the energy amount of the target profile, the better is the local quality. This can be explained as follows: If more electrical energy has to be produced, the agents choose schedules with longer runtimes. Thus, less cold starts are expected.

For one of the simulation setups (target profile 50 kWh), the raw data are depicted in Fig. 7. It can be seen that using the extended search space model (S'), the number of schedules with 2 cold starts is reduced, whereas the number of schedules without cold starts is increased. There is a slight rise in the number of schedules with 1 and 3 cold starts. This rise is considered to be non-significant compared to the effect regarding the reduction of schedules without cold starts. In general, a shift to schedules with less cold starts can be observed. The results are similar for the other simulation setups but not displayed here.

With the given results, we consider hypothesis H1 strengthened: The integration of local soft constraints in the distributed scheduling enhances the performance regarding the modeled soft constraint.

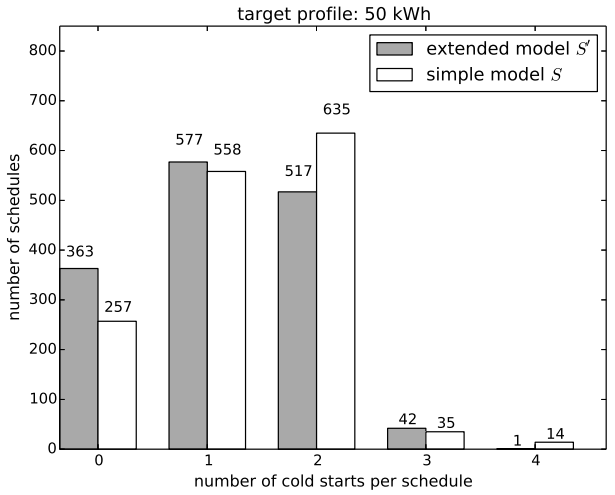

Fig. 7. Detailed simulation results for a VPP with 30 CHPs and target profile 50 kWh. Regarding 100 simulation runs, the distribution of schedules with respect to the amount of cold starts per schedule is shown.

C. Global Quality (Hypothesis H2)

We now focus on the effects of the integration of soft constraints in the scheduling process on the global quality. In Table II the normalized global quality regarding the target profile fulfillment is summarized using the mean values over 100 simulation runs for different target profiles. In general, the energy unit aggregations perform best for a profile with either 50 or 55 kWh, although a high quality could be reached for all simulation settings. This depends on the chosen aggregation of energy units and their feasible schedules: Within the defined range from 40 to 65 kWh, enough operational flexibility is given to adapt to a defined target profile. We now compare the global quality within one target profile simulation setting with and without the reflection of soft constraints: It can be seen that for all profiles, the values differ only very slightly. This effect can be understood from the chosen concept of soft constraint integration: If an agent manages to identify an operation schedule that will outperform the current target fulfillment, this would be chosen although this schedule might decrease local quality. With the chosen concept of guiding the search within the schedule search space along the soft constraint performance though, the heuristic COHDA tends to find those local optima that not only increase global quality but additionally show better local quality.

With the given results, we consider hypothesis H2 strengthened: The integration of local soft constraints does not reduce the quality of the chosen solution regarding the target profile delivery significantly for the chosen setting.

TABLE II
COMPARISON OF TARGET PROFILE FULFILLMENT WITH AND WITHOUT REFLECTION OF SOFT CONSTRAINTS. MEAN VALUES FROM 100 SIMULATIONS RUNS PER TARGET PROFILE ARE GIVEN.

40kWh	**45kWh**	**50kWh**	**55kWh**	**60kWh**	**65kWh**
with reflection of soft constraints					
0.9862	0.9886	0.9921	0.9939	0.9874	0.9590
without reflection of soft constraints					
0.9850	0.9907	0.9931	0.9937	0.9830	0.9605

VI. CONCLUSION AND OUTLOOK

In this contribution we presented an approach on how to include local soft constraints in the fully distributed algorithm COHDA for the task of energy units scheduling in virtual power plants (VPP). For this task, we extended a flexibility representation based on SVDD using indicator values and used these indicators to guide the search for a new schedule. Using the example of preventing frequent cold starts for CHP plants, we could show that the presented approach enables the agents to reflect the modeled local soft constraint without sacrificing the global result quality. As the information on local soft constraints is not communicated within the system and considered only locally, the presented approach reveals benefits regarding privacy without sacrificing global result quality.

With these results, further work should be done on the integration of extended search spaces in the presented distributed scheduling heuristic COHDA. With the extension of the search space using indicators, an implicit weighting is given by the length of the schedules and the number of indicators. Additional evaluation effort is needed to yield an appropriate weighting depending on the specific soft constraint. A straightforward approach would be to adapt the weights of an indicator by multiplying its value during the SVDD training phase, thus

yielding an explicit weighting. The formalization given in the contribution at hand is compatible with this concept.

Additionally, the boundaries of effectiveness for energy unit aggregations with less flexibility should be evaluated, especially compared to other multi-objective optimization concepts: With the presented approach, soft constraints guide the search in the search space. Therefore it has to be evaluated, if for some types of DER the global quality would be reduced to an unaccepted extent. Straight-forward extensions of the presented approach like time-dependent soft constraint relaxation could overcome such problems.

Software Systems Development & Applications

SSD&A is a FedCSIS conference area aiming at integrating and creating synergy between FedCSIS events that thematically subscribe to the discipline of software engineering. The SSD&A area emphasizes the issues relevant to developing and maintaining software systems that behave reliably, efficiently and effectively. This area investigates both established traditional approaches and modern emerging approaches to large software production and evolution. Events that constitute SSD&A are:

- BTMSPA'16—1st Symposium on Balancing Traditional and Modern Software Process Approaches
- MDASD'16—4th Workshop on Model Driven Approaches in System Development
- MIDI'16 - 4th Conference on Miltimedia, Interaction, Design and Innovation
- SEW-36—The 36th IEEE Software Engineering Workshop

1st Symposium on Balancing Traditional and Modern Software Process Approaches

RESEARCH studies conducted in the area of software engineering have proposed hundreds of techniques and recommendations. On the other hand, software projects are performed in frame of several constraints including required quality, time and budget constraints as well as staff competences. Thus there is a need for selection of the techniques which allow practitioners to achieve a fair balance between time and effort spent on performing these techniques and benefits they provide.

Several traditions exist in software engineering including formal, methodological, user-centered, reuse and agile approaches. Additionally, novel approaches are still being proposed, e.g. collaborative approaches. Each of the approaches focuses on solving a different kind of problems. The proper balance between approaches and, consequently techniques in use, depends on the characteristics of the project at hand.

This symposium aims at exchanging experience and making progress in the knowledge about software process configuration with fair balance between traditional and modern approaches. We invite both experience reports from industry and scientific studies of integrated approaches.

TOPICS

- Balance between agile and disciplined approaches
- Innovation and creativity in software engineering
- Collaborative games in software processes
- Business-IT alignment
- Enterprise integration, business integration and systems integration
- IT-enabled innovations in organizations
- Cooperative, distributed, and collaborative software engineering
- Variability across the software life cycle
- Innovative platforms, architectures and technologies for IS
- Quality assurance and management
- Social media, open data, Internet of Things in business processes
- Methods, tools and human factors in IS/IT management
- Industrial case studies and experience reports related to the above topics

Abstract — **Managing a software development project is a challenging task; time and effort is required to monitor the project's health and progress. In this context, organizations look for proposals that would assist them in this task. Recently a new and light alternative was introduced: ALPHAs, which are central elements of ESSENCE – Kernel and Language for Software Engineering Methods OMG standard. This paper presents the experience of a Mexican organization that uses ALPHAs to enhance its processes. The paper summarizes the actual use of ALPHAs in the organization, their advantages and disadvantages, and outlines some advice for organizations wishing to adopt ALPHAs. We conclude that ALPHAs are useful for monitoring and controlling software endeavors. Moreover, their harmonization with the organization's current process was a beneficial factor in renewing the CMMI-DEV and CMMI-SVC level 5 appraisals.**

Keywords: ALPHA, ESSENCE, CMMI, quality, software process.

I. Introduction

SOFTWARE development is a challenging task that involves soft and hard skills, such as technical knowledge to create software products of quality and social abilities to make the participants of a project work together in order to achieve a goal.

The characteristics of a software development project, in particular, asset specificity and uncertainty, affect the choice of governance structure of a project [1]. For that reason, it is important to define a governance structure for monitoring and controlling the project according to its particular context.

According to [2], this governance structure can follow a top-down or a bottom-up approach. The top-down governance approach corresponds to process-centered methodologies and bottom-up governance is similar to agile methodologies.

On the one hand, process-centered methodologies are based on process reference models, standards or body of knowledges. Examples of these are CMMI [3], ISO/IEC 12207 [4] or PMBOK [5]. To follow such a plan driven process is essential since it is the backbone of the endeavor and reduces time and cost deviations; yet, to follow it tightly requires a great effort and does not assure a high quality product.

Altogether, it is important to take into account that executing project management activities alone does not mean *managing* a software development project, and communication is vital in order to determine its health and progress.

On the other hand, agile approaches, like SCRUM [6], KANBAN [7] or ESSENCE [8], are an effective strategy for communicating with work teams in a timely and accurate fashion; their primary focus is on the people involved in the project and on delivering a product that fully satisfies the client's needs. It is important to bear in mind that the use of agile methods does not guarantee the appearance of the mentioned benefits in each project, or their contribution to a higher efficacy of the whole organization [9].

Agile or traditional, all these activities aim at figuring out how the project is progressing and allowing team members to make competent decisions. As a whole, no matter what approach is chosen, project management activities consume a large part of the project's time and effort.

In this context, organizations constantly explore alternatives to improve their processes and product quality and incorporate best practices from different sources, no matter agile or traditional. Some early works provide interesting proposals that show a growing interest in recent years on the part of the software engineering community regarding process improvement environments where multiple models are involved. [10].

In particular, this paper describes two models relevant for this study: ESSENCE and CMMI. ESSENCE is an Object Management Group (OMG) standard of a great value. It provides a domain model for organizing different factors that influence the success of a software engineering endeavor [11]. One of the values added by ESSENCE is to surface unknown issues, support the evaluation of the team, generating reflective team discussions through a thinking framework that is holistic, state-based, goal-driven, and method-agnostic [12].

As for CMMI, it is a well-known set of practices divided into three models: for Development (CMMI-DEV) [13], for

Acquisition (CMMI-ACQ) [14] and for Services (CMMI-SVC) [15]. Its last version 1.3 was published in 2010.

This paper presents the experience of a Mexican organization, evaluated CMMI level 5 that introduced ESSENCE into its processes, and uses it as an agile mechanism to evaluate the progress of its projects and its work products quality.

The structure of this paper is as follows: in Section II a general background of the ESSENCE standard, its ALPHAs and the description of the organization are presented. Section III describes how the ALPHAs were used within a CMMI based organizational process. Section IV concentrates the results and lessons learned. Finally, Section V contains conclusions and future work.

II. Background

This section presents an overview of the ESSENCE standard and its ALPHAs. Later, the context of the organization under discussion is detailed.

A. ESSENCE

ESSENCE – Kernel and Language for Software Engineering Methods was published in 2014. Its origins date back to the SEMAT initiative that supported re-foundation of Software Engineering discipline through the identification of its "common ground" [16] as a set of elements essential for software engineering endeavors. This initiative was launched in 2009 and was endorsed by the OMG in 2010.

ESSENCE consists of two parts: the Kernel and the Language. The Kernel contains a small number of "things we always work with" and "things we always do" when developing software systems [16], while the Language is used to describe methods and practices. The Kernel consists of a set of concepts called ALPHAs that provide an object-oriented state-based model of a software engineering endeavor [11].

According to [11], ESSENCE main benefits are the following:

- It provides a comprehensive model for a large-scale process improvement endeavor;
- It is a context aware model, making visible to practitioners both theory and practice;
- It is an evolvable and participatory model, it can be used in any time and by anybody of the work team.

Another value of ESSENCE comes by providing a structure for analyzing and organizing the context and factors of software engineering endeavors from different dimensions [11].

It is worth mentioning that the initial objective of the standard was to refound Software Engineering, placing it a solid theory base and giving professionals the means to define their own practices and methods. However, this study shows that the main usage addresses project management issues.

B. ALPHAs

ALPHAs are the top-level concepts, which refer to the essential elements of software engineering endeavors, relevant to an assessment of progress and health [17]. In fact, ALPHA originated as an acronym for Abstract Level Progress and Health Attribute, and its main purpose is to determine fast and at any time how the project is doing. ALPHAs provide consistent language and measurable objectives with which to assess the current state, or articulate next steps and goals [18].

An ALPHA's components are the following:

- A representative and unique name.
- A set of states through which an ALPHA passes during its lifecycle.
- A checklist for each state used to determine if the state is reached or not.

This structure allows practitioners to evaluate the project based on the states of each ALPHA. The checklist for an ALPHA state contains a number of checkpoints that can be referenced to determine whether and to what degree the project has reached that state [19]. Therefore, it is possible to establish the state of a software engineering endeavor through the ALPHAs states [11].

There are seven ALPHAs divided into three groups, which are called Customer, Solution and Endeavor areas of concern. Figure 1 displays all the ALPHAs within their areas of concern:

- Customer (green)
  1. Opportunity (6 states)
  2. Stakeholder (6)
- Solution (yellow)
  3. Requirements (6)
  4. Software System (6)
- Endeavor (blue)
  5. Work (6)
  6. Team (5)
  7. Way of Working (6)

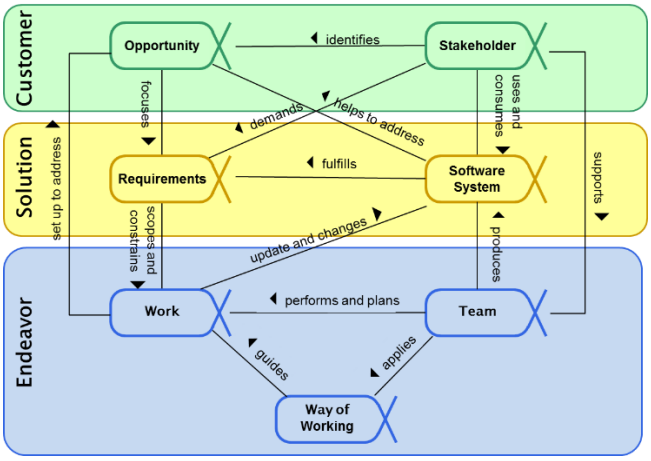

Fig. 1 Areas of concern and their ALPHAs [8]

For an easy and practical use, ALPHAs were represented as cards. Each card corresponds to one state of an ALPHA, and the color code indicates to which area of concern it belongs. As an example, Figure 2 shows the state *Addressed* of the ALPHA Opportunity.

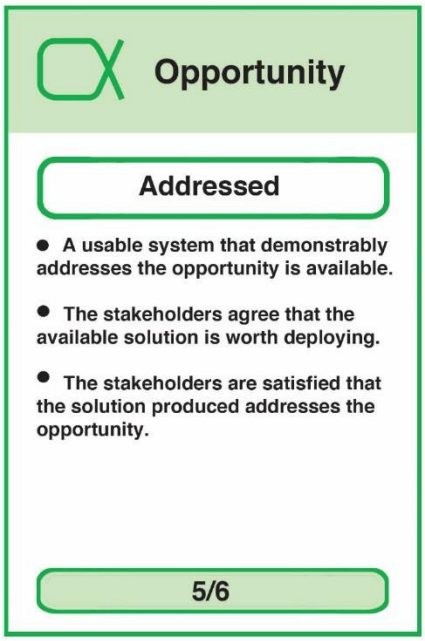

Fig. 2 An ALPHA card, based on [8]

For an opportunity to be *addressed*, the three elements of the checklist should be achieved. Notice that it is the fifth of the six states.

C. Organization

Ultrasist is a Mexican organization founded in 1994. It started as a software development organization, evolving during the last years into a service-oriented enterprise focused on Business Analysis, Enterprise Architecture, Security and Software Quality Assurance. In 2015, they renewed the CMMI-DEV appraisal and obtained CMMI-SVC, both at level 5.

The organization is constantly looking for process optimization and improvement; they carry out a weekly workshop where they discuss the ongoing work and analyze new proposals from the IT community. During such a workshop session, Ultrasist got to know ESSENCE and its ALPHAs through advice from a coauthor of this paper.

In October 2014, they started using ALPHAs for the sake of innovation. At that moment, ESSENCE was close to become an OMG standard, which happened one month later (November 2014).

In January 2015, the ALPHAs were already part of the organization's way of working. The first use of ALPHAs was to verify punctual quality attributes of work products and later on, to develop software quality assurance reviews.

In May 2015, the organization presented their use of ALPHAs as a part of software processes improvement when renewing CMMI level 5 appraisal.

The organization has a hierarchical structure (see Figure 3). The areas colored in green are those directly involved in the use of ALPHAs (the "mid-layer" of the organization):

- Internal SQA
- Sales, Marketing & Clients
- Business Analysis
- Software Construction
- SQA Specialized Services
- Project Management Office

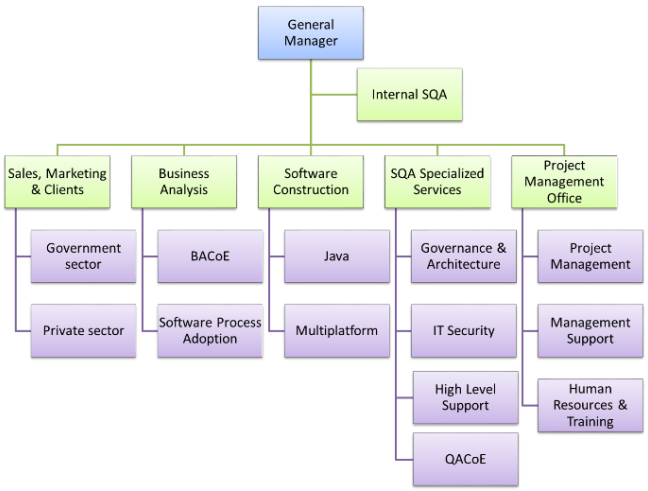

Fig. 3 Ultrasist org chart

One of improvement opportunities recognized by the organization was, for example, the quality of its work products in the Business Analysis area. Particularly, they were interested in a finer verification and validation process of Software Requirements Specification (SRS) work products.

In addition, the Internal SQA wanted to promote a better team integration and communication.

Another and even bigger concern arose after getting the CMMI appraisal, due to which the organizational processes suffered changes. Therefore, the General Manager needed to transmit the new processes to employees, especially new ones, and to generate a pocket guide for technical leaders and project managers.

The first step towards achieving this goal was to carry out a gap analysis versus their process and the actual way of working; next, the organization institutionalized the ALPHAs integrating them into its processes and in the working routine of the people.

Each ALPHA state was analyzed in order to associate organizational processes and the checklists items. When the association was established, the role in charge of the process became responsible for following the ALPHA states. Figure 4 shows the mapping between the organization's processes and the Team ALPHA.

TEAM	State	Responsible	Processes involved
	Seeded	SQA	• APS/Mgm
	Formed	SQA	• APS/Mgm • HR/Training • SQA
	Collaborating	SQA	• APS/Mgm
	Performing	SQA	• APS/Mgm
	Adjourned	SQA	• APS/Mgm

Fig. 4 Mapping between Team ALPHA and organization's process

The next section describes the actual usage of ALPHAs within the organization.

D. Methodology

The data were collected through direct interviews with the people involved in the initiative. Seven persons were interviewed individually in a face-to-face dynamic. Six interviewees lead their respective internal areas, while the seventh is the general manager of the organization.

The interviews were conducted in the following manner: (i) A set of questions on the topic of interest were designed; (ii) The questionnaire was sent to the interviewees; (iii) The interviews took place individually in the organization's facilities; (iv) Each interview was recorded and lasted in average for 20 minutes.

After the data were collected, the recorded interviews were analyzed and the fragments that were relevant for the purposes of the paper were transcribed. Later, the transcriptions were synthesized to obtain the observations listed in the discussion. This work was done by the first and second authors of this paper; this is to enrich the analysis and to moderate the threats to validity in this research.

In addition, the work products arising from the integration of ESSENCE and CMMI were analyzed in order to describe how both proposals, agile and traditional, coexist.

III. ALPHAS USAGE

First, the ALPHAs were translated from English into Spanish; some terms were modified according to the organization's customs and habits. Then, technical leaders got the ALPHA cards printed. They had to define which ALPHA state corresponds to which process or area.

The next step was to start using ALPHAs in a pilot group exclusively for verification and validation activities. Later, the rest of team members started to use the ALPHAs as a means of self-evaluation. Currently, the ALPHAs are being used in other activities and by other roles within the organization; however, this paper is based on the data obtained from the mid-layer roles.

The following paragraphs describe the actual uses of ALPHAs by different areas of the organization.

A. Internal SQA

Internal SQA processes are involved in almost all activities developed in the organization, so the SQA leader makes the most of the ALPHAs. He especially exploits the Requirements ALPHA that helps to trace requirements and verify their level of specification. During his activities, the SQA leader uses ALPHAs for:

- Checking the sufficiency of the work to be done.
- Determining if a work product is finished.
- Integrating agile practices into processes.
- Checkpoints during any time of a project.
- Tracing the requirements.

The Work ALPHA was helpful to determine if the people worked according to the organizational process, and they knew the organizational processes well.

The frequency of ALPHAs use varies depending on the process to monitor. If a SQA process is developed completely within the organization, the ALPHAs are used only during review phases, which happen at least every two weeks. However, if a SQA service is provided to clients, the ALPHAs are used almost daily.

B. Sales, marketing and clients

Sales area uses the Opportunity ALPHA for identifying clients' needs and as a support in creating requests for proposals.

Here, the ALPHAs resulted useful for reporting at what exact point the working team is. The mid-layer has found an adequate way of delivering valuable information of the project to higher levels of the organization who do not need to know all the details, but still need to know the exact progress of the project. Besides, they are especially useful when reporting progress to clients.

Moreover, using ALPHAs with clients helped to get a better understanding of the consequences of not providing a certain feature; the organization found a polite way of showing its clients cumulative effects of product absence as well as presenting missing quality attributes in terms of consequences and negative effects. So, it was possible not only to establish the existence/inexistence of a work product, but also what possible consequences it brought.

The ALPHAs became a favorable alternative for representing a state and a light way to report progress. For example, Figure 5 shows a radial graph that reports in a simple and accurate manner the state of each ALPHA in a particular moment. The ALPHA Opportunity is at state 4

(meaning that the opportunity is *Viable*), Stakeholder at state 3 (*Involved*), Requirements at state 3 (*Coherent*), Software system at state 1 (*Architecture selected*), Team at state 4 (*Performing*), Work at state 3 (*Started*) and, finally, Way of working at state 4 (*In place*).

Fig. 5 ALPHAs radial graph

The graph makes visible a general state of the project and allows work teams to decide which next state of an ALPHA to pursue.

C. Software construction

The JAVA leader guides Daily Scrums and evaluates the team progress using ALPHAs as checklists. The Software System ALPHA, in particular the *Architecture established* state, was took advantage of. He and his team also used other ALPHAs: Stakeholder, Requirements and Team.

D. Business analysis

The SRS Leader used the Stakeholder and Requirements ALPHAs, which were introduced gradually in their daily routine. First, the ALPHAs names were introduced to the work team. Later, when the ALPHAs became more familiar, the states of some ALPHAs were introduced. Thus, the complexity of adopting a new terminology was avoided. Now the SRS leader uses the states names as part of the everyday language when communicating with the team.

On the other hand, the ALPHAs were used to create a SQA Requirements guide (checkpoints for software requirements specification), which aims at improving the work products quality by making a more precise specification of requirements.

The ALPHAs states were grouped into levels of granularity corresponding to different target groups: the ALPHAs are related to the top management level, their states – to the project management, and checklists of work products – to developers. This partition helped the work team to understand ALPHAs and simplified their adoption.

An interesting fact is that the SRS leader actually uses the printed cards and prefers them in the original English version.

E. SQA specialized services

The IT Security technical leader uses the Team ALPHA as a checklist when he forms a team. He also uses the Stakeholder and Requirements ALPHAs.

Similar to the other areas, here the ALPHAs assist in controlling and improving the product quality and the work team's adherence to the process. He reported that he resorts to the ALPHAs, mostly at the moments of hesitation.

Besides that, the Governance Director uses the Opportunity ALPHA to discover client's needs and to understand the project's objective.

Another use of ALPHAs is to identify risks and to classify defects of a process or product. This, in turn, helps to evaluate the problem and to find a solution.

The Team and Software System ALPHAs contributed to know whether the people are working as a team and the communication is healthy; both are crucial factors for a successful project development.

F. How ALPHAs transformed some work products

The organization developed a series of new artifacts influenced by the ALPHAs. The first the SQA checklist that supports the SQA service provided by the organization to their clients. The SQA service usually consists in a reviewing and monitoring a particular business process of the client.

Initially this service used a checklist that consisted of quality attributes identified by the client, the organization, and more importantly, those defined in CMMI-ACQ. However, upon incorporating the ALPHAs internally, the organization observed that the ALPHAs states and checklists made the process lighter and more productive.

Derived from the observed benefits, Ultrasist decided to incorporate the ALPHAs checklist and states into the original document. In the first place, the quality attributes were classified under the scope of each ALPHA and were defined as "quality rules" in the language of the organization. These quality rules are based on the specific goals (SG) and specific practices (SP) of CMMI-ACQ process areas (PA).

For example, the Acquisition Requirements Development PA has SG3 Analyze and Validate Requirements – SP 3.2 Analyze requirements to balance stakeholder needs and constraints. It is mapped to the Requirements ALPHA, specifically to the *Bounded* state, see Figure 6, first row.

Using this rationale, when the team needs to verify the SP 3.2, it runs the checklist of the particular state, instead of reviewing all the subpractices established by CMMI-ACQ or consulting a work product. Importantly, the use of ALPHAs does not replace generation of the CMMI-ACQ related work products, but facilitates assessing the progress and health of a particular concern. Finally, this approach to ALPHAs use is independent from the reference model.

SQA service	CMMI-ACQ			Quality rule	Questions	Category (ALPHA)	Sub-category (ALPHA states)
Functional requirements	ARD	SG3	SP 3.2	The definition of the functionality and required quality attributes is established	• What is the definition of the architecture functionality and quality attributes?	3. Requirements	3.2. Bounded
Techincal Docs	TS	SG3	SP 3.2	The documentation to install, operate and maintain the system is developed	• What kind of supporting documentation is developed? • Are any standards used to generate the supporting docs? • How do you guarantee that the installation, operation and maintenance specifications will work out according to the plan? • What is the exact moment of generating those docs? • How are the generated docs checked?	4. Software system	4.2. Demonstrable
Project Management	RSKM	SG3	SP 3.2	Implement risk mitigation plans	• How often are the risks monitored? • In what way are the mitigation plans implemented?	6. Work	6.4. Under control

Fig. 6 SQA Checklist fragment

IV. Results

This section collects advantages and disadvantages of using ALPHAs. In addition, some advice from the participants involved in this experience, is listed.

A. Advantages and disadvantages

During the interviews, the practitioners expressed the following advantages of the use of ALPHAs:

- ALPHAs are easy to understand and apply, because *"they represent general concepts and put them in black and white"*.
- ALPHAs provide a common language, *"anybody in the work team can understand what you are talking about"*.
- ALPHAs are compatible with any process or lifecycle.
- ALPHAs colors help to associate them quickly to areas of concern, and the state-machine style makes the states flow clear.
- ALPHAs are useful for maintaining discussions focused and collecting clear arguments to make decisions, "*you can ask how the Opportunity is going and get clear answers*".
- ALPHAs help to accelerate convergence during meetings and discussions.
- ALPHAs work as communication facilitators between members of the organization and with the client.

Several disadvantages were also pointed out:

- ALPHAs have too many states; sometimes the cards sets are not handy.
- Some terminology needs to be adapted to the particular context of the organization, for example the *in-place* state or the *Endeavor* area of concern.
- Some states and checklists may have a different interpretation between team members, mainly between juniors and seniors. *"Experience in software development is needed in order to uniform interpretations"*.
- Compared to the mid-layer, the operational layer of the organization required more time to understand ALPHAs.
- ALPHA is not a *universal* term neither a common software engineering word.
- ALPHAs resulted of little help in bigger projects; their simplicity became an obstacle. For example, how to manage many stakeholders or how to evaluate big quantities of requirements with ALPHAs?

B. Threats to validity

The following threats to validity to this particular research were detected.

The internal validity:

- The trustworthiness of the survey responses can be considered a major issue since one of the authors is the general manager of the organization. It is possible that some negative issues were not completely expressed by the interviewees, which may explain the fact the very few disadvantages of the ALPHAs use were detected.
- The coverage of roles in the organization may be considered a threat as well. Only members of the mid-layer of the organization were interviewed, which could affect the perspective of the benefits and drawbacks of the ALPHAs as compared to the point of view of the rest of the organization.
- On the other hand, the number of interviewees that constitutes the sample is representative of the target group who used ALPHAs.

The external validity:

- The organization was not intentionally selected; they took the initiative to start to use ALPHAs and, then, to share their experience.

As for reliability, it should be mentioned that the second and the third authors of the paper has been involved in the organization for a long time (years) and are fully capable to understand the needs of the organization.

Also, the first author, who conducted the interviews, had worked in the organization and developed a trusting relationship with the participants. This fact minimizes the surveys' trustworthiness threat.

After considering the above mentioned threats, we conclude that the results of this research were not affected; however, the data collection methodology can be improved.

Finally, in order to discuss the results and findings from the interviews, peer debriefing took place, which is an extra point to the validity of the research.

C. Some advice

This experience left some useful lessons learned that are summarized in the following paragraphs.

Avoid implementing all the ALPHAs at the same time. Use the ALPHA you need and then add them one by one depending on what you need in a particular moment. Besides, let the team decide which ALPHAs they want or need to use. *"Take the best (that fits for you) of each world and apply it in your context"*. As [20] establishes, an organization has to understand that the organization itself cannot be agile, but its employees can be.

Actually, in the organization's case, the Way-of-Working ALPHA was used occasionally or almost never because they have a well-defined and mature process; in the words of the general manager: *"Everybody knows what to do and how to do it"*.

Do not be afraid to modify ALPHAs, you won't break it down. Some ALPHAs were adapted to become more familiar for the work teams, for example, the Way-of-Working ALPHA was renamed as Working-Methodology. In fact, the ALPHAs should be adapted to the organization's language in order to fit in its process, however minimal these adaptations are.

Do not see ALPHAs as a sequential set of steps, they are not a process. In many cases they were confused with a sequential method. The ALPHAs were created as a tool to be applied at any moment during a project.

It is not necessary to read the whole standard to understand ALPHAs. Actually, only one practitioner read the whole OMG document and the rest consulted section 8.1 Overview to be able to get ALPHAs going. To be more specific, apart from section 8.1 of the standard, in which ALPHAs are presented, it is advisable to read sections 8.2 through 8.4 that provide detailed descriptions of each area of concern, their related ALPHAs, states and checklists.

Try ALPHAs in the presentation you feel comfortable with. Using the printed cards or the electronic version turned out to be a discussion topic. Some participants consider having to carry all the cards a disadvantage; others believe the opposite and prefer the printed version because *"cards are like a cheat sheet to keep quality monitored"*.

V. Conclusions

ALPHAs brought benefits and improvement even for a mature and solid organization that already had its ways of working at a high level. They represented an innovation factor in order to renew the level 5 in CMMI-DEV and CMMI-SVC. Importantly, the quality of the process and the product was systematically improved with the ALPHAs states guide. ALPHAs are not technical-oriented; they are focused on serving as control points and checklists for the teams.

It was shown that ALPHAs can be integrated with other standards, and their independence is a plus when an organization decides to integrate them to the actual way of working and harmonize the whole process. According to [10] harmonizing processes allow organizations to improve, mature, acquire and institutionalize best practices and management systems from multiple approaches.

On the other hand, there are inconsistencies related to the initial objective of ESSENCE: provide practitioners with the means of describing their methods and practices [11]. This issue was addressed by creating activity spaces "descriptions of the challenges a team faces when developing, maintaining, and supporting software systems" [8]. However, in case that the organization does not execute a formal process, the activity spaces make little sense; on the contrary, if an organization possesses a well-defined process, the activity spaces are not necessary, and in the case of Ultrasist, were not used. Instead of supporting the definition of methods and practices, ALPHAs were used to guide the team's way of working. This issue affects small organizations since the simplicity and flexibility of ALPHAs require a well-predefined way-of-working.

Nowadays, the ESSENCE standard is being widely applied in many countries and with diverse objectives. However, the Latin American context features far less impact of this standard in the industry. We believe that the experience described in this paper will motivate Latin American software development industry to work with ALPHAs.

As future work, three lines are identified: (i) to establish patterns, like *usage scenarios*, of when, how and what particular problem ALPHA(s) could solve; and (ii) to determine how the ALPHAs overlap with other standards in order to define a harmonized multi-model process and not implement each one separately. Lastly, (iii) the organization under discussion started to explore how the ALPHAs could be integrated into enterprise architecture services.

***Abstract*—The crucial element of any agile project is people. Not surprisingly, principles and values such as "Respect for people", "Communication and Collaboration", "Lead using a team approach", and "Learn and improve continuously" are an integral part of Open Kanban. However, Open Kanban has not provided any tools or techniques to aid the human side of software development. Moreover, as a Lean initiative, it is not as comprehensively defined process as Scrum or XP. Accordingly, inexperienced Kanban teams may feel a bit lost. To deal with these challenges, we propose an extension to Open Kanban, which contains a set of 12 collaborative games. The feedback received from three Kanban teams who leveraged our extension in commercial projects, indicates that the adopted games improved participants' communication, commitment, motivation and creativity.**

I. Introduction

In more recent years, the software industry has started to look at Lean as a new approach that could complement Agile Software Development [16]. Lean is a general term for finding ways to eliminate waste and increase efficiency [13]. One of the agile methodologies that adds a vast Lean heritage is Open Kanban [11]. The distinguished characteristics of Open Kanban are: (1) visualization of the workflow with Kanban board, (2) limitation of the work in progress (WIP), and (3) measurement of the lead time [15]. The motivation behind visualization and limiting WIP was to identify the constraints of the process and let each member of a team focus on a single item at a time [1]. This technique promotes the pull approach, which means that the team "pull" work when they are ready, rather than having it "pushed" in from the outside [14].

In contrast to other agile methodologies, Open Kanban leaves almost everything open. It does not prescribe iterations, it does not define roles or meetings, and finally, it does not contain process artifacts [14], [15]. Moreover, although Open Kanban emphasizes the human factor of software development and its founding declaration states that "without teamwork Kanban fails" [11], it does not provide any tools or techniques to aid the human side of software development. Accordingly, inexperienced Kanban teams may feel a bit lost.

Fortunately, Open Kanban can be extended by organizations that wish to create an Agile and Lean method that is customized for their particular audience. We took this opportunity to equip our teams with a set of collaborative games, structured as an extension to Open Kanban. Our research was inspired by the ActiveAction workshop [17], which combines classical and game-based techniques to foster stakeholders' involvement and collaborative identification of objectives and risks.

II. Research Method

Our study was conducted as Action Research (AR). In AR, the researcher works in close collaboration with a group of practitioners, acting as a facilitator, to solve a real-world problem while simultaneously studying the experience of solving the problem [5]. The researcher brings his knowledge of action research while the participants bring their practical knowledge and context [3]. The goal of AR is to improve practical matters as well as to improve scientific knowledge [3]. A precondition for action research is to have a problem owner willing to collaborate to both identify a problem, and engage in an effort to solve it. The problem owner in this research was a software development department of a world wide aviation IT provider (the company wishes to remain anonymous). The department experienced typical challenges of adopting a new methodology (i.e. Open Kanban). Its authorities were open to new ideas and willing to implement collaborative games. Three teams that participated in our research are presented in Table I.

Table I.
Participating teams

Team	Comments
T1, 6-8 people	The multicultural team of junior developers who provided services for external customers. All team members were familiar with Open Kanban.
T2, 8-10 people	The team of developers and testers guided by an agile coach. They developed solutions for internal departments. All team members had over 6 months of experience with agile development, but they got started with Open Kanban.
T3, 6-8 people	The distributed team of instructors with an extensive experience in programming or project management. They worked on a project designed to train engineers within the company. All team members were experienced with Agile practices, but they got started with Open Kanban.

III. Identification of Deficiencies

Action Research assumes that theory and practice can be closely integrated by learning from the results of intervention

that is planned after a thorough diagnosis of the problem context [5]. To identify deficiencies in the adoption of Open Kanban, we prepared a survey that contained a total of 13 questions (Fig. 1). Respondents rated, on a Likert scale of 5 points, their degree of agreement regarding the implementation of Kanban values and practices in their teams. In total, 18 respondents from 3 teams (T1, T2, T3) completed the survey. The respondents were also asked to provide their free comments on the usage of Open Kanban by their organization. The survey was anonymous, so we assumed that the responses were honest.

It is not accidental that "Plan-Do-Check-Act cycle", "Systematic approach to improvement", and "Collecting feedback on the process" received the lowest rates. Open Kanban does not define retrospective meetings, nor does it prescribe timeboxed iterations. Thereby, the investigated teams had practiced only occasional retrospectives.

In the open-ended comment question a few respondents mentioned that their team had problems with complex work items. Indeed, in Open Kanban, no particular item size is prescribed. Since there is no requirement to break down items so they are small enough to fit into a specific time box, the management of the workflow is cumbersome. The results of the survey also suggest that the respondents were familiar with Open Kanban, but their knowledge was incomplete (most of them were neutral on "Understanding of Kanban mechanisms"). Besides, "Work-In-Progress limits" scored slightly above 0, so the limits probably needed adjustment. Furthermore, the detailed results show that only half of the respondents reported communication between team members as satisfactory.

IV. Our extension to Open Kanban

For each deficiency identified in the previous section, we suggest collaborative games that might be a remedy for it. Collaborative games refer to several structured techniques inspired by game play and designed to facilitate collaboration, foster customer involvement, and stimulate creative thinking [12]. Fig. 1 presents the mapping between the problematic issues and Open Kanban principles with collaborative games superimposed. The following subsections explain how we intend to enrich Open Kanban by our extension.

A. Visualize the workflow

Although the teams used a Kanban Board to visualize work, different work item types, and WIP limits, we found room for improvement. Work items were not estimated. As a consequence, it was difficult to manage the workflow and make commitments. Therefore, we set the rule that a work item could not make its way from the backlog onto the board until it had been estimated with Planning poker [9].

B. Learn and improve continuously

Before our research went into work, every time someone saw an issue which seemed worth reviewing, the team started an ad-hoc kaizen meeting. However, Kanban suggests to make incremental improvements to the existing processes at regular intervals called cadences. Accordingly, during our research we chose a four weeks cadence for retrospectives. A key element of a retrospective is that the team must agree, together, to trust each other and to believe that every comment or suggestion is intended for the sole purpose of improving the team's performance [12]. We expected that collaborative games would make the team feel safe to discuss any issue that concerns them.

The Snake Game stimulates memories and helps the team to gather data from many perspectives [6]. Its objective is to create a shared picture of what has happened since the last retrospective. Participants write sticky notes to represent memorable, personally meaningful events and then post them in chronological order on a large poster of a snake. The more recent the event is, the closer to the head it should be posted. The collected notes can constitute an input to other games for retrospectives.

The Perfection Game [www.mccarthyshow.com/online] is a tool for continuous improvement of the process, team and organization. With this game team members are invited to participate in improvements as they give feedback to each other. To get feedback, team members are asked to: rate (on a scale of 1 to 10) the action, process, item or event being considered; state what they like; suggest what to do to make it perfect. Participants can only withhold points if they provide suggestions to improve the considered issue. If they cannot say how to make it better, the default score is a 10. If participants give a high rating then they have to state what went good, what makes it so good, where does the value come from, etc. Since participants have to motivate their ratings (the rating is coupled to what participants like about it and what they think can be done to do it better), the quality of the feedback is improved.

The Coaching Cards Game uses a deck of colorful cards with various images to represent team members' feelings. At the beginning of each round, each participant chooses one card that illustrates his feelings related to the event being considered. Then, the team discusses their feelings. The game creates a non-threatening opportunity to gather data about feelings during the last release cycle by connecting the feelings to events that happened in the cycle [7]. Even though someone does not want to express his opinion directly, the game allows the team to gather the opinion indirectly. With this game, the team can identify events that provide benefits and events that cause problems.

The Sailboat Game [7] lets a team think about their impediments, risks, good practices, and where they go as a team. The game starts by drawing a sailboat, rocks, wind, and an island. The island represents the team's objectives/vision. The rocks represent the risks the team

might encounter along the way. The anchor on the boat is everything that slows them down on their journey. The wind represent everything that helps them to reach their objectives [7]. Next, participants write ideas on sticky notes and then post the ideas into the different areas according to the picture. Then, the team discusses how to continue the practices that are written on the clouds/wind area, how to mitigate the identified risks, and what actions can be taken to fix the problems.

C. Limit Work-in-Progress

Open Kanban advices limiting the WIP so as to optimize the workflow of the system in accordance with its capacity [11]. A limit on WIP constrains how many work items can be in each workflow step at a time [2]. Limiting the WIP has two major benefits: it reduces the time it takes to get any one thing done (lead time); and it improves quality by giving greater focus to fewer tasks [13]. We suggest two games that demonstrate this principle to new teams.

The Ball Flow Game [availagility.co.uk/2010/11/17/the-ball-flow-game]. The aim of this game is to pass as many balls as possible through the team in 2 minutes. However, the activity is constrained by the following rules: (1) balls cannot be passed to a direct neighbor (the team arrange themselves in a circle); (2) each ball must be touched at least once by every player; (3) each ball must have air-time as it is passed between players; (4) each ball must return to the same player who introduced it into the system; and (5) if a ball drops, it cannot be picked up. The game is played a total of 3 times with 1-minute breaks in between to inspect and adapt the process. Before each round, the team estimates of how many balls they can pass through the system. In addition, the team has two minutes of preparation time for the first round to self organize and discuss the strategy. The game demonstrates that every system has a natural velocity and to improve the system significantly, it is often not a case of working harder, but a case of changing the process. Players will find out that when balls are pushed into the system, it results in dropped balls and decreases performance. Therefore, they will arrange a pull system – i.e. a system where the balls are not passed until the downstream player is ready.

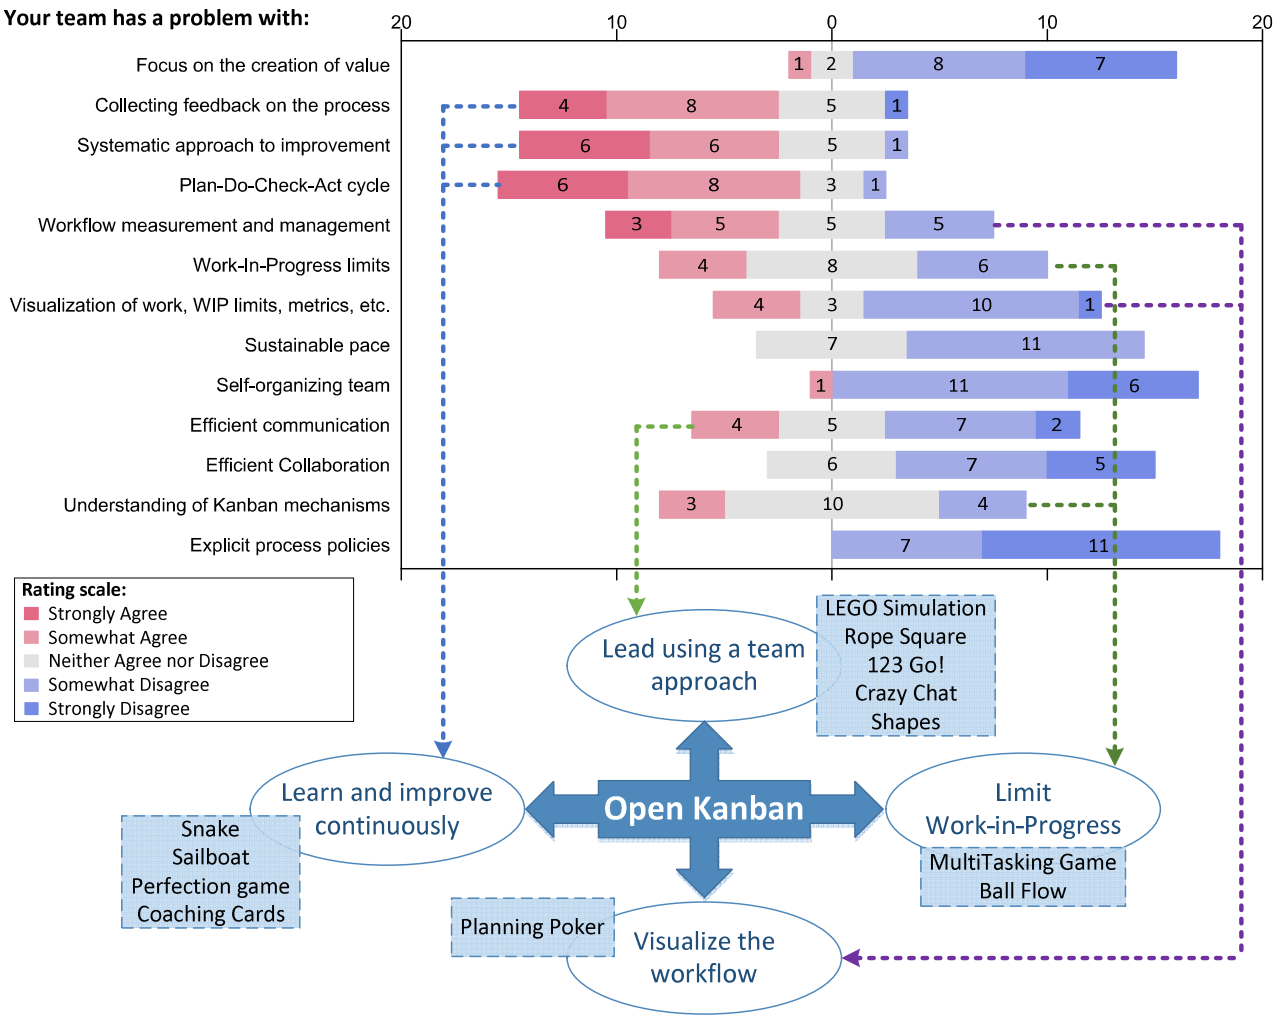

Fig. 1 Summary of questionnaire responses and the proposed extension

The Number Multitasking Game [10] illustrates the effect of multi-tasking and context switching. It consists of two rounds. In each round, each participant is given a page divided into three columns. The task is to fill out the left column with the Roman numerals I through X, the middle column with the letters A through J, and the right column with the Arabic numerals 1 through 10. In the first round, the participants are asked to write row by row, while in the second round, they are asked to work column by column. The game shows why limited WIP improves lead times and lets developers understand Kanban better.

D. Lead using a team approach

Building successful teams and team leadership are crucial to deliver value. At the center of teamwork are effective collaboration and communication. We suggest playing Rope Square and LEGO Simulation as a means of team building and a way to socialize. Besides, these games entail collaboration in decision-making. Other games in this section emphasize the importance of communication.

The Rope Square Game [4] is an icebreaker for team building. The team has to form a perfect square with the rope. Each member must be blindfold and grab the rope with both hands. When the team feels like they are finished and all agree that the rope is in a perfect square, they put the rope to the ground. The game reveals how people fulfill different roles in a group. It also allows the team to build cooperation and trust between members.

LEGO Simulation. The team's task is to build a space base on Mars with LEGO bricks. The facilitator plays the role of the Product Owner. He writes stories, is available to answer questions and to provide feedback. The game encourages the team to communicate with the Product Owner, work in cooperation and reach a consensus.

The 123-go! Game. In this game [8], the facilitator explains that after he counts to three and says "go", everyone should clap their hands. The task for the facilitator is to count to three slowly then clap his hands, pause for a second and say "go". Usually, people will clap when the facilitator claps, rather than when he says "go". This game emphasizes the importance of listening before acting when working in a team.

The Crazy Chat Game teaches players to be more aware of the importance of paying attention. The team split themselves into pairs. Then, for one minute one person talks about something he is most passionate about in life. The other person has to act as disinterested as possible. After a minute they should switch roles.

The Shapes Game. This game teaches that the way we communicate impacts our ability to succeed. The team has to form pairs. Each pair decides who will draw and who will instruct. The instructor is given a picture with shapes. The drawer can not see the shapes or ask any questions. The instructor has to describe the picture giving only verbal instructions, while the drawer has to reproduce the original shapes. The instructor can see what the drawer is doing and provide feedback.

V. EVALUATION AND RESULTS

The evaluation took place in 2015 and 2016. All games presented in Section IV were implemented in both the T1 and T2 teams. In addition, Planning Poker, Coaching Cards, Perfection Game, Rope square, and Tennis Balls were implemented in the T3 team. The implementation of each game was planned with Agile Coach, Service Leader, or Project Manager.

After each game session, we issued a questionnaire. The participants were asked to indicate their level of agreement with statements about game-playing activity. The responses were on a Likert scale of 1 to 5 (Table II). At the end of the survey, the participants were also invited to specify any additional remarks. We used two different sets of questions – one for the retrospective games and Planning Poker (games A), the other for the remaining games (games B). For each game and question, we first took the average per team, and then the average of the averages (the detailed charts are available on http://przybylek.wzr.pl/FedCSIS16). The differences in averages between teams were always less than 1 point, except for Coaching Cards and LEGO Simulation.

Games A aim to directly support teams in their work and were perceived positively. Note, that Planning Poker got a low score in "fostering creativity", but it is not a downside because this game has different objectives. All participants appreciated this game and wanted to use it on a regular basis. Among the retrospective games, Sailboat performed the best but should be used interchangeably with the Perfection game as suggested by a few respondents. Indeed, teams should have a set of possible games to avoid monotony that leads to fatigue and a lack of motivation. In turn, Coaching Cards was not appreciated by the T1 team. They rated the game lower than both other teams and commented that they did not feel comfortable enough to share their problems, opinions and concerns. In addition, someone mentioned that the results strongly depend on the openness and honesty of participants. Surprisingly, only 2 persons in both the T1 and T2 teams wanted to use the Snake game in the future, even though the game obtained high scores in improving commitment and communication.

Games B make teams aware of some of the key Kanban values or mechanisms and generally should be played only once by each team. According to the comments received, these games should be used during training sessions. Note, that the 123-Go! and Crazy Chat game were carried out during one meeting and jointly evaluated due to their common purpose. Although some games received low scores in certain aspects, this is not a downside because they still meet their objectives. For instance, everyone strongly agreed that Shapes, 123-Go! and Crazy Chat revealed the importance of effective communication. In turn, Number Multitasking demonstrated the cost of context switching.

TABLE II.
SUMMARY RESULTS

Rating scale: 1 (Strongly disagree) 2 (Disagree) 3 (Neutral) 4 (Agree) 5 (Strongly Agree) The game:	**Games A**					**Games B**					
	Planning Poker	**Snake Game**	**Perfection Game**	**Coaching Cards**	**Sailboat Game**	**Ball Flow**	**Number Multitasking**	**Rope square**	**LEGO Simulation**	**123 Go!/Crazy Chat**	**Shapes Game**
- produces better results than the standard approach	4,6	3,2	4,7	3,5	4,6						
- should be implemented permanently instead of the standard approach	4,2	3,0	4,7	2,5	4,7						
- may be considered as complementary to the standard approach	2,7	3,2	4,7	4,3	4,4						
- fosters participants' creativity	2,4	4,0	3,5	4,5	4,3						
- fosters participants' commitment and motivation	4,3	4,5	4,0	3,2	4,6						
- improves participants' communication	4,8	4,6	3,0	3,5	4,7						
- is easy to understand and play	4,9	5,0	4,9	5,0	5,0	4,8	5,0	4,3	4,2	4,8	5,0
- makes participants aware of the importance of effective communication						4,9	3,4	4,7	4,6	5,0	5,0
- makes participants aware of the importance of team collaboration						5,0	2,7	5,0	4,9	2,4	2,7
- allows participants to better understand Kanban mechanisms						4,1	4,4	3,1	4,7	3,0	2,9

VI. CONCLUSIONS

This paper reports on an Action Research project designed to explore the ways in which collaborative games could benefit Kanban teams. We started by carrying out a survey among three Kanban teams of a world wide aviation IT provider in order to identify deficiencies in their current practices. Each problematic issue was mapped to the affected Open Kanban principle. Based on the survey results, we proposed an extension to Open Kanban, which specifies 12 collaborative games, divided into four categories in compliance with four Open Kanban principles.

The feasibility of our extension was evaluated by three Kanban teams with encouraging results. We found that the adopted games: (1) improved participants' communication, commitment, motivation and creativity; (2) helped the teams understand the main mechanism, values or practices of Open Kanban; (3) produced better results than the standard approach; and (4) were easy to understand and play. Moreover, the teams intended to continue playing the games after the project finished. We hope that the reported experience will encourage other practitioners to implement collaborative games in their projects. Future studies may consider examining other collaborative games or adopting games into other software development processes.

Towards the participant observation of emotions in software development teams

Michal R. Wrobel
Faculty of Electronics, Telecommunications and Informatics,
Gdansk University of Technology, Poland
Email: wrobel@eti.pg.gda.pl

***Abstract*—Emotions, moods and temperament influence our behaviour in every aspect of life. Until now plenty of research has been conducted and many theories have been proposed to explain the role of emotions within the working environment. However, in the field of software engineering, interest in the role of human factors in the process of software development is relatively new. In the paper the research design process that has been proposed details a novel approach using the method of participant observation in order to investigate the role of emotions in IT projects. The participant observation protocol presented was developed in an iterative manner, where successive phases were validated in two preliminary studies.**

I. Introduction

COMPUTER programs are used in almost every aspect of our lives. At the same time, a considerable part of IT projects fail. Budgets or schedules are exceeded, applications are low quality. The Standish Group estimated in their "2015 CHAOS Report" that 19% of the IT projects failed, and only 29% were entirely successful [1]. Available techniques and methods of software engineering solve the problems only partially. One of the directions of research that can improve the success factors of an IT project is the analysis of human factors in the process of software development. Emotions, moods and temperament influence our behaviour in every aspect of life. Such impact is sometimes more, sometimes less significant. Modern research of emotions in the workplace were initiated in 1983 by Hochschild's book "The Managed Heart". Since then, numerous research has been conducted and many theories have been proposed so as to explain the role of the emotions in work [2].

However, in the field of software engineering interest in the role of human factors in the process of software development is relatively new. Software development is considered as one of the most complicated tasks performed by humans, not only because of the technical complexity, but also due to human factors [3]. Nowadays, software development require a high level of cooperation between a number of individuals with different personalities, which may raise interpersonal conflicts. While the technical and management issues have been covered in numerous studies, the awareness of importance of human aspects is still minimal.

This low awareness of the role of emotions in the software engineering is partly due to the small number of research in this field. In Section II studies on emotions in the software development process are presented. In most studies quantitative methods were used, however, these methods allow confirmation of the hypothesis, or more accurate data on the phenomenon to be obtained, which, at least in part, is understandable. Whereas knowledge about the impact and the role of emotions in the software development is still negligible. To fill this gap, I propose to conduct experiments using the method of participant observation, taken from ethnography science. In Section III the experiment design is proposed. To confirm the validity of the assumptions and design, preliminary studies were conducted. Information about its execution and results are presented in Section IV.

With the current state of knowledge concerning the role of emotions in the work of IT professionals, it is necessary to carry out further detailed observations. The application of the proposed and validated participant observation study should allow a better insight on the impact of emotions in the software development process.

II. Studies on emotions of software developers

Credible studies on the role of emotions in the software development process started only in the XXI century. However, so far they have been conducted mainly without immersion in the work of software developers. Graziotin et al. compared self-assessed affective states with self-assessed productivity of the programmers. Their study revealed correlation between productivity and both valence and dominance [4]. A similar study was conducted by Khan et al. In the experiment, participants watched short video clips that were meant to affect their mood. Before conducting programming and debugging tasks, they assessed their emotional state. Results showed weak correlation between arousal and productivity [5].

Recently a few studies on emotions of software developers were conducted using sentiment analysis technique. This is a completely passive method of gathering information regarding the attitude of the authors based on the analysis of their texts. Garcia et al. performed such study on the basis of artifacts generated by the Gentoo Community, such as mailing lists and bug tracker. Results of their experiment showed a correlation between developers' emotional states and activity [6]. A similar experiment, performed by Muriga et al. showed that only a small subset of emotions can be detected based on data mining techniques [7].

The common element among all this research is the lack of direct contact with respondents during data collection. Collecting such confidential and ambiguous data, in the form of information concerning emotions, require gaining the trust of the respondent. Another issue is the problem with the naming of emotions. People ambiguously interpret names of emotions, which leads to biased data.

A novel approach to recognizing the emotions of software developers was proposed by Muller et al. In two experiments, they used biofeedback devices to gather EEG, EDA, fMRI and eye-tracker signals of developers during their work [8]. Biometric signals provide objective information about reactions of the human body to emotional stimuli. Nevertheless, current knowledge does not allow unambiguous assignment of emotional states on the basis of this data [9].

Another approach was proposed by Graziotin et al. During their study, a researcher constantly supervised the experiment and respondents were observed while programming. Before and after the development task, a face to face interview was performed [10]. Such approach allows more accurate observation of the behaviour of developers, and thus better understanding of the impact of emotions upon their work.

III. The research design

To gather significant insights in the role of emotions within the software development process, I propose to use a participant observation method, known from ethnography science. Review of the emotion management literature performed by Fisher et al. showed usefulness of participant observation and interviews in examining emotions in the workplace [2].

Observation is a research method that allows detail qualitative information to be gathered. It is defined as systematic description of the events and behaviours in environment [11]. A particular type of this method is participant observation, where the researcher takes an active part in daily events and activities of the group and interacts with its members [12]. Seaman et al. confirmed that participant observation allows to obtain comprehensive data about software development process [13].

For the purpose of the study, in order to obtain information about emotions and moods of the developers and the impact of these factors on their work, participant as an observer method was chosen. It means that the observer is a member of the group and she or he takes full part in its activities. Other members of the group are aware of being the subject of the experiment. The observer during work can collect data about the colleagues, but also observe her or his own behaviour and the factors that influence them. This permits deeper, though subjective, behavioural analysis. In order to eliminate subjective factors it is planned to make a number of observations by independent researchers.

Research is supposed to be fully overt. Employers of the researchers should provide formal agreement to place studies in their facilities. Also, team members will be informed about studies and will have to give their approval. All data will be anonymised to prevent identification of individual employees. The employer will not have access to the collected data, and will only receive a final report containing summary information.

Information will be collected in a continuous manner. The observer will separately take notes about emotional states, as well as events occurred throughout the work day.

A. Preliminary studies

The participant observation study was designed in an iterative manner. Initial experiment assumptions about the observation were verified during two subsequent preliminary studies. Such approach allowed the identification of the design flaws and to propose a better, more mature research design.

There were two participant observations conducted. Both were performed by software developers with bachelors' degrees in Computer Science (polish engineer's degree). They were students of second level studies and they were working part-time (20 hours per week) in two different IT companies as software developers.

The first observation took place in May 2015 and lasted for three weeks. During this time the observer made 121 notes about himself, and his colleagues made 79 notes about their own emotional states.

The second observer worked with 3 other software developers. During four weeks in June 2015, he made 162 observations about his own emotions and 78 notes about emotions of his colleagues. Furthermore, his co-workers made 81 notes about their own emotions.

B. Notes templates

For the purpose of the observation initially two template notes were prepared, named as the Sheet S and the Sheet A.

Information on the emotions of the observer will be collected continuously, i.e. during work, she or he must pay attention to emotional states and well-being, as well as to analyse their impact on the productivity. After every hour the observer makes notes about his emotions and productivity using Sheet S. Additionally, at the end of the working day, each co-worker is asked to describe her or his emotional state and productivity during the day, their insights are then documented on the Sheet A. Each observation is documented on the sheet by filling in four fields: emotional state, fatigue, productivity and additional notes.

For purposes of denoting emotional states the Russell circumplex model of affect was chosen [14]. According to this model, emotions are described with two continuous dimensions of valence and arousal. The valence (pleasure) dimension differentiates positive from negative emotions, and as it is continuous, both directions might be graded. Values close to zero correspond to neutral emotional states. The dimension of arousal (activation) allows the differentiation of active and passive emotional states. The value of zero means relaxed or calm, while four indicates excited or stimulated [15].

In the fatigue field it is possible to indicate whether it was present or not. Information regarding the productivity is denoted using a grade 5 scale, where 0 represents no

Participant observation of software developers

Observer code:	**Date:**	**Experiment day:**	**Work hours:**	**S**

Work hour	**Emotional state**	**Fatigue**	**Productivity**	**Notes**
1	Valence -2 -1 0 1 2 Arousal: 0 1 2 3 4	yes / no	0 1 2 3 4	
2	Valence -2 -1 0 1 2 Arousal: 0 1 2 3 4	yes / no	0 1 2 3 4	
3	Valence -2 -1 0 1 2 Arousal: 0 1 2 3 4	yes / no	0 1 2 3 4	
4	Valence -2 -1 0 1 2 Arousal: 0 1 2 3 4	yes / no	0 1 2 3 4	
5	Valence -2 -1 0 1 2 Arousal: 0 1 2 3 4	yes / no	0 1 2 3 4	
6	Valence -2 -1 0 1 2 Arousal: 0 1 2 3 4	yes / no	0 1 2 3 4	
7	Valence -2 -1 0 1 2 Arousal: 0 1 2 3 4	yes / no	0 1 2 3 4	
8	Valence -2 -1 0 1 2 Arousal: 0 1 2 3 4	yes / no	0 1 2 3 4	
9	Valence -2 -1 0 1 2 Arousal: 0 1 2 3 4	yes / no	0 1 2 3 4	
General notes:				

Fig. 1. Observer notes template – Sheet S

productivity, and 4 the highest productivity. Furthermore, for each observation as to the events influencing the emotional states and productivity should be described within the notes field.

After the first participant observations, lack of regularity and credibility in fulfilling sheets by co-workers was noticed. Therefore, an additional template, marked as Sheet O, was prepared. It is meant for taking notes by the observer about emotions of colleagues and their productivity. During his work, observer should non-invasively watch her or his co-workers. Particular attention should be paid to the events affecting their emotions.

Sheet S (Fig. 1) contains 9 rows of the fields described above, each row for every hour of the working day. The number of rows in the Sheet A, corresponds to the number of co-workers observed. Sheet O contains just one row. Sheets also includes additional information, such as observer code, date of observation and working hours. After each working day n+2 sheets should be collected, where n is the number of co-workers.

IV. Results of preliminary study

In the context of designing the participant observation research, the most important outcome of the preliminary study refers to the issue of observing co-workers. The first observation revealed, and the second confirmed, that co-workers are not willing to systematically fill observation sheets, even if it is required only once a day. Only 25% of the notes were taken on time – at the end of the working day, or at the beginning of the next one, the remaining were delivered with delay.

Therefore, during the second execution, the observer was asked to take notes about her or his colleagues. These notes have been compared with the notes taken by the co-workers observed. The analysis showed that the external evaluation agreed only on not more than 25% of notes with the self-assessment. While the assessment of valence and arousal were sometimes under, and sometimes over-estimated, in the case of productivity, co-workers always have reported greater diligence than suggested by the external evaluation.

TABLE I
Number of reported high and low productivity depending on the Arousal and the Valence

Productivity	**Arousal**				
	0	*1*	*2*	*3*	*4*
Low	31	42	63	42	1
High	9	16	123	51	2
Total	59	98	285	106	3

Productivity	**Valence**				
	-2	*-1*	*0*	*1*	*2*
Low	5	31	61	54	28
High	0	11	37	121	40
Total	6	67	154	250	82

These results indicate the necessity to involve objective methods for identifying emotions and productivity evaluation. Without proper tools support [16], observation of emotional states and productivity of co-workers is useless. Therefore, in further studies only self-assessment of a trained observer will be conducted.

Based on the collected data, analysis of the impact of emotional states on productivity has been conducted. Fig. 2 and Table I show the number of reported high and low

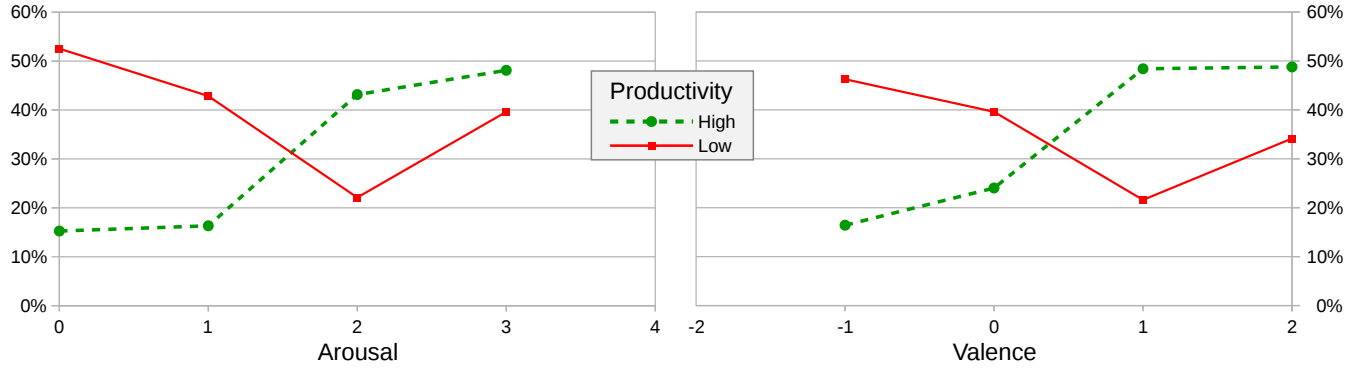

Fig. 2. Percentage of high and low productivity of software developers, depending on their arousal and valence

productivity periods depending on the arousal and valence. Due to the small number of observations, results with the highest arousal and the lowest valence were removed from the chart.

Low productivity is least likely to occur at an average arousal and higher value of valence. Correlation between high productivity and both arousal and valence seems to be more linear. High value of productivity was reported more frequently along with high arousal and high valence. Considering the results above, it appears that the optimum in terms of productivity of software developers, is medium arousal and high valence.

V. Conclusion

Preliminary studies have proved that the proposed research design may bring new and useful information on the role of emotions in the software development process. The use of qualitative research methods may allow for a better understanding the role of emotions in productivity of IT professionals.

Preliminary studies have also discredited the legitimacy of both external and self-assessment of co-workers. Therefore, it is proposed that observers make out notes only on their own emotional states and productivity. Observation of other team members will be possible only after the development of a reliable and non-intrusive methods of emotion recognition and productivity evaluation.

In addition, the results of the two preliminary participant observation studies showed the correlation between high productivity and both arousal and valence. Optimal, in the case of productivity, emotional states include, among others, joy, amusement, surprise and anxiety.

Understanding the role of emotions in the software engineering may lead to the development of new affect-aware extensions to both traditional and modern software development management methodologies.

Acknowledgment

I thank my students R. Lewandowski and J. Falenczyk for conducting the preliminary participant observations described in the paper.

Abstract—This article introduces AgileSafe, a new method of incorporating agile practices into critical software development while still maintaining compliance with the software assurance requirements imposed by the application domain. We present the description of the method covering the process of its application and the input and output artefacts.

I. Introduction

AGILE software development methods have been introduced in response to particular concerns emerging from the changing needs of the market. In practice, volatile requirements, demanding clients from diverse backgrounds and a growing need for shortening time-to-market made a growing number of software companies seek alternatives to their own traditional approaches. A similar tendency can be presently observed in many domains, including the public sector [1] and further in what seemed to be a leading plan-driven environment - the safety-critical software domain. In this case, however, strictly agile methods will not be the answer as they are insufficient on the safety assurance and certification side. The question is if and how to enrich the agile practices with safety and risk management practices without sacrificing agility and still providing the necessary assurance level.

While process optimization is vital to the business and economical aspect of a software development project, in the safety-critical software domain its profits will not be sufficient unless a company is able to conform to standards and guidelines, which regulate a particular industry. Clients demand their products to be of high quality, on time and within a reasonable budget but at the same time the software need to be certified by an appropriate authority in order to be licenced for use in its destined environment. For this reason, in safety-critical software domain it is not enough to improve the software development process to provide financial profits to the company. It is also necessary that the safety requirements are adequately identified and assured throughout the process. Changing the process will likely result in changes in the safety evidence collected during the development, which may affect the scope and structure of the certification process. Therefore, each change to the process should be carefully analysed from the viewpoint of future audits and potential consequences to the outcome of these audits. This makes a change in safety-critical software development process a complicated and potentially costly operation depending on how the company is introducing new elements to the process. This may be a problem for SMEs where budget constrains can be a significant barrier in introducing the change.

Attempts to provide a hybrid, disciplined-agile, approaches bringing together best of the two worlds are already in effect for several years. A growing body of evidence, including industrial reports, shows that obtaining the right balance is doable and profitable especially when the companies decide to employ competent experts to develop a custom made approach. Examples of such reports can be found in [2], [3], [4], [5] and were surveyed in [6]. What is more, in 2012 FDA (Food and Drug Administration) recognized the AAMI TIR45:2012 - Guidance on the use of AGILE practices in the development of medical device software [7]. It concludes that agile practices can be successfully used in safety-critical software development and that such practices can be compliant with IEC 62304 [8] standard. It also provides a mapping between agile methods and IEC 62304 activities.

However encouraging these reports are, 'tailoring' a software development method can be a costly and complicated process. If hybrid approaches are to be applied in a larger scale, more available and ready to use solutions are needed. An example can be SafeScrum [9], which concentrates on adapting Scrum into safety-critical software development. The method has been already applied in a number of real life projects and most of them ended in success as well as required standard certification [10]. Another approach is AV-Model [11] combining the traditional V-Model with Scrum and focusing on medical device software development and the IEC 62304 standard.

In this article we propose a new method, called AgileSafe, of incorporating agile practices into critical software development while still maintaining compliance with the software assurance requirements imposed by the application domain, which is complementary to the existing methods. AgileSafe is addressed mainly to SMEs developing safety-critical software, to support them in the process of introducing new practices into their software development environment. AgileSafe provides a user with tools enabling her/him to create, with a help of guidelines and questionnaires, a hybrid agile approach customized for the project. It also provides a tool

978-83-60810-90-3/$25.00

for handling conformance with standards and norms while introducing this new approach.

II. Overview of the AgileSafe Method

To provide and maintain control over the safety requirements and over the scope and level of their assurance, AgileSafe employs evidence-based arguments which are explicitly maintained during the software development process. These arguments follow the ISO/IEC 15026 [12] recommendations on *assurance cases*. The main idea is to provide assurance cases both for the software development process and for the end product itself. While the latter is the essence of demonstrating product conformance with the stated safety objectives, the former is complementary to it and allows to demonstrate adequacy of the chosen software development practices and in particular their conformity with safety requirements imposed by relevant standards. AgileSafe focuses on an explicit development process assurance case demonstrating that the selected range of software development practices is conformant with the requirements of the relevant safety related standards.

Although, for demonstration reasons we concentrate on the medical domain, the method is generic and can be adapted to different safety-critical domains. In order to address a broad range of products resulting from development, the process assurance arguments are based on the standards that are relevant for a particular application domain.

The prerequisite for applying AgileSafe to a particular (planned) safety-related software development project is that we have identified a set of relevant standards we want to be compliant with. Then, the main results of applying AgileSafe to this project are:

- *Project Practices Set* (*PPS*)– a custom prepared hybrid approach composed of plan-based and agile software development practices;
- *Assurance arguments*, for each selected standard.

Figure 1 presents a BPMN model of the AgileSafe.

Based on the *Project characteristics,* prepared during the AS.P.1 *Analyse the project process*, a user is guided through the set *AgileSafe Practices Knowledge Base,* which contains descriptions of software development practices. The method suggestions are based on the good practices for software development as well as the results of experiments conducted in the course of our research.

The customized *Project Practices Set*, prepared in the AS.P.2 *Select practices* process, should be later implemented in the software development process (AS.P.7 *Apply Practices*). For each given *Standard* a *Practices Compliance Argument* need to be *developed/updated* (AS.P.3). These *Practices Compliance Arguments* are then *adapted* (AS.P.4), depending on the *PPS*, into *Project Practices Compliance Arguments*. Based on them, the *Project Compliance Arguments* are *prepared* (AS.P.5) and they are the end products of the method allowing the user to AS.P.6 *Assert conformance*, using the *Evidence* prepared during the AS.P.7 *Apply practices* process.

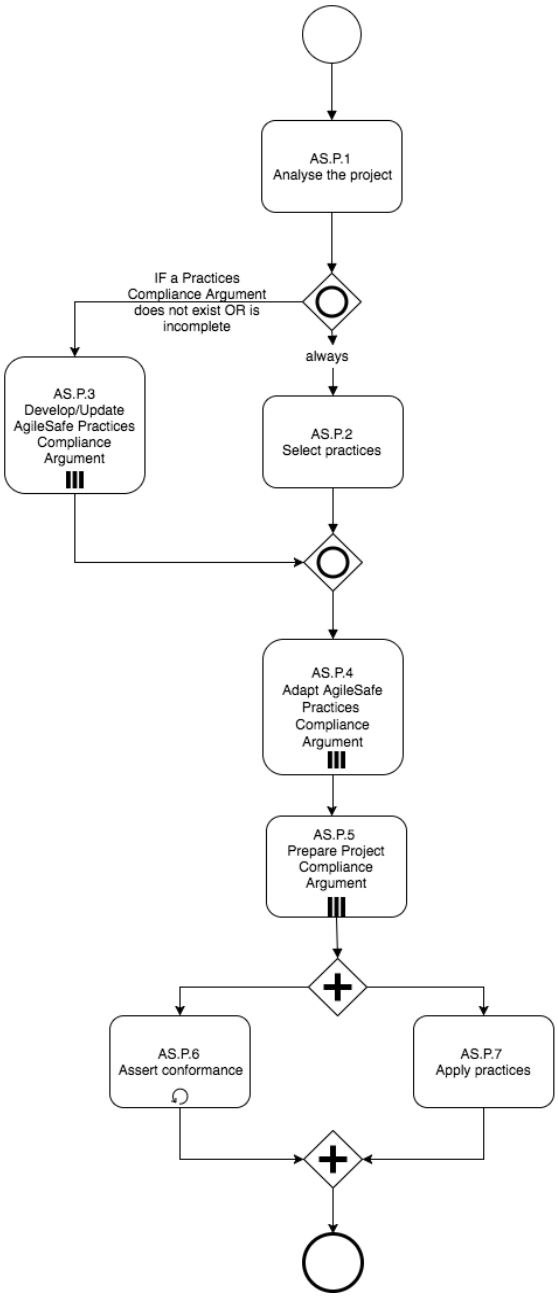

Fig. 1 Diagram of AgileSafe method

In further sections we explain components of the method in more detail.

III. Assurance Arguments in AgileSafe

An assurance argument is a structure of claims, which is based on explicitly provided evidence and demonstrates that a product or a system satisfies a detailed set of requirements. Recommendation on the structure of assurance arguments (called *assurance cases)* can be found in ISO/IEC 15026 standard [12].

Since 2005 the idea of safety assurance arguments has been analysed in depth by both FDA and SEI (Software Engineering Institute) [13]. This partnership resulted in series of documents presenting potential uses of assurance arguments in FDA certification process [13],[14]. With FDA

currently recommending the use of assurance arguments in the process of qualification of medical devices in order to present compliance with safety requirements, explicit use of assurance cases is gaining increasing recognition.

In AgileSafe there are two types of assurance arguments: for process assurance and for product assurance, as shown in Figure 2.

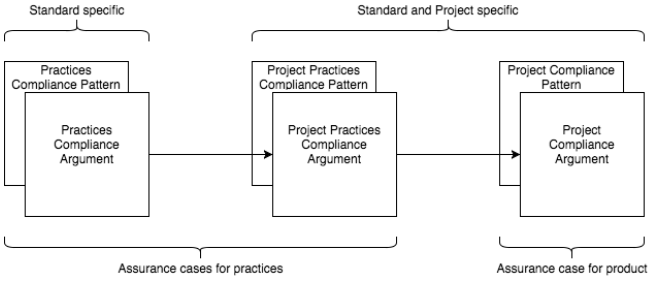

Fig. 2 Assurance cases in AgileSafe

The patterns for assurance arguments hold the information about the argument's structure and are used as a template for creating specific arguments.

In AgileSafe, assurance arguments are developed separately for each applicable standard in order to support certification on the standard by standard basis. A more detailed description of the assurance cases employed in AgileSafe (see Figure 2) is given below.

A. Practices Compliance Argument

Practices Compliance Argument is a template which is developed separately for each relevant standard. Its structure is based on the standard requirements. To make such templates uniform, each template is following the *Practices Compliance Pattern*. This pattern is generic and focuses on the conformance of practices from *AgileSafe Practices Knowledge Base* with particular requirements of the considered standard. For each such requirement it proposes an argumentation strategy and the range of software engineering practices used for collecting evidence demonstrating the compliance. It also contains explicit justification that the argumentation strategy is adequate on the condition that the evidence is collected and integrated with the argument. A list of claims concerning different types of practices, which may contribute to satisfying the standard demand, is presented, each claim postulating the potential of a given practice to generate the evidence needed to demonstrate compliance.

If the *Practices Knowledge Base* is complete, the *Practices Compliance Argument* once prepared for a specific standard remains unchanged and can be used in multiple projects which have to comply with the standard. Nevertheless, in the 'learning period' of the AgileSafe method the *Practices Knowledge Base* is expected to grow acquiring new practices and therefore the *Practices Compliance Arguments* will change and evolve in time.

B. Project Practices Compliance Argument

Project Practices Compliance Argument is a *Practices Compliance Argument* adapted to a specific project and is characterized by the *Project Practices Set* specific to this project. The *Project Practices Compliance Argument* refers only to the practices used in the project along with the description of *Evidence* they are providing. Its structure is defined in the *Project Practices Compliance Pattern*.

C. Project Compliance Argument

Project Compliance Argument is an assurance argument in its traditional form. It is structured around a particular standard and is used to collect the required product related evidence to demonstrate conformance with given standard. The *Evidence* should be collected with accordance to the *Project Compliance Pattern* and be an effect of AS.P.7 *Apply practices* process.

D. Tool support for assurance cases

To handle assurance cases AgileSafe follows the TRUST-IT methodology [15] and uses the Argevide NOR-STA [16] services. NOR-STA provides means for developing, maintaining and assessing assurance cases and integrating them with the supporting evidence. All the assurance cases presented in Section VI were developed using this tool.

In NOR-STA, argument conclusion is represented by a *claim* node. A node of type *argumentation strategy* links the claim with the corresponding premises and uses a *rationale* node to explain and justify the inference leading from the premises to the claim. A premise is a sort of assertion and can be in particular another claim to be further justified by its own premises or a *fact* represented by an assertion to be demonstrated by the supporting evidence. The evidence is integrated by nodes of type *reference* which point to external resources (files of any type, web pages, etc.). In addition, *information* nodes can be used in any place to provide explanatory information.

IV. Practices Selection Process

In order to support users while selecting the software engineering practices from the *AgileSafe Practices Knowledge Base,* AgileSafe offers the guidance, which is based on *Project characteristics.* The practices maintained in the *AgileSafe Practices Knowledge Base* include both plan-driven and agile methods documented in the literature, and may also include custom developed hybrid practices. Upon the selection of the practices an assurance argument is composed along with assurance arguments for selected standards.

Users are able to introduce their own practices into the *Knowledge Base* by following the AS.P.2.1 *Introduce new practice p*rocess.

V. Assessing Conformance

The process of assessing conformance with given standards is based on the set of assurance arguments, mainly the *Project Compliance Arguments*.

The *Project Compliance Arguments* are being developed in parallel to the software development process (AS.P.7 *Apply practices*). The *Evidence* prepared in the course of AS.P.7 *Applying practices* from the *Project Practices Set*

should be placed in the accurate nodes as indicated in the *Project Practices Compliance Arguments*. Upon the certification process for a particular *Standard* User should be able to prove conformance by presenting the applicable *Project Compliance Argument* along with *Project Practices Compliance Argument*, which contains additional reasoning behind the choice of practices (*PPS*) and *Evidence* used in the process.

VI. Conclusion

In this article we presented an overview of AgileSafe, a method of agile software development with simultaneous controlling conformity with selected safety related standards.

The ultimate objective is to help SMEs involved in safety-critical software development to introduce agile practices in the most profitable way while meeting the requirements imposed by safety standards and certification bodies.

Recently we conducted a case study which goal was to use AgileSafe to incorporate selected risk management practices into an agile project with safety requirements. We have followed all of the steps of the AgileSafe method algorithm and prepared the artefacts as specified in the method, collecting all the metrics that we planned to collect. A complete set of AgileSafe assurance cases was prepared for ISO 14971 standard. The basic result of the case study was that it was possible to conduct an agile project while still controlling its conformity to the ISO 14971 requirements.

In the nearest future we plan to interview experts in the field of safety certification as well as practitioners who were involved in adapting agile practices to safety-critical system development in order to obtain their feedback on AgileSafe.

4th Workshop on Model Driven Approaches in System Development

FOR many years, various approaches in system design and implementation differentiate between the specification of the system and its implementation on a particular platform. People in software industry have been using models for a precise description of systems at the appropriate abstraction level without unnecessary details. Model-Driven (MD) approaches to the system development increase the importance and power of models by shifting the focus from programming to modeling activities. Models may be used as primary artifacts in constructing software, which means that software components are generated from models. Software development tools need to automate as many as possible tasks of model construction and transformation requiring the smallest amount of human interaction.

A goal of the proposed workshop is to bring together people working on MD languages, techniques and tools, as well as Domain Specific Languages (DSL) and applying them in the requirements engineering, information system and application development, databases, and related areas, so that they can exchange their experience, create new ideas, evaluate and improve MD approaches and spread its use. The intention is to target an interdisciplinary nature of MD approaches in software engineering, as well as research topics expressed by but not limited to acronyms such as Model Driven Software Engineering (MDSE), Model Driven Software Development (MDSD), Domain Specific Modeling (DSM), and OMG's Model Driven Architecture (MDA).

1st Workshop on MDASD was organized in the scope of ADBIS 2010 Conference, held in Novi Sad, Serbia. From 2012, MDASD becomes a regular bi-annual FedCSIS event.

TOPICS

***Abstract*—In this paper, we present our approach which aims at improving the mechanism of constructing language semantics over the interoperability of domain-specific modeling languages (DSMLs) developed for Multi-agent Systems (MAS) and hence providing a more efficient way of extension for the executability of modeled agent systems on various underlying agent platforms. Differentiating from the existing MAS DSML studies, our proposal is based on determining entity mappings and building horizontal model transformations between the metamodels of MAS DSMLs which are in the same abstraction level. The applicability of the approach is demonstrated in the paper by constructing horizontal transformations between two full-fledged agent DSMLs, called SEA_ML and DSML4MAS. Use of these transformations has enabled SEA_ML instance models now to be executable on new agent platforms and that feature has been provided with less effort comparing with the implementation of needed transformations between SEA_ML and those new agent platforms from scratch.**

***Keywords*—Metamodel; Model transformation; Domain-specific Modeling Language; Multi-agent System**

I. Introduction

Multi-agent systems (MASs) are those systems having software agents within an environment where agents interact to solve problems in a competitive or collaborative manner. In MASs, software agents are expected to be autonomous, mostly through a set of reactive/proactive behaviors designed for addressing situations likely to happen in particular domains [1]. Both internal agent behavior model and interactions within a MAS become even more complex and hard to implement when taking into account the varying requirements of different agent environments [2]. Hence, working in a higher abstraction level is of critical importance for the development of MASs since it is almost impossible to observe code level details of MASs due to their internal complexity, distributedness and openness [3].

In order to master the abovementioned problems of developing MASs, agent-oriented software engineering (AOSE) researchers define various agent metamodels (e.g. [4-7]), which include fundamental entities and relations of agent systems. In addition, many model-driven agent development approaches are provided such as [8-10] and by enriching MAS metamodels with some defined syntax and semantics (usually translational semantics [11]), researchers also propose domain-specific languages (DSLs) / domain-specific modeling languages (DSMLs) (e.g. [12-20]) for facilitating the development of MASs. DSLs / DSMLs [21-23] have notations and constructs tailored toward a particular application domain (e.g. MAS) and help to the model-driven development (MDD) of MASs. MDD aims to change the focus of software development from code to models [24], and hence many AOSE researchers believe that this paradigm shift introduced by MDD may also provide the desired abstraction level and simplify the development of complex MAS software [3].

In AOSE, perhaps the most popular way of applying model-driven engineering (MDE) for MASs is based on providing DSMLs specific to agent domain with including appropriate integrated development environments (IDEs) in which both modelling and code generation for system-to-be-developed can be performed properly. Proposed MAS DSMLs such as [13], [17], [19] usually support modelling both the static and the dynamic aspects of agent software from different MAS viewpoints including agent internal behaviour model, interaction with other agents, use of other environment entities, etc. Within this context, abstract syntaxes of the languages are represented with metamodels covering those aspects and required viewpoints to some extent. Following the construction of abstract and concrete syntaxes based on the MAS metamodels, the operational semantics of the languages are provided in the current MAS DSML proposals by defining and implementing entity mappings and model-to-model (M2M) transformations between the related DSML's metamodel and the metamodel(s) of popular agent implementation and execution platform(s) such as JACK[1], JADE[2] and JADEX[3]. Finally, a series of model-to-text (M2T) transformations are implemented and applied on the outputs of the previous M2M transformations which are the MAS models conforming to the related agent execution platforms. Hence, agent software codes, MAS configuration files, etc. pertaining to the implementation and deployment of the modeled agent systems on the target MAS platform are generated automatically.

When we take into account the different abstractions covered by the metamodels of MAS DSMLs and the underlying agent execution platforms, DSML metamodels can be accepted as the platform-independent metamodels (PIMMs) of agent systems while metamodels of the agent execution platforms are platform-specific metamodels

This study is funded by the Scientific Research Projects Directorate of Ege University under grant 16-UBE-001.

(PSMMs) according to the OMG's well-known Model-driven Architecture (MDA)[4] as also indicated in [5] and [9].

Above described methodology applied in the current MAS DSML development approaches for the derivation of operational semantics unfortunately requires the definition and implementation of new M2M and M2T transformations from scratch in order to make the DSMLs functional for different agent execution platforms. In other words, for each new target agent execution platform, MAS DSML designers should repeat all the time-consuming and mostly troublesome steps of preparing the vertical transformations between the related DSML and this new agent platform.

Motivated by the similarity encountered in the abstract syntaxes of the available MAS DSMLs, we are quite convinced that both the definition and the implementation of M2M transformations between the PIMMs of MAS DSMLs would be more convenient and less laborious comparing with the transformations required between MAS PIMMs and PSMMs in the way of enriching the support of MAS DSMLs for various agent execution platforms. Hence, in this paper, we present our approach which aims at improving the mechanism of constructing language semantics over the interoperability of MAS DSMLs and hence providing a more efficient way of extension for the executability of modeled agent systems on various underlying agent platforms. Differentiating from the existing MAS DSML studies (e.g. [13], [16], [17], [19], [20]), our proposal is based on determining entity mappings and building horizontal M2M transformations between the metamodels of MAS DSMLs which are in the same abstraction level. In this paper, we also investigate the applicability of the proposed DSML interoperability approach by constructing horizontal transformations between two full-fledged agent DSMLs called SEA_ML [19] and DSML4MAS [5] respectively.

The rest of the paper is organized as follows: In Sect. 2, the approach for the MAS DSML interoperability is presented. Applicability of the approach is discussed in Sect. 3 by taking into consideration two MAS DSMLs. In Sect. 4, a case study on the development of an agent-based stock exchange system with using the proposed approach is given. Related work is given in Sect. 5. Finally, Sect. 6 concludes the paper and states the future work.

II. Proposed Approach for the Interoperability of MAS DSMLs

As indicated in the introduction, support of current MAS DSMLs for each agent execution platform is enabled by repetitively defining and implementing a chain of vertical M2M and M2T transformations. Available M2M and M2T transformations are specific for each different agent platform and almost all of them can not be re-used while extending the executability of the MAS models for a new agent platform. Due to the difficulty encountered on repeating those vertical model transformation steps, current MAS DSML proposals (e.g. [13-15], [17], [19]) mostly support the execution of modeled agents on just one agent platform. Rarely, two different platforms are supported (e.g. [5], [9]) and as far as we know, there is no any MAS DSML which provides an operational semantics for more than two different agent execution platforms. In order to increase the platform variety, we propose benefiting from the vertical transformations already existing between the syntax of a MAS DSML (let us call $DSML_1$) and metamodels of various agent platforms for enabling model instances of another MAS DSML (let us call $DSML_2$) executable on the same agent platforms by just constructing horizontal transformations between the PIMMs of the MAS DSMLs in question. Therefore, instead of defining and implementing N different M2M and M2T transformations for N different agent platforms, creation of only one single set of M2M transformations between $DSML_1$ and $DSML_2$ can be enough for the execution of $DSML_2$'s model instances on these N different agent platforms.

Fig. 1 depicts the construction of model transformations between MAS DSMLs and hence re-use of already existing transformations between those DSMLs and agent platforms. Let the abstract syntaxes of $DSML_1$, $DSML_2$ and $DSML_3$ be the metamodels MM_1, MM_2 and MM_3 respectively. Horizontal lines between these MAS DSMLs represent the M2M transformations between these metamodels. According to the figure, agent systems modeled in $DSML_1$ are already executable on the agent platforms A and B (due to the existing vertical transformations for these platforms), while $DSML_2$ model instances are executable on the agent platforms X, Y and Z. Similarly M2M and M2T transformations were already provided for the execution of $DSML_3$ model instances on the agent platforms α, β, θ respectively. If $DSML_1$ is required to support X and Y agent platforms, designers should prepare new model transformations separately for those agent platforms (shown with dotted arrows in Fig. 1) in case of the absence of horizontal transformations between MM_1 and MM_2. Hence, construction of only one set of horizontal M2M transformations between $DSML_1$ and $DSML_2$ enables $DSML_1$'s automatic support on agent platforms X, Y (and also Z). Conversely, same is also valid for extending the $DSML_2$'s support for agent execution platforms. Interoperability between $DSML_1$ and $DSML_2$ over these newly defined horizontal transformations also makes transformation and code generation of $DSML_2$ model instances for the agent platforms A and B. In addition to the important decrease in the number of transformations, construction of horizontal model transformations between the PIMMs of MAS DSMLs is more feasible and easier than the vertical transformations since the DSMLs are in the same abstraction level according to MDA.

III. Interoperability between SEA_ML and DSML4MAS

In this section, we discuss the applicability of the proposed approach by taking into account the construction of the interoperability between two MAS DSMLs called SEA_ML and DSML4MAS. Both DSMLs enable the

[4] http://www.omg.org/mda/ (last access: June 2016)

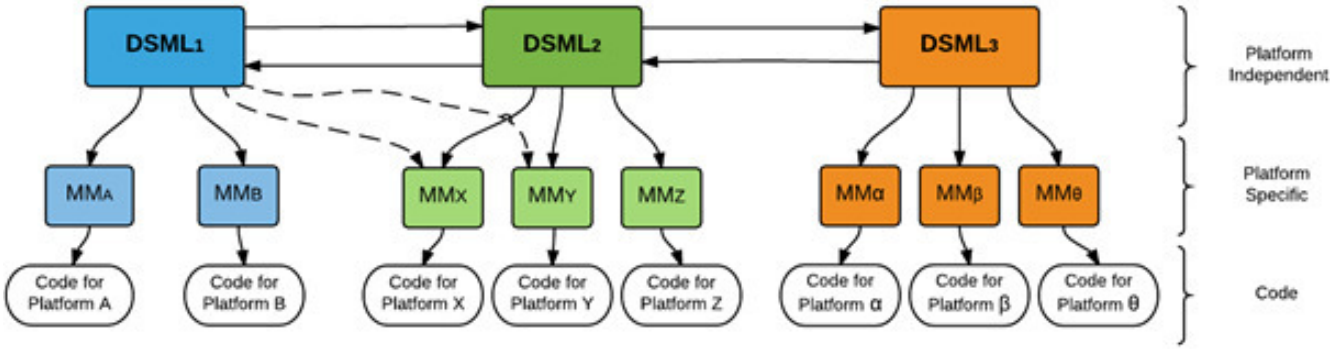

Fig. 1 Interoperability of MAS DSMLs via horizontal model transformations

modeling of agent systems according to various agent internal and MAS organizational viewpoints. They provide a clear visual syntax for MAS modeling and code generation for agent implementation and execution platforms. Moreover, both languages are equipped with Eclipse-based IDEs in which modeling and automatic generation of MAS components are possible. These features of the languages led us to choose them in this study. In the following subsections, brief introduction of these DSMLs and implemented model transformations between these languages are given.

A. SEA_ML

SEA_ML [19] provides a convenient and handy environment for agent developers to construct and implement software agent systems working on various application domains. In order to support MAS experts when programming their own systems, and to be able to fine-tune them visually, SEA_ML covers all aspects of an agent system from the internal view of a single agent to the complex MAS organization. In addition to these capabilities, SEA_ML also supports the model-driven design and implementation of autonomous agents who can evaluate semantic data and collaborate with semantically-defined entities of the Semantic Web, like Semantic Web Services (SWS) [25]. That feature exactly differentiates SEA_ML and makes unique regarding any other MAS DSML currently available. Within this context, it includes new viewpoints which specifically pave the way for the development of software agents working on the Semantic Web environment. Modeling agents, agent knowledgebases, platform ontologies, SWS and interactions between agents and SWS are all possible in SEA_ML.

SEA_ML's metamodel is divided into eight viewpoints, each of which represents a different aspect for developing Semantic Web enabled MASs [19]. *Agent's Internal Viewpoint* is related to the internal structures of semantic web agents (SWAs) and defines entities and their relations required for the construction of agents. It covers both reactive and Belief-Desire-Intention (BDI) agent architectures. *Interaction Viewpoint* expresses the interactions and communications in a MAS by taking messages and message sequences into account. *MAS Viewpoint* solely deals with the construction of a MAS as a whole. It includes the main blocks which compose the complex system as an organization. *Role Viewpoint* delves into the complex controlling structure of the agents and addresses role types. *Environmental Viewpoint* addresses the use of resources and interaction between agents with their surroundings. *Plan Viewpoint* deals with an agent Plan's internal structure, which are composed of Tasks and atomic elements such as Actions. *Ontology Viewpoint* addresses the ontological concepts which constitute agent's knowledgebase (such as belief and fact). *Agent - SWS Interaction Viewpoint* defines the interaction of agents with SWS including the definition of entities and relations for service discovery, agreement and execution. A SWA executes the semantic service finder Plan (SS_FinderPlan) to discover the appropriate services with the help of a special type of agent called SSMatchMakerAgent who executes the service registration plan (SS_RegisterPlan) for registering the new SWS for the agents. After finding the necessary service, one SWA executes an agreement plan (SS_AgreementPlan) to negotiate with the service. After negotiation, a plan for service execution (SS_ExecutorPlan) is applied for invoking the service.

The collection of SEA_ML viewpoints constitutes an extensive and all-embracing model of the MAS domain. SEA_ML's abstract syntax combines the generally accepted aspects of MAS (such as MAS, Agent Internal, Role and Environment) and introduces two new viewpoints (Agent-SWS Interaction and Ontology) for supporting the development of software agents working within the Semantic Web environment [2].

SEA_ML can be used for both modeling MASs and generation of code from the defined models. SEA_ML instances are given as inputs to a series of M2M and M2T transformations to achieve executable artifacts of the system-to-be-built for JADEX agent platform and semantic web service description documents conforming to *Web Ontology Language for Services (OWL-S)* ontology[5]. It is also possible to automatically check the integrity and validity of SEA_ML models [26]. Complete discussion on SEA_ML can be found in [19].

[5] https://www.w3.org/Submission/OWL-S/ (last access: June 2016)

B. DSML4MAS

DSML4MAS [5], [13] is perhaps one of the first complete MAS DSMLs in which a PIMM, called PIM4Agents, provides an abstract syntax for different aspects of agent systems. Similar to SEA_ML's viewpoints, both internal behavior model of agents and agent interactions in a MAS are covered by PIM4Agents views / aspects. *Multiagent view* contains all the main concepts in a MAS such as Agent, Cooperation, Capability, Interaction, Role and Environment. *Agent view* focuses on the single autonomous entity (agent), the roles it plays within the MAS and the capabilities it has to solve tasks and to reach the environment resources. *Behavioural view* describes how plans are composed by complex control structures and simple atomic tasks like sending a message and how information flows between those constructs. In here, a plan is a specialized version of behavior composed of activities and flows. Activities and tasks are minimized parts of the work and flows provide the communication between these parts. *Organization view* describes how single autonomous entities cooperate within the MAS and how complex organizational structures can be defined. Social structure in the system is defined with cooperation entity where agents and organizations take part in. The structure has its own protocol defining how the entities interact in a cooperation. Agents have "domainRoles" for the interaction and these roles are attached to actors by "actorBinding" entities where actors are representative entities within the corresponding interaction protocol. *Role view* examines the behaviour of an agent entity in an organization or cooperation. An agent's role covers the capabilities and information to have access to a set of resources. *Interaction view* describes how the interaction in the form of interaction protocols takes place between autonomous entities or organizations. Agents communicate over the PIM4Agents Protocol which refers to actors and "messageFlows" between these actors. Finally, *Environment view* contains the resources accessed and shared by agents and organizations. Agents can communicate with the environment indirectly via using resources. Resources can store knowledge from BDI agents for changing beliefs by using Messages and Information flows.

As indicated in [5], grouping modelling concepts in DSML4MAS allows the metamodel evolution by adding new modelling concepts in the existing aspects, extending existing modelling concepts in the defined aspects, or defining new modelling concepts for describing additional aspects of agent systems. For instance, SWS integration into the system models conforming to DSML4MAS is provided via introducing the SOAEnvironment entity [27] which extends the Environment entity and contains service descriptions. Agents use service descriptions to specify the Services they are searching for and then service interaction is realized by InvokeWS and ReceiveWS tasks which are inherited from Send and Receive task entities described in PIM4Agents.

Similar to SEA_ML, DSML4MAS also enables the MDD of MAS including a concrete graphical syntax [28] based on the abovementioned PIMM (PIM4Agents) and an operational semantics for the execution of modeled agent systems on JACK or JADE agent platforms. Extensions to the language introduced in [27] provide the description of the services inside an agent environment according to specifications such as *Web Services Modeling Language (WSML)*[6] or *Semantic Annotation of WSDL and XML Schema (SAWSDL)*[7]. Interested readers may refer to [5], [13] and [27] for an extensive discussion on DSML4MAS.

C. Horizontal Model Transformations between SEA_ML and DSML4MAS

We have applied the horizontal transformability approach described in Sect. 2 for establishing the interoperability between SEA_ML and DSML4MAS. As shown in Fig. 2, SEA_ML currently supports the MAS implementation for JADEX BDI architecture and SWS generation according to the OWL-S ontology. In order to extend its platform support capability, new M2M and M2T transformations should be prepared for each new implementation platform. For instance, M2M transformations are needed between the abstract syntax of SEA_ML and PSMM of JADE framework to make SEA_ML instances also executable on the JADE platform. It is worth indicating that definition and application of M2T transformations are also required for the code generation from the outputs of the previous SEA_ML to JADE transformations. Instead, we can follow the approach introduced in Sect. 2 by just writing the horizontal transformation rules between the metamodels of SEA_ML and DSML4MAS and running those transformations on SEA_ML instances for the same purpose: making SEA_ML models executable also on JADE platform. That is possible since DSML4MAS has already support on JADE and JACK agent platforms and SAWSDL and WSDL semantic service ontologies via vertical transformations between its metamodel and metamodels of the corresponding system implementation platforms. Realization of horizontal transformations between SEA_ML and DSML4MAS has extra benefits such as the execution of SEA_ML instances also on JACK platform and/or implementation of the modeled SWS according to SAWSDL or WSDL specifications (Fig. 2).

Before deriving the rules of transformations, we should determine the entity mappings between both languages since the transformations are definitely based on these entity mappings. Comparing with the mappings we previously provided in [15] or [19] for the transformability of SEA_ML instances to MAS execution platforms, we have experienced that the determination of the entity mappings in this study was easier and took less time. We believe that the reason of this efficiency originates from the fact that metamodels of SEA_ML and DSML4MAS are in the same abstraction level and provide close entities and relations in similar viewpoints for MAS modeling.

[6] http://www.wsmo.org/wsml/ (last access: June, 2016)
[7] https://www.w3.org/TR/sawsdl/ (last access: June, 2016)

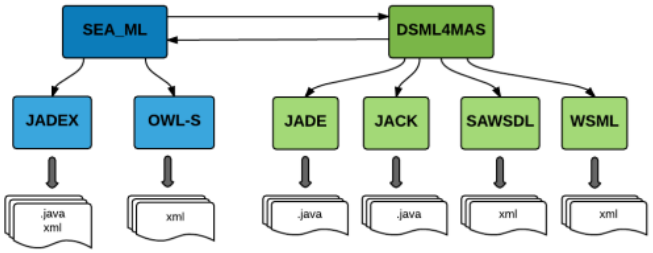

Fig. 2 Interoperability of SEA_ML and DSML4MAS

Table 1 lists some of the important mappings constructed between first-class entities of these two languages. For instance, two agent types (SWA and SSMatchmakerAgent) defined in SEA_ML are mapped onto the autonomous entity Agent defined in DSML4MAS. Likewise, meta-entities pertaining to agent plan types (SS_RegisterPlan, SS_FinderPlan, SS_AgreementPlan and SS_ExecutorPlan) required for the interaction between the semantic services are mapped with the Plan concept of DSML4MAS. Since Actor entity in DSML4MAS has access to resources and owns capabilities needed for agent interactions, SEA_ML's Role entity is mapped onto Actor entity.

One interesting mapping is encountered between SEA_ML's SWS entity and DSML4MAS's SOAEnvironment since it enables the representation of SEA_ML semantic services in DSML4MAS model instances. On the DSML4MAS side, SOAEnvironment entity, which is extended from Environment entity, includes services in general. Hence, SEA_ML SWS entity is mapped onto SOAEnvironment entity and SEA_ML WebService entities are mapped onto Service entities. In SEA_ML WebService definition, every service has Interface, Process and Grounding. Interface entity represents the information about service inputs, outputs and any other necessary information. Process entity has internal information about the service and finally Grounding entity defines the invocation protocol of the web service [19]. DSML4MAS services are described with Blackbox and Glassbox entities [27]. BlackBox is used to define a service's functional and non-functional parameters while Glassbox includes the description of the internal service process. The Functionals are described in terms of service signature that are input and output parameters, and specifications that are preconditions and effects. The NonFunctionals are defined in terms of price, service name and developer. Hence, Interface and Process entities of services defined in SEA_ML are mapped onto DSML4MAS Functionals which have input and output definitions. On DSML4MAS side, agent interactions with services are provided by InvokeWS and ReceiveWS tasks. So, SEA_ML Grounding, which represents the physical structure of the underlying web service executed for the corresponding SWS, is mapped to InvokeWS. Remaining mappings listed in Table 1 (e.g. SEA_ML SWO to DSML4MAS Organization, SEA_ML Environment to DSML4MAS Environment) are very simple to determine since the related entities on both sides have similar or almost same functionality within the syntaxes of the languages.

TABLE I.
ENTITY MAPPINGS BETWEEN THE METAMODELS OF SEA_ML AND DSML4MAS

SEA_ML MM	DSML MM
SWA (Semantic Web Agent)	Agent
SSMatchmakerAgent	Agent
Role	Actor
SWS (Semantic Web Service)	SOAEnvironment
Environment	Environment
WebService	Service
Interface	Functionals
Process	Functionals
Grounding	InvokeWS
Input	Input
Output	Output
Precondition	Precondition
SS_RegisterPlan	Plan
SS_FinderPlan	Plan
SS_AgreementPlan	Plan
SS_ExcecutorPlan	Plan
SWO (Semantic Web Organization)	Organization

After determining the entity mappings between SEA_ML and DSML4MAS, it is necessary to provide model transformation rules which are applied at runtime on SEA_ML instances to generate DSML4MAS counterparts of these instances. For that purpose, transformation rules should be formally defined and written according to a model transformation language. In this study, we preferred to use ATL Transformation Language (ATL)[8] to define the model transformations between SEA_ML and DSML4MAS. ATL is one of the well-known model transformation languages, specified as both metamodel and textual concrete syntax. An ATL transformation program is composed of rules that define how the source model elements are matched and navigated to create and initialize the elements of the target models. In addition, ATL can define an additional model querying facility which enables specifying the requests onto models. ATL also allows code factorization through the definition of ATL libraries. Finally, ATL has a transformation engine and an IDE that can be used as a plug-in on an Eclipse platform. These features of ATL caused us to prefer it as the implementation language for the horizontal transformations from SEA_ML to DSML4MAS.

ATL is composed of four fundamental elements. The first one is the header section defining attributes relative to the transformation module. The next element is the import section which is optional and enables the importing of some existing ATL libraries. The third element is a set of helpers

[8] https://eclipse.org/atl/(last access: June, 2016)

that can be viewed as the ATL equivalents to the Java methods. The last element is a set of rules that defines the way target models are generated from source models.

Following listings include some excerpts from the written ATL rules in order to give some flavor of M2M transformations provided in this study. To this end, rule in Listing 1 enables the transformation of the elements covered by the Agent-SWS Interaction viewpoint of SEA_ML to their counterparts included in DSML4MAS's Multiagent system viewpoint. In line 1, rule is named uniquely. In line 2, the source metamodel is chosen and renamed as swsinteractionvp with "from" keyword. The target metamodel is indicated and renamed as pim4agents with "to" keyword (Line 3). In the following lines (between 4 and 14), instances of SEA_ML SWA and SSMatchmakerAgent entities are selected and transformed to DSML4MAS Agent instances. Transformation of agent roles and plans are also realized by using "Set" and "allInstances" functions. It is worth indicating that types of Plan instances seem to be transformed to DSML4MAS behavior in the given listing although all SEA_ML Plan types are semantically mapped to DSML4MAS Plan as listed in Table 1. That is because some of the DSML4MAS meta-entities are collected with tag definitions in Ecore representations which take the same name with the related viewpoint. For instance, plans are not defined solely with their names; instead they are collected in behavior definitions. Hence, in order to provide the full transformations of the plans with all their attributes, ATL rule is written here as mapping SEA_ML plan instances to the DSML4MAS behaviors. Inside another helper rule, those behaviors are separated into the corresponding plans and so exact transformation of SEA_ML plan instances to DSML4MAS plans are realized.

```
01 rule SWSInteractionVP2MultiagentSystem {
02  from   swsinteractionvp: SWSInteraction!SWSInteractionViewpoint
03  to     pim4agent: PIM4Agents!MultiagentSystem(
04       agent <- Set{SWSInteraction!SemanticWebAgent.allInstances()},
05       agent <- Set{SWSInteraction!SSMatchmakerAgent.allInstances()},
06       role <- Set{SWSInteraction!Role.allInstances()},
07       role <- Set{SWSInteraction!RegistrationRole.allInstances()},
08       behavior <- Set{SWSInteraction!SS_AgreementPlan.allInstances()},
09       behavior <- Set{SWSInteraction!SS_ExecutorPlan.allInstances()},
10       behavior <- Set{SWSInteraction!SS_FinderPlan.allInstances()},
11       behavior <- Set{SWSInteraction!SS_RegisterPlan.allInstances()},
12       environment<-Set{SWSInteraction!SWS.allInstances()},
13       environment<-Set{SWSInteraction!Grounding.allInstances()} )
14 }
```

Listing 1 An excerpt from the SWSInteractionVP2MultiagentSystem rule

Another example can be given for the transformation of SEA_ML SWS instances to DSML4MAS SOAEnvironment instances. In Listing 2, the first rule provides the related transformation. After controlling the name of the SWS by applying the helper rule "nameControl", its attributes are converted to their counterparts in the abstract syntax of DSML4MAS. Again with using helper rules, the web services composed by this semantic service are determined and transformed to DSML4MAS Service instances. Only a fragment of SWS2SOAEnvironment can be given in here due to space limitations. The remaining part of this rule provides the transformation of each SEA_ML semantic service's discovery, engagement and execution components (e.g. Interface, Process and Grounding) to their counterparts in DSML4MAS models according to the mappings given in Table 1.

```
01  rule SWS2SOAEnvironment{
02    from  envIN: SWSInteraction!SWS(envIN.nameControl)
03    to envOUT: PIM4Agents!SOAEnvironment (
04          name <- envIN.setName(),
05          service<-envIN.setWebServices()
06    )
07  }

08  rule WebService2Service{
09    from  webService: SWSInteraction!WebService
10    to service: PIM4SWS!Service (
11          ID<- webService.setName()
12    )
13  }
```

Listing 2 Excerpts from the SWS2SOAEnvironment and WebService2Service rules

In Listing 3, the helper rules used in above transformation rules are given. "nameControl" helper is executed on the SEA_ML SWS instances. It controls whether a SWS has a name attribute. Based on this attribute's existence, the rules returns true (line 4) or false (line 5). That Boolean result is evaluated by the caller rule given in Listing 2. In the second helper rule, the name attribute of a semantic service is controlled. In case of the name is empty, the string given in line 10 is assigned as the value for the transformed service's (SOAEnvironment) name attribute. Otherwise, the name of the source SWS is returned back to the called rule (SWS2SOAEnvironment) to be assigned as the name of the transformed SOAEnvironment instance which will be included in the target DSML4MAS model.

```
01  helper context SWSInteraction!SWS
02    def: nameControl: Boolean =
03      if not (self.name.oclIsUndefined())
04        then  true
05        else  false
06      endif;

07  helper context SWSInteraction!SWS
08    def: setName(): String =
09      if (self.name = '')
10        then 'SERVICE_NAME_IS_EMPTY'
11        else  self.name
12      endif;
```

IV. Case Study: Agent-Based Stock Exchange System

In this section, the interoperability of SEA_ML and DSML4MAS is demonstrated by applying the proposed horizontal model transformations for the development of an agent-based stock exchange system. The system is modeled in SEA_ML and transformed to a DSML4MAS instance to use the generation power of DSML4MAS language. In this way, the implementation of this system's agents on JADE (or JACK) platform and services as SAWSDL or WSML ontology instances can be possible by using the operational semantics of DSML4MAS which is already provided for the

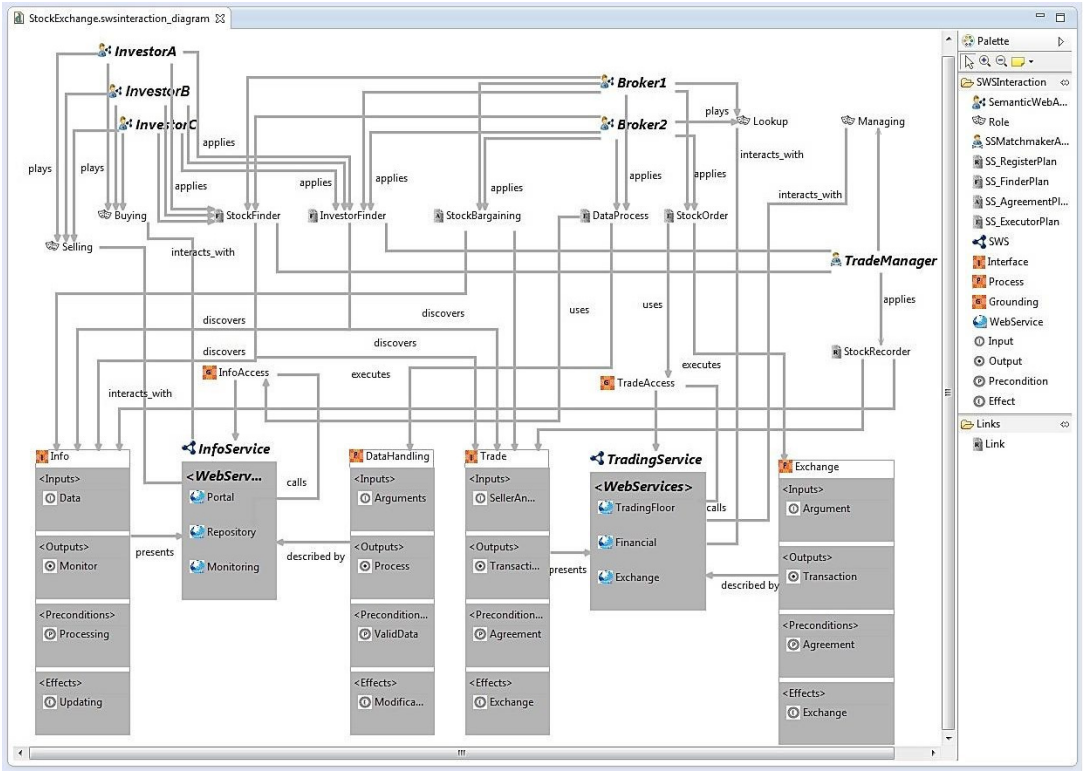

Fig. 3 Instance model of the multi-agent stock exchange system in SEA_ML with including the agents, semantic web services and their relations

execution of agents and the generation of semantic web services (see Fig. 2).

Stock trading is one of the key items in economy and estimating its behavior and taking the best decision in it are among the most challenging issues. Agents in a MAS can share a common goal or they can pursue their own interests. That nature of MASs exactly fits to the requirements of free market economy. Moreover, Stock Exchange Market has lots of services which are offered for Investors (Buyer or Seller), Brokers, and Stock Managers. These services can be represented with semantic web services to achieve more accurate service finding and service matching.

When considering the structure of the system, the semantic web agents work within a semantic web organization for Stock System including sub-organizations for Stock Users where the Investor and Broker agents reside, and the Stock Market where the system's internal agents, e.g. Trade Manager (a SSMatchmaker agent instance) work. The Stock Market organization also has two sub-organizations, the Trading Floor and the Stock Information System. These organizations and sub-organizations have their own organizational roles. These organizations also need to access some resources in other environments. Therefore, they have interactions with the required environments to gain access permissions. For example, agents in the Stock Market sub-organization need to access bank accounts and some security features, so that they can interact with the Banking & Security environment. All of the user agents including Investors and Brokers cooperate with Trade Manager to access the Stock Market. Also, the user agents interact with each other. For instance, Investor Agents can cooperate with Brokers to exchange stock for which Brokers are expert. More information on developing such stock trading agents can be found in [29].

To model the system in SEA_ML, Agent-SWS Interaction viewpoint is considered as the representative for SEA_ML viewpoints. This viewpoint is the most important aspect of MASs working in semantic web environments. Fig. 3 shows a screenshot from the SEA_ML's modeling environment in which instances of both the semantic services and the agent plans required for the stock exchange are modeled, including their relations according to Agent-SWS interaction viewpoint of SEA_ML. Investor and Broker agents can be modeled with appropriate plan instances in order to find, make the agreement with and execute the services. The services can also be modeled for the interaction between the semantic web service's internal components (such as Process, Grounding, and Interface), and the SWA's plans. It is important to indicate that the stock exchange system given in here was already modeled in the SEA_ML environment before this study and instead of re-modeling the whole system (e.g. in DSML4MAS), the existing model is intentionally adopted in here to examine the applicability of the proposed approach. In fact, the model in question is much more complicated and we can only consider the agent-SWS interaction aspect due to page limits of this paper. Discussion on the whole model can be found in [19] and the sources of the model are available at the SEA_ML's distribution website[9].

[9] SEA_ML, its modeling tool and the instance models for the case study are available at: http://serlab.ube.ege.edu.tr/resources.html (last access: June 2016)

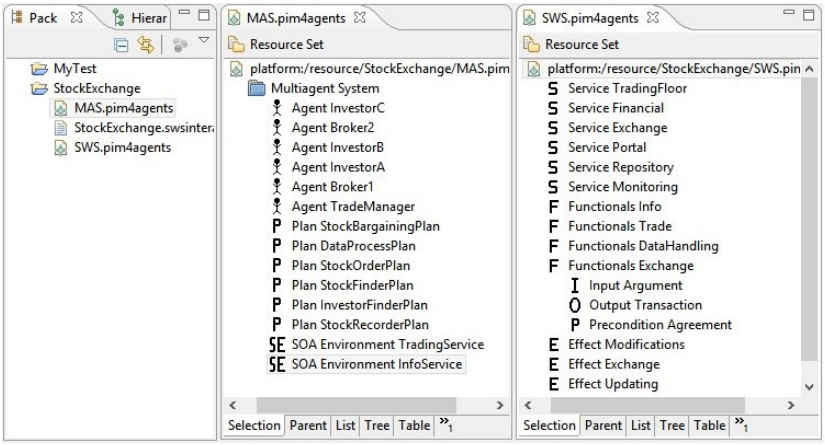

Fig. 4 An excerpt of the output in its Ecore tree view representation achieved after executing the M2M transformations on the SEA_ML instance

We can see from the instance model given in Fig. 3 that an investor agent (e.g. InvestorA) would play the Buying role and apply its StockFinder plan for finding an appropriate Trading service interface of one TradingService SWS in order to buy some stocks. This plan would realize the discovery by interacting with the TradeManager SSMatchmakerAgent which has registered the services by applying the StockRecorder plan. As InvestorA cooperates with Broker1 in order to receive some expert advice for its investment, at the next step, the Broker1 agent applies its StockBargaining plan for negotiating with the already discovered services. This negotiation would be made through the Trade interface of the SWS. Finally, if the result of the negotiation were positive, the agent would apply the StockOrder plan to call the TradingFloor of the SWS by executing its Exchange process and using its TradeAccess grounding with which the service would be realized. In a similar way, Investor agents could cooperate with Brokers and interact with the TradeManager in order to collect some information about the market, e.g. the rate of exchange for a currency or the fluctuation rate for a specific stock.

The designed instance model is controlled based on the provided constraint rules in SEA_ML tool to check its validity. Then, the horizontal model transformations discussed in the previous section are executed on this SEA_ML instance model and as result, we have succeeded to automatically achieve the counterpart models conforming to DSML4MAS. To realize the transformation, the SEA_ML metamodel, the SEA_ML instance models for this case study, and the DSML4MAS metamodel are given to the ATL engine as input and the instance models of the case study in DSML4MAS are generated by the engine with executing our transformation rules. An excerpt of the XMI file containing the output DSML4MAS instance model is given in Fig. 4 in which the output instance can be seen in its Ecore tree view representation.

The generated model conforms to the specification of DSML4MAS's abstract syntax, so it can be handled with DSML4MAS's graphical editor[10]. To visualize the instance model in DSML4MAS, the only thing needed is to add the related graphical notations to the generated instance model. The screenshot given in Fig. 5 shows the appearance of output instance model in the concrete syntax of DSML4MAS. We can examine from the figure that the agents and their relations we modeled in SEA_ML are exactly reflected to a DSML4MAS model after execution of the M2M transformations proposed in this study. From now on, it is straightforward to automatically achieve platform-specific executables and documents of this MAS model for JADE or JACK agent platforms and SAWSDL or WSML semantic service ontologies since DSML4MAS has already own a chain of M2M and M2T transformations for these agent execution platforms and service ontologies as discussed in Sect. 3.2.

V. Related Work

In the last decade, AOSE researchers have noteworthy efforts on the derivation and use of DSLs / DSMLs for MAS. For instance, the Agent-DSL [12] is used to specify the agency properties that an agent needs to accomplish its tasks. However, the proposed DSL is presented only with its metamodel and provides just a visual modeling of the agent systems according to agent features, like knowledge, interaction, adaptation, autonomy and collaboration. Likewise, in [30], the authors introduced two DSMLs. These languages are described by metamodels which can be seen as the representations of the main concepts and relationships identified for each of the particular domains again introduced in [30]. The study included only the abstract syntax of the related DSMLs and does not give the concrete syntax or semantics of the DSMLs.

As previously discussed in this paper, Hahn [13] introduced a DSML for MAS called DSML4MAS. The abstract syntax of the DSML was derived from a platform independent metamodel [5] which was structured into several aspects each focusing on a specific viewpoint of a MAS. In order to provide a concrete syntax, the appropriate graphical notations for the concepts and relations were defined [28]. Furthermore, DSML4MAS supports the

[10]The IDE of DSML4MAS is available at: https://sourceforge.net/projects/dsml4mas/ (last access: June 2016)

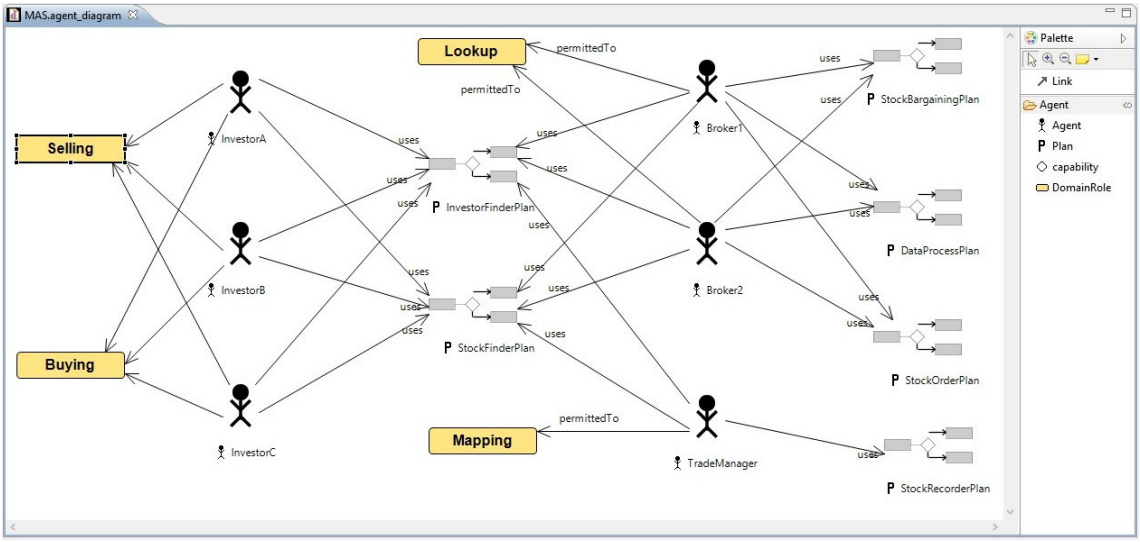

Fig. 5 Partial instance model of the agent-based stock exchange system in DSML4MAS achieved after application of the defined M2M transformations

deployment of modeled MASs both in JACK and JADE agent platforms by providing an operational semantics over model transformations.

Another DSML was provided for MASs in [17]. The abstract syntax was presented using the Meta-object Facility (MOF)[11] , the concrete syntax and its tool was provided with Eclipse Graphical Modeling Framework (GMF)[12], and finally the code generation for the JACK agent platform was realized with model transformations using Eclipse JET[13]. However, the developed modeling language was not generic since it was based on only the metamodel of one of the specific MAS methodologies called Prometheus. A similar study was performed in [14] which proposes a technique for the definition of agent-oriented engineering process models and can be used to define processes for creating both hardware and software agents. This study also offers a related MDD tool based on a specific MAS development methodology called INGENIAS.

Originating from a well-formalized syntax and semantics, Ciobanu and Juravle defined and implemented a language for mobile agents in [16]. They generated a text editor with auto-completion and error signaling features and presented a way of code generation for agent systems starting from their textual description. A recent work conducted in [20] aimed at creating a UML-based agent modeling language, called MAS-ML, which is able to model the well-known types of agent internal architectures, namely simple reflex agent, model-based agent, reflex agent, goal-based agent and utility-based agent. Representation and exemplification of all supported agent architectures in the concrete syntax of the introduced language are given. MAS-ML is also accompanied with a graphical tool which enables agent modeling. However, the current version of MAS-ML does not support any code generation for MAS frameworks which prevents the execution of the modeled agent systems.

Finally, by considering our previous studies, in [15] and [18], we showed the derivation of a DSL for the MDE of agent systems working on the Semantic Web. That initial version of the language was refined and enriched with a graphical concrete syntax in [19]. This new language, called SEA_ML, covered an enhanced version of agent-SWS interaction viewpoint in which modeling those interactions can be elaborated as much as possible for the exact implementation of agent's service discovery, agreement and execution dynamics. We also presented the formal semantics of the language [26] and discussed how the applied methodology can pave the way of evolutionary language development for MAS DSLs [2]. Moreover, qualitative evaluation and quantitative analysis of SEA_ML have been recently performed over a multi-case study protocol [31].

The work presented in this paper contributes to the above mentioned MAS DSL/DSML studies by introducing the interoperability of the languages and hence the proposed MDE technique helps to facilitate the platform support of the MAS DSMLs comparing with the existing agent platform extensibility approaches which deal with the definition and implementation of new M2M and M2T transformations for each execution platform. To the best of our knowledge, the work herein is the first effort on the interoperability of the MAS DSMLs and it is the first study in AOSE which employs horizontal model transformations to enable this interoperability. It is worth indicating that apart from our proposal, only the work conducted in [10] considers the application of horizontal transformations. However, that study just provides the transformation between the metamodels of two specific AOSE methodologies (Prometheus and INGENIAS) to realize MAS implementation on exactly one agent deployment platform and does not consider MAS DSML interoperability or language extensibility on various agent platforms.

II. Conclusion

An approach for extending the execution platform support of MAS DSMLs over language interoperability is presented in this paper. The interoperability is provided by defining and implementing horizontal M2M transformations between the agent metamodels which constitute the syntaxes of MAS DSMLs. Due to being at the same abstraction level, both mapping the model entities and implementing the model transformations are more convenient and less laborious comparing with the M2M and M2T transformation chain required in the way of enriching the support of DSMLs for various agent execution platforms. The applicability of the approach is demonstrated by constructing transformations between two full-fledged agent DSMLs.

As the future work, we first plan to extend the applicability of this interoperability approach for some other MAS DSMLs such as MAS-ML [20]. Later, the assessment of the language interoperability will be performed e.g. by taking into consideration the amount and quality of the automatically generated artifacts for MAS software. For this purpose, an improved version of the evaluation framework described in [31] can be employed.

Development of Human-friendly Notation for XML-based Languages

Sergej Chodarev
Technical University of Košice, Department of Computers and Informatics, Letná 9, Košice, Slovakia
Email: sergej.chodarev@tuke.sk

***Abstract*—XML is a popular choice for development of domain-specific languages. In spite of its popularity, XML is a poor user interface and a lot of languages can be improved by introducing custom notation. This paper presents an approach for development of custom human-friendly notation for existing XML-based language together with a translator between the new notation and XML. This approach is based on explicit representation of language abstract syntax that can be decorated with mappings to both XML and the custom notation. The approach supports iterative design and development of the language concrete syntax, allowing its modification based on users feedback. Development process is demonstrated on a case study of language for definition of graphical user interface layout.**

I. Introduction

XML is very common and easy to parse generic language, it is well supported by existing tools and technologies and therefore it is a popular basis for domain-specific languages (DSLs). While XML is appropriate choice in many cases, especially for program-to-program communication, it is not well suited for cases, where humans need to manipulate documents. Although they are able to create, modify and read XML documents, it is not a pleasurable experience, because of uniformity and syntactic noise that makes it difficult to find useful information visually [1].

While a more appropriate syntax can be chosen for development of new languages, a lot of languages was already implemented based on XML and their reimplementation would be complicated and time-consuming. One of the possible ways to solve this problem is to develop a translator that would read documents written in a specialized human-friendly notation and output them in the XML for further processing using existing tools. Ideally, the new notation would be specifically tailored to the domain of the language as is usual for DSLs [2].

Development of the translator requires implementation of parser and generator. Proper separation of these two components also involves some internal representation of the language that would be created by the parser and then traversed to generate the XML. Development of all these components may be very tedious, even using parser generators.

This paper presents an approach to development of the translator that simplifies the process and allows to evolve the new syntax iteratively. The main idea of the approach is in extracting definition of language structure into a format that can be easily augmented with the definition of a new notation. For example, Java classes representing the structure of an XML-based language can be generated automatically from the XML Schema using JAXB[1]. The generated classes are already annotated in a way that allows automatic marshalling and unmarshalling their instances in the XML form. Additional annotations can be added to the classes that define their mapping to a different textual notation. In the next step an annotation based parser generator, like YAJCo [3], can be used to generate a parser for the new notation. Connecting the parser with the XML unmarshaller one would get a complete translator from a custom human-friendly notation to the original XML-based.

Main topics discussed in the paper and its contributions are the following:

- It explains the approach to language translator development that is based on explicit representation of language *abstract syntax* in a format that allows attaching definitions of different concrete notations (Section II).
- The approach allows to develop a round-trip translator based on a single specification of abstract syntax. This enables *iterative development* of the notation in contrast to classical approach where complete syntax should be defined upfront. The process of iterative notation development is described in Section III.
- The whole approach is demonstrated on a case study of a language for specifying layout and properties of graphical user interface components (Section IV). The case study shows possible challenges of the approach and can be used as a guide to develop similar translators.

Presented case study also demonstrates that object-oriented programming language like Java can be successfully used as a format for abstract syntax description, provided that it allows attaching structured meta-data [4] (known as annotations or attributes) to program elements. This allows to use numerous existing tools and also avoids the need for special purpose representations and related technologies.

II. Model-driven Development of Language Translator

Similarly to model-driven software development [5] it is possible to drive development of the language translator by the model of the language – metamodel[2]. The metamodel defines language concepts with their properties and relations to other

[1]Java Architecture for XML Binding, available at https://jaxb.java.net/.

[2]If we consider documents written in a language to be *models*, then a model of the language itself is *metamodel*.

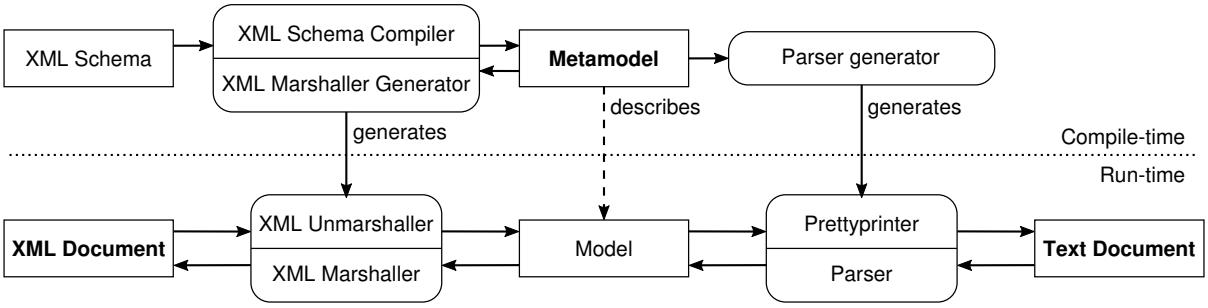

Fig. 1. Model-driven language translator development (arrows represent data-flow)

concepts. It can be annotated with additional information about concrete syntaxes of the language that need to be translated.

Figure 1 shows the whole architecture of model-driven language translator development in the case of translating XML to textual notation and vice versa. The metamodel augmented with definition of concrete notations is the central element. It is used as an input to generate parser and prettyprinter for both the textual notation (using parser generator) and XML (using XML marshaller generator). The generated tools can be connected into a pipeline that handles translation of one notation to the other with the internal representation of the model (defined by the metamodel) as an intermediate format.

What is important, the first version of the metamodel itself can be retrieved from the existing description of XML-based language – XML Schema. This allows to significantly shorten the development process, because large part of the language definition – its abstract syntax – is derived automatically. This style of development also follows the "Single Point of Truth" principle, because the structure of the language is defined only once and its mappings to concrete notations are attached to it.

The described approach does not depend on concrete tools. It, however, requires an XML marshaller and a parser/prettyprinter generator that both use the same format for metamodel specification. In Section IV is presented the case study that uses Java classes to represent the metamodel. They are augmented using annotations, JAXB is used as an XML marshaller and YAJCo as a parser generator. Alternative solution can use Ecore from Eclipse Modeling Framework (EMF) [6] to represent the metamodel and Xtext [7] as a parser generator.

III. Iterative Development of the Translator

Design of notation for an existing language is, actually, design of a user interface. As such, it requires evaluation of various alternatives, and testing new alternatives in conditions similar to real-life. This process is iterative by nature [8]. On the other hand, classical approach to language development assumes that the language syntax is designed upfront (for example [9]). A complete specification of grammar is then augmented with semantic actions and processed to generate a parser. Changes in the syntax often require modification of semantic rules, making the process laborious.

The fact, that the model-driven approach described above allows to easily receive bidirectional translator, makes it possible to use a different process:

1) Extract language metamodel from the XML Schema.
2) Augment the metamodel with initial definition of the new concrete syntax.
3) Generate a prettyprinter based on the definition and convert examples of existing XML documents to the new notation.
4) Evaluate the new notation on examples of converted documents.
5) If the notation is not satisfactory, modify concrete syntax definition and go back to the step 3.
6) If the notation is satisfactory, complete the syntax definition and generate a parser.

This process allows to easily use existing documents for testing new notation instead of some artificial examples. Complete real-life documents in the new notation can be generated automatically immediately after the definition of the syntax has changed. This allows very fast evaluation and modification cycles, so problems in the notation can be spotted and resolved, even if they occur only in complex documents.

This approach also provides a simple method for testing correctness of the developed translator, i.e. that no information is lost or corrupted during translation. A set of example XML documents can be automatically converted to the new notation and then back to the XML. Result of the conversion can be compared with the original XML documents to reveal missing support for some language features or other errors. If the translator is correct, no data is lost and documents are identical (except of differences in formatting that can be removed using normalization before the comparison).

IV. Case Study

The approach can be demonstrated on the development of a new textual notation for the GtkBuilder language. GtkBuilder is a part of the GTK+ GUI toolkit that allows to declaratively specify layout of a user interface using an XML-based language[3]. There is a Glade tool[4] that allows to edit GtkBuilder specifications visually, however it tends to lack support for

```
1  <interface>
2    <object class="GtkDialog" id="dialog1">
3      <child internal-child="vbox">
4        <object class="GtkVBox" id="vbox1">
5          <property name="border-width">10</property>
6          <child internal-child="action_area">
7            <object class="GtkHButtonBox" id="hbuttonbox1">
8              <property name="border-width">20</property>
9              <child>
10               <object class="GtkButton" id="save_button">
11                 <property name="label" translatable="yes">Save</property>
12                 <signal name="clicked" handler="save_button_clicked"/>
13               </object>
14             </child>
15           </object>
16         </child>
17       </object>
18     </child>
19   </object>
20 </interface>
```

Fig. 2. Example of user interface definition using XML notation

newest GTK+ widgets, requiring manual modification of XML files.

The translator was implemented using two tools: JAXB and YAJCo. JAXB is a standard solution for marshalling and unmarshalling Java objects to XML. YAJCo[5] (Yet Another Java Compiler Compiler) is a parser generator for Java that allows to specify language syntax using a metamodel in a form of annotated Java classes [3]. This allows declarative specification of a language and its mapping to Java objects [10]. In addition to parser, YAJCo is able to generate pretty-printer and other tools from the same specification [11].

This section describes a process of development of the translator using the chosen tools. It also explains challenges that arise during the implementation and their solutions. Readers can use it as a guide to develop their own translators. The complete source code of the translator is available for download at http://hron.fei.tuke.sk/~chodarev/gtkbuilder/.

A. GtkBuilder Language

The GtkBuilder UI definition language allows to specify a layout of widgets forming a user interface and their properties using an XML notation. Each instance of a widget is defined using an *object* element, which contains its type, identifier, properties, signal bindings, and child objects. Fig. 2 presents an example UI definition in the XML notation.

The XML notation for the language, while familiar, is very hard to read. Document contains a lot of syntactic noise that makes fast scanning of the definition very hard. The same definition can be expressed using a custom notation as shown in Fig. 3. The notation uses special symbols to provide concise representation for language elements. For example, *object* is expressed using "`[ Class id ... ]`" notation (e.g. line 1), properties are written simply as pairs in a form

[5]Available at https://github.com/kpi-tuke/yajco

```
1  [ GtkDialog dialog1
2  %child vbox :
3     [ GtkVBox vbox1
4     border-width : 10
5     %child action_area :
6        [ GtkHButtonBox hbuttonbox1
7        border-width : 20
8        %child :
9           [ GtkButton save_button
10          label : _ Save
11          clicked -> save_button_clicked ]]]]
```

Fig. 3. Example of user interface definition using custom textual notation

"`name : value`" (e.g. line 4), signal binding is expressed as "`signal_name -> handler`" (line 11), and strings that should be translated in localized versions of UI are marked with underscore (line 10). The notation is short and quite intuitive at the same time.

In the rest of the section the development of the custom notation and conversion tools is described in more detail.

B. Metamodel Extraction

As was mentioned earlier, the metamodel represented by Java classes can be generated based on the existing XML schema using the XML binding compiler (`xjc`) that is a part of JAXB. It generates Java classes corresponding to elements of XML-based language. Generated classes contain annotations that define mapping to XML elements and attributes. JAXB uses these annotations to create instances of the classes and set their properties based on XML document contents. The same annotations are used to serialize objects to the XML form.

This means that after the metamodel was extracted it is possible to use JAXB to read existing UI definition from the XML notation to an internal representation defined by the

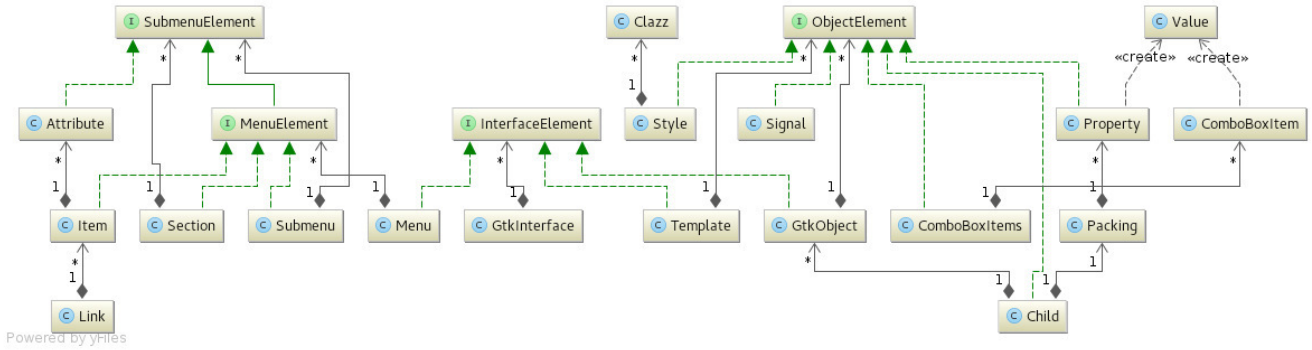

Fig. 4. Class diagram of the GtkBuilder language metamodel

metamodel and also to marshall the internal model back to the XML form.

In the case study, extracted classes directly corresponded to elements of the XML-based language. Therefore, they included classes like *Interface*, *Object*, *Child*, *Property*, *Signal*, classes for definition of menus, etc. In total, 13 classes was generated by JAXB. Full metamodel, including modifications and additions described in next sections is depicted in Fig. 4.[6]

Encountered problems: Unfortunately, the schema of the GtkBuilder language is available only in the RelaxNG format. Because the support for RelaxNG schemas in JAXB is only experimental, it was converted to the XML Schema format using the Trang tool[7].

In addition, the schema does not define the language completely. Each widget type can support additional elements for widget-specific functionality. These elements, however, are not specified in the schema. Instead, arbitrary elements are allowed inside the *object* element.

The support for the most common widget-specific extensions, that was not specified in the schema, was added later by defining new classes in the metamodel. Generated classes obviously need to be modified to include declaration of added child elements of new types.

Shortcomings of the GtkBuilder language definition make it impossible to create the metamodel fully automatically. But on the other hand, it shows that the approach is applicable even in such cases.

C. Syntax Definition

Definition of new concrete syntax is provided in form of annotations added to the metamodel classes. This means that the metamodel generated using JAXB needs to be augmented to include YAJCo-specific annotations.

YAJCo infers abstract syntax of the language from the inheritance relations between the metamodel classes and from their constructors. Each constructor is transformed into a grammar rule and parameters of a constructor determine the

[6]Classes *Object* and *Interface* was renamed to *GtkObject* and *GtkInterface* to avoid clashes with Java keywords in the generated parser.

[7]Available at http://www.thaiopensource.com/relaxng/trang.html

```
@Before("%child")
public Child(@Token("ID") @After(":")
             String internalChild,
             @NewLine @Indent
             List<GtkObject> object) {
    this.object = object;
    this.internalChild = internalChild;
}
```

Fig. 5. Example class constructor with YAJCo annotations

right hand side of the rule. YAJCo annotations are attached to constructors to specify details of the grammar that cannot be inferred automatically. For example, Fig. 5 presents one of the constructors of the *Child* class. It defines that a child can be constructed from a string representing an internal child name and a list of objects (e.g. lines 2 and 5 in Fig. 3). The child definition would start with the "`%child`" token followed by the `ID` token representing an identifier, followed by colon and a sequence of objects. Annotations also contain hints on indentation and new-line placement for prettyprinter (they are ignored by the parser).

Such constructors need to be added to the metamodel classes. Each variation of the element concrete syntax requires its own constructor. For example, the *Child* can be defined with *internalChild* property specified, or without it (e.g. line 8 in Fig. 3) and therefore it needs at least two constructors. In addition to constructors, factory methods can be used as an annotation target. This makes it possible to define different syntaxes even if they have the same types of parameters in Java.

Each class also needs a non-parametrized constructor required by JAXB. This constructor must be marked using the YAJCo `@Exclude` annotation so it would be ignored by the YAJCo tool.

In the following subsections are described some details of the implementation, typical problems and their solutions.

1) Completing the abstract syntax specification: In some cases several alternative values of different types are expected in the same place. For example, *object* definition contains a sequence of properties, child definitions or signal bindings. In

```
public class GtkObject {
    @XmlElements({
        @XmlElement(name = "property",
                    type = Property.class),
        @XmlElement(name = "signal",
                    type = Signal.class),
        @XmlElement(name = "child",
                    type = Child.class)
    })
    protected List<java.lang.Object>
        propertyOrSignalOrChild;
    ...
```

Fig. 6. Alternative types of values by as defined by JAXB

```
public class GtkObject {
    @XmlElements( ... )
    protected List<ObjectElement>
        propertyOrSignalOrChild;
    ...

public interface ObjectElement {}

public class Property implements ObjectElement{
    ...
public class Signal implements ObjectElement {
    ...
public class Child implements ObjectElement {
    ...
```

Fig. 7. Alternative types of values defined using inheritance

object-oriented model this situation can be expressed by inheritance. JAXB, however, does not use this technique in generated metamodel classes. Instead, it uses type *java.lang.Object* in the container and adds `@XMLElements` annotation to specify all possible concrete types that can be used as is shown in Fig. 6.

On the other hand, YAJCo requires the use of inheritance or implementation relations in these situations. So a new marker interface needs to be created and classes of all elements that can appear in specific context are marked to implement it. The container class is then modified to reference the marker interface. An example of all these modifications is presented in Fig. 7.

2) Conflict between reserved keywords and identifiers: The problem arises from the different treatment of keywords in different notations. XML uses special syntax for language elements (tags delimited by angle brackets) and therefore it can allow to use language keywords as identifiers inside XML attributes and text fragments. For example, menu can be named simply "menu": `<menu id="menu">...</menu>`

On the other hand, if element names, like "`menu`" or "`child`", become reserved keywords in the custom notation, they could not be used as identifiers anymore, because standard lexical analyzer would not be able to distinguish them. Such conflicts can be resolved by decorating either language keywords or identifiers with some special symbols that would distinguish them. In our case percent sign was used as a starting symbol of all language keywords. For example, the menu would be defined like this: `%menu menu { ... }`

3) Model transformations: Representation of the metamodel using Java classes allows to implement simple model transformations using constructors. Constructors of the metamodel classes can transform their parameters before storing to class fields. It makes possible to define helper classes with own syntax rules, that are not stored in the model.

For example, at different places in the language it is possible to specify value, that can be a number, a symbol, or a string, all with different notations. Each class where such value can be used would need at least three constructors (for each notation of the value). Instead of this, it is possible to define a new helper class that would handle this aspect of concrete syntax using its own constructors and factory methods. It would also implement appropriate pre-processing of the values (e.g. removing quotation marks from strings). Instances of the helper class would become constructor parameters of the original classes, but only the actual value would be stored in the model, not the instance of the helper class. This allows to avoid modification of the metamodel and XML bindings.

D. Other Implementation Notes

1) Project setup: It is useful to split the project into two submodules: one for the metamodel definition and the code generated based on it, and other for code that uses the generated parser and prettyprinter to translate language sentences. This setup explicitly divides generated code and the code that depends on it.

The second submodule contains implementation of a command-line tool for converting between different notations of the language. This tool instantiates JAXB marshaller and unmarshaller and also YAJCo generated parser and prettyprinter and uses them to produce the internal model from one notation and convert it to the other notation.

In addition, the project contains script that tests the implementation by running round-trip transformation and comparing results with original versions of example documents. In the case study this script was implemented as a *Makefile* that would produce report on differences between documents if modifications of the code would cause errors in translation. This approach helped to find several problems described in this section and led to successful translation of tested examples.

2) Prettyprinter customization: Some syntax constructs can not be handled by the YAJCo generated prettyprinter automatically. For example, strings that should be translated in localized versions of the application are marked using an underscore "_" symbol. In the model, however, it is stored as a value of *True* in the field *translatable*. This correspondence is not inferred by the prettyprinter generator. As a solution, a prettyprinter can be simply extended by a new class, that would override the corresponding method to provide the needed functionality. This is greatly simplified by the fact that the generated prettyprinter is based on the visitor pattern.

V. Related Work

The presented approach and technologies are not limited to development of textual notation for the language. As was shown in the work of Bačíková et al. [12], it is possible to use the same metamodel definition to generate a graphical user interface. This interface would consist of forms allowing to edit language sentences. Input for the metamodel extraction is not limited to XML Schema: it is possible to extract metamodel from some non-XML notation [13], existing application [14] or it user interface [15]. It is also possible to avoid modification of generated metamodel code to augment definition of the metamodel and add different methods of its processing by using aspect-oriented programming [16].

The most similar work to the one presented in this paper is XMLText by Neubauer et al. [17]. They use EMF for representing metamodels and Eclipse Xtext [7] for generating parser, prettyprinter (*serializer* in the Xtext terminology), and editing support for the Eclipse integrated development environment. They integrate these tools and develop round-trip transformation between XML based languages defined by XML Schema and textual notation. Their tool, however, does not directly support custom syntax definition for each language element. On the other hand, customization of the textual notation should be possible using manual modification of the generated Xtext grammar.

Therefore, it should be possible to use the iterative approach described in this paper with EMF and Xtext as well. The main difference compared to technologies presented in this paper is the fact that EMF and Xtext use specialized language for defining metamodel — Ecore, while JAXB and YAJCo rely on Java for this purpose. This allows to lower the entry barrier by minimizing the amount of new technologies needed to be learned. It also allows to implement model transformations in Java using the techniques well-known by industrial programmers. On the other hand EMF promises independence on the concrete programming language. Together with Xtext they also provide a more mature platform for development of languages with their tooling, first of all – editing environment.

A real-life example of migrating UML and XML based modeling language to these technologies was presented by Eysholdt and Rupprecht [18]. They, however, did not use a single metamodel for different notations. Instead, they used model-to-model transformations to migrate models.

Other alternative would be the use of different generic language instead of the XML. YAML is a popular choice, for example, Shearer [19] used it to provide textual representation for ontologies. YAML (Yet Another Markup Language) was specially designed as a human-friendly notation for expressing data structures [20]. Its syntax is readable and quite simple, but the use of generic language does not allow to use specialized short-hand notations tailored for a developed language. While the basic structure of our example language may be expressed similar to the custom notation, problems start in the details. For example, the custom notation allows to mark any string as translatable by simply writing underscore before it, YAML would require a different and more noisy solution.

Similar solution is the use of OMG HUTN (Human-Usable Textual Notation) which specifies generic textual notation for MOF (Meta-Object Facility) based metamodels [21], again without possibility to customize concrete syntax.

The approach presented in this paper is also similar to tools supporting development of DSLs based on existing ontologies [22], [23]. In our case, however, existing XML-based language is used as a basis for a DSL instead of ontology.

VI. Conclusion

Presented case study showed the applicability of the model-driven translator development approach. It also allowed to formulate several advises for practical usage of the approach (described in Section IV). While most of them are specific to the tools used in the study, some may be applicable to other tools as well. The approach itself is tool-independent and can be used with any language metamodel representation that can be mapped to both XML and custom textual syntax.

Future work may include identification, validation and comparison of tools and metamodel representations that support the described translator development approach. The YAJCo tool itself requires further development, especially in the area of generating tool support for the language beside parser and prettyprinter.

Preliminary Report on Empirical Study of Repeated Fragments in Internal Documentation

Milan Nosáľ, Jaroslav Porubän

Technical University of Košice
Letná 9, 042 00, Košice, Slovakia
Email: milan.nosal@gmail.com, jaroslav.poruban@tuke.sk

***Abstract*—In this paper we present preliminary results of an empirical study, in which we used copy/paste detection (PMD CPD implementation) to search for repeating documentation fragments. The study was performed on 5 open source projects, including Java 8 SDK sources. The study shows that there are many occurrences of copy-pasting documentation fragments in the internal documentation, e.g., copy-pasted method parameter description. Besides these, many of the copy-pasted fragments express some domain or design concern, e.g., that the method is obsolete and deprecated. Therefore the study indicates that the cross-cutting concerns are present in the internal documentation in form of documentation phrases.**

I. Introduction

PRESERVING and comprehending developer's concerns (intents) in the source code is still a current challenge in software development [1], [2], [3], [4]. In this paper we analyze the internal documentation (source code comments, JavaDoc, etc.) to recognize repeating documentation fragments that document those concerns (or features [5]). Our research question for this work is: *Does internal documentation contain significant duplication?* To answer this question we performed a copy/paste detection study, in which we analyzed JavaDoc comments in 5 open source projects. In this report we present preliminary results that indicate that there is a significant duplication of text in internal documentation. These repeating documentation fragments constitute documentation phrases discussed in several works – e.g., our previous work [6], or the one by Horie et al. [7]. This way the study has a potential to highlight the importance of those works and it may stimulate further attention to this topic.

II. Documentation Phrases

A documentation phrase is a set of documentation fragments with the same or similar formulation (part of sentence, sentence, a set of sentences) that can be found across the software system or even across multiple systems. Documentation fragments that represent the same documentation phrase usually document the same domain or design property that is shared by the documented program elements [6]. Horie et al. [7] likened the documentation phrases to crosscutting concerns from aspect oriented programming (AOP [8]).

As an example we can use the Swing library for component graphical user interfaces in Java. The library is not thread safe and therefore the programmer has to pay extra caution when using it in multithreaded systems (she has to use Event Dispatch Thread to safely work with the Swing components). Swing JavaDoc documents it and for each affected class includes a warning (see JPanel documentation in Figure 1).

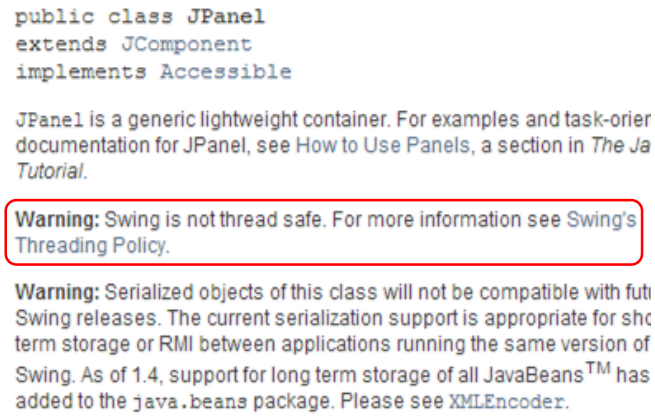

Fig. 1. A NotThreadSafe documentation phrase instance in the Swing JPanel documentation

For this warning to be included in the JavaDoc, its HTML snippet has to be copy-pasted in the JavaDoc comment of each affected class.

III. Documentation Copy/paste Study

In this study we analyzed the internal documentation of several Java frameworks and libraries to detect currently existing documentation phrases. In order to find documentation phrases, we performed a copy/paste detection[1] on the documentation.

We have modified the PMD Copy/Paste Detection (CPD) tool[2] to support copy/paste detection on JavaDoc documentation. The tool was fed preprocessed sources of several libraries and open source projects in Java and it analysed them to detect duplications in documentation that would indicate the potential

[1]Copy/paste detection is usually used to search for code that needs to be refactored, or to detect plagiarism [9].

_
```

documentation phrases. We will discuss the process phases in more details in following sections.

A. Java Sources Preprocessing

In our experiment we used the tool to detect simple non-parametrized documentation phrases in the JavaDoc documentation. However, the PMD CPD was designed to be a code analysis tool and as such its purpose was to detect duplication in programming languages. Documentation phrases are fragments of documentation in a natural language.

PMD CPD tool works with language lexical tokens that it compares to detect duplications in their usage. To reduce tokenization complexity we pre-processed the sources to remove all the characters and tokens that are not the documentation. In other words the preprocessed sources are source files with only JavaDoc comments in their comments. Let us consider a simple class with JavaDoc from Listing 1.

This source file would be transformed to the content presented in Listing 2[3]

Java lexical tokens were discarded along with asterisks indicating that following lines are part of JavaDoc (lines are preserved for backtracking to original sources). At the end of each JavaDoc comment we added a randomly generated unique "anchor" (DummyClass.jdoc.6.1394135902525 .0.-2042003928. in the example) that prevented detection of duplicates spanning multiple comments.

B. PMD CPD Modification

PMD CPD tool uses a tokenizer to read files and obtain lexical tokens of the language. In our experiment we used our custom tokenizer that divided the preprocessed files into sentences. Each sentence in the file was a single token. If we consider the `DummyClass` example from section III-A, the tokenizer would return following three tokens:

- "Dummy class."
- "Created by Milan on 5.3.2016."
- "DummyClass.jdoc.6.1394135902525.0.-2042003928."

Separators for the tokenization were characters '.', '?', and '!' followed by a whitespace character (therefore the date in the second token from the example was not divided in multiple tokens), or a new line character followed by an empty line.

C. Document Phrases Detection

For the duplication detection process we used the standard PMD CPD implementation (according to http://pmd.sourceforge.net/pmd-4.3.0/cpd.html they use Karp-Rabin string matching algorithm). We registered our modification in `LanguageFactory` and `GUI` classes and used the graphical user interface provided by the `GUI` class to run the tool.

In the setup of the copy/paste detection we set the 'Report duplicate chunks larger than:' option to a single token. This way PMD CPD reported even duplication of a single token – a single line in the documentation. The results were serialized as XML so that we could use XPath with XSLT to process them. First post-processing removed all the results that did not have at least 4 duplications – we considered 4 instances of a documentation phrase a reasonable threshold for considering it a significant documentation phrase.

IV. Results

We performed the experiment on the following open source Java projects:

- sources of Java 8 standard edition[4] with 7703 source files,
- PicoContainer[5] with 1067 source files,
- JasperReports library[6] with 2834 source files,
- JoSQL[7] (SQL for Java Objects) with 85 source files, and
- jEdit[8] with 573 source files.

A. Copy/paste Detection Results

The PMD CPD tool discovered 6102 duplicated fragments of various lengths in Java 8 source code. 2221 of them were duplicated fragments that had 4 instances. The highest number of instances of a single duplicated fragment was 344. Second highest were two duplicated fragments both with 299 instances. Figure 2 shows an overview of obtained results. We will provide a more detailed analysis of these data below.

PicoContainer contained 70 duplicated fragments ranging from 36 duplicated fragments with 4 instances to a single fragment duplicated 634 times. Figure 2 presents results for PicoContainer in a simple chart. Closer inspection of the results showed that duplicated fragments with the highest

[3]We used underscores here to highlight empty lines.

[5]https://github.com/picocontainer/picocontainer, commit `0f8172b`

[6]http://sourceforge.net/projects/jasperreports/files/jasperreports/, version 6.0.0

[7]http://sourceforge.net/projects/josql/files/josql/, version 2.2

[8]http://sourceforge.net/projects/jedit/files/jedit/, version 5.2.0

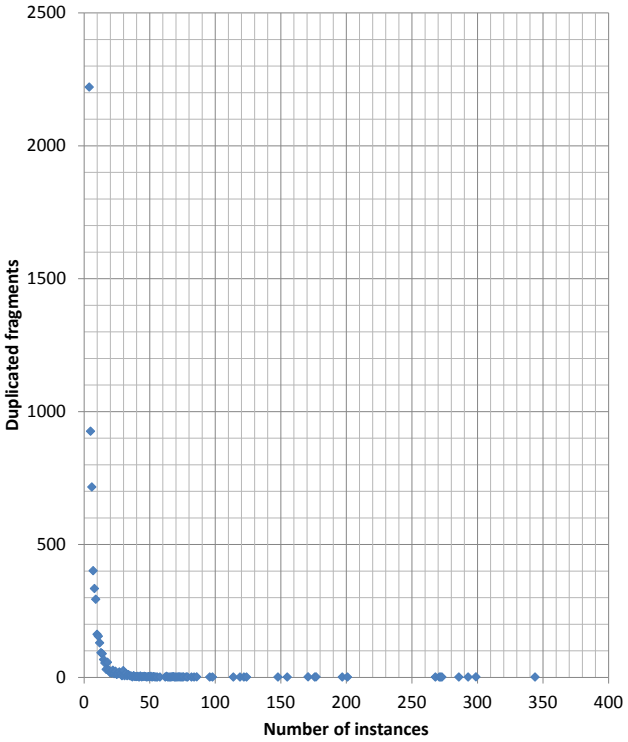

Fig. 2. Duplicated fragments detected by PMD CPD in standard Java

numbers of instances were just lines consisting of asterisks (*) probably used as a visual separator in the documentation.

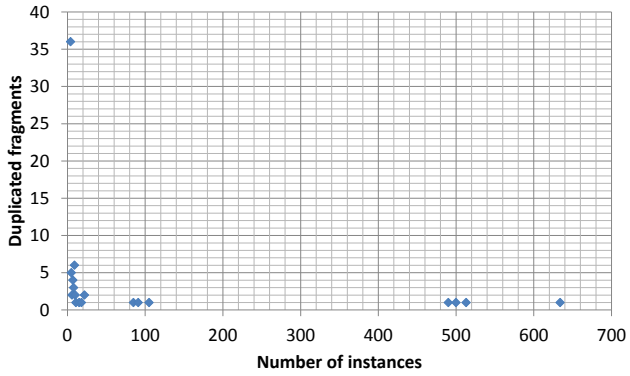

Fig. 3. Duplicated fragments detected by PMD CPD in PicoContainer sources

JasperReports contained 131 duplicated fragments ranging from 44 duplications with 4 instances to a single duplicated fragment with 106 instances. Figure 4 presents results for JasperReports in a simple chart. In this case the duplicated fragment with 106 instances was a documentation phrase reporting that the documented program elements were deprecated and to be removed: '@deprecated To be removed.'. Deprecation naturally expresses design concern – the given program element became obsolete and should not be used anymore.

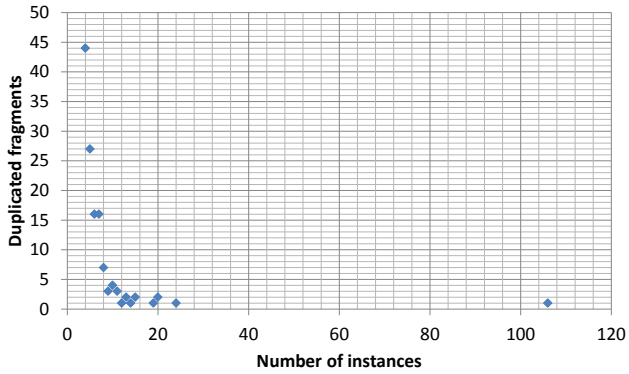

Fig. 4. Duplicated fragments detected by PMD CPD in JasperReports sources

In JoSQL the PMD CPD discovered 31 duplicated fragments. The most 'potent' duplicated fragment with 54 instances was a paramater description: '@param q The Query object.'. Parameter descriptions, especially this simple, could hardly be considered reasonable documentation phrases. The rest of results can be seen in Figure 5.

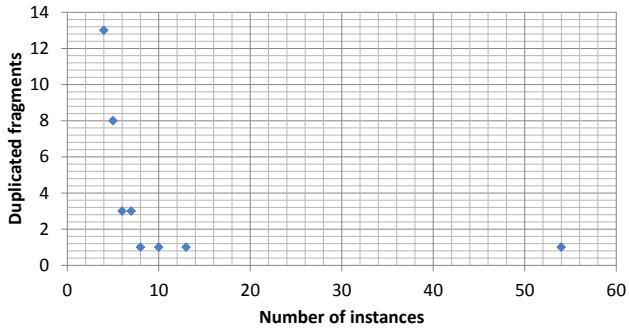

Fig. 5. Duplicated fragments detected by PMD CPD in JoSQL sources

jEdit project sources manifested 76 duplicated fragments with 4 or more instances. Again, the most 'potent' duplicated fragment (with 78 instances) was a line of asterisks. However, the second most 'potent' duplicated fragment was a sentence reporting that the documented method is thread-safe: 'This method is thread-safe.', thus showing that the thread-safe documentation phrase would be useful even beyond the scope of standard Java sources. The results overview can be seen in Figure 6.

We can conclude that duplicated fragments (documentation phrases) are common in practice.

V. Threats to Validity

We should mention several threats to validity that should to be considered for this study. First, the copy/paste detection found all the duplicated sentences in the documentation, even those that could hardly be assigned a concern. In those

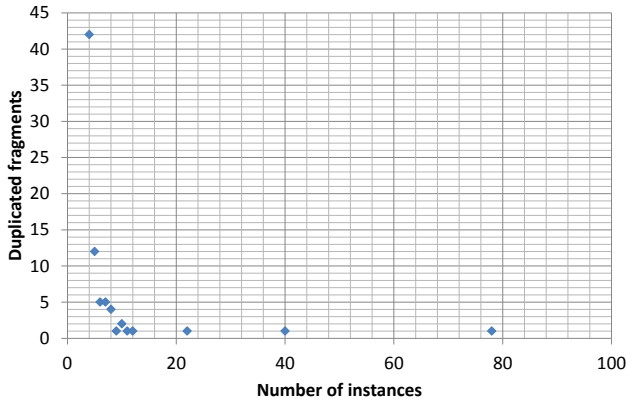

Fig. 6. Duplicated fragments detected by PMD CPD in jEdit sources

cases using documentation weaving [7] would be impractical. Further examination would be useful.

Second, the modified PMD CPD detected solely static phrases – fragments of the documentation that were copy/-pasted in documentation. Inclusion of parametrized documentation phrases [6] would be welcome.

VI. Related Work

Maalej et al. in [10] present a study of knowledge patterns in API reference documentation. They define patterns as knowledge types that categorize types of information expressed by a particular documentation unit (a fragment of API documentation documenting one API element). As example we can mention types like the *Functionality and Behavior* knowledge type that describes what the API does or the *Code Examples* that provides a code sample showing how to use the API.

The work of Horie et al. [7] discusses documentation phrases from the aspect-oriented viewpoint. They view documentation phrases as cross-cutting concerns. Their tool CommentWeaver is able to weave documentation phrases the same way as advices are woven in aspect-oriented programming. Our work presented in [6] continues in their work. There we propose using source code annotations to indicate program elements that should be documented by a given documentation phrase.

Shi et al. in [11] present an empirical quantitative study of API documentation evolution. They analyze the documentation to detect which parts of documentation are frequently revised, how often these revisions indicate behavioral changes in API and how often do these revisions occur. The contribution of their work is in emphasizing the importance of API documentation evolution in order to prevent defects in software using the given API.

VII. Conclusion

In conclusion, the presented results underline the significance of approaches like the one we presented in [6], or the one by Horie et al. [7], which centralize the management of such a documentation phrase into one place and thus ease their maintenance and evolution.

In the future work we need to further examine the results and confirm the significance of fragments that can be considered a concern (intent). An interesting modification of the experiment would be inclusion of the parametrized fragments as well.

Abstract—**An important phase of a data-oriented software system reengineering is a database reengineering process and, in particular, its subprocess – a database reverse engineering process. In this paper we present one of the model-to-model transformations from a chain of transformations aimed at transformation of a generic relational database schema into a form type data model. The transformation is a step of the data structure conceptualization phase of a model-driven database reverse engineering process that is implemented in IIS*Studio development environment.**

I. Introduction

A MODEL-DRIVEN (MD) approach to information system (IS) and software (re)engineering addresses complexity through abstraction. A complex system consists of several interrelated models organized through different levels of abstraction and platform specificity. Through a forward engineering process models need to be refined and integrated and used to produce code and therefore they would undergo a series of transformations. Each transformation adds levels of specificity and detail. A chain of model-to-model (M2M) transformations is completed starting from an initial model at the highest level of abstraction (Platform Independent Model, PIM), through the less abstract models, with different levels of platform specificity (Platform Specific Models, PSMs), and resulting in an executable program code that represents a model at the lowest level of abstraction (fully PSM). Conversely, in a reverse engineering process, the abstraction level of models and degree of platform independency are increasing throughout the chain of transformations.

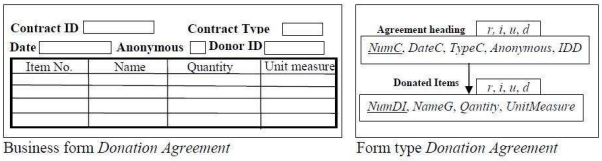
Through a number of research projects on MD intelligent systems for IS development, maintenance and evolution, we have developed the IIS*Studio development environment. It is aimed to provide the IS design, generating executable application prototypes and IS reverse engineering. Our approach is mainly based on the MD information system and software engineering [1] and domain specific language (DSL) paradigms ([2], [3]). In [4] we discuss the importance of meta-modeling in the context of database reverse engineering and review different database meta-models (MM) that are used in the database reengineering process applied in IIS*Studio. In [5] we propose an MD approach to data structure conceptualization phase of database reverse engineering process that is conducted through a chain of M2M transformations. In this paper we present the final step of the conceptualization phase—the M2M transformation of a generic relational database schema into a form type model.

The form type concept and the IIS*Studio architecture are given in Section 2. Classifications of form types and relation schemes are described in Section 3. The transformation of a generic relational database schema into a form type data model is presented in Section 4 and related work is discussed in Section 5.

II. Form Type Concept

A form type is central IIS*Studio PIM concept, used to model the structure and constraints of various business forms that are broadly used in organizations to conduct daily operations and to communicate with their affiliated entities. They are a source for eliciting user information requirements and for designing and developing user-oriented information systems. Initially, each form type (FT) is an abstraction of a business form. However, it may be enriched by additional specifications like specifications of: key and unique constraints; check constraints; allowed database CRUD (Create, Retrieve, Update and Delete) operations applied by means of screen computerized forms to manipulate data of an IS; functionalities concerning relationships between generated screen forms, i.e. transaction programs. The business form *Donation Agreement* (*DA-bf*) is presented on the left-hand side of Fig. 1. It is business form used in the Safe House Center (SHC) that provides support for those children impacted by domestic violence. The SHC is in a great extent based on donations and SHC IS has to support donation process. One of the activities is keeping track about the donation agreements. The business form *Donation Agreement* may be modeled by the form type *Donation Agreement* (*DA-ft*). The simplified representation of the structure of the *DA-ft*, which generalizes the *DA-bf*, is presented on the right-hand side of Fig. 1. A form type is a hierarchical structure of form type components. The form type *Donation Agreement* (Fig. 1) has two component types: *Agreement Heading* and *Donated Items*.

Research presented in this paper was supported by Ministry of Education, Science and Technological Development of Republic of Serbia, Grant III-44010, Title: Intelligent Systems for Software Product Development and Business Support based on Models.



Business form *Donation Agreement* Form type *Donation Agreement*

Fig. 1 The business form *Donation Agreement* and its form type

A form type in IS design by means of IIS*Studio has a dual role. On the one hand it provides an important input data for database design, and on the other hand it is a source for the generation of a sole transaction program and its screen or report form. IIS*Studio introduces *FT data model* based on FT concept [6] aimed at conceptual database design.

IIS*Studio comprises: IIS*Case, IIS*UIModeler, and IIS*Ree tools that communicate by means of shared repository aimed at storing project specifications. The IIS*Case tool supports IS forward engineering process. The IIS*UIModeler is aimed at modeling of graphic user interface (GUI) static aspects via UI templates. The IIS*Ree tool enable reverse engineering (RE) of relational databases to conceptual data models. The RE process is implemented by means of a series of M2M transformations between database models (*database model transformations*) based on meta-models that are conformed by the source and target database models. A blueprint of IIS*Studio database RE process is presented in [5]. Here we present one step of that process aimed at transformation of a generic relational database schema into a form type data model.

III. Classifications of Form Types and Relation Schemes

A *form type* $\mathcal{F}$ is a named tree structure, whose nodes are called *component types* (CTs). Let $C(\mathcal{F})$ denotes a set of CTs making up the form type $\mathcal{F}$. Each CT is identified by its name within the scope of a FT, and has nonempty sets of attributes and keys, and a possibly empty set of unique constraints. Formally, a CT is a named pair $N(Q, O)$, where N denotes name of the CT, Q is the set of CT attributes $Q=\{A_1, .., A_n\}$ and O is a set of CT constraints. O is a union of: a set of key constraints, a set of unique constraints and a singleton containing a tuple constraint. The tuple constraint of a CT refers to a set of attribute-based constraints (attribute data type specification and not-null constraint) paired with a tuple-based constraint (constraint on tuple value).

Let $C(\mathcal{F}) = \{N_i(Q_i, O_i) \mid i = 1, ... m\}$. $W(\mathcal{F})$ denotes a set of the form type attributes that satisfies (1) and (2).

$$\bigcup_{i=1}^{m} Q_i = W(\mathcal{F}) \text{ and} \quad (1)$$

$$(\forall N_i, N_j \in C(\mathcal{F}))(i \neq j \Leftrightarrow Q_i \cap Q_j = \varnothing). \quad (2)$$

Three categories of FTs can be identified: $\mathcal{F}\_Basic$—an elementary form type containing only one root component type (Fig. 2); $\mathcal{F}\_Tree^2$—a form type containing a root component type with only one child component type (Fig. 3); and $\mathcal{F}\_Tree^n$—a form type that apart from a root component type contains an arbitrary number of child component types (Fig. 4).

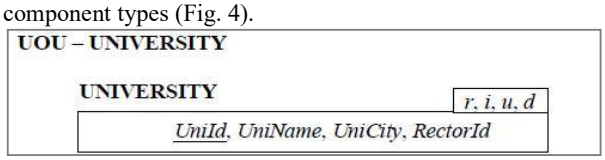


Fig. 2 An example of $\mathcal{F}\_Basic$ form type

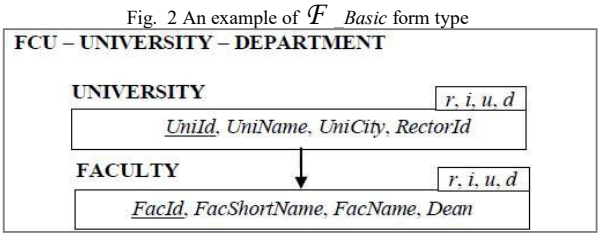

Fig. 3 An example of $\mathcal{F}\_Tree^2$ form type

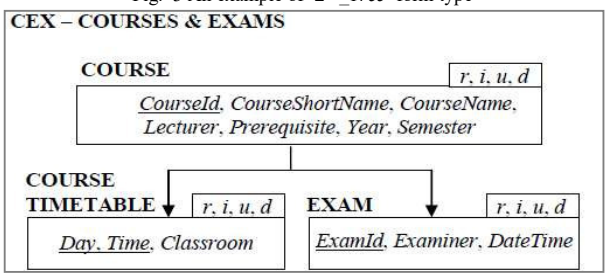

Fig. 4 An example of $\mathcal{F}\_Tree^n$ form type

Hammer et al. [7] have proposed a classification of relation schemes in the context of the transformation of a relational database schema into Entity-Relationship (ER) database schema. Here we present a classification that is adapted according to the target FT data model. There are three kinds of relation schemes: basic (BR); weak (WR); and all keys (AK) relation scheme. A BR relation scheme is a relation scheme whose PK does not properly contain a key attribute of any other relation. A WR relation scheme N satisfies the following three conditions: i) a proper subset of its PK contains key attributes of other basic or weak relation schemas; ii) the remaining attributes of its PK do not contain key attributes of any other relation scheme; and iii) it has an identifying parent relation scheme and properly contains the PK of its parent relation scheme. An AK relation scheme contains only key attributes of other relation schemes, and does not contain any other self-inherent attributes.

A graphic representation of a relational database schema is presented in Fig. 5. Underlined attributes belong to a key of a relation scheme. If a relation scheme has two candidate keys their attributes are underlined with different lines. The relation schemes *University* and *Project* are BR relation schemes. *Faculty*, *Department* (first version), *Employee*, the second version of *Department* relation schema (below the first version) and relation scheme *Lecturer* are WR relation schemes. The relation scheme *WorkOn* is an example of AK relation scheme.

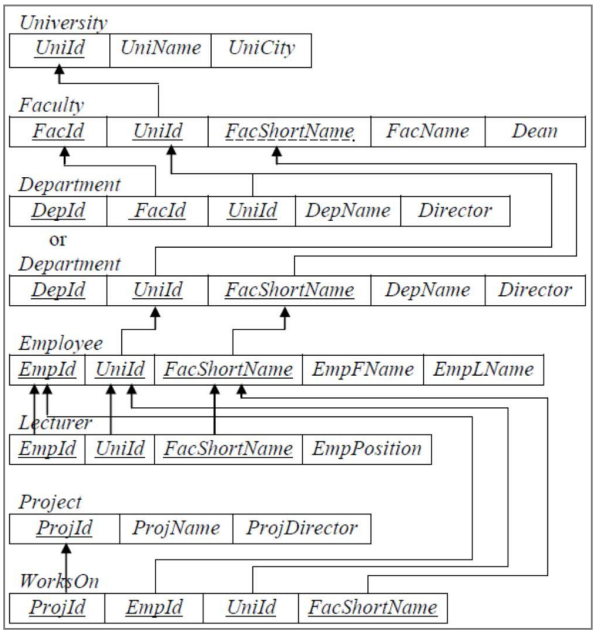

Fig. 5 An example of a relational database schema

IV. Transformation of a Generic Database Schema into a Form Type Data Model

The transformation of a model conformant with generic relational database meta-model into a model conformant with FT meta-model is PSM2PIM transformation. It generates all relevant combinations of form types. It is a user who chooses form types to be introduced in the form type data model. The remaining form types are deleted. The proposed transformation is carried out in three steps. In the first step, a $\mathcal{F}$ _Basic form type is created for each relation scheme from a relational database schema. The input parameters for this transformation are:

$$S = \{N_i(R_i, O^{RS}_i) \mid i = 1,.., n\}, \text{ and} \quad (3)$$

$$O^{RS} = K^{RS} \cup UQ^{RS} \cup CH^{RS}, \quad (4)$$

where S is a set of the relation schemes $N_i(R_i, O^{RS}_i)$. N_i is relation scheme name, R_i is nonempty set of its attributes and O^{RS}_i (4) is a union of three sets containing: key constraints, unique constraints, and tuple constraints.

In Fig. 6 parts of generic relational schema MM and FT meta-model are presented in the first row. In the next raw ATL rules are presented that specify a mapping between the concepts of these MMs alongside with five lazy rules aimed at mapping: optional and mandatory relation scheme attributes to optional and mandatory CT attributes; and relation scheme key, unique and tuple constraints to CT key, unique and tuple constraints, respectively.

In the next step of the transformation a $\mathcal{F}$ _$Tree^2$ form type is generated for each referential integrity constraint, having WR relation scheme on the left-hand side. The set of input parameters in addition to (3) and (4) contains a set of referential integrity constraints of a relational database schema (5):

$$RIC = \{ric_i: N_l[LHS] \subseteq N_r[RHS] \mid i = 1,.., m\}, \quad (5)$$

where N_l and N_r are relation schemes, *LHS* and *RHS* are subsets of attribute sets R_l and R_r of relation schemes N_l and N_r, respectively. For each ric_i from *RIC*, with N_l that is WR relation scheme, a $\mathcal{F}$ _$Tree^2$ FT is created.

In the last step of the transformation an $\mathcal{F}$ _$Tree^n$ form type is created for each relation scheme that is referenced by at least two WR relation schemes. Besides, an $\mathcal{F}$ _$Tree^n$ form type is created for each relation scheme that is referenced by at list one WR relation scheme that is referenced by some WR relation scheme, too.

V. Related Work

Hainaut et al. in [8] describe main steps of database RE. Vendor-specific physical or standard relational meta-model mainly are found on the source side of RE transformations. On the other side, ER [9], object-oriented [9]–[11], standard/vendor-specific relational [12] or object-relational [13] MMs occur on the target side. There are various research works about the use of forms in different contexts: Tsichritzis [14] introduces the concepts of form type, Shu [15] proposed using forms to specify system requirements, in [16] is presented a usage of business forms as input data for the process of database schema design. A form-based approach for reverse engineering of relational databases is proposed in [17].

VI. Conclusion

The main reason to develop our IIS*Ree reverse engineering tool was to take advantage of our approach to database schema generation during: the integration of independently designed ISs, legacy database schema restructuring and improvement of empirically designed database schemas. FT specification models system as-is in a platform independent way. At the same time, the specification is platform independent prescription model of future screen and report forms and input for series of M2M transformations that ends up with M2T transformation generating application prototype. The MMs and models that we use in our approach are intensional data models. System evolution can be supported by automatic MD data migration and extensional database MMs could play important role in its implementation. Our future research has to consider extensional database MMs and possible usage of category theory [18] for PIM specification of model transformations in order to automate the process of database model transformations generation.

***Abstract*—OntoUML is an ontologically well-founded conceptual modelling language that distinguishes various types of classifiers and relations providing precise meaning to the modelled entities. Efforts arise to incorporate OntoUML into the Model-Driven Development approach as a conceptual modelling language for the PIM of application data. In a prequel paper, we have introduced and outlined our approach for a transformation of OntoUML PIM into a PSM of a relational database. In this paper, we discuss the details of various variants of the transformation of Rigid Sortal types of OntoUML.**

I. Introduction

SOFTWARE engineering is a demanding discipline that deals with complex systems [1]. The goal of software engineering is to ensure high quality software implementation of these complex systems. To achieve this, various software development approaches have been developed.

Model-Driven Development (MDD) is a very popular approach in the recent years. It is a software development approach based on elaborating models and performing their transformations [2]. The product to be developed is described using various types of models specifying the requirements, functions, structure and deployment of the product. These models are used to construct the product using transformations between models and code.

The most usual part of the MDD approach used in the practice is the process of *forward engineering*: transformations of more abstract models into more specific ones. The most common use-case of such process is the development of conceptual data models and their transformation into source codes or database scripts.

To achieve a high-quality software system, high-quality expressive models are necessary to define the requirements for the system [1]. To use such models in the Model-Driven Development approach, the model should define all requirements and all constraints of the system. Moreover, it should hold that more specific models persist the constraints defined in the more abstract models [3].

This research was partially supported by grant by Student Grant Competition No. SGS16/120/OHK3/1T/18.

OntoUML was formulated in 2005 as a graphical modelling language for developing ontologically well-founded conceptual models [3]. As it is based on cognitive science and modal logic, it helps to create expressive models that are able to describe the domain very precisely. As OntoUML is domain-agnostic, it may be used for any domain. In our research, we focus on the domain of software application data and therefore we use OntoUML to create the PIM of the system. Such model can be then transformed into a PSM of the data persistence. However, as OntoUML uses various types of entities and relations to provide additional ontological meaning to the model elements, the transformation needs to deal with these aspects.

As relational databases represent a very common type of data storage, we focus on the transformation of an OntoUML PIM of application data into an ISM of a relational database. To achieve that, we divide the transformation into the following steps:

1) Transform an OntoUML PIM into a UML PIM including all the aspects defined by the OntoUML constructs.
2) Transform the UML PIM with the additional constraints into a PSM of a relational database including the required additional constraints.
3) Transform the PSM with the additional constraints into the ISM to define the constructs in the database to hold the data and maintain the constraints.

In the prequel paper [4], we outlined the various possibilities of the transformation of Sortal universal types used in OntoUML. In this paper, we discuss the details of the transformation of Rigid Sortal types (Kinds and Subkinds) and illustrate various possibilities on examples. The parallel research focused on the transformation of OntoUML Anti-rigid universal types is discussed in the parallel paper [5].

The structure of the paper is as follows: in section II, the work related to our approach including the OntoUML notation is discussed; in section III, the running example of the OntoUML PIM is explained; in section IV, our approach is discussed and illustrated on the running example; in section V, discussion to our approach is provided; finally, in section VI, the conclusion of the paper results is provided.

II. Background and Related work

A. Model-Driven Development

Model-Driven Development (MDD) is a very popular approach in the recent years. It is a software development approach based on elaborating models and performing their transformations [2]. The product to be developed is described using various types of models specifying the requirements, functions, structure and deployment of the product. These models are used to construct the product using transformations between models and code generation.

MDD was originally based on Model-Driven Architecture (MDA) [6] designed by OMG in 2001. MDA defines these types of models:

- Computation Independent Model (CIM),
- Platform Independent Model (PIM),
- Platform Specific Model (PSM),
- Implementation Specific Model (ISM) [7].

Although established already in 2001, there is still deep interest in this approach, as can be seen in recent publications. The book *Model-Driven Software Development: Technology, Engineering, Management* by Stahl et al. [8] provides a great overview of the MDD approach including the terminology, specifications, transformations and case studies. Another book *Model-Driven Software Engineering in Practice* by Brambilla et al. [9] presents the foundations of MDSE approach and also deals with the technical aspects of MDSE including the basics of domain-specific languages, transformations and tools. Also, the survey by da Silva [10] provides a good overview of the MDD approach and terminology related to MDE, MDD and MDA. Another survey was published by Whittle et al. [11] that focused on the support of the MDE approach in tools and provides a taxonomy of tool-related considerations.

The most usual part of the MDD approach used in the practice seems to be the process of *forward engineering*: transformations of more abstract models into more specific ones. The most common use-case of such process is the development of conceptual data models and their transformation into source codes or database scripts. In our research, we focus on the modelling of application data creating a PIM in OntoUML and performing transformations to generate creation scripts of a relational database schema.

B. UML

Unified Modeling Language (UML) [12], [13] is a popular modelling language for creating and maintaining variety of models using diagrams and additional components [10]. UML defines a set of building blocks – various types of elements (e.g. classes, use cases, components, etc.), relations (e.g. association, generalization, dependency, etc.) and diagrams (e.g. class diagram, use case diagram, sequence diagram, etc.). It defines also the syntax and semantics of models and a general architecture of the model [7]. In context of the data modelling, UML Class Diagram is the notation mostly used to define conceptual models of application data. Also, to describe the structure of a relational database schema, UML Data Model profile as an extension to the UML Class Diagrams may be used [14].

The main elements of a UML Class Diagram are classes, which serve to classify various types of objects in the domain of interest and specify their features and behaviour [13]. Between the classes, associations and generalization/specialization relations can be defined. The associations are used to define the fact that various instances of one class can be related to some instances – according to association multiplicities – of the other class.

Generalization is a taxonomic relationship between a more general class – *superclass* – and a more specific class – *subclass* [13]. It is used in situations when there are multiple special cases of the more general class with additional features and/or specialised meaning. In such a situation, the subclasses inherit all features of their superclass and add their own features, so their instances have all the features of both the superclass and the subclass[1]. As UML is designed following the object-oriented programming approach, an object can be an instance of only one class [7]. As UML is based on object-oriented paradigm, an object is either an instance of the superclass or an instance of the subclass, inheriting the features from the superclass but not being its direct instance.

The subclasses of the same superclass may form a *generalization set* to define a partition of subclasses with common meaning [13]. For each generalization set, two meta-properties should be set to restrict the relation of an instance to the individual subclasses: *isCovering* – expressing whether each instance of the superclass must be also an instance of some subclass in the generalization set – and *isDisjoint* – expressing whether an object can be an instance of multiple subclasses in the set at the same time. The default setting of these properties differ in the various versions of UML: UML 2.4.1 [12] and older define the `{incomplete, disjoint}` as default, while UML 2.5 [13] defines the `{incomplete, overlapping}` as default. As each object is an instance of exactly one class in the most current programming languages, the concept of generalization sets can be used only in conceptual models and it must be transformed before its realization.

C. OCL

Object Constraint Language (OCL) [15] is a specification language that is part of the UML standard. It can be used for the following purposes:

- to access model elements and their values,
- to define constraints and restrictions for model elements and their values,
- and to define query operations [7].

Several types of OCL constructs may be used to define the constraints for the model elements. *Invariants* are defined in context of certain class of the attached UML model and they are used to define constraints which must be satisfied

[1] In fact, the features of the superclass may be overriden by features of the subclass, but this situation is not considered here.

by all contextual instances at any moment. *Preconditions* and *postconditions* are defined in context of certain method of a class in the attached UML model. Preconditions define the constraints that must be satisfied before executing the method (e.g. the values of the method parameters), while postconditions define the constraints which must be satisfied after the method execution (e.g. the value of the result).

In [16], the authors define basic syntax and semantics of OCL constructs and introduce several tools that support modelling and evaluation of OCL constraints. In [17], the authors define a technique for transformations of OCL constructs into other equivalent forms to support their definition, validation and transformation.

In our approach, we use OCL invariants to define the constraints on the UML PIMs and PSMs derived from the semantics of OntoUML universal types that cannot be expressed directly in the diagram.

D. OntoUML

OntoUML is a conceptual modelling language focused on building ontologically well-founded models. It was formulated in Guizzardi's PhD Thesis [3] as a light-weight extension of UML based on UML profiles.

The language is based on *Unified Foundational Ontology* (UFO), which is based on the cognitive science and modal logic and related mathematical foundations such as sets and relations. Thanks to this fact, it provides expressive and precise constructs for modellers to capture the domain of interest. Unlike other extensions of UML, OntoUML does not build on the UML's ontologically vague "class" notion, but builds on the notion of *universals* and *individuals*. It uses the basic notation of UML Class Diagram like classes, associations and generalization/specialization together with stereotypes and meta-attributes to define the nature of individual elements more specifically. On the other hand, it omits a set of other problematic concepts (for instance aggregation and composition) and replaces them with its own ontologically correct concepts.

UFO and OntoUML address many problems in conceptual modelling, such as part-whole relations [18] or roles and the counting problem [19]. The language has been successfully applied in different domains such as interoperability for medical protocols in electrophysiology [20] and the evaluation of an ITU-T standard for transport networks [21].

However, being domain-agnostic, we believe that it may be suitable even for conceptual modelling of application data in the context of MDD. Using OntoUML, we can create very precise and expressive models of application data. These models can be later transformed into relational database schema containing various domain-specific constraints to maintain consistency according to the OntoUML model.

The following description of the OntoUML and UFO aspects is based on [3].

1) Universals and individuals: UFO distinguishes two types of things. *Universals* are general classifiers of various objects and they are represented as classes in OntoUML (e.g. `Person`). There are various types of universals according to their properties and constraints as discussed later. *Individuals*, on the other hand, are the individual objects instantiating the universals (e.g. `Mark`, `Dan`, `Kate`).

The fact that an individual is an instance of a universal means that – in the given context – we perceive the object *to be* the Universal (e.g. `Mark` is a `Person`). Important feature of UFO is the fact that an individual may instantiate multiple universals at the same time but all the universals must have a common ancestor providing the identity principle (e.g. `Mark` is a `Person` and he is a `Student` as well).

2) Identity principle: Identity principle is a key feature of UFO, which enables individuals to be distinguished from each other. Various universals define different identity principles and thus different ways how to distinguish their individuals (e.g. a `Person` is something else than a `University`); different individuals of the same universal have different identities (e.g. `Mark` is not `Kate` even when both are `Persons`).

Each individual always needs to have a single specific identity, otherwise there is a clash of identities (e.g. `Mark` is a `Person` and therefore it can never be confused with another concept such as a `University`). The identity of an individual is determined at the time the individual comes to existence and it is immutable – it can never be changed (e.g. `Mark` will always be `Mark` and he will always be a `Person`).

The types of universals that provide the identity principle for their instances are called *Sortal universals* (e.g. `Person`, `Student`). The types of universals not providing the identity principle are called *Non-Sortal universals* (e.g. a `Customer` may be a `Person` or a `Company`). In this paper, we discuss only the transformations of the Sortal types of universals, as they form the basis of models.

3) Rigidity: UFO and OntoUML are built on the notion of worlds coming from Modal Logic – various configurations of the individuals in various circumstances and contexts of time and space. *Rigidity* is, then, the meta-property of universals that defines the fact if the extension of the universal (i.e. the set of all instances of the universal) is world invariant [22]. UFO distinguishes rigid, anti-rigid and semi-rigid universals:

- `Rigid universals` are such types of universals whose extension is rigid – instances of the Rigid universals cannot cease to be their instances without ceasing to exist (e.g. `Mark` will always be a `Person`). Certain types of both Sortal and Non-Sortal universals are rigid.
- `Anti-rigid universals` are such types of universals which, in one world, contain an instance in their extension, which is not included in the extension in another world. It means that an individual that is an instance of the Anti-rigid universal in one world may not be an instance of that universal in another world without ceasing to exist (e.g. `Mark` is a `Student` now, but he will not be a `Student` 50 years later). Certain types of both Sortal and Non-Sortal universals are anti-rigid.
- `Semi-rigid universals` are such types of universals that can include both rigid and anti-rigid instances in

their extension. Only Non-Sortal types of universals are semi-rigid.

In this paper, we focus only on the Rigid Sortal types of universals and we discuss the details of the transformation of such universals into the relational databases.

4) Generalization and Specialization: In contrast to UML, in UFO and OntoUML, the generalization relation defines the inheritance of the *identity principle*. According to that, an individual which is an instance of the subclass is also an instance of the superclass automatically through inheriting the identity principle from the superclass. Also, the relation is rigid in UML – when an instance of the superclass is also an instance of the subclass, it cannot cease to be so without losing its identity – while in OntoUML, the relation may be non-rigid: a single individual may be an instance of both the superclass and subclass in one world and it may be an instance of only the superclass in another world.

The generalization sets in OntoUML are much more common as they define the required identity for various universal types. Unless altered, *{incomplete, non-disjoint}* is considered the default value of the meta-properties.

5) Kinds and Subkinds.: The backbone of an OntoUML model is created by Kinds. *Kind* is a Rigid Sortal type of universals that defines the identity principle for its instances, thus defining the way how we are able to distinguish individual instances of that universal. In OntoUML, the Kind universals are depicted as classes with the $\ll Kind \gg$ stereotype. Examples of Kind universals are a `Person` and a `University`.

Subkind is a Rigid Sortal universal type that does not define its own identity principle, but it inherits it from its ancestor and provides it to its instances. Therefore, Subkind universals form generalization sets of other Kind or Subkind universals; they form inheritance hierarchies with the root in a Kind universal. In other words, each instance of a Subkind universal is automatically – through the transitive generalization relation – also an instance of all the ancestral Kind and Subkind universals, receiving the identity principle from the root Kind universal. The inheritance may have any combination of values of the *isDisjoint* and *isCovering* meta-properties. Examples of Subkind universals may be a `Man` and a `Woman` as subkinds of a `Person`.

6) Other universal types.: UFO and OntoUML define several other universal types such as Role, Phase, Relator, Mixin, Quantity et al. However, they are out of scope of this paper.

E. Tools

There are tools supporting certain parts of the transformation process described in section IV. Although none of them supports the full transformation, they can be used for the individual steps or serve as an inspiration for a complex tool to be developed.

Enterprise Architect[2] is a complex CASE tool supporting the whole software development process. Beside the modelling in UML and other notations, it offers transformation between models and source code generation. In context of our work, the transformation of a class model into a database model and the generation of SQL DDL scripts are useful. Beside Enterprise Architect, there are many other tools providing similar functions for UML and relational databases (e.g. Visual Paradigm[3]).

There are also several tools supporting definition of OCL constraints and their evaluation on a given model instance, such as DresdenOCL[4], OCLE[5] or USE[6]. DresdenOCL even provides functions to generate Java source code with AspectJ for the OCL constraints or SQL DDL scripts with views for the OCL constraints.

For OntoUML, there are a few tools available, as well. OntoUML lightweight editor (OLED)[7] is an environment for modelling with OntoUML which also offers functions for model visualisation, validation and transformation into OWL. However, it does not offer transformation into UML nor into relational databases. Menthor Editor[8] is a successor of OLED, providing more convenient environment for modelling and providing transformations of an OntoUML model along with OCL constraints into OWL, RDF and UML. As for other tools, there is an Enterprise Architect plugin[9] and a palette for UMLet editor[10] available for OntoUML modelling.

F. Previous work

In our previous work, we focused on the transformation of special multiplicity values in a UML PIM into PSM for relational databases [23] and the possible realizations of such constraints [24]. The approaches described in these papers may be used for the realization of the constraints derived from the OntoUML constructs used in the PIM as discussed in this paper.

In [25] we focused on the transformation of an ontological conceptual model in OntoUML into a pure object implementation model in UML and also the instantiation of such model to validate it. In the paper [4], we outlined our approach to the transformation of OntoUML PIM into an ISM of a relational database. In the parallel paper [5], we discuss the details of the transformation of OntoUML Anti-rigid Sortal types. This paper presents the parallel research focused on the transformation of OntoUML Rigid Sortal types (Kinds and Subkinds).

III. Running Example

Our approach to the transformation of the Sortal Rigid universal types in an OntoUML PIM into ISM of a relational database is illustrated on the running example shown in Figure 1. The model shows an excerpt of the domain of an automotive company. The company takes care about

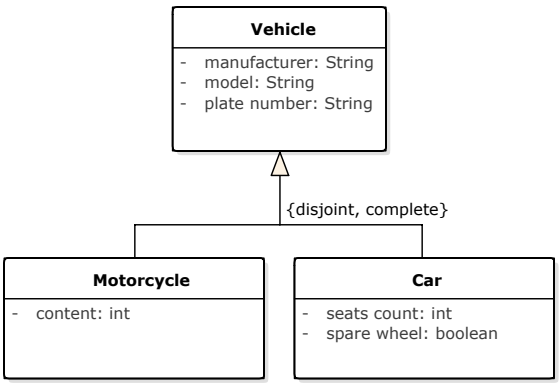

Fig. 2. UML PIM of vehicle types

motorcycles and personal cars in their fleet. These two types of vehicles are represented by the `Motorcycle` and `Car` Subkinds of the common ancestral Kind `Vehicle` defining the identity of a vehicle.

As the company uses only motorcycles and personal cars, the generalization set is `complete`. Also, it is not possible for a single vehicle to be both the motorcycle and the car, therefore the generalization set is `disjoint`.

IV. Our Approach

Our approach to the transformation of a PIM in OntoUML into its realization in a relational database consists of three steps which are discussed in the following sections:

1) subsection IV-A discusses the transformation of an OntoUML PIM into a UML PIM,
2) subsection IV-B discusses the transformation of the UML PIM into a PSM for relational database,
3) subsection IV-C discusses the transformation of the PSM into an ISM of the relational database.

As mentioned in the introduction, it should hold that no information should be lost when transforming from a more abstract model into a more specific one. As OntoUML applies certain constraints based on the OntoUML type used for an entity, these constraints should be carried over to the other models. In our approach, we use OCL to define such constraints in the UML models that cannot be expressed directly in the diagrams.

Although we may formulate a direct transformation from OntoUML into the relational database, the transformation via an auxiliary UML model enables to leverage all the available knowledge (e.g. [26], [24] and tools for transformation of a UML PIM into database models such as Enterprise Architect[11]. Also, various optimizations and refactoring may be applied whenever possible (e.g. when the entity does not hold any attributes, they can be expressed by a mere attribute of the superclass).

In the approach presented here, we assume the (most common) situation where all attributes of the model classes have multiplicities `[1..1]`. In the conclusions, we discuss how the situation changes for different multiplicities.

[11]http://www.sparxsystems.com.au/products/ea/

A. Transformation of OntoUML PIM into UML PIM

This phase of the transformation deals with the transformation of various types of universals in an OntoUML model into a pure UML model while preserving all the semantics defined by the universal types.

In this phase of the transformation, the semantics of the OntoUML model is mostly realized by the multiplicities of the relations between the classes in the UML model.

As various OntoUML universal types define different semantics, they are also transformed in a different manner. However, we discuss only the transformation of Rigid Sortal types (Kinds and Subkinds) and their variants in this paper.

1) Kinds and Subkinds: As both Kind and Subkind universals in OntoUML are rigid, their instances cannot cease to be their instances without ceasing to exists. The same applies in UML for the relation between the instances and their classes. Therefore, the representation of Kinds and Subkinds in UML may stay the same: each $\ll Kind \gg$ and $\ll Subkind \gg$ class is transformed into a standard UML class keeping all its features – attributes and relations.

The resulting transformed PIM into UML for the vehicle domain shown in Figure 1 is shown in Figure 2. Each of the $\ll Kind \gg$ and $\ll Subkind \gg$ classes has been transformed into standard UML class.

2) Generalization sets: A Subkind in OntoUML represents a special case of a Kind or other Subkind, forming a generalization set together with other Subkinds. As both Kinds and Subkinds are rigid, also the generalization set is rigid: when an object is an instance of the Subkind, it is also an instance of its rigid ancestor – a Kind or another Subkind – and it cannot cease to be the instance of any of them without loosing its identity.

Thanks to the rigidity, the generalization sets of $\ll Subkind \gg$ classes in the OntoUML model can be transformed into the standard UML generalization set. Also, the meta-properties `isDisjoint` and `isCovering` of the

generalization set remain the same. The example of this transformation can be seen in Figure 2.

B. Transformation of PIM into PSM

The second step is the transformation of the UML PIM into a PSM of a relational database. The UML Data Model profile – an extension to the UML class diagrams – is used in the examples to define the structure of relational databases in UML [14]. Additional constraints required to preserve the semantics derived from the OntoUML model are defined as OCL invariants, as OCL is part of the UML standard and there are tools supporting the transformation of OCL constraints into database constructs such as DresdenOCL[12]. The basics of this transformation was already discussed in [24]. In this paper, we focus on the transformation of the constraints derived from the OntoUML Rigid Sortal universal types.

In general, when performing transformation from a UML PIM into a PSM of a relational database, classes are transformed into database tables, class's attributes are transformed into table columns and associations are transformed into FOREIGN KEY constraints. Also, PRIMARY KEY constraints are defined for unique identification of individual rows in the tables.

The transformation of classes representing various Kind universals is straightforward – the class with its attributes is transformed into a table with its columns as discussed in [24]. However, more complicated situation arises for the subclasses representing the Subkind universals, as they always form generalization sets. There are multiple standard variants of the transformation of generalization [27], however, they have certain limitations regarding the OntoUML Subkind universal constraints, as discussed in the following sections.

1) Single table: In this variant of generalization realization, the superclass and all its subclasses are realized by a single table. Such table contains the columns for all the attributes of the superclass and all its subclasses. Instances of the superclass are represented by rows with the subclasses' columns containing NULL values, instances of a subclass contain values only in the superclass columns and their respective subclass columns – the other columns remain NULL. Usually, a special column to discriminate the subtypes is also defined in the table. The resulting transformed model of the PIM in Figure 2 is shown in Figure 3, where the column `id` serves as the PRIMARY KEY and the column `type` serves as the discriminator.

As our assumption is that attribute multiplicities are `[1..1]` – as mentioned at the beginning of this section – all columns of a class should be NOT NULL in the table. This can be easily defined by the NOT NULL constraints for the columns of the superclass, as they have values even for the instances of the subclasses. However, the constraints for the subclasses' columns depend on the subclass of the instance, which the row represents – the other columns may contain NULL values. Moreover, all columns of a single subclass – not only a subset of them – should have a value.

[12]https://github.com/dresden-ocl

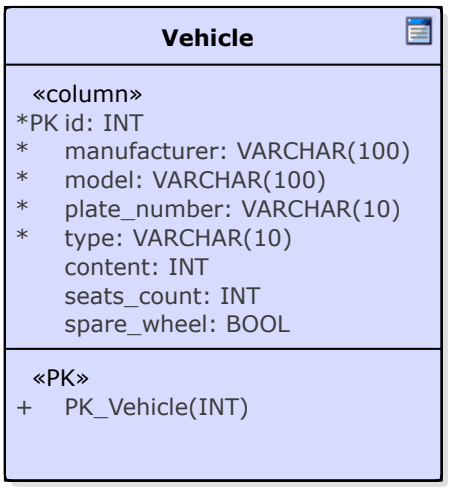

Fig. 3. PSM of vehicle types realized by a single table

As such constraints are not defined on the column level, they cannot be captured directly in the UML model. Instead, they must be defined as additional OCL invariants that are later transformed into their realization in a relational database (see subsection IV-C). For the example in Figure 3, these constraints can be defined for the individual subclasses as shown in Algorithm 1.

Furthermore, the constraints should be defined in respect to the meta-properties of the generalization set according to the following variants:

- `{complete, disjoint}`: For each row, all the columns of the superclass and all the columns of a single subclass must contain NOT NULL values, the other columns must contain NULL values.
- `{complete, overlapping}`: For each row, all the columns of the superclass and all the columns of at least a single subclass cannot contain NULL values.
- `{incomplete, disjoint}`: For each row, all the columns of the superclass must contain NOT NULL values. At the same time, all the columns of at most one of the subclasses may contain NOT NULL values, the other columns must contain NULL values.
- `{incomplete, overlapping}`: For each row, all the columns of the superclass must contain NOT NULL values. All the columns of any subclass may or may not contain NOT NULL values.

Such OCL invariant for the example shown in Figure 3 is shown in Algorithm 2. Because the generalization set is `{disjoint, complete}`, the `Vehicle` columns must contain a value – this is achieved by the NOT NULL constraints of the columns – and the columns of `Motorcycle` class must contain NOT NULL values while the `Car` class must contain NULL values, and vice versa.

The constraints discussed above become the more complicated the more attributes there are in the subclasses because

Algorithm 1 OCL invariants for the NOT NULL constraints of the subclasses

```
context v:Vehicle inv MotorcycleNotNull:
v.type = 'Motorcycle' implies v.content <> OclVoid

context v:Vehicle inv CarNotNull:
v.type = 'Car' implies v.seats_count <> OclVoid and v.spare_wheel <> OclVoid
```

Algorithm 2 OCL invariant for the `{disjoint, complete}` generalization set realized by a single table

```
context v:Vehicle inv MotorcycleOrCar:
def: validMotorcycle:Boolean =
        v.content <> OclVoid and v.seats_count = OclVoid and v.spare_wheel = OclVoid
def: validCar:Boolean =
        v.content = OclVoid and v.seats_count <> OclVoid and v.spare_wheel <> OclVoid
validMotorcycle xor validCar
```

of the exclusivity of the NOT NULL values. Therefore, we would recommend this variant of the transformation only in cases there are not many subclasses and their attributes.

2) Subclasses' tables: In this variant of the transformation, the tables are created only for the subclasses. The attributes of the superclass are transformed into columns in all the tables of all the subclasses. Therefore, each instance of a subclass is able to store also the values of the superclass's attributes along with their own in a single table. Because of this, all the NOT NULL constraints can be easily defined for all columns.

However, in this variant, it is more complicated to ensure the unique values for attributes of the superclass, as the data are distributed in several distinct tables.

Also, this variant cannot be used for an `incomplete` generalization set as it does not allow the storing of an instance of only the superclass. Even if the NOT NULL constraints on the subclasses' columns would not be defined, it would not be clear in which table to store the instance[13].

Moreover, this variant is not suitable for `overlapping` generalization sets either, as storing the data of multiple subclasses to their respective tables also duplicate the data of the superclass.

Therefore, based on the mentioned restrictions and complications, we would not recommend this variant of the transformation in any situation and we will not discuss it anymore.

3) Superclass and subclasses' tables: According to this variant, the superclass and all the subclasses are transformed each into their own table and the individual subclass's tables contain the FOREIGN KEY referring to the superclass's table. This direction is determined by the fact that an instance of the subclass is also an instance of the superclass. Therefore a record in the subclass's table requires exactly one record in the superclass's table – thus being related to `1..1` parent records. More details about determination of the FOREIGN KEY direction based on the multiplicities can be found in [28].

In this variant, the NOT NULL constraints are easier to define, as all columns in a table represent attributes of the same class and they can be expressed by simple NOT NULL constraints defined directly for each column. Still, an additional constraint must be defined for the meta-properties of the generalization set of the subclasses according to the following combinations:

- `{complete, disjoint}`: exactly one row from only one of the subclass's tables refers to the row in the superclass's table.
- `{complete, overlapping}`: at most one row from each of the subclass's tables refers to the row in the superclass's table, but at least one in total.
- `{incomplete, disjoint}`: at most one row from only one of the subclass's tables refers to the row in the superclass's table.
- `{incomplete, overlapping}`: at most one row from each of the subclass's tables refers to the row in the superclass's table.

The restriction of *at most one row from a table* can be realized by a UNIQUE KEY constraint on the FK column; the same column may also be part of the PRIMARY KEY constraint. However, the exclusivity must be checked by a special constraint, still.

In the running example, the subclasses `Motorcycle` and `Car` are transformed into their respective tables (see Figure 4). As their generalization set is `complete` and `disjoint`, the FK column is part of the PRIMARY KEY constraint to make it unique. Furthermore, the constraint shown in Algorithm 3 must be defined.

The other variants of the generalization meta-properties are not discussed here.

[13]Technically, it is possible to designate one of the subclass's tables for this purpose. However, we find this approach inconceptual.

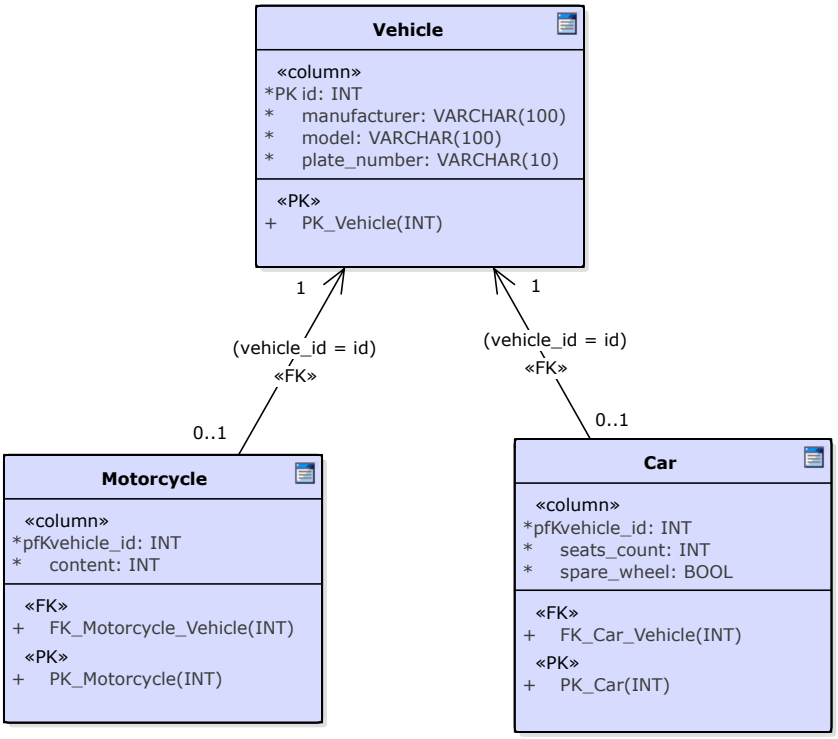

Fig. 4. PSM of vehicle types realized by a separate superclass's and subclesses' tables

Algorithm 3 OCL invariant for the `{disjoint, complete}` generalization set realized by a superclass's and subclasses' tables

```
context v:Vehicle inv MotorcycleOrCar:
def:validMotorcycle:Boolean = Motorcycle.allInstances()->exists(m|m.vehicle_id=v.id)
def:validCar:Boolean = Car.allInstances()->exists(c|c.vehicle_id = v.id)
validMotorcycle xor validCar
```

C. Transformation of PSM into ISM

The last step is the transformation of the PSM of a relational database into an ISM. This model consists of database scripts for the creation of the database tables, constraints and other constructs.

As we have the PSM of the relational database, the transformation is quite easy. Most of the current CASE tools such as Enterprise Architect or Visual Paradigm[14] can be used to generate SQL DDL scripts. These scripts usually include the CREATE commands for the tables, their columns, NOT NULL constraints and PRIMARY and FOREIGN KEY constraints.

However, the OCL invariants defined for the additional constraints require special transformation. Only a few tools currently seem to offer transformation of such constraints – e.g. DresdenOCL[15], OCLE[16] or USE[17].

[15]https://github.com/dresden-ocl
[16]http://lci.cs.ubbcluj.ro/ocle/
[17]http://sourceforge.net/projects/useocl/

Our approach to the realization of the OCL constraints derived from the OntoUML universal types is inspired by the approach for special multiplicity constraints discussed in [24]. Based on that approach, the following constructs may be used to prevent violating the derived constraints:

- *Database views* can be used to query only the valid data meeting the constraints. They do not slow down the DML operations, but they do not prevent inserting data violating the constraints.
- *Updatable database views with CHECK option* can be used to manipulate only the valid data, preventing to create invalid data by insert, update and delete operations. However, the use of such views is restricted by several constraints for the query expression.
- *CHECK constraints* can be used to check the values inserted to various columns of the table, but the common current database engines (e.g. Oracle 11g) do not support subqueries in the CHECK constraint expression and therefore they cannot be used for relational constraints.

- *Triggers* can be defined on the DML operations to prevent creating invalid data in the tables. In the triggers, complex queries and checks can be realized, and therefore they are capable to deal with almost every possible constraint. The constraint checks slow down each DML operation, however as shown in [24], the time increase is typically not substantial.

In [24], the research was focused on the realization of special multiplicity constraints. The same approach, however, may be used also for the realization of the constraints derived from the Rigid Sortal universal types and their generalization sets in OntoUML.

In the following sections, the transformation of the resulting PSMs from subsection IV-B is discussed using the approaches listed above (marked by italics).

1) Single table: For the generalization set transformed into a single database table, the constraint was defined as shown in Algorithm 2. Its realization using the *database view* is simple: query only such rows from the table that have either the `Motorcycle` columns or the `Car` columns filled with values. The resulting database view is shown in Algorithm 4. The WHERE condition filters out such vehicles that are neither motorcycle nor car as well as such vehicles that are both – and it exactly meets the `{complete, disjoint}` property of the generalization set.

Moreover, as the view definition meets the constraints for an *updatable view*, it can be defined WITH CHECK OPTION and used even for DML operations like inserts, updates and deletes. The WITH CHECK OPTION makes the database engine to check the view after each such operation executed on the view and prevents inserting a row that will not be accessible by the view or updating a row to make it inaccessible.

The same effect might be achieved also by defining a *CHECK constraint* which is checked after each operation on the table. The resulting CHECK constraint is shown in Algorithm 5. Using such constraint, it is not possible to create invalid data in the table and therefore the table can be used directly for querying the valid data.

As the CHECK constraint does not contain any subqueries, it is supported by the common database engines without any problems. The realization by triggers would achieve the same results but with more complex definition and slower evaluation. Therefore, it is not worth to use the *triggers* approach in this case.

2) Superclass's and subclasses' tables: For the generalization set transformed into database tables for the superclass and all the subclasses, the constraint was defined as shown in Algorithm 3.

The resulting *database views* for the realization of the OCL invariant are shown in Algorithm 6. The view `Valid_Vehicles` is used to query only such rows from the `Vehicle` table that have a row either in the `Motorcycle` or in the `Car` table referring to it. Therefore, using this view, we can access data about such vehicles that are either a motorcycle or a car, the vehicles having invalid data are hidden from the view.

To query the data of valid motorcycles, the view `Valid_Motorcycles` can be used that filters out invalid motorcycles using the `Valid_Vehicles` view. By analogy, the view `Valid_Cars` can be used to query only the valid cars.

All of these views are updatable – meeting the criteria for an *updatable view* – and therefore they can be defined WITH CHECK OPTION and used to manipulate with the vehicles to prevent creating vehicles without the motorcycle or car data. However, it would not be possible to insert data into any of the views as inserting into the `Valid_Vehicles` would violate the view condition while inserting into the `Valid_Motorcycles` or`Valid_Cars` would violate the FOREIGN KEY constraint. Therefore, the FOREIGN KEY constraint must be defined as *deferrable*, so it is checked at the end of the transaction and not at the time of execution of the command. Then, it is possible to insert data to the `Valid_Motorcycles` or `Valid_Cars` views, first referring to a not-existing vehicle and then to insert data into the `Valid_Vehicles` view.

However, the existence of such views does not prevent the manipulation with the data directly in the tables and thus violating the constraints. Therefore, another database construct should be used. A *CHECK constraint* might have been used as discussed in subsubsection IV-C1, however, as the constraint would contain subquery, it is not supported by the common current database engines [24]. Therefore, the CHECK constraint cannot be actually used in this situation.

Instead, according to the *triggers* approach, triggers might be defined for each of the tables for all the DML operations – insert, update, delete – to check that the operation will not violate the constraint. The following triggers would be needed:

- `BEFORE INSERT ON Vehicle`: This trigger would check there are car data or motorcycle data available in their respective tables for the vehicle. If violated, an error is raised and the operation is cancelled.
- `BEFORE UPDATE OR DELETE ON Motorcycle`: The trigger would check there are no vehicle data in the `Vehicle` table, to which the updated or deleted rows refer. If violated, an error is raised and the operation is cancelled.
- `BEFORE UPDATE OR DELETE ON Car`: The similar trigger should be defined as for the `Motorcycle` table.

Defining such triggers, along with the FOREIGN KEY constraints a PRIMARY KEY constraints, would prevent creating invalid data in the tables during any DML operation. However, the FOREIGN KEY constraints must be defined as *deferrable* – same as for the views – to allow inserting the subclasses' data before inserting the superclass's data or to delete the superclass's data before deleting the subclasses' data.

V. Discussion

As mentioned above, our approach to the realization of the constraints derived from the OntoUML Sortal universal types is based on the approach discussed in [24]. In this paper, the authors discuss possible ways to realize constraints for

Algorithm 4 Database view to query valid data from the combined `Vehicle` table

```
CREATE VIEW MotorcycleOrCar AS
SELECT * FROM Vehicle v WHERE
  (v.content IS NOT NULL AND v.seats_count IS NULL AND v.spare_wheel IS NULL)
  OR
  (v.content IS NULL AND v.seats_count IS NOT NULL AND v.spare_wheel IS NOT NULL)
WITH CHECK OPTION
```

Algorithm 5 CHECK constraint for the combined `Vehicle` table

```
ALTER TABLE Vehicle ADD CONSTRAINT MotorcycleOrCar CHECK
  (v.content IS NOT NULL AND v.seats_count IS NULL AND v.spare_wheel IS NULL)
  OR
  (v.content IS NULL AND v.seats_count IS NOT NULL AND v.spare_wheel IS NOT NULL)
```

Algorithm 6 Database views to query only valid data from the `Vehicle`, `Motorcycle` and `Car` tables

```
CREATE VIEW Valid_Vehicles AS
SELECT * FROM Vehicle v WHERE
  (EXISTS (SELECT 1 FROM Motorcycle m WHERE m.vehicle_id = v.id)
       AND NOT EXISTS (SELECT 1 FROM Car c WHERE c.vehicle_id = v.id))
  OR
  (NOT EXISTS (SELECT 1 FROM Motorcycle m WHERE m.vehicle_id = v.id)
       AND EXISTS (SELECT 1 FROM Car c WHERE c.vehicle_id = v.id))

CREATE VIEW Valid_Motorcycles AS
SELECT v.*, m.content FROM Valid_Vehicles v
  JOIN Motorcycle m ON (v.id = m.vehicle_id)

CREATE VIEW Valid_Cars AS
SELECT v.*, c.seats_count, c.spare_wheel FROM Valid_Vehicles v
  JOIN Car c ON (v.id = c.vehicle_id)
```

special multiplicity values using database views and triggers. The authors also provide results of experiments, proving that their realization guarantees database consistency in context of the multiplicity constraints with just a slight decrease in efficiency.

The OCL constraints derived from the OntoUML Sortal universal types have the same structure – they are based on multiplicities of related objects or their exclusivity. Therefore, also their realization using the views and triggers is very similar. Based on this, we can expect the same impact on the efficiency of the DML operations and queries. However, as our research is not yet fully concluded, experiments are yet to be done to prove that.

Also, in this paper, we focused on the most common situation of mandatory attributes (attribute multiplicity `[1..1]`). In case of optional attributes (minimal multiplicity `0`), some of the constraints will simplify – e.g. the NOT NULL constraints for individual columns representing the attributes of the subclasses (Algorithm 1 and Algorithm 2). On the other hand, collection attributes (attributes with the maximal multiplicity $*$) lead to the realization in the form of relations, references and FOREIGN KEYs.

VI. Conclusions

In this paper, we introduced our approach to the transformation of an OntoUML PIM of application data into an ISM of a relational database. This transformation is separated into three sequential steps: the transformation of an OntoUML PIM into a UML PIM, the transformation of the UML PIM into a PSM for relational database and the transformation of the PSM into an ISM of a relational database.

During these transformations, various options and additional constraints should be defined and realized to maintain the semantics defined by the OntoUML universal types. In this paper, we discussed the details of the transformation of Rigid Sortal universal types – Kinds and Subkinds and their generalization sets – discussing various possible realizations of the constraints derived from the semantics of these OntoUML

constructs. All the variants are described using a running example of a simple OntoUML PIM of vehicle types.

As for the future research, a similar work should be elaborated for the Non-sortal universal types – e.g. Category, Mixin, RoleMixin – and relational constructs – part-whole relations, Relators, etc. Also, combinations of multiple generalization sets of a single universal with various combinations of the meta-properties should be investigated. Finally, experiments should be carried out to study the finer points of individual variants of the constraints realization.

Applying Mutation Testing for Assessing Test Suites Quality at Model Level

Joanna Strug

Email: pestrug@cyf-kr.edu.pl

***Abstract*—Models are commonly used in software testing to select test suites. Application of mutation testing at a model level can contribute to reliable and early assessment of the quality of the test suites. It can also support selection of test suites achieving high fault detection rates. The main issue related to using mutation testing at the early development stage is to determine how reliably the quality of test suites can be measured at the model level. The research presented in this paper addresses this problem for object-oriented systems. It focuses on describing an experiment aiming at comparing results of applying mutation testing at a model level with results of applying this technique at an implementation level and presents and discusses the outcomes of the experiment. The paper presents also mutation operators applicable at the model level.**

I. Introduction

MODELS play an important role in developing object-oriented software systems. They are also commonly used by researchers and practitioners involved in software testing as a source of data for selecting tests [25]. As the main goal of software testing is to detect faults in a tested system, an adequate assessment of suites of tests provided by any test generation approach is essential. Mutation testing is a well established techniques that helps to assess the quality of test suites with regard to their ability to detect faults [7]. To assess test suite quality, by means of this technique, a number of faulty versions of the system (called mutants) is generated, by introducing small changes into the original system, and executed against tests from the suite. The ratio of the number of mutants detected (killed) by these tests over the total number of non-equivalent mutants (called a mutation score for a test suite) determines the test suite ability to detect faults. The higher the mutation score for a test suite, the better the suite is in detecting faults. Although mutation testing is an effective test suite assessment technique, its application area is mostly limited to implementation level and high computational costs still prevent it from becoming a practical approach.

Application of mutation testing at a model level could be a good alternative or at least a valuable addition to the current practice in assessing the quality of test suites derived from models. It would allow to use the most reliable assessment technique at the same early level and may also lower the costs of generation and execution of mutants, as system models are less complex than the implementations.

However, two issues should be considered before applying the approach in practice:

1) choice of models for representing a system, and
2) evaluation of the reliability of results of a model level test suite quality assessment.

The research presented in this paper concerns object-oriented systems, therefore UML/OCL class diagrams were used to describe the systems at the model level.

The second issue is essential, when increasing the level of abstraction at which mutation testing is applied. A model represents only certain aspects of a final system, thus it is not possible to predict all implementation level faults based only on faults that appear at a model level. Moreover, faults introduced into a model target only features of the model, not of the language used to implement the system, and hence application of mutation testing at a model level assesses a test suite ability to detect faults specific to that level. Even in context of object-oriented systems modeled with UML/OCL and implemented in an object-oriented language, there are significant differences between both description formalisms. Thus, it is unclear if test suite assessment results (provided in the form of a mutation score) obtained at model level are sufficiently reliable to be accepted as a measure of a test suite quality in terms of its ability to detect faults in a final, implemented system. To the author best knowledge, the problem has not been studied before. The paper presents an approach to model level, UML/OCL-based assessment of test suite quality and describes an experiment carried out to address the problem. It provides a description of mutation operators applicable to UML/OCL models, the procedures for conducting the experiment and its results.

II. Related Work

Mutation testing was originally introduced at the implementation level [7] and the majority of papers describing different aspects of mutation testing dealt with problems concerning implementation level mutation only (a survey of such papers can be found in [11]). However, application of mutation testing at model level seems to gain popularity [1], [2], [16], [18], [19], [23], [24]. Authors of the approaches have focused mainly on selecting tests, but some of them have addressed also the problem of assessing tests at the model level [24], [23] and discussed selected aspects related to the problem of

978-83-60810-90-3/$25.00

assessing tests quality at different levels [23]. Although the problem considered by authors of the work in [23] is partially related with the one studied in this work, their approach is not applicable in the context of object-oriented systems, because the formalisms used in the paper cannot support adequately object-oriented aspects of the systems.

Relevant to this research are mainly papers describing application of mutation testing to UML and OCL based models [1], [2], [14], [16] and papers providing information that can help to design mutation operators applicable to UML and OCL. The set of UML/OCL related mutation operators introduced by the author in [17] was developed based on the fault taxonomy for UML [9], traditional mutation operators, operators adapted from other formalisms [8], [15] and operators defined for specifications [5], [12] and contracts [12] and was supplemented with five new OCL-specific operators.

The work presented in this paper differs from other works concerning model or implementation level mutation testing, as it targets UML/OCL class diagrams (standard models in developing object-oriented systems) and attempts to find out if test suites ability to detect implementation level faults can be assessed reliable at the model level.

III. Experimental Evaluation of a Reliability of Model Level Test Suite Quality Assessment Results

The goal of the research was to determine how reliably one can assess test suite quality, in terms of its ability to detect real faults in an object-oriented software system, by assessing the test suite using mutation testing at a the model level. Empirical studies on mutation testing have provided evidences that application of the technique at the implementation level provides adequate measurement of test suite quality (in terms of its ability to detect real faults in a final, implemented system) [6], [13]. Thus, the implementation level measurements can be referred to to determine the reliability of the test suite quality assessment results obtained at the model level.

A. Experimental measures

Application of mutation testing provides a mutation score for a test suite. The mutation score is a quantitative measure of the suite ability to detect mutants. For the rest of the paper let T denote a test suite, $MS_{IL}(T)$ denote a mutation score calculated for T at the implementation level and $MS_{ML}(T)$ denote a mutation score calculated for T at the model level.

Implementation level mutation score $MS_{IL}(T)$ for a test suite T expresses its ability to detect implementation level mutants (and thus their ability to detect real faults) and is defined in the following way:

$$MS_{IL}(T) = \frac{MI_D}{MI_T}, where$$

- MI_D is the number of implementation level mutants detected by T,
- MI_T is the total number of non-equivalent, implementation level mutants.

Model level mutation score $MS_{ML}(T)$ for a test suite T expresses its ability to detect model level mutants and is defined in the following way:

$$MS_{ML}(T) = \frac{MM_D}{MM_T}, where$$

- MM_D is the number of model level mutants detected by T,
- MM_T is the total number of non-equivalent, model level mutants.

The reliability of a model level test suite assessment result is measured for a test suite T by comparing the value of $MS_{ML}(T)$ with the value of $MS_{IL}(T)$.

B. Mutation Operators

Mutation operators are defined as transformation rules that produce faulty versions (so called mutants) of a program or a model [7]. Each operator can produce a number of mutants by changing instances of some construction of the formalism to which the operator is applied.

Within the work generation of mutants was controlled by two sets of mutation operators. At the implementation level mutation operators designed for Java and implemented in mujava [15] were used, and at the model level operators modifying UML/OCL class diagrams were used. The second set was divided into two groups: class diagram related mutation operators, and OCL related mutation operators.

The first group consists of the following operators:

- Hiding attribute deletion (IHD) - deletes in a subclass an attribute having the same name and type as an attribute in a parent class,
- Hiding attribute insertion (IHI) - inserts in a subclass an attribute having the same name and type as an attribute in a parent class,
- Attribute multiplicity change (CAMC) - changes a multiplicity of an attribute,
- Operation arguments order change (OAO) - changes the order of arguments in an operation definition,
- Operation arguments type replacement (ADR) - changes a declared type of a method argument to the parent of the originally declared type,
- Overriding operation deletion (IOD) - deletes an overriding operation in a subclass,
- Generalization association deletion (GAD) - deletes a generalization association between two classes,
- Generalization association direction change (GDC) - changes a direction of a generalization association,
- Association type replacement (ATR) - replaces a type of an association with another type,
- Association end multiplicity change (EMC) - changes multiplicity of an association end to other one,
- Association end class replacement (ECR) - replaces an association end class with a parent class or a subclass,
- Association role swap (ARS) - swaps role names of two associations between the same two classes or their subclasses.

The second group consists of the following operators:

- Operand Replacement Operator (ORO) - replaces an operand with another one, applies also for components of a navigation path,
- Arithmetic Operator Replacement (AOR) - replaces a binary arithmetic operator with another one,
- Arithmetic Operator Insertion (AOI) - inserts an unary arithmetic operator,
- Arithmetic Operator Deletion (AOD) - deletes an unary arithmetic operator,
- Relational Operator Replacement (ROR) - replaces a relational operator with another one,
- Conditional Operator Replacement (COR) - replaces a conditional operator with another one, supports operators: and, or, xor,
- Conditional (unary) Operator Insertion (COI) - inserts an unary conditional operator (not),
- Conditional (unary) Operator Deletion (COD) - deletes an unary conditional operator (not),
- @pre Deletion (POD) - deletes @pre operator,
- @pre Insertion (POI) - inserts @pre operator,
- Collection Operation Replacement (OCR) - replaces an invocation of a collection operation with another one,
- Collection Operation Deletion (OCD) - deletes an invocation of a collection operation,
- Contextual Instance Replacement (CIR) - replaces a contextual instance with another one.

C. Experimental procedures

The experiment was divided into two stages (Fig. 1):

1) model level test suites quality assessment, and
2) implementation level test suites quality assessment.

The experiment was performed on six experimental test suites provided for two object-oriented systems. The experiment, at each stage, was carried out following the same scenario, but dealt with the systems at different levels of abstraction (i.e. models or implementations) and was supported by different tools.

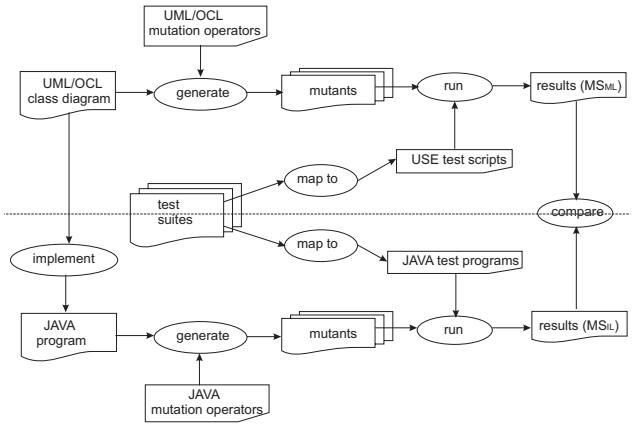

Fig. 1. An outline of the experiment

In the first stage each system was specified in a form of a UML/OCL class diagram, according to USE notation and each test suite was described as a USE command script [10]. Next, for each system, mutants of the system model were manually generated by applying mutation operators designed for UML/OCL models, and executed against tests from the test suites prepared for the system. The undetected mutants were then analyzed manually to remove the equivalent ones and for each test suite T its model level mutation score ($MS_{ML}(T)$) was calculated. At this stage the execution of the mutants was automated by use of USE (UML based Specification Environment) [10].

At the beginning of the second stage the UML/OCL models developed in the first stage were used to implement the systems in Java and the test suites for the systems were mapped into muJava test programs [15]. Next, for each system, its implementation was mutated by applying mutation operators defined for Java. The mutants were then executed against the test suites provided for the system and implementation level mutation score ($MS_{IL}(T)$) for each test suite T was calculated. This stage was fully automated due to the use of mujava [15].

Finally, for each test suite T the values of $MS_{ML}(T)$ and $MS_{IL}(T)$ were compared. Results of the experiment are presented and briefly discussed in Section III-D.

D. Experimental results and discussion

During the experiment each test suite T was assessed twice: first to get its model level mutation score ($MS_{ML}(T)$) and then to get its implementation level mutation score ($MS_{IL}(T)$). Table I shows the results of the experiment.

As it can be observed in Table I, for each test suite T the values of its $MS_{ML}(T)$ and $MS_{IL}(T)$ are very close to each other, in fact the results show that for each assessed test suite its model level mutation score differs from its implementation level mutation score by no more that 3%.

The results of the experiment let us to observe that:

- the model level mutation score of all test suites, but T4, was slightly (between 0.015 and 0.028) higher than their implementation level mutation score, and
- the difference between $MS_{ML}(T)$ and $MS_{ML}(T)$ for test suites that reached the model level mutation score over 0.80 remained at nearly constant level of about 0.02.

Both observations seem to suggest that the model level test suite assessment results may be seen as a reliable measurement of the test suite quality in general. The slightly higher fault detection rate observed for most of the test suites at the model level was to be expected, as the UML/OCL models do not define the processing of data as the implementations.

TABLE I
MUTATION SCORE FOR EXPERIMENTAL TEST SUITES

T	T1	T2	T3	T4	T5	T6
$MS_{ML}(T)$	0.78	0.87	0.90	0.76	0.83	0.84
$MS_{IL}(T)$	0.75	0.85	0.89	0.79	0.81	0.83

Nevertheless, the nearly constant difference between the model level and the implementation level results seems to indicate a regularity that would predict the quality of test suites based on the assessment results obtained at the model level alone.

The results obtained for test suites T1 and T4 shows that, for test suites attaining low model level mutation score, the test suite quality assessment performed at model level provides less predictable results than for the suites attaining higher model level mutation score. However, neither the overestimation of the quality of T1 nor the underestimation of the quality of T4 did not exceeded the 3% threshold. Moreover, a test designer, having developed a suite of such a low quality as T1 and T4, would most likely tend to improve it to achieve better score. Thus, it seems that the irregular behavior of T1 and T4 does not contradict the earlier conclusion regarding the reliability of model level test suite assessment results.

IV. Conclusions and Future Works

Mutation testing is an effective and reliable technique for assessing test suite quality with regard to their ability to detect faults specific to the given level, but a transferability of the assessment results between different levels of abstraction was not evaluated before. An experimental way to assess the relability of results obtained at model level was proposed in this paper. The results of the experiment let us to presume that for object-oriented systems, modeled in a form of UML/OCL class diagrams, the test suite's ability to reveal real faults can be reliably assessed at the model level. However, more experiments on larger systems should be carried out to verify the preliminary conclusions.

Future research concerning model level mutation testing should deal with the costs reduction problem. It seems that the migration to the model level alone lowers the number of generated and executed mutants, but other techniques should also be considered. The most efficient techniques should be the ones taking into account individual characteristics of modeled systems, such as proposed in [20], [21], [22].

Works on applying mutation testing at the model level should also include development of tools supporting generation of mutants. Availability of such tools would significantly increase the possibility of adapting such approach in practice.

***Abstract*—Several important choices need to be made during the development of domain-specific languages, including the one regarding which concrete syntax to implement. There are several alternatives, with graphical and textual syntaxes being the most common ones. Having in mind that the developers and domain experts often have different preferences, supporting both is sometimes the best option. This means that models created using textual editors might need to be opened using separately developed graphical editors. Graphical elements corresponding to model elements must then be automatically created and positioned. Doing so in an aesthetically pleasing way requires usage of graph layout algorithms. Since implementing them is not an easy task, most developers have to rely on existing solutions. There are many Java libraries which have such capabilities, but they all have certain limitations and room for improvement, some of which are addressed in a new graph drawing and analysis library presented in this paper.**

I. Introduction

DOMAIN-SPECIFIC languages (DSLs) are computer languages specialized to a particular domain [1]. Development of such languages also includes the decision of how to present the concrete syntax to the users, who can be both developers and non-technical domain experts. There are several alternatives, with the most popular being the textual and graphical ones.

Each of these choices has its own advantages and disadvantages, so supporting both is the best solution at times. The textual concrete syntaxes can express any formal language, help in understanding all technical details of a DSL and are often preferred by the developers. On the other hand, end-users, who work in a non-technical domain, don't find them particularly appealing. These users generally prefer the graphical concrete syntax, which makes it possible to design DSL models using a completely functional graphical editor [2]. Graphical concrete syntaxes, if designed correctly, are intuitive and easy to understand. Having all of this in mind, it can be concluded that if a DSL needs to appeal to both developers and non-technical end-users, both textual and graphical concrete syntaxes should ideally be implemented. A similar conclusion was reached in [3], where the authors discussed the positive and negative experiences of using both the textual syntax, described in [4] and a graphical one to define the static structure of database applications.

Implementing both syntaxes leads to one problem: what happens if a part of the model is specified using the textual syntax and needs to be viewed and/or edited using the graphical editor? Graphical elements corresponding to previously described concepts need to be created automatically. These elements have additional visual properties, including positions which need to be calculated. This can be accomplished by applying a layout algorithm.

Implementing even the simplest of layout algorithms that would guarantee a somewhat pleasing arrangement of elements requires excessive knowledge of graph theory and can be rather time consuming. This is why the developers often rely on existing solutions. This paper focuses on libraries for the Java programming languages, but there are many similar ones for other languages like C/C++ and Python. The most popular open-source libraries offering the possibility of laying out elements of a diagram for Java projects include JUNG framework, JGrapX and Prefuse. All of these solutions put emphasis on visualization, providing their own visual components and thus strongly coupling layout capabilities with them. This makes the integration with separately developed graphical editors overly complex [5]. Furthermore, they only support a small number of different classes of layout algorithms, despite offering several algorithms belonging to the same classes. Even though the available algorithms can be used to lay out any diagram with acceptable results, it can be noticed that there is room for improvement. Certain classes of layout algorithms were designed with the goal of getting excellent results when applied to diagrams satisfying some special conditions (e.g. planar, straight-line, symmetric, rectangular). The mentioned libraries implement very few of them. Also, they don't offer a way of automatically choosing an appropriate algorithm based on properties of the diagram or on the wishes of the users regarding diagram aesthetics.

In order to address the mentioned issues, we are developing another graph drawing and analysis Java library, called GRAD (GRaph Analysis and Drawing) [6]. GRAD's main goals are to:

- offer a large number of different graph drawing algorithms, including some that haven't been implemented in Java yet
- provide a very quick and easy way to lay out elements of any existing graphical editor
- offer algorithms for graph analysis, which can later be used to automatically select a suitable layout algorithm
- enable the users to specify aesthetic criteria and automatically choose an appropriate layout algorithm based on their wishes

978-83-60810-90-3/$25.00

GRAD is not intended to be used as a visualization tool, but it also provides a simple graphical editor which can be used for familiarization with different algorithms.

The rest of the paper is structured as follows. Section 2 gives an overview of basic graph theory concepts, graph drawing aesthetic criteria, and different classes of graph drawing algorithms. Section 3 showcases some popular Java graph drawing and analysis libraries. Section 4 presents GRAD. Finally, section 5 concludes the paper and outlines future work.

II. Graph Drawing Aesthetics and an Overview of Graph Layout Algorithms

In the following section a short overview of the graph aesthetic criteria and the most popular classes of graph layout algorithms will be given. Firstly, the most important concepts which will be referenced later will be defined.

A. Basic graph drawing theory definitions

A graph (V, E) is an ordered pair consisting of a finite set V of vertices and a finite set E of edges, that is, pairs (u, v) of vertices [7]. If each edge is an unordered (ordered) pair of vertices, the graph is undirected (directed). A graph is simple if it doesn't contain any edges that join a vertex to itself or more than one edge connecting the same two vertices (multiple edges). A graph is said to be connected if there is a path from any vertex to any other vertex in the graph. A biconnected graph is a connected graph which has no vertices whose removal would disconnected it. Graphs which contain at least one cycle are called cyclic graphs, while the ones that do not are known as acyclic. A tree is a connected acyclic graph. Finally, a graph is planar if it can be drawn in a plane without graph edges crossing. A planar drawing partitions the plane into connected regions called faces.

The process of creating a drawing of a graph from the underlying structure is known as automatic graph layout. There is a great number of graph layout algorithms, with plenty of researchers still working on discovering new and enhancing existing ones. The quality of an algorithm is determined based on its computational efficiency as well as various aesthetic criteria. The following sections will give an overview of the mentioned criteria and the most popular layout methods.

B. Aesthetic Criteria

Many different quality measures or aesthetic criteria have been defined for graph drawings. Authors often optimize certain aesthetics claiming that the resulting drawing is therefore more understandable and more visually pleasing to a human observer. The most common criteria includes the following: Minimization of the number of edge crosses, maximization of the minimal angle between edges extending from a node, minimization of the total number of bends in polyline edges, even distribution of edges within a bounding box, appropriate lengths of edges, neither too short nor too long, similar length of edges, same flow of edges in directed graphs (as much as possible),orthogonality, and symmetry [8].

Some layout methods put emphasis on one of the measures trying to produce a drawing which, for example, has no edge crosses (planar drawing) or is maximally symmetric, while the other ones attempt to optimize as many as possible. The desired aesthetic criterion or criteria can be the deciding factor in choosing an appropriate layout algorithm. However, certain layout algorithms which insist on a particular aesthetic criterion might not be applicable to all graphs. Obviously, it is not possible to produce a drawing with no edge intersections of a graph which is not planar. Therefore, properties of the graph which is to be laid out can also be an important indicator of the best choice of the algorithm.

C. An Overview of Graph Layout Algorithms

There is a very large number of different classes of graph layout algorithms and the following paragraphs will present the most popular ones.

Tree drawing is one of the best studied areas of graph drawing. That is not surprising since automatic generation of drawings of trees finds many practical applications. Namely, a tree whose vertices represent entities and whose edges represent relationships is a typical data structure for modeling hierarchical information. There are various approaches to drawing trees and their detailed overview and comparison can be found in [9].

A *circular drawing* of a graph is its visualization where it is partitioned into clusters whose nodes are placed onto the circumference of an embedding circle. Each edge is drawn as a straight line. Simply placing nodes on a circumference of a circle might result in a drawing which is not particularly aesthetically pleasing due to a very large number of edge crossings, which is why there are techniques which also minimize this number when determining positions of the nodes [10].

Symmetric graph drawing algorithms aim to draw a graph with nontrivial symmetry, or, more ambitiously, with as much symmetry as possible. Some consider symmetry as one of the most important aesthetic criteria which clearly reveals the structure and properties of a graph. For example, graphs in textbooks on graph theory are normally drawn symmetrically and a symmetric drawing is in some cases preferred over a planar one.

Planar straight-line drawing algorithms rely on the fact that if a graph can be drawn with no crossings using edges of an arbitrary shape, then it can be drawn in the same way using only straight-line segments. Convex drawings are planar straight-line drawings where all faces are drawn as convex polygons. In [11] the author claims that the convex drawings of planar graphs make it possible for readers to easily and rapidly recognize structures of the graphs, such as adjacency of vertices.

Planar orthogonal and polyline drawing algorithms focus on angular resolution as the most important aesthetic criterion. Orthogonal drawings only use horizontal and vertical line segments for edges and are, therefore, often quite visually pleasing. A more specific type of orthogonal drawings are

rectangular drawings, which also make sure that each face is drawn as a rectangle. However, they have a pretty serious limitation of only being applicable to graphs which don't contain a vertex whose degree is higher than four. Polyline drawing are more general and don't have the mentioned disadvantage. They usually focus directly on sizes of the angles (which should not be smaller than some fixed threshold) and not on the type of edges.

Force-directed algorithms are among the most important and most flexible algorithms. Unlike many previously mentioned ones, which can only be applied if a graph is planar or satisfy some other specific conditions, force-directed algorithms can be used to calculate layouts of all simple undirected graphs. They only need the information contained within the structure of the graph itself.

Graphs drawn with these algorithms tend to be aesthetically pleasing, exhibit symmetries, and tend to produce crossing-free layouts for planar graphs. There are many force-driven algorithms, the most popular of which include the spring layout method of Eades [12], Kamada-Kawai [13] and Fruchterman-Reingold [14] methods.

Hierarchical drawing algorithms can be used when dealing with directed graphs (or digraphs) which represent hierarchies. These algorithms name uniform "flow" of edges as one of their main goals. More precisely, the edges should either go from left to right or top to bottom, depending on a particular application.

III. Related Work

There are quite a few libraries for graph analysis and visualization for Java. The next section will present the most popular ones, primarily focusing on their layout capabilities and mentioning implemented graph analysis algorithms which could be used to determine the best choice of the drawing algorithm.

It is important to mention that visualization tools which generate static drawings of graphs in a variety of output formats will not be taken into consideration since they are not suitable for this particular purpose. Furthermore, commercial solutions will not be considered since our focus is on open-source ones.

A. JUNG Framework

JUNG — the Java Universal Network/Graph Framework [15] is an open-source software library that provides a common and extendible language for modeling, analysis, and visualization of data that can be represented as a graph or network. JUNG framework is licensed under the permissive BSD license.

The current distribution of JUNG includes implementations of a number algorithms from graph theory, data mining, and social network analysis. However, most of them are of little importance to this research. Only Dijktra's shortest path and decomposition of a graph into biconnected components can be singled as potentially useful in the mentioned case.

JUNG framework offers implementations of several layout algorithms, some of which are quite complex. Most importantly, these include three tree layout algorithms and a number of force-directed ones. The tree layout algorithms include the following: an implementation of a level-based approach, radial tree method, and the balloon method. The radial tree method displays a tree structure in a way that expands outwards, radially. The balloon method positions vertices using associations with nested circles or "balloons". The force-directed algorithms are the already mentioned popular and flexible spring method, Kamada-Kawai and Fruchterman-Reingold, as well as an algorithm based on Bernd Meyer's self-organizing graph methods [16]. JUNG framework also contains a relatively basic circle layout drawing algorithm, which simply places vertices on a circumference of a circle of a given radius.

B. JGrapX

JGraphX is a Java Swing graph visualization library which is also licensed under the BSD license. JGraphX provides visualization and interaction with node-edge graphs, as well as a decent number of algorithms for graph analysis, such as graph traversal, forming the minimum spanning tree and Dijkstra's shortest path [17]. The minimum spanning tree is defined as the set of all vertices with minimal lengths that forms no cycles. Graph traversal includes deep-first search and bread-first search, both of which construct spanning trees with certain properties useful in other graph algorithms.

JGraphX provides various usable implementations of graph drawing algorithms. Similarly to JUNG framework, these include a tree and several force-directed layouts, but also a hierarchical one meant to be used if a graph is too complex to be laid out using the tree drawing algorithm. The tree layout in question is the compact tree layout, which improves the standard level-based approaches by trying to make the resulting drawing as compact as possible. Furthermore, JGraphX provides two force-directed layout algorithms: fast organic and organic. The fast organic method is best applied to smaller graphs with a more regular structure, but is supposed to be one of the faster force-directed layouts. The organic layout is one of the most complex algorithms implemented in JGraphX and is based on Davidson and Harel's simulated annealing layout [18].

JGraphX doesn't stop there and offers a very nicely implemented hierarchical layout. This implementation not only positions the vertices, but also routes the edges.

C. Prefuse

Prefuse is a software framework for creating dynamic visualization of both structured and unstructured data, that provides theoretically-motivated abstractions for the design of a wide range of visualization applications [19]. Like other mentioned libraries, Prefuse is also licensed under the BSD license.

Prefuse is bundled with a library which, among other actions, provides a host of layout and distortion techniques.

Available layout algorithms include random, circular, grid-based, forced-directed, and several tree ones.

The force-directed layout positions graph elements based on a physical simulation of interactive forces acting on bodies. The force simulator used to drive this layout can be set explicitly, allowing custom force-directed layouts to be created.

Tree layouts provided by Prefuse are previously mentioned balloon and radial algorithms, as well as an additional node-link tree layout, which lays out a rooted tree so that each depth level of the tree is on a shared line.

Based on the previous overview, it can be noticed that the mentioned libraries offer many layout algorithms which would be a good addition to any graphical editor in need for such features. However, all of them put heavy emphasis on data visualization and thus strongly couple it with graph drawing algorithms. Therefore, simply calling the desired algorithm and retrieving the results (positions of vertices and edges determined during the execution of the algorithm) requires an understanding of how a library works. GRAD aims to offer a solution to this problem.

Moreover, certain classes of graph drawing algorithms are substantially represented in these libraries (like tree and force-directed ones), while the other classes are barely or not present at all. For example, no symmetric, straight-line or orthogonal algorithms are available. Out library aims to remedy this and offer implementations of certain algorithms, that, according to our knowledge, have not been implemented in Java yet.

Finally, none of these libraries offer a way of automatically choosing an appropriate layout algorithm based on properties of the graph or according to the desired aesthetic criteria specified by the users. Implementing both of these features is among the goals of our solution. It can also be pointed out that none of the libraries provide many graph analysis algorithms which are of great significance to graph drawing.

IV. GRAD (Graph Analysis and Drawing Library)

In the following section different algorithms supported by our graph drawing and analysis library-GRAD will be shown. Additionally, possible ways of choosing appropriate drawing algorithms based on the properties of graphs will be discussed. It can be noted that GRAD can be used both to transform and existing drawing and to form a completely new one when nothing is known about the positions of the graph's vertices. The later is used in our open-source Kroki tool [21] for laying out imported class diagrams created by other modeling tools.

Like it was already mentioned, GRAD also provides a simple graphical editor which can be used to draw graphs we want to experiment with. This editor was used to create all examples of laid out graphs which will be shown in the upcoming sections.

A. Supported graph drawing algorithms

The most important objective of GRAD is to provide a large number of different graph drawing algorithms, both those which can only be applied if a graph has certain properties (e.g. is planar) and those that can be applied to all graphs with acceptable results. GRAD ports the best algorithms from the JUNG framework, JGraphX and Prefuse, and adds a number of new implementations of various graph drawing algorithms, not offered by any of the mentioned libraries. Summarily, the current version of GRAD includes several tree and force-directed drawing algorithms, a hierarchical, two straight-line, a circular which minimizes the number of edge crossings, symmetric, and a so-called box layout, which places elements in a table-like structure. The last four algorithms are GRAD's original implementations. The box layout positions a predefined number of vertices in one row, before continuing to the next row. Due to its simplicity, it will not be discussed in more detail.

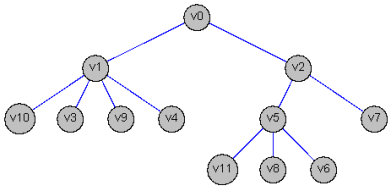

Fig. 1. Resulting drawing of applying the level-based tree drawing algorithm

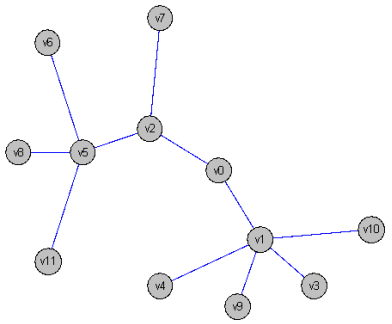

Fig. 2. Resulting drawing of applying the radial tree drawing algorithm

1) Tree and hierarchical drawing algorithms: Tree drawing algorithms included in GRAD consist of a level-based, radial, balloon and compact tree drawing algorithms, ported from the previously mentioned libraries. The best available implementation of a specific algorithm was selected. Fig. 1 shows the result of applying the level-based tree drawing algorithm to lay out a graph, while fig. 2 show the same graph laid out using the radial algorithm.

If a graph is too complex to be laid out using a tree layout and if it is important to emphasize the overall flow, a hierarchical layout can be used. GRAD ports this layout from JGraphX.

2) Force-directed graph drawing algorithms: Similarly to tree drawing algorithms, the force-directed ones were ported from the three mentioned libraries and the best one they had to offer were selected. They include spring, Fruchterman-Reingold, Kamada-Kawai and organic, and fast organic algorithms ported from JGraphX. Since the final results are relatively similar, only one of them will be shown. Fig. 3 show drawing of a graph laid out using the organic force-directed

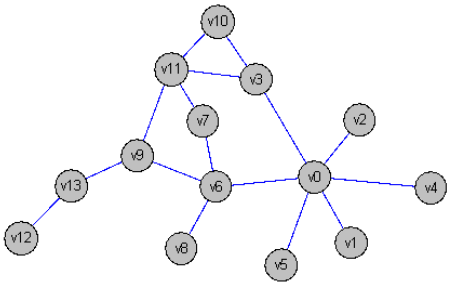

Fig. 3. Resulting drawing of applying organic force-directed drawing algorithm

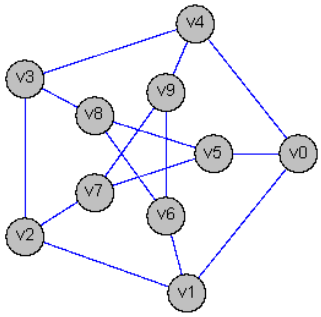

Fig. 4. Resulting drawing of applying the symmetric drawing algorithm

drawing algorithm.

Like it was already mentioned, force-directed algorithms tend to produce satisfactory drawings in most cases. However, the users might be looking for some specific aesthetic criteria, so GRAD doesn't stop here.

3) Symmetric graph drawing: Symmetric drawing algorithms are among the classes of drawing algorithms that the popular graph drawing libraries do not support. GRAD currently offers one such algorithm, with another one being implemented. The available symmetric layout algorithm is based on the work of Carr and Kocay [22], which, given a permutation (automorphism) and a graph, produces a drawing which displays the desired symmetry. The permutations can previously be discovered using an implementation of McKay's canonical graph labeling algorithm [23]. An example of a drawing computed by GRAD's symmetric graph drawing algorithm is shown in fig. 4. This drawing shows a very well-known view of the famous Peterson graph.

4) Straight-line drawings: Straight-line drawings are another class of drawing algorithms which are not provided by the most popular libraries. While not applicable to all graphs (they have to be planar, and in some cases, 2 or 3-connected), they can guarantee a crossing-free drawing.

The first of the provided methods is the one based on Tutte's or barycentric embedding [24]. Given a simple 3-connected planar graph, Tutte's theorem produces a crossing-free straight-line embedding whose outer face is a convex polygon. It is considered to be the first force-directed algorithm at the same time. This method is not difficult to implement, but is only recommended to be used on smaller graphs, with 100 or less vertices.

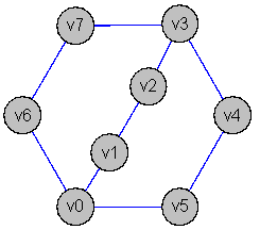

Fig. 5. Drawing of a graph on which Chiba's algorithm was applied

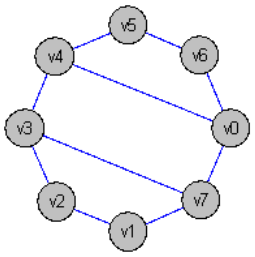

Fig. 6. A circular drawing of a graph

The second straight-line drawing algorithm is a much more complex one. The implementation is based on Chiba's linear algorithm for convex drawing of planar graphs [11], which firstly determines if a graph has a convex drawing and then draws one if the mentioned condition is satisfied. An example of this algorithm's application is shown in fig. 5.

5) Circular drawing: Practically all libraries which deal with graph drawing in some form, provide a circular drawing algorithm. Most of them, however, simply position vertices on a circumference of a circle. In addition to doing so as well, GRAD also implements an algorithm, described in [10], which determines the order in which vertices are placed so that the number of edge-crossings is as small as possible. An example is shown in 6.

It can be noticed that if, for example, vertices v_0 and v_7 switched places, the drawing wouldn't be planar.

Finally, it should be stressed that GRAD allows execution of drawing algorithms which were designed to be applied on simple graphs even if the given one is not simple. Upon execution of the desired algorithm in such case, GRAD detects multiple edges and loops and routes them in order to avoid overlapping of edges and correctly show those which connect one vertex to itself. Furthermore, GRAD provides a very simple way of calling any desired algorithm from a separately developed graphical editor, thoroughly explained in [5].

B. Graph analysis algorithms and choosing the appropriate graph drawing algorithm

Being a graph analysis library as well, GRAD provides a wide array of different algorithms of this sort. They can be used to reveal useful information regarding properties of a graph, which can later influence the decision of which drawing

algorithm to apply in the given situation. Some of these algorithms were of great importance to the implementations of the existing drawing algorithms and can be used to help the implementation of additional ones. Among others, GRAD provides several algorithms for planarity testing, algorithms for splitting of graph into biconnected components based on depth-first search, Hopcroft-Tarjan splitting into triconnected components [25], different algorithms for finding cycles of graphs and previously mentioned McKay's graph labeling algorithm.

By applying appropriate algorithms it can be determined if a graph is, for example, a tree, if it has a planar straight-line drawing or non-trivial automorphisms. Taking advantage of this fact, GRAD provides a way of automatically invoking an algorithm which might be best suited for the graph in question. If a graph is a tree or a forest, a tree drawing algorithm is used. If it is planar, convex drawing is performed. If no special properties are detected, a force-directed layout is applied. Also, if the graph is disjoint, an algorithm is chosen for each component independently and these drawings are later combined to get the final one. An example of this is a class diagram with several disjoint groups of classes where some represent hierarchies, while the other ones do not. This offers users who have no special preferences a simple way to lay out their graphs, even if they don't know anything about graphs and graph drawing.

Furthermore, every somewhat sophisticated drawing algorithm puts emphasis on one or more aesthetic criteria. By naming the criteria, the users can basically choose the algorithm without even knowing its name. In order to accomplish this, a DSL for describing the desired properties of the drawing is currently being developed.

V. Conclusion

This paper explained the need to automatically lay out diagram elements, gave and overview of different classes of graph drawing algorithms and the most popular Java libraries offering some of them. Some difficulties one might encounter when using layout capabilities of the mentioned libraries within a separately developed graphical editor, as well as certain areas of improvement were pointed out. For example, a developer of a DSL which needs to support both textual and graphical syntaxes might run into these issues. They were addressed in our new graph drawing and analysis library called GRAD.

GRAD provides a number of different graph layout algorithms and a quick and easy way of using them to position elements of a diagram in any graphical editor. In addition to porting the best layout algorithms provided by other open-source Java graph drawing libraries, it implements various other ones, not offered by the other mentioned libraries. These include symmetric and two straight-line algorithms, as well as an enhanced version of a circular one. Additionally, GRAD offers ways of automatically choosing appropriate algorithm or their combination to get the best possible result. GRAD is currently being used in our open-source Kroki tool for laying out imported class diagrams created by other modeling tools. These diagrams can contain over 600 classes.

Plans for future improvements of GRAD include:

- implementation of additional drawing algorithms, including a better symmetric and one or more orthogonal ones
- labeling algorithms which address automatic placement of text symbol labels
- a better way of letting user specify desired aesthetic criteria by developing a DSL.

4th Conference on Multimedia, Interaction, Design and Innovation

MIDI Conference provides an interdisciplinary forum for academics, designers and practitioners to discuss the challenges and opportunities for enriching human interaction with digital products and services.

The main focus of MIDI Conference is exploring design methods for creating novel human-system interaction, developing user interfaces and implementing innovations in user-centred development of advanced IT systems and on-line services.

TOPICS

Topics of interest include (but are not limited to) the following areas:

- interactive multimedia and multimodal interaction design
- novel interaction techniques, voice interfaces, interactive multimedia
- ubiquitous, multimodal, pervasive and mobile interaction, wearable computing
- novel information visualization and presentation techniques, Augmented/Virtual Reality
- design methods for usability, accessibility and outstanding user experience
- prototyping of user interfaces and interactive services
- human-centred design practices, methods and tools, user interface design
- unfolding trends in HCI research and practice, customer experience, Service Design
- advances in user-centred interaction design
- understanding people and interactions: theory, concepts, models and methods
- understanding people and interactions: contextual, ethnographical and field studies
- critique and evolution of methods, processes, theories and tools for human-computer interaction
- novel methodologies for conceptualization, design and evaluation of interactive products and services

***Abstract*—Visual impairment limits a person mainly in ability to move freely and independently. Even with many navigation aids and tools currently on the market, almost one third of the visually impaired do not travel independently without a guide, and human-prepared landmark-enhanced itineraries of the route are the most useful. We designed a system which based on a specific efficiently collected geographical data generates human-like landmark-enhanced navigation instructions. The studies we conducted (quantitative n = 16, qualitative n = 6) proved usability and efficiency of the system. Further we provide set of design recommendations to increase the usability of the system along with specific examples of usage with particular landmarks.**

I. Introduction

THE ability to travel independently is required for satisfactory level of quality of life and self confidence. Visual impairment limits mainly person's mobility and reduces travel-related activities [1]. This can lead to loss of work, friends, and hobbies and eventually to worsening psychical condition of a person. Even though visually impaired people undergo special training of navigation and orientation skills, 30 % of them never leave home alone without sighted guide [2], [3] and this number remains stable for last twenty five years.

The mobility of a person is mainly influenced by the efficiency of the wayfinding process [4]. This process consists of two parts. First, environment sensing such as avoiding obstacles and hazards. Second, the navigation to remote destination. Both parts of the wayfinding process can be supported by navigation aids, which assist the visually impaired pedestrian. The basic criteria for evaluation of navigation aids are safety, efficiency, and stress level, as defined by Armstrong [5].

Currently, this problem is solved by means of car navigation systems, which are not suitable for visually impaired, or better by assistance of orientation and mobility specialists. These specialists can prepare route itinerary to remote destination for visually impaired person for a particular route in advance and provide it in a form of a itinerary. This solution suffers from time requirements (it has to be prepared in advance) and rigidity (there is no option to change the route at user's will).

In our work we focused on developing efficient navigation aid which supports navigation to remote destination. We aimed to generate route itineraries similar to those prepared by orientation and mobility specialist. By using sophisticated data structures and algorithms we addressed the issue of time requirements (the itinerary is created immediately) and rigidity (user can select whichever origin and destination s/he want).

To compare our solution to state-of-art electronic navigation systems we developed two versions of the navigation system. The first version (*Landmark*), with itineraries enhanced by landmarks. The second version (*Metric*), simulating current metric-based navigation systems. For fair comparison of both conditions, *Metric* version also used pedestrian network for routing (sidewalks, crossings). Further, we provide the insights from qualitative study conducted on *Landmark* version.

II. Related Work

A. Pedestrian Navigation

Successful navigation and orientation in a space depends on building of spatial knowledge about the given environment. Siegel and White [6] define three levels of spatial knowledge. These levels are: landmark knowledge, route knowledge, and overview knowledge.

Relations between objects represent an overview knowledge. These relations may be represented by angles or distances between objects not necessarily located or related to the route itself.

The landmarks (representing landmark knowledge) represent the most frequently-used category of navigation cues used by pedestrians [7] (unlike distance, junctions or road type). Ross et al. [8] have shown that inclusion of landmarks within pedestrian route itinerary increased user confidence and reduced navigation errors. Findings of Ross et al. [8] extend also to voice-only navigation [9], where inclusion of landmarks was clearly more prefered by participants.

There are also some experimental designs of navigation systems, which rely primarily on landmarks to navigate users from origin A to destination B, e.g. Millonig and Schechtner [10].

In our system we aim to enhance metric-based navigation instructions with carefully selected landmarks suitable for navigation of visually impaired people.

978-83-60810-90-3/$25.00

B. Orientation and Navigation of Blind

In large spaces visually impaired pedestrians use different cognitive strategies from sighted ones, based on egocentric frames [11], [12]. Visually impaired people have to memorize large amount of information [13] in sequential order [11] while traveling. Fortunately a study by Raz et al. [14] has shown that congenitally blind people are better in both item memory and serial memory than sighted people. Their memory skills are outstanding namely for long sequences of information. Bradley and Dunlop [15] also discovered that blind people were significantly faster with verbal guidance from blind navigator than from sighted one.

Many navigation aids for visually impaired pedestrians have been developed. Some of the aids use special sensors to identify object along the route like cameras [16], or RFID based white canes [17]. Other navigation aids are based on concepts described in [18], and use some kind of position system (e.g. GPS) in combination with geographical information system (GIS) to navigate the pedestrian, e.g. Ariadne GPS, BlindSquare. Navigation aids based on special interaction techniques, e.g. an auditory display [4] or a tactile compass [19], has also been developed.

The navigation systems based on major GIS (e.g. OpenStreetMap) typically suffer from inappropriate level of detail (missing sidewalks, leading lines, slopes of sidewalk), ambiguity (inadequate description of pedestrian crossing so it cannot be located without sight), or they do not optimize routing algorithm to meet specific abilities of visually impaired people (e.g. inability to cross large open spaces).

In cooperation with major national data provider we focus on development of sustainable and scalable GIS with deeply modified data structure (see subsection Geographical Information Database), which allows us to generate specific landmarks for navigation of visually impaired people.

III. Landmark-enhanced Instructions Generation

To implement feasible solution to generate a landmark-enhanced navigation instructions, we need specially modified GIS which is capable of representing special features of the urban environment. Further we need algorithms, which use the landmarks and their parameters to generate route itinerary in a natural language. In our case each route itinerary is composed of navigation instructions for each segment of a route (typically part of a route from corner to corner, corner to crossing, etc.). For each navigation instruction we have chosen the following structure: environment description and action that should be performed by the blind pedestrian.

A. Geographical Information Database

Generally, we distinguish line, point and area features. Line features are tied to large part of pedestrian segment (e.g. geometry representation of a sidewalk in GIS) and represent their properties (like slope, surface quality) or phenomena along the segment (e.g. parking cars, railings). Point features describe phenomena that covers very small part of pedestrian segment (typically less than 3 m), they act as barriers or landmarks (e.g. crossing entry points, narrowings, steps, corners). Area features are landmarks extending over a certain area like traffic noise (busy streets, certain types of public transport, etc.).

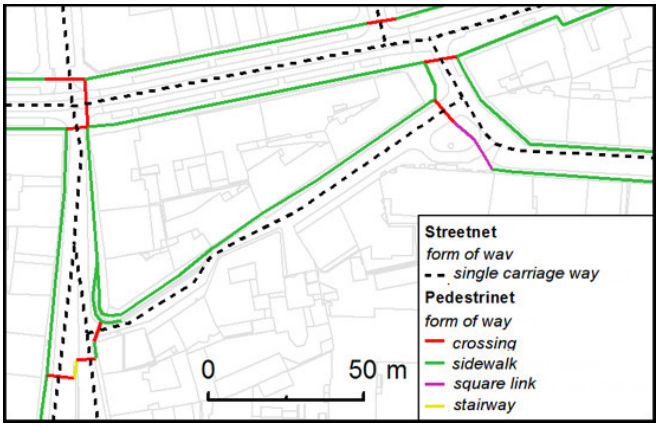

Fig. 1: Comparison of StreetNet and PedestriNet – background data: Digital city map - Map of town utilities (source: Open data).

The nature of those new features and the range of descriptive information reflect the needs of both visually impaired and wheelchair users. The complete data model was proposed in cooperation with Central European Data Agency, a.s. (CEDA), Faculty of Transportation Science and Faculty of Electrical Engineering (Czech Technical University in Prague) within project ROUTE4ALL. Data model was implemented as ArcGIS Geodatabase[1].

Pedestrian segment network. To be able to collect desired landmarks and their properties, the existence of the pedestrian segment network is essential. The national provider of digital vector road geodatabase StreetNet, thus proposed a new product PedestriNet that represents all paths designated for pedestrians. StreetNet is currently used for pedestrian navigation for users without disabilities. For disabled users it is not suitable due to simplified representation of crossings and sidewalks that does not reflect real topology of pedestrian network.

PedestriNet is characterized by very high positional accuracy - it represents footpaths in their real position in the level of Map of town utilities (see Fig 1) and maintain the topology of the pedestrian network. It covers special pedestrian segments like sidewalk, crossing, square link (a sidewalk crossing large open area of a quare) as well as pedestrian segments already represented in StreetNet database (e.g. pedestrian zone, walkway, gallery).

Geodatabase. All features of geodatabase include reference information to PedestriNet - ID of segment, orientation towards it (left/right/on). Thus they can be used for routing along the pedestrian network and generation of route itinerary.

[1] ArcGIS – http://www.arcgis.com/

To minimise data collection costs it is necessary to use existing data as much as possible. City municipalities administer Map of town utilities in high accuracy level that may be used to locate some features (e.g. stairways, corners) or to derive some properties (e.g. width of sidewalk). Unfortunately, these maps are mostly CAD drawings and therefore full automation of data processing is impossible. Further, Land-use map can be used to derive land-use of adjacent footpath area, digital terrain model can be used to calculate slope of footpath, etc. Another source of information may be actual video recordings. Field survey remains necessary to derive quantitative data for wheelchair users (e.g. height of curbs) and to verify collected data. Here, community reports may be of high importance.

Prototype of the geodatabase that is used for validation and testing covers area of about 1 km^2 / 52 km of pedestrian segments. This area took around 5 man/days to collect data and fill the geodatabase.

B. Navigation Instruction Structure

As described above, each navigation instruction is composed of environment description and action that should be performed by the blind pedestrian (similarly to [20]).

The environment description is generated from street names, addresses, corners, and crossings. The action is generated from geometry, street names, corners, slopes, land-use, and point features.

Table I shows how each navigation instruction is composed on a short 5 segment route itinerary with one crossing.

C. Algorithm

First a route is found by Dijkstra algorithm on PedestriNet graph. Then, for each segment, which is represented by vector data, we create a navigation instruction.

For generation of navigation instruction we find best matching sentence templates, which are selected based on a type of a segment, context (available metadata, adjacent segments, direction of the user, etc.), and priority (e.g. the template for corner is more prefered than the template for crossing) (see Listing 1).

An example for sentence template for environment description of a place *"You are at a beveled corner of streets Odboru and Karlovo namesti."* (see Listing 2).

In this way we created landmark-enhanced navigation instruction for blind pedestrians (*Landmark*), which were later compared with metric-based navigation instructions (*Metric*).

Listing 1: Selecting best sentence template.

```
ISituation actualSituation = new StartSituation();
ISituation endSituation = new EndSituation();

while(actualSituation != endSituaton) {
  ITemplate template = FindBestTemplate(actualSituation);
  ISituation actualSituation = template.Apply(actualSituation);
}

function FindBestTemplate(ISituation situation) {
  ITemplate[] availableTemplates = GetAvailableTemples();
  ITemplate bestTemplate = availableTemples
      .Where(template => template.Accepts(situation)
      .OrderByDescending(template => template.Priority)
  return bestTemplate
}
```

Listing 2: Application of a sentence template.

```
class CornerDescriptionTemplate : ITemplate {

  function Accepts(situation) {
    return IsAtCorner(situation) && situation.IsNotApplied(this)
  }

  function Apply(situation) {
    templateText
      = "You are located at a {0} corner of streets {1} and {2}"
    FillSituationVariables(template)
    return SituationWithAppliedTemplate(this)
  }

}
```

IV. Comparative Study

In our experiment we raised the question whether the error rate is lower for *Landmark* condition than for *Metric* condition, and whether measured completion time is lower for *Landmark* condition than for *Metric* condition.

Further we investigated subjective judgement of the participants about the level of safety, comprehension, and ambiguity of the generated itineraries, along with qualitative observations.

A. Participants

Sixteen visually impaired participants (10 female, 6 male) were recruited via e-mail leaflet sent to a group of our long term collaborators of our University. The participants in the experiment were aged from 23 to 66 years ($mean = 35.75$, $SD = 11.23$). Eleven participants had Category 5 visual impairment (no light perception); 5 participants had Category 4 visual impairment (light perception) [21]; 4 participants were late blind, 12 participants were congenitally blind. All of the participants were native Czech speakers.

B. Apparatus

Routes. For our experiment, we selected two routes in city center outdoor environment. Environments for this type of experiment are usually real environments [9], [15] rather than artificial (lab) environments, though exceptions are possible [22]. The location of the routes was in quiet area in the city center of Prague, Czech republic (see Fig. 2). Both of the routes were approximately 350 meters long. Both of the routes consisted of 7 segments and 8 decision points (points where the participant changes his/her direction). They had the same number of turns and pedestrian crossings. Thus we consider the routes to be the same similar to [23].

TABLE I: Main building blocks used for automated generation of route itineraries.

No.	**Environment description**	**Action**						
X/Y	*Corner / Street / Crossing*	*Direction*	*Action*	*Distance approximation*	*Slope*	*Endpoint*	*Landmarks*	*Land-use*
1/5	You are at address Karlovo namesti 293/13.	Turn to the left	and walk	approximately 150 meters	–	to round corner with street Odboru.	–	Keep buildings on your left hand side.
2/5	You are at round corner of streets Karlovo namesti and Odboru.	Continue straight	and cross street Odboru	–	–	to opposite corner	via crossing with light signalization and one-way traffic from right.	–
3/5	You are at beveled corner of streets Karlovo namesti and Odboru.	Turn to the left	and walk	approximately 100 meters	slightly downhill	to corner with street Myslikova	street bends to the right.	Keep buildings on you right hand side.
4/5	You are at corner of streets Odboru and Spalena.	Turn right	and walk	approximately 30 meters	–	to address Myslikova 282/26.	–	Keep buildings on you right hand side.
5/5	You are at destination. You are at address Myslikova 282/26.	–	–	–	–	–	–	–

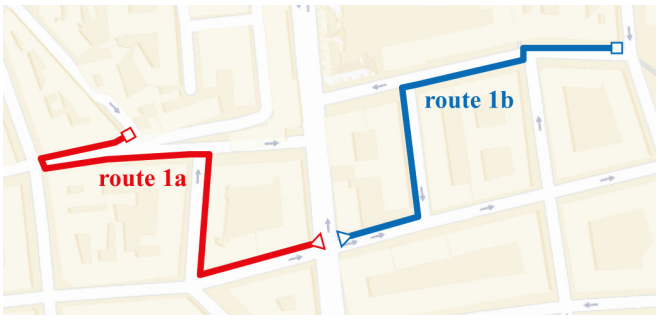

Fig. 2: Routes used in comparative study, the triangle depicts the beginning of a route, the square depicts destination of a route.

Equipment. The participant was equipped with a Nokia 6120 mobile phone with a lanyard which hung from his/her neck. In this way, the phone was protected from being dropped unintentionally, and the participant was able to release it and have an empty hand when needed, and s/he could also find it again quickly. The mobile phone was set to Czech language, and it was equipped with the MobileSpeak text-to-speech (TTS) screen reader application by CodeFactory.

Data collection. In each session, we recorded two video streams of the participant's activities. The first camera (GoPro Hero 3) recorded 1^{st} person view and was installed on a shoulder strap of the backpack that was carried by the participants during the session, while the second camera (Sony DLSR) recorded a 3^{rd} person view by the experimenter shadowing the participant.

C. Procedure

The experiment consisted of two walkthroughs of each route and it lasted around 1.5 hour. In the first walkthrough the experimenter guided the participants to the beginning of the first route, explained the purpose of the experiment to the participants, explained operation of the navigation application, and asked the participant to adjust the phone on a lanyard or to hold it in a hand, according to his/her own preference. The participant was asked to proceed as quickly and accurately as possible. The task was given as follows: *"You have a meeting in Hostel Emma (for route A; Cafe Amandine for route B). To reach the destination use the navigation application. Proceed as if you were alone, but we will be watching for your safety from a distance."* Than the participant started out.

After the first walkthrough the participant was returned to the start of the route and walked the route with the experimenter. The participants were retrospectively asked their about subjective judgement about level of safety ("Did the participant feel safe?"), comprehension ("Did the participant understand what to do?") and ambiguity ("Was the description of the environment ambiguous?") for each segment of a route (Likert scale 1-5 was used).

Then the experimenter took the participant to the start of the second route and proceeded same as on the first route. After the experiment the participant was debriefed and received their payments.

D. Design

The experiment was one factor (two levels) within subject design. The independent variable was itinerary quality (*Landmark*, *Metric*). The itinerary quality and route were balanced using a Latin square. The main measures were an error rate, defined as 0,1 if there was a navigation error (e.g. participant missed the turn, crossed the road on different place, etc.) on a particular segment of a route, and a completion time, calculated as time taken for traveling from start to destination of a route. For analysis of error rate and completion time we use confidence intervals (according to [24]).

E. Results and Discussion

The following subsections describe findings observed during the experiment. We collected the data from 16 sessions and based on the results we propose general design recommendations for creation of navigation instructions.

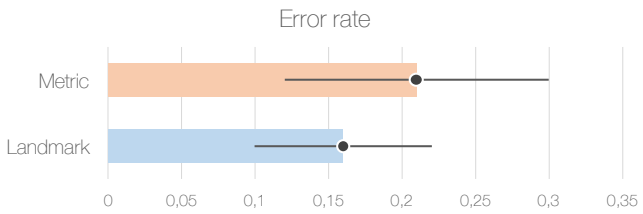

Fig. 3: Mean error rates with 95 % confidence intervals for Landmark and Metric condition (n = 16, lower is better).

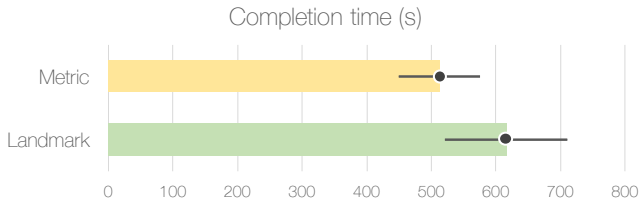

Fig. 4: Mean completion times with 95 % confidence intervals for Landmark and Metric condition (n = 16, lower is better).

Error rate. Fig. 3 provides evidence on error rates and 95% confidence intervals. It seems that error rate for *Landmark* ($mean = 0.16$, 95 % CI $[0.10, 0.22]$) was very similar as for *Metric* ($mean = 0.21$, 95 % CI $[0.12, 0.30]$) and the results are largely inconclusive concerning the difference between the test conditions, although with small favor for *Landmark*.

We could not decide whether the lack of difference in error rate was caused by random variables occuring during the experiment (see paragraph Random variables) or by selection of rather easy routes as described by participants.

Completion time. Fig. 4 provides evidence on completion times in seconds and 95 % confidence intervals. It seem that completion time for *Landmark* ($mean = 615.4$ $seconds$, 95 % CI $[520.89, 709.99]$) is 1.2× higher on average than for *Metric* ($mean = 513.00$ $seconds$, 95 % CI $[450.33,\ 575.67]$) and the results show that there is an effect of the test conditions on completion time. The completion times ranged from 267 to 917 seconds for *Landmark* test condition and it ranged from 292 to 757 seconds for *Metric* test condition.

It cannot be decided whether the difference in completion times for *Landmark* and for *Metric* was caused by longer text in the navigation instructions (participant waited longer time to listen it whole) or by occurrence of random variables (sometimes participants stopped because they didn't feel secure, see paragraph Random variables). It would be necessary to repeat the experiment in more controlled conditions, however it would affect external validity of the experiment.

Subjective judgment. During the second walkthrough we asked the participant about their subjective judgment of each segment of a route. The results suggest that comprehension is higher for *Landmark* (85 % of the participants strongly agree) than for *Metric* (65 % of the participants strongly agree). Ambiguity and safety were evaluated similarly for both test conditions (see Fig. 5).

Further we asked the participant for the comments on navigation instructions for both conditions. In *Landmark* condition, the participants highlighted information about traffic direction or information about land-use. However, in both test conditions they had problems with lack of the corner descriptions and lack of endpoints at crossings. In both test conditions, the participants often confused individual navigation instructions with each other as they started similarly. In *Metric* condition, the participant lacked information about endpoints and they were surprised by very precise distances (precision up to meters; in *Landmark* distances are rounded to tens of meters) reported by the system ("I cannot tell how far did I went precisely", P07, participant P01 laughed about it).

Random variables. Similarly to Rehrl et al. [9] our measurement were influenced by random variables (unpredictable urban environment). Further we classify the problems we observed into 4 categories.

Collision with objects – 28×. We observed that participants frequently collide with traffic signs, poles, beer gardens or parking-ticket machines. This seems as a common problems for the visually impaired pedestrians.

Interference of passerby people – 10×. During the experiment we observed the participant from a distance (shadowing method). Sometimes passerby people stopped the participants and offered them help (4×), however 6× they grabbed, dragged or guided the participant to some arbitrary chosen spot, which resulted in loss of orientation of the participant.

Disruption of the senses – 16×. As a hearing is one of primary orientation and navigation senses for visually impaired pedestrians, its disruption strongly affects the wayfinding process. We observed following sources of hearing disruption: garbage disposal trucks, road cleaning trucks, and rain. Another case was problem with finger sensitivity and operation of our Nokia smartphone.

Stress – 2×. One participant was anxious about the experiment even though we tried to calm him/her during briefing, it affected his/her performance (s/he proceeded much better towards the end of the experiment than in the beginning). Another case was when participant dropped his/her white cane (s/he was immediately assisted and handed the cane).

Allover we counted 32 common problems (collisions and offering a help of passersby people), 17 in *Metric* conditions and 15 in *Landmark*. Next we counted 24 serious problems (grabbing, dragging, guiding by passerby people, disruption of senses, stress), 14 in *Metric* condition, 10 in *Landmark* condition.

F. Recommendations for Design

Following design recommendations for navigation instruction creation were extracted from the findings collected during the experiment:

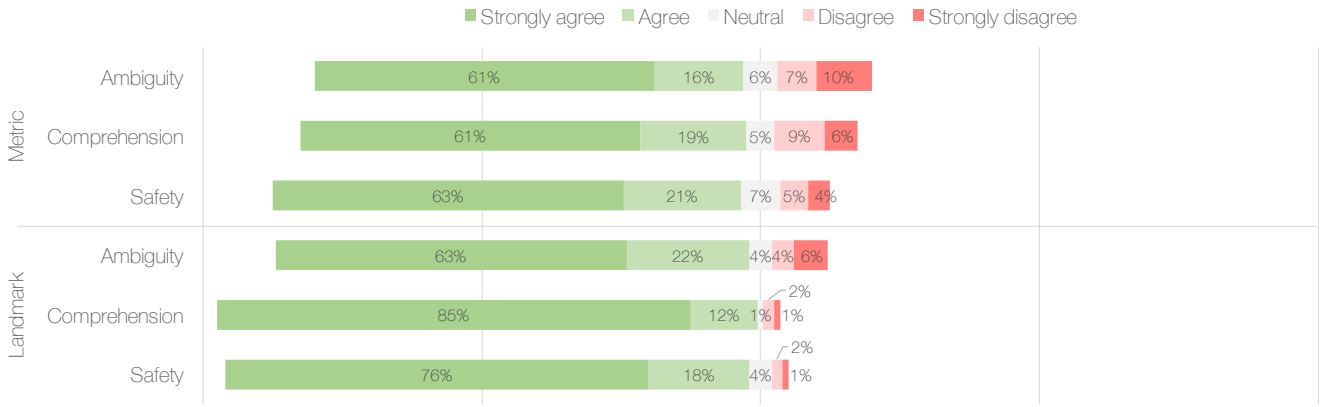

Fig. 5: Subjective judgements about level of safety, comprehension and ambiguity of navigation instructions, summarized over all segments, for both conditions (n = 16).

R1: *The shape of a corner should be added to the itinerary if the shape is different than sharp/plain.*

We observed, that participants were confused at corners, which were not sharp but bevelled or rounded.

R2: *The endpoint should be added for pedestrian crossings like the pavement on the other side of the street, the opposite corner, the opposite side of the street.*

The participants expected the information about the other side of the street when they used a pedestrian crossing.

R3: *Change the beginning of the navigation instructions by adding a sequential number and total number of navigation instruction.*

Some participants were confused when the beginning of the navigation instruction was the same one after another (i.e. crossing the street from one corner to the other corner).

R4: *Changing the naming conventions for pedestrian crossings without "zebra".*

One of the participants expressed concerns about usage of term "unmarked crossing" instead of "a place for crossing" for a place where there are lowered curbs but no zebra drawn on the street.

Others. Some of the participants mentioned that they would benefit from usage of GPS geofencing, which would notify them about next navigation instruction. Other participant found the *Landmark* version too detailed and s/he would prefer *Metric* version on a routes which s/he knew.

V. Qualitative Study

After the first experiment we implemented recommendations R1-R4 into the algorithms and geodatabase of our system. We further investigated automatically generated itineraries in a different, much more complicated urban environment (busy streets, park, passages).

A. Participants

Six visually impaired participants (3 female, 3 male) were recruited via e-mail leaflet sent to a group of our long term collaborators of our University. The participants in the experiment were aged from 30 to 68 years ($mean = 48.67$, $SD = 15.74$). Three participants had Category 5 visual impairment (no light perception; 3 participants had Category 4 visual impairment (light perception); 4 participants were late blind, 2 participants were congenitally blind. All of the participants were native Czech speakers. Originally we recruited 7 participants however participant P02 canceled the appointment.

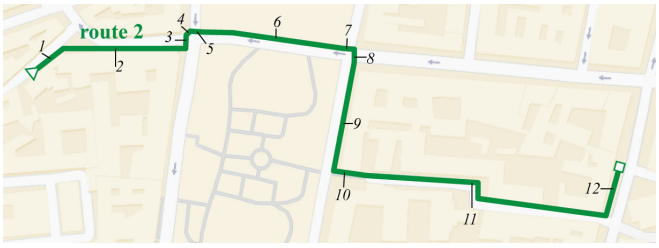

Fig. 6: Route used in qualitative study, the triangle depicts the beginning of a route, the square depicts destination of a route. Numbers represents segments numbers.

B. Apparatus

Route. For our experiment we selected a route in city center outdoor environment. The route went through busy square in a city center of Prague and ended in a quiet area (see Fig. 6). The route was 670 meters long and consisted of 12 segments and 13 decision points. There were 4 pedestrian crossings on a route.

Equipment and **Data collection.** The equipment and the data collection were the same as in the first Comparative Study (see IV).

C. Procedure

The experiment consisted of one walkthrough of the route and the whole session lasted about 45 minutes. At the beginning the experimenter guided the participant to the beginning of the route, explained the purpose of

the experiment and explained operation of the navigation application. The participants were asked to use think-aloud protocol. The task given to the participants was: *"You stand in front of your house on an address Na Zborenci 276/14. To reach the destination use the navigation application. Proceed as if you were alone, but we will be watching you for your safety from a distance, we will also assist you on pedestrian crossings if needed"* Then the participant started out.

When the participant reached the destination s/he was asked out his/her subjective judgment about level of comfort ("Was the navigation instruction comfortable for the participant?"), efficiency ("Did the participant think s/he proceeded efficiently?") and safety ("Did the participant feel safe?") (Likert scale 1-5 was used). The factors of subjective judgement were selected differently from the Comparative Study (see IV) as the subjective evaluation was done per route not per segment. After the experiment the participant was debriefed and received their payments.

D. Results and Discussion

All participants reached the destination successfully without any serious problems.

At the second decision point (bevelled corner) two participants missed the corner and described it as "unclear", P03, P04, however they found out that they missed the corner themselves after few meters.

At the second pedestrian crossing (fifth decision point) all participants turned right to face the pedestrian crossing even though they were not asked to. The next navigation instruction asked the participant to turn right, however this did not confused P07, P03, P01. On the other hand P06 and P05 crossed the pedestrian crossing immediately without selecting next navigation instruction, the did it on the other side of the street and they got confused by instruction to turn right and cross the street. P04 reported this as "weird" but was not confused by it.

At the sixth segment (pavement around greenery) all participants followed a curb on a left side along grass even though they were asked to have street on their right hand. P03 described that s/he used street as acoustic landmark on the right and followed curb on the left hand side.

Five participants found entrance to passage without any problems. Only P06 missed the passage and reported that s/he did not hear it. Participants P06 and P04 missed information about slope in a passage (it was steeply uphill).

The most problematic part of the route was segment 11. The problematic part was "the street is bend twice". Five participants reported that they were not sure they did perceive the second bent. P03 and P07 requested directions of the bends to be present in the itinerary. P01 did not have any problems with the bends.

Surprisingly all participants found destination in the middle of the block of buildings (30 meters from the corner) within 5 meter precision.

Subjective judgement. After the experiment we asked the participant about their subjective judgement of efficiency, comfort and safety during the walkthrough. Fig. 7 shows that 33 % of the participants strongly agreed on comfort, 50 % of the participants strongly agreed on efficiency and 33 % of the participants strongly agreed on safety of the navigation instructions. One participant disagreed on safety due to malfunction of acoustic signalisation on a crossing.

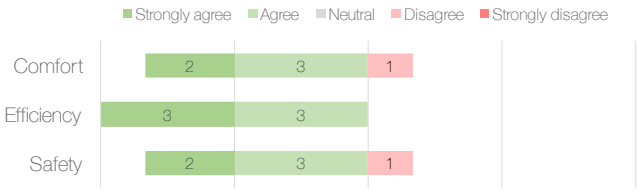

Fig. 7: Subjective judgements about level of safety, efficiency and comfort of navigation instructions (n = 6).

E. Recommendations for Design

Following design recommendations were extracted from the findings collected during the experiment:

R5: *If the corner is less than 90 degrees use "slightly right/left", if the corner is more than 90 degrees use "sharply right/left".*

Some participants did not recognize the corner between first and second segment of a route because the angle was not 90 degrees.

R6: *If the pavement does not follow the building on one side, mention land-use on both sides (i.e. "there is greenery on your left hand side, there is street on your right hand side").*

The participants followed curb along greenery and not the the street. They mentioned they would prefer knowing both sides of the pavement at this segment of the route.

R7: *If there are bends on a street mention them and add directions "first right, second left".*

The most problematic part of the route was where the street bends twice. Many participants did not perceive the second bend of the street.

R8: *Mention pavement slope in passages.*

The participants missed description of a pavement slope in a passage.

VI. Conclusions

We developed a method for automatic generation of landmark-enhanced navigation instruction for blind pedestrians, which is based on modification of GIS data structures and development of algorithm for routing and navigation instruction generation in natural language. We conducted a comparative study of landmark-enhanced navigation instruction (*Landmark*) with metric-based navigation instruction (*Metric*) with 16 visually impaired participants. Although previous studies [8] show that landmark-based navigation is better for pedestrian navigation, the measured results were inconclusive. However subjective evaluation suggested preference of landmark-enhanced condition. Moreover we provide a

set of design recommendations for creation of navigation instructions related mainly to corners and crossings.

Further we investigated improved landmark-enhanced method (*Landmark*) in qualitative study with 6 visually impaired participants resulting in additional recommendations related to leading lines or passages. Subjective evaluation suggested acceptance of the users in levels of safety, effectivity and comfort.

In the future, we will focus on integrating more landmarks such as recessed buildings or traffic sounds.

ACKNOWLEDGMENT

This research has been supported by the project Navigation of handicapped people funded by grant no. SGS16/236/OHK3/3T/13 (FIS 161 – 1611663C000) and by the Technology Agency of the Czech Republic through project Route4all (TA04031574).

***Abstract*—The paper describes application of the crowdsourcing system to pre-process X-ray tomography images. In this paper, we show the analysis of the crowdsourcing system applied to process tomography imaging to investigate granular flow with aid of tracking particles. Applying crowdsourcing approach coupled with a proper system interface design enhances the performance of the workers and elevates the attitude. We show here how analysis of the proposed systems in terms of user adoption and performance. Proposed interface features are designed based on previous work evaluation in order to reduce the cognitive and physical workload demands.**

I. Introduction

CROWDSOURCING can be a delegation of work to be done, usually such that can be completed with Internet-connected computers [1]–[2], with an open call for people to contribute on an online task where the crowd here refers to an undefined, but aimed to be large, group of participants. Crowdsourcing systems coordinate those workloads to be completed by large groups of people to solve problems that a single individual could not achieve at the same scale, within the same budget or limited time, or a problem at high level of complexity. Another associated concept often revoked is the crowd intelligence that may result in either reaching the distinctive solutions to problems that are not so easily achievable for a single workers or is sometimes called power of averaging over large numbers of solutions to the same portion of work that leads to a perfect solution with no deviations form the correctly done work. Crowdsourcing system has been recently proved as an effective alternative to solve complex and mundane tasks [3] that can be solved by experts or as an alternative option may be distributed to several non-expert human operators that are willing to do the job or fragments of the job and therefore contribute to a joint solution of the problem. Sub-tasking the problem by the system typically lies to specific work flow depend on the problem, in dependent task, crowd system proves effectiveness in results while most of daily problems are more depend and much complex. Such task requires deep trained knowledge and experience that is difficult to formalize it in algorithms [4]. In crowdsourcing applications, contributors invited to accomplish system tasks using the human intelligence and capabilities [5]. During task submission, crowdsourcing serve as tool to gather information from the crowd intelligence. In the other side, the system relies on individual agent defined as expert serving for study and review the data gathered from the non-experts and processed by the core system. This paper focus on developed crowdsourcing system that contributes non-experts crowd for analysis if industrial tomographic images. The system introduce specific interface and features that work for enhance the crowd yield.

II. Related Work

Crowdsourcing systems raised as a sort of mediation between the way computer systems process the surrounding world's parameters in comparison to how humans sense it. Most of tasks submitted to a widely available crowdsourcing servers (www.mturk.com, www.crowdflower.com, www.crowdmed.com) can possibly be processed by computer systems. Unfortunatelly due to a number of reasons such as difficulty of tasks, uniqueness, complexity, problems with achieving high accuracy or just the economical settings give rise to the need to use different methods for processing these datasets. Taking into account this work, especially image processing for research purposes is widely noted in [13]–[16]. Another interesting example of this type may be referred to a case of possible submission of the own medical results to the medial community around the world or in search for a diagnosis [17]–[19].

In this section, we review different examples of crowdsourcing applications, which demonstrate advantages of crowdsourcing aspects. Reviewing related work allows better to understand the aim of the paper concerning design and extensions of functionality dedicated to industrial process investigations.

A. Crowdmapping

In 2014, NASA launch a space research project 'Be a Martian' [6] based on crowdsourcing approach. The project invite people to mark the craters on mars and size it using bubble-marking interface that compute after user identify a mark. Similarly, The 'The Milki Way project' [7] is a research project that looks through tens of thousands of images from the 'Spitzer' Space Telescope. At the project website, crowd workers mark in specific platform galaxies, star clusters and space objects. The project give volunteers to enter the unknown or unusual things so they identify and size or telling what they see in the infrared data. After gathering

978-83-60810-90-3/$25.00

all this information from crowds, it's easy to the system to classify and mining it.

B. Crowdsourcing in Journalism

Crowdsourcing is used in journalism to find story topics, information and sources. In recent years, a large amount of popular writing and relatively little academic research have been done in the areas of wisdom of the crowdsourcing, co-creation, and networked journalism. In 2009, the Guardian newspaper used crowdsourcing where readers (the crowd) were invited to investigate thousands of political documents that will help the newspaper to parse the data faster by CrowdSourcing. The online newspaper Huffington Post invited in 2009 their readers to compare the original stimulus bill from the US senate with the compromise. The volunteers asked to mark any the differences precisely identified examples of wasteful spending or corporate give ways that aren't stimulative.

C. Crowdfunding

Crowdfunding refers to funding a project or venture by raising monetary contributions from crowds online. Crowdfunding can be used in variety of purposes for instance Philanthropy and civic projects, Real estate crowdfunding, start-up investments, etc. At Kickstarter one of the famous platforms for crowdfunding, people gather funds for projects and ideas on various topics. In February 2012, a project named 'Double Fine Adventure' [8] collected over three million dollars to make a movie, in what was a record-breaking crowdfunded project. In Crowdfunding, individual investments or donated funds typically are small and the funding power is based on the number of participants and whether investments or donated crowd-funding is an ideally way to quickly fund a project by this it can be better than the traditional funding models.

In this work we propose crowdsourcing system is dedicated to image processing of industrial processes and presents progress presented in comparison to system described in the [3]. As data processed in the system constitutes the image sequences, each person has at his disposal the ability to use not only the spatial information (based only on one image), but also temporal information. The presented system provides additional information to the current image, which is taken from previous images. The time relationship presented on the images is an added feature in comparison to previously presented crowdsourcing systems and should increase effectiveness of work.

III. The Crowdsourcing System

The developed crowdsourcing system consists of several elements. Besides the data module, significant position is assigned to user interfaces, from customer (researcher/-expert) and crowd point of view, also additional module dedicates to improve comfort of users work and thus obtain better results. Before describing crowdsourcing system, we present a short characteristic of X-ray measurement system with a deep explanation in interpretation tomography and radiography images to understand better the problem of analysis experimental data.

A. X-ray tomography visualization

The described system and the proposed approach to image processing and analysis is new solution in terms of industrial process investigations as the standard methods not always give sufficient information [20] - [25]. The images of gravitational flow in silo models were obtained with aid of X-ray industrial tomography system [10] - [11]. Data recorded from X-ray system can be presented in form of 3D images (see fig. 1). However for this kind of data visualization is necessary to stop flow process, in analyzed case stopping of gravitational flow of solid, and rotated silo in space between the source and X-ray detector to have the whole set of projections. The 3D image is result of reconstruction procedure based on 2D radiography images (projections). But such approach, for flow phenomena investigation, forces stopping the flow what can be reason of flow characteristic changes - invasion in process. The better option is to apply the continuous record of data. This solution was used during experiments and results were saved in form of 2D radiography images, an example of single raw radiography is presented in figure 2. Quality of this visualization is lower than the case of 3D images (see fig. 1), what causes more complication in image processing and analysis procedure. The quality of radiography images are resulted of absorption of X-ray radiation by all material located on line between source of radiation and a single pixels on X-ray detector. In presented investigation was used 2D flat panel detector. The level of signal detected in a pixel, is due to absorption of X-ray radiation by material structure on path between source and detector pixel. The radiography image provides information about average value of absorption level, which is directly related with material concentration. More details about application of X-ray system to gravitational flow of solid can be find in [10].

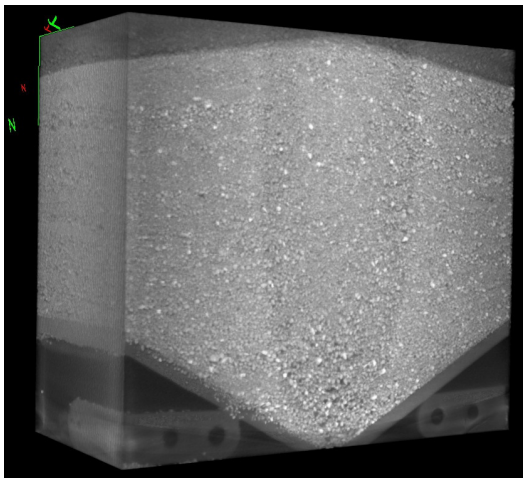

Fig. 1. 3D X-ray tomography of gravitational flow in silo

Fig. 2. RAW X-ray radiography image

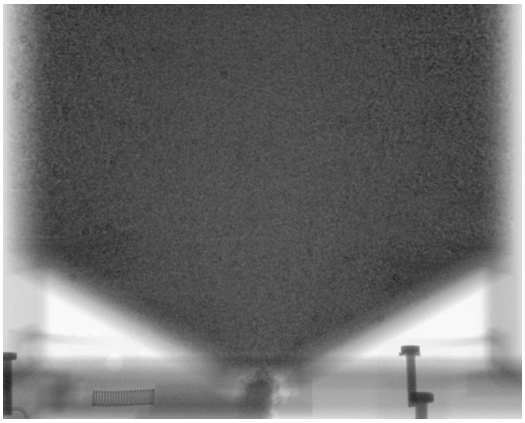

Fig. 3. Radiography image with stopped granular flow

After continuously recorded flow in sequence of 2D radiography images was applied correction of the tomographic images. The result of this processing is presented in figure 3, radiography image for stopped flow, and in figure 4, radiography image for continuously flow. Further improvement based on normalization procedure allows to better visualize center region of silo [11]. Figure 5 presents an example of a normalized radiography image.

As was mentioned the radiography images provide information about the material concentration distribution. On the presented images (see fig. 3-5) it's visible the different area of granular material with different level of concentration. Such flow phenomena is characteristic for funnel flow [9], where in the center of silo material is at lower concentration than at silo wall - stagnant zone appear. The distinguish of these two area is much easier to noticed in 3D tomography (see fig. 2) than in 2D radiography image (see fig. 3-5). Non moving material in silo allows to obtain better radiography image (see fig. 3) than for moving material (see fig. 4). But the influence of breaking flow on process causes different granular behavior than for free flow.

The main task for flow investigation was analyzed dynamic of gravitational flow in funnel area. In order to achieve the intended task the tracking particles, with higher X-ray absorption were added to granular material. The algorithm of image analyzes should provide trajectories of each single particles. It is not easy task to find all tracking particles, What is visible on figures (see. fig. 3-5). The results of automatic image processing algorithm doesn't provides full information about all particles [10]. The development of the crowdsourcing system should allow to find more particles in sequence of radiography images and complete knowledge about flow.

Fig. 4. Radiography image with free granular flow

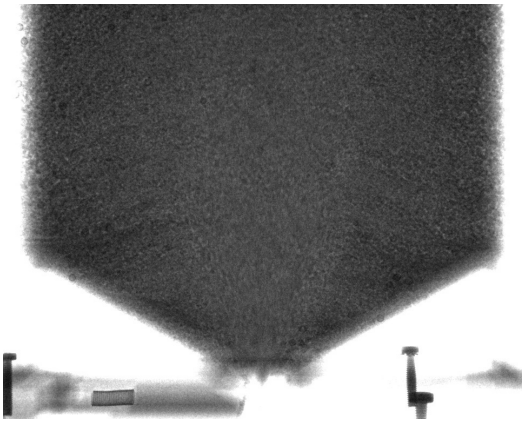

Fig. 5. Radiography image after normalization procedure

B. System workflow

The system is based on user oriented interface. First, the experts identify the task to accomplish and take series of X-ray images of the silos. Then, the obtained data will processed for correction and optimization.

The system workflow runs in three steps, first experts how prepare the x-ray data (in this paper there are radiography images) upload them using the system core into the database. Then the system core can generates tasks from the uploaded data whenever any person of the crowd access to the tasks webform. The system core here select set of data in the database that is not submitted yet by the person, from these

collection, tasks are created in form of 7 to 25 images per task in random way. The creation of task is happen at crowd workers side that means every person of the crowd has his own tasks display. At the third step, the worker chooses a specific task the core system task the task frames into specific interface for analysis of frames. Once worker launch his work submission the system core collect the frames mark data in structured form and save it into the database for later data mining.

C. System interface

Each workers' crowd member can browse the automatically generated task with information about the number of frames like presented on figure 6, then he could choose the one to accomplish. The system redirects the worker to an appropriate interface where all task frames are presented in slide show display together with variety of tools developed to enhance the task performance in time and quality meaning.

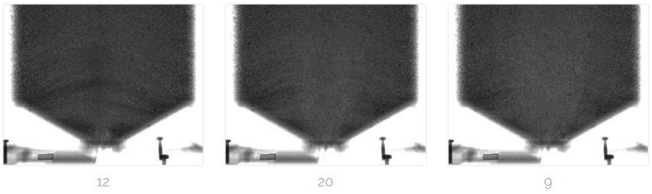

Fig. 6. Tasks interface

D. Task web interface

Once the worker chooses a task to accomplish automatically we be redirected to the another web-interface dedicated to analysis of the tomographic image. The new interface informs the worker at the very begin about the next interface component, features available to help him in doing the task and timing count for his work per frame in background. This interface is presented in figure 7. Such tool panel on the right-hand side is well known in other domains of crowdsourcing applications, but has not been reported for analysis of research tomography images yet.

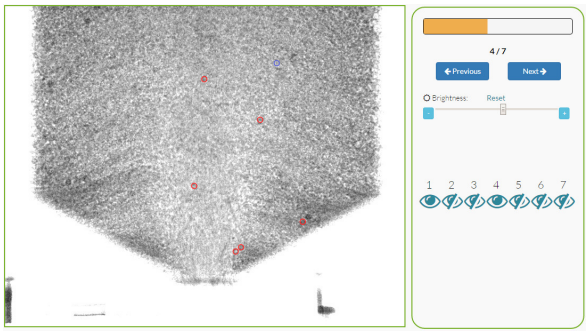

Fig. 7. System interface

E. System Features

1) Interface interactivity: In each frame, worker has to mark with double-click each particle that appears to him in the current frame.

- Double-click on mark will remove it from the frame.
- Single-click on mark will result to be selected.
- Moving the mouse on keep the mouse-key down will let the particle to move according the mouse coordinate in the frame.

2) Frame adjustment: Furthermore, the interface offer on the right-hand panel more features to adjust and ease the job of visual working on the tasks.

First a workload progress bar on the top right shows the progress of the job. Next, a frame caption below shows the index of current frame over the total number of processed frames. The user can browse between the frames easily while doing the task so he can learn from the changes in frames to identify the mark. The interface offer an image processing functions to adjust the current frame. The adjustment of frame brightness help the user to recognize better a particle inside the silo that was not well visible for him in the regularly displayed x-ray frame (as shown on figure 8).

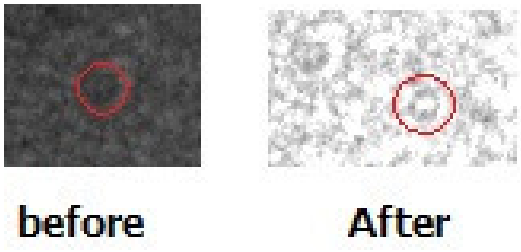

Fig. 8. Brightness adjustment effect on area of the frame.

3) Particles visualization: The system has an 'eye-bar' appear below the brightness control allows the worker to review his particle trace of previous frame on the current frame (reviewing by hide and show the others frame particles). this feature work for increasing the performance of the worker in the frame.

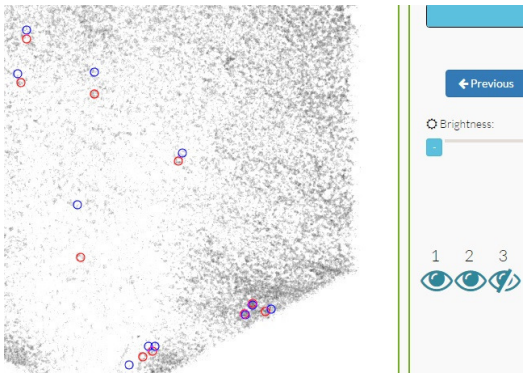

Fig. 9. Worker at frame 2 made mark in red and seeing the marks from previous frame in blue in the same frame.

IV. Pre-study & Results

System was firstly tested and evaluated by experts (2 people with skills in system design, X-ray image analysis, flow process analysis knowledge and previous experience with scientific images crowdsourcing systems). Experts prepared content of the test for the regular users' study. During the study and the evaluation on the system, we conducted tests with 7 non-expert workers completing the tasks. The workers were asked to accomplish task of 41 frames. Chosen frames were a fragment of a time series of X-ray consecutive radiography images and were specially selected to constitute a relatively difficult dataset in terms of marking trace particles. The results are archived by the system after every frame submitted by the workers. Besides the regular study goals, we also inquired workers about their experience in different aspects of using the system and this feedback help us in qualitative evaluation of the system performance.

A. System-side results

Since the main goal of the system is to enable correct identification of the trace particles the proposed design aimed at supporting to achieve this goal. Figure 10 shows an example of results where plots of different colors indicate the number of particles marked by the users for consecutive frames. These results were obtained only with possibility to change the brightness (no temporal hints). One can see a specific spread of counted values, however experts assessed these results as acceptable provided the quantitative analysis (visual inspection) shows that missed particles are not significant regarding the domain analysis. Including the temporal factor into the workflow, i.e. enabling users to use previous frames' results as well as possibility to browse frames back and forth significantly reduced the spread of particles count for different workers. The min difference between expert results and crowd study results decreased from 7% to 1% while max difference decreased from 24% to 9% and in general lead to equalize the results of the crowd, approaching the number expected by experts.

Figure 11 shows the marked particles pointed out by the crowd on the images. The particle easiest to find, located at silo wall, are marked by all workers. The main problem is the discrepancy visible in the funnel area of the flow (central zone of the image). However, when using the temporal options of the interface results tend to the similar homogeneity as for the by-the-walls zones that proves our concept of using additional information in order to ease the process of finding the particles and increasing the accuracy of the system.

In this situation, the system applies basic algorithm to compute real number of particles. In order to do that system considers a particle where most of users marked circles close to anothers' marks by applying an unsupervised clustering at high inner criteria measurements.

B. Human-side results

The other type of analysis we did concerns the crowd workers performance but this time it is associated with the

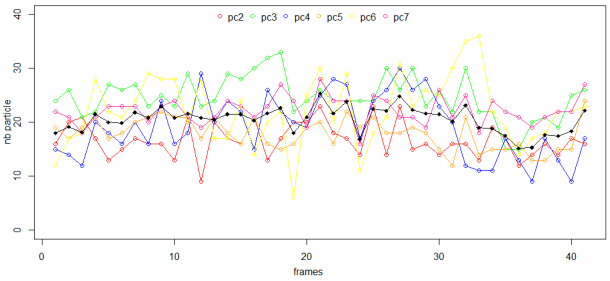

Fig. 10. Plot of numbers of particles marked by users on consecutive images.

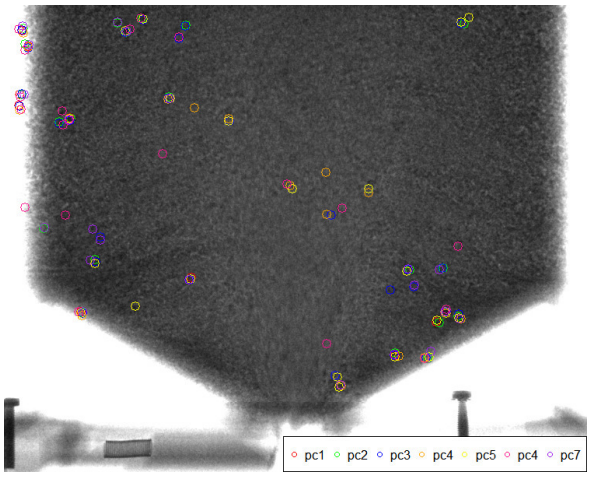

Fig. 11. Image showing particles marked by different users superimposed on a single frame.

other factors of humans' work disregarding the numerical results of particle counted. The analysis of these additional parameters is expected to give insight for further system development. One of the core modules is the time meter recording the period spent by the worker on each frame within the task. It may give some information about the difficulty of the task (or a given frame; especially if the particle count of the different workers for this frame has a large spread of values) but it require a longer study and more participants to derive specific conclusions about that. The system notifies the worker about timer counting per frame before launch the task. The timer feature count time per frame with possibility of browsing the collection back and forth and this enables to measure the performance of the system for the crowd in different frames. Figure 12 shows a heat map of a single experiment where each column represents time performance of a single worker in time from the bottom up to the top for all 41 frames. Yellowish colors indicate more time spent on a single frame while navy blue corresponds to shorter processing of a single frame. After experiments a survey was conducted. Workers answered 8 questions related to task demands and system features. Figure 13 shows a subjective performance in a perceived sense of time users felt themselves in completing the task.

Workers were also asked about the perceived workload in

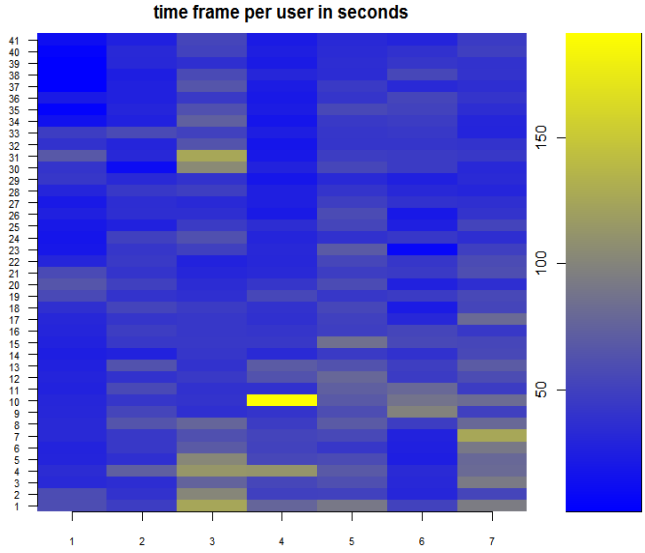

Fig. 12. Work-time per frame for all user

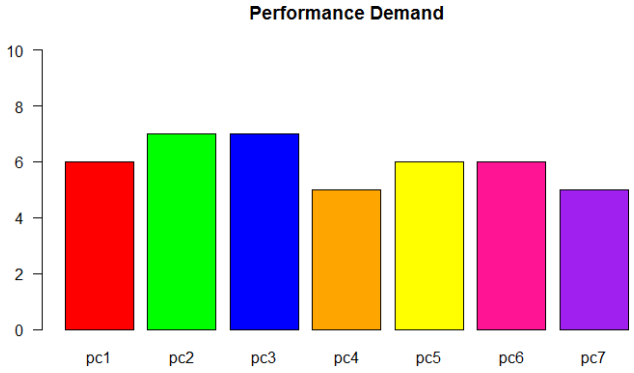

Fig. 13. Crowd workers perceived self-performance.

terms of effort, frustration level, learning, mental, temporal and physical aspects during accomplishing the task. Results are given on figure 14.

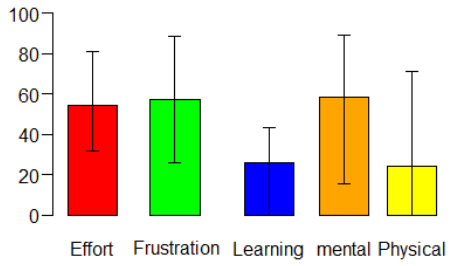

Fig. 14. Results on subjective crowd workers' feedback about perceived workload during the study.

The workers feedback reflect the computation advantage in realizing, the learning level is 20% as average and reach zero even. This indirectly means that the majority of workers do not browse the collection of frames to learn how to identify the particle. This is interesting since the flexibility of the interface was a very demanded feature by the experts. The conclusion for future is to take a deeper look into this aspect. One of the possibility is that the initial training of the users before the experiment/task has to be more detailed.

The level of physical demand is nearly the same this back to the efficacy of the features in the system interface. We have asked the crowd how much the interaction with mouse and brightness control was helpful in accomplishing the frame analysis. The results are promising as presented on figure 15.

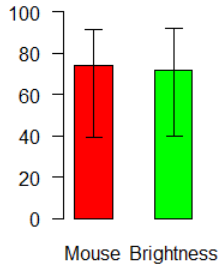

Fig. 15. Crowd workers feedback on system features.

V. Discussion & Future Work

When looking a the results for a system and humans as interpreted in the previous section we noticed a significant level of effort demand against the physical demand beside similar level of frustration. This a general and widely known problem concerning repetitive tasks and can be explained in a way that worker marks the particles in the frame and the same for the rest of collection even with the eye bar feature that reduces at him computing mark again and it may get higher harder if the choose a large collection to work. To enhance the system framework for better feedback results, we work on changing the manner how the work must perform to accomplish a task, so we may aim to decrease the effort by mouse clicking with automatically displaying the previous frame marks to the current and the worker will have just to drag the copy-particle to their new position. However, the previous experience of the experts reveal that this solution may be perceived as distraction for some workers. Therefore, flexibility of the interface in this aspect is required.

In order to cope with high complexity during the clustering of marked particles future work on parallelisation of trajectory calculation with the work of crowdworkers at the same time when he mark the particles may be considered.

Finally, we work on technique that tight the visual search space for the worker. We expect that the implication of this technique in the crowdsourcing system will result in decreasing the effort, mental, physical and temporal demand and at the same time hopefully increase the feasibility and scalability of the crowd system. Heading for these improvements will lead us to semi-automated crowd system that may be comparable with possible automatic algorithms in this complex problem. It seems to be interesting to utilize the eye tracking system to find out how worker use

crowd system [26]. Results will allow to improve the system from worker point of view. Similarly hands gesticulation recognition can be very useful to explore new direction of human computer interaction development in crowdsourcing based system [12].

VI. Conclusion

In this research study we analyzed the design aspects of crowdsourcing system developed for the investigation of gravitational flow with aid of X-ray images. The results are presented on the background of the distinct elements of system design. The additionally introduced features of brightness and especially a feature allowing to use the temporal information, i.e. browsing frames of the current task back and forth allowed to obtain more stable results; less diverse distribution of results delivered by different workers was observed. From the further research on the scientific crowdsourcing systems point of view, the presented heat map is a valuable tool for quantitative estimation of workload per frame since it enables analysis of time spent as well as another valuable information about how often workers used back and forth option. The designed system allows to generate dynamic tasks at worker-side. With the task interface features, we get satisfactory results from the experiments that build on the earlier published work for similar application. The crowd study on the system shows the system feasibility in solving the target problem and improvement in some aspects of the interface performance over the previous design for investigation of industrial flow processes.

***Abstract*—The article describes the idea of detecting stress among programmers on the basis of keystroke dynamics. An experiment with a group of students of artificial intelligence classes was performed. Two samples of keystroke data were recorded for each case, the first while programming without stress, the second under time pressure. A number of timing and frequency parameters were calculated for each sample. Then statistical analysis was performed to evaluate the significance of keystroke parameters changes. It turned out that some of the defined features might be indicators of being stressed.**

I. Introduction

STRESS is nowadays present in most occupations. IT professionals is one of the groups that is exposed to stress the most. There are many reasons for such situation, e.g. deadlines, pressure from clients, high workload [1]. Some research has been made to show that emotions have impact on software developers' productivity [2]. Moreover, negative emotions such as stress may also influence employers' physical health and their mental state. Therefore it is worth detecting them and, if possible, reacting adequately to alleviate negative effects.

Affective computing, a domain intensively explored in recent times, meets the needs of the above problem. It "relates to, arises from, and influences emotions" [3]. Affective applications implement not only emotion recognition methods, but also interpret and react to the recognized affective states. One of possible areas of applying affective methods is software engineering, where emotion recognition may be used to improve software development process [4].

Various input channels may be considered while designing an emotion recognition tool, i.e. visual [5], depth [6], audio [7], textual [8], physiological [9], standard input devices [10]-[15] or multi-modal input [16]. Not all of them seem practical in any situation, e.g. physiological signals not only require specialized devices and disturb computer users, but these measurements are also disturbed by motions typical for human-computer interaction [17].

Analyzing keystroke dynamics and mouse movements is completely non-intrusive, as it does not require any special hardware and may be invisible for users. The aim of this study is to answer a question whether or not stress caused by time pressure influences programmers' keystroke dynamics.

II. Related work

There is a number of research studies on recognizing emotions on the basis of keystroke dynamics [10]. They deal with a number of problems, i.e. inducing emotions, collecting and labeling data samples, defining and calculating characteristic features and finally training and testing the models. Various solutions are designed to be applied for different emotional states. In some cases a number of emotions are recognized. Other works focus on detecting one selected emotional state.

In [11] for example an experiment on recognizing stress on the basis of keystroke and linguistic features has been presented. The stress was induced by giving some stressful tasks to the participants. Several machine learning techniques were applied to solve that task, i.e. SVM, k-NN, neural networks, decision tress and AdaBoost. It was possible to recognize cognitive and physical stress with accuracies 75% and 62.5% respectively. The authors also showed there was a strong relation between the emotional state and the use of backspace, delete, end, arrow keys and also the time per keystroke and pause length.

Another example of stress recognition was presented in [12]. In this case stress was only one of fifteen emotional states recognized during usual computer activities, e.g. using word processor, sending e-mails. Applying decision trees let recognize some of the emotions with high accuracies 77.4-87.8% (confidence, hesitance, nervousness, relaxation, sadness, tiredness) if the recognition was based on fixed texts. Stress was not one the best recognized emotions.

Detecting stress is an important issue in e-learning systems. A framework for stress detection system applied among Moodle students has been proposed in [13]. The authors of that idea not only chose to analyze keystrokes measured as frequency and intensity of keyboard usage, but

This work was supported in part by Polish-Norwegian Financial Mechanism Small Grant Scheme under the contract no Pol-Nor/209260/108/2015 as well as by DS Funds of ETI Faculty, Gdansk University of Technology.

also information from mouse, webcam, touch screen and accelerometer.

In [14] an intelligent tutoring system, which recognizes boredom and frustration on the basis of keystroke and mouse dynamics, is presented. The data in this study were gathered from students learning a programming language by performing programming tasks and then filling a short questionnaire about the level of the two mentioned emotional states. The obtained accuracies for boredom and frustration were over 83% and 74% respectively.

Another approach to stress detection has been presented in [15] where the possibility of using a pressure-sensitive keyboard and a capacitive mouse to discriminate between stressful and relaxed conditions was investigated. It turned out that under stress the typing pressure increased and more contact with the surface of mouse was observed.

This study focuses on the possibility of detecting stress among programmers by analyzing their keystroke dynamics. The essential assumption of the presented experiment was to perform it in a real-world stressful situation.

III. Experiment design and methodology

A. Research objective

A hypothesis stated in this research is that a programmer's keystroke dynamics change depending on whether or not he or she works under stress caused by time pressure. To verify this idea a proper experiment among programmers should be performed. This study might be treated as a preliminary experiment enabling to reveal all issues necessary to be taken into account before starting to cooperate with a group of programmers in their real life working environment.

B. Participants

Two groups of computer science students have been asked to take part in the experiment in order to collect data. They attended a course on artificial intelligence, where different tasks were solved using Matlab. Each group took part in three sessions performing three different tasks. Only those students, who agreed to participate in the experiment, were collecting the data.

C. Data collection procedure

To collect data coming from keyboard, an application running in background was used [18]. The students started the application themselves at the beginning of a session. The application did not disturb them in any way. Each session was organized in a similar way, as it always happened during that course. The fact, that some keystroke data was gathered, did not cause any changes in the standard way of class conducting, already experienced by the students. During the first part they were supposed to write a piece of code in Matlab script to implement a fragment of an artificial intelligence method. They were given instructions and prompts, both verbal and on the blackboard. They were given clues, when they asked for. Then another task from the same domain, was given to them. This time the students were supposed to solve it individually. They were given specified amount of time for this and they were evaluated at the end. All keystrokes were recorded by the application running in the background. Although the students knew about data recording, they did not know the details of the experiment, especially the stated hypothesis. They only knew the keystrokes would be analyzed later. This was to prevent from intentional change of keystroke behaviors.

16 students took part in the data collection phase, some of them in all three sessions, some in two, and some in one session only. Eventually, 36 data samples were collected, each consisting of two parts. The first part of a sample contained keystroke data from the first part of a session, when stress should not have appeared. The second subsample contained data from the second part of a session, i.e. when the students were working under time pressure.

D. Data preprocessing

The first stage of data processing was segmentation. The whole sequence of keystrokes was split into many shorter sequences depending on the presence of pauses. No one types continually. Every programmer types and stops for a while or a longer time. To identify the limits of typing sequences an idle threshold has been introduced. If the time between depressing a key and pressing the next one exceeded the idle threshold, then the split was made. The greater the value of the threshold the longer keystroke sequences were extracted. All timing characteristics described later in this section were calculated regarding the extracted partial sequences. The segmentation was performed for different values of the idle threshold: 0.3 s, 0.5 s, 0.7 s, 1 s. It lead to creating four sets of data to be analyzed.

E. Feature extraction

After segmenting the data, feature extraction procedure was performed. A number of parameters was calculated from raw data. They may be divided into the following groups: digraph features, trigraph features, special digraph features, frequency features and typing speed.

Digraph and trigraph features are timing characteristics for two-key and three-key sequences. They are all based on parameters commonly used in keystroke dynamics analysis, i.e. dwell time (the time a key is pressed), the time between releasing a key and pressing the next one, the duration of key sequences (the time between pressing the first and depressing the last key in a sequence) and the times between subsequent key presses. Moreover, the number of events for a digraph or trigraph was also calculated. These are the numbers of all key down an key up events in a graph, so it is usually 4 for a digraph and 6 for a trigraph. Sometimes, especially when a user types quickly, it happens that a user presses the next key before depressing one. In such cases additional events may appear between those coming from a graph and then the values for these attributes may differ from 4 or 6. A data

sample contains many digraphs and trigraphs. The parameters were calculated for all of them and then their mean values and standard deviations were saved. The detailed list of digraph and trigraph features is presented in Table I.

TABLE I.
PARAMETERS CALCULATED FROM RAW DATA

Feature subsets	Description (feature identifier)
12 digraph features (mean and standard deviation calculated for each parameter)	dwell time for the first key (di_01, di_02)
	dwell time for the second key (di_03, di_04)
	time between pressing the first and the second key in a digraph (di_05, di_06)
	time between depressing the first and pressing the second key (di_07, di_08)
	digraph duration (time between pressing the first and releasing the second key) (di_09, di_10)
	number of events for a digraph (di_11, di_12)
18 trigraph features (mean and standard deviation calculated for each parameter)	dwell time for the first key (tri_01, tri_02)
	dwell time for the second key (tri_03, tri_04)
	dwell time for the third key (tri_05, tri_06)
	time between pressing the first and the second key in a trigraph (tri_07, tri_08)
	time between pressing the second and the third key in a trigraph (tri_09, tri_10)
	time between depressing the first and pressing the second key (tri_11, tri_12)
	time between depressing the second and pressing the third key (tri_13, tri_14)
	trigraph duration (time between pressing the first and releasing the third key) (tri_15, tri_16)
	number of events for a trigraph (tri_17, tri_18)
10 special digraph features (mean and standard deviation calculated for the timing parameters)	time between pressing the first and the second key in a digraph starting from the left shift (di_L_01, di_L_02)
	duration of digraph starting from the left shift (time between pressing the first and releasing the second key) (di_L_03, di_L_04)
	percentage of times when the left shift starting a digraph is released before releasing the second key (di_L_05)
	time between pressing the first and the second key in a digraph starting from the right shift (di_R_01, di_R_02)
	duration of digraph starting from the right shift (time between pressing the first and releasing the second key) (di_R_03, di_R_04)
	percentage of times when the right shift starting a digraph is released before releasing the second key (di_R_05)
17 frequency features	frequency of using the following keys: enter (freq_ENTER), spacebar (freq_SPACE), tab (freq_TAB), backspace (freq_BCKSPC), delete (freq_DEL), up (freq_UP), down (freq_DOWN), left (freq_LEFT), right (freq_RIGHT), left shift (freq_LSHIFT), right shift (freq_RSHIFT), home (freq_HOME), end (freq_END), pgup (freq_PGUP), pgdn (freq_PGDN), percent (freq_PERC)
	number of capital letters to the total number of letters (freq_CAPS)
typing speed	average number of keystrokes per second (speed)

Some digraphs have been treated as special sequences in the case of this applications. These are digraphs containing either left or right shift key as the first one. Digits, operators, brackets, which require using shift to enter them, are common characters while programming. Therefore some digraph parameters were calculated for digraphs starting from the left and the right shift. The detailed list of these characteristics is presented in Table I.

Another group of features are frequency parameters. In contrast to digraphs and trigraphs they do not describe keystroke rhythm. Some of them may indicate the way users make corrections (backspace, delete), move across the code (pgup, pgdn, home, end, up, down, left, right), take care of programming style issues. For example the percent (%) symbol is used in Matlab to start a comment. The frequency was calculated as the number of a selected symbol to the total number of keystrokes. One of the frequency features was calculated in a different way, i.e. the number of capital letters to the total number of letters. The complete list of frequency features is shown in Table I.

Finally, the typing speed, which indicates the number of keystrokes per second, was calculated.

The total number of parameters calculated was 58, which is rather high. Some of the features are redundant. e.g. digraph duration is the sum of dwell times for the two keystrokes and the time between depressing the first and pressing the second key. However, in this study, this set of features is not going to be used for classification purposes for example. That is why dimension reduction is not priority. The aim of this research is to find out whether some of the parameter changes might be caused by stress. Therefore statistical analysis was performed for each of the proposed 58 features.

F. Statistical apparatus for data analysis

To verify the stated research hypothesis a statistical test should be applied. In this case dependent t-test was used. This is a proper test when the data from a person are gathered several times and their changes are investigated. The advantage of analyzing the changes, not the values themselves, is also the fact that in this way differences between the subjects may not be taken into account. In the case of this experiment the difference between the participants and between keyboard types are hidden by analyzing the values changes only.

The keystroke statistics of a person performing a task are measured twice, i.e. while coding without being evaluated and then while writing under time pressure a piece of code to be evaluated. The question is whether the changes of the values of keystroke parameters are significant. To answer this question the dependent t-test of the following form may be used:

$$t = \frac{\bar{d}}{s_d}\sqrt{n-1}$$

where $\bar{d}$ is the mean difference between the values of two measures obtained in two situations; s_d is the standard deviation of the differences; n is the number of degrees of freedom, i.e. the number of pairs of samples, for which the difference is calculated. Because of the fact that no assumption is made on the direction of the observed changes, i.e. keystroke parameters may either increase or decrease, the applied t-test should be two-tailed.

IV. Analysis of Results

A. Results

The values of t-test were calculated for all defined keystroke parameters and the corresponding levels of significance (p-values) have been presented in Table II. Only the features, for which t-statistic exceeded critical value for p=0.05 have been shown.

The results are divided into four sections obtained for different values of the idle threshold. Moreover, each section (table column) is divided into three parts depending on the observed level of significance of parameters' changes. The three subsections correspond to $p \leq 0.001$, $0.001 < p \leq 0.01$ and $0.01 < p \leq 0.05$ respectively. As it can be seen from Table II, about half of the parameters change significantly. The differences among the results obtained for different values of the idle threshold are not very clear. The number of significantly changed features is lower for the lowest threshold of 0.3 s. It can be noted that the subsets of parameters are quite similar. Most features appear in all four sections (columns). It is possible to indicate the parameters which seem to be the best indicators of keystroke dynamics changes. These parameters are potential candidates to be analyzed in a stress detection system.

TABLE III.
NUMBER OF FEATURES CHANGED SIGNIFICANTLY

p-value	Idle threshold			
	0.3 s	**0.5 s**	**0.7 s**	**1 s**
Task 1				
$p \leq 0.001$	0	0	0	0
$0.001 < p \leq 0.01$	2	2	2	2
$0.01 < p \leq 0.05$	0	3	0	0
Task 2				
$p \leq 0.001$	9	14	10	9
$0.001 < p \leq 0.01$	11	9	7	7
$0.01 < p \leq 0.05$	13	7	11	11
Task 3				
$p \leq 0.001$	3	3	7	6
$0.001 < p \leq 0.01$	4	8	6	8
$0.01 < p \leq 0.05$	7	5	6	5

Most of the top parameters are digraph and trigraph characteristics, e.g. mean digraph duration (di_09), mean time between depressing the first and pressing the second key in a digraph (di_07), mean dwell time for the second key (di_03), mean time between pressing the second and the third key in a trigraph (tri_09), mean dwell time for the second key in a trigraph (tri_03), mean trigraph duration (tri_15). Typing speed also turned out to change significantly. Some parameters calculated for digraphs starting from the left shift, i.e. mean time between pressing the left shift and the subsequent key (di_L_01) and standard deviation for digraph duration (di_L_04). Regarding the frequency features, it may be observed that only five keys seem to be worth taking into account. These are: backspace, right arrow, left arrow, enter. It confirmed some observations made in other studies [11].

The mentioned observations have been made on the basis of data coming from different people. It is possible that analyzing the results individually would let draw different conclusions. First of all the idle threshold could be adjusted regarding one's typing speed. Then the subsets of significantly changed parameters could be also found individually. However, it would require gathering more samples from one person performing different tasks.

B. Limitations

Although significant changes for some of the defined characteristics have been observed, these results should be analyzed with precaution. The experiment was not free from limitations.

The first issue, which should be discussed, is the difference between the results obtained for different tasks. As it has been mentioned in Section III C, the 36 samples were collected while performing three different tasks. The number of samples form the three tasks was 15, 12 and 8 respectively. The significance of feature changes was also estimated for each task independently. Table III contains numbers of features found to change significantly in each case. Only a few parameter changes turned out to be significant in the case of task 1, whereas for other two tasks there were more of them. One of the reasons for this difference is the fact that the level of difficulty of the three tasks was not the same. The first one was the easiest although it required more coding than in the second case. The second task was more difficult but in this case the students were supposed to spend some time on designing before starting coding so the amount of code written was smaller. The third task was the most difficult and it required the highest number of code lines to be written. Moreover, in all three cases the students were precisely instructed during the first part of the lesson. The blackboard was used to explain the details of the problems being solved. In the case of the second and the third task more instructions were given on the blackboard and it was possible to make use of it by copying some of the lines to students' code. The amount of rewriting in the first task was much lower. During the second, i.e. the stressful, part of the lesson, no lines to be copied were given on the blackboard. Although few lines could be written by copying from the blackboard, keystroke dynamics with rewritten fragments might be different than without it.

It should be also noted that some of the features turned out to be useless, e.g. the frequency parameters for the pgup, pgdn keys. It was because of the specificity of the three given tasks, which did not require writing many pages of code. However, in real programming environments, these parameters could be worth calculating. Possible different behaviors are worth paying attention, e.g. either pressing pgdn/pgup quickly many times or keeping it pressed for some time to move down/up.

Another limitation of this study is neglecting the fact that people are not equally prone to stress and they react to stress in different ways. There are some factors such as marital status, age, gender, income, experience, which have been found as having influence on individual stress level [1]. Some of these factors (e.g. age, experience, income) were not present in the case of the presented experiment, due to the peculiar study group of students attending the same class, but some of them still remained.

Finally, it has to be highlighted, that although the stressful situation was induced in a way, there is no certainty that the participants were really stressed, because they were not asked for any self-assessment at the end of each session. The only way to make sure that the task given to the students really induced stress would be applying one of numerous questionnaires which cover a wide range of symptoms induced by stress and are used in the field of psychology [19]. Another interesting approach would be incorporating some physiological measurements, which could be indicators

of stress. However, this would require usage of special devices and coping with the problem of the sensitiveness of some biometric sensors to finger movements [16][17]. Thus it could not be implemented in an experiment performed in a real life situation as the one described.

I. Conclusions

The results of the presented survey may be treated as the preliminary ones, which could be useful in designing a deliberate experiment to be performed among programmers. Regarding the mentioned issues it can be noticed, that more factors should be taken into account to make sure on the influence of stress on programmers' keystroke dynamics. The presented results give some clues: the tasks performed with and without time pressure should be as similar in the sense of difficulty and length, as possible; effort should be made in order to ensure similar working conditions; the idle threshold should be adjusted individually depending on the typing speed. Finally, the experiment results should be also compared to the results of a proper psychological questionnaire.

Moreover, some other ideas could be explored. One of the most interesting ones is adding to the set of analyzed parameters the timing characteristics specially defined for a given programming language. It could be for example key words and also common sequences of symbols instead of calculating all digraph and trigraph parameters.

Another interesting idea is to incorporate information from mouse as well. There are some known studies on recognizing emotions from mouse movements [10]. Such analysis could be adapted to a given programming environment by tracking the way it is operated, e.g. using menus, moving across various windows etc.

The observed changes in keystroke dynamics are also worth investigating in another application, i.e. intelligent tutoring systems. Analyzing keystroke changes could be applied to detect specific situations, that might reduce the efficiency of the learning process.

***Abstract*—Proper break taking during office work iss necessary to prevent musculoskeletal disorders and reduce the risk of heart disease. We present APOEW — an avatar for preventing continuous office work without taking breaks. APOEW is a system that uses a personalized robot avatar to encourage proper break behaviour during office work. The avatar signals the need for a break by stooping. The system was designed to be unobtrusive and blend well with the office environment. The avatars are customisable in order to enable users to design their work environment freely. We conducted a user study where we observed developers working in front of their computers next to the avatar. Preliminary results indicate it has no negative impact on the work environment and users are intrigued by the system. Moreover, a survey on attitude to our concept reveals interesting and positive feedback that will help to develop an APOEW system further.**

I. Introduction

THE SEDENTARY nature of office work is universally recognised as detrimental to health [4]. Employees are advised to take regular breaks as this results in benefits to cardiovascular health. Yet, workers often forget about the need for break for a variety of reasons. As digital artefacts have already pervaded the work environment and users often have multiple devices present on their desks, we propose introducing an additional object that would remind workers of taking regular breaks. APOEW (pronounced ape-oh) is a humanoid physical avatar robot that alters its posture to suggest a break is needed. We designed an avatar which can easily integrate with the work environment and attempt at persuading the user to take a break without disrupting the work. Being a humanoid robot, it visualises possible negative changes to the user's posture if a proper break regime is not followed. In the remainder of this paper, we present the past work that motivated the creation of APOEW and describe the design process of the avatar. We then provide details about the implementation of the system and report on a preliminary user study. This paper concludes with a discussion of future directions for the design of tools that support proper posture and break taking.

This work-in-progress paper contributes: (1) the design and implementation of a persuasive physical avatar aimed at promoting a proper break regime in office work and (2) initial design insights for future work on personal avatars in office spaces.

II. Related work

Personal avatars (both virtual and physical) have been used for a variety of purposes such as remote collaboration [10] or instant messaging [11]. Past research indicates that avatars can have a persuasive effect and it has been observed in virtual worlds [6]. Our work explores how physical avatars may influence users and promote a particular behaviour. We also build on the fuzzy avatar [3] concept (i.e. an avatar that does not provide direct messages, but merely offers hints) and thus explore ambiguity as a factor in persuasion.

Design interventions in workspaces have a long history in Human-Computer Interaction (HCI). Our work is particularly concerned with systems that attempt to change user behaviour in the work environment and measure office activity. Miro [1] informed office workers on the overall emotional climate in the building. The Clouds [12] attempted at persuading users to use the stairs instead of the lift. These works inspire our research as they prove that introducing new artefacts to office spaces can benefit the communities of office workers.

As we interpret APOEW as a system that addresses the domain of designing persuasive technology [2], our work is highly influenced by past achievements in this domain. Nakajima et al. [9] used persuasive technology successfully to promote healthy habits such as brushing teeth. Hong et al. [7] addressed posture issues while working with computers through a flower-shaped avatar, which provided real-time feedback. A similar approach can be found in [14], where an abstract shape of avatar is designed to reflect human behaviour. Morris et al. [8] investigated how proper break behaviour may be elicited by encouraging hands-free interactions during breaks. Haller et al. [5] used a sensor chair to provide posture feedback through digital and physical means. Also [13] addressed the problem of sedentary lifestyle, but with the use of an ambient display. APOEW is interestingly different from the above past work as it uses a partly ambiguous physical avatar and its feedback is based on cumulative data.

III. Design

Our design work was influenced by personal avatars described in past work as well as previous deployments of interactive technologies in office spaces. We imagined a scenario where an office worker could place a humanoid robot on their desk. The avatar would be personalisable in order

to make it blend well with the rest of the office space and add a personal touch to the desk. In spaces where desks are assigned dynamically, it could function as an easy way to make the space cosier. Continuous, accumulated avoiding of the necessary breaks would result in APOEW stooping. It would also use audio output in extreme cases when a break is really needed. While audio output is bound to cause a distraction, we reckoned that actively refusing to take break must be prevented using more direct means. This action would serve as a direct persuasive factor to suggest a break is much needed. Fig.1 presents the design of APOEW in the form of design sketches.

Our system also explores ambiguity as resource for design. We aimed for APOEW to provide persuasive cues that are not obvious and do not simply impose particular behaviours on the user. We decided to use a humanoid robot as we believed it would make the user reflect on the long-term effects of not taking regular breaks during office work. Customisable clothing would enable the user to make the desk space more personal. We aimed for making it possible for the user to have the avatar represent them. This would potentially trigger additional reflection potential. Furthermore, we enabled the user to notify the system of actually taking a break by pressing a button on the back of the robot. As the robot was designed to stand next to the computer screen, this would require some movement, perhaps prompting a break, even if the user intended to cheat the system. As our design goal was reflection and realising the importance of break taking, we opted for selfmonitoring instead of an elaborate activity sensing system.

IV. Implementation

APOEW was implemented iteratively and two major research prototypes were studied so far. First one was prototyped with the Lego Mindstorms NXT robotics set. There were two robots programmed using Java for the initial user study of the system. This prototype employed a single NXT controller, ´intelligent bricks´, based on 32-bit Atmel AT91SAM7S256 main microcontroller (with 256 KB flash memory and 64 KB of RAM). The robot was additionally equipped with a custom 'backpack' with the RaspberryPi and dedicated speakers, so that the robot could play sounds of higher quality than those provided by the NXT platform and produce synthesised speech. Three motors and two touch sensors were used to move the humanoid body, allow it to stoop and facilitate user input. Custom-made clothing was made for the robot using paper and cloth. Fig. 2 depicts the constructed and programmed humanoid robot next to a programmer at work.

A schedule for changing the avatars posture according to continuous work time was implemented. The robot would move slightly after 50 minutes without a break to signal that a work cycle was about to end. A more significant movement informed about a full cycle ending, after 55 minutes of work. After 65 minutes, the posture of the robot changed significantly and, after 75 minutes, sounds were produced. These effects were even stronger if the worker was skipping multiple breaks during a day.

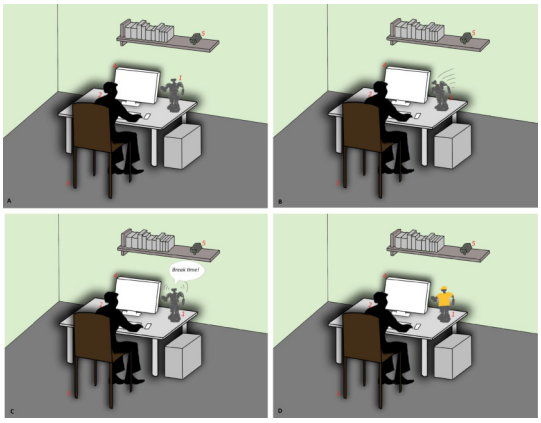

Fig. 1. Conceptual sketches for APOEW: (a) A personal avatar on an office desk. (b) APOEW suggests that a break is need by adjusting its posture. (c) A notification sound is played when the user excessively refuses to take a break. (d) A personalised version of APOEW featuring custom clothing.

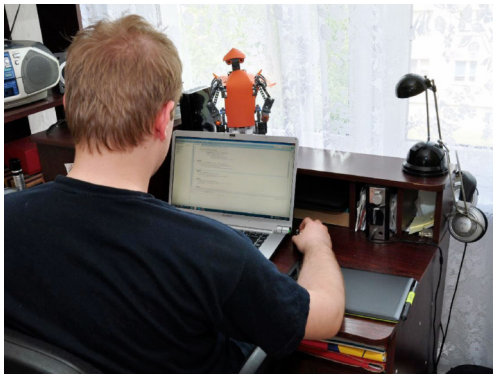

Fig. 2. The first implementation of APOEW. Note the custom clothing of the robot. APOEW is placed next to the computer screen so that interacting with the robot requires movement.

V. Initial evaluation

We conducted a preliminary user study to assess the effectiveness of APOEW, verify the design assumptions and investigate the user experience created by the avatar.

APOEW was deployed in a controlled office environment. Four office workers (two developers and two graphic designers) from a local IT company were recruited for the study that lasted for three days. As work behaviour data was being gathered, a detailed privacy policy was presented and explained to the participants. We monitored two workers at a time using a video camera. A total of 96 hours of video was recorded (4 workers x 3 days x 8 hours). The first day of the study was used as a sample workday for comparison purposes. APOEW was introduced to the office space on day two. After the conclusion of the study, we performed semistructured interviews with the participants.

Three researchers performed independent qualitative analysis of the video and interview material. A joint discussion session was then held and observations were made. The introduction of the avatars to the office space drew attention

Fig. 3. An in-situ picture of the preliminary user study. Two IT professionals are performing their regular work with two APOEW (circled in red) units standing next to their screens. Four users spent a total of eight days working with APOEW.

Fig. 4. The implementation of chair sensor during a second study - a Bioloid robot during the study on the left-hand side. Prototype sensors on the chair on the right-hand side.

of the participants. They were intrigued by APOEW and immediately started discussing its purpose. The participants quickly proceeded to personalize the robots on their desks, by adding features related to hobbies or favourite movies. The extra attention generated by APOEW suggests that our future work should concentrate on a long-term study of the system where the novelty effect of APOEW will be minimised. This is why this work-in-progress paper does not report quantitative data on the break taking behaviour of the participants. We also noted that the implementation of the prototype needs improvements — the noises generated by the servomotors may cause unintended distractions.

The next study was conducted using Bioloid robots and a prototype of a fully functional, yet not final, version of the system, i.e. we also prepared a set of sensors to be roughly mounted on top of chairs - on-top both of the seat and back of the chair. Such a design was to provide the automatic control of the system since the sensors were supposed to communicate the fact of the chair being released by the user and for how long, as well to trigger the APEOW procedure for persuasion if the chair is eventually not empty for a least 5 minutes. However, due to communication problems we were not able to conduct a proper study at that time. Fig. 4 shows the robot during the study with a Bioloid design (left-hand side of the picture) and a sensors prototype shown on the top: seat and back of an office chair. 2 Workers were monitored by 2 days each that gives in total 32 hours of this second design test.

In the interviews, users expressed their satisfaction at the

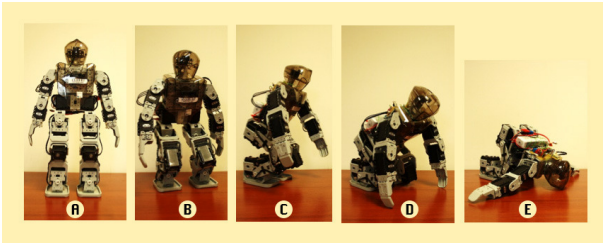

Fig. 5. The changes in the Avatar posture during the planned period.

fact the work environment became more attractive with the introduction of APOEW:

I really like this little fella. His bright clothing makes the office cosier.

The participants also wondered what would be the long-term effects of the system and suggested alternative uses or even peer pressure:

I'd like to see what happens when he stays here longer. I could also use this to see how in fact my friend is working or even pressure him to take a break through my avatar. And, I can dress him as Iron Man.

Overall, we can conclude that APOEW can potentially be integrated into an office environment and users are willing to consider the possibility of introducing personal avatars to their workspace. Privacy is a concern and we will aim to address that issue in future work. Further studies are required to measure the persuasive effect of APOEW.

In order to conduct further development of the project a survey was conducted to gain broader knowledge about the attitude towards the proposed concept. Fig. 5 shows the sequence of photos illustrating the consecutive phases of the APEOW persuasive movement.

N=198 people responded to our survey including 41.4% women and 58.6% men. 47% working, 27.3% working and studying, 23.2% studying and 2.5% unemployed or retired. 47.2% of workers are employed in big companies related to IT business (1000+ employees). Results of the survey revealed that 59.6% declare that they do or try to do periodic breaks from sitting work while most of people (between 68.9% to 88.6% depending on the issue inquired) shown great concern about possible negative results of refraining from conducting these breaks. Feedback shown that majority of respondents express their positive attitude towards the concept as the following data show: Idea assessment: 58% positive vs. 21.2% negative and 20.8% neutral. Anticipated efficiency: 41.4% positive vs 26.8% negative and 31.8% neutral. Possible interfering with the work expected: 31.8% confirm vs. 43.4% not agree and 23.8% neutral. Expected deterioration of the work conducted: 16.6% confirm vs. 67.2% not agree and 16.2% neutral. As one can see from these numbers the APEOW concept was warmly welcomed by the respondents with more then half supporting the main idea and only nearly one fifth being explicitly against it. One third of users see potential interference with the work conducted positive generally but at

the same time only about 17% foresee substantial disruption of the work and more than 67% not anticipating any significant issues with it. Another interesting results show possible ideas for how the proposed APEOW concept could work: Conviction of possibility to modify the look of the APEOW may strengthen its impact: Agree 36.4% vs 33.9% disagree and 29.7% not sure. Willing to personalize own APEOW: 60.6% by look: 38% using sound/voice: 27.2% adjusting the work-break intervals: 77.8% other changes in persuasive behaviour procedure, etc.: 61%. On the other hand, respondents think the following features would diminish the efficiency of the APEOW: personalisation: 11%, sound/voice emission: 73.2%.

Lastly, users answered questions related to anticipated adoption of the APEOW in the workplace and the results show that most of employers are expected to accept the proposed concept in their offices. 51% respondents declared it explicitly, 29.3% said they would probably accept it vs. 5% disapprove at all and 13.1% rather disapprove.

VI. Conclusions and future work

This paper presented the design, implementation and initial evaluation of APOEW; a persuasive physical personal avatar that helps uses maintain a proper work break regime. The avatar was designed to integrate well with an office environment and offer personalisation features. We explored how a humanoid robot can trigger personal reflection in users. An initial user study with four participants working for three days showed that the robot gained that attention of the users and may have had impact on the workers work regime. The results also indicate that feedback forms require further investigation as privacy concerns were raised.

In the near future, we aim to improve the prototype by conducting further studies. We also aim to develop new interactions with the environment, e.g. the robot could make use of user's eye movements [15] or hand movements [16]. First, we aim to compare different types of posture, personalisation options and other output parameters and their effectiveness on altering break regimes. Next, we plan to run a long-term in-the-wild study that will verify the effectiveness of our approach.

In the larger picture, given the rapid advancement of robotics, we believe that HCI should address the role personal physical avatars can play in future everyday spaces. Our work explores only a fragment of what personal avatars may offer. We wonder how systems similar to APOEW can be used not only as persuasive technology, but also whether they can improve workflows, communication or social relationships. We hope that our work will inspire further inquiries into how physical avatars can be integrated in the computing landscape.

VII. Acknowledgments

Authors of this paper would like to express their deepest appreciation for Tomasz Kosiński, who has greatly contributed to the work on this project.

***Abstract*—This paper concerns how an affective-behavioural-cognitive approach applies to the evaluation of the software user experience. Although it may seem that affect recognition solutions are accurate in determining the user experience, there are several challenges in practice. This paper aims to explore the limitations of the automatic affect recognition applied in the usability context as well as to propose a set of criteria to select input channels for affect recognition. The results are revealed via a semi-experiment based on the case study of an educational game. As a result, a number of concerns were identified, providing a list of pros and cons for affective computing methods applied in the usability testing context. The lessons learned might be interesting for both researchers that develop emotion recognition algorithms and for practitioners, who apply them to diverse areas.**

I. Introduction

ADVANCES in mobile and ubiquitous technologies have made human-system interaction everyday practice in multiple aspects of life. As a result, natural interaction and positive experience of technology is receiving more and more attention. The traditional notion of software usability, as defined by the ISO 9241 standard, includes the effectiveness, efficiency and satisfaction with which specified users achieve specified goals in particular environments [1]. The term *user experience* goes beyond this definition, emphasising the affective component and forming a more holistic picture of human-system interaction [2].

Producers and the marketing/branding industry are interested in the affective aspect of user experience in terms of software products and create a demand for automatic emotion recognition techniques as a tool for getting a larger quantity of more objective data. However, the application of emotion recognition methods in UX testing is not so straightforward. An analysis of only the affective aspect of the user experience might be not enough to determine the issues of effectiveness, efficiency and satisfaction. Therefore Ahn and Picard [3] proposed the affective-behavioural-cognitive (ABC) framework that combines diverse techniques in order to evaluate the user experience in a more holistic manner. The framework was validated with an experiment on beverages [3] and an evaluation of web applications [4]. The ABC framework intends to address goals and interest of diverse stakeholders.

In our research, we develop and study educational games, where user satisfaction is a key affective component, although there are also typical usability issues involved. We turned to the ABC framework as a solution to evaluate the user experience of the software. However, we uncovered many challenges in the practical application of automatic emotion recognition methods. This paper presents the lessons learned and some adjustments in method, that might be useful for researchers who develop emotion recognition algorithms and for practitioners, who apply them in diverse contexts.

The main research questions addressed by this paper might be formulated as follows: *Which emotion recognition and affect representation techniques are applicable within the procedures of usability/user experience testing? What are the main limitations/challenges in their use? How to provide valuable information derived from affective analysis?*

This paper presents a semi-experiment based on a usability case study of an educational game and is organised as follows. Section 2 outlines the previous research on which we based our study. Section 3 includes the operationalisation of the variables and a study plan, while section 4 and 5 provide details of the study execution along with the results. Section 6 provides a summary of the results and a discussion, followed by some concluding remarks (section 7).

Although the authors are aware of the fact, that user experience is a broader term than usability [5], the paper sometimes uses these terms interchangeably, although in the broader (UX) sense.

II. Related work

Work that is mostly related to this research falls into two categories: (1) studies on emotion recognition based on different input channels and their comparison; (2) the use of affect elicitation techniques in user experience evaluation.

(1) There are numerous emotion recognition algorithms, that differ in terms of input information channels, output

This work was supported in part by the Polish-Norwegian Financial Mechanism Small Grant Scheme under the contract no Pol-Nor/209260/108/2015 as well as by DS Funds of the ETI Faculty, Gdansk University of Technology.

labels or representation model and classification method. The most frequently used emotion recognition methods that might be considered when designing an UX evaluation include: facial expression analysis [6], audio (voice) signal analysis in terms of modulation, textual input analysis, physiological signals as well as behavioural pattern analysis [7].

As literature on affective computing tools is very broad and has already been summarised several times, only a sample of papers on recognition methods are provided here. For a more extensive bibliography on affective computing methods, one may refer to Zeng et al. [8] or to Gunes, et al. [9]. The most important conclusions from a review of the literature related to emotion recognition that are the most relevant to this study might be formulated as follows:

(1) Emotion recognition techniques provide results in diverse models of emotion representation (from dimensional models through Ekman's six discrete basic emotions down to two-class classifiers) [10]; there is no common standard model for representing affect;

(2) No input channel is superior to any other in terms of the accuracy and granularity of emotion recognition [11]; a multimodal approach combining diverse input channels provides the most accurate results in most cases; for a multimodal approach, early or late fusion might be considered [12].

(3) Self-report of emotions, although subjective, is frequently used as a "ground truth" (another approach is manual tagging by qualified observers or physiological observations) [13].

The aforementioned results influenced the decisions made concerning the design of this study, especially that it is advisable to use more than one observation channel. The study design is reported in detail in section III.

(2) The second part of the literature review performed under this study was aimed at exploring how automatic affect elicitation techniques are applied in usability and/or user experience evaluation.

There are a few studies on fusing affect recognition and usability evaluation [2][4][12-17]. Most of them consider the usability of food or everyday items and evaluate the overall experience taking emotional factors into account. The most important paper related to this study introduces the Affective-Behavioural-Cognitive approach to UX evaluation [3]. Another is by Lew et al., providing an example of affect evaluation applied to quality assurance procedures for web applications [4].

Kołakowska et al. proposed involving affect recognition in usability evaluation and have suggested four different scenarios: a first impression test, task-based usability test, free interaction test and comparative test [14][15]. The main contribution of the study is the proposal of an emotional state set that might be important in usability evaluation scenarios: *frustration*, *empowerment*, *interest* (*excitement*), *boredom*, *disgust*, *engagement* and *discouragement*.

Partala and Kallinen suggested using the Positive and Negative Affect Schedule (PANAS) scale in self-reporting user experience [16].

Hazlet and Bendek described two studies that used facial electromyography (EMG) measures combined with verbal and performance measures to provide feedback on the user's emotional state. The multimodal approach used in this study was able to provide a measure of the desirability of features, a measure of emotional tension and mental effort expended while performing tasks [17]. There are also some studies of games that utilise the channels used in emotion recognition [18][19][20].

Zimmerman et al. proposed a new method for measuring mood based on the effects of affective processes on motor-behaviour and uses log-files from the mouse and keyboard as a proxy of the mood of the user [21].

There is one study on the limitations on affect recognition in the usability context and it proposed the following criteria: accuracy of emotion recognition, susceptibility to disturbance, independence of human will and interference with usability testing procedures. These criteria were used in an analysis of the recordings from a case study regarding usability evaluation, however were not put into practice [22].

Although some studies on blending affect recognition and usability testing exist, their practical applicability and interference of emotion recognition with IT user experience testing still requires more exploration.

III. Study Design and Research Methods

In order to verify the applicability of emotion recognition in the software UX evaluation context, a semi-experiment was conducted, based on a typical usability study of an educational game extended with user emotion recognition channels. The concept was to use multiple observation channels at the same time, but only those that do not significantly interfere with the typical usability evaluation procedure. Typical usability tests involve 5-10 participants, as this number is enough to reveal 75-90% of usability issues. We planned up to 10 participants for the experiment, as more participants are rarely involved in usability studies.

In order to conduct the study, we chose an educational game, still at the developmental stage, that would be suitable for performing usability evaluation. This choice influenced the participant group. The experiment had to include both the target group of the software under investigation (at least 5 people) and some participants outside the target group since the target group of the application was quite narrow, and we wanted to involve more age groups in the evaluation of emotion recognition techniques.

A. The software under research and UX evaluation goals

GraPM – an educational game about project management [23] was selected for the study. In this game the player assumes the role of a project manager and aims to complete a given product in a given time with some resources under

the uncertainty of some risks. Different product features have different business value, effort and impact on quality. Resources offer different productivity. Threats and opportunities appear and materialize randomly during the development process, requiring the player to take appropriate actions that he chooses from a given set. The effectiveness of particular actions is left for the player to discover during the game-play. Additionally, the satisfaction of the customer and the team must be monitored, as low ratings can result in the abandonment of the project and losing the game. GraPM involves both deterministic and random factors and requires considerable project optimisation to win the game.

The target group of the GraPM game includes two subgroups: (1) students wanting to develop their knowledge and skills in terms of project management; (2) players who enjoy strategy and management games.

The emotional activations that assist in achieving goals were identified as follows: (a) interest – the player should want to learn; (b) slight confusion – the player must be aware that he does not know everything; (c) joy – the player is pleased that he improves and learns; (d) sense of control – the player is content that he can fully control the project/game and win.

The emotional activations that hinder the achievement of goals were identified as follows: (a) fear – the player should not be afraid of learning; (b) strong confusion (frustration) – the player should not be lost and not know what to do; (c) anger – the player should not get angry that he does not understand the game and cannot win; (d) boredom – the game should not be too repeatable and unchallenging; (e) disregard – the player should not consider the game to be of no educational value.

The evaluation of the user experience of the GraPM game is expected to assess to what extent the user experience goals were achieved, with particular focus on learnability. The players should broaden their understanding of the aspects of project management as well as some principles of effective management such as planning, risk management and project supervision. In terms of the game mechanics, the user experience study is expected to provide observations on where the players encounter problems in manipulating the game, which will limit their ability to learn.

The affective extension of the usability study with the emotion recognition should provide additional information on which features of the game enhance learning and which hamper them. Overall, the extended usability study should allow conclusions to be drawn on how to develop the game to improve its educational efficiency, playability, and enjoyment.

B. ABC framework applied in the operationalisation of UX variables

The affective-behavioural-cognitive approach was used in the transformation of the UX study goals into a definition of the semi-experiment variables. We defined the following three general criteria for UX evaluation: understanding, engagement and enjoyment and the criteria were further operationalised into metrics.

Understanding means that the game is comprehensible for a player and this factor corresponds to the cognitive perception of the game mechanics and the game logic (C-cognitive aspect in the ABC approach). According to the information provided on the game, the mechanics understandability should be evaluated after the 2nd and 3rd game, while the understanding of the game logic should be assessed after the 4th and 5th game. Additionally, a learning curve might be derived based on the progress in consecutive game-play.

Engagement indicates that the game is engaging, that it attracts and maintains interest. This factor is a representation of an observable (B - behavioural) aspect of player-game interaction.

Enjoyment determines whether interaction with the game results in a growth in positive affect symptoms, which corresponds to the affective factor (A - affective aspect in the ABC approach).

The author's description of the game provides a list of desirable emotions: interest, slight confusion, joy and feeling of control and a list of undesirable emotional states: fear, strong confusion (frustration), anger, boredom and disregard.

The emotions were listed spontaneously without any guidance or presentation of affect representation models. This approach was chosen purposefully, as a presentation of the models might have influenced the choice. The emotions were mapped into the models provided by the algorithms chosen for the study and the mapping is described in section V.

In this paper we limit our report to the enjoyment factor, although all three aspects were measured and delivered to the game designers as the result of the study [24].

C. Experiment design

In this study we have used the semi-experiment as a research technique. It was a semi-experiment, as it was not possible to fully randomise the choice of subjects to sample. The experiment was based on a real case study, and a group of convenience was used instead of a randomised sample. However, the sample consisted of: representatives of the game target group (students) and some participants outside the group to represent some confounding variables (e.g. age, education and domain). We also set the group size limit (10), as more participants are rarely involved in UX evaluation and this limitation should be taken into account while assessing the affective factor of the game. In other words, one of the challenges was to determine whether 10 people is enough to provide valuable information on affect.

During the study, a limited the number of input channels were recorded (three). Audio (voice) signal analysis and textual input analysis were not considered for inclusion, because in the case study scenario, these channels of human-system interaction were not used. We decided to capture

video image for facial expressions analysis, to ask for self-report based on the PAD emotion representation model and to record physiological signals for reference (skin conductance). The use of other input channels (e.g. keystroke dynamics or mouse usage patterns analysis) are planned in future experiments.

The game-play (which was performed 5 times) was interspersed with questionnaires that measured: competence progress, self-report on emotions, usability questions, including System Usability Scale and questions on the subjective notion of camera and sensor disturbance.

D. Operationalisation of experiment variables

The main goal of the semi-experiment was to answer the research questions as specified in the introduction section — i.e. to determine which emotion recognition techniques are applicable and provide most value in the UX context.

This challenge was conceptualised using a Goal-Question-Metric technique.

GOAL: Analyse the emotion recognition solutions in order to characterise it with respect to applicability from the point view of experimenters relative to the user experience evaluation.

Q1: Is the procedure of software user experience compatible with emotion elicitation techniques?

Q2: Does application of such techniques hinder the process of usability evaluation?

Q3: Does the application of emotion elicitation techniques provide valuable information from the viewpoint of the UX evaluation goals?

These questions are mapped into the following three criteria: applicability, interference and affect-awareness gain.

Applicability represents the degree to which the emotion recognition techniques might be deployed into UX study and the criterion is divided into two factors: input channel availability and susceptibility to noise.

Input channel availability in the UX context was measured by the metric (AP1) time available/time of study ratio.

This study was not focused on the accuracy of classifiers, but rather on the interference (disturbance) introduced by the UX context, as the input channel might be unavailable or significantly noisy.

Susceptibility to noise was evaluated with different proxy metrics for diverse input channels and then qualified to the metric (AP2) level of susceptibility with a common scale of high-medium-low values. The proxy metric for the skin conductance input channel was the number of events that disrupt the channel per time unit (minute) and the events were defined as mouse clicks, which introduced movement artefacts to the EDA signal. The SC sensors (we used two) were placed on the base of the finger and on the wrist [25] and although not all mouse clicks introduced artefacts, most of them did.

For the video channel we used the quality of consecutive frames as the proxy metric.

The ***Interference*** factor measures the influence of emotion recognition application on the usability study. Changes in the usability study (introduced by emotion recognition) should not significantly influence the main goals of the usability study – i.e. gathering information on user effectiveness and learning with software. The factor was measured by 2 metrics: self-report on the subjective notion of camera (IN1) and sensor disturbance (IN2). In the self-report we used a 5-item scale from: 5 - very intrusive to 1 - not intrusive.

Affect-awareness gain is a factor that represents the value of introducing emotion recognition techniques into the software UX context. The criterion is divided in this study into three factors: (AA1) compatibility of the emotion classifier output with emotional states recognition requirements (the ones specified in advance); (AA2) consistency of multimodal observations; (AA3) subjective opinion of the customers of the extended UX study on the value provided by different information on the affective states of the user.

The compatibility metric (AA1) was evaluated for four emotion representation model types (6 basic emotions, arousal only, valence-arousal and PAD positiveness-arousal-dominance models). We used the following scale: 0 – no representation in the chosen model; 1 – could be represented, but might be confused with other emotions; 2 – could be easily and unambiguously mapped; 3 – directly available in the representation model.

Remarks on the consistency of multimodal observations (AA2) were introduced to this study but they will not be evaluated quantitatively. This criterion added, as we observed, huge discrepancies between emotional states estimated on diverse input channels. However, the evaluation of the discrepancy, its scale and analysis of its causes go far beyond the scope of this study. We decided to merely report it, as the differences might compromise the affect-awareness gain.

The results of the players' affect elicitation and analysis were presented to the game designer (the second author of this study) and were evaluated based on the criterion of value they bring to the understanding of the user experience with the game (AA3 metric). The value was measured on a 5-point scale ranging from: (5) very informative to (1) no affect-awareness gain. The designer evaluated the following: the perspectives offered in the presentation of the study results, the views used to visualise data and overall affect-awareness gain in understanding usability and the user experience.

IV. STUDY EXECUTION AND THE PRESENTATION OF THE UX RESULTS

The case study was carried out in 2016 at the Emotion Monitor Stand at Gdansk University of Technology [26]. The The following equipment was used: (1) for physiological signals tracking and analysis: Thought Technology ProComp Infiniti coder, compatible sensors,

Biograph Infiniti Physiology Suite software; (2) for video analysis: a standard Internet camera and video capture software from Logitech, for analysis of facial expressions, Noldus FaceReader was used; (3) for screen capture and user activity tracking and analysis – Morae Recorder, Observer and Manager were used. The three capturing sets were operated at three computer workstations.

We used 2 skin conductance sensors placed on: left-hand fingers and right-hand wrist (for right-handed participants). The locations of the sensors were chosen based on a previous study on the interference of mouse and keyboard usage movements with physiological signals from the fingers [25].

The camera was located above the monitor screen, centrally. Video capture was performed with a 29 FPS rate, 1280x720 resolution and saved as a mp4 file. The analysis of facial expressions was performed using Noldus FaceReader software, providing both Ekman's six basic emotion vectors for each frame as well as valence and arousal model time series.

Morae Recorder was used to capture the screen and gather questionnaire responses and Morae Manager was used to analyse the results.

The study was carried out in April and May 2016. The entire experiment involved 10 participants aged 23 to 43 (8 of them belonged to the game target group), 5 male and 5 female.

The results of the affective aspect of the UX study were reported to the game designer using three perspectives and seven views:

Perspective 1. All UX study participants – information on emotions was summarized for all UX study participants and all tasks performed. The perspective used the following views:

View #1. Declared emotional states versus desired and undesired emotional states

View #2: Recognized emotional states versus desired and undesired emotional states

Perspective 2. Single participant between-task analysis – provides information on fluctuation of emotional states between consecutive gameplays and uses following views:

View #3. Declared emotional states after each gameplay

View #4. Declared/recognized emotional states per gameplay

Perspective 3. Single participant single gameplay analysis – provides detailed information on how emotional state fluctuated during single gameplay, which might be combined with the events. This perspective uses following views:

View #5. Relative frequency of emotional states in Ekman's six basic emotions model;

View #6. Fluctuation of valence (positive/negative state);

View #7. Fluctuation of arousal (calm/active state).

Figure 1 provides sample analytical views on emotion as provided as a result of the UX study.

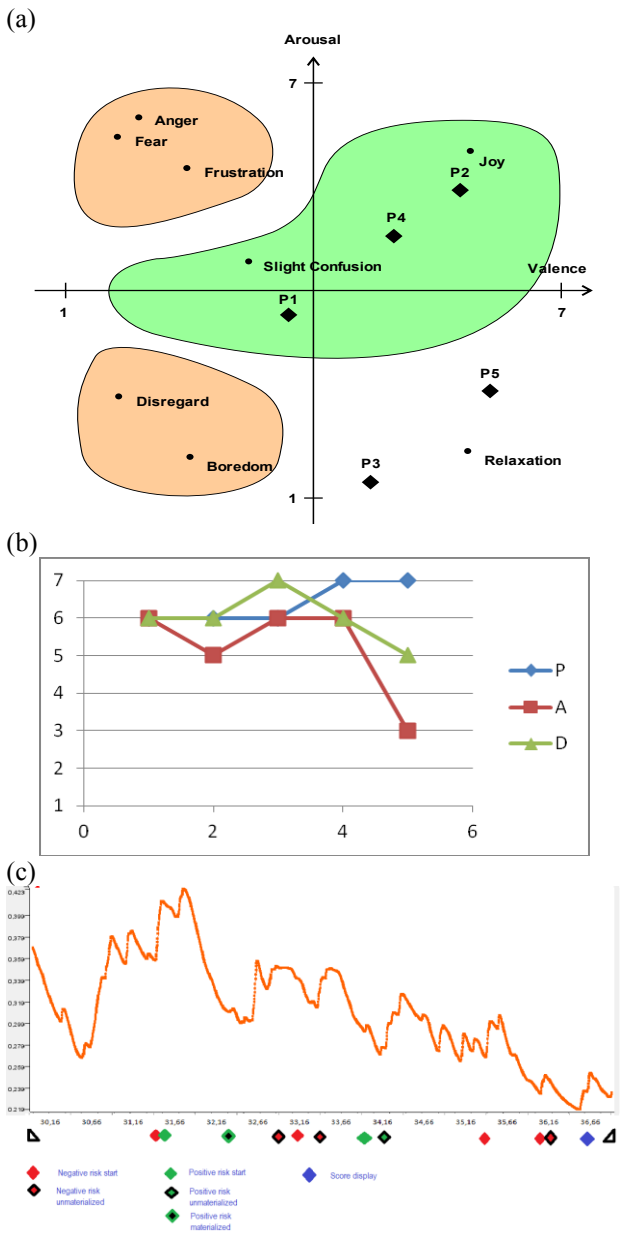

Fig. 1 Sample views from the UX emotion analysis report (a) view #1 (b) view #3 and (c) view #7

View #1 provided in Figure 1 (a) combines various information regarding emotional states. Firstly, it visualises desired and undesired emotional states using the valence-arousal model for emotion representation. The emotions listed by the game designers were clustered into three regions (the scope of the regions was a result of the preliminary mapping of emotional labels to the model and then discussion with the game designer). This preliminary clustering was used in a number of perspectives showing: reported emotional states versus desired/undesired (view #1), recognised emotional states versus desired/undesired (view #2) and one-player emotional state fluctuation from task to task (view #4).

The view provided in Figure 1(b) visualises the change in reported emotional state after consecutive game-plays. It uses the same scale as was used in the questionnaire (1 to 7).

The view provided in Figure 1(c) visualises the changes in the recognised level of arousal accompanied by event markers.

A detailed report on emotional states is not provided here; the views are provided in order to exemplify how the emotions were reported and to show the subject of the evaluation with the affect-awareness gain metrics.

V. Study results

The case study led to some qualitative and quantitative observations. First of all, most of the emotion recognition channels merge naturally with the software usability testing procedure — e.g. the video captured from the camera located near the screen as well as the filling-in of self-report questionnaires on affect. This section reports the results of the study and follows variables as defined in section III.D: applicability, interference and affect-awareness gain. The players participating in the study are coded P1 to P10.

A. Availability and noise susceptibility of the input channels

Applicability was represented with the metric (AP1) time available/time of study ratio and the metric (AP2) level of susceptibility to noise.

The results obtained for the AP1 metric are provided in Table I.

TABLE I.
METRICS OF AVAILABILITY OF THE INPUT CHANNELS

Participant	Self-report (AP1)	Video			Galvanic Skin Response (AP1)
		No of frames	Available frames	AP1	
P1	100%	56313	56313	100%	100%
P2	100%	67392	46323	69%	100%
P3	100%	97354	83601	86%	100%
P4	100%	69325	68512	99%	100%
P5	100%	90101	59275	66%	100%
P6	100%	*	*	*	100%
P7	100%	181135	76423	42%	50%**
P8	100%	56124	54753	98%	100%
P9	100%	70929	70747	99%	100%
P10	100%	69325	65451	94%	100%
Total	100%	na	na	77%	95%

* due to some disk error the video file was corrupted and unrecoverable

** one of the SC sensors detached during the recording session

The self-report on emotional state was merged with the usability study procedure and therefore all participants filled in all 5 questionnaires. Physiological signals were recorded and in one case (P7) only one of the sensors slipped off before the end of the recording. As sensor detachment is a random event, we might assume that such events might occur while hands are used in the human-computer interaction. Video availability varied among participants from 42% up to 100% and this is a result of individual movement patterns. Some participants were seated straight during most of the game-play time. Those with lower video channel availability displayed a number of behaviours that made facial expressions unavailable, e.g. moving sideways (outside the camera range), significant head movement, manipulating the hands in front of the face etc.

The susceptibility to noise (AP2) metrics are provided in table II.

TABLE II.
METRICS OF THE INPUT CHANNELS SUSCEPTIBILITY TO NOISE

Input channel	Proxy metric	Statistics		Susceptibility to noise (AP2)
		Avg	Min	
Video	Frame quality	0,87	0,70	23%
Skin conductance	Time between events causing artifacts [s]	7,79	1,81	80%
Self-report	Subjectivity	na	na	na

Video quality was relatively high and this factor might be improved by using a proper lighting rig as well as improvement in camera resolution. The channel, if available, is quite robust to noise.

One of the prerequisites in recording skin conductance is to restrict the movement of the particular body part that the sensor is attached to. As sensors for skin conductance are placed on the hands, a significant number of movement artefacts occur while using the keyboard and mouse in the UX evaluation procedure. If a keyboard and mouse must be used, the susceptibility to noise is quite high and the condition might be eliminated by moving the sensors to an off-hand location. Feet are mentioned as one of the possible SC locations, although the comfort of the participant might be compromised thereby.

B. Interference with UX procedure

After taking part in the UX evaluation procedure, each participant was asked about the subjective disturbance of the video observation. Camera presence was rated as 1 – non intrusive by 9 out of 10 participants, the other one rated the camera 2 on a 5-point disturbance scale, providing an average disturbance (IN1 metric) equal to 1.1.

We expected that using the camera and screen capture might cause the Hawthorne effect (people behave differently, while being observed), but we did not notice such symptoms.

Physiological measurements require the placement of sensors at the base of the fingers base and on the wrist. Sensor presence was rated as 1 (non -intrusive) by 5 out of 10 participants and 2 (slightly intrusive) by 5 of them Only one rated the sensors 3 on the scale of disturbance so, as a

result, the average disturbance of the sensors (IN2 metric) was equal to 1.6

The result indicates that both sensors and camera were non-invasive, on the whole, for the participants. Some of them even claimed, that they forgot that they were being recorded.

C. Affect-awareness gain

The first aspect of affect-awareness gain is the compatibility of the provided results with the desired/undesired emotions in terms of the affect representation model. The results from facial recognition according to the Noldus FaceReader might be obtained in the form of a 7-item vector of values within <0,1> range corresponding to: anger, joy, disgust, sadness, surprise, fear and neutral state. The results might be also exported to the valence-arousal model of emotions. Physiological signals mainly provide information on arousal and less on valence and therefore should be cautiously interpreted as a labeled emotional state.

The author's description of the game provided a list of desirable emotions: interest, slight confusion, joy and feeling of control and a list of undesirable emotional states: fear, strong confusion (frustration), anger, boredom and disregard. Some of them map directly into the models used by emotion recognition algorithms, and some others require a model of mapping. Table III shows how well the emotions map into diverse models for representation. We used the following scale: 0 – no representation in the chosen model; 1 – could be represented, but might be confused with other emotions; 2 – could be easily and unambiguously mapped; 3 – directly available in the representation model.

TABLE III.
DESIRED/UNDESIRED EMOTIONS AND THEIR MAPPING INTO EMOTION REPRESENTATION MODELS.

Emotion label	Model compatibility (AA1)			
	6 basic +neutral	Valence-Arousal	Arousal only	Valence-Arousal-Dominance
interest	0	1	0	1
slight confusion	2	2	1	2
joy	3	2	1	2
feeling of control	0	0	0	2
Fear	3	1	1	2
strong confusion (frustration)	2	1	1	2
anger	3	1	1	2
boredom	0	2	2	2
Disregard	2	1	1	2
Total	15	11	8	17

Out of the four specified desired emotional states, two are hard to map: interest as a more cognitive than affective state and the feeling of control, which is expressible only with the third dimension of the PAD model – dominance. Some of the desired states are directly available in Ekman's six basic emotions model that includes joy, fear, anger, disgust, surprise and sadness. However, boredom and feeling of control have no representation in this model. Therefore in this study we decided to use the PAD model of emotions. The affect self-report questionnaires were based on this model. For visualisation purpose only, we omitted dominance in some charts (view #1, #2 an #4).

If we use a PAD representation model, the dimensions must be obtained independently from the input channels. The video channel is able to provide valence and some estimation of the arousal, but not in terms of the dominance factor. Physiology-based emotion recognition contributes mainly to the arousal dimension. The only channel that provides the dominance is the self-report. This means that it is difficult to provide one value of emotion estimation reliability. Three independent metrics – one for each dimension should be provided instead.

During the study, we encountered huge discrepancies between the input channels — the self-report and the emotions recognised from the facial expressions were especially contradictory. Sample result showing the inconsistency is provided in figure 2. The figure presents the single-player all-task view #4. Consecutive game-plays were coded as G1 to G5. Diamonds shapes show the reported emotional states, while fuzzy circles depict the recognised ones. The middle of the circle is placed in an area close to the mean recognised state and the fuzziness corresponds to some fluctuations of the recognised emotional state around the average value.

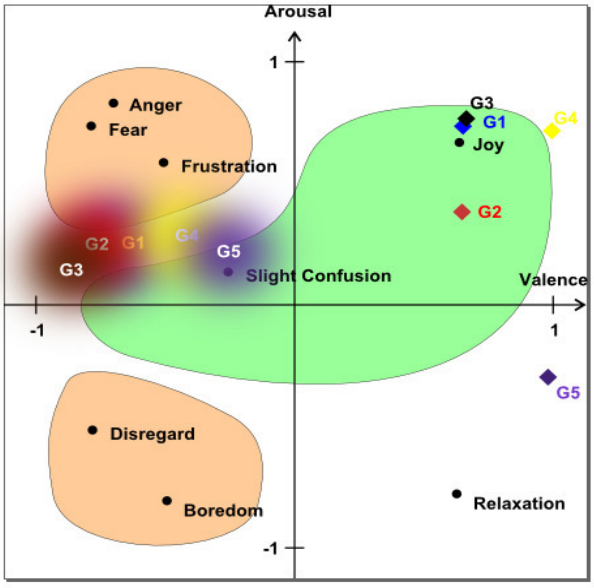

Fig. 2 Single player all-task view illustrating the inconsistency of reported and recognised emotional states

One might observe that the reported emotional states are mainly positive, with varying arousal. The recognised emotional states oscillated in the negative, high arousal quarter (but no extreme arousal levels were observed). The inconsistencies were observed for multiple users and game-plays and the systematic nature of this observation suggests some measurement or recognition error. The consistency of the multimodal observations (AA2) will not be evaluated quantitatively, as this goes far beyond the scope of this study. In trying to explain the reasons for the discrepancy, we watched some sample recordings. We did not notice signs of anger, which was recognised as a dominant emotion in the video. It seemed that perhaps the observable symptoms of concentration (lowered eyebrows) were mistakenly taken as signs of anger. One hypothesis is that the location of the camera above the screen was inappropriate. The inconsistency requires further research and we are planning more experiments to study it.

In this study we adapted to the inconsistency by reporting both recognised and reported emotional states in the UX emotional analysis reports.

The results of the players' affect elicitation and analysis were presented to the game designer (the second author of this study) and were evaluated. The results on the value they bring to the understanding of the user experience with the game (AA3 metric) are provided in table IV.

Some of the perspectives and views provide more information than others. Moreover, it seems that an application of the ABC approach provides more insight into user experience than usability, as was expected.

TABLE IV.
SUBJECTIVE MEASURE OF AFFECT-AWARENESS GAIN

Item type	Item name	Affect-awareness gain (AA3)
Perspective	All UX study participants	4
	Single participant between-task analysis	4
	Single participant single gameplay	2
View	View #1. Reported emotional states versus desired and undesired emotional states	5
	View #2: Recognized emotional states versus desired and undesired emotional states	3
	View #3. Declared emotional states after each gameplay	5
	View #4. Declared/recognized emotional states per gameplay	3
	View #5. Relative frequency of emotional states	2
	View #6. Fluctuation of valence	2
	View #7. Fluctuation of arousal	3
General	Usability understanding	2
	UX understanding	4

Apart from quantitative questions, the survey presented to the game designers included some open questions whereby multiple valuable observations and suggestions were provided:

(1) regarding perspectives: the single-player single-game-play perspective was considered as the least informative, as there were too few in-game events identified to make it interesting; a fourth perspective was proposed to report multiple player single game-play experience;

(2) regarding views: the emotions should be defined using the desired/undesired emotions as listed by the UX goals; some views should have a different scale; a new view should be added that indicates the fluctuation of emotions averaged among the users;

(3) regarding visualisation and reporting: legends and more detailed information should be provided to improve the understanding of the charts;

(4) regarding inconsistencies: the designer tends to believe in self-reporting rather than recognised emotional state, suggesting recognition error.

The most surprising comment was the question: "What is *neutral emotional state*?" This question raises the important issue concerning the proper understanding of the scales and models used for representing emotional states.

One of the expectations, which was not fulfilled in this report, was to provide a chart tagged with events, indicating that certain events caused anger and others caused joy, averaged among the participants. As emotional reactions are very individual, perhaps it would be easier to spot a single nervous system activation than to average the reaction to certain events among the users.

The most important information on affect-awareness gain is that despite the inconsistencies, reporting and visualisation imperfections, the designer claimed that he gained a valuable insight into user experience with the software (rated 4 on a scale from 1 to 5).

VI. SUMMARY OF RESULTS AND DISCUSSION

The main observations revealed through this case study might be summarised with the following statements:

1. It is possible to incorporate emotion elicitation techniques into UX procedures and it seems that emotion recognition has no negative impact on the usability evaluation;
2. Some input channels used in emotion recognition are hard to introduce (e.g. sentiment analysis from text), while others, especially video, self-reporting (and also keystroke dynamics) merge naturally into the UX context;
3. The accuracy of the emotion recognition techniques is compromised by: temporary unavailability of the input channels and susceptibility to noise;
4. Understanding the emotion representation models and mapping the desired and undesired affect to those

models is a preliminary step in providing valuable results.

The practical implications of this study on further applications of emotion elicitation in UX evaluation procedures include:

(1) The advisability to start with the definition of the desired and undesired emotional states and then to map them into one of the representation models for obtaining results.

(2) Selection of the emotion elicitation technique using a set of criteria: availability and susceptibility to noise, possible direct or indirect mapping of the desired/undesired emotional states to the algorithm's output.

(3) As all input channels are subject to temporal unavailability and noise, the challenge might be addressed using a multimodal approach;

(4) While using multiple observation channels, one must look for inconsistencies and the reasons behind them; in the case of discrepancies, perhaps manual tagging by a qualified psychologist might be considered.

(5) Present the results in the form of simple, standard views and provide detailed explanations (assume there is no obvious term regarding emotions).

The results obtained in this study might have some implications for the research on emotion recognition solutions and their integration. The following list of challenges have been identified during this study:

(1) The integration requires a common affect representation model or some mapping between the models. It is quite difficult to integrate and compare results based on labels — a discrete or continuous model might be considered instead.

(2) Emotion recognition algorithms still require improving accuracies and special attention should be given to wild-like conditions, in accordance with current trends in research.

(3) The temporary unavailability of the input channels might be bypassed if the algorithms provide some estimate of the quality of the result (although currently no algorithm does).

We are aware of the fact that the validity of this study has some limitations. We identified and addressed the following threats to its validity: (1) sample size – we engaged 10 users as the usability tests show that 5-10 users reveal 75-90% of the usability issues; (2) sample as a group of convenience – we selected the sample for the UX evaluation to ensure its diversity; (3) confounding variables – we performed the study in a strictly controlled environment, where we limited the possible influences of external factors; (4) subjective measurements – we operationalised most of the variables to objective metrics, the number of subjective self-reports is minimal; (5) observations are based on one case study only – more are planned in the future.

In the future research we would shift to a quantitative approach with results based on a couple of experiments/case studies of UX evaluation procedures based on the ABC framework.

VII. Conclusions

The study revealed three types of challenges: technical, organisational, and related to the cost/value ratio.

Technical challenges (e.g. the accuracy and disturbance robustness of emotion recognition algorithms) might be solved with the future evolution of the affective computing domain, as nowadays emotion recognition in-the-wild conditions is receiving more and more attention. Organisational issues might be eliminated with more experience and trying out different approaches (e.g. multiplying cameras, re-locating sensors). The main challenge remains to provide a reasonable cost/value ratio. Typical usability tests involve 5 to 10 participants, as this number allows 75-90% of usability issues to be revealed. The analysis of emotional states, even when employing automatic affect recognition, is labor-intensive. Multiplying input channels results in higher accuracies, but also introduces the challenge of integration, especially when the observations are contradictory.

Acknowledgment

Authors thank Dominika Makowiecka, who helped in the experiment setting and execution as well as colleagues from the Emotions in HCI Research Group at GUT (emorg.eu), who provided valuable comments on this study.

***Abstract*—This paper describes the modern Immersive 3D Visualization Lab (I3DVL) established at the Faculty of Electronics, Telecommunications and Informatics of the Gdańsk University of Technology (GUT) and its potential to prepare virtual tours and architectural visualizations on the example of the application allowing a virtual walk through the Coal Market in Gdańsk. The paper presents devices of this laboratory (CAVE, walk simulator etc.), describes methods of "immersing" a human in a virtual environment (city, building etc.) and discusses future possibilities for development (directions of research and limitations of today's hardware and software).**

I. Introduction

VIRTUAL reality (VR) is over 50 year old, now. The first devices like *virtual reality video arcade Sensorama Simulator* or *stereoscopic-television apparatus for individual use* (HMD Head-Mounted Display) were invented in the 1960s [1]. Initially, applications of VR devices were very restricted due to their high price and technological limitations, but now, fifty years later, such devices become very popular on the customer market (e.g. *Oculus Rift*, *HTC Vive*). Their relatively low price, acceptable reliability and passable level of immersion (despite screen-door effect) allow us to use them commonly for video games and other kinds of virtual reality experience.

The virtual reality CAVE is much younger than the HMD. The first *Cave Automatic Virtual Environment* (CAVE) came into being in the early nineties at the University of Illinois [1, 2]. Generally, the CAVE may be defined as a cuboidal chamber that has stereoscopic projection screens instead of the walls, the floor, and sometimes the ceiling. A human visitor, wearing only lightweight 3D glasses, is surrounded by a 3D virtual scene projected by projectors placed outside the CAVE. The three-dimensional impression is intensified by additional adjustment of the images forming the scene to the location of a human head. Visual effects are often supported by a 3D surround audio system. Therefore, the level of immersion is very high for CAVEs.

Dozens of CAVEs have been constructed within the last twenty five years [3, 5]. Some of them are rather simple and consist of only four screens, usually three walls and a floor (e.g. the first CAVE in Poland [6]). Other CAVEs are more sophisticated and contain more screens [12]. Four walls indicate that one of them has to be a gate. The complete six-faced cuboidal CAVEs with four walls, a floor and a ceiling are rather rare.

This work was supported in part by DS Funds of the Faculty of ETI of the Gdańsk University of Technology.

II. Immersive 3D Visualization Lab

The Immersive 3D Visualization Lab [7, 8, 9, 10] contains complete six-faced cubical CAVE made of thick square acrylic plates (Fig. 1). A spectator can see a 3D scene on each CAVE's face using a 120 Hz stereoscopy system in passive mode (spectrum channels separation by selective interference filters) or active one (separation in time with active shutter glasses [10]). The viewer's glasses have special markers that are tracked by four infrared cameras placed in the upper corners of the CAVE. Eight speakers located in the same corners and a subwoofer standing outside the CAVE provide surround audio system.

Fig. 1 The CAVE in the I3DVL (the gate of the CAVE is open)

Simulation participants may walk freely in the CAVE from wall to wall, as in any typical CAVE. However, unlimited virtual wandering is also possible using a handheld controller, called wand or fly-stick. Unlike other common solutions, the CAVE in the I3DVL can use a spherical walk simulator as an additional movement controller (Fig. 2). The spherical walk simulator [4, 11, 13] has a form of an openwork sphere, that freely rotates on rollers with a small friction. One can treat it like a human size omnidirectional "hamster wheel". A user may walk

inside the sphere watching, through its rotating surface, the images on the CAVE screens that change according to the direction and speed of the sphere revolutions. This solution allows the user to march on foot through the virtual world projected on the CAVE screens without any space limitations. There are no other CAVEs in the world with such possibility.

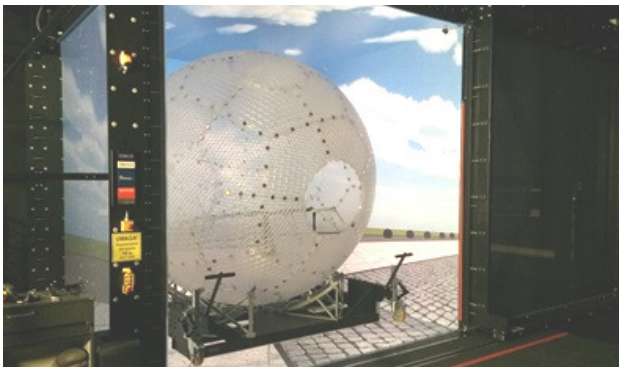

Fig. 2 The spherical walk simulator inside the CAVE in the I3DVL (the gate of the CAVE is open)

The CAVE in the I3DVL can be used with the spherical walk simulator, but both devices can also work separately: the CAVE in the typical configuration with a handheld controller and the spherical walk simulator with the HMD. The specially designed and constructed transport trolley allows to roll the spherical walk simulator in and out (Fig. 2) without a risk of collision with the CAVE's screens. The diameter of the spherical walk simulator is 3.05 m, and the edge of the cubical CAVE is 3.4 m long. Hence, there is only about 17 cm between the surface of the 250 kg sphere and the wall of the CAVE from each side.

Every wall-screen obtains two images from two WUXGA (1920 × 1200) projectors. The final image, combined by blending, has a resolution 1920 × 1920. Thus, all six screens require twelve projectors driven by dozen computers. Two additional computers control virtual scene dynamics, real object tracking, sound generation, and video surveillance.

III. Software Platforms

The Immersive 3D Visualization Lab can work in various software environments that support multicomputer (cluster) process synchronization. Each computer can operate under control of Windows or Linux operating systems, and VR programmers may use both of them. At present, the most popular software platform in the I3DVL is Unity – the environment dedicated to video game developers. Low-level graphics programming in C++/C# and OpenGL or Direct X is also used, particularly for experiments with global illumination rendering methods like raytracing and radiosity. Use of other tools for game development (e.g. Unreal Engine) or virtual reality applications (e.g. Bohemia VBS3, Presagis Vega Prime) is possible, too.

The computational power of I3DVL computers might not be sufficient for some complex tasks, such as sophisticated rendering, nontrivial physics calculations, advanced artificial intelligence or prediction of user behavior. In such cases, in order to provide efficient real-time processing, the power of high performance cluster Tryton from the Academic Computer Center in Gdańsk (CI TASK), connected via the fast optical fiber InfiniBand, can be used [14]. This connection allows treating the computers of the I3DVL and the nodes of the cluster Tryton as one uniform cluster.

IV. The Coal Market virtual sightseeing

The Coal Market is one of the historical squares of Gdańsk with many landmarked buildings, e.g. the Great Armoury (Fig. 3), the Straw Tower, the Court of the Brothership of St. George (Fig. 4), the Torture House, the Prison Tower, the Golden Gate (Fig. 4), the Upland Gate, and several cultural institutions. Regrettably, the contemporary buildings at the Coal Market's western frontage contrast with the historic and cultural character of the Market. Therefore, the City Council of Gdańsk announced a competition for new urban-architectural concepts of this square. Over 10 teams from Faculty of Architecture at GUT took part in this contest and, finally, three architectural projects were awarded (Fig. 5-7).

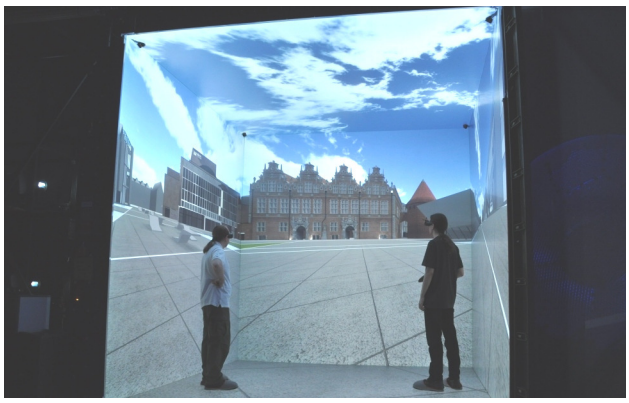

Fig. 3 The virtual Great Armoury

Fig. 4 The Court of the Brothership of St. George and the Golden Gate

This contest provided a good opportunity to propose a new approach to visualize the awarded projects not only as a limited set of static architectonic sketches but as dynamic, interactive real time visualization in the CAVE environment. Spectators, e.g. architects or council members, could observe the modeled urban area from practically any

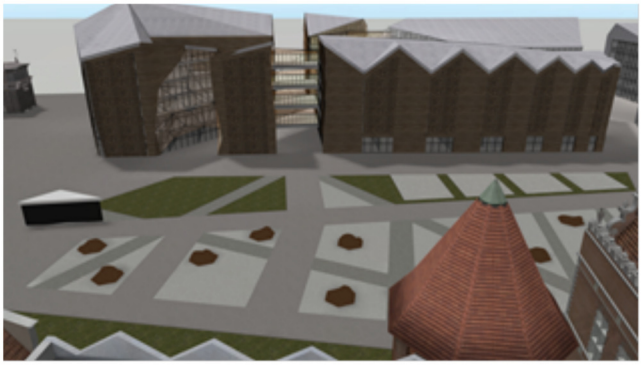

Fig. 7 Visualization of the western frontage of the Coal Market (project by Ł. Plata *et al.*)

viewpoint, and freely walk along virtual houses and buildings with true 360° 3D surrounding view.

Thus, the goal of the project described in this paper was to fully model the Coal Market urban area with three different variants of its western frontage buildings. Additionally, the requirements specification assumed automatic and free walk functionality, and capability of switching between several predefined viewpoints and frontage versions.

Although all models from competition were available in electronic form, two severe reasons prevented their direct usage in the CAVE visualization. Firstly, all adjacent buildings were modelled as single, large 3D objects. While such approach may be used for not real-time architectural visualizations, it prohibits the use of any optimization algorithms in modern 3D graphics engines, such as Level of Detail (LOD) techniques, occlusion culling, and other. Secondly, visualization of all unchanged historical buildings was based on very simplified low-poly models with no textures nor normal vectors but with some geometric errors instead. Although these imperfections were hardly noticeable in static architectural visualization, where these buildings provided the background for contest models, they were unacceptable for interactive CAVE visualization, where all buildings at the Coal Market were equally important.

For these reasons the project's decision was made to model all the Coal Market's buildings from scratch as separate 3D objects. Such models should have significantly reduced complexity while still preserving visualization quality. According to these assumptions, two architect students created new 3D models both for three contest propositions, as well as for ten buildings located in other untouched frontages of the square.

Based on provided models three 3D scenes of the Coal Market were designed in Unity environment with three different variants of the square's western frontage (Fig. 5-7). Unfortunately, the models prepared by the architect students were too detailed, with hundreds of thousands of vertices, even for not significant architectonic details, such as ornate wrought-iron gate's lattice (Fig. 8), dome-like roof details or roof sculptures. Initially, the whole scene consisted of over 5 million vertices, which occurred too complex for real-time visualization, resulting in low refresh ratio lower than 10 fps. Thus, most models had to be simplified by dramatic reduction of the number of their vertices with minimal loss of quality. This reduction was performed by an IT student with 3D modelling skills. Sample effects of performed complexity reduction are presented in Fig. 8. The original 3D model of wrought-iron lattice (a) consisted of nearly 670 thousand vertices and 1.2 million triangles, while the simplified one (b) is built from only 25 vertices and one partially-transparent mid-resolution texture. Original high complexity of the model (c) is not visible during standard CAVE visualization (d).

Finally, the scene complexity were reduced by a factor of 10 resulting in about 500 000 vertices in total. This reduction, accompanied by well-known optimization techniques such as LOD, occlusion culling and light mapping, allowed for effective real-time scene visualization in CAVE environment at refresh rate of about 120 fps.

Additional feedback from architects pointed the way of visualization's improvement by adding simplified building models that would surround the modelled Coal Market and provide some visual background both for a bird's-eye view of the square as well as for wandering around its neighborhood. Such buildings were added based on the simplified building models consisted of only 10 vertices each, which did not increase the overall scene complexity in practice. The results are presented in Fig. 9 where additional buildings are visible in the background.

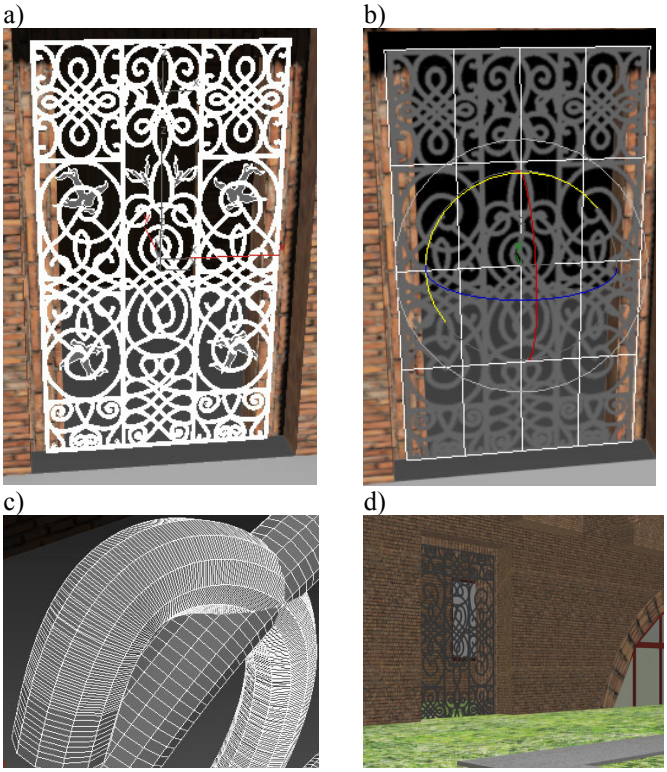

Fig. 8 Sample model of wrought-iron gate's lattice: a) highly detailed original (white color is used for vertices and edges), b) simplified flat model, c) magnified detail of the original model, d) final appearance in 3D visualization

V. VIRTUAL SIGHTSEEING

Visualization of the Coal Market became the first application demonstrating I3DVL capabilities. It was presented to many visitors who confirmed high usability of the CAVE environment in the field of architectural visualizations. Possibility of almost free interaction within a 3D scene and high immersion level, which is guaranteed by the surrounding view, allow for better scene perception. For example, most interaction participants enjoyed the possibility of visiting every nook and cranny of the buildings and courtyards. This possibility of visual testing of all inner passages and communication courses occurred as vital as the general view of building frontage.

Also, the possibility of immediate switching between different scene versions makes their comparison easier than at traditional exhibition as it gives the same visual context. Additional application feature allows for real-time switching between daylight and night scenes (Fig. 10, 11), and thereby the visitors can verify how the place would look like by night with artificial illumination. Yet another kind of experience is the possibility of bird's eye view from highly located viewpoints (Fig. 5-7,9) which is especially realistic inside the CAVE.

A wide multitude of presentations for different peoples have allowed for many interesting observations. For example, some visitors have serious problems with movement control in the CAVE. For such persons the automatic walk mode occurred a real salvation, allowing for simple looking around while being moved forward along the predefined path as inside a sightseeing trolleys or bus. It was also confirmed that some people do have some problems with 3D image perception using 3D glasses. Fortunately, most of them reported that the problem is far less than with the HMDs such as Oculus Rift. This surely results from much higher image quality as well as from better user orientation inside the CAVE. Moreover, a man inside the CAVE can see his own body and other participants of the simulation. The depth of immersion in the CAVE over the HMD seems to be unquestionable, but conclusive proving this general thesis requires further research comparing the reactions of people using different VR devices and various scenarios by means of questionnaires, behavioral observation and biological measurements (as heart rate, blood pressure and electrical activity of the brain).

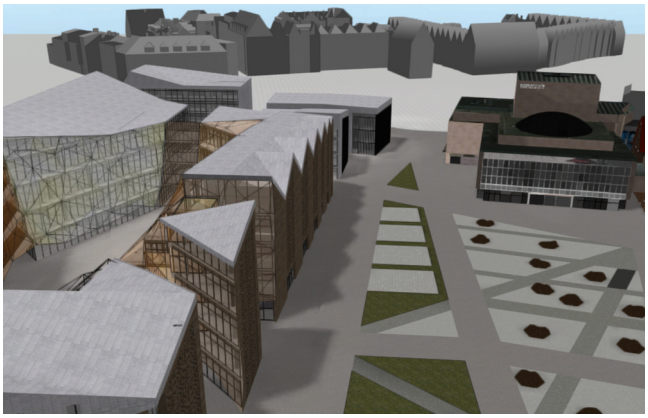

Fig. 9 The bird's-eye view of the virtual Coal Market with simplified buildings in the background

The project realization allows also for gathering invaluable experience and clues for further application development for I3DVL's CAVE environment. For example, many inbuilt Unity mechanisms, such as scene switching or interface elements, had to be redesigned due to the client-server architecture of the CAVE and the need of the network synchronization between I3DVL's computers. Moreover, such a presentation of 3D image requires higher rendering rate than for a PC demonstration.

Fig. 11 A night scene of the Coal Market with crowd simulation

VI. Conclusion and Future work

Virtual sightseeing can be useful not only for virtual tourism, but also for virtual prototyping, allowing assessment of designed objects, like urban areas, squares, streets, buildings with their interiors, and even crafts, vehicles, machines etc. Believable visualization can help in decision-making without the use of spatial imagination. Just take a stroll through the virtual scene and decide.

Future works are focused on using of additional computational power, provided by the high performance Tryton cluster at CI TASK, to expand the Coal Market scene with crowd, snow and rain simulations. The first experiments with developed scalable particle system for cluster-aided visualization proved successful in weather phenomena and crowd simulation (Fig. 10, 11), though many problems of latency-critical processing have to be solved, yet.

Acknowledgment

Authors would like to thank Małgorzata Chrzanowska and Łukasz Plata for preparing 3D architectural models, and Adrianna Szwoch for 3D scene modelling and scripting.

Abstract— **User experience (UX) has been defined in several ways. In general terms, it refers to everything that is individually encountered, perceived, or lived through. The literature on UX reports studies mostly focused on specific interaction events, which may have an impact on the user's emotions and feelings. This paper provides a reflection on how UX evolves over time. We performed a medium term study comparing four types of UX: Anticipated, Momentary, Episodic and Remembered (or Cumulative) experience [1]. Anticipated UX refers to the period of time before first use, and focuses on the expectations a person has on the product, service or system. Momentary UX refers to any perceived change during the interaction in the very moment it occurs. Episodic UX is an appraisal of a specific usage episode extrapolated from a wider interaction event. Remembered UX is the memory the user has after having used the system for a while. The different facets of UX have been analysed in a medium term research spanning over four weeks. The study compared the experience of ten users of a pedometer/fitness app that counts steps and burned calories all day long. The results show that the experience of use changed over time decreasing significantly before, during and after the interaction. The evaluative judgment related to the overall satisfaction with the product, was largely formed on the basis of an initial high expectation on pragmatic aspects (i.e. utility and usability) before and during the first encounters. After four weeks of use, the problems related to usability, reliability of data, and battery drain became a dominant aspect of how good the product was perceived. Hedonic qualities and Attractiveness were negatively impacted as well. The continuous reflection on the use, documented in online diaries, made the problematic aspects prevailing on the overall UX in particular on the evaluation of Episodic and Remembered UX. This prevented any change in behaviour in the participants.**

I. Introduction

Roto et al. [1] edited the "User Experience White Paper", a document reporting the results from Dagstuhl Seminar on Demarcating User Experience, held in September 2010, where 30 experts from academia and industry worked together to define the concept of UX. In this document the editors highlight the multidisciplinary nature of UX, which has led to several definitions of and perspectives on UX. Interestingly they underline the importance of analysing time spans of user experience, stating that the actual experience of usage does not cover all relevant aspect of UX. Time spans matter in determining the UX. People have expectations on a certain product or system before the first encounter. Expectations are often generated by advertisements or others' opinions and have impact on the way people approach the system and prepare to use it.

At the first encounter and during the actual use people may change their appraisal of the system. Pragmatic and hedonic qualities of the product play a fundamental role in determining visceral responses related to momentary feeling perceived during usage [2]. Different episodes of momentary experiences lead to a reflection on the experience itself. Reflection often determines a person's overall impression of a product and many factors come into play when thinking back and reflecting upon the total appeal and experience of use. The outcome of episodic experience is not necessarily equal in value to the sum of momentary experiences. Over time the perception of usage might change again. In remembering the overall experience, people select only few elements, positive or negative, which will determine the general opinion of the product and the chance that it will be recommended to others for later use Fig. 1.

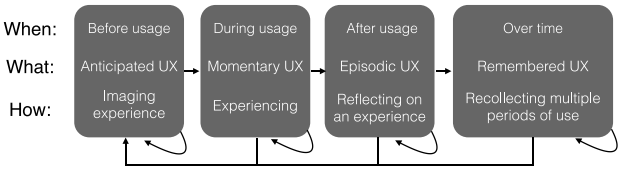

Fig. 1 Time spans of user experience adapted from Roto et al. 2011

Barbara Fredrickson and Daniel Kahneman [3] proposed the model of remembered utility, which dictates that an event is not judged by the entireness of an experience, but by prototypical moments or "snapshots" that are considered representative of an event under uncertainty. The remembered value of snapshots determines the actual value of the entire experience. Fredrickson and Kahneman [3] explained such phenomenon saying that the selected snapshots correspond to the average of the most affectively intense moments of an experience and are related to the resulting feeling experienced in the end. So the duration of the experience does not affect the final

judgment (“duration neglect” effect) while the most intense moments experienced in the end do.

Kahneman [4] studied the differences in perception between the actual and remembered experience through a series of experiments. In 1996, Redelmeier and Kahneman [5] assessed patients' appraisals of a painful colonoscopy procedure. They found that patients evaluated the discomfort of the experience in relation to the intensity of pain occurring in the end of the procedure (peak-end rule). So a peak painful short event occurring in the end is remembered as more negative than a prolonged painful episode occurring in the beginning or the middle of the experience. Length or variation in intensity of pain does not matter.

II. State of the Art

In the field of Experience Design the evaluation of the experience of prolonged use of interactive products is becoming a critical issue. Until few years ago, UX studies have mostly focused on short-term evaluations and the aspects relating to the initial adoption of new product design.

Only recently, an increasing number of studies have started focusing on assessing the changes in a person’s experience in interaction with a product over time [6], [7], [8].

Consequently new methods and models have been defined to understand how the relationship between the user and the product evolves over long periods of time.

Karapanos et al. [9] developed “UX Curve”, a method which aims at assisting users in retrospectively reporting how and why their experience with a product has changed over time.

Mahlke and Thüring [10] developed a model which defines three components of user experience: perception of instrumental qualities (usability and usefulness), emotional reactions and perception of non-instrumental qualities (appeal and attractiveness). Applying this model, they provided evidence that instrumental and non-instrumental qualities influence emotional reactions in the use of interactive systems.

However, the majority of current UX evaluation methods still concentrate on single behavioural episodes and momentary evaluations. Vermeeren et al. [11] report that only 36% of methods focus on long-term period of experience.

Whilst measuring first encounters and momentary experiences is important for collecting feedback from users in particular in the early prototyping phases of the development process [11], recent researches demonstrated that different user experience aspects changes over time [12], [9].

Marti and Iacono [13] compared the experience of use of two tablet applications for zooming in and out while taking photos. They confronted two interaction modalities in the short and medium term: the classic “Slide to zoom” and the novel “Squeeze to zoom”, a squeezable interface. Results obtained in the short-term evaluation revealed that “Squeeze to zoom” was awarded higher values than the “Slide to zoom” in the hedonic quality-stimulation and attractiveness dimensions, whilst it obtained lower values in the pragmatic quality and hedonic quality-identity. However, in the longitudinal study, the usability of “Squeeze to zoom” improved whilst the attractiveness of “Slide to zoom” decreases significantly. Furthermore “Squeeze to zoom” was significantly more appreciated for its hedonic qualities and the effect was maintained over time.

Karapanos et al. [9] evaluated the experience of use of six participants for 1 month after the purchase of an Apple iPhone. They found that the relevance of novelty quickly faded away, while over time different the hedonic quality of the iPhone emerged.

Fenko et al. [12] found also that the perception of importance of sensory modalities changes over time. At the moment of purchasing a mobile phone, they found that vision was the most important perceived modality. After 1 month touch and audition became more important than vision.

In the following we report the result of a medium term study assessing the experience of use of a fitness application for mobile phone, conducted with ten participants.

The study compares four types of experiences as defined by Roto et al. [1]: anticipated experience, momentary experience, episodic experience and remembered experience. Anticipated UX refers to the expectations a person has before the first encounter with the product. Momentary UX refers to individual interaction episodes and the perceived change in use. Episodic UX refers to a usage episode extrapolated from a wider interaction event. Remembered UX refers to the memory of the user after having used the system for a while.

III. Experimental Protocol

The study was conducted in Siena, Italy. Participants were asked to try out over four weeks, Pacer, a fitness application running on smartphone.

Pacer is a free app developed by Pacer Health, Inc. [14] running on Android and iOS platform Fig. 2.

Fig. 2 Pacer interface

It allows to track the steps, whether the phone is in the hand, pocket, in a belt or bag. Pacer records steps, distance, active time and calories burned all day, every day, and gives reminders to keep the person going. It allows to set health goals (e.g. to set the ideal weight) and to stay on target. Pre-defined programs like "from walking to slow ride" are also available. Through a GPS the app allows to track the walking, running or bicycling routes on a map. The ultimate goal is to bring together people based on common health goals and interests with the objective to improve health behaviour change outcomes. Users can create groups, connect with friends via Facebook, motivate each other in physical activities, achieve and compare performances, and ultimately create competitions.

B) Methodology

Ten subjects (M = 5 and F = 5) with an average age of 25.90 were involved in the study for a period of four weeks on a voluntary basis. Five participants were students of the MA course in Experience Design (University of Siena). Five participants were invited to join the study among their groups of friends.

As said above the study aimed to analyse any change among the anticipated, momentary, episodic and remembered experience of use over a month.

The study was conducted using different methods of data collection: an ad-hoc questionnaire to appraise the anticipated and remembered experience, an online-shared diary to assess the momentary experience, and AttrakDiff [15] to assess the episodic and remembered experience Fig. 3.

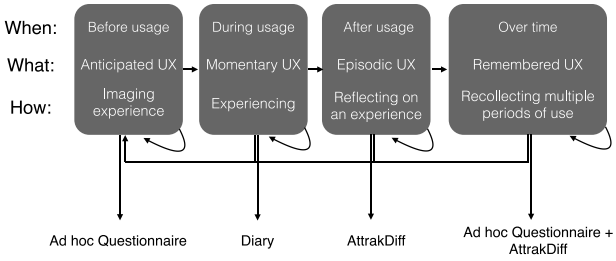

Fig. 3 Overview of the methods used to assess the four types of UX

More in detail the anticipated experience was assessed using an ad-hoc questionnaire focused on the main functionality of Pacer: Step counter, Burned calories, Community, Reminders/Notifications, Settings and use of GPS.

A 5-point Likert scale with values from -2 to 2 was associated to each of the abovementioned functionality. The values were represented in the form of emoticons (-2 = very negative, -1 = negative, 0 = neutral, 1 = positive, 2 = very positive). To evaluate the anticipated experience, the questionnaire was administered at baseline before the app was installed on the participants' smartphones. None of the participants had ever used Pacer. At the beginning of the study all of them received a brief description of the six assessed functionality.

The momentary experience was evaluated using self-reporting. A closed group on Facebook was created to keep a shared diary. All participants joint the group.

The subjects were asked to take note of their experience on the everyday use of the application. The aim of keeping a diary was to express in a narrative form the impressions resulting from the use of the app in the very moment they were experienced by the subject (Momentary UX). The diary entries could be expressed in a free format, using text or images (e. g. screenshots of the app). However, participants were asked to associate an emoticon to each diary entry, the same used to assess the anticipated and remembered experience (-2 = very negative, -1 = negative, 0 = neutral, 1 = positive, 2 = very positive).

The episodic experience was evaluated using AttrakDiff, a questionnaire administered 5 times over a period of four weeks: T_0 = first encounter, T_1 = after 1 week, T_2 = after 2 weeks, T_3 = after 3 weeks, T_4 = after 4 weeks at the end of the study.

AttrakDiff, is a method developed by [15] to assess the user's experience and feelings in relation to interactive products and therefore a product's overall attractiveness. The questionnaire uses the technique of the semantic differential on pairs of opposite adjectives to evaluate the user experience. Users are asked to assess their experience and their perception of the product, responding to

pairs of opposite adjectives. The adjectives are assessed on a seven-point Likert scale, from -3 to 3, in which 0 indicates neutrality. The questionnaire was developed in German and then translated into many languages including English. It consisted of 28 items, broken down into four dimensions:

- *Pragmatic quality or PQ*: describes a product's usability. Indicates how the user can successfully achieve his or her goals using the product. A product need not be particularly beautiful or well-designed to satisfy this quality.
- *Hedonic quality – Identity or HQ-I*: indicates to what extent the product allows the user to identify with it in a certain social context. It relates to what we communicate socially when we use a product. Identification with a brand, for example a certain type of mobile phone, defines our inclinations and preferences of use of that product. Some products are preferred by certain categories of users because they are seen as cool, and not necessarily for the features they offer.
- *Hedonic quality – Stimulation or HQ-S*: indicates to what extent the product can support users' needs in terms of novelty, content, stimulating interaction, presentation of style. It is defined by attributes that encourage users to improve their skills of use of the product. Examples of hedonic stimulation are those features of software applications that are usually little used, and the shortcuts for some commands. Some products offer the user flexibility of use, and the person feels gratified to learn or to find alternative or more effective and efficient modes of use of the product.
- *Attractiveness or ATT:* describes the product's overall value on the basis of perceived quality.

Hedonic and pragmatic qualities are independent of one another, but together contribute to determining attractiveness.

For the present study we used an Italian version of the questionnaire translated by the authors. The same version was used in a previous study [16].

The questionnaire contained 28 items broken down as follows:

Pragmatic quality: *Technical- Human; Complicated-Simple; Impractical- Practical; Cumbersome- Straightforward; Unpredictable- Predictable; Confusing - Clearly structured; Unruly- Manageable*.

Hedonic-identity quality: *Isolating- Connective; Unprofessional- Professional; Tacky-Stylish; Cheap-Premium; Alienating-Integrating; Separates me- Bring me closer; Unpresentable-Presentable.*

Hedonic-stimulation quality: *Conventional-Inventive; Unimaginative-Creative; Cautious-Bold; Conservative-Innovative; Dull-Captivating; Undemanding-Challenging; Ordinary-Novel*.

Attractiveness: *Unpleasant–Pleasant; Ugly-Attractive; Disagreeable-Likeable; Rejecting-Inviting; Bad-Good; Repelling-Appealing; Discouraging –Motivating.*

The remembered experience was assessed in two different ways: 1) using the same ad hoc questionnaire used to evaluated the anticipated experience, in order to compare what was expected with what was remembered; 2) conducting a paired-samples t-test to compare the four UX dimensions of AttrackDiff at time T_0 (first encounter) and T_4 (end of the study).

IV. Results

A) Anticipated and Remembered UX (ad hoc questionnaires)

The data collected on the anticipated UX are reported in Fig. 4.

The 10 participants had a high expectation on the use of the functionality Step counter, Community, Settings and GPS. They did not expect to have a similar positive experience associated to the functionality Calories and Notifications.

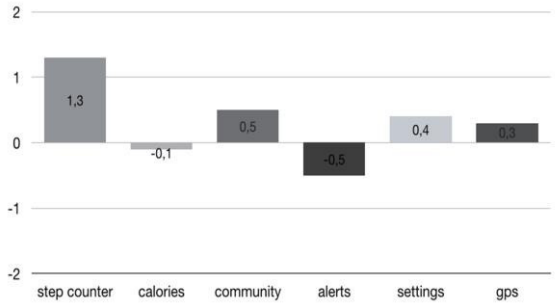

Fig. 4 Mean value of the Questionnaire on Anticipated UX

The data related to the remembered UX after 4 weeks are reported in Fig. 5.

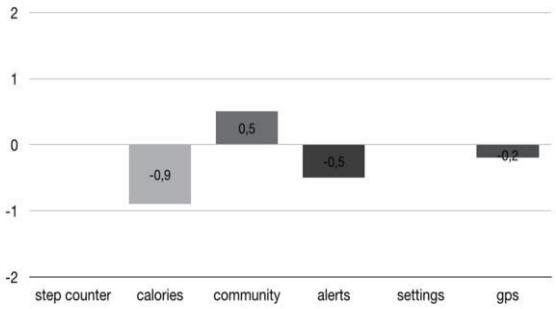

Fig. 5 Mean value of the Questionnaire on Remembered UX

Apparently participants had negative memories on the use of the app. After four weeks all functionality were rated between 0 and -1, except for Community, which maintained the same evaluation of the Anticipated UX.

B) Momentary UX

The 10 participants kept the diaries regularly recording events as soon as they occurred. In total, the corpus of 10 diaries contained 59 entries of which 29 comments were negative, 6 were neutral and 24 were positive. The negative comments were mostly related to poor usability of the app and to an improper way of functioning, which did not comply with the user expectations. These outcomes are consistent with the data collected through the questionnaire on the Anticipated UX.

After the first week of use, a 22-year-old boy wrote the following comment "*The app drains the battery. Therefore if you value more saving battery rather than being sporty and burning calories, you have to start and stop it continuously...*".

A similar comment was entered by a 25-year-old girl "*I receive continuous alerts on the battery draining. This is annoying. I'll try to find a way to stop this. ☹*". (Fig. 6).

Fig. 6 This app could drain the battery.

Another negative comment on the usability was reported by a 33-year-old girl who wrote "*not very positive ... I would say daunting: I tried a challenge but I failed and the app did not tell me why*". A 26-year-old boy wrote: "*After one hour walking the app marks only 223 steps. It is unreliable. I would like to uninstall it*".

After two weeks of use, a 25-year-old boy wrote "*I received a notification asking me if I would recommend the app to a friend, based on my experience of use. I discovered also the possibility to send feedback to developers. Honestly I would not recommend this version to a friend, and I'm tempted to send a full list of negative remarks to the developer"* (Fig. 7).

Fig. 7 "Based on your experience with this version of Pacer, would you recommend it to a friend? Certainly yes, probably, maybe or maybe not, probably no, definitely no."

A 23-year-old girl commented the following: "*I have received this notification for the third time today ... I find it annoying especially if you have been walking the whole day. It pops up when having meal or when sitting for more than an hour ☹. I wish to turn the notifications off*" (Fig. 8)

Fig. 8 "You've been sitting for more than an hour, start moving!"

A 25-year-old girl manifested her disappointment: "*Yesterday afternoon I did jogging and tried the program "from walking to jog". I started the application and discovered that the program required a Premium subscription. ☹ I downloaded another free app that offers the same service for free*".

Some comments explicitly referred to the hedonic-stimulation quality. A 33-year-old girl wrote "*After the initial excitement, after four weeks I find it not really useful. I have not been very active in the past days and Pacer does not motivate me in doing more ☹"*

The most positive comments relate to the Community, that is the possibility to connect to others and share the performance and the achievement of common goals. A 22-year-old boy wrote "*I've just beaten my record of 15.000 steps today!" ☺. This is the notification from Pacer!!!* (Fig. 9).

Fig. 9 Goal achievement

A 33-year-old girl wrote: "*My friend invited me to join her network ... it is nice, I can send her messages and see how many steps she does during the day ☺... I didn't think this functionality would be so engaging for me*".

A 30-year-old boy wrote "*I can see the percentage of people who walk less than me ☺... It is an interesting information since it relates to all people using the app and not only my friends (the numbers wouldn't have been meaningful)*". A 23-year-old girl reported: "*As soon as I woke up this morning, I received a notification of yesterday activity. I discovered I walked more than 32% of users…it is a small but meaningful achievement for me… very positive ☺*" (Fig. 10).

Fig. 10 Goal achievement

After the first week of use, a 25-year-old boy wrote "*I discovered a fantastic functionality!!! I set the program "Sleep eight hours a day and exercise the abdominal muscles". Just after, a weekly calendar appeared on the screen associated to a chat where it was possible to share in real time comments of all users who set the same goal. ☺ An entire world of opportunity disclosed to me*".

To summarise, the negative diary entries were mostly related to low usability of the app, to an untimely use of notifications, and a scarce accuracy of data (e.g. the burned calories or steps). Some participants confronted the data obtained with Pacer with the ones provided by other step counters, realising that Pacer was not reliable. The app was not really motivating for participants and the majority of them uninstalled it at the end of the study. Furthermore, Pacer does not seem to meet the requirements of runners. It displays the pace stat as the overall pace for the whole run, rather than a lap-by-lap breakdown of the pace, which is what the typical runner's app shows. Runners want to know whether the first mile was as fast as the third, for example, and Pacer doesn't tell this.

The positive comments were mainly associated to the Community, Social sharing and Security aspects. In fact, to use the product, it is not necessary to create an account and provide the email address and personal data. For those who are concerned about security, that is a plus.

Overall Pacer did not offer much to explore beyond the basics and this caused a drop of interest after four weeks. The diary entries followed a negative trend over four weeks. Negative comments increased at T_3 and T_4.

C) Episodic UX

As said before, the episodic experience was evaluated using AttrakDiff. The graph presented in Fig. 11 shows the mean values obtained for the 4 dimensions of analysis (PQ; HQ-I; HQ-S and ATT) at time T_0, T_1, T_2, T_3, and T_4.

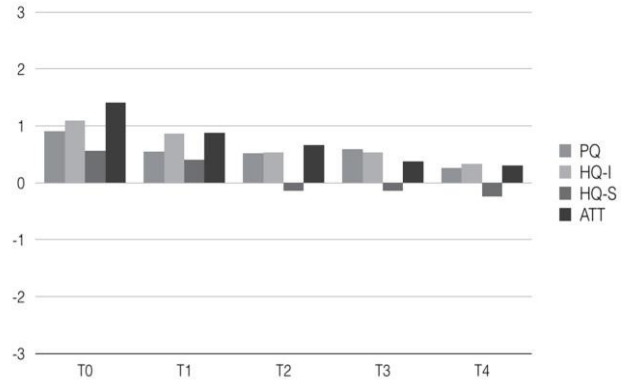

Fig. 11 Mean values for the four AttrakDiff dimensions over the time

Data show a decreasing trend for all dimensions of the analysis, from an initial positive attribution to all dimensions, to a progressive decreasing assessment over the four weeks. The HQ-S at T_4 scored below zero. The dimensions that obtained the highest values during the

evaluation are ATT, HQ-I, and PQ although the decreasing trend is the same for all of them.

Table I provides the average values obtained for the four dimensions and the relative standard deviation (Table I).

A closer look at the evaluation of specific items contained in the PQ dimension *Impractical- Practical; Cumbersome- Straightforward* show clearly how the judgement on pragmatic qualities decreased over time (Fig. 12). At the end of the study, the product was considered non-practical to use and cumbersome. The assessment of the item *Impractical- Practical* changed significant since over four weeks the pragmatic aspects were evaluated in real contexts of use (e.g. battery drain affected the entire use of the smartphone, the step counter stops when the person receives a call), and compared with other products considered more effective.

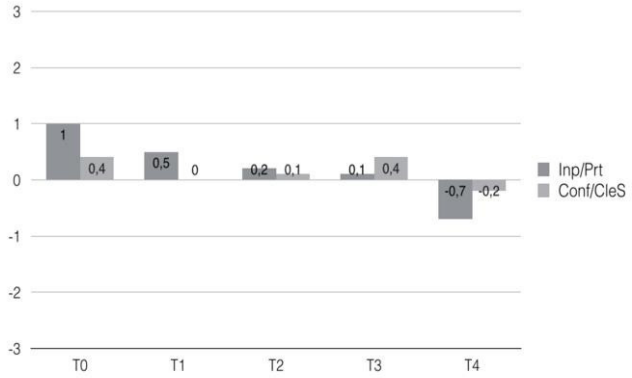

Fig. 12 PQ items *Impractical- Practical; Cumbersome- Straightforward* over four weeks

Also the items related to HQ-I: *Isolating- Connective; Alienating-Integrating; Separates me- Bring me close,* decreased over time (Fig. 13), even if the social features like the possibility to form or join groups and to create personal goals were generally appreciated in the diaries, and judged positively in the questionnaire on Anticipated and Remembered UX.

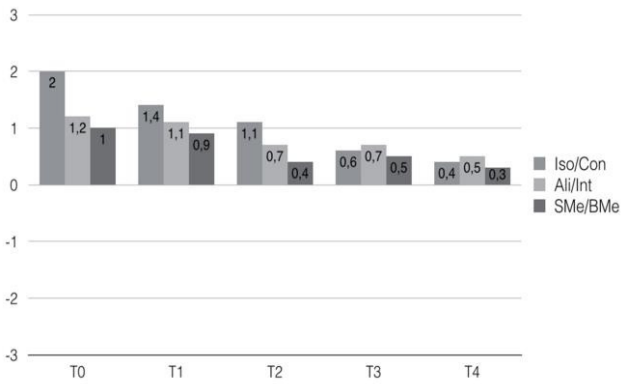

Fig. 13 HQ-I: *Isolating- Connective; Alienating-Integrating; Separates me- Bring me close* over four weeks

The app was unsuccessful in motivating participants. The items relating to the ability of the app to create enjoyable and captivating experience (HQ-S, ATT) decreased significantly over time (Fig. 14, Fig. 15). The following Fig. 14 reports the assessment of the HQ-S items: *Unimaginative-Creative; Dull-Captivating; Undemanding-Challenging; Ordinary-Novel;* and Fig. 15 the ATT items: *Unpleasant–Pleasant; Ugly-Attractive; Disagreeable-Likeable; Rejecting-Inviting; Bad-Good; Repelling-Appealing; Discouraging –Motivating.*

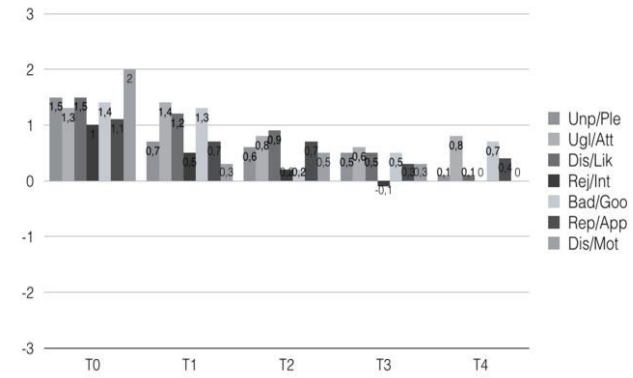

Fig. 15 ATT: *Unpleasant–Pleasant; Ugly-Attractive; Disagreeable-Likeable; Rejecting-Inviting; Bad-Good; Repelling-Appealing; Discouraging –Motivating* over four weeks

There were no differences between male and female participants (Fig. 16 and Fig. 17).

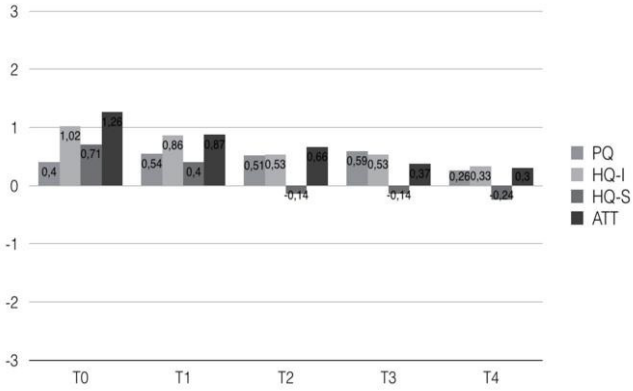

Fig. 16 Mean values for the four AttrakDiff dimensions over the time for male

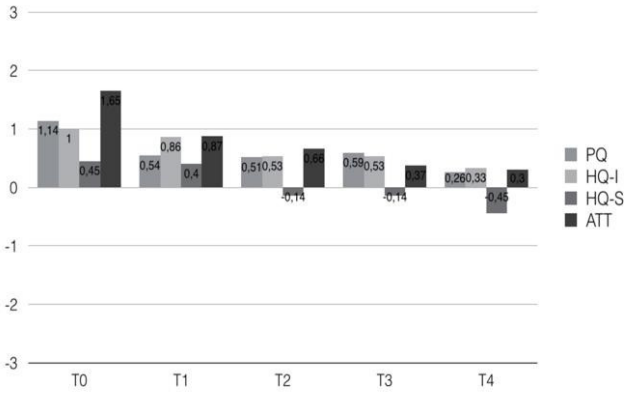

Fig.17 Mean values for the four AttrakDiff dimensions over the time for female

D) Remembered UX (AttrakDiff)

As said above, the remembered experience was assessed using an ad hoc questionnaire and AttrackDiff. The results of the ad hoc questionnaire are reported in section A above. The results of AttrakDiff related to the remembered experience were analysed conducting a paired-samples t-test to compare the four UX dimensions (PQ; HQ-I; HQ-S; ATT) at the first encounter (T_0) and after four weeks (T_4).

The test revealed that there were statistically significant differences between T_0 and T_4 on three dimensions HQ-I; HQ-S and ATT. The scores for HQ-I at T_0 (M=1,08, SD=0,62) was higher than the HQ-I at T_4 (M=0,32; SD=0,65) , t(9)=3,03; p=0,014. The score for the HQ-S at T_0 (M=0,55, SD=0,34) was higher than the HQ-S at T_4 (M=-0,24; SD=0,30) , t(9)=3,00; p=0,015. The score for the ATT at T_0 (M=1,40 , SD=0,19) was higher than the HQ-S at T_4 (M=-0,30; SD=0,179), t(9)=4,40; p=0,02.

On the contrary, there is no statistically significant difference for PQ.

Apparently after four weeks the participants remembered far better their dissatisfaction related to the hedonic qualities and the overall attractiveness of Pacer. These qualities were predominant with respect to the pragmatic qualities of the app. In fact other fitness app offer similar functionality, therefore the overall attractiveness makes the difference for a memorable UX. The participants clearly reported this in their qualitative comments.

The paired-samples t-test confirms that the user experience of using Pacer decreased over the time and the difference is statistically significant.

V. Discussion and Conclusions

The data obtained from the questionnaire on the Anticipated UX were consistent with those collected with AttrakDiff at T_1 (Episodic UX) and the diaries after the first encounter (Momentary UX). The same consistency can be noted between the data related to the Remembered UX and those collected with AttrakDiff at T_4.

Time seems to have an impact on the importance people attribute to different qualities of the experience with interactive products, as confirmed by previous studies [9]. Despite the crucial importance of usability in the product's initial acceptance, aspects of reliability, motivation, comparison with other products, change in behaviour and touch points (how the product communicates with the user, for example by notifications and alerts) are even more crucial for a user to resonate with a product and value it in the long term. That is why the UX evaluation in the long term is crucial.

Furthermore, even if it is not possible to proceed to general conclusions after a study involving a limited number (10) of subjects, the present study offers an original contribution that we hope could stimulate additional studies taking time systematically into account using different methods for the evaluation. Longitudinal studies on UX evaluation reported in literature assessed users' per-

ceptions focusing on specific times (Episodic UX) rather than assessing how their perceptions changed over time (Momentary and Episodic UX) and what memories people form in the long term that are crucial in stimulating later use. The diaries combined to questionnaires allowed us to reduce concerns about the reliability of the absolute measures collected with AttrakDiff where judgments were taken at predefine times and without reference points to single functionality. From one side diaries allowed us to assess the qualities of UX in context, that is in specific moments of interaction that were meaningful for participants. On the other side, the questionnaires on Anticipated and Remembered UX allowed us to associate the evaluation on expectations and memories to specific functionality of the product. The importance of such judgement was recognised also by Jordan and Persson [17] who suggested a hierarchical structure of qualities that contribute to positive experience, having the functionality of the product as a baseline. In addition to Jordan and Persson [17], we assumed the importance of UX qualities to vary with several personal and contextual factors including time as a fundamental source of diversity in UX, considered in its many facets Anticipated, Momentary, Episodic and Remembered.

Designing effective educational games - a case study of a project management game

Jakub Miler, Agnieszka Landowska
Gdansk University of Technology,
Faculty of Electronics, Telecommunications and Informatics,
Narutowicza Street 11/12, 80-233, Gdansk, Poland
Email: {jakubm, nailie}@eti.pg.gda.pl

***Abstract*—This paper addresses the issues of designing effective educational games. We aim at investigating how the cognitive, behavioral and emotional aspects of the games influence their educational effectiveness. The results were obtained with an observational user experience study extended with affect analysis carried out for a project management game GraPM. We analyzed the players' understanding of the game mechanics and logic, their engagement and emotional state. Then we confronted it with the educational effects achieved. In this case study the key identified factors of educational effectiveness were: understanding game mechanics, player's engagement, and feeling of control. Invoking other desired emotions was not required for effective education, which was also generally unrelated to the player's initial knowledge.**

I. Introduction

EDUCATION has always been an important part of human's activity. Effective education requires satisfaction of multiple goals according to Bloom's taxonomy and its newer revisions [1]. One of the recognized tools to provide multi-layer educational experience are games, with computer games in particular. The use of games in education is additionally promoted by the "serious games" approach [2].

Playability is a commonly used term for computer games, however it can be evaluated the same way as usability [3]. Usability of software as defined by ISO 9241 standard includes effectiveness, efficiency, and satisfaction with which specified users achieve specified goals in particular environments [4]. User experience (UX) extends traditional usability with affective aspects forming more holistic picture of human-system interaction.

The evaluation of user experience is particularly important for educational games as the cognitive, behavioral and emotional aspects of a game can largely influence its educational effectiveness. Our research goal is to understand the factors that influence the educational effectiveness of computer games and utilize it to design better educational games. This leads to the following research questions of this paper: (RQ1) how usability of a game affects its educational effects? (RQ2) how user experience of a game affects its educational effects?

This paper presents an extended user experience study of an educational game GraPM and is organized as follows. Section II discusses the related work. Section III describes briefly the game under study and its usability goals. Sections IV and V provide the study plan and results, respectively, followed by the concluding remarks in section VI.

II. Related Work

The related work for our study can be divided into two main topics: (1) educational games; (2) usability and user experience research.

We are mostly interested in the management games in general and project management games in particular. The example project management training games are Symulator Projektu and Symulator Zachowań Menadżerskich from Grupa ODiTK [5], That Project Management Game [6], or Scrum Game [7]. No usability, user experience or educational effectiveness studies for most of these games were identified. Scrum Game has been evaluated preliminarily, but only with a simple questionnaire.

Broad discussions of the issues of game usability are presented in [8], but they do not address specifically the educational games. P. Mirza-babaei introduced biometrics to evaluate the gameplay experience, but applied it to a non-educational FPS-type game [9]. Parodi *et al.* measured the player's education with their Competence Performance Analyser tool with limited use of UX and biometrics [10]. Raabe, Santos, Paludo, and Benitti carried out an extensive evaluation of serious games teaching project management, however the evaluation did not include the usability [11].

Research on both user experience and affective computing is broad and have already been summarized several times, e.g. in the work of Vermeen et al. [12] or the book by Albert and Tullis [13]. There are a few studies on fusing affect recognition and usability evaluation [14]–[16]. The most important work is the one by Ahn and Picard, that proposed the Affective-Behavioral-Cognitive (ABC) framework for

This work was supported in part by Polish-Norwegian Financial Mechanism Small Grant Scheme under the contract no. Pol-Nor/209260/108/2015 as well as by DS Funds of ETI Faculty, Gdansk University of Technology.

the user experience evaluation. The framework was validated with an experiment on beverages [14]. Lew, Olsina, Becker, and Zhang applied the affect evaluation in the quality assurance procedures for web applications [15]. Kołakowska, Landowska, Szwoch, Szwoch, and Wróbel proposed the application of affect recognition in usability evaluation in four different scenarios: first impression test, task-based usability test, free interaction test and comparative test [16].

III. The Game under Study

We carried out this research with a project management educational game GraPM, which was conceived and designed by J. Miler based on his earlier research on project management [17]–[18]. GraPM stands for "game on project management", where "gra" is game in Polish. This game puts the player in the role of a project manager. The target group of this game includes: (1) people who want to increase their project management knowledge and skills; (2) players who like management and strategy games.

The GraPM game was implemented within an engineering diploma project in 2014 [19]. It is a JavaScript-based rich internet application run in a web browser, see Fig. 1.

Fig. 1 The GraPM game user interface mid-game

The user experience goals for the GraPM game assume that the player understands the game mechanics after the 2nd gameplay and the game logic after the 5th gameplay. The player's engagement should be maintained high across multiple gameplays to ensure game replayability.

The game is also expected to generate the following emotions desired for educational effectiveness: (a) interest – eagerness to learn; (b) slight confusion – feeling there is something to learn; (c) joy – satisfaction from learning and playing better; (d) feeling of control – the confidence of fully controlling the in-game project and winning the game. On the other hand, the following emotions are undesired for the educational effectiveness and should be avoided in the gameplay: (a) fear – being afraid of controlling the game and learning; (b) strong confusion (frustration) – feeling lost due to not knowing how to play the game; (c) anger – irritation due to not understanding the game and inability to win; (d) boredom – loss of motivation to play, learn and win; (e) disregard – considering the game poor, unchallenging and non-educating.

IV. User Experience Study Design and Execution

A. UX Study Design

In the study of the user experience of GraPM, we have used typical scenario-based procedure for usability testing. The procedure was performed and analyzed using the Affective-Behavioral-Cognitive (ABC) approach, that combines participant perception (cognitive component retrieved by self-report) with observational scores (behavioral component) and emotion analysis techniques (affective component). The study was a part of an experiment that aimed at evaluation of applicability of automatic emotion recognition in the context of usability testing [20]. It was performed at the Emotion Monitor stand, which is a multi-modal setting designed for human-computer interaction observation [21].

An initial questionnaire was filled before playing the game. It covered: sex, age, year and field of study, knowledge of the GraPM game or other project management games, participation in project management courses and evaluation of initial project management knowledge (IPMK).

The gameplay (which was performed 5 times) was intertwined with questionnaires that included: subjective competence progress evaluation and self-report on emotions. The questionnaires covered cognitive component of the ABC approach. In order to perform behavioral analysis, the Morae Recoder software was used, that allowed to capture screen and user mouse/keyboard activities.

Affective component used in this study was based on three input channels: video capturing for facial expressions analysis (with Logitech Internet camera and compatible software solution), self-report based on PAD (Pleasure-Arousal-Dominance) emotion representation model [22] and physiological signals recording as a reference (skin conductance, blood-volume pulse and respiration rate recorded with ProComp Infiniti hardware coder together with Biograph software).

B. UX Evaluation Criteria

We have applied three general UX evaluation criteria: understanding, engagement and enjoyment, as well as purposely added educational effectiveness. All evaluation criteria were further operationalized into metrics.

Understanding covers the cognitive aspect of user experience and describes the comprehension of the game by the player on the level of its mechanics and its internal logic. The understanding of game mechanics means that the player is able to manipulate the game and affect the gameplay. The understanding of game logic means that the player learned the rules of the game and is able to win. According to the user experience goals of GraPM, the understanding of the

game mechanics should be evaluated after the 2nd gameplay, while the understanding of the game logic should be evaluated after the 5th gameplay.

Engagement is related to the behavioral aspect of the player-game interaction and characterizes the ability of the game to attract the player, maintain his interest and motivate him to play, learn and win. It should be evaluated over several gameplays.

Enjoyment covers the emotional aspect of the user experience and describes to what extend the game is able to stimulate desired emotions and avoid undesired emotions, as defined by the game designer. It should also be evaluated over multiple gameplays.

The educational effectiveness corresponds to the main business goal of the GraPM game. The other factors of user experience form, in our opinion, an indispensable foundation for the educational effects to emerge. The educational effects should be evaluated after the 5th gameplay.

C. Operationalization of UX Evaluation Criteria

The understanding factor was operationalized with two metrics: understanding of game mechanics (UM) and understanding of game logic (UL). UM measured the number of mechanics understood by the player out of 15 mechanics. UL measured the number of game logic rules understood out of 10 rules in total. The values of these metrics were measured by the game designer based on the recorded gameplay.

The engagement factor was operationalized with the following metrics: (EN1) number of pauses to adjust the project; (EN2) percentage of risks to which player reacted in any way; (EN3) number of threats eliminated (reduced to zero); (EN4) number of opportunities enhanced or exploited (materialized); (EN5) number of tooltips read; (EN6) number of mouse clicks (left button only); (EN7) distance of mouse movement (in thousands of pixels); (EN8) gameplay duration (in minutes); (EN9) summary evaluation of engagement based on EN1-EN8 in a 5-point Likert-type scale (very low VL, low L, medium M, high H, very high VH). The EN1-EN8 metrics were measured in an open scale of intensity. Metrics EN1-EN5 were measured by the game designer based on the recorded gameplay. Metrics EN6-EN8 were measured automatically by Morae Manager tool. EN9 was evaluated by the game designer.

Enjoyment factor was operationalized with the following metrics: (EJ1) average level of valence per user, representing positive vs. negative dimension; (EJ2) average level of arousal per user, representing calm vs. energetic dimension; (EJ3) compatibility of the EJ1 and EJ2 with desired or undesired emotional states in a closed scale (D – desired emotional state; UD – undesired emotional state, O – other emotional state than specified); (EJ4) dominance after 5th gameplay, which is the proxy for the feeling of control.

Educational effectiveness was operationalized with the following metrics: (ED1) self-reported degree of improvement in the project management competencies in 5-point Likert-type scale, from 1 - “very low” to 5 - “very high”; (ED2) number of additional unique project management aspects listed by the player after 5 gameplays as compared to the initial questionnaire.

D. UX Study Execution

The study was carried out in April and May 2016. The entire experiment involved 10 participants aged 23 to 43 (8 of them belonged to the game target group), 5 male and 5 female. 5 participants were selected for the user experience study based on the following criteria: (1) belonging to the target group; (2) no prior playing GraPM; (3) diverse fields of study; (4) inclusion of both male and female; (5) diverse levels of initial project management knowledge. In the entire experiment we recorded 50 gameplays, 5 for each participant. The time of a single participant recording (5 gameplays and the questionnaires) varied from 34 up to over 90 minutes. The players in the study are coded P1 to P5.

V. User Experience Evaluation Results

A. Understanding

The understanding of the game mechanics and logic by the sample players are presented in Table I. It can be observed that, apart from player P1, the players understood at least 80% of the game mechanics only after the 2nd gameplay. The results also show that 2 out of 5 players (P1 and P4) understood at most 50% of the game logic, while the other 3 at least 80%. The players P1 and P4 were not able to win the game as they had considerable usability problems only at the game mechanics level. Only 2 players (P3 and P5) could achieve full project success and win the game.

TABLE I.
EVALUATION OF UNDERSTANDING

Metric	P1	P2	P3	P4	P5	Avg.
UM	8	13	15	12	13	12,2 (2,6)
UL	5	8	9	4	9	7 (2,3)

B. Engagement

The results of the engagement evaluation are presented in Table II. The values of metrics EN1 to EN5 were averaged over the 2nd and the 5th gameplay, while the values of metrics EN6 to EN8 were averaged over all 5 gameplays of a particular player.

Interpreting these results, we can see that the least engaged player was P4. P4 influenced the project course to a very limited extent (EN1), generally ignored the risks (EN2–EN4), clicked and moved the mouse little (EN6, EN7) as well as played for the shortest time (EN8). The most engaged player was P3. P3 adjusted the project many times (EN1), managed successfully the risks (EN2–EN4), read many tooltips (EN5), intensely clicked and moved the mouse (EN6, EN7), and played for the longest time (EN8). The

engagement of P2 was also very high, similar to P3. The P4's engagement was high, close to the average. The anomalous case is the player P1. P1 did not understand how to pause the game (EN1) and react to risks (EN3 and EN4) on the game mechanics level (compare to Table I), thus the 0 values of these metrics. However, P1's engagement was at least medium, which can be evaluated from the metrics EN2, and EN6 to EN8. These metrics show that P1 wanted to control the project and manage the risks, but did not know how to manipulate the game to do this. These interpretations are reflected in the values assigned to the metric EN9.

TABLE II.
EVALUATION OF ENGAGEMENT

Metric	P1	P2	P3	P4	P5	Avg.
EN1	0	12,5	25,5	1	14	10,6 (10,5)
EN2	80%	100%	100%	42%	72%	78,7% (24%)
EN3	0	3,5	3,5	0,5	2	1,9 (1,6)
EN4	0	1,5	1,5	0	1	0,8 (0,8)
EN5	0	0	7	4	0	2,2 (3,2)
EN6	50 (14,9)	87 (6,2)	108 (31,3)	17 (5,0)	73 (11,8)	67,2 (34,9)
EN7	59,0 (16,9)	97,5 (21,4)	90,8 (18,0)	30,7 (14,1)	75,8 (8,6)	70,8 (26,9)
EN8	5:44 (1:26)	6:32 (1:26)	8:32 (2:40)	4:29 (0:38)	6:24 (0:35)	6:20 (1:28)
EN9	M	VH	VH	L	H	H

C. Enjoyment

The evaluation of enjoyment in 5 gameplays for each player is presented in Table III and Fig. 2.

TABLE III.
EVALUATION OF ENJOYMENT

Metric	P1	P2	P3	P4	P5
EJ1	3,6 (0,9)	6,2 (0,4)	5 (0)	5,4 (1,3)	6,4 (0,5)
EJ2	3,8 (0,4)	5,6 (1,1)	1 (0)	5,2 (0,8)	2,4 (1,7)
EJ3	D	D	O	D	O
EJ4	5	5	5	3	7

Desired emotional states region contains majority of the 1st quarter together with the states of neutral arousal from the negative region. Out of the four specified desired emotional states (section III), two are not expressible in the valence-arousal model: interest as a cognitive state and a feeling of control, which is expressible with the third dimension of PAD model – dominance (EJ4). Undesired emotional states were clustered as two regions: negative states of very high arousal and negative states of very low arousal. Please note, that fear, anger and frustration are very close to each other in this model.

The players P1, P2 and P4 fall into the desired emotional states region. The players P3 and P5 do not fall into the desired nor un-desired region; it seems, that for them the game was a relaxing experience.

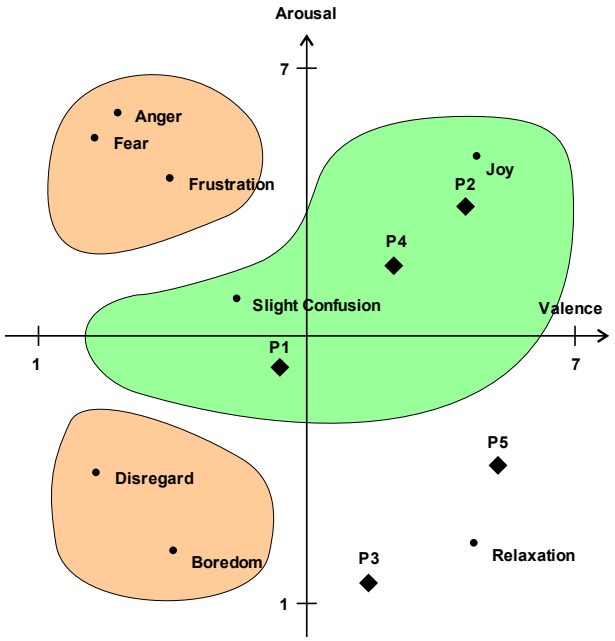

Fig. 2 Players' emotional states compared to the desired and undesired emotional state regions in the valence-arousal model

D. Educational Effectiveness

The evaluation of the educational effectiveness after the 5th gameplay is presented in Table IV. The values of metrics ED1 and ED2 are confronted with the initial player's knowledge of project management before playing the GraPM game (IPMK). It can be observed that the players P2 and P5 reported the highest educational effectiveness, however in case of P5 the high self-reported estimate (ED1) was not confirmed with the knowledge verification (ED2). P3 reported low estimate of education (ED1), but still exhibited considerable increase in knowledge (ED2). The lowest educational effectiveness was observed for P1 and P4.

TABLE IV.
EVALUATION OF EDUCATIONAL EFFECTIVENESS

Metric	P1	P2	P3	P4	P5	Avg.
ED1	2	4	2	1	4	2,6 (1,3)
ED2	1	3	3	2	1	2 (1,0)
IPMK	3	4	5	2	1	3 (1,6)

E. Summary and Discussion of Results

This study leads to the following observations:

- the understanding of the game mechanics forms the basis for understanding of the game logic;
- the engagement seems unrelated to understanding of the game mechanics, which can be seen by cases of player P1 (at least medium engagement with low understanding of the mechanics) and player P4 (low engagement with high understanding of the mechanics);
- the engagement is related to understanding of the game logic, however the nature of this relation is still to be investigated;

- the educational effectiveness is enhanced by the player's understanding of the game mechanics and logic, as well as his engagement (P2, P3, and P5);
- the educational effectiveness seems unrelated to the initial knowledge of the player: players P2 and P3 reported the highest initial knowledge but still exhibited high educational effects; player P5 reported the lowest initial knowledge and high educational effectiveness; players P1 and P4 reported medium initial knowledge and medium educational effects;
- the educational effectiveness was not disturbed with undesired emotions for any player, however 2 out of 3 players (P3 and P5) exhibited rather ambivalent emotions regarding the game goals (relaxation);
- the educational effectiveness is related to the player's feeling of control: the player P4 with the lowest educational effects also had the lowest feeling of control, while the player P5 with high educational effects exhibited the highest feeling of control.

We are aware of the fact that the validity of this study has some limitations. We identified and addressed the following threats to its validity: (1) sample size – we engaged 5 users as the usability tests show that 5 users reveal 75-90% of the usability issues; (2) sample as a group of convenience – we introduced the initial questionnaire and selected the sample for UX evaluation to ensure its diversity; (3) confounding variables – we performed the study in a strictly controlled environment, where we limited the possible influences of external factors; (4) subjective measurements – we operationalized most of the variables to objective metrics, the number of subjective self-reports is minimal; (5) small number of gameplays – due to resource limitations in manual measurements we focused on 2nd and 5th gameplay, which were specified in the UX design goals.

VI. Conclusion

The study provides preliminary evidence that usability and user experience affect the educational effectiveness of a computer game. The results revealed the flaws in the GraPM game UX design at the cognitive and behavioral levels. Together with the analysis of the emotional impact it may be used to improve the game and increase its effectiveness.

Based on the data collected we plan to evaluate the GraPM learning curve based on the understanding of logic across gameplays, analyze players' emotional state in consecutive gameplays as well as identify affects related to particular game events.

Acknowledgment

J. Miler thanks the engineering diploma project team that implemented the GraPM game: Rafał Piechowski, Damian Płatek, Anna Wasik, and Sylwia Grabowska. The authors thank Dominika Makowiecka, who helped in the experiment setting and execution.

***Abstract*—Designers adopt a large amount of general-purpose tools for supporting their remote collaborative tasks. Each tool provides very diverse functionalities: from file sharing to instant communication and video collaboration. The designer struggles when filtering and combining the right information spread across the multitude of tools. This research extends McGrath's framework of task circumflex to map the collaborative demands of the design practitioner and proposes Peepdeck, a design exploration to support them. Peepdeck is a dashboard that assembles information scattered across multiple tools in a personalized and organized way. Through two design iterations followed by evaluations of the user interface, several requirements were identified for supporting collaboration awareness in design teams. Insights confirmed the relevance of combining information from different but already familiar tools, rather than attempting to replace them. It was identified the importance of optimizing for visual scanning, supporting search of content and allowing users to customize the tool.**

I. Introduction

Design studios operate in a much more distributed fashion nowadays than in the past. Designers may be distributed geographically, potentially even in different time zones. This paper discusses the design of an application for supporting distributed collaborative design work. There is a myriad of new tools and online services available as shown by *Fig 1*. Tools like Dropbox, GoogleApps, Basecamp, Atlassian, Slack, Skype and Trello are just some examples of the diversity of commercial applications available on the Internet that support teamwork in the design studio. These technologies support very diverse functionalities and services, from file sharing, online edition of documents to instant communication and video collaboration.

Previous research [13] revealed a collection of patterns of behavior that the designers conduct in the context of collaboration tools. A surprising finding was that designers adopt a large amount of generic tools that they appropriate for supporting collaborative design tasks, choosing different tools for different parts of the design process. Tools like Facebook (social media), Dropbox (file sharing) and Skype (instant communication) were some of the most popular.

While some of the tools are used throughout the whole design process, each of the categories of behavior imposes its own challenges to each of the tools. Individuals switch fluently from one tool to another depending on the activity, the personal needs, the project needs and how the tool covers those needs. The designer must be able to filter and combine the right information spread across the given multitude of tools, each with different information (file, contact, folder, application) and user interfaces. This is the starting point that motivates the present work in order to facilitate the current collaborative practices of designers.

The current research presents a design exploration into how collaboration practices for distributed design teams can be supported. The paper starts by taking as reference McGrath's framework of task circumflex [12] to analyze how the current collaboration tools are incapable of covering the demands of the design practitioner. Then, the paper proposes as a solution an application called Peepdeck, which assemble information scattered across multiple tools in a personalized and organized way. Afterwards, the two iterations of the design and evaluation of the user interface of the application are presented. Finally, the paper discusses a reflection to the proposed design, the design requirements

This work was funded by the COnCEPT project as part of the European Commission 7th Framework ICT Research Programme: Project Number 610725. For further details visit: http://www.concept-fp7.eu

and further issues pertaining the design of such groupware applications.

II. Fitting Technology in Practice

The vast amount of existing research in the field of CSCW [21] has illustrated how groups adopted IT tools and integrated them into their social dynamics to support teamwork. Researchers have identified specific patterns of behavior supported by the appropriation of collaboration tools [10; 17; 18; 19] and how those patterns changed through their appropriation [24].

McGrath [12] defined a framework, called task circumflex, to classify technology according to the type of task that they were supporting within the team. McGrath classified collaboration tools in 4 quadrants based on whether they supported (1) generation activities: for planning and idea creation, (2) choice activities: for problem solving and decision-making, (3) execution activities: for the task execution and performance, or (4) negotiation activities: for tasks that focus in resolving conflicts between the individuals (*Fig 2*).

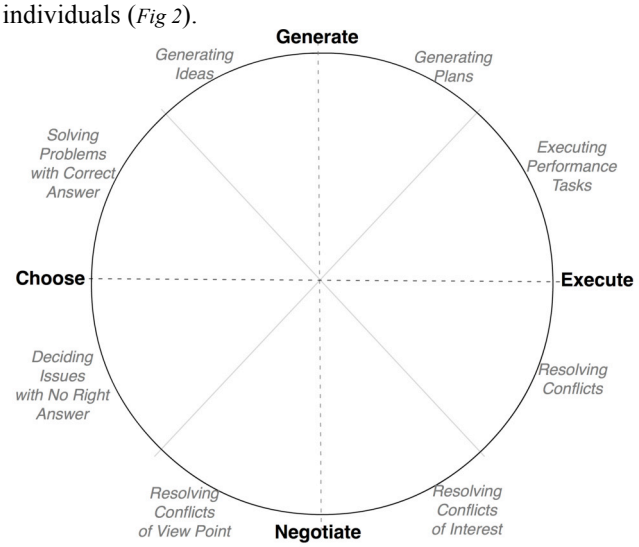

Fig 2. The task circumflex defined by McGrath (1984)

In the context of remote design teams, Muñoz-Alcántara and colleagues [13] performed a series of interviews and surveys to professional designers in order to understand the activities that designers engage to support their collaborative practices. Their results described 5 categories of collaborative activities: (1) creating ideas and concepts (e.g., ideation, brainstorming and inspiration), (2) developing ideas and concepts (e.g., sketching and prototyping), (3) making sense of the material, resources, and experiential knowledge (e.g., giving and receiving feedback), (4) keeping the team on track (e.g., notifying the team and solving issues in the team), and (5) managing the development of the project (e.g., defining and managing tasks and deadlines). As shown in *Fig 3*, the first 3 categories described the core activities of the design practice, while the last 2, described the social dynamics that enable the completion of the first set of processes.

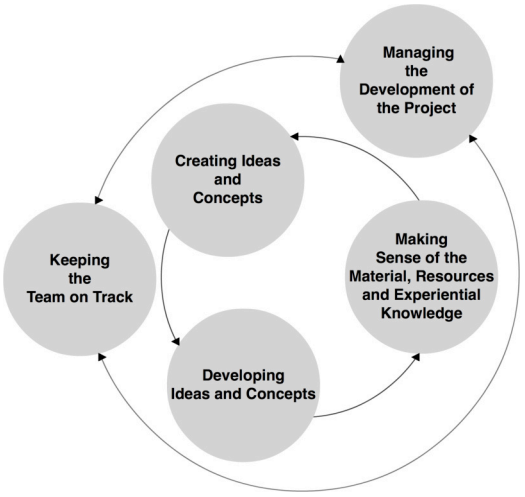

Fig 3. This diagram shows the flow of the five categories of collaborative activities described by Muñoz-Alcántara et al. (2015)

Additionally, Muñoz-Alcántara et al. [13] compiled a list of specific tools that designers use during each of the activities, as shown in Table I. The list reveals that professional designers use few specialized tools compared to the total amount of tools involved during the creative stages of their work. Furthermore, Table I illustrates how various tools appear repeatedly in more than one of the activities. This clearly shows that a large collection of different tools supports the designers on more than one of their daily tasks.

Table I. List of tools used on each design activity

Activity	Tools involved
Creating ideas and concepts	Google Docs, Google Spreadsheets, Mindmaps, Skype, Evernote, Dropbox, Pinterest, Facebook
Developing ideas and concepts	Paper, iPad (Adobe Ideas, Paper 53), Axure, Excel, Illustrator, SVN, Github, Bitbucket, Dropbox, Google Docs
Making sense of the material, etc.	Skype, Evernote, Facebook Groups, Facebook Chat, Lynk, email and Google Hangouts, Email, WeTransfer, Dropbox, Axure, Interactive documents
Keeping the team on track	Facebook Group, Facebook Chat, Skype, email, Whatsapp
Managing the development of the project	Redmine, Gantt charts, Teambox, spreadsheets, Trello, Outlook, Google Docs, Dropbox, Google Drive, Facebook Groups

Each of these collaborative processes can be mapped into the classification given by McGrath in order to reflect how each tool is used on every stage of the creative design process. The core process of creating ideas and concepts belongs to the quadrants of generation support tools and choice support tools. Tools aimed for generation and for execution activities mainly support the process of developing ideas and concepts. The process of making sense of the material is mainly covered by the quadrant of tools for choice but it also includes tools focused on negotiation. Keeping the team on track is primarily achieved by the support of negotiation tools while managing the development of the project depends on generation and

execution means. Fig 4 displays the task classification defined by McGrath combined with the group activities described by Muñoz-Alcántara and colleagues. These sets of behaviors provide the starting point for understanding how each different activity provides a specific value to the effort of the design team.

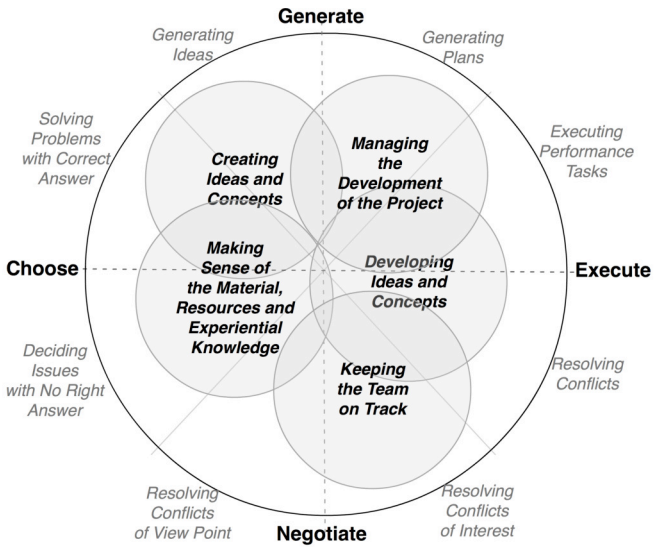

Fig 4. This diagram maps the task circumflex of McGrath (1984) with the specific patterns of behavior of a designer described by Muñoz-Alcántara et al. (2015).

Traditionally, design studios have a high material character. For example, office walls and desks are typically full of notes, post-it, sketches, prototypes and physical models. The material and physical aspects embedded in the design studio such as designer's practices, the use of artifacts and the space during collaboration, have a key role on the coordination of the creative activities [23]. Design artifacts (e.g. sketches, physical prototypes) located in the studio inform activity and progress of the group and trigger awareness in the team [2, 6]. The use of space is also productivity-focused, displaying information that supports time management, scheduling and division of workload. The designer takes advantage of the space and the artifacts to enable the coordination with the team. The design process often demands fast switching between activities, and thus, between artifacts and tools. Most activities require the selection and combination of information spread across several sources. Moreover, every person requires a unique set of information based on the roles, responsibilities, and also personal preferences and interest in the projects they are working on.

However, on a distributed setting, the digital information is usually managed and visualized through very different interfaces and organized in different information architecture. Since general-purpose tools are generally adopted to support certain design activities, extra work is needed for annotations, documentation, and organizing files and folders on each of the tools. As a consequence designers fail to integrate and coordinate the information, effort and outcomes of other team member's activities. Furthermore, when using a large collection of tools it is difficult to have an overview of the design process and the performance of the individual is affected by the huge amount of information provided by the collection of tools.

The question raised is how a groupware application could support design collaboration by focusing on the integration of the current tools while addressing the core requirements of the design tasks.

The design of the user interface of the dashboard followed a user-centered approach with two iterative cycles. Each design iteration consisted of the following steps: specification finding, conceptualization, development of the concept through prototyping and the evaluation of the prototype. The first iteration focused on creating and evaluating the concept of the dashboard. Drawing from the problems we identified during the literature research, this iteration explored what is the meaningful content of such a tool, what is the way how designers can use it, its information architecture and how they can incorporate it into their typical work routine. This was first evaluated on a paper prototype. In the second iteration an interactive digital prototype was developed and its UI was evaluated in terms of interactions, ease of use, and clarity of the application. The final outcome of this work is to bridge the gap between the existing qualitative fieldwork studies and the design recommendations based on the actual design and evaluation of a tool that enables remote collaboration in the design practice.

III. Initial Concept

The insights gathered from the literature review suggested to focus on solving the problem of scattered information and losing oversight rather than creating yet another specialized tool that solves narrowly scoped problems for designers. The concept of a dashboard emerged. The dashboard aggregates information from (multiple) existing tools and services, and displays them in a personalized manner at one place. This approach enables keeping a single UI for the user regardless of the actual tools and data sources integrated on a lower level. As one of the consequences, exchanging of the backend infrastructure or the connected tools does not need to be noticeable by the users.

IV. First Design Iteration

I. Design specifications

The success of the dashboard mainly depends on addressing the challenge of accessibility of the information and implementation complexity. A number of design challenges were identified on which the success of the dashboard depends:

- Making a glanceable display [11] that collects salient information for design collaboration in one place?
- What is the right amount of information? [4] (Lack of awareness vs. Information overload)

- How to design simple and intuitive interface? (Minimizing learning curve [15; 16])
- Information visualisation: overview / information display (Optimized for visual searching [8; 9])

The dashboard should incorporate the existing tools and provide an extra layer where designers can access the selected content and information streams, and filter them as (individually) preferred. Finally, it should also enable users to stay updated by checking only a single place (tool), instead of multiple different tools and their different notification areas, status bars, streams, feeds, and other elements meant for updating the user.

II. Peepdeck concept

The Peepdeck concept was conceived to address the challenges identified above. Peepdeck is envisioned as an online service that connects existing tools and services that users already use for collaborative design; it aggregates information from the connected services, and classifies it into four main categories resolved from the common groups of items described in the enabling activities discussed above: tasks management, shared calendar items, communication streams, and cloud storage with file management facilities. These categories contain information merged from various sources in a way that the information does not define the attributes or features of the item (i.e., a file from Dropbox is treated equally as a file from OneDrive, or Google Drive).

The central goal of Peepdeck is to display the information that is currently relevant to the user – reflecting their role, context, projects they are involved in, co-workers, personal preferences, and other aspects. The user can adjust the content of the dashboard so it matches his requirements. The dashboard contains shortcut to the connected services – so the user does not replace them with the Peepdeck, but Peepdeck just enables easy and quick access to the important parts (folders, files, and other items) in each connected tool.

III. Concept development

Concept development was the goal of the first iteration. After defining the concept of the Peepdeck as described above we created minimal version of the UI in a form of a wireframe, and then created a paper prototype that we used in the following user research.

IV. Wireframe

The concept of the UI consisted of the vertical columns placed one next to each other (see *Fig 5*). Each of these columns consists of a title and number of items of different types. These items could be in a stream of information from selected source – such as stream of the updates of files from the connected cloud storage, or stream of the activities of the teammates.

The content of each item in each stream is dependent on the nature of the item, which can be a file, an activity, a calendar item, or a task. The items that are not in a stream represent a list of tasks, list of persons, or a block of multiple items of a different character. Variants of the prototype represented different levels of complexity for different items.

A wireframe was designed that was aimed at minimizing the content, abstracting away from the source of the content, and focusing on the type of information. That means, that the items of the same character (e.g., file, task) are represented on the screen similarly, regardless of the source of the item (e.g., whether the file is from Dropbox, OneDrive, or Google Drive). This way, the items are displayed with emphasis on their meaning, instead of structural features such as location where they are stored.

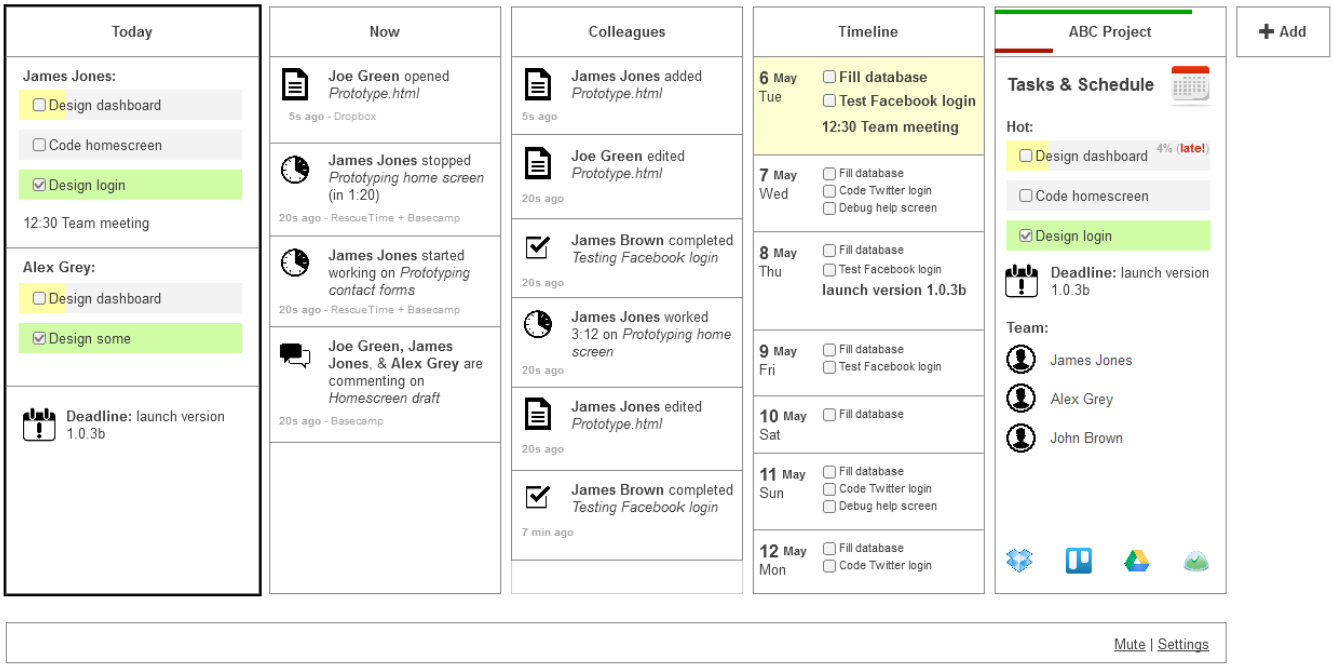

Fig 5. Wireframe of the first version of the UI of Peepdeck

V. Evaluation

The purpose of the evaluation was to validate the design concept and to investigate how to display relevant content at a single place. The test sessions also explored the amount and type of information and how to combine the information in a simple and intuitive way.

A formative user test was conducted with seven participants (six males and one female, with an average age of 30 years old). All participants were full-time employed designers working in the Netherlands on various design positions such as interaction designer, industrial designer, usability engineer, game designer, or graphic designer. All of them worked at middle- to large-size Dutch or international companies, in a team of six to ten people, some of them in multiple teams at the same time. User sessions were conducted in English; the interviewer and the five participants were not native English speakers, however all were proficient English speakers and no communication difficulties were noticed. Each session took about 60 minutes.

The user test involved a combination of a semi-structured interview and thinking-aloud method followed by co-design activities, where participants proposed alternative designs. . In the beginning of the session the interviewer asked about tools currently used, the size of the team, the roles of their current teammates, and typical information required in their work. Additionally, they were asked about the way they collaborate, and what tools or methods they use in their team.

For the evaluation, a paper prototype of the interface was created from the wireframe models so that interactions could be simulated by manipulating paper cut outs (*Fig 6*). We experimented with excluding different types of items to test whether users actually miss them. Participants were given a set of tasks pertaining to understanding one's current state in the context of the status of tasks, projects, deadlines, files and the activities of other team member activities. During the tasks participants were thinking aloud, and after the (successful or unsuccessful) completion of each task, the interviewer asked about the relevance of the elements of the dashboard for completing that task.

Fig 6. User testing of the version 1 of Peepdeck on a paper prototype

During the whole session both participant and interviewer had pens and markers available (each of different color) and participant was asked to add information into the dashboard that was missing for completing any task. Participants were also asked to cross out information that they find useless, or draw extra elements of the dashboard they are missing (*Fig 6*).

VI. Results

The results of the user test revealed that the concept of the dashboard was evaluated very positively. Participants often related the UI elements, interaction or their expectations about the interface to the existing tools they were familiar with; and not only tools they use for work. Examples of the UI elements they mentioned were "badge counters" known from iOS applications, showing in a small field at the corner of the app's icon number of notifications this app has; stacking information as known from Facebook (e.g., when an item is shared by multiple persons, the item is shown once with the list of all persons who shared it, instead of repeating the item for each person); or iconography known from OS X and Facebook. In general, participants often related to the tools they were using at work already, which confirmed previous findings about the list tools they actually use. Participants usually asked for better visual clarity, showing context of the items and relationships between related items. All participants executed the tasks in different ways suggesting the need to allow flexibility in the user interface.

In terms of general problems and requirements, participants stated that they often work on multiple projects at the same time, or switch between projects every few days during a month. Therefore, the interface should support multiple project views and easy handling of them (adding, hiding, showing, and removing). The presented categories of items (such as events, tasks, files and messages) were understood, however the relationships between items on the dashboard and the persons or projects were not clear. Especially for project-related items such as tasks or deadlines, they missed clear hints about the project it relates to. The opinions and preferences on how to present extra information were divergent. A common remark was that the dashboard must be easy to scan visually supported by colors, spacing and the typography.

When referring to missing information or features, the most common concern was to include filtering and search functions. Participants referred to the possibility to stack similar items together, manipulate content (list of tasks, current files), edit privacy settings (shared or not shared), and to show and hide details of each item (tasks' status, deadlines, last time of synchronization). Besides, each of the items should have a link to the original source and other related items. The dashboard should also include the availability of colleagues (chat, IM, call, personal meeting). An integrated social media stream was also suggested with the possibility to disable specific applications when they do not want to be disturbed.

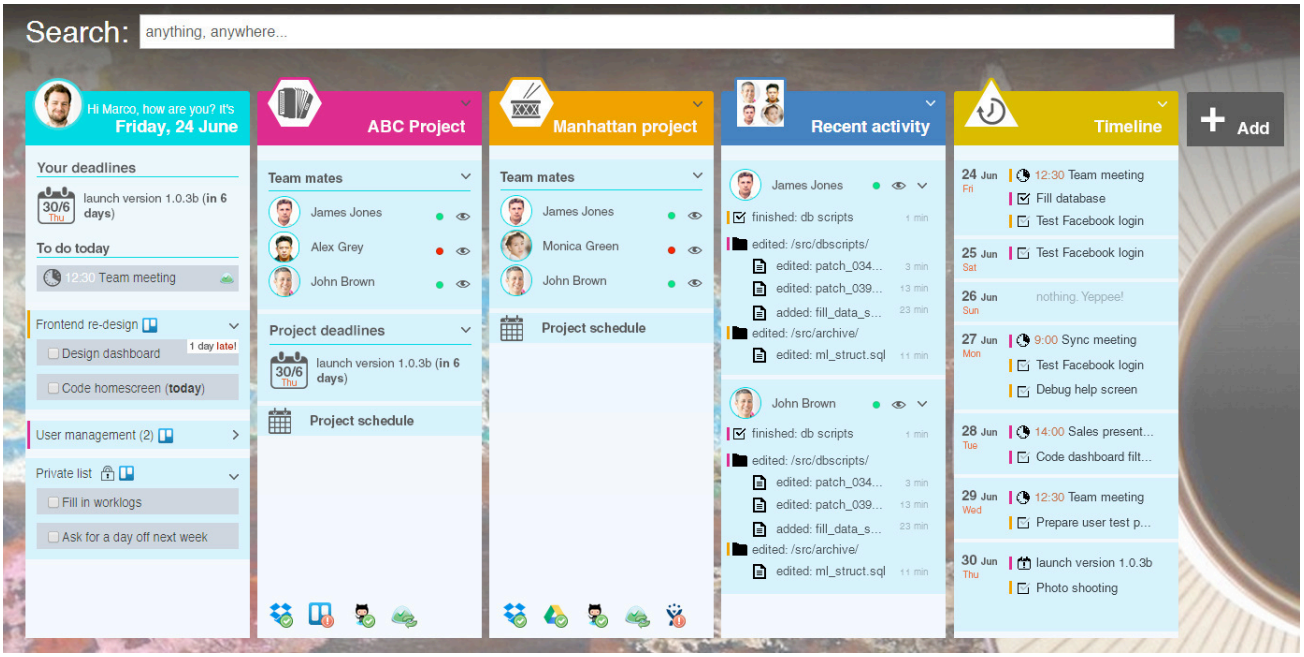

Fig 7. Final version of the UI of Peepdeck on a high-fidelity prototype

V. Second Design Iteration

The second iteration focused on creating and testing an interactive digital prototype implementing the guidelines resulting from the first iteration and user test. For instance, visual clarity, spaciousness and segmentation of the interface should dominate in order to support visual searching and effective scanning of the updates on the dashboard. Other components such as integrated search and availability of team members were included in the UI.

I. UI design

The wireframe of the first version of the dashboard was redesigned and then with the help of a mood board a visual design was created using colors and shapes with a meaning to support visual searching and peripheral scanning of the dashboard [1]. The interface, shown in *Fig 7*, consists of several columns, where the basic set of columns included: a "Today" column, a "Project" column, a "Team activity" column and a "Timeline" column. A full text search is placed visibly above all, to indicate that it searches all the content of the dashboard.

The "Today" column contains today's date and day of the week, photo and greeting of the user to attract attention and make user start reading the screen here. Then it lists the upcoming deadlines, lists of tasks, and a private list of tasks that are stored locally, and not shared. The "Project" column contains the header with the project name and an icon. This column contains a list of teammates, which are aggregated from tools that contain the defined team (e.g., Basecamp), or the users from the shared project folder (e.g., Dropbox). Each person has an indicator of availability on any connected communication service, and a visibility icon that can toggle the content related to this person in the whole dashboard. Underneath there is a list of upcoming deadlines of this project, a link to the project schedule (in selected tool where the project shares the calendar), and icons of all connected tools/services with the indication of synchronization status; these icons are shortcuts to the relevant project pages (e.g., Dropbox folder, or Basecamp project). The "Team activity" column contains the blocks of users and their recent activities such as edited files, or completed tasks. The "Timeline" column lists the simple linear calendar view with the upcoming events such as deadlines, meetings, and tasks. Users can add more columns into the dashboard, which will scroll horizontally.

II. Prototype development

An interactive prototype with high visual refinement based was created in the software Axure RP Pro 7.0. The result was an interactive mockup on HTML, CSS and JavaScript. The prototype implemented the designs created in the previous stage. It also added interactions allowing to manipulate the interface, such as collapsing and expanding the elements in the columns, hiding and adding new columns, do full text search with autocomplete function showing the search results during typing of the search phrase, adding new items on the private task list, hiding and showing content of each person on the dashboard, and showing extra information about elements on mouse hover. The prototype displayed in *Fig 7* is the improved version after the insights from the second evaluation. The prototype is available on the URL: http://ojwz1v.axshare.com/.

III. Evaluation

User tests were conducted with seven designers (four males and three females, all in their early 30s). All participants were employed full-time at the time of the tests by middle- to large-size Dutch or international companies, and they work in a team of six to ten people, often being part of multiple teams at the same time. The individuals held various design positions such as interaction designer,

industrial designer, usability engineer, game designer, or graphic designer. User sessions were conducted in English. Each session took about 60 minutes.

The goal of the evaluation was to test the UI, regarding its visual clarity, the information architecture and the amount of information presented. The connections and data on the dashboard were simulated. User interactions with the interface were specially observed: how they explore and understand the elements on the screen. The terminology and wording used in the interface were also evaluated.

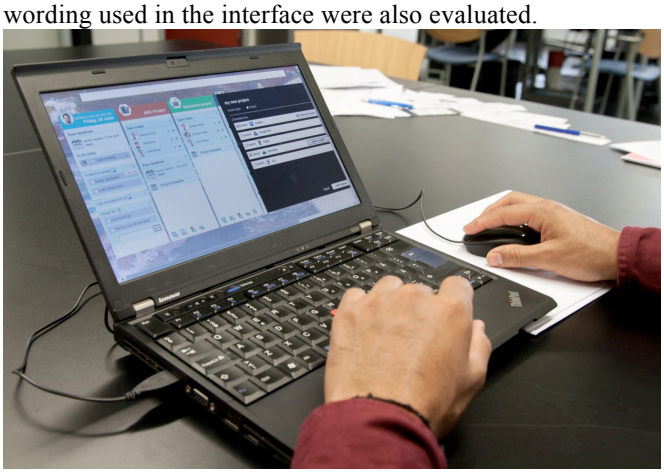

Fig 8. User evaluation of the version 2 of Peepdeck's UI using an the interactive prototype

The interactive prototype was tested on a computer with a mouse, in a full screen mode (*Fig 8*). A similar protocol to the first evaluation was executed during this evaluation. The user test was set up as a combination of a semi-structured interview, thinking-aloud while completing given tasks, and observation. The prototype was presented to participants, and then they were asked to complete a set of tasks while thinking aloud. These tasks were very similar to set of task performed during the first evaluation. The tasks pertained to the current status of one's activities, other member's activities, deadlines and projects. Some tasks focused on the added features such searching for a particular file, directly contacting a team member or unsubscribing from certain notifications. After each attempt the interviewer was asked about which elements of the dashboard were helpful for completing this task, and which parts of the dashboard were not. At the end, participants were asked several open-ended questions about situations in which they find this tool useful, and in which they think it would not be useful.

IV. Results

In summary, the feedback on the tool was very positive as some participants noted that they wanted or needed such a tool already. The visual segmentation and organization of the dashboard was positively evaluated, and people reported that searching was easy, and clear. The results showed that users want to customize the order of the sections – natural action is drag and drop the column to another place (almost all participants attempted to do this). Columns should have an option to manage its content (add, remove, edit, rename and reorder panels) and must allow the management of the tools connected to each column. Let people develop their own widgets for the dashboard (either elements in the columns or whole columns).

The observations also revealed that people were very actively exploring the interface, and learnt how to use it immediately or within one or two tries. This implies that the interface also supports fast learning, and motivates users to explore its functionality. Participants related many actions and interface elements to the tools or environments they are familiar with – Facebook, iOS, OS X, Gmail. It should be possible to collapse columns into tabs or icons, so that they can be opened easily and immediately when needed, but are not taking place on the screen when not needed (analogy to browser tabs, or minimizing applications in OS).

The participants highly valued the aggregation of the tools they usually use. As one designer explains: "I think I would really love it. Because from here, from this interface, I can easily go straight to certain file, certain person, (…) instead of searching: Where is this? Where is that?" [ppn1]. Another designer commented: "It's handy because you don't need to learn all the new tools. If someone prefers this and someone prefers others" [ppn3].

Since the dashboard integrates many activities, services and files, participants noted that there should be a visible confirmation after each action with the possibility to undo the action. Some suggested that, ideally, the dashboard should have a full integration with the connected services and with local files and that the interface should point directly to the aggregated content. Finally the interface should provide means for immediate interaction (instant message or email) with the people in the list of contacts.

VI. Discussion

Designers use many general-purpose tools for different collaborative tasks. Mastering the diversity and combination of the tools and functionalities, and keeping an overview of the process is a recurrent problem in design practice. The present study has explored means to link different tools, to filter relevant information across them and to switch easily between tasks during collaborative design projects. Through two design iterations followed by user tests, it was confirmed the relevance of a dashboard application presenting status information compiled from several general purpose tools for enabling designers to maintain an overview of their work and of the activities of the design team.

So far, feedback from users confirms the general design direction chosen: the dashboard should combine information from different but already familiar tools [7], rather than attempting to replace them. The first iteration identified the importance of optimizing the dashboard for visual scanning and support the search of content. The second iteration identified one more important requirement: to allow users to customize the dashboard as needed (by individual preference, role, workload, number of projects and team size).

Awareness is critical for collaboration. It provides an understanding of others and their activities and it helps guiding ones actions [2]. Awareness is dynamically built through practices [20]. In the design studio, the use of space and artifacts support the creation of awareness [23].

However, on remote environments, different awareness mechanisms should be developed to support seamless collaboration [4]. Through the integration and visualization of the different collaboration tools, Peepdeck aims to facilitate some the most relevant components of the design practice: social interactions supported by the exchange of artifacts [22] and information. Additionally, Peepdeck uses a user-centered approach [5] and adopts several awareness mechanisms such as personalization [4], workspace awareness [6], team availability [3] and work progress [2]. Further iterations involving different methods of evaluation on real scenarios must be done to ensure the generalization, precision and realism of these findings [14]. One can imagine that tools like Peepdeck can support other professionals for other types of collaborative work e.g., to quickly interact with the team (through sending emails or instant messages directly to team members), keeping and self-updated about the project development (following the activity of the colleagues, following the deadlines, tasks and their statuses), and accessing the shared resources easily.

VII. Conclusion

Two iterations were presented of the design, prototyping and testing of PeepDeck an application that aggregates information from tools and online services that are popular amongst design teams, allowing them to be aware of project work. This process identifies several requirements for the design of tools to support collaboration awareness for design teams, these are: a) support the use of collections of widespread tools rather than replace them with a special purpose one b) design the system as a glanceable display to support awareness and peripheral interaction c) allow customization to individual needs and practices.

While these requirements have been identified in related literature regarding collaborative work, the emphasis on the combining general-purpose tools for supporting design activities is new. Further, the notion of personalization and glanceability refer to specific needs of design teams, which differ from the interpersonal awareness applications that have occupied CSCW literature in the past. Future work will explore how functional prototypes of such awareness functionality can be implemented and the extent to which they can be accepted by design teams and to which they succeed in fostering awareness.

***Abstract*—We have developed a method and a process with which we can simulate the functionality and the space requirements of different actions in buildings. We utilize Gamification of Building Information Modeling (BIM). The essential goal of Building Design is to produce designs corresponding to customers' needs. In our method the electronic CAD model is inserted into a Game Engine and is gamified. Features and limitations that correspond to the reality as exactly as possible are generated for the virtual objects steered in the game by the designers. In addition, the space requirements for the actions performed by a simulated user can be dimensioned by our Functional Design Method. We generate 3D space objects of maximum space requirements for actions from videos of real human actions. The 3D space objects created this way can be Collider Objects used by the designers attending to the Gamification. We get simulated User Experiences from the rooms under design. This method helps to understand better than before different end users and their needs. The result is buildings that fit the requirements of the users.**

I. Introduction

The Pilot Experiments described in this article use our method to generate computer game like environments out of a Building Information Models (BIM) by Gamification. The gamified Building Model enables us to simulate actions in buildings.

With the aid of the gamified model we can simulate different User Experiences in a building already when the building is under design.

The ”Players” following different roles can move like the First Person Controller (FPC) or the Third Person Controller (TPC) in the virtual space. Features and limitations according to a role (e.g. a Handicapped using a wheelchair) can be realised.

The Game Object can include the space requirements belonging to the actions of the role. The space requirements are from our Functional Design Method, FDM [1],[2]. From the space requirements we can generate variable Collider Functions around the Game Object. The method makes it possible to simulate different functionalities and space requirements related to actions. The Player can e.g. take the role of a person using a rollator. With the aid of the gamified Building Model he can get the User Experience of moving around with a rollator. We detect already in the beginning the possible problems and shortcomings, and corrections are then low coast and fast compared to during the construction or even after the building project.

The developed method also helps designers of the Construction Industry to better understand the needs and limitations of buildings. It is also possible to involve the user groups to the design via the method of gamified Building Model. The end users can get a view that is understandable and real enough. We can then achieve buildings that match more closely their purpose.

With the method it is also possible to automate the testing against the Universal Design principles, by moving 3D-models with their space requirements (like a wheelchair patient with two assistants) automatically through the model. After the tests the possible problems and their locations can be found in the report automatically generated.

If the designer uses VR glasses, like Oculus Rift, the User Experience of the gamification of Building Information Models can be quite realistic.

The gamification of the models serves all phases of the construction project from sales and marketing until the completion of the Architectural Design. By the aid of the gamified model it is possible to communitise and crowdsource by distributing the gamified model in the Internet. The end users can then be given an opportunity to present ideas, test functionalities and so attend to the design.

This article first describes the methodologies and software related to the research. Then we present the new method and the process for gamification of Building Information Models as an aid in design. Finally, we observe the meaning of the new results and scenarios for the next steps.

II. Methodologies and software used in the Research

The developed method utilises a work based invention report at Mikkeli University of Applied Sciences Ltd (Mamk) filed by Jukka-Pekka Selin. The maximum space requirement in dimensions x,y and z can be derived from video clips of real human actions. In this method the real actions are videoed with at least two video cameras that are situated at right angles. The need of space from the actions in three

dimensions is measured and a corresponding geometrical object is created. This 3D object in IFC file format is compatible with CAD software. The goal is to ensure that the required actions can fit the space under design. [1],[2],[3].

During the research program the application that is BIM compatible, under development and is meant for Lifecycle Management of Building Data, and the application extension Value Add Data of Mamk R&D, were used for creating 3D objects. The application extension realizes the functionality of the FDM. The Colliders describing the space requirements for different actions to the gamified model were created via the execution of the Value Add Data software.

The 3D-model that contains a Building Model was realised with the ArchiCAD design software and it was gamified with the Unity Game Engine.

III. The FDM together with the Gamification of the Building Information Models enhance the quality, visibility and understandability in Design

When the practices of BIM develop, new ways to design, visualise and analyse buildings are developed in parallel. The earlier the issues are detected and corrected, the lower are the costs and related work efforts. The FDM we developed earlier is a method and process born out of need. It can be applied very well in parallel with BIM, and could even be standardised to be an integral part of it.

The FDM can be the basis for developing new analysis functions, techniques and methods to support the design process and the designers.

We combined the FDM to the gamification of the Building Models and did research on whether it could be possible to create User Experiences about how the usage of e.g. a wheelchair or a rollator succeeds in the spaces under design.

With the aid of the 3D space objects from the FDM we can generate e.g. Colliders around the functional unit (e.g. a wheelchair user with two assistants). Collider is a term used in Game Design. The Collider then corresponds to the measured space requirements of the human action. In the First Person Controller concept the Colliders created this way can be attached to the virtual model of a wheelchair Use Case. After this we could move around with the wheelchair in the gamified Building Model and swap the Collider according to the actions the handicapped and his assistants were doing.

When VR glasses like Oculus Rift are used, we got a very realistic User Experience about how it would feel to move and perform different kinds of functions with a wheelchair in a real building.

Our partners agreed this kind of visualisations and generation of User Experiences are one of the directions for forcefully developing BIM and its applications. This kind of approach is quite new in the relatively conservative Contruction Industry, but we think it will become more common.

The virtualisation of buildings and gamification open new perspectives to the whole construction business and the design processes used there. It e.g. enables to involve the future users to the idea gathering phase and to the design work in ways not possible earlier.

A. The space required by Human Actions is converted into a 3D object by the FDM

The design needs described earlier get means of enhancement from the FDM from Phil.Lic. Jukka-Pekka Selin. The method helps especially in a situation where the building operations are not yet active but there exists a digital model of the building.

In addition to a mere idea we offer a ready process that enables to transfer the space requirements of real Human Actions to the BIM based designs via our 3D IFC-objects. It is possible to test and simulate with the Building Model how the functional demands fit the rooms under development. The diagram below shows the process of the FDM:

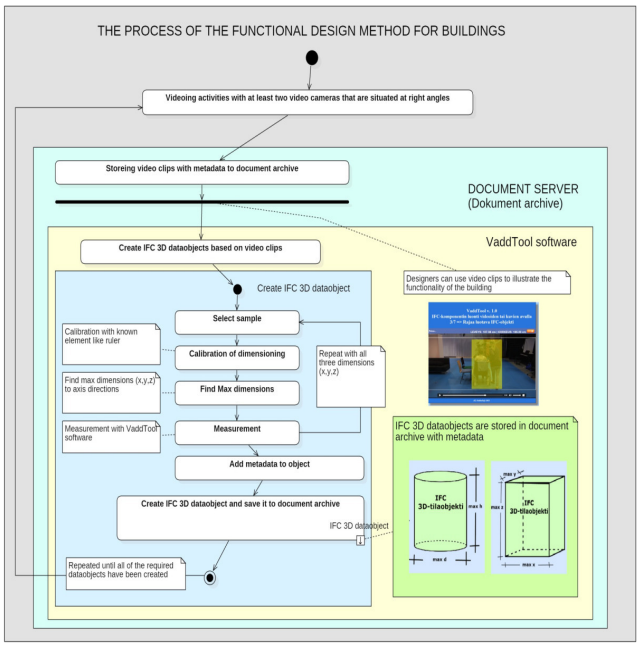

Fig 1. The process of the FDM for Buildings.

An example of the meant human activities is “an assistant who helps a wheelchair user to dress on outdoors clothes“. The invention to use real human activities and turn them into 3D CAD objects is from Licentiate of Philosophy Jukka-Pekka Selin who is the principal lecturer of data processing at Mamk.

Fig. 2 shows how the dimensioning (x, y, z) of the forthcoming IFC data object is performed.

Fig 2. A screen shot of the Space Required by Activity dimensioning function of the Value Add Data software prototype.

B. The Gamification of Building Models with the Unity Game Engine

We realised a pilot project at Mamk where we gamified the building model of the headquarters of the construction company U.Lipsanen Oy. The foundation was the 3D-model from ArchiCAD software. It was a part of the building model [4]. The Unity Game Engine supports importing data in various 3D file formats. After iterative testing and piloting we ended up to recommend that the import format should be the FBX format developed by Autodesk, Inc. [5]. Unity has native FBX support.

C. Simulating the actions of a handicapped building user

We piloted the methods by simulating a wheelchaired, moving person. The space requirements for different actions where first generated by the FDM. The original material was a set of video clips about real actions that were input to our Value Add Data software for creating IFC files.

Fig 3. A 3D building model converted first to FBX has been imported to the Unity Game Engine.

In the pilot we created a Third Person Controller-type Player who moved with a wheelchair. As much realism as possible was programmed for the dimensions, the movements and the building automation. We also created swappable Colliders around the virtual player. This way the space requirements can be swiftly selected according to the action under test. We can see and experience in a concrete way how well the action fits the spaces under design.

The dimension data from the FDM, representing the space need of a real action, can be utilised as such when creating Colliders in the Game Engine. One of the future research topics is to develop an automated creation procedure of Colliders based on the 3D IFC files. The next table below shows as an example the space requirements of two actions studied in piloting.

TABLE I.
MAXIMUM SPACE REQUIREMENTS FOR THE DIMENSIONING OF THE COLLIDERS CREATED BY THE FDM

The dimensioned Action (VaddTool)	Space Requirement (m)
The wheelchair user is helped to dress on or off his shoes by his assistant	1.10 x 1.90 x 1.51 (x,y,z)
The assistant walks with the wheelchair user on the side or behind the wheelchair	1.07 x 1.90 x 1.30 (x,y,z)

Respectively it is possible to dimension and simulate all kinds of actions, also not related to Building Design, by using the Functional Design Method and Gamification of 3D Models. There is a lot of potential in generalisation.

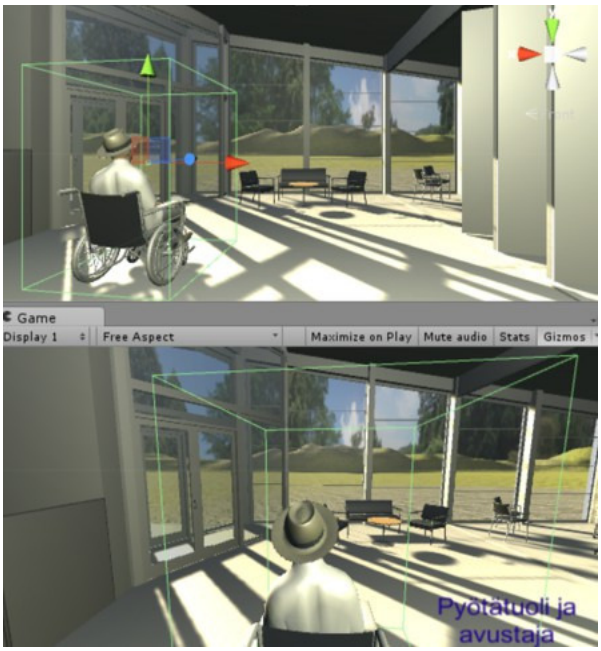

Fig 4. A handicapped virtual player with an added Collider Box (in green) derived with the FDM. Respectively it is possible to dimension and simulate all kinds of actions, also not related to Building Design, by using the FDM and Gamification of 3D Models.

D. Work process oriented, location aware document management and viewing services for the whole Lifecycle

After testing the creation of 3D IFC objects and short term document storage with the Value Add Data software prototype we began to negotiate with the public financiers about developing a service that would manage the documents during the whole lifecycle of buildings. In December 2015 the construction company U.Lipsanen Oy won a partial public financing for their development project RedHal.

The new targeted functionality differs from the presently available services in several features. After the documents reach the status " As built – Ready ", we will move the documents to a long term data repository with a targeted service life of 100 years. The University is an expert in Data Migration through storage technologies and in semantic digital archiving [7].

We are targeting to use indoor positioning in the 0.5 metre accuracy range together with tablets and Augmented Reality services. The data structures both in the Pre As built service and in the long term repository are according to the semantic structures of buildingSMART.

The document viewing will be of an active type. It takes into account the role of the viewer, the location, the orientation and the current phase of the design or construction process. The co-operation between designers will be based on Building Models according to the BIM standards. This project will be finalised by June 2018.

IV. Results and Conclusions

The following picture describes the process aspect in piloting our method.

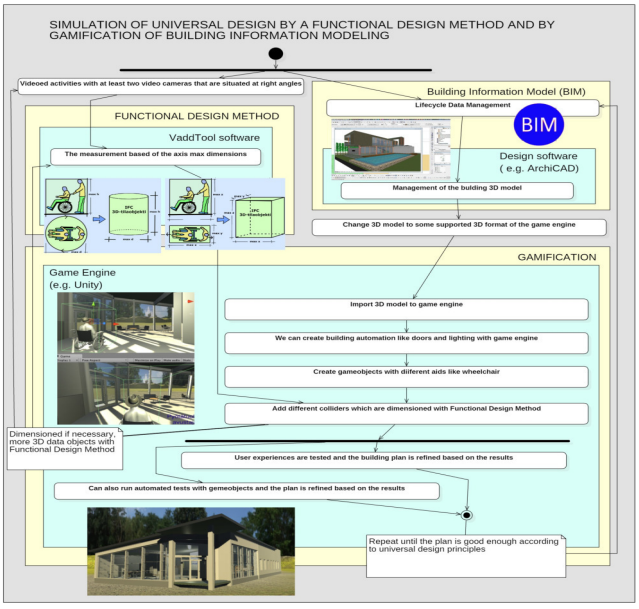

Fig 5. The process developed at Mamk in simulation of Universal Design with the aid of a gamified Building Model.

The results from the piloting are promising. The User Experience in the gamified model can be highly natural. The attendants of the Design Game thought that by bringing a handicapped virtual player to the game, a demonstrative and mind-expanding understanding was created about how well the building corresponds to users' needs.

Their opinion was that the method helps any designer to take the position of a handicapped user and this way to understand their needs and take them into account. The method also helps to test how well the building automation (e.g. active doors and adaptive lighting) serve different users. The FDM was found during the piloting also to be practical in ensuring that the spaces are dimensioned according to real needs. The idea behind the developed method about FDM based Colliders for the Players in a simulation based on gamified Models was found to be good and practical.

We also studied the automating of dimensioning testing by moving Players with Space Requirement Colliders automatically through pre-selected rooms in a way that the collisions and reroutings were documented to a log. Now we saw at once the locations which were too small or narrow for the required actions. It was also possible to study the steepness of ramps. The partners said the gamification of Building Models and the virtualisation of the usage of buildings create new and necessary dimensions to the whole building design process and we have the right future direction in our research. The development of Design Processes can now move towards crowdsourcing and communitisation by bringing the gamified Building Model e.g. via the WebGL technology to the Net and by enabling the future users of buildings access to the preliminary designs, for commenting. We think these processes can help in creating buildings that really fit the users' needs.

Evaluation of Affective Intervention Process in Development of Affect-aware Educational Video Games

Mariusz Szwoch
Gdańsk University of Technology
Faculty of Electronics, Telecommunications and Informatics
G. Narutowicza St. 11/12, 80-233 Gdańsk, Poland
Email: szwoch@eti.pg.gda.pl

***Abstract*—In this paper initial experiences are presented on implementing specific methodology of affective intervention design (AFFINT) for development of affect-aware educational video games. In the described experiment, 10 student teams are to develop affect-aware educational video games using AFFINT to formalize the whole process. Although all projects are still in progress, first observations and conclusions may already be presented.**

I. Introduction

AFFECTIVE computing is an emerging field of computer science that deals with human affects. As affective applications try to automatically recognize, interpret and react to human emotions, their development demands interdisciplinary research incorporating not only computer vision or pattern recognition but also human behavior studies such as psychology and cognitive science. If such affective awareness is built into an application to extend its functionality, it is called *affect-aware*; in contrary, the primary goal of *affective applications* is focused on human emotions. The concept and potential of affective and affect-aware applications may be effectively exploited in the nearest future in many fields, such as healthcare, education, entertainment etc.

Video games seem to be among the most natural application area of affect-aware concept. Practically all entertainment provided by video games to a player is somehow based on his or her emotions. It is usually informally introduced into the game at its development stage based on the assumed model of so-called representative player. Unfortunately, such a static approach does not take into account that each player differs to a certain extent from that averaged model and, more importantly, a player's affective state can dynamically change, even radically, from session to session making it almost impossible to predict the current emotions at the development stage. That is why, it is so important to create at the development stage emotional model of the player and implement some methods of emotion recognition or estimation.

Unfortunately, there are no standards of development affective or affect-aware software. Existing methodologies of software engineering have no intrinsic rules or templates that would enable development of affect-aware or affective applications. Recently, a new methodology of affective intervention design (AFFINT) has been proposed [1] for development of affect-aware intelligent systems. The proposed process consists of 10 development steps with a predefined order of their implementation. The practical implementation of AFFINT process have been explained using three case studies of Gerda tutoring system and two prototype affect-aware video games.

Despite the exhaustive description of AFFINT process and given case studies the question arise whether it is already ripe enough to be directly used by software engineers to develop affect-aware and affective applications. In this paper, the initial experiences are described of using AFFINT process in development of 14 prototype affect-aware educational video games. Although, games are developed for different platforms and using different technologies their common denominator is their educational aspect and mandatory use of AFFINT. Gathered programmers experiences allow to supplement AFFINT description with some practical comments and examples.

II. Background

In general, the main goal of adding affect-awareness into any software is to enhance its primary purpose, or functionality, by adjusting some of its elements to the current emotional state of the user. Such modification of a system behavior according to the user's affective state is called *affective intervention*. There are possible different aims of such affective intervention, depending on such aspects as the application area, the system goal etc. For example, an educational program may try to keep the user in the so called *flow state* that provides the best learning

This work was supported in part by Polish-Norwegian Financial Mechanism Small Grant Scheme under the contract no Pol-Nor/209260/108/2015 as well as by DS Funds of ETI Faculty, Gdansk University of Technology.

effects [2]. In contrary, a video game do not always has to keep the player in a specific emotional state; instead, it can adapt the gameplay, especially its difficulty, to give the player the best playing experience at the moment [3].

In order to effectively implement affect-aware functionality in any application software engineers have to formally define *affect model* of its user and *affective intervention model*. The first model defines what emotional states of the user are taken into consideration, while the second one defines conditions and realization way of the performed affective intervention [1]. What is the most important these models have to be defined in the very early development stage of software development, regardless the methodology used. Such approach guarantees that affect-awareness is taken into account already in the project phase preventing from adding affect-awareness as additional feature to already developed application.

Unfortunately, there are no specific software development methodologies defined for development of affect-aware of affective applications and AFFINT process is the only formalized proposition enabling the design and evaluation of affective intervention models [1]. Affect-aware and affective software is obviously dependent on various methods of recognition or estimation of user's emotion. Such methods may use, in general, different input channels according to different ways of emotions' expressing [4]. The most frequently used emotion recognition methods include:

- facial expression recognition (FER) based on video input channel [5], thermovision or depth sensors[6];
- voice analysis based on audio channel [7];
- analysis of physiological signals such as heart rate or skin conductance [8][9];
- textual input analysis in using a system interface [10];
- analysis of different behavioral patterns in using standard input devices such as mouse, keyboard, and pad [11][12];
- analysis of the current user's progress within the application, e.g. in a quiz or gameplay, and additional application events, such time lapse, new challenge [3].

Although these methods can be used alone, better results are usually obtained by fusing information from diverse input channels (*early fusion*) or different methods and algorithms (*late fusion*) [13].

The second element of affective and affect-aware software is *affective intervention*, which is a program response to the recognized emotional state of a user. There are many studies concerning affective phenomena in human-computer interaction (HCI). They focus on many different aspects, such as defining users' emotional states appearing during satisfying and unsatisfying experiences with applications [14], using affective interventions to reduce users' frustration [15] and increase their efficiency in the performed tasks in particular application domain, e.g. e-learning.

Another group of publications focuses on design and evaluation of affective applications and their affective interfaces and interactions [16]. Many studies emphasize the fact that abandoning the concept of a 'standard user' (or player for video games) in favor of adaptive affective approach often leads to greater users' satisfaction and more efficient and effective performance of their tasks [3][16]. On the other side, affective interventions must be subject to certain rules, restrictions and limitations concerning their frequency or influence upon the user [17]. Such rules allow combining emotion recognition methods and affective interventions into *affective feedback loop*.

III. AFFINT PROCESS

AFFINT approach proposes a ten-step process that formalizes incorporation of affect-awareness into the software development methodology [1]. These ten activities are numbered in the desired application order and mapped into the four stages of system development (Fig.1):

I. System definition consisted of three activities:
1) *Application goals and tasks* that should be supported by affective subsystem;
3) *Available input channels in application environment* that can be used by emotion recognition or estimation algorithms;
6) *Available output channels in application interface metaphor* that can give the user a feedback about the recognized user's emotional state or the performed affective intervention;

II. Affective intervention solution set that includes:
2) *Effective emotional activations* that defines a subset of user's emotional states that are optimal to reach the application's goals;
4) *Available emotion recognition solutions and representation models* that can be used in the application;
7) *Possible affective interventions of an application* that define list of possible scenarios;

III. Affective intervention model layer that comprises:
5) *Emotion recognition granularity and methods* that define the specific emotion representation model and characteristics to be used in emotion recognition;
8) *Affective intervention triggering rules* that binds possible emotional states of the user with affective interventions;
9) *Affective intervention constraint rules* that limits the frequency and scale of affective interventions to create less artificial human-computer interaction;

IV. Evaluation of intervention model layer containing
10) *Validation with end users*, which is a natural assessment of application's quality.

As the proposed order of performing particular activities is not absolute within each layer, additional precedence, or dependence, relations are proposed to ensure their proper and logical sequence (Fig.1). The detailed description of AFFINT is available in [1].

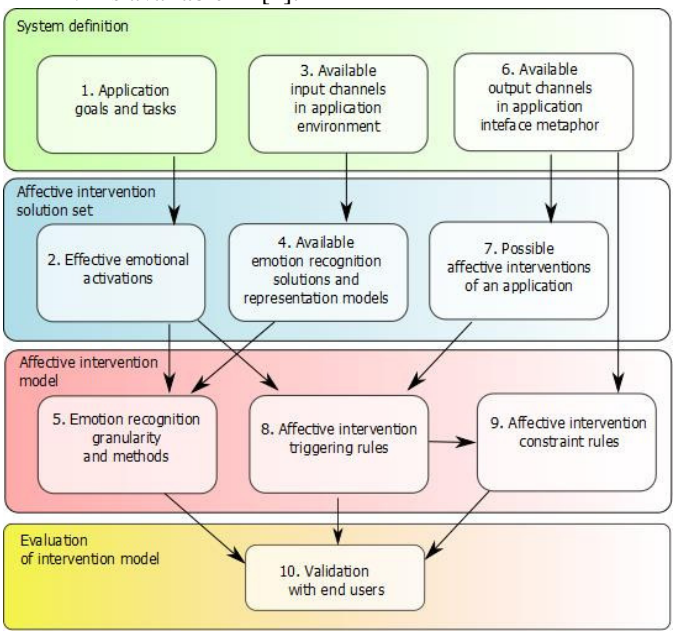

Fig. 1 AFFINT process of affective intervention design (arrows indicate precedence) [1]

IV. Experiment Assumptions

Although AFFINT process and its three case studies have been described in details, its applicability in practical software projects remains unknown. Three important questions have to be answered. Firstly, whether the AFFINT process is general enough that it can be used in wide spectrum of affective and affect-aware applications? Secondly, whether its description is sufficiently comprehensive, detailed and coherent to be easily followed be software engineers for such applications? Finally, is the proposed order of defined activities correct and how it should be mapped into development stages of different software development technologies?

An exhaustive answer to all these questions demands in-depth analysis of many different projects developed in different fields of applications using different methodologies of software engineering. This paper describes the first of series of planned experiments. In this experiment, 10 groups of experienced IT students at Gdańsk University of Technology (GUT) were given a task of designing and developing an affect-aware educational video game during a one-semester project within Interactive Multimedia Systems course. Narrowing the topic allows to focus on the second and the third of the asked questions, e.g. easiness of AFFIT's implementing in his specific domain by software engineers with no previous experience in affective computing.

All participating groups were allowed to choose the main target platform of the game, their preferred development environment and, of course, to design their own concept of the game. One additional requirement of using specific Emotion Recognition Framework (ERF) [3] was bound to PC target platform. Finally, four teams decided to develop a game for PC platform, three teams target at mobile devices (with Android system), and two groups decided to develop web applications (Table I). Almost all teams preferred to use Unity 3D environment, except one team whose members decided to use Phaser framework. These choices where made mainly based on their knowledge of particular environments. Additional advantages of Unity taken into account were its popularity and the fact that it allows deploying the same project to different target platform with relative easiness.

TABLE I.
PROJECT DECISIONS ON TARGET PLATFORM AND DEVELOPMENT ENVIRONMENT

Target platform	Development Environment	Number of teams
PC (Windows)	Unity	5
Mobile (Android)	Unity	3
Web (HTML5)	Unity	1
	Phaser framework	1

V. Validation of AFFINT Process

All teams' members participated in a special lecture dedicated to affective computing, video games and educational software. This allowed to specify the general characteristics, goals, limitations, and minimum requirements. With this background, students were given the article [1] describing the AFFINT process to verify whether the given description and case studies provide a sufficient basis for its direct implementation. Due to the short time of the project, the development process has been arbitrarily divided into four reported stages, namely Requirements Specification (RS), Game Concept and Design (GCD), Implementation and Tests (IT), Verification of Requirements and Product Validation (VRPV). Within the experiment, all teams were to map and to define particular AFFINT activities into these stages on their own.

Unfortunately, most teams reported that despite the detailed description, they still had some doubts and questions. The most important problem was that the suggested order of implementing particular activities is not always obvious and possible to follow. For example, it was quite easy to define some elements of the activity 5 (e.g. emotion recognition granularity) at the GCD or even RS stage, while proper identification of available emotion

recognition solutions demands sometimes in-depth studies that postpone reaching another development phase.

All these problems indicated that design and development of affect-aware applications, even using formal and detailed AFFINT model, requires some knowledge and experience in the field of affective computing. In this experiment, additional training lectures were offered to the students as well as individual tutoring for each project. This allowed to overcome most initial difficulties and problems with proper definition of AFFINT activities. In order to deal with some knowledge gaps at the early stages of the project, an incremental approach was accepted, that will allow to extend or even modify previously defined AFFINT activities when new information becomes available.

After two first stages of video games' development, some interesting observations and conclusions may be drawn from using AFFINT process in the described experiment. Definition of activities 1-3 & 6 was quite easy and natural. Application goals and tasks (act.1) are strictly bound to the specific concept of the application. For the definition of effective emotional activations (act.2), all teams, except one, assumed usage of one axis of the Pleasure-Arousal-Dominance (PAD) emotional space. It significantly simplified the description of users' emotions by using single variable with negative and positive values. All these teams defined exactly three recognized emotions: positive (e.g. joy), zero (neutral), and negative one (e.g. sadness). One team assumed usage of two axes (PA) and recognition of five emotions, but subject to possible reducing after initial tests of recognition methods.

All teams targeting at PC platform planned to use video as a base input channel (act. 3) additionally supported by analysis of usage of standard input devices, e.g. keyboard (three teams) and mouse (two teams). This was an optimal choice taking into account existence of few off-the-shelf libraries for face detection and facial expression recognition like Noldus FaceReader, and other. Unfortunately, there are no such trusted and freely available solutions for the mobile devices, and web applications has serious limitations in the access to system resources. That is why other teams relied mostly on emotions estimation by analysis of the players' behavior during the gameplay. Additionally, one team planned to use fitness bend with Android driven smartphones and tablets, while developers of web application planned to analyze mouse movements and clicks during the play. Finally, available output channels in all designed games were defined as gameplay difficulty and additional visual effects.

Although all teams were on the same development stage, the progress of their concepts, design and AFFINT description varied considerably. While some teams assumed additional tests and research of emotion recognition possibilities, other teams presented consistent and complete vision of the game. For example, Fish Quiz game for young players assumed development of motor skills of the player as well as broadening his or her knowledge in ichthyology. The goals of the player are to click on different fish species (Fig.2a), avoiding crabs, and correctly answer quiz questions to advance in experience levels and receive medals (Fig.2b). The affective model of the player consists of two states, namely joy and frustration, which are controlled by only one parameter influenced by successful and failed clicks. Thus, the input channel contains only mouse clicks and players advances within the gameplay. In turn, affective intervention controls the fish speed, their attraction to the mouse cursor, and the frequency of crabs appearance.

Conclusion and Future Work

The described experiment has brought several interesting conclusion about development of affective and affect-aware software in general, and usage of AFFINT process, specifically. First of all, development of such applications demands software engineers with some experience in this field or at least trained in the appropriate theory. Contrary to initial expectations, it seems impossible to correctly project and develop such applications using AFFINT

without basic understanding of advantages and limitations of affective feedback loop, possible emotion recognition methods and their input channels, and also about the possible spectrum of affective interventions.

Secondly, not all AFFINT activities can be precisely defined at the early stage of requirements specification or game concept and design, as they may need some additional tests or at least tuning. Using an incremental model for AFFINT definition seems to be a good approach. Despite described problems, AFFINT process proved to be very useful formalism that enforces taking affective issues into account during the whole design and development of affect-aware and affective software, especially in e-learning and video games.

Our future work will focus on introducing some modifications to AFFINT process in order to make it more flexible and thus better tailored to deal with possible uncertainty in various aspects in development affect-aware applications as well as with the specificity of agile methodologies of software development. Additionally, analysis of AFFINT documentation from all ten projects along with some feedback from developers will allow us to enrich the process with a set of predefined solutions for different stages of development of affect-aware applications.

***Abstract*—In this paper we present the results of a study that aims to evaluate the usability of three selected web services, based on eye–tracking and thinking aloud techniques. The gathered comments and observations, recapitulated and supported by particular measures, allow us to discover and describe typical user behavior pertaining to given tasks to solve.**

I. Introduction

WEB portals are one of the main sources of information and news. These were some of the first information services that nearly a quarter of a century ago appeared on the Internet. Initially, they delivered information in a similar way to newspapers, but they also contained links to other subject-related services. However, the most important role of a portal is still to provide timely and reliable information, relevant to Internet users' needs. Unfortunately, as shown by the results of the research presented in this paper, users often have trouble finding even basic information that, due to the nature of the service, should be available there.

It may be noted that Internet users seek information in two ways: if the type of information is sought occasionally (e.g. only once), then they use a search engine, such as Bing, Google or Yahoo [1]. In contrast, when they frequently seek information of the same type (e.g. exchange rates on the current day), then they use proven and trusted web services, such as Internet portals [2].

Over the years, we can observe how, under the influence of development of technology and design trends, the appearance of web pages and the way information is exhibited is changing. User behavior patterns of searching for information are changing as well. These patterns are affected by many factors (which enforces a different way of seeking information), e.g. the more intensive use of mobile devices, the age or even the gender of users [3, 4]. It was the basis for the research enabling the observation and description of patterns that can be found among current users, and also the determination of the reasons why access to some types of information is difficult (or even unavailable) and how to prevent this.

II. Related Works

Montero *et al.* [5] showed that the essence of design patterns is to capture the design experience in such a form which can be used effectively and repeatedly. However, adapting patterns is not a straightforward task, because the designer must demonstrate expertise and flexibility in the design process and operate on a high level of abstraction. The authors proposed conceptualizing web design pattern knowledge into the form of an ontology. The depicted generic hypermedia model, which describes the structure of a hypermedia application, includes such elements as: *node* (an information holder, e.g. a web page, a frame, a pop-up window), *content* (a piece of information, e.g. a text, a binary file or an executable application), *link* (a connection between two or more nodes or contents) and *anchor* (a source or target reference to an internal or external content or node). Design pattern format, usually expressed in natural language, is typically specified by such attributes as: *name* (an unambiguous identifier), *category* (used to classify the pattern body based on several criteria, like purpose or scope), *problem* (outlines the adaption scenario), *solution* (outlines the desired outcome) and *related-patterns* (depicts equivalents).

Based on Jakobson's communication model, Thorlacius [6] introduced and elucidated a visual communication model, where web-specific aspects in terms of navigation and interaction were taken into account. The model consists of the six following factors: *product*, *context*, *medium*, *code*, *the addresser* (actual or implicit) and *the addressee* (actual or implicit). The product is both the content and the form, along with two communication functions: formal and sublime aesthetic. The first one is the concept of visual symbols, considered in terms of colors, illustrations, typography and design in accordance with modern conventions of website layout; it reflects user experiences that contribute to "good look and feel". The second function is the question of when and where to use visual elements like flash animations and expressive illustrations, and whether innovative design should be applied; it arises from "the space between the known and the unknown" and is harder to describe in detail. The context refers to the featured (core)

content of the product. The medium is the connecting link between the addresser and the addressee in order to establish a communication channel. The code is a system of signs where each unique sequence returns a different meaning, which is presumed known to both sides. The addresser is a single person or persons responsible for the content being published on the website, where the actual is the only person who speaks for himself about the real intentions which lay behind the website, and the implicit is directly personified by visible means on the website. Finally, the last factor in the cited model is the addressee, who is the content receiver, who can actually experience the product (actual) or who can be identified through an appearance analysis (implicit).

III. Experimental Setup

A. Participants

43 participants were involved in the experiment: 21 males and 22 females, with the age average of 22.53, all students of the Gdansk University of Technology, the Faculty of Management and Economics.

B. Apparatus

In our research, eye movements (saccades, fixations, pupil diameter) were recorded with the infrared camera-based Tobii TX300 eye-tracker system, where the light source and camera are permanently affixed to a monitor. It has a 300Hz sampling frequency, and the tracking technique is "dark pupil". We used Tobii Studio software working under MS Windows7 (x64).

During the experiment the voice conversation between the moderator and participant was recorded and we made handwritten short notes of comments and remarks, and evidenced the results of tasks given to solve. Tobii Studio allowed us only to use Internet Explorer as a web browser, from this reason we were not able to examine other web browsers.

C. Objects and stimuli

The set of objects consists of three different web portals that bring information together from diverse topics and sources in a uniform way. Onet and Wiadomosci24 are the most recognizable Polish-language web portals in Poland, along with the English-language BBC. All of them are information-aware, where up-to-date news, gossip and advertisements play a major role. The context surrounding the examined websites is largely the same, where the top three mainstream contexts can be distinguished: political, social and economic. However, they differ significantly if the context scope is taken into consideration. The addressers are a group of people involved in developing, maintaining and promoting particular sections of a website, in cooperation with journalists that comment on the current information stream, carry out interviews, and report events and facts on the site. The addressees are generally users who purposely request access to website resources, using a suitable electronic device (e.g. personal computer, tablet or smart phone).

D. Procedure

The procedure consisted of 18 steps (Fig. 1), including 8 instructions (I), 3 questions (Q) and 6 tasks (T). The first instruction (I1) was a welcome screen and briefly described the purpose of the research. Next, in three questions (Q1-Q3) we asked the participant respectively about their sex, age and English language skills. Each of the second to the seventh instructions (I2-I7), preceded and described the subsequent tasks (T1-T6), and the last instruction (I8) was an acknowledgment of participation.

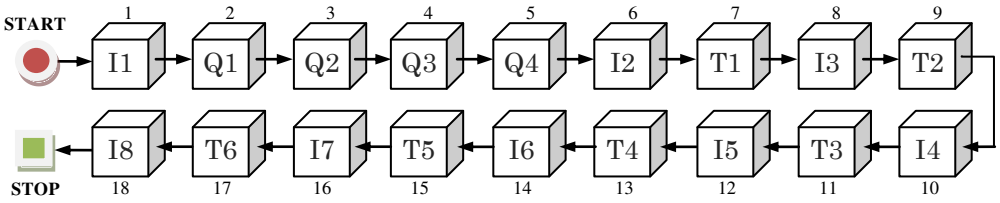

Fig. 1. The research procedure sequence

There were two separate tasks defined: the first was to find the current weather in Gdansk and the second was to find the exchange rate of Polish currency to the Euro. The maximum time allowed per task was 60 seconds. Tasks T1 and T2 were performed on Onet, T3 and T4 on the BBC site and T5 and T6 on Wiadomosci24. We decided to use the thinking aloud technique during the test to help in understanding the manner of each participant's behavior while performing the task.

E. Eye movement analysis

A quite apparent assumption laid the foundation-stone for the concept of areas of interest: *informative regions of a scene receive more of an observer's attention than the less informative regions do*. In this context, the qualifier "informative" reflects the degree of how much that particular area contributes to the understanding (perception) of the scene of sight from which the area is taken. However, a separation of such areas still poses many challenges for the development and research community. In Tobii Studio, AOIs are created by drawing ellipses, rectangles or polygons over any type of stimuli to get statistics for eye-tracking metrics for one or more recordings.

IV. Results

Quantitative and qualitative methods to collect data were concurrently used that respectively correspond to the eye-tracker device and thinking aloud technique. The quantitative analysis (heat map method) helped to identify the main areas of the participants' interest which drew their attention the most.

The analysis of the Onet service (Fig. 2) shows the largest concentration of the participants' sight on the information in the upper right corner of the site. The influencing factor for this might be the fact that the participants declared the greatest knowledge of this web service.

Fig. 2 The Onet heat map

In case of the BBC service (Fig. 3) we observed an increased interest in the upper part of the service. This was the location of the menu bar which was thoroughly followed by the participants.

Fig. 3. The BBC heat map

Interestingly, the participants also declared the lowest knowledge of the BBC service. This means that their behavior was the most natural and intuitive, and that there were no disturbance factors, such as prior acquaintance with the site.

The analysis of the Wiadomosci24 heat map (Fig. 4) allows for the observance of an increased concentration on the largest graphic and a field in the upper right corner of the service. The interest in the field (in the upper right corner) could result from the order of task execution.

Fig. 4. The Wiadomosci24 heat map

In this case the participants sought required information in the similar areas like in the case of Onet service. Such behavior was probably a result of prior connotations and users' experience with previously tested websites.

In addition, the quantitative analysis involved the reconstruction of video records and the verification of handwritten notes from the study. The data analysis helped to identify three dominant patterns of behavior among users in terms of how they try to reach the necessary information:

- *search tool*, a method based on finding the website search tool, which leads the user to the desired information by entering a user keyword;
- *menu bar*, a method based on finding the options bar or toolbar; analogically to the software application, the user tried to use a systematized and categorized tool (e.g. the menu bar), which should lead the user to the desired information;
- *home page*, a method based on searching the website's home page content for information; the user that decided to search the information service expected that they would find information on the home page.

Table I shows how often the particular method of

Table I
The Results Summary Of The Conducted Observations

Method of search information	Onet		BBC		Wiadomosci 24		AVG
	T1	T2	T1	T2	T1	T2	
Search tool	2	5	25	19	27	20	16.3
Menu bar	15	25	30	42	39	40	31.8
Home page	41	42	39	40	39	37	39.7
Number of participants	43	43	43	43	43	43	-

information search were used in the particular web service. The results of the first task showed the differences among the participants in the selection sequence of a particular model of behavior. Some of the participants decided to seek information through the menu bar, some by analyzing the contents of the home page, and some by using the search tool (both available in the information service, as well as a built-in web browser). Such behavior patterns may have many origins: previous experience in use of the particular service or knowledge of the language in which the content is presented (the participants declared different level of English language skills). These are certainly factors requiring further research on their impact on the behavior of users of information services in their search for desired information.

In the second stage of the analysis of the results of these studies, information for previously identified ways to search was verified. For this purpose, we defined areas of interest (AOI) for each of the services. They included a specific part of the site which contained information belonging to one of three identified groups ("search tool", "menu bar", "index/home page").

The quantitative analysis of models of user behavior, in the context of the search for information in each individual information service, was carried out using the following variables: *time to first fixation*, *fixations before the participant appears in the AOI, fixation duration*, *fixation count*, *visit duration*, *total visit duration*, *percentage fixated*, and *percentage clicked*.

An analysis showed significant differences regarding the usability of the home site, as well as allowed to identify changes in the behavior of tested users, depending on the home page services. In the case of the Wiadomosci24 service the study participants focused their sight on a two-column layout. The structure of other services resulted in a single-column data analysis. The reason for this and no other particular behavior was probably the difference in the system frame, which in the case of Wiadomości24 was more diffuse. The participants enjoyed situations when sought information was displayed directly on the screen and it did not require the user to additionally scroll through. However, the lower the content was on the home site, the decreasing level of interest was observed. The Wiadomosci24 service was a kind of exception. In this case, the participants analyzed the content available at the bottom of the website for much longer. The reason for this was probably the form that resembles the structure of a typical “toolbar menu”. For the rest of the websites there was the same trend (as in the case of the Onet and BBC services) – the lower the position of the content, the less the interest of the user.

V. Conclusions

The aim of the study was to analyze the typical behavior of users of web services in the search for information. The research helped to identify not only common patterns and behaviors that occurred among users. The first stage of the analysis of the study results allowed typical patterns to be identified, which consisted in an attempt to find the desired information through the search tool, the menu bar, or an analysis of the home page. Then quantitative analysis confirmed the foundations of the first stage of data analysis and identified probable causes of the different behavior of study participants.

All participants completed the first three tasks, whereas none of them were able to complete the last three. We purposely designed a set of tasks in such a manner where the first part was solvable while the second was unsolvable. Such a scenario aimed to stimulate participants to comment on obstacles and constraints, which eventually led to evaluate the usability of a particular service on the one hand, while on the other hand, random surfing progressively and subconsciously increased their concentration and cognition in order to solve given tasks. In consequence, we observed different kind of reactions: surrender (task abandonment after a few failed attempts), impatience (increasing tension and distraction over time) and self-inventiveness (out-of-the box actions, i.e. taking advantage of web browser functionality, opening new tab windows, simultaneously using well-known search engines).

To the best of our knowledge, eye-tracking analysis combined with the thinking aloud technique can provide valuable guidance to designers on the construction of information services and a starting point for further refinement of usability. In the near future, we plan to evaluate different structure patterns of websites and investigate the scale of interactions between three different groups of artefacts (i.e. standards, interface schema and data flow diagrams) in order to embody modifications included in subsequent prototypes, developed in Python. Moreover, we will verify the usefulness of the evaluation matrix template, introduced in [7].

***Abstract*—Face emotions analysis is one of the fundamental techniques that might be exploited in a natural human-computer interaction process and thus is one of the most studied topics in current computer vision literature. In consequence face features extraction is an indispensable element of the face emotion analysis as it influences decision making performance. The paper concentrates on classification of human poses based on mouth. Mouth features extraction, which next to eye region features becomes one of the most representative face regions in the context of emotions retrieval. Additionally, in the paper, original mouth features extraction method was presented. It is gradient based. Evaluation of the method was performed for a subset of the Yale images database and classification accuracy for single emotion is over 70%.**

I. Introduction

VISUAL determinants revealing human emotions comprise [1]: emotional voice, body pose, gestures, gaze direction end facial expressions. Thorough and complete human emotion analysis should consider also state of human environment, both current and passed, that may originate emotions. Typical spontaneous, emotions accompanying, muscular activity last usually between 250 ms and 5s – very rarely longer [1]. As a result not only location of human action is important, but intensity and its dynamics as well. In 1971 Ekman and Friesen [2] postulated 6 basic emotions that reveal distinctive set of features with unique facial expressions. These are happiness, sadness, fear, disgust, surprise and anger. Face poses visual recognition or even monitoring may have considerable influence not only on building playful and intelligent social living environment, control employing nonexpert workers (i.e. crowdsourcing [3]) but also on our security as well (i.e. video surveillance system).

Surveying facial expressions, mouth region seems to be the most representative next to the eyes region. This paper concentrates on visual mouth features extraction which have key influence on further facial expression and emotion detection analysis. The new approach bases on local intensity gradients and subsequent dedicated impulse filter responses. Precise extraction of mouth features can increase the efficiency of a classifier by decreasing its complexity. Authors present a new, alternative method of mouth characteristics extraction and evaluate effectiveness of the method on the well known and reliable Yale faces database [4]. The paper shows also classification results based on elaborated method for common used classifiers.

II. Related work

Biologically facial expressions are generated by contractions of facial muscles, which cause face features temporal deformations. The most evident changes concern eye lids, eye brews, nose, lips or skin possible wrinkles. Facial expression intensity can be measured by geometric deformation of facial features or facial texture analysis, i.e. density of face appearing wrinkles.

Among anthropologically justified face core landmarks forming unquestionable framework for face features extraction researches [5] proposed 11 points: pronasale, alare (left & right), subnasale, chelion (left & right), endocanthion (left & right), exocanthion (left & right) and sellion (fig. 1). Subsequently some minor landmarks can be evaluated.

Face features extraction methods, presented in literature, can be classified into two main groups: appearance based and geometric based methods [6]. Though the appearance based approach seems to be currently the most popular, the geometric based methods seem to be recently neglected but still promising. Even though the geometric approach seems to be very well studied [7], [8], according to Pali [9], among the most evident aspects that can be still improved, within face features extraction, there are dimensionality reduction, features extraction techniques and features subset selection. Thus, the geometrical approach can almost automatically reduce space dimension problem and behave more reliably in demanding scenarios where pose (in-plane and out of plane face rotations) and illumination are not controlled [10].

Face features detection is a challenging task as, due to the quantity of local face image structures, classical corner detectors are useless without considering their context. Researches estimating face inherent features and edges date back to well known Kanade work [11] and were further intensively developed (i.e. [12]). Authors attempted to reconstruct horizontal and vertical lines applying Laplacian operator and evaluating horizontal and vertical integral image projection obtaining effectiveness of about 75% on dedicated, self-prepared databases.

Castrillon [10], Castille [13] and Yang [14] suggested Viola-Jones object detection algorithm for coarse face parts (i.e.: eyes, mouth, nose) localization but it did not localize precisely face landmarks and required further, more detailed features detectors. Even Panning [15] and Wang et al. [16] approaches, measuring distances between face regions, detected with originally elaborated features or Lienhart [17] extended Haar-like

978-83-60810-90-3/$25.00

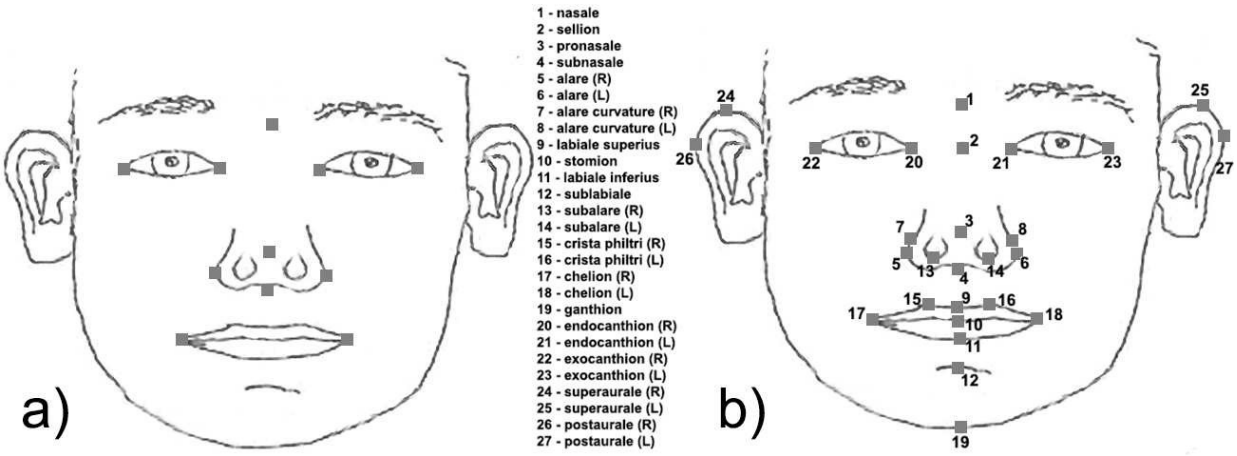

Fig. 1. a) Set of 11 anthropological landmarks (small square) used for face identification and face expression analysis b) Minor landmarks (small square) to improve accuracy

features, required consequent holistic extensive well trained classification.

The process of face landmark thorough detection should be introduced by an appropriate in-image face detection. Subsequently extracted landmarks can be used then for facial expression classification. Face localization and general face features extraction can be performed in tances between face regions, detected with originally elaborated features or Lienhart [17] different manner. Common solutions encompass deploying of a sequence of Haar-like features according to Viola-Jones algorithm [13], [18], eigenspaces [19] also referring to 3D model [20], skin color segmentation [21], statistical methods [22], [23] or active contour or shape models [24], [21].

Some authors [25], [26] exploited local binary patterns (LBP) idea for face image features extraction. Their extension: Local Direction Patterns (LDP) and locally assembled binary (LAB) features [27] appeared to be quite efficient for face edges detection and partly inspired authors of this paper for gradient distribution analysis.

If dedicated mouth features are further required, within face region analysis should be performed. Kim [28] and Chien [29] analyzed grid-based and coordinate-based lips features (width/height of outer/inner lips edges) for Korean language words recognition support. Matthews [30] exploited AAM and ASM for mouth visual shape description for lips reading. Shen [31] and Lewis [32] analyzed color space for lip features retrieving. He et al. [33] proposed modified Biologically Inspired Model of face features extraction improving the SVM classification of face smile. Su [34] suggested geometrical and Gabor filter retrieved face features fusion for better facial expression recognition.

Aforementioned approaches, though well studied and elaborated, lack of generic simplicity which lies in mouth lines detection. Presented method robustly extracts simplified lips edges by means of originally elaborated gradient-based approach which can be subsequently interpreted. Presented solution provides a representative set of features for mouth classification and consequent facial emotions recognition. It was additionally tested on a subset of Yale faces database [4]. It uses many of commonly used classifiers to show that presented method provides sufficient information which enables the detection or identification of face emotions.

III. Mouth features extraction method

To detect mouth shape features we need to find human face and relative localization of the mouth. Next, we can try extract mouth shape from it. Aggregated mouth features extraction process can be completed within subsequent steps:

1) Finding face,
2) Finding mouth on the face,
3) Mouth segmentation,
4) Features extraction.

In image face localization can be performed by means of Haar-like features method [17], but it will not be described here, because it is a part of another problem. Localization of mouth within the face region is a similar problem and can be completed with an analogical set of Haar-like features. That is why further, core mouth features analysis, assumes that face image is cropped to mouth with some border, as shown in fig. III

Mouth segmentation is then performed in several steps. These can be described as:

1) Gradient calculation,
2) Resulting image normalization,
3) Resulting image filtering,
4) Resulting image thresholding,
5) Noise removal.

To retrieve information from mouth images, at the first step **gradient** should be calculated. Gradient of an image is calculated with formula 1.

$$\nabla f = \begin{bmatrix} g_x \\ g_y \end{bmatrix} = \begin{bmatrix} \frac{\partial f}{\partial x} \\ \frac{\partial f}{\partial y} \end{bmatrix} \tag{1}$$

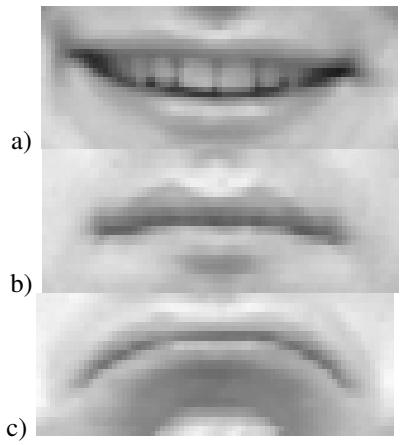

Fig. 2. Example of mouth images: (a) happy, (b) neutral, (c) sad, for subject no. 1

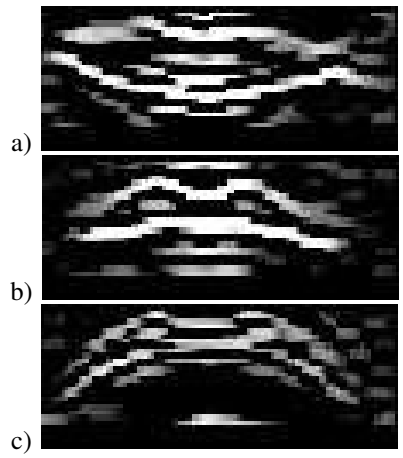

Fig. 3. Example gradient for exemplary mouth images: (a) happy, (b) neutral, (c) sad, for subject no. 1

During the experiments, it was noticed that for descent mouth retrieval there is no need to calculate the whole gradient, but only its vertical part. Using both dimensions of gradient does not give noticeable results improvement, thus, in the segmentation process there was used only vertical component.

To calculate a vertical gradient g_y of image A we can use simple filter, as it is shown in equation 2.

$$g_y = \frac{\partial f}{\partial y} = \begin{bmatrix} -1 \\ 0 \\ 1 \end{bmatrix} * A \tag{2}$$

Additionally, extended 3x3 matrix (eq. 3) was used to reduce noise, which introduces additional column on the left and on the right side of pixel position.

$$\begin{bmatrix} -1 \\ 0 \\ 1 \end{bmatrix} \Rightarrow \begin{bmatrix} -1 & \mathbf{-1} & -1 \\ 0 & \mathbf{0} & 0 \\ 1 & \mathbf{1} & 1 \end{bmatrix} \tag{3}$$

The first step results in images with vertical gradient calculated over the whole their area. Additionally, gradient values were squared in order to level up output and remove useless noise (fig. 3).

$$A = \begin{bmatrix} -1 & -2 & -1 \\ 0 & 0 & 0 \\ 1 & 2 & 1 \end{bmatrix} \quad B = \begin{bmatrix} -3 & -10 & -3 \\ 0 & 0 & 0 \\ 3 & 10 & 3 \end{bmatrix}$$

$$C = \begin{bmatrix} -1 & -1 & -1 \\ 2 & 2 & 2 \\ -1 & -1 & -1 \end{bmatrix}$$

Fig. 4. Filter matrices used for edge extraction

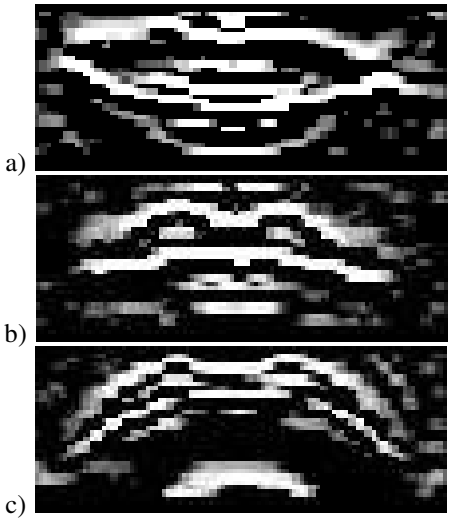

Fig. 5. Exemplary outputs obtained with matrix B from fig. 4: (a) happy, (b) normal, (c) sad, for subject no. 1

The next image processing step was the gradient **normalization**. MIN-MAX type normalization was used to adjust gradient to image full spectrum of brightness.

In the next step gradient image filtering was considered as to extract edges from it. Various filters was tested to extract shapes from images. The best results were obtained by filters represented in fig. 4. Corresponding outputs obtained with matrix B are presented in fig. 5.

After the filtering step a process of **thresholding** was applied to extract shape of lips. It was done by simple cut off image value below certain threshold of pixel brightness. Results were verified for a few threshold values, but overall the best was achieved with 250. Example results obtained with different values of threshold are shown in fig. 6

The subsequent step of the proposed method is the noise reduction. It was achieved by morphological operations performed on image. The best noise reduction was obtained for closing, which is a combination of erosion and dilation. In result shape of mouth was closed as it is shown in fig. 7.

The last stage concerned segmented image features extraction. Mouth corners were selected as initially considered features. They were found by the most extreme edges in all directions: down, left, right and up.

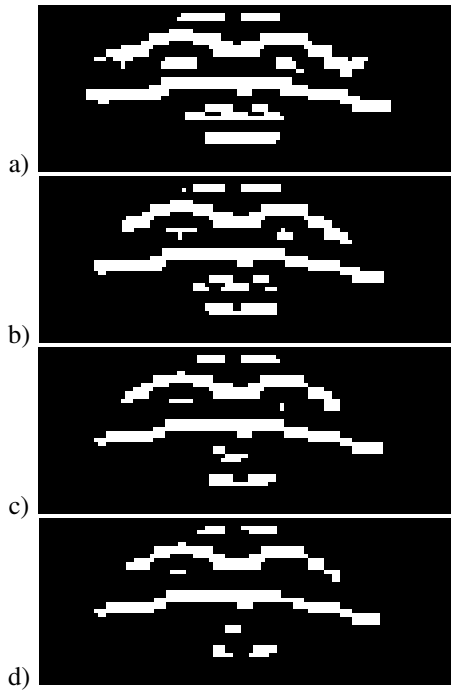

Fig. 6. Example results obtained with different threshold values: (a) 100, (b) 150, (c) 200 and (d) 250, for subject no. 1

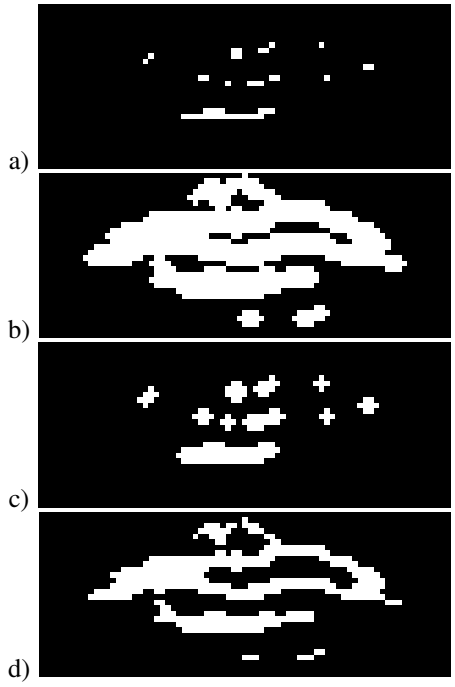

Fig. 7. Example results with different noise reduction: (a) erosion, (b) dilatation, (c) opening, (d) closing, for subject no. 12

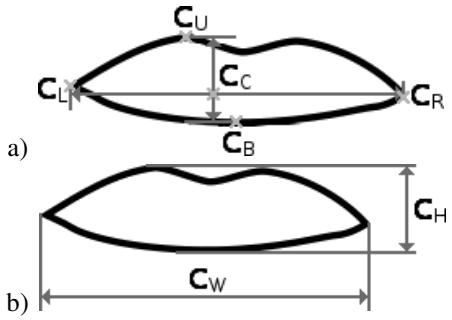

Fig. 8. Feature extraction corners: (a) positions, (b) sizes, for subject no. 1

Edge point c_e is defined as the farthest point in specified direction, as is shown in equation 4.

$$c_e = (x, y) \tag{4}$$

where

$$e = \{ \texttt{B} - \text{bottom}, \texttt{L} - \text{left}, \texttt{R} - \text{right}, \texttt{U} - \text{topmost} \}$$

In case of the left edge $c_{\texttt{L}}$, it is the most distant left point of the largest contour area. $c_{\texttt{R}}$ can be defined analogously, but for the right edge. More difficult is to find the bottom and topmost edge points: $c_{\texttt{B}}$ and $c_{\texttt{U}}$, because often the contour is composed of several separated pieces, so we need to check if the contour size is sufficiently large in relation to the image size. Calculation of the shape size was simply done by following each white pixel connected to initially located edge points ($c_{\texttt{L}}$ and $c_{\texttt{R}}$). In case of contour inconsistence, averaged extreme values (bottom and topmost), retrieved from two separate edges, anchored independently from left and right corners were calculated.

The farthest edges are marked with white and light grey dashed lines. Brighter color is used to mark part of shape with features determining edges (fig. 8).

The collected information was sufficient to easily determine the next two parameters: $c_{\texttt{W}}$ and $c_{\texttt{H}}$. The first one determines the maximum distance stretching horizontally the mouth area, between $c_{\texttt{L}}$ and $c_{\texttt{R}}$, on the average height between them. Similarly value of $c_{\texttt{H}}$ was determined.

With a **cross-section** $c_{\texttt{C}}$ of width $c_{\texttt{W}}$ and height $c_{\texttt{H}}$, it is possible to interpret shape of the the mouth. Cross-section is always defined, because interpreted shape corners c_e are also determined.

Additionally, c_{h_i} as height of some part of mouth shape can be extracted similar to $c_{\texttt{H}}$, but calculated as height between the top most point in shape and the lowest one for some i position horizontally.

IV. Features extraction

To evaluate the method a subset of the Yale's face database was used. It comes from UC San Diego Computer Vision [4]. It contains 165 grayscale images of 15 people, originally sized 320x243 pixels, but had manually cropped mouth region with size of 75x30 pixels. Each subject had several images in different face expressions, quality and light conditions, but for

all people those conditions were the same. It allowed us to test elaborated method in various conditions of image quality.

Each image was marked by expert as shown in fig. 9: shape of mouth was built out of 6 points and it was marked by expert with white line, maximum width and maximum height. Marked elements were measured and noted as m_e, i.e. width as $m_{\mathtt{W}}$, analogically to computed values $c_{\mathtt{W}}$ from authors' method.

Exemplary results are shown in fig. 10. In analogy to the reference images, maximum widths (red) and heights (blue) are marked over the image.

Mouth key features evaluation method results c_e were subsequently compared with reference, expert marked points m_e (labeled data). For i-th image, each of key features c_e estimation accuracy ACC was calculated according to equation 5. For cross-section feature $c_{\mathtt{C}}$ estimation accuracy ACC was calculated according to equation 8, where `distance` is Manhattan distance between points and $\mathtt{distance}_{MAX}$ is the maximum possible distance on the image.

$$ACC_i(c_e) = \frac{\min\{c_e.x; m_e.x\} \times 100\%}{\max\{c_e.x; m_e.x\}} \text{ where } e = \{L, R\} \quad (5)$$

$$ACC_i(c_e) = \frac{\min\{c_e.y; m_e.y\} \times 100\%}{\max\{c_e.y; m_e.y\}} \text{ where } e = \{B, U\} \quad (6)$$

$$ACC_i(c_e) = \frac{\min\{c_e; m_e\} \times 100\%}{\max\{c_e; m_e\}} \text{ where } e = \{W, H\} \quad (7)$$

$$ACC_i(c_c) = 100\% - \frac{(\|c_c.x - m_c.x\| + \|c_c.y - m_c.y\|) \times 100\%}{75 + 30} \quad (8)$$

In table I selected features positioning accuracy results are presented. The results were calculated as averaged value of selected ($n = 66$) Yale database images individually estimated accuracies $ACC_i(c_e)$ (eq. 9).

$$ACC(c_e) = \frac{\sum_i ACC_i(c_e)}{n} \quad i \in \{1, 2, \ldots, n\},\ e = \{L, R, B, U, W, H, C\} \quad (9)$$

As extracted feature vector of single image was tuple of $c_L, c_U, c_R, c_B, c_W, c_H, c_C, c_{h_0} c_{h_n}$, where c_{h_i} means additionally height for a few positions, equally distributed over width of mouth. For tests n was 7.

The highest results of extraction accuracy were reported for left (81.42%), bottom (88.29%) and right (95.53%) part of mouth features detection. More problematic was upper part, what is strongly related to differences received in gradient of mouths. Resulting emotion characteristic determinants: mouth width (92.78%), height (72.77%) and cross-section point (86.18%) revealed also high evaluation accuracy. Weak mouth upper part features estimation influences negatively effectiveness of mouth shape determination, but can be counterbalanced by adding a number of measuring points for the lower edge and the height of shape characteristics measured for several positions, not only centrally located.

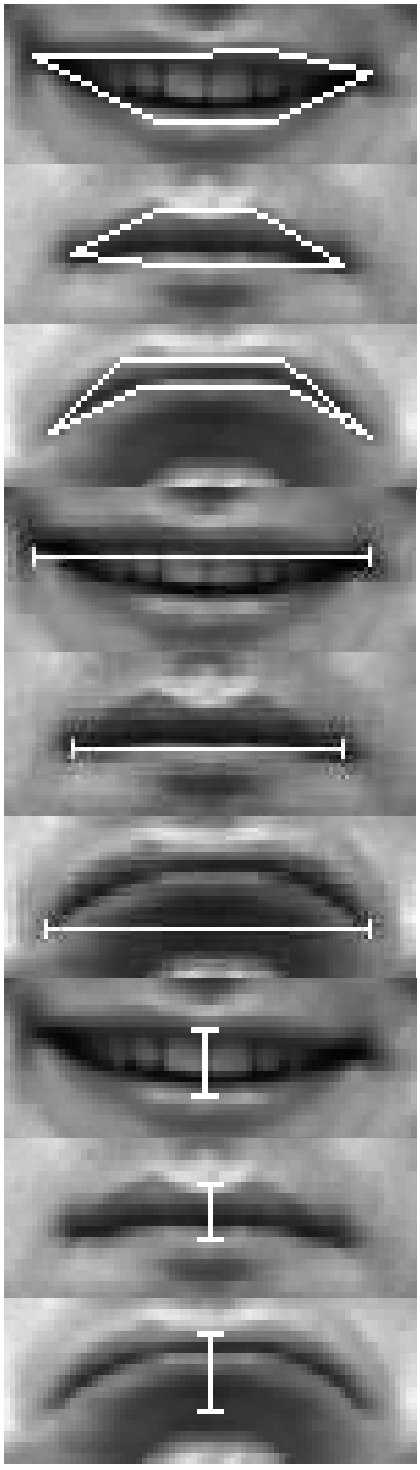

Fig. 9. Example labeled dataset with marked with white lines: shape, width and height

TABLE I
MOUTH FEATURES RECOGNITION RESULTS

Measurement	Size		Position				
	$ACC(e_W)$	$ACC(e_H)$	$ACC(e_L)$	$ACC(e_R)$	$ACC(e_U)$	$ACC(e_B)$	$ACC(e_C)$
Result [%]	92.8	72.8	81.4	95.5	43.6	88.3	86.2
Std dev. [%]	7.1	17.9	18.4	3.8	25.5	13.1	9.4

V. EMOTION CLASSIFICATION

After features' set extraction their classification is performed. Classifier predicts a label – one class from a few available. It is based on mathematical evaluation of input vector, due to selected classifier, and as output it has received a number, which represents assignment of input vector to some class [35], [36].

4 types of classical one-label classifiers were used for classification: Random Trees, *k*–Nearest Neighbors, Multi–Layer Perceptrons and Support Vector Machines. These are well known and widely used classifiers. There also others approaches like statistical methods based on Bayesian modelling combined with a Markov chain Monte Carlo (MCMC) sampling algorithm [37] etc., but was not considered in this paper. Weka was used for implementation, as a good base to train and test various classifiers with different options – explorer module [38].

At first, Random Trees (RT) was used, which was originally described to resolve classification and regression problems [39]. It constructs a tree that considers $log_2($ predicators $)+1$ randomly chosen attributes at each node, it doesn't perform pruning. It has used estimation of class probabilities basing on a hold-out set (backfitting).

K-nearest neighbors (*k*NN) classifier calculates distance between feature vector of input vector and others feature vectors from training set [40]. It has used Euclidean distance metrics, $k = 3$ and distance weighting with equation: $1/$distance.

Multi-Layer Propagation is a classifier that uses backpropagation to classify instances. This network is built by an algorithm: input layer = input features vector, hidden layer = input layer / 2 and output layer = number of classes. The nodes in this network are all sigmoid, except for output when the class is numeric in which case the nodes become unthresholded linear units.

Support Vector Machine (SVM) is a discriminative classifier formally defined by a separating hyperplanes. It has used linear kernel and C–SVC, because it is commonly used for n-class classification. In this research the libsvm library [41] was used.

The effectiveness of all methods was measured by Classification Accuracy (CA) as the basic evaluation measure. This measure provides a very precise evaluation because it reflects relation between set of correct labeled instances and all existing ones in the training set. It is defined as:

$$CA = \frac{1}{N}\sum_{N=0}^{N} y_i = f(x_i) \tag{10}$$

where: x_i are instances, i = $1..N$, N is their total number in the test set, y_i denotes the label of x_i and $f(x_i)$ is predicted label during classification process.

The experiments were carried out on popular database, which is often used to test methods working on face images. From selected images features vectors were extracted, which were used for classification.

Extracted features from previous section were divided into three groups of datasets:

1) Single – which was used for binary classification. All instances of features were labeled to belong to single class or not, for example instance can be classified as

TABLE II
EMOTION BINARY CLASSIFICATION WITH MOUTH FEATURES

	RT [%]	KNN [%]	MLP [%]	SVM [%]
happy	80.3	87.9	88.9	89.4
normal	71.2	75.8	75.8	83.3
sad	77.3	86.4	80.3	83.3
sleepy	75.8	77.3	81.8	83.3
surprised	72.7	86.4	84.8	83.3
wink	74.2	77.3	78.8	83.3

TABLE III
EMOTION CLASSIFICATION WITH MOUTH FEATURES

	RT [%]	KNN [%]	MLP [%]	SVM [%]
Three	53.0	37.9	37.9	45.5
Three2	30.3	31.8	28.8	30.3
Six	24.8	27.3	25.8	18.2

happy or unhappy (opposite emotion). There were six classes: happy, normal, sad, sleepy, surprised, wink.

2) Three – instances were grouped into three simple emotions: happy, normal and sad, where surprised was added to happy and wink to sad, because their vectors were similar.
3) Six – all instances were joined together in one dataset, but original labels were left for classification. This was the hardest dataset, which shows bad separation of instances.

Additionally, second Three dataset (named Three2) was used, which contains features of image space from the last step of features extraction, to better compare results.

Results of binary classification were shown in tab. II and from multi class classification in tab. III. For this context, the best recognized pose was happy, with almost 90% of accuracy detection for single emotion detection, over 70% True Positive (TP) detection in three–poses dataset and over 50% TP in six-poses dataset, with over 50% overall detection. It was high detectable emotion in all experiments.

The next poses which were well diagnosed these are surprised and sad. Detection rate was over 86% and 50% TP in six-poses dataset respectively. Other poses had much worse results, because individual classes were tightly mixed to each other, so they were hard to detect. Almost the same situation exists for binary classification, where some of the poses were hard detectable, but overall results is based on not classified non-poses, e.g. normal emotion was non detected for few of classifiers. SVM almost perfect detects non-poses for all emotions. Generally False Positive ration was very low or 0 for all tests.

VI. CONCLUSION

In this paper, it was proposed method to extract a few facial features from mouth image to expression recognition. The experiments were carried out on popular database, which is often used to test methods working on face images. As was shown in the last section, it gives overall good results, especially in horizontal measurement and they should be enough to right description of many facial expressions. In the future work it will be possible to collect other facial features and merge them together to better understand face and identify poses.

***Abstract*—The paper regards supporting behavioral therapy of autistic children with mobile applications, specifically applied for measuring the child's progress. A family of five applications is presented, that was developed as an investigation tool within the project aimed at automation of therapy progress monitoring. The applications were already tested with children with autism spectrum disorder. Hereby we analyse children' experience with the games, as a positive attitude towards the application is the key factor enabling practical application of the solutions in therapy. The study might be interesting for both researchers and practitioners applying e-technologies in autistics therapy.**

I. Introduction

AUTISM is a developmental disorder, that influences the ability to socialize, communicate as well as learning skills. Autistic children have diverse level of deficits in language understanding, speaking and other areas, that make the therapy and education very difficult [1]. Educating children with autism spectrum disorder could be a challenge in the best of circumstances [2]. There are premises for supporting therapy with e-technologies [3], [4], as most of the autistic children are eagerly using computers and tablets once they are taught how to use them [2]. Autistics require repetitive environment for functioning and learning. Technologies are able to perform the same activities in exactly the same way and with indefinite patience. Moreover, systems and devices might be customized in order to adjust to a unique set of deficits of an individual [5].

This study is performed under the AUTMON (Automated therapy monitoring for children with autism spectrum disorder) project, that aims at development of methods and tools to allow for the automatic evaluation of the therapy progress among children with autism spectrum disorder (ASD) [6]. Therapy monitoring is based on automatic detection of behavioral patterns in tablet and application usage. During the project 5 applications were developed or adjusted to fit the deficits of autistic children. The apps have the potential of being applicable in the therapy progress monitoring. However, the crucial question is: whether the autistic children are eager to use those games. This study aims at verification of this issue. In this paper, the applications and their adaptation to autistic users is described, and the data from interaction sessions is analyzed. Moreover, we report our observations on autistics interaction with tablets and applications. The study might be interesting for both producers of solutions for autistic children as well as for researchers investigating effective methods for ASD support and therapy with e-technologies.

The paper is organized as follows: Section II reports work related to this study and especially previous works on monitoring autistic users performance. Section III presents the study context and study design. Section IV and V present the results of games evaluation, and those sections are followed by a summary of results and discussion (Section VI) and the conclusions describing future works (Section VII).

This research is supported by the National Centre for Research and Development, Poland under grant AUTMON no IS-2/6/NCBR/2015, as well as DS Programs of the Faculty of Electronics, Telecommunications and Informatics, Gdansk University of Technology. This research is also inspired by European Cooperation in Science and Technology (COST) Action TD1309 Play for children with disabilities (LUDI).

II. Related work

New technologies are used while working with people suffering from autism both at the stage of diagnosis and therapy. The use of technology in this field is usually based on software implementations for common therapeutic tasks. Supporting diagnosis is limited to the use of computer versions of diagnostic questionnaires. Although there are some advanced technological solutions that can help to diagnose autism, they are still experimental methods, used in laboratories only or tested on small groups of people. In many cases they require specialized hardware. Some of these solutions are based on: eye tracking [7], automatic analysis of children video recordings [8], automatic analysis of individual hand movements [9] and machine learning algorithms applied to predict the state of a person [10].

Much more often than in the diagnosis, new technologies are used in the therapy of autism. In most cases, these solutions are computer implementations of paper-based therapeutic tools. There are numerous programs supporting daily activities, allowing for arranging and following procedures that consist of sequences of activities represented as images or text [5].

Numerous tools are created to help to acquire emotional intelligence skills. These include programs that help in learning face and emotion recognition, learning expressing emotions through facial expressions [11] and recognizing emotions of encountered people [12]. There are also solutions, that incorporate special hardware measuring physiological signals

to interpret an emotional state of a person, which may be especially valuable information in case of autistic children, who often are not able to show their emotions [13], [14].

Apart from solutions designed for people with autism, there are also some applications supporting work of the therapists.

III. Study context and study design

A. Study context and purpose

In 2015 a project named AUTMON was started by a consortium consisting of Gdansk University of Technology, Harimata LTD and Hippotherapy Foundation [6]. Its goal is to develop methods and tools for automated monitoring of progress in the therapy of children with autism.

The goal is addressed by (1) the development of technology identifying behavioral patterns associated with autism, which could be used to test and evaluate the progress of therapy and by (2) implementation of a system that automatically tracks these patterns during therapy. A specially designed tablet applications have been created to record the behavioral patterns during the childs interaction with tablet. These patterns, which may be analyzed for diagnostic or therapeutic purposes, contain information on: touch screen gestures, e.g. tap and swipe device movements identified by accelerometer; the application usage, i.e. navigationpatterns, objects that attract attention (goals/distractors), strategies of decision making etc. The research goal of the AUTMON project is to verify, that the proposed solution might support the therapists by providing them with objective data on the progress of therapy of autistic children in various areas of their development.

The first step in the project research is verification of the children' experience with the games, as attitude towards the application is the key factor enabling practical application of the solutions in therapy. Reporting the study of children experience with the games is the main goal of this paper.

The key research question addressed by the presented study might be formulated as follows: Which applications provide experiences positive enough for the child to perform and continue interaction allowing (as a result) to monitor progress.

B. Applications under investigation

The applications developed during the project were developed in the cooperative and iterative process engaging psychologists, therapists and data scientists. They were designed for the tablet devices. The solution set includes five games, which allows to gather information about children interactions with the device, using touch screen sensors and gyroscope.

Each game consists of training phase and actual game. During the training phase child may get acquainted with the game concept. At the beginning of training session interactive tutorial is presented. Later child may try to use application by herself/himself. During the whole training therapists should instruct the child and may use either verbal and physical guidelines. Depending on game, training session lasts from 2 to 5 minutes. At any time training session may be terminated by tapping three fingers at the top of the screen.

After finishing training session, actual game, which is used to collect data, begins. In order to obtain the undisturbed results, during this phase, the therapist should not interact with the child. Like during the training phase the session can be terminated, when a child looses interest in the game. Fig. 1 presents the games screenshots.

1) Boxes: Boxes is a game designed for warm-up. The goal is to place the balls in boxes by matching corresponding colors.

2) Sharing: The goal of the second game is to share food among four animated children. Child has to tap on the displayed food article (watermelon, apple, cake) and swipe portions to four plates in front of the children.

3) Cat & Dog: Based on the experimental paradigm of Go/NoGo, the game is intended to be used by older children. Typically developing 3-4 years old's are not ready to proceed with this cognitively demanding task.

4) Pinwheel: The pinwheel is slowly turning around while a color ball balances at the base of its stem. A child has to flip the tablet (previously only touch screen data were gathered, now accelerometer and gyroscope provide the data) precisely to move the color ball to the corresponding "pinwheel petal".

5) Creativity: Drawing and coloring pictures seem to be the most rewarding game for most children.

Fig. 1. Sample games screenshots

C. Study design

Two evaluation methods were applied: (1) a behavioral study of video recordings of children interacting with the games and (2) on-line behavioral tagging during measurement sessions.

The first part of the study was performed before measurements sessions were started and aimed at evaluation of user experience with the games. The second part of the study is performed on-line during each measurement session and this paper summarizes the results as a validation of the chosen approach. The target group in those studies are children aged 3 up to 7 (kindergarten education level), diagnosed (or during diagnosis) with autism spectrum disorder. As children measurements require consent from parents, randomization of selection to sample was not possible. Children were recruited among pupils of ten therapeutic centers in Poland. Parents' agreement rate was very high (more than 90%).

1) User experience study: This study was aimed at analyzing the experience of the children play. The first step of this study was to find a definition and unambiguous indicators of good UX. Previous research on the subject mentioned: engagement, playfulness and fun as indicators of good UX in children [15]. Previous studies [16] used some combinations of behavioral observation with survey and interview techniques. This approach was hard to apply in this study, because children with autism are mostly nonverbal or of poor communication skills, so we couldn't ask them straightforward for their opinions. Therefore in this study behavioral observation was chosen as an investigation tool. Moreover, the gameplay was recorded and analysis were made post-hoc by independent observers. This approach allowed for measuring consistency of manual tagging in order to achieve higher reliability. Steps of the study preparation:

1) An exploratory observation of gameplay was performed resulting in a list of observational indicators of interest and having fun with the games. Three independent judges (two psychologist with specialization in autism therapy and a naive observer not familiar with the symptoms of autism) were watching videos and listing observational indicators of good/bad experience of play.
2) Behaviors listed by observers in the previous step were clustered into three categories of: engagement, understanding and enjoyment.
3) The three factors were conceptualized and operationalized with three behavioral indicators each forming 9-item behavioral observation scheme.
4) Each item was assigned a five-point discrete scale (1-5) with descriptive explanations assigned to first and last item. As a result an observation sheet was prepared, that was used in manual tagging of the video recordings.
5) Using the elaborated scale and observation sheet, manual tagging of videos was performed by 5 independent observers. Total number of 21 recordings were analyzed.
6) The manual markers from observers were checked against consistency criteria using commonly used Kappa coefficient. The data was used to evaluate the applications using the understanding, engagement and enjoyment criteria.
7) Final results were formulated regarding inclusion or exclusion of the games from the measurement procedure. Some additional recommendations were formulated for the measurement procedure.

Understanding factor characterizes, that the device functions and the games are understandable for a child. First of all, child realizes that tablet screen can be used to interact with the tablet. There is a range of algorithms of interaction (based on set of possible actions provided) that result in successful interaction with the game, meaning when child achieves the goal of the game. Child wins the game if (s)he acquires a final stage of task completion, e.g. feeds all four children, draws a picture, paints a picture etc.) Children may get to win by themselves or with a standarized verbal or motor prompt from the experimenter.

Engagement factor characterizes, that the function of the tablet and the game is engaging, meaning, that tablet and game attracts childs attention. If in childs sight, in proximity of his/her hands there is a possibility of engaging. It can be observed how often, regular and persistent is childs interaction with the touch screen.

Enjoyment factor characterizes, whether interaction with tablet results in growth of positive affect symptoms, which were operationalized as laughing and vocal expressions, verbal expressions, mimic expressions and motor and postural expressions (clapping hands, jumping, shrugging). Facial expressions were not observable due to to the fact, that video materials were filmed from the chin down (which was explicitly stated in the parent-experimenter agreement for the privacy reasons).

The results of the study are provided in Section IV.

2) Validation during measurement sessions: The second study is on-line observation made during the measurement sessions.

The children are supposed to play all five games during the sessions. The detailed criteria used in the usability study were significantly simplified for the measurement stage. From the 9-item scale only 2 indicators were used in the on-line tagging procedure. For each game the following two factors are estimated by an observer: the level of difficulty, which may be 1-easy, 2-adequate, 3-difficult; the level of interest, which may be 0-none, 1-low, 2-average, 3-high. If a child does not want to play a game in spite of some encouragement, 0 is assigned to the level of interest and no value is given as the level of difficulty. If, for some reasons, a therapist decides not to try to play a game, neither difficulty nor interest are assigned a value. The reasons for childs intentional exclusion from play might fall into following categories: a child performed an extremely negative reaction to the game (eg. fear of sounds); a child is in bad disposition on this specific session day (regular therapist opinion); a child got upset during the study procedure.

The difficulty factor corresponds to understandability criteria from the UX study, the interest factor corresponds to engagement criteria from the UX study.

IV. Usability evaluation of applications for progress monitoring

This section provides results of usability evaluation of the applications. 21 recordings of nine children have been annotated. All children were boys, aged 3-7. Each of them played from one to four of the created games.

To evaluate the consistency of the annotations done by four observers, kappa coefficient was calculated. The values obtained for all nine behavior indicators defined in section III-C were averaged over all games. The highest agreement was obtained for engagement factors (0.79; 0.70 and 0.61 respectively), moderate for understanding factors (0.57; 0.54 and 0.43) and the lowest for enjoyment (0.40; 0.30 and 0.38).

To provide final evaluation scores for the three categories (engagement, understanding, enjoyment) the following procedure has been followed independently for each game:

1) in each category the scores for three behavior indicators were summed getting total category scores;
2) the total category scores were averaged over four judges; as a result three values for engagement, understanding and enjoyment were obtained for each recording;
3) the obtained recording scores were averaged over all films presenting a given game.

The final results are presented in Table I. Sharing received the highest scores for understanding and engagement. Surprisingly, Cat & Dog took the second place in these two categories and the first one in enjoyment. That game seemed to be rather difficult, some of the children did not play it at all. In spite of these obstacles, it turned out to be entertaining. Creativity game received the lowest scores for understanding and enjoyment, Pinwheel for engagement. Although Creativity seemed to be understandable for the children, as most of them intuitively drew lines with their fingers, precise drawing turned out to be quite difficult bringing about the low scores. It can be observed that more understandable games get higher scores in engagement and enjoyment, however the relationship between the variables would require further analysis.

V. On-line tagging - execution and results

To summarize the results the first three sessions of each child have been taken into account. Due to some absence rate not all participants have already gathered three data records. From the total number of 42 children, 29 of them were present during all three sessions. The absence rate is typical for the kindergarten children age range.

The results obtained for each game are averaged over all children. The final scores for the levels of difficulty and interest are shown in Table II.

It can be seen that three of the games (Sharing, Boxes, Creativity) turned out to be much more interesting than other two (Pinwheel, Cat and Dog). Some relation between interest and difficulty may be observed. The more difficult game, the less interesting and vice versa. Boxes and Sharing were the easiest ones. Pinwheel, which requires motor skills while flipping the tablet, and Cat & Dog requiring being focused, were the most difficult, just as it was expected. Some of the kids were not able to play Cat & Dog at all.

Another interesting observation is the fact that the levels of interest and difficulty do not change much over the time. It meant that data collected while playing are not affected by confounding factor such as history effect.

VI. Summary of results and discussion

The aim of this paper was to evaluate, whether the applications developed for monitoring progress of children with autism have a chance to be used in practice. The question was raised, whether the applications are engaging, understandable and enjoying enough to trigger and maintain childs focus and interaction.

The main results might be formulated as follows:

- understanding, engagement and enjoyment are partially dependent, eg. some children are fascinated with pinwheel although they do not understand the purpose of the game, for the others, if they do not understand a game, they are not interested in it.
- both studies confirmed, that three of the games: Sharing, Creativity and Boxes are mostly understandable for the children; out of the three, Sharing seems to be the favorite game;
- game Cats & Dogs and Pinwheel seems less intuitive and half of the children refuse to use them, however, once a child understands the game, it seems to be engaging,
- although it seemed, that some of the children do remember the games after a month (average time distance between recording sessions), the data do not confirm the history effect, which is convenient for measurement.

All recording and measurement sessions revealed also some qualitative observations:

- Most of the children with autism were eager to use tablets, typical behavior was to grab a tablet in the proximity of hand and to follow it, when it was taken away,
- Most of the children know very well, how to turn the tablet on and how to switch to another game, we have used the parent mode in order to prevent children from switching the games off;
- Some lower functioning children got frustrated, when they did not understand the game;
- Some higher functioning children got bored easily and even though they started eagerly, it was hard to keep them play for longer than a minute;

Authors are aware of the fact, that this study is not free of some limitations, such as small number of videos analyzed and low consistency of manual tagging for some of the variables. Despite some limitations of the study, the performed analysis allowed us to determine, which applications provide experiences positive enough for the child to perform and continue interaction allowing (as a result) to monitor progress. The goal of the study was achieved.

TABLE I
USER EXPERIENCE RESULTS OBTAINED FOR THE APPLICATIONS

Game name	Understanding				Engagement				Enjoyment			
	Min	Max	Avg	SD	Min	Max	Avg	SD	Min	Max	Avg	SD
Boxes	10	13	nd	nd	15	15	nd	nd	8	11	nd	nd
Sharing	8	15	12,8	3,3	14	15	14,7	0,6	7	12	8,9	2,3
Pinwheel	4	15	9,5	5,2	8	15	12,9	3,1	4	12	8,8	3,3
Creativity	6	13	8,9	3	11	14	13,4	1,5	2	10	7,8	1,8
Cat & Dog	6	15	11,3	4,3	12	15	14,2	1,5	5	13	9,3	3,3

TABLE II
INTEREST AND DIFFICULTY LEVELS FOR THREE MEASUREMENT SESSIONS

Game name	Interest				Difficulty			
	Total*	1st session**	2nd session**	3rd session**	Total*	1st session**	2nd session**	3rd session**
Boxes n*=100 n**=28	2,5 (0,8)	2,4 (0,8)	2,4 (0,7)	2,5 (0,8)	1,9 (0,5)	1,8 (0,6)	1,9 (0,6)	1,9 (0,5)
Sharing n*=104 n**=28	2,6 (0,6)	2,7 (0,5)	2,7 (0,6)	2,6 (0,5)	1,8 (0,5)	1,9 (0,5)	1,9 (0,5)	1,7 (0,5)
Pinwheel n*=85 n**=22	1.9 (0,9)	2,1 (0,9)	1,8 (1,0)	2,1 (0,8)	2,6 (0,6)	2,6 (0,5)	2,6 (0,5)	2,4 (0,7)
Creativity n*=102 n**=28	2,4 (0,8)	2,6 (0,7)	2,5 (0,7)	2,4 (0,7)	2,3 (0,5)	2,2 (0,5)	2,4 (0,5)	2,2 (0,5)
Cat & Dog n*=49 n**=13	1,8 (1,0)	1,9 (0,9)	1,9 (1,0)	1,9 (1,0)	2,7 (0,6)	2,6 (0,8)	2,8 (0,4)	2,7 (0,5)

n* - total no of gameplays evaluated (all children, up to 3 sessions)
n** - no of gameplays evaluated (only children with 3 sessions)

VII. CONCLUSIONS

Our study shows the potential for use of tablet-based technology in children therapy. Children are generally enthusiastic about tablets and other mobile devices and this rapture can be utilized in the area of research, diagnosis and therapy. Future works in this discipline should focus on to developing tools for monitoring progress and better means for their evaluation. As our study concludes, its not easy to evaluate in terms of child experience, especially in autistic population, where raters agreement is hard to reach.

Objective measures of therapy progress can bring quality data to the therapy providers. As they have better knowledge of childs state and developmental pace and direction, thy can provide adjusted intervention to best fit the individual needs of the child. Better therapy means better life for children with ASD, as enormous amount of evidence shows that personalized and early onset intervention improve their future quality of life.

The 36th IEEE Software Engineering Workshop

THE IEEE Software Engineering Workshop (SEW) is the oldest Software Engineering event in the world, dating back to 1969, and with the last 35th workshop organized in Heraclion, Crete, Greece, 12-13 October 2012.

The workshop was original run as the NASA Software Engineering Workshop and focused on software engineering issues relevant to NASA and the space industry. After the 25th edition, it became the NASA/IEEE Software Engineering Workshop and expanded its remit to address many more areas of software engineering with emphasis on practical issues, industrial experience and case studies in addition to traditional technical papers. Since its 31st edition, it has been sponsored by IEEE and has continued to broaden its areas of interest.

TOPICS

The workshop aims to bring together all those with an interest in software engineering. Traditionally, the workshop attracts industrial and government practitioners and academics pursuing the advancement of software engineering principles, techniques and practice. The workshop provides a forum for reporting on past experiences, for describing new and emerging results and approaches, and for exchanging ideas on best practice and future directions.

Topics of interest include, but are not limited to:

- Experiments and experience reports
- Software quality assurance and Metrics
- Formal methods and formal approaches to software development
- Software engineering processes and process improvement
- Agile and Lean Methods
- Requirements engineering
- Software architectures
- Real-time Software Engineering
- Software maintenance, reuse, and legacy systems
- Agent-based software systems
- Self-managing systems
- New approaches to software engineering (e.g., search based software engineering)
- Software engineering issues Cyber-physical systems
- Software Engineering for social media

***Abstract*—For modelling of real-time safety critical systems, when traditional testing techniques cannot be applied, formal system verification is crucial. Alvis is a modelling language that combines possibilities of formal models verification with flexibility and simplicity of practical programming languages. Solutions introduced in Alvis make the development process easier and help engineers to cope with more complex systems. The paper deals with a state-based approach to the verification of Alvis models. Until the research presented in the paper were conducted, the verification process was mostly action-based. The nuXmv tool, as one of the top model checkers, was selected for the task of state-base verification of Alvis models translated into the SMV modelling language. The paper presents a translation algorithm and usability studies performed on existing safety critical systems.**

I. Introduction

Alvis [1], [2] is a formal modelling language developed at AGH-UST in Kraków, Department of Applied Computer Science (*http://alvis.kis.agh.edu.pl*). The motivation behind its creation and development is to provide a formal language which could be used by an average software engineer to model and verify complex systems. To this end, Alvis combines advantages of high level programming languages with a visual modelling language for defining communication channels between subsystems. Its most significant advantage over classical formal methods (Petri nets [3], [4], timed automata [5], [6] and process algebras [7], [8], [9]) is an engineer-friendly syntax. The heavy mathematical foundations are hidden from the user without compromising the capabilities and expressive power of the formalism. Alvis, as a formal language, has an advantage over the industry programming languages – Alvis models can be formally verified using model checking techniques [10]. Using Alvis language, an average software engineer is able to model and verify complex systems which can be then easily implemented. This is particularly important in concurrent and distributed systems where traditional methods of software testing are not applicable. The formal verifications of such systems is a ground for many current scientific projects [11]. The ongoing research on the Alvis language include also building an Alvis simulator, Alvis Virtual Machine [12] and automatic Java code generation [13].

The nuXmv tool [14], [15] is currently one of the top-notch and mainstream model checkers for temporal logics. It features a prominent and state-of-the-art verification engine. The project is still supported and developed, new versions of the tool are released regularly.

The nuXmv can check whether a given finite state model satisfies a given temporal logic formula and if not, it can provide a proper counter-example. System requirements specification, in the form of a set of LTL [16] and CTL [16], [17] temporal logics formulae, can be therefore automatically verified by the tool. In addition, it has a dedicated modelling language called SMV [15] which is relatively easy to use for modelling the system. Furthermore, according to the authors of the project it can verify systems of high complexity, i.e. containing more than 10^{20} states.

These outstanding features initially made nuXmv the best possible choice for the task of state-base Alvis model verification. The main goal of the conducted research was to verify whether nuXmv can be effectively used in the process of verification of complex systems modelled in the Alvis language. In order to prove the concept, a translation algorithm was conceived and then implemented. Extensive experiments of the solution were performed, including modelling and verification of existing real-time safety critical systems.

The paper is organised as follows. Section II contains a short introduction to the Alvis language and basic information about the process of designing and verification of Alvis models. In Section III formal definitions concerning Alvis state space representation are provided. Section IV deals with the algorithm of Alvis model translation into nuXmv. Usability studies conducted on two examples of real-time safety critical systems are presented in Section V. A short summary is given in the final section.

II. Alvis modelling language

An Alvis model is basically a collection of subsystems called *agents* that may run concurrently, communicate with each other, compete for shared resources etc. The concept of *agent* is borrowed from CCS [8], [18]. Agents are divided into *active* and *passive* ones and mimic, to some degree, tasks and protected objects in the Ada programming language [19].

Active agents may perform some activities and are treated as threads of control in a concurrent system. *Passive agents* provide a mechanism for the mutual exclusion and data synchronization.

Interconnections between agents are defined on *communication diagrams*, a visual part of the Alvis language. These

978-83-60810-90-3/$25.00

diagrams present agents as nodes and communication channels as arcs in a directed graph. To model the behaviour of the agents, the *code layer* is used. Alvis source code is similar to the one of high level programming languages. Alvis statements may also incorporate elements of the Haskell functional programming language [20].

Furthermore, the complex systems may be modelled using hierarchical communication diagrams [21]. They introduce a concept of a hierarchical node which represents a subsystem defined at the lower level. Therefore, it allows to describe a system on many different levels of abstraction. A summary of Alvis graphical elements and code statements is presented in Fig. 1.

Alvis models are designed using an Alvis design toolkit including *Alvis Editor*, *Alvis Simulator* and *Alvis Compiler* tools. *Alvis Editor* is a visual modelling environment featuring design of Alvis models. *Alvis Simulator* enables step-by-step simulations of the models. *Alvis Compiler* [22] translates designed models into Haskell program. The Haskell middle-stage representation is used to generate LTS graphs (*labelled transition system* [23]) of the Alvis models. LTS graphs will be explained in more detail in the next section. They can be used to formally verify models using model checking techniques. LTS graphs are checked in terms of satisfaction of model properties described as temporal logic formulae. The original verification process included only action-based verification with μ-calculus [24] in CADP toolbox [25]. The approach presented in this paper employs nuXmv tool to allow the usage of LTL and CTL temporal logics. The modelling and verification process of Alvis models is presented in Fig. 2.

More details on this topic may be found in the manual at the website of the Alvis project.

III. Alvis state space representation

Before an Alvis LTS to nuXmv translation algorithm can be introduced, some of the key concepts regarding Alvis state space must be defined.

Definition 1. A state of an agent X is a tuple:

$$S(X) = (am(X), pc(X), ci(X), pv(X)),$$

where $am(X)$ is an agent mode, $pc(X)$ is a program counter, $ci(X)$ is a context information list, and $pv(X)$ is parameters values.

Each agent state can be described unambiguously with information contained by this four-tuple. Where necessary, to every one of am, pc, ci and pv symbols, there can be a state index added, e.g. pv_{S_i}, to indicate which state it refers to.

The *agent mode* can take one of the five following values: *Finished* (F), *Init* (I), *Running* (R) and *Taken* (T). *Finished* means that an agent has finished its work. *Init* is the default mode for agents that are inactive in the initial state. *Running* means that an agent is performing one of its statements. *Taken* means that one of the passive agent's procedures has been called and the agent is executing it. *Waiting*, for passive agents, means that the corresponding agent is inactive and waits for another agent to call one of its accessible procedures. For active agents, this mode means that the corresponding agent is waiting either for a communication with another active agent, or for a currently inaccessible procedure of a passive one.

The *program counter* points at the current statement of an agent i.e. the next statement to be executed or the statement that has been already executed by an agent but needs a feedback from another agent to be completed (e.g. a communication between agents).

The *context information list* contains additional information about the current state of an agent e.g. if an agent is in the waiting mode, ci contains information about events the agent is waiting for.

The *parameters values list* contains the current values of the agent's parameters.

Definition 2. A state of a model $\boldsymbol{A} = (D, B, \alpha^0)$, where $D = (\mathcal{A}, \mathcal{C}, \sigma)$ and $\mathcal{A} = \{X_1, ..., X_n\}$ is a tuple $S = (S(X_1), ..., S(X_n))$.

The concept of an Alvis model state is explained in Fig. 3.

Execution of any step is expressed as a transition between formally defined states of an Alvis model. States of a model and transitions among them are represented using a labelled transition system (LTS graph).

Definition 3. A Labelled Transition System is a tuple:

$$LTS = (S, A, \rightarrow, s_0),$$

where S is a set of states, A is a set of actions, $\rightarrow \subseteq S \times A \times S$ is the transition relation and s_0 is an initial state.

For an Alvis model, an LTS is a four-tuple:

$$LTS = (\mathcal{R}(S_0), \mathcal{T}, \rightarrow, S_0),$$

where $\mathcal{R}(S_0)$ is a set of states reachable from the initial state, $\mathcal{T}$ is a set of all possible steps for a given model, $\rightarrow = \{(S, t, S') : S - t \rightarrow S' \wedge S, S' \in \mathcal{R}(S_0)\}$, where $t \in \mathcal{T}$, and S_0 is an initial state. In untimed Alvis models arcs are labelled with names of individual steps performed by agents. In the timed models arcs are labelled with the sets of parallel steps.

In order to describe the translation algorithm in the next section, a few additional terms need to be introduced:

- $B(X)$ – Agent X dynamics definition (code);
- $card(B(X))$ – number of steps in $B(X)$;
- $\mathcal{N}(t)$ – a name of the t transition.

NuXmv models are basically *finite state transition systems* [15] which can be defined as *Kripke structures* [26].

Definition 4. A *finite state transition system* is a tuple $TS = (S, I, \rightarrow, L)$, where:

- S is a finite set of *states*,
- $I \subseteq S$ is the set of *initial states*,
- $\rightarrow \subseteq S \times S$ is the *transition relation*, specifying the possible transitions from state to state,
- L is the *labelling function* that labels states with *atomic propositions* that hold for the given state.

IV. Alvis LTS to nuXmv translation algorithm

Finite state transition systems in nuXmv tool are modelled with a dedicated modelling language called SMV [15]. In the presented approach, a nuXmv model after translation consists of three main parts: Variables definitions (`VAR` and `IVAR`), `ASSIGN` section and specification of transitions' availability

(TRANS). The first one of them, the IVAR section, contains definition of an input variable action. It is used to contain transitions' labels.

The VAR section is used to contain definitions of standard variables. These include set of states and atomic propositions variables. The ASSIGN section is composed of three main parts. The first one initializes the state variable, the second is responsible for defining transitions between the states and the final one assigns values to the atomic propositions for specific states. The set of atomic propositions is given implicitly using variables and their domains. The last main part, the TRANS section, specifies for every state which actions are available in it. For instance, line `TRANS s = s1 -> (action = a1) | (action = a2)` determines that when the system is in state s1, the only available actions are a1 and a2.

A translation algorithm of an Alvis model LTS into the nuXmv code is presented in Fig. 1. In the adopted notation, ▷ symbol indicates generated nuXmv code, # represents string concatenation, $Label()$ produces a variable name and $Type()$ returns a variable's data type.

The first part of the algorithm is responsible for generation of a declaration of the input variable action. In the proposed approach, this variable is used to define names of the transitions between the model states as edges' labels in the nuXmv transition system. It enables using transition names in LTL formulae during the verification process. During the model simulation this additional information is a major enhancement that allows to analyse not only the state changes, but also the steps that led to them. The $action$ set is initialised with a single element representing empty action named NOP. Every transition label is added to the set then.

In the next step, the domain of the state variable s is defined. Its value denotes the current state of an Alvis model. For every reachable state ($S \in \mathcal{R}(S_0)$), the state name is added to the set of nuXmv states.

Lines 13–41 contain steps required to define variables representing elements of the model's state. This section starts with L_{am}, L_{pc}, L_{ci} and L_{pv} sets initialisation. They represent the sets of defined variable labels for agent mode, program counter, context information list, and parameters values correspondingly. Every agent has exactly one am and pc variable, while possibly multiple ci and pv variables.

For every agent of the model, variable labels are generated by concatenating agent's name with a two letter abbreviation indicating the element of the agent state's tuple it refers to. Agent mode variable is an enumeration and can have assigned one of the x, w, f, i and t values. Program counter variable is a bounded integer, ranging from 0 to $card(B(X_i))$, where X_i is the given agent. Context information variable labels, in addition to the basic naming convention, contain also information about the possible values of the original ci. They are booleans and the TRUE value implies that the given ci entry is present in the context list in the given state. Parameters values labels are generated by concatenating agent name, pv keyword, pv order number. If pv variable's type in the code layer is integer or boolean, the nuXmv variable is of the same type. In other case pv value is appended to the label and the type of the nuXmv variable is boolean. TRUE means that the given agents parameter is of the value specified as the last part of nuXmv variable label in the given state.

The next part of the algorithm starts with adding of the beginning of the ASSIGN section and initialization of the s variable with the name of the initial state. Then the transition relation switch statement is opened (line 44). $successors_{ik}$ is the set of successors of the si state, reachable through transition t_k. In the nested loops that follow, successors lists for every reachable state are generated.

The next section of the algorithm contains five similar blocks of pseudocode (lines 57–63, 64–70, 71–80, 81–95, 96–104). Each generates labelling functions for the agent state variables defined in the VAR section. Labelling functions are basically switch statements in which the proper value is assigned to the variable depending on the current state of the system. pv variables labelling functions are divided into two separate loops, depending on the type of the variable in the code layer.

The last part of the algorithm (lines 105–114) defines availability of the transitions. It is determined by the value of the si variable. TRANS line is generated for every reachable state. It contains a list of available transitions. NOP action is not listed there because it is only available when no successor exists. This situation indicates a terminal state of the system.

end if
▷ `TRANS s = si ->`
`(action = Ti_0|action = Ti_1 | ... );`
end for
end for

The main purpose of including the above algorithm in this paper is to convey the basic concept behind the translation. Therefore, as one may notice, the above algorithm is not optimal. Nonetheless, after many optimizations and enhancements, this algorithm was implemented as an additional module to the PetriNet2ModelChecker tool. This module enables automatic conversion of an LTS graph of an Alvis model stored in .dot file into nuXmv code, and therefore allows to verify any Alvis model using LTL and CTL logics in one of the top model checkers available.

V. Usability studies

The presented approach was tested against models of existing safety-critical systems. Among them, the tests were conducted on railway switch system and fire alarm contol panel. The former is the solution manufactured by Grupa ZUE S.A. [27] and employed in public transport in Krakow, Szczecin and Wroclaw [28]. The latter is a project of the SITP organization [29]. More information on this system can be found in [30]. The approach presented in this paper will be illustrated on the first one of them. A schematic of the system

is shown in Fig. 4.

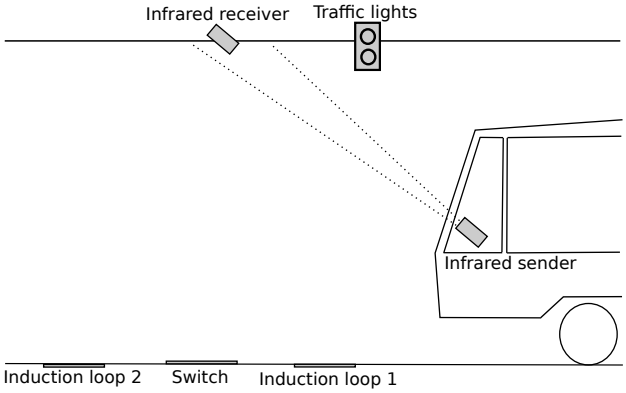

Figure 4: Railway switch system.

In every tram, there is an NP03 infra-red transmitter used to send IR signals to the switch control system. It is located on a tram driver console panel. An OP03 receiver is responsible for collecting infra-red signals and sending them to system driver. It is usually installed on overhead lines or on special poles placed before the switch. Traffic lights are providing a motorman with two pieces of information, i.e. the current direction of the tracks and a status of a switch blades lock.

A motorman's responsibility is to ensure that switch blades are set in the right direction and locked before he can drive a tram through a switch. He can change blade's direction using an NP03 transmitter. On receiving a signal, an IR receiver sends a pulse to a switch motor controller, which in turn sends a signal to blades controller to change direction of the rails. The change is possible only in the operating range of the receiver. Tram driver has limited time for choosing the expected direction, depending on the speed of the tram. If the motorman does not change the direction while the tram is in a reach zone of the IR receiver, he would have to stop the tram and manually change the direction using a special lever.

In a switch zone, there are also two induction loops installed, one before and one after switch blades. They are responsible for detecting a tram entering and leaving the crossing zone. When a tram is detected, an electrical switch lock mechanism is locking blades in the current position, in order for tram to pass safely through the switch zone. They are unlocked immediately after the tram leaves the crossing.

An Alvis model of this system was constructed. Its communication diagram is presented in Fig. 5.

Using the implementation of the algorithm presented in Section IV the system model was automatically translated into a nuXmv source file. The nuXmv representation maintains every piece of the original information about system behaviour stored in the LTS. The next step involves verification of system properties. In the presented approach they are described as LTL and CTL formulae. Three examples of such formulae are given in Listing 1.

Listing 1: Examples of LTL and CTL formulae for the railway switch system model.

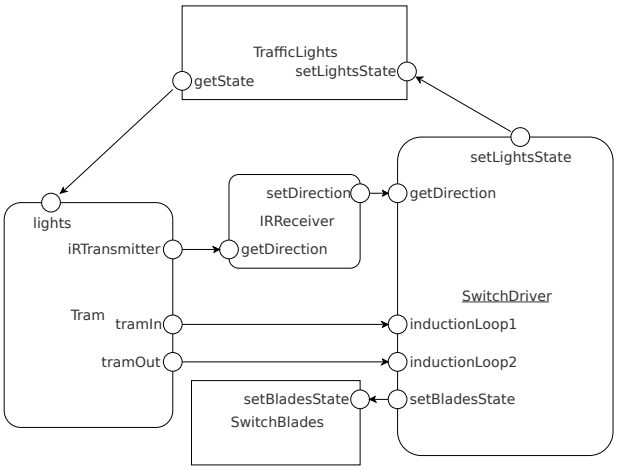

Figure 5: Railway switch system communication diagram.

```
--1) TramPassed = false U BladesLocked = true
LTLSPEC (SwitchDriver#pv3 < 2) U (SwitchBlades#pv1 <
  ↪  0)

--2) EF TramPassed = true
CTLSPEC EF (SwitchDriver#pv3 = 2)

--3) F TramPassed = true
LTLSPEC F (SwitchDriver#pv3 = 2)
```

`SwitchDriver#pv3` denotes a `tram` variable from the *SwitchDriver* agent. It can have three values: 0 when the tram is before the first induction loop, 1 when tram passed the first induction loop and 2 when the tram passed the crossing (the second induction loop). `SwitchBlades#pv1` is a `bladesState` variable. When its value is positive, the switch blades are not locked and when the value is negative, the blades are locked.

The first formula verifies whether the switch is being locked before the tram passes the crossing. This formula is crucial for the safety of railway switch mechanism. The nuXmv confirmed that it is satisfied in the model. The second formula checks whether there is a path in which a tram passes through the crossing. It is also true. The last one is similar to the previous, except it checks whether a tram always finally passes through the crossing. This one is not satisfied. The true potential of nuXmv is in providing the counterexample. If a formula is not true, nuXmv provides a path that proves it. In this case the tram does not pass through the crossing if the driver did not manage to send the signal to change the blades direction when the tram was in the zone of the infra-red receiver. Driver has to stop the tram, step out of it and manually change the direction. It is a desired behaviour of the system.

Three versions of the same model were prepared with varying complexity, each describing the system on a different level of abstraction. For each one of them, the same set of properties was verified. They were categorized into three groups: reachability, safeness and liveness properties. For each

group an average verification time was measured and presented in Table I. Tests were performed on a PC with AMD Phenom II X6 processor and 16 GB of RAM. The verification times are growing fast with complexity but even for the most complex railway switch system version, they are quite acceptable.

For the comparison, translation to nuXmv was performed also on the fire alarm control panel system. Its communication diagram is presented in Fig. 6. As this system is significantly more complex, the amount of states in the LTS is adequately larger. Although the translation itself was fast, nuXmv couldn't handle loading of such a complex system on the testing machine. The amount of memory needed to load the model exceeded available resources (RAM and swap space) and the nuXmv process was killed by the operating system. Therefore, the average verification times are not provided.

The results of the tests confirm that the presented approach is performing well for models of medium complexity. More complex ones require a lot of resources, especially RAM. Provided enough RAM or swap space, the approach can be applied to most models.

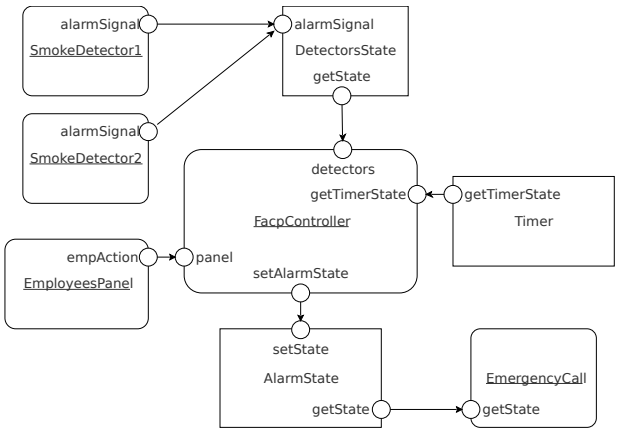

Figure 6: Fire alarm control panel communication diagram.

VI. Summary

The paper introduces state-base approach to verification of Alvis models. The presented solution enables to automatically verify properties of the modelled system using the mainstream model checking tool nuXmv. It employs formulated and implemented algorithm of Alvis LTS translation into nuXmv source code.

The usability studies of the concept were conducted on models of actual real-time safety critical systems, railway switch system and fire alarm control panel. Illustrative properties of these systems have been specified as LTL and CTL formulae and verified with nuXmv to demonstrate the capabilities and limitations of the approach. The results of the tests have been presented and summarised.

The proposed verification method proved to be handling most middle-sized models with ease, even on a regular PC. Although nuXmv supposed capabilities exceed the current needs, the solution is limited by the amount of RAM available. Complex systems require a great deal of memory to load. Compared to the amount of memory required to verify systems using action-based approach in CADP, nuXmv seems ineffective. On the other hand, state-based solution allows much more thorough verification because of the information stored about the states. The combination of both state- and action-based verification is currently the most optimal option.

Future work on state-based verification of Alvis models will focus on other possibilities. The most promising is a concept of a dedicated query language operating on the middle-stage Haskell representation.

***Abstract*—Modified Condition / Decision Coverage (MC/DC) is the second strongest coverage criterion in white-box testing. According to DO178C/RTCA criterion it is mandatory to achieve Level A certification for MC/DC. Concolic testing is the combination of Concrete and Symbolic execution. It is a systematic technique that performs symbolic execution but uses randomly-generated test inputs to initialize the search and to allow the tool to execute programs when symbolic execution fails. In this paper, we extend concolic testing by computing MC/DC using the automatically generated test cases. On the other hand Feedback-Directed Random Test Generation builds inputs incrementally by randomly selecting a method call to apply and find arguments from among previously-constructed inputs. As soon as the input is built, it is executed and checked against a set of contracts and filters.**

In our proposed work, we combine feedback-directed test cases generation with concolic testing to form Java-Hybrid Concolic Testing (Java-HCT). Java-HCT generates more number of test cases since it combines the features of both Feedback-Directed Random Test and Concolic Testing. Hence, through Java-HCT, we achieve high MC/DC. Combinations of approaches represent different tradeoffs of completeness and scalability. We develop Java-HCT using RANDOOP, jCUTE, and COPECA. Combination of RANDOOP and jCUTE creates more test cases. COPECA is used to measure MC/DC% using the generated test cases. Experimental study shows that Java-HCT produces better MC/DC% than individual testing techniques(feedback-directed random testing and concolic testing). We have improved MC/DC by $\times$1.62 and by $\times$1.26 for feedback-directed random testing and concolic testing respectively.

I. Introduction

SOFTWARE Testing is the technique to detect bugs in software. Manual software testing accounts for 50-80% of the cost of software development. Manually created test cases are expensive, error-prone, and generally not exhaustive [2]. Therefore, automated software testing techniques have been discovered [3], [4].

There exists some controversy regarding the relative advantages of random testing and systematic testing. Some work [5], [6] suggest that random testing is same effective as systematic testing techniques. Existing work [7] found that random test case generation achieves less code coverage than systematic generation techniques. These systematic generation techniques include chaining, exhaustive generation, model checking, and symbolic execution.

Pacheco et al. [8] proposed Feedback-Directed Random testing. They have addressed random generation of unit tests for object-oriented programs. Their proposed work indicates that feedback-directed random generation retains the benefits of random testing (scalability, simplicity of implementation), and avoids redundant test cases.

Concolic testing is a systematic technique that performs symbolic execution. Concolic testing uses randomly generated test cases to start the search and to allow the tool to make progress when symbolic execution fails due to limitation of the symbolic technique (e.g. native calls) [9].

MC/DC is a criterion for code coverage and was introduced by the RTCA DO-178B standard [10]. MC/DC must satisfy the following criteria [11]:

- All the entry and exit points of the input programs must be invoked at least once.
- All possible outcomes of a decision must be affected by the changes made to each condition.
- All possible outcomes of every decision must execute.
- All the conditions in a decision must execute.

According to Majumdar et al. [2], in hybrid concolic testing, the concolic testing phase is initiated whenever random testing saturates, i.e, does not find new coverage points even after running a predetermined number of steps. Majumdar et al. [2] observed that CUTE and jCUTE tools have ultimately run up against path explosion. Concolic testing can only cover a small fraction of branches, those that can be reached using “short" executions from the initial state of the program. Therefore concolic testing requires “deep" program status to be explored.

We have implemented Java-Hybrid Concolic Testing using RANDOOP, jCUTE, and COPECA, and applied it to achieve high Modified Condition/Decision Coverage for Java programs.

The rest of the article is organized as follows: Section 2 presents the background concepts. Section 3 presents the proposed approach Java-HCT. Section 4 shows the experimental study. Section 5 compares the proposed approach with some of the existing approaches. Section 6 concludes the paper and suggests some future work.

II. Background Concepts

In this section we discuss some important background concepts, which are required to understand our work.

Definition 1: Feedback-Directed Random Testing: “It is a combination of random and systematic approach that results a test suite consisting of unit tests for the classes under test. Systematic approach deals with Feedback-Directed, i.e

as soon as an input value is built, it is executed and checked against a set of contacts and filters. The result of the execution determines whether the input is redundant, illegal or useful for generation of more input [8]."

There is a tool available for Feedback-Directed Random Testing called RANDOOP[1]. RANDOOP stands for Random Tester for object-Oriented Programs. It is a fully automatic tool and requires no input from the user, and scales to realize applications with hundreds of classes.

Definition 2: Concolic Testing: "Concolic testing is defined as a variant of symbolic execution where symbolic execution is run simultaneously with concrete executions, i.e., the program is simultaneously executed on concrete and symbolic values, and symbolic constraints generated along the path are simplified using the corresponding concrete values. The symbolic constraints are then used to incrementally generate test inputs for better coverage by combining symbolic constraints for a prefix of the path with the negation of a conditional taken by the execution [9], [15]."

JCUTE[2] is a Java concolic unit test engine based on concolic testing to execute Java programs.

Definition 3: Java-HCT: "Java-Hybrid Concolic Testing is the combination of Feedback-Directed Random Testing and Concolic testing for Java programs to result high MC/DC coverage."

Java-HCT is implemented using RANDOOP, jCUTE, and COPECA. RANDOOP and jCUTE are open source testing tools and used performing Random testing and Concolic testing respectively. We have developed the tool COPECA (COverage PErcentage CAlculator), which is plugged into RANDOOP and jCUTE to measure MC/DC%, using the generated test cases. COPECA is based on Extended Truth Table.

Definition 4: Modified Decision / Condition Coverage: "MC/DC is some kind of Predicate Coverage technique, where condition is a leaf level Boolean expression and decision controls the program flow. MC/DC% is defined as the total number of independently affected conditions (I) out of total conditions (C) present in a program [11] mathematically."

$$MCDC\% = \frac{|I|}{|C|} * 100\% \quad (1)$$

III. Proposed Approach: Java-HCT

In this section, we discuss the detailed and algorithmic description of Java-HCT followed by the proposed steps of the technique.

A. Overview

Our proposed technique Java-HCT consists of seven modules. These are i) Syntax_Converter, ii) RANDOOP, iii) jCUTE, iv) TCs Extractor, v) TCs Combiner, vi) TCs Minimizer, and vii) COPECA. These modules are shown in Fig. 1. Java-HCT accepts a Java program and produces MC/DC%.

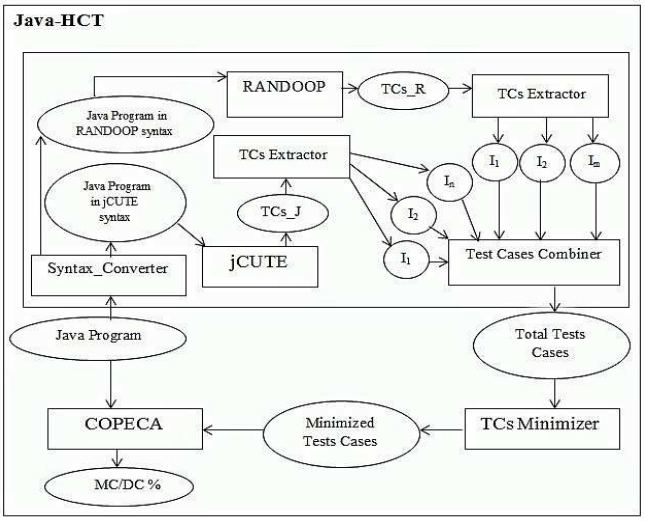

Fig. 1. Schematic representation of Java-HCT

Basically Java-HCT is the combination of RANDOOP and jCUTE which produce test cases combining. These tools RANDOOP and jCUTE are plugged into COPECA so that, the hybrid tool will be capable of computing MC/DC%. Our proposed technique provides deep as well as wide exploration of concolic execution.

B. Detailed Description

Java-Hybrid Concolic Testing is the best combination to achieve better MC/DC, and is the hybrid combination of Feedback-Directed Random testing and Java Concolic Testing. We have inspired from the core-idea proposed by Majumdar et al.[2]. They proposed a Hybrid Concolic Testing algorithm, that interleaves random testing with concolic execution to obtain both a deep and a wide exploration of program state space. They have implemented their algorithm on top of concolic tester (CUTE) and experimented to obtain high branch coverage for two large programs;*VIM 5.7* and *Red black tree*. Similarly, we extend the work of Majumdar et al.[2] by measuring MC/DC and that too for Java programs. Majumdar et al.[2] implemented their algorithm using undirected random testing and concolic testing, whereas we propose an efficient hybrid concolic testing for Java programs i.e. Feedback-Directed Random testing with concolic testing to obtain high MC/DC.

Fig. 1 shows the proposed tool for Java-Hybrid Concolic Testing (Java-HCT)[3]. Java-HCT is developed by integrating seven modules. The process starts by supplying a Java program. From Fig. 1 we can observe that, this Java program is converted into two different syntaxes using *Syntax_converter*. Since, we supply this Java program into both RANDOOP and jCUTE, it is essential to convert the original Java program into respective tool syntaxes. Now, the Java program in RANDOOP syntax is supplied to *Random tester for Object-Oriented Programs (RANDOOP)* to generate *TCs_R* automatically. Similarly, the Java program in jCUTE syntax is supplied to *Java Concolic Unit Testing Engine (jCUTE)* to generate *TCs_J* automatically. Unfortunately, TCs_R and TCs_J are not in same syntax. Therefore, *TCs Extractor* module is uses both the test suites to extract the input values those are present in TCs_R and TCs_J as described in Fig. 1. Then all extracted input values are supplied to *TCs Combiner* to produce Total test cases. Since, these test cases may be redundant and useless for MC/DC, therefore we have developed *TCs Minimizer* that accepts all the input values and checks which are essential to compute MC/DC percentage and removes rest of the those non-essential test cases. Now, the minimized test cases are supplied to *COverage PErcenatge CAlculator (COPECA)*. Since, we focus to increase MC/DC percentage, so we have developed this COPECA to measaure MC/DC percentage. COPECA accepts the minimized test cases along with the original Java program to produce MC/DC%.

[3]https://sourceforge.net/projects/java-hct/

C. Algorithmic Description

Algorithm 1 deals with the pseudocode of Java-Hybrid Concolic Testing (Java-HCT). We supply a Java program to our algorithm. Java-HCT to produce MC/DC%.

Algorithm 1 Java-HCT

Input: J (Java Program)
Output: MC/DC%

1: $J_R, J_J \leftarrow Syntax\_Converter(J)$
2: $TCs\_R \leftarrow RANDOOP(J_R)$
3: $TCs\_J \leftarrow jCUTE(J_J)$
4: $Input\_values \leftarrow TCs\_Extractor(TCs\_R, TCs\_J)$
5: $Total\_TCs \leftarrow TCs\_Combiner(Input\_values)$
6: $Minimized\_TCs \leftarrow TCs\_Minimizer(Total\_TCs)$
7: $MC/DC\% \leftarrow COPECA(J, Minimized\_TCs)$
8: **return** $MC/DC\%$

In Line 1 of Algorithm 1, the Syntax_Converter takes a Java program as input and produces a Java program in RANDOOP syntax (J_R) and a Java program in jCUTE syntax (J_J) as outputs. Line 2 shows the execution of RANDOOP tool. RANDOOP takes J_R as input and generates test cases (TCs_R) as output. Line 3 shows the execution of jCUTE tool. J_J as input and generates test cases (TCs_J) from jCUTE as output. Now, these two generated test case sets (TCs_R, TCs_J) are forwarded to Test Cases Extractor (TCs Extractor) modules to separate each input values as presented in Line 4.

Line 5 shows the execution of Test cases Combiner (TCs Combiner). This Combiner module collects all the input values created from TCs Extractor and generate a single set called Total Test Cases (Total TCs). Line 6 shows minimization of the test cases generated through Test Cases Minimizer (TCs Minimizer). This module produces the Minimized Test Cases (Minimized TCs).

Line 7 deals with the computation of MC/DC% through COPECA. COPECA takes the original Java program along with the Minimized TCs as input. Line 8 returns the final MC/DC% as output.

IV. Experimental Study

In this section we discuss our experimental setup, the result analysis, and threats to validity.

A. Setup

The experimental programs are ran on a computer system with 4GB of memory (RAM) Intel(R) Core(TM)i5 CPU 650 @ 3.20 GHz 3.19 GHz and 32-bit operating system.

B. Result Analysis

Table I deals with the characteristics of forty input Java programs. Column 3 shows the size of programs in Lines of codes (LOCs). Columns 4,5,6, show the Predicates, Conditions, and Variables respectively.

Table II presents the generated test cases and MC/DC% for RANDOOP, jCUTE, and Java-HCT. Column 3 shows the

TABLE II
RESULTS ON EXECUTION OF COPECA

test cases generated by Feedback-Directed Random Tetsing. RANDOOP is the tool that generates these test cases. Column 4 presents the test cases generated by Java Concolic Unit Testing Engine (jCUTE). Column 5 shows the total test cases of RANDOOP and jCUTE. TCs Minimizer accepts these total test cases and only selects essential test cases according to MC/DC criterion. Column 6 presents the number of minimized test cases. Columns 7,8,9 deal with the MC/DC percentages achieved by RANDOOP, jCUTE, and Java-HCT respectively. These percentages are defined below:

Definition 5: MC/DC_1%: This MC/DC percentage is computed through RANDOOP and COPECA.

Definition 6: MC/DC_2%: This MC/DC percentage is computed through jCUTE and COPECA.

Definition 7: MC/DC_3%: This MC/DC percentage is computed through RANDOOP, jCUTE and COPECA or Java-HCT.

Column 10 and 11 deal with the increase in MC/DC. Column 10 is named as Inc_1 and shows the difference between MC/DC_1% and MC/DC_3% using Eq.2, whereas Column 11 named as Inc_2 shows the difference between MC/DC_2% and MC/DC_3% using in Eq.3.

$$\text{Inc\_1} = \text{MC/DC\_3\%} - \text{MC/DC\_1\%} \quad (2)$$

$$\text{Inc\_2} = \text{MC/DC\_3\%} - \text{MC/DC\_2\%} \quad (3)$$

We have experimented forty Java programs. We computed the values of Inc_1 and Inc_2 for these programs which are 29.91% and 16.26% (on average) respectively. According to the observation of our experimental study, Java-HCT achieved better MC/DC by $\times$ 1.62 as compared to RANDOOP and by $\times$ 1.26 as compared to jCUTE.

V. COMPARISON WITH RELATED WORK

Majumdar et al. [2] presented a hybrid concolic testing for C programs. They have proposed an algorithm that interleaved random testing with concolic testing to achieve both a deep and a wide exploration of program state space. They had implemented their algorithm on top of CUTE tool and applied it to achieve better branch coverage for two large C based applications. For the same testing budget, almost they obtained $4\times$ branch coverage and $2\times$ branch coverage of random testing and concolic testing, respectively. We inspired from Majumdar et al. [2]'s core idea and proposed a new technique called Java-Hybrid Concolic Testing, which is implemented in Java language. Java-HCT is the combination of Feedback-Directed Random Testing and Java Concolic Testing.

Ganai et al. [12] and Ho et al. [13] proposed a technique of VLSI design validation where a combination of formal (symbolic execution or BDD based reachability) and random simulation engines were used to improve the design coverage

for big scale designs. Our proposed approach combines the Feedback-Directed Random Testing and Java Concolic Testing for Java programs to obtain better MC/DC.

Pacheco et al. [14], [8] presented a technique that improved random test generation by incorporating feedback obtained from executing test cases as they were created. Their proposed approach produced a test suite consisting of Java unit tests for the classes to be tested. Their experimental study showed that, use of feedback-directed random test generation was far better than systematic and undirected random test generation in term of coverage and error detection. In our approach, we used this improved random testing with the combination of Java concolic testing to obtain high MC/DC.

Sen et al. [9] proposed concolic testing in Java version called jCUTE and it is available online. jCUTE automatically selects the input values both symbolically and concretely, simultaneously. In our proposed work, we used this jCUTE tool to form Java-Hybrid Concolic Testing and obtained increased MC/DC.

Godefroid et al. [15] proposed an improved random testing technique by providing Directed fashion (Systematic way) combined with symbolic execution to generate test input values. In our proposed work, we used feedback-directed random testing instead of only directed because feedback-directed provides better code coverage. According to Pacheco et al. [8] RANDOOP is better in completeness and scalability, as compare to other approaches like DART. So, we have chosen feedback-directed technique to use.

Godboley et al. [16] proposed an approach to improve distributed concolic testing. They have proposed an approach for code transformation that supported to enhance MC/DC by generating extra test cases for C programs. Godboley et al. [17], [18], [19] has also developed transformation techniques for object oriented Java programs. They have also proposed green computation of testing tools.

VI. Conclusion and Future Work

To improve existing concolic testing and obtain high Modified Condition/Decision Coverage (MC/DC), we proposed a novel technique called Java-Hybrid Concolic Testing (Java-HCT). This technique is called as hybrid because it is the combination of two testing techniques Feedback-Directed Random Test and Concolic Testing. We experimented Java-HCT for forty Java programs and found there is an increase of 29.91% and 16.26% (on average), when compared to feedback-directed random testing and concolic testing respectively. We have improved MC/DC by $\times 1.62$ and by $\times 1.26$ in comparison to feedback-directed random testing and concolic testing, respectively.

In our future work, we will extend the proposed work by plugging with some transformation techniques to obtain better results.

***Abstract*—Adaptive software is a class of software which is able to dynamically modify at runtime its own internal structure and hence its behavior in response to changes in its operating environment. Adaptive software development has been an emerging research area of software engineering in the last decade. Many existing approaches use techniques issued from software product lines (SPLs) to develop adaptive software. They propose tools, frameworks or languages to build adaptive software architectures (ASAs) but do not guide developers on the process of using them. In this paper, we propose an adaptive software architecture development process to guide developers building an ASA. One of the important activities of this development process is software specification based on models. In our process, we propose to use the models and basic tools of Common Variability Language (CVL, proposed as an OMG standard) to generate an ASA and a subprocess to specify these models.**

I. Introduction

MAINTENANCE phase is one important stage of a software development process. Maintenance aims at evolving and updating software to meet new requirements or to satisfy new conditions in the software execution context. In order to be maintained and evolved, software is usually stopped, then updated, and finally restarted. However, in certain circumstances, stopping the software is unacceptable, e.g., cloud gaming, medical, and finance systems as stopping the software has consequences for business, or even dangerous for humans.

One solution to solve this problem is to add dynamic reconfiguration mechanisms to modify the software architecture at runtime. Several works are interested in determining when the architecture reconfiguration can occur [1], [2]. Other works are interested in tools and methods to develop an ASA [3], [4], [5]. Particularly, they allow specifying variation points in the software architecture. A variation point is a particular point in the architecture specification where choices can be realized. In SPL, variation points are specified in a variability model. Such a model describes commonality and variability of the product line. Commonality represents common parts of all products in the family. Variability represents the parts that may be different in different software products [6]. A product contains all the common parts and the choices made on all the variation points. Once all the variation points are resolved (a choice has been made for all of them), the variability model is said to be configured.

Many existing works use techniques issued from SPLs to develop adaptive software [7], [8]. These works use a variability model to specify the software variability and propose the mapping between the variability model and the software architecture. When the variability model is configured, the corresponding component architecture is deduced. During software execution, a new configuration of the variability model can be decided and the corresponding software architecture deduced. Then, by calculating the differences between the current and the new architecture, reconfiguration actions are identified. However, these approaches do not specify a software development process to guide developers to build the adaptive software architecture.

To deal with the above limitation, we are working on a development process to guide developers to specify information needed to generate an ASA. In this paper, we focus on identifying the information to be specified in a development process. All along the development process we use CVL metamodels [9] to manage variability and propose a subprocess to describe how to specify this variability.

The remainder of the paper is structured as follows. Section II describes the CVL approach. Our general development process for building an ASA is presented in Section III. Section IV focuses on the variability modeling stage of our process and how a variability model is configured in order to generate an adaptive software. Related work is discussed in Section V then the paper concludes.

II. Common Variability Language

CVL [9] is a domain-independent language, and also an approach for specifying and configuring variability. We use CVL in our approach for two main reasons:

- CVL has been proposed as an OMG standard and we think it will be largely used in the near future.

- It proposes a MOF-based variability language which means that any MOF-based product model can be easily extended with variability information using CVL.

An overview of the CVL approach is depicted in Figure 1. The base model is used to specify the elements of the architecture that does not contain any information about variability. Variability information is specified in the variability model. In order to generate the configuration of a specific product, the resolution model consists of VSpecResolutions each determining a decision for a VSpec.

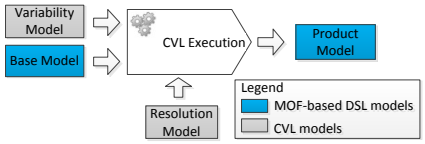

Fig. 1. CVL approach

In CVL, a variability model consists of three main parts:

- **VSpec tree.** A VSpec tree consists of VSpecs which are similar to features in feature models (FMs) [10]. There are four types of VSpecs: *Choice*, *Variable*, *VClassifier* and *CompositeVSpec*. A *Choice* allows to specify binary selections (true/false). A *Variable* should be used to specify a parameter which value may change. A *VClassifier* allows to specify a min and max number of instances of the VSpec. Finally, *CompositeVSpec* is used for modularity purposes.
- **Variation points.** A variation point links a VSpec to the corresponding elements in the base model.
- **OCL constraints.** CVL supports the definition of OCL constraints among VSpecs of a VSpec tree that cannot be directly captured by hierarchical relations.

Let *CVL model* denote the three models: the base model, the variability model, and the resolution model.

CVL offers tools and meta-models to specify variability of a product family but it does not offer a method to specify the variability model and the base model. Additionally, the product is generated without runtime variability.

III. A DEVELOPMENT PROCESS FOR BUILDING AN ADAPTIVE SOFTWARE ARCHITECTURE

In order to help engineers on developing adaptive software, we propose a development process that includes variability as a first-class stage. Although our process is based on CVL models and meta-models, other tools and frameworks may be used. The process we propose encompasses the variability specification issue to generate the architecture of the product. On the other hand, a reconfiguration process (at runtime) is out of the scope of this paper, but appears in the process in order to give an overview of the whole picture.

Our process is based on SPL engineering. The SPL engineering distinguishes two phases: domain engineering and application engineering [11] (see Figure 2).

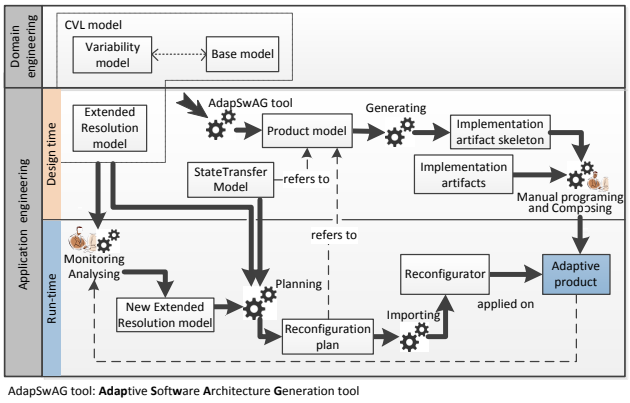

Fig. 2. General Adaptive Software Architecture Development Process

Domain engineering is the process responsible for defining the commonality and variability of the product line. The variability model and the base model are artifacts of this phase. The base model in our approach corresponds to a component-based architecture model specified by using an architecture description language (ADL).

Application engineering refers to the process of actually combining the artifacts obtained during the domain engineering phase, in order to generate a software product. In our approach, this phase is partitioned into two subprocesses: one at design time and another one at runtime.

At design time, a resolution model is specified to configure the variability model. This resolution model is extended from the CVL resolution meta-model for generating the necessary elements in an ASA. Generating the architecture is realized by our **Adap**tive **S**oft**w**are **A**rchitecture **G**eneration (AdapSwAG) tool. As depicted in Figure 2, the input of this tool is the CVL model and its output is a particular architecture (the product model). Compared to the CVL execution of the CVL approach, the software architecture generated by AdapSwAG tool includes part of its initial variability, and is specified in the same language as the base model. Based on the product model and a given target platform, a text generation module generates implementation artifacts skeleton. Each of them corresponds to a component specified in the product model and consists of component implementations, a component specification, and a configuration file. Once the implementation artifacts skeleton is generated, implementation artifacts that are either available or should be developed are integrated into it to build operational components. This task is performed by an application engineer. The result is an adaptive product that can be executed in the target platform.

If the product embeds variability, then, its architecture may change at runtime, and the components state affected by the changes should be migrated to the new ones. As the semantic of this state is component-specific, the state migration task is never completely automated. Thus, engineers have to specify a state transfer model that gives actions to effectively migrate state between components. The state transfer model represents the state mapping between previous components and the new

ones in the product model. It is specified at design time and used at runtime.

At runtime, because of new user requirements or execution environment changes, a change decision may be made. In this case, a new resolution model (new configuration) must be specified. This configuration may be either defined by engineers or computed thanks to analysis activities by a decision module integrated into the adaptive product. The current resolution model, the new one, and the state transfer model are processed to generate a reconfiguration plan that refers to the product model. Finally, the reconfiguration plan is injected into the reconfigurator to execute the reconfiguration actions. The moment when these actions are executed at runtime is important since the components must be driven to safe state (e.g., quiescent [1] or tranquility [2]), but this is out of the scope of this paper.

In this paper, we focus on the domain engineering phase and the design subprocess of the application engineering and give details on how to specify the VSpec tree, the base model, and the variation points to generate an ASA.

IV. Variability Modeling and Configuration

Variability modeling plays an important role in our approach. This section presents strategies to specify variability models according to CVL meta-model.

A. Variability Modeling Process

There may be different strategies to specify the variability and the base models.

- "Variability-driven process" (top-down approach): in this strategy the VSpec tree is specified first from information collected by engineers such as documentation or already existing products. Following this model, a base model may be built. Finally, variation points may be specified. This strategy allows specifying variability at high level of abstraction towards the diversity of components at concrete level.
- "Architecture-driven process" (bottom-up approach): in this strategy the base model is specified first. Then, VSpec tree is deduced and finally, variation points identified. This strategy allows specifying components at concrete level towards high level abstraction.
- "VSpec tree - base model independent process" (hybrid approach): in this strategy the VSpec tree and the base model are independently specified. Once the VSpec tree and the base model are specified, variation points can be identified to do the mapping between them. The advantage of this strategy is to allow independent specifications. Unlike the two first strategies, there is no guarantee to have a variation point for each VSpec.

As our approach is focused on guiding developers to identify information for generating adaptive products, we consider the first strategy as the process to be followed by engineers. In this strategy, variability modeling plays an important role. We focus on this task to represent the changes that an ASA may undergo. Based on the variability model, the base model can be created appropriately. The adopted strategy is depicted in Figure 3. In order to specify the VSpec tree and the base model, engineers need to identify variability and commonality. To do this, they can use documentation of existing applications of a product line, domain experts may also participate on the specification (step 1 in Figure 3). Once commonality and variability are identified, they are represented as a VSpec tree (step 2 in Figure 3). In step 3, a base model is defined with respect to the VSpec tree and the set of commonality and variability in the first step. Finally, step 4, variation points are defined to map VSpecs in the VSpec tree and elements in the base model. Steps 1 and 2 have to be manually realized by variability engineers. Step 3 should be realized by a software architecture expert. Step 4 can be manually (by an expert) or semi-automatically done thanks to similar characteristics of elements in the two models. To this end, in our development process, the domain engineering process encompasses all activities of this variability modeling process.

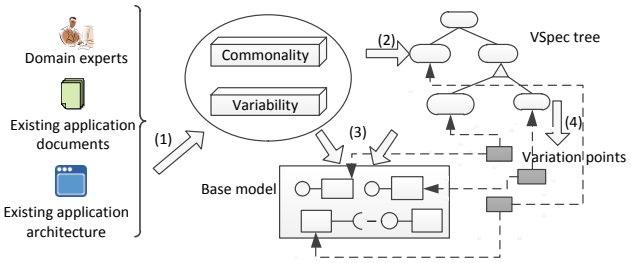

Fig. 3. "Variability-driven process" strategy

B. Product model generation

The first activity in Figure 2 shows the stage of the development process where the variability model is configured and the product model is generated. As previously mentioned, the product model is generated by configuring the variability model based on the resolution model. The task is realized by the AdapSwAG tool. It considers the CVL model as its input. Its output is a product model that contains the necessary components for adaptation. The AdapSwAG tool generates this product model by applying the following rules:

1) A component in the base model will be present and activated in the product if the corresponding *Choice* VSpec is resolved by a True value in the VSpecResolution.
2) A component in the base model will be present in the product at runtime if the corresponding *Choice* VSpec is not resolved by a True value in the VSpecResolution.
3) An attribute in a component in the architecture is assigned the value that is specified to the *value* attribute of its VSpecResolution.
4) Connections between components that are activated in the product are maintained in the product model.

Unlike the CVL approach, the generated product model contains all components in the base model and only connections between components which corresponding *Choice* VSpecs are resolved by True values in the resolution model.

V. Related work

SPL engineering has proven to be a well-suited methodology for developing a diversity of software products and software-intensive systems [11]. Several approaches are based on SPL engineering to develop adaptive software. Parra et al. [3] propose an approach to build a dynamic SPL. In this approach, activities such as analysis, composition generation, transformation, and runtime reconfiguration are separated into domain engineering and application engineering processes as in SPL engineering. Moreover, the role of developers in the process is defined such as application architect, platform architect, and asset developer. Lee et al. in [4] propose an approach to develop dynamically reconfigurable products. They introduce the activities of product line development, e.g., feature and feature binding analysis, behavior and functional specifications of feature binding units, product line architecture, and component design. They provide guidelines for designing dynamically reconfigurable architectures. Authors in [8] represent a process to automatically build a dynamic SPL from a feature model based on the assumption that a feature can be modeled as a component. This process consists of four steps: defining the core and dynamic architecture, adding the configurator, and defining the initial product. The reconfiguration action at runtime is simple to activate or deactivate components. The MADAM approach [5] is based on SPL techniques to build adaptive systems. They propose five steps to develop adaptive applications as follows: identifying fixed and varying user needs and resource constraints, designing the architecture, implementing the components identified by the architecture and deriving runtime plan objects, designing the utility function and property predictors for the components and composition.

Almost all these approaches use a feature model to specify variability. The feature model is configured to generate an initial product. However, they do not define how to specify variability and build an ASA. In our approach, an adaptive software development process based on SPL engineering with a set of specific steps has been proposed to guide engineers building an ASA. Activities to specify the variability model and the base model in our approach are considered as steps in the domain engineering process. The other activities are separated into two subprocesses in the application engineering process. Moreover, our approach identifies an explicit activity for maintaining the software state integrity based on specifying a state transfer model at design time.

VI. Conclusion

In this paper, we have presented a variability-driven development process for building an ASA. The process is based on CVL tools and meta-models to model variability of the software architecture but identifies an ordered set of tasks to be performed by engineers from variability specification up to the software architecture.

In order to validate our process, we have implemented a simple client-server application. The server is implemented with two different versions and can dynamically switch. In order to represent the variability of this application, a VSpec tree in CVL that conforms to the CVL meta-model is finally specified. Its architecture (base model) is specified by using ACME - an ADL. In order to generate a product, a resolution model is specified. Then, AdapSwAG tool generates a product model as an ASA. In this example, we have used the iPOJO component model and the Apache CXF framework to develop components. Based on their specification, a text generation module is implemented by using Xpand generator framework to generate implementation artifacts skeleton that includes packages. Each of them corresponds to a component specified in the product model and consists of component implementations, a component specification represented in XML documents, and a configuration file to create iPOJO components. To this end, the generated packages can be manually completed by an engineer, or the implementation artifacts developed independently by an engineer are integrated into them to build the iPOJO components of the adaptive product. Due to space constraints we can not give more details of our implementation, but the example is available at https://github.com/nthohuynh/.

Efficient Data-Race Detection with Dynamic Symbolic Execution

Andreas Ibing
Chair for IT Security, TU München
Boltzmannstrasse 3, 85748 Garching, Germany

***Abstract*—This paper presents data race detection using dynamic symbolic execution and hybrid lockset / happens-before analysis. Symbolic execution is used to explore the execution tree of multi-threaded software for FIFO scheduling on a single CPU core. Compared to exploring the joint scheduling and execution tree, the combinatorial explosion is drastically reduced. An SMT solver is used to control a debugger's machine interface for adaptive dynamic instrumentation to drive program execution into desired paths. Data races are detected in concrete execution with available static binary instrumentation using hybrid analysis. State interpolation using unsatisfiable cores is employed for path pruning, to avoid exploration of paths that do not contribute to increasing branch coverage. An implementation in Eclipse CDT is described and evaluated with data race test cases from the Juliet C/C++ test suite for program analyzers.**

***Index Terms*—race detection; symbolic execution; interpolation; branch coverage.**

I. Introduction

A DATA race means, that there are concurrent accesses from different threads to the same variable, of which at least one is a write. Data race bugs are introduced in multi-threaded software when the developer forgets to lock a resource, that is shared between threads. Because races are observed only for certain thread interleavings depending on the scheduler's decisions, they are difficult to reproduce and sometimes called 'Heisenbugs'. Exactly locating feasible data races is known to be NP hard [1].

Data race detection is typically implemented as dynamic analysis with binary instrumentation. It follows happens-before analysis with vector clocks [2], or lockset analysis [3], or a hybrid algorithm [4]. These algorithms introduce some false positive and / or false negative detections. A prominent example is ThreadSanitizer [5], which is integrated with the GNU and Clang C compilers. It is reported to slow down execution speed by at least a factor of ten. Therefore, it is typically applied as dynamic analysis with a manually written test-suite. The achievable code coverage is then limited to execution coverage of the test suite. Therefore, data race detection in this approach also depends on the size of the available test suite, which is limited by cost constraints.

Symbolic execution [6] automatically performs a systematic program path exploration and enables program coverage independent of a test suite. Program input is treated as symbolic variables, and operations on the variables are translated into logic equations. The feasibility of program paths (feasible with any program input) is then decided with a Satisfiability Modulo Theories (SMT, [7]) solver. Symbolic execution is often applied as dynamic analysis in the form of 'concolic' (concrete and symbolic) execution [8], [9]. The program is executed with concrete input, while symbolic constraints are collected on the program path. The input for the next path is generated by the SMT solver, so that the program takes the desired path. Concolic execution offers the possibility for consistent concretization of formulas (fallback to concrete value). This is useful if certain constructs can not be handled with the solver. Concretization does not introduce false positive path satisfiability decisions or error detections, but in general introduces false negatives.

The prominent symbolic execution tools DART [8], CUTE [9] and KLEE [10] currently do not feature data race detection. Symbolic execution tools that do support race detection are jCUTE [11], Con2colic [12] and LCT [13]. They use a solver to search paths through the program's joint execution and scheduling tree, i.e., the solver determines both program input and thread scheduling. The combinatorial explosion can be partly mitigated with partial order reduction [14]. The resulting race detection with symbolic execution is considerably more complex and slower compared to symbolic execution of single-threaded code.

This paper presents data race detection using dynamic symbolic execution and hybrid lockset / happens-before analysis. Symbolic execution is used to explore the execution tree of multi-threaded software for FIFO scheduling on a single CPU core. Complexity and scaling of symbolic execution are improved by interpolation based path pruning.

The remainder of this paper is organized as follows: Section II motivates and describes the algorithm, Section III depicts its implementation. In Section IV, the implementation is evaluated with data race test cases from the Juliet test suite [15]. Related work is reviewed in Section V. Results of the experiments are discussed in Section VI.

II. Algorithm

A. Motivation

The algorithm is motivated by the following aspects:

- The operating system scheduler can be used in concolic execution for speed-up. Code execution is faster than interpretation. Symbolic execution needs a reproducible execution tree, also for multi-threaded software. This can be achieved by restricting the scheduling to one CPU core

and to reproducible scheduling independent of system load.
- Race detection works faster during concrete execution. Event tracing and instrumentation do not need a symbolic interpreter.
- The analysis of a program path should continue after the detection of a potential data race, in order to detect further errors along path extensions. This means, that actual races should be avoided while still detecting them. Program behaviour without races is independent of scheduling. Data races can be prevented by using FIFO scheduling on one CPU core. With this scheduling, potential data races can still be detected (using happens-before, lockset or hybrid analysis).
- State interpolation can be used to improve scaling of symbolic execution. Unsatisfiable branches can be interpolated by computing unsatisfiable equation cores [16]. The interpolation can be used to prune paths, that are redundant with respect to coverage. Unsatisfiable cores can be backtracked by approximate weakest-precondition computation. This requires depth-first path exploration.

An advantage of this approach is that bugs other than races (e.g., buffer overflows) can be found just like with symbolic execution of single-threaded code. Only one representative thread interleaving is analyzed per executed program path. With FIFO scheduling on one CPU core, there is also the possibility to apply standard code coverage criteria like in single-threaded execution.

B. Dynamic Symbolic Execution

Code execution is faster than interpretation, and especially faster than translation into logic formulas. Therefore, only as few code locations as needed are interpreted symbolically, otherwise the code is executed concretely. These locations are the definition of input-dependent variables (symbolic variables) and input-dependent branch decisions (dependent on a symbolic variables). Because it is context-sensitive which variables are symbolic, adaptive dynamic instrumentation is used. The program under analysis is executed concretely. If a program location needs formula generation, the analysis switches to symbolic interpretation and generates the constraint formula. Then, further dependent locations are marked for symbolic interpretation, and the concrete execution is continued.

1) Reproducible Execution Tree for Multi-Threaded Programs: Multi-threaded software can be described as state transistion system with a combined scheduling and execution tree. Considering a deterministic scheduling algorithm without outside parameters (independent of system load etc.), the execution tree for this scheduling is yielded. Here, FIFO scheduling on one CPU core is used. This avoids data races because only one thread at a time is active, and it is not preempted. Computations in a thread between calls to the scheduler become atomic. Data race detection is still possible. The execution further becomes reproducible: when restarted with the same program input, the identical thread interleaving is yielded.

2) Execution Tree Exploration: Symbolic program input is configurable. It can comprise command line parameters and system call return values. In the execution of the first program path, pre-configured stardard return values (that are always valid) from the symbolic system calls are used for concrete execution. Then, the solver is used to generate concrete input values for the next path from the collected constraints of the previous path. The last symbolic branch condition is negated, if the negation is not yet covered in this context. If the resulting equation system is unsatisfiable, the branch decision is backtracked. This path exploration is depth-first search. Without state interpolation and path pruning, it explores all satisfiable program paths.

3) Interpolation Based Path Pruning: The state interpolation uses unsatisfiable core (unsat-core) computation with serial constraint elimination as described in [16]. Given an unsatisfiable conjunction of formulas, an unsat-core is a subset of the formulas whose conjunction is still unsatisfiable. If input generation for a path is unsatisfiable, an unsat-core is computed from the path constraint. Unsat-cores are backtracked during depth-first path exploration. A constraint is removed from the unsat-core when the control flow graph (CFG) node is backtracked, for which the constraint was generated.

a) Pruning: Prune formulas are the backtracked unsat-cores. When a control flow decision node is backtracked, the conjunction of the branch prune formulas is used. Branch targets are used as potential prune points. When symbolic execution reaches a branch for that a prune formula has been computed, then the solver is used to decide whether the current path is redundant and can be pruned. If the current path's path constraint implies the prune formula, then the path is pruned. This approach can prune paths from different contexts [16]. The implication means that all branches, that were unsatisfiable in the previous context, are also unsatisfiable in the current context. Extensions of the path would therefore not contribute to increasing branch coverage [17].

C. Dynamic Race Detection

Data races are detected with hybrid dynamic analysis during concrete execution, using the ThreadSanitizer algorithm [5]. This subsection shortly reviews the algorithm. Happens-before analysis with vector clocks is combined with lockset analysis to reduce the number of false negative detections. The hybrid detection has false positive detections. False positives can be eliminated by adding annotations to the program. Binary instrumentation is used to trace the relevant events [5]:

- memory access events: read and write
- synchronization events: locking and happens-before arcs. Locking events are write lock, read lock, write unlock and read unlock. Happens-before events are signal and wait.

The events are traced as state machines in shadow memory. The state machines can be run as pure happens-before or as hybrid analysis, with configurable context tracing information (speed versus information).

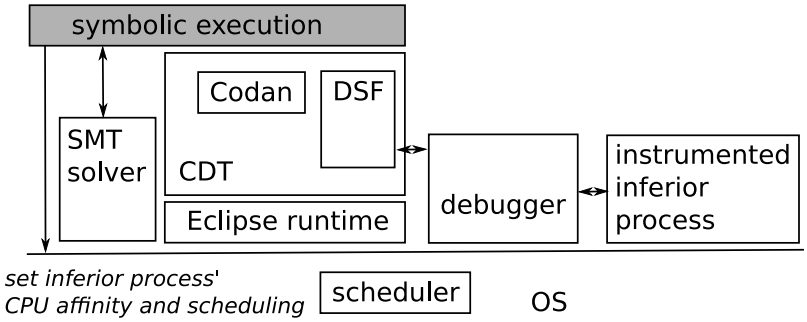

Fig. 1. Overview

III. Implementation

An overview of the main components is shown in Figure 1. These comprise the Eclipse runtime with plug-ins for the C/C++ development tools (CDT). CDT contains a code analysis framework (Codan) and debugger services framework (DSF). The instrumented program under test is controlled through DSF using a debugger (here the GNU debugger `gdb`). The debug inferior process is scheduled by the operating system scheduler. Symbolic execution is implemented as Eclipse plug-in on top of CDT. Logic formulas are decided using the Z3 SMT solver [18].

A. Debugger based concolic execution of multi-threaded code

The implementation extends the dynamic symbolic execution engine for single-threaded code presented in [17]. It uses the C/C++ parser from Eclipse CDT and the control flow graph builder from Codan. The debugger services framework is an abstraction layer over debuggers' machine interfaces. The program under test is executed in a debugger.

a) Selective symbolic interpretation: Only when the debugger hits a breakpoint, then a constraint is generated for the respective code location. The breakpoints are updated so that the debugger breaks on usage and definition of symbolic variables, then the debugger continues. At a breakpoint, the CFG node is resolved for the thread that stopped. Tree-based translation is used to generate the logic constraint. The debugger is queried for values of concrete variables where needed. Variables can become symbolic (by assignment of a symbolic value) and concrete (by assignment of a concrete value).

b) Static pre-analysis: Initial breakpoint locations are determined with static analysis before starting the symbolic execution. These locations are the definition of symbolic program input and input-dependent branches (branch locations that are input-dependent on any branch). In addition, the analysis overapproximates the set of pointers that might on any program path point to a symbolic target. If a target becomes symbolic during symbolic execution, a breakpoint is set on usage and definition of all pointers, that might point to this target. The static pre-analysis could be called 'maybe symbolic' analysis.

c) Single-core FIFO scheduling: The implementation currently runs on Linux, which supports different scheduling algorithms at the same time for different processes. Differing from the standard scheduler `SCHED_OTHER`, for the program under test the FIFO scheduler (`SCHED_FIFO`) is used. The CPU affinity is restricted to one CPU core. The corresponding Linux commands are `chrt` (to set the scheduling) and `taskset` (for CPU affinity).

d) Translation into SMT logic: The tree-based translation is implemented with CDT's abstract syntax tree (AST) visitor class. A control flow graph node references an AST subtree, that is traversed to generate a logic constraint. The translation uses bit-vectors and arrays. The solver is neither aware of multiple threads, nor of any scheduling. It just gets a conjunction of constraints that were collected along the program path.

e) Backtracking unsat-cores and path pruning: Unsat-cores are computed with serial constraint deletion as in [16]. There is one pass through the collected constraints on the path beginning from program start. Each constraint is tested once: if it can be removed and the rest remains unsatisfiable, then it is removed. Backtracking considers only CFG nodes that have been interpreted (where the debugger stopped). If a CFG node is backtracked, then any constraint generated for this node is removed. When a decision node is backtracked, the conjunction of the formulas from the branches is used [16]. When backtracking reaches a branch node, a prune formula is connected with this location. The prune formula is the conjunction of backtracked unsat cores. When a branch target is reached in (forward) symbolic execution, it is checked, whether there is a prune formula. If yes, then it is checked with the solver whether the path constraint implies the prune formula (i.e., whether the negation of the implication is unsatisfiable). In this case, the path can not contribute to increase branch coverage, and therefore is pruned.

B. Race detection in concrete execution using ThreadSanitizer

The implementation uses compiler instrumentation with `ThreadSanitizer` [5], which is featured by the GNU C compiler. The program under test is linked statically with the `ThreadSanitizer` library, and a breakpoint is set on the race detection error report function. If this breakpoint is hit,

```
1  #define N_ITERS 1000000
2  void CWE366_Race_Condition_Within_Thread__int_byref_12_bad() {
3    if(global_returns_t_or_f())      {
4      std_thread thread_a = NULL, thread_b = NULL;
5      int val = 0;
6      if (!std_thread_create(helper_bad, (void*)&val, &thread_a)) {
7        thread_a = NULL;
8      }
9      if (!std_thread_create(helper_bad, (void*)&val, &thread_b)) {
10       thread_b = NULL;
11     }
12     if (thread_a && std_thread_join(thread_a)) std_thread_destroy(thread_a);
13     if (thread_b && std_thread_join(thread_b)) std_thread_destroy(thread_b);
14     printIntLine(val);
15   } else {
16     std_thread thread_a = NULL, thread_b = NULL;
17     int val = 0;
18     if (!std_thread_lock_create(&g_good_lock)) { return; }
19     if (!std_thread_create(helper_good, (void*)&val, &thread_a)) {
20       thread_a = NULL;
21     }
22     if (!std_thread_create(helper_good, (void*)&val, &thread_b)) {
23       thread_b = NULL;
24     }
25     if (thread_a && std_thread_join(thread_a)) std_thread_destroy(thread_a);
26     if (thread_b && std_thread_join(thread_b)) std_thread_destroy(thread_b);
27     std_thread_lock_destroy(g_good_lock);
28     printIntLine(val);
29 } }
30 static void helper_bad(void *args) {
31   int *p_val = (int*)args;
32   for (int i = 0; i < N_ITERS; i++)     {
33     *p_val = *p_val + 1;
34 } }
35 int global_returns_t_or_f() {
36   return (rand() % 2);
37 }
```

Fig. 2. Example 'bad' function from [15] that contains a data race in line 33

the stack is traced back to a source file location, where the race is reported.

`ThreadSanitizer` supports dynamic annotations (C makros), which can be used if standard Posix threads are not used. They can also be used to eliminate false positive detections and to hide benign races [5]. Parts of the code can be marked as safe by the tool user. `ThreadSanitizer` can be run as happens-before or hybrid analysis. Also in pure happens-before mode it can report the involved locks. The slow-down by the instrumentation is reported as factor 20 – 50, and up to several hundred MB can be consumed for shadow memory [5].

IV. Experiments

a) Test cases and test setup: The implementation is evaluated with the data race test cases from the Juliet suite [15] for common weakness CWE-366 'race condition within a thread'. The test cases are 38 small artificial programs with 5-7 threads each. They contain 'good' functions (without data race) as well as 'bad' functions (that contain a data race) in order to measure false positive and false negative detections. There are two sets of 19 programs each. One set contains data races on global variables, the other contains data races on stack variables with access through pointers. Both sets cover the same 19 different data and control flow variants, that include conditional branches, loops, goto statements etc. The tests are run as JUnit plug-in tests with Eclipse 4.5.1

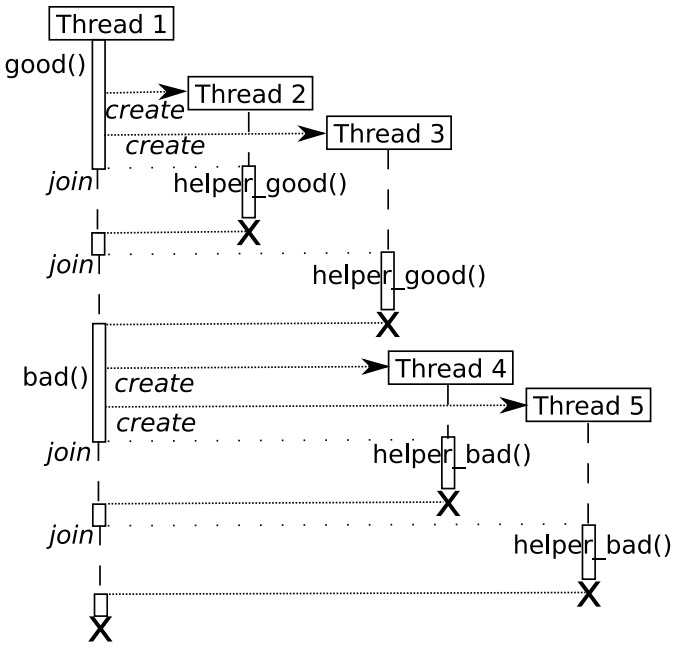

Fig. 3. Example, FIFO scheduling on one CPU core

and `gdb` version 7.10 on Linux kernel 4.2.0, on a Core i7-4650U CPU. The programs under test are run as unoptimized

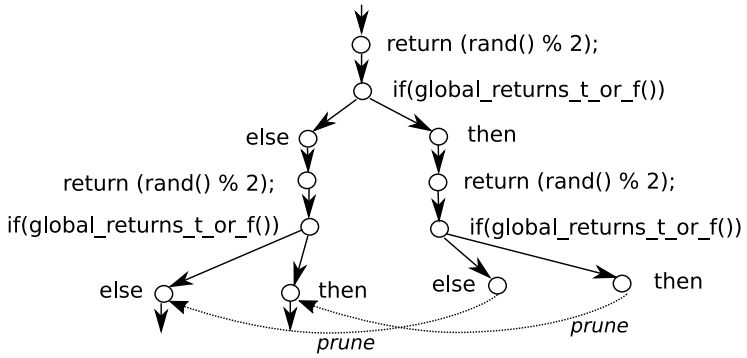

Fig. 4. Example, traversed part of execution tree

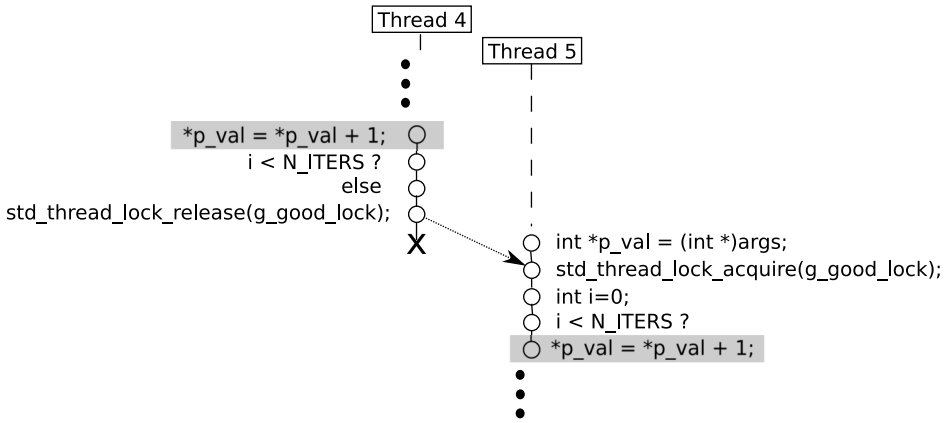

Fig. 5. Happens-before analysis, no data race for example 'bad' function if the `else` branch is taken (Figure 2 line 16)

code with default `ThreadSanitizer` settings without any annotations.

b) Example: An example 'bad' function is shown in Figure 2. It contains a data race on a stack variable with access by reference in line 33. The control flow depends on random input that is returned by a global function. The `rand()` call in line 36 generates this program input, i.e., the debugger breaks at this call, and the return value of `rand()` is treated as unconstrained symbolic variable. Before this 'bad' function, the program executes a similar 'good' function with proper locking in both branches, that also executes a loop with 10^6 iterations. The test program contains many branches, but few of them are input dependent. The loops in the 'good' and 'bad' functions are executed concretely. Because they contain only input-independent variables and branches, there is no need for symbolic interpretation. The symbolic execution finds four satisfiable program paths that non-deterministically depend on two `rand()` calls, and of which two paths exhibit the data race. FIFO scheduling on one CPU core for this program is illustrated in Figure 3. This figure looks the same for any of the four paths. The part of the execution tree (under this scheduling), that is traversed by symbolic execution, is illustrated in Figure 4. It only shows the locations where the debugger stopped. Two paths are followed to program end, the other two are pruned as indicated in the figure. The data race is accurately detected by `ThreadSanitizer`. An example part of the happens-before analysis is illustrated in Figure 5, for the `else` branch of the example function, where proper locking is used. The shaded memory access events are separated by a locking arc.

c) Results: All data races in the 38 test programs are accurately detected without false positives or false negatives. The (wall-clock) analysis runtimes are shown in Figure 7. The horizontal axis indicates the Juliet flow variant number. The average analysis runtime is below 2s. Error reporting through the Codan framework in the Eclipse GUI is shown in Figure 6.

V. Related Work

Exactly locating feasible data races is known to be NP hard [1]. The main approaches for practical race detection are usage of the happens-before relation with vector-clocks [2], or usage of locksets [3], or a combination of them. These approaches detect races when they might occur, i.e., not only with the current thread interleaving, but also with different interleavings. Main analysis methods are static analysis, model checking, dynamic analysis and symbolic execution.

a) Static Analysis: offers a possibility to detect races without false negatives. A method that requires programmer annotations and is based on type inference is described in [19]. The tools `RELAY` [20] and `LOCKSMITH` [21] apply lockset

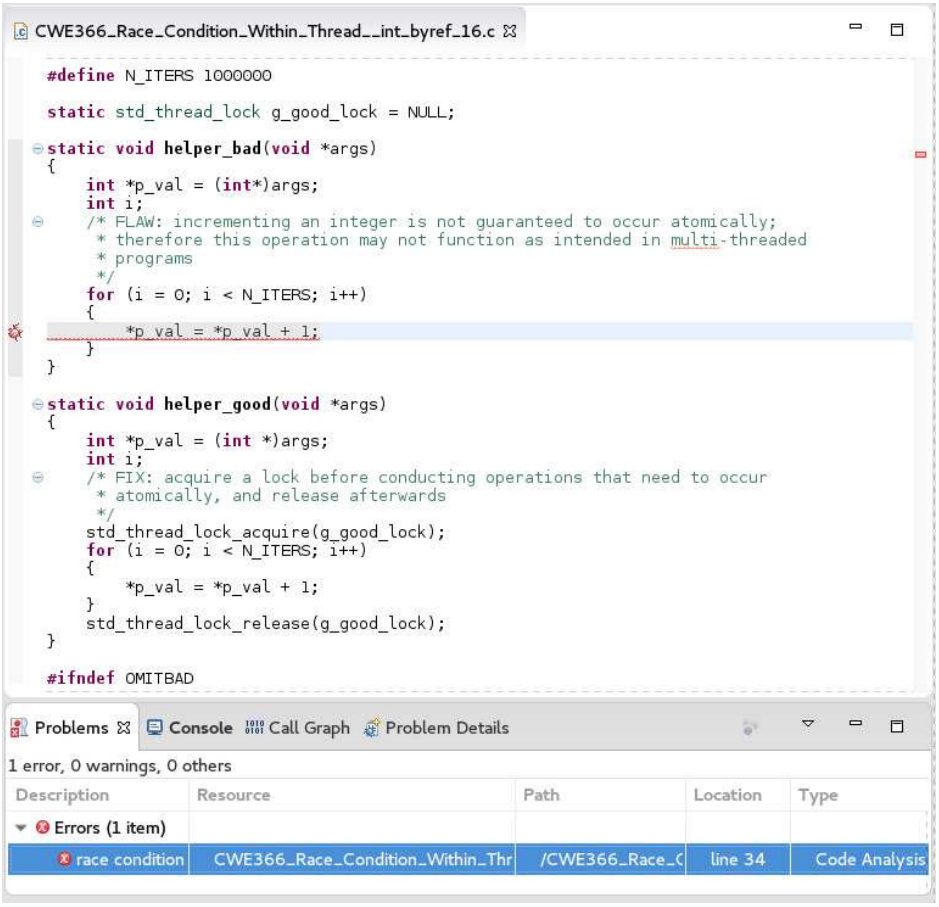

Fig. 6. Error reporting

analysis statically with data flow analysis. According to Palsberg [22], ”the best existing static technique” is implemented in `Chord` [23], but it ”reports a large number of false positives that would be daunting to examine by hand”.

b) Model Checking: In symbolic model checking, a program is translated into a logic formula, and properties are checked with an SMT solver. In theory, model checking allows for accurate race detection. It explores the symbolic state-space, that is the combined execution and scheduling tree. In practice, model checking does not scale well due to combinatorial explosion. One practical approach is bounded model checking [24], [25], [26], where the combined execution and scheduling tree is pruned with limits for the number of context switches and loop unrollings. Another way of pruning the tree is partial order reduction [27], [28], [14], [29], which prunes away irrelevant thread interleavings. Dynamic partial order reduction [14] traces the happens-before relation for thread interactions to find backtracking points for branching [14]. Optimal dynamic partial order reduction [29] explores a minimum number of representative thread interleavings.

c) Dynamic detection at runtime: is a practical way for race detection. It does not need a constraint solver. One technique is to instrument memory accesses and thread interaction with binary instrumentation and check for races using the happens-before relation [2] with vector-clocks. Happens-before analysis may have false negative detections depending on the scheduling. It is more sophisticated than lockset analysis, but scales worse with an increasing number of threads. `LiteRace` applies sampling, i.e., it monitors only a subset of all memory accesses. It can detect a majority of races by monitoring a small number of accesses [30]. `FastTrack` is an optimized implementation of happens-before analysis with reduced complexity [31]. `Pacer` [32] combines sampling with `FastTrack`. `DataCollider` [33] implements memory access sampling with hardware breakpoints and watchpoints and applies it to kernel code. Lockset analysis is used in `Eraser` [3]. It instruments memory accesses and traces thread locksets and variable locksets. If a variable access is not protected by a lock, then a warning is issued. Lockset analysis is lightweight and scales well. On the downside, it leads to more false positive detections than happens-before analysis. Hybrid race detection is presented in [4] as a two-pass solution. First, locksets are used to find problematic variables. Then, happens-before analysis is applied only to those variables. In [34], the DJIT algorithm is presented, which is a variation of happens-before analysis. `MultiRace` [35] combines DJIT with locksets to reduce false positives. A location’s lockset is reset

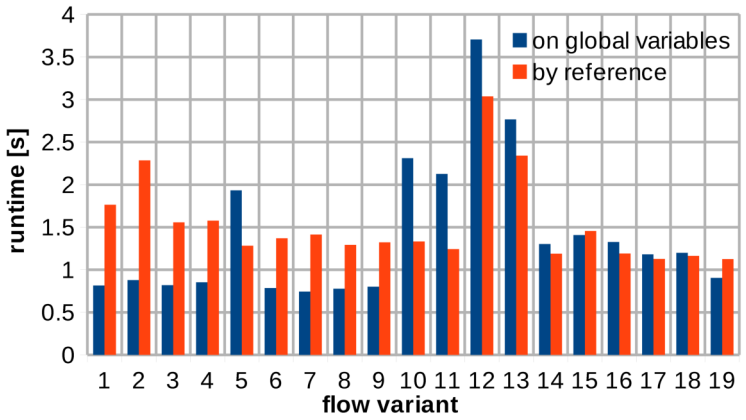

Fig. 7. Analysis runtime for data race tests from Juliet suite

at synchronization barriers. `ThreadSanitizer` [5] applies static binary instrumentation for happens-before and lockset analysis and is integrated with several current C compilers. Dynamic race detection is integrated in the managed runtime environments `RaceTrack` [36] and `Goldilocks` [37]. In [38], [39], it is proposed to integrate hardware acceleration for race detection into CPUs.

d) Symbolic execution: The prominent symbolic execution tools `DART` [8], `CUTE` [9] and `KLEE` [10] currently do not feature race detection. `jCute` [11] determines program input and thread schedule with the solver to explore different paths and interleavings, and it detects races when they occur. `Con2colic` also determines input and schedule with the solver. It implements a heuristic to first achieve branch coverage, and then explore an increasing number of context switches. Also `Con2colic` can detect a race when it occurs (no happens-before or lockset analysis). `LCT` [13] implements concolic execution with dynamic partial order reduction. In [22], the tool `Racageddon` is described. It starts with race candidates that have been found with an existing hybrid technique. It then uses concolic execution to search for input and schedule that lead to a real race (to remove false positives). `WHOOP` [40] considers races between pairs of entry points to driver code and runs a symbolic lockset analysis with SMT solver. In [16], [41], it is described that a program path can be pruned if the context implies a previously computed interpolant for the same program location. A combination of partial order reduction with interpolation based path pruning is described in [42].

e) This paper: differs from previous work on race detection with symbolic execution both in that it factors out the scheduling, and in that it applies hybrid data race detection during concrete execution. It extends own prior work [17] (on dynamic symbolic execution of single-threaded code with interpolation based path pruning) with support for multi-threaded execution and with data race detection.

VI. Discussion

Symbolic execution with FIFO scheduling on one core is used to automatically drive concrete execution into program paths of interest. The scheduling effectuates a reproducible execution tree for multi-threaded code. FIFO scheduling avoids triggering data races. Races are detected during concrete execution by instrumenting the program under test with the available `ThreadSanitizer`. The analysis is comparatively fast through concrete scheduling and concrete race detection. Path pruning is used based on interpolation of unsatisfiable branches with unsatisfiable cores. Implication checking with SMT solver assures that only paths are pruned, that can not contribute to increasing branch coverage. It is also possible to run the analysis in a virtual machine like `qemu`, that contains a `gdb` server.

***Abstract*—Successful software is often enhanced and adapted to the needs of new users. During evolution, a software system grows in size, becomes more complex, and costly to maintain. In this paper, we point to big clones—large granular duplicated program structures such as files or directories—as one of many reasons why this happens. Using the Linux kernel as an example, we show that big clones arise in the Linux kernel despite careful architecture design and a systematic approach for managing variability. We propose a solution to avoid these big clones by representing them as generalized templates in ART (Adaptive Reuse Technique). ART templates are constructed on top of the Linux code, without conflicts with the state-of-art techniques and tools used to manage the Linux kernel. Benefits include simplification of the Linux kernel due to non-redundancy, easier comprehension, and traceability of the change impact during evolution. The proposed technique is general and the Linux example discussed in this paper also illustrates general phenomena.**

I. Introduction

CHANGES in user features, design decisions, and platforms arise naturally during software evolution. Sometimes, these changes are contained at the architectural level [1]. But, most often the impact of changes spreads widely throughout the code. It has been reported that after years of evolution software systems grow in size, their structure decays, and become more and more difficult to maintain [2]. Evolution may lead to cloning [3]. New system versions are generally built by cloning (copy-paste-modify practice) code from the earlier versions. However, less cloning happens in advanced Software Product Line (SPL) solutions [4] where reuse and evolution are aided by systematic variability management rather than by cloning. There is a large body of research on reasons why clones arise—both within and across system versions—and whether clones are good or bad [5][6][7]. These studies show that designers may intentionally create certain clones to fulfill some design goals (e.g., for performance, readability, or yet other reasons) [5]. Other clones may result from careless design and can be refactored [6][8], and yet others may not play any useful role, but cannot be eliminated using conventional design techniques [7]. Nevertheless, cloning is a reality and there is need to deal with it [9]. No matter if clones are good or bad, it is beneficial to know where clones are in programs. It is particularly true for big clones such as duplicated files or directories. Big clones happen even if software evolution is systematically managed with variability management techniques [10]. In the paper, we use the Linux kernel to illustrate why this happens, and how we can manage big clones.

The Linux kernel is among the largest well documented evolving systems systematically managed with variability techniques [11]. In that sense, a family of the Linux-kernel versions forms an SPL whose reusable core assets include a carefully designed architecture, systematically identified and documented configuration options (SPL features), a code base managed with the C preprocessor (cpp) as a main variability technique, Kconfig, and other tools and techniques. The reason why we find big clones in the Linux kernel—and, we believe, in many other evolving systems—is that commonly used variability management techniques fail to avoid them in a convenient way.

Using generics (or C++ templates), we can non-redundantly represent similar classes differing in type parameters [12]. Big clones found in industrial systems need not be classes, but files or directories–program structures of any kind and size that differ in arbitrary ways, not just in type parameters. In this paper, we use Adaptive Reuse Technique (ART: https://sourceforge.net/projects/vclang/) to represent big clones as generalized templates. Like generics or C++ templates, ART templates can be instantiated in variant forms. Unlike other templates, ART templates can be built for groups of similar program structures of any kind (e.g., files or directories) that differ in variety of ways typically found in real systems. ART is an enhanced, lightweight and XML-free version of XVCL [13].

We briefly introduce variability management in the Linux kernel in Section II. In Section III, we discuss examples of big clones in Linux kernel version 3.10. Section IV describes how ART blends into Linux kernel development and use cycles. Sections V and VI describe explain how we manage big clones with ART. We evaluate the benefits and trade-offs of the proposed solution in Section VII. Related work and conclusions end the paper.

II. Variability Management in the Linux Kernel

Despite technological advancements in programming technologies, preprocessors are still indispensable. Preprocessing solves some niche problems better than other techniques do. One such problem area is variability management in software evolution and reuse. To some extent

we can manage variability at the level of software architecture [1]. But from architecture variability leaks to the code, and here that preprocessors along with configuration files and other similar techniques [14] become handy.

The Linux kernel developers applied clean architectural design, cpp, build tools, shell scripts, and other tools to facilitate adaptation of the Linux kernel to the specifics of target computers. Close to eleven thousand configuration options control the adaptation process. These options correspond to cpp parameters that navigate execution of cpp directives (such as #ifdef's) that select code relevant to the target computer of user's choice. The high-level configuration tool Kconfig maps these configuration options to the chains of relevant cpp directives embedded in the Linux code. Having selected required options, Kconfig automatically triggers execution of cpp directives and selects compilation units via the make utility to build a custom Linux kernel for a specific computer. Users do not have to understand the details of the adaptation mechanism. While the complexities of cpp instrumentation are hidden from the users, developers who maintain and extend the Linux kernel must understand code instrumented with cpp.

III. Motivating Example: Big Clones in the Linux

In the Linux kernel, the Journaling Block Device (JBD) provides an interface for the file system journaling. There are two directories namely /jbd and /jbd2 implementing this functionality, with /jbd2 being an evolutionary branch of /jbd. /jbd2 compatibly extends /jbd with new features such as support for 64-bit computers, check-summing of journal transactions, and asynchronous transaction commit block write.

Each directory consists of six files shown in Fig. 1. Much similarity in functionality and code (Table I) among files corresponding by names suggests that /jbd2 files were created by copying and modifying /jbd files. Fig. 2 sketches code snippets highlighting the code similarities and differences between the two checkpoint.c files.

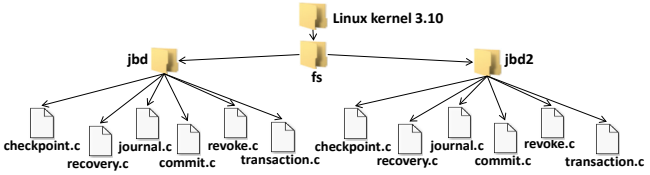

Fig. 1. Motivating example: cloned directories /jbd and /jbd2

Identical Code Fragments : ~554 LOC

```
51: static inline void __buffer_unlink(struct journal_head *jh)
52: {
53:         transaction_t *transaction = jh->b_cp_transaction;
54:
55:         __buffer_unlink_first(jh);
56:         if (transaction->t_checkpoint_io_list == jh) {
57:                 transaction->t_checkpoint_io_list = jh->b_cpnext;
58:                 if (transaction->t_checkpoint_io_list == jh)
59:                         transaction->t_checkpoint_io_list = NULL;
60:         }
61: }
```

```
51: static inline void __buffer_unlink(struct journal_head *jh)
52: {
53:         transaction_t *transaction = jh->b_cp_transaction;
54:
55:         __buffer_unlink_first(jh);
56:         if (transaction->t_checkpoint_io_list == jh) {
57:                 transaction->t_checkpoint_io_list = jh->b_cpnext;
58:                 if (transaction->t_checkpoint_io_list == jh)
59:                         transaction->t_checkpoint_io_list = NULL;
60:         }
61: }
```

Code Fragments with Parametric Changes: ~47 LOC

```
128: while (__log_space_left(journal) < nblocks) {
129:         if (journal->j_flags & JFS_ABORT)
130:                 return;
131:         spin_unlock(&journal->j_state_lock);
132:         mutex_lock(&journal->j_checkpoint_mutex);
```

```
124: while (__jbd2_log_space_left(journal) < nblocks) {
125:         if (journal->j_flags & JBD2_ABORT)
126:                 return;
127:         write_unlock(&journal->j_state_lock);
128:         mutex_lock(&journal->j_checkpoint_mutex);
```

Code Modification: ~12 LOC

```
333: set_buffer_jwrite(bh);
334: bhs[*batch_count] = bh;
335: __buffer_relink_io(jh);
336: jbd_unlock_bh_state(bh);
337: (*batch_count)++;
338: if (*batch_count == NR_BATCH) {
339:         spin_unlock(&journal->j_list_lock);
340:         __flush_batch(journal, bhs, batch_count);
```

```
311: journal->j_chkpt_bhs[*batch_count] = bh;

312: __buffer_relink_io(jh);
313: transaction->t_chp_stats.cs_written++;
314: (*batch_count)++;
315: if (*batch_count == JBD2_NR_BATCH) {
316:         spin_unlock(&journal->j_list_lock);
317:         __flush_batch(journal, batch_count);
```

Code Insertion: ~29 LOC

```
306: spin_unlock(&journal->j_list_lock);
```

```
276: transaction->t_chp_stats.cs_forced_to_close++;
277: spin_unlock(&journal->j_list_lock);
278: if (unlikely(journal->j_flags & JBD2_UNMOUNT))
279:         /* The journal thread is dead; so starting and
281:          * waiting for a commit to finish will cause
282:          * us to wait for a _very_ long time.*/
284:         printk(KERN_ERR "JBD2: %s: "
285:                 "Waiting for Godot: block %llu\n",
286:                 journal->j_devname,
287:                 (unsigned long long) bh->b_blocknr);
```

Code Deletion: ~95 LOC

```
520: journal_update_sb_log_tail(journal, first_tid, blocknr,
521:         WRITE_FLUSH_FUA);
522: spin_lock(&journal->j_state_lock);
523: /* OK, update the superblock to recover the freed space.
524:  * Physical blocks come first: have we wrapped beyond the end of
525:  * the log? */
526: freed = blocknr - journal->j_tail;
```

```
460: __jbd2_update_log_tail(journal, first_tid, blocknr);
```

Fig. 2. Motivating example: code snippets of cloned file /jbd/checkpoint.c (left) and /jbd2/checkpoint.c (right)

TABLE I. SIMILARITY AMONG FILES IN DIRECTORIES /JBD2 AND /JBD

File Name	Total LOC in corres-ponding jbd/jbd2 files	Identical LOC	LOC with parametric differences	Modified LOC	Inserted LOC	Deleted LOC
checkpoint.c	782/705	554	47	12	29	95
commit.c	1002/1192	523	93	35	364	218
journal.c	2122/2146	1266	287	29	690	229
recovery.c	594/862	420	52	12	234	0
revoke.c	740/769	544	94	3	25	0
transaction.c	2229/2348	1346	130	56	516	399

The directories /jbd and /jbd2 exemplify the situations that can benefit from ART as they cannot be effectively handled by other techniques. The reasons why we find such situations in the Linux kernel are functional similarities among different subsystems, extensions to the existing functionalities, adaptation of the existing subsystem code for the new one (incremental development), evolutionary development, and decentralized development [15][16][17].

IV. ART FOR THE LINUX KERNEL

In this section, we show how ART blends with the Linux-kernel development and uses cycles (Fig. 3). A *Linux Developer*, a member of an open-source community evolves the Linux kernel, e.g., by adding new devices into it. The *Linux SysAdmin* adapts the kernel for her computer using tools such as Kconfig.

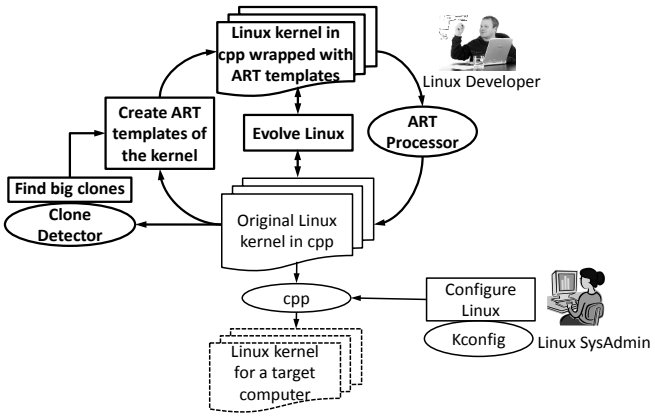

Fig. 3. An overview of Adaptive Reuse Technique (ART)

Big clones can be identified in the Linux kernel with aid of a suitable clone detector (we used Clone Miner [18]). The Linux Developer builds ART templates for big clones on top of the Linux code managed by cpp. From that point onwards, big clones are maintained via ART templates. ART templates do not affect the work of the Linux SysAdmin.

The ART Processor converts ART templates back to the original Linux code. The ART Processor instantiates templates in the same way as the C Preprocessor expand cpp directives. For example, for a template representing a group of similar files, the ART Processor generates code for these files based on specifications of deltas—differences between the template and each of these files. The generated Linux code is in the original form, and can be processed as normal by Kconfig, cpp, or make tool.

ART-template view of the Linux kernel and the original Linux kernel can be used together in two independent cycles of maintaining and using the kernel.

V. TYPES OF CLONES THAT WE HANDLE WITH ART

We categorized big clones in the Linux kernel based on their granularity.

A. Similar Directories

In the example of Section III, /jbd and /jbd2 play the same role, with /jbd2 being an evolutionary branch of /jbd addressing a new computer architecture and its capabilities. Each of the two directories contains six files, with much similarity between files corresponding by names. We found five other cases in Linux kernel following the pattern of /jbd and /jbd2, with the number of files in these directories varying between 19 and 46. In some cases, a directory contained one or more files that do not have similar counterparts in the cloned directory.

B. Similar Files

We found many cases of similar files within the same directory, as well as across directories. A common reason for replicating a file in the same directory is to make a certain existing functionality available for yet other computer architecture, device, or tool. An example is drivers for different brands of touchscreen devices—in directory /drivers/input/touchscreen, 10 files share the same structure and much code. Two directories having almost similar purpose (vide our motivating example) may contain similar files. Sometimes, the same or similar file may be required in two or more directories, even if these directories have not enough code similarity. For example, functionality for handling extended user attributes is needed in directories /fs/ext2, /fs/ext3 and /fs/ext4, therefore file "xattr_user.c" that defines this functionality appears in all three directories.

C. Duplicated Code Fragments

At times, creating templates for duplicated code fragments can be useful too, provided these fragments are long enough, play some specific role (e.g., represent some meaningful function), or recur in many places in programs. For example, code fragments in Fig. 4 implement a device specific queue handling procedure for different wireless network adapters. An instance of this code fragment occurs once in each of the files "rt2400pci.c", "rt2500pci.c", "rc2800pci.c" and "rt61pci.c", and twice in each of the files "rt2500usb.c", "rc2800usb.c" and "rt73usb.c".

VI. CONSTRUCTION AND PROCESSING OF ART TEMPLATES

In this section, we explain how we represented big clones as ART templates. We start with a brief overview of how ART works, followed by the explanation of how we build ART templates, illustrated with the Linux kernel example.

rt73usb.c

```
static void rt73usb_start_queue(struct data_queue *queue) {
        struct rt2x00_dev *rt2x00dev = queue->rt2x00dev;
        u32 reg;
        switch (queue->qid) {
        case QID_RX:
                rt2x00usb_register_read(rt2x00dev, TXRX_CSR0, &reg);
                rt2x00_set_field32(&reg, TXRX_CSR0_DISABLE_RX, 0);
                rt2x00usb_register_write(rt2x00dev, TXRX_CSR0, reg);
                break;
        case QID_BEACON:
                rt2x00usb_register_read(rt2x00dev, TXRX_CSR9, &reg);
                rt2x00_set_field32(&reg, TXRX_CSR9_TSF_TICKING, 1);
                rt2x00_set_field32(&reg, TXRX_CSR9_TBTT_ENABLE, 1);
                rt2x00_set_field32(&reg, TXRX_CSR9_BEACON_GEN, 1);
                rt2x00usb_register_write(rt2x00dev, TXRX_CSR9, reg);
                break;
        default:
                break;
        }
}
```

rc2800usb.c

```
static void rt2800usb_start_queue(struct data_queue *queue) {
        struct rt2x00_dev *rt2x00dev = queue->rt2x00dev;
        u32 reg;
        switch (queue->qid) {
        case QID_RX:
                rt2x00usb_register_read(rt2x00dev, MAC_SYS_CTRL, &reg);
                rt2x00_set_field32(&reg, MAC_SYS_CTRL_ENABLE_RX, 1);
                rt2x00usb_register_write(rt2x00dev, MAC_SYS_CTRL, reg);
                break;
        case QID_BEACON:
                rt2x00usb_register_read(rt2x00dev, BCN_TIME_CFG, &reg);
                rt2x00_set_field32(&reg, BCN_TIME_CFG_TSF_TICKING, 1);
                rt2x00_set_field32(&reg, BCN_TIME_CFG_TBTT_ENABLE, 1);
                rt2x00_set_field32(&reg, BCN_TIME_CFG_BEACON_GEN, 1);

A. An Overview of ART

For each group of clones, we distill common code into ART templates and mark the locations where clones differ one from another with ART commands (*italicized* for clarity in the description below). Fig. 5 outlines the overall solution, which consists of an ART-template hierarchy in which templates at the lower-level serve as building blocks for the higher-level templates. The ART templates are linked together by *#adapt* commands. The top-most template, called the specification file (SPC), specifies how to adapt other templates lower in the hierarchy to accommodate required variations. The ART Processor checks the templates for their conformance to the ART grammar definitions. It then traverses the template hierarchy in the depth-first order, starting with the SPC and performs adaptations by executing the ART commands embedded in the SPC and other ART templates. During traversal, each ART template adapts other templates from its sub-hierarchy. At the end, the ART Processor produces the required cloned instances.

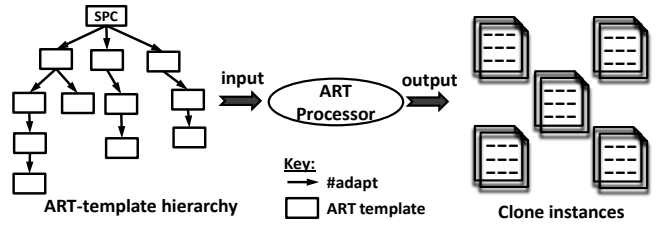

Fig. 5. An overview of the ART-template solution

Fig. 6 depicts steps in template processing. The ART Processor starts by reading the SPC (step-1). It fetches the ART commands step-by-step in the order in which they appear in the SPC (step-2). Whenever it hits an *#adapt* command (step-3), the processing will switch immediately to the adapted template (step-4) and switch back when the adapted template finishes its processing. Within a template, each ART command is processed one after another, in the same way as in the SPC. For the other commands, the Processor executes the ART command and builds the output (step-4') incrementally. Once the Processor reaches the end of the SPC (step-5), it generates the required source code files (step-6); if not, the ART Processor fetches the next ART command from the SPC (step-6').

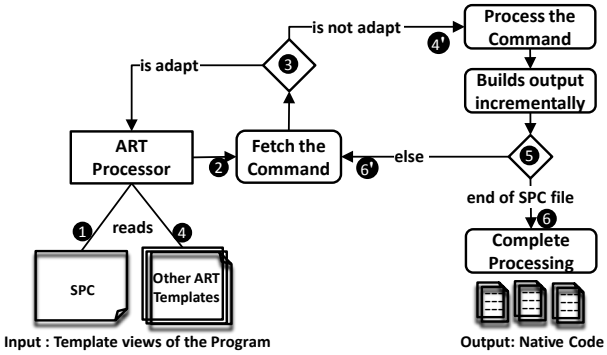

Fig. 6. Traversal mechanism of the ART Processor

B. ART-template Construction Mechanism

Despite a large fraction of the code common to all the clone instances (i.e., identical code fragments in the corresponding clone instances), as shown in Fig. 2, the three main types of differences among corresponding clone instances are parametric differences (code with parametric changes), alternatives (code modifications), and extras (code insertions and deletions).

The first task during the ART-template construction process is to identify these similarities and differences among corresponding clone instances. Once the corresponding similarities and differences are identified, ART templates record exact locations of these variation points at which the clone instances differ. ART commands can be used systematically to mark these variation points. Identical code fragments can be used directly as-it-is in the corresponding ART templates. ART variables treat parametric differences. The ART command *#select* allows choosing one among pre-defined alternatives (options), and *#insert* into *#break* mechanism handles additions and deletions of extra code.

C. Example: Template Construction for JBD

Fig. 7 shows the structure of ART solution for the JBD files. Each pair of similar files (e.g., checkpoint.c in /jbd and /jbd2) is represented by a template (e.g., checkpoint.art). The associated template checkpoint.spc specifies the differences between the two source files as deltas from checkpoint.art. The top-most template jbdX.spc navigates the process of instantiating the templates to form the Linux source files in their original form (i.e., instrumented with cpp).

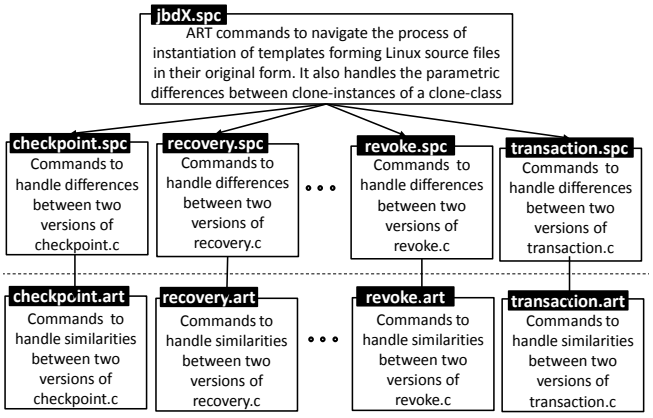

Fig. 7. Constructing ART templates: JBD example

Fig. 8 shows the details of ART templates. In jbdX.spc, ART variables are declared using *#set* commands (lines 1–6). Variable "dirName" is assigned two values, "jbd" and "jbd2" (line 2) that control the *#while* loop (line 7). The loop executes twice, with the value of "dirName = jbd" in the first iteration, and the value of "dirName = jbd2" in the second one. The Variable "fileName" is set to six values, each representing a file name (line 3).

The ART variable "action" helps represent lines:

*spin*_unlock(&journal->j_state_lock); //in jbd/checkpoint.c

*write*_unlock(&journal->j_state_lock); //in jbd2/checkpoint.c

in a single line in checkpoint.art (line 4):

*?@action?*_unlock(&journal->j_state_lock);

The two values of "action" are defined by:

#set action = "spin", "write" // line 4 in jbdX.spc

The generation loop defined in line 7:

#while dirName, action,…, tagByte

is controlled by a list of variables that cater for all parametric differences between the two checkpoint.c files. The command *#output* (line 9) instructs the ART Processor to create a directory and to place any further output into this directory (if the output file or directory is not specified, the ART Processor emits the code to an automatically generated default file named "defaultOutput"). Expression "?@fileName?" is used to fetch the value of an ART variable filename (line 9).

Similar to cpp's #include directive, an *#adapt* command (line 10 in jbdX.spc) instructs the ART Processor to include the designated template to the output. In addition, the *#adapt* command also tells the Processor to customize the designated template and assemble the customized result into the output. For example, given two ART templates *t* and *t'*, the statement "*#adapt t*" in template *t'* suspends processing of the current template (i.e., *t'*), and transfers processing to the template *t*. The ART Processor applies all the customizations specified under template *t*. Commands below *#adapt* in template *t'* indicate customizations to be applied after the template *t* is processed.

Variation points at which the two corresponding files (e.g., checkpoint.c) in /jbd and in /jbd2 directories differ are marked using ART commands—references to the ART variables, *#select*, *#break*, and possibly other commands. ART variables control selection of the code in case of alternative differences. This is illustrated as "*#select* dirName" in the template checkpoint.spc (line 4). *#option* (line 5 and 10 in checkpoint.spc) controls the variable values.

File checkpoint.c in one directory contains some extra lines as compared to checkpoint.c in another directory. These extra lines are specified using *#insert* commands in various "*#select* dirName" options. "*#insert* process_buffer" (line 11 in checkpoint.spc) propagates the code to "*#break* process_buffer" in checkpoint.art (line 12). *#insert-before* and *#insert-after* (line 6–9 in checkpoint.spc) add their code before or after the code contained in the matching *#break* (line 7 in checkpoint.art). While *#select* instruments a template with known variations, *#break* allows for extensions to a template in unexpected ways in the specific context of adaptation, without affecting others. These provisions for unexpected evolutionary changes give ART templates flexibility and stability.

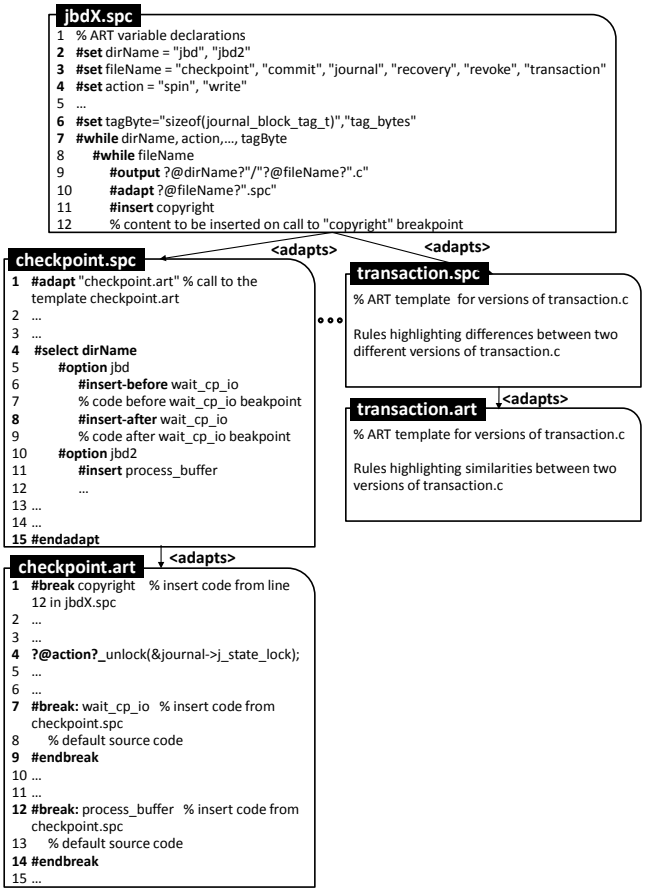

Fig. 8. Code snippet of ART templates for the JBD example

The ART Processor generates Linux code traversing the template hierarchy and emitting the code for the six files in the /jbd and /jbd2 directories from their respective templates. After that, the Linux code can be configured with Kconfig, and processed with cpp in the usual way. Template views expose the fact that the two directories and corresponding files in them are similar to each other, and also explicate every detail of similarities and differences among them. This information is implicit in the Linux code. Explicating it using

ART can be useful in further evolution of the JBD file system (Section VII).

D. Other Similarity Patterns at the Directory Level

Other cases of similar directories may not follow such a regular similarity pattern as in /jbd and /jbd2. For example, in the directories /drivers/infiniband/hw/qib and /drivers/infiniband/hw/ipath, in addition to similar files, /drivers/infiniband/hw/qib contains some extra files that do not have a counterpart in /drivers/infiniband/hw/ipath. Still, there is enough similarity in the concept and code between /drivers/infiniband/hw/ipath and /drivers/infiniband/hw/qib to build an ART-template solution for these two directories. The scheme used for building ART templates for /jbd and /jbd2 is also applicable in these situations, as templates manage pairs of similar files only and the remaining other files remain intact in the directories.

E. Constructing Templates for Similar Files

In this case, we deal with the similar files found in the same directory and the similar files in different directories, bearing in mind that directories as a whole are not considered good candidates for representing them as templates. For each such situation, we can create ART templates for similar files if we think that exposition of similarities and differences among these files can aid developers in reuse, program understanding, maintenance, and evolution of the Linux kernel. The solution follows the similar scheme as shown in Fig. 7 and Fig. 8.

VII. Evaluation

ART and its predecessor XVCL have been applied in industrial projects as a variability technique to manage reuse in product lines of web portals, and command and control systems [19][20]. In these projects, the productivity impact of applying the technique was measured and evaluated. An industry partner also participated in the Linux study described in this paper. In this section, we evaluate our ART solution for Linux, complementing it with lessons learned from other industrial projects with ART.

A. Reusing Templates within a Version of the Linux kernel

In a large system such as the Linux kernel, it is common to find clones within subsystems or modules, as well as across subsystems or modules. Each clone group can be managed by ART templates as long as such a non-redundant representation is deemed useful. Therefore, ART solution takes form of template hierarchies (Fig. 9) that explicates the location of clones and the exact nature of similarities and differences among replicated program structures. This knowledge is generally useful in understanding program design.

The example in Fig. 9 shows how ART templates reveal implicit couplings among bigger structures that contain repetitions. The same functionality defined in the templates commonConnectDisconnect.art and serioDriverStructure.art is needed in /touchscreen/common.art and /joystick/common.art. Templates for these two directories explicitly show the fact that this functionality is needed in both "touchscreen" and "joystick" drivers. If such implicit dependency among program modules is not documented, it may be overlooked during program evolution that may lead to errors.

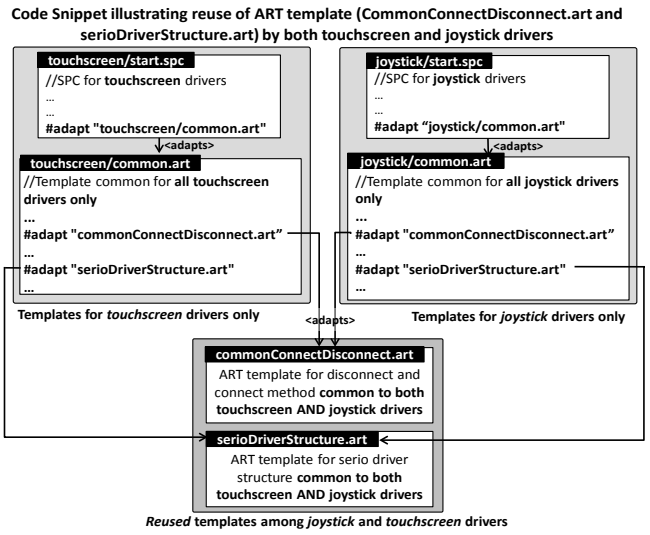

Fig. 9. Template reuse

B. Reusing Templates across Versions of the Linux kernel

Template reuse interconnects ART-template solutions developed for different groups of clones from the bottom, as shown in Fig. 9. It is also useful to interconnect partial ART-template solutions from the top, by introducing higher-level umbrella templates that trigger ART processing of some or all templates in the solutions.

Umbrella templates help developers manage multiple versions of the Linux kernel from the common base. A case study performed on 136 stable versions of the Linux kernel shows clone coverage of approximately 67% [21]. The coverage was found to be even higher between two consecutive versions due to small changes in successive releases of the kernel. Using umbrella templates, as shown in Fig. 10, we represented the commonalities between two versions, together with the version-specific code in different templates.

C. Handling Evolutionary Changes

Evolution often brings forward changes to the requirements and related code. For example, there might be a need to add a new directory /jbd3, or add more files to the JBD directories. ART has provisions to accommodate evolutionary changes to the templates (e.g., adding jbd3), without affecting existing code derived from the templates (e.g., jbd and jbd2).

Assuming that the new directory /jbd3 also contains six files that are similar to their counterparts in the /jbd and /jbd2, we need to make the following changes to the templates shown in Fig. 8:

jbdX.spc:

#set dirName = "jbd", "jbd2", **"jbd3"**

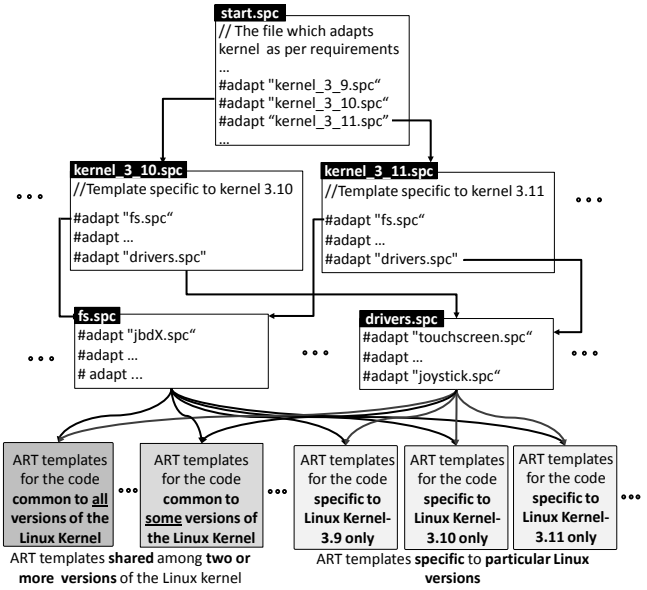

Fig. 10. Umbrella templates for an overall ART solution

```
#set fileName = "checkpoint",…, "recovery"
…
#while dirName , action,…, tagByte
#while filename
#output ?@dirName?"/"?@fileName?".c"
   #adapt: ?@fileName?".spc"
   …
checkpoint.spc:
   #adapt: "checkpoint.art"
   #select dirName
   #option jbd3
   …
% Customization to other templates with regards to jbd3
checkpoint.art:
   % Customizations to checkpoint.art specific to jbd3
% Customizations to other templates considering jbd3
```

In case of new variation points between the template and the file in /jbd3, we place new *#break* commands in the template. These new *#break* commands will cater for the differences specific to /jbd3, injected by *#insert*s in "*#option* jbd3" without affecting /jbd or /jbd2.

D. Aid in Program Understanding and Maintenance

Ease of comprehending program relations that matter during maintenance: ART templates enhance important relationships among program elements that matter to programmers trying to understand and modify the code. Instead of dealing with each directory or file separately, programmers can comprehend them in groups, and see the commonalities and differences among members of each group. It reduces ripple effects and the risk of update anomalies. In this way, if one wants to change a file, it is easy to check whether the changes also affect other files. For example, as illustrated in Fig. 7, similarities and differences are explicitly visible for jbd and jbd2 file systems. Such relations are generally hidden in conventional programs. Making them visible and easily tractable improves program maintenance. It also makes impact of changes easy to comprehend (as shown in Section VII.C).

Non-redundancy: ART templates eliminate redundant code from the software systems. For example, in our Linux experiment, ART templates reduced the size of code with redundancies by 30-50%. As both code and comments are important in software maintenance and program understanding, the upside of the proposed technique is that it is possible to manage both duplicated code and comments using it. ART allows a clean separation of various sources of changes that affect program during evolution. ART templates reduce the number of points at which affected changes must be made. Changes done to one template consistently propagate to all the contexts in which that template is adapted. Even if the changes are not uniform, adaptations can be made at specific variation points using the ART commands without directly modifying the code fragments. The ART template hierarchy explicitly reflects the impact of changes on the program structure. We can easily trace how different features affect the code.

Enhancing program understanding and conceptual integrity: According to Brooks [22], program understanding and conceptual integrity are among the most important considerations in system design. Big clones often embody domain-specific abstractions or design concepts. By formally capturing these abstractions and concepts, ART templates aid in program understanding and enhance conceptual integrity of the design.

Creating templates can be considered as refactoring at the meta-level: In some cases, developers seek to improve certain program qualities but due to some unavoidable reasons cannot achieve this at the code level. In such cases, we can do that at the level of meta-level templates. We benefit from non-redundancy at the meta-level templates, while still keeping repetitions in programs (as it is often desirable or unavoidable [7][23]).

Formally representing multiple design views: Program modules often belong to many logical groups that matter to developers at different times. Each logical partitioning reflects a certain aspect of program design that matters at a given time in the development in a given context. For example, for a given business function in business software, the modules for user interface, business logic, and database are usually implemented in different system partitions. Logically these modules belong to each other and sometimes we must know which modules implement a given business function completely. But, only one logical partitioning can be formally represented in a program physical structure. ART provides means to overlay programs with a web of meta-structures formally defining these logical partitions linked to code and without conflicts with the code.

Other Benefits: ART makes it easy for the programmers to do any program modifications and extensions at the template level. So there is no need to modify the code, and templates always remain in sync with the code as programs evolve.

In addition, with reference to the Linux kernel, aiding Linux Developers without affecting Linux SysAdmins is one cornerstone of the proposed solution. ART templates are non-intrusive, i.e., they do not affect the way cpp is normally used, but it improves understandability and maintainability of the programs instrumented with cpp. Also, the Linux code can be re-generated in the original form, and processed as normal by Kconfig, cpp or make tools. It provides a two-way view to understand and maintain the kernel—one with state-of-art variability technique (i.e., cpp), and another using ART.

Like cpp, ART manipulates code in an unrestrictive way, with no concern for the syntactic or semantic rules of the underlying programming language. Freeing from language constraints makes ART powerful to represent the groups of similar structures of arbitrary kind differing in arbitrary ways in generic forms.

E. Trade-offs and Threats to Validity of Results

The flexibility of manipulating the code in unrestricted way comes at the price of not being able to quarantine the correctness of the generated code. Unrestrictive program manipulation decreases the type-safety of the program. Also, the trade-off is between the benefits and cost of learning the new technique. ART syntax is very simple and consists of only few constructs (such as *#adapt*, *#insert-break* mechanism, *#while*). Yet, building quality ART templates require skilled experts, so that the benefits of ART outweigh the burden of learning and adopting it.

The benefit of ART depends on the degree of redundancy in a software system that cannot be fixed by simple refactoring. The bigger the size of software systems, the higher the likelihood of redundancies and evolutionary changes, and hence more will be the benefits of using ART. It follows that families of similar systems should be prime candidates for ART template views, as there is much similarity among components of such systems. Thus, the proposed technique seems to have more direct relevance in the SPL context, where we have the role of domain engineer who is responsible for building reuse-based productivity solutions that serve many systems in long run. ART templates belong to that category of solutions.

VIII. Related Work

We discuss related work on cloning in the Linux kernel and techniques that help programmers achieve non-redundancy, including XVCL (the predecessor of ART).

A. Cloning in the Linux Kernel

Cloning in the Linux kernel has been extensively studied in the literature [15][16][17][21][24] mainly focusing on the detection of small cloned code fragments. In the Linux v2.4.0, Casazza et al. [17] reported cloning of 15.5% between arch and drivers subsystems. They also reported 13.6% cloning between arch and kernel subsystems. Other study showed that file subsystem had 12% clone coverage in the Linux v2.4.19 [16]. In the Linux v2.6.37.6, 8% code similarity between drivers (/sound and /drivers directories) has been reported [15]. An empirical study of cloning among SCSI drivers is done by [24]. We found these cloning rates to be lower than those reported in similar studies for web applications [19] (60%-90%) or class libraries [7] (68%).

Compared to other studies, this paper aims at the detection and analysis of big clones instead of small cloned code fragments that are detected and analyzed by other studies.

B. Managing Redundancies in Software Systems

Simple-minded development often leads to cloning (copy-paste-modify practice). As mentioned earlier, cloning may also be done for good reasons [5]. Still, non-redundancy has been always considered an important quality of well-designed software. The Software Engineering principle of generality encourages avoiding repetitions and building parameterized software solutions that can be reused in many contexts. Macros were an early attempt to make programs adaptable to various contexts. Goguen popularized the ideas of parameterized programming [25]. Among programming language features, type parameterization [12] (called generics in Ada, Eiffel, Java and C#, and templates in C++), higher-order functions, and inheritance can help avoid repetitions in certain situations. Design techniques such as iterators, design patterns, table-driven design (e.g., in compiler-compilers), and modularization with information hiding are supportive in building generic programs. The Standard Template Library (STL) is a premier example of engineering benefits gained by generality [26]. Techniques have also been proposed to lift sufficient code similarity from the code to the architectural level [27][28].

ART uses templates and code generation to achieve non-redundancy. ART templates can represent any groups of clones (e.g., files or directories) with arbitrary differences among them (as opposed to only type-parametric differences in C++ templates or Java generics).

C. ART versus cpp + scripts and XVCL

One can also achieve non-redundancy by parameterizing and wrapping the code with cpp, shell scripts, and make files. An example of that can be found in the JDK buffer library described in [7]. SUN developers used cpp, scripts, and make files to build a non-redundant representation from which actual buffer classes are derived. A quick inspection of the code reveals that such representation may serve only its author and cannot be considered as a viable method to engineer programs.

Sample ART templates shown in the paper may also look complex. At the first glance they do. But, the fact is that ART is governed by only five important constructs (i.e., *#adapt*, *#output*, *#insert-break* mechanism, *#while*, and *#select*) that are neatly integrated to form a method that can be learned easily. Experience with XVCL (the ART predecessor) demonstrates that large code can be effectively managed achieving non-redundancy in the program areas where it matters [19]. Despite user-defined syntax, ART further

improves the user experience by providing the following improvements to XVCL:

Easy to learn: XVCL is a dialect of XML and uses XML trees and a parser for processing. ART parts with XML syntax and processing. It offers a cpp based flexible and more readable user-defined syntax. Just because cpp is so widely used, learning ART is not so tedious.

More generalized: Contrary to XVCL, developers can easily blend ART with the programming technologies of their choice. It is because the developer can define their own syntax and hence can avoid conflicts with the base languages.

Expanding the customization options under #adapt command: In XVCL, the only command that you can place under *adapt* is *insert*. ART allows to use any command under *#adapt*. We found using *#set*, *#while* and *#select* commands under *#adapt* to be particularly very useful.

Robust structure instead of unreadable loops: In XVCL, *while* loops using many multi-value variables can be quite confusing. ART introduces a structure called *set-loop* which gives the possibility to store and use more multi-value variables together as one loop descriptor data structure.

More flexible: ART is more flexible than XVCL, as it allows the adaptation of a file even though the file might not contain any ART commands. Such adaptation would simply copy the adapted file to the output stream.

D. Comparison with Other Techniques

Companies today often develop and maintain custom versions of the same software system for different customers using SPL [4]. The core idea is to manage the system family as a whole from a base of core assets designed for ease of adaptation in various reuse contexts.

In the SPL context, ART attempts to capture and streamline the end-to-end process of adapting software from the specifications of variant features (e.g., in Linux called configuration options) to the architectural structures and the code. ART templates can manipulate any textual file independent of their contents. So, it can also manage variability in documentation and test cases, keeping all textual SPL core assets in sync with evolving code.

Techniques proposed in research to manage variability in SPL are mostly based on the principle of separation of concerns (SoC), introduced by Dijkstra in early 1980's [29]. The goal of SoC is to deal with concerns one by one, independently from other concerns. When applied at the level of design and implementation, SoC attempts to compose software from components implementing different concerns. Concerns that nicely fit into conventional modules are easy to deal with. The challenge is to tackle cross-cutting concerns that are tightly coupled with the rest of a program, and cannot be easily modularized in a conventional way. There have been attempts to bring SoC down to the design and implementation levels. Aspect-oriented programming (AOP) [30], multi-dimensional SoC (MDSOC) from IBM [31], feature-oriented programming (FOP) [32], and colored IDE (CIDE) [33] are among the most widely published of such techniques. Among these techniques, AOP has been widely used. In AOP, various computational aspects are programmed separately and weaved at specified join points into the base program. AOP can separate a range of programming aspects such as synchronization, persistence, security transaction management, authentication/authorization, and others. Separated aspects can be easily modified and added/deleted to/from program modules. Because of that, a number of authors proposed AOP as a variability technique in the SPL. A study to test this hypothesis revealed difficulties in using AspectJ to deal with features that have chaotic impact on the base code [34]. While AOP deals with big chunks of functionalities (i.e., aspects) reasonably, it lacks a mechanism to handle variations at the lower levels of granularity. ART on the other hand, can handle variations at any levels of granularity. Walkingshaw et al. [35] provided a systematic and broader perspective on variational data structures. Properties related to program customizations are encapsulated in these variability-aware data structures.

IX. Conclusions

A study of industrial systems has shown that around 50% of small cloned code fragments tend to be contained in big clones [36]. While big clones are certainly intentional, they contribute to the increased program size and complexity. Therefore, big clones create a useful window from which to understand and manage clones at all levels of granularity.

In this paper, we presented a technique for managing big clones with non-redundant templates built with ART. ART templates manage big clones without conflicts with programming languages and other techniques used for managing variability. We demonstrated the technique with examples from the Linux kernel that uses cpp (among other techniques) to manage variability.

In various similarity groups, by unifying clones into non-redundant templates, ART eliminated 30-50% of the code. Non-redundant views revealed by ART templates improve program understanding. Program relations that have to do with the impact of changes are important in program understanding, maintenance and evolution, but remain mostly implicit in conventional programs. ART templates expose and explicate some of these program relations. For example, when maintaining duplicated code we often must know where such duplicates are and how they are different, in order to decide if and how each of them should be modified. ART makes such information more visible and tractable, reducing the risk of unexpected errors when changing programs.

ART blends without conflicts with the underlying programming language and any other techniques used to manage variability in a software system. Therefore, we can use ART to handle big clones, while other techniques (e.g., cpp and Kconfig in the Linux kernel) deal with other aspects of the overall variability management problem. Such seamless integration is necessary to allow the developers to painlessly inject ART templates into the projects in mature stages of evolution when big clones start emerging. ART syntax is user-defined to make such injection easy, without

affecting already existing software solutions and people who work with them. In the Linux context, ART can be viewed as an extension of cpp where ART commands syntactically resemble cpp directives, and can be incrementally learned as extensions that enhance reuse capabilities of cpp. The Linux Developers work with ART templates of the program, while the ART Processor generates the Linux code in its original form for the Linux SysAdmins.

Any new technique brings some overhead, requires learning and skillful application. ART is no different from other techniques in this respect. ART templates are not created for quick gains during development, but for long-term gains during software evolution and reuse. ART aims to benefit long-lived systems that undergo extensive evolutionary changes, or need to be tailored to the needs of multiple customers.

Acknowledgment

We are thankful to Ulf Pettersson, Technical Director, Info-Software Systems, ST Electronics Pte. Ltd., Singapore for applying ART in his projects and providing us with invaluable feedback.

***Abstract*—Most industrial embedded systems requirements are specified in natural language, hence they can sometimes be ambiguous and error-prone. Moreover, employing an early-stage model-based incremental system development using multiple levels of abstraction, for instance via architectural languages such as EAST-ADL, calls for different granularity requirements specifications described with abstraction-specific concepts that reflect the respective abstraction level effectively.**

In this paper, we propose a toolchain for structured requirements specification in the ReSA language, which scales to multiple EAST-ADL levels of abstraction. Furthermore, we introduce a consistency function that is seamlessly integrated into the specification toolchain, for the automatic analysis of requirements logical consistency prior to their temporal logic formalization for full formal verification. The consistency check subsumes two parts: (i) transforming ReSA requirements specification into boolean expressions, and (ii) checking the consistency of the resulting boolean expressions by solving the satisfiability of their conjunction with the Z3 SMT solver. For validation, we apply the ReSA toolchain on an industrial vehicle speed control system, namely the Adjustable Speed Limiter.

I. Introduction

MOST often, the development of dependable automotive systems that are nowadays increasingly complex [1] relies on intricate requirements, given the nature of the system that has to interact with the environment. Therefore, the importance of establishing non-ambiguous and consistent requirements is even higher than for closed systems. Despite this acknowledged situation, current specification methods and tools [2][3][4] lack adequate support to formally analyze the logical consistency of high-level natural language requirements, in order to improve the quality of their specification.

Moreover, to be able to manage the complexity of automotive embedded systems during development, incremental model-based design approaches that assume multiple levels of abstraction are becoming appealing to industry. Among others, dedicated architectural languages, such as Electrical and Software Technology - Architectural Description Language (EAST-ADL) [5] are good candidates for such approaches. In EAST-ADL, an automotive system's structure and function are modeled at multiple levels of abstraction, that is, vehicle, analysis, design, implementation levels, and each abstraction level employs distinct concepts worth considering during requirements specification. For instance, the vehicle level of EAST-ADL abstraction describes the high level function of the system. Therefore, it would be inappropriate to use concepts from the design level, such as ports, signals, hardware elements, to describe requirements at the vehicle level, since such details usually hinder communication with non-technical stakeholders. Consequently, the requirements specifications need to be adapted to the appropriate levels of abstraction.

In this paper, we propose an Eclipse-based tool chain for structured requirements specification in ReSA [6], which scales to multiple EAST-ADL levels of abstraction. ReSA is an ontology-based requirements specification language tailored to automotive embedded systems development, which uses requirements boilerplates to structure the specification in natural language. Furthermore, we propose a consistency-check function that seamlessly integrates into the tool chain, for the automated consistency check of requirements using Z3 SMT solver [7]. The consistency checking is a preliminary task during elicitation and specification of requirements that paves the way for formal verification at later stages of software development. Our approach for consistency checking does not require a behavioral, or architectural model of the system, which might increase its attractiveness to industry as there is often the case that no system models exist for industrial systems. Checking for requirements consistency has been widely used in the field of requirements engineering, e.g., to describe consistent use of terms (words, phrases), logical consistency of requirements statements, or consistency between requirements and subsequent refinements [8][9]. The term can also refer to checking against type errors, or circular definitions [10]. In this paper, the consistency checking refers to checking the logical consistency of ReSA requirements specifications, in Z3.

Consistency checking of requirements specification helps detect possible logical errors at early stages of software development, and reduce the communication cost between manufacturers and suppliers [11]. However, checking for logical consistency of requirements expressed in natural language is not an easy task, mainly because: (i) unconstrained natural language is inherently ambiguous when it comes to reasoning, (ii) substantial assumptions used during requirements specification are hidden, and (iii) the size and complexity of requirements specifications are considerable.

In this work, we reduce the problem of checking the logical consistency of ReSA requirements to a boolean satisfiability problem, hence we propose algorithms for transforming the ReSA specification into boolean expressions, encode the latter into Z3 assertions, and perform consistency check using the Z3 SMT solver. The remainder of the paper is organized as follows. In section II, we recall the main features of ReSA,

978-83-60810-90-3/$25.00

the EAST-ADL levels of abstraction, xText grammar, and the boolean satisfiability problem. We introduce the ReSA toolchain in section III, after which we describe our consistency checking steps in section IV. The applicability of the tool is shown in section V, where we specify and check the consistency of sample requirements from an industrial use case, called the Adjustable Speed Limiter (ASL). We compare to related work in section VI, before concluding the paper in section VII.

II. Preliminaries

In this section, we overview the ReSA language, and its adaptation to EAST-ADL levels of abstraction, as well as the xText grammar, and the basic boolean satisfiability problem.

A. Overview of ReSA

ReSA [6] is an ontology-based requirements specification language tailored to automotive embedded systems development. The language (i) renders natural language terms (words, phrases), and syntax, (ii) uses an ontology that defines concepts and syntactic rules of the specification, and (iii) uses requirements boilerplates to structure specification.

1) Requirements Specification Ontology: A snippet of the ontology specification is shown below.

$$[System\ *x1][ActOnPara\ *x2][Para\ *x3] \quad (1)$$

$$(Is\text{-}fb\ ?x1\ ?x2)(Is\text{-}fb\ ?x2\ ?x3) \quad (2)$$

This ontology snippet defines requirements specification concepts (1), and syntactic rules between instances of concepts (2). The specification states that an instance of *System* precedes both an instance of *ActOnPara*, and an instance of *Para* in a requirement specification, e.g., `ASL:system shall control:ActOnPara vehicle speed:para`, is a valid example that conforms to the ontology specification.

2) Requirements Boilerplate: The language uses *requirements boilerplates (or boilerplates)* [12] in order to structure a requirement. A boilerplate is a reusable specification template, which is constructed from variable, and fixed syntactic elements, e.g., `if <button> is <pressed> then <system> shall be <state> within <10><ms>`, where syntactic elements within pairs of angle brackets are variable syntactic elements, and the rest are fixed syntactic element. Table I displays the boilerplate elements of the language.

TABLE I: The ReSA Language Boilerplates

Boilerplate	Description
Simple	Instantiates a simple statement, and contains a modal verb, such as, *shall*, e,g., `system shall be activated.`
Proposition	Similar to *Simple*, except it is a proposition (or an assertive statement) [13, p.435], e.g., `button is pressed.`
Complex	Instantiates a complex statement, and is constructed from a Simple, a Proposition boilerplate, and an adverbial conjunctive (such as while, when, until). For example, `the error shall be reported while the fault is present`
Compound	Instantiates a compound statement, and is composed of two or more *Simple* or *Proposition* boilerplates and the logical operators, AND/OR, e.g., `system shall be activated and driver shall be notified.`
Conditional	Instantiates a conditional statement. The boilerplate can be instantiated to a different variant of conditional statements, i.e., *if*, *if-else*, *if-elseif*, or *if-elseif-else*, and conditional nesting.
Prepositional Phrase	Instantiates a prepositional phrase, and can be used to describe timing properties, occurrence of events, other complements to the subject of a main phrase. e.g., `within 5ms, by the driver`

B. EAST-ADL Levels of Abstraction

The ReSA language can be tailored to express requirements at multiple levels of abstraction in the development of automotive systems. This helps achieving a consistent specification style across several abstraction levels. We show this for automotive embedded systems development based on EAST-ADL. EAST-ADL [14] is a model-driven approach to the development of complex automotive embedded systems. It covers a wide range of development aspects, such as analysis, design, implementation, verification&validation. The language uses various levels of abstraction to conceptualize a system with different degrees of detail, that is, vehicle, analysis, design, and implementation levels. We briefly describe the levels of abstraction in light of requirements modeling.

- Vehicle level: a vehicle is modeled using interconnected vehicle features, that satisfy high level requirements.
- Analysis level: the vehicle feature is refined using analysis level functions, that are design, and hardware independent. These functions satisfy the refined version the high level requirements specified at the vehicle level.
- Design level: the analysis level functions are refined using design level functions, that are enriched with periodic triggering, and execution time constraints. These functions satisfy the refined version of requirements specified at the analysis level.
- Implementation: the design level requirements are refined, and are satisfied by AUTOSAR [15] implementation, which we don't discuss it in this paper.

The specialization of the ReSA language to express requirements for EAST-ADL's levels of abstraction is done by specializing the ReSA concepts to appropriate concepts found in EAST-ADL. Table II shows an example of the specialization of the *System* concept at vehicle, analysis, and design levels of EAST-ADL levels of abstraction.

C. XText Grammar

ReSA is implemented in xText Eclipse framework, a powerful, and popular Integrated Development Environment (IDE) for the development of Domain Specific Languages (DSL), and programming languages. The main component of the framework is the xText grammar language [16]. Among other constructs, the xText grammar contains the declaration of an xText file header (1-3), and parser rules (4-7). Line (1) states

TABLE II: Concept specialization for *System* concept

Vehicle-level	Analysis-level	Design-level
VehicleFeature (VF)	AnalysisFunctionType (AFT) FunctionalDevice (FD)	DesignFunctionType (DFT) BasicSoftwareFunction (BSF) LocalDeviceManager (LDM) HardwareFunctionType (HFT)

the grammar's name to be a valid java extension; (2) states the reuse of common terminal rules, e.g. rules for string, whitespace; (3) generates EPackage for the implementation of the grammar with the name *resaDSL* located at the stated Uniform Resource Identifier (URI). Rules (4-7) state the different parser rules in Extended Backus-Naur Form (EBNF) notation [17][18].

```
(1) grammar org.volvo.resadsl.ResaDsl
(2) with org.eclipse.xtext.common.Terminals
(3) generate resaDsl
    "http://www.volvo.org/resadsl/ResaDsl"
...
(4) UnAssignedPRule: AssignedRule;
(5) AssignedPRule: feature = STRING;
(6) DataTypePRule: 'dType ' name = ID;
(7) CrossRefPRule: feature = [DataTypePRule];
```

D. The Boolean Satisfiability Problem (SAT)

The consistency of ReSA specifications can be reduced to a satisfiability problem of boolean expressions (propositional formulas) [6]. A requirement specification in ReSA is constructed from one or more propositions connected by logical operators (*and*, *or*, *implies*, *not*), and parentheses. SAT techniques can be used to determine if the conjunction of ReSA requirements are satisfiable.

The *satisfiability problem* (SAT) [19] is defined as follows: given a propositional formula ϕ = f($x_1, \ldots, x_n$), over a set of boolean variables $x_1, \ldots, x_n$, decide whether or not there exists a truth assignment to the variables such that ϕ evaluates to true. SAT problem instances are usually expressed in a standard form called *conjunctive normal form* (CNF). A propositional logic formula is said to be in CNF if it is a conjunction (*and*) of disjunctions (*or*$_s$) of literals. A literal is either x, or its negation $\neg x$, for a boolean variable x. The disjunctions are called clauses.

Theorem 1 (Inconsistency of requirements specifications): Let $\Psi = \psi_1, ..., \psi_n$ denote the system requirements specification, where each of the formulas (ψ_1, ..., ψ_n) encodes requirements. We say that the set is inconsistent if the following implication is satisfied: $\psi_1 \wedge \psi_2 \wedge \ldots \psi_n \Rightarrow False$.

In order to check the consistency of requirements specification, one has to disprove Theorem 1 by showing its negation *true*, that is, find a counterexample that satisfies the CNF of the requirements specification, Ψ. In this paper, we check the consistency of ReSA requirements via the Z3 tool [7]. Z3 is an efficient Satisfiability Modulo Theories (SMT) solver developed at Microsoft Research, which integrates several decision procedures for verification.

In the following consecutive sections, we describe the main contribution of the paper regarding the tool implementation, including its architecture, and consistency checking.

III. The ReSA Toolchain

The ReSA toolchain is an Eclipse-based implementation of our requirements specification language [6]. The toolchain supports contextual content completion, and text validation features. Furthermore, it seamlessly integrates a function for checking the logical consistency of requirements using the Z3 SMT solver [7]. The toolchain also supports specifying requirements at different levels of software development, using appropriate concepts valid at a specific level of abstraction. We specialize this approach for EAST-ADL, with respect to the vehicle, analysis, and design level of abstraction. The Graphical User Interface of the toolchain is shown in Figure 1, displaying demo projects for ASL, both EAST-ADL generic specification, as well as EAST-ADL abstraction level aware specification. The toolchain is available for download from the web link: `https://github.com/nasmdh/ReSA-Tool-0.0.git`

A. The Toolchain Architecture

Figure 2 shows the architecture of the ReSA toolchain. It consists of requirements specification and consistency checking of requirements. The specification part is basically the ReSA specification editor (a.k.a. *Resa App*), and a domain model. During writing requirements specifications, domain elements can be accessed from the domain model, but also model elements can be populated during specification. Such approach allows the consistent use of terms among different requirements engineers, reduces typographic errors, and maintains a knowledge base for later system refinements. The consistency checking part consists of a consistency checking plugin that calls the Z3 SMT solver. The result of the consistency checking is returned to the editor perspective.

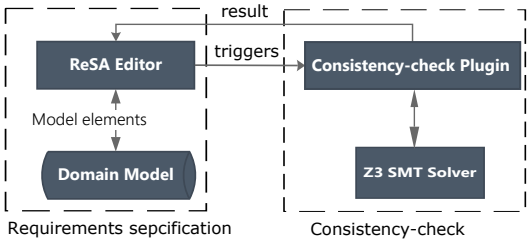

Fig. 2: The ReSA toolchain architecture

1) ReSA Specification Framework: Figure 3 shows the framework for specifying requirements with our ReSA tool. The framework consists of the Hierarchical Grammar, the ReSA Application, and the System Model. The Hierarchical Grammar is composed of a generic grammar, Gs, and grammar definitions for each EAST-ADL abstraction level, indicated by Gv, Ga, Gd, for vehicle, analysis, and design

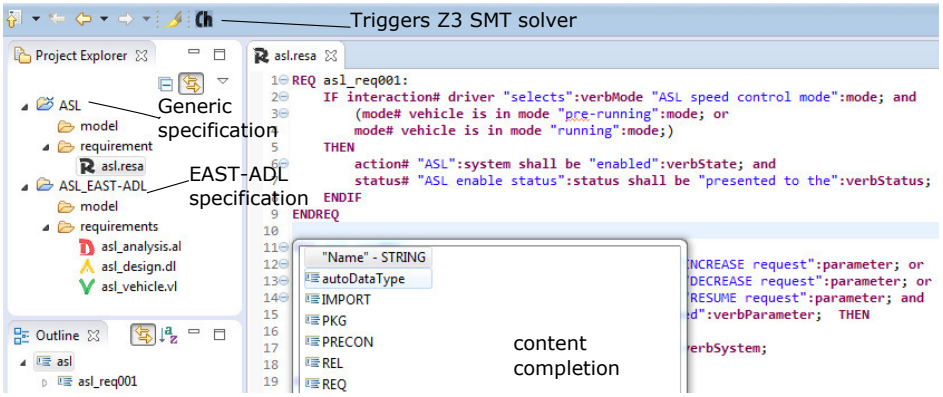

Fig. 1: The ReSA toolchain user interface

levels of abstraction, respectively. The grammar definitions for the EAST-ADL levels of abstraction are specializations of the generic grammar (indicated by the relation `<specialize>`), that is, concepts and syntactic rules are adapted to suit the specification at each levels. Through the `<import>` relation, concepts, and rules from the top level grammar are imported to the low level grammar, which enables referring to higher level concepts from lower level abstractions.

The ReSA Application is an implementation of the Hierarchical Grammar, and an editor for ReSA, indicated by the relation `<implements>`. The file extension **.resa* implements the application for the generic grammar, whereas file extensions **.vl*, **.al*, **.dl* represent the applications for vehicle, analysis, and design levels, respectively, and implement their corresponding grammar definition. The System Model provides access to the model elements of the application, during the specification at the respective abstraction level.

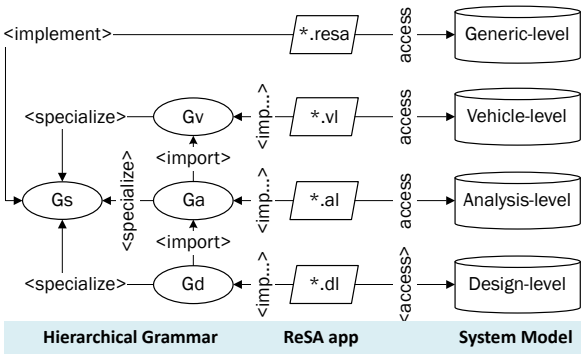

Fig. 3: Grammar architecture, and support for EAST-ADL

B. Implementation

We have implemented the toolchain in the xText Eclipse Framework. The framework provides an xText editor for grammar specification using the xText grammar language, and generates a start-up IDE based on Eclipse, which includes Parser, Compiler, Linker, and textual editor [16]. In this subsection, we go through the implementation of the ReSA grammar, and its adaptation to EAST-ADL.

1) Generic Grammar: This grammar defines the generic rules of constructing requirements specification in automotive systems. It uses automotive concepts to typeset domain elements, and action verbs associated to instances of concepts. The grammar defines the syntax of the boilerplates, and the requirements specification that is built from the boilerplates.

a) Boilerplate Rules: The following grammar rules define how a requirement specification is structured using boilerplates. Line (1) defines an unassigned rule that delegates rules to the compound boilerplate (2), and the conditional boilerplate (4). Lines (2) and (4) define a left-refracturing to handle the left-recursive nature of compound, and conditional boilerplates. Line (4) defines a rule for the different cases of conditional boilerplates, i.e., if, if-else, if-elseif, if-elseif-else, and nested-if.

```
(1) Boilerplate : Compound | Conditional;
(2) Compound:
    cx=Simple ({cmOp.left=current} biOp=LgOp
                rt=Compound)?;
(3) Condition:
    pr=Proposition ({cnOp.left=current}
                biOp=LgOp rt=Condition)?;
(4) Conditional:
    'IF'cnl=Condition 'THEN'({cnlOp.left =
                current} rt=Conditional)?
    then=Compound?
    ('ELSE' else=Compound | elseif=Elseif)?
    'ENDIF';
```

b) Syntactic Element Rules: The following grammar snippet states rules for constructing boilerplates elements. Rule (1) creates *datatypes*, that is, *system* and *state*; rule (2), (3) create syntactic elements. The syntactic elements can be typed inline, e.g., `"ASL":system`, or referred from a model; rule (4) creates the fixed syntax element *shall be*, and finally rules (5) and (6) create Simple, and Proposition boilerplates using the above parser rules, respectively. For example, Simple boilerplate, such as, `<term:system> shall be <term:state>`, and Proposition boilerplate, such as, `<term:system> is <term:state>`.

```
(1) System: name=STRING; State: name=STRING;
(2) System_Rule: System | system=[System];
(3) State_Rule: State | state=[State];
(4) PModal: "shall be" | "shall be able to";
(5) Simple:
    (not)? (sub=System_Rule modal=PModal
            obj=State_Rule";" |...);
(6) Proposition:
    (not)? (sub=System_Rule "is"
            obj=State_Rule";" |...);
```

2) Specialization of Generic Grammar to EAST-ADL: The requirements specification is adapted to EAST-ADL using specialization of types, and syntactic rules defined in the generic grammar. In the xText framework, such functionality can be supported using *grammar mixin*, a feature that allows the reuse of previously defined grammars. Rules (1), (2), (3) show how the datatype *System* is specialized at vehicle, analysis, and design levels, respectively. Furthermore, a rule in the generic grammar can be extended to cover more requirements specification scenarios, using the keyword *super*, e.g., (4) shows the extension of the *Main* rule with *MainDesign*, which includes a signal related specification, e.g., `<term:signal> shall be "received on":verb <term:port>`.

```
(1) System: VF;
(2) System: AF | FD | FP
(3) System: DF | BSFT | HFT
(4) Main returns reSADSL::Main:
    super | MainDesign
    MainDesign:
        sub=Signal_Rule modal=PModal
        verb=Verb_Rule  obj=InPort_Rule?';'
```

If we consider the previous example, that is, ”ASL”:system shall be ”activated” :state, the counterpart specification of this requirement at Vehicle-level is, ”ASL”:VF shall be ”activated”:state.

IV. Automated Consistency checking

In this paper, consistency checking refers to checking the logical consistency of ReSA requirements specifications without the use of a formal architectural model. This is in contrast to the use of the term to describe the consistent use of terms (i.e., words and phrases) in a specification [8][9], or type checking, or identification of circular definitions [10]. Since manual inspection of requirements specification is cumbersome, and sometimes impractical for finding inconsistencies, computer-assisted (automated) methods and tools, such as model checking, and theorem proving, have gained popularity in embedded systems. However, most of these methods, and tools require a formal specification language, such as LTL, CTL, which is expensive to use in industry due to the associated cost employing formal methods. We address this challenge by using the ReSA language, a relatively readable, and close to natural language, and a seamless integration of the consistency checking (with z3) in the requirements specification toolchain.

A. Consistency Checking Approach

Our consistency checking approach does not require a behavioral,or architectural model, instead the input is simply requirements specification document written in ReSA. Since, such models are not readily available in practice, our approach is appealing and useful to industry. The problem of consistency checking is reduced to a satisfiability problem as follows. The requirements, Req_i, are expressed using propositional formulas, and the conjunction of these requirements, $\bigwedge_i Req_i$, is checked for satisfiability, $M \models \bigwedge_i Req_i$, where M is an interpretation (assignment of the proportional variables that satisfies) $\bigwedge_i Req_i$. The propositional formulas are mostly expressed by conditional statements, $(P \Rightarrow Q)$ that hold globally in the system, where P, Q are propositional formula, which contains $\wedge$, $\vee$, $\rightarrow$, and $\neg$ logical operators [6].

The consistency-check is briefly described as follows:

- input: ReSA requirement specification.
- step1: ReSA requirement specification is transformed into a boolean expression of propositions (or propositional formula); check Section IV-B.
- step2: Boolean expressions are encoded into the SMT-LIB2 format [20], with each of the expressions as an assertion.
- step3: Z3 SMT solver is triggered to check the satisfiability of the expressions; check Section IV-C.
- output:The user is notified of the consistency check result.

B. ReSA-to-boolean Transformation

Algorithm 1 shows a function that transforms a ReSA requirement specification into a propositional formula. A ReSA specification can be treated as a composition of propositions, logical operators, *(and, or)*, and fixed syntactic elements, like *if...else*. The propositions are instantiations of the `Simple`, or `Proposition` boilerplates. In the ReSA requirement of Example 1, `<Btn1: inDevice> is <pressed: actOnInDev>` is an instantiation of the *Proposition* boilerplate, and `<ASL: system> shall be <activated: state>` is an instantiation of the *Simple* boilerplate:

Example 1:

```
if <Btn1: inDevice> is <pressed: actOnInDev>;
then
   <ASL: system> shall be <activated: state>;
endif
```

Line 1 of Algorithm 1 reads the requirements specification (*.resa) file, and buffers the content into *reqsBuffer*. For each requirement specification, the *Simple* and *Proposition* boilerplates are respectively replaced with temporary variables for later use (3). Next, propositions $props$ are extracted from the requirement specification $reqSpec$ (4), after which, for each proposition, propositional variables pvs are generated (5). Finally, a boolean expression is generated by substituting the temporary variables with pvs in the preserved requirement structure (6). Applying this algorithm to Example 1, we get $(p1 \Rightarrow p2)$, where $p1$ represents `<Btn1:inDevice> is <pressed:actOnInDev>;`, and $p2$ represents `<ASL:system> shall be <activated:state>;`.

Definition 2: A proposition p_2 is the negation of proposition p_1 ($p_2 = not\ p_1$), if there exists a word at position i of p_2

Algorithm 1: ReSA to boolean transformation

```
1  reqsBuffer[]← ReadReqs(*.resa)
   Function ReSAToBoolean(reqsBuffer)
2      foreach req in reqsBuffer do
           (id, reqSpec...) ← ParseReq(req)
3          reqSpecStruct ←
            PreserveReqSpecStruct(reqSpec)
4          props[]← ParseProps(reqSpec)
           foreach p in props do
5              pvs[]←GetPropVars(p)
           end
6          booleanExps[]←
            GenerateBooleanExp(reqSpecStruct,pvs)
       end
       return : booleanExps
   end
```

(word$_i^{p_2}$) that is the antonym (opposite) of a word at position i of p_1 (word$_i^{p_1}$), while the rest of p_2 syntactic structure matches p_1 (valid also for the reverse case, that is, $p_1 = not\ p_2$).■

The antonyms dictionary is a two dimensional list of antonyms (or words with opposites). The first word in the list represents a root word, and the rest represent opposite words to the root word. An opposite word is replaced with its root word. For example, the antonyms dictionary contains the word *activated* as a root word, and its opposite word *deactivated*. For the example below, we say that p_2 is a negation of p_1:

$$p_1 = ASL : system\ \ shall\ \ be\ \ \textbf{activated} : state$$
$$p_2 = ASL : system\ \ shall\ \ be\ \ \textbf{deactivated} : state$$

Algorithm 2: Generates a proposition variable

```
1  antonymsBuffer[]← ReadAntonyms(antonyms.txt)
2  propositionsBuffer[]← Null
   Function GetPropVars(proposition)
3      pn ←NormalizeProp(proposition, antonymsBuffer)
4      foreach p in propBuffer do
           if pn = p then
               return : p.pv
           end
       end
5      newPv ←GeneratePropVars()
       AddProp (pn, newPv)
       return : newPv
   end
```

Algorithm 2 implements Definition 2, hence, replaces an antonym with its root word (3). Further, Line (4-5) checks the *propositionsBuffer* for match of the proposition pn, and returns its propositional variable if found. Otherwise, Line 5 generates a new propositional variable for the proposition pn, and Line (5) adds the new proposition, and its propositional variable to the *propositionsBuffer*.

C. Consistency Checking

In this section, we introduce Algorithm 3 that illustrates the function for invoking the Z3 SMT Solver. Line (1) transforms boolean expressions into an SMT-LIB2 format, which is the input format of Z3; line (2) creates a logical context that enables interaction with the solver; line (3) parses SMT-LIB2 into the context, and finally, lines (4) and (5) create an instance of the solver, and invoke the solver, respectively.

Algorithm 3: consistency-check using Z3 SMT Solver

```
   Function CheckConsistency(booleanExp)
1      smtLibStr ← GenerateSMTLIBStr(booleanExp)
2      ctx ← new Context()
3      ctx.parseSMTLIBString(smtLibStr, null, null, null,
        null)
4      z3Solver ← ctx.mkSolver()
5      return : z3Solver.check(ctx)
   end
```

V. Industrial Use Case: Adjustable Speed Limiter

We have conducted an initial validation of our approach on requirements from the Adjustable Speed Limiter (ASL) [6]. ASL is an automotive safety-critical function, which is found along other vehicle limitation and control functions, such as Cruise Control (CC), in modern Volvo trucks. It limits the truck speed not to exceed a predefined and configurable vehicle speed. ASL provides an HMI interface for interaction with the driver, and has access to the powertrain engine in order to limit the engine positive torque. Therefore, it is a complex and safety-critical function.

ASL realizes 304 functional and extra-functional requirements, such as timing, safety, vehicle configurability, and variability. The requirements of ASL are found at multiple levels of abstraction according to EAST-ADL requirements modeling approach, that is, requirements defined at the lower level of abstraction are refinements of the upper level abstraction. In our validation process, we rewrite the requirements of ASL, which have been previously written in natural language (English), in ReSA. Furthermore, we evaluate the language and the tool with practitioners at Volvo Group Trucks Technology (VGTT). In this section, we show the validation result, and explain the consistency check function of the ReSA toolchain.

A. ASL Requirements Expressed in ReSA

Requirements of ASL describe a wide range of ASL functional and extra-functional properties, including:

- Interaction of the function with the driver (Human Machine Interface, HMI Requirements)
- High level ASL functions, which are less technical, and independent of implementation (High level FR).
- Functional-block Responsibility Requirement (Functional-block RR) briefly describe the responsibility of a functional block in precise and short statement.
- Low level functional requirements are more technical and implementation dependent (Low level FR).
- Performance Requirements express, such as timing, and concurrency, related requirements.
- Safety Requirements, such as response during faulty operation of ASL function.

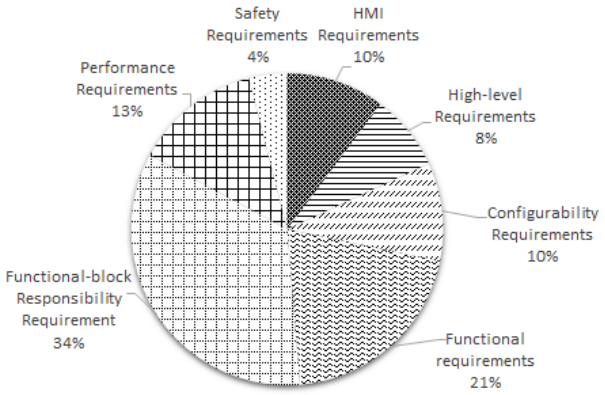

Fig. 4: The ASL Requirements Distribution

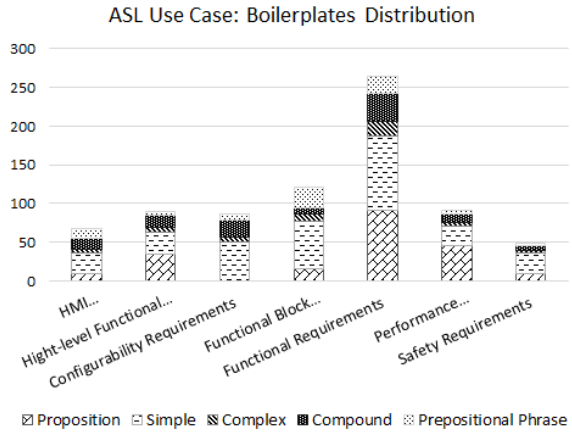

Fig. 5: The ASL Boilerplates Distribution

Req# 1 (ASL activation display): ...HMI Requirement

```
if <ASL:vf> is <selected:actOnSys> then
  <"the ASL indication light":hft> shall be
  <"lit":actOnDev>; on <the free wheel>;
endif
```

Req# 2 (ASL activation): ...High-level FR

```
if <increaseBtn:inDev> is <pressed:actOnDev>
then
  <ASL:vf> shall be <activated:state>;
  within <0.25><s>;
endif
```

Req# 3 (ASL activation): ...Configurability Requirement

```
<ASL_min:ffp> and <ASL_max:ffp> shall be
<configurable>;
```

Req# 4 (RSLM - ASL activation): ...Functional-block RR

```
<RSLM:fd> shall be <responsible>; for
<"activating ASL">;
```

Req# 5 (ASL activation request): ...Design-level FR

```
if <"ASL activation request":ffp> is
  <received:actOnPara>; while <ASL:vf> is
  <overriden:state>;
then
  <"ASL target speed":ffp> shall be set to
  <"ASL set speed":ffp>; and
  <"ASL":state> shall be <activated:state>;
endif
```

Req# 6 (ASL activation request): ...Performance Requirement

```
<The engine torque":ffp> shall <"release
control on":actOnPara> <"engine":hct>;
within <0.25><s>;
```

Req# 7 (ASL activation request): ...Safety Requirement

```
if <"fault affecting ASL function":event>
  occurs; while <ASL:vf> is <active:state>;
then
  <ASL:vf> shall be <deactivated:state>;
  in <a safeway>;
endif
```

In order to observe how much of information is encoded in the different requirements categories mentioned above, we analyze the boilerplates that are used to express requirements of ASL. Figure 5 shows that *Simple* and *Proposition* boilerplates are the most widely used boilerplates, followed by *Compound* boilerplates. Even though the number of Functional-block Requirements are more than the Low-level Functional Requirements, as shown in Figure 4, the amount of information encoded in the requirements is higher in the Low-level Functional Requirements, as indicated in Figure 5. This is witnessed by the fact that far more boilerplates are used to express the Low-level Functional Requirements than to express Functional-block Requirements.

B. Evaluation of the ReSA Toolchain with Practitioners

We have carried out an initial evaluation of the ReSA tool with 8 practitioners from VGTT. The practitioners include requirements engineers, software engineers and architects, test engineers, and researchers. The main goal of the evaluation is to get an initial result of using the tool. The evaluation criteria can be accessed using the web link, https://goo.gl/HwQ1vO. The response from the practitioners is Table III.

TABLE III: The ReSA toolchain evaluation

Role	Summary Feedback
Software engineers	found structuring of requirements appealing; they suggested more expressiveness in the language.
Verification engineers	found the tool usable, especially in test case development.
Requirement engineers	found that reusability and extensibility of the specification method was appealing, and suggested adding alternative graphical specification.
Researchers	found the specification method, and specialization to EAST-ADL abstractions useful.

In the following subsection, we show a sample of the ASL specification in ReSA. Further, we apply our consistency checking approach on ASL requirements.

C. Consistency Checking on the Use Case

Using the ReSA toolchain, we express 37 functional requirements of the ASL system, that are related to the activation and deactivation of the system. Next, we check consistency of the requirements specifications using the consistency-checking feature of the toolchain. In this subsection, we show the point

of inconsistency reported by toolchain, and also demonstrate how the consistency-checking function works.

The following requirement describes enabling ASL.

```
req req001_ENABLING_ASL:
(p1) if interaction#driver "selects":verb
            "ASL speed control":mode; and
(p2) (mode# vehicle is in mode
            "pre-running"; or
(p3) mode# vehicle is in mode "running";)
     then
(p4) action# "ASL":system shall be
            "enabled":verbState; and
(p5) status# "ASL enabled":status shall be
            "presented to" driver
     endif
endreq
```

The boolean expression for the above requirement becomes $(p1 \wedge (p2 \vee p3)) \Rightarrow (p4 \wedge p5)$.

To show how the consistency function catches inconsistencies in requirements specifications, we now introduce a bogus requirement for disabling ASL, as follows:

```
req req002_bogus_DISABLING_ASL:
(p6) if interaction#driver "selects":verb
            "ASL speed control":mode
     then
(p7)   action# "ASL":system shall be
                "disabled":verbState;
    endif
endreq
/* "disabled" is antonymic to "enabled" */
```

Since the word *disabled* is antonimic to the word *enabled*, p7 becomes the negation of p4 according Definition 6; and p6 is equivalent to p1. Therefore, the boolean expression for the above requirement becomes $p1 \Rightarrow \neg p4$. To demonstrate how the consistency check function works, let us assume, and assert in the specification that ASL is enabled, and the vehicle is in pre-running mode. The SMT-LIB2 equivalent format of the above two requirements including the assertions, as obtained from our transformation, appears as follows:

```
(set-option :produce-unsat-cores true)
; declare boolean constant
(declare-const p1 Bool)
...
;req001_ENABLING_ASL
(assert (! (=>(and p1 (or p2 p3))
(and p4 p5)) :named req001))
;req002_bogus_DISABLING_ASL
(assert (!(=> p1 (not p4)) :named req002))

;Assert that driver selects ASL control
(assert (! (= p1 true) :named assumption1))
;Assert vehicle is in pre-running mode
(assert (! (= p2 true) :named assumption2))
```

If the Z3 solver is triggered to check the satisfiability of the 37 requirements specifications, it returns *unsat*, as there exists an inconsistency within the requirements specification. Obviously, the ASL cannot be activated and deactivated at the same time, given the assumptions, and this inconsistency is identified using the toolchain. A feature of Z3's unsat-core tries to localize the region of inconsistency by listing the requirements associated with the inconsistency problem using the labels of requirements defined during the requirements specification. For example, the following result from the solver indicates that the region of inconsistency is related to the two requirements, and the assertions we made.

```
unsat
(req001 req002 assumption1 assumption2)
```

The engineer is supposed to use this feedback from the solver, and make necessary changes to the specification, and repeat the consistency checking process until no more inconsistency is found.

VI. Related work

The related work focuses on toolchains that use template-based specification methods, computer-processable Controlled Natural Languages (CNLs), and perform automated consistency checking without the need for system models. These are in contrast to tools that use tabular specification techniques [21], graphical specification methods, or formal specification methods, e.g., Z notation, LARCH, Linear Temporal Logic (LTL) [22].

A. Template-based Specification Tools

In this paper, we define a template-based specification method that uses predefined specification templates extracted from experience in requirements engineering, in order to express requirements in a more structured way. The most popular methods of this type are requirements boilerplates [23][24][25], and Specification Pattern System (SPS) [26][27][28]. Specification templates are reusable artifacts, and consist of variable and fixed syntactic elements, where the variable part is filled by the engineer. The specification templates facilitate communication among engineers due to the fact that engineers use the same templates for similar requirements from a common repository of templates. The challenges of template-based approaches are: 1) the selection of an appropriate template out of seemingly similar templates; the Natural Language Processing (NLP) technique is found to ease this challenge in the case of DODT tool [2] while manual intervention is still necessary, and 2) the extension of the template repository with new templates for requirements that could not be expressed with the existing templates. The templates extension requires a careful approach, as templates could be ambiguous, or conflicting to each other. Therefore, such extension mechanism should subscribe to some syntactic, or semantic rules. By using the ReSA tool, the creation of new boilerplates is constrained by the syntactic and semantic rules of the ReSA language.

Boilerplate tools, such as DODT, and Requirements Authoring Tool (RAT), use requirement boilerplates to express requirements. Requirements boilerplate, e.g., the `if <button> is <pressed> then <system> shall be <activated>; within <0.25><sec>; endif`,

is a typical boilerplate in ReSA language. The primary goal of using boilerplates is to provide structure to requirements, and make them readable, and more comprehensible than their temporal logic counterparts. However, some tools use knowledge management, e.g., an ontology, to analyze the quality of requirements (such as consistency, completeness, redundancy, vagueness), according to quality metrics defined in their knowledge-base.

DODT [2] is a research prototype tool, which is developed in the European CEASAR project. The tool supports boilerplates, and unconstrained natural language (English) to write requirements. The unconstrained natural specification is matched to existing boilerplates using Natural Language Processing (NLP) technique, and boilerplate mismatches are manually corrected. The tool can assess the quality of requirements specification based on the analysis of Ambiguity, Inconsistency, Completeness, Opacity, and Noise, by referring to the ontology that defines attributes, attribute relations, various axioms of the boilerplates, e.g., for contradiction, subclassing, equivalence [29]. RAT [30] is an industry level tool, which is being developed by the REUSE Company. It supports advanced features, such as guides writing of requirements using *IntelliSense* from Microsoft, quality analysis on-the-fly using metrics, such as Inconsistency, Ambiguity, Overlapped requirements, non-atomicity with the help of a separate knowledge-manager that stores vocabulary, patterns, syntax, and semantic representation. Due to its proprietary nature, it is not clear if the boilerplate extension mechanism relies on any syntactic or semantic rules like in the ReSA toolchain.

The Specification Pattern System (SPS) proposed by Dwyer et al. [27] is a set of property specification patterns, that can better be understood, and used by domain practitioners than, for instance, LTL specifications. Konard and Cheng extended the SPS with real-time support [26]. Using ReSA, temporal requirements can be expressed using the *Prepositional Phrase* boilerplate, e.g, `within <time>, after <time>...`; however, our transformation is limited to proportional formulas only. The toolchain by Post and Hoenicke [28] is an implementation of the real-time SPS grammar. The toolchain allows expression of requirements in restricted English grammar, e.g., `Globally, it is always the case that P holds after at most 10 seconds`, where `P` is a property to be checked, and the pattern translation into Duration Calculus [31]. Furthermore, their toolchain can check inconsistency, rt-inconsistency (checks timing boundaries), and vacuity (requirements that can never be enabled). However, we couldn't gain access to the toolchain to do hands-on experience. As compared to the boilerplate-based specification, the SPS mentioned above uses architectural elements in constructing the property, e.g., `vehicleSpeed > setSpeed`, where `vehicleSpeed`, and `setSpeed` are elements of our ASL architecture. Moreover, the SPS has representations in formal logic. Unlike boilerplate-based specification, the SPS targets behaviour description, therefore its coverage is limited, but more precise due to its formalized nature. ReSA, on the other hand can express a wide range of requirement types, including behavioural, and requirements that express performance, and safety. Further more, as compared to the SPS, ReSA is close to natural language. Elen et. al [32] propose an existential bounded consistency analysis using Bounded Model Checking (BMC), and implement their prototyping using iSAT model checker. The analysis does not require a system model, and checks if a run exists that satisfies the specification in BTC pattern [33].

B. Computer-processable CNL Tools

Computer-processable Constrained Natural Languages (CNLs), such as the Attempto Control English (ACL), and the Processable ENGlish (PENG), use limited words, phrases, syntax and semantics of natural language express texts in a simplified English language. Moreover, computer-processable CNLs have formal semantics, e.g., in first-order-logic (FOL), which makes them amenable to automated analysis, that is for checking logical consistency, redundancy, and ambiguity. The ReSA toolchain uses transformation of requirements to proportional formula to do the consistency checking, and supports features, such as specification guide, and provides tips for error correction during requirements specification.

ACE supports the construction of simple, and composite sentences (complex and compound), coordination of phrases using *and*, subordination, quantification, negation, and query-answer interfaces [34]. Texts in ACE can be translated into formal specifications, such as FOL [35]. The Attempto toolchain is a suite of tools. The tool has support for text completion, and inline checking for ambiguity, inconsistency via its predefined lexicon, and grammar rules. Attempto does not allow the use of passive sentences, verb phrases, modal verbs, which is natural to use in requirements specification, for example, `system shall be activated`. Inspired by ACE, PENG [36] is also a computer-processable language. The PENG system uses ECORE, which is a look-ahead editor, in order to predictively provide possible alternatives during writing. This feature lowers the burden of memorising the syntax rules of PENG. Yan et. al [37], in the tool SpecCC, transformed their own CNL into LTL, and synthesize the LTL specification using G4LTL in order to check for realizability.

VII. Conclusion

In the automotive industry there is a stringent need for semi-formal requirements specification methods and tools that integrate seamlessly into industrial practice. In this paper, we propose an implementation of the previously proposed ReSA requirements specification language, and provide algorithms for the logical consistency checking of requirements formulated in ReSA for a particular system. Our consistency checking approach first automatically transforms ReSA requirements specifications into expressions in propositional logic first, and then uses Z3 SMT solver to check the satisfiability of the boolean specifications.

In order to handle the complexity of automotive embedded systems development, the use of multiple levels of abstraction

is a known, and usually common practice for designing a complex electrical/electronic function in architectural languages such as EAST-ADL. In this paper, we specialize the ReSA toolchain to support specifications tailored to EAST-ADL levels of abstraction. We have conducted a validation of the toolchain on the Adjustable Speed Limiter use case. The language is expressive enough to express the 304 use case requirements. Furthermore, the toolchain has also undergone an initial evaluation by VGTT engineers, who answered questionnaires and specified certain requirements with our tool. In our future work, we plan to scale the consistency checking to support requirements with temporal, and quantifiers properties. We also plan to extend the validation process to various automotive use cases, including from other companies besides VGTT, such as from Scania. In the near future, the toolchain will be integrated into Synligare Eclipse[1] for the EAST-ADL language.
